## Digital System Design

## Objectives:

1. Understanding decimal, binary, octal and hexadecimal numbers.
2. Counting in decimal, binary, octal and hexadecimal systems.
3. Convert a number from one number system to another system.
4. Advantage of octal and hexadecimal systems.

## 1. Understanding decimal, binary, octal and hexadecimal numbers

## Decimal number systems:

$\checkmark$ Decimal numbers are made of decimal digits:
(0,1,2,3,4,5,6,7,8,9
$\qquad$ 10-base system)
$\checkmark$ The decimal system is a "positional-value system" in which the value of a digit depends on its position.

## Examples:

* $453 \rightarrow 4$ hundreds, 5 tens and 3 units.
$\checkmark 4$ is the most weight called "most significant digit" MSD.
$\checkmark 3$ carries the last weight called 'least significant digit" LSD.
* number of items that a decimal number represent:

$$
9261=\left(9 \times 10^{3}\right)+\left(2 \times 10^{2}\right)+\left(6 \times 10^{1}\right)+\left(1 \times 10^{0}\right)
$$

* The decimal fractions:
$3267.317=\left(3 \times 10^{3}\right)+\left(2 \times 10^{2}\right)+\left(6 \times 10^{1}\right)+\left(7 \times 10^{0}\right)+\left(3 \times 10^{-1}\right)+$ $\left(6 \times 10^{-2}\right)+\left(1 \times 10^{-3}\right)$
$\checkmark$ Decimal point used to separate the integer and fractional part of the number.
$\checkmark$ Formal notation $\rightarrow(3267.317)_{10}$ •
$\checkmark$ Decimal position values of powers of (10).

## Positional values "weights"

| $10^{4}$ | $10^{3}$ | $10^{2}$ | $10^{1}$ | $10^{0}$ |  | $10^{-1}$ | $10^{-2}$ | $10^{-3}$ | $10^{-4}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{4}$ | $\boldsymbol{4}$ | $\mathbf{4}$ | $\mathbf{4}$ | $\mathbf{4}$ |  | 4 | 4 | $\uparrow$ | 4 |
| 2 | 7 | 7 | 8 | 3 | . | 2 | 3 | 4 | 5 |
| MSD |  |  |  |  |  |  |  |  | LSD |

## Binary numbers:

- Base-2 system (0 or 1).
- We can represent any quantity that can be represented in decimal or other number systems using binary numbers.
- Binary number is also positional-value system (power of $\mathbf{2}$ ).

Example: 1101.011

## Notes:

- To find the equivalent of binary numbers in decimal system, we simply take the sum of products of each digit value $(0,1)$ and its positional value:

## Example:(1011.101)2

$=\left(1 \times 2^{3}\right)+\left(0 \times 2^{2}\right)+\left(1 \times 2^{1}\right)+\left(1 \times 2^{0}\right)+\left(1 \times 2^{-1}\right)+\left(0 \times 2^{-2}\right)+\left(1 \times 2^{-3}\right)$
$=8+0+2+1+\frac{1}{2}+0+\frac{1}{8}=11.625_{10}$
In general, any number (decimal, binary, octal and hexadecimal) is simply the sum of products of each digit value and its positional value.

- In binary system, the term binary digit is often called bit.
- Binary values at the output of digital system must be converted to decimal values for presentation to the outside world.
- Decimal values must be converted into the digital system.
- Group of 8 bits are called a byte.

## Octal Number System

- octal number system has a base of $8:(\mathbf{0 , 1}, \mathbf{2}, \mathbf{3}, 4,5,6,7)$

## Examples:

. $(1101.011)_{8}$

- $(4327)_{8}$
$=\left(4 \times 8^{3}\right)+\left(3 \times 8^{2}\right)+\left(2 \times 8^{1}\right)+\left(7 \times 8^{0}\right)$
- $372.36_{8}$
$=\left(3 \times 8^{2}\right)+\left(7 \times 8^{1}\right)+\left(2 \times 8^{0}\right)+\left(3 \times 8^{-1}\right)+\left(6 \times 8^{-2}\right)$

## Note: octal number don't use digits 8 or 9

## Hexadecimal number system (16-base)

$\checkmark$ Hexadecimal numbers are made of 16 digits, it uses the digits $\mathbf{0}$ through $\mathbf{9}$ plus the letters $\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D}, \mathbf{E}, \mathbf{F}$.

