Illnesses caused by contaminated food are among the most widespread of health problems. This project enhances the development of models for quantitative microbial risk assessments. The endotoxin, lipopolysaccharide (LPS), was biosynthetically labeled with 3H and 14C incorporated into the fatty acyl-chains and glucosamine residues, respectively, of Salmonella enterica. The distribution of 14C- and 3H-LPS in plasma and organs was determined in Sprague-Dawley rats following IP dose of 14C, 3H-LPS (200 μg/kg). Plasma concentrations were biphasic, with a relatively rapid decay followed by a long slow decline for the 48 hour sampling period. Similar biphasic results were found in the kidney and heart and in the meninges and choroid plexus. In the liver, the peak concentration was not followed by a biphasic decline, instead sustained elevation of 14C and 3H activities were observed indicating that both 14C and 3H moved relatively slow through the liver. The spleen followed by the liver contained the highest concentration of radioactivity. The concentration in the spleen was approximately 1.6 fold higher than that of the liver and approximately 34 fold for 3H and 67 fold for 14C greater than the brain values. In the brain tissue, the exposure increased linearly for both 3H and 14C until 18 hr and then a further increase for 3H activity, whereas 14C-activity was decreased. The exposure in the brain relative to the plasma was increased by factors of 0.04 (3H) and 0.02 (14C) at the peak level, and decreased to a factor of 0.006 for 14C at 48 hr.The levels in meninges relative to the plasma were increased by factors of 0.32 (3H) and 0.33 (14C), and an increment of factors by 0.42 (3H) and 0.52 (14C) was revealed in choroid plexus; indicating a higher affinity for 14C by choroid plexus.

The elevation of 3H and 14C in the spleen is indicative of the role of the immune response consistent with lipid participation in the endotoxic response during infection.

PS 953 EVALUATION OF FECAL AND URINARY EXCRETION PRODUCTS AFTER INHALATION OF AEROSOLIZED S-8 SYNTHETIC JET FUEL IN RATS.

R. T. Tremblay, S. A. Martin and J. W. Fisher. *Environmental Health Science, UGA, Athens, GA.*

The US Air Force is transitioning from petroleum-based Jet Propellant-8 (JP-8) to a blend of JP-8 and synthetic jet fuel (S-8) produced from gas or coal using the Fischer-Tropsch process. The composition of S-8 fuel differs from JP-8 fuel primarily by a complete lack of aromatic hydrocarbons and a substantial increase in the amount of branched alkanes. Limited toxicological information is available for S-8 fuel. The present research evaluates hydrocarbons found in tissues and excreta of male F344 rats exposed in a nose-only chamber for 4 hours to 1000 mg m-3 of aerosolized S-8 fuel. A portion of the animals were placed in metabolism cages for 48 hours after exposure while the others were sacrificed and blood and tissues (liver, brain, lungs and fat) collected two hours into the exposure and up to one-hour post exposure. Several metabolites associated with the fuel exposure were identified in tissues and excreta. The burden of metabolites appeared to be greatest in the liver compared to other tissues. Identifications of hydrocarbon structures suggest that the hepatic cytochrome P450 system is involved in the metabolism of these chemicals. In separate inhalation exposures, n-alkane metabolites were found in liver and lung of rats exposed to a mixture of n-alkanes (n-C10 to n-C15). This study is part of a larger ongoing study to develop a hydrocarbon mixture Physiologically Based Pharmacokinetic (PBPK) model for jet fuel. This abstract is first to report on the metabolism of S-8 fuel. (This research was supported by AFOSR Grant FA9550-07-1-0132)

PS 954 COMPARATIVE PHARMACOKINETICS OF PERFLUORONONANOIC ACID IN RATS AND MICE.

K. R. Tatum[1], R. Zehr[2], K. Das[2], M. Strynar[3], A. Lindstrom[3], J. Wambaugh[4] and C. Lau[2]. *[1]Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC, [2]Developmental Biology Branch, U.S. EPA, Research Triangle Park, NC, [3]Human Exposure and Atmospheric Sciences Division, U.S. EPA, Research Triangle Park, NC and [4]National Center for Computational Toxicology, U.S. EPA, Research Triangle Park, NC.*

Perfluorononanoic acid (PFNA) is a fluorinated organic chemical found at low levels in the environment, but is detectable in humans and wildlife. This study compared the pharmacokinetic properties of PFNA in two laboratory rodent species. Male and female Sprague-Dawley rats (n = 3) were given PFNA by oral gavage at 1, 3, or 10 mg/kg, and blood was collected from tail vein at 1, 2, 3, 4, 7, 16, 21, 28, 35, 42 and 50 days after treatment. CD-1 mice were given a single oral dose of PFNA at 1 or 10 mg/kg, and 4 males and 4 females were killed at similar time intervals; trunk blood and liver were collected. Serum and liver concentrations of PFNA were determined by HPLC-MS-MS. Serum elimination of PFNA was linear with exposure doses in both species. In the rat, half-lives of 24 and 3.8 days were estimated for males and females, respectively. In the mouse, serum disappearance of PFNA was biphasic. The initial distribution phase of the chemical was significantly faster in the males than in the females (Vd = 0.0231 1/h for males and 0.141 1/h for females), although the subsequent elimination phase appeared to be similar between the two sexes ($t_{1/2}$ = 58 days for males and 41 days for females). Correspondingly, the appearance of PFNA in the liver was faster, and the chemical reached higher levels in the male mice than in the females. These data thus suggest that (1) PFNA is more persistent in the mouse than in the rat; (2) there is a major sex difference in the serum elimination of PFNA in the rat, but much less so in the mouse; and (3) there is a significantly higher accumulation of PFNA in the liver of male mice than that in the females. This abstract does not necessarily reflect U.S. EPA policy.

PS 955 THE FATE OF ARBUTIN IN AQUEOUS ACID AND IN RATS AND MICE.

J. M. Sanders, D. E. Barlaz, P. Chan and L. T. Burka. *NIEHS, Research Triangle Park, NC.*

Arbutin (ARB), a glycoside of hydroquinone (HQ), is present in pears and herbals such as bearberry and damiana. Consumer products containing ARB have been used to treat urinary tract infections and as skin-lightening agents. ARB is hydrolyzed to HQ in humans. HQ is primarily conjugated and excreted in urine, but

could be metabolized to reactive species. ARB has been reported to be easily hydrolyzed by dilute acid; however, this contradicts evidence that ARB is stable at pH of 2 and is excreted unchanged in the urine of gavaged rats. The fate of ARB in mice has not been reported. The present studies were designed to investigate the stability of the glycosidic bond of ARB in aqueous acid and to determine the chemical's *in vivo* fate in male rats (F344 and Wistar Han) and mice (B6C3F1). Results of the present work indicated that little or no hydrolysis of ARB occurred in aqueous acid at pH as low as 0.1. In the *in vivo* studies, a 100 mg/kg orally administered dose of ^{14}C-labeled ARB was rapidly absorbed from the gut, with greater than 95% of the recovered dose (96 ± 6, 105 ± 2, and 87 ± 9% for F344 rats, Wistar Han rats, and B6C3F1 mice, respectively) excreted in the urine within 24 h post-dosing. The major tissues, including blood, contained little or no ^{14}C at the timepoint. Results were similar for rats and mice receiving 0.1 mg/kg. Over 90% of the ^{14}C excreted in 0-4 hr urine of F344 or Wistar Han rats (75 ± 5 and 84 ± 10% total dose, respectively) consisted of a peak eluting at the retention time of parent ARB in the HPLC system. The peak, accounting for greater than 75% of the ^{14}C excreted in mouse urine, was isolated and confirmed as ARB by LC/MS analysis. In conclusion, the present studies demonstrated the stability of the glycosidic bond of ARB in aqueous acid well below gastric pH and *in vivo* in the rat and mouse. Humans may in fact be more sensitive to the effects of ARB than rats and mice; therefore, ARB-treated rodents are probably poor models for predicting effects of exposure to the chemical in humans.

PS 956 IN VITRO METABOLISM AND GENDER SPECIFIC PHARMACOKINETICS OF K777, A NOVEL CYSTEINE PROTEASE INHIBITOR.

L. V. Iyer[1], C. E. Green[1], L. Rausch[1], A. M. Furimsky[1], L. Tang[1], J. McKerrow[2] and J. Mirsalis[1]. *[1]SRI International, Menlo Park, CA and [2]Univ California San Francisco, San Francisco, CA.*

K777 (N-methyl-piperazine-Phe-homoPhe-vinylsulfone-phenyl) is a novel cysteine protease inhibitor under investigation as a therapeutic candidate for Chagas Disease. Metabolism and pharmacokinetic profiles of K777 were evaluated in this study. Human and rat liver microsomes (0.2 mg/ml) were incubated with K777 (0 to 100 μM), MgCl2 (3.3 mM) and NADPH (2.5 mM) in a phosphate buffer (pH=7.4) medium. The major metabolites of K777 identified include *N*-desmethyl and *N*-oxide metabolites with apparent K_m values of about 20 and 18 μM (human) and 8 and 5 μM (rat), respectively. A hydroxyl metabolite of K777 was also formed by human liver microsomes (K_m~10μM). The bioavailability and pharmacokinetics of K777 was determined in male and female rats after oral (20 and 100 mg/kg) and iv (20 mg/kg) administration. Plasma exposure of K777 was 2 to 8-fold higher in females than males, as shown by AUC values; iv group (20 mg/kg): 5758 (males) and 6924 (females); oral groups (20 and 100 mg/kg): 101 and 6394 (males), 799 and 12852 (females) μg.hr/ml. Oral bioavailability was higher in females (12 and 37%) than in males (2 and 22%) at K777 doses of 20 and 100 mg/kg. Plasma concentration time profiles in rats of both genders showed the presence of secondary peaks indicative of enterohepatic circulation. K777 was also studied in a toxicity study after 7-day repeat oral administration. Plasma concentrations at 30 min post-dose on days 1 and 7 indicated 2.5 to 13-fold higher levels of K777 in females than in males. In addition, there were marked decreases (1.5 to 3-fold) in plasma concentrations of K777 on day 7 versus day 1 in both genders. This indicated an increased clearance of K777 with multiple oral doses, which may be due a possible autoinduction of its metabolism with chronic administration. Additional studies are in progress to further evaluate the gender differences in K777 disposition, and mechanisms of induction of own its metabolism after chronic administration. *Funded by NIAID Contract N01-AI-60011.*

PS 957 IDENTIFICATION OF TRANSPORTERS INVOLVED IN RENAL ELIMINATION OF PERFLUORINATED CARBOXYLATES IN RATS.

Y. M. Weaver and B. Hagenbuch. *Pharmacology Toxicology&Therapeutics, The University of Kansas Medical Center, Kansas City, KS.* Sponsor: G. Guo.

Perfluorinated carboxylates (PFCAs) are globally distributed environmental chemicals that are widely used in many industrial processes. Readily absorbed through contaminated water, they can affect lipid metabolism in animal models. Both hepatic accumulation and renal clearance of PFCAs are influenced by chain length and gender in rats. PFCAs with shorter chain length are in general excreted in urine while the longer ones accumulate in liver. We wanted to test the hypothesis that this renal elimination and liver accumulation are caused by tissue and gender specific expression of candidate transporters. We transiently transfected HEK 293 cells with Oat1 and Oat3. For Oatp1a1, we used a stable CHO cell line. We measured uptake of the model substrates p-aminohippurate (Oat1), estrone-3-sulfate (Oat3) and estradiol-17β-glucuronide (Oatp1a1) in the absence or presence of 10 μM of PFCAs with chain lengths from 2-18 carbons. To determine direct transport of PFCAs, we used LC-MS/MS analysis. Oat1-mediated transport was inhibited strongest by perfluoroheptanoic acid (PFHA), followed by perfluorooctanoic acid (PFOA) and perfluorononanoic acid (PFNA). PFOA and PFNA were the strongest inhibitors for Oat3-mediated estrone-3-sulfate transport. Oatp1a1-mediated transport of estradiol-17β-glucuronide was inhibited strongest by perfluorodecanoic acid (PFDA), followed by perflourounidecanoic acid (PFUDA) and PFNA. With respect to transport, uptake into Oat1 expressing cells was highest for PFHA and PFOA, followed by PFNA. Uptake into Oat3 expressing cells was highest for PFOA and PFNA, followed by PFHA. In Oatp1a1 expressing cells, uptake of PFDA was highest followed by PFNA and PFOA. In summary, for the three tested transport proteins, the strongest inhibitors are also the best substrates. Based on their cellular localization, we conclude that Oat1 and Oat3 may be responsible for active renal secretion of PFHA, PFOA and PFNA while Oatp1a1 may be responsible for reabsorption of PFDA, PFNA and PFOA.

PS 958 IDENTIFICATION OF HUMAN GENES THAT COMPLEMENT A GLUTATHIONE TRANSPORT DEFICIENCY IN YEAST.

S. Shi, S. Notenboom and N. Ballatori. *Environmental Medicine, University of Rochester, Rochester, NY.*

Reduced glutathione (GSH; l-γ-glutamyl-l-cysteinylglycine) is a major intracellular thiol, and disturbances in its homeostasis are associated with a number of human diseases. GSH export from cells is one of the two major mechanisms involved in regulating GSH levels, although relatively little is known about the proteins responsible for GSH export. To examine whether unidentified GSH transport mechanisms exist in the human genome, a human mammary gland cDNA library was screened using a yeast (*S. cerevisiae*) functional complementation strategy. Unlike mammalian cells, yeast cells are able to uptake GSH from the extracellular space utilizing hgt1p, a high affinity GSH uptake transporter. The deletion of the *HGT1* gene (*hgt1-Δ* strain) leads to a deficiency in GSH uptake and the inability to grow in sulfur-deficient media in which GSH is the only sulfur source. This screening strategy initially identified more than 300 colonies that grew faster in sulfur-deficient medium, and from this pool five human genes were identified, namely: *TMEPAI*, transmembrane, prostate androgen induced RNA; *LAPTM4α*, lysosomal-associated protein transmembrane 4 alpha; *SLC25A1*, solute carrier family 25, member 1; *LITAF*, lipopolysaccharide-induced TNF factor; and *CYYR1*, cysteine/tyrosine-rich-1. All five genes are predicted to encode for small membrane proteins. The expression of these five genes was able to rescue growth of *hgt1-Δ* cells and to increase intracellular glutathione levels when cells were cultured in sulfur-deficient medium supplemented with 750 μM GSH. [^{3}H]GSH uptake was measured in whole cells, and the result confirmed that GSH uptake abilities in yeast cells transformed with these five huamn genes was increased. Altered expression of *TMEPAI, SLC25A1, LITAF*, and *CYYR1* has been reported in a number of human diseases, but little is known about the normal biological functions of these five genes. The present results suggest that they may be involved in plasma membrane transport events and/or the regulation of GSH homeostasis.

PS 959 THE EFFECTS OF TEMPERATURE AND TIME ON THE GENERATION OF ALCOHOL IN STORED BLOOD.

D. H. Petroni and W. J. George. *Pharmacology, Tulane University, New Orleans, LA.*

The present study was conducted to investigate whether and, if so, under what conditions spontaneous alcohol generation would occur in blood stored over extended periods of time in sterile collection tubes. Fresh blood was collected from our blood bank and aliquots of blood were transferred into red top Vacutainer tubes containing no added preservative or anticoagulant. The tubes were divided into two groups for storage and maintained for up to 1 week after collection. One group was placed in a refrigerator where the temperature range was between 7-9°C. The other group was kept on a bench top, where the median room temperature was maintained at 25°C. Samples of blood (100μl) were drawn from each tube at time zero, 48, 72, 96, 120 and 144 hours after initiation of storage. The specimens were analyzed for alcohol content on a Shimadzu 14-A Gas Chromatograph, equipped with a Supelco 5% Carbowax packed column. The refrigerated specimens developed no significant levels of ethanol within the entire time frame while those stored at room temperature began to produce slight but detectable levels of ethanol by 120 hours. By the 144 hour time point, all blood stored at room temperature showed detectable levels

of alcohol, whereas blood stored at 7-9o C produced no evidence of alcohol production. This study indicates that both temperature and duration of storage are factors, which may result in the generation of blood alcohol in such specimens used for toxicological assessment, even when maintained in sterile blood tubes.

PS 960 INHALATION PHARMACOKINETICS AND METABOLISM OF 8-2 FLUOROTELOMER ALCOHOL IN RATS AND EXTRAPOLATION TO HUMAN EXPOSURE.

M. W. Himmelstein[1], J. T. Weinberg[2], M. P. Mawn[1], M. H. Russell[1], T. L. Serex[1] and R. C. Buck[1]. [1]*E.I. DuPont de Nemours & Co Inc., Newark, DE and* [2]*WIL Research Laboratories LLC, Ashland, OH.*

This study investigated the profile of 8-2 fluorotelomer alcohol (8-2 FTOH, F(CF2)8CH2CH2OH) and its metabolites in plasma under controlled inhalation exposure as the basis for comparison with potential environmental exposure. Male and female rats were exposed to 8-2 FTOH at 3 or 30 mg/m^3 for 6 h. Blood was collected at 1, 3 & 6 h during nose-only exposure and at 6 & 18 h after the end of exposure. Plasma samples were analyzed by LC/MS/MS for the alcohols (8-2 FTOH, 7-2 sFTOH), carboxylic acids (PFPeA, PFHxA, PFHpA, PFOA, PFNA), and polyfluorinated acids (8-2 FTA, 7-3 Acid, 8-2 FTUA, 7-3 UA). The nanomoles of each plasma analyte were calculated from the 0-24 h AUC (nM*h) and estimated plasma volume, then divided by the inhaled dose. 8-2 FTOH was detected in plasma at 30 mg/m^3 but not 3 mg/m^3. Extensive metabolism was observed based on transient quantifiable metabolite concentrations during and after exposure. The ranking of the top four metabolites (as % of dose in plasma) in male rats was PFOA (0.09-0.12%) > 7-3 Acid (0.08%) > 8-2 FTA (0.02-0.03%) > PFNA (0.01-0.03%). In female rats, the 7-3 Acid (0.05-0.06%) was similar to male rats, but the PFOA (0.02%) was 4-6x lower than males. All other metabolites in plasma were <0.01%, and female rats were generally lower than male rats. An oral dose study shows that the majority of the dose was eliminated in feces, bile, and to a lesser extent in urine. Extrapolation of the PFOA results to human exposures is possible using in vitro data for 8-2 FTOH metabolism. The highest concentration of 8-2 FTOH reported in environmental monitoring of ambient air (2.5 ng/m^3) in locations directly impacted by local industrial emissions is six orders of magnitude less than the concentrations used here (3-30 mg/m^3). Because the fractional formation of PFOA from 8-2 FTOH in humans is extremely small (e.g. 0.02% based on in vitro data), it can be concluded that inhalation of ambient concentrations of 8-2 FTOH is a negligible source of PFOA in humans.

PS 961 PHARMACOKINETIC MODELING OF PERFLUOROOCTANOIC ACID DURING GESTATION AND LACTATION IN MICE.

C. E. Rodriguez, R. Setzer and H. A. Barton. *National Center for Computational Toxicology, U.S. EPA, Research Triangle Park, NC.*

Perfluorooctanoic acid (PFOA) is used industrially as a processing aid in the polymerization of commercially valuable fluoropolymers. Its widespread environmental distribution, presence in human serum, and adverse effects in animal toxicity studies have triggered attention to its potential adverse effects to humans. PFOA is not metabolized and exhibits dramatically different plasma half-lives across species. Estimated plasma half-lives for humans, monkeys, mice, and female rats are 3-5 years, 20-30 days, 12-20 days, and 2-4 hours, respectively. Developmental toxicity is one of the most sensitive adverse effects associated with PFOA exposure in rodents. In mice, developmental delays and reduced postnatal growth and survival occurred at much lower administered doses than in rats. Risk assessment of PFOA is currently hampered by the lack of understanding of its cross-species pharmacokinetics in animal toxicity studies. To address this uncertainty, a biologically-supported dynamic model was developed whereby a two-compartment system linked via placental blood flow described gestation and milk production linked the lactating dam to a growing pup litter compartment. The model incorporated changes in body weight, placental blood flow, milk yield, and PFOA-specific pharmacokinetic information. Postnatal serum levels of PFOA for 129S1/SvImJ mice at doses of 1 mg/kg or less were reasonably simulated while prenatal and postnatal measurements for CD-1 mice at doses of 1 mg/kg or greater were simulated via addition of a biologically-based renal resorption description. Our results suggest that a linear model may suffice for describing the pharmacokinetics of PFOA at low doses while a more complex model may be needed to describe non-linear behavior at higher doses. Based on internal dose estimates, the mouse achieves much higher levels as compared to rats which may help explain the observed differences in developmental toxicity in these two species. (This work was reviewed by EPA and approved for publication but does not necessarily reflect official Agency policy).

PS 962 *IN VITRO* TO *IN VIVO* EXTRAPOLATION WITH A PBTK MODEL FOR 2-CHLORO-1, 3-BUTADIENE.

Y. Yang[1], H. J. Clewell[1], Y. Tan[1], M. E. Andersen[1], M. Sochaski[1] and M. W. Himmelstein[2]. [1]*The Hamner Institutes for Health Sciences, Research Triangle Park, NC and* [2]*DuPont Haskell Global Centers, Newark, DE.*

Beta-chloroprene (2-chloro-1,3-butadiene) (CD) is a volatile, flammable liquid monomer used for the production of synthetic rubber and latexes. Although human cancer epidemiology studies have been inconclusive, animal studies have demonstrated carcinogenic effects of CD in B6C3F1 mice and Fischer rats. In this study, in vitro kinetic data for CD metabolism in liver and lung were used to predict in vivo kinetics in female mice after single and repeated inhalation exposures. For parameterization of CD metabolism, a 2-compartment kinetic model was used to describe the distribution and metabolism of CD in an in vitro closed vial system. The ratios for liver Vmax/Km (mL/hr/mg) were 112 and 86 in the mouse and rat, respectively. Metabolism in the lung was slower (Vmax/Km = 9.1 for mice and 0.9 for rats). The Vmax values were scaled for use in the PBTK model. In vivo exposure of female mice to 13, 32, or 90 ppm CD for 6 hrs resulted in end exposure blood concentrations that were non-linearly related to exposure concentration and required addition of metabolism in the upper respiratory tract and kidney (as 5% and 10% of the liver Vmax, respectively) for the model to fit the reduced blood concentrations at days 5 and 15, relative to day 1. These additions only partially accounted for the reduced blood concentrations and a 50% reduction in the ventilation rate from the 1-day exposure was needed for the model to reproduce the observed data. Ventilation was measured experimentally on day 1 and corresponded to a QPC = 34 L/hr/kg^0.75. The 1-day minute volumes were not affected by increasing CD exposure concentration, suggesting physiological adaptation with repeated exposure. With the revised PBTK model structure and the in vitro metabolic parameters, the PBTK model successfully predicted the time-course of CD in the blood after single and repeated exposures. This in vitro to in vivo extrapolation (IVIVE) approach could be used with human metabolism data to predict human kinetics.

PS 963 ANALYTICAL METHOD VALIDATION OF 2-METHOXY-4-NITROANILINE IN NTP-2000 AND NIH-07 RODENT DIETS.

J. W. Algaier[1], A. K. Clay[1], G. L. Goodman[1], A. S. Haynes[1], O. L. Beverly[1], K. E. Schnare[1], S. E. Griffin[1], V. F. Ault[1], A. Kazerooni[1], B. M. O'Brien[1], P. J. Schebler[1], R. K. Harris[1], B. Jayaram[2] and C. S. Smith[2]. [1]*Product Sciences Division, Midwest Research Institute, Kansas City, MO and* [2]*National Toxicology Program, NIEHS, Research Triangle Park, NC.*

2-Methoxy-4-nitroaniline (MONA), selected for toxicological evaluation by the National Toxicology Program (NTP), is used as a textile dye, in the printing industry, and in the synthesis of azo dyes with applications in tattoo inks, emulsion paints, and toy enamels. An analytical method was developed and validated for MONA in both NTP-2000 and NIH-07 rodent diets to cover a dose formulation range of 750 μg/g to 30,000 μg/g. MONA was extracted from feed with acetonitrile using a wrist-action shaker for 15 min followed by centrifugation for 5 min, 2,200 rpm. Afterwards an aliquot was combined with 4-nitroaniline, the internal standard (IS), and analyzed using high performance liquid chromatography (HPLC) with ultraviolet (UV) detection with a Supelco Ascentis RP-Amide (250 x 4.6 mm, 5-μm particle size) column. The mobile phase was acetonitrile:water (50:50, v/v, isocratic) with resulting retention times of 7.4 min for MONA and 6.4 min for IS. Both method validations were linear ($r \geq 0.999$), accurate (from -11.9 to 2.1% relative error), and precise (% RSD ≤ 0.5). Following method validation, a 42-day dose formulation stability study and a 7-day simulated dosing study were performed at 1,500 μg/g MONA in both diets. The 42-day dose formulations were stored under ambient (25°C), refrigerated (5°C), and freezer (-20°C) conditions. When compared to Day 0, the results indicated losses up to 39.6% under ambient conditions, up to 9.7% under refrigerated conditions, and up to 2.4% under freezer conditions. The 7-day simulated dosing formulations were stored in stainless steel hoppers under ambient (25°C) temperature with 50% relative humidity and 12-hr daily light cycles. When compared to Day 0, the results indicated losses up to 12.2%.

PS 964 EFFECT OF NARINGENIN ON DISPOSITIONS OF DEOXYNIVALENOL IN PIGLETS.

A. Poapolathep[1, 2], S. Poapolathep[1, 2], Y. Sugita-konishi[3], K. Machii[3], Y. Itoh[3] and S. Kumagai[2]. [1]*Veterinary Pharmacology, Kasetsart University, Bangkok, Thailand,* [2]*Veterinary Public Health, The University of Tokyo, Tokyo, Japan and* [3]*National Institute of Health Sciences, Tokyo, Japan.*

Naringenin (NAR) is a naturally occurring flavonone glycoside obtained from grapefruit, which is expressed on a diuretic effect. The aim of this present research is to evaluate the effect of NAR on dispositions of deoxynivalenol (DON) in piglets

following intravenous (i.v.) administration. Piglets were then divided into two groups; three piglets (group 1) were pretreated orally with NAR at a dosage of 25 mg/kg body weight (bw), once a day for 3 consecutive days, followed by a single i.v. administration of DON at a dosage of 1 mg/kg bw. The other three piglets (group 2) were i.v. administered with DON at the same dosage. The level of DON in plasma and various tissues were determined using liquid chromatography/tandem mass spectrometry (LC/MS/MS). Plasma levels of DON were measurable up to 20 h in both groups after administration of DON. However, DON level in piglets pretreated with NAR was lower than that of piglets untreated with NAR. The level of DON in plasma with respect to time was analyzed with a non-compartmental pharmacokinetic model. The elimination half-life was longer in piglets untreated with NAR than in piglets pretreated with NAR. The values of peak concentration at initial time, area under the curve and mean residence time were also higher in piglets untreated with NAR than in piglets pretreated with NAR. The tissue depletion of DON corresponded well with the plasma level in piglets pretreated with NAR. In addition, plasma biochemical parameters were monitored, aspartate aminotransferase, alanine aminotransferase, creatine phosphokinase, blood urea nitrogen and creatinine levels were remarkably lower in piglets pretreated with NAR than in piglets untreated with NAR. Based on the toxicokinetic data and biomarker enzyme activities, indicating NAR can enhance the excretion of DON and reduce opportunity for damage in piglets. Consequently, the toxicity would be greater in piglets untreated with NAR than in piglets pretreated with NAR.

PS 965 VALIDATION OF PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODEL PREDICTIONS OF PRESYSTEMIC ELIMINATION OF TRACE ORAL DOSES OF TRICHLOROETHYLENE (TCE).

J. V. Bruckner, J. Qiu, Y. Liu, S. Muralidhara and M. G. Bartlett. *PBS, University of Georgia, Athens, GA.*

TCE is a common contaminant of groundwater and drinking water in the U.S. Concentrations range from ppt to a few ppm. Ingestion of such water should not pose a non-cancer or cancer risk of injury to extrahepatic organs, if all of the TCE is removed from the venous blood by the liver and lungs (i.e., by pre-systemic elimination) before it reaches the arterial circulation. Unanesthetized male S-D rats were given TCE iv and by gavage in doses of 0.0001, 0.001, 0.01, 0.1, 1, 2.5, 5 and 10 mg/kg. Serial blood samples from the cannulated rats were analyzed by headspace solid phase microextraction-gas chromatography with negative chemical ionization mass spectrometry. The method's LOQ was 0.025 ng/ml. Blood time-course data were analyzed by WinNonlin to estimate pharmacokinetic parameters. Bioavailablity was inversely related to dose, ranging from 25% at 10 mg/kg to ~12 % at the lower doses. Thus, not all of environmentally-relevant oral dosages of TCE are removed from portal blood of rats by presystemic elimination. A miniscule amount of TCE was detected in the blood (AUC=0.9 ng-min/ml) for the first 15 minutes following ingestion of 1 μg TCE/kg. A 7-compartment PBPK model, based on that of Hack et al. (2007), accurately predicted the TCE time-course data and simulated first–pass uptake by the gut, liver and lungs. Supported in part by U.S. DOE Coop. DE-FC09-02CH11109.

PS 966 ANALYTICAL METHOD VALIDATION OF TRIS(CHLOROPROPYL) PHOSPHATE, MIXTURE IN NTP-2000 AND NIH-07 RODENT DIETS.

B. Jayaram[2], G. L. Goodman[1], S. E. Griffin[1], A. S. Haynes[1], A. K. Clay[1], O. L. Beverly[1], V. F. Ault[1], A. Kazerooni[1], B. M. O, Brien[1], P. J. Schebler[1], J. W. Algaier[1], R. K. Harris[1] and C. S. Smith[2]. *[1]Product Sciences Division, Midwest Research Institute, Kansas City, MO and [2]National Toxicology Program, NIEHS, Research Triangle Park, NC.*

Tris(chloropropyl) phosphate (TCPP; mixture of four isomers), selected for toxicological evaluation by the National Toxicology Program (NTP), is a flame retardant added to flexible polyurethane foam used in home furnishings. In this work, an analytical method was developed and validated for the analysis of TCPP in both NTP-2000 and NIH-07 rodent diets to cover a dose formulation range of 1,500 μg/g to 75,000 μg/g. TCPP was extracted from feed with methanol using a wrist-action shaker for 15 min followed by centrifugation for 5 min at 2,200 rpm. Afterwards an aliquot was combined with Isodrin, the internal standard (IS), and analyzed using gas chromatography (GC) with flame ionization detection (FID) with a J & W Scientific DB-5 (30 m x 0.53 mm I.D., 1.5-μm film thickness) column. The oven program was 160°C (5-min hold) to 180°C (5-min hold) at 1.0°C/min. The retention times for the three major isomers of TCPP were 13.9 min, 14.5 min, and 15.1 min with 25.6 min for IS. Both method validations were linear ($r \geq 0.9999$), accurate (from -7.0 to 1.3% relative error), and precise (% RSD ≤ 2.4). Following method validation, a 42-day dose formulation stability study and a 7-day simulated dosing study were performed at 3,000 μg/g TCPP in both diets. The 42-day dose formulations were stored under ambient (25°C), refrigerated (5°C), and freezer (-20°C) conditions. When compared to Day 0, the results indicated losses up to 10.8% under ambient conditions, up to 5.9% under refrigerated conditions, and up to 5.8% under freezer conditions. The 7-day simulated dosing formulations were stored in stainless steel hoppers under ambient (25°C) temperature with 50% relative humidity and 12-hr daily light cycles. When compared to Day 0, the results indicated losses up to 7.1%.

PS 967 PK/PD EFFECTS OF VARIOUS MMB-4 DOSING REGIMENS ON ATROPINE BIOAVAILABILITY IN RATS.

S. Hong[1], B. Roche[2], T. Vinci[2], B. Burback[1], L. Cabell[3], J. McDonough[3], J. D. Johnson[1] and T. Underwood[4]. *[1]Chemistry Technical Center, Battelle, Columbus, OH, [2]Safety Pharmacology, Battelle, Columbus, OH, [3]Chemistry and Chemical Engineering Division, Southwest Research Institute, San Antonio, TX and [4]Chemical Biological Medical Systems, Chemical and Biological Defense, Frederick, MD.*

Concomitant administration of atropine with pralidoxime (2-PAM) is standard treatment following organophosphorous poisoning. Human studies demonstrated a delay in atropine absorption when injected with 2-PAM (Sidell, 1974, C. Pcol. Ther.; Friedl et al., 1989, J. Pharm. Sci.). This delay was attributed to the osmolality of the 2-PAM. 1,1'-methylenebis {4-[(hydroxyimino)methyl] pyridinium} dimethanesulfonate (MMB-4), a potential new oxime therapeutic for organophosphorous poisoning, will be co-administered with atropine if approved. This study determined what the impact of co-administered MMB-4 would be on atropine absorption, i.e. could these two compounds be co-administered or would they require separate administration. Adult male Sprague-Dawley rats (3 animals/group) were cannulated (femoral vein) for automated serial blood sample collection (Culex) and implanted with telemetry devices for collection of heart rate. Plasma atropine concentrations were measured using an LC/MS method. Single intramuscular injections of saline (control), atropine (0.2 mg/kg), and/or MMB-4 (160 mg/kg) or 2-PAM (60 mg/kg) were administered. PK parameters used to assess atropine absorption (ka, Cmax, Tmax, AUC) were similar for all treatment groups. The maximum heart rate response was similar for all treatment groups. Initial results indicate that the time to maximum heart rate response occurred earliest when atropine and MMB-4 were co-mixed but the temporal difference compared to the separate injections was not considered biologically relevant. Co-mixed atropine and 2-PAM resulted in a 1.5 to 3-fold delay in the time to maximum heart rate response compared to the atropine and MMB-4 groups. The results for this study suggest that co-mixing atropine and MMB-4 does not reduce atropine absorption in rats. [Supported by CBRNIAC contract #SP0700-00-D-3180]

PS 968 CHARACTERIZATION OF THE TRANSPORT AND INHIBITORY EFFECTS OF NBUPY-CL AND ITS STRUCTURALLY RELATED IONIC LIQUIDS BY HOCT2.

Y. Cheng[1], M. J. Hooth[3], S. H. Wright[2] and I. Sipes[1]. *[1]Pharmacology, University of Arizona, Tucson, AZ, [2]Physiology, University of Arizona, Tucson, AZ and [3]National Toxicology Program, NIEHS, Research Triangle Park, NC.*

N-butylpyridinium chloride (NBuPy-Cl) is known as an ionic liquid (IL) with solvent properties. In vivo studies in rats revealed that the systemically available NBuPy-Cl was eliminated in urine as the parent compound. Since its plasma clearance exceeded glomerular filtration rate, NBuPy-Cl appears to be secreted by organic cation transporters (OCTs) in the kidney. Here, we determined the transport by and inhibitory effects of NBuPy-Cl and other structurally related ILs on human OCT2 (hOCT2) expressed in Chinese hamster ovary cells. NBuPy-Cl was effectively transported by hOCT2 (kt=18±3 μM) and was also a potent inhibitor of hOCT2 mediated transport of tetraethyl ammonium (TEA, IC50=1.7±0.1 μM) and metformin (IC50=0.7±0.1 μM). Another butyl substituted IL, 1-butyl-3-methylimidazolium chloride, had similar inhibitory characteristics on hOCT2 as NBuPy-Cl, but 1-butyl-3-methylpyrrolidinium chloride was a more potent inhibitor of hOCT2 mediated transport of TEA (IC50=0.5±0.1 μM) and metformin (IC50=0.14±0.01 μM). Results of SAR studies showed that the inhibitory effects of alkyl substituted pyridinium ILs decreased dramatically as the length of the side chain decreased. The IC50 values were 0.3, 2.3, 37, 790 μM (C6H13-, C4H9-, C2H5-, H- pyridinium chloride) and 0.1, 0.7, 20, 555 μM (same order) for hOCT2 mediated transport of TEA and metformin, respectively. These data demonstrate the transport of the tested ILs by hOCT2 and their inhibitory effects on hOCT2 are greatly dependent on the chemical structure and size. This research was supported by the NIEHS NTP Grant No. N01-ES-45529 and NIEHS-sponsored Southwest Environmental Health Science Center Grant Number P30-ES-06694.

PS 969 DRIED BLOOD SPOT METHODOLOGY EVALUATION STUDY IN RATS AND DOGS GIVEN A SINGLE ORAL (CAPSULE) DOSE OF ACETAMINOPHEN OR DEXAMETHASONE.

S. A. Ploch[1], P. Chamberlain[2], B. Stitcher[2], S. Howery[1], S. Godfrey[2], T. Addison[1], X. Liang[1] and F. Kirchner[1]. *[1]Covance Labs, Inc., Madison, WI and [2]Covance Labs, Inc., Vienna, VA.*

Analysis of blood spots dried on specialized filter paper has been reported for therapeutic drug monitoring of certain immunosuppressive drugs and antiretroviral compounds in patients, as well as in screening newborns for metabolic disorders. The small 15 μL volume blood sample required for this analysis can provide a number of advantages over traditional sample volumes collected from laboratory animals for toxicokinetic evaluations in preclinical safety assessment studies. The advantages include eliminating or reducing the need for subgroups in rodent toxicity/toxicokinetic studies, resulting in a significant reduction in animals required for these studies, potentially higher quality rodent toxicokinetic data as a result of serial sample collection from individual animals for better correlations of exposure to toxicity, simplified handling, storage, matrix preparation and transfer, and less invasive sampling. To determine the utility of the dried blood spot (DBS) methodology in a standard safety assessment setting, two commonly used laboratory animal species (rat and dog), were given a single oral (capsule) dose of acetaminophen (150 mg/kg rat, 50 mg/kg dog) or dexamethasone (100 mg/kg rat, 2.5 mg/kg dog). Blood samples were collected using either the DBS methodology or traditional blood and plasma preparation to compare the toxicokinetic profile for each species using the two techniques. Samples from either dried blood spots or plasma will be analyzed by validated LC-MS/MS methodologies. Use of the DBS technique has the promise of providing high quality toxicokinetic data with much smaller sample collection volumes while also enhancing one of the principle goals of a reduction of animal use on preclinical safety assessment studies

PS 970 BAYESIAN ANALYSIS OF PHYSIOLOGICALLY–BASED PHARMACOKINETIC (PBPK) MODELING OF PERCHLOROETHYLENE (PCE) IN HUMANS.

J. Qiu[1], J. V. Bruckner[1], J. W. Fisher[1], Y. C. Chen[2] and H. J. Clewell[3]. *[1]PBS, University of Georgia, Athens, GA, [2]Industrial Safety and Health, Hunkuang Institute of Technology, Taichung, Taiwan and [3]The Hammer Institute, Research Triangle Park, Raleigh, NC.*

PCE is widely distributed in the environment and the primary chemical used in dry-cleaning. A human PBPK model developed by Covington et al. (2007) was modified and used to predict target tissue (e.g., brain and liver) doses of PCE and its major metabolite, Trichloroacetic acid (TCA), during and following inhalation exposures. A Bayesian approach using Markov chain Monte Carlo (MCMC) analysis was employed to combine information from prior distributions of model parameters and data on individuals from 5 previous human kinetic studies of PCE. Interindividual variability can thereby be captured and estimated more readily. Use of posteriors resulted in more accurate predictions of alveolar PCE levels, blood concentrations of PCE and TCA, and urinary excretion of TCA under different exposure conditions. The 95th percentile for the fraction of PCE metabolized upon continuous inhalation of 1 ppm was forecast to be just 1.89 %. Values as high as 58 and 79 % have been adopted by regulatory agencies in estimating cancer risks for low-level PCE exposures.

PS 971 DISPOSITION OF C_{60} FULLERENE AFTER INTRAVENOUS INJECTION, INTRATRACHEAL INSTILLATION, OR INHALATION IN MALE F344 RATS.

Z. Gao[1], B. Hedtke[1], J. Marsters[1], M. Lehman[1], T. Holmes[1], J. Lucak[1], L. Ferguson[1], J. McDonald[1] and N. Walker[2]. *[1]Lovelace Respiratory Research Institute, Albuquerque, NM and [2]National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

Fullerene-C_{60} nanoscale materials have been selected by the National Toxicology Program (NTP) to represent "nanoparticles" for the evaluation of nanoscale material disposition and toxicity. LC-MS and HPLC-UV (330 nm) methods were developed to measure C_{60} fullerene. Male F344 rats were treated with C_{60} in PBS/1% Tween through intravenous (IV) injection or intratracheal (IT) instillation, or aerosol inhalation, and the animals were sacrificed at different time points up to 168 h. Blood, liver, lung, spleen, and kidneys were harvested and lyophilized, and the C_{60} in these tissues was extracted with toluene. Jugular vein-cannulated rats receiving an IV dose of C_{60} (11.6 mg/kg) through the cannula showed that C_{60} was removed from the blood within 1 h, and most of the dose was taken up by the liver. IT instillation of C_{60} (1 and 5 mg/kg) in normal rats showed that C_{60} did not distribute from lung to any other surveyed tissues at 0.5, 2, 6, 24, and 168 h post-dosing. Normal rats exposed to C_{60} (amorphous particles of approximately 20 nm) aerosols at a concentration of 1 mg/m^3 for 6 h showed no distribution of C_{60} from lung to any other surveyed tissues at 0.5, 1, 2, 4, 60, and 168 h post-dosing, except trace amounts were detected in kidneys. The lung half-life of C_{60} nanoparticles in the inhalation study was estimated to be 22 days, although how C_{60} was cleared remains unknown. In conclusion, C_{60} was mostly taken up by liver from IV administration, and remained in lung after IT or inhalation exposure. [Supported by NIEHS Contract N01-ES-75562 (HHSN291200775562C)]

PS 972 ABSORPTION, DISTRIBUTION, AND EXCRETION OF [CARBONYL-^{14}C]-PERFLUOROHEXANOIC ACID IN RATS AND MICE.

S. Gannon[1], T. Johnson[3], T. Serex[1] and R. Buck[2]. *[1]DuPont Haskell Global Centers for Health and Environmental Sciences, Newark, DE, [2]DuPont Chemical Solutions Enterprise, Wilmington, DE and [3]WIL Research Laboratories, Ashland, OH.*

To study the pharmacokinetics of perfluorohexanoate (PFHx, $F(CF_2)_5COO^-$), male and female rats and mice were dosed with either 2 or 100 mg/kg of the sodium salt of ^{14}C-PFHx. A plot of plasma concentration (C) versus time shows rapid elimination with half-lives of approximately 2 hrs in male and 0.5 hr in female rats. Absorption was rapid and complete as evidenced by a short time to maximum concentration (T_{max}) of 30 min (male) and 15 min (female) and the nearly complete elimination in urine by 24 hrs. C_{max} was approximately equal in both sexes (6 μg equiv/g at 2 mg/kg; 250 μg equiv/g at 4 mg/kg). The area-under-the-curve (AUC) integrated from zero to infinity was 3 and 2 times higher in males than in females (2 and 100 mg/kg dose, respectively). As with rats, absorption in the mouse was rapid with a T_{max} achieved 0.5 hrs after dosing. The plasma concentration shows biphasic elimination that precludes facile calculation of half-life using a noncompartmental model. Absorption appears to be nearly complete. There is a sex difference in elimination rate in mice, but the C_{max} was similar to that observed in rats. The AUC integrated from 0 to the last time point with a quantifiable concentration was 3 and 2 times higher in male than in female mice (2 and 100 mg/kg, respectively). Material balance was determined in both rats and mice. Nearly 100% of the dose was excreted in the urine in both sexes, both species, and both doses. Rat hepatocyte data shows that PFHx in not metabolized. This result implies that bioavailability was close to 100%. The majority of the dose was eliminated within the first 24 hrs in both sexes of rats and mice. Additional groups of rats and mice were dosed with ^{14}C-PFHx and sacrificed at T_{max}, $T_{max/2}$, and 24 hrs and tissues were then analyzed for total radioactivity. The rates and extent of elimination from tissues were consistent with the observation that the dose was rapidly and completely eliminated through the urine.

PS 973 METHYLTETRAHYDROFURAN (MTHF) BRAIN CONCENTRATIONS FOLLOWING A SINGLE INTRAVENOUS OR GAVAGE ADMINISTRATION OF MTHF TO F344 RATS AND B6C3F1 MICE.

J. D. Johnson[1], S. Hong[1], S. Gibbs[1], J. Merrill[1], B. Burback[1], S. Graves[1], V. Godfrey[2] and C. Smith[2]. *[1]Chemistry Technical Center, Battelle, Columbus, OH and [2]NIEHS, NIH, Research Triangle Park, NC.*

A TK study of MTHF, a component of alternative fuels (P-series fuels), was conducted in Fischer 344/N rats and B6C3F1 mice to correlate toxic effects with systemic availability and to improve the usefulness of toxicity study results in risk assessment. Rats and mice (12 to 13 weeks old) were given a single IV administration at dosages of 2.5, 10, or 40 mg/kg for rats, and 10 (females only), 20, 40, or 80 (males only) mg/kg for the mice and a single gavage administration at dosages of 10, 30, 100, or 400 mg/kg for rats and 20, 100, or 400 mg/kg for mice. Milli-Q water was the vehicle. Brain MTHF concentrations were measured using a validated headspace capillary GC method with mass selective detection (MSD) for the low range and with flame ionization detection (FID) for the high range. MTHF brain concentrations were measurable within 2 to 5 min after IV or gavage administration. Cmax and AUC increased with increasing dose. IV group rats had a larger than proportional increase from 10 to 40 mg/kg (not biologically relevant) and IV group mice exhibited proportional increases with dose. Gavage group rats had a greater than proportional increase from 10 to 100 mg/kg but not from 100 to 400 mg/kg; however, there was a substantial increase in the half-life for the 400 mg/kg group. For the mice, a larger than proportional increase was observed at 100 and 400 mg/kg. These results suggest that dosages ≥ 400 mg/kg for rats and 100 mg/kg for mice produce brain MTHF concentrations greater than what would be expected based on the increase in the dose. IV and gavage group brain:plasma ratios tended to be below 1 for rats and mice at all dose levels, thereby indicating that MTHF was not sequestered in the brain. Although there were no overt differences in the MTHF brain:plasma ratio between the sexes of either species, males generally had a slightly higher ratio than the females. [This work was supported by NIH, N01-ES-55551.]

PS 974 TOXICOKINETICS OF BIS-(2-CHLOROETHOXY)METHANE (CEM) AFTER A SINGLE DERMAL APPLICATION TO F344 RATS AND B6C3F1 MICE.

V. Godfrey[2], S. Hong[1], S. Gibbs[1], J. D. Johnson[1], S. W. Graves[1], B. Burback[1], J. Merrill[1] and C. Smith[2]. *[1]Battelle Memorial Institute, Columbus, OH and [2]NIEHS, NIH, Research Triangle Park, NC.*

Bis-(2-chloroethoxy)methane (CEM), a colorless liquid haloether, is used as a starting material in manufacturing processes to produce polysulfide elastomers. CEM does not occur naturally in the environment but can be released by volatilization during manufacturing and translocates through plants and animals. The present study was conducted to evaluate the time course of CEM in plasma following a single dermal application to male and female F344 rats and B6C3F1 mice. The subscapular dorsal skin, clipped of fur, was used as the dermal application site. Single application dosages were 100, 200 or 400 mg/kg for F344 rats and 300, 450 or 600 mg/kg for B6C3F1 mice (vehicle was 95 percent ethanol). Dosing volumes were 0.5 and 2 mL/kg for rats and mice. Plasma CEM concentrations were measured using a validated gas chromatography method with selected ion monitoring (2 ng/mL was the limit of quantitation). CEM plasma concentration-time profiles for rats and mice were characterized using a two-compartment pharmacokinetic model. CEM was rapidly absorbed into the systemic circulation after the dermal application (absorption half-life ranged from 5 to 12 min for rats and mice). Absorption was not dose-, gender-, or species-dependent. Cmax and AUC values increased in a dose-proportional manner for rats and mice, except for the rat high dose (400 mg/kg) indicating a potential saturation in CEM elimination. Elimination half-life ranged from 15 to 29 min (rats) and 8 to 14 min (mice), except for the rat high dose (67-76 min). Elimination was dose- (rats only) and species-dependent but not gender-dependent. There were no overt gender-related differences in CEM toxicokinetics for rats and mice following a single dermal application of CEM. The absolute bioavailability of CEM following a single dermal application was 14.4% (male rats), 24.4% (female rats), 5.9% (male mice), and 11.9% (female mice). [This work was supported by NIH, N01-ES-55551.]

PS 975 PHARMACOKINETICS AND DOSIMETRY OF CARBON MONOXIDE IN THE U.S. EPA INTEGRATED SCIENCE ASSESSMENT.

E. Oesterling Owens[1, 2], D. Johns[1] and V. Benignus[3]. *[1]NCEA, Environmental Media Assessment Group, U.S. EPA/ Office of Research and Development, Research Triangle Park, NC, [2]ORISE Postdoctoral Fellow, Research Triangle Park, NC and [3]NHEERL, Neurotoxicology Division, U.S. EPA/ Office of Research and Development, Research Triangle Park, NC.*

The EPA is mandated by Congress through the Clean Air Act to review and revise the scientific bases for setting the National Ambient Air Quality Standards (NAAQS) for 6 criteria air pollutants, including carbon monoxide (CO). The agency evaluates the current scientific evidence relevant to the health effects associated with ambient pollutant exposure. Major studies on the pharmacokinetics of carbon monoxide date back to the early nineteenth century, however recent models and experiments have added to and revised the understanding of the kinetics and actions of CO within the body. Improved analytic methods for detecting CO provide evidence for tissue CO accumulation. New multicompartment models demonstrate that CO washout occurs in a biphasic nature, and the models attempt to predict carboxyhemoglobin (COHb) formation by taking into account tissue and myoglobin binding, as well as arterial and venous blood pools. A physiological model based on the Coburn Forster Kane (CFK) equation is presented which replicates and extends data in the literature focusing on exercise and CO exposure in both healthy individuals and individuals suffering from stable angina pectoris. Our analysis includes an evaluation of the model against published clinical data. This research and evaluation will enhance the scientific assessment used as the major scientific foundation for EPA decisions pertaining to the CO NAAQS.

PS 976 METABOLISM AND DISPOSITION OF DIMETHYLETHANOLAMINE AND ITS EFFECT ON THE DISPOSITION OF CHOLINE CHLORIDE IN RODENTS.

L. C. Ferguson[1], D. Kramer[1], Z. Gao[1], L. Thomas[1], J. McDonald[1] and M. Sanders[2]. *[1]Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM and [2]National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

Dimethylethanolamine (DMAE) is a high volume chemical used in industrial and consumer products, including dietary supplements. DMAE is structurally similar to the essential nutrient, choline, and may interfere with its *in vivo* uptake. However, the fate of DMAE and its interactions with choline have not been well characterized. Therefore, the present studies were designed to determine the metabolism and disposition of 500 mg/kg [^{14}C]DMAE administered by gavage to male Wistar Han rats and female B6C3F1 mice and to investigate the effects of single oral 1 h-pretreatment of DMAE on the disposition of [^{14}C] choline chloride in male rats. Within 24 h, male rats excreted 62% of the [^{14}C]DMAE dose in urine, 0.2% in feces, 4.8% as $^{14}CO_2$, and 0.2% as volatile organics. Female mice excreted 43% in urine, 0.6% in feces, 12% as $^{14}CO_2$, and 1.5% as volatile organics. Ca. 24 and 38% of the dose remained in the tissues of rats and mice, respectively. Liver, muscle, skin, small intestine, adipose, blood (rats only), kidney (mice only), and stomach (mice only) contained more than 1% of the total dose. Parent DMAE and DMAE oxide were identified by HPLC and MS analysis in urine of [^{14}C]DMAE-treated animals. Formation of choline by methylation of DMAE was not confirmed due to co-elution of DMAE and choline upon HPLC analysis and presence of endogenous choline in urine. Rats receiving [^{14}C]choline (160 mg/kg) by gavage, excreted 33% of the dose in urine, 22% in feces, 13% as $^{14}CO_2$, and 0.1% as volatile organics within 24 h. Tissues contained 22% total dose. The disposition of choline was not affected by pretreatment with 100 mg/kg unlabeled DMAE; in contrast, a 500 mg/kg DMAE dose delayed choline-derived CO_2 excretion. In conclusion, DMAE was well absorbed following oral dosing in male rats and female mice, and DMAE administration may affect the disposition of choline in male rats. [Supported by NIEHS Contract N01-ES-75562 (HHSN291200775562C)]

PS 977 PHARMACOKINETIC STUDIES OF GINSENOSIDE RG1 IN RATS.

M. Kang, S. Lee, J. Kim, Y. Seo, S. Shin, J. Choi and T. Jeong. *Pharmacy, Yeungnam University, Gyeongsan, Gyeongbuk, Korea, South.*

Ginsenoside Rg1, one of the active components of Panax ginseng, is known to have various immune-modulating effects such as increased activity of T helper cells. Meanwhile, the pharmacokinetics of ginsenoside Rg1 has been little studied. In the present study, a sensitive method was applied for the determination of ginsenoside Rg1 in rat serum following oral and intravenous administration, together with the pharmacokinetic feature of ginsenoside Rg1. A sensitive liquid chromatography-electrospray tandem mass spectrometry (LC/ESI-MS) was used to determine ginsenoside Rg1 following an oral administration at 100 mg/kg and an iv administration at 10 mg/kg. The pharmacokinetics of Rg1 in rat serum could be described by a non-compartment model. Oral Tmax and Cmax of Rg1 were 0.4 ± 0.0 hr and 1154 ± 257 ng/ml. Two phase of Rg1 decline was observed from concentration-time profile after oral administration. The half-life of α-phase was 0.17 ± 0.07 hr and that of β-phase was 2.13 ± 0.86 hr. Rg1 in serum was not quantifiable beyond 4 hr after administration. The half-life of β-phase in an iv administration was 0.28 ± 0.09 hr and AUC_∞ was 5.05 ± 0.31 mg hr/ml. The absolute bioavailability of ginsenoside Rg1 in rat serum was estimated as 1.5%.

PS 978 IN VITRO DETERMINATIONS OF THE SITES OF HYDROLYSIS OF SULFURYL FLUORIDE AND FLUOROSULFATE IN THE RAT AND HUMAN.

M. Bartels[1], E. R. Lowe[1], D. L. Rick[1] and D. L. Eisenbrandt[2]. *[1]Toxicology, Dow Chemical, Midland, MI and [2]Dow AgroSciences LLC, Indianapolis, IN.*

Sulfuryl fluoride (SO_2F_2) is a structural and post-harvest fumigant used to control a wide variety of insect pests. SO_2F_2 is a key alternative to methyl bromide, a stratospheric ozone depleting substance scheduled for phaseout by the Montreal Protocol. A physiologically based pharmacokinetic (PBPK) model was recently developed which includes a quantitative description of the processes that regulate the kinetic disposition of SO_2F_2 in blood and target tissues in the adult rat after inhalation exposure. Our previous *in vitro* studies of hydrolysis rates in various tissues and cell fractions showed that blood was the primary tissue responsible for the hydrolysis of SO_2F_2. There was a greater than 80% decrease in SO_2F_2 levels that occurred in the presence of adult rat blood. In the current study, we show that *in vitro* hydrolysis of SO_2F_2 in adult rat blood leads to a stoichiometric increase in the metabolites fluorosulfate (FSO_3) and fluoride. The secondary hydrolysis of FSO_3 to fluoride was not found to occur *in vitro* with blood, liver or lung tissue from adult rats or human donors, at various substrate and protein concentrations when FSO_3 was added directly to these tissues. This finding is consistent with the relatively slow *in vivo* hydrolysis of iv-dosed FSO_3. *In vivo* kinetic data indicate that the absorbed SO_2F_2 is rapidly hydrolyzed at the point of contact with respiratory tract tissues. The results of this *in vitro* study suggest that blood within the local respiratory tissues may be important for hydrolysis because no parent SO_2F_2 has been detected systemically following *in vivo* exposures up to 300 ppm. These *in vitro* and *in vivo* studies,

taken together, increase the understanding of the sites of hydrolysis of SO_2F_2 and help parameterize the PBPK model that will be used to calculate internal dosimetry of SO_2F_2, FSO_3 and fluoride at environmentally relevant concentrations.

PS 979 SINGLE INTRAVENOUS ADMINISTRATION TOXICOKINETIC STUDY OF BIS(2-CHLOROETHOXY)METHANE USING FISCHER 344 RATS AND B6C3F1 MICE.

S. Gibbs[1], V. Godfrey[2], S. Hong[1], J. D. Johnson[1], S. W. Graves[1], B. Burback[1], J. Merrill[1] and C. Smith[2]. *[1]Battelle Memorial Institute, Columbus, OH and [2]NIEHS, NIH, Research Triangle Park, NC.*

Bis-(2-chloroethoxy)methane (CEM), a colorless liquid haloether, is used as a starting compound in manufacturing processes to produce polysulfide elastomers. CEM does not occur naturally in the environment but can be released by volatilization during manufacturing and translocates through plants and animals. CEM is found in industrial waste of metal finishing, plastics, chemical manufacturing, and steam electric power industries. Groups of rats (12 to 14 weeks old) and mice (11 to 13 weeks old) were given a single IV administration of CEM in cremophor/ethanol/water (1:1:8;v/v/v) at a dosage of 20 or 40 mg/kg (rats) and 50 or 100 mg/kg (mice). Plasma CEM concentrations were measured using a validated gas chromatography method with selected ion monitoring. CEM plasma concentration-time profiles were characterized using a two-compartment pharmacokinetic model. Cmax and AUC values increased in a dose proportional manner, from 12.4 to 24.1 μg/mL and 357 to 882 μg/ml*min in rats and from 38.2 to 63.1 μg/mL and 282 to 638 μg/ml*min in mice, respectively. CEM was rapidly eliminated without any dose dependence. The elimination half-life ranged from 16.3 to 25.4 minutes in rats, and 4.86 to 7.01 minutes in mice. There were no gender- or dose-related effects on clearance or volume of distribution. Clearance ranged from 45.4 to 64.1 mL/min/kg in rats and from 157 to 234 mL/min/kg in mice. The volume of distribution of the central compartment ranged from 1510 to 1660 mL/kg in rats and from 1310 to 1640 mL/kg in mice. The only species difference occurred in elimination of CEM where mice had a shorter elimination half-life and faster clearance than rats. There were no gender differences in either the rats or mice. The results of this study provided TK parameters for CEM in rats and mice to correlate toxic effects with systemic availability and to improve the usefulness of toxicity study results in risk assessment. [Supported by NIH, N01-ES-55551.]

PS 980 ANALYTICAL METHOD DEVELOPMENT FOR THE EXTRACTION AND ANALYSIS OF TRIS(CHLOROPROPYL)PHOSPHATE, MIXTURE, 1-CHLOROACETONE AND N-ACETYL-L-CYSTEINE.

P. J. Schebler[1], A. L. Warren[1], R. L. Mathias[1], S. P. Kerns[1], S. J. Bradford[1], L. A. Moody[1], L. L. Haney[1], R. K. Harris[1], J. W. Algaier[1], B. Jayaram[2] and C. S. Smith[2]. *[1]Product Sciences Division, Midwest Research Institute, Kansas City, MO and [2]National Toxicology Program, NIEHS, Research Triangle Park, NC.*

Tris(chloropropyl)phosphate (TCPP), a mixture of four isomers, is used in construction as a flame retardant in rigid polyurethane foam and has been suggested for use in flexible polyurethane foam for flame retardant furnishings as a substitute for pentabromodiphenyl ether (penta-BDE). Because of its use in the construction industry, TCPP has been found in various indoor and outdoor environs, indicating the potential for widespread human exposure. This exposure would likely increase if TCPP is also used in flame retardant furnishings. Midwest Research Institute is currently providing analytical support to the National Toxicology Program on a study of TCPP and 1-chloroacetone (a potential metabolite) in Wistar Han rats. Also being studied is N-acetyl-L-cysteine (NAC) which can be used by the body as a precursor in the synthesis of glutathione and may be affected by TCPP. The present work includes the analytical method developed to extract and analyze for TCPP, NAC and 1-chloroacetone from Wistar Han rat blood using Solid Phase Extraction. During the extraction, NAC is separated from TCPP and 1-chloroacetone. The eluent containing TCPP and 1-chloroacetone was analyzed using gas chromatography/mass spectrometry. Initial NAC analysis indicated that it formed disulfide bonds which needed to be reduced prior to analysis. The NAC eluent was analyzed using liquid chromatography/mass spectrometry. Because of its volatility, 1-chloroacetone required extensive method development to improve recovery. To facilitate this, initial studies were performed in saline solution. Recoveries for TCPP were greater than 85 percent while recoveries for 1-chloroacetone were inconsistent. Multiple methods were examined to improve the recovery of 1-chloroacetone. The lower limit of detection was explored for each compound and the method was suitable for the analysis of the analytes.

PS 981 PHARMACOKINETIC AND TISSUE DISTRIBUTION STUDY OF 14C-FLUASTERONE IN MALE BEAGLE DOGS.

M. Lindeblad[1], I. M. Kapetanovic[2], A. G. Schwartz[3], K. S. Bauer[4] and A. V. Lyubimov[1]. *[1]Toxicology Research Laboratory, Chicago, IL, [2]National Cancer Institute, Bethesda, MD, [3]Temple University, Philadephia, PA and [4]University of Maryland, Baltimore, Baltimore, MD.*

The purpose of this work was to compare the pharmacokinetics (PK) and tissue distribution of 14C-fluasterone following intravenous (IV), subcutaneous (SC) and oral (PO) administration in male Beagle dogs. Fluasterone is a product of the synthesis of a derivative of dehydroepiandrosterone (DHEA). The route of administration may have a profound effect on the efficacy and side effects of a drug. Two groups of animal (4/dose) received an IV dose of 14C-fluasterone in Phase I of the study. In Phase II of the study, Group 1 received a single SC dose while Group 2 received a single PO dose. The 14C-fluasterone dose was followed by 25 days of non-labeled fluasterone administration (Group 1: SC; Group 2: PO). The PO 14C-fluasterone formulation had a lower bioavailability (47%) compared to the SC formulation (84%). PO and SC administration resulted in similar times of maximum concentrations (Tmax); however, the Cmax following SC dose was less than half of the PO dose. The elimination half-life of the subcutaneous dose was nearly double that of the oral route (SC=41.38 hr; PO=24.38 hr), indicating a more sustainable systemic level with the SC dose, which is also evident in the overall systemic exposure as seen in the AUC0-∞. Tissue distribution analysis 2 hours post intravenous dosing showed that excretory organs (gall and urinary bladder, liver, kidney, and ureter) and adipose tissue accumulated high levels of 14C-fluasterone-derived radioactivity. The mean percentage of the total administered dose of 14C-fluasterone-derived radioactivity measured in the body was equal to ~81%. In conclusion, the SC route of administration had greater exposure and more sustainable levels than the PO and IV routes, which is evident in the differences in systemic exposure, as well as rates of absorption and elimination. This was also evident in weight loss observed in the SC group, possibly as a result of an anti-glucocorticoid effect of the test article.

PS 982 BILIARY CLEARANCE AND ENTEROHEPATIC CYCLING OF MYCOPHENOLIC ACID IN RATS.

D. E. Harbourt[1, 2] and P. C. Smith[1, 2]. *[1]Toxicology, UNC-Chapel Hill, Chapel Hill, NC and [2]School of Pharmacy, UNC-Chapel Hill, Chapel Hill, NC.*

Mycophenolic acid (MPA) and its prodrug mycophenolate mofetil (MMF) are both used in the clinic as immunosuppressants and for prophylaxis of organ rejection in transplant patients. Although MPA is generally well tolerated, 20% of treated patients experience delayed onset diarrhea resulting in cessation of MPA therapy leading to potential life threatening complications. MMF undergoes esterase hydrolysis and subsequent metabolism through the actions of UGT enzymes within the liver to form the phenolic (MPAG) and acyl glucuronide conjugates (acMPAG) which are effluxed into the biliary tract or sinusoid. Hepatic efflux of these conjugates can result in either irreversible elimination through the urine or feces or cleavage within the intestinal lumen. Glucuronide cleavage and reuptake of MPA back into the liver through enterohepatic cycling (EHC) can affect both the efficacy and toxicology of MPA. Male rats were dosed with 50 mg/kg MMF followed by bile cannulation and blood collection over 8 hours. ACN and suprofen internal standard were added to plasma samples followed by centrifugation, then the supernatant was dried and reconstituted. Bile aliquots were diluted and centrifuged followed by addition of suprofen internal standard. HPLC analysis was employed on a RP C18 column with UV detection at 250nm. MPA and MPAG levels were quantified and then analyzed to examine total and biliary clearance of MPA. Biliary clearance was not statistically different between PO (0.81 mL/min) and IV (1.10 mL/min) treated rats. Relative MPAG exposure levels (AUCMPAG(0-∞))/ (AUCMPA(0-∞)) are lower for male rats compared to humans (ratio of 0.52 in rats and 4.76 in humans). Rats also extensively eliminate MPAG through the biliary tract (rat Febile 0.64) and 18% of MPA exposure is derived through EHC in rats. The data obtained indicate that rats have similar metabolism, significant biliary excretion and EHC of MPA, as occurs in humans, thus the rat model is appropriate to employ for studying MPA toxicity. Supported in part by NIH training grant T32-ES007126.

PS 983 ZEBRAFISH: A PREDICTIVE MODEL FOR ASSESSING P-GLYCOPROTEIN INHIBITORS.

