Eucaryotic cells and microorganisms

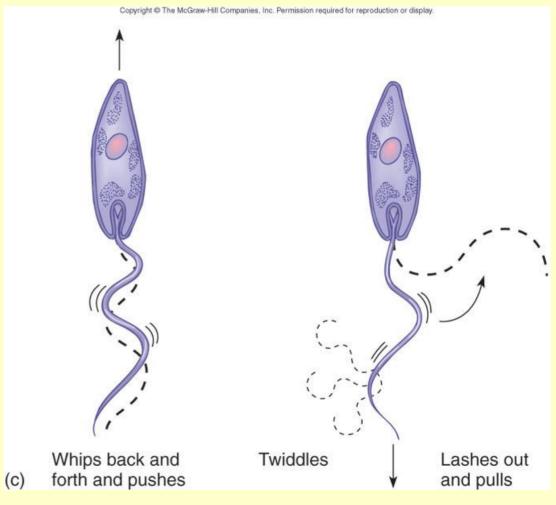

Chapter 5

3 Eucaryotic cells

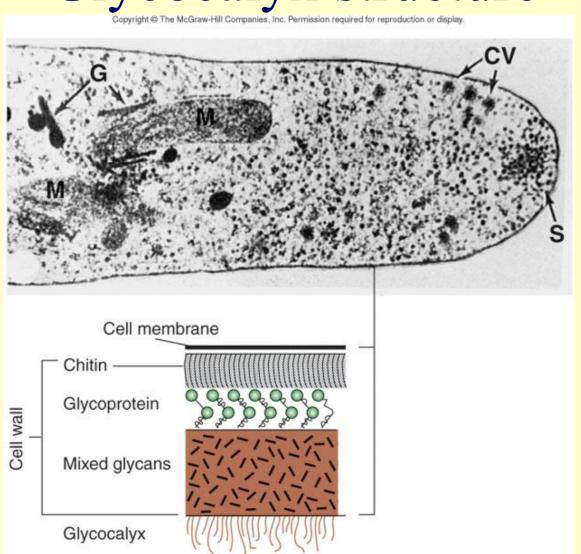

Flagella

Cilia

- similar in overall structure to flagella, but shorter and more numerous
- found only on a single group of protozoa and certain animal cells
- function in motility, feeding & filtering

Glycocalyx structure

Cell wall

- rigid & provide structural support & shape
- fungi have thick inner layer of polysaccharide fibers composed of chitin or cellulose & a thin layer of mixed glycans
- Algae varies in chemical composition; substances commonly found include cellulose, pectin, mannans, silicon dioxide, & calcium carbonate

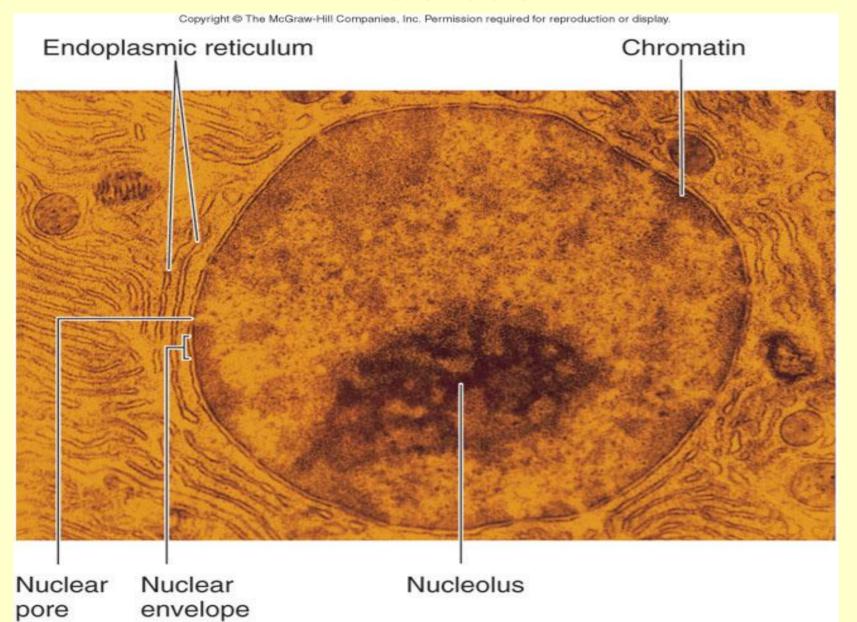

Cell membrane

- typical bilayer of phospholipids and proteins
- sterols confer stability
- serve as selectively permeable barriers in transport
- eucaryotic cells also contain membranebound organelles that account for 60-80% of their volume

nucleus

- compact sphere, most prominent organelle of eucaryotic cell
- nuclear envelope is composed of two parallel membranes separated by a narrow space & is perforated with pores
- contains chromosomes
- nucleolus dark area for rRNA synthesis & ribosome assembly

