Chapter 11 Chemical Reactions

11.1 Describing Chemical Reactions

**11.2 Types of Chemical
Reactions**

11.3 Reactions in Aqueous Solution

What happens to the wax when you burn a candle?

When you burn a candle, a chemical reaction called combustion takes place.

11.2 Types of Chemical Reactions>

Classifying Reactions

By classifying chemical reactions, you can more easily predict what products are likely to form.

The five general types of reactions include combination, decomposition, single-replacement, double-replacement, and combustion.

Not all chemical reactions fit uniquely into one category.

- Occasionally, a reaction may fit equally well into two categories.
- Patterns of chemical behavior will become apparent and allow you to predict the products of reactions.

11.2 Types of Chemical Reactions>

Types of Chemical Reactions

Combination Reactions

The first type of reaction is the combination, or synthesis, reaction.

- A **combination reaction** is a chemical change in which two or more substances react to form a single new substance.

Combination Reactions

Magnesium metal and oxygen gas combine to form the compound magnesium oxide.

Combination Reactions

Notice that in this reaction, as in all combination reactions, the product is a single substance (MgO), which is a compound.

- The reactants in this combination reaction (Mg and O_2) are two elements, which is often the case.
- Two compounds may also combine to form a single substance.

Combination Reactions

When a Group A metal and a nonmetal react, the product is a binary ionic compound.

Combination Reactions

When two nonmetals react in a combination reaction, more than one product is often possible.

Combination Reactions

More than one product may also result from the combination reaction of a transition metal and a nonmetal.

Decomposition Reactions

Some chemical reactions are the opposite of combination reactions.

- When mercury(II) oxide is heated, it decomposes or breaks down into two simpler substances.

Decomposition Reactions

A **decomposition reaction** is a chemical change in which a single compound breaks down into two or more simpler products.

- Decomposition reactions involve only one reactant and two or more products.
- The products can be any combination of elements and compounds.
- Most decomposition reactions require energy in the form of heat, light, or electricity.

Decomposition Reactions

Did you know that a decomposition reaction happens when a vehicle's air bag inflates?

- A device that triggers the reaction is placed in the air bag along with sodium azide pellets.
- When the device is triggered, the sodium azide pellets decompose and release nitrogen gas, which inflates the air bag quickly.

Single-Replacement Reactions

Dropping a small piece of potassium into a beaker of water creates the vigorous reaction.

- The released hydrogen gas can ignite explosively.

Single-Replacement Reactions

If you drop a piece of zinc into a solution of copper nitrate, this reaction occurs:

Single-Replacement Reactions

These equations describe two examples of single-replacement reaction.

- A **single-replacement reaction** is one in which one element replaces a second element in a compound.
 - You can identify a single-replacement reaction by noting that both the reactants and the products consist of an element and a compound.

Single-Replacement Reactions

In the equation above, zinc and copper change places.

- The reacting element Zn replaces copper in the reactant compound $\text{Cu(NO}_3)_2$.
- The products are the element Cu and the compound $\text{Zn(NO}_3)_2$.

Writing Equations for Single-Replacement Reactions

Write a balanced equation for the single-replacement reaction.

Single-Replacement Reactions

Whether one metal will displace another metal from a compound depends upon the relative reactivities of the two metals.

- Iron will displace copper from a copper compound in solution, but iron does not similarly displace zinc or calcium.

Activity Series of Metals		
	Name	Symbol
Decreasing reactivity ↓	Lithium	Li
	Calcium	Ca
	Sodium	Na
	Magnesium	Mg
	Aluminum	Al
	Zinc	Zn
	Iron	Fe
	Lead	Pb
	Copper	Cu
	Mercury	Hg
	Silver	Ag

Single-Replacement Reactions

Whether one metal will displace another metal from a compound depends upon the relative reactivities of the two metals.

- The **activity series** of metals lists metals in order of decreasing reactivity.
- A reactive metal will replace any metal listed below it in the activity series.

Activity Series of Metals		
	Name	Symbol
Decreasing reactivity ↓	Lithium	Li
	Calcium	Ca
	Sodium	Na
	Magnesium	Mg
	Aluminum	Al
	Zinc	Zn
	Iron	Fe
	Lead	Pb
	Copper	Cu
	Mercury	Hg
	Silver	Ag

Single-Replacement Reactions

A halogen can also replace another halogen from a compound.

- The activity of halogens decreases as you go down Group 7A of the periodic table—fluorine, chlorine, bromine, and iodine.
- Bromine is more active than iodine, so this reaction occurs:

- But bromine is less active than chlorine, so this reaction does not occur:

Double-Replacement Reactions

Mixing aqueous solutions of potassium iodide and lead(II) nitrate results in a chemical reaction in which a yellow precipitate of solid lead(II) iodide is formed.

Double-Replacement Reactions

This is an example of a **double-replacement reaction**, which is a chemical change involving an exchange of positive ions between two compounds.

- Double-replacement reactions are also referred to as double-displacement reactions.
- They generally take place in aqueous solution and often produce a precipitate, a gas, or a molecular compound such as water.

Double-Replacement Reactions

For a double-replacement reaction to occur, one of the following is usually true:

1. One of the products is only slightly soluble and precipitates from solution.
2. One of the products is a gas.
3. One product is a molecular compound such as water.

Writing Equations for Double- Replacement Reactions

A precipitate of barium carbonate is formed when aqueous solutions of barium chloride react with potassium carbonate. Write a balanced chemical equation for the double-replacement reaction.

Combustion Reactions

The flames of a campfire, candle, or gas grill are evidence that a combustion reaction is taking place.

Combustion Reactions

A **combustion reaction** is a chemical change in which an element or a compound reacts with oxygen, often producing energy in the form of heat and light.