D. Park, M. Haldi, W. L. Seng and P. McGrath. *Phylonix Pharmaceuticals, Inc., Cambridge, MA.*

Major central nervous system disorders are refractory to small molecules (Pardridge 2007) and some drugs delivered by direct injection or by an implantable devices are pumped out by transporters such as Pgp. Inhibition of Pgp-dependent efflux is one

strategy for enhancing drug retention in the brain. Currently, there is no efficient in vivo model for assessing compound effect on Pgp-dependent efflux from the brain. Conventional methods including HPLC and microprobe/liquid chromatography, mouse brain uptake and rat microdialysis assays are time consuming and expensive (Wang et al. 1995; Deguchi et al. 2001). Zebrafish have been shown to exhibit drug metabolism that is comparable to mammals (McGrath et al. 2008) and we recently developed a novel zebrafish bioassay to identify potential Pgp inhibitors. Since zebrafish brain structure is transparent during development, drug effects on dye retention can be assessed without complicated surgery and histology. In this research, we determined that Pgp is expressed at 5 days post fertilization (dpf) and is fully functional by 7 dpf. In order to monitor Pgp-dependent dye clearance kinetics, we injected rhodamine conjugated horseradish peroxidase into the midbrain of zebrafish and quantitated fluorescence intensity using morphometric image analysis. Our results demonstrate that zebrafish exhibit Pgp-dependent efflux transport machinery and effectively transfer xenobiotics from the brain to the blood. To validate this zebrafish model, we then assessed effects of 7 compounds shown to inhibit Pgp-dependent efflux in mammals. We confirmed that 6 positive control drugs: Verapamil, Phenytoin, Loperamide, Cyclosporine, RU486, Quinidine, inhibited Pgp-dependent efflux in zebrafish brain; results for Alanine were inconclusive. Caffeine, a negative control drug, did not exhibit significant inhibitory effects. 85-100% correct prediction is considered excellent by ECVAM. The transparent zebrafish brain can serve as an excellent animal model for studying drug effects on ABC efflux transporters.

PS 984 PHARMACOKINETICS OF AN ANTISENSE OLIGONUCLEOTIDE ADMINISTERED AS A CONTINUOUS INTRATHECAL INFUSION IN MONKEY.

R. A. Fey[1], R. S. Geary[1], R. B. Boyd[2] and S. P. Henry[1]. *[1]TOX/PK, Isis Pharmaceuticals, Carlsbad, CA and [2]Northern Biomedical Research, Muskegon, MI.*

The pharmacokinetics of ISIS 333611, a 2'-O-methoxyethyl phosphorothioate (2'-MOE) antisense oligonucleotide to human SOD-1, was evaluated in Rhesus monkeys after continuous lumbar intrathecal (IT) infusion. Time-specified plasma, cerebrospinal fluid (CSF) and tissue samples were evaluated after a 12-hour infusion at total doses of 0, 0.05, 0.3 and 1.5 mg and after a subsequent 13-week continuous infusion. The continuous infusion consisted of loading doses of 0, 0.1, 0.6 and 3 mg/day for the first 28 days, and then maintenance doses of 0.05, 0.3 and 1.5 mg/day, thereafter. Plasma and CSF pharmacokinetics demonstrated dose-dependent and dose-proportional exposure during and following continuous infusion. Steady-state concentrations were attained within a few days of starting the infusion and in plasma were approximately 150-fold less than CSF. Turnover from CSF resulted in continuous systemic exposure. The 50% reduction in dose after 28 days resulted in a similar reduction in CSF and plasma concentrations. Estimated distribution half-life associated with the initial rapid CSF distribution phase was less than 2 hours after stopping infusion and likely reflects both CNS tissue uptake and turnover into the systemic circulation. Estimates for the terminal elimination half-life in CSF and plasma were approximately 10 days, reflective of the slower tissue elimination kinetics. Tissue concentrations increased with dose, but less than would be predicted by dose alone suggesting saturable uptake. Lumbar and thoracic spinal cords were the sites of highest concentration. Concentrations were measured in brain also and immunolocalization of oligonucleotide indicated good uptake in neuronal cells. Systemic tissue (kidney) concentrations were generally less than the spinal cord, consistent with the intrathecal route of administration but also demonstrating the ultimate fate of drug in the CNS; return to the central circulation and elimination via the kidney. The lowest concentrations were observed systemically in liver.

PS 985 PHARMACOKINETIC INTERACTIONS BETWEEN BISPHENOL A AND NAPROXEN IN HUMANS.

S. Haddad, E. Blanchette, I. Rheault and M. Verner. *sciences biologiques, TOXEN, Université du Québec à Montréal, Montr√©al, QC, Canada.*

Bisphenol A (BPA) was shown to disrupt endocrine signals in animals and human cell lines. The toxicity of this compound is limited by its rapid elimination through glucuronidation, a metabolic pathway leading to the production of an inactive metabolite. The pharmacokinetics of BPA is susceptible of being altered when co-exposure with pharmaceuticals occurs. Considering a previous study which showed the high inhibitory potential of naproxen on BPA metabolism in rat hepatocytes and hepatic microsomes, we aimed to (i) determine if BPA binding to human serum albumin (HSA) is altered by the presence of naproxen or other drugs (naproxen, salicylic acid, carbamazepine and valproic acid) at a concentration 10-fold higher than the reported maximal blood concentration (Cmax) in humans, and (ii) characterize metabolic interactions between BPA and naproxen in human microsomes. Displacement assays of BPA-HSA using equilibrium dialysis showed that naproxen, valproic acid and salicylic acid can significantly lower BPA binding to HSA. Further assessment of naproxen inhibition of BPA-HSA binding showed that the reported Cmax of naproxen in humans (374 μm) yielded a 20% increase in BPA free fraction. Human microsomal assays were carried out to determine the type of inhibition and related constants for naproxen inhibitory potential on BPA glucuronidation. Naproxen was shown to inhibit BPA glucuronidation non-competitively with a Ki of 293 μM, a concentration below the reported Cmax in humans. The results of this study suggest that administration of drugs such as naproxen might interfere with BPA glucuronidation and increase its free fraction in blood at therapeutic levels in humans. These findings prompt further investigation to i) characterize the displacement constant of naproxen on BPA binding to human albumin, and ii) assess the impact of observed interactions on the risk assessment of medicated population through physiologically-based pharmacokinetic (PBPK) modeling of BPA in human. Supported by NSERC.

PS 986 PHARMACOKINETIC (PK) ANALYSIS AND OPTIMAL SAMPLING STRATEGY (OSS) FOR A RECOMBINANT PROTEIN (ENB-0040) IN ADULT AND JUVENILE RATS.

M. Beliveau[1], I. Lemire[2], M. Reimer[1], J. Marier[1] and P. Leonard[2]. *[1]Pharsight Corporation, Montreal, QC, Canada and [2]Enobia Pharmacology Inc., Montreal, QC, Canada.* Sponsor: S. Morseth.

The primary objective of this study was to derive a quantitative method for determining the minimum number and timing of blood draws to assess exposure (Cmax and AUC) of ENB-0040 in juvenile rats in a toxicology study. Using knowledge of PK parameters derived from prior rat studies, a two-compartment population model with a maturation function as a covariate (to account for changes in body weight over time) was developed using NONMEM® (v6.2). Following model development, an OSS was derived that took into consideration: 1) the body weight of juvenile rats, 2) a maximum of 1 blood draw for PK assessment on Day 1 of the planned study, and 3) additional blood draws beginning at 4 weeks for the more mature rats. Using partial derivatives from PK model equations developed in WinNonlin® (v5.2), the 0.08-, 0.5-, 1- and 5-h time points were identified as potential optimal sampling times. The predictive performance of the PK model was then validated by comparing the PK of ENB-0040 evaluated from a rich simulated dataset to a sparse simulated dataset for a number of candidate scenarios (e.g. 9 rats all sampled at the same time point (0.08, 0.5, 1, or 5 h post dose) or 3 rats sampled at 3 time points (0.5, 1 and 5 h post dose or 0.08, 0.5 and 1 h post dose) on Day 1. Precision and bias on Cmax, AUC and effective half-life (t1/2eff) were calculated to determine the robustness of the model according to the proposed OSS after single dose or multiple doses. The best overall precision and bias resulted from sampling at 0.5 h (n=9, %MPE and %RMSE for AUC was 2% and 25%, respectively) and 0.08, 0.5 and 1 h post dose (n=3, %MPE and %RMSE for AUC was 4% and 26%, respectively). This study provides a quantitative approach for deriving optimal sampling strategies in technically challenging and sample-limited toxicology studies.

PS 987 REGULATION OF EFFLUX TRANSPORTERS AT THE BLOOD-BRAIN BARRIER (BBB) BY XENOBIOTICS.

X. Wang, D. Sykes and D. S. Miller. *Laboratory of Pharmacology and Chemistry, National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

The BBB, which resides within the brain capillary endothelium, is a major obstacle to the delivery of CNS-active drugs and thus to treatment of brain diseases. ATP-driven efflux transporters, such as p-glycoprotein (p-gp), multidrug resistance-associated protein 2 (Mrp2) and breast cancer resistance protein (BCRP), are selective components of this barrier. In other barrier and excretory tissues efflux transporter expression is under control of xenobiotic-activated nuclear receptors, e.g., pregnane-X-receptor (PXR) and constitutive androstane receptor (CAR). Here we identify CAR as a regulator of p-gp, Mrp2 and BCRP expression in rat and mouse BBB. Freshly isolated brain capillaries were used to investigate CAR-mediated modulation of drug efflux transporter function. Capillaries were incubated with fluorescent substrates specific for each transporter, imaged with confocal microscopy and luminal substrate accumulation quantitated by digital image analysis. Three hour exposure rat brain capillaries to the CAR ligand, phenobarbital (PB), increased p-gp-mediated transport. This induction was abolished by the protein phosphatase 2A inhibitor, okadaic acid (OA at 2nM), a finding consistent with previous reports showing that OA blocks CAR upregulation of cytochrome P450 2B in rodent liver. Western blot analysis confirmed increased expression of p-gp, Mrp2 and BCRP in rat brain capillaries treated with PB. In mouse brain capillaries, p-gp, Mrp2 and BCRP transport activity was increased by in vitro exposure to the specific CAR agonist TCPOBOP (50-500nM). No such increases were found in capillaries from CAR knockout mice. Finally, TCPOBOP dosing of mice (0.33mg/kg) increased p-gp, Mrp2 and BCRP mediated transport in brain capillaries assayed ex vivo. Thus, CAR ligands increase transport activity and expression of p-gp, Mrp2 and BCRP. This is another a molecular signaling pathway through which the selective BBB is tightened. Exposure to xenobiotics that activate CAR (e.g. antiepileptic drugs) could contribute to pharmacoresistance in clinic.

R 988 IS THERE A FUTURE FOR ANIMAL MODELS IN THE INVESTIGATION OF IDIOSYNCRATIC DILI IN HUMANS?

A. Regev[1], C. Thomas[1] and G. Kenna[2]. [1]*Eli Lilly & Co., Indianapolis, IN and* [2]*Astra Zeneca, Alderley Park, Macclesfield, Cheshire, United Kingdom.*

Idiosyncratic drug induced liver injury (DILI) remains a concern for drug development and patient safety, and continues to be the leading cause for regulatory action including withdrawal of drugs from the market, restrictions in indications, and warnings to health care providers and patients. Idiosyncratic DILI is typically unpredictable, and is largely undetectable, in preclinical animal studies. Accordingly, it is only in large scale clinical trials or, more often, post-marketing, that such toxicities are revealed. To date there is no universally accepted animal model for investigation or prediction of idiosyncratic DILI in humans. A lofty goal for preclinical scientists and physicians is to, not only develop animal models that detect idiosyncratic DILI, but to translate such knowledge into the clinic and allow identification of patients who would be susceptible or tolerant to a particular drug. Much effort has been expended in the study of improved/enhanced animal models that better predict untoward human idiosyncratic drug reactions. In some instances, the data imply that we can in fact identify drug candidates that may be predisposed to DILI. On the other hand, the multiple etiologies potentially underlying idiosyncratic DILI may render it difficult to routinely evaluate for, and predict, these events. A case example will be presented to illustrate this point. The complexities of using non-standard animal models and endpoints in regulatory safety assessment studies also must be considered. These discussions are designed to highlight the current thinking on animal models for idiosyncratic DILI, and focus attention on the future direction of such research.

R 989 NATIONAL CHILDREN'S STUDY: OPPORTUNITIES AND CHALLENGES FOR TOXICOLOGISTS.

S. P. Darney. *ORD, U.S. EPA, Research Triangle Park, NC.*

The National Children's Study (NCS) is the first-of-its kind U.S. study tracking children's health from womb to adulthood. Involving 100,000 children across the country, the NCS will be the largest long-term study of children's health and development ever conducted in the U.S.. Initiated in response to the Children's Health Act of 2000, the NCS is led by a consortium of agencies which include the U.S. Department of Health and Human Services, including the National Institute of Child Health and Human Development, the National Institute of Environmental Health Sciences at NIH, and the Centers for Disease Control and Prevention, and the U.S. EPA. The study seeks to address questions that can only be answered through a longitudinal study of this size and scope. The study's hypotheses incorporate the following main outcomes — pregnancy outcomes, neurodevelopment and behavior, asthma, obesity and growth, injury, and reproductive development. NCS will ultimately reduce the public health burden of childhood chronic diseases and disorders, including not only pain and suffering, but also missed school days, health care expenses, and other costs to children, their families, and society at large. It will also be large enough to assess factors related to health disparities and differences in disease occurrence between groups of people. What does this study mean for toxicologists? The time is ideal to obtain input from toxicologists, as this landmark study is beginning to recruit families, to apply lessons learned from ongoing children's studies, including the application and interpretation of new biomarkers, and to develop exposure and dose models for pregnant women and infants. Its design and innovative approaches will provide unique opportunities to collect and relate early biomarkers of exposure and effect to disease outcomes later in development, and it will help the U.S. tease apart the complex interplay between environmental factors and genetic influences that impact health.

R 990 SETTING A SAFE STARTING DOSE IN INITIAL CLINICAL TRIALS WITH BIOTHERAPEUTICS: DO I USE THE NOAEL OR THE MABEL?

J. Bussiere[1], C. Horvath[2], M. Rogge[3], H. Ghantous[4], M. Pallardy[5] and L. Burns Naas[6]. [1]*Amgen, Thousand Oaks, CA,* [2]*Archemix, Cambridge, MA,* [3]*Biogen Idec, Cambridge, MA,* [4]*U.S. FDA, Washington, DC,* [5]*University of Paris, Paris, France and* [6]*Pfizer, San Diego, CA.*

Years ago, establishment of safe exposures to new therapeutics utilized the determination of NOEL/NOAELs derived from routine toxicology studies followed by some form of dose adjustment prior to human exposure, an approach that evolved a few years later to include an interspecies scaling factor. In the past 15 years, however, approaches to clinical trial design have become more specific to the TA and questions being asked in these initial studies. During this same time, biotechnology-derived therapeutics have also evolved, becoming increasingly more diverse in nature and are much more specific to their targets. As a result of this evolution, an array of regulatory guidance has also arisen describing several approaches to establishing appropriate starting doses for clinical trials of a specific nature, for specific therapeutic areas, and high risk therapeutics. The most recent of these is pharmacology-based and involves the determination of the MABEL. This method is recommended for therapeutics that may present defined/perceived risk to those in FIH/FIP trials that is beyond what is generally accepted for new molecular entities. The choice to use the NOAEL or MABEL in selecting the starting dose falls to toxicologists and clinicians and may represent starting doses differing by orders of magnitude. A key starting point is determination of what constitutes elevated risk, an evaluation that depends on a combined assessment of the nature of the target, pharmacology, toxicology, and the intended patient population. Accurate estimation of the human efficacious dose is also critical and the complexity surrounding this prediction can have significant impact on the starting dose. Low and slow provides maximum safety but can also result in unnecessary time delays evaluating doses where little information may be gained, and in at least some instances may make it impossible to recruit patients who may have no benefit for weeks.

EC 991 THE FUTURE OF ENVIRONMENTAL HEALTH SCIENCE: FEATURING NIEHS FUNDED EARLY CAREER INVESTIGATORS.

C. Shreffler[1] and V. S. Vaidya[2]. [1]*Division of Extramural Research and Training, National Institute of Environmental Health Sciences, Research Triangle Park, NC and* [2]*Medicine-Renal, Brigham and Women's hospital, Harvard Medical School, Boston, MA.*

An essential element of the mission of the NIEHS is the support and career promotion of the future generation of exceptionally talented and creative new scientists who will push forward research in understanding the impact of environmental exposures and human health. Support through critical transition stages has been identified as being particularly important in developing a cadre of talented early career scientists. In response, the NIH and the NIEHS has started the Outstanding New Environmental Scientist (ONES) Award which is one of many initiatives that it has taken to provide the funding for the research and career enhancement of scientists during the transition from postdoctoral to faculty positions, and to allow selected outstanding junior faculty to flourish. The ONES scientists are expected to make a long term career commitment to the environmental health sciences, and to bring innovative, ground breaking research thinking to bear on the problems of how environmental exposures affect human biology, human pathophysiology, and human disease. In the first three years, 21 awards have been made and the NIEHS ONES program has become an important showcase for the future leaders in environmental health sciences research. Three ONES awardees have been chosen to present who have had innovative publications in the first year of the award and who display a broad spectrum of research in the environmental health sciences. These exeptional scientists, who will present cutting edge science at the interface of molecular toxicology and environmental health sciences, are a model for junior faculty attendees who are considering applying for these competitive but highly rewarding grants.

PS 992 NITROGEN-CONTAINING BISPHOSPHONATES INHIBIT FARNESYL DIPHOSPHATE (FPP) SYNTHASE IN THE KIDNEY: IMPLICATIONS FOR RENAL SAFETY.

A. Lühe[1], K. Künkele[2], M. Haiker[1], K. Schad[1], C. Zihlmann[1], F. Bauss[2], L. Suter[1] and T. Pfister[1]. [1]*Nonclinical Drug Safety, F. Hoffmann-La Roche, Basel, Switzerland and* [2]*Pharmacology Research Penzberg, Roche Diagnostics GmbH, Penzberg, Germany.* Sponsor: M. Stephan-GV°ldner.

Bisphosphonates are potent inhibitors of osteoclast-mediated bone resorption and play an important role in the treatment of osteoporosis, metastatic bone disease, and Paget disease. However, nephrotoxicity has been reported with some bisphosphonates. Nitrogen-containing bisphosphonates directly inhibit farnesyl diphosphate (FPP) synthase activity (mevalonate pathway) and reduce protein prenylation leading to osteoclast cell death. The aim here was to elucidate if this inhibition also occurs in kidney cells and may directly account for nephrotoxicity. In an exploratory study in rats receiving zoledronate or ibandronate an approximate 2-fold increase in FPP synthase mRNA levels was observed in the kidney. The involvement of the mevalonate pathway was confirmed in subsequent in vitro studies with zoledronate, ibandronate, and pamidronate, using the non-nitrogen containing bisphosphonate clodronate as a comparator. In vitro changes in FPP synthase mRNA expression, enzyme activity, and levels of prenylated proteins were assessed. Using two cell lines (a rat normal kidney cell line, NRK-52E, and a human kidney proximal tubule cell line, HK-2), ibandronate and zoledronate were identified as most cytotoxic (EC50: 23 / >1000 μM and 16 / 82 μM, respectively) and as the most potent inhibitors of FPP synthase (IC50; 1.6/7.4 μM and 0.5/0.7 μM, respectively). In both cell lines, inhibition of FPP synthase activity occurred prior to a decrease in levels of prenylated proteins followed by cytotoxicity. This further supports that the mechanism responsible for osteoclast inhibition (therapeutic effect) might also underlie the mechanism of nephrotoxicity.

PS 993 TIME- AND DOSE-DEPENDENT EFFECTS OF DIETARY TCDD IN JUVENILE RAINBOW TROUT.

Q. Liu[1, 2], M. L. Rise[3], C. A. Struble[4], J. M. Spitsbergen[5], R. J. Hutz[2] and M. J. Carvan[1, 6]. [1]*Great Lakes WATER Institute, UW-Milwaukee, Milwaukee, WI,* [2]*Department Biological Sciences, UW-Milwaukee, Milwaukee, WI,* [3]*Ocean Sciences Centre, Memorial Univ Newfoundland, St. John,Äôs, NF, Canada,* [4]*Department Mathematics, Statistics, and Computer Science, Marquette University Milwaukee, WI,* [5]*Center for Fish Disease Research, Oregon State University Corvallis, OR and* [6]*Marine& Freshwater Biomedical Sciences Center, UW-Milwaukee, Milwaukee, WI.*

TCDD (2,3,7,8-tetrachlorodibenzo-p-dioxin) is a highly toxic, widespread environmental contaminant. The goal of this project is to use functional genomic and bioinformatic methods to identify molecular biomarkers as indicators of the impact of TCDD exposure. Specifically we investigated the effects of chronic TCDD exposure on developing rainbow trout global gene expression anchored to histopathological analysis. Juvenile rainbow trout were fed Biodiet starter with TCDD added at 0, 0.1, 1, 10 and 100ppb, and fish were sampled from each group after 1, 2, 4, and 6 weeks. Gene expression analysis was performed using the cGRASP 16K cDNA microarray. At the end of six weeks, significant mortality was not seen in treatment groups below 10 ppb TCDD, but the 100 ppb diet was 100% lethal by day 40. Condition factor was not affected by the TCDD exposure. A number of genes were dysregulated by dietary TCDD that function in cell division, cell cycle progression, neuronal function and transmission, retinal phototransduction, steroid metabolism, skeletal development, ion binding and homeostasis, stress response, transcriptional regulation and proteolysis. Histological analysis revealed that by week six significant lesions were found in the liver, kidney, gills, skin, and heart, and caused a delay in the development of the skull, ovary, and brain. TCDD has dramatic effects in juvenile rainbow trout well below lethal levels by disrupting molecular pathways involved in the growth and development of multiple organ systems. These dysregulated genes may be useful as biomarkers for TCDD exposure in aquatic environment to assess the potential impacts of low-level environmental TCDD in the food chain and on the health of humans and animals.

PS 994 TCDD EFFECTS ON HEPATIC METABOLITES –MOUSE *VERSUS* RAT.

M. N. Kent[1], M. K. Makley[1], G. L. Jahns[2], N. DelRaso[3], L. Burgoon[4], T. R. Zacharewski[4] and N. V. Reo[1]. [1]*Biochem & Mol Biol, Boonshoft School of Medicine, Wright State University, Dayton, OH,* [2]*BAE Systems, San Diego, CA,* [3]*AFRL/HEPB, Wright-Patterson AFB, Dayton, OH and* [4]*Biochem & Mol Biol, National Food Safety & Toxicol Ctr, Ctr Integrative Toxicol, Michigan St University East Lansing, MI.*

TCDD (2,3,7,8-tetrachlorodibenzo-p-dioxin) elicits a broad range of tissue-, sex-, and species-specific effects. We previously reported TCDD-induced effects on genomic and NMR measured hepatic lipid metabolites in immature ovariectomized (i.o.) C57BL/6 mice (30 μg/kg) and i.o. Sprague-Dawley rats (10 μg/kg) at 72, 120, and 168 h post-exposure. Here we report the hepatic aqueous metabolite data measured in the same animals by quantitative 1H and 31P NMR (at 14.1 T), and provide a more comprehensive view of the metabolic responses to a single oral dose of TCDD. Principal Components Analysis (PCA) of aqueous metabolites observed by 1H NMR show treatment-specific separation in both species, with different metabolite signals accounting for the separation. In mice, liver aqueous extracts revealed a 25% decrease in the lactate/pyruvate ratio, and 49% decrease in the dihydroxyacetone phosphate concentration ($p<0.05$). These findings are consistent with a decrease in the cytosolic NADH/NAD+ ratio and upregulation of triacylglyceride (TAG) synthesis. Indeed, TCDD induced fatty liver in mice, where TAG levels were elevated 2- to 3-fold relative to vehicle controls at 72-168 h postdose. In contrast, TCDD-treated rats exhibited ca. 34% lower levels of hepatic sphingomyelin at 72 and 168 h, and phosphocholine levels were 3-fold higher than controls at all times postdose. Overall, these observations are consistent with the reported differences in hepatic histopathology and gene expression between the rat and mouse, and further support the hypothesis that TCDD elicits species-specific aryl hydrocarbon receptor-mediated effects. Funded by RO1 ES013927.

PS 995 METABONOMIC STUDY OF OCHRATOXIN A TOXICITY AFTER REPEATED ADMINISTRATION: PHENOTYPIC ANCHORING ENHANCES MODEL PREDICTIVITY AND BIOMARKER IDENTIFICATION.

M. Sieber[1], S. Wagner[1], A. Amberg[2], A. Mally[1] and W. Dekant[1]. [1]*Department of Toxicology, University of Würzburg, Würzburg, Germany and* [2]*Drug Safety Evaluation, Sanofi-Aventis, Frankfurt, Germany.*

For early detection of toxicity and improved mechanistic understanding, GC/MS, 1H-NMR and LC/MS based metabonomics were applied to urine samples from a 90 days rodent toxicity study on the mycotoxin and renal carcinogen ochratoxin A (OTA). OTA was administered at doses of 0, 21, 70 and 210 μg/kg bw for up to 90 days. Urine samples were collected for 24 h intervals 14, 28 and 90 days after start of treatment and analyzed with GC/MS, 1H-NMR and LC/MS. Principal component analysis and orthogonal projection to latent structures discriminate analysis (OPLS-DA) based on GC/MS and NMR data discriminated controls from animals dosed with 210 μg/kg bw OTA as early as 14 days and animals dosed with 70 μg/kg bw 28 days after start of treatment, correlating with mild histopathological changes in the kidney. Integration of histopathology scores as discriminators in OPLS-DA models resulted in better multivariate model predictivity and facilitated marker identification. Decreased 2-oxoglutarate and citrate and increased glucose, pseudouridine, 5-oxoproline and myo-inositol excretion was detected with GC/MS. Decreased 2-oxoglutarate and citrate and increased taurine excretion was found with NMR. Some markers are well-established markers of kidney damage (glucose and creatinine) and indicate disturbances in mitochondrial energy production (citrate and 2-oxoglutarate). Others are associated with cell proliferation (pseudouridine), changes in renal osmolyte handling (myo-inositol and taurine), and oxidative stress (5-oxoproline), established mechanisms of OTA-toxicity. LC/MS was also able to discriminate controls and treated animals but contained more noise and marker annotation was only speculative due to lack of reference databases. Use of multiple analytical platforms for metabonomics analysis may result in a more comprehensive metabolite coverage and may be applied to obtain mechanistic information from conventional rodent toxicity studies.

PS 996 IDENTIFICATION OF RAT BRAIN CYTOSOL PROTEIN TARGETS OF ACRYLONITRILE *IN VIVO* USING TWO-DIMENSIONAL GEL ELECTROPHORESIS AND MASS SPECTROMETRY.

F. W. Benz, E. Campian, D. E. Nerland and J. Cai. *Pharmacology & Toxicology, Univ of Louisville Medical School, Louisville, KY.*

Acrylonitrile (AN) is an organic compound produced in large quantities by the chemical industry. It is used as a monomer in the production of various polymers. Acrylonitrile is an acute toxin. The long-term goal of this research is to identify the mechanism responsible for the acute lethality of AN. Several mechanisms have been proposed to explain the toxicity of AN: Glutathione depletion with subsequent oxidative tissue damage, metabolism by P450 followed by release of cyanide (CN) and covalent binding to tissue proteins. Glutathione depletion doesn't seem to be the major factor involved in lethality because diethylmaleate, which is a potent glutathione depletor, is not particularly toxic. Cyanide, although toxic by itself, is not the only mechanism involved in the acute toxicity of AN, because preventing CN formation by P450 inhibitors does not prevent AN induced lethality. Covalent binding to tissue proteins could alter the function of vital proteins and might prove to be a major component in AN-induced toxicity. This study addresses this last mechanism. Rats were treated with 115 mg/kg (LD90) of C14 labeled AN. Brain cytosolic proteins were separated by two-dimensional polyacrylamide gel electrophoresis using immobilized gradients of pH 3-10. Radiolabeled spots were in-gel digested and identified by peptide mass fingerprinting using matrix-assisted laser desorbtion/ionization mass spectrometry. Sixty one radioactively labeled proteins have been identified to date. These include proteins involved in glycolysis (GAPDH, Pyruvate kinase), TCA cycle (Isocitrate dehydrogenase), energy balance (Creatine kinase, ATP synthase), redox balance (SOD, Peroxiredoxin), and neurotransmission (Glutamine synthetase, Synapsin). This dataset will be a valuable resource for investigating the biochemical basis of acute AN toxicity. (The project described was supported by grant number ES06141 from the National Institute of Environmental Health Sciences, NIH).

PS 997 RESPONSES OF HUMAN ALVEOLAR MACROPHAGES TO DIESEL EXHAUST EXPOSURE: A LIPIDOMICS APPROACH.

K. Sawyer[2] and M. C. Madden[1]. [1]*ORD, NHEERL, HSD, Clinical Research Branch, U.S. EPA, Chapel Hill, NC and* [2]*Department of Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC.*

Human exposure studies demonstrate that acute exposure to diesel exhaust (DE) stimulates mild airway inflammation, characterized by the production of inflammatory mediators and neutrophil influx into the airways. The mechanism(s) by which diesel exposure induces lung inflammation and injury is unclear, but may involve biochemical manipulation of phospholipid metabolic pathways. The current study employed a lipidomics approach to evaluate the effect of in vivo DE exposure and an in vitro DE particle (DEP) exposure on human alveolar macrophage (AM) phospholipid concentration. Ten healthy human adults were exposed to DE (100μg/m3) and to filtered air for two hours with intermittent exercise. Twenty hours after exposure, bronchoalveolar lavage was performed and AM collected.

Phospholipids (2x106AM/sample) were extracted by the Bligh and Dyer standard method and then identified by electrospray ionization tandem mass spectrometry. DE exposure induced decreases in two AM lysophospholipid classes as well as altered the concentration of several individual lipid species (5.5% of 411 lipid species examined). Preliminary results from in vitro exposure studies up to 24 hr demonstrate that endotoxin, diesel exhaust particle (DEP), and urban dust (UD) exposure may generate unique phospholipid "fingerprints" This study demonstrates that a lipidomics approach may be useful to investigate pollutant mechanism(s) of action, exposure-specific metabolic pathways, and biochemical pathways that are not considered by a candidate approach. Comprehensive lipid analysis also enabled the evaluation of the uniqueness of a pollutant-induced lipid response. [This abstract may not reflect official US EPA policy. Support: NHEERL-DESE Cooperative Training in Environmental Science Research, EPA CT826513.]

PS 998 TRANSCRIPTIONAL MICROARRAY ANALYSIS AND CELL PROLIFERATION IN B6C3F1 FEMALE MOUSE LUNG FOLLOWING REPEATED INHALATION EXPOSURE TO 2-CHLORO-1, 3-BUTADIENE.

L. Pluta[1], R. S. Thomas[1], E. Bermudez[1], E. A. Gross[1] and M. W. Himmelstein[2]. *[1]The Hamner Institutes for Health Sciences, Research Triangle Park, NC and [2]DuPont Haskell Global Centers, Newark, DE.*

Beta-chloroprene (2-chloro-1,3-butadiene) (CD), a monomer used in the production of neoprene elastomers, is of regulatory interest due to the production of mouse lung tumors in the two-year rodent bioassay. A significant increase in female mouse lung tumors was observed at the lowest dose of 12.8 ppm. In support of a mode-of-action based risk assessment, gene expression microarray analysis was performed following exposure at 0.3, 3, 13, and 90 ppm for a period of 5 and 15 days. Lung histology and cell proliferation by BrdU labeling was also performed to provide phenotypic anchoring for the gene expression data. Benchmark dose (BMD) methods together with gene ontology classification were used to model the transcriptional dose-response data and calculate dose estimates at which different cellular processes are altered. Following exposure to CD, the most sensitive transcriptional changes at the 5 and 15 day time points were associated with zinc ion homeostasis and glutathione biosynthesis with median BMD values of approximately 1 ppm. From a cancer mode-of-action perspective, changes in DNA damage and apoptosis-related processes were observed at 10 ppm at the 5 day time point followed by an increase to 15 ppm at 15 days. The median BMD values for genes related to glutathione biosynthesis decreased from 13 ppm to 1 ppm at the 5 and 15 day time points, respectively. Changes in gene expression associated with cell proliferation were not observed until 40 to 50 ppm. Lung histology showed minimal hyperplasia in the terminal bronchioles at the highest exposure (90 ppm). BMD values the BrdU labeling were 3 and 23 ppm at 5 and 15 days, respectively. Overall, the changes in genes associated with glutathione biosynthesis suggest the potential generation of reactive metabolite(s) or oxidative stress and subsequent DNA damage. The dose response changes in these processes are consistent with the tumor response.

PS 999 EARLY DETECTION OF (NON-GENOTOXIC) CARCINOGENESIS: IDENTIFICATION OF THE MODE OF ACTION THROUGH METABOLOMICS.

B. van Ravenzwaay[1], G. Coelho-Palermo Cunha[1], M. Herold[2], H. Kamp[1], E. Fabian[1], E. Leibold[2], R. Looser[2], G. Krennrich[2], W. Mellert[1], A. Prokoudine[2], V. Strauss[1], T. Walk[2] and J. Wiemer[2]. *[1]BASF SE, Ludwigshafen, Germany and [2]Metanomics, Berlin, Germany.* Sponsor: A. Doi.

Compared to other 'omics technologies, metabolomics has the advantage that changes can be determined in non invasive matrices such as blood and urine. Based on LC- GC_MS-analysis of blood samples, BASF has established a very large metabolomics data base using rat studies with chemicals, agrochemicals and pharmaceuticals. As the liver is one of the major targets for chemically induced toxicity it is of particular interest to recognize liver toxicity modes of action relevant for carcinogenesis as early as possible in the compound development. Several metabolite changes (metabolome patterns) which are specific for different toxicological modes of action in the liver have been established. One of the mechanisms involved in liver carcinogenesis is peroxisome proliferation. For this mode of action we have established a metabolome pattern using reference compounds such as clofibrate, benzofibrate and WY 14,643. With this pattern we find other compounds associated with peroxisome proliferation such as diethyl-hexyl-phthalate, dichlorprop, mecoprop and MCPA. Furthermore,we used MCPA to evaluate if the metabolome patterns in the rats induced with this compound in our data base (using Crl:Wi(Han) rats) are similar to those of other rat strains fed with this compound (Han:RCC:WIST, Crl:CD® and F344/Crl). The results indicate that (1) the patterns are sufficiently similar to identify the MCPA treatments for rats of all four strains as the most likely treatment in a data base containing studies with more than 400 other compounds and (2) that the greatest similarity is between the rats of both Wistar strains (Crl:Wi(Han) and Han:RCC:WIST) compared to the others. In conclusion, metabolomics is a new and promising tool for the (early) identification and characterization of toxicological modes of action and can be applied to develop early markers of (chemically induced) disease.

PS 1000 TEMPORAL PATHWAY ACTIVITY ANALYSIS OF TRANSCRIPTIONAL PROFILING OF *IN UTERO* EXPOSURE TO D-N-BUTYL PHTHALATE (DBP).

M. A. Ovacik[1], M. Ierapetritou[1], P. Georgopoulos[2], W. Welsh[2], B. Sen[3], K. Gaido[4] and I. Androulakis[1]. *[1]Chemical Engineering, Rutgers University, Piscataway, NJ, [2]ebCTC, EOSHI, Piscataway, NJ, [3]EPA, Washington, DC and [4]HIIS, Research Triangle Park, NC.*

A novel extension of the pathway activity methodology[1] was applied to microarray data to develop a method of identifying pathways affected after toxic chemical exposure over time rather than first identifying differentially expressed genes (DEGs). This approach was tested within the context of identifying pathways affected after in utero exposure to Di-n-butyl phthalate (DBP). Transcriptional studies in rats after in utero exposure to DBP leads to a repression of genes involved in cholesterol transport, steroid biosynthesis, in turn leading to a decrease in fetal testicular testosterone. The analysis of microarray data from the rat testis[2] after in utero DBP exposure focused on individual genes whose expression changed statistically. We developed
an alternative approach focusing on the genes by analyzing the microarray data for pathways that are significantly altered. The pathway activity level (PAL) analysis entails a singular value decomposition (SVD) of the expression data of the genes constituting a given pathway. The PAL is therefore the weighted sum of gene expression of individual genes in the given pathway and represents the change of all gene expressions in a given pathway regardless of specifying up or down regulation.The microarray study has both control and treated profiles over time which enables us to include the temporal changes of control profile into the analysis. This novel methodology led to the identification of pathways that were consistent with the published literature and pathways that were not identified in the published literature. We were able to monitor the temporal evaluation of pathway behaviors, which allowed for the development of a regulatory network model for DBP. [1]Tomfohr J. et al. **BMC Bioinformatics**, 2005. 6:225. PS 1001 COMPARATIVE SCREENING OF THE GENE EXPRESSION FOR NONYLPHENOL IN HUMAN CELL LINES.

S. Hwang[1], M. Oh[2, 3], S. Kim[1, 3], S. Paul[1], J. Kim[3], J. Youn[3], H. Park[2, 3], H. Kim[5], C. Lee[5], K. Choi[5], Y. Kim[4] and J. Ryu[4]. *[1]Biochemistry, Hanyang University, Ansan, Gyeonggi-do, Korea, South, [2]Bio-Nanotechnology, Hanyang University, Ansan, Gyeonggi-do, Korea, South, [3]GenoCheck Co. Ltd., Ansan, Gyeonggi-do, Korea, South, [4]Cellular and Toxicology Lab., KIST, Seoul, Korea, South and [5]Environmental Exposure Assessment, NIER, Incheon, Korea, South.* Sponsor: S. Lee.

Nonylphenol (NP), product of industrial synthesis, is very similar in structure with estrogen and it has known to be an environmental estrogen which induces estrogenic disturbance. It has been used in the industries for the manufacture of skin cleaning materials, kitchen detergents, cosmetics, fabric detergents, and ink binder. Because of its characteristic strong estrogenic potency, NP disturbs the reproductive hormone system. Exposure to NP for a long period of time increases the chances of having breast and lung cancers. In this study, we examined comparative expression profiles using Agilent whole genome microarrays between HK (Human Kidney), MCF-7 (Human breast cancer cell), and LNCaP (Human prostate cancer cell) cells treated with NP at the value of IC20. After comparative analysis, we detected some specific expression patterns in each cell lines. However, expression patterns from HK-2 and MCF-7 cells are very similar. Interestingly, estrogen receptor 1 and 2 genes have only down regulated in MCF-7 cell, whereas androgen receptor (AR) gene has shown over expression in all of 3 cell lines. PDZK1 gene, which is known as an estrogen-responsive gene, has also shown over expression in all of 3 cell lines. The majority of differentially expressed genes in NP treatment were involved in the cell proliferation, transcription, and signaling. These results may establish a framework for understanding toxicity mechanism of NP.

PS 1002 DEVELOPMENT OF A DNA MICROARRAY TO EVALUATE GENE EXPRESSION PROFILES OF DRUG-METABOLIZING GENES IN THE CYNOMOLGUS MONKEY.

R. Ise[1], Y. Uno[1], H. Akiyama[2], S. Kondo[2], H. Nobumasa[2] and R. Nagata[1]. *[1]Shin Nippon Biomedical Laboratories (SNBL), Ltd., Tokyo, Japan and [2]Toray Industries, Inc., Kanagawa, Japan.*

Drug-metabolizing enzymes impact the efficacy and adverse effects of drugs under development. Currently, there is limited information on the molecular mechanisms of drug metabolism in the cynomolgus monkey (*Macaca fascicularis*) which is widely used in preclinical studies. To address this issue, we produced a DNA microarray that includes 43 probes specific for metabolic enzymes in the cynomolgus monkey. We evaluated the ability of the DNA microarray to detect tissue-specific metabolic enzyme gene expression and compared microarray results for five key metabolic enzymes with real-time RT-PCR results. We measured gene expression profiles of the liver, intestinal tract, and kidney for adult five male cynomolgus monkeys. In the liver, *CYP2C76*, *2E1*, *2A23*, *3A8*, and *2C20* were highly expressed. In the intestinal tract, we found that although the genes expressed were similar, the expression level of these genes was greater in the jejunum than the ileum. In the kidney, expression profiles were similar in the cortex and medulla. Thus, the DNA microarray successfully detected tissue-specific gene expression. Results from DNA microarray and real-time RT-PCR produced similar patterns in the detection of *CYP2C43*, *2C75*, *2D17*, *3A5*, *3A8*; all genes with human homologs that frequently influence xenobiotic metabolism. Overall, we have shown that this DNA microarray reliably measures metabolic enzyme genes expression in the cynomolgus monkey. Future work with this DNA microarray could focus on identifying metabolic enzyme expression patterns for species-specific drug metabolism. An enhanced understanding of metabolic enzyme activity in cynomolgus monkeys can help to determine the extent to which monkey study data can be used to predict drug effects in humans. In conclusion, we developed a reliable DNA microarray that can contribute to a more thorough evaluation of efficacy and safety in new drug development.

PS 1003 ANALYSIS OF SECRETED PROTEINS AS AN IN VITRO MODEL FOR DISCOVERY OF LIVER TOXICITY MARKERS.

J. A. Lewis[1], W. E. Dennis[1], J. Hadix[2] and D. A. Jackson[1]. *[1]U.S. Army Center for Environmental Health Research, Frederick, MD and [2]SAIC, Inc., Frederick, MD.*

Despite the wealth of sequence data and new technologies that can probe large portions of the transcriptome or proteome in a single experiment, attempts to identify human biomarkers of toxicity have met with limited success. We have developed an *in vitro* system using the hepatoma-derived cell line, HepG2/C3A, to model protein secretion by hepatocytes in response to toxic insult. Using quantitative proteomics we are able to characterize qualititative and quantitative changes in the abundance of secreted proteins that are likely to be detectable in blood samples of exposed animals. In a proof of concept experiment, conditioned medium from cells exposed to ethanol, after immunodepletion of abundant proteins, was subjected to quantitative mass spectral analysis. Nearly 250 proteins were identified with almost half changing in abundance. A large portion of these was only identified in the highest dose and is presumably a result of tissue leakage due to disruption of the cell membrane upon cell death. However, a small number was also identified which represent known effects of ethanol toxicity or alcoholism. This approach shows promise as a targeted system for identification of human biomarkers for liver damage. Disclaimer: Opinions, interpretations, conclusions, and recommendations are those of the authors and are not necessarily endorsed by the U.S. Army. The research described herein was sponsored by the U.S. Army Medical Research and Materiel Command, Military Operational Medicine Research Program.

PS 1004 PREDICTION OF LIVER TOXICITY – AN *IN VITRO* TOXICOGENOMICS APPROACH.

F. Boess, A. B. Roth, G. Steiner, E. Durr, K. Schad, N. Schaub, C. Zihlmann and L. Suter-Dick. *F. Hoffmann-La Roche Ltd., Basel, Switzerland.*

Prediction of organ toxicity early in the compound selection process would help to decrease attrition in later development. Therefore we are establishing a method to predict liver toxicity in rat using genomics data obtained from cultured rat hepatocytes. Method: Proprietary and non-proprietary compounds (56) were selected to build a database. The compounds were well-balanced distributed to represent rat liver toxicants (divided into phenotypic subgroups termed "steatosis", "cholestasis", "direct acting" and "PPAR agonist") and compounds showing no liver toxicity in rats in vivo. Primary rat hepatocytes (batch size: 5) were treated with test compound concentrations 2 to 4 times below the determined cytotoxic concentration. After exposure for 24 hours microarray analysis was performed. Gene expression changes relative to vehicle treatment form the same series were calculated and used to train classifiers based on a support vector machine (SVM) algorithm. The obtained SVM models were evaluated using a compound drop cross validation. Results: Treatment with PPAR ligands could be identified with almost perfect accuracy. For the other compound classes, a 3-class model distinguishing between the classes "non- toxic", "direct acting" and "cholestatic or steatotic" compounds performed best (overall accuracy: 69%). Differentiation of the "cholestatic/steatotic" compounds from the rest worked better than differentiation of either the "direct acting" or "non-toxic" compounds from the rest. We suggest two main reasons that influence the performance of the presented approach: 1) The heterogeneity of toxicity mechanism of the compounds in the "direct acting" group and 2) the concentration selection approach, which - on purpose - disregarded the pharmacologically- or toxicologically-relevant in vivo plasma compound concentrations. Conclusion: Prediction of in vivo toxicity from in vitro gene expression data is possible for compounds of distinct phenotypic subgroups or with well defined modes of action.

PS 1005 ESTABLISHING A PROFILE OF GENE EXPRESSION IN AVIAN SPECIES EXPOSED TO PCBs .

M. B. Bohannon, T. E. Porter and M. Ottinger. *Animal Sciences, University of Maryland, College Park, MD.*

Genotoxic effects of exposure to endocrine disruptors are a hazard of environmental pollution. Issues of concern include changes in gene expression associated with detoxification, developmental alterations in neuroendocrine and endocrine systems, and other alterations . We are endeavoring to establish a gene expression profile in birds in response to PCBs using microarray technology. With the power to measure the expression levels of an entire genome at once, microarray technology presents itself as an excellent candidate for detecting patterns of gene expression. Using Japanese quail (Coturnix coturnix) as a lab model, we injected eggs on the third day of incubation with a vehicle control or a PCB mixture (6, 12, and 49 μg/g egg) and sampled organs at hatch. RNA was extracted from hatchling livers and applied to the Del_Mar Chicken Integrated Systems Microarray. Validation showed roughly a 90% correspondence between quail liver samples and the chicken microarray, 75% correspondence in quail hypothalamus, as well as 60-85% correspondence in turkey and duck livers and hypothalami, and tree swallow and American kestrel livers. Further application of quail samples to the microarray revealed a number of candidate genes, including cytochrome P450 1A5 (CYP1A5), which was expressed greater than control in 6 μg/g and 49 μg/g-injected eggs; and mitochondrial ribosomal protein S16, which was expressed 3-fold under control in 6 μg/g injected eggs, but only 1.24-fold under control in 12 μg/g-injected eggs. Other genes that have shown differential expression in the microarray experiments include ornithine decarboxylase antizyme, signal transducer and activator of transcription (STAT) 6, and NADH Dehydrogenase (Ubiquinone) Flavoprotein 1, among others. These genes may be used as toxicogenomic biomarkers for hatchling birds exposed to PCBs. Further examination of the microarray study reveals several biological processes for further genotoxicological screening, including the immune system, pathways relating to oxidative stress, as well as regulatory pathways for regulation of gene expression.

PS 1006 TRANSCRIPTOMIC COMPARISON OF TCDD-ELICITED GLOBAL GENE EXPRESSION RESPONSES IN HUMAN PRIMARY HEPATOCYTES.

E. Dere[1, 2], L. D. Burgoon[1, 2, 3] and T. R. Zacharewski[1, 2, 3]. *[1]Department of Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI, [2]National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI and [3]Center for Integrative Toxicology, Michigan State University, East Lansing, MI.*

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is a ubiquitous environmental contaminant that causes physiological and toxic effects in a species-specific manner. In order to further elucidate these differences, a comparative genomic approach was utilized to examine species-specific differential gene expression elicited by TCDD. Primary human hepatocytes isolated from 3 post-menopausal, non-obese, non-smoking Caucasian donors were used to examine TCDD-elicited temporal gene expression responses. Gene expression changes were measured using Agilent whole genome oligonucleotide microarrays following treatment with 10 nM TCDD or vehicle control (DMSO) for 1, 2, 4, 12 and 48 hrs. Using Empirical Bayes p1(t)

values (>0.80) and fold change (>1.5), 447 differentially expressed genes were identified with responses ranging from +40.1- to -5.5-fold. This included the induction of CYP1A1 and CYP1A2, while other notable TCDD responsive genes, such as ALDH3A1 and NQO1 were not statistically significant due to the inherent variability between human donors. Hepatocyte responses were compared to the top 500 ranked genes from in vitro human HepG2 and mouse Hepa1c1c7 gene expression data sets, as well as to the top ranked hepatic responses from immature ovariectomized female C57BL/6 mice treated with 30 μg/kg TCDD. These comparisons identified 35, 21 and 15 orthologous gene responses that were common between the HepG2, Hepa1c1c7 and C57BL/6 hepatic tissue, respectively. Therefore, despite the conservation of the AhR signaling pathway, there are significant differences in the subsequent gene expression profiles between species, which likely contribute to the species-specific toxic effects of TCDD. Supported by SBRP P42ES04911.

PS 1007 ANALYSIS OF PHASES 1 AND 2 METABOLIZING ENZYMES IN HUMAN SKIN SUGGESTS IMPORTANT ROLE OF PHASE 2 ENZYMES IN THE DETOXIFICATION.

D. Duche[2], V. Luu-The[1], C. Ferraris[2], J. Leclaire[2] and F. Labrie[1]. *[1]Oncology and Molecular Endocrinology Research Center, Laval University Hospital Research Center (CRCHUL) and Laval University, Quebec, QC, Canada and [2]Safety Research Department, L'Oreal Advanced Research, Aulnay sous Bois, France.* Sponsor: E. Dufour.

Skin plays a role of physical barrier and protects the deeper tissues from injury, excess water loss and invasion by foreign substances and organisms. It also expresses a certain number of detoxification enzymes to help dealing with environmental chemicals. To gain a better knowledge about these chemical protection enzymes in the skin, we quantified mRNA expression levels of multiple enzymes involved in phases 1 and 2 metabolism using Affymetrix GeneChip® and RealTime PCR in total skin and epidermis. There is a good correlation between these two methods of quantification. Among phase 1 enzymes, alcohol dehydrogenase 1B (ADH1B) is expressed at very high levels (approximately 400 000 copies/μg total RNA), while CYP450s are expressed at approximately 10-fold lower. The latter represent mostly isozymes involved in hydroxylation of endogenous compounds such as retinoids (CYP26B1), prostanoids (CYP4F8), inflammatory mediators (CYP4F12), arachidonic acid (CYP2J2) and cholesterol (CYP39A1). On the other hand, most of phase 2 enzymes, namely, glutathione-s-transferase P1 (GSTP1), catechol-O-methyl transferase (COMT), steroid sulfotransferase (SULT2B1b) are highly expressed with an expression level varying from 200 000 to 1 000 000 copies/μg total RNA. It is noteworthy that 10 000 - 20 000 copies/μg total RNA represent 1 copie/cell. Our data suggest that, in contrast with detoxification in the liver which involves many CYP450 isoforms, in the skin, detoxifying process uses mostly phase 2 enzymes, while CYP450s are rather involved in the elimination of endogenous compounds.

PS 1008 LOW-DOSE MODULATION OF EMBRYONIC GENE EXPRESSION NETWORKS BY INORGANIC ARSENIC.

A. Planchart, N. E. Griffin and C. J. Mattingly. *Mount Desert Island Biological Laboratory, Salisbury Cove, ME.*

Inorganic arsenic (arsenite, As3+) is an environmentally ubiquitous contaminant that presents a serious health risk to populations exposed primarily via drinking water. Associated risks include, increased incidence of certain cancers, diabetes, and high blood pressure. The biochemical processes recruited during arsenic detoxification are well characterized yet the effects of arsenic on development, modulation of gene expression, disease origin and the potential for long-term trans-generational effects are poorly understood. A large-scale microarray analysis of zebrafish embryos exposed to very low (10 ppb) and moderately high (100 ppb) As3+ concentrations during the early-phase (24 hours post-fertilization; hpf) and late-phase periods of development (48 hpf) was performed in order to determine the effect low-level arsenic exposure has on the expression profiles of embryonically active gene networks. In addition to the occurrence of pleiotropic developmental abnormalities concentrated in the area of anterior-posterior axis development, arsenic elicited global changes in gene expression. Non-parametric statistical analysis of the microarray datasets identified approximately 100 genes that are significantly affected by exposure to As3+ yet the observed expression changes are not necessarily linearly related to As3+ concentrations. Instead, there is a probabilistic component to the changes in expression levels apparent predominantly at low concentrations. The variability in response suggests low As3+ concentrations affect embryonic gene expression by a different mechanism compared to higher concentrations—one wherein stochasticity, and not necessarily dose, determines whether an embryo will undergo observable changes in gene expression. Several arsenic-perturbed networks were identified and expression changes were validated by quantitative RT-PCR. The results of this study may have uncovered a novel mechanism by which low levels of arsenic could lead to potentially detrimental effects during embryonic development.

PS 1009 AN INTEGRATIVE STATISTICAL FRAMEWORK FOR THE METABOLOMIC ANALYSIS OF NON-GENOTOXIC HEPATOCARCINOGENESIS IN THE RAT.

D. Rubtsov[1], C. Waterman[1], R. Currie[2], D. Salazar[2], J. Wright[2] and J. Griffin[1]. *[1]Department of Biochemistry, University of Cambridge, Cambridge, United Kingdom and [2]Human Safety, Syngenta, Bracknell, United Kingdom.*

Metabolomics makes use of high throughput global profiling technologies, including nuclear magnetic resonance (NMR) spectroscopy and mass spectrometry (MS), to profile the metabolic compliment of a cell, tissue or biofluid. The informatic tools for the integration of data from such global methods significantly lags behind the rapid progress made in analytical techniques. We have applied modern statistical and signal processing techniques in order to improve information recovery from large multivariate datasets. Data was obtained from male F344 rats continuously exposed to ten compounds for up to 91 days. The chemicals were selected from the National Toxicology Program database to provide examples of both genotoxic and non-genotoxic carcinogens and hepatotoxic non-carcinogens. Metabolomics was performed on liver, blood plasma and urine alongside transcriptomics and histopathology of liver tissue. Applying Bayesian statistics and Markov Chain Monte Carlo (MCMC) methods for the automated processing of NMR signals, datasets were produced from the NMR spectra that represented individual resonances without the inclusion of noise. This approach significantly improved classification according to the treatment group and aided interpretation of the biological changes. An ANOVA based approach was applied to the resultant metabolomic data to cross-correlate the information with transcriptomics, Gas Chromatography MS based metabolomics, clinical chemistry and histopathology. This approach has highlighted key mechanisms associated with the mode of action of the hepatocarcinogens used in the study. While the data set was dominated by the effects of PPAR agonists on fatty acid metabolism, classification could be achieved between genotoxic and non-genotoxic carcinogens, demonstrating the potential of distinct mechanisms of response between these two classes of compounds.

PS 1010 FUNCTIONAL ROLE FOR CLASS A SCAVENGER RECEPTORS IN THE RECOGNITION OF ENGINEERED NANOPARTICLES BY MACROPHAGES.

B. Thrall, W. B. Chrisler, M. Markillie, R. C. Zangar, R. Tan and G. Orr. *Pacific Northwest National Laboratory, Richland, WA.*

The initial mechanism of cell entry is a potentially important parameter that determines how cells respond to engineered nanomaterials. Previous studies have implicated class A scavenger receptors in mediating some macrophage effects induced by larger (micron size) environmental particulates, including metal oxides. However, little is known about the role these receptors play in mediating uptake and responses to nano-scale (<100 nm) materials. We hypothesis that anionic nanoparticles serve as ligands for scavenger receptor A (SR-A) and contribute to the inflammatory signaling in macrophages. Stable RAW 264.7 cell mutants where expression of the major class A receptors, SR-AI/II, was silenced were developed using lentiviral siRNA transduction. Flow cytometry analysis demonstrated that SR-AI/II was functionally inhibited by siRNA, as indicated by reduced endocytosis of fluorescent acetylated low density lipoprotein. Cellular uptake of 20 nm fluorescent polystyrene nanoparticles was also reduced in SR-AI/II mutants compared to wildtype cells. In contrast, gain of function experiments in human cells devoid of endogenouos SR-AI/II protein demonstrated uptake of 20nm nanoparticles was significantly augmented when SR-AI expression was introduced. Using live cell microscopy, fluorescent silica nanoparticles were found in vesicular structures and co-localized with transferrin receptor, a marker of clathrin-dependent endocytosis. Protein microarray assays also showed that the pattern of cytokines secreted in response to amorphous silica nanoparticle treatment was altered in the SR-AI siRNA mutants compared to wildtype RAW 264.7 cells, indicating a functional role for SR-A in macrophage signaling. These results provide direct evidence that SR-AI constitutes at least one pathway for the internalization of anionic nanoparticles in macrophages. A molecular understanding of these interactions will aid in future design of safe nanomaterials. Supported by the Laboratory Research and Development Program at PNNL and R01 ES016212 to BDT.

PS 1011 ABSENCE OF AN ENDOTHELIAL CELL TRANSCRIPTOMIC SIGNATURE IN THE PERIPHERAL BLOOD AFTER ADMINISTRATION OF THREE ONCOLOGY TUBULIN BINDERS.

I. Mikaelian[1], D. Coluccio[1], C. Kanwal[1], A. Buness[2], M. Setlem[1], J. C. Downing[1], H. W. Char[1], R. Nicklaus[1], H. Hilton[1], J. Funk[2], C. de Vera-Mudry[2], J. Hoflack[2], M. Fielden[3] and F. Herting[4]. *[1]Non-Clinical Safety, Hoffmann-La Roche, Inc., Nutley, NJ, [2]Non-Clinical Safety, Hoffmann-La Roche, Basel, Switzerland, [3]Non-Clinical Safety, Hoffmann-La Roche, Palo Alto, CA and [4]Hoffmann-La Roche, Penzberg, Bavaria, Germany.* Sponsor: K. Pendino.

Transcriptomic analysis, histopathology and immunohistochemistry identified acute endothelial damage and apoptosis in the heart of rats following intra-venous administration of oncology tubulin binders. Therefore, the transcriptomic profile of the peripheral blood may transiently be enriched in endothelial cell markers subsequent to the administration of tubulin binders. In this study, the transcriptomic profile of the whole peripheral blood collected in PaxgeneTM tubes was evaluated in rats 6 and 24 hours after intravenous dosing with the 3 tubulin binders vincristine, vinblastine and colchicine. All three compounds induced an increase in apoptotic cells and a mitotic arrest in the heart, as well as hematologic changes, including a decrease in platelet, lymphocyte, monocyte and eosinophil counts with an increase in neutrophil counts. There was no enrichment of endothelial cell-associated genes in the whole peripheral blood. Possible causes for this result include inadequate collection times, dilution ofthe transcriptomic signal of endothelial cell-specific transcripts, decreased expression of endothelial cell-specific genes in apoptotic endothelial cells, or rapid clearance of damaged of endothelial cells by the reticulo-endothelial system. The transcriptomic profile correlated well with the hematologic changes, except for the decrease in eosinophil counts, possibly because of the relative scarcity of these cells in the peripheral blood. Protein- and cell-based technologies may provide better inroads for the identification of novel biomarkers of endothelial damage.

PS 1012 COMBINED METABONOMIC/TRANSCRIPTOMIC EVALUATION OF THE EFFECTS OF OVERNIGHT (16HR) FASTING ON SD RATS.

S. A. Stryker[1], S. Ruepp[2], N. Aranibar[1], S. Petia[1], S. Hnatyshyn[1], W. Foster[2], M. Reily[1] and R. Donald[1]. *[1]Applied and Investigative Metabonomics, Bristol-Myers Squibb, Princeton, NJ and [2]Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ.*

The overnight fast prior to necropsy or blood collection is a routine procedure in many toxicology studies. With "omics" evaluations becoming more common in these routine studies, it became apparent that the effect of fasting on transcript and metabolite profiles, relative to ad lib feeding prior to sample collection, required evaluation. Male and female Sprague-Dawley rats (5/group) were fasted for 16 h hours and effects of fasting on the liver transcriptome, urine and serum metabolic profiles and clinical pathology parameters were determined relative to rats maintained on an ad lib diet. Fasted rats lost ~9% and 7% bodyweight in males and females, respectively while their ad lib counterparts gained ~ 3 and 4%, respectively. Urine volumes and serum phosphorus were significantly increased in fasted animals while urine osmolality and protein and serum, TRIG, GLU, AP, ALT were all decreased. The number of transcriptional changes in the liver significantly affected by fasting (> 1500) exceeded effects typically seen in preclinical toxicology studies, even compared to compounds associated with hepatotoxicity. Transcript changes included genes with roles in fatty acid, glucose, cholesterol and bile acid metabolism. About 7% of trancripts in males and 10 % in females changed. Urine metabonomic profiles revealed that the metabolic response to fasting was similar in males and females. Fasted animals had decreased urinary citrate, oxoglutarate, taurine, glucose, hippurate, and N-methyl nicotinic acid. While increases were noted in N-methylnicotinamide, creatinine, lactate, circulating M/S chain fatty acids, and acetate. No changes in urinary ketone bodies (acetoacetate, acetone, 3-hydroxybutyric acid) were noted. While some changes were anticipated, the number and magnitude of omic changes suggests that significant attention needs to be paid to fasting state when such data are to be generated in toxicological studies.

PS 1013 MIXTURE TOXICOGENOMICS: THE CASE OF HAIR DYES.

D. A. Sarigiannis, E. Marafante, G. Cimino Reale, B. Casati, R. Brustio and A. Collotta. *Institute for Health and Consumer Protection, European Commission - Joint Research Centre, Ispra, Italy.* Sponsor: M. Mumtaz.

There is an increasing policy need to provide novel scientific tools for improving the health risk assessment of chemical mixtures in consumer products such as cosmetics and in particular hair dyes (HD). Genetic biomarkers of exposure and effects related to chronic exposure to typical low doses of commercially relevant hair dye preparations could be identified with gene expression micro-arrays. Our study comprised in vitro analysis on two human cell lines and in vivo analysis on selected rat tissue for the determination of gene expression patterns in target organs. The chemicals considered were representative of commercial hair dyes. Comparison was made among formulations with commonly found agents like p-phenylendiamine (PPD). Two commercially relevant formulations were tested including hair dyes using nanoparticle-bound PPD for better dyeing and duration effects (HD nano). The in vitro studies were dose-response driven. Gene expression, cytotoxicity and endocrine disruption were considered. Gene expression results were corroborated with quantitative RT-PCR using micro-fluidic cards for specific gene families and the related biological processes. Weak cytotoxicity was induced in all cell lines used. The results were confirmed by the very weak gene expression modulation observed in vitro. Hair dye preparations showed estrogenic activity as suggested by the E-screen assay. Toxicogenomics analysis on adrenal glands in rats treated intra-tracheally and epidermally confirmed that in female rats genes related to estrogenic activity and endocrine equilibrium were strongly modulated. In the lungs of male and female rats exposed to HD, HD-nano and PPD, gene networks related to immunological responses were modulated; yet the number of genes affected in the males was much higher than in the females. Toxicogenomics analysis of urinary bladder showed a significant difference between male and female rats both in terms of total genes modulated and in terms of the effects on specific biological processes induced by exposure to hair dyes.

PS 1014 GENE EXPRESSION EFFECTS OF DIETARY FAT AND METASTASIS IN MICE PREDISPOSED TO OBESITY AND MAMMARY CANCER.

M. La Merrill[1, 2], R. Gordon[3], K. Hunter[4], D. Threadgill[2] and D. Pomp[3, 2]. *[1]Community & Preventive Medicine, Mount Sinai School of Medicine, New York, NY, [2]Genetics, UNC, Chapel Hill, NC, [3]Nutrition, UNC, Chapel Hill, NC and [4]Metastasis Susceptibility, NIH/NCI, Bethesda, MD.*

The prevalence of obesity is growing rapidly, and this has been attributed in part to diets high in fat and to oral exposures to some environmental chemicals. Obesigenic diets and metastatic load play a significant role in breast cancer prognosis. In order to extensively examine the mechanisms underlying the interaction of obesity with breast cancer and its metastasis, we developed an obese mouse model of breast cancer metastasis. Among a F2 mouse population co-segregating obesity QTL and the MMTV-PyMT transgene, those mice fed high fat diet had decreased mammary cancer latency, and increased pulmonary metastases compared to those fed normal fat diet. Genome-wide SNP analyses demonstrated 8 modifier loci for pulmonary metastasis, where diet significantly interacted with novel QTL at all of these loci. Here, gene expression microarray was preformed on mammary tumors from the same F2 population, and analyzed for functional significance using Ingenuity software. Despite the substantial impact of diet on metastasis and its interaction with QTL, diet only altered mammary tumor gene expression of five genes. pten and tnf are central nodes of this network of diet-induced differential gene expression. Metastatic load was modulated by substantial alterations in the gene expression of mammary tumors, including many genes known to be involved in endocrine cancers, cell morphology, cell movement, angiogenesis and invasion. The top metastasis network forms central nodes at nfκb, mapk, insulin, tgfβ, jnk, and ras. Tight junction signaling was the only canonical pathway associated with central nodes molecules of both the differential diet- and metastasis- analyses. In conclusion, aberrant tight junction signaling may be the unique biological mode of metastatic action among obese animals with mammary cancer.

PS 1015 A COMPARATIVE 'OMICS APPROACH TO UNDERSTANDING TUMOR SUPPRESSION BY P19ARF DURING SKIN CANCER PROGRESSION.