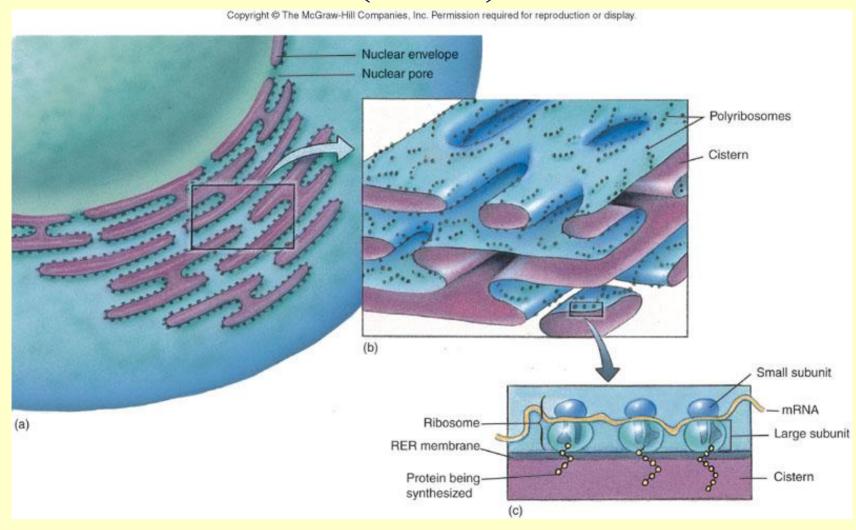

nucleus

Endoplasmic reticulum

- Rough endoplasmic reticulum (RER)— originates from the outer membrane of the nuclear envelop & extends in a continuous network through cytoplasm; rough due to ribosomes, proteins are synthesized & shunted into the ER for packaging & transport. First step in secretory pathway.
- Smooth endoplasmic reticulum (SER)— closed tubular network without ribosomes, functions in nutrient processing, synthesis & storage of lipids, etc.

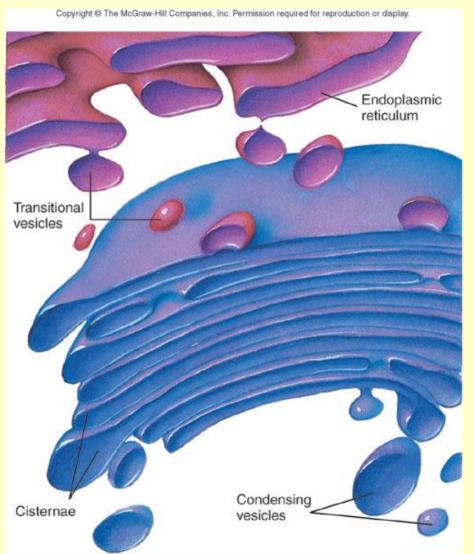

rough endoplasmic reticulum (RER)

Golgi apparatus

- consists of a stack of flattened sacs called cisternae
- closely associated with ER
- Transistional vesicles from the ER containing proteins go to the Golgi apparatus for modification and maturation
- Condensing vesicles transport proteins to organelles or secretory proteins to the outside