## Examples:

```
    - (A29)}\mp@subsup{)}{16}{
=(10\times162) +(2\times1\mp@subsup{6}{}{1})+(9\times1\mp@subsup{6}{}{0})=(2601)}\mp@subsup{)}{10}{
    - (2c7.38)
=(2\times16}\mp@subsup{6}{}{2})+(12\times1\mp@subsup{6}{}{1})+(7\times1\mp@subsup{6}{}{0})+(7\times1\mp@subsup{6}{}{0})+(3\times1\mp@subsup{6}{}{-1})+(8\times1\mp@subsup{6}{}{-2}
```

Note:
$\checkmark$ For hex numbers the digits $10,11,12,13,14,15$ are represented by $\mathbf{a}, \mathbf{b}, \mathbf{c}, \mathbf{d}, \mathbf{e}, \mathbf{f}$ as shown in the following table:

| Number Systems |  |  |  |
| :---: | :---: | :---: | :---: |
| Decimal | Binary | Octal | Hex |
| 0 | 0000 | 0 | 0 |
| 1 | 0001 | 1 | 1 |
| 2 | 0010 | 2 | 2 |
| 3 | 0011 | 3 | 3 |
| 4 | 0100 | 4 | 4 |
| 5 | 0101 | 5 | 5 |
| 6 | 0110 | 6 | 6 |
| 7 | 0111 | 7 | 7 |
| 8 | 1000 | 10 | 8 |
| 9 | 1001 | 11 | 9 |
| 10 | 1010 | 12 | A |
| 11 | 1011 | 13 | B |
| 12 | 1100 | 14 | C |
| 13 | 1101 | 15 | D |
| 14 | 1110 | 16 | E |
| 15 | 1111 | 17 | F |

2. Counting in decimal ,binary, octal and hexadecimal systems

## Decimal counting:

- Start with 0 in the units position and take each digit in progression until reach 9.
- Add 1 to the next higher position and start over 0 in the first position.
- Continue process until the count 99.
- Add 1 to the third position and start over with 0 in the first position.

Note: the largest number that can be represented using 8 bits is

$$
2^{n}-1=2^{8}-1=255_{10}=11111111_{2}
$$

## Counting in hexadecimal:

$\checkmark$ For $\mathbf{n}$ hex digit positions, we can count for decimal $\mathbf{0}$ to $\mathbf{1 6}^{\mathbf{n}} \mathbf{- 1}$, for a total of $16^{\mathrm{n}}$ different values.
$\checkmark$ The general representation for a number in the form:

$$
a_{4} a_{3} a_{2} a_{1} a_{0} \cdot a_{-1} a_{-2} a_{-3}
$$

Using r-base/radix number system, in which the number of radix $r$ can be written as

$$
\begin{aligned}
\mathbf{n}_{r}= & +a_{4} \cdot r^{4}+a_{3} \cdot r^{3}+a_{2} \cdot r^{2}+a_{1} \cdot r^{1} \\
& +a_{0} \cdot r^{0}+a_{-1} \cdot r^{-1}+a_{-2} \cdot r^{-2}+\ldots
\end{aligned}
$$

| Numbering System | Radix |
| :--- | :--- |
| Decimal | $\mathbf{r}=10$ |
| Binary | $\mathbf{r}=2$ |
| Octal | $\mathbf{r}=8$ |
| Hex | $\mathbf{r}=16$ |

## Counting in binary system: (counting range)

$\checkmark$ Using $\mathbf{n}$ bits, we can represent decimal numbers ranging from $\mathbf{0}$ to $\mathbf{2}^{\mathbf{n}} \mathbf{- 1}$, a total of $\mathbf{2}^{\mathbf{n}}$ different numbers.

## Examples:

- for $\mathrm{n}=4$ bits

We can count from $\mathbf{0 0 0 0}$ to $\mathbf{1 1 1 1}_{2}$ (see table above) which is $0_{10}$ to $15_{10}$ (16 different numbers).

- How many bits are needed to represent decimal values ranging from 0 to 12500?

Answer:
= With $\mathbf{1 3}$ bits, we can count from $\mathbf{0}$ to $2^{13}-1=8191$ (not enough)

- With $\mathbf{1 4}$ bits, we can count from $\mathbf{0}$ to $\mathbf{2}^{\mathbf{1 4}} \mathbf{- 1}=\mathbf{1 6 . 3 8 3}$ (okay)
- What is the total range of decimal values that can be represented in 8 bits?

Answer:
For $\mathbf{N}=\mathbf{8}$, we can represent form $\mathbf{0}$ to $\mathbf{2}^{\mathbf{8}} \mathbf{- 1}=\mathbf{2 5 5}$.