S. C. Tilton[1], K. S. Kelly-Spratt[1], K. Kim[1], N. Lemeur[1], R. Gentleman[1], H. Zhang[2], S. Letarte[3] and C. J. Kemp[1]. *[1]Fred Hutchinson Cancer Research Center, Seattle, WA, [2]Johns Hopkins University, Baltimore, MD and [3]Institute for Systems Biology, Seattle, WA.*

Tumor progression involves genomic, proteomic and chromosomal changes within cells as they transform from a normal state to benign hyperplasias, malignant carcinomas and finally to a metastatic phenotype. Our laboratory has previously found that p19Arf suppresses DMBA/TPA-induced skin cancer in vivo by inhibiting the growth, progression and metastasis of Hras-driven carcinomas. To determine the specific mechanisms of p19Arf activity during tumor progression, we have examined gene expression patterns in papillomas and carcinomas from wild type and p19Arf-null mice by microarray analysis. Profiles for papillomas and carcinomas were significantly enriched in genes related to cell proliferation (including cell cycle progression, transformation, ribogenesis, ubiquitination and sumoylation) and cellular movement (including adhesion, invasion, migration and metastasis), respectively. While activating mutations in Hras were detected in 100% of tumors from

both genotypes, Hras overexpression was only observed in papillomas and carcinomas from p19Arf-null mice. Changes in gene expression are supported by array-CGH structural data showing over representation (gain) of chromosome 7, which contains Hras, in p19Arf-null tumors. Further, LTQ MS/MS analysis of plasma from tumor bearing p19ARF deficient mice also identified specific proteins related to cell cycle, cell migration and localization, and cell death. Overall, these data indicate (1) p19Arf suppresses tumorigenesis through distinct mechanisms that are dependent on tumor stage, (2) loss of p19Arf facilitates an increase in Ras levels, which may be a major driving force throughout progression of DMBA/TPA skin cancer, and (3) comparative 'omic' analysis is a useful tool for identification of candidate biomarkers and processes important for disease progression.

PS 1016 USE OF MICRORNA EXPRESSION ADDS A REGULATORY COMPONENT TO MICROARRAY DATA: A CASE STUDY.

M. Scicchitano, R. A. Thomas, W. K. Weiner, K. S. Frazier and H. C. Thomas. *GlaxoSmithKline, King of Prussia, PA.*

Microarrays have been used to correlate gene expression with physiological endpoints such as liver toxicity to create biomarkers for specific clinical or pathological conditions and have enabled toxicologists to generate mechanistic hypotheses. MicroRNAs (miRNA) are small non-coding RNA transcripts expressed in a tissue-specific manner and are responsible for regulation of gene expression. Development of "antagomiRs" have demonstrated successful synergistic down-regulation of transcripts responsible for pathological conditions. To investigate the utility of using mid-throughput miRNA arrays in toxicologic assessment, rats were dosed with 100mg/kg Atorvastatin or vehicle for 4 days. RNA was collected from livers and used for Affymetrix microarray and TaqMan® miRNA analysis. Little is currently known and widely accepted regarding the regulatory roles of miRNA in many specific pathological and physiological conditions as this is a rapidly expanding field, however, our analysis of livers from rats treated with Atorvastain revealed 22 up-regulated and 20 down-regulated miRNAs and microarray expression analysis revealed that many genes known to be regulated by these miRNAs were down- and up-regulated, respectively. These included genes associated with lipid metabolism, fatty acid biosynthesis, molecular transport, amino acid metabolism, carbohydrate metabolism, biosynthesis of steroids and cell signaling pathways. The targets of the regulated miRNA's were regulatory components of the genes identified in the Affymetrix microarray. The coupling of miRNA with microarray expression analysis has the potential to add a strong regulatory component to clearly identify signaling pathways which may be acting synergistically and therefore provide insight into mechanisms more relevant to pathological/toxicological endpoints than microarray expression alone.

PS 1017 EFFECTS OF VARIOUS HEPATOTOXICANTS ON HEPATIC GENE EXPRESSION IN RATS AND CHIMERIC PXB-MICE® WITH HIGHLY HUMANIZED LIVER.

S. Nagatsuka[1], G. Onishi[1], D. Hynes[1], S. Ninomiya[1], M. Kakuni[2], C. Tateno-Mukaidani[2], T. Shimada[2] and Y. Yamazoe[3]. *[1]ADME & Toxicology Research Institute, Sekisui Medical, Co., Ltd., Tokai-mura, Ibaraki, Japan, [2]Phoenix Bio, Co., Ltd., Higashi-Hiroshima, Hiroshima, Japan and [3]Tohoku university, Sendai, Miyagi, Japan.* Sponsor: T. Miyaoka.

Drug-induced liver injury (DILI) is one of the leading causes of withdrawal of a newly developed drug. In order to find out promising biomarkers for DILI, toxicogenomic approaches have been imployed using in vivo (experimental animals, mainly rats) or in vitro (human hepatocytes or hepatoma cells) systems. Recently, chimeric PXB-mice®, in which more than 70% of hepatic parenchymal cells are replaced by human hepatocytes, are attracting much attention as a unique animal model to mimic human-type drug metabolism. This animal model has a potential to bridge the gap between rodent-type and human-type livers and to explain the difference of in vivo and in vitro response of human hepatocytes against hepatotoxicants. We have analyzed changes in hepatic gene expression in rats and PXB-mice® treated with 20 different hepatotoxicants (acetaminophen, amiodarone, diclofenac, d-penicillamine, flutamide, erythromycin, valproate, sulindac, indomethacin, perhexilene, methyldopa, amitriptyline, tamoxifen, acetylsalicylic acid, methotrexate, demeclocycline, hydrazine, hydroxyurea, imipramine, orotic acid) and six non-hepatotoxicants. These drugs were orally administered to rats and PXB-mice® thee-times daily at high doses (ca. 20% of reported LD50), followed by hepatic total RNA preparation and gene expression analyses using oligonucleotide microarray chips. Several maker gene candidates, which specifically responded to the hepatotoxicants, were extracted and further evaluated by using a score method in which DILI prediction score for each drug is calculated from marker gene expression levels and weight factors optimized by least-squares fitting. One-by-one omit analyses revealed that PXB-mice® gave better predictability of hepatotoxicant as compared with rats. Differences of gene expression in rats and PXB-mice® will also be discussed in terms of biological pathways related to liver functions.

PS 1018 INVESTIGATING THE MECHANISM OF 2-BROMOETHANAMINE-INDUCED GLUTARIC ACIDURIA.

J. D. Vassallo[1], N. Aranibar[2], A. J. Campbell[3], M. Coen[3], J. M. Onorato[2], P. Shipkova[2], L. D. Lehman-McKeeman[1], J. C. Lindon[3] and J. K. Nicholson[3]. *[1]Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ, [2]Bioanalytical and Discovery Analytical Sciences, Bristol-Myers Squibb, Princeton, NJ and [3]Biomolecular Medicine, Imperial College, London, United Kingdom.*

2-Bromoethanamine (BEA) causes renal papillary necrosis (RPN) after acute administration. This compound has been used for studying RPN as the pathophysiological course parallels the morphological and functional changes associated with excessive use of nonsteroidal anti-inflammatory drugs. While the mechanism of BEA-induced RPN has not been established, urinary metabonomic evaluations have demonstrated marked increases in glutaric acid in rats at BEA doses ≥ 25 mg/kg. Functional loss of glutaryl-CoA dehydrogenase (GCDH) causes glutaric aciduria in humans and animal models suggesting that BEA may inhibit GCDH. BEA is a known mechanism-based inhibitor of enzymes such as semicarbizide-sensitive amine oxidase. Therefore, the purpose of this investigation was to determine if BEA or a major metabolite, aziridine is a mechanism-based inhibitor of GCDH. Incubations containing purified GCDH and BEA or aziridine at 50 and 500 μM were prepared and aliquots were removed at various times and added to a complete enzymatic reaction consisting of the intermediate (electron transfer flavoprotein) and terminal (2,6-dichlorophenolindophenol) electron acceptors as well as the glutaryl-CoA substrate. Compared to a control enzyme reaction, no GCDH inhibition was observed with either BEA or aziridine up to 500 μM. Since substrates for GCDH are CoA-containing moieties, additional experiments were conducted to determine whether BEA could form a covalent adduct with glutaryl-CoA. When incubated at equimolar concentrations, BEA formed two unique adducts with glutaryl-CoA (molecular weight 924.2) in the presence of sodium bicarbonate. These results indicate that BEA covalently adducts glutaryl-CoA and may directly inhibit GCDH to cause glutaric aciduria.

PS 1019 TEMPORAL PATTERNS IN THE TRANSCRIPTOMIC RESPONSE OF RAINBOW TROUT, ONCORHYNCHUS MYKISS, TO CRUDE OIL.

S. Hook[1], M. A. Lampi[2], E. J. Febbo[2], J. A. Ward[1] and T. F. Parkerton[2]. *[1]Battelle, PNWD, Sequim, WA and [2]ExxonMobil Biomedical Sciences Inc, Annandale, NJ.*

Time is often not characterized as a variable in ecotoxicogenomic studies. In this study, the temporal kinetics in gene expression were determined during exposure to crude oil and subsequent recovery. Juvenile rainbow trout, Oncorhynchus mykiss, were exposed for 96 hours to the water accomodated fractions of either 0.4, 2 or 10 mg/L crude oil loadings. Following 96 h of exposure, fish were transferred to recovery tanks for 96 h. Gill and liver samples were collected after 24 and 96 h of exposure, and after 96 h of recovery for RNA extraction and microarray analysis. Fluorescently labeled cDNA was hybridized against matched controls, using salmonid cDNA arrays. Genes that were a minimum 1.5 fold changed relative to control and significant ($p < 0.05$) by t-test were considered up or downregulated. The expression profile of cytochrome P450 1A, a biomarker for oil exposure, did not predict the majority of gene expression profiles in any tissue or dose. More genes responded to crude oil in the gill than in liver. The Gene Ontology terms associated with gill responsive genes implicated membrane narcosis, a toxic mechanism for crude oil. In the gill, 1,137 genes had altered expression at 24 hours, 2,003 genes had altered expression levels at 96 h of exposure, yet by 96 h of recovery, no genes were significantly altered in expression. By contrast, in the liver at 10 mg/ L, only five were changed at 24 h, yet 192 genes had altered expression after 96 h recovery. At 2 mg/L in the liver, many genes had altered regulation at all three timepoints. The 0.4 mg/L timepoint also showed 289 genes upregulated at 24 h after exposure. A direct dose response profile is not seen when hepatic transcription profiles from the three crude oil doses at 24 h are compared. These results demonstrate that changes in gene expression with time and dose should be characterized in controlled laboratory settings before responses from field collected organisms are interpreted.

PS 1020 TOWARDS AN INTEGRATED UNDERSTANDING OF GENES CONTROLLING SEXUAL MATURATION IN SALMONIDS.

S. Hook[1], I. R. Schultz[1], J. Verducci[2], W. Hayton[2], Y. Liu[2], J. Kim[2], T. Cavileer[3] and J. J. Nagler[3]. *[1]Battelle, PNWD, Sequim, WA, [2]The Ohio State University, Columbus, OH and [3]University of Idaho, Moscow, ID.*

As the use of high density gene arrays based on fully or largely sequenced genomes increases in fish toxicological studies, several trends are emerging that limit the interpretation of the results. Many genes successfully identified have no obvious link

to the presumed toxic mode of action and are either ignored or considered a non-specific stress response. Many genes altered in expression, although considered statistically significant, are still only marginally affected (e.g. <2-3 fold) and the biological significance within the context of a gene's normal range of expression is unknown. These problems have been especially apparent in toxicogenomic studies of endocrine disruptors in fish. Therefore, to improve our knowledge regarding gene expression and sexual maturation in fish, we characterized the natural changes in gene expression in tissues comprising the brain-pituitary-ovary-liver axis (BPOL) in female rainbow trout during a 12 month reproductive cycle. At 18 different time points during the cycle, groups of fish were euthanized, BPOL tissues removed, gene expression characterized using a 16K salmonid cDNA microarray (GRASP consortium). Changes in gene expression during the cycle were compared against levels occurring immediately after spawning. A second group of female trout was placed under an accelerated photoperiod regime, which was designed to compress the normal 12 month cycle to 7 months and thus force many of the biological variables involved in maturation to reach their respective maximum / minimum values in a more pronounced manner. Initial results from the microarray analysis indicate the ovaries undergo the most dynamic changes among BPOL tissues during the normal reproductive cycle. The photo-compressed trout were not able to fully complete their reproductive cycle, which may also have contributed to the difference.

PS 1021 EXPRESSION QUANTITATIVE TRAIT LOCI MAPPING IDENTIFIES NEW GENETIC MODELS OF GLUTATHIONE-S-TRANSFERASE VARIATION.

M. T. Pletcher[1], K. R. Hayes[2] and B. M. Young[3]. [1]*Investigative Toxicology, Pfizer Global Research and Development, Groton, CT,* [2]*Pioneer Hi-Bred International, Johnston, IA and* [3]*The Scripps Research Institute - Florida, Jupiter, FL.* Sponsor: J. Cook.

Expression Quantitative Trait Loci (eQTL) mapping can be utilized to identify the genetic variations that underlie inherited differences in gene transcription. Combining whole genome transcriptional data from the hypothalami of thirty three strains of inbred mice with a detailed haplotype map of those same strains revealed 10,655 *trans* associations and 31 *cis* associations between genotype and gene expression that reached statistical significance. One of the *cis* associations was found to be driven by strain-specific variation in the expression of *Glutathione-S-transferase mu 5* (*Gstm5*). *Gstm5* is one of seven members of the glutathione-S-transferase mu family of genes. The glutathione-S-transferases are phase II metabolic enzymes and are key regulators of drug and toxin clearance. In mouse, all seven family members are tightly clustered on chromosome 3. Investigation in multiple tissues types of the *Gstm5 cis* association revealed that an 84kb region on MMU3 acts as a haplotype-specific locus control region for the majority of the glutathione-S-transferase mu family. In the strains that share the minor haplotype, drastic reductions in mRNA levels in multiple members of the Gst mu family were observed. The strain-specific differences in Gst mu transcription characterized here accurately models the human population. It has been estimated that upwards of 50% of certain human populations are null for the *GSTM1* locus, but not the other GST mu family members. Further, the reduction in Gst mu levels has important relevance for pharmacology and toxicology studies conducted in these strains. For instance, the reduced levels of Gst mu in general, and *Gstm5* in particular, has implications in models of dopamine metabolism, Parkinson's disease, and chemical neurotoxicity.

PS 1022 EVALUATION OF FOOD AND DRUG INTERACTIONS ON DNA MICROARRAY ANALYSIS IN CAENORHABDITIS ELEGANS.

M. Takahashi[1], A. Inokuchi[2], M. Nihira[2], K. Hayamizu[1] and K. Arizono[2]. [1]*Fundamental Research Facility, FANCL Research Institute, FANCL Corporation, Yokohama, Japan and* [2]*Laboratory of Toxicological Science, Faculty of Environmental and Symbiotic Sciences, Prefectural University of Kumamoto, Kumamoto, Japan.*

It is important to clarify the interaction between foods and therapeutic drugs because these interactions may enhance the side effects and reduce the efficacy of medicines, e.g., the interaction of grapefruit juice and calcium antagonist or between St. John's wort and the immunosuppressant cyclosporine. Drug-drug interactions are assessed with enzyme inhibition tests using human microsomes and probes or using cell lines in vitro. However, there may be a problem due to the species specificity of the pregnane X receptor, which is known as the human nuclear receptor that regulates cytochrome P-450 (CYP) 3A4 gene expression in vivo. We investigated the gene expression of the CYP of Caenorhabditis elegans (C. elegans) by using the cDNA microarray analysis. C. elegans is widely used in research because of the ease of handling this organism. Also, it is known that C. elegans entire genome has been coded. In our study, we aimed to prove that C. elegans is useful in the study of drug-drug interactions. Rifampicin (40 mg/L), which is a CYP3A4 inducer in humans, induces CYP13A4, 13A5, and 13A7 on 24-hour exposure and 13A5 on 48-hour exposure in the larva of C. elegans. On the other hand, SJW (50 mg/L) did not induce CYP genes on 24- or 48-hour exposure, but exposure to SJW tended to reduce the expression of CYP genes. It was reported that CYP3A4 and the other CYP genes were decreased on acute exposure to SJW. So, it was supposed that these results were shown as acute effect of SJW. In conclusion, it was suggested that the CYP genes of C. elegans could be used to evaluate the effect of CYP3A inducers in humans. Although many subjects required PCR verification, protein evaluation, and clarification of the mechanism of action on the CYP induction of C. elegans, C. elegans was valuable for investigation as an alternative technique of animal examination.

PS 1023 GENOME-WIDE RESPONSES TO ARSENITE IN SACCHAROMYCES CEREVISIAE.

X. Zhou[1], A. Arita[1], T. P. Ellen[1], T. J. Begley[2] and M. Costa[1]. [1]*Nelson Institute of Environmental Medicine, New York University School of Medicine, Tuxedo, NY and* [2]*Department of Biomedical Sciences, University at Albany–State University of New York, Rensselaer, NY.*

We have used Saccharomyces cerevisiae to identify toxicologically important proteins and pathways involved in arsenic-induced toxicity and carcinogenicity in humans. We performed a systemic screen of the complete set of 4,733 haploid S. cerevisiae single gene deletion mutants that affect growth upon exposure to sodium arsenite (NaAsO2). We identified 203 arsenite-sensitive mutants and 61 arsenite-resistent mutants that have human homologues. IC50 values for all sensitive and resistant mutants were determined in another validation screen and the most highly sensitive or resistant mutants upon arsenite exposure were identified. We categorized the identified sensitive mutants based on various functions including protein binding, phosphate metabolism, vacuolar/lysosomal transport, protein targeting, sorting, and translocation, cell growth/morphogenesis, cell polarity and filament formation and etc. Our studies have potential implications for understanding toxicity and carcinogenesis of arsenic-induced human diseases, such as cancer and aging.

PS 1024 GROWTH FACTORS AND EXTRACELLULAR MATRICES INFLUENCE THE EXPRESSION OF GENETIC MARKERS DURING THE DIFFERENTIATION OF MOUSE STEM CELLS.

A. R. Calabro and F. A. Barile. *Pharmaceutical Sciences, St. John's University, Queens, NY.*

Mouse embryonic stem cells (mESC)(ES-D3, ATCC) are pluripotent cells derived from the inner cell mass of mouse blastocysts. The cells are capable of forming multicellular aggregates (MAs) as an intermediate stage of differentiation. We examined the effect of three growth factors (GF), (EGF, KGF, and LIF) in conjunction with two different ECM components (collagen type IV or fibronectin), known to influence gene expression in mESC. Five genes (Afp, Oct-4, Egfr, Tgfβr/2 and Arnt) were used as markers to monitor the differentiated state and gene expression was detected using RT-PCR from mRNA purified from confluent monolayers cultured up to 18 days on culture inserts. Concurrently, transmembrane electrical resistance (TMER) was measured as an indicator of tight junction formation. The expression of Afp, a marker for endodermal cell differentiation, showed a 3-fold increase when grown in the presence of EGF on Col IV inserts. Arnt and Tgfβr/2, expressed in MA and immortal cells respectively, were decreased in the presence of LIF when grown on either ECM. This is consistent with the ability of LIF to maintain mESC in the undifferentiated state. Expression of Egfr, a marker for differentiated cells, was decreased regardless of which GF or ECM was used. Cytotoxicity experiments showed that when mES were exposed to arsenic (As) on day 1, TMER was suppressed. Furthermore, after an initial rise for 7 days without As, TMER declined to near baseline when the chemical was introduced at day 7. Concurrently, the expression of Oct 4, a marker for mESC maintainance, was reduced upon introduction of As at day 7. Interestingly, ECM did not influence Oct 4 expression with As. Thus, the culture insert system represents a model for inducing biological membrane formation in drug screening and cytotoxicity testing. It is also capable of dectecting the effects of chemicals on cell differentiation during the early stages of embryogenesis. (Supported in part by grants from Alternatives Research and Development Foundation & International Foundation for Ethical Research).

PS 1025 CLONING, EXPRESSION, AND PHARMACOLOGICAL CHARACTERIZATION OF THE ZEBRAFISH DOPAMINE TRANSPORTER.

A. L. Green[1], L. A. White[2] and J. Richardson[1]. [1]*RWJMS, Piscataway, NJ and* [2]*Biochemistry and Microbiology, Rutgers, The State University of New Jersey, New Brunswick, NJ.*

The use of the zebrafish model system is receiving increased attention for its potential for developing new disease models and for the development of drugs. However, for the zebrafish model to be validated for such studies, more information is needed

on the specific interactions of drugs with their molecular target and how the zebrafish target compares with the human target. The dopamine transporter (DAT) is the molecular target for drugs of abuse such as cocaine and methamphetamine and a target for therapeutic drugs such as methylphenidate. In order to assess the potential use of zebrafish as a model for testing drugs that interact with the DAT, we cloned the zebrafish DAT (zDAT) and inserted it into a vector expressing green fluorescent protein (pIRES-EGFP). Following transient transfection into SK-N-AS neuroblastoma cells, zDAT demonstrated strong expression with a punctuate expression at the plasma membrane. zDAT expression resulted in functional 3H-dopamine uptake that was abolished by the DAT inhibitor nomifensine (10 μM) and was similar to mock-transfected cells and cells transfected with empty vector demonstrating the specificity and dependence of dopamine upake on the expression of zDAT. To assess the specificity of drug interactions with the zDAT, we measured dopamine uptake in the presence of various concentrations of inhibitors specific for the DAT (methylphenidate and nomifensine), the serotonin transporter (fluoxetine) and the norepinephrine transporter (desipramine). Both methylphenidate and nomifensine inhibited zDAT-mediated dopamine uptake in the nM range, while fluoxetine and desipramine had no effect until concentrations reached 10 μM. Taken in concert, these data suggest that zebrafish may represent a good model for testing drugs and toxicants that interact with the DAT.
Supported in part by NIEHS Grants R01ES015991 and P30ES005022

PS 1026 HISTOPATHOLOGICAL AND TOXICOGENOMIC ANALYSES IN THE LIVER OF HETEROZYGOUS SOD2 KNOCKOUT MICE TREATED WITH TROGLITAZONE OR ACETAMINOPHEN.

K. Fujimoto[1, 2], K. Kumagai[1], K. Ito[1], S. Arakawa[1], Y. Ando[1], S. Oda[2], T. Yamoto[1] and S. Manabe[1]. *[1]Medicinal Safety Research Labs., Daiichi Sankyo Co., Ltd., Fukuroi, Shizuoka, Japan and [2]Graduate School of Bioagricutural Sciences, Nagoya University, Nagoya, Aichi, Japan.*

Heterozygous superoxide dismutase 2 gene knockout (Sod2+/-) mice have been suggested to be useful as an animal model with higher sensitivity to mitochondrial toxicity because their mitochondrial SOD activity is only half that of wild-type mice. Recently, it was reported that the intraperitoneal administration of 30 mg/kg/day troglitazone to Sod2+/- mice for 28 days caused liver injury, manifested by increased serum ALT activity and hepatic necrosis (Ong et al., Toxicol. Sci. 97, 205-213, 2007). Therefore, we evaluated the reproducibility of troglitazone-induced liver injury in Sod2+/- mice, as well as their validity as an animal model with higher sensitivity to mitochondrial toxicity by single dose treatment with acetaminophen in Sod2+/- mice. Although we conducted a repeated dose toxicity study in Sod2+/- mice treated orally with 300 mg/kg/day troglitazone for 28 days, no hepatocellular necrosis was observed in our study. Furthermore, toxicogenomic analysis using Affymetrix GeneChip showed no observation of liver injury in Sod2+/- mice administered with troglitazone, despite of a lower expression level of genes involved with mitochondrial functions in Sod2+/- mice than in wild-type mice. On the other hand, at 6 h and 24 h after an intraperitoneal administration of 300 mg/kg acetaminophen, plasma ALT activity was significantly increased in Sod2+/- mice, compared to wild-type mice. In particular, at 6 h after the administration, hepatic centrilobular necrosis was observed only in Sod2+/- mice. These results suggest that Sod2+/- mice are valuable as an animal model with higher sensitivity to mitochondrial toxicity. However, in our study, troglitazone-induced liver injury was not observed even in Sod2+/- mice.

PS 1027 REALIZING THE GENOMIC POTENTIAL THROUGH COLLABORATION TO DERIVE AND EVALUATE GENE EXPRESSION SIGNATURES FOR CARCINOGENICITY PREDICTION AND RISK ASSESSMENT.

M. Fielden[1], R. Dunn[2], T. Davison[4], J. Sherlock[3], E. Walker[5], W. Mattes[5], P. Lord[7] and B. Car[6]. *[1]Roche Palo Alto, Palo Alto, CA, [2]Amgen, Thousand Oaks, CA, [3]Applied Biosystems, Foster City, CA, [4]Asuragen, Austin, TX, [5]Critical Path Institute, Tucson, AZ, [6]Bristol-Myers Squibb, Princeton, NJ and [7]Johnson and Johnson, Raritan, NJ.*

The Carcinogenicity Working Group of the Predictive Safety Testing Consortium aims to collaboratively advance our ability to predict and mechanistically understand rodent non-genotoxic hepatocarcinogens to facilitate the early risk assessment of chemicals. Retrospective evaluation of published microarray signatures for predicting non-genotoxic carcinogens indicated that hepatic gene expression data can predict the likelihood of chemical-induced hepatic tumorigenicity with reasonable accuracy, however, variability in measurement platform and treatment protocols across laboratories rendered the signatures unsuitable as is. This prompted the consortium to re-derive the signature on a higher throughput and cost-effective measurement platform and begin to standardize the treatment protocol to enable robust predictions across laboratories. Through refinement of the signature, we identified a subset of 26 unique genes from the original signatures that showed potential for classification of carcinogens. To standardize the assay platform, we re-derived the signature on a quantitative real-time PCR platform using liver RNA samples from rats treated with over 70 non-genotoxic carcinogens and non-carcinogens. Comparison of the QPCR data with the original microarray data generated on the same RNA indicated good correlation (r>0.7) between platforms for most genes, suggesting that we could re-establish the signature on the QPCR platform. This facilitated wider evaluation of historical samples to further define the accuracy and study parameters important for robust classification of potential carcinogens. Further sample sharing and collaboration with technology companies allowed us to realize the practical utility of our genomic knowledge-base to make early risk assessment for carcinogenic compounds possible.

PS 1028 COMBINED CONVENTIONAL AND 'OMICS EVALUATION OF 4 HEPATOTOXICANTS WITH BILE DUCT OR CHOLESTATIC EFFECTS.

H. C. Ellinger-Ziegelbauer[1], A. Mally[7], A. Walijew[2], C. Schmitt[2], P. Hewitt[2], K. Matheis[3], M. Raschke[1], B. Riefke[1], A. Brandenburg[4], H. Gmuender[4], A. Amberg[5], L. Mulrane[6], W. Gallagher[6], M. Sieber[7] and M. Adler[7]. *[1]Bayer Schering Pharmacology AG, Berlin, Germany, [2]Merck KGaA, Darmstadt, Germany, [3]Boehringer Ingelheim Pharmacology GmbH & Co.KG, Biberach, Germany, [4]Genedata AG, Basel, Switzerland, [5]Sanofi-Aventis, Frankfurt, Germany, [6]University College Dublin, Dublin, Ireland and [7]University of Wuerzburg, Wuerzburg, Germany.* Sponsor: H. Ahr.

Combining results from -omics technologies (transcriptomics-Tx, proteomics-Px and metabonomics-Mx) with data from conventional endpoints may allow more informed and earlier decision making in preclinical safety evaluation, which is being evaluated by the InnoMed PredTox project. In 14-day in vivo rat studies with samples taken after 1, 3, and 14 days of treatment, 4 (BAY164749, EMD335823, BI-3, ZK226830) of the 16 compounds used showed similar phenotypes, incl. degeneration/regeneration of hepatocytes and bile ducts and/or increased bilirubin and cholestasis. Gene expression profiles of livers were analyzed using microarrays and metabolite changes in urine and serum were examined using 1H-NMR and LC/MS. Potential biomarkers were further evaluated using immunological methods. Tx identified common changes in the livers which revealed a potential damage–effect sequence on a mechanistic level in accordance with histopathological observations. The localization of cell degeneration/regeneration to either bile ducts or hepatocytes was provided by immunohistochemistry detection of proteins encoded by deregulated genes. Classification analysis revealed a potential for 1H-NMR Mx of urine to classify samples with respect to bile duct damage. Targeted bile acid analysis using LC/MS showed increased levels of bile acids in serum and urine, confirming the hypotheses proposed from classical and Tx data. Thus Tx data led to mechanistic hypotheses explaining classical observations, guiding further investigations to refine this mechanistic model. Mx contributed confirmatory information, and NMR Mx may allow toxicity-associated sample classification in case of intra- or extrahepatic cholestasis.

PS 1029 COMPARISON OF THE TRANSCRIPTIONAL RESPONSES TO SULFUR MUSTARD, HALF MUSTARD AND NITROGEN MUSTARD EXPOSURE IN HUMAN KERATINOCYTES.

J. F. Dillman, C. S. Phillips and C. C. Rothwell. *Cell and Molecular Biology, USAMRICD, Aberdeen Proving Ground, MD.*

Sulfur mustard (SM) is a potent vesicant that targets epithelial cells and tissues. Most vesicant research has been performed using bona fide SM; however, some studies have used simulants, most notably half mustard (2-chloroethyl ethylsulfide; CEES) and nitrogen mustard (mechlorethamine; NM). Although CEES and NM have similarities to SM and can cause vesication, there are distinct differences in the chemical structures and physical properties of these compounds that may impact their toxic effects. Microarray analysis of cultured primary human epidermal keratinocytes (HEK) exposed to each of these vesicants was performed to directly compare the transcriptional responses induced by these vesicants. HEK were exposed in triplicate to concentrations ranging from 0-1000 μM for SM and NM and 0-4000 μM for CEES. Cells were harvested at 1, 2, 4, 8, 16, and 24 h and the RNA isolated for microarray analysis. Transcriptional responses were phenotypically anchored to cell morphology. The dataset was filtered by exposure and timepoint, and an analysis of variance was performed using dose as the factor. The top 500 genes ranked by p-value were analyzed using gene ontology algorithms to identify biological pathways significantly affected by each vesicant. At 2 h post-exposure, p53 signaling, EGF signaling, Erk/MAPK signaling and PDGF signaling were significantly affected by all three vesicants. At 4 h post-exposure, only p53 signaling and glucocorticoid receptor signaling were significantly affected by all three vesicants. At 8 h

post-exposure, there were no significant pathways commonly affected by all three vesicants. These results suggest that, although there are similarities in the transcriptional responses to each of these vesicants, the transcriptional responses appear to differ over time. Thus, extrapolation of results obtained with one vesicant to other vesicants may be complex and may have important implications for the development of vesicant therapeutics.

PS 1030 DNA ADDUCTS AND GENE EXPRESSION PROFILES IN VENOUS AND CORD BLOOD AND PLACENTA OF MOTHERS IN PRAGUE.

J. Topinka[1], Z. Novakova[1], A. Milcova[1], H. Libalova[1], P. Rossner Jr.[1], K. Hanzalova[1], I. Balascak[2], M. Merkerova[3], A. Kracmarova[3], H. Bruchova[3], R. Brdicka[3] and R. J. Sram[1]. [1]*Genetic Ecotoxicology, Institute of Experimental Medicine ASCR, v.v.i., Prague, Czech Republic,* [2]*2nd Medical Faculty, Charles University, Prague, Czech Republic and* [3]*Institute of Hematology and Blood Transfusion, Prague, Czech Republic.* Sponsor: J. Vondracek.

In context of the molecular epidemiology study dealing with the biological effects of ambient air pollution in humans, 32P-postlabelling method was employed to analyze total bulky DNA adducts in venous and umbilical cord blood and placenta of 79 mothers giving birth to living babies in the University Hospital in Prague (Czech Republic). Benzo[a]pyrene specific DNA adducts were analyzed in placenta by ELISA. Simultaneously, gene expression profiles were determined in all 3 tissues using Illumina Human Ref-8 Expression BeadChips Among mothers, 67 was classified as non-smokers and 12 as passive or active smokers (plasma cotinine levels were higher than 3 ng/ml). Together with written informed consent, detailed lifestyle and medical questionnaire was filled. DNA adduct patterns of subjects in this study were evaluated as diagonale radioactive zones (DRZ) of various intensities (total DNA adduct levels) and as B[a]P-like spots corresponding to the TLC position (chromatographic mobility) of major B[a]P-derived DNA adducts. Significantly higher total DNA adduct levels were detected in maternal and cord blood than in placenta (1.15 ± 0.67 and 1.07 ± 0.43 vs. 0.81 ± 0.19; $p<0.001$). In nonsmokers, the DNA adduct levels in maternal venous blood and umbilical cord blood are comparable (1.13 ± 0.66 and 1.10 ± 0.44), while in smokers higher DNA adduct levels were found in maternal than in cord blood (1.27 ± 0.71 vs. 0.92 ± 0.28), suggesting efficient detoxification of transplacental barrier for tobacco smoke specific genotoxic compounds. BPDE-DNA adducts detected by ELISA in placenta did not reflect tobacco smoke exposure, but correlate with the expression of some enzymes involved in DNA repair (APEX1, XPC, ERCC5, LIG1). Supported by the Ministry of Education CR grant #2B06088 and by the Academy of Sciences CR grant #AVOZ50390512.

PS 1031 BIOMARKER DISCOVERY : NMR SPECTRAL DATA OF URINE AND PLASMA AND HEPATOTOXICITY BY CARBON TETRACHLORIDE, ACETAMINOPHEN, AND D-GALACTOSAMINE IN RATS.

K. Kim[1], M. Chung[1], S. Um[1], J. Oh[1], S. Kim[1], M. Na[1], H. Oh[1], W. Cho[2] and K. Choi[1]. [1]*Pharmacology, National Institute of Toxicological Research, Seoul, Korea, South and* [2]*Toxicology, National Institute of Toxicological Research, Seoul, Korea, South.*

The primary objective of this study was to discover biomarkers which are correlated with hepatotoxicity induced by chemicals using 1H NMR spectral data of urine and plasma. A procedure of nuclear magnetic resonance (NMR) urinalysis using pattern recognition was proposed for early screening of hepatotoxicity of CCl4, acetaminophen (AAP), and D-galactosamine (GalN) in rats. Those compounds were expected to induce necrosis to hepatocytes and this was confirmed through blood biochemistry and histopathology. CCl4 (1 ml/kg, po) and GalD (0.8 g/kg, ip) were single administered to Sprague-Dawley (SD) rats and urine was collected every 24 h pre-dose and 2 days post-dosing. Animals were sacrificed 24 h or 48 h post-dosing and blood and liver were collected for 1H NMR analysis. AAP (2 g/kg, po) was administered for 2 days and then the animals were sacrificed 24 h after last treatment. Urinary, plasma, and hepatic 1H NMR spectroscopies revealed evidently different clustering between control groups and hepatotoxicants treatment groups in metabolic profilings through partial least aquare (PLS)-discrimination analysis (DA). In targeted profilings, endogenous metabolites of allantoin, citrate, taurine, 2-oxoglutarate, acetate, lactate, phenylacetyl glycine, succinate, phenylacetate, 1-methylnicotinamide, hippurate, and benzoate were selected as biomarkers for hepatoxicity by CCl4, AAP, and GalN in urine. Comparison of rat 1H NMR PLS-DA data with histopathological changes suggest that 1H NMR urinalysis can be used to predict hepatotoxicity induced by CCl4, AAP, and GalN.

PS 1032 1, 2-NAPHTHOQUINONE DISRUPTS CREB TRANSCRIPTIONAL ACTIVITY THROUGH MODIFICATION OF CYS286.

A. Endo, D. Sumi, N. Iwamoto and Y. Kumagai. *Graduate school of comprehensive human sciences, University of Tsukuba, Tsukuba, Japan.* Sponsor: A. Naganuma.

1,2-Naphthoquinone (1,2-NQ) is an environmental electrophile that reacts readily with thiolate anions in proteins to yield a stable thioether adduct. Thiols are more reactive in proteins with basic amino acids in close proximity bacause the latter reduce the thiol pKa. cAMP response element-binding protein (CREB) is a transcription factor and plays an important role in mammalian cells. CREB has a basic leucine-zipper (bZIP) domain that governs binding efficiency to its cognate promoter element CRE, a consensus sequence. bZIP transcription factors contained a highly conserved cysteine residue at regions, which have nearby basic amino acid in their DNA binding domain. Based these findings, we hypothesized that 1,2-NQ could bind to a CREB, resulting in suppression of DNA binding activity, transcriptional activity and thus altered expression of CREB-regulated proteins. To test above hypothesis, we conducted immunoprecipitation, western blot analysis and EMSA in bovine aortic endothelial cells (BAECs) and cell-free system. Exposure of BAECs to 1,2-NQ resulted in a covalent binding to CREB. Under these conditions, DNA binding activity of CREB was dramatically inhibited by 1,2-NQ. 1,2-NQ also suppressed CRE-dependent gene transcription and expression of CREB-regulated gene product, Bcl-2. The modification of CREB and inhibition of DNA binding activity of CREB during 1,2-NQ exposure were effectively blocked by DTT, suggesting that a 1,2-NQ formed covalent bounds with CREB through reactive thiol groups. To identify the modification sites in 1,2-NQ, MALDI-TOF/MS analysis was performed. Results indicate that Cys286, Lys290 and Lys319 were covalently modified by 1,2-NQ. Mutation experiments revealed that CREB disruption was, at least in part, due to covalent attachment of the 1,2-NQ to Cys286 at DNA binding domain. These results suggest that CREB is a molecular target for 1,2-NQ and that such an irreversible binding of 1,2-NQ to Cys286, causes functional loss of this transcription factor.

PS 1033 PHYTOESTROGEN PUERARIN PROTECTS AGAINST TERT-BUTYL HYDROPEROXIDE-INDUCED CELL DEATH THROUGH THE ESTROGEN RECEPTOR DEPENDENT PI3K/AKT/HO-1 PATHWAY.

Y. Hwang and H. Jeong. *BK 21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South.*

Phytoestrogens are polyphenolic non-steroidal plant compounds with estrogen-like biological activity. The phytoestrogen puerarin, the main isoflavone glycoside found in the root of Pueraria lobata, has been used for various medicinal purposes in traditional Chinese medicines for thousands of years. Recent studies have indicated that the estrogen receptor (ER), through interaction with p85, regulates phosphoinositide 3-kinase (PI3K) activity, revealing a physiologic, non-nuclear function of ER that may be relevant in cytoprotection. In this study, we demonstrate that the phytoestrogen puerarin inhibits tert-butyl hydroperoxide (t-BHP)-induced oxidative injury via an ER-dependent Gb1/PI3K/Akt and heme oxygenase-1 (HO-1) pathway. Pretreatment of Hepa1c1c7 and HepG2 cells with puerarin significantly reduced t-BHP-induced caspase-3 activation and subsequent cell death. Also, puerarin up-regulated HO-1 expression and this expression conferred cytoprotection against oxidative in¬jury induced by t-BHP. Moreover, puerarin in¬duced Nrf2 nuclear translocation, which is upstream of puerarin-induced HO-1 expression, and PI3K activation, a pathway that is involved in induced Nrf2 nuclear translocation, HO-1 expression and cytoprotection. Puerarin-induced up-regulation of HO-1 and cytoprotection against t-BHP were abolished by silencing Nrf2 expression with specific siRNA. Also, puerarin-mediated increases in PI3K activation and HO-1 induction were reversed by co-treatment with ICI 182,780 and pertussis toxin. Taken together, these results suggest that puerarin augments cellular antioxidant defense capacity through ER-dependent HO-1 induction via the Gb1/PI3K/Akt-Nrf2 signaling pathway, thereby protecting cells from oxidative stress.

PS 1034 PROTHYMOSIN-ALPHA MEDIATES NUCLEAR IMPORT OF INRF2/CUL3-RBX1 COMPLEX TO DEGRADE NUCLEAR NRF2.

S. K. Niture and A. K. Jaiswal. *Department of Pharmacology and Experimental Therapeutics, University of Maryland School of Medicine, Baltimore, MD.* Sponsor: B. Moorthy.

Nrf2-mediated coordinated induction of a battery of defensive genes is a critical mechanism in cellular protection and survival. INrf2 (Keap1), an inhibitor of Nrf2 functions as an adaptor for Cul3-Rbx1 mediated degradation of Nrf2. A majority

of the INrf2/Cul3-Rbx1 complex is localized in the cytosol that degrades cytosolic Nrf2. However, 10-15% INrf2 is also localized inside the nucleus. INrf2 does not contain a defined nuclear import signal and the mechanism of nuclear import of INrf2 and its function inside nucleus remain obscure. Present studies demonstrate that DGR region of INrf2 is required for nuclear import of INrf2. Studies also demonstrate that Cul3 and Rbx1 are also imported inside the nucleus in complex with INrf2. Interestingly, Nrf2 and prothymosin-α both bind to DGR region of INrf2. However, it is prothymosin-α and not Nrf2 that mediates nuclear import of INrf2/Cul3-Rbx1 complex. Antioxidant treatment increases nuclear import of INrf2/Cul3-Rbx1 complex. INrf2/Cul3-Rbx1 complex inside the nucleus exchanges prothymosin-α with Nrf2 resulting in degradation of Nrf2. These results led to the conclusion that prothymosin-α mediated nuclear import of INrf2/Cul3-Rbx1 complex leads to ubiquitination and degradation of Nrf2 inside the nucleus presumably to regulate nuclear level of Nrf2 and rapidly switch off the activation of Nrf2 downstream gene expression.

PS 1035 AN AUTO-REGULATORY LOOP BETWEEN NRF2 AND CUL3-RBX1 CONTROLS THEIR CELLULAR ABUNDANCE.

J. W. Kaspar and A. K. Jaiswal. *Pharmacology and Experimental Therapeutics, University of Maryland, Baltimore, MD.*

Nrf2:INrf2 acts as a sensor for oxidative stress. When a cell encounters any form of stress Nrf2 dissociates from INrf2 and translocates into the nucleus. In the nucleus, Nrf2 activates a myriad of antioxidant genes that protect cells. Nrf2 is then exported out and degraded. INrf2 serves as a substrate adaptor to link Nrf2 to the Cul3-Rbx1 complex. Cul3-Rbx1 makes up the ubiquitin ligase complex that is responsible for the ubiquitination and degradation of Nrf2. Previously we have shown a feedback auto-regulatory loop between Nrf2 and INrf2 indicating that Nrf2 regulates INrf2 by controlling its transcription. Here we are extending this research by demonstrating the presence of another feedback auto-regulatory loop between Cul3-Rbx1 and Nrf2. Western blotting and Real Time PCR experiments using various cell lines indicate that Nrf2 controls its own degradation by regulating expression and induction of the Cul3-RBX1 genes. Treatment with the antioxidant tert-Butylhydroquinone (tBHQ) leads to induction of Cul3-RBX1 genes. Mutagenesis and transfection identified an antioxidant response element in the Cul3 and RBX1 promoters that binds to Nrf2 and regulates expression and antioxidant induction of Cul3-RBX1 genes. In conclusion, the data suggests that Nrf2 regulates Cul3-RBX1 by controlling the transcription, and Cul3-RBX1 control Nrf2 by ubiquitination and degradation of Nrf2.

PS 1036 CHARACTERIZATION OF NRF2-INDEPENDENT NUCLEAR IMPORT ACTIVITY OF KEAP1 DURING ANTIOXIDANT RESPONSES.

Z. Sun, T. Wu, C. M. Birch, W. Chen and D. Zhang. *University of Arizona, Tucson, AZ.*

The transcription factor Nrf2 has emerged as a master regulator of cellular redox homeostasis. Nrf2 binds to the antioxidant responsive element (ARE) and regulates the transcription of many antioxidants, phase II detoxification enzymes, and transporters. Keap1 negatively regulates Nrf2 by both mediating redox-sensitive ubiquitination/ degradation of Nrf2 in the cytoplasm and targeting Nrf2 for nuclear export in the nucleus. However it is not clear how Keap1 gets into the nucleus. In this study, we have characterized the nuclear import activity of Keap1. We found that Keap1 travels into the nucleus independently of Nrf2 or Nrf1. The amino acid sequence responsible for Keap1 nuclear import was mapped to the Kelch domain. Site-directed mutagenesis and fluorescence labeling by GFP showed that a hydrophobic cluster within the Kelch domain of Keap1 is required and sufficient in mediating the Nrf2-independent nuclear import of Keap1. These findings suggest that Keap1 may contain a non-classical nuclear import sequence (NLS) that plays an important role in the repression of Nrf2 under basal redox balanced conditions. [NIEHS 1RO1ES015010-01, ACS RSG-07-154-01]

PS 1037 LYSOSOMAL NON-ESTERFIED CHOLESTEROL CONTENT MODULATES THE FUSION OF AUTOPHAGOSOMES WITH LYSOSOMES.

M. Kleinman, J. Caruso and J. Reiners. *Institute Environmental Health Sciences, Wayne State University, Detroit, MI.*

Macroautophagy (hereafter referred to as autophagy) is a normal physiological process whereby cytosol and entire organelles are encapsulated in a double membrane vesicle termed the autophagosome. Subsequent fusion of autophagosomes with lysosomes results in the degradation of the encased components. In this study we asked if lysosomal non-esterified cholesterol content influenced autophagosome-lysosome fusion. We used the cationic amphiphilic drug U18666A to induce the accumulation of non-esterified cholesterol in lysosomes, and fluorescence microscopy to monitor non-esterified cholesterol staining with filipin. Exposure of murine hepatoma 1c1c7 cultures to 0.1-1.0 μM U18666A resulted in a concentration-dependent increase in filipin staining, which co-localized with Lamp-1 positive (i.e., lysosomes) organelles. Elevated filipin staining was observed within 18 h of exposure, and was persistent as long as U18666A was present. Increased filipin staining was paralleled by the accumulation of autophagosomes. Autophagosome formation was monitored by Western blot analyses of the conversion of LC3-I to LC3-II, and the aggregation of a stably expressed GFP-LC3 fusion protein into very fluorescent punctate structures. Fluorescence microscopy indicated minimal co-localization of GFP-LC3 and Lamp-1 punctate structures in U18666A-treated cultures. In contrast, a high degree of co-localization of GFP-LC3 and Lamp-1 were observed in drug-free cultures following the induction of autophagy by leucine deprivation. Filipin staining in U18666A-treated cultures returned to normal levels within 72 h of drug removal. Decreases in filipin staining were paralleled by a transient co-localization of GFP-LC3 and Lamp-1, and the subsequent loss of autophagosomes. These findings suggest that lysosomal cholesterol content, which is elevated by numerous therapeutic drugs, and as a consequence of several diseases, influences autophagosome-lysosome fusion. Hence, lysosomal cholesterol content could be a modifier of the autophagic process.

PS 1038 CPG-OLIGODEOXYNUCLEOTIDES INHIBITS THE TUMOR NECROSIS FACTOR-ALPHA-INDUCED EXPRESSION OF CELL ADHESION MOLECULES IN ENDOTHELIAL CELLS BY SUPPRESSING NF-KB ACTIVATION.

H. Yun, H. Kim and H. Jeong. *BK21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South.*

Expression of cell adhesion molecules (CAM) responsible for leukocyte-endothelium interactions plays a crucial role in inflammation and atherogenesis. Up-regulation of vascular CAM-1 (VCAM-1), intracellular CAM-1 (ICAM-1), and E-selectin expression promotes monocyte recruitment to sites of injury and is considered to be a critical step in atherosclerotic plaque development. Bacterial unmethylated cytosine-phosphothioate-guanine (CpG)-rich oligodexoynucleotides (CpG ODNs) elicit immunostimulatory effects similar to that of bacterial DNA. This study examined the effects of CpG-ODN on the cytokine-induced monocyte/human endothelial cell interaction, which is a crucial early event in atherogenesis. CpG-ODN inhibited the adhesion of tumor necrosis factor-alpha (TNF-alpha)-induced monocytes to endothelial cells and suppressed the TNF-alpha-induced protein and mRNA expression of the cell adhesion molecules, VCAM-1 and ICAM-1. Furthermore, CpG-ODN inhibited the TNF-alpha-induced NF-kB activation pathway in these cells. Overall, CpG-ODN has anti-atherosclerotic activities, which occurs partly by down-regulating the pathway that affects the expression and interaction of the cell adhesion molecules on endothelial cells.

PS 1039 TRANSCRIPTOMICS ANALYSIS IN MOUSE LUNG EXPOSED TO MAINSTREAM SMOKE FROM TWO DIFFERENT SMOKING REGIMENS.

Q. Meng[1], N. Machesky[2], K. Gideon[1] and M. Lee[1]. *[1]Battelle Toxicology Northwest, Richland, WA and [2]Battelle Biomedical Research Center, Columbus, OH.*

The purpose of this study was to compare the changes of gene expression profiles in the lungs of mice exposed to mainstream smoke of 2R4F reference cigarettes from two different smoking regimens: 1) diluted continuous smoking per ISO at 250 μg/L WTPM, 5 h/d, 5 d/wk for 3 wks and 2) undiluted sporadic smoking (4 cigarettes [filter removed]/d, 6 d/wk for 4 wks). AKR/J mice were exposed to regimen 1 using an automated smoking machine, while mice for regimen 2 were exposed using a direct-pump smoking machine. Gene expression profiles were defined in lungs of smoke-exposed mice and the concurrent control mice at the end of exposure using microarray analysis. The number of differentially expressed genes (with a fold change of ≥ 2-fold, and a P value of ≤ 0.05 compared to the concurrent control mice) were 255 in the regimen 1 mice, and 220 for the regimen 2 mice, respectively. The overall response in mice exposed to regimen 2 was minor when compared to mice exposed to regimen 1. This was reflected by smaller fold changes for individual genes and lower significance levels of top biological processes in mice exposed to regimen 2. Top regulated genes in mice exposed to regimen 1 included Mmp12, Noxo1, Saa3, Cxcl5, Hspa1b, etc. Top regulated genes in mice exposed to regimen 2 included Mitf, Cyp1a1, Mmp8, etc. Significant biological processes associated with changed genes in regimen 1 mice included response to heat, response to protein folding, immune and inflammatory response, chemotaxis, and DNA repair, etc, while chemotaxis, proteolysis, and cell cycle regulation, etc., were the top

biological processes in the regimen 2 mice. The observed differences in transcriptomics analysis between the two regimens could be partially related to differences in smoke dosimetry between the two smoking regimens. (Funded by Battelle Biology and Health Science Initiative).

PS 1040 CHROMIUM (VI) INHIBITS MOUSE METALLOTHIONEIN-I GENE TRANSCRIPTION BY PREVENTING THE ZINC-DEPENDENT FORMATION OF AN MTF-1–P300 COMPLEX.

T. Kimura[1], Y. Li[2], F. Okumura[1], N. Itoh[3], T. Nakanishi[4], T. Sone[1], M. Isobe[1] and G. K. Andrews[2]. *[1]Toxicology, Faculty of Pharmaceutical Sciences, Setsunan University, Hikakata, Japan, [2]Biochemistry and Molecular Biology, University of Kansas Medical Center, Kansas City, KS, [3]Toxicology, Graduate School of Pharmaceutical Sciences, Osaka University, Suita, Japan and [4]Laboratory of Hygienics, Gifu Pharmaceutical University, Gifu, Japan.* Sponsor: K. Tanaka.

Mouse metallothionein-I (MT-I) transcription is regulated by metal response element-binding transcription factor-1 (MTF-1) which is recruited to the promoter in response to zinc. Chromium(VI) [Cr(VI)] pretreatment blocks zinc-activation of the endogenous MT-I gene and attenuates zinc-activation of MT-I- promoter-driven luciferase reporter genes in transient transfection assays. Chromatin immunoprecipitation assays revealed that Cr(VI) only modestly reduces recruitment of MTF-1 to the MT-I promoter in response to zinc, but drastically reduces the recruitment of RNA polymerase II. These results suggest that Cr(VI) inhibits the ability of MTF-1 to transactivate this gene in response to zinc. Zinc has been recently shown to induce the formation of a co-activator complex containing MTF-1 and the histone acetyltransferase p300 which plays an essential role in the activation of MT-I transcription. Herein, co-immunoprecipitation assays demonstrated that Cr(VI) pretreatment blocks the zinc-induced formation of this co-activator complex. Thus, Cr(VI) inhibits mouse MT-I gene expression in response to zinc by interfering with the ability of MTF-1 to form a co-activator complex containing p300 and recruit RNA polymerase II to the promoter. (Supported by KAKENHI grant 17790104 and NIH grant ES05704)

PS 1041 ZINC-INDUCED EPIGENETIC CHANGES IN THE MOUSE METALLOTHIONEIN-I PROMOTER CHROMATIN ARE MEDIATED BY THE ZINC-SENSING TRANSCRIPTION FACTOR MTF-1.

F. Okumura[1], T. Kimura[1], Y. Li[2], N. Itoh[3], T. Nakanishi[4], T. Sone[1], M. Isobe[1] and G. K. Andrews[2]. *[1]Toxicology, Faculty of Pharmaceutical Sciences, Setsunan University, Hikakata, Japan, [2]Biochemistry and Molecular Biology, University of Kansas Medical Center, Kansas City, KS, [3]Toxicology, Graduate School of Pharmaceutical Sciences, Osaka University, Suita, Japan and [4]Laboratory of Hygienics, Gifu Pharmaceutical University, Gifu, Japan.* Sponsor: K. Tanaka.

Mouse metallothionein-I (MT-I) transcription is regulated by metal response element-binding transcription factor-1 (MTF-1) which is recruited to the promoter in response to zinc. Here, we show that MTF-1 is essential for zinc-induced epigenetic changes in the mouse MT-I promoter. Chromatin immunoprecipitation (ChIP) assays demonstrated that zinc-treatment lead to a decrease of Lys4-trimethylated, Lys9-acetylated H3 and total H3 in the MT-I promoter. Micrococcal nuclease sensitivity of the MT-I promoter was increased in response to zinc. These results suggest that chromatin structure is locally disrupted in response to zinc. In the absence of MTF-1, these changes were not observed. A deletion mutant of MTF-1, which recruits to the MT-I promoter in response to zinc but fails to recruit the co-activator p300 and activate MT-I transcription, also did not change the amount of histone H3 in MT-I promoter in response to zinc. Furthermore, interleukin-6, which induces MT-I transcription in an MTF-1-independent manner, did not cause a decrease the amount of histone H3 in MT-I promoter. These studies indicate that the rapid disruption of nucleosome structure at the MT-I promoter is mediated by recruitment an active MTF-1 coactivator complex to this promoter in response to zinc.

PS 1042 CONSEQUENCES OF ALTERED CYTOCHROME P450 2S1 EXPRESSION IN LUNG CELLS.

A. M. Rowland[1, 2] and G. S. Yost[2]. *[1]Chemistry and Biochemistry, NMSU, Las Cruces, NM and [2]Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

Cytochrome P450 2S1 exhibits a unique expression profile among cytochrome P450s. It is one of the few P450 metabolic enzymes that display both selective expression in extrahepatic tissues and constitutive expression throughout development. Elevated CYP2S1 expression is observed in the hyperproliferative disorders psoriasis and cancer. Increased CYP2S1 expression in colorectal cancer and ovarian cancer correlates with poor prognosis and metastasis, respectively. These data suggest an important role for CYP2S1-mediated metabolism in extrahepatic cells. To determine whether CYP2S1 expression was necessary for pulmonary cell physiology, we performed RNA intereference in multiple pulmonary cell types including cancer, immortalized, and primary cell lines. CYP2S1 knockdown, using a small interfering RNA directed toward the 3'UTR produced a significant reduction in CYP2S1 gene expression as demonstrated using quantitative PCR. CYP2S1 protein was also reduced by approximately 50%. Initial phenotypic observations suggest that CYP2S1 may influence aspects of pulmonary cell growth. This research was supported by NIH grant #HL60143; NRSA Postdoctoral Fellowship (#F32HL087636) from the National Heart, Lung, and Blood Institute; and the Colgate-Palmolive Postdoctoral Fellowship in In Vitro Toxicology through the Society of Toxicology.

PS 1043 QUANTITATIVE ASSESSMENT OF WHOLE BLOOD RNA PROFILING AS AN EARLY TEMPORAL MARKER OF TOXICOLOGICAL EFFECTS.

D. Harris[1], Y. Tessier[1], M. Hartness[1], M. Craigon[2], T. Freeman[2], T. Forster[2], G. Rubin[2], A. Ivens[2] and P. Ghazal[2]. *[1]Aptuit, Edinburgh, United Kingdom and [2]University of Edinburgh, Edinburgh, United Kingdom.* Sponsor: P. Berthe.

Systemic molecular profiling as an early temporal screen for toxicity could markedly improve timelines, costs, animal use and the late attrition in the development of drugs. Our aim was to quantitatively assess, at the whole genome level, whether global alterations in whole blood gene expression can provide a statistically robust early correlate to toxicological events in rats. A 14-day oral toxicity study was conducted looking at the effects of acetaminophen (0, 100, 600,1200 mg/kg/day). Groups of rats (6M) were sacrificed at 24h, 3 and 14 days, clinical pathology measurements taken, and histopathology conducted on tissues. Blood samples were collected at sacrifice and RNA extracted, labeled and applied to Affymetrix rat whole genome arrays for gene expression profiling. Integration of histopathology data with the genes that were significantly differentially expressed enabled candidate markers of early toxicity to be identified. Acetaminophen (1200 mg/kg) caused an acute necrosis and inflammation of the liver in animals at 24h and 3 days. Transaminase levels associated with liver function were markedly increased. Changes were also evident in the kidney, salivary gland, spleen, thymus, bone marrow, testes, submandibular lymph nodes and the small intestine at 24h and 3 days. Alterations were observed in the gene expression profiling data, disclosing a specific systemic genomic signature of toxicity, detectable within the first 24h of the toxic response. Specific innate immune signaling and T-cell marker responses were observed, predictive of an immunocyte infiltrate in the liver. RNA biomarkers extracted via a non-invasive blood sampling procedure and analyzed using microarray-based analyses can provide a statistically robust platform to reproducibly monitor drug responses in whole blood, supporting its potential use as an early stage toxicity screen. The potential of an immune-correlate to hepatotoxicity has also been identified.

PS 1044 EVIDENCE FOR THE INVOLVEMENT OF XENOBIOTIC-RESPONSIVE NUCLEAR RECEPTORS IN TRANSCRIPTIONAL EFFECTS UPON PERFLUOROALKYL ACID EXPOSURE IN DIVERSE SPECIES.

H. Ren[1], B. Vallanat[1], J. C. Corton[1], D. M. Nelson[2], L. Y. Yeung[3, 4], K. S. Guruge[3], P. S. Lam[4] and L. D. Lehman-McKeeman[2].
[1]NHEERL/ORD/Toxicogenomics Core, U.S. EPA, Durham, NC, [2]Discovery Toxicology, Bristol-Myers Squibb Company, Princeton, NJ, [3]Safety Research Team, National Institute of Animal Health, Ibaraki, Japan and [4]Department of Biology and Chemistry, City University of Hong Kong, Hong Kong SAR, China.

Humans and other species have detectable body burdens of a number of perfluorinated alkyl acids (PFAA) including perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS). In mouse and rat liver these compounds activate the nuclear receptor peroxisome proliferator-activated receptor alpha (PPARα). Recent studies indicate that along with PPARα, other nuclear receptors are required for transcriptional changes in the mouse liver after PFOA exposure including the constitutive activated receptor (CAR) and pregnane X receptor (PXR) that regulate xenobiotic metabolizing enzymes (XME). To determine the potential role of CAR/PXR in mediating effects of PFAAs in rat liver, we performed a reanalysis of transcript profiles from published studies in which rats were exposed to PFOA or PFOS. We compared the profiles to those produced by exposure to prototypical activators of CAR, (phenobarbital (PB)), PXR (pregnenolone 16 alpha-carbonitrile (PCN)) or PPARα (WY-14,643 (WY)). As expected, PFOA and PFOS elicited

transcript profile signatures that included many known PPARα target genes. Numerous XME genes were also altered by PFOA and PFOS but not WY. These genes exhibited expression changes shared with PB or PCN. Reexamination of the transcript profiles from chickens exposed to PFAAs indicated that although the expression of some XMEs was altered, there was no evidence that PFAAs altered the expression of typical PPARα target genes. Our results indicate that PFAAs activate PPARα, CAR and PXR in rats but PPARα does not appear to be activated in exposed chickens. Lastly, we provide evidence that human populations with higher CAR expression have lower body burdens of PFAAs. (This abstract does not necessarily reflect US EPA policy.)

PS 1045 IDENTIFICATION OF TRANSCRIPTIONAL NETWORKS INVOLVED IN PEROXISOME PROLIFERATOR CHEMICAL-INDUCED HEPATOCYTE PROLIFERATION.

B. Vallanat[1, 2], R. Currie[3], J. R. Pirone[2], A. Singh[4, 2], F. Elloumi[2], C. Corton[1] and I. Shah[2]. *[1]NHEERL, U.S. EPA, Durham, NC, [2]NCCT, U.S. EPA, Durham, NC, [3]Central Toxicology Laboratory, Syngenta, Cheshire, United Kingdom and [4]NCCT, Lockheed Martin, RTP, NC.*

Peroxisome proliferator chemical (PPC) exposure leads to increases in rodent liver tumors through a non-genotoxic mode of action (MOA). The PPC MOA includes increased oxidative stress, hepatocyte proliferation and decreased apoptosis. We investigated the putative genetic regulatory events leading to hepatocellular proliferation following short-term exposure to the PPC di-2-ethylhexylphthalate (DEHP). Male B6C3F1 mice were exposed to DEHP via oral gavage at a single concentration of 1150 mg/kg/day and sacrificed after 2, 8, 24 and 72 hours. Liver samples were analyzed using the Affymetrix Mouse 430_2 genechip and had identified 794 (2hr), 1921 (8hr), 2019 (24hr) and 2076 (72hr) transcript clusters to be statistically significant. Cell proliferation was markedly increased at 72 hrs. Analyzing differentially expressed genes (DEGs) in the context of cell proliferation showed roughly 10% be related to cell cycle at each time point with very little overlap across the time points. This suggests sequential non-overlapping regulatory events controlling cell cycle gene expression. Putative transcription factor binding sites were predicted in the 10 Kb 5' upstream region of DEG's at each time point by sequence analysis (using the TRANSFAC® 2008.2 database). Statistically significant transcriptional sub networks were inferred computationally from putative genetic-regulatory interactions. The putative transcription networks of regulated cell cycle genes were compared with published data. This work identified a number of genes that may underlie the increase in cell proliferation observed upon PPC exposure.
This work is being conducted to model toxicity pathways in the USEPA Virtual Liver (v-Liver) project. This abstract does not necessarily reflect USEPA policy.

PS 1046 MECHANISMS OF ZINC OXIDE-INDUCED IL-8 EXPRESSION IN HUMAN AIRWAY EPITHELIAL CELLS.

W. Wu[1], J. M. Samet[2], D. B. Peden[1] and P. A. Bromberg[1]. *[1]Center for Environmental Medicine, University of North Carolina, Chapel Hill, NC and [2]Human Studies Division, U.S. EPA, Research Triangle Park, NC.* Sponsor: I. Jaspers.

Inhalation of zinc oxide (ZnO) in occupational settings has been associated with "metal fume fever", a flu-like illness characterized by increases in pulmonary tumor necrosis factor-alpha and interleukin-8 (IL-8). In this study, the effect of ZnO on IL-8 expression and the mechanisms underlying this event have been investigated in human airway epithelial cells. ZnO exposure induced increased expression of IL-8 in human primary airway epithelial cells and the airway epithelial cell line BEAS-2B. Pretreatment of BEAS-2B cells with the transcriptional inhibitor actinomycin D blocked ZnO-induced IL-8 expression, demonstrating the involvement of transcriptional regulation. This was corroborated by the observation of increased IL-8 promoter activity in ZnO-treated BEAS-2B cells transfected with a construct encoding IL-8 promoter-driven luciferase reporter. ZnO exposure was also shown to increase canonical NFκB-dependent promoter activity. Chromatin immunoprecipitation assay showed that ZnO stimulation increased binding of p65 to the IL-8 promoter in BEAS-2B cells. Relative to BEAS-2B cells that were co-transfected with wild type p65 constructs, cells overexpressing constructs encoding mutated p65 at S276, S529, and/or S536, showed significant reduction in ZnO-induced increase in IL-8 promoter activity. In addition, ZnO treatment also resulted in increased IL-8 mRNA stability. In summary, these data indicate that ZnO exposure can increase IL-8 expression through induction of p65 phosphorylation and stabilization of IL-8 mRNA in human airway epithelial cells. This work was supported by the US EPA COOP Agreement CR83346301.

PS 1047 DISRUPTION OF THE LARGEMOUTH BASS (*MICROPTERUS SALMOIDES*) STEROIDOGENIC ACUTE REGULATORY PROTEIN BY ENDOCRINE DISRUPTING CHEMICALS: A ROLE FOR ESTROGEN RECEPTOR SIGNALING?