Golgi apparatus

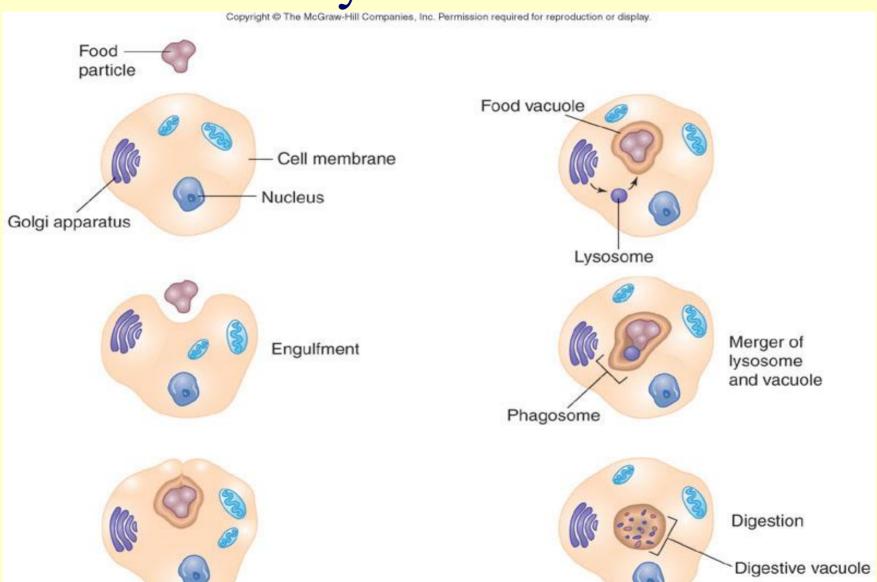

Transport process

lysosomes

- vesicles containing enzymes
- involved in intracellular digestion of food particles & in protection against invading microbes

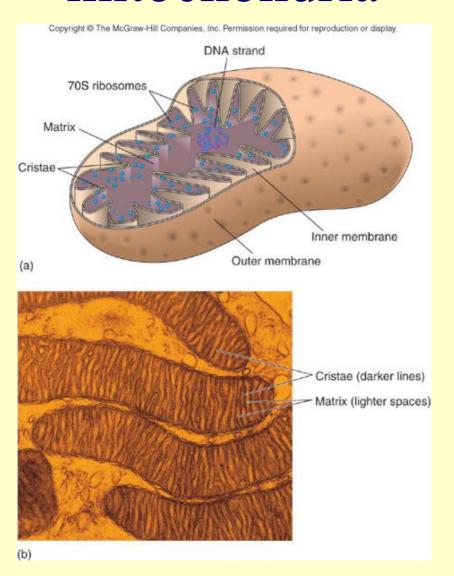

lysosomes

mitochondria

- consists of an outer membrane & an inner membrane with folds called **cristae**
- cristae hold the enzymes & electron carriers of aerobic respiration
- divide independently of cell
- contain DNA and procaryotic ribosomes
- function in energy production