- A combustion reaction always involves oxygen as a reactant.
- Often the other reactant is a hydrocarbon, which is a compound composed of hydrogen and carbon.

Combustion Reactions

The complete combustion of a hydrocarbon produces carbon dioxide and water.

- But if the supply of oxygen is limited during a reaction, the combustion will not be complete.
- Elemental carbon (soot) and toxic carbon monoxide gas may be additional products.

Combustion Reactions

The complete combustion of a hydrocarbon releases a large amount of energy as heat.

- That's why hydrocarbons such as methane (CH_4), propane (C_3H_8), and butane (C_4H_{10}) are important fuels.

Combustion Reactions

Gasoline is a mixture of hydrocarbons that can be approximately represented by the formula C_8H_{18} .

- The complete combustion of gasoline in a car engine is shown by this equation:

Materials such as candle wax contain hydrogen and carbon. One type of wax has a formula of $C_{25}H_{53}$. The wax reacts with oxygen in the air. So, what happens to the wax as it burns?

Materials such as candle wax contain hydrogen and carbon. One type of wax has a formula of $C_{25}H_{53}$. The wax reacts with oxygen in the air. So, what happens to the wax as it burns?

The wax undergoes a combustion reaction with oxygen and is converted into carbon dioxide and water.

Writing Equations for Combustion Reactions

An alcohol lamp often uses ethanol as its fuel. Write a balanced equation for the complete combustion of ethanol.

Now that you have learned about some of the basic reaction types, you can predict the products of many reactions.

- The number of elements and/or compounds reacting is a good indicator of possible reaction type and, thus, possible products.

11.2 Types of Chemical Reactions >

Classifying Reactions

In a combination reaction, two or more reactants (elements or compounds) combine to form a single product.

1 Combination Reaction

General Equation: $R + S \longrightarrow RS$

Reactants: Generally two elements, or two compounds (where at least one compound is a molecular compound)

Probable Products: A single compound

Example: Burning magnesium in air

11.2 Types of Chemical Reactions>

Classifying Reactions

In a decomposition reaction, a single compound is the reactant; two or more substances are the products.

2 Decomposition Reaction

General Equation: $RS \longrightarrow R + S$

Reactants: Generally a single binary compound or a compound with a polyatomic ion

Probable Products: Two elements (for a binary compound), or two or more elements and/or compounds (for a compound with a polyatomic ion)

Example: Heating mercury(II) oxide

11.2 Types of Chemical Reactions >

Classifying Reactions

An element and a compound are the reactants in a single-replacement reaction.

3 Single-Replacement Reaction

General Equation: $T + RS \longrightarrow TS + R$

Reactants: An element and a compound

In a single-replacement reaction, an element replaces another element from a compound in aqueous solution. For a single-replacement reaction to occur, the element that is displaced must be less active than the element that is doing the displacing.

Probable Products: A different element and a new compound

Example: Potassium in water

11.2 Types of Chemical Reactions>

Classifying Reactions

In a double-replacement reaction, two ionic compounds are the reactants; two new compounds are the products.

4 Double-Replacement Reaction

General Equation: $R^+ S^- + T^+ U^- \longrightarrow R^+ U^- + T^+ S^-$

Reactants: Two ionic compounds

In a double-replacement reaction, two ionic compounds react by exchanging cations to form two different compounds.

Probable Products: Two new compounds

Double-replacement reactions are driven by the formation of a precipitate, a gaseous product, or water.

Example: Reaction of aqueous solutions of potassium iodide and lead(II) nitrate.

11.2 Types of Chemical Reactions>

Classifying Reactions

The reactants in a combustion reaction are oxygen and usually a hydrocarbon. The products of most combustion reactions are carbon dioxide and water.

5 Combustion Reaction

General Equation: $C_xH_y + (x + y/4) O_2 \longrightarrow xCO_2 + (y/2)H_2O$

Reactants: Oxygen and a compound of C, H, (O)
When oxygen reacts with an element or compound, combustion may occur.

Probable Products: CO_2 and H_2O
With incomplete combustion, C and CO may also be products.

Example: The combustion of methane gas in air

Identifying Chemical Reactions

2

S = Synthesis D = Decomposition SR = Single Replacement DR = Double Replacement

11.2 Types of Chemical Reactions>

Why might you want to classify a chemical reaction?

Classifying a chemical reaction helps you predict what products will form.

11.2 Types of Chemical Reactions > Key Concepts

The five general types of reactions are combination, decomposition, single-replacement, double-replacement, and combustion.

The number of elements and/or compounds reacting is a good indicator of possible reaction type and, thus, possible products.

In a combination reaction, there is always a single product.

11.2 Types of Chemical Reactions > Key Concepts

A decomposition reaction involves the breakdown of a single compound into two or more simpler substances.

In a single-replacement reaction, both the reactants and the products are an element and a compound.

A double-replacement reaction generally takes place between two ionic compounds in aqueous solution.

A combustion reaction always involves oxygen as a reactant.

11.2 Types of Chemical Reactions > Glossary Terms

- **combination reaction**: a chemical change in which two or more substances react to form a single new substance; also called a synthesis reaction
- **decomposition reaction**: a chemical change in which a single compound is broken down into two or more simpler products
- **single-replacement reaction**: a chemical change in which one element replaces a second element in a compound; also called a displacement reaction

11.2 Types of Chemical Reactions > Glossary Terms

- **activity series**: a list of elements in order of decreasing activity; the activity series of halogens is F, Cl, Br, I
- **double-replacement reaction**: a chemical change that involves an exchange of positive ions between two compounds
- **combustion reaction**: a chemical change in which an element or a compound reacts with oxygen, often producing energy in the form of heat and light