M. S. Prucha[1], D. S. Barber[2] and N. D. Denslow[2]. *[1]Pharmacology and Therapeutics, University of Florida, Gainesville, FL and [2]Physiological Sciences, University of Florida, Gainesville, FL.*

The largemouth bass (LMB) is highly sensitive to endocrine disrupting chemicals (EDCs) and serves as a good model for EDC studies. The steroidogenic acute regulatory protein (StAR), responsible for the rate-limiting step in steroidogenesis, is a target for EDCs known to disrupt estrogen receptor (ER) signaling. To investigate the potential role of ERs in disruption of StAR by EDCs, testes from 4 recrudescent LMB were dissected, cultured, and treated for either 6h or 20h with ICI 182,780 (ICI), a potent inhibitor of ER signaling, alone and in combination with 1U/mL human chorionic gonadotropin (hCG), a potent activator of StAR transcription. Using quantitative real-time PCR, it was observed that hCG treatment induced StAR mRNA >2X after 6h. This response to hCG was not present at 20h, except when ICI was added in combination with hCG which showed a 2.5X induction of StAR mRNA from basal levels. To characterize transcriptional regulation of StAR, we used a 2.9kb portion of the LMB StAR promoter previously cloned by our group in transient transfections in MA-10 mouse Leydig cells. Initial transfections verified that the StAR promoter is hCG-responsive. *In silico* analysis of the promoter sequence revealed a putative estrogen response element (ERE). Prior to conducting further transfections, functionality of the ERE was verified using electromobility shift assays (EMSAs). EMSAs showed that specific proteins from MA-10 cells, including ERβ (verified by supershift), bind to the putative ERE. Transfections with the StAR promoter are being conducted to identify the role of ERs in regulating StAR, yielding insight into regulatory mechanisms and downstream effects of EDCs on StAR transcription. Research funded by NIEHS SBRP R01 ES015449.

PS 1048 MICRORNA EXPRESSION AND PERMISSIVE TISSUE REGENERATION.

J. A. Franzosa, L. K. Mathews, S. Sengupta, J. La Du and R. L. Tanguay. *Environmental and Molecular Toxicology, Environmental Health Sciences Center, Oregon State University, Corvallis, OR.*

Previously we identified a number of genes that are coordinately regulated during the course of zebrafish epimorphic tissue regeneration. To investigate whether microRNAs (miRNAs) play a role in the post-transcriptional regulation of regeneration specific genes, we conducted a series of miRNA expression studies using arrays that contained 219 miRNA targets. The caudal fins of adult zebrafish were surgically amputated and RNA was isolated at 1 day post amputation (dpa). miRNA microarray analysis was also conducted using RNA isolated from nonamputated (control) fin tissue. In total, 25 miRNAs were increased specifically in the regenerates, and 29 miRNAs were repressed. miRNAs that potentially regulate target genes previously reported as important for regeneration were identified. Numerous regeneration specific transcripts were determined to be potentially targeted by the differentially expressed miRNA. Genes known to have important roles in regeneration, such as wnt10a, dlx5a, junb, msxb, and mvp, were predicted to be targeted by a number of the miRNAs significantly repressed during regeneration. Since optimal expression of regeneration-promoting genes is required to initiate tissue regeneration, these results suggest that repression of particular miRNAs must occur to permit expression of initiators of regeneration. We specifically hypothesize that repression of critical miRNAs is more important than induction of miRNAs for epimorphic tissue regeneration. Consistent with this hypothesis, the enzyme responsible for miRNA processing, Dicer, is dispensable for tissue regeneration since antisense repression of Dicer1 expression does not impact cellular differentiation or regenerative progression and the tissue regenerates normally. Collectively, these results indicate that the zebrafish regeneration model is a useful tool to identify the importance of miRNA regulation in complex biological processes. This research was supported by NSF 0641409, NIH R01 ES10820, and NIH P30 ES00210.

PS 1049 EVALUATION OF ESTROGENIC ACTIVITY OF ZEARALENONE BY TRANSCRIPTOME ANALYSIS OF ESTROGEN RESPONSIVE GENES.

M. Parveen and R. Kiyama. *Signaling Molecules Research Groups, AIST, Tsukuba, Ibaraki, Japan.* Sponsor: M. Khan.

Zearalenone (ZEA) is a *Fusarium* -derived mycotoxin commonly found in food commodities worldwide. Two major alcoholic metabolites of ZEA, α- and β-zearalenol, have been associated with reproductive tract disorders in mammals due to

their estrogenic activity. However, the estrogenic activity of ZEA and its metabolites at the molecular level is not exactly known yet. It has an ability to act as an agonist for the estrogen receptor (ER) and can disrupt endocrine signaling by affecting the expression of ER target genes. Here, we used DNA microarrays of estrogen responsive genes to examine gene expression profiles in MCF-7 cells treated with 10 nM of either E2 or ZEA compounds: zearalenone, α-zearalenol, β-zearalenol, zearalanone, α-zearalanol and β-zearalanol. We found that all of the ZEA compounds showed growth promoting activity in MCF-7 cells, as strong as E2. Gene expression profiles obtained from MCF-7-cells treated with E2 and ZEA compounds were analyzed by cluster analysis or using correlation coefficients or *R*-values. We found no significant differences in *R*-values between E2 and ZEA compounds. However, a wide range of *R*-values were found between pairs of ZEA compounds. This suggests that expressions of some genes are variables in response to various ZEA compounds. Furthermore, when we extended our analysis to six functional groups of genes (enzymes, signaling, proliferation, transcription, transport and others) we found that, except for the signaling-related genes, all showed common responses to ZEA compounds. Some genes in the signaling category revealed unique responses to different ZEA compounds and whose expression most likely contributed to the differences in *R*-values. In conclusion, DNA microarray-based gene profiling may help to explore the estrogenic activities of ZEA and similar compounds at the molecular level and to identify unique genes, which could be used as biomarkers for the investigation of environmental estrogenic compounds.

PS 1050 EFFECTS OF SODIUM ARSENITE ON DNA METHYLATION, MTHFR, C-MYC, MT 1/2, PROTEIN LEVELS AND CELL CYCLE ALTERATIONS IN MCF-7 CELLS.

R. Ruiz-Ramos[1], L. Lopez-Carrillo[1] and M. E. Cebrian[2]. [1]*Centro de Investigacion en Salud Poblacional, INSP, Cuernavaca, Morelos, Mexico and* [2]*Toxicologia, CINVESTAV, Mexico, City, Mexico, City, Mexico.*

Arsenic (As) metabolism yields As-methylated species and contributes to deplete methyl donor pools, which may result in DNA hypomethylation and activation of genes, such as c-myc and MT, which regulate proliferation and apoptotic processes and are potentially important in oncogenesis. Our aim was to evaluate the effects of acute As exposure (0-10 μM) on global DNA methylation, methylenetetrahydrofolate reductase (MTHFR), DHFR, c-Myc and MT1/2 protein levels and cell cycle profile in the human breast cell line MCF-7. As-treated cells showed DNA hypomethylation as measured by methylation-specific PCR. Western blot assays showed a decrease in MTHFR protein levels without significant changes on DHFR. We also observed an increase in c-Myc and MT 1/2 proteins along with an increased cell recruitment in S-phase of cell cycle as evaluated by FACS, as well as increases in cell proliferation evaluated by BrdU incorporation into cellular DNA. The reduction in MTHFR protein levels suggest that arsenite alters the one-carbon metabolic pathway which produces SAM, the major methyl group donor in the cell, and that this effect is playing a role in the depletion of the SAM pool produced by As. This effect contributes to the understanding of the mechanisms underlying DNA hypomethylation associated with As exposure. DNA hypomethylation could be related with the increased c-Myc and MT 1/2 protein levels which are involved in cell cycle progression and proliferation. However, cells treated with arsenite at concentrations ≥5 μM showed an increased proportion of cells in apoptosis, probably related with an almost complete elimination of MTHFR levels at higher doses, suggesting that proliferative or apoptotic effects are dependent on the dose and time of exposure. In summary, our results suggest that arsenic exposure disrupts the one-carbon cycle, DNA methylation events and cell cycle progression in mammary epithelial cells.

PS 1051 EFFECTS OF BENZO[A]PYRENE EXPOSURE ON *FUNDULUS HETEROCLITUS* EMBRYONIC GNMT mRNA EXPRESSION AND ADULT HEPATIC ENZYME ACTIVITY.

X. Fang[1], W. Dong[1], C. Thornton[1], B. E. Scheffler[2] and K. L. Willett[1]. [1]*Department of Pharmacology, Environmental Toxicology Research Program, The University of Mississippi, University, MS and* [2]*USDA-ARS-CGRU MSA Genomics Laboratory, Stoneville, MS.*

Glycine-N methyltransferase (GNMT) is a hepatic cytosolic enzyme. It is responsible for the transfer of a methyl group from S-adenosylmethionine (SAM) to glycine forming S-adenosylhomocysteine (SAH) and sarcosine. Mutations of GNMT are associated with hepatocellular carcinoma and prostate cancer. In 1994, it was reported that the GNMT was also the 4S PAH-binding protein and could induce CYP1A expression. To further understand the role of GNMT in benzo[a]pyrene (BaP)-related toxicity, full length *Fundulus* GNMT cDNA was cloned from adult liver. It was 1759 base pair (bp) long and contained a 5' non-coding region of 63 bp, an open reading frame of 888 bp, and a 3' non-coding region of 785 bp to the polyA tail. It encoded a deduced protein of 295 amino acids which is 74% similar to human GNMT. A 186 bp GNMT probe was designed for whole-mount *in situ* hybridization. Expression of GNMT mRNA was dose-dependently increased in the liver region of 7 and 14 dpf *Fundulus* embryos exposed up to 100 μg/L BaP. In order to determine the effects of BaP-treatment on GNMT enzyme activity, a GNMT assay using glycine substrate and S-adenosyl-L-[methyl-^{3}H]methionine was optimized. Both control rat and *Fundulus* liver cytosolic preparations had GNMT activity, which averaged 12 + 0.9 and 2.3 + 0.12 pmol/mg*min, respectively. In addition, the linearity of GNMT activity with time or protein concentration was confirmed. In conclusion, altered expression of GNMT may represent a new target gene for consideration in BaP-mediated embryonic and liver toxicities (Supported by NIEHS R01ES012710).

PS 1052 TISSUE DISTRIBUTION AND CHEMICAL INDUCTION OF THE CYSTINE TRANSPORTERS XCT AND RBAT IN MICE.

K. Wu, S. A. Reisman and C. D. Klaassen. *Department of Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Cationic amino acid transporter, y+ system (xCT) and related to b0,+ amino acid transporter (rBAT) are cystine uptake transporters that aid in maintaining adequate intracellular concentrations of cysteine, the rate-limiting amino acid in glutathione synthesis. The purpose of the present study was to determine the tissue distribution of these two cystine transporters in male and female mice, and whether hepatic xCT and rBAT mRNA expression are altered by chemical activators of xenobiotic sensors (AhR, CAR, PXR, PPARα,and Nrf2). xCT mRNA was expressed highest in brain and gonads. xCT mRNA in brain was 135% higher in male than female mice, whereas xCT mRNA was 75% higher in ovaries than testes. rBAT mRNA was expressed highest in kidney, small intestine, and liver. rBAT mRNA in duodenum and liver was higher in female than male mice (1450 and 130%, respectively). Activation of the xenobiotic sensors did not increase hepatic mRNA expression of xCT or rBAT. However, all three PPARα activators (clofibrate, ciprofibrate, di[2-ethylhexyl] phthalate) decreased hepatic rBAT mRNA 40-50%. In addition, clofibrate administered to PPARα-null mice did not lower hepatic rBAT mRNA expression, indicating that the decrease in rBAT is PPARα dependent. The current findings show that xCT is mainly expressed in brain and gonads, whereas rBAT is mainly expressed in kidney, small intestine, and liver. In addition, the hepatic expression of rBAT is decreased by PPARα activators, which is PPARα dependent. (Supported by NIH grants ES-09649, ES-013714, ES-09716, ES-07079, and RR-021940)

PS 1053 PREGNANE X RECEPTOR REGULATES THE mRNA TURNOVER THROUGH INTERACTION WITH CCR4-NOT.

N. Eagleton, D. Liu, S. Ke, Y. Xie, N. Ouyang and Y. Tian. *Toxicology, Texas A&M University, College Station, TX.*

Pregnane X receptor (PXR, NR1I2) is a nuclear receptor that regulates the metabolism and functions of various xenobiotics and endobiotics. PXR has been considered the xeno-sensor because of its remarkable ability to bind a wide range of structurally diverse ligands and coordinately regulate the Phase I and Phase II drug metabolizing enzymes as well as the "Phase III" transporters. PXR plays an important role in drug-drug interactions, adverse drug responses, cholestatic liver diseases and colon cancer. In order to understand the mechanisms of transcriptional regulation of PXR, we performed yeast two-hybrid screenings to search the interactive proteins in human liver cDNA library, using PXR ligand binding domain as the bait. More than one million independent clones were screened; the known PXR interactive partners were among the positive clones, including NcoR2 and RXRβ. One positive clone was a partial cDNA of cNOT2 (amino acids 183-540). cNOT2 is a component of Ccr4-NOT which is a multi-subunit protein complex highly conserved from yeast to humans. The Ccr4-NOT complex plays critical roles in various aspects of transcriptional regulation, including initiation, repression, activation and mRNA degradation. Using a mammalian two-hybrid system in CV-1 cells and GST-pulldown assays, we confirmed the direct interaction between PXR and cNOT2. In HepG2 cells, over expression of cNOT2 suppresses the PXR-regulated luciferase gene activity. siRNA knockdown of cNOT2 potentiated PXR transcriptional activity. The immunoprecipitated cNOT2 complex contained deadenylase activity as determined by an in vitro RNA decay assay. The presence of transfected

PXR inhibited the cNOT2-associated deadenylase activity. Cellular localization of PXR and cNOT2 by immunofluorescence staining indicate that the interaction may be occurring within Cajal Bodies where RNA modification is highly involved. Taken together, these results suggest that PXR regulates the mRNA turnover through direct interaction with the CCR4-NOT complex.

PS 1054 EXPRESSION/ACTIVITY OF GLUTATHIONE S-TRANSFERASE ISOFORM (GST-θ) IS ASSOCIATED WITH INCREASED SENSITIVITY TO 4-TERTIARY BUTYLPHENOL (4-TBP) TOXICITY: IMPLICATIONS FOR OCCUPATIONAL VITILIGO.

K. A. Hoey, S. Kerr and R. Sarangarajan. *Massachusetts College of Pharmacy and Health Sciences, Worcester, MA.*

Environmental exposure to 4-TBP causes patchy depigmented skin due to destruction of melanocytes in occupational vitiligo. Evidence suggests that oxidative stress induced by *o*-quinone of 4-TBP may be responsible for melanocyte cell death. Since glutathione S-transferase (GST) mediated conjugation with glutathione (GSH) protects against quinone induced oxidative stress, effect of inhibition of GST activity and cell GSH content on 4-TBP induced toxicity was investigated. Melanoma cells SK-MEL-19 (M19) and SK-MEL-23c22 (C22) maintained in Dulbecco's Modified Eagle Medium (10% bovine serum, 1% antibiotic/antimycotic) were seeded ($1x10^4$ cells/well) in 96 well plates. Approximately 24 hours post-seeding, cells were exposed to 0, 100, 250 or 500μM concentration of 4-TBP in the absence or presence of (100, 150, 200μM) GST inhibitors ethacrynic acid (EA) or 1,2-epoxy-3-(*p*-nitrophenoxy)propane (ENPP). Toxicity was determined at 72 hours using MTS cell proliferation assay and data expressed as percent control±SD. Expression of GST isoforms was identified by Reverse Transcriptase Polymerase Chain Reaction (RT-PCR) using isoform specific primers. At the end of 72 hours, neither cell line was susceptible to cytotoxic potential of 4-TBP at all concentrations tested. Although total GSH content were comparable, M19 had significantly higher GST activities compared to C22 cells. Pretreatment of both cell lines (6 hours) with 1mM BSO significantly decreases cell GSH content but did not influence 4-TBP (≤ 250μM) toxicity. In presence of EA, a known inhibitor of GST isoforms (μ, π, α), both cell lines were equally sensitive to 4-TBP at 500μM concentration. In contrast, at 100μM ENPP, which preferentially inhibits GST (θ) activity, there was increased sensitivity of C22 cells to 4-TBP (250 & 500μM) toxicity as compared to M19 cells. The above data and differential expression of GST isoforms between C22 & M19 cells suggest that GST (θ) influences 4-TBP toxicity in melanoma cells.

PS 1055 MICROBIAL TRANSFORMATION PRODUCTS OF BROMINATED FLAME RETARDANTS RESULTS IN CHEMICAL SPECIFIC LESIONS IN THE DEVELOPING ZEBRAFISH (DANIO RERIO) EMBRYO.

J. M. McCormick and L. A. White. *Biochemistry and Microbiology, Rutgers University, New Brunswick, NJ.*

Our goal is to determine the environmental fate and the effects of brominated flame retardants (BFRs) and their metabolites on aquatic species. This study focused on tetrabromobisphenol-A [TBBPA, 4,4'-isopropylidenebis (2,6-dibromophenol)], and its microbial transformation products, bisphenol A (BPA) and tetrabromobisphenol A –dimethyl ether (TBBPA DME). TBBPA is one of the most abundant BFRs in use today and is persistent in the environment. Because TBBPA exposure appears to be highest in young organisms, there is increasing concern about the potential developmental effects of these compounds. Our hypothesis is that embryonic exposure of developing fish to BRFs results in abnormal development, as a result of altered expression and activity of the matrix metalloproteinases (MMPs). MMPs are a family of Zn2+ and Ca2+ dependant proteases that are involved in the regulation of tissue morphogenesis through altering matrix metabolism, cell proliferation and angiogenesis. Developing zebrafish were exposed to TBBPA and its microbially-mediated transformation products, Bisphenol A (BPA) and TBBPA dimethyl ether (TBBPA DME). TBBPA (3, 1.5, 0.75μM) exposed embryos exhibited the highest levels of mortality and lesion occurrence, including pathoneumonic lesions such as trunk and tail malformation. BPA (15, 10, 5 μM) and TBBPA DME (10, 5, 1μM) exhibited edema and hemorrhage in a dose dependent manner. Additionally, both TBBPA and BPA delayed hatching of zebrafish embryos, unlike TBBPA DME, which did not appear to alter hatching. TBBPA exposure also increased expression of MMP-2, MMP-9 and MMP-13; whereas exposure to BPA or TBBPA-DME exposure did not. The results presented here illustrate that in the embryonic larval assay system TBBPA is more acutely toxic than BPA or TBBPA DME. Furthermore, these data suggest that one mechanism of TBBPA-induced lesions may be through alteration in MMP gene expression. Supported by the Hudson River Foundation.

PS 1056 DIFFERENTIAL REGULATION OF IL-8 EXPRESSION BY HUMAN AIRWAY EPITHELIAL CELLS EXPOSED TO DIESEL PARTICLES.

T. Tal[1, 2], S. Simmons[3], R. Ramabhadran[3, 2], R. Silbajoris[4] and J. M. Samet[4, 2]. *[1]Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR, [2]Toxicology, UNC Chapel Hill, Chapel Hill, NC, [3]Neurotoxicology, U.S. EPA, RTP, NC and [4]Human Studies, U.S. EPA, Chapel Hill, NC.*

Diesel exhaust particles (DEP) are a ubiquitous component of ambient particulate matter. Exposure to DEP induces inflammatory signaling characterized by activation of NFκB and AP-1 in cultured human airway epithelial cells (HAEC) and in bronchial biopsies from human subjects exposed to DEP. IL-8 is a major proinflammatory chemokine synthesized by HAEC whose expression is increased by inflammatory stimuli. Although DEP exposure is known to cause increases in IL-8 mRNA levels, the mechanism by which this occurs is not well understood. To identify signaling pathways through which DEP induces IL-8 expression, we examined the role of response elements in the IL-8 promoter in BEAS2B cells exposed to 10 $\mu g/cm^2$ DEP containing low (L-DEP), intermediate (I-DEP), or high (H-DEP) organic content for 4 hr. Exposure to these DEP differentially induced IL-8 expression in both primary human lung epithelial cells and BEAS2B cells with similar ranked potencies: H-DEP > L-DEP > I-DEP. Through the use of IL-8 lentiviral promoter reporters, we show that treatment with H-DEP or L-DEP stimulates IL-8 promoter reporter activity while I-DEP fails to induce detectable IL-8 promoter reporter activity. Furthermore, mutation of the NFκB response element abolished L-DEP-induced IL-8 promoter reporter activity. In contrast, IL-8 promoter reporter activity induced by exposure to H-DEP was not affected by the ablation of the NFκB response element. Data obtained independently using BEAS2B cells transduced with a lentiviral promoter reporter carrying a tandem repeat of the consensus NFκB binding site confirmed that L-DEP, but not H-DEP activates NFκB -dependent transcriptional activity. These data show that DEP of varying organic content can induce IL-8 expression by multiple, yet specific, mechanisms in the human lung. This abstract of a proposed presentation does not necessarily reflect EPA policy.

PS 1057 DEVELOPMENT AND VALIDATION OF AN INTEGRATED GENOME-WIDE APPROACH TO DETECT CHROMOSOMAL STRUCTURAL ABERRATIONS.

J. L. Freeman and S. Peterson. *Health Sciences, Purdue University, West Lafayette, IN.*

Assessing the genotoxic properties of persistent and emerging contaminants is paramount in establishing proper safety standards and regulations. Current genotoxicity assays are optimized to detect single nucleotide mutations or large chromosomal aberrations and have limited capability of integrating alterations with a reference genome sequence. However, undetectable by most of these assays are structural chromosomal aberrations that range in size from a few thousand to a few million base pairs. These chromosomal aberrations can possibly lead to altered gene expression, adverse developmental effects, and cancer. It is thus important to develop a means by which to efficiently determine if specific compounds are capable of altering chromosome structure at this level and to directly integrate these structural alterations with a genome sequence of interest. In this study, a molecular cytogenetic technique called array comparative genomic hybridization (array CGH), which is used to detect and map chromosomal imbalances in an unbiased genome-wide fashion, was developed and applied in a genotoxicity assay to assess the potential for chemicals to induce chromosomal aberrations. The array CGH technology measures relative DNA copy number by competitive hybridization of a test and a reference sample to a microarray containing genomic DNA elements. Recently, a genome-wide array CGH platform for the zebrafish model system was constructed. The zebrafish array CGH platform contains 385,000 oligonucleotide probes spaced across the genome (with a median probe spacing of 3.2 kb). The goal of this study was to validate the use of the array CGH technology in a toxicological-based assay using known genotoxic compounds (e.g., cytosine arabinofuranoside and ethyl methanesulfonate). Chemical-specific genomic imbalances are being detected, proving the utility of this approach to detect chromosomal structural alterations. Upon validation this assay will then be applied to start identifying biomarkers of genotoxicity following exposure to environmental stressors using the zebrafish model system.

PS 1058 TOPOISOMERASE II INHIBITION INVOVLED IN DNA DOUBLE-STRAND BREAKS BY EMODIN AND ITS GENOTOXICITY.

Y. Li[1], Y. Luan[1], T. Suzuki[2] and J. Ren[1]. [1]*Center for Drug Safety Evaluation and Research, Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, China and* [2]*Division of Cellular and Gene Therapy Products, National Instituite of Health Sciences (NIHS), Tokyo, Japan.*

Emodin (EM) has been widely used for the treatment of many diseases in China, but its genotoxicity is still unclear and controversial. In this study, we investigated the in vitro genotoxicity of EM in human lymphoblastoid TK6 cell by thymidine kinase gene mutation (TK) assay, neutral comet (COM) assay and micronucleus (MN) test, the in vivo genotoxicity of EM was evaluated by MN test in male C57 and Genechip (Affymetrix, MOE430A) analysis. In a 4 h treatment without metabolic activation, EM was mildly genotoxic in TK assay and MN test at 40μg/mL. The neutral COM assay and the detection of γ-H2AX, a reliable marker to DNA double-strand breaks (DSBs), demonstrated that EM yielded significant DSBs at 40μg/mL. EM induced MN increase about 3 times in mouse bone marrow after a single dose of 4g/kg. tRNA from liver and kidney tissue were isolated from the same animals used in MN test, gene expression analysis showed the expression of some genes involved in DNA damage were changed by EM. Above results indicate EM is potential genotoxic and the toxicity may be due to DSBs of DNA. To better understand the DSBs mechanism, a topoisomerase II (topo II) catalytic inhibitor aclarubicin (Acla) was used in γ-H2AX assay, we found the up-regulated expression of γ-H2AX induced by EM was antagonized by Acla, further analyses revealed that EM inhibited Topo IIα-mediated kDNA decatenation at 100μM, but not Topo I-mediated supercoiled pBR322 relaxation even at 500μM, which suggested EM may act as a Topo II poison. Molecular modeling studies predict that EM binds to the ATP pocket in the hTopoIIα ATPase domain. Taken together, EM inhibits the catalytic activity of Topo II by unique interference with ATP binding of Topo II, at least in part, may contribute to DNA DSBs and its genotoxicity.

PS 1059 ELEVATED ETHYL METHANESULFONATE (EMS) IN NELFINAVIR MESYLATE (VIRACEPT®, ROCHE): ANIMAL STUDIES CONFIRM TOXICITY THRESHOLD AND ABSENCE OF RISK TO PATIENTS.

L. Müller[1], E. Gocke[1], P. Larson[2], T. Lavé[1] and T. Pfister[1]. [1]*Nonclinical Drug Safety, F. Hoffmann-La Roche, Basel, Switzerland and* [2]*Virology and Transplantation, F. Hoffmann-La Roche, Nutley, NJ.*

Background: Roche's protease inhibitor nelfinavir mesylate (Viracept) produced between March 2007–June 2007 was found to contain elevated levels of ethyl methanesulfonate (EMS), a known mutagen (alkylator) – leading to a global recall of the drug. EMS levels in a daily dose (2500mg Viracept/day) were predicted not to exceed a dose of ~2.75mg/day (~0.055mg/kg/day based on 50kg patient). As existing toxicology data on EMS did not permit an adequate patient risk assessment, a comprehensive animal toxicology evaluation of EMS was conducted. Methods: Two studies for DNA damage were performed in mice; chromosomal damage was assessed using a micronucleus assay and gene mutations were detected using the MutaMouse transgenic model. In addition, experiments designed to extrapolate animal exposure to humans were undertaken. Results: Studies for chromosomal damage and mutations in mice demonstrated a clear threshold effect with EMS at 25mg/kg/day, under chronic dosing conditions. Exposure analysis (Cmax) demonstrated that ~370-fold higher levels of EMS, than that ingested by patients, are needed to saturate known, highly-conserved, error-free, mammalian DNA repair mechanisms for alkylation. Conclusions: Animal studies confirmed that patients who took nelfinavir mesylate with elevated levels of EMS are at no increased risk for carcinogenicity or teratogenicity over their background risk, since mutations are prerequisites for such downstream events. These findings are applicable to >40 marketed drugs that contain mesylate.

PS 1060 CHARACTERIZATION OF VALPROIC ACID-INITIATED HOMOLOGOUS RECOMBINATION.

K. Sha and L. M. Winn. *Queen's University, Kingston, ON, Canada.*

Use of the first-line antiepileptic agent, valproic acid (VPA) during pregnancy is associated with an increased incidence of major congenital malformations; however the molecular mechanism of its teratogenicity has not been elucidated. Our previous study showed an increase in the frequency of homologous recombination (HR) repair in Chinese hamster ovary 3-6 (CHO 36) cells after exposure to VPA. Homologous recombination is not an error free process and can result in detrimental genetic changes. Since proper development requires tight regulation of gene expression, changes leading to disruption of this process may underlie a mechanism of VPA induced teratogenticity. In this study we evaluated if and how VPA affects DNA double-strand break (DSB) repair. To investigate whether VPA affects the activity of DNA DSB repair, CHO 33 cells containing the neo direct repeat recombination reporter substrate were transfected with either the Saccharomyces cerevisiae mitochondrial endonuclease I-SceI to induce a site specific DSB within the recombination substrate or the empty plasmid, pGem. Cells were then exposed to 5 mM VPA for 24 hrs and two weeks later, the frequency of HR was determined by counting the number of functional neo expressing G418-resistant colonies per cells plated. A significant increase in the frequency of HR was observed in the presence (I-Sce1) or in the absence (pGem) of a DSB after exposure to VPA; however there was no increase in the fold difference in HR between VPA and vehicle (media) exposed I-Sce1 transfected cells compared to cells transfected with pGem. To determine whether VPA induces DNA DSBs to elicit repair, CHO 33 cells were exposure to 5 mM VPA for 10, 16 or 24 hrs and γ-H2AX foci, a marker of DNA DSBs, was detected by immunefluorescence microscopy. A significant increase in the number of γ-H2AX foci per cell was observed for all time points with the greatest increase at 16 hrs after exposure to VPA. These results suggest that VPA does not affect the activity of HR but induces DNS DSBs to elicit HR repair. [Support: CIHR]

PS 1061 CYTOGENETIC EVALUATION OF MULTI-WALLED CARBON NANOTUBE TOXICITY IN SWISS-WEBSTER MICE.

A. Patlolla[1], S. Patlolla[3], S. Hussain[2], J. Schalager[2] and P. Tchounwou[1]. [1]*Jackson State University, Jackson, MS,* [2]*Air Force Research Laboratory, Dayton, OH and* [3]*Emory University, Atlanta, GA.*

The development of nanotechnologies may lead to considerable release of nanomaterials in the environment, potentially harmful to human health. Among the nanomaterials, multiwalled carbon nanotubes (MWCNT) are already commericialized in various products which can be in direct contact with populations. They not only are produced by high-technology laboratories but also are found in particulate matter from ordinary combustion of fuel gases. Although a few reports on the cytotoxicity of CNTs have been published, very few report about their toxicity or genotoxicity in mammalian cells. We compared the clastogenic/genotoxic potential of pristine and purified oxidized multi-walled carbon nanotube (MWCNT) in bone marrow cells of Swiss-Webster mice; using mitotic index (MI), chromosome aberrations (CA), micronuclei (MN) formation and DNA damage in peripheral blood leukocytes as toxicological endpoints. Thirty five mice were randomly divided into seven groups; five for each group were used in this study. Pristine MWCNT was directly injected into the mice. Chromosome, micronuclei preparation was obtained from bone marrow and leukocyte DNA damage following standard protocols. The results demonstrated that MWCNT exposure significantly increased the number of structural chromosomal aberrations, the frequency of micro-nucleated cells, the level of DNA damage, and decreased the mitotic index in treated groups compared to control groups. In summary purified oxidized MWCNT has more clastogenic/genotoxic potential than the pristine form as measured by the bone-marrow CA, MN and DNA damage in Swiss-Webster mice. Our studies do not imply that CNTs should be abandoned for biological or medical purposes. However, our proposed mechanism of toxicity of these nanomaterials based on their surface properties can assist material scientists to design/synthesize biocompatible materials. It also assist toxicologist to further characterize clastogenicity/genotoxicity of dispersed carbon nanomaterials in in vitro or in vivo studies.

PS 1062 THE WERNER SYNDROME PROTEIN FUNCTIONS IN REPAIR OF CR(VI) INDUCED STALLED DNA REPLICATION FORKS.

F. Liu, A. Barchowsky and P. L. Opresko. *Department of Environmental and Occupational Health, University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA.*

Werner syndrome, an autosomal recessive premature aging disease characterized by cancer predisposition and genetic instability, results from loss of the WRN helicase/exonuclease DNA repair protein. WRN has been implicated in several pathways to repair DNA double strand breaks and stalled DNA replication forks caused by DNA damaging agents. Chromium acts as a human carcinogen through multiple mechanisms, including the induction of genomic instability by interfering with DNA replication progression through formation of bulky DNA adducts or interstrand cross-links. To test the hypothesis that WRN functions in the restoration of stalled and broken replication forks caused by Cr(VI), we exposed multiple cell lines to Cr(VI) at noncytotoxic concentrations and evaluated cellular response with various markers. We found that cells deficient in WRN were hypersensitive to Cr(VI), suggesting WRN functions in the repair of Cr(VI) induced damage.

Consistent with this, WRN translocates into nucleoplasmic foci from the nucleoli in response to Cr(VI) in a time- and dose-dependent manner, and localizes to sites of Cr(VI) induced γH2AX foci, a marker of DNA damage. Replacement with Cr(VI)-free medium led to WRN relocalization back to the nucleoli and a reduction in γH2AX foci within 48 hrs. However, γH2AX foci persisted longer in WRN deficient cells following recovery. Furthermore, Cr(VI) stimulated accumulation of cells in S-phase, indicative of DNA replicative stress, and increased WRN nucleoplasmic and γH2AX foci in S-phase cells. Therefore, we conclude that WRN functions in repair of DNA damage resulting from replication fork stress induced by noncytotoxic levels of Cr (VI). This novel observation also implies that replicative stress-inducing environmental genotoxins may enhance premature aging and age-related disease. *Supported by NIEHS grant ES015051-01 (PLO).*

PS 1063 POLYPLOIDY-INDUCTION BY DIHYDROXYLATED MONOCHLORO-BIPHENYLS: STRUCTURE-ACTIVITY-RELATIONSHIP.

S. M. Flor[1] and G. Ludewig[1, 2]. *[1]Occupational and Environmental Health, University of Iowa, Iowa City, IA and [2]Human Toxicology, University of Iowa, Iowa City, IA.*

Recently semivolatile lower chlorinated biphenyls have been identified in inner city air, in schools and at many other sites. Inhalation exposure to these compounds, which are readily metabolized to mono- and dihydroxy-biphenyls and further to quinones, is of concern. New studies demonstrated that 4-monochlorobiphenyl (PCB3) has initiating activity in the rat liver, induces gene mutations in transgenic (BigBlue) rats and PCB3 quinone metabolites induce gene mutations in Chinese hamster V79 cells. We wanted to know whether the quinone precursors, the para- (hydroquinone, HQ) or the ortho- (catechol, Cat) dihydroxybiphenyls possess genotoxic activities. We measured the effects of the hydroquinones of PCB1, PCB2 and PCB3 and of PCB3-3,4-catechol on sister chromatid exchange (SCE) levels, cytotoxicity, proliferation and chromosome number in V79. SCE are coordinated reciprocal single strand breaks-and-rejoining events during the S-phase. Only PCB3-Cat significantly increased the SCE levels. After treatment with 7.5 – 10 μM PCB2- and PCB3-HQ ~40% and ~70%, respectively, of their metaphase chromosomes were dark-stained, indicating a strong delay in cell cycle progression. Most surprisingly, ~90% of metaphases in these samples were tetraploid. Such tetraploid cells, which are genetically unstable, can arise by a variety of mechanisms, including mitotic slippage, cytokinesis failure, viral-induced cell fusion or karyokinesis. Since nearly all cancer cells are hyperdiploid, polyploidization as an intermediate to aneuploidy due to uneven chromosome loss are hypothesized as an underlying mechanism of carcinogenesis. Understanding of the mechanism and structure-activity-relationship of this astonishing activity of some PCB hydroquinones is needed to fully understand the significance of this effect for human health. (Supported by NIEHS P42 ES013661 and DOD DAMD17-02-1-0241)

PS 1064 INDIRECT GENOTOXICITY TRIGGERED BY INTRACELLULAR PH CHANGES.

H. Kauffmann[1], K. Braun[1], K. Braham[2], A. Czich[1], U. Hemmann[1], I. Stammberger[1] and G. Troschau[1]. *[1]Drug Safety Evaluation, sanofi-aventis, Frankfurt, Germany and [2]Drug Safety Evaluation, sanofi-aventis, Alfortville, France.*

The identification of genotoxic mechanisms plays a key role in the risk assessment of pharmaceuticals showing signals for genotoxicity. Several indirect threshold mechanisms are known, e.g. pH extremes of culture medium can cause clastogenic effects in vitro. Therefore, compounds that could modulate the intracellular pH, like inhibitors of sodium/hydrogen exchangers (NHEs), are of special interest. The NHE-inhibitor A002200657A was found to be negative in the Ames test and the micronucleus assay in vivo on rat bone marrow, but positive in the mouse lymphoma assay and the in vitro chromosomal aberration assay on V79 cells. To investigate the dependency on cell origin, a second assay using human lymphocytes was performed, which was also positive. This assay was followed by a chromosome aberration assay in rat bone marrow and an ex vivo unscheduled DNA synthesis assay in rat liver, both being negative. In vitro clastogenicity was also observed with other NHE inhibitors structurally not related to A002200657A suggesting that the positive study outcome is not related to the chemical structure but the NHE inhibitor properties (effect on intracellular pH, pHi). To strengthen the argumentation of an indirect in vitro effect, the influence of the compound on the pHi in V79 cells was investigated and additional in vivo genotoxicity assays were conducted: the comet assay in vivo and a 14-day repeat-dose chromosome aberration study in rat bone marrow were both negative. The change of pHi was investigated in V79 cells by flow cytometry. Intracellular acidification was detected after a very short treatment period at concentrations causing clastogenicity in vitro demonstrating the influence of pHi lowering on the chromosomal stability. Using the weight of evidence approach the investigations (negative in vivo results, pHi lowering) demonstrated that the observed in vitro clastogenic potential of A002200657A is not likely to be translated into an in vivo risk.

PS 1065 FOLLOW University of POLY (ADP-RIBOSE) POLYMERASE-1 EXPRESSION IN HUMAN LUNG CELLS IN CULTURE.

H. Foth[1], M. Ahmad[1], A. Torky[1] and R. J. Scheubel[2]. *[1]Environmental Toxicology, Martin Luther University, Halle / Saale, Germany and [2]Cardiothoracic Surgery, Martin Luther University, Halle / Saale, Germany.*

Poly (ADP-ribose) polymerase-1 (PARP-1) is a key element in recognition and regulation of DNA repair or entry into apoptosis and is an important mechanism to keep homeostasis after exposure to noxious agents. The experiments were undertaken to determine the expression and function and inter-individual differences of PARP-1 in normal human lung cells. Another goal was to monitor PARP expression and function over a longer time period. Normal human bronchial epithelial cells (NHBEC)and peripheral lung cells (PLC) from lung cancer patients were grown as explants cultures. The expression of PARP-1 protein was analysed by Western Blot analysis of the total protein fraction of lung cells. PARP-1 activity was determined immunohistochemically after induction of DNA damage with H2O2 (0.05 – 0.3 mM, 5 min). The fluorescence signal for ADP-ribose polymers attached to chromatin proteins correlated well with the applied concentrations of H2O2. PARP-1 protein was expressed in all explant cultures from bronchial epithelium. The levels for PARP protein differed between individuals by a factor of 2.3 in the first explants. Three cases were followed for more than 100 days. The expression levels varied intra-individually by a factor 1.3 to 1.4 over this time period. PARP-1 activity differed by a factor of 3.1 in NHBECs obtained from the first generation of explants from 11 cases. PARP-1 activity is present in NHBECs until the 8th and in PLCs until the 12th week and declined to about half of the start level. In summary, PARP-1 protein is well expressed over a long time by normal bronchial cells in culture. Its expression is variable in cell cultures obtained from different individuals, which may be due to life style factors. PARP-1 protein expression and function is conserved in primary lung cells in vitro over a time period of 8 to 12 weeks. This indicates that primary lung cell cultures are a useful experimental model to study the control mechanisms for PARP-1 expression and function in human lung.

PS 1066 GENOTOXICITY OF SINGLE-WALL AND MULTI-WALL CARBON NANOTUBES *IN VITRO* .

K. Savolainen[1], H. Lindberg[1], G. Falck[1], H. Järventaus[1], S. Suhonen[1], J. Catalán[1, 2], M. Vippola[1, 3], E. Vanhala[1] and H. Norppa[1]. *[1]Finnish Institute of Occupational Health, Helsinki, Finland, [2]University of Zaragoza, Zaragoza, Spain and [3]Tampere University of Technology, Tampere, Finland.*

Carbon nanotubes are increasingly used in various consumer applications, but information on their possible genotoxicity is still scanty. We examined the potential genotoxicity of single-wall (SWCNT; length 1-5 μm, outer diameter <2 nm; SES Research) and multi-wall (MWCNT; length 1-2 μm, outer diameter 10-30 nm; SES Research) carbon nanotubes in vitro. Genotoxicity was assessed by the analysis of DNA damage in human bronchial epithelial cells (BEAS 2B) and mesothelial cells (MeT 5A) and micronuclei (MN) in BEAS 2B cells. The cells were cultured with various doses (5-80 μg/cm2) of SWCNT and MWCNT. The single cell gel electrophoresis (comet) assay was applied to study DNA damage, and the induction of MN was examined by the cytokinesis-block method. The treatment lasted for 24 or 48 h in the comet assay and 48 or 72 h in the MN assay. We also examined structural chromosomal aberrations (CAs) in 72-h cultures of isolated human lymphocytes after a 24-h or 48-h treatment with both materials at several doses (6.25-300 μg/ml). In BEAS 2B cells, only SWCNT induced DNA damage after the 48-h treatment, while both nanomaterials increased DNA damage in MeT 5A cells. Only SWCNT induced MN in BEAS 2B cells. Both types of nanotubes produced an increase in the frequency of lymphocytes with CAs after the 48-h treatment, but not after the 24-h treatment. Both chromatid-type and chromosome-type aberrations were induced. In conclusion, MeT 5A cells appeared to be more sensitive than BEAS 2B cells to the induction of DNA damage by carbon nanotubes. In BEAS 2B cells, SWCNT were more genotoxic than MWCNT. Further studies are required to clarify, whether the increase of CAs by carbon nanotubes is due to higher cumulative effects after the longer treatment time or to an increased ability of the nanomaterial to get access to the nucleus in cell division and to interfere with DNA and chromosomes.

PS 1067 MICRONUCLEUS FREQUENCIES AND DNA DAMAGE IN MALE RATS ADMINISTERED METHYLPHENIDATE HCL (RITALIN) FOR 28 DAYS.

K. L. Witt[1], L. Recio[2], K. Shepard[2], A. Green[2], C. Baldetti[2], J. Winters[2], J. Davis[3], W. Caspary[1] and C. A. Hobbs[2]. *[1]National Toxicology Program, National Institute of Environmental Health Sciences, Research Triangle Park, NC, [2]Genetic Toxicology, ILS, Inc., Research Triangle Park, NC and [3]Integrative Toxicology, ILS, Inc., Research Triangle Park, NC.*

A variety of studies have been conducted recently to clarify the risk of genetic damage following exposure to methylphenidate HCl (MPH), a frequently prescribed drug for treatment of attention deficit/hyperactivity disorder. Although most reported no changes in genetic damage endpoints associated with MPH exposure, one recent study [Andreazza et al. 2007, Prog Neuropsychopharmacol Biol Psychiatry 31(6):1282-8] reported an increase in DNA damage detected by the comet assay in blood and brain of juvenile and adult male Wistar rats exposed to 1, 2, or 10 mg/kg MPH for up to 28 days; no increases in micronucleated lymphocyte frequencies were observed. To clarify this report of MPH-induced DNA damage, we treated adult male Wistar-Han rats with 0, 2, 10 or 25 mg/kg MPH by gavage once daily for 28 consecutive days and assessed micronucleated reticulocyte (MN-RET) frequencies in blood, and DNA damage in blood, brain, and liver 4 hr after the last dosing. At the end of the 28-day exposure period, no clinical signs of toxicity were observed and weight gain in MPH-exposed rats was similar to controls. Flow cytometric evaluation of blood samples revealed no significant increases in MN-RET, and the %RET among total erythrocytes, a measure of bone marrow toxicity, was unaltered at any dose. Furthermore, evaluation of primary DNA damage in leukocytes, liver, striatum, hippocampus, and frontal cortex tissues using the alkaline (pH > 13) comet assay revealed no increases in MPH-treated rats in any of the three treatment groups. Finally, neurohistopathological examination of 30 subanatomic sites, including grey and white matter, in the 3 brain tissues assessed for DNA damage showed no treatment-related changes. Thus, the earlier reported observations of MPH-induced DNA damage in blood and brain of rats exposed for 28 days were not confirmed in this study.

PS 1068 CYCLOPHOSPHAMIDE AND ETOPOSIDE CANINE STUDIES DEMONSTRATE THE CROSS-SPECIES POTENTIAL OF THE PERIPHERAL BLOOD MICRONUCLEATED RETICULOCYTE ENDPOINT.

M. McKeon[2], D. Torous[1], G. Schmuck[4], Y. Xu[2], S. Burgess[2], S. Avlasevich[1], S. Dertinger[1] and D. Kirkland[3]. *[1]Litron Laboratories, Rochester, NY, [2]Covance, Vienna, VA, [3]Covance, Harrogate, United Kingdom and [4]Bayer HealthCare, Leverkusen, Germany.*

Accumulating data suggests that peripheral blood micronucleated reticulocytes (MN-RETs) represent an endpoint of cytogenetic damage, even in species with efficient splenic filtration function. Studies performed evaluated both dose response and time-course of micronucleus (MN) induction in the bone marrow and blood of beagle dogs after dosing with cyclophosphamide (CP) or etoposide (Eto). CP was administered daily via intravenous injection for 5 days at 0, 6.25, 12.5 or 25 mg/m2/day. Eto was administered via iv injection for 2 days at 0, 1.56, 6.25, and 12.5 mg/m2/day. Blood specimens were collected for analysis before dosing as well as at several intervals during treatment, and bone marrow was prepared at necropsy. Blood was prepared using the In Vivo MicroFlow® method and analyzed at Litron, while bone marrow was analyzed at Covance via microscopy (May-Grunwald and also acridine orange staining). Robust MN-RET induction was observed in the blood of all CP-treated dogs by Day 4, with dose-related increases evident by Day 3. Comparable dose-related increases were observed in the bone marrow with microscopy-based scoring. While significant MN induction was not observed in the blood or bone marrow of dogs treated with Eto at 1.563 mg/m2/day, marked dose-related increases were noted in both compartments for the 6.25 and 12.5 mg/m2/day groups. Collectively, these results demonstrate the utility and sensitivity of blood-based automated MN-RET measurements in canines. These data have important implications in regard to the reduction and refinement of animal usage in genetic toxicology investigations.

PS 1069 PERFORMANCE CHARACTERISTICS OF A MINIATURIZED AND AUTOMATED *IN VITRO* MICRONUCLEUS ASSAY.

S. Bryce, S. Phonethepswath, S. Avlasevich, S. Raja, J. Bemis and S. D. Dertinger. *Litron Laboratories, Rochester, NY.*

This laboratory has described a flow cytometric method for scoring in vitro micronuclei (MN) [Environ. Molec. Mutagen. (2006) 47:56-66]. This "In Vitro MicroFlow" method labels necrotic and mid-/late-stage apoptotic cells with ethidium monoazide. Cells are then washed, stripped of their cytoplasmic membranes, and incubated with RNase plus a pan-nucleic acid dye. Here, we report modifications to the method whereby all procedures are accomplished in the same 96 well plate. For these experiments, human TK6 cells were treated continuously for 24 - 30 hrs with 68 diverse chemicals over a range of concentrations up to 10 mM. With the assistance of liquid handlers, treatments and staining occurred automatically. Furthermore, a Becton Dickinson HTS device was used to deliver the contents of each well to a FACSCanto flow cytometer for walk-away data acquisition. Flow cytometry-based MN frequencies were calculated based on the analysis of 10,000 nuclei per well. Since a consistent number of latex particles were added to each specimen, nuclei to bead ratios were collected concurrently with MN frequencies, and these data were used to calculate relative survival values. Top concentrations were limited to 10 mM, solubility, or else 50% relative survival. Overall, the automated assay agreed well with expected in vitro cytogenetics results (concordance = 88.2%; positive predictivity = 87.5%, negative predictivity = 92.9%). These data suggest that in vitro MN screening can be accomplished in a miniaturized and highly automated format. Further work is needed to assess the transferability of the method through inter-laboratory trials.

PS 1070 BATTERY OF GENOTOXICITY STUDIES CONDUCTED ON A GROUP OF STRUCTURALLY RELATED NITRILES.

S. P. Bhatia, V. T. Politano and A. Api. *Research Institute for Fragrance Materials Inc., Woodcliff Lake, NJ.*

A battery of genotoxicity studies were conducted on a group of 8 structurally related nitriles (Benzonitrile; Cinnamyl nitrile; 3-Methyl-5-phenylpentanenitrile; 2,2,3-Trimethylcyclopent-3-enylacetonitrile; 3-Methyl-5-phenylpent-2-enenitrile; α-Cyclohexylidene benzeneacetonitrile; Citronellyl nitrile; Dodecanenitrile) that are used as fragrance materials. All the studies were conducted according to the OECD Testing Guidelines. In an in vitro chromosome aberration test using Chinese Hamster V79 cell line,citronellyl nitrile induced structural chromosome aberrations in presence of S9. In an in vitro micronucleus assay using V79 cell line, cinnamyl nitrile and 3-Methyl-5-phenylpent-2-enenitrile induced micronuclei in V79 cells in the presence and absence of S9, while 3-Methyl-5-phenylpentanenitrile induced micronuclei in the presence of S9 activation only. 2,2,3-Trimethylcyclopent-3-enylacetonitrile induced statistically significant increase in micronuclei in presence of S9, however there was a lack of dose dependency and the values were within the historical range of the control. No effects were observed in an in vitro chromosome aberration test using Chinese Hamster V79 cell line with Dodecanenitrile. No effects were observed in in vivo micronucleus assays in NMRI mice (high doses ranged from 200 to 2000 mg/kg) in all the five nitriles (cinnamyl nitrile; benzonitrile; 3-Methyl-5-phenylpentanenitrile; 3-Methyl-5-phenylpent-2-enenitrile; α-Cyclohexylidene benzeneacetonitrile) that were tested. It is concluded that these 8 nitriles are not genotoxic.

PS 1071 HIGH CONTENT ANALYSIS OF PHOSPHO-H2AX AND PHOSPHO-ATM IN CONJUNCTION WITH THE *IN VITRO* MICRONUCLEUS TEST TO DETERMINE THE CLASTOGENIC POTENTIAL OF GENOTOXIC COMPOUNDS.

D. M. Miller, A. M. Peters and J. R. Haskins. *Cellular Imaging & Analysis, Thermo Fisher Scientific, Pittsburgh, PA.* Sponsor: A. Barchowsky.

The in vitro micronucleus assay is used to detect genotoxic chemicals that induce the formation of micronuclei within interphase cells. The test is capable of detecting both clastogens and aneugens, but is not capable of directly distinguishing between the two as FISH or kinetochore antibodies can. In order to investigate another possibility of distinguishing between clastogenic and aneugenic compounds, three proteins involved in the cells response to DNA damage were studied: H2AX, ATM and p53. H2AX is a histone protein that is rapidly phosphorylated by ATM, a serine/threonine kinase, in response to DNA damage. ATM also autophosphorylates in response to genotoxic stress. TP53 is a tumor suppressor gene that is phosphorylated in response to DNA damage prohibiting its degredation resulting in the accumulation of p53 in the nucleus. For this study, BALB/3T3 A31 cells were treated with various concentrations of different aneugenic and clastogenic compounds for both 4h and 20h. After fixation, the cells were stained with either Phospho-ATM and p53 Activation HCS Reagent kit or Phospho-H2AX HCS Reagent kit. Plates were run on the Cellomics ArrayScan VTI Reader to measure the percent micronucleus frequency, p-ATM and p-H2AX expression and p53 translocation to the nucleus. An increase in both p-ATM and p-H2AX after 4h treatment of the three clastogenic compounds was found. An increase in both p-ATM and p-H2AX was also seen after 20h treatment of mitomycin and cytarabine, but not with chlorambucil. Expression of p53 in the nucleus was unchanged for

both treatment times. In contrast, aneugenic compounds showed no change or a decrease in p-ATM and p-H2AX staining at both 4h and 20h. These initial findings indicate a correlation between clastogenic compound treatment and increases in p-ATM and p-H2AX expression.

PS 1072 USING HIGH CONTENT ANALYSIS TO EVALUATE THE USE OF RECOVERY TIME AND ITS EFFECT ON MICRONUCLEUS FREQUENCY IN MONONUCLEATE CELLS.

A. M. Peters, D. M. Miller and J. R. Haskins. *Cellular Imaging and Analysis, Thermo Fisher Scientific, Pittsburgh, PA.* Sponsor: A. Barchowsky.

The micronucleus assay is used to detect potential aneugenic and clastogenic compounds in cells that undergo cell division. Not finding the correct doubling time of all cell lines could lead to false negatives or decreases in micronucleus frequency. In this study various cell lines (CHO-K1, CHL, and Balb 3T3/a31) were treated with three aneugenic compounds (vinblastine, colchicine, and nocodazole) and three clastogenic compounds (cytarabine, mitomycin C, and chlorambucil) for 20h, followed by either a 24hr rest period (removing compound and replacing with media) or immediately fixing the plate. Cells were fluorescently stained so that the nuclei, micronuclei, and cytoplasm were visible. Plates were run on the Cellomics ArrayScan VTI Reader, evaluating a minimum of 1000 targeted cells per well. Values for Micronucleus Frequency were calculated and cells were evaluated based on set guidelines (intact cytoplasm, not mitotic, micronucleus 1/3 diameter of nearest nucleus, etc.). Under normal circumstances, it is during cell division that micronuclei are created after compound treatment. For all cell types tested, both clastogens and aneugens exhibited a fold-difference over control for micronucleus frequency equal to or greater in cells that had a recovery period than those treated for only 20h. Therefore, letting the cells recover from treatment allowed the majority of cells to undergo cell division, giving rise to micronuclei at proper genotoxic concentrations.

PS 1073 MECHANISM(S) OF DNA DAMAGE INDUCTION BY 4-MONOCHLOROBIPHENYL (PCB3) METABOLITES.

W. Xie, L. Robertson and G. Ludewig. *The University of Iowa, Iowa city, IA.*

PCB3 is readily metabolized to dihydroxy-metabolites and quinones. The PCB3 hydroquinone (PCB3-HQ) induces chromosome loss in Chinese Hamster V79 cells, whereas the para-quinone (PCB3-pQ) very efficiently induces gene mutations and chromosome breaks. We hypothesized that the genotoxicity of HQ requires enzymatic activation by peroxidases, whereas the p-Q reacts directly with DNA and/or proteins. We used myeloperoxidase (MPO)-rich HL-60 and MPO-deficient Jurkat cells to measure cytotoxicity, DNA damage (Comet assay), MPO activity, intracellular levels of reactive oxygen species (ROS), free –SH groups, and GSH after exposure to PCB3 metabolites and also examined the effects of normal/low temperature, pre-treatment with a MPO inhibitor (succinylacetone, SA), or GSH depletion. PCB3-pQ increased intracellular ROS levels and induced DNA damage in both, HL-60 and Jurkat cells at 37°C and 6°C. It also strongly reduced intracellular free –SH groups and GSH in normal and GSH-depleted cells. Thus the ROS increase could be the result of GSH-depletion or non-enzymatic autoxidation of the resulting PCB3-HQ-GSH adduct. PCB3-HQ had no effect on GSH in HL-60 cells and reduced free –SH groups only at the highest concentration in GSH depleted cells. Moreover, PCB3-HQ induced DNA damage and ROS production only at 37°C in HL-60 cells, not at 6°C or in Jurkat cells at either temperature; no significant DNA damage and ROS production was observed in HL-60 cells at 37°C if MPO activity was inhibited by SA. These studies show that the effects of PCB3-HQ are enzyme dependent, i.e. PCB3-HQ is oxidized by MPO in HL-60 cells with the generation of ROS and induction of DNA damage. However, PCB3-pQ may produce DNA damage by direct interaction with DNA or nuclear proteins like topoisomerase II, or possibly by indirectly increasing intracellular ROS levels by GSH depletion. These different modes of action explain not only the different types of genotoxicity observed previously, but also suggest different organ specificity of these genotoxins. (Supported by NIEHS P42 ES013661 and DAMD17-02-1-0241)

PS 1074 MECHANISM OF GENOTOXIC EFFECTS OF SILVER NANOPARTICLES RELATED TO OXIDATIVE STRESS.

H. Kim, H. Oh, Y. Park, S. Kang, S. Oh and K. Chung. *Sungkyunkwan University, Suwon, Korea, South.*

In the single-cell gel electrophoresis (Comet assay) and micronucleus assay (MN assay) in human normal lung epithelial BEAS-2B cells, Ag-NPs stimulated DNA breakage and micronucleus formation in a dose-dependent manner (from 0.01 ug/ml to 10 ug/ml). The genotoxic effect of Ag-NPs (10 ug/ml) was partly blocked by scavenger agents such as mannitol (Mannitol, OH radical scavenger), catalase and sodium selenite (H2O2 radical scavenger), whereas SOD (superoxide dismutase, superoxide scavenger) completely blocked. Furthermore, in the modified comet assay using endonuclease III, Ag-NPs induced a significant increase of DNA strand breaks compared with control levels, indicating that Ag-NPs stimulate oxidation of pyrimidine. Furthermore, in DCFH-DA assay, Ag-NPs showed a significant increase (**$p<0.01$) of oxidative stress. These results indicate that oxidative stress of Ag-NPs, especially superoxide and oxidized pyrimidine play an important role in genotoxicity of silver nanoparticles.

PS 1075 INVESTIGATIONS INTO THE GENOTOXIC POTENTIAL OF ORGANOPHOSPHATES.

S. E. Remington, P. A. Jowsey, F. M. Williams and P. G. Blain. *The Medical Toxicology Centre, Newcastle university, Newcastle upon tyne, United Kingdom.* Sponsor: N. Monteiro-Riviere.

Organophosphates (OP's) are acutely toxic to man by inhibition of acetylcholinesterase (AChE) but chronic toxicity is less well explained. Several studies have suggested that OP's can cause DNA damage in vitro. In this study the potential of dichlorvos (DCV), an oxon and chlorpyrifos (CPF) a thiophosphate to cause DNA damage was investigated using the Comet assay in parallel with the measurement of cytotoxicity and DNA damaging signalling pathways. TK6 human lymphoblastoid cells in culture were exposed to either DCV or CPF (0.01, 0.1, 1, 10 and 100μM) for 1 or 24 hours. DNA damage was measured using the Comet assay and cytotoxicity using the MTT assay. Western blotting was used to investigate DNA damage signalling and apoptosis by monitoring p53 induction and PARP-1 cleavage in TK6 cells after 1, 2, 4 and 24 hours. The background DNA damage measured as olive tail moment (OTM) for 50 cells was <1 and increased with dose of OP. After 1 hour 100μM DCV gave an OTM of 4.04 ±1.04 (mean ± SE) whilst CPF gave a value of 2.35 ±0.72. 1μM DCV gave an OTM of 2.61 ±0.79 whilst 1μM CPF 1.45 ±0.26. After 24 hours 100μM DCV gave an OTM of 4.8 ±1.67 whilst CPF gave a value of 3.97 ±1.16. 1μM DCV gave an OTM of 2.15 ± 0.69 whilst 1μM CPF 2.24 ±0.71. Both OP's proved to be cytotoxic after 24 hours in TK6 cells at 100μM, a 40% or 80% loss occurred with DCV and CPF respectively. Western blotting analysis in TK6 cells showed that levels of cleaved PARP-1 slightly increased at 24 hours after 100μM DCV, indicative of apoptosis. The p53 level was increased, with a maximum induction at 4 hours after 100μM DCV. Lower doses of DCV showed no increase in p53 or cleaved PARP-1 after 24 hours. This study has confirmed that both DCV and CPF can induce DNA damage after exposure for an hour. This DNA damage leads to a subsequent induction of p53 and a loss in cell viability at the higher doses of OP. It will be important to investigate the nature of this DNA damage and the cellular repair mechanisms employed by the cell to restore the integrity of the DNA (UK Home Office funded research)

PS 1076 ESTABLISHMENT OF A SIMPLE *IN VITRO* COMET ASSAY AND ITS VALIDATION.

A. Kimura[1], H. Sakamoto[1, 3], K. Saigo[1], T. Sukamoto[1], R. Nagata[1] and M. Honma[2]. *[1]Drug Safety Research Laboratories, Shin Nippon Biomedical Laboratories (SNBL), Ltd., Kagoshima, Japan, [2]Division of Genetics and Mutagenesis, National Institute of Health Sciences, Tokyo, Japan and [3]Canon Inc., Kanagawa, Japan.*

The comet assay has been widely used as a genotoxicity test for detecting initial DNA damage in individual cells. The purpose of this study was to establish a practical methodology without losing sensitivity and we examined a simple comet assay method using a water-repellent slide glass (Matsunami MAS coat) instead of the conventional bottom layer of agarose. Additionally, the results were compared with those from a micronucleus assay with a different end-point, conducted concurrently. Human lymphoblast TK6 cells and Chinese hamster lung cells were treated for 4 hours with genotoxic (EMS, MMC, H_2O_2, and others) and non-genotoxic (cycloheximide and triton X-100) compounds, and an in vitro alkali comet assay was performed immediately after the treatment. Following a 48-hour recovery period, cytotoxicity was evaluated by both a relative suspension growth (RSG) as determined by daily cell growth and a viability as indicated by a dye (trypan blue)-exclusion assay and clastogenicity was assessed by the in vitro micronucleus assay. This simple comet assay showed that chemical genotoxicity can be clearly detected, regardless of cell type, and qualitative agreement with the results of the micronucleus assay was found. MMC, which is known as an interstrand cross-linker, was not shown to be genotoxic in the comet assay, however, because the induced DNA-DNA crosslinks prevent separation of the DNA duplex, as reported previously. Despite this, a simple in vitro comet assay is expected to be the most useful test system to detect DNA damage for hazard identification, because this simple comet assay had the same degree of power as a clastogenicity-detecting micronucleus assay.

PS 1077 COMET ASSAY ON RECONSTRUCTED HUMAN SKIN: AN ALTERNATIVE ASSAY IN GENOTOXICITY.

G. Ouédraogo, J. Belaïdi, A. Ginestet, I. Lafosse, L. Marrot and J. Meunier. *L'Oréal Life Sciences Research, Aulnay sous Bois, France.* Sponsor: E. Dufour.

Starting in March 2009, the testing ban in genotoxicity (and in other 3 endpoints) imposed by the 7th amendment to the European Cosmetic Directive will enter into force. To face this regulation, the EU Cosmetics Association's (COLIPA) Genotoxicity Project Team has set up a project using reconstructed skin models. Generally, results obtained from monolayer cell-based in vitro genotoxicity assays are sensitive but lack specificity. The reconstructed tissues were chosen as biological models in the purpose to overcome this limitation and take into account the dermal route of exposure. The comet assay (together with the micronucleus assay) is one the endpoints evaluated in this project. Based on the scientific literature, the comet assay is a sensitive assay for screening genotoxic hazard. It is used in biomonitoring studies, early in drug/chemical development and for studying UV or other radiation related DNA damage. It can detect a large variety of DNA damage very early after the onset of the insult. Therefore, it can be used to screen for gene mutagens as well as chromosome damaging agents. Combined with antibodies and/or restriction enzymes, this assay can be used to get a mechanistic insight into the genotoxic insult. Several multi-laboratory studies have been conducted on the in vitro comet assay. Nevertheless no "validated" protocol is available. Here, the results obtained with the RealSkiin (a reconstructed full-thickness skin model) are discussed. This model is a promising tool for detecting genotoxins as well as photo-genotoxins.

PS 1078 *IN VITRO* MICRONUCLEUS ASSAY USING A CO-CULTURE SYSTEM: TOWARDS NEW TOOLS FOR *IN VITRO* RISK ASSESSMENT OF DERMALLY APPLIED COMPOUNDS?

N. Flamand, G. Ouédraogo, M. Feltès, L. Bourouf and J. Meunier. *L'Oréal Life Sciences Research, Aulnay sous Bois, France.* Sponsor: E. Dufour.

In vitro reconstructed skin models such as Episkin® (reconstructed epidermis) and Realskin (reconstructed full-thickness: epidermis + living dermis) are biological models mimicking human skin. They are of growing interest in safety or efficacy pre-screening tests and for regulatory purposes as alternatives to animal testing (7th amendment to the European Cosmetic directive, REACH). The reduction and eventually the replacement of in vivo toxicity testing require the development of new complementary biological models and methods with improved ability to predict the genotoxic or other endpoint risk with in vitro data. This can be achieved if these new assays take into account the exposure conditions in a more relevant way than the current ones. To that end, new approaches using human reconstructed skin models for in vitro toxicology assessment are proposed.
A co-culture system (made of Episkin® or RealSkin and target) cells waq used to perform the micronucleus assay. The results obtained from six different compounds are shown. This way of using human reconstructed skin aims at improving the relevance of exposure conditions in in vitro genotoxicity assays for dermally applied compounds. The skin is indeed a biologically active barrier driving the exposure to compounds and their possible metabolites. The exposure of the target cells to a given substance can be assessed after topical application as was the case here. Episkin® and Realskin were used as a metabolically active tissue and a physiologic barrier. The test compound can be metabolized by the skin and/or by the target cells (± S9 if needed).
Metabolism is an important event to consider in genotoxicity and skin sensitization evaluation. Compared to cell models, a broad variety of chemicals with different physico-chemical features can be evaluated in this system (after topical or systemic application). The data highlight the value-added of this co-culture system.

PS 1079 THE PHOTOCLASTOGENICITY OF FUROCOUMARINS: BERGAMOTTIN AND ISOPIMPINELLIN.