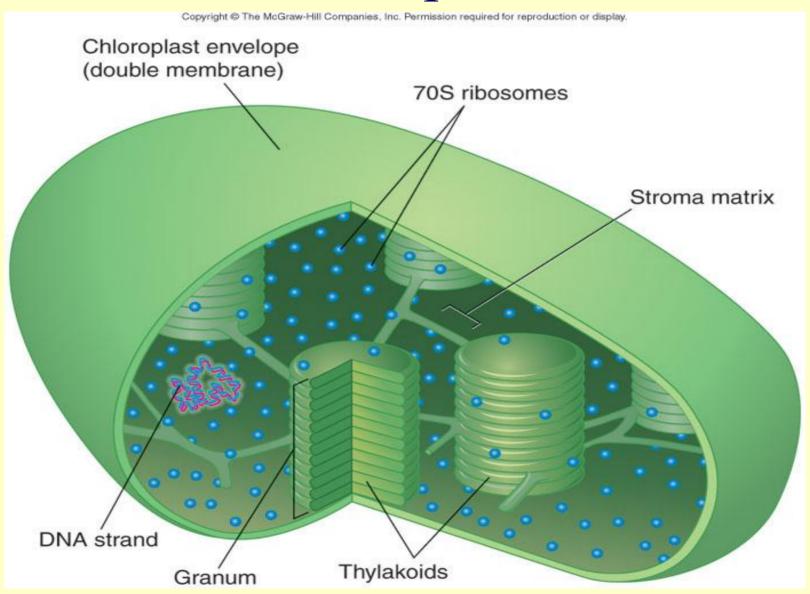

mitochondria

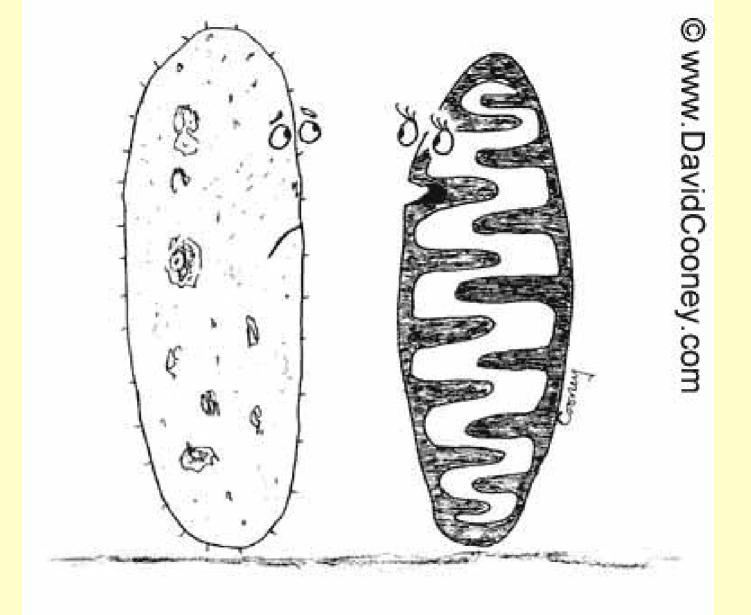

chloroplast

- found in algae & plant cells
- outer membrane covers inner membrane folded into sacs, **thylakoids**, stacked into grana
- larger than mitochondria
- contain photosynthetic pigments
- convert the energy of sunlight into chemical energy through photosynthesis
- primary producers of organic nutrients for other organisms

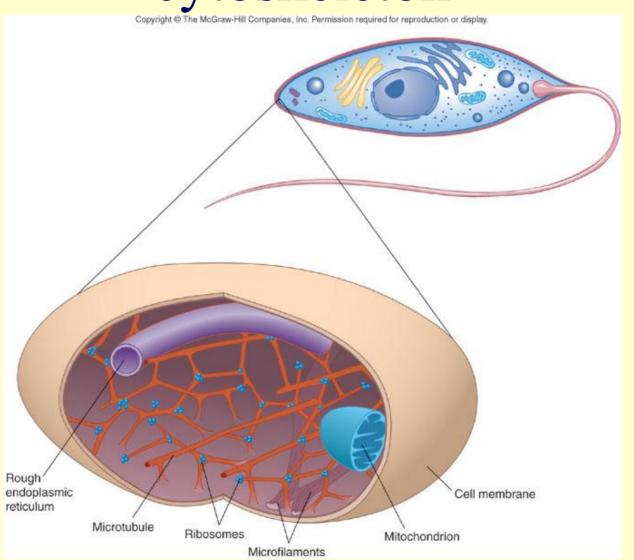

chloroplast

"Let's face it, this just isn't going to work out. You're a bacterium and I'm a mitochondrion."

cytoskeleton

ribosomes

- composed of rRNA and proteins
- 40S and 60S subunits form 80S ribosomes
- larger than procaryotic ribosomes
- function in protein synthesis

Survey of eucaryotic microbes

- Fungi
- Algae
- Protozoa
- Parasitic helminths

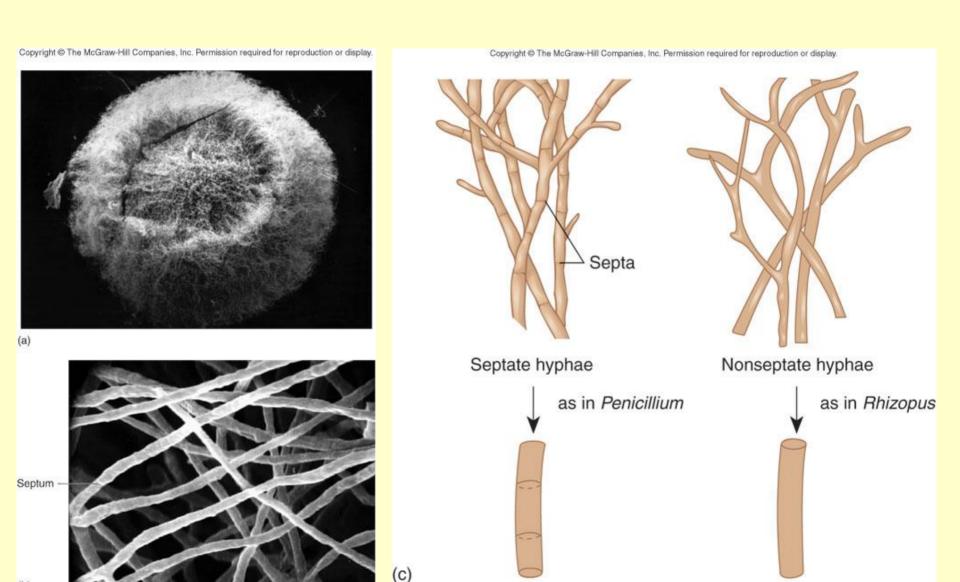

Kingdom Fungi

- 100,000 species divided into 2 groups:
 - macroscopic fungi (mushrooms, puffballs, gill fungi)
 - microscopic fungi (molds, yeasts)
- majority are unicellular or colonial, a few have cellular specialization

microscopic fungi

- exist in 2 morphologies
 - yeast round ovoid shape, asexual reproduction
 - hyphae long filamentous fungi or molds
- some exist in either form **dimorphic** characteristic of pathogens