D. McGinty, V. T. Politano and A. Api. *Research Institute for Fragrance Materials, Woodcliff Lake, NJ.*

Phototoxic and photomutagenic properties have been reported for certain furocoumarins, but cannot be translated to all of the materials within the family since they constitute a highly diverse group of natural chemicals. Photoclastogenicity was tested for bergamottin and isopimpinellin, found in citrus oils, by chromosome aberration studies in cultured Chinese hamster ovary cells with and without the presence of ultra-violet light. Quadruplicate cultures were treated with the vehicle (DMSO) and duplicate cultures were treated with 6.597 - 120.0 μg/ml bergamottin, 5.0 - 225.0 μg/ml isopimpinellin, or the positive controls. After incubation in the dark for 15 minutes, flasks were exposed to 700 mJ/cm2 UV light or remained non-irradiated. An Atlas Suntest CPS+ solar simulator light source encompassing UVA and UVB wavelengths was used. Post irradiation, all flasks were incubated for at least 2 hours. Treatment media was removed and cultures were incubated for 17 hours before harvesting. Approximately 1.5 hours prior to harvest, colchicine was added to arrest dividing cells in metaphase. Slides were prepared with one hundred metaphases from each and analyzed for chromosome aberrations. The frequencies of cells with structural chromosome aberrations (including and excluding gaps) was determined and compared to negative (vehicle) controls and to equivalent concentrations treated in the absence of UV light. Treatment with bergamottin in the presence of UV light resulted in significant increases in structural chromosome aberrations at 8.246-20.13 μg/ml compared to vehicle controls. No such increases in structural chromosome aberrations were observed in the absence of UV light, indicating a photoclastogenic response. Isopimpinellin at 25-150 μg/ml induced structural chromosome aberrations that were similar to, and not statistically different from, vehicle controls in the presence of UV light. As such, isopimpinellin did not induce photoclastogenicity.

PS 1080 COMPARISON OF BASELINE AND CHEMICAL-INDUCED DNA DAMAGE IN WISTAR HAN AND FISCHER 344/N RATS.

C. A. Hobbs[1], L. Recio[1], K. Shepard[1], C. Baldetti[1], J. Winters[1], A. Green[1], P. Allen[1], M. Streicker[2], W. Caspary[3] and K. Witt[3]. *[1]Genetic Toxicology, ILS, Inc., Research Triangle Park, NC, [2]Investigative Toxicology, ILS, Inc., Research Triangle Park, NC and [3]National Toxicology Program, National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

The National Toxicology Program is considering the use of Wistar Han rats as a replacment for F344 rats in its toxicity and carcinogenicity bioassays. Therefore, studies were conducted to compare baseline and chemical-induced DNA damage between these strains of rats. Three genotoxic chemicals evaluated previously in F344 rats were tested in Wistar rats using a combined 4-day protocol for in vivo evaluation of micronuclei induction in reticulocytes (MN-RET), as measured by flow cytometry, and DNA damage as assessed by the Comet assay. Two clastogens, ethyl methylsulfonate (EMS) and cyclophosphamide, and an aneugen, vincristine sulfate, were tested. Significant differences in MN-RET frequencies were measured between Wistar and F344 rats exposed to cyclophosphamide and vincristine sulfate, but not EMS. As assessed by the olive tail moment (OTM) endpoint in the Comet assay, there were significant strain differences in the extent of DNA damage in blood leukocytes following exposure to EMS and cyclophosphamide, but not vincristine sulfate. In liver, there were significant differences in OTM between the two strains when treated with EMS and vincristine sulfate. Statistical differences in OTM were also observed in duodenum tissue following treatment with cyclophosphamide and vincristine sulfate. Untreated control data from these three studies were compared against historical control data for F344 rats. The baseline MN-RET frequencies were 2.5-fold higher in Wistar rats ($p<0.0001$). A statistical difference in DNA damage, as measured by OTM, was found in the duodenum, but not in blood leukocytes or liver. Our results indicate that, as compared to F344 rats, Wistar rats exhibit higher baseline levels of micronuclei and DNA damage in some tissues, and may be more susceptible to some genotoxic chemicals.

PS 1081 HIGH CONTENT FLOW CYTOMETRY-BASED MICRONUCLEUS SCORING METHOD IS APPLICABLE TO ATTACHMENT CELL LINES.

J. Shi[1], S. Bryce[2], J. Nicolette[3], M. Diehl[3], P. Sonder[3], S. Phonethepswath[2], S. Avlasevich[2], S. Raja[2], J. Bemis[2] and S. D. Dertinger[2]. *[1]BioReliance, Rockville, MD, [2]Litron Laboratories, Rochester, NY and [3]Abbott Laboratories, Abbott Park, IL.*

A flow cytometric method for scoring in vitro micronuclei (MN) in lymphoblastoid cells based on a sequential, two dye staining process has been described [Environ. Mol. Mutagen., 47 (2006) 56-66]. The experiments reported herein were undertaken to evaluate the compatibility of the method with the attachment cell lines CHO-K1 and V79. Initial work with CHO-K1 was focused on simplifying cell processing by eliminating the need for trypsin and centrifugation steps, and also by incorporating concurrent means of measuring cytotoxicity. Nine independent experiments with mitomycin C- and cyclophosphamide-treated cells verified the effectiveness of the simplified cell processing procedure for simultaneously measuring MN and cytotoxicity. Subsequently, dose response experiments with seven prototypical genotoxicants and three nongenotoxicants indicated that the method is capable of reliably detecting MN induced by different modes of action. Further work was then directed at evaluating interlaboratory transferability. For these experiments, three laboratories used a common cell handling/analysis protocol to study each of the ten chemicals listed in Annex 3 of the Draft OECD Guidance Document 487 in either CHO-K1 or V79 cells. With the exception of benzo[a]pyrene, each site observed increased MN frequencies for the genotoxicants, whereas no significant effects were noted for the nongenotoxicants. Also noteworthy is that throughout these studies, two aneugenic signatures were evident whereby MN were larger and high frequencies of hypodiploid nuclei were induced in the cases of vinblastine, colchicine, and taxol treatments, but not with clastogens or

non-genotoxicants. Taken together, these data indicate that flow cytometric scoring of MN can be accomplished in attachment cells using an efficient protocol that minimizes the number of manipulations required, and the high content assay appears capable of discriminating between aneugenic and clastogenic modes of action.

PS 1082 PREGNANE X RECEPTOR (PXR) PROTECTS LIVER CELLS AGAINST DNA DAMAGES: EVIDENCE AND MECHANISMS.

H. Cui[1], X. Gu[1], Y. Xie[1], C. Naspinski[2], S. Ke[1], K. C. Donnelly[2] and Y. Tian[1]. *[1]Veterinary Physiology and Pharmacology, Texas A&M University, College Station, TX and [2]Texas A&M University System Health Science Center, Texas A&M University, College Station, TX.*

Pregnane X receptor (PXR) is a nuclear receptor that plays an important role in the pharmacokinetics of a broad spectrum of endogenous and xenobiotic compounds through coordinated-regulation of phase I, II enzymes and membrane bound transporters. Benzo[a]pyrene (BaP) is a known carcinogen and ubiquitous environmental contaminant. In an earlier study, using HepG2 with stable-transfection of PXR, we found that PXR plays a role in reducing BaP-induced DNA damages as determined by P32-postlabeling experiments. There are three potential mechanisms to account for the overall reduction of BaP induced DNA damages: (1) PXR regulates metabolic detoxification of BaP, (2) PXR represses AhR thereby inhibiting AhR/CYP1A1-mediated metabolic activation of BaP and (3) PXR regulates DNA repair machinery to reduce DNA damage. Evidence and mechanism (1) have been discussed in our earlier report (Toxi. Sci. 104, 67). In this study, we showed expression of PXR in HepG2 cells suppressed AhR transcriptional activity. The CYP1A1 and CYP1B1 mRNA levels and EROD activity decreased significantly in PXR-transfected HepG2 cells. Interestingly, the UV irradiation induced phospho-H2Ax was significantly reduced in PXR-transfected HepG2 cells as determined by Immunoflurescence microscopy, suggesting PXR plays a role in DNA repair mechanism. Taken together, these results suggest that in addition to metabolic detoxification, PXR protects cells against BaP induced damages through regulating DNA repair machinery as well as inhibiting AhR-mediated metabolic activation of the BaP. (This research is supported by ES09859 and ES09106.)

PS 1083 FLOW CYTOMETRIC EVALUATION OF MICRONUCLEATED POLYCHROMATIC ERYTHROCYTES IN BONE MARROW AND MICRONUCLEATED RETICULOCYTES IN PERIPHERAL BLOOD FOLLOWING ACUTE AND REPEAT DOSING REGIMEN OF CHEMICALS.

D. K. Torous[2], J. Shi[1] and L. Krsmanovic[1]. *[1]BioReliance Corporation, Rockville, MD and [2]Litron Laboratories, Rochester, NY.*

The flow cytometric (FCM) method for evaluating micronuclei (MN) in erythrocytes has been developed and proven to be more sensitive, reliable and reproducible compared with traditional microscopic enumeration. To validate the FCM method at BioReliance using In Vivo MicroFlow®, we conducted a systematic evaluation of bone marrow and peripheral blood of mice treated with a number of well-characterized MN inducers such as cyclophosphamide, methyl methanesulfonate and vinblastine, as well as nongenotoxic chemicals. Bone marrow and peripheral blood samples were harvested at 24 and 48 hours following a single dose, 24 hours following the 5th repeat dose and on Days 1, 8, 15, 22 and 29 in a 4-week repeat dosing study. The frequencies of micronucleated polychromatic erythrocytes/reticulocytes (% MN-PCEs/MN-RETs) were determined by microscopy (BioReliance), and flow cytometry at both BioReliance and Litron. The MN frequencies determined by FCM were essentially in agreement with the microscopic results and the FCM data obtained from BioReliance and Litron showed a high-degree correlation. In addition, sampling once a week in a 4-week repeat dosing study provided valuable insight into the generation, turnover and relationship between MN-PCEs in bone marrow and MN-RETs in peripheral blood. The robustness of the assay was also examined where blood samples prepared from the same animals were analysed by 4 independent FCM runs and the MN data were highly reproducible. In conclusion, the presented data support the use of FCM to evaluate MN frequencies in bone marrow and peripheral blood of mice following chemical exposure. Future validation will be conducted in more species including rat, canine and human.

PS 1084 CURCUMIN REGULATES CELL CYCLE PROGRESSION AND DNA REPAIR PROTEINS IN A P53-DEPENDENT MANNER.

E. N. Rogers, G. H. Jiang and J. States. *Pharamcology and Toxicology, University of Louisville, Louisville, KY.*

Benzo(a)pyrene-7,8-dihydrdiol-9,10-epoxide (BPDE) is the ultimate carcinogen produced by benzo[a]pyrene bioactivation. BPDE is believed to play an important role in lung carcinogenesis by covalently binding to DNA. Although curcumin, a component in turmeric, shows promising effects against BPDE-induced carcinogenesis, its exact mode of action remains unclear. We propose that pretreatment with curcumin lowers the threshold of p53 activation in response to BPDE-induced damage. To test this hypothesis, lung epithelial cells were pretreated with or without curcumin for 24 h followed by 300 nM BPDE for 1 h. Here we show that p53(-) cells exhibited higher BPDE-DNA adduct levels than p53(+) cells after BPDE treatment. Curcumin pretreatment significantly reduced BPDE-DNA adducts in p53(+) cells yet had no effect on p53(-) cells. Flow cytometric analysis indicated S phase arrest between 6 and 16 h in p53(+) cells treated with BPDE alone. The p53(+) cells recovered from S-phase arrest after 16 h. The time dependent S-phase arrest in p53(+) cells correlated with an induction of p53, p53 phosphorylated at Ser15 (p53S15), p21WAF1/CIP, and a down–regulation of phosphorylated retinoblastoma (P-pRb). In contrast, pretreatment with curcumin further decreased the induction of P-pRb and increased S phase arrest and p53, p53S15, and p21WAF1/CIP expression. BPDE induced DNA damage recognition protein XPC in p53(+) cells while levels of DDB2 remained unchanged. Pretreatment with curcumin enhanced the expression of XPC. Moderate S phase arrest occurred in p53(-), however pretreatment with curcumin had little affect. The expression of DDB2, but not XPC, was observed in p53(-) cells. DDB2 however was not induced in response to BPDE and curcumin did not affect its expression. In conclusion, the present study suggests that curcumin could play an important role in preventing lung carcinogenesis by modulating p53-regulated cell cycle progression and DNA damage recognition proteins in response to BPDE-induced damage. Supported by USPHS grants ES016719, CA119295 and ES014443.

PS 1085 CENTROSOMAL AMPLIFICATION, A GENOTOXIC MECHANISM INDUCED BY MULTIPLE NUCLEOSIDE REVERSE TRANSCRIPTASE INHIBITORS, IS INHIBITED BY THE AMINOTHIOL WR-1065.

M. Yu[1], Y. Ward[2], K. Davila[1], M. C. Poirier[1] and O. A. Olivero[1]. *[1]LCBG, National Cancer Institute, Bethesda, MD and [2]CCBB, National Cancer Institute, Bethesda, MD.*

In cultured cells, exposure to the highly-effective nucleoside reverse transcriptase inhibitor (NRTI) Zidovudine (AZT) induces cell cycle arrest, micronuclei, sister chromatid exchanges, shortened telomeres and genomic instability. Previously, we demonstrated for the first time that increasing AZT doses induced increasing centrosomal amplification (>2 centrosomes / cell) in hamster and human cells exposed for 24 hours to AZT. Here, we have expanded the original observations by exposing Chinese hamster ovary (CHO) cells and normal human mammary epithelial cell (NHMEC) strains, M99005 and M98040 to additional NRTIs. Cytotoxicity dose-response curves were obtained for Lamivudine (3TC), Didanosine (ddI) and Stavudine (d4T). Thymidine was used as a control to rule out nucleotide pool imbalance as a cause of centrosomal amplification. The treatments were as follows: 12.2 and 122 μM 3TC, 10.2 and 102 μM ddI, 8.9 and 89 μM d4T, and 9.9 and 99 μM thymidine. Cells (n = 1000/group) were scored under fluorescence microscopy. Compared to the unexposed control, a dose-dependent increase in centrosomal amplification was observed in CHO cells and in NHMEC strain M99005 cells for all NRTIs studied ($p < 0.05$). Centrosomal amplification was not induced by thymidine. Since clinical toxicity of these compounds can affect their therapeutic value, we used a combination of the aminothiol WR-1065 plus an NRTI to determine if genotoxicity could be reduced. CHO cells and NHMEC strains were exposed to a non-toxic dose of WR-1065 (10 μM) along with AZT, 3TC, ddI or d4T. Although WR-1065 alone did induce some centrosomal amplification, a 30-45% reduction in the incidence of NRTI-induced centrosomal amplification was observed in cells treated with an NRTI plus WR-1065. Therefore, WR-1065 appears to protect cultured cells from NRTI-induced DNA damage, but further studies may be required to evaluate protection in vivo.

PS 1086 GLOBAL APPROACHES TO BROMOMETHYL PROPANEDIOL GENOTOXICITY: REPAIR ENZYMES TO MICROARRAY ANALYSIS.

R. Kuester, W. Kong, A. Gallegos and I. Sipes. *Pharmacology, The University of Arizona, Tucson, AZ.*

Bromomethyl propanediol (BMP) is a flame retardant used in urethane foams and polyester resins. In a two year bioassay, BMP was shown to cause neoplastic lesions in the bladders of mice and rats. The studies reported here assessed possible DNA damage and repair by BMP in-vitro and in-vivo. Human derived bladder cells (UROtsa) were treated with BMP (in-vitro) and the effects of dose (0.1-100 μM) and time (1-24 h) on the expression of Poly (ADP-ribose) polymerase-1 (PARP-1), cyclooxygenase 2 (COX-2) and vascular endothelial growth factor (VEGF) were determined by Western blot analysis. Single cell DNA strand breaks induced by BMP in UROtsa cells were determined via the comet assay. Gene expression in the

bladders of mice after 6 h BMP exposure (300 mg/kg, PO) was determined using Affymetrix mouse ST arrays. In UROtsa cells BMP increased the expression of PARP-1, COX 2 and VEGF, and caused DNA strand breaks within 4 h. Following exposure in-vivo, the expression levels of genes associated with apoptosis (eg. Gadd 4, 2 fold), stress (eg. ATPase, 8 fold), DNA repair (eg. polymerase [DNA direct], 2 fold), and cell cycle (eg. VEGF, 2 fold) were increased in the bladders of mice treated with BMP. These results demonstrate that BMP exposure can induce DNA damage and repair and affect genes associated with these processes. This research was supported in part by the NIEHS NTP Grant No. N01-ES-45529 and NIEHS-sponsored Southwest Environmental Science Center Grant Number P3-ES-06694.

PS 1087 DEVELOPMENT OF HUMAN CELL MODELS FOR ASSESSING THE CARCINOGENIC POTENTIAL OF CHEMICALS.

W. Chen[1], Y. Pang[1], W. Li[1], Y. Yang[1], Y. Xiao[1], Z. Zhuang[2] and Y. Zheng[3]. *[1]Toxicology, School of Public Health, Sun Yat-sen University, Guangzhou, China, [2]The Laboratory of Toxicology Research, Shenzhen Center for Disease Control and Prevention, Shenzhen, China and [3]National Institute of Occupational Health and Poison Control, Chinese Center for Disease Control and Prevention, Beijing, China.*
Sponsor: W. Chen.

To develop human cell models for assessing the carcinogenic potential of chemicals, we established transgenic human cell lines and tested the sensitivity of known carcinogens using a cell transformation assay. A retroviral vector encoding an oncogenic allele of H-Ras (HBER) or c-Myc (HBEM) was introduced into human bronchial epithelial cells (HBE) immortalized by SV40 large T (LT) antigen, leading to increased cell proliferation but failing to confer a transformed phenotype characterized by anchorage-independent cell growth and tumor formation of immunodeficient mice. When these pre-transformed cells were treated with nickel sulfate (NiSO(4)), we found that it shortened the latency of malignant transformation at least by 19 wk in HBER cells or 16 wk in HBEM cells compared to vector control cells. Similarly, the latency of cell transformation was shorter by 15 wk in HBER cells or 9 wk in HBEM cells when cells were treated with benzo(a)pyrene-diol epoxide (BPDE). HBER cells appeared to be more sensitive to TPA, NiSO(4) or BPDE-induced cell transformation compared to human embryonic kidney cells expressing H-Ras (HEKR), implying that cell-type specificity is one of important factors determining the effectiveness of the assay. Using AFB(1) and BaP as the representative pro-carcinogens, we also compared the efficiency of three different metabolic conditions in mediating cell transformation. Low dose chemical induction seems to be a prospective system used for metabolic activation of pro-carcinogens. Our findings provided direct evidence that a genetically modified human cell transformation model can be applied to the assessment of potent carcinogens.

PS 1088 CHEMINFORMATICS ANALYSIS OF EPA TOXCAST CHEMICAL LIBRARIES TO IDENTIFY DOMAINS OF APPLICABILITY FOR PREDICTIVE TOXICITY MODELS AND PRIORITIZE COMPOUNDS FOR TOXICITY TESTING.

L. Zhang[1], H. Zhu[1], I. Rusyn[1], R. Judson[2], D. Dix[2], K. Houck[2], M. Martin[2], A. Richard[2], R. Kavlock[2] and A. Tropsha[1]. *[1]Carolina Center for Computational Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC and [2]National Center for Computational Toxicology, U.S. EPA, RTP, NC.*

An important goal of toxicology research is the development of robust methods that use in vitro and chemical structure information to predict in vivo toxicity endpoints. The US EPA ToxCast program is addressing this goal using ~600 in vitro assays to create bioactivity profiles on a set of 320 compounds, mostly pesticide actives that have well characterized in vivo toxicity. These 320 compounds (EPA-320 set evaluated in Phase I of ToxCast) are a subset of a much larger set of ~10,000 candidates that are of interest to the EPA (called here EPA-10K). Predictive models of in vivo toxicity are being constructed from the in vitro assay data on the EPA-320 chemical set. These models require validation on additional chemicals prior to wide acceptance, and this will be carried out by evaluating compounds from EPA-10K in Phase II of ToxCast. We have used cheminformatics approaches including clustering, data visualization, and QSAR to develop models for EPA-320 that could help prioritizing EPA-10K validation chemicals. Both chemical descriptors, as well as calculated physicochemical properties have been used. Compounds from EPA-10K are prioritized based on their similarity to EPA-320 using different similarity metrics, with similarity thresholds defining the domain of applicability for the predictive models built for EPA-320 set. In addition, prioritized lists of compounds of increasing dissimilarity from the EPA-320 have been produced, to test the ability of the EPA-320 models to extrapolate. These lists are further prioritized based on availability of toxicity data in the EPA ACToR database (actor.epa.gov/actor). Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.

PS 1089 BIOLOGICAL PROFILING OF ENDOCRINE RELATED EFFECTS OF CHEMICALS USING TOXCAST.

R. J. Kavlock, D. Dix, K. Houck, M. Martin and R. Judson. *National Center for Computational Toxiology, U.S. EPA, Research Triangle Park, NC.*

The Food Quality Protection Act of 1996 mandates that EPA implement a validated screening program for detecting estrogenic chemicals, as well as other endocrine targets deemed appropriate by the Administrator. EPA's Endocrine Disruptor Screening Program (EDSP) has been developing and validating screening assays for disruption of estrogen (E), androgen (A) and thyroid (T) signaling pathways. The EDSP includes in vitro and in vivo assays for detecting E, A or T activity; and 73 chemicals have been proposed for initial screening. ToxCast is an EPA research program using a broad range of high-throughput screens to profile the bioactivity of chemicals and develop predictive signatures of toxicity, based on modeling in vitro assay data to in vivo toxicity phenotypes. ToxCast profiled 56 of the 73 EDSP chemicals using in vitro assays which characterized receptor binding, activation, inhibition and target gene regulation, providing biological fingerprints relevant to E, A, T and other endocrine related activities. Of the over 600 ToxCast assays, six assess E, and 5 each are related to A and T receptor signaling. In addition to E, A and T endpoints, ToxCast also measured interactions with progesterone, glucocorticoid and PPAR receptors, aromatase activity, and other nuclear receptors including AhR, CAR, FXR, LXR and PXR that may modulate endocrine metabolism. Many assay targets were human proteins, but in some cases rodent or other species were targeted, affording cross-species comparisons. Results for the prototypic xenoestrogen bisphenol A, and the anti-androgen vinclozolin support the ability of ToxCast to identify potential endocrine disruptors, while screening other endpoints beyond E, A and T offers broader insights into the bioactivity of the EDSP chemicals. Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.

PS 1090 THE TOXCAST PATHWAY DATABASE FOR IDENTIFYING TOXICITY SIGNATURES AND POTENTIAL MODES OF ACTION FROM CHEMICAL SCREENING DATA.

H. Mortensen, D. Dix, K. Houck, R. Kavlock, I. Shah and R. Judson. *NCCT, U.S. EPA, Research Triangle Park, NC.*

The U.S. Environmental Protection Agency (EPA), through its ToxCast program, is developing predictive toxicity approaches that will use in vitro high-throughput screening (HTS), high-content screening (HCS) and toxicogenomic data to predict in vivo toxicity phenotypes. There are two major goals of this effort: 1) to produce toxicity signatures that can be applied to a large number of environmental chemicals for screening and prioritization; 2) to provide a more mechanistic understanding of chemical toxicity pathways. Towards these goals, we are developing a database and associated tools that organize the ToxCast data generated from over 600 different assays into pathways (e.g. toxicological, biochemical, metabolic, cellular), and then identifying pathway networks from which modes of action can be inferred. ToxCast in vitro assay data probe many biological domains and span multiple levels of biological organization. The ToxCast Pathway Database will be used to organize this extensive dataset, to perform network analyses, and to visualize putative modes of action that are activated by particular chemicals. Network analysis will facilitate the inference of predictive toxicological signatures by providing a visually intuitive representation of quantitative chemical effects across multiple levels of biological organization, including relationships to in vivo toxicity endpoints. This will define relationships between chemicals and disease states in whole animals, and potential disease states in humans. Initial analysis of ToxCast assays based on Entrez GeneID identified 113 human and 39 rat pathways within Ingenuity Pathway Analysis that contained at least one ToxCast assay target. This database will contribute to the larger goals of toxicogenomics by clarifying the role of gene-environment interactions in disease states. Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.

PS 1091 HIGH THROUGHPUT GENOTOXICITY PROFILING OF THE U.S. EPA TOXCAST CHEMICAL LIBRARY.

S. Little[1], A. W. Knight[2], L. Birrell[2], G. Akerman[3], N. McCarroll[3], D. Dix[1], K. Houck[1], R. Judson[1], R. Kavlock[1] and M. Martin[1]. *[1]National Center for Computational Toxicology, Office of Research & Development, U.S. Environmental Protection Agency, Research Triangle Park, NC, [2]Gentronix Ltd., Manchester, United Kingdom and [3]Health Effects Division, Office of Pesticide Programs, U.S. Environmental Protection Agency, Washington, DC.*

A key aim of the ToxCast project is to investigate modern molecular and genetic high content and high throughput screening (HTS) assays, along with various computational tools to supplement and perhaps replace traditional assays for evaluating

chemical toxicity. Genotoxicity is an area of toxicity testing that would greatly benefit from this approach. The hypothesis tested was that useful and predictive genotoxicity data can be obtained by integrating the results from a battery of individual HTS in vitro tests. The ToxCast Phase I set of 320 chemicals, primarily pesticides with significant in vivo toxicity data, were subjected to various HTS genotoxicity assays including the GADD45a-GFP (GreenScreen HC) assay from Gentronix, and p53 based assays from other ToxCast assay sources. In addition, compound structures were analysed in silico for predicted genotoxicity and carcinogenicity endpoints using DEREK for Windows. Results from these assays were compared to historical mutagenicity, genotoxicity, tumorigenicity and carcinogenic potential data collected from a variety of sources, including the ToxRefDB database. Historical data indicated some level of mutagenic concern for approximately 20% of the ToxCast chemicals, over 50% of the chemicals caused some form of tumor in high-dose chronic tests, and approximately 20% of the chemicals were classified as possible or probable human carcinogens. Similar percentages of chemicals had either ToxCast HTS genotoxicity assay or DEREK in silico alerts for mutagenicity or carcinogenicity, and these data will be used for ToxCast predictive modeling. *Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.*

PS 1092 BIOCHEMICAL ACTIVITIES OF 320 TOXCAST CHEMICALS EVALUATED ACROSS 231 FUNCTIONAL TARGETS.

T. B. Knudsen[1], K. Houck[1], R. Judson[1], A. Singh[2], D. Dix[1] and R. Kavlock[1]. *[1]ORD / NCCT, U.S. EPA, Research Triangle Park, NC and [2]Lockheed Martin, Research Triangle Park, NC.*

EPA's ToxCast research program is profiling chemical bioactivity in order to generate predictive signatures of toxicity. The present study evaluated 320 chemicals across 231 biochemical assays. ToxCast phase I chemicals include 309 unique structures, most of which are pesticide actives and metabolites (www.epa.gov/ncct/toxcast) for which a rich complement of in vivo toxicity data is available, and several replicates for quality control. The battery of 231 assay services provided by Caliper Life Sciences (www.caliperls.com) included 80 G-protein coupled receptors, 18 ion channels, 29 kinases, 19 phosphatases, 15 nuclear receptors, 11 transporters, 30 cytochrome P450s (CYPs), 15 proteases, and 14 other metabolic enzymes. Compounds were initially screened at 25 μM in 0.4% DMSO, or 10 μM in 1% ACN for CYPs. Normalized data were scaled to +1.0 (100% inhibition) and Z-score provided a composite measure of dynamic range and variability. To assess screening 'hits' we used median absolute deviation (MAD2) or >30%-inhibition. Preliminary results at >30% showed the following. Each chemical was active in an average of 10.2 assays (median 6); 12 chemicals were active in >15% assays and only 6 of 320 chemicals were inactive in all of the assays. Each assay on average had 14.3 chemical actives (median 7); 8 assays had >20% active chemicals and only 11 of 231 assays were not hit by any of the chemicals. These results suggest direct effects depending on the physics and chemistry of the platform, or effects of chemical depending on biochemistry of the system, or effects on target depending on the assay and selection criteria for 'hits'. Follow-up 8-point concentration response on a subset of 8,234 chemical-assay combinations is underway. Because ToxCast assay targets are both rodent- and human-based, the concentration-response may help build better linkage of existing rodent toxicity data to potential human health effects. [This work has been reviewed by EPA and approved for publication but does not necessarily reflect official Agency policy].

PS 1093 NOVEL INFORMATIC APPROACHES TO ANALYZE GENE EXPRESSION DATA WITH THE TOXCAST 320 CHEMICAL LIBRARY IN CULTURES OF PRIMARY HUMAN HEPATOCYTES.

A. Beam[1], D. Rotroff[2], K. Pott[1], A. Farmer[1], H. Bondell[3], K. Houck[2], D. Dix[2], R. Judson[2], E. LeCluyse[1] and S. Ferguson[1]. *[1]CellzDirect, invitrogen corporation, Morrisville, NC, [2]National Center for Computational Toxicology (NCCT), U.S. EPA, Research Triangle Park, NC and [3]Statistics, North Carolina State Universtiy, Raleigh, NC.*

Prevailing methodologies in the analysis of gene expression data often neglect to incorporate full concentration and time response due to limitations in throughput and sensitivity with traditional microarray approaches. We have developed a high throughput assay suite using primary human hepatocyte cultures as in vitro models that retain liver-like functionality (e.g. induction, metabolism and transport) to generate more comprehensive data across time and concentration. Using the ToxCast 320 chemical library, mRNA expression was determined using a quantitative nuclease protection assay using the Omix Imaging System (HTG, Tucson, AZ). Fourteen gene targets representing Phase I/II metabolism and transport were monitored based on their role in liver function and sensitivity to receptor pathways (AhR, CAR, PXR, PPARα, FXR). Techniques from machine learning were used to cluster compounds by gene response profiles. Dose-responses were mathematically abstracted as vectors in multidimensional space (rather than classical scalar representations traditionally associated with standard microarray analyses) and used in algorithms such as K-means and algometric clustering to create representative chemical phylogenies. Unique to this approach is assessment of concentration-response changes over time (6, 24, 48hr in culture) as well as correlation of gene targets with one another. From these analyses, inclusion of data from all time points resulted in more accurate clustering of the replicate ToxCast 320 and reference chemicals that reduced donor-dependent variability. This approach has significant implications in standardizing primary hepatocyte data analysis across donors and profiling chemical response with in vivo endpoints. Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.

PS 1094 MODE OF ACTION FROM DOSE-RESPONSE MICROARRAY DATA: CASE STUDY USING 8 ENVIRONMENTAL CHEMICALS.

J. R. Pirone[1], D. J. Dix[1], M. DeVito[2] and I. Shah[1]. *[1]National Center for Computational Toxicology (NCCT), U.S. EPA, Durham, NC and [2]National Health and Environmental Effects Lab. (NHEERL), U.S. EPA, Durham, NC.*

Ligand-activated nuclear receptors regulate many biological processes through complex interactions with biological macromolecules. Certain xenobiotics alter nuclear receptor signaling through direct or indirect interactions. Defining the mode of action of such xenobiotics is difficult due to the many perturbations in the cellular signaling networks resulting from exposure. Microarray data, when collected in a dose-response setting, is a rich source of information for determining the MOA. Analysis presents several challenges: namely, it is difficult to choose a single quantitative model that can be applied to each gene. We have developed a method for analyzing microarray dose-response data that is flexible, while still capable of capturing the complexity of the responses. Rat primary hepatocytes were incubated with solutions of 0, 10, 30, and 100 μM of 4-nonylphenol, MEHP, myclobutanil, propiconazole, or triadimefon or 1, 3, and 1 μM of DE-71, PCB-118, or PCB-153. In all cases, the control consisted of the 1% DMSO dosing solution. RNA was extracted 72 hrs after dosing and analyzed using Affymetrix Rat Genome 230 2.0 arrays. Natural cubic splines were fit to the dose-response data for each gene. Statistical significance of each fit was assessed using bootstrap analysis. A set of curve shape and intensity features was extracted from the fit for each gene found to exhibit a significant dose-response. Features included first-derivatives, maximum/minimum expression, dose at maximum/minimum expression, and area under the curve. Using subsets of curve features, genes were first partitioned into groups that responded with a similar shape then into groups with similar expression intensities. Partitioning was performed on a chemical by chemical basis. Gene groups were subjected to functional and pathway analysis.
This work was reviewed by EPA and approved for publication but does not necessarily reflect official agency policy.

PS 1095 SCREENING FOR CHEMICAL EFFECTS ON NEURONAL PROLIFERATION AND NEURITE OUTGROWTH USING HIGH-CONTENT MICROSCOPY.

J. M. Breier[1, 3], N. M. Radio[4], K. Houck[2], D. J. Dix[2], W. R. Mundy[3] and T. J. Shafer[3]. *[1]Toxicology, UNC, Chapel Hill, NC, [2]U.S. EPA, ORD, NCCT, Research Triangle Park, NC, [3]U.S. EPA, ORD, NHEERL, NTD, Research Triangle Park, NC and [4]Cellumen, Inc., Pittsburgh, PA.*

The need to develop screening methods for developmental neurotoxicity to reduce the cost, time, and animals required for in vivo toxicity studies is well recognized. The U.S. EPA ToxCast program aims to develop rapid and cost-effective toxicity testing approaches. Data collected from various high-throughput assays to contributes to computational models designed to forecast potential human toxicity. As part of this effort, we have screened a library of 320 chemicals (primarily pesticide compounds tested in vivo) using previously developed in vitro assays. Using high-content microscopy, chemical effects (40 μM; 24 hr) on ReNcell CX cell proliferation and viability were assessed by BrdU incorporation and propidium iodide exclusion, respectively. NS-1 cells, a PC12 subclone, were assessed for chemical-induced changes (40 μM; 96 hr) in neurite outgrowth (NOG) and viability by βIII-tubulin staining and ATP quantification assays, respectively. Effects on any endpoint were defined as changes beyond 3x the standard deviation of control means. 112 chemicals inhibited ReNcell CX cell proliferation, while 62 decreased viability; of these, 49 chemicals decreased both measures. NOG in NS-1 cells was

enhanced by 4 chemicals, but inhibited by 29 chemicals. NS-1 cell viability was decreased by 43 chemicals; all chemicals that inhibited neurite outgrowth also inhibited viability. Viability in both cell types was decreased by 28 chemicals, and 20 chemicals produced effects on all endpoints. These results demonstrate that these cell models can be used to screen large numbers of chemicals for effects on proliferation, neurite outgrowth, and viability using a high-content platform, and will contribute to ongoing data collection in ToxCast for the creation of predictive models for human chemical toxicity. (This abstract does not represent EPA policy)

PS 1096 IDENTIFICATION OF GENOMIC BIOMARKERS THAT PREDICT FUTURE ONSET OF DRUG-INDUCED RENAL TUBULAR INJURY.

Y. Minowa[1], C. Kondo[2], T. Uehara[2], Y. Okuno[3], N. Nakatsu[1], A. Ono[4], T. Maruyama[2], I. Kato[2], H. Yamada[1], Y. Ohno[4] and T. Urushidani[1,5]. *[1]National Institute of Biomedical Innovation, Ibaraki, Osaka, Japan, [2]Shionogi & Co., Ltd., Toyonaka, Osaka, Japan, [3]Kyoto University, Kyoto, Kyoto, Japan, [4]National Institute of Health Sciences, Setagaya, Tokyo, Japan and [5]Doshisha Women's College of Liberal Arts, Kyotanabe, Kyoto, Japan.*

Drug-induced renal tubular injury is one of the major concerns in preclinical safety evaluation. Recently, toxicogenomics is becoming a generally accepted approach for identifying chemicals with potential safety problems. In this research, we elucidated time- and dose- dependent global gene expression changes associated with drug-induced proximal tubular toxicity using 25 nephrotoxicans. Male Sprague-Dawley rats were dosed orally or intravenously once daily. The animals were exposed to 4 different doses (vehicle, low, middle, and high) of the compounds, and kidney tissues were collected on day 1, 4, 8 15, and 29. Gene expression profiles were generated from kidney RNA using Affymetrix GeneChip. We previously reported the analysis of the gene expression profiles on day 4, 8, 15, and 29 in conjunction with histopathological findings, and identified 40 genomic biomarkers for concurrent diagnosis. This time, we identified genomic biomarkers for future onset prediction using the gene expression profiles on day 1, when histopathological changes of most of the nephrotoxicants (12/16) had not been observed yet. Filter-type gene selection and linear classifier were employed to discriminate future onset of positives (high dose of 16 compounds) from the negatives (low dose of 25 compounds). 5-fold cross-validation was executed by dividing 25 compounds into 5 subsets 100 times. In summary, we achieved the sensitivity of 82% and the selectivity of 90% with 72 genomic biomarkers. The gene list contains well-known biomarkers, such as Kim1, Timp1, Cp, Gpx2, and also novel biomarker candidates, which are different from the genomic biomarkers for concurrent diagnosis. Toxicogenomics would be especially useful for future onset prediction of renal tubular injury.

PS 1097 INDEPENDENT VALIDATION OF GENE EXPRESSION-BASED HEPATOCARCINOGENICITY PREDICTION MODELS.

S. Auerbach[1], D. Mav[2], R. Shah[2], M. K. Vallant[1], N. J. Walker[1], G. A. Boorman[1] and R. D. Irwin[1]. *[1]NTP, NIEHS, Research Triangle Park, NC and [2]SRA International. Inc., Research Triangle Park, NC.*

Identification of carcinogenic activity is the primary goal of the 2-year bioassay. The expense of these studies limits the number of chemicals that can be studied and therefore chemicals need to be prioritized based on a variety of parameters including suspected carcinogenic activity. Recent work has suggested gene expression signatures from target organs of subacutely exposed rodents can identify chemicals with carcinogenic potential. To determine whether such an approach can be used to prioritize a class of allyl/propyl benzene flavoring agents nominated to the NTP we developed a support vector machine-based, hepatocarcinogen classification model using liver gene expression from male F344 rats that were exposed for 90 days or less to structurally diverse hepatocarcinogens (aflatoxin B1, 1-amino-2,4-dibromoanthraquinone, N-nitrosodimethylamine, methyleugenol) or non-carcinogens (acetaminophen, ascorbic acid, tryptophan). The models were optimized using recursive feature elimination and 10-fold leave-one-whole-chemical-set-out cross-validation. Models based on 2-, 14- and 90-day exposures achieved 100% cross-validation accuracies using as few as 3, 6 and 13 array features (minimum feature models), respectively. Independent validation of the models demonstrated their ability to differentiate between the hepatocarcinogens, estragole and safrole, and the non-hepatocarcinogens, eugenol and isoeugenol, all of which were previously studied in the NTP bioassay. Finally, the gene expression models predicted that the untested flavoring agents myristicin and isosafrole would be hepatocarcinogenic if studied at a dose level of 2 mmole/kg/day, whereas anethole (0.2 and 2 mmole/kg/day), isosafrole (0.2 mmole/kg/day) and myristicin (0.2 mmole/kg/day) would not produce significant increases in hepatic cancer in male F344 rats. Based on these findings isosafrole and myristicin should be given higher priority for carcinogenicity testing relative to other untested chemicals in this class.

PS 1098 AN INTEGRATED SPECIES COMPARISON ANALYSIS BASED ON BIOLOGICAL PATHWAYS.

M. A. Ovacik[1], M. Ierapetritou[1], B. Sen[2], P. Georgopoulos[3], W. Welsh[3], K. Gaido[4] and I. Androulakis[1]. *[1]Rutgers University, Piscataway, NJ, [2]EPA, Washington, DC, [3]ebCTC, EOSHI, Piscataway, NJ and [4]HIIS, RTP, NC.*

There are certain fundamentals remains invariable from bacteria to eucarya, therefore cross-species comparison provides insights into underlying principles behind complex biological phenomena[1]. Evolutionary and organizational relationships among species have been investigated for through multiple sequence alignment of a single protein or genome.Yet, not only limited number of genome sequences is available but also comparing genome sequences may not represent the highest level organization of organisms such as metabolic pathways and protein interaction networks.Comparative analysis of metabolic and signaling pathways allows examining the biological processes rather than the individual elements. There have been bioinformatics approaches[2] such as genomics and proteomics are used to determine biomarkers, for cross-species analysis. Phylogenetic analysis and bioinformatics approaches, taken together, raise the question whether an underlying similarity measure between the mode of action i.e. pathways, across species can be quantified; can we assess a pathway in human is more similar to its replacement in mice or rats? We combine pathway topology similarity, enzyme sequence similarity and promoter region similarity of the genes, which codes for the enzymes. Pathway topology similarity and enzyme sequence similarity in a given pathway will indicate if the pathways function in the same manner and we explore how likely two pathways are regulated in a similar means by comparing promoter regions.We present the similarity trees based on the combined features for each pathway among a large collection of pathways that are constructed in KEGG. By doing so it may guide our selection as to the most appropriate model to use to study a given biological phenomenon.

PS 1099 BENCHMARK DOSE DETERMINATION OF DIOXIN DOSE-DEPENDENT CHANGES IN BIOLOGICAL PATHWAYS IN PRIMARY HUMAN HEPATOCYTES.

J. Rowlands[1], R. Budinsky[1], B. Gollapudi[1], D. Cukovic[2], S. Salagrama[2], A. Dombkowski[2] and R. Thomas[3]. *[1]The Dow Chemical Company, Midland, MI, [2]Institute of Environmental Health Sciences, Detroit, MI and [3]The Hamner Institutes for Health Sciences, RTP, NC.*

Assessing health risks associated with mixtures of dioxins and dioxin-like compounds (DLCs) utilizes the toxic equivalency factor (TEF) approach that calculates a potency estimate for a DLC relative to that of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). This study used microarray-based gene expression changes in primary human hepatocytes treated with seven log-order concentrations of TCDD, 2,3,7,8-tetrachlorodibenzofuran (TCDF), or 2,3,4,7,8-pentachlorodibenzofuran (4-PeCDF) to calculate relative potencies for induced changes in biochemical pathways. The data were analyzed using the BMDExpress software application that combines traditional benchmark dose (BMD) methods with gene ontology classification in the analysis of dose-response data from microarray experiments. The BMD values for CYP1A1 expression were 0.4, 0.4, and 2.9 nM for TCDD, 4-PeCDF, and TCDF, respectively. These BMD estimates are consistent with TEF values for these compounds and serve to validate the underlying gene expression data used in the analysis. However, when the gene expression changes were grouped based on biological processes, significant differences were noted between the three chemicals. Overall, 50% to 80% of the gene ontology categories had substantially different average BMD values when compared between TCDD, 4-PeCDF, and TCDF. Changes in the expression of genes related to glucose transport and MAPK activity were among the most sensitive biological processes following treatment with TCDD and had average BMD values of 0.9 and 4.7 nM, respectively. By comparison, the average BMD values for these categories ranged from 22 to 31 nM for 4-PeCDF and TCDF. These results suggest that the inherent assumption in the TEF approach, that all DLCs produce equivalent responses based on relative potency, may not be appropriate when examined on a genome-wide transcriptional level, which may also extend to higher order biological endpoints.

PS 1100 TWO PATTERNS OF GENE EXPRESSION IN THE MITOCHONDRIAL OXIDATIVE PHOSPHORYLATION PATHWAY IN RAT LIVER CORRESPOND TO DIFFERENT CLASSES OF DRUG TREATMENTS.

J. Gollub, C. Pearson and A. H. Roter. *Entelos, Inc., Foster City, CA.* Sponsor: C. Thomas.

A potential toxicologic effect of drugs and their metabolites is the production of reactive oxygen species, which induce apoptosis and disrupt the mitochondrial oxidative phosphorylation pathway, the main source of ATP in eukaryotic cells. Drug-induced gene expression changes can provide insight into the molecular mechanisms of such "off-target" effects and are increasingly being used as diagnostic and predictive biomarkers during drug development. Two distinct gene expression patterns in the mitochondrial oxidative phosphorylation pathway were identified using a software tool (publicly available at http://connectivity.entelos.com) based on the "connectivity map" algorithm (Lamb et al., 2006 Science, 313:1929), and the Entelos DrugMatrix® Database, a database of gene expression profiles of hundreds of preclinical rat studies, from 1,695 compound treatments (the full microarray dataset is available in the GEO microarray repository (GSE8858)). One pattern matched a set of compounds enriched in PPARalpha agonists, such as fenofibrate and pirinixic acid ($p < 0.001$). These compounds induce an overall increase in expression of most genes in the pathway relative to vehicle treatment, presumably due to increased fatty acid beta oxidation leading to increased ATP production. A second pattern is characterized by upregulation of NADH dehydrogenase (ubiquinone) 1 beta subcomplex; cytochrome c oxidase, subunit VIa, polypeptide 1; and other genes; and downregulation of several genes including acyl-CoA synthetase long-chain family member 1; cytochrome c, somatic; and mitochondrial glutamate oxaloacetate transaminase 2. Compounds that match this pattern are otherwise unrelated and do not induce significant hepatotoxicity. In contrast, many hepatotoxic treatments caused a general, though less consistent, repression of most genes in the pathway. These results indicate that connectivity analysis can be used to segregate drug treatments into different groups sharing similar mechanisms of action for on- and off-target effects.

PS 1101 COMMON GENE EXPRESSION RESPONSES BETWEEN RAT LIVER AND RAT PRIMARY HEPATOCYTES.

A. H. Roter[1], J. Gollub[1], K. M. Goldstein[2], R. A. Jolly[2] and C. E. Thomas[2]. *[1]Entelos, Foster City, CA and [2]Eli Lilly & Co., Indianapolis, IN.*

Hepatotoxicity is a major cause of compound attrition in drug development. Primary hepatocytes treated in vitro hold potential as a surrogate system for detecting and understanding liver toxicity early in drug discovery. Gene expression profiles of cultured rat primary hepatocytes (RPH) differ from those derived from in vivo liver studies, however, raising concerns about the relevance of in vitro results. To characterize the similarities and differences in gene expression between in vivo and in vitro profiles, we compared gene expression data from rat liver and RPH compound treatments in the Entelos DrugMatrix® database. Seventy-four compounds were profiled both in vivo after 5 days treatment at the maximum tolerated dose, and in vitro for 24 hours at a concentration causing 20% cytolethality. For each probe, the correlation between liver and RPH was computed across all compounds and across specific classes of compounds with known in vivo outcomes such as DNA damage or hepatic necrosis. The set of probes most positively correlated across all compounds was significantly enriched with genes involved in metabolic pathways, such as beta-oxidation of fatty acids, regulation of glucose utilization, xenobiotic metabolism, and the P450 family, consistent with previous analyses. Additional pathways were significantly over-represented only for subsets of the compound treatments. The Wnt/b-Catenin signaling pathway was significant in treatments with DNA damaging compounds, indicating common responses to DNA damage in vivo and in vitro, and the bile acid biosynthesis via oxysterols pathway was significant in compounds that cause phospholipidosis. Other results suggested potentially novel associations. For example, the TGF-beta signaling pathway was significantly associated with phospholipidosis in this analysis, but this association has not been reported in the literature. These findings demonstrate that many biological domains in RPH are predictive of liver gene expression in vivo, thereby increasing confidence that in vitro toxicogenomic assays can aid in drug development.

PS 1102 GENE-EXPRESSION INTERPRETATION TOOL FOR TOXICOGENOMICS.

A. Boorsma[1, 2] and R. Stierum[1]. *[1]TNO Quality of Life, Zeist, Netherlands and [2]Maastricht University, Maastricht, Netherlands.* Sponsor: B. Blaauboer.

One of the aims of toxicogenomics is to classify compounds based on their toxicity. In order to compare the toxic response of compounds in different species, tissues and in vivo and in vitro, cross comparison of gene expression profiles is of great importance. The majority of the microarray analysis methods used within toxicogenomics are based on the single gene level. The use of gene groups can improve the sensitivity of analysis and has the advantage that interpretation of the data is more straightforward. Hereto, we created a web-application based on T-profiler[1]. T-profiler is a method that quantifies the expression of a gene group within a gene expression profile, by means of unpaired t-test calculation of an enrichment score ('t-value'). Our application is used for the analysis of gene expression profiles at gene group level, and the comparison of gene groups of interest to those derived from public toxicogenomics-related gene expression data. A possibility to upload custom gene sets is included together with a database of public available toxicogenomics experiments that can be used as reference material. We illustrate the utility of our application by showing gene specific response for compound classes and dose dependent responses for the HMG-CoA reductase inhibitor Atorvastatin. We also performed correlation analysis between t-values of gene groups and physiological parameters; this revealed mostly significant results for immunology related gene groups. Finally, we used cluster analysis to visualize the relation between the gene groups over all experiments. Altogether, we think that our web-application is a valuable contribution to the field of toxicogenomics.

PS 1103 GENERATION OF COMPOUND SPECIFIC PATHWAYS FOR BIOINFORMATICS ANALYSIS OF TOXICOGENOMICS DATASETS.

Y. Staal[1], C. Wierling[2], R. Herwig[2] and R. Stierum[3]. *[1]Toxicology and Applied Pharmacology, TNO Quality of Life, Zeist, Netherlands, [2]Max Planck Institute for Molecular Genetics, Berlin, Germany and [3]Physiological Genomics, TNO Quality of Life, Zeist, Netherlands.* Sponsor: B. Blaauboer.

The EU 6th framework Carcinogenomics project(www.carcinogenomics.eu) aims to improve toxicogenomics-based in vitro models for prediction of chemical carcinogenesis. To this extend, systems toxicology-based methods are developed to assess possible carcinogenic properties of compounds in in vitro models for liver, lung and kidney. Transcriptome and metabolome data will be generated within the consortium using selected model compounds (Vinken et al. (2008) Mutation Research Reviews, in press). Bioinformatics will involve, next to statistical approaches, pathway analysis tools such as GenMAPP (www.genmapp.org), which contain predefined expert MAPPs. Comparison of in vitro toxicogenomics findings for these compounds within the context of in vivo compound-specific knowledge enables to address whether the affected processes in target organ specific in vitro models involve primarily early effects (e.g. metabolism, DNA damage processing) or downstream effects related to the potential onset of carcinogenesis (e.g. cell proliferation or apoptosis). A start has been made to create in silico pathway MAPPs for selected model compounds (thioacetamide, benzo[a]pyrene, 2-nitrofluorene). Literature based pathways are first drafted in GenMAPP format. Finally, the obtained pathway information, initially for benzo[a]pyrene, will be integrated with an existing mathematical model for in silico prediction of cancer-specific signalling pathways (Hanahan and Weinberg (2000) Cell, 100, 57-70) using the PyBioS systems biology tool (Wierling et al. (2007) Brief Funct Genomic Proteomic, 6, 240-51). In an iterative step, the outcome of these predictions for carcinogens and non-carcinogens with respect to cancer initiation and development will then be validated by experimental in vitro toxicogenomics data derived from Carcinogenomics.

PS 1104 THE MOUSE GENOME INFORMATICS DATABASE: DATA INTEGRATION PROVIDING INSIGHTS INTO THE RELATIONSHIPS BETWEEN PHENOTYPES, GENE FUNCTIONS AND GENOMICS.

S. M. Bello, C. L. Smith, H. Dene, D. L. Burkart, L. L. Washburn, I. Lu, T. Monika, A. Anagnostopoulos, B. Richards-Smith, H. Onda, R. Babiuk, M. Knowlton, T. Meehan and J. T. Eppig. *Mouse Genome Informatics, The Jackson Laboratory, Bar Harbor, ME.*

The Mouse Genome Informatics Database (MGI, http://www.informatics.jax.org) is a free international resource for the genetics, genomics, and biology of the laboratory mouse. MGI includes annotations of descriptions of mouse mutant phenotypes and relationships of genes and gene products to molecular function, biological process, and cellular component using controlled vocabularies. These annotations are integrated with other biological data in MGI allowing users to search, compare, and analyze data that are not effectively retrieved through text searches. To access these integrated resources, users may either use a simple quick search tool or more complex database query forms. The quick search tool allows users to search for specific genes, alleles, or keywords. For example one can search for "oxidative stress" to find all genes and vocabulary terms that are associated with

this term. Query forms allow users to combine multiple criteria in structured queries to take advantage of the integration of data within MGI. Queries can simultaneously include parameters for phenotype, expression, biochemical function, subcellular location, sequence, and genome location. For example one can ask "What genes have products that are localized to the nucleus and have mutations resulting in alterations in oxidative stress baseline levels or induced responses?" Results from both the quick search tool and query forms may be viewed on the web or sent in tab delimited format to the MGI ftp site and downloaded. Integration and the use of structured vocabularies for annotations assists in robust and accurate data mining when posing such complex questions in both computational and individual formats at MGI.
The Mouse Genome Database (MGD) at MGI is supported by NIH/NHGRI grant HG0000330.

PS 1105 THE COMPARATIVE TOXICOGENOMICS DATABASE: A DISCOVERY TOOL FOR IDENTIFYING CHEMICAL-GENE-DISEASE NETWORKS.

A. P. Davis, C. G. Murphy, C. A. Saraceni-Richards, M. C. Rosenstein, T. C. Wiegers and C. Mattingly. *Bioinformatics, MDIBL, Salisbury Cove, ME.*

The Comparative Toxicogenomics Database (CTD; http://ctd.mdibl.org) is a curated database that promotes understanding about the effects of environmental chemicals on human health. This is a critical area of research because the etiology of many chronic diseases involves interactions between environmental factors and genes and proteins that modulate important physiological processes. CTD combines manual curation and integration of diverse data sets to provide a centralized, freely available resource for exploring cross-species chemical-gene and protein interactions and chemical- and gene-disease relationships. Over 122,000 interactions between 4,000 chemicals and 13,500 genes have been curated from 270 species, and 6,800 gene-disease and 3,200 chemical-disease relationships have been captured. By integrating these data, 390,000 gene-disease relationships and 93,000 chemical-disease relationships can be inferred. CTD also integrates external data sets like the Gene Ontology and KEGG pathways and maintains reciprocal links with many biological databases. Several new features were implemented to enhance data access and analyses including data download options, batch queries and the ability to compare associated data sets for chemicals, genes/proteins or diseases using a custom Venn Viewer tool. CTD's integrative approach provides researchers with important connections between chemicals, genes/proteins and diseases that may not otherwise be apparent, but provide the basis for testable hypotheses about the mechanisms underlying the etiology of environmental diseases. This presentation will demonstrate the current scope and functionality of the database using a CTD-curated data set for arsenic.

PS 1106 GENOME-LEVEL ANALYSIS OF GENETIC REGULATION OF SEX-SPECIFIC GENE EXPRESSION IN MOUSE LIVER.

N. Zhao[1], D. M. Gatti[1], E. J. Chesler[2], L. Lu[3, 4] and I. Rusyn[1]. *[1]Department of Environmental Sciences and Engineering, UNC-CH, Chapel Hill, NC, [2]Life Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN, [3]Department of Anatomy and Neurobiology, University of Tennessee Health Science Center, Memphis, TN and [4]Key laboratory of Nerve Regeneration, Nantong University, Nantong, Jiangsu, China.*

Sexual dimorphism in the expression of many genes is thought to play an important role in disease susceptibility, drug metabolism, and xenobiotic response in both humans and other species. This study dissected the genetic regulation that controls sex-specific gene expression in mouse liver through a combination of mRNA expression analysis and genetic mapping in a reference population of BXD recombinant inbred mouse strains. While previous research has explored sex-specific gene expression patterns in liver following various chemical challenges, we explored gene expression differences in a population of naïve mice. We analyzed gene expression data in the livers of untreated male and female mice from C57BL/6J, DBA/2J, B6D2F1, and 37 BXD strains. As expected, thousands of transcripts exhibited considerable differences in expression between females and males. Functional analysis of the differentially expressed genes revealed several pathways related to xenobiotic metabolism that are heavily dependent on subject's sex. Transcription factor binding site analysis of these same genes showed enrichment for the HNF1A, IRF2 and NR2F1 binding sites. Expression Quantitative Trait Locus (eQTL) mapping was also performed and revealed sex-dependent patterns of transcriptional regulation. Taking into account the influence of single nucleotide polymorphisms in microarray probes and the regions which are identical by descent between C57BL/6J and DBA/2J strains, we identified several eQTLs that are major sex-specific regulators of gene expression and proposed possible regulatory candidate genes that may define these loci.

PS 1107 NOVEL CLASSIFICATION APPROACH FOR BIOMARKER IDENTIFICATION AND CARCINOGENICITY PREDICTION.

R. Shah[1], D. Mav[1], S. Auerbach[2] and R. Irwin[2]. *[1]SRA International, Durham, NC and [2]National Toxicology Program, NIEHS, RTP, NC.*

We present a novel machine learning approach that utilizes gene expression profiles from livers of subacutely exposed rodents to predict the carcinogenicity of compounds. Our approach builds on the recursive feature elimination procedure using support vector machine that employs a leave one compound out training procedure along with novel scoring methodology to generate predictive models. We demonstrate the utility of our approach using liver gene expression profiles of rats exposed to structurally diverse hepatocarcinogens (aflatoxin B1, 1-amino-2,4-dibromoanthraquinone, N-nitrosodimethylamine, methyleugenol) or non-carcinogens (acetaminophen, ascorbic acid, tryptophan). We begin the modeling procedure using 40K probes as individual features and optimize model using recursive feature elimination where 10% of features are eliminated at every step of cross validation. Models based on 2, 14 and 90 day exposures achieved 100% cross-validation accuracies using as few as 3, 6 and 13 array features respectively. We demonstrate the robustness of our approach by performing a validation using independent test dataset consisting of rat liver gene expression profiles where animals were treated with flavoring agent compounds that are structurally different from those employed in the training set. Our models were able to differentiate between the hepatocarcinogens, estragole and safrole, and the non-hepatocarcinogens, eugenol and isoeugenol, all of which were previously studied by the NTP. The models also predicted that the untested compounds myristicin and isosafrole would be hepatocarcinogenic if studied at a dose level of 2 mmole/kg/day, whereas anethole (0.2 and 2 mmole/kg/day), isosafrole (0.2 mmole/kg/day) and myristicin (0.2 mmole/kg/day) will not produce significant increases in hepatic cancer in rats. In summary, we have developed and validated a novel machine learning approach to produce classifiers that can accurately predict carcinogenic potential of compounds. Our approach is widely applicable for toxicogenomic biomarker identification.

PS 1108 DEVELOPMENT OF LIVER TOXICITY KNOWLEDGE BASE (LTKB) TO EMPOWER THE FDA REVIEW PROCESS.

M. Chen[1], Q. Shi[1], L. Guo[1], L. Guo[1], E. Blann[1], S. Dial[1], J. Fuscoe[1], Y. Gao[1], R. D. Holland[1], R. Berger[1], L. Schnackenberg[1], L. Shi[1], L. Yu[1], D. Arasappan[2], H. Fang[2], F. Goodsaid[3], J. Senior[3], M. Orr[3] and W. Tong[3]. *[1]Division of Systems Toxicology, FDA's NCTR, Jefferson, AR, [2]Z-tech, the NCTR on-site contractor, jefferson, AR and [3]The Center for Drug Evaluation and Research, FDA, Silver Sprin, MD.*

A significant amount of drugs to be withdrawn from the market and to fail during clinical trial stage of development is due to liver toxicity. In order to understand liver toxicity at the mechanistic level and develop novel tools for identifying liver toxicity issues along the various stages of drug development, there is a need to develop content-rich resources to improve our basic understanding of liver toxicity and facilitate the efficient development of novel knowledge and tools for utilization by research, industry and regulatory groups. In the NCTR/FDA, we are developing Liver Toxicity Knowledge Base (LTKB) that will provide a wealth of focused knowledge and data mining tools for hepatotoxicity in the form of networks between chemicals (and drugs), molecular signatures, liver specific biomarkers, genes/proteins functions, pathways and liver diseases (and pathology). Specifically, five sets of data/information are being generated and integrated through an in silico approach to develop LTKB. These are (1) Liver Ontology that characterizes liver pathology and toxicity to guide data collection/curation, classification and analysis; (2) Gene Expression Data was collected from public databases and through collaboration; (3) Conduct text mining on >18 millions abstracts in PubMed with an emphasis on liver-related data; (4) Collecting hepatotoxicants and their associated mechanism Known Data through manual curation; and (5) Conducting in house omics experiment on >50 chemicals to augment and validate in silico results.

PS 1109 NEW DEVELOPMENTS IN FDA/CDER'S COMPUTATIONAL TOXICOLOGY PROGRAM.

N. L. Kruhlak[1], E. J. Matthews[1], L. G. Valerio[1], B. L. Minnier[1, 2], W. Liu[1, 2], T. Dao[1, 2] and R. Benz[1]. *[1]CDER/OPS/SRS/ICSAS, Food and Drug Administration, Silver Spring, MD and [2]GlobalNet Services, Rockville, MD.*

The Informatics and Computational Safety Analysis Staff (ICSAS) at FDA's Center for Drug Evaluation and Research (CDER) is an applied regulatory research group that creates databases of toxicological and clinical studies for the development of quantitative structure-activity relationships (QSARs). ICSAS employs leveraging mechanisms such as cooperative research and development agreements (CRADAs)

to obtain access to a variety of computational software programs that offer predictive (Q)SAR modeling capabilities (MC4PC, Leadscope Predictive Data Miner, Derek for Windows, MDL-QSAR). ICSAS is also involved in initiatives to harvest and publicly share toxicity data to support its modeling activities, and promotes the use of computational techniques that allow scientific knowledge to be extracted from proprietary chemical structures without revealing their identities. Recently, ICSAS has expanded its computational toxicology capabilities, including: (1) the creation of new comprehensive database and QSAR model suites describing adverse human health effects; (2) the assessment of pharmaceutical mechanism-of-action and potential off-target effects; (3) the evaluation and application of several off-the-shelf metabolite prediction programs; and (4) the development of a weight-of-evidence approach for interpreting (Q)SAR predictions from multiple models and software platforms. In addition, ICSAS' ongoing research program continues to upgrade its existing databases and models with new studies as they become available, and identify new areas of interest, such as QSAR modeling of phospholipidosis and maximum tolerated dose. This presentation provides case studies and describes ICSAS' efforts to provide in silico tools for evaluating the toxicological profiles of chemicals for which little or no traditional test data are available or results are equivocal. This supports FDA's Critical Path Initiative which encourages the use of computational tools in a regulatory environment to enhance the approval process for FDA-regulated products.

PS 1110 COMPUTATIONAL PREDICTION OF THE HUMAN METABOLISM OF HEPATOTOXIC DRUGS.

L. G. Valerio, E. J. Matthews, N. L. Kruhlak and R. Benz. *CDER / OPS / SRS / ICSAS, Food and Drug Administration, Silver Spring, MD.*

Predicting human drug metabolism is an essential part of drug discovery and the regulatory safety review of new drugs. Species-specific metabolism is a common problem encountered; drug metabolites identified in animal pharmacokinetic studies often differ from those formed in humans, leading to potential drug safety issues related to therapeutic efficacy, chronic toxicity, or drug-drug interactions. Computational prediction of human metabolites offers a rapid and inexpensive way of high-throughput screening for constructing metabolic profiles of drugs early in their development and for safety analyses. However, few computational prediction programs have been evaluated for their performance in predicting human drug metabolites. For the study reported here, 17 hepatotoxic drugs now withdrawn from the market were screened using the MetaDrug computational software program to assess the ability to predict human drug metabolites. Predicted first and second pass, and phase I and II metabolic reactions were considered with prioritization set to 80% probability cut-off. Accuracy was judged by comparing the phase I and II in silico predictions to known in vivo metabolites of the hepatotoxic drugs determined in human clinical studies. This study found that the percentage of correct predictions for the drugs was 38% when considering all known human metabolites, while correct predictions based on major metabolites was significantly higher at 62%. In some cases the software was able to predict potential pathways for toxic metabolite formation. The results of this external validation study were promising. However, further research is needed and is under way in our applied regulatory research unit to design new strategies for prioritizing predicted metabolites to reduce over-prediction. These may include combining in vitro liver microsomes and in silico predictive data, or using multiple computational prediction paradigms to achieve consensus predictions.

PS 1111 COMPUTATIONAL PREDICTION OF THE CARCINOGENICITY OF PESTICIDES.

E. J. Matthews and L. G. Valerio. *CDER / OPS / SRS / ICSAS, Food and Drug Administration, Silver Spring, MD.*

Estimating the carcinogenic and genotoxic potentials of a pesticide product, including its active ingredient(s), its metabolites and contaminants, is an essential part of the risk assessment and risk management safety review for pesticides. The presence of carcinogenic and/or genotoxic activities of this product can limit its commercial applications and its regulatory approval. Accurate knowledge of these toxicological activities could facilitate: (1) Tiered Testing: A sequential results-driven approach where data from one tier of testing is used to determine the next step in testing; (2) Integrated Testing Strategies: A hypothesis-driven integration of different types of hazard and exposure information to guide prioritization and the type of testing; and (3) Lead Selection: A safer and more profitable lead selection and discovery process by the pesticide industry. Computational prediction of pesticide product activities offers a rapid and inexpensive way of screening these chemicals early in their development and performing safety analyses. However, few computational prediction programs have been evaluated for their performance in predicting pesticide activities with a comprehensive test set. In this validation study, 500 pesticide chemicals with known carcinogenic potential were evaluated using quantitative structure-activity relationship (QSAR) models generated with MC4PC, Leadscope FDA Model Applier (LFMA), and BioEpisteme software. Comparative predictive performance using coverage, specificity and sensitivity as indices were investigated using QSAR models enhanced incrementally with 100, 200, 300, 400, or 500 pesticides. Results of this study found there is an optimal number of rodent carcinogenicity bioassays required to accurately predict the carcinogenic potential of pesticide products using QSAR models.

PS 1112 USING QSAR TO PREDICT ADVERSE EFFECTS OF ALKALOIDS IN BOTANICAL PRODUCTS.

C. D. Ellison[1,2], E. J. Matthews[1], A. Nguyen-Pho[2], N. L. Kruhlak[1], B. L. Minnier[1,3], L. G. Valerio[1] and R. Benz[1]. *[1]CDER/OPS/SRS/ICSAS, Food and Drug Administration, Silver Spring, MD, [2]CDER/OPS/OTR/DPQR, Food and Drug Administration, Silver Spring, MD and [3]GlobalNet Services, Rockville, MD.*

Purpose: Products containing herbs and other botanicals are becoming increasingly popular as a means of promoting health. The components of such products may contain hundreds of organic moieties, many of which are poorly described or understood. In particular, many botanicals contain alkaloids – a diverse group of nitrogen-containing compounds with high potential for biological activity. Our purpose is to use Quantitative Structure Activity Relationship (QSAR) models to identify potential adverse activities of alkaloids found in botanical products. Methods: The chemical compositions of 63 botanical species were found using multiple electronic resources, primarily "Dr. Duke's Phytochemical and Ethnobotanical Databases" (www.ars-grin.gov/duke). 179 distinct alkaloids (and 40 stereoisomers) were identified in these species. Two-dimensional molecular structures of these alkaloids were generated as machine-readable SMILES codes or .mol files, and submitted into approximately 100 validated QSAR toxicology models in each of three QSAR programs, including predictions for adverse reactions in human liver, kidney, bladder, or heart, rodent reproductive and development toxicity, genetic toxicity, and carcinogenicity testing. The QSAR modeling programs used were Model Applier (Leadscope), MC4PC (Multicase), and BioEpisteme (Prous). Results: 80% of the alkaloids were in the "chemical space" of 60% of the current models, including most human organ models, rodent developmental models, and carcinogenicity models. Microbe, neurotox, and reprotox simulations were insufficient to make predictions for many alkaloids. 35 of the alkaloids showed activity in at least 20% of the models. 33 of the alkaloids showed activity for at least half of the human cardiac models. Conclusion: Upon QSAR analysis, alkaloids in botanicals were found to present signals for certain types of toxicities, indicating additional studies may be necessary to establish safe levels.

PS 1113 PREDICTING MAXIMUM TOLERATED DOSE USING STRUCTURE-BASED SIMILARITY SEARCHING AND DOSE *VS.* EXPOSURE TIME DATA.

W. Liu[1,2], T. Dao[1,2], E. J. Matthews[1], N. L. Kruhlak[1], B. L. Minnier[1,2], L. G. Valerio[1] and R. Benz[1]. *[1]CDER / OPS / SRS / ICSAS, Food and Drug Administration, Silver Spring, MD and [2]GlobalNet Services, Rockville, MD.*

Computational methods for predicting the toxicity of pharmaceutical substances are currently being developed and implemented by the Informatics and Computational Safety Analysis Staff at the FDA's Center for Drug Evaluation and Research. A new method for predicting the maximum tolerated dose (MTD) in rodents for pharmaceuticals and other organic chemicals is presented in this study. A database of approximately 5000 chemicals was compiled from National Toxicology Program studies, FDA archives, and various literature sources. Molecular structure data were then linked to the dosage and exposure information for each chemical. MTDs were obtained for study durations ranging from 2 days to 2 years, with some durations being more highly represented, reflecting common regulatory requirements (15-day, 90-day, 180-day, 1-year, 2-year). Acute toxicity (LD50) study data were also harvested with an emphasis on oral routes of exposure. Sets of non-linear equations describing the change of MTD with exposure period were then derived for each compound. Modelable compounds were imported into Predictive Data Miner (Leadscope, Inc.), in which a similarity search using the Tanimoto coefficient was performed. Similarity searches using test compounds were then performed on the original dataset. Predictions of test compound MTD at different exposure times were made based on the time-dose equations of compounds sufficiently similar to each test chemical. Prediction performance was determined by adjusting the residuals of these predictions according to the degree of similarity between the test and training data set chemicals. The results of an external validation of this method are reported, indicating this method and the database are useful for predicting MTD in rodents.

PS 1114 ADVERSE EFFECTS OF PHARMACEUTICALS: CONSTRUCTION OF A RELATIONAL DATABASE OF IMMUNOLOGICAL AND PULMONARY ADVERSE EFFECTS USING FDA ARCHIVES, PHARMAPENDIUM, AND PUBLIC SOURCES.

R. Benz[1], T. Dao[1,2], W. Liu[1,2], E. J. Matthews[1], N. L. Kruhlak[1], B. L. Minnier[1,2] and L. G. Valerio[1]. *[1]CDER / OPS / SRS / ICSAS, Food and Drug Administration, Silver Spring, MD and [2]GlobalNet Services, Rockville, MD.*

The Informatics and Computational Safety Analysis Staff at the FDA's Center for Drug Evaluation and Research has created a database of drug adverse effects (AEs) and toxicology findings linked to drug chemical structure, class, clinical indication, and receptor target in humans. The database is being used to develop quantitative structure-activity relationship (QSAR) models that predict AEs of drugs. The preclinical, clinical, and post-marketing AE observations were obtained from: FDA's Spontaneous Reporting System, PharmaPendium (PP) software, and MicroMedex. PP includes information from FDA drug approval packages, Meyler's Side Effects of Drugs, drug monographs from Mosby's Drug Consult, FDA's Adverse Event Reporting System, and the published literature. PP's standard MedDRA vocabulary was employed for all AE endpoints and drug generic names in order to integrate the data from multiple sources. The total database contains ~4000 drug substances, ~10,000 AE endpoints, and ~10,000,000 AEs. To account for variations in AE reports due to different patient populations for each drug, exposure was estimated based upon the proportional reporting ratio (PRR) of reports for each drug expressed as a percentage of the total reports in the database. The PRR values were used to identify drugs with significant findings. This study reports an evaluation of two organ systems. The immune system included 1,030,961 reports corresponding to assorted hematological, dermatological, and immunological endpoints. The pulmonary system included 347,224 reports corresponding to breathing abnormalities, bronchospasms, laryngeal, respiratory tract, pulmonary disorders and additional endpoints. The results demonstrated that the AEs could be clustered into 52 endpoints that can be used for constructing models to predict immunological and pulmonary AEs of pharmaceuticals.

PS 1115 PREDICTION OF HUMAN ADVERSE IMMUNOLOGICAL AND PULMONARY EFFECTS USING MC4PC, BIOEPISTEME, AND PREDICTIVE DATA MINER SOFTWARE PROGRAMS.

T. Dao[1,2], W. Liu[1,2], E. J. Matthews[1], N. L. Kruhlak[1], B. L. Minnier[1,2], L. G. Valerio[1] and R. Benz[1]. *[1]CDER / OPS / SRS / ICSAS, Food and Drug Administration, Silver Spring, MD and [2]GlobalNet Services, Rockville, MD.*

The Informatics and Computational Safety Analysis Staff (ICSAS) at the FDA/CDER is currently conducting research in the use of in silico methods in predicting pulmonary and immunological adverse effects (AE) of drugs in humans. This research uses a novel AE database in conjunction with quantitative structure-activity relationship (QSAR) models created using MC4PC (MultiCASE, Inc.), BioEpisteme (Prous Institute for Biomedical Research), and Predictive Data Miner (Leadscope, Inc.). Significant AEs related to immunological and pulmonary endpoints were identified using a weight-of-evidence (WOE) approach that employed proportional reporting ratio (PRR) values of AEs to estimate patient population exposure and contingency table statistics to identify toxicologically related AE endpoints. Twenty-six immunological endpoints, and 26 pulmonary endpoints were modeled, using 1,638 modelable compounds. Because QSAR model predictive performance is affected by the ratio of active to inactive (A/I) drugs in the dataset, models were optimized by adjusting A/I ratios. All QSAR models individually exhibited high specificity (>80%), high coverage (>90%), but low sensitivity. Higher sensitivity was obtained using a WOE approach, utilizing the predictions of all three programs. Results indicated that AEs were correlated with both the clinical indications for which each drug was prescribed and to off-target mechanisms of action (MOAs) predicted by BioEpisteme.

PS 1116 PREDICTION OF CARCINOGENICITY USING TOXLITE STRUCTURE ACTIVITY RELATIONSHIP SOFTWARE.

J. Mayer, N. Dowla and M. Cheeseman. *FDA, College Park, MD.* Sponsor: M. Twaroski.

Toxlite, v1.900 (Multicase, Inc.) is a structure-activity relationship (SAR) analysis software program used to screen compounds for potential carcinogenicity. In a series of experiments, the predictive capability of Toxlite was examined using seven-hundred and ten compounds with TD50 values from the Carcinogenic Potency Database (CPDB)(http://potency.berkeley.edu/). The compounds were assessed via three different predictive outputs within the Toxlite program: the Food and Drug Administration's ICSAS (Informatics and Computational Safety Analysis Staff) call, case units, and biophores. The results of the Toxlite analysis were accumulated in a database with the lowest TD50 values from the CPDB and compared to the carcinogenicity calls (positive or negative) for compounds from the CPDB. Several subsets of data were then stratified by TD50, and examined for concordance, false positives, false negatives, specificity, and sensitivity when compared to the CPDB. It is concluded that for indirect food additives, the ICSAS call alone is not a reliable method of predicting carcinogenicity, but can be used in addition to case units and biophore data to predict carcinogenicity with high confidence. One interesting note is that experiments conducted using compounds in the Toxlite training set produced results similar to those obtained in experiments with no training set compounds.

PS 1117 STRUCTURE-ACTIVITY RELATIONSHIPS: SITE-SELECTIVE CARCINOGENESIS.

G. States, N. Malik, C. A. Carrasquer, S. L. Cunningham and A. R. Cunningham. *James Graham Brown Cancer Center, University of Louisville, Louisville, KY.*

Structure-activity relationship (SAR) models are can investigate the mechanisms of action of carcinogens and to predict the potential carcinogenicity of untested compounds. We describe here SAR analyses of site-selective rat carcinogens as described in the Carcinogenic Potency Database. The categorized data for the these models consisted of compounds determined to be carcinogenic to a specific organ and an equal number of compounds carcinogenic to (m)any other sites except the one of interest (e.g., kidney carcinogens and non-kidney carcinogens). Since both categories for the models were populated with carcinogens, these models are different from previous carcinogenesis models that sought to determine why chemicals cause cancer. Rather, these models seek to determine why carcinogens are only active at a certain site. We describe here several models for rat site-selective carcinogenesis (i.e., clitoral gland, hematopoietic system, kidney, liver, large intestine, mammary gland, lung, nasal cavity, small intestine, and uterus). Each model was parameter optimized and validated by leave-one-out methodology to determine concordance, sensitivity, specificity, and coverage. The best concordance for each model was: clitoral gland 82; hematopoietic system 73; kidney 76; liver 77; large intestine 75; mammary gland 78; lung 80; nasal cavity 81; small intestine 88; and uterus 80%. For comparison, a cat-SAR model based on 1049 carcinogens and noncarcinogens had a concordance of 73%. Considering the good predictivity of the models described here for organ selective carcinogenesis, we speculate that the structural information that they contain can lead to insight for organ-selective carcinogenesis. In essence, just as traditional SAR models of carcinogens and non-carcinogens identified potential electrophilic moieties associated with DNA interaction, these organ-selective models may similarly indentify structural moieties associated with chemical interactions with molecular targets relating to cancer and uniquely expressed in the carcinogen-sensitive tissue.

PS 1118 USING ALL THE DATA IN COMPREHENSIVE RISK ASSESSMENT OF THE MUTAGENIC POTENTIAL OF DRUGS.

C. Hasselgren, L. Carlsson and S. Boyer. *Safety Assessment, MÑlndal, Sweden.*

The Genotoxic potential in any candidate drug is carefully assessed during the discovery and development of new drugs. This is commonly done using in silico screens early on and continued with in vitro and in vivo experiments as the drug progresses closer to regulatory submission. In silico screens have several purposes, selection of compounds for experimental testing and/or to get early warning of any potential risk associated with the compound in the form of e.g. alerting substructures. We have previously reported a comprehensive warning system (Genetox Warning System, GWS) for assessing the mutagenic potential of our compounds. This system is built on Ames assay data from public sources such as NTP and MultiCASE but also includes our internal data. Any molecule submitted to the system is passed through a series of steps and the output lists i) structural near neighbours with experimental results (Positive and Negative), ii) alerting substructures iii) consensus Ames QSAR results consisting of three different QSAR models. A set of rules to aid the interpretation of the output and enhance the overall predictive performance was also derived and implemented. Using only QSAR predictions, accuracy is ~80-85% with sensitivity being slightly lower than specificity. To improve our assessments, further development of the GWS was undertaken to include data from other experimental assays, such as carcinogenicity, mouse lymphoma, chro-

mosome aberration etc. These data are available as exact matched or structural near neighbours. The validity of structural alerts was also improved by comparing the statistical significance of each alert for the different assays. Finally, all the data were combined in a weight of evidence approach to give an overall assessment of the genotoxic risk associated with each compound. This approach proved to enhance both the predictive accuracy and the breadth of chemical coverage.

PS 1119 COMPARATIVE EVALUATION OF (Q)SAR MODELS FOR PREDICTING GENOTOXICITY ENDPOINTS.

M. Osterloh-Quiroz[1], L. Kan[2], K. M. Kleinert[2] and D. R. Boverhof[2]. [1]*Toxicology and Environmental Research & Consulting, Dow Europe GmbH, Horgen, Switzerland and* [2]*The Dow Chemical Company, Midland, MI.*

New chemical regulations such as REACH are advocating the use of non-testing approaches to fill data gaps. The knowledge-based expert system DEREK, the rule-based statistical system TOPKAT and the hybrid expert system OASIS (TIMES) are among the QSAR models referred to in the European Chemical Agency's Guidance for REACH. However, the guidance does not provide an evaluation on the performance of these models. A comparative analysis of currently available QSAR models against experimental data is needed to gain experience surrounding the application of modeling approaches as they relate to chemical-induced toxicity. The Dow Chemical Company has generated extensive data on the genotoxic potential of a wide variety of chemical substances using the Ames test (mutagenicity) and the in vitro chromosome aberration assay (clastogenicity). This has provided a unique opportunity to evaluate currently available QSAR models against experimental data for two endpoints included in the basic information requirements for REACH. In the scope of this project, 40 chemicals were analyzed with the models DEREK, TOPKAT and OASIS for mutagenicity and/or clastogenicity followed by an evaluation of the model predictions in comparison with experimental test data. For the mutagenicity endpoint, the overall concordance between experimental data and predicted values was 72%, 69% and 72% with a specificity of 76%, 72% and 79% and a sensitivity of 57%, 57% and 43% for the models OASIS, TOPKAT and DEREK, respectively. For the clastogenicity endpoint, the overall concordance between experimental data and predicted values was 67% and 75% with a specificity of 79% and 89% and a sensitivity of 20% and 20% for the models OASIS and DEREK, respectively. Overall the performance of the three models was comparable, showing a high specificity but rather low sensitivity. The data presented will provide valuable insight for developing approaches for the application of (Q)SAR data to chemical safety assessments.

PS 1120 EVALUATION OF (Q)SAR MODELS FOR THE PREDICTION OF MUTAGENICITY POTENTIAL.

S. Ringeissen, R. Note, C. Dochez, N. Flamand, G. Ouédraogo-Arras and J. Meunier. *L'Oréal, Aulnay sous Bois, France.* Sponsor: E. Dufour.

(E-mail: sringeissen@rd.loreal.com)

The development of alternative methods to in vivo testing is critical to the cosmetic industry based on ethical reasons, the REACh reglementation and the 7th Amendment of the European Directive on Cosmetics. Alternative methods include in vitro assays and in silico models.

A number of in silico predictive (Q)SAR models are commercially available. Building an in silico strategy based on more than one such system is relevant considering the differences in the models (SAR versus QSAR, expert system versus artificial intelligence–based systems) and applicability domains (chemical space and toxicological endpoint coverage). The predictive performance of such models has to be assessed on a regular basis, given the chemical diversity and reactivity of new chemical entities, and regular updates in the software versions.

Three major commercially available computer-assisted prediction models were evaluated with regards to bacterial mutagenicity. Those systems include (i) Derek for Windows (DfW), a knowledge-based expert system; (ii) MULTICASE, an artificial intelligence expert system which dissociates each input molecule into fragments, and (iii) TIMES, a 3D QSAR system comprising a metabolism simulator. The mutagenicity test set selected for this evaluation contains chemicals with AMES data on 6 different Salmonella typhimurium strains, in the presence or the absence of metabolic activation (S9), and pre-incubation.

For each system, applicability domains and predictive performance are compared and discussed. It appears that such predictive systems provide a valuable support for the screening and categorization of chemicals in addition to further understanding of mechanistic rationale. Because our chemical space is not fully covered by these systems, there is a need for expanding their applicability domains by integrating in-house data.

PS 1121 COMPUTATIONAL APPROACHES FOR THE PREDICTION OF SKIN IRRITATION: EVALUATION AND IMPROVEMENT OF EXISTING TOOLS THROUGH DATA CATEGORIZATION AND ALERT EXTRACTION.

C. Yang[1], S. Ringeissen[2], R. Note[2], S. Loisel-Joubert[3], M. Lopez[2], C. Boulle[2], J. Ovigne[2], A. Trotier-Faurion[2], G. Ouédraogo-Arras[2] and J. Meunier[2]. [1]*Leadscope, inc., Columbus, OH,* [2]*L'Oréal, Aulnay sous Bois, France and* [3]*L'Oréal, Asni√®res-sur-Seine, France.* Sponsor: E. Dufour.

The 7th Amendment to the EU Cosmetics Directive has made in vitro and in silico approaches a key issue to warrantee the safety of products. A ban on animal testing for chemicals to be used in cosmetics comes into effect in the EU in March 2009 for acute toxicity, genotoxicity, and skin or eye irritation. Over the past years there have been great efforts to develop alternative strategy, including in silico methods that would comply with regulatory constraints. Some commercial and free software tools integrate global models targeting the 2009 endpoints. For the cosmetic industry, the predictive performance of such models has to be evaluated on chemical series of interest for: Chemical prioritization; Mechanistic understanding; and, Elaboration of regulatory dossiers by providing additional information. In the present study, skin irritancy (SI) data of chemicals representative of a cosmetic industry portfolio were used to (i) challenge some of the global models available and (ii) extract knowledge to improve existing tools. Models for prediction of SI available in the Derek for Windows (V10.0) and Toxtree (v1.50) software were evaluated. The Toxtree module integrates both inclusion-rules based on structural alerts and exclusion-rules based on a selection of physico-chemical parameters (PCP). Since no PCPs were submitted in the present evaluation, only structural rules were applied. To improve the existing models, data were categorized on the basis of the structural features generated by the Leadscope Enterprise software. Multivariate analysis was performed to identify Leadscope chemical features most relevant to skin irritation. Additional molecules were compiled from the RTECS database for chemical domain analysis and validation of new or refined structural alerts.

PS 1122 COMPARATIVE EVALUATION OF THREE (Q)SAR MODELS FOR PREDICTING DERMAL SENSITIZATION POTENTIAL.

L. K. Sosinski, D. R. Boverhof, M. Osterloh-Quiroz and M. R. Woolhiser. *Toxicology and Environmental Research & Consulting, The Dow Chemical Company, Midland, MI.*

Determination of the dermal sensitization potential of a chemical is a key component of the safety assessment process for registration. Regulatory legislation such as REACH encourages the use of animal alternatives to address toxicology endpoints, including sensitization. There are currently no validated in vitro approaches for the assessment of dermal sensitization potential, however, there are a number of in silico (Q)SAR models. (Q)SAR models with sensitization endpoints that are referenced under REACH include the knowledge-based expert system DEREK, the rule-based statistical system TOPKAT, and the hybrid expert system TIMES. The assessment of the comparative predictive accuracy of these models has not been conducted but is necessary for their effective utilization in chemical safety assessments. To address this, the predictive accuracy of these models was compared to previous in vivo evaluations on the sensitization potential of 65 industrial and agricultural chemicals. In vivo data were derived from guinea pig (n = 50 chemicals), mouse LLNA (n = 21) and human (n = 7) evaluations, and consisted of a balance of positive and negative sensitization results. Comparison of the in vivo data to the results of each (Q)SAR model revealed comparable predictive accuracies with concordances of 60, 60 and 55% for DEREK, TOPKAT and TIMES, respectively. Sensitivity was comparable for DEREK and TOPKAT with values of 44 and 48%, while TIMES displayed a sensitivity of 66%. Specificity was also similar between DEREK and TOPKAT with values of 72 and 69%, while TIMES displayed a specificity of 47%. Data were further stratified to evaluate the predictive value relative to each in vivo model (guinea pig, mouse or human), and yielded similar results. Overall these data indicate only a modest performance accuracy for each of the in silico models and will provide valuable insight for developing strategies for the incorporation of (Q)SAR sensitization data in chemical safety assessments.

PS 1123 CHEMICAL REACTIVITY IN METABOLISM AND DEGRADATION REACTIONS IN RISK ASSESSMENT WORKFLOW.

J. Gasteiger[1], A. Tharkov[1], L. Terfloth[1] and C. Yang[2]. [1]*Molecular Networks GmbH, Erlangen, Germany and* [2]*Leadscope, inc., Columbus, OH.*

Initiatives such as Canadian Domestic Substance List and REACH (Registration, Evaluation, Authorisation and Restriction of Chemicals) and 7th Amendment for Cosmetic Directive in European Union have put heavy emphasis on non-testing

methods for hazard and risk assessment of chemicals. In particular, computational methods have become increasingly important for profiling environmental fate and evaluating toxicity of chemical compounds, which lead to risk assessment. Many of the currently available computational methods do not consider chemical reactivity and fate either in environment and biological compartments. In this paper, we will present a chemoinformatics approach for predicting chemical reactivity in metabolism and degradation reactions. Structural alerts on chemical reactivity can be used as indicators for safety issues due to reactivity. The application of reaction rules which combine reaction types with a physicochemical evaluation of the reactions allows a more sophisticated assessment of a chemical compound. The integration of the prediction of chemical reactivity into the workflow of the hazard and risk assessment process will be demonstrated. This paper will also report on two tools funded by ECB [1]: 1) START (Structural Alerts for Reactivity in Toxtree [2]); 2) CRAFT (Chemical Reactivity and Fate Tool implemented in Ambit [3]). [1] European Commission's Joint Research Centre (JRC), Consumer Product Safety and Quality (CPS&Q) Unit, formerly known as European Chemicals Bureau (ECB, http://ecb.jrc.it/). [2] An open source decision tree application to estimate toxic hazard (http://ambit.acad.bg/toxTree/) [3] An open source chemoinformatics data management system (http://ambit.acad.bg/)

PS 1124 QUANTITATIVE STRUCTURE TOXICITY RELATIONSHIPS (QSTR) MODELS FOR PREDICTING ACUTE/SUB-ACUTE AND SUB-CHRONIC/CHRONIC ADVERSE EFFECT LEVELS.

M. Easterling[1], A. Tropsha[2], L. Ye[2], J. Pirone[4], H. Zhu[2], T. Martin[3] and C. Moudgal[3]. *[1]SRA International, Durham, NC, [2]University of North Carolina, Chapel Hill, NC, [3]ORD/NHSRC, U.S. EPA, Kansas City, KS and [4]National Center for Computational Toxicology (NCCT), U.S. EPA, RTP, NC.*

An important step in dose-response assessment is the identification of a critical effect level. The measure of critical effect often is presented as a no-observed-adverse-effect level (NOAEL), or a lowest-observed-adverse-effect level (LOAEL). Quantitative Structure Toxicity Relationships (QSTR) models are mathematical models that may be used to predict toxicity from physical characteristics of a chemical structure. In this research, QSTR models were developed to estimate critical effect levels from chemical structure. The modeling focus was on machine learning methods, Random Forest, k-Nearest Neighbor, and Support Vector Machine, as well as models using Partial Least Squares. The models were built using over 2700 toxicity values and 472 unique chemicals. Models were built with three commercial descriptor sets (Dragon, MOE, Molconnz) and one descriptor set from the US EPA. The performance of each model was assessed using a validation set not used in model development. These models show that it is very reasonable to predict critical effect values from chemical structure based on predictions of the validation set. The mean absolute error of the log scaled LOAEL and NOAEL values was close to 0.5 across models, giving confidence in the order of magnitude of the predictions. In addition, the applicability domains of these models were also evaluated Among the fours modeling methods used, all methods, with the exception of PLS, performed equally well. The models can be used as an additional tool for dose-response assessment when experimental data pertaining to critical effect levels do not exist.
Disclaimer: This research does not necessarily represent the views of the U.S. Environmental Protection Agency.

PS 1125 COMBINATORIAL QSAR MODELING OF RAT ACUTE TOXICITY BY ORAL EXPOSURE.

H. Zhu[1, 2], T. M. Martin[3], L. Ye[1, 2], D. M. Young[3] and A. Tropsha[1, 2]. *[1]School of Pharmacy, University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Carolina Center for Computational Toxicology, Chapel Hill, NC and [3]Sustainable Technology Division, National Risk Management Research Laboratory, Office of Research and Development, U.S. EPA, Cincinnati, OH.*

Few Quantitative Structure-Activity Relationship (QSAR) studies have successfully modeled large, diverse mammalian toxicity endpoints. In this study, we have applied a combinatorial QSAR approach in the development of robust and predictive models of chemical acute toxicity of rat by oral exposure. To this end, we have compiled a comprehensive dataset of 7385 compounds with their median lethal dose (LD50) values in the oral exposure test of rats. To compare the predictive power of our models with an available commercial toxicity predictor, we used the same training set of 3472 compounds as the TOPKAT (Toxicity Prediction by Komputer Assisted Technology) software. The remaining 3913 compounds which were not present in the TOPKAT training set were used as the external validation set for our toxicity models. We have developed 7 different types of QSAR LD50 models for the modeling set. The internal prediction accuracy for the modeling set ranged from 0.52 to 0.96 as measured by the leave-one-out cross-validation correlation coefficient (Q2). The prediction accuracy for the external validation set ranged from 0.24 to 0.70 (linear regression coefficient R2). The use of applicability domain threshold implemented in most models generally improved the external prediction accuracy but led to the decrease in chemical space coverage. Finally, several consensus models were developed by averaging the predicted LD50 for every compound using all 7 models. We find that consensus models afford higher prediction accuracy for the external validation dataset with the highest coverage as compared to individual constituent models. The best validated LD50 models developed by our collaboration can be used as reliable computational predictors of in vivo acute toxicity and will be made publicly available from the participating laboratories.

PS 1126 RESOLVIN E2 PROTECTS AGAINST ACETAMINOPHEN (AA)-INDUCED HEPATOTOXICITY.

C. R. Gardner[1], L. B. Joseph[1], J. A. Cervelli[1], G. Lambert[2], N. Bremer[1], E. S. Stenroos[2], J. D. Laskin[2], B. W. Spur[3], A. Rodriguez[3] and D. L. Laskin[1]. *[1]Rutgers University, Piscataway, NJ, [2]UMDNJ-RWJ Med School, Piscataway, NJ and [3]UMDNJ-SOM, Stratford, NJ.*

Ingestion of toxic doses of AA causes centrilobular hepatic necrosis. Evidence suggests inflammatory mediators released by cytotoxic macrophages contribute to the pathogenic process. Resolvins are naturally occurring anti-inflammatory mediators derived from eicosapentaenoic acid. They inhibit production of IL-1β, IL-12, TNFα and nitric oxide, and suppress leukocyte chemotaxis. In the present studies, we analyzed the protective effects of resolvins against AA-induced hepatotoxicity. Treatment of B6129F2 mice with AA (300 mg/kg, i.p.) induced hepatotoxicity resulting in increases in serum transaminase levels within 3 hr peaking at 24 hr. This was correlated with histological evidence of centrilobular hepatic necrosis. Pretreatment of the mice with resolvin E2 (RvE2) (50 μg/kg/day, i.p., 3 days) abrogated these effects. TNFα exerts its biologic activity by binding to two distinct cell surface receptors, TNFR1 and TNFR2. AA-induced hepatotoxicity was associated with increased expression of TNFR2 in the liver. This response was response was inhibited by RvE2 pretreatment of the mice. RvE2 also reduced hepatic expression of cyclooxygenase-2, which mediates the generation of proinflammatory eicosanoids. Heme oxygenase (HO-1) is a potent antioxidant known to protect against AA-induced liver injury. Western blotting and immunohistochemistry (IHC) demonstrated that HO-1 was up-regulated in livers of mice treated with AA. This was predominantly observed in liver macrophages. RvE2 treatment, by itself, also upregulated HO-1 in the liver, but had no effect on expression of this antioxidant in AA treated mice. Similarly, RvE2 upregulated levels of glutathione in the liver. These data suggest that RVE2 may be useful in mitigating AA-induced hepatotoxicity by its ability to block the generation or activity of inflammatory mediators and upregulate antioxidants (Supported by NIH GM034310 and ES005022).

PS 1127 S-ADENOSYLMETHIONINE (SAME) REVERSAL OF ACETAMINOPHEN (APAP) EFFECTS ON HEPATIC GLUTATHIONE PEROXIDASE AND HEPATIC SAME LEVELS.

T. Williams[2], J. Brown[1], J. G. Ball[1], A. Hogsett[1] and M. Valentovic[1]. *[1]Pharmacology, Physiology and Toxicology, Marshall University School of Medicine, Huntington, WV and [2]University of Charleston, Charleston, WV.*

Overdose of the over the counter analgesic acetaminophen (APAP) is associated with hepatic damage. Previous work form our laboratory and by others have shown that S-adenosyl-L-methionine (SAMe) is protective for APAP induced hepatotoxicity. This study tested the hypotheses that: 1) SAMe reduces APAP mediated oxidative stress by maintaining glutathione peroxidase activity and 2) SAMe treatment prevents APAP mediated decline in total hepatic SAMe levels. Male C57BL/6 mice (16-25 g) were randomly divided into 4 groups (n=5/group): Vehicle (VEH), SAMe, APAP and SAMe+APAP. Mice were fasted overnight, injected intraperitoneal (ip) with water (VEH; 5ml/kg) or 250 mg/kg APAP (15 ml/kg) followed 1h later by ip injection of 1.25 mmol/kg SAMe. Plasma and liver were collected 4 or 6h after APAP administration. SAMe treatment did not alter hepatic function as plasma ALT and liver weight (wt) were comparable to VEH values. APAP administration increased plasma ALT levels and hepatic liver wt. when compared to VEH and SAMe groups confirming hepatic toxicity. Hepatic glutathione peroxidase activity was diminished ($p<0.05$) 4 and 6 h after APAP injection compared to VEH. APAP mediated decline in hepatic glutathione peroxidase activity was partially corrected at 4 hr in the SAMe+APAP when compared to the APAP treated mice. Total hepatic SAMe levels were diminished 4 h after APAP treatment when compared to the VEH and SAMe groups. Depletion of total hepatic SAMe levels was prevented

in the SAMe+APAP group. These findings indicate that SAMe partially protects the liver from APAP induced oxidative stress and depletion of hepatic SAMe levels. (Supported by NIH Grant 5P20RR016477 to the West Virginia IDeA Network for Biomedical Research Excellence).

PS 1128 TEMPORAL STUDY OF ACETAMINOPHEN (APAP) AND S-ADENOSYL-L-METHIONINE (SAME) EFFECTS ON SUBCELLULAR HEPATIC SAME LEVELS AND METHIONINE ADENOSYLTRANSFERASE (MAT) EXPRESSION.

J. Brown[1], J. B. Ball[1], A. A. Hogsett[1], T. Williams[2] and M. Valentovic[1]. *[1]Pharmacology, Physiology and Toxicology, Marshall University School of Medicine, Huntington, WV and [2]University of Charleston, Charleston, WV.*

Acetaminophen (APAP) is the leading cause of drug induced liver failure in the United States. The antidote, N-acetylcysteine, is most effective when given within 8 hours of APAP overdose. S-adenosyl-L-methionine (SAMe) is the principle biological methyl donor participating in methylation of nucleic acids, proteins, and phospholipids. SAMe also participates in the transsulfuration pathway to provide cellular glutathione. SAMe is critical for growth of liver cells which would be important in recovery of APAP toxicity. SAMe is synthesized in cells through the action of methionine adenosyltransferase (MAT). MAT I/III is constitutively expressed in cells, while MAT II is expressed in regenerating cells. This study tested the hypothesis that hepatic mitochondrial SAMe levels are decreased by APAP toxicity. A separate experiment examined alterations of MAT expression in response to APAP toxicity. Male C57BL/6 mice (16-22 grams) were treated with vehicle (VEH; water 15ml/kg ip injections). 250 mg/kg APAP (15 ml/kg, ip) or SAMe (1.25 mmol/kg) which was administered 1 h after APAP injection (SAMe and SAMe+APAP). Hepatic tissue was collected 4 and 6 h after APAP administration. SAMe levels were determined by HPLC analysis. MAT expression was examined by Western blot. APAP depressed mitochondrial SAMe levels at 4 and 6 h relative to the VEH group. SAMe administration following APAP (SAMe+APAP) prevented APAP associated decline in mitochondrial SAMe levels. Hepatic MAT II expression was not present at 4 hr in any of the groups. In conclusion, the maintenance of SAMe may provide benefit in preventing mitochondrial damage associated with APAP toxicity. (Supported by NIH Grant 5P20RR016477 to the West Virginia IDeA Network for Biomedical Research Excellence).

PS 1129 ANALYSIS OF CYTOKINES AND RELATED SIGNALING MOLECULES IN A CO-CULTURE MODEL OF PRIMARY MOUSE HEPATOCYTES AND KUPFFER-CELL ACETAMINOPHEN EXPOSURE.

C. Tatis-Rios[1], D. Ferreira[2] and J. Manautou[2]. *[1]Science and Technology, Universidad Metropolitana, San Juan, PR and [2]Pharmaceutical Science, University of Connecticut, Storrs, CT.*

Acetaminophen (APAP) is a popular pain killer that produces liver damage when ingested at high doses. Kupffer cells are liver macrophages that become activated with toxic APAP treatment. Depletion of Kupffer cells prior to APAP treatment protects mice against hepatotoxicity. In the present study, a mouse Kupffer cell and a hepatocyte co-culture system were used to investigate the interaction of these cell types during APAP toxicity and the gene expression profile of cytokines. Kupffer cells and hepatocytes were isolated from naïve C57Bl/6J mice and cultured. Co-cultures and mono-cultures were exposed to APAP (50uM) and cytotoxicity was determined by lactate dehydrogenase (LDH) leakage into the culture media at 24 hr. Cytokine gene expression was analyzed by real-time PCR at 6 and 24 hr after APAP. Treatment of hepatocytes with APAP resulted in a significant release of LDH into the media as compared to control hepatocytes. In contrast, LDH released into the media was significantly less when hepatocytes were co-cultured with Kupffer cells, indicating that Kupffer cells protect hepatocytes from APAP toxicity. Tumor necrosis-alpha (TNFα) gene expression was increased only when hepatocytes were co-cultured with Kupffer cells either in the presence or absence of APAP. Gene expression for all interleukins examined (IL-13 and Il-1β) were elevated only in mono-cultures of hepatocytes exposed to APAP and not in control hepatocytes or any of the co-cultured groups of cells. In addition, nitric oxide synthase 2 and prostaglandin synthase 2 gene expressions were also elevated only in APAP-treated hepatocytes. By contrast, cyclooxygenase-1 gene expression was higher in co-cultures of hepatocytes and Kupffer cells exposed to APAP. Collectively, these results indicate that Kupffer cells protect hepatocytes from APAP toxicity and the presence of Kupffer cells along with hepatocytes in culture is needed for the expression of certain cytokines in response to APAP.

PS 1130 INDUCTION OF HEAT SHOCK PROTEIN 70 BY POLAPREZINC INHIBITS ACETAMINOPHEN-INDUCED HEPATOTOXICITY IN MOUSE PRIMARY HEPATOCYTES.

T. Nishida[1], T. Matsura[1], J. Nakada[2], Y. Ohta[3] and K. Yamada[1]. *[1]Department of Pathophysiological and Therapeutic, Tottoti University Faculty of Medicine, Yonago, Japan, [2]Department of Anesthesiology, Aichi Cancer Center Hospital, Nagoya, Japan and [3]Department of Chemistry, Fujita Health University School of Medicine, Toyoake, Japan.*

Polaprezinc, an anti-ulcer drug developed in Japan, is a chelate compound consisting of zinc and L-carnosine. In this study, we examined the effect of polaprezinc and its components, zinc and L-carnosine against acetaminophen (APAP) toxicity in mouse primary hepatocytes. All studies were carried out in accordance with the National Institutes of Health Guide for the Care and Use of Laboratory Animals. Hepatocytes were treated with 100 μmol/L polaprezinc, 100 μmol/L ZnSO4 or 100 μmol/L L-carnosine for 9 h and then exposed to 10 mmol/L APAP. The effects were evaluated by cell viability, lipid peroxide content and heat shock protein 70 (HSP70) expression. The cell viability decreased to 61% at 12 h after APAP exposure. Treatments with polaprezinc and ZnSO4 9 h before APAP increased cell viability to 97% and 100%, respectively. In contrast, L-carnosine treatment failed to improve cell viability (62%). The lipid peroxide content increased to 2.1-fold of normal level at 12 h after APAP exposure. Treatment with polaprezinc or ZnSO4 9 h before APAP exposure significantly reduced lipid peroxide content to normal level. HSP70 expressions 9 h after polaprezinc and ZnSO4 treatments increased 3.9- and 6.4-fold of control level, respectively. L-carnosine treatment did not increase HSP70 expression. Intracellular zinc level reached maximum 1 h after polaprezinc and ZnSO4 treatments (1.5- and 1.7-fold of control level, respectively). These results indicate that polaprezinc, in particular its zinc component, induces HSP70 expression, and inhibits lipid peroxidation, resuting in an improved viability in mouse primary hepatocytes.

PS 1131 MECHANISM OF PROTECTION BY METALLOTHIONEIN AGAINST ACETAMINOPHEN HEPATOTOXICITY.

C. Saito, H. Yan and H. W. Jaeschke. *Pharmacology, Toxicology & Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Acetaminophen (APAP) overdose is the most frequent cause of drug-induced liver failure in the US. Metallothionein (MT) gene expression attenuates APAP-induced liver injury. However, the mechanism of this protection remains incompletely understood. To address this issue, fasted C57Bl/6 mice were treated with 13.5 mg/kg zinc chloride (s.c.) for 3 days to induce MT. Twenty-four hours after the last dose of zinc, the animals received 300 mg/kg APAP. After 6 h and 24 h, groups of animals were sacrificed and liver injury (plasma ALT activities, area of necrosis), DNA fragmentation, peroxynitrite formation (nitrotyrosine staining), MT expression, and hepatic glutathione (GSH), glutathione disulfide (GSSG) levels were determined. APAP alone caused severe liver injury with oxidant stress (increased GSSG levels), peroxynitrite formation and DNA fragmentation, all of which were attenuated by zinc induced MT expression. However, the severity of hydrogen peroxide-induced cell injury in isolated murine hepatocytes was dependent on the intracellular GSH levels but not on MT expression. These data suggest that the protective effect of MT in vivo is not due to the direct scavenging of reactive oxygen and peroxynitrite. Thus, MT expression has to prevent the initiation of the oxidant stress. However, zinc treatment had no effect on the early GSH depletion kinetics after APAP administration, which is an indicator of the metabolic activation of APAP to its reactive metabolite NAPQI. Most of the zinc-induced MT protein was found in the cytosol of hepatocytes in the midzonal area. Since it is well known that MT can covalently bind NAPQI, the most likely explanation for our in vivo and in vitro findings is that MT scavenges some of the excess NAPQI after GSH depletion and thus prevents covalent binding to mitochondria, which is the trigger for the mitochondrial oxidant stress. (Supported in part by NIH grant R01 DK070195)

PS 1132 COMPARATIVE ANALYSIS OF SHORT-TERM *VS.* LONG-TERM CULTURES OF PRIMARY MOUSE HEPATOCYTES FOR MODELING *IN VIVO* RESPONSES TO ACETAMINOPHEN.

K. A. Fay, C. C. White, J. Wilkerson, F. M. Farin and T. J. Kavanagh. *Environmental and Occupational Health, University of WA, Seattle, WA.*

Maintaining differentiated function of primary mouse hepatocytes (PMHs) in culture is exceptionally difficult. Relative success appears to be achieved by culturing PMHs with a serum-free chemically defined medium supplemented with 2.25%

dimethylsulfoxide (DMSO) and 5 nM epidermal growth factor (EGF). Furthermore, PMHs appear to dedifferentiate during the first week in culture, and then recover some liver-specific functions, peaking at 3 weeks. Comparing PMHs isolated from male C57BL/6 mice and cultured for less than 24 hours to those cultured for 3 weeks, some advantages are apparent in the long-term cultures. PMHs remain fairly isolated shortly after attachment whereas by three weeks, they orient into cords. Western immunoblotting indicates that albumin, GSTα, and Cyp1A1 are all upregulated at 3 weeks, while GSTπ is slightly downregulated. ATP levels are depleted post-isolation, but dramatically recover (70 fold) after 3 weeks in culture. RT-PCR results indicate that the 3 week cultures treated with 10 mM acetaminophen (APAP) mimic better in vivo APAP treatments (300 mg/kg). The in vivo 6 hr treatment was better represented by a 6 hr treatment in vitro than a 2 hour treatment in vitro, suggesting the toxicokinetics in vivo and in vitro may be similar. Further support for similar toxicokinetics is found in the peak appearance of APAP-protein adducts in APAP-treated cultures after 2 hours of treatment, which is similarly observed in vivo. This work was supported by NIEHS grants 1U19ES11387, R01ES016189 and P30ES07033.

PS 1133 GENE EXPRESSION PROFILES IN LIVERS FROM DICLOFENAC-TREATED RATS REVEAL INTESTINAL BACTERIA-DEPENDENT AND -INDEPENDENT PATHWAYS ASSOCIATED WITH LIVER INJURY.

X. Deng[1], E. Sparkenbaugh[1], M. Liguori[2], J. Waring[2], E. Blomme[2], P. Ganey[1] and R. Roth[1]. *[1]Michigan State University, East Lansing, MI and [2]Abbott Laboratories, Abbott Park, IL.*

Diclofenac (DCLF) is a nonsteroidal anti-inflammatory drug (NSAID) that is associated with idiosyncratic adverse drug reactions (IADRs) in humans. Previous studies revealed a crucial role for intestine-derived bacteria and/or lipopolysaccharide (LPS) in DCLF-induced hepatotoxicity. We explored further this mechanism by conducting gene expression analysis of livers from rats treated with LPS or a hepatotoxic dose of DCLF (100mg/kg) with or without oral antibiotic pretreatment. K-Means clustering revealed similarity between the gene expression profiles of the toxic DCLF dose group and the LPS group. Genes for which expression was altered by DCLF were divided into two groups: genes with expression altered by antibiotic treatment and those unaffected by antibiotics. The former group of genes represented the ones for which DCLF-induced alterations in expression depended on intestinal bacteria. The expression of the latter group of genes was likely changed by direct effect of DCLF rather than by intestinal bacteria. Functional analysis of genes in the former group revealed fatty acid metabolism, protein transport and trafficking as well as LPS-related signaling, which further suggested a role for bacterial endotoxin in the liver injury. Functional analysis of genes in the latter group revealed changes in signaling pathways related to inflammation, hypoxia, oxidative stress, the aryl hydrocarbon receptor and peroxisome proliferator-activated receptor alpha (PPARα). Hypoxia occurred in the livers of rats treated with DCLF, and in vitro hypoxia rendered hepatocytes sensitive to DCLF-induced cytotoxicity. These results suggest that both intestinal bacteria-dependent and –independent mechanisms contribute to DCLF-induced hepatotoxicity and that hypoxia plays an important role in the pathogenesis. (Supported in part by NIH grant GM 75865.)

PS 1134 HEPATOTOXIC INTERACTION OF SULINDAC WITH LIPOPOLYSACCHARIDE: ROLE OF THE HEMOSTATIC SYSTEM.

W. Zou[1], S. S. Devi[2], E. Sparkenbaugh[2], H. S. Younis[3], R. A. Roth[2] and P. E. Ganey[2]. *[1]Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI, [2]Pharmacology and Toxicology, Center for Integrative Toxicology, Michigan State University, East Lansing, MI and [3]Pfizer Global Research and Development, Drug Safety R&D, San Diego, CA.*

Sulindac (SLD) is a nonsteroidal anti-inflammatory drug (NSAID) that has been associated with a greater incidence of idiosyncratic hepatotoxicity in human patients than other NSAIDs. In previous studies, lipopolysaccharide (LPS)-induced inflammation potentiated SLD-mediated liver injury in rats. Neither SLD nor LPS alone caused liver injury. The goal of this study was to evaluate the role of the coagulation system in SLD/LPS hepatotoxicity. Cotreatment with SLD/LPS led to increased activity of serum biomarkers of both hepatocellular injury and cholestasis. Histological evidence of liver damage was found only after SLD/LPS cotreatment. Thrombin-antithrombin dimer, a biomarker of coagulation system activation, as well as plasminogen activator inhibitor-1, a down-regulator of the fibrinolytic system, was elevated in the plasma of SLD/LPS-cotreated rats. As a result of activation of hemostasis induced by SLD/LPS cotreatment, fibrin and hypoxia were present in livers of cotreated rats before the onset of the hepatotoxicity. Therefore, we tested the hypothesis that LPS and SLD interact to cause liver injury by a mechanism that involves the hemostatic system. Pretreatment of rats with heparin reduced hepatic fibrin deposition and hypoxia and protected against liver injury induced by SLD/LPS cotreatment. These results indicate that the hemostatic system is activated by SLD/LPS cotreatment and plays an important role in the development of SLD/LPS-induced liver injury. (Supported by NIH GM075865 and ES004139.)

PS 1135 ACTIVATION OF CASPASE-8, BUT NOT CALPAIN, IS CRITICAL IN DICLOFENAC-INDUCED BID TRUNCATION AND MITOCHONDRIAL PERMEABILIZATION IN HUMAN HEPATOCYTES.

V. M. Kale and U. A. Boelsterli. *Pharmaceutical Sciences, University of Connecticut, Storrs, CT.*

Diclofenac (DCF)-induced lethal cell injury to cultured human hepatocytes is a cellular model for reactive metabolite-mediated mitochondrial permeabilization and cell death. We have previously demonstrated that an oxidative metabolite of DCF causes increases in $[Ca^{2+}]_c$, which is critical for cleavage of the cytosolic protein Bid and which results in mitochondria-mediated apoptosis. However, the signaling pathways that link $[Ca^{2+}]_c$ and Bid truncation are unknown. The aim of this study was to explore the mechanistic role of various death proteases that activate Bid and thus initiate mitochondrial permeabilization. Immortalized human hepatocytes (HC-04) exposed to cytotoxic concentrations of DCF (>500 μM) for up to 48 h underwent apoptotic cell death as demonstrated by LDH release and staining of apoptotic nuclei with Hoechst 33342. As early as 4 h, DCF increased the mitochondria-specific production of superoxide as demonstrated with the mitochondrially-targeted fluorescent probe, mito-HE (1 μM) using superoxide-specific new assay conditions (396 nm exc/580 nm ems). Diclofenac (1 mM) caused activation of caspase-8 that became apparent at 12 h and which decreased to control levels at 24 h. The caspase-8 inhibitor, Z-IETD-FMK (10 μM) significantly decreased the extent of DCF-induced cell injury. In contrast, calpain was activated and remained high at 6, 12, 18, and 24 h. The calpain inhibitor-III, Z-Val-Phe-CHO (500 nM) blocked calpain activity but failed to rescue HC-O4 cells from DCF-induced apoptosis. Combined treatment of cells with DCF and cyclosporin A (2 μM), an inhibitor of mitochondrial permeabilization, completely abolished caspase-8 activation, suggesting a likely mitochondrial origin of procaspase-8. Collectively, these results indicate that calcium- and/or superoxide-mediated activation of caspase-8, but not calpain, is critically involved in mitochondrial permeabilization and cell death induced by DCF in hepatocytes.

PS 1136 LIVER EFFECTS IN MICE GIVEN TRICHLOROACETIC ACID (TCA) IN A 14-DAY DRINKING WATER STUDY ARE PPAR-DEPENDENT.

P. Dugard[1] and C. Bevan[2]. *[1]Halogenated Solvents Industry Alliance, Inc., Arlington, VA and [2]The Sapphire Group, Inc., Dayton, OH.*

Exposure of mice to perchloroethylene (perc) is known to increase peroxisomes and cell proliferation in the liver, hepatocellular hypertrophy, and liver tumors. TCA is the major metabolite of perc and is known to induce the same responses, including tumors, in the livers of mice when given in drinking water. This study was conducted to determine whether the liver effects seen in mice exposed to TCA in drinking water are PPARα-dependent. Male and female B6C3F1 mice, male 129/sv wild-type (WT) and male PPARα-null mice were given 0, 1 or 2.5 g/L TCA in drinking water for 5 (male B6C3F1 mice only) or 14 days. Liver tissue was examined by light and electron microscopy, cell proliferation was quantified by BrdU labeling, and apoptosis was measured by using Tdt-mediated dUTP nick end labelling (TUNEL) staining. Effects in B6C3F1 mice were: increased relative liver weights (1 and 2.5 g/L); increased palmitoyl CoA oxidase activity, with males > females (1 and 2.5 g/L); increased number and volume density of peroxisomes (1 and 2.5 g/L); non-statistically significant increase in cell proliferation in males at 5 days (316% and 267%, respectively); dose-dependent decrease in apoptosis in males at 5 days (12% and 31%, respectively); and eosinophilia and/or hepatocyte hypertrophy (1 and 2.5 g/L). Similar effects were seen in the WT male mice at 14 days, except that there was no change in cell proliferation. Palmitoyl CoA oxidase activity was increased to a greater extent in male WT mice compared to B6C3F1 mice. No liver effects were seen in the PPARα-null mice except for evidence of fatty vacuolation in all PPARα-null mice, which appeared more widespread in the treated versus non-treated mice. Thus, peroxisome proliferation occurring in the livers of TCA-treated mice is dependent on PPARα. The results also suggest that perc-induced liver effects in mice are mediated by PPARα.

PS 1137 EFFECT OF PPARα AGONISM DURING PRE-NATAL DEVELOPMENT.

P. S. Palkar, J. E. Foreman, C. R. Anderson and J. M. Peters. *Vet Sci, Pennsylvania State University, State College, PA.*

Recent work indicates that PPARα is required to mediate perfluorooctanoic acid (PFOA)-induced post-natal lethality but the mechanisms identifying this effect are uncertain. The present study examined the effect of administering two PPARα ag-

onists (clofibrate or Wy-14,643) on pre- and post-natal development using wild-type, PPARα-null or PPARα humanized mice. Mice were mated overnight, and the presence of a copulatory plug was indicative of pregnancy and considered gestation day (GD) 0. Plugged female mice were fed either a control diet or one containing clofibrate (0.5%) or Wy-14,643 (0.005%) diet until GD18. These concentrations of PPARα agonists were chosen to potentially model exposure to PFOA which is a considerably less potent PPARα activator as compared to Wy-14,643. Mice were euthanized on GD18 to isolate maternal and fetal livers and assess developmental parameters in the dam and fetuses. No significant changes in the maternal weight gain and average uterine weight between treatment groups were observed. An increase in relative maternal liver weight was found in response to clofibrate and Wy-14,643 in wild-type mice and this effect was not observed in similarly treated PPARα-null mice. An increase in relative liver weight in fetuses was not found in response to either PPARα agonist. Additionally, no significant changes in average fetal weight, crown:rump ratio or placental weight were found. Interestingly, the mRNA levels of CYP4A10 and acyl-CoA oxidase (Aco), markers of PPARα activation, were significantly increased by clofibrate and Wy-14,643 in wild-type maternal and fetal livers but not in PPARα-null mice. These results demonstrate clear PPARα-dependent changes in both the maternal and fetal compartments. Whether these changes lead to differences in post-natal lethality is currently being examined in ongoing studies. Additionally, whether there is a species difference in the responses will be determined from the studies with PPARα humanized mice. (Supported by unrestricted gifts from 3M Company and Dupont Haskell Global Centers of Health and Environmental Sciences).

PS 1138 CHRONIC ALCOHOL CONSUMPTION INCREASES CYCLOPHILIN D CONTENT IN LIVER MITOCHONDRIA.

A. L. King and S. M. Bailey. *Environmental Health Sciences, University of Alabama at Birmingham, Birmingham, AL.*

Previously it has been shown that chronic alcohol consumption increases the sensitivity of mitochondria to undergo the permeability transition, which leads to impaired energy conservation and hepatotoxicity. The mitochondrial permeability transition pore (MPTP) refers to the opening of a "pore" due to assembly of an oxidant and calcium sensitive protein complex comprised of the voltage dependent anion channel (VDAC), the adenine nucleotide translocator (ANT), and cyclophilin D (CypD). Herein, we examine whether increased alcohol-dependent sensitivity to MPTP induction is due to alterations in MPTP proteins and the pro-apoptotic protein, apoptosis inducing factor (AIF). For this, male Sprague Dawley rats were pair-fed control or alcohol-containing diets for 5 weeks and calcium-mediated induction of the MPTP was measured using the swelling assay. Levels of VDAC, ANT, CypD, and AIF were measured by western blot. Liver mitochondria from alcohol-fed rats were more sensitive to calcium induced MPTP opening than controls. We observed a significant increase in VDAC and CypD proteins in mitochondria from alcohol-fed rats compared to controls, whereas there was no change in ANT. It is proposed that CypD binding to ANT is increased by oxidative stress and that this interaction facilitates MPTP induction via a conformational change in ANT. Levels of AIF were also elevated in the alcohol group compared to controls. While the normal function of AIF is unclear, AIF released from mitochondria during apoptosis moves to the nucleus and contributes to DNA fragmentation. Taken together, these results indicate that the increased alcohol-dependent sensitivity to MPTP induction in liver mitochondria may be related to an alteration in the levels of the proteins that comprise the MPTP complex and increased levels of pro-apoptotic proteins. Importantly, increased CypD in alcohol exposed mitochondria may increase the sensitivity to MPTP induction contributing to mitochondrial dysfunction, ATP depletion, increased oxidant production, and hepatocyte cell death.

PS 1139 ACUTE ETHANOL-INDUCED LIVER MITOCHONDRIAL DEPOLARIZATION IN VIVO IS DEPENDENT ON ALCOHOL DEHYDROGENASE (ADH) AND CYTOCHROME-P450 2E1 (CYP2E1).

Z. Zhong, V. K. Ramshesh, H. Rehman and J. J. Lemasters. *Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC.*

Our recent study showed that ethanol ingestion causes widespread hepatic mitochondrial depolarization *in vivo*. This study investigated the role of ethanol metabolic pathways in this mitochondrial depolarization. Mice were gavaged with one inebriating dose of ethanol (6g/kg). Mitochondrial polarization, cell death and mitochondrial inner membrane permeability were assessed by intravital multiphoton microscopy of rhodamine 123 (Rh123), propidium iodide (PI) and calcein, respectively. Mitochondrial depolarization indicated by loss of Rh123 fluorescence occurred as early as 1 h after ethanol treatment and peaked at 6 h when ~95% hepatocytes contained depolarized mitochondria. Subsequently, depolarization declined to ~15% of hepatocytes after 24 h. Loss of cell viability, as indicated by nuclear PI fluorescence, was minimal after acute ethanol treatment. Ethanol-induced mitochondrial depolarization was dose-dependent in the range of 1-6 g/kg. This mitochondrial depolarization caused by ethanol was associated with hepatic steatosis but little overt cell injury. Ethanol-induced mitochondrial depolarization was independent of the mitochondrial permeability transition, opening of mitochondrial K_{ATP} channels and uncoupling protein-2. Without ethanol treatment, hepatocytes of ADH-positive and ADH-negative deer mice contained polarized mitochondria. After ethanol treatment, mitochondria depolarized in most hepatocytes of ADH-positive deer mice. By contrast, mitochondrial depolarization did not occur in most hepatocytes of ADH-negative deer mice. The cytochrome P450 inhibitor, aminobenzotriazole (100 mg/kg), blunted mitochondrial depolarization in ~25% of hepatocytes. Ethanol-induced depolarization was similarly decreased in CYP2E1-deficient mice. Taken together, the data show that acute ethanol causes widespread, reversible hepatic mitochondrial depolarization. Ethanol metabolism by ADH plays a major role in ethanol-induced mitochondrial depolarization whereas CYP2E1 plays a more minor role (NIDDK).

PS 1140 THE ROLE OF ETHANOL METABOLISM IN ALCOHOL-INDUCED HEPATOTOXICITY.

M. J. Ronis[1], M. Ferguson[1], K. Hale[1], T. Fletcher[1], J. Badeaux[1], M. Blackburn[1], S. Korourian[2] and T. M. Badger[1]. *[1]Arkansas Children's Nutrition Center, University of Arkansas Medical Sciences, Little Rock, AR and [2]Pathology, University of Arkansas Medical Sciences, Little Rock, AR.*

The role of ethanol (EtOH) metabolism in liver injury remains a topic of controversy. In the current study, groups of male Sprague-Dawley rats (n = 4-8) were infused with 12 g/kg/d EtOH as part of isocaloric liquid diets fed via total enteral nutrition for 45 d. Some groups were given 200 mg/kg/d diallylsulfide (DAS) in the diet which prevented induction of CYP2E1 apoprotein or activity after EtOH treatment. Other groups were infused diets supplemented with 164 mg/kg/d of the alcohol dehydrogenase inhibitor 4-methylpyazole (4MP) and dosed at 2-3 g/kg/d EtOH to maintain average blood ethanol concentrations in the 200-400 mg/dL range. Resulting liver pathology scores and levels of apoptosis did not differ significantly between EtOH, EtOH + DAS or EtOH + 4MP groups, although serum ALT values were lower after 4MP treatment ($p < 0.05$). Hepatic oxidative stress measures (lipid peroxidation, (TBARS) and reduction in GSH concentrations) were increased after EtOH ($p < 0.05$), but unaffected by DAS or 4MP. DAS and 4MP blocked EtOH increases in TNF alpha mRNA ($p < 0.05$), and 4MP prevented EtOH increases in expression of the chemokine CXCL-2 ($p < 0.05$). However, neither inhibitor prevented EtOH suppression of IL-4 or IL-12 mRNAs or increases in TGF beta mRNA ($p < 0.05$). The ER stress marker TRB3 was elevated by EtOH ($p < 0.05$) and while this was partly attenuated by 4MP, DAS had no effect. DAS in combination with EtOH increased the number of hepatocytes in S-phase ($p < 0.05$). These data suggest that oxidative stress and many of the cytokine changes associated with hepatic injury following EtOH exposure are not mediated via CYP2E1 or acetaldehyde, but that EtOH metabolism by CYP2E1 may be linked to induction of TNF alpha; whereas, acetaldehyde production may be linked in part to necrosis, chemokine production and ER stress. (Supported in part by R01 AA08645 T.M.B.)

PS 1141 NRF2 DELETION IMPAIRS GLUCOSE TOLERANCE AND EXACERBATES HYPERGLYCEMIA IN TYPE I DIABETIC MICE.

L. M. Aleksunes[1], S. A. Reisman[1], R. L. Yeager[1], M. J. Goedken[2] and C. D. Klaassen[1]. *[1]Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS and [2]Pathology, Schering-Plough Research Institute, Lafayette, NJ.*

The transcription factor Nrf2 induces numerous protective detoxification and antioxidant genes following electrophilic or oxidative stress. Nrf2 aids in liver regeneration by altering insulin signaling, however, whether Nrf2 plays a role in hepatic glucose homeostasis is unknown. In the present study, blood glucose, serum insulin, urine output, and hepatic expression of glucose-related genes were examined in male diabetic wild-type (C57BL/6) and Nrf2-null mice. Type 1 diabetes was induced with a single dose of streptozotocin (STZ 200 mg/kg ip). Blood glucose levels were elevated in both genotypes by 3 days after STZ. Five days after STZ, Nrf2-null mice had higher blood glucose levels (714 mg/dl) than wild-type mice (442 mg/dl) (control mice:160-180 mg/dl). Ten days after STZ, polyuria occurred in both genotypes with higher urine output from Nrf2-null mice (11-fold) than from wild-type mice (7-fold). Histopathology and decreased serum insulin levels confirmed reduced pancreatic islet β-cells in both genotypes. Higher urine output and blood glucose levels in STZ-treated Nrf2-null mice corresponded with enhanced gluconeogenesis (glucose-6-phosphatase and phosphoenolpyruvate carboxykinase) and reduced glycolysis (pyruvate kinase) related mRNA expression in liver. STZ reduced hepatic glycogen content in both genotypes, with lower levels observed in Nrf2-null mice. To examine glucose sensitivity in naïve mice, a glucose tolerance study was conducted. Blood glucose increased within 15 min after an ip dose of

20% D-glucose in feed-deprived wild-type and Nrf2-null mice. Whereas blood glucose returned to baseline within 2 h in wild-type mice, levels remained elevated at 2 h in Nrf2-null mice and did not return to baseline until 4 h. Collectively, these data indicate that the absence of Nrf2 worsens hyperglycemia in Type I diabetic mice and impairs glucose tolerance. (Supported by NIH grants DK-080774, ES-09649, ES-09716, ES-07079, ES-013714, RR-021940.)

PS 1142 ROSIGLITAZONE/METFORMIN (AVANDAMET®) INCREASES MITOCHONDRIAL BIOGENESIS IN GOTO-KAKIZAKI RATS: BIOENERGETIC CONSEQUENCES FOR DIABETES.

C. M. Palmeira, A. Gomes, A. Varela, J. Soeiro, F. Duarte and A. Rolo. *Center for Neurosciences and Cell Biology, Mitolab, University of Coimbra, Coimbra, Portugal.*

Given the worldwide increase in diabetes mellitus, it is critical to understand the upstream genetic and transcriptional mechanisms mediating mitochondrial dysfunction. In this work, we evaluated the effects of the in vivo administration (for 6 weeks) of Rosiglitazone/Metformin on rat liver mitochondria bioenergetics, as well as on mitochondrial gene expression in a rat model of type 2 diabetes (Goto-Kakizaki rat). GK treated animals showed a normalization of the glycemia levels, while GK rat liver mitochondria from treated animals showed improvement of mitochondrial respiration and membrane potential capacities. Induction of mitochondrial permeability transition (MPT), involved in several vital cellular signalling pathways, was prevented in GK treated animals. Gene transcripts associated with mitochondrial energy production clearly shown an increase in adenine nucleotide translocator (ANT) and cytochrome oxidase (COX) in GK treated animals, as well as PGC-1alpha (transcription factor involved in mitochondrial biogenesis regulation). The increase in mRNA content was confirmed by western blot. All these data was further confirmed by the observed increase in mitochondrial biogenesis, after 6 weeks in vivo administration of Rosiglitazone/Metformin in GK rats. The efficiency of this formulation as antidiabetic is certainly related with the observed improvement of mitochondrial bioenergetic capacity in GK treated animals, being this improvement related with increased mitochondrial biogenesis.

PS 1143 OVARIAN HORMONES SENSITIZE THE LIVER TO HALOTHANE-INDUCED HEPATOTOXICITY IN FEMALE MICE.

A. E. MacDonald[1], C. M. Dugan[2], R. A. Roth[1] and P. E. Ganey[1]. *[1]Pharmacology and Toxicology, Michigan State University, East Lansing, MI and [2]Cell and Molecular Biology, Michigan State University, East Lansing, MI.*

Estrogen has been shown to increase the sensitivity of mice to toxicant-induced liver injury. Halothane is an inhaled anesthetic that induces a rare fulminent liver injury in 1 in 30,000 human patients, and female gender is a predisposing risk factor. We tested the hypothesis that ovarian hormones enhance the sensitivity to severe halothane hepatotoxicity in female Balb/c mice. Halothane (45mmol/kg, ip) caused severe liver injury at 24 hrs in female mice as indicated by serum alanine aminotransferase (ALT) activity exceeding 10,000 U/L. Less injury (ALT ~ 2000 U/L) developed in male mice given the same dose. The severity of halothane-induced liver injury in female mice correlated with the phase of the estrous cycle in which the mice were administered halothane. When treated with 5mmol/kg (ip), females in estrous phase developed more severe hepatic injury at 12 hrs than mice in either diestrous or proestrous phase. To study the influence of ovarian hormones on this response, mature female mice were ovariectomized (OVX) or sham-operated (SHAM) and treated with 15mmol/kg halothane (ip), and hepatotoxicity was assessed at 12 hrs. The SHAM mice had serum ALT activity > 10,000 U/L with pronounced centrilobular necrosis on histological analysis. The OVX mice had significantly less liver injury (ALT ~ 500 U/L) and mild liver lesions. Serum tumor necrosis factor alpha (TNFα) concentration in SHAM mice was approximately 500 pg/ml, whereas it was undetectable in OVX mice. These results suggest that ovarian hormones sensitize the liver to halothane hepatotoxicity, perhaps by enhancing production of proinflammatory cytokines. (Supported by NIH grant GM075865.)

PS 1144 DEPLETION OF MOUSE KUPFFER CELLS BY CLODRONATE LIPOSOMES *VERSUS* GADOLINIUM CHLORIDE TREATMENT: DIFFERENTIAL GENE EXPRESSION ANALYSIS.