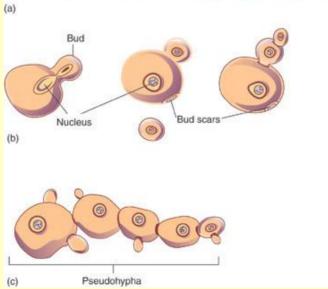

Morphology of yeasts

Hyphae or mold

Fungal nutrition

- all are heterotrophic
- majority are harmless saprobes living off dead plants & animals
- some are **parasites**, living on the tissues of other organisms, but none are obligate; **mycoses** fungal infections
- growth temperature 20°-40°C
- extremely widespread distribution in many habitats

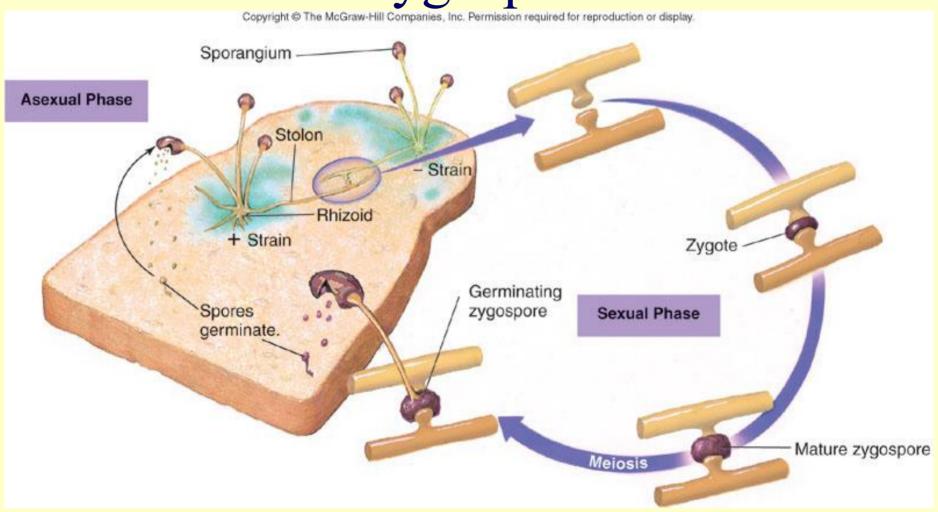

Fungal Reproduction

- primarily through spores formed on special reproductive **hyphae**
 - asexual reproduction spores are formed through budding or in conidia or sporangiospores
 - sexual reproduction spores are formed following fusion of male & female strains & formation of sexual structure
- sexual spores are one basis for classification

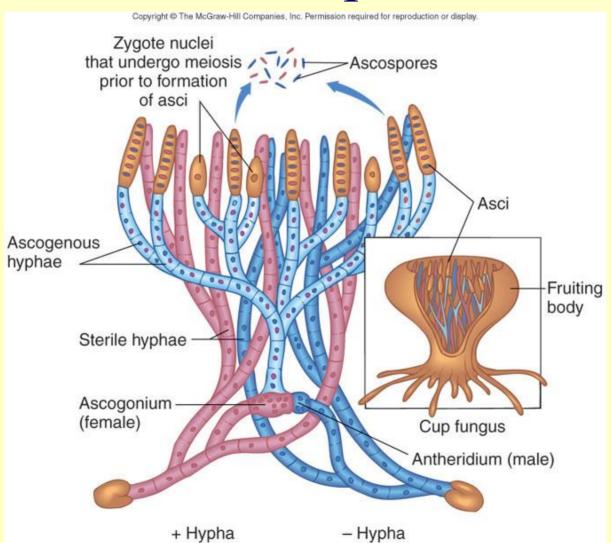

Asexual mold spores

I. Zygospores

II. Ascospores

III. Basidospores

Roles of fungi

- decomposers of dead plants and animals
- sources of antibiotics
- used in making foods & in genetic studies
- adverse impact food spoilage, mycoses, toxin production