M. A. O'Connor[1], S. N. Campion[1], P. H. Koza-Taylor[2], M. P. Lawton[2] and J. E. Manautou[1]. *[1]Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT and [2]Pfizer Inc, Groton, CT.*

Gadolinium chloride has been used extensively to deplete and/or inactivate Kupffer cells from rodent livers. Animals with compromised Kupffer cell function are less susceptible to hepatotoxicants such as acetaminophen (APAP) and carbon tetrachloride. Recently, administration of clodronate encapsulated in liposomes has been used as an alternative approach to deplete Kupffer cells. Interestingly, mice treated with liposomal clodronate are actually more susceptible to APAP hepatotoxicity. The reason for this differential effect is not known. In this study, C57BL/6J mice were treated with either 10 mg/kg gadolinium chloride or 0.1 ml clodronate liposomes. Liver samples were obtained 48 hours later and total RNA was isolated and hybridized to Affymetrix Mouse Genome MU430_2 GeneChips. Clodronate liposome treatment significantly decreased expression of genes involved in several immune processes, including migration (CD44), binding and adhesion (MARCO), signaling and activation (C1QA) as well as inflammatory response. Similarly, the expression of genes involved in arachidonic acid metabolism (PTGS1) and leukocyte extravasation signaling (VCAM1) was also suppressed in clodronate liposome treated mice. By contrast, treatment with gadolinium chloride did not result in the down regulation of many of the immune-specific genes altered by clodronate liposomes. This indicates that suppression of immune response and Kupffer cell function differs between these two modes of Kupffer cell depletion, which could explain the differential susceptibility to the action of hepatotoxicants in rodents treated with these agents.

PS 1145 AMODIAQUINE-INDUCED LIVER TOXICITY IN THE RAT.

P. Cai and J. Uetrecht. *Fculty of Pharmacy, University of Toronto, Toronto, ON, Canada.*

Background: Amodiaquine (AQ) is a 4-aminoquinoline antimalarial drug. However, life-threatening agranulocytosis or hepatotoxicity occurs in about 1 in 2000 patients. AQ forms a reactive iminoquinone metabolite and these idiosyncratic reactions appear to be immune-mediated but the details of how this reactive metabolite might induce an immune response is unknown. The purpose of this study is to establish an animal model of idiosyncratic hepatotoxicity. Methods and Results: Male Wistar or Brown Norway (BN) rats were treated with AQ at 62.5 mg/kg/day, 6 days/week for 5 weeks via gavage. A significant increase in serum ALT was detected in both Wistar (65.8 U/L ±3.2 in treated vs 26.7 U/L ± 4.2 in controls) and BN (65.5U/L ± 6.7 in treated vs 36.8 U/L ±3.0 in controls) rats after 4 weeks of treatment, which then returned to almost normal despite continued treatment. 24 serum cytokines and chemokines in Wistar rats were determined by Luminex; RANTES and MCP-1 were significantly increased. The number of ED1 stained Kupffer cells and lung macrophages were significantly increased in both rat strains but the increase was greater in BN rats. Using the TUNEL stain, an increase in apoptotic cells in lung and liver were found in BN rats. Covalent binding of AQ was found in lung, spleen, and liver and it was much greater in Kupffer cells than in hepatocytes. Co-treatment with poly I:C (TLR 3) or imiquimod (TLR 7) appeared to lead to an earlier onset of ALT increase while co-treatment with LPS (TLR 4) appeared to delay the onset; however, none of the co-treatments had a significant effect on the level of ALT increase. Conclusion: AQ binding was greatest to Kupffer cells/macrophages and presumably was responsible for their activation. It also caused a delayed onset mild liver injury but the response was limited and not significantly increased by agents that stimulate the immune system via toll-like receptors. It appears that AQ damage is limited by tolerance and the key to developing an animal model of drug-induced idiosyncratic liver failure is overcoming tolerance. This research was supported by grants from CIHR.

PS 1146 MITOCHONDRIA-MEDIATED LIVER INJURY INDUCED BY FLUTAMIDE IN HETEROZYGOUS *SOD2*$^{+/-}$ MICE.

R. Kashimshetty[1], V. G. Desai[2], T. Lee[3], C. L. Moland[2], W. S. Branham[2], L. S. New[4], E. C. Chan[4] and U. A. Boelsterli[1]. *[1]Department Pharmaceutical Sciences, University of Connecticut, Storrs, CT, [2]Division Systems Toxicology, NCTR, Jefferson, AR, [3]Department Information and Mathematics, Korea University, Jochiwon, Korea, South and [4]Department Pharmacy, National University of Singapore, Singapore, Singapore.*

Flutamide (FLU) is an antiandrogen widely used in the treatment of prostate cancer. Its use has been compromised by reports of rare but severe idiosyncratic liver injury (DILI-2). The susceptibility factors implicated in FLU-induced hepatotoxicity remain unknown, but mounting evidence points to mitochondrial impairment and oxidative stress. We have previously shown that heterozygous *Sod2*$^{+/-}$ mice, featuring an asymptomatic decrease in mitochondrial superoxide dismutase, are sensitized to a superimposed oxidant drug stress. The aim of this study was to explore the effects of repeated FLU exposure on liver mitochondria and transcript expression in this mouse model. FLU or vehicle was administered to both *Sod2*$^{+/-}$ and wild-type control mice (0, 30,100 mg/kg, i.p.) daily for 4 weeks. At the high dose, FLU increased the hepatic GSSG/GSH ratio, indicating a compromised redox balance. Furthermore, hepatic protein carbonyl and serum lactate levels (markers of

cumulative oxidant stress and mitochondrial dysfunction) were significantly increased. FLU treatment also resulted in drastically higher numbers of apoptotic hepatocytes and produced small areas of hepatic necrosis in *Sod2*$^{+/-}$, but not wild-type, mice. In addition, microarray analysis of 542 mitochondria-related genes (MitoChip) revealed striking alterations in hepatic transcript expression, including lower levels of mtDNA-encoded genes of complexes I and III and mitochondrial tRNAs, as well as downregulated pathways of fatty acid oxidation. These results demonstrate that FLU can cause oxidative damage and overt liver injury in mice with underlying compromised mitochondrial function. The data are compatible with our hypothesis that individuals with mitochondrial abnormalities may be predisposed to DILI-2 caused by mitochondria-targeting drugs.

PS 1147 EFFECTS OF PERINATAL EXPOSURE TO A COMMERCIAL POLYBROMODIPHENYLETHER (PBDE) MIXTURE ON LIVER GENE EXPRESSION AND PROTEIN EXPRESSION IN SD RATS.

C. Foster-Hunt, I. Curran, S. Gurofsky, V. Liston, A. Nunnikhoven and G. S. Bondy. *Toxicology Research Division, Health Canada, Ottawa, ON, Canada.*

PBDE's are a mixture of chemicals used as flame retardants in a variety of textiles, plastics, and furniture. A study using the PBDE mixture DE-71 orally administered to Sprague-Dawley (SD) rats was undertaken to assess the impacts of PBDE's on developing rats. Adult (F0) rats were administered PBDEs in the form of DE-71 technical mixture by gavage at doses of 0, 0.5, 5 or 25 mg/kg body weight (bwt)/day for 10 weeks, after which the rats were bred. Weanling (F1) rats received the DE-71 mixture by gavage from postnatal day (PND) 21 to 42. Liver has been previously identified as a target organ for toxicity by PBDE's. Liver samples from F1 PND 42 male and female rats were examined for changes in gene expression between control and high dose rats via Agilent 22k rat microarray and by monitoring specific gene expression using real-time PCR. Western blots were used to examine changes in protein expression for selected targets. Analysis of microarray data from rat liver found gender specificity with greater effects in females due to PBDE treatment (24 significantly differentially expressed genes) than males (6 significantly differentially expressed genes). Further gene expression analysis using real-time PCR found multi-fold changes in gene expression for CYP1A1, CYP1A2, CYP2B1, CYP3A3, UDPGTR2, ABCG5, IGFBP1 and CEACAM10. Protein expression monitored via western blots observed significant increases in CYP protein levels for medium and high dose groups. Phase I and Phase II genes and proteins were generally up-regulated in male rat livers compared to treated females. Pathway analysis of female liver data indicate changes in PXR/RXR pathways which may relate to previously reported changes in serum cholesterol levels. Analyses also indicates pathways for thyroid homeostasis and lipid metabolism are affected. Changes in gene expression of CEACAM also indicate DE-71 exposure may increase the potential for cellular changes related to carcinogenesis.

PS 1148 ROLE OF METALLOTHIONEIN INDUCTION IN HEPATOPROTECTION AGAINST CARMUSTINE TOXICITY IN NORMAL AND GLIOMA-BEARING RATS.

K. Alharbi, G. Helal and S. Albakheet. *Pharmacology, King Saud University, Riyadh, Saudi Arabia.* Sponsor: N. Zawia.

One of the serious toxic effects during treatment of cerebellar glioma using carmustine (BCNU) is hepatotoxicity as a result of oxidative stress and apoptosis. Metallothionein (MT) documented to play a decisive role in protection against oxidative stress insults. This study aims to find out if MT induction by zinc can attenuate BCNU-induced hepatotoxicity in rat cerebellar glioma model and to what extent this may affect the antitumor activity of BCNU. Male Wistar albino rats were implanted with rat C6 glioma cells then classified into 4 groups. The first group is tumor-bearing control group. The second group injected with ZnSO4 (15mg/kg.i.p). The third group administered BCNU (20mg/kg, i.p). The fourth group injected with ZnSO4 15mg/kg then 24 hours later with 20 mg/kg BCNU. After 48 hours from BCNU administration, animals were sacrificed where cerebella were isolated and blood samples were collected. Antitumor activity of BCNU was evaluated in 2 groups one of them administered a single dose of BCNU (20mg/kg) and the other group administered ZnSO4 (15mg/kg, i.p) then 24 hours later 20mg/kg BCNU (i.p) where survival curve has been done. Our data revealed that zinc administration induced liver but not brain MT. Also, we found that BCNU administration significantly increased the extent of hepatic apoptosis, LPO, TNF-alpha, bilirubin and the activities of GGT and ALP along with marked histological deterioration but marked depletion of liver GSH and GR enzyme. ZnSO4 administration before BCNU resulted in marked decreases in hepatic apoptosis, lipid peroxides and bilirubin, serum level of TNF-alpha and activities of GGT and ALP but increased liver GR activity and GSH content along with improved histological features. The antitumor activity had not affected by zinc. In conclusion, zinc can induce liver but not brain MT due to its inability to pass the BBB. Peripheral induction of MT protects against BCNU hepatotoxity without affecting the antitumor activity. This can provide a new therapeutic strategy during treatment of brain tumors.

PS 1149 HEPATOPROTECTIVE EFFECTS OF SELECT WATER-SOLUBLE PARP-1 INHIBITORS.

J. D. McCluskey, S. C. Harbison, D. Sava and R. D. Harbison. *Environmental Occupational Health, University of South Florida, Tampa, FL.*

Induction of Poly(ADP-ribose) polymerase-1 (PARP-1) is one possible mechanism of carbon tetracholoride (CT) hepatotoxicity. Therefore, inhibition of PARP-1 may be an important pathway for reducing hepatic injury. We hypothesize that PARP-1 inhibition may ameliorate CT toxicity by preserving hepatic ATP levels required for apoptosis or cell repair. The current study assesses the ability of water-soluble PARP-1 inhibitors, including 3-aminobenzamide (ABA), 5-aminoisoquinolinone (AIQ) and PJ-34, to attenuate CT-induced hepatotoxicity in male ICR mice. Dose dependent PARP-1 induction followed CT treatment at doses of 0.3, 0.6 and 1.2 mL/kg. Each dose significantly elevated serum ALT levels, up to13.6 times controls. Lipid peroxidation was also increased in liver tissue, up to 5.3-fold. Hepatic tissue glutathione (GSH) and superoxide dismutase (SOD) levels were decreased 2.2 and 2.3-fold, respectively. A dose dependent reduction of mitochondrial SOD was also observed. In a previous investigation, we reported inconsistent results with water- insoluble PARP-1 inhibitors. In contrast, the current study indicates that select water-soluble PARP-1 inhibitors can alter CT-induced hepatotoxicity. Treatment with 3 mg/kg AIQ 1 hour before CT reduced elevation of serum ALT 2.1-fold. The most profound reduction followed PJ-34, while ABA pretreatment also reduced ALT elevation. Pretreatment of animals with PJ-34, ABA or AIQ significantly decreased PARP-1 activity in liver tissue (3.4, 2.0 and 1.9 times, respectively) following hepatotoxic doses of CT. Biochemical data indicate that inhibition of PARP-1 can alter hepatotoxicity and protect the liver against CT-induced cytotoxicity. All of the tested PARP-1 inhibitors reduced CT-induced lipid peroxidation and partially restored GSH levels. There were no visible tissue defects in liver from the animals treated with a PARP-1 inhibitor and CT. Thus, select water-soluble PARP-1 inhibitors can attenuate chemical-induced hepatotoxicity.
(Supported in part by the U.S. Department of Defense Contract #DAAD13-01-C-0055)

PS 1150 POSSIBLE ROLES OF METABOLIC ACTIVATION IN 1-BROMOPROPANE-INDUCED HEPATOTOXICITY.

S. Shin, S. Lee, J. Kim, Y. Seo, J. Choi, M. Kang and T. Jeong. *Pharmacy, Yeungnam University, Gyeongsan, Gyeongbuk, Korea, South.*

1-Bromopropane (1-BP) would be metabolized by two different pathways: the formation of both glutathione (GSH) conjugates by glutathione S-transferase and metabolites by cytochrome P450 (CYP). In the present study, a possible role of CYP in 1-BP-induced hepatotoxicity was investigated in mice. The depletion of GSH by the formation of GSH-conjugate was involved in the increased hepatotoxicity in 1-BP treated mice. Moreover, the formation of reactive metabolites of 1-BP by CYPs could be involved in the 1-BP-induced hepatotoxicity. The decreased content of hepatic GSH by 1-BP was parallel not only with the increased activities of ALT and AST but also with the increased content of hepatic malondialdehyde in the group that metabolic enzymes were induced by pretreatment with phenobarbital. The hepatotoxicity induced by 1-BP was significantly protected in mice by the co-treatment with N-acetyl cysteine used to supply the biological content of GSH and silymarin as an antioxidant. Taken together, the formation of metabolites by CYP as well as the depletion of GSH in the CYP-induced animals would play important roles in hepatotoxicity induced by 1-BP. (Supported by a grant from Korea Research Foundation)

PS 1151 THE NON-GENOTOXIC HEPATOCARCINOGEN PHENOBARBITAL ALTERS MICRORNA EXPRESSION IN THE MALE FISCHER RAT.

C. Koufaris[1], J. Wright[2], R. Currie[2] and N. Gooderham[1]. *[1]Biomolecular Medicine, Imperial College London, London, United Kingdom and [2]Human Safety, Syngenta, Bracknell, United Kingdom.*

Phenobarbital (PB) is a classic, thoroughly studied rodent hepatocarcinogen acting via non-genotoxic mechanisms, involving the CAR nuclear receptor. Exposure to PB has pleiotropic effects on the liver of rodents, both in the short and long term. Short-term administration of PB causes liver enlargement via hypertrophy, and transient cell proliferation. MicroRNAs (miRNA) are non-coding RNA molecules

~23 nucleotides in length that post-transcriptionally regulate gene expression. Aberrant miRNA expression is increasingly associated with human diseases, including cancer. The role miRNA play in chemically induced toxicity is undefined at present. This study examined the effect on the miRNA profile of livers from male Fischer rat following short-term dietary exposure to a carcinogenic regimen of PB sodium salt. The objectives were to examine (1) whether PB causes deregulation of miRNAome (2) If short-term exposure to this chemical generates miRNA signatures predictive of long term exposure to a non-genotoxic carcinogen. Male Fischer rats were treated daily with four different doses of PB (0,50,500, and 1000ppm). Previous studies have reported the 1000ppm dose to be carcinogenic while the 500 and 50ppm are non-carcinogenic. Animals were sacrificed at four different timepoints (1,3,7, and 14 days of PB exposure) and livers were excised. RNA was harvested from the liver tissue and the miRNA gene expression was profiled using microarrays containing 350 miRNA genes. Unsupervised clustering methods and Significance Analysis of Microarrays (SAM) were used to determine whether PB influences miRNA expression. SAM identified a number of miRNA genes that were significantly different between the treatments. Similarly, clustering revealed separation between the treatments. Both methods indicated that PB altered miRNA profiles were dose and time dependent. It will be important to assess the correlation of these PB-induced miRNA alterations with the associated transcriptional changes.

PS 1152 TROVAFLOXACIN AND TUMOR NECROSIS FACTOR α SYNERGIZE TO CAUSE LIVER INJURY IN A MURINE MODEL OF IDIOSYNCRATIC TOXICITY.

P. J. Shaw, K. M. Beggs, P. E. Ganey and R. A. Roth. *Pharmacology & Toxicology, Michigan State University, East Lansing, MI.*

Therapy employing the fluoroquinolone antibiotic, trovafloxacin (TVX) was curtailed due to idiosyncratic hepatotoxicity. The incidence of TVX-induced hepatotoxicity was estimated at 1 in 18,000 patients, and in 10% of these patients the pathogenesis progressed to severe liver injury, including liver failure. Liver biopsies from affected patients revealed centrilobular hepatocellular necrosis and the presence of inflammatory cells. Previous studies in rodents showed that an inflammatory stress induced by lipopolysaccharide (LPS) rendered nontoxic doses of TVX hepatotoxic and that TVX/LPS-induced liver injury was TNFα-dependent. The interaction of TVX with tumor necrosis factor α (TNFα) was explored further in this study. TVX given 3 h before LPS administration caused significant hepatocellular damage. TVX/LPS-induced liver injury was significantly attenuated in both p55-/- (TNF-R1 knockout) and p75-/- (TNF-R2 knockout) mice. Since TNFα is a critical mediator of TVX/LPS-induced liver injury, we explored whether TVX could interact with TNFα. A nonhepatotoxic dose of TVX synergized with a nonhepatotoxic dose of TNFα to cause liver injury. The hepatocellular lesions were primarily localized to midzonal regions and were characterized by both oncotic necrosis and apoptosis. TVX pretreatment enhanced early TNFα-induced inflammatory stress, as evidenced by an increase in hepatic neutrophil accumulation. In addition, a nontoxic dose of TVX sensitized a murine hepatocyte cell line to cytotoxicity induced by TNFα. In summary, TVX/LPS-induced liver injury was dependent on both TNF receptors. Furthermore, TVX interacted directly with TNFα to cause liver injury by both enhancing TNFα-induced inflammation and sensitizing hepatocytes to TNFα-induced cell death. (Supported by NIH grant DK061315.)

PS 1153 HYPEROXIA-INDUCED OXIDANT STRESS IN THE LIVERS OF NEWBORN MOUSE PUPS.

L. K. Rogers[1, 2], T. E. Tipple[1, 2], L. D. Nelin[1, 2] and S. E. Welty[1, 2]. *[1]Center for Perinatal Research, The Research Institute at Nationwide Children's Hospital, Columbus, OH and [2]Department of Pediatrics, The Ohio State University, Columbus, OH.*

Hyperoxic lung injury is a serious medical complication in vulnerable populations such as premature infants. Systemic responses to inflammation or injury have been described and often involve reciprocal responses in the lung and liver. These studies tested the hypothesis that oxidant stress would be evident in the livers of hyperoxia-exposed newborn mice. Newborn mice were placed in either room air (RA) or >95% O2 for 1, 3, 7, or 14 days. Data were analyzed by two-way ANOVA, and a modified t-test was used for post-hoc testing. There were no differences in liver-to-body weight ratios between the 2 exposure groups. Analysis of hepatic GSH contents indicated an effect of day, an effect of treatment, and an interaction between day and treatment with lower GSH contents in the pups exposed to >95% O2 than in the RA controls at 3, 7, and 14 days (0.9 vs 2.9; 4.8 vs 6.1; and 4.2 vs 6.2 umol/g tissue, respectively). An effect of day was observed on GSSG levels but no effect of exposure was detected. Thioredoxin-1 and thioredoxin-2 protein levels were greater in the livers of pups exposed to >95% O2 than the RA controls at day 1 but were not different at days 3, 7, and 14. As markers of mitochondrial redox status, CoASH and CoASSG levels were measured. An effect of day and an interaction between day and exposure were observed on CoASH levels with higher levels in the >95% O2-exposed animals than the RA controls at day 1 but lower levels at day 14. An effect of exposure was observed on CoASSG levels with greater levels in the >95% O2 group than the RA group by day 7 (4.1 vs 5.8 nmol/g tissue). These data indicate that oxidant stress is present in the livers of newborn mouse pups exposed to hyperoxia. We speculate that hepatic oxidant stress contributes to the pathogenesis of hyperoxic lung injury.

PS 1154 ACUTE EFFECTS OF ORAL EXPOSURE TO MIDDLE EAST PM10 DUST ON SYSTEMIC PARAMETERS IN LABORATORY MOUSE (MUS MUSCULUS).

V. Mokashi[1], D. Wagner[1], A. Olabisi[1], D. Carson[2], G. Babcock[2], P. G. Gunasekar[1] and G. Chapman[1]. *[1]Naval Health Research Center Detachment Environmental Health Effects Laboratory, Wright-Patterson AFB, Dayton, OH and [2]Surgery, University of Cincinnati, Cincinnati, OH.*

Inhalation of particulate matter (PM)-associated silica, metal and microorganisms can result in adverse pulmonary and systemic health effects. In addition, U.S. military personnel deployed in Iraq and other parts of the Middle East have experienced health effects, particularly Desert Storm pneumonitis, as a result of exposure to desert sand or desert dust, a major component of ambient particulate matter (PM). We hypothosize that Iraq desert dust oral exposure will result in circulation and increased bioavailability of PM-associated components resulting in a significant systemic response. Here, we examine in mice the acute effects of oral exposure to desert sand. In this study, mice received a single dose oral gavage of either PM10 Middle East dust in saline or saline alone. At 4 hr and 24 hr following gavage administration, animals were euthanized to analyze the tissue distribution of PM components and the generation of reactive oxygen species (ROS) in tissue. Bioavailability of metals found in PM was assayed in major organs including heart, liver, skin and brain by Inductively Coupled Plasma-Mass Spectroscopy (ICP-MS). In addition, ROS scavenger phenyl-N-tert-butylnitrone (PBN) was administered 30 min prior to sacrifice, to trap radical species for electron paramagnetic resonance (EPR) spectroscopy. As a positive control for ROS formation, mice were orally given endotoxin (LPS), which generates elevated ROS in liver within 4 hr of exposure. This work may provide a broaderunderstanding of the mechanistic basis for PM-associated health effects such as severe acute pneumonitis.

PS 1155 COMPROMISED KUPFFER CELLS COULD LEAD TO TCE-MEDIATED SLE-LIKE DISEASE.

S. Kondraganti[1], P. J. Boor[2], M. Khan[2], R. Konig[3], B. S. Kaphalia[2] and G. Ansari[1, 2]. *[1]biochemistry and Molecular Biology, UTMB, Galveston, TX, [2]pathology, UTMB, Galveston, TX and [3]microbiology and immunology, UTMB, Galveston, TX.*

We have shown that trichloroethene (TCE) causes SLE-like disease in female MRL+/+ mice. We hypothesize that TCE-mediated SLE-like disease is due to increased apoptosis and/or decreased clearance of apoptotic bodies. Therefore, female MRL+/+ mice exposed to TCE through drinking water (0.5 mg/ml) were sacrificed after 24, 36, and 48 weeks. The livers of exposed and age-matched control mice were analyzed for histopathological changes, apoptosis, and functional status of Kupffer cells. Hematoxylin and Eosin (H&E) staining demonstrated absence of lymphocytic infiltration at 24 weeks, but showed diffuse periportal and central vein infiltration at 36 weeks, and increased infiltration and areas of mild hepatocellular necrosis at 48 weeks. TUNEL staining showed increased apoptosis at 24 weeks, but no significant changes at 36 and 48 weeks in TCE- treated mice compared to controls. When apoptotic bodies are not cleared by Kupffer cells, secondary necrosis and inflammation can result, which was observed at 48 weeks. The delayed clearance could be due to compromised endocytosis by Kupffer cells. To evaluate the functional status of Kupffer cells, we used the monoclonal antibody RM-4, which selectively binds to Kupffer cells. The intensity of antibody binding reflects endocytic function. In mice treated with TCE for 36 and 48 weeks, Kupffer cell function was decreased. These studies suggest that increased apoptosis and compromised Kupffer cell function may be a potential mechanism leading to TCE-mediated SLE-like disease.

PS 1156 LIPIDOMICS OF ALCOHOL-INDUCED FATTY LIVER.

H. Fernando*[1], S. Kondraganti[2], K. K. Bhopale[1], M. Neerathilingam[2], D. E. Volk[2], B. S. Kaphalia[1], B. A. Luxon[2], P. J. Boor[1] and G. A. Ansari[1, 2]. *[1]Pathology, UTMB, Galveston, TX and [2]biochemistry and Molecular Biology, UTMB, Galveston, TX.*

Hepatic steatosis (fatty liver) is an early and reversible stage of alcoholic liver disease which is a major cause of liver-associated illnesses and deaths. To study the mechanism, and identify early biomarkers of alcoholic disease, Fisher 344 rats were fed

Lieber-DeCarli liquid diet containing 5% alcohol for one month. Control animals were pair-fed with liquid diet containing equivalent calories substituted by maltose-dextrin. After sacrificing the animals, livers were removed, weighed and subjected to morphological and immunohistochemical analysis. Plasma was extracted with methyl-tert-butyl ether and analyzed by 750 MHz proton nuclear magnetic resonance (NMR) spectroscopy. The body and liver weights were not significantly changed in ethanol-fed vs. control group. Fatty infiltration was confirmed by H&E and Oil O Red staining of the liver sections of ethanol-fed group. No indication of inflammation (lack of CD3 positive cell) or oxidative stress (lack of HNE positive staining) were found in alcohol-fed vs. control group. Cluster analysis and principal component analysis (PCA) of NMR data of plasma lipids were significantly different for the alcohol-fed group. Preliminary evaluation of NMR spectra corresponding to 1.18-1.19 (free/esterified cholesterol), 2.10-2.13 (fatty acyl acids), 3.64-3.66 (phosphatidyl choline) and 3.91-3.94 (glycerol backbone of phospholipids) ppm showed decrease in alcohol-fed vs. control rats. These studies indicate that fatty liver is an early change that precedes oxidative stress and inflammation, and may be identified by the altered plasma lipid profile.

PS 1157 UPTAKE AND METABOLISM OF INHALED SULFURYL FLUORIDE (SO_2F_2) AND URINARY EXCRETION OF FLUOROSULFATE (FSO_3) AND FLUORIDE (F) IN RATS.

J. A. Hotchkiss[1], S. M. Krieger[1], D. L. Rick[1], D. A. Markham[1], F. Zhang[1], M. J. Bartels[1] and D. L. Eisenbrandt[2]. *[1]The Dow Chemical Company, Midland, MI and [2]Dow AgroSciences, LCC, Indianapolis, IN.*

Sulfuryl fluoride is a structural and post-harvest fumigant and is a key alternative to methyl bromide which is scheduled for phaseout by the Montreal Protocol. Examination of nasal and pulmonary uptake and hydrolysis of 300 ppm SO_2F_2 in F344/DuCrl rats with and without surgical isolation of the upper (nasal) airways indicated that both the upper and lower respiratory tract contributed to a total SO_2F_2 uptake of 12.5%. No SO_2F_2 was detected in nasal (NLF) or bronchoalveolar (BALF) lavage fluid or plasma immediately after exposure, however, the metabolites FSO_3 and F were detected (insufficient NLF for F analysis). This suggests that hydrolysis of SO_2F_2 is essentially complete at the portal of entry and not available systemically. Excretion of FSO_3 and F in urine was measured after exposure to 0, 3, 30, or 300 ppm SO_2F_2. Urinary elimination of FSO_3 was roughly proportional to the SO_2F_2 concentration. Inhaled SO_2F_2 is rapidly hydrolyzed to FSO_3 and F and excreted in the urine with a clearance half-time of 2.0 and 4.1 h, respectively. The contribution of FSO_3 metabolism to urinary excretion of F was examined by injecting rats with potassium-FSO_3 and measuring the concentration of FSO_3 and F in the urine. Overall, 41.2% of the administered FSO_3 was hydrolyzed to F during the 48 hr collection period and 96% of the FSO_3 excreted in urine was eliminated within 12 hours of dosing. A signature peptide approach was used to quantify FSO_2-albumin adducts in BALF and plasma 24 h after exposure to 0, 3, 30, or 300 ppm SO_2F_2. The concentration of FSO_2-albumin in BALF and plasma was proportional to SO_2F_2 exposure. Formation of FSO_2-albumin represented a minor degradation pathway (0.5-2.7%) compared to the hydrolysis of SO_2F_2 to FSO_3 (97.3-99.5%). The higher ratio of FSO_2-albumin/FSO_3 measured in BALF vs plasma indicated that SO_2F_2 is rapidly hydrolyzed at the point of contact with the tissues and extracellular lining fluid of the upper and lower respiratory tract.

PS 1158 KINETICS OF CARBARYL BIOTRANSFORMATION BY FRESHLY ISOLATED SPRAGUE-DAWLEY RAT HEPATOCYTES.

G. L. Kedderis[1], M. Yoon[2], Y. Tan[2] and H. J. Clewell[2]. *[1]Independent Consultant, Chapel Hill, NC and [2]The Hamner Institutes for Health Sciences, RTP, NC.*

Carbaryl is a widely used insecticide with significant human exposure. Detoxication of carbaryl occurs by hydrolysis and oxidation. While these pathways have been investigated in vitro, the metabolism kinetics of carbaryl in isolated liver cells has not been reported. The goal of the current study was to determine the kinetic constants for carbaryl biotransformation in isolated hepatocytes and use this information in a physiologically based pharmacokinetic (PBPK) model for carbaryl. Hepatocytes ($0.25*10^6$ cells/ml) from adult male Sprague-Dawley rats were incubated with carbaryl (1-75μM) and rates of carbaryl disappearance and metabolite formation were determined. Carbaryl and its metabolites were quantified using HPLC with known standards. The identity of the metabolites was also confirmed by LC-MS. Chemical hydrolysis of carbaryl to 1-naphthol (0.0009 min^{-1} at pH 7.4) was enhanced by enzyme-mediated hydrolysis in the cells. Most of the 1-naphthol was rapidly converted to the sulfate conjugate, which was the major metabolite observed. Two hydroxylated metabolites were identified, 3-hydroxy- and trans-5,6-dihydroxy-carbaryl. The glucuronide conjugate of carbaryl was not observed. Formation of the identified metabolites followed Michaelis-Menten kinetics, with apparent KM values of 60-150 μM and apparent Vmax values 0.5-1.5 nmol/min. Metabolic rates for formation of each indentified metabolite were calculated and the sum of the individual rates was used to simulate total carbaryl disappearance kinetics in hepatocytes. Simulated carbaryl kinetics were in close agreement with the determined carbaryl metabolism rates in hepatocytes. This information on carbaryl metabolism in hepatocytes will be extrapolated to whole animals to refine the previously developed PBPK model for carbaryl in rats. Predictions from the refined model together with in vitro kinetic studies of carbaryl in human hepatocytes will be used to develop a human PBPK model to assess risks from carbaryl in humans using biomonitoring data (supported by EPA G-2006-STAR-N1).

PS 1159 DEVELOPMENTAL EXPOSURE TO AMITRAZ ALTERS THE DOPAMINE SYSTEM.

M. R. Martinez-Larrañaga, J. Del Pino, M. A. Martinez, M. J. Diaz and A. Anadon. *Department of Toxicology and Pharmacology, Faculty of Veterinary Medicine, Universidad Complutense, Madrid, Spain.*

Amitraz is a formamidine pesticide. The reported biological activity of the formamidines includes MAO inhibition, inhibition of prostaglandin synthesis, local anaesthetic effects and alpha-2 adrenergic activity. The continue presence of amitraz residues may be of particular concern to children and pregnant women. The objective of the present study was to investigate if perinatal amitraz exposure of rats during gestation and lactation alters dopaminergic neurochemistry in their offspring. Pregnant Wistar rats were orally gaved with amitraz (20 mg/kg) or with corn oil (1.0 ml/kg). The dosing period covered the period from day 6 of gestation through day-10 postnatally. Within each group, a total of 24 offsprings of different litters [12 of them control and 12 experimental (six males and six females)] were randomly culled on the lactation day 10. At 60 days of age, male and female offspring of control and amitraz-treated animals were killed and their brains removed. The hippocampus, frontal cortex and striatum were dissected and analyzed for content of dopamine (DA) and its metabolites dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) using a HPLC method with electrochemical detection. Developmental amitraz exposure decreased DA levels of male and female offspring at 60 days of age in the hippocampus (32%, $P<0.001$ and 8%, $P<0.05$), frontal cortex (17%, $P<0.001$ and 29%, $P<0.001$) and striatum (12%, $P<0.01$ and 13%, $P<0.001$). In contrast, amitraz caused a statistically significant increase in the turnover [(DOPAC+HVA)/DA] of male and female offspring at 60 days of age respectively, in the hippocampus (69%, $P<0.001$ and 58%, $P<0.001$) and striatum (41%, $P<0.001$ and 42%, $P<0.001$) respect to corn oil controls. These results suggest there are long-term alterations in the dopamine system after developmental amitraz exposure that might lead to enhanced vulnerability of the dopamine system. Work supported by projects No. CCG07-UCM/AGR-2618 & Consolider-Ingenio 2010 No.CSD2007-063 (MEC), Spain.

PS 1160 OCCUPATIONAL PESTICIDE EXPOSURE OF COUNTRY RESIDENTS AND POTENTIAL HEALTH EFFECTS IN CHINA.

Z. Zhou. *School of Public Health, WHO Collaborating Center for Occupational Health, Fudan University, Shanghai, China.*

Introduction This is to investigate the current situation of pesticides use in rural area and potential health effects on the operators, so that prevention against occupational pesticide poisoning can be effectively brought forward.
Methods A cross-sectional study was carried out among the rural residents in 57 teams. The demographic data and the information on the use of pesticides and protective way during a previous year were interviewed with questionnaire.
Results This study covered 3242 adult persons, among them 1315 (40.6%) had records of use of pesticides. The most uses occurred in the rice field, vegetable field, garden and green houses and spraying was done mostly in the summer (84.4%). Female had a higher exposed opportunity than the male, especially those aged from 40 to 60 ages. Various types of pesticides were used and the first ranking was insecticides (85.6%). The time of spraying varied from 1 to 81 and average time was 2 hours. 40.6% of farmers liked to use the mixed pesticides prepared by themselves in their agriculture activities. 78.3% of spraying apparatus were manual pressure sprayers, which had a lower quality with a frequent leak. When performing pesticides spraying, most of them did not use glove (63.3%), mask (86.2%) and glasses (92.0%). 97 persons reported that they had discomfort symptoms resulting from pesticide exposure and 29 persons saw a doctor. The gender, the mixing of pesticide, the diluting operation, gloves use during pesticide spraying had statistical relation with these complaints.

Discussion Obviously there were occupational health problems in the pesticides use in real area. It is important to popularize the safety knowledge of pesticide use and strengthen the management of pesticide mixture, spraying equipment and the sense of individual protection. More attention should be focused on the negative health effect among the elderly and women.

PS 1161 A DIETARY DOSE RANGE-FINDING AND TOXICOKINETIC (TK) STUDY OF 2, 4-DICHLOROPHENOXYACETIC ACID (2, 4-D) IN ADULT CRL:CD(SD) RATS AND THEIR OFFSPRING: I. TOXICOKINETICS.

S. A. Saghir[1], M. S. Marty[1], A. J. Clark[1], C. L. Zablotny[1], J. S. Bus[1], A. W. Perala[1], B. L. Yano[1] and B. H. Neal[2]. [1]*The Dow chemical Company, Midland, MI and* [2]*The Weinberg Group, Washington, DC.*

TK and toxicity data from a range-finding one-generation study were used to determine appropriate doses for an extended one-generation dietary toxicity study of 2,4-D in rats. Groups of 10 male (M) and female (F) CD rats were treated with 0, 100, 200, 400, 600, 800, 1200 or 1600 ppm 2,4-D in diet from pre-breeding through weaning. F1 offspring were exposed through postnatal day (PND)35. 2,4-D AUC24 h was calculated from 3 plasma samples collected at 6, 9 AM and 5 PM on designated sample days (based on Saghir et al., TAAP, 211:245, 2006). 2,4-D in milk was determined on lactation day (LD)4 and LD14 and in plasma of nursing pups by collection of a single 9 AM sample on PND4, 14, 21 and 28. Due to saturation of renal clearance, nonlinear TK was observed in parental M rats at 1600 ppm (test day [TD]28) and 1200 ppm (TD71). Onset of nonlinear TK in parental females was observed at <400 ppm (TD29 and 95; AUC100 ppm = 25, AUC400 ppm = 201 μg h ml-1). During gestation and lactation F 2,4-D levels were higher due to higher diet consumption; nonlinear TK occurred at <400 ppm (GD17 and LD14) and >400 and <800 ppm (LD4). The shift in nonlinear TK on LD4 may have been due to excretion into milk (levels approximately 50% of F plasma). Plasma 2,4-D in pups was 30-70% lower than the dam on LD4 (M/F TK nonlinear <800 ppm) but similar to or higher than dam on LD14 (M/F TK nonlinear <400 ppm). Maximal 2,4-D in pups was reached on PND21 when pups were consuming 2,4-D diet in addition to nursing, but dropped to levels equal to dams' on TD29 and TD95 levels on PND35. Thus, the kinetically-derived maximum dose (KMD) was 400 ppm (~25 mg/kg/day) for F and 1200 ppm (~65 mg/kg/day) for M. Increased dam and pup AUCs during lactation supported dietary dose adjustment during lactation. TK data support a definitive study high dose for females and pups lower than that derived by traditional toxicity. (Sponsored by the Industry Task Force II on 2,4-D Research Data)

PS 1162 HUMAN HEPATIC CYTOCHROME P450-SPECIFIC METABOLISM OF CHLORPYRIFOS, PARATHION AND METHYL PARATHION.

C. A. Ellison, R. J. Foxenberg, B. P. McGarrigle, J. B. Knaak and J. R. Olson. *Pharmacology & Toxicology, University at Buffalo, Buffalo, NY.*

Organophosphorous pesticides (OPs) are a concern to human health because of their continuing worldwide use. OPs are metabolized by cytochromes P450 (CYPs) either by a desulfuration reaction that results in an active oxon moiety which is a potent acetylcholinesterase inhibitor or by a dearylation reaction that results in detoxification of OPs. The balance between the rates of desulfuration (activation) and dearylation (detoxification) should, in-part, determine the risk to humans for a given OP. This study investigated the rate of desulfation and dearylation of parathion, methyl parathion and chlorpyrifos. Pooled human liver microsomes were used to assess the metabolism of parathion, methyl parathion and chlorpyrifos by measuring the rate of formation of their metabolites, paraoxon and p-nitrophenol (PNP), methyl-paraoxon and PNP or chlorpyrifos-oxon and 3,4,5-trichloropyrindinol, respectively. Kinetic parameters for the OPs varied as did the ratio of dearylation/desulfation products. Km and Vmax values for the formation of the active oxon moiety were determined to be 17.7uM, 790pmol/min/mg protein for parathion, 66.8uM, 1844pmol/min/mg protein for methyl parathion and 2.5uM, 346pmol/min/mg protein for chlorpyrifos. While, Km and Vmax values for formation of each OP's detoxified metabolite were 25.1uM, 588pmol/min/mg protein for parathion, 2.0uM, 123pmol/min/mg protein for methyl parathion and 16.2uM, 453pmol/min/mg protein for chlorpyrifos. In addition, recombinant human CYPs were used to quantify CYP-specific kinetic values for each compound. CYP2B6, 1A2, and 2C19 were the primary enzymes involved in bioactivation of the three OPs to their active oxon moiety, while CYP2C19 > 1A2 > 2B6 were the major CYPs involved in detoxification of parathion and chlorpyrifos. In contrast, CYP mediated dearylation of methyl parathion only occurred to a limited extent with CYP1A2 and 3A4. The OP- and CYP-specific kinetic values will be helpful for future use in refining human models of OP exposure. (EPA STAR grant R833454)

PS 1163 METHOXYCHLOR MAY CAUSE TOXICITY THROUGH THE ARYL HYDROCARBON RECEPTOR PATHWAY.

M. Basavarajappa, I. Hernadez-Ochoa, R. Gupta and J. Flaws. *Veterinary Biosciences, University of Illinois, Urbana, IL.*

Methoxychlor (MXC) is an organochlorine pesticide used against pests and insects that attack agricultural crops, gardens, trees, pets, and livestock. MXC has been shown to reduce fertility, cause ovarian atrophy, decrease the number of healthy antral follicles and induce atresia of antral follicles in female rodents. Further, MXC has been shown to inhibit the growth and induce atresia of antral follicles *in vitro*. Little is known about the mechanisms by which MXC inhibits antral follicle growth. Studies have shown that MXC binds to estrogen receptors α and β (ERα and β) as well as the aryl hydrocarbon receptor (AhR) in non-ovarian cells. While some studies have investigated the potential role of ER in mediating the toxicity of MXC, very few studies have examined whether the AhR mediates MXC toxicity. Thus, we hypothesized that MXC induces antral follicle toxicity through an AhR mediated pathway. To test this hypothesis, antral follicles were mechanically isolated from the ovaries of C57/BL6 female wild-type and AhR null (AhRKO) mice aged 30-35 days. The isolated antral follicles (10-15 per treatment group) were cultured in dimethyl sulfoxide (control; DMSO) or MXC (1,10,100μg/ml) for 168 hours at 37°C and 5%CO2 in α-minimum essential media. During culture, follicle growth was monitored every 24 hours by measuring follicular diameter on two perpendicular axes. The results indicate that MXC (10,100μg/ml) significantly inhibits follicular growth in wild-type antral follicles by 168 hours (DMSO=147.87±5.96μm, MXC10μg/ml=98.89±5.44μm, MXC100μg/ml=103.73±2.7, $p<0.05$, n=3). Conversely, MXC (10μg/ml) did not inhibit antral follicle growth in AhRKO follicles(DMSO=156.23±7.36μm, MXC10μg/ml=128.13±11.18μm, $p>0.05$, n=3). Collectively these data indicate that AhR deletion partially rescues antral follicles from MXC-induced growth inhibition. These data suggest that MXC may inhibit antral follicle growth through the AhR pathway. Support: NIH R01 ES012893, NIH R01 HD047275, and the Environmental Toxicology Program at UIUC.

PS 1164 AN EVALUATION OF THE MODE OF ACTION FRAMEWORK FOR MUTAGENIC CARCINOGENS: CHROMIUM (VI).

G. Akerman[1], N. McCarroll[1], J. Chen[1], N. Keshava[2], A. Kligerman[3] and E. Rinde[1]. [1]*Office of Pesticide Programs, U.S. Environmental Protection Agency, Washington, DC,* [2]*Office of Research and Development, U.S. Environmental Protection Agency, Washington, DC and* [3]*Office of Research and Development, U.S. Environmental Protection Agency, Research Triangle Park, NC.* Sponsor: M. Manibusan.

In response to the 2005 revised U.S Environmental Protection Agency's (EPA) Cancer Guidelines, a strategy is being developed to determine whether a carcinogen operates through a mutagenic mode of action (MOA). This information is necessary for EPA to decide whether age-dependent adjustment factors (ADAFs) should be applied to the cancer risk assessment. Chromium (VI), which is carcinogenic in animals and humans via the inhalation route, was assessed for carcinogenicity by the Cancer Assessment Review Committee (CARC) of the Office of Pesticides' Health Effects Division (HED) using the data from the National Toxicology Program (NTP) 2-year drinking water studies in rats and mice. From these data, CARC classified Cr (VI) as "Likely to be Carcinogenic in Humans" via the oral route, based on oral cavity tumors in male and female rats and tumors of the small intestine in male and female mice. Cr (VI) was also mutagenic in numerous in vitro assays, in animals and in humans occupationally exposed to Cr (VI). Accordingly, Cr (VI) was processed through the framework analysis and key steps leading to tumor formation were identified: interaction of cellular components (DNA) with Cr (VI), mutagenesis, cell proliferation (hyperplasia) and tumor formation. Supporting evidence is also found for cell proliferation, indicating that mutagenicity, associated with oxidative damage, DNA adduct formation and cytotoxicity, leads to a proliferative response in the process of tumor induction. Overall, the weight of evidence evaluation supports Cr (VI) acting through a mutagenic MOA. Therefore, the Cancer Guidelines recommend a linear extrapolation for the oral exposure risk assessment. The views expressed in this abstract are those of the authors and do not necessarily reflect those of the U.S. EPA.

PS 1165 DERMAL ABSORPTION OF PESTICIDE VAPORS.

M. H. Dong and S. Beauvais. *California Department of Pesticide Regulation, California EPA, Sacramento, CA.*

It is well accepted that for humans and rodents exposed to chemical vapors, the dermal intake (DI, mg/cm^2-event) may be approximated by Fick's first law of diffusion: $DI = K_p \times A \times C \times t$, where K_p = permeability constant (cm/h), C = vapor con-

centration (mg/cm^3), A = surface area exposed (cm^2), and t = exposure time (h/event). In line with this acceptance, over the years many investigators have proposed various equations to estimate the K_p of chemical vapors. These equations all used one or more of a vapor's physicochemical properties as input parameters, such as octanol-water partition coefficient (K_{ow}), Henry's Law constant (K_H), and vapor pressure (VP). In this study, a revisit of these equations indicated that overall the one expressing $\log K_p = a - b\,x\,(\log K_{ow}) - c\,x\,(\log VP)$ appeared to be most effective. Four datasets of experimental K_p available in the literature were used to support the equation selection, as well as to determine the values of the constants (a, b, c, etc.) in each equation attempted. For the above selected equation, the correlation coefficients *r* (for predicted vs. experimental K_p) ranged from 0.73 to 0.97. The selected equation was deemed highly practical because both the input parameters VP and K_{ow} of an organic vapor are readily obtainable. The equation was also considered to have great biological plausibility in that the DI of a vapor is supposed to be a function of the chemical's volatility (e.g., as measurable by K_H or VP) and lipophilicity (e.g., as measurable by K_{ow}). The four datasets on human or rodent skins were all for volatile organics not used as pesticides. Insofar as these data and the equations so derived can be extended to (highly) volatile pesticides (e.g., those with $K_H > 10^{-3}$ atm-m^3/mol), the K_p of regulatory concern are most likely <2 cm/h. This in turn suggests that regardless of the pesticide vapor concentration involved, the DI at issue are negligible when compared to the inhalation component, unless the person is required to wear a self-contained breathing apparatus during the exposure period.

PS 1166 A PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODEL FOR CYPERMETHRIN IN THE RAT AND HUMAN.

X. Zhang[1], R. Tornero-Velez[2], J. B. Knaak[3], L. S. Harrison[1], R. Goldsmith[2], S. Peterson[4] and C. C. Dary[4]. *[1]General Dynamics Information Technology, Henderson, NV, [2]NERL, U.S. EPA, Research Triangle Park, NC, [3]Department of Pharmacology and Toxicology, SUNYAB, Buffalo, NY and [4]NERL, U.S. EPA, Las Vegas, NV.*

Cypermethrin, known as (RS)-α-cyano-3-phenoxybenzyl (1RS)-cis-trans-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate, is a type II pyrethroid that is widely used for insect pest control. To better understand human exposure to cypermethrin, a physiologically-based pharmacokinetic (PBPK) model was developed for the rat and human using the software package, Exposure Related Dose Estimating Model (ERDEM). The ERDEM model included various physiological tissues/organs, a full gastro-intestinal compartment, bilary and urinary excretion, and fecal elimination of various metabolites. To better describe the distribution of the parent compound in the fat and slowly perfused tissue, a diffusion-limited (intracellular and extracellular) model was further implemented in these two compartments. Complete metabolic pathways were determined based on the literature, including the metabolic difference between cis- and trans-cypermethrin and two important urinary biomarkers, 3-phenoxy benzoic acid and dichlorocyclopropane carboxylic acid. Tissue blood partition coefficients for all chemicals were predicted by a computational model. Michaelis-Menten kinetic parameters describing the metabolism and urinary excretion were based on experimental evidence from the literature. The human model was extrapolated from the rat model and further optimized with human exposure data. Visual comparison between the experimental measurement and the simulated results indicated that both the rat and human model could simulate the tissue distribution and excretion data with satisfaction. With the constructed PBPK cypermethrin model, human exposure data can be analyzed and a further cumulative model for multiple pyrethroids can be considered.

PS 1167 EVALUATION OF THE ANTIFUNGAL ACTIVITY OF TWO ANALOGS OF EBSELEN.

B. Billack[1], M. Pietka-Ottlik[2], M. Santoro[1], S. Nicholson[1], J. Mlochowski[2] and C. Lau-Cam[1]. *[1]Pharmaceutical Sciences, St. John's University, Jamaica, NY and [2]Organic Chemistry, Wroclaw University of Technology, Wroclaw, Poland.*

The yeast plasma membrane H+-ATPase (Pma1p) is a high capacity proton pump which plays a critical role in intracellular pH regulation and nutrient uptake among yeast and other fungi. The antifungal activity of ebselen (**1**), an organoselenium compound, stems, at least in part, from its inhibitory action on the fungal Pma1p. In the present study, the antifungal activity of 2-(3-pyridinyl)-benzisoselenazol-3(2H)-one (**2**) and 2-phenylbenzisoselenazol-3(2H)-one 1-oxide (**3**), two ebselen analogs, was evaluated using a strain of *S. cerevisiae* and compared against that of **1**. The study has also examined the inhibitory potential of these three compounds towards the Pma1p of *S. cerevisiae*. Based on mean IC50 values, the antifungal potency was found to decrease in order **3**>**1**>**2**. However, in terms of inhibitory action on Pma1p, the potency decreased in the order **1**>**3**>**2**. The magnitude of these activities appear to correlate with the corresponding log P values, with compound **2** being the most hydrophilic and the least active of the three. The possible occurrence of a covalent interaction between the test compounds and critical cysteine residues in Pma1p was inferred from the results of a thin-layer chromatographic study of the products obtained by reacting **1**, **2** or **3** with L-cysteine and detecting, in each case, a chromatographic spot having a migration behavior different to that of the organoselenium compound. Future studies will be required to determine the number and location of the cysteine residues in Pma1p that are susceptible to modification by ebselen and its analogs.

PS 1168 COMPARATIVE CHLORPYRIFOS PHARMACOKINETICS *VIA* MULTIPLE ROUTES OF EXPOSURE AND VEHICLES OF ADMINISTRATION.

J. N. Smith[1], J. A. Campbell[1], A. L. Busby[1], T. S. Poet[1], D. B. Barr[2] and C. Timchalk[1]. *[1]Biological Monitoring and Modeling, Pacific Northwest National Laboratory, Richland, WA and [2]National Center For Environmental Health, CDC, Atlanta, GA.*

There have been numerous studies evaluating toxic and pharmacokinetic effects of the organophosphate insecticide chlorpyrifos (CPF) in which, CPF has been administered using different routes and vehicles. The objective of this study was to compare CPF pharmacokinetics using oral, intravenous (IV), and subcutaneous (SC) routes as well as corn oil, saline, and dimethyl sulfoxide (DMSO) vehicles in the rat. In the first study, CPF and isotopically labeled CPF (L-CPF) were co-administered, at doses of 5 mg/kg each, orally and IV in a saline with 5% Tween 20 vehicle. In the second study, the same doses of CPF and L-CPF were co-administered SC using corn oil and DMSO. Blood and urine samples were collected and analyzed for CPF and trichloropyridinol (TCPy). Oral CPF administration resulted in the highest peak concentration of TCPy (7-11 times higher), which also occurred most rapidly (1.5 hr prior to the next closest). SC administration with a corn oil vehicle led to faster absorption/metabolism of CPF than did SC administration using DMSO as a vehicle (ka/f: 0.6 and 0.2 μmol/hr, respectively). IV administration of CPF caused bimodal pharmacokinetics, probably due to CPF partitioning into fat once in the body. For all exposure routes and vehicles, ~85% of the molar dose of CPF was excreted as some conjugated form of TCPy. Overall, orally administered CPF underwent much more extensive and rapid metabolism than did other routes investigated, probably due to first-pass metabolism. This suggests that CPF administered systemically could result in a greater body burden of CPF than would an equivalent dose administered orally, potentially leading to a higher CPF concentration at target tissues. These results will be useful for elucidating differences regarding potential uncertainty in CPF pharmacokinetics due to varying exposure routes and vehicles of adminsitration. (Funded by CDC/NIOSH Grant R01 OH008173 and AGR05FED40077.02)

PS 1169 THE EFFECTS OF ZIRAM ON RAT HIPPOCAMPAL ASTROCYTES.

A. Matei and L. D. Trombetta. *Pharmaceutical Sciences, St. Johns University, New York, NY.*

Ziram (zinc-bis(dimethyldithiocarbamate)) is an agricultural dithiocarbamate fungicide that is used on a variety of plant diseases. In recent years, epidemiological studies have linked exposure to environmental agents such as pesticides with an increased risk of developing neurodegenerative diseases. In spite of their generally acknowledged low toxicity, dithiocarbamates are known to cause a wide range of neurobehavioral effects as well as neuropathological changes in the brain. Furthermore, the dithiocarbamate, ziram, has been reported to cause hepatotoxicity, thyroid toxicity and have adverse effects on the reproductive system and the developmental process. This investigation studied the effects of ziram on rat hippocampal astrocytes. Cells were maintained in Dulbecco's Modified Eagle's Medium supplemented with 10% fetal bovine serum. Astrocytes were exposed to 1uM of ziram and 300 uM of zinc chloride for one hour at 37 degrees C and then re-fed with complete medium for 24 hours. Morphological observations, by phase contrast and scanning electron microscopy, in treated astrocytes showed blebbing, increased numbers of retraction fibers and distortion of cellular processes. Inductively Coupled Plasma-Optical Emission Spectroscopy (ICP-OES) demonstrated, in all cases of treatment with Ziram,a significant increase of copper when compared to controls. However,zinc levels in the ziram treated astrocytes and the control astrocytes were not statistically different. The ICP-OES analysis of the zinc chloride treated astrocytes revealed a significant increase of zinc levels and no statistical difference of copper levels when compared to control astrocytes. The total antioxidant assay revealed a significant decrease in the antioxidant capabilities of ziram treated astrocytes. This preliminary data suggests that the cytotoxic effects observed in the ziram treatments may be related to the increased copper levels resulting in oxidative stress. Further studies will be needed to elucidate the mechanism of action induced by ziram on rat hippocampal astrocytes.

PS 1170 PREDICTIVE CAPACITY OF SELECTED (Q)SAR MODELS FOR PESTICIDES IN A REGULATORY SETTING.

M. Manibusan[1], E. Scollon[1], C. Moudgal[2] and C. Olinger[1]. *[1]Office of Pesticide Programs, U.S. EPA, Washington, DC and [2]Office of Research and Development, U.S. EPA, Washington, DC.*

In pursuit of the Agency's goal for the protection of human health and the environment, the Office of Pesticide Programs (OPP) is examining alternative methods to enhance the comprehensiveness of pesticide risk assessments. Toxicity testing in the 21st century will feature alternative methods such as in silico technologies that will potentially reduce or refine animal testing requirements while increasing the efficiency and confidence in risk assessments. Although submissions for pesticide registration generally include comprehensive toxicity data sets, OPP is investigating the use of predictions from Quantitative Structure Activity Relationship ((Q)SAR) models to support the assessment of pesticides and/or to demonstrate the need for additional testing. Commercial (Q)SAR programs TOPKAT®, Multicase®, and DEREK for Windows® were assessed for their ability to predict carcinogenicity, genotoxicity, and developmental toxicity individually and in a consensus modeling approach. Model results were compared to empirical data for approximately 50 pesticides spanning 10 classes. Individually, the models were equivalent in their ability to correctly predict cancer, genotoxicity, and developmental toxicity endpoints compared to the empirical data. Concordance values were highest and lowest for the genotoxicity and developmental endpoints, respectively. Furthermore, confidence in the developmental endpoint predictions was low because the pesticides routinely fell outside the models' applicability domain. Consensus modeling generally provided greater predictive accuracy than the individual models alone. This study indicates it is critical to populate training sets with pesticide data to increase the applicability of these (Q)SAR models for pesticide structures. The approaches investigated in this study will contribute to EPA's ongoing efforts to work toward the vision of toxicity testing in the 21st century.
The views expressed in this abstract are those of the authors and do not necessarily reflect those of the U.S. EPA.

PS 1171 ASSESSMENT OF PESTICIDE CYTOTOXICITY USING CEREBROMICROVASCULAR ENDOTHELIAL CELLS.

K. Nisar[1], J. Wright[2], P. Mistry[2], C. Cantrill[1] and J. Penny[1]. *[1]School of Pharmacy, University of Manchester, Manchester, United Kingdom and [2]Human Safety, Syngenta, Bracknell, United Kingdom.*

The blood-brain barrier (BBB) acts as a protective interface between peripheral and central environments and limits brain exposure to environmental toxicants. P-glycoprotein (P-gp) is expressed in BBB cerebromicrovascular endothelial cells (CEC) and plays an important role in protecting the brain from toxic insult.
The aims of this study were to (i) identify a series of pesticides reported to interact with P-gp, (ii) assess pesticide toxicity towards CEC (iii) establish a physiologically representative in vitro BBB model.

Methods: Identification of pesticides: Thorough literature searches using Pubmed and Medline were carried out to identify structurally diverse compounds. Isolation of CEC: Freshly obtained porcine brain tissue was homogenised and the microvessels treated with collagenase, typsin and DNase I. Cytotoxicity assay: CEC were cultured in 96-well plates. Pesticide toxicity was assessed using the MTT assay and measurement of product formation at 550nm. Culture of CEC on Transwell inserts: CEC were cultured on Transwell inserts over seven days in the presence and absence of astrocytes. Monolayer transendothelial electrical resistance (TEER) was measured using a voltohmeter.
Results: Nine structurally diverse P-gp substrates were identified and toxicity profiles obtained. CEC possessed typical morphology, expressed the tight junction protein ZO-1 and routinely exhibited a TEER between 1475 and 2000 Ω.cm2.
Conclusion: CEC have been successfully isolated from porcine brain and maintained in culture. CEC may offer a valuable in vitro model to measure xenobiotic cytotoxicity. A physiologically representative porcine BBB in vitro model has been successfully established which will allow the study of toxicant interaction with BBB-associated transporter proteins.

PS 1172 AVERMECTIN TRANSPORT BY MDR1 IN SH-SY5Y NEUROBLASTOMA CELLS.

A. M. Dalzell[1], F. M. Williams[3], P. Mistry[2], J. Wright[2] and C. Brown[1]. *[1]Cell and Molecular Biosciences, University of Newcastle, Newcastle, United Kingdom, [2]Human Safety, Syngenta, Bracknell, United Kingdom and [3]Medical Toxicology Centre, University of Newcastle, Newcastle, United Kingdom.*

Avermectins are used as agricultural insecticides and as anti-helminthic treatments in man. Avermectins have a good safety profile in a variety of species; however toxicities observed in the CF-1 mouse model initiated investigations into the relevance of this model for human risk assessment. The CF-1 mouse lacks a functional xenobiotic efflux transporter, multidrug resistance protein or P-glycoprotein (mdr1a or P-gp). In humans a non-functional MDR1 has yet to be identified, although polymorphisms do exist and their significance in efflux transport needs to be better understood. The aim of this study was to assess the MDR1 efflux transport of avermectins in human neuroblastoma cells (SH-SY5Y), previously characterised for uptake and efflux transporter expression. SH-SY5Y cells were loaded with the MDR1-substrate Hoechst 33342 (H33342) in the absence or presence of avermectins (0-10μM) and the intracellular retention of H33342 was measured by fluorescence spectroscopy. The impact of avermectins (5μM) upon the intracellular retention of H33342 was compared with that of cyclosporin A (MDR1 substrate). Cytotoxicity was measured using the MTT assay to confirm integrity of the model system. Incubation of cells with abamectin or emamectin resulted in a significant ($p<0.05$) increase in H33342 dye retention by the cells which was of a similar order of magnitude as that achieved in the presence of cyclosporin A. Dose response curves for the ability of abamectin and emamectin to inhibit MDR1-mediated H33342 dye efflux gave apparent Ki values of 2.31.±.0.30 and 0.20 ±0.09μM respectively. These values compared with a Ki of 2.52±0.31μM for the interaction of cyclosporin A with MDR1. SH-SY5Y cells are a good model in which to investigate the efflux of avermectins and confirm the involvement of human MDR1 in avermectin disposition. Future work will involve establishing in vitro overexpression systems to investigate the role of specific polymorphisms in avermectin efflux.

PS 1173 ISOFENPHOS-INDUCED DNA DAMAGE IN HUMAN LYMPHOCYTES IS MEDIATED *VIA* THE PRODUCTION OF OXIDATIVE STRESS.

S. O. Heyliger, M. D. Saulsbury, K. Wang, J. K. Morse and D. J. Johnson. *Pharmaceutical Sciences, Hampton University, Hampton, VA.*

Recent studies suggest that individuals who are chronically exposed to organophosphate pesticides may suffer higher incidences of chromosomal damage and leukemia. An organophosphate which may pose significant carcinogenic risks is Isofenphos (IFP) and its metabolite Isofenphos-oxon (IFP-oxon). IFP is utilized to control soil-based insects and is applied to fruits and vegetables including corn, carrots and bananas. It is also used to control termite population in edifices. It should be noted that IFP persists in soil and water for several months and weeks and its metabolite IFP-oxon may be just as potent and may persist longer in the environment than its parent. This study was designed to determine if Isofenphos exposure promotes genomic instability in human lymphocytes. Isofenphos (IFP) produced dose-dependent toxicity in Jurkat lymphocytes. Exposure to IFP for 24 hours induced dose dependent toxicity and dose dependent reductions in cellular GSH levels. Pretreatment with Atropine (10uM), Mecamylamine (100uM), L-NAME (100uM), Caspase inhibitor QVDOPh (50uM) failed to alter IFP-induced toxicity. However, the addition of antioxidants N-acetylcysteine (5mM) and Vitamin E (50uM) significantly reversed the effects of IFP ($p<0.05$). In the comet assay, IFP caused significant DNA damage in a dose-dependent mechanism. Moreover, IFP-induced DNA damage was partially attenuated by pretreatment by 100uM Vitamin E ($p<0.05$). Our data indicates that IFP is indeed genotoxic and that IFP-induced DNA damaging properties is mediated by the production of oxidative stress rather than by cholinesterase inhibition.

PS 1174 TISSUE DISTRIBUTION AND ELIMINATION KINETICS OF FLUOROSULFATE (FSO_3) AND FLUORIDE (F) IN ADULT RATS EXPOSED TO SULFURYL FLUORIDE (SO_2F_2).

D. L. Rick[1], S. M. Krieger[1], D. A. Markham[1], M. J. Filary[1], M. J. Bartels[1], J. A. Hotchkiss[1] and D. L. Eisenbrandt[2]. *[1]The Dow Chemical Company, Midland, MI and [2]Dow AgroSciences, LLC, Indianapolis, IN.*

Sulfuryl fluoride (SO_2F_2) is a structural and post-harvest fumigant and a key alternative to methyl bromide, a stratospheric ozone-depleting fumigant scheduled for phase-out by the Montreal Protocol. Inhaled SO_2F_2 is rapidly hydrolyzed to fluorosulfate (FSO_3) and one equivalent of fluoride (F). FSO_3 is subsequently hydrolyzed to sulfate and a second F equivalent. Fluoride appears to play a role in the mechanism of action of SO_2F_2 in both insects and mammals. Groups of adult male F344/DuCrl rats were exposed to 0, 3, 30, or 300 ppm SO_2F_2 for 4 h in order to examine the absorption, distribution, metabolism and elimination of inhaled SO_2F_2 and the metabolites FSO_3 and F. Plasma, kidney, cerebrum, olfactory bulb, nasal and pulmonary tissues were analyzed for FSO_3 and F levels at 0, 2, 4, and 8 h after exposure. Rats were fed a low F diet and deionized water for two weeks prior to exposure to enhance the ability to detect elevated F levels in treated vs control groups. Tissue FSO_3 levels were measured using ion chromatography with negative ion electrospray ionization mass spectrometry (IC/NESI/MS), while F was measured by micro-diffusion with ion-selective electrode detection (MD/ISE). Fluoride concentrations above the lower limit of quantitation (0.027 μg F/g tissue) were measured in all tissue samples from 0 ppm (control) rats. Immediately after exposure,

FSO_3 and F were measured in approximately equimolar amounts in plasma, kidney and lung. Tissue F levels were roughly dose proportionate in rats exposed to 30 or 300 ppm SO_2F_2. Both FSO_3 and F were rapidly cleared from tissues with elimination half-lives of less than 3 h. These data will aid in the development of a multi-compartment PBPK model which can be utilized for human risk assessments.

PS 1175 OXIDATIVE STRESS AND GENOTOXIC EFFECTS INDUCED BY *IN UTERO* AND LACTATIONAL EXPOSURE TO ENDOSULFAN ON RAT PITUITARY. A.