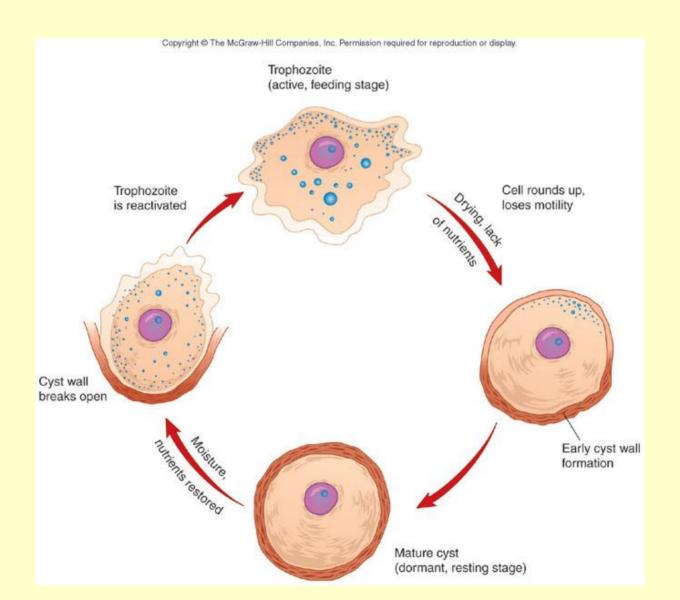

Kingdom Protista

- algae
- protozoa

Protozoa

- 65,000 species
- most are unicellular, colonies are rare
- most have locomoter structures flagella, cilia, or pseudopods
- vary in shape
- lack a cell wall & chloroplasts
- can exist in trophozoite- motile feeding stage or cyst – a dormant resistant stage

Protozoa

Protozoa

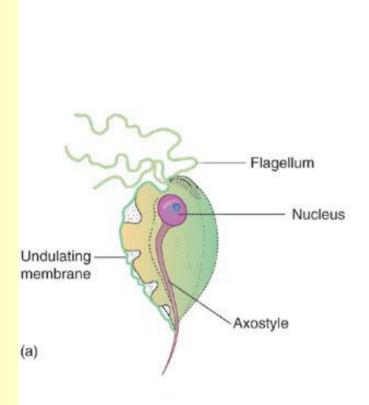

- all are heterotrophic,
- most are free-living in a moist habitat
- feed by engulfing other microbes & organic matter
- some are animal parasites & can be spread by insect vectors
- asexual and sexual reproduction

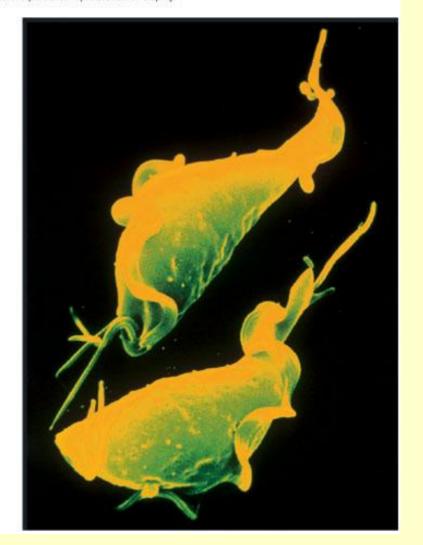

Groups based on locomotion & reproduction

- Mastigophora flagellates
- Sarcodina amebas
- Ciliophora ciliates

Sarcodina – amebas

Ciliophora – ciliates

Parasitic Helminths

- multicellular animals, organs for reproduction, digestion, movement, protection
- parasitize host tissues
- have mouthparts for attachment to or digestion of host tissues
- most have well-developed sex organs that produce eggs and sperm.
- fertilized eggs go through larval period in or out of host body

Major groups of helminths

- 1. flatworms flat, no definite body cavity; digestive tract a blind pouch; simple excretory & nervous systems
 - cestodes (tapeworms)
 - trematodes or flukes, are flattened, nonsegmented worms with sucking mouthparts
- 2. roundworms (nematodes)- round, a complete digestive tract, a protective surface cuticle, spines & hooks on mouth; excretory & nervous systems poorly developed

Helminths

- 50 species parasitize humans
- acquired though ingestion of larvae or eggs in food; from soil or water; some are carried by insect vectors
- afflict billions of humans