A. Lafuente[1], T. Cabaleiro[1], A. Caride[1], B. Fernandez-Perez[1] and A. Anadon[2]. *[1]Toxicology Laboratory, Faculty of Sciences, Vigo University, Orense Campus, Orense, Orense, Spain and [2]Department of Toxicology and Pharmacology, Faculty of Veterinary Medicine, Universidad Complutense, Madrid, Spain.*

Endosulfan is an organochlorine insecticide that is considered an endocrine disruptor and induces oxidative stress. We have investigated at pituitary level whether the expression of prolactin, luteinizing hormone (LH), growth hormone (GH) and thyroid stimulating hormone (TSH) and of the prooxidant enzymes nitric oxide synthase (NOS) 1 and 2, and heme oxygenase-1 (HO-1) can be affected by the xenoestrogen endosulfan treatment during gestation and lactation. For that, dams were treated orally with 0.61 or 6.12 mg endosulfan/kg/day from the gestation beginning until the weaning. Dams were sacrificed the day after the weaning and offspring were sacrificed at postnatal days (PND) 15, 30 and 60. Endosulfan increased prolactin mRNA levels in PND 30 and 60 female rats and dams, however decreased in PND 30 male rats. The expression of LH and GH decreased in male and female at PND 30 after pesticide exposure, but GH mRNA levels were increased in dams. TSH mRNA expression diminished in both PND 30 males and dams. In addition, NOS-1 and NOS-2 mRNA levels were increased in offspring, but it was decreased in mothers. HO-1 expression was increased in males, adult female offspring and dams, however it was decreased in PND 15 and 30 female rats. Altogether our results are consistent with endosulfan having main effects on pubertal rats hormone expression on pituitary gland and inducing the expression of enzymes related with oxidative damage, and supports the genotoxicity of this pesticide. This work was supported by a grant from the Ministry of Education and Science, Spain (AGL2004-04543/ALI).

PS 1176 SAFETY DOSSIERS FOR AGROCHEMICALS DON'T NEED A 12-MONTH STUDY IN DOGS.

I. Fegert[1], R. Billington[2], R. Lewis[3], K. S. Bentley[4], W. Bomann[5], P. A. Botham[3], B. Stahl[5] and B. van Ravenzwaay[1]. *[1]BASF SE, Ludwigshafen, Germany, [2]Dow AgroSciences, Oxon, United Kingdom, [3]Syngenta, Bracknell, Berkshire, United Kingdom, [4]The DuPont Company, Newark, DE and [5]Bayer CropScience SA, Sophia Antipolis, France.*

Safety for users and consumers is a key element in the development of crop protection products and their active ingredients. The toxicology database required for the registration of a pesticide has been developed since the 1950's. Repeat dose studies with rodents and non-rodents are a core element, and for more than three decades it was an established standard to perform subchronic and chronic oral studies in rats and dogs in order to evaluate systemic toxicity in accordance with international (OECD, EU) and national test guidelines (US-EPA, JMAFF and many others). The subchronic study normally lasts for three months, while the chronic dog study should last one year. A review of publications on pesticides dealing with the need to investigate toxicity in dogs and the duration of such studies was performed. A substantial number of publications confirm the need for systemic toxicity tests in a second species (non-rodent) in the hazard assessment for agrochemicals. Three key publications with different approaches investigated the value of a 12-month dog study in addition to a 3-month study. Despite different databases and approaches, all conclude with the recommendation to limit dog testing with pesticides to 3-month studies. A synthesis of these reviews was performed and the conclusion was drawn that the conduct of a 12-month study in addition to a 3-month study is not needed to adequately assess the safety of pesticides. It is recommended to abandon the requirement for a 12-month dog study and adapt the pesticide legislation where it is still a requirement. This is in agreement with the recommendation from ILSI's HESI Agricultural Chemical Safety Assessment (ACSA) committee.

PS 1177 ALLOWABLE DRINKING WATER CONCENTRATIONS FOR NON-RELEVANT METABOLITES OF PESTICIDES – PROPOSAL FOR A HEALTH BASED APPROACH.

S. Melching-Kollmuss[1], W. Dekant[2] and F. Kalberlah[3]. *[1]BASF SE, Ludwigshafen, Germany, [2]Department of Toxicology, University of Würzburg, W√ºrzburg, Germany and [3]FoBiG, Freiburg, Germany.*

Pesticides are strictly regulated and an extensive toxicological testing of each Active Ingredient is required. In Europe a clear Cut-Off criterion is a concentration of the pesticide or its relevant metabolite in ground and drinking water of above 0.1 µg/L. Limits for allowable concentrations of non-relevant metabolites of pesticides in drinking water between 0.1 and 10 µg/L are discussed and their regulation is not strictly health-based. The Acceptable Daily Intakes (ADI) of 429 pesticides have been converted to ground/drinking-water concentrations using the WHO formula (10% ADI, 2L water/day, 70 kg body weight). The toxicological properties of 47 non-relevant metabolites and their parents have been studied and compared. The transferability of the threshold of toxicological concern (TTC) concept to the regulation of non-relevant metabolites in water has been investigated. A testing strategy has been developed, considering aspects of costs, time, reduction of animal testing and protection of public health. Different safety factor approaches have been compared. Only for 5% of the plant protection products - which are not toxic, mutagenic, reprotoxic, or carcinogenic - the toxicologically allowable drinking water concentration are < 10 µg/L. In general the non relevant metabolites are not more toxic than the parent. At concentrations < 4.5 µg/L (intake of 10% ADI via drinking water) no toxicological testing – except for genotoxicity - is necessary. At concentrations ≥ 4.5 µg/L enhanced 28/90-day studies (reproduction, endocrine disruption) are proposed. Safety factors of 300/1000 are used in chemicals regulation at an outside estimate. It is concluded, that the TTC concept should be applied to non relevant metabolites (no toxicological testing in concentrations < 4.5 µg/L), that safety factors of 300/1000 are protective and that a default of 10% ADI allocation is precautious.

PS 1178 *IN VITRO* AND *IN VIVO* ASSESSMENT OF ESTROGENIC ACTIVITY OF THE PYRETHROID METABOLITES 3-PHENOXYBENZOIC ACID AND 3-PHENOXYBENZYL ALCOHOL.

M. Pine, B. Laffin and M. Chavez. *Veterinary Integrative Biosciences, Texas A&M University, College Station, TX.*

One of the most frequently used classes of pesticide is the synthetic pyrethroids. While less acutely toxic to humans than organochlorines or organophosphates, in vitro studies have suggested that pyrethroids may be potential endocrine disrupting agents. Our laboratory recently showed that low doses of the type II pyrethroid esfenvalerate suppressed serum estradiol and delayed pubertal onset in female rats. Interestingly, the chemical structure of some pyrethroid metabolites indicate that they may be more likely to interact with the estrogen receptor than the parent compounds. Two metabolites, 3-phenoxybenzoic acid (3PBA) and 3-phenoxybenzyl alcohol (3PBalc) have been reported to be antiestrogenic and weakly estrogenic, respectively, in a yeast based assay. To determine if the metabolites were able to cause the same effects in a mammalian system, MCF-7 cells were treated with 1.0 or 10.0 µM concentrations of each metabolite and cell proliferation was measured. Both concentrations of PBA and PBalc increased cell proliferation over controls after 5 days ($P<0.05$). However, neither metabolite was able to induce an Estrogen receptor α / ERE controlled luciferase reporter in MCF-7 cells, suggesting that proliferation increases were not mediated via ERα transcriptional activity. The metabolites were then evaluated in vivo using female Sprague Dawley rats. Neither metabolite (0, 1.0, 5.0, or 10.0 mg/kg; gastric gavage) had any effect on uterine wet weight following a 3-day uterotrophic assay. Finally, immature female rats were orally gavaged (0, 1.0, 5.0, or 10.0 mg/kg) beginning one day post weaning until the onset of puberty as evidenced by vaginal opening (VO). Again, neither metabolite had any effect on the onset of VO. Based on the results from the in vivo assays, this study suggests that neither metabolite exhibit any potential to cause adverse estrogenic effects.

PS 1179 EFFECT OF CYPERMETHRIN (RIPCORD/CYMBUSH) ON THYROID FUNCTIONS OF ALBINO WISTAR RATS.

K. V. Olorunshola[1], D. O. Akanbi[2] and M. E. Ekanem[3]. *[1]Department Of Human Physiology, Faculty Of Medicine, Ahmadu Bello University, Zaria, Kaduna, Nigeria, [2]Department Of Physiology And Pharmacology, Faculty Of Veterinary Medicine, Ahmadu Bello University, Zaria, Kaduna, Nigeria and [3]Department Of Chemical Pathology, Ahmadu Bello University Teaching Hospital, Ahmadu Bello University, Zaria, Kaduna, Nigeria.* Sponsor: C. Nduaka.

Cypermethrin is a pyrethroid insecticide in use extensively in agriculture and public health. Neurotoxicity and hepatotoxicity of cypermethrin are widely reported. The effect of 1mg and 6mg/kg b.w. of cypermethrin administered orally daily for 8 weeks on weekly body weight, serum levels of T3, T4 and TSH were determined in two groups of rats (8 rats per group). Histopathological sections of the thyroid glands were also examined. The results were compared with those of control animals. Both doses of cypermethrin lead to statistically significant decrease in body weight ($P < 0.05$). Mean serum T3 level was significantly higher and showing a dose dependant steady rise ($P < 0.05$) in rats treated with cypermethrin. Mean T4 level was significantly increased ($P <0.05$) from the 3rd week of the experiment to

the end with 1mg/kg bw of cypermethrin. Mean serum levels of TSH was significantly raised by 6mg/kg bw of cypermethrin. Histologically, the thyroid gland of cypermethrin treated rats showed mild to moderate atrophy of the follicles with lymphoid infiltration.

PS 1180 PHARMACOKINETIC EVALUATION OF PERMETHRIN ENANTIOMERS IN RAT TISSUES.

Y. M. Sey[1], R. A. Harrison[1], E. M. Ulrich[2] and M. J. Devito[1]. *[1]NHEERL, U.S. EPA, Research Triangle Park, NC and [2]NERL, U.S. EPA, Research Triangle Park, NC.*

Pyrethroids are neurotoxic insecticides that are used in agricultural, residential, and public health activities. The ubiquitous exposures to pyrethroids require understanding of the risk posed to human and ecological health. Since identification of the active toxicophore is essential for improved risk analysis, understanding the active stereoisomer is not only important but remains largely unresolved. While evaluation of the exposure, toxicity and disposition of pyrethroid isomers has been examined at the diastereoisomer level, information at the enantiomer level is limited. Thus, this study aimed to develop a LC/MS method to identify and quantitate all four permethrin stereoisomers in rat tissues for improved risk analysis. Adult male Long Evans rats were exposed to a single dose of permethrin (40:60% cis:trans) orally at 10 mg/kg or intravenously (IV, jugular vein) at 5 mg/kg body weight. Serial blood samples were collected over 24 hrs. Permethrin isomers were extracted from samples, cleaned by solid phase extraction, dried, and reconstituted before analysis by LC/MS. Stereoisomer separation was achieved on a Chiralcel-OJ stationary phase with 98:2 hexane:ethanol mobile phase at 0.8 ml/min. Detection of selected ions was by atmospheric pressure chemical ionization mass spectrometry in the positive mode. For both blood and brain, the limit of quantitation was between 50-150 pg/µl per permethrin enantiomer. Matrix based calibration curves were linear for each enantiomer over a range of 50-5000 pg/µl with regression coefficient exceeding 0.99. Initial findings indicate that the IV and oral area under the plasma concentration time curve (AUC) for the cis- isomers was greater than the trans-, indicating slower degradation/elimination of cis-permethrin. However, there was no difference in the AUC among the cis- and trans-enantiomers. These studies suggest that the pharmacokinetics of the permethrin diastereomers are different but at the enantiomeric level, the pharmacokinetics are similar. (This abstract does not reflect EPA policy).

PS 1181 PHEROMONES - TOXICOLOGY AND PUBLIC HEALTH.

A. Fan, D. Ting, M. Verder-Carlos, J. Wisniewski, W. Ngai, C. Steinmaus and G. Alexeeff. *Cal EPA, Oakland, CA.*

This study evaluates the toxicologic properties and components of a public health program in addressing the use of pheromones (Straight chain lepidopteran pheromomes, SCLPs) as an integrated pest management tool in California for combating the light brown apple moth which is native to Australia. SCLPs are a class of chemicals with low acute toxicity (high LD50s, irritation). Subchronic tests showed no or minimal effect. SCLPs have been granted federal exemptions from food tolerances and long-term testing. They are used in various formulations and in tools such as dispensers, sprays and traps. These synthetic chemicals are identical to natural pheromones that attract (but do not kill) the moths and are used in a manner to prevent mating and propagation of future generations. Aerial applications of a synthetic pheromone formulation in 2007 at very low levels were followed by reports of symptoms, mostly self-reported irritation in nature. We analyzed these reports including those from physicians under the current Pesticide Illness Reporting system and were unable to identify an associated cause. We conducted additional analyses of the physician reports and surveys to identify possible ways of improving this reporting system. We are setting up a toll-free telephone system to provide a resource for health related information and a centralized means for future symptom reporting. We conducted education and outreach activities to address health issues of concern relating to the active and inert chemical ingredients involved and routes and forms of exposure. We evaluated prior experience in the U.S., Australia, New Zealand and Canada regarding invasive pests and pesticide use, toxicology and health issues. Results indicated that notification, knowledge of toxicology, recognition of concerns, education and outreach, and health risk assessments are important components in addressing the use of pesticides to combat invasive species

PS 1182 ROLE OF HUMAN SERUM ALBUMIN IN THE DETOXICATION OF ORGANOPHOSPHORUS INSECTICIDES.

M. A. Sogorb, E. Vilanova, E. Encarnación Quesada, S. Sara García-Argüelles and V. Carrera. *Toxicolgia. Instituto Bioingeniería, Universidad Miguel Hernández de Elche, Elche, Spain.*

The capability of human serum albumin (HSA) to detoxify the organophosphorus compounds (OPs) paraoxon and chlorpyrifos-oxon was studied at high and low OP concentrations. OP hydrolysis was studied using classical colorimetric methods, while the assays at low concentrations were performed by a method based on the comparison of the capability of OP solutions to inhibit acetylcholinesterase just before and immediately after incubation with HSA. Chlorpyrifos-oxon was hydrolyzed by HSA with a Km of 2.6 mM and Kcat of 6.4 x10-4 s-1, while the corresponding figures for paraoxon hydrolysis were 0.38 mM and 2.4 x 10-5 s-1. Thus, HSA hydrolyzed chlorpyrifos-oxon with a catalytic efficacy around 3.7 times higher than paraoxon. Paraoxon and chlorpyrifos-oxon also were hydrolyzed by HSA at significant rates at OPs concentrations in the same order of magnitude than their respective acetylcholinesterase inhibition constants for 3 minutes of exposure. Chlorpyrifos-oxon was again better substrate than paraoxon for HSA. The incubation (8 h at 37 °C) of a 2 µM chlorpyrifos-oxon solution in presence of 13 mg HSA/mL caused 93% of hydrolysis (estimated by recording a reduction of acetylcholinesterase inhibition power of 67%). However, the hydrolysis was only 26% (9% of acetylcholinesterase inhibition reduction) after incubation in the same conditions of a 14 µM paraoxon solution. It is concluded that HSA exhibits capability to detoxify paraoxon and chlorpyrifos-oxon even at concentrations 27 and 1300 times lower than the respective Km and despite the low Kcat. Furthermore, taking into consideration the high HSA concentration circulating in blood (around 40 mg/mL) these data suggest that HSA might play a relevant role in the detoxication of OPs. Work partially supported by grants GV2007/033 (Generalitat Valenciana) and A051/2007/3-14.4 (Environmental Ministry of Spanish Government)

PS 1183 PARAOXONASE 1 STATUS AND ACTIVITY LEVELS AS RELATED TO RACE AND SEX IN HUMAN POPULATIONS IN THE DEEP SOUTH.

H. Coombes[1], H. W. Chambers[2], J. A. Crow[1], E. C. Meek[1] and J. E. Chambers[1]. *[1]College of Veterinary Medicine, Mississippi State University, Mississippi State, MS and [2]Department of Entomology and Plant Pathology, Mississippi State, Mississippi State, MS.*

Paraoxonase1 (PON1; a calcium-dependent A-esterase) can hydrolyze and thereby detoxify a variety of organophosphates (OP's), including the active metabolites (oxons) of a number of insecticides, such as chlorpyrifos and diazinon. Comparisons of paraoxonase to diazoxonase activities in the serum can characterize an individual into one of three genotypes (i.e., PON1 status: QQ, QR or RR) for the most important PON1 polymorphism, the Q192R polymorphism. PON1 is associated with the HDL particle and is involved in hydrolyzing oxidized lipids and protecting cardiovascular health. The Q form of PON1 is more efficient at hydrolyzing diazoxon and is more protective of cardiovascular health, while the R form is more efficient at hydrolyzing paraoxon and chlorpyrifos-oxon and is less protective of cardiovascular health. With 200 purchased serum samples, African American populations in the South displayed a higher proportion of the RR genotype than Caucasians, which corresponds to their higher prevalence of cardiovascular disease. Cardiovascular health status of these individuals was not known. Males and females displayed similar activity levels of both paraoxonase and diazoxonase. Arylesterase activity, monitored with phenyl acetate hydrolysis, did not characterize genotypes as effectively as diazoxonase activity. None of these samples were from smokers, as indicated by low cotinine levels. A pilot study is in progress that obtains blood samples from individuals in Mississippi with known cardiovascular health status. PON1 status of these Mississippi individuals corresponds to the same relationships observed with the purchased blood samples, i.e., a higher prevalence of the QQ genotype in the Caucasian individuals. Both the genotype and the activity levels with respect to OP substrates of interest will determine the susceptibility of an individual to potential toxicity following OP insecticide exposure. Supported by NIH R21 ES015107.

PS 1184 EXPOSURE TO PYRETHROIDS AND CONTRIBUTING FACTORS IN RESIDENTS OF URBAN AND RURAL AREAS OF THE PROVINCE OF QUEBEC, CANADA.

M. Bouchard, M. Fortin, C. Couture and G. Carrier. *Environmental & Occupational Health, Université de Montréal, Montreal, QC, Canada.*

Residents of rural (agricultural) areas are often suspected of being exposed to higher levels of pesticides than residents of urban areas. However, only a limited number of studies have specifically evaluated the impact of the geographical area of residence on pyrethroid exposure in the general population. This study aimed at comparing pyrethroid exposure between an urban and rural population of the Province of Quebec, Canada. A total of 154 urban (Montreal) and 154 rural (Monteregie) participants provided a complete overnight timed-urine collection and filled a self-administered questionnaire. Urine samples were analyzed for pyrethroid metabolites: chrysanthemum dicarboxylic acid (CDCA), dichloro- and dibromo-vinyl dimethylcyclopropane carboxylic acids (tDCCA, cDCCA and DBCA), and phenoxybenzoic acids (PBA and FPBA). Levels of pyrethroid metabolites (pmol/12 h/kg bw) and their frequency of detection in the two populations were compared.

Cross-comparisons with questionnaire data were also conducted. tDCCA and PBA excretion was higher in the rural population, when considering both adults and children combined (p's = 0.010 and 0.017, respectively). This difference/trend was maintained when adults and children were considered separately. The relative frequency of detection of FPBA was also consistently higher (p's<0.001) in the rural population contrary to that of the other pyrethroid metabolites. In addition to the difference in the area of residence, according to the questionnaire, the use of mosquito repellents and household insecticides could also contribute to those differences. Overall, the frequency of exposure to some specific pyrethroids and the level of exposure to the most commonly used pyrethroids appear higher in individuals living in rural/agricultural areas. This could be explained by the proximity of spreading zones but also by different patterns of household pesticide use.

PS 1185 ADVERSE HEALTH EFFECTS IN PESTICIDE RETAILERS FROM MEXICO.

E. Rojas[1], I. M. Medina-Díaz[1], M. L. Robledo-Marenco[1], J. B. Velázquez-Fernández[1], M. I. Girón-Pérez[1], B. Quintanilla-Vega[2], M. Fuentes-Reyes[1], E. González-Barbosa[1], A. Jarquín-Mendez[1] and F. Monroy-Rivera[1]. [1]*Laboratorio de Contaminación y Toxicología Ambiental, Universidad Autónoma de Nayarit, Tepic, Nayarit/Tepic, Mexico and* [2]*Sección Externa de Toxicología, CINVESTAV-IPN, M√©xico, DF, Mexico.*

Pesticides use has reached massive proportions worldwide. This has been beneficial but also has caused adverse effects for environment and human health. There are several studies evaluating the adverse effects of pesticides in agricultural workers. Nevertheless, there are no reports in pesticide retailers. In Mexico, these workers are vulnerable because of the lack of personal protection and the low ventilation at work places. The aim of this study was to evaluate the health of pesticide retailers by monitoring blood parameters, serum butyrilcholinesterase (BuChE) activity and adverse health symptoms. We carried out a cross-sectional study in 132 workers (mean age=34.8 years; 36.4% women) and 102 non-exposed subjects (mean age=34.5 years; 34% women). Information about anthropometrical characteristics, lifestyle, health status, adverse health symptoms, and exposure to pesticides was obtained by questionnaire. BuChE activity was determined spectrophotometrically and blood parameters in a certified laboratory. BuChE in workers (7010.9 U/L, CI= 6679.5-7358.7) and in the control group (8580.9 U/L, CI= 8248.6-8926.6) was within the normal values; however, BuChE activity in workers was lower (p< 0.0001) than in the control group. Hematological alterations in workers were found, such as low hemoglobin content, hematocrit value and white blood cell. The most frequent adverse symptoms self-reported by workers were: headache, weakness, burning sensation in eyes or face, dizziness, tremors, salivation, nausea, and vomiting. These preliminary results strongly suggest that pesticide retailers present poisoning symptoms related to chronic pesticides exposure and deserve attention. Project supported by Conacyt Grant CO1-44169.

PS 1186 URINARY ARSENIC, ETHNICITY AND SERUM MMP-9: A BINATIONAL STUDY.

J. L. Burgess[1], M. Kurzius-Spencer[1], S. R. Littau[1], J. Roberge[1], E. Shahar[1], M. M. Meza[2], L. E. Gutierrez Millan[3], M. J. Kopplin[4] and R. B. Harris[1]. [1]*Mel & Enid Zuckerman College of Public Health, University of Arizona, Tucson, AZ,* [2]*Technological Institute of Sonora, Ciudad Obregon, Mexico,* [3]*Universidad de Sonora, Hermosillo, Mexico and* [4]*College of Pharmacy, University of Arizona, Tucson, AZ.*

Arsenic (As) exposure is associated with cardiovascular disease and cancer. Matrix metalloproteinase (MMP) -9 plays a role in the development of these diseases. Methods: In a study of 487 randomly-selected residents of Sonora, Mexico (n=262) and Arizona, USA (n=225), questionnaires, sources of water used for drinking and cooking, blood and first morning void urine samples were collected. Water was assayed for total As, urine As was speciated and serum samples were analyzed for MMP-9 using ELISA. The relation between tertiles of urine As sum of species (As3 + As5 + MMA + DMA) and categorical health and demographic characteristics were evaluated using a $\chi 2$ statistic. Cut points were <14.9, 14.9-48.45, and >48.45 µg/L. Linear regression models assessed the relation of serum levels of MMP-9 (log transformed) with urinary As, gender, ethnicity, country, age, BMI, diabetes, and physical activity. Results: In both univariable and multivariable models, US non-Hispanics had statistically significantly (P<0.05) higher MMP-9 concentration than Mexican Hispanics, and BMI was a negative predictor. In the multivariable model, urinary As in the highest vs. the lowest tertile was associated with a 29% increase in serum MMP-9 concentration (adjusted geometric mean ratio (95% C.I.): 3rd vs. 1st tertile 1.29 (1.04, 1.69); 2nd vs. 1st 1.01 (0.84, 1.22)). In addition, MMP-9 concentrations were higher in US non-Hispanics than in Mexican Hispanics (adjusted geometric mean ratio (95% C.I.) 1.59 (1.31, 1.93)), though there was no statistically significant difference in serum MMP-9 between US and Mexican Hispanics (1.19 (0.90, 1.55)). Conclusions: Arsenic exposure measured as urinary As may be a determinant of serum MMP-9, as may be country of origin/ethnicity. Additional study is needed to determine whether these effects are clinically relevant.

PS 1187 ACTION PLAN OF JAPAN NATIONAL CHILDREN'S STUDY (JNCS).

M. Hasegawa[1], N. Tsukamoto[1], T. Kawamoto[2], F. Kayama[3], H. Nitta[4], K. Murata[5], R. Kishi[6] and H. Satoh[7]. [1]*The Ministry of Environment, Tokyo, Japan,* [2]*University of Occupational and Environmental Health, Kitakyushu, Japan,* [3]*Jichi Medical School, Shimotsuke, Japan,* [4]*National Institute for Environmental Studies, Tsukuba, Japan,* [5]*Akita University, Akita, Japan,* [6]*Hokkaido University Graduate School of Medicine, Sapporo, Japan and* [7]*Tohoku University Graduate School of Medicine, Sendai, Japan.*

In 2007, the Ministry of Environment, Japan decided to work on a nation-wide birth cohort study (Japan National Children's Study; JNCS) . According to the Advisory Commission's recommendation in 2008, the working group of JNCS (WG) has set up and been discussing the action plan. The WG proposed 10 working hypotheses to clarify the effects of the exposure to chemical and physical environmental factors on the health and development of children in Japan. Pilot studies have started at three areas by the WG in advance. The full-scale survey will start in 2010. The WG will select dozens of communities which participate in JNCS. Each community registers maternity hospitals in it as many as possible (more than 70%) and participants (pregnant women) are recruited at their first visit at the hospitals. Around 60,000 pregnant women will be recruited from 2010 to 2012 for three years. Their children are observed from fetus to age 12. In order to evaluate the exposure to environmental factors, we are going to measure heavy metals, dioxins, POPs and so on in biospecimens from mother and their children besides questionnaires or interviews. The targeted outcomes are physical development (low birth weight, developmental retardation, etc.), congenital anomalies (hypospadias, cryptorchidism, cleft palate, GI obstruction, ventricular septal defect, Down's syndrome, etc.), psycho-neurodevelopment impairments: autism (learning disorder), ADHD (attention-deficit hyperactivity disorder,, etc.), immunologic impairments (allergy, atopic dermatitis, asthma, etc), metabolic/endocrinologic impairments (genital hypoplasia, brain sexual differentiation, thyroid dysfunction, impaired glucose tolerance, obesity, etc.). The WG will publish findings obtained from JNCS at appropriate time.

PS 1188 EXPOSURE TO DIOXINS AND FURANS IN THE POPULATION LIVING NEAR A HAZARDOUS WASTE INCINERATOR: A FOLLOW-UP STUDY.

J. L. Domingo, M. Nadal, R. Marti-Cid, F. Garcia and M. Schuhmacher. *Toxicology, Rovira i Virgili University, Reus, Spain.*

Although incineration is an effective way of treating municipal and hazardous waste (HW), in many countries the potential health risks associated with stack emissions, especially polychlorinated dibenzo-p-dioxins and furans (PCDD/F), have become a cause of great controversy and concern. In 1999, the only HW incinerator (HWI) in Spain initiated regular operations in Tarragona County (Catalonia). Since then, a wide environmental and biological monitoring program is being carried out. In 2007, human samples of plasma (n = 20), milk (n = 15) and adipose tissue (n = 15) of individuals living near the facility were collected. The concentrations of PCDD/F were determined by HRGC/HRMS and compared with those found in 2002. The current mean PCDD/F levels (pg WHO-TEQ/g lipid or fat) were 9.5, 7.6 and 14.6, vs. 17.8, 8.3 and 9.9, obtained for plasma, milk and adipose tissue, respectively. It means decreases of 40% and 8% for plasma and milk, respectively. In contrast, the mean PCDD/F concentration in adipose tissue increased (P > 0.05) a 47%, although it was still notably lower than the mean level found in the baseline (1998) survey, 40.1 pg WHO-TEQ/g lipid. On the other hand, the dietary PCDD/F intake of the assessed population was also determined, being currently 27.8 pg WHO-TEQ/day vs. 63.8 pg WHO-TEQ/day in 2002. These results indicate that emission of PCDD/F from the stack of the HWI do not mean an additional significant exposure for the population living near the facility. Moreover, it seems obvious that the levels of PCDD/F in plasma are a better biological indicator of exposure to these pollutants than those in adipose tissue.

PS 1189 BLACK & WHITE SMOKERS OF CIGARETTES EXHIBIT SIMILAR LEVELS OF EXPOSURE BIOMARKERS.

M. Hagan Hughes and J. Heck. *Scientific Affairs, Lorillard Tobacco Company, Greensboro, NC.*

Epidemiological studies have suggested that black smokers are at higher risk for some smoking-related diseases than are white smokers. Other investigations have reported that black smokers exhibit higher levels of cotinine than do white smokers,

despite smoking fewer cigarettes daily. Metabolic and pharmacogenetic explanations for these observations have been offered, as has speculation that differences in cigarette preferences or cigarette smoking behavior may play a role. Further clarification of black/white differences in biomarkers of cigarette smoke constituent exposure is indicated. We conducted the current analysis to determine whether racial differences in smoke constituent exposure biomarkers may be evident among smokers of cigarettes having a machine-measured smoke yield of about 10 mg "tar". A total of 28 black & 84 white smokers (mean 27.6 & 27.8 cigarettes/ day, respectively) participated in a study to determine whether ad libitum smoking resulted in differences in smoke constituent exposure biomarkers. Carboxyhemoglobin (CoHb) levels were measured in blood samples drawn at mid afternoon following two 24-hour urine collection periods. Six urinary nicotine metabolites and respective glucuronides were determined as measures of nicotine intake, and urinary 4-(N-nitrosomethylamino)-1-(3-pyridyl)-1- butanol (NNAL) and its glucuronide were determined to assess exposure to the tobacco-specific nitrosamine 4-(N-nitrosomethylamino)-1-(3-pyridinyl)-1-butanone (NNK). CoHb values did not differ significantly by race (6.2% for blacks vs. 6.6% for whites). Neither creatinine adjusted NNAL per 24 hr urine (ng/mL) (365 for blacks vs. 422 for whites) nor creatinine adjusted nicotine equivalents (mg/mL) (19 for blacks vs. 22 for whites) differed significantly by race. There was also no significant difference in the trans-3'-hydroxycotinine to cotinine ratio, a measure of CYP2A6 activity (2.4 for blacks vs. 2.1 for whites). These findings indicate that in this sample, black and white smokers exhibit essentially the same levels of biomarkers of smoke constituent exposure.

PS 1190 A WEIGHT-OF-EVIDENCE APPROACH TO EVALUATING EPIDEMIOLOGICAL DATA ON STYRENE CANCER HAZARDS.

J. E. Goodman and L. R. Rhomberg. *Gradient Corporation, Cambridge, MA.*

The May 22, 2008 National Toxicology Program (NTP) *Report on Carcinogens: Draft Background Document for Styrene* describes the state of the literature on the carcinogenicity of styrene. With regard to the epidemiology literature, NTP describes several key studies, primarily of 12 cohorts, and their strengths and weaknesses. We conducted a weight-of-evidence analysis of the association between styrene exposure and the risks of each of the cancer types on which NTP focused in these cohorts, which includes cancers of the esophagus, pancreas, larynx, and lung, all lymphohematopoietic cancers combined, as well as lymphoma, Hodgkin's disease, multiple myeloma, and leukemia. We assessed the consistency of risk estimates within and among studies for each cancer type and, for each study, we considered factors that could affect study results – such as study power, inclusion criteria, methodologies, exposure metrics, confounders, etc. – and discuss their bearing on the results. We assessed exposure-response relationships within and across studies, with an emphasis on comparing estimates that were based on the same exposure metric. We also assessed associations across industries. We found that, although some positive associations were reported in certain exposure groups of some cohorts in some studies, so, too, were null and negative effects. There were no consistent findings of effect for any cancer type in the reinforced plastics and composite (RPC), styrene-butadiene rubber (SBR), or the polystyrene/styrene (PS) industries. If styrene were a causal factor for any of these cancers, one would expect to see associations in the RPC industry, which has the highest exposures to styrene and the fewest likely confounding exposures, and particularly in the highest-exposed RPC workers. This was not the case. Taken together, the epidemiology data do not support a causal association between styrene and cancer risk in humans. This work was supported by the Styrene Information and Research Center (SIRC).

PS 1191 NO EVIDENCE OF INFECTION WITH AVIAN INFLUENZA AMONG U.S. POULTRY WORKERS, DELMARVA PENINSULA.

J. Leibler[1], E. K. Silbergeld[1], A. Pekosz[2] and G. Gray[3]. *[1]Department of Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [2]Department of Molecular Microbiology and Immunology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD and [3]Department of Epidemiology, College of Public Health, University of Iowa, Iowa City, IA.*

Poultry workers are recognized as the front line for transmission of avian influenza (AI) to humans. Studies of AI transmission between poultry and workers in industrial facilities are limited, due in part to the perception that these facilities are biosecure and biocontained. To assess frequency of industrial poultry worker exposure to AI, we analyzed serum of poultry workers and community residents from the Delmarva Peninsula, one of the top five poultry production areas in the United States, for antibodies against five subtypes of AI. We interviewed a convenience sample of workers and community residents and collected serum samples in 2003 and 2005. Microneutralization assays were used to detect antibodies to five AI subtypes (H4N6, H5N2, H6N2, H7N2 and H9N2) representative of those circulating in poultry the US. Sera were also analyzed for antibodies that recognize currently circulating H1N1 and H3N2 human influenza A viruses using the hemagglutination inhibition assay protocol. We observed no evidence of seroconversion among poultry workers or community residents to the AI subtypes in our study, implying a lack of exposure to these viruses. Low levels of reported use of personal protective equipment suggest that worker protection does not explain this negative finding. The most likely explanations are that the workers in our study were either not exposed to AI viruses because none were present in their occupational environments, or that the viruses present were incapable of infecting humans. We observed high rates of seroconversion to human influenza subtypes in both the poultry workers and community residents. Since co-infection with avian and human influenza viruses is a risk factor for the emergence of a novel influenza strain, the prudent vaccination of poultry workers against human influenza is critical.

PS 1192 DEVELOPMENT OF ENANTIOSELECTIVE POLYCLONAL ANTIBODIES TO DETECT STYRENE OXIDE PROTEIN ADDUCTS.

S. Shen[1, 2, 3], F. Zhang[2], S. Zeng[1], Y. Tian[1], X. Chai[1], S. Gee[4], B. D. Hammock[4] and J. Zheng[2, 3]. *[1]Department of Pharmaceutical Analysis and Drug Metabolism, College of Pharmaceutical Sciences, Zhejiang University, Hangzhou, Zhejiang, China, [2]Center of Developmental Therapeutics, Children's Hospital Research Institute, Seattle, WA, [3]Department of Pediatrics, University of Washington, Seattle, WA and [4]Department of Entomology, University of California, Davis, Davis, CA.*

Styrene has been reported to be hepatotoxic and pneumotoxic in humans and animals. Styrene oxide, a major reactive metabolite of styrene, has been found to form covalent binding with proteins, such as albumin and hemoglobin. Styrene oxide has two optical isomers and it was reported that the (*R*)-enantiomer was more toxic than the (*S*)-enantiomer. The objective of this study was to develop polyclonal antibodies that can stereoselectively recognize proteins modified by styrene oxide enantiomers at cysteine residues. Immunogens were prepared by alkylation of thiolated keyhole limpet hemocyanin (KLH) with styrene oxide enantiomers. Polyclonal antibodies were raised by immunization of rabbits with the chiral immunogens. Titration tests showed all six rabbits generated high titers of antisera that recognize (*R*) or (*S*)-coating antigens accordingly. No cross-reaction was observed toward the carrier protein of the coating antigen (BSA). All three rabbits immunized with (*R*)-immunogen produced antibodies which show enantioselectivity to the corresponding antigen, while only one among the three rabbits immunized with (*S*)-immunogen generated antibodies with enantioselectivity of the recognition. The enantioselectivity was also observed in competitive ELISA and immunoblot analysis. Additionally, competitive ELISA tests showed that the immuno-recognition required the hydroxyl group of the haptens. Immunoblot analysis demonstrated that the immuno-recognition depended on the amount of protein adducts blotted and hapten loading in protein adducts. In summary, we successfully developed polyclonal antibodies to stereoselectively detect protein adducts modified by styrene oxide enantiomers.

PS 1193 SERUM COTININE LEVELS OF SMOKELESS TOBACCO USERS AND CIGARETTE SMOKERS: AN ANALYSIS OF NHANES 1999-2006 DATA.

S. Kathman[1], W. Butler[2], Z. Naufal[3] and C. Wilson[1, 3]. *[1]RJ Reynolds Tobacco Co, Winston-Salem, NC, [2]Environmental Risk Analysis, Inc., San Mateo, CA and [3]Duke University, Durham, NC.*

Cotinine is widely used as a biomarker of nicotine uptake, and of tobacco consumption in general. Reports indicate that smokeless tobacco (ST) users tend to have higher levels of serum cotinine compared to cigarette smokers, with moist snuff users possibly having higher levels than users of chewing tobacco. The relationship between serum cotinine levels and the use of snuff (any form), chewing tobacco (chew), and cigarettes was examined using data collected from the National Health and Nutrition Examination Survey (NHANES) Mobile Examination Centers for 1999-2006. Multiple linear regression models for the natural-log transformed serum cotinine values (accounting for the design of the surveys) were used to compare the cotinine levels for the three tobacco categories, adjusting (when necessary) for age, gender, ethnicity, frequency of use (number of days used out of last five), and time since last used. The data suggest that snuff and chew users have higher levels of serum cotinine compared to users of cigarettes ($p < 0.05$) when the models include frequency of use. There is some evidence of higher levels for snuff users compared to chew users, and of an interaction between tobacco category and frequency of use, but both failed to achieve statistical significance ($0.05 < p < 0.10$). When the analyses are done separately for each frequency of use category (used 5 days, 4 days, or <3 days out of last 5 days), snuff users had the highest levels, followed by users of chew and cigarettes, with the statistical significance varying for

the frequency categories. These results are consistent with others in that cotinine levels are higher for ST users, with a possible difference between snuff and chew. Interpretation of these findings as suggesting a difference in nicotine exposure should be made with caution since systemic cotinine levels are affected more than systemic nicotine levels by the pre-systemic first pass metabolism of the nicotine in swallowed tobacco juice.

PS 1194 PRENATAL EXPOSURE TO MERCURY, PARTITIONING OF TOTAL AND ANA IMMUNOGLOBULINS IN MATERNAL AND CORD BLOOD, AND ASSESSMENT OF A BIOMARKER OF MERCURY IMMUNOTOXICITY.

J. F. Nyland[1, 2], S. Wang[2], E. C. Santos[3], A. Ventura[3], J. M. deSouza[3] and E. K. Silbergeld[2]. *[1]Pathology, Microbiology & Immunology, University of SC School of Medicine, Columbia, SC, [2]Environmental Health Sci, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD and [3]Fundacao Nacional da Saude, Institute Evandro Chagas, Belem, Brazil.*

Mercury (Hg) is a ubiquitous environmental contaminant with known neurodevelopmental effects at high exposures. Recent studies on the toxic properties of Hg have highlighted the implications at lower exposures particularly on the immune system. Low level prenatal exposure through maternal contaminated fish consumption has the potential to impact the immune system of the fetus. Many studies have been undertaken to identify a reliable biomarker of the immunotoxic effects of Hg. We have previously reported that antigen-specific autoantibodies (anti-nuclear, ANA) may be informative biomarkers of Hg induced immunotoxicity. In this study, we assessed the effects of prenatal exposure to Hg on total and ANA immunoglobulins (Ig) in a cross sectional sample from a prospective mother-infant cohort study in Amazonian Brazil. We compared maternal and cord blood Hg and antibody levels with maternal covariates obtained by questionnaire. The geometric mean of Hg in mothers was 6.9 and in cord blood it was 9.6 ug/L; 36 percent of maternal and 52 percent of cord blood samples were above the US EPA estimated safe level of 5.8 ug/L and fetal-maternal Hg levels were correlated but not equivalent. We found that total and ANA IgG, but not IgM, levels were correlated with both maternal and cord blood Ig. These findings are consistent with research on the ability of IgG, but not IgM, to cross the placenta in the absence of infection. Moreover, total IgG level in cord blood was significantly associated with fetal Hg but not with maternal Hg level. ANA titer in either maternal or cord blood was not significantly associated with either maternal or cord blood Hg levels. These data provide further evidence for the immunotoxicity of Hg but ANA may not be a specific biomarker for effects in the mother or developing fetus.

PS 1195 SINGLE NUCLEOTIDE POLYMORPHISMS (SNPS) IN METABOLIC ENZYMES AND THEIR INFLUENCE ON NEUROBEHAVIORAL RESPONSE TO CHRONIC SOLVENT EXPOSURE.

H. Qian[1], J. Hong[2], S. Wang[1], N. Fiedler[3] and C. Weisel[1]. *[1]Exposure Science, EOHSI, Piscataway, NJ, [2]Toxicology, EOHSI, Piscataway, NJ and [3]Clinical Research and Occupational Medicine, EOHSI, Piscataway, NJ.* Sponsor: J. Laskin.

Chronic exposure to solvent derived Volatile Organic Compounds during bridge painting has been associated with adverse neurobehavioral outcomes. This relationship could be modified by an individual's unique genetic make-up. Polymorphisms in enzymes involved in the metabolism of organic solvents could potentially increase neuropsychological impairment susceptibility from solvent exposures. In this study, we've identified five known human neurotoxicants: ethyl acetate, methyl ethyl ketone, toluene, xylene, and n-hexane, from air samples collected during bridge painting from 2005 to 2007 in New York, New Jersey, and Pennsylvania. Based on enzymes kinetics, ten metabolic enzymes of these neurotoxicants were selected, including CYP2E1, CYP1A1, ALDH2, NAT1, NAT2, GSTM1, GSTT1, GSTP1, SOD1, and EPHX1. Twenty six SNPs in the ten metabolic enzymes which have potential to significantly modify the enzyme activities were genotyped using SNPstream instrument. The frequencies of the variant alleles in the Caucasian painters (n=84) are 14.88% for CYP1A1*2A, 25.00% for NAT2*6A, 32.14% for GSTM1 null genotype, 25.00% for GSTT1 null genotype, 43.10% for GSTP1a, 24.07% for EPHX1*3 and 15.48% for EPHX1*4. Other genetic variants genotyped had frequencies below 10% in the study population, thus the study has insufficient power to determine their role in modifying neurobehavioral response. A dose-response relationship is determined between an estimate of a painter's lifetime solvent exposure reconstructed from a questionnaire completed by each painter and his neurobehavioral effects on attention, working and visual memory from the Cambridge Neuropsychological Test Automated Batteries. The modification effects of these genetic polymorphisms on the dose-response relationship then are examined using multivariate regression analysis, adjusted with confounding factors: age, education, body mass index, and lifetime alcohol consumption. Supported by NIOSH grant RO1 OH008198.

PS 1196 MECHANIC AND BYSTANDER CHRYSOTILE EXPOSURES DURING HEAVY EQUIPMENT BRAKE REMOVAL.

S. H. Gaffney[1], A. K. Madl[1], J. L. Balzer[2] and D. J. Paustenbach[1]. *[1]ChemRisk, Inc., San Francisco, CA and [2]J. LeRoy Balzer, Alamo, CA.*

Heavy-duty construction equipment utilized asbestos brake linings prior to the 1980s. Most published studies of asbestos exposures to mechanics during brake repair work focused on automobiles and not on heavy agricultural or construction vehicles. The purpose of this study is to characterize worker and bystander exposures to chrysotile asbestos from brake wear debris during the removal of brakes within 12 loader/backhoes and tractors manufactured between 1960 and 1980. Asbestos content in brake lining and brake wear debris was also quantified. Breathing zone samples on the lapel of a volunteer mechanic (n=44) and area samples at bystander (n=34), remote (n=16), and ambient (n=12) locations were collected during 12 brake changes and analyzed using Phase Contrast Microscopy (PCM) (NIOSH 7400) and Transmission Electron Microscopy (TEM) (NIOSH 7402). In addition, the fiber distribution by size and morphology was evaluated according to the ISO method for asbestos. Applying the ratio of asbestos fibers:total fibers (including non-asbestos) as determined by TEM to the PCM results, the average airborne chrysotile concentrations (PCM equivalent) was 0.024 f/cc for the mechanic and 0.008 f/cc for persons standing 4-5 feet from the activity. Considering the time involved in the activity and assuming three brake jobs per shift, these results would convert to an average 8-hr TWA of 0.01 f/cc for a mechanic, and 0.006 f/cc for a bystander. In conclusion, these results showed that 1) the airborne concentrations for worker and bystander samples were below the occupational exposure limit of 0.1 f/cc, 2) <2% of respirable fibers were >20μm in length, and 3) approximately 95% of chrysotile in the brake linings degraded in the friction process. These findings indicate that exposures to airborne chrysotile during heavy equipment brake removal are comparable to those reported for automobile brake repair and should provide useful information for reconstructing individual worker exposures and assessing possible health risks.

PS 1197 COMBINED EPIDEMIOLOGICAL, STATISTICAL AND BIOLOGICAL APPROACH TO INVESTIGATE POSSIBLE RELATIONSHIPS BETWEEN PCB MIXTURES AND ENDOMETRIOSIS.

C. Gennings[1], E. W. Carney[2], R. T. Sabo[1], E. Schisterman[3] and G. M. Buck Louis[3]. *[1]Biostatistics, Virginia Commonwealth University, Richmond, VA, [2]Tox&Env Research and Consulting, The Dow Chemical Company, Midland, MI and [3]Epidemiology Branch, NICHD, Rockville, MD.*

Epidemiological approaches for investigating complex environmental health issues can be enhanced by improved statistical methods and integration with toxicological data in an iterative fashion. Toward this aim, exploratory statistical analyses were conducted on an epidemiological data set examining the relationship between exposure of women to PCB mixtures (62 congeners analyzed) and risk of endometriosis (Buck-Louis et al., Human Reprod 20:279-85, 2005). In that study, the association between endometriosis and the sum of four antiestrogenic PCBs (PCB 105, 114, 126, 169) was significant (P=0.001), whereas there was no association (P=0.68) with the sum of 12 estrogenic PCBs. This finding was inconsistent with the widely held notion that endometriosis is an estrogen-dependent disease, prompting further statistical analyses to explore these associations in more detail. An optimization algorithm was developed that determines weights in the linear combination of scaled PCB levels which maximized the standardized slope estimate. Application of this method to the antiestrogenic PCB subgroup revealed that only one, PCB 114, was responsible for nearly 100% of the association. The fact that PCB 114 is neither the most potent antiestrogen nor the most abundant antiestrogen in the mixture suggests that the association might be driven by a different mechanism. Use of this statistical weighting method to further analyze the 12 estrogenic PCBs showed a stronger, but not statistically significant, association with endometriosis (P=0.060) driven mainly by PCBs 99 and 188. These results demonstrate how the integration of refined statistical methods coupled with toxicological interpretation can generate testable hypotheses that might not otherwise have been generated. Funded by American Chemistry Council, Arlington, VA.

PS 1198 EXPOSURE TO POLYCHLORINATED BIPHENYLS (PCBs) AMONG AFRICAN AMERICAN NEONATES.

B. L. Williams and M. S. Magsumbol. *NCEH, Centers for Disease Control, Atlanta, GA.* Sponsor: D. Barr.

There are relatively limited data on exposures to transplacental toxicants such as polychlorinated biphenyls (PCBs) in neonates. The purpose of this study was to quantify exposure to PCB's among a sample of high risk neonates. We measured concentrations of PCB's congeners in umbilical cord serum and examined sources of environmental exposures to PCB's in a predominantly African American population. We collected reproductive histories, questionnaire data, and blood samples

from 102 women, aged 16 45 years, who delivered at an inner city hospital in Memphis, TN. The distribution and determinants of exposures to PCB's in this population will be discussed.

PS 1199 EXPOSURE SCIENCE FOR CHEMICAL PRIORITIZATION AND TOXICITY TESTING.

E. Cohen Hubal. *National Center for Computational Toxicology, U.S. EPA, Research Triangle Park, NC.* Sponsor: J. Blancato.

Currently, a significant research effort is underway to apply new technologies to screen and prioritize chemicals for toxicity testing (Dix et al. 2007, Toxicol Sci; NRC, 2007, Toxicity Testing in the 21st Century; Collins et al, 2008, Science). US EPA is completing the Phase I pilot for a chemical prioritization research program, called ToxCastTM. Here EPA is developing methods for using computational chemistry, high-throughput screening (HTS), and toxicogenomics to predict potential toxicity and prioritize testing. These high visibility efforts raise important research questions and opportunities for exposure scientists. As an explosion of HTS data for in vitro toxicity assays becomes available, exposure science is required to provide critical real-world information for interpreting these toxicity data, and predicting risks. The EPA National Center for Computational Toxicology has identified the immediate need to include exposure information for chemical prioritization. The EPA Exposure Science Community of Practice (ExpoCoP) formed in May 2008 to advance application of exposure science to inform and support EPA research in computational toxicology. The goal of ExpoCoP is to provide input on the research program in exposure science to address EPA needs for chemical prioritization, screening, and toxicity testing. The ExpoCoP, with a membership representing over 15 public and private sector organizations, is focusing initially on issues associated with classifying chemicals based on potential for human exposure and linking results with ToxCast™. An important component is to consider how best to consolidate and link human exposure data for this purpose. These sorts of linkages have the potential to bring toxicology and exposure science research communities into closer alignment and to improve risk assessment. In this presentation, potential links between research in computational toxicology and human exposure science are identified and activities of the ExpoCoP are highlighted. This work has been reviewed and approved by the US EPA for publication but does not necessarily reflect Agency policies.

PS 1200 WATER ADHERENCE FACTORS FOR HUMAN SKIN.

J. Gujral[1], D. Proctor[1], S. Su[2] and J. Fedoruk[1]. *[1]Health Sciences, Exponent, Inc., Irvine, CA and [2]Health Sciences, Exponent, Inc., New York, NY.*

Dermal exposure to chemicals in water occurs in occupational and environmental settings in situations that involve incidental contact such as a splash. In which case, one key exposure factor is the amount of water that adheres to the skin. Although soil adherence factors have been developed by researchers and adopted by EPA and other regulatory agencies for risk assessment, measurements of water adherence on human skin have not been described to date. Currently, dermal dose is based upon the flux rate across the skin, assuming that an infinite amount of chemical is available for absorption. However, real-life occupational and environmental exposures to contaminated water frequently involve scenarios where the available chemical for absorption is limited by the amount of water adhering to the skin.
We conducted studies in human volunteers to investigate the mass of water adhering per unit area of skin after brief contact with water. Two different exposure conditions were evaluated: application of water to a 10-cm^2 area of the lower leg, foot and hand using a micropipette, and brief immersion of the foot and hand in water. In males, using a micropipette for direct application of water to the skin, water adherence ranged from 1.93 (foot) to 7.13 $\mu L/cm^2$ (lower leg). In females, it ranged from 1.10 (lower leg) to 4.83 $\mu L/cm^2$ (hand). Hand and foot immersion resulted in relatively higher values of 6.89 and 4.97 $\mu L/cm^2$, respectively, in males, and 5.40 and 6.70 $\mu L/cm^2$ in females. Water adherence was affected by the amount of body hair, presence of creases or folds in the skin, and the type of exposure, i.e., direct application versus immersion. Application of commercial skin moisturizer did not significantly impact water adherence.
Water dermal adherence factors in combination with chemical concentration data can be used to calculate the applied dose per unit area for exposure scenarios involving intermittent water contact scenarios.

PS 1201 CRYPTOSPORIDIUM EXPOSURE AND RECREATIONAL WATER CONTACT IN PERSONS WITH HIV/AIDS IN BALTIMORE, MARYLAND.

C. C. McOliver, E. K. Silbergeld and T. K. Graczyk. *Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Exposure to urban surface waters poses a risk for recreational water illnesses (RWIs) to persons who engage in recreational water activities. Cryptosporidium, a common infectious pathogen associated with RWIs, is prevalent in surface waters across the US and is not detected by standard microbiological methods of recreational water testing. Persons with HIV/AIDS are at increased risk of serious morbidity and even mortality from cryptosporidiosis of waterborne etiology. Few studies have examined risks of exposure among this population associated with water recreation. Baltimore City has one of the highest prevalence rates of HIV/AIDS in the US and is situated within a watershed that is extensively used for recreation. We undertook a study to determine if persons with HIV/AIDS are at risk of exposure to pathogens in the Baltimore watershed. Methods: We enrolled patients attending the Johns Hopkins Moore Outpatient AIDS Clinic in Baltimore, Maryland. Oral interviews were conducted in 2007 on a convenience sample of 157 HIV/AIDS patients to ascertain the sites utilized for recreational water contact within Baltimore waterways. A 5-month environmental sampling was undertaken at 5 of the most frequently utilized recreational sites identified by patients. A combined fluorescent in situ hybridization and direct Immunofluorescence antibody (FISH/IFA) technique was used to detect the presence of viable Cryptosporidium oocysts in water samples. Results: 48% of patients reported taking part in recreational water activities; female patients were as likely to engage in recreational water activities as were males; 67% of patients reported consumption of their own seafood catch and/or wild-catch from friends and family members; and 61% of patients who reported recreational water contact ate their own catch. Cryptosporidium oocysts were detected in water samples. Conclusion: This is the first study to show that persons with HIV/AIDS are in contact with Cryptosporidium-contaminated waterways in Baltimore.

PS 1202 BISPHENOL A EFFECTS ON GENE EXPRESSION OF ADIPOKINES.

C. Lin[1], C. Chuang[1], J. Chen[3] and C. Chou[2]. *[1]Biomedical Engineering and Environmental Sciences, National Tsing Hua University, Hsinchu, Taiwan, [2]Veterinary Medicine, National Chung-Hsing University, Taichung, Taiwan and [3]Environmental Engineering and Health, Yuanpei University, Hsinchu, Taiwan.*

Bisphenol A (BPA) is generally used for polymerization of plastic materials to produce food containers, baby bottles and dental sealants, and human expose BPA mainly through oral uptake. BPA has been considered as an endocrine-disrupting chemical to interfere with endocrine system and cause adverse health effects of reproduction and development in biological organisms and their progeny. Adipokines (e.g. leptin and adiponectin) secrete from adipose cells and regulate energy metabolism, endocrine system and immune homeostasis relevant to metabolic and degenerative diseases. Because of persistent nature, this organic pollutant BPA would accumulate in adipose cells and have the potency to affect adipokine secretion. This study was to determine BPA level in maternal and fetal core blood, and investigated its effect on gene expression of leptin and adiponectin in placenta tissue. With informed consent and physician interview, maternal and umbilical cord blood, and placenta tissue (n = 100) were obtained during childbearing. Preliminary results of high performance liquid chromatography showed the average BPA level in maternal blood was 27.35 ± 4.59 ng/ml (mean ± SEM, median 15.26 ng/ml), and the BPA level of fetal cord blood was consistent with that of maternal blood. Additionally, the result of quantitative polymerase chain reaction displayed that maternal subjects with higher BPA level had repression of leptin ($r = -0.306$, $p = 0.136$) but augment of adiponectin ($r = 0.124$, $p = 0.470$). It suggested that fetuses exposed BPA from their parent, and the increased BPA level affected gene expression of adipokines. Regarding median BPA value as cutoff and interference factors, analysis of binary logistic regression appeared that subjects with higher BPA level had potentially risk to decrease the ratio of leptin over adiponectin (OR = 2.08, 95% CI 0.52-8.34). These findings are consistent with our cellular study. It is necessary to notice BPA manipulation.

PS 1203 TURNING A BLIND EYE ON SMOKING DURING PREGNANCY – NICOTINE METABOLITES IN URINE OF PREGNANT WOMEN.

H. Käfferlein[1], H. Koch[1], M. Kumbartski[2] and T. Brüning[1]. *[1]BGFA, Ruhr University Bochum, Bochum, Germany and [2]University Duisburg/Essen, Essen, Germany.*

Maternal smoking results in low birth weight. In our study, 50 pregnant women (including 17 smokers) underwent multiple consulting sessions during pregnancy. All women were informed about the general risks of drug abuse and in particular were advised to quit smoking and remove themselves from areas with environmental tobacco smoke. At the hospital prior to delivery, smoking habits, socio-economic status and use of medication were assessed by questionnaire, and the status of fetal health was assessed by ultrasound. Spot urine samples were collected to analyze nicotine (NIC), cotinine (COT) and 3-hydroxycotinine (3-OHC) by high performance liquid chromatography and tandem mass spectrometry (2D-HPLC-

MS/MS). Limits of quantification were ≤0.1 μg/L depending on the analyte examined. A high concordance (98%) on smoking habits between self-reported questionnaire information and analytical results were observed. Despite prior counseling, only 1 out of 17 maternal smokers quit smoking during pregnancy. Based on actual analytical results, NIC, COT and 3-OHC in urine of smokers were 464.2, 1979.0 and 2724.7 μg/L respectively, whereas 1.3, 3.7 and 4.6 μg/L was found in nonsmoking mothers. NIC and COT as well as COT and 3-OHC were highly associated to each other (P≤0.0001, r≥0.79), whereas a moderate association between NIC and 3-OHC was observed (P=0.0001, r=0.50). Smoking habits were associated to socio-economic status as COT levels in women with low, middle, and high school degrees were 80.0, 12.6 and 2.6 μg/L respectively. Similar decreases were observed for both NIC and 3-OHC. The prevalence of low birth weight in the offspring was 25% for maternal smokers and 15% for nonsmokers, and two newborns (both of smoking mothers) showed either polycystic kidneys or intrauterine growth retardation. Our results show that the advice to avoid smoking during pregnancy is generally not heeded by the majority of women. Therefore, smoking must be considered a serious confounder in developmental studies after exposure to environmental toxicants.

PS 1204 ORGANOPHOSPHATE PESTICIDE RESIDUES IN HOME ENVIRONMENT DUST OF ORCHARD WORKERS.

W. C. Griffith[1], G. D. Coronado[2], B. Thompson[2], E. M. Vigoren[1] and E. M. Faustman[1]. *[1]Univ of Washington, Seattle, WA and [2]Fred Hutchinson Cancer Research Center, Seattle, WA.*

Farmworkers and their families are at risk for chronic organophosphate pesticide (OP) exposure and it is necessary to characterize these exposures to predict health risks from OP toxicity. Data is from 203 orchard workers in Eastern Washington enrolled in a community randomized intervention trial to reduce the take-home pathway of OP exposure. Dust samples were collected in the room most commonly used by a referent child (aged 2–6) and family vehicles. A total of 172 dust samples were collected from carpeted surfaces and 27 from smooth surfaces. Dust was collected from 183 living rooms, and 20 other types of rooms and analyzed for azinphos-methyl (AZM) and five other OPs. Markov Chain Monte Carlo Methods were used to analyze the OP data as a multivariate log-normal distribution with measurements below the limit of detection treated as left-censored. AZM was the OP in the highest concentrations. Thick or thin carpeted surfaces had statistically significant greater mass of AZM per square meter than smooth surfaces—geometric means (GM): thick carpets 1430 ng/m2, thin carpets 1550 ng/m2, smooth surfaces 110 ng/m2. The mass of AZM in the living room was not significantly different from other rooms—GM: living room 3450 ng/m2, other rooms 1000 ng/m2. There were no significant differences for the mass of AZM from vehicles when classified by type (GM: auto 3630 ng, truck 6260 ng, other 2570 ng) or floor surface coverings (GM: plush mat 3220 ng, hard mat 4190 ng, or no mat 5100 ng). The results provide support for the theory that pesticide residues accumulate on carpeted surfaces prolonging exposure of people in the household. Intervention efforts to reduce in-home exposure should target carpeted surfaces and frequent cleaning of all areas where young children play in the home. (Supported by grant 2-P01-ES009601 from National Institutes of Environmental Health Sciences and RD-8370901-0, STAR RD-83273301-0 from Environmental Protection Agency.)

PS 1205 A META-ANALYSIS OF THE RELATIONSHIP BETWEEN OCCUPATIONAL EXPOSURE TO HEXAVALENT CHROMIUM AND CANCERS OF THE GASTROINTESTINAL TRACT.

N. M. Gatto[1], M. Kelsh[2], D. Ha Mai[1], M. Suh[1] and D. M. Proctor[1]. *[1]Exponent, Irvine, CA and [2]Exponent, Menlo Park, CA.*

Recent rodent cancer bioassays have demonstrated that high concentrations of hexavalent chromium [Cr(VI)] in drinking water cause oral cavity cancers in rats and small intestine tumors in mice at levels >20 mg/L. To evaluate the risk of human gastrointestinal (GI) tract cancers from Cr(VI) exposure, we conducted a systematic literature review and meta-analysis of epidemiologic studies of GI tract cancers, including oral cavity, esophageal, stomach, colon, and rectal, among workers occupationally exposed to Cr(VI). Meta standardized mortality ratios (meta-SMRs) were calculated using random-effects models among 33 studies reporting risk estimates for GI cancers, and for subgroups within studies based on level of Cr(VI) exposure, industry, and geographic region. Meta-SMRs for any Cr(VI) exposure were, for oral cancer: 1.02 (95% CI=0.77–1.34); esophageal cancer: 1.14 (95% CI=0.87–1.49); stomach cancer: 1.08 (95% CI=0.93–1.25); colon cancer: 0.91 (95% CI=0.71–1.16); and rectal cancer: 1.16 (95% CI=0.97–1.39). Confounding by smoking could not be ruled out. None of the three studies that evaluated small-intestine cancer reported a statistically significant increased risk. Elevated SMRs were found for esophageal cancer in the high Cr(VI) exposure subgroup and the US subgroup, but these analyses were limited by the small number of studies in each subgroup. Occupational exposures are estimated to be generally consistent with the current US chromium drinking water standard (0.1 mg/L) but lower than those that caused cancer in rodents. These meta-analysis results of epidemiologic studies indicate that workers exposed to Cr(VI) do not experience a greater risk of GI cancers than the general population, and that GI tract cancers in rodents may be of limited relevance to Cr(VI)-exposed humans due to the high doses of Cr(VI) administered in these studies or to species-specific differences in the cancers detected.

PS 1206 URINARY AFLATOXIN M_1 AND 1-HYDROXYPYRENE LEVELS IN A U.S. POPULATION COMPARED TO A HIGH RISK POPULATION IN GHANA.

N. M. Johnson[1], D. Tietze[1], A. Marroquin-Cardona[1], A. Robinson[1], J. Taylor[1], E. Afriyie-Gyawu[1], M. Rodriguez[2], L. Kaufman[2], K. Cunningham[2], J. Wittmer[2], F. Guerra[2], K. C. Donnelly[1], J. Wang[3] and T. D. Phillips[1]. *[1]College of Veterinary Medicine, Texas A&M University, College Station, TX, [2]San Antonio Metropolitan Health District, San Antonio, TX and [3]College of Public Health, The University of Georgia, Athens, GA.*

Aflatoxin (AF) B_1, a metabolite produced by Aspergillus fungi, is a potent hepatocarcinogen in humans. An association between increased incidence of hepatocellular carcinoma (HCC) and co-exposure to AFs and polycyclic aromatic hydrocarbons (PAHs) has been evidenced in a recent study in Taiwan. In our current study levels of aflatoxin M_1 (AFM_1) and 1-hydroxypyrene (1-OHP) were measured in urine collected from participants in a predominantly Hispanic population in a dense maize consuming region of Texas known to have an increased incidence of HCC. A cross-sectional study was conducted within three zip code regions in San Antonio, Texas. A sociodemographic survey was administered to 185 participants and urine samples were analyzed for biomarkers via HPLC analysis with fluorescence detection. Of the total samples analyzed, 11.6% had detectable levels of AFM_1. Detectable levels of 1-OHP in the urine totaled 62.3%; however, of these participants with measurable 1-OHP values, greater than 50% were identified as tobacco smokers by the questionnaire. Results from this study were compared to our previous findings, determining urinary biomarkers in a West African population known to be at high risk for aflatoxicosis. Of the total samples collected from participants in the Ashanti Region of Ghana, 88.3% and 98.3% had positive peaks for AFM_1 and 1-OHP, respectively. Furthermore, tobacco smokers accounted for only 5.5% of the study population implying a predominant environmental exposure. Our findings suggest that the study population in San Antonio is not at high risk for aflatoxicosis. Further work is warranted to standardize data with creatinine levels in individual urines in order to compare exposure levels with those found in Ghana. (Supported by NIEHS ES 09106)

PS 1207 ETIOLOGICAL CHARACTERIZATION OF EMERGENCY DEPARTEMENT ACUTE POISONING.

M. Khlifi[1], L. Zun[2], L. A. Downey[3], G. T. Johnson[1] and R. D. Harbison[1]. *[1]Environmental Occupational Health, University of South Florida, Tampa, FL, [2]Department of Emergency Medicine, Rosalind Franklin University of Medicine and Science/Chicago Medical School, Chicago, IL and [3]School of Policy Studies, Roosevelt University, Chicago, IL.*

An investigation of emergency department (ED) poisonings was conducted to characterize poisoning demographics and evaluate associations with co-morbidities. Risk factors for suicidal poisoning and the relationship with mental illnesses was also evaluated. The study population consisted of 649 poisoning cases admitted between 2004 and 2007 to the ED of Mount Sinai hospital in Chicago. Ethnicity, age, and gender were socio-demographic factors with substantial impact on the population distribution as poisoning cases were predominantly African Americans (79.9%) between 36-45 years old with a 1.3 male to female ratio. Intentional illicit drug overdose was the most prevalent cause of poisoning, heroin being the most frequent substance found in 35.4% (n=230) of cases, followed by cocaine overdose at 31.7% (n=206), concomitant heroin and cocaine overdose at 4.3% (n=28), multiple drug poisoning at 5.5% (n=36), and antidepressant/antipsychotic poisoning at 6% (n=39). Significant correlations were found between heroin poisoning and asthma (F=20.29, DF=1, p= .0001), cocaine poisoning and hypertension (F=33.34, DF=1, p=.0001), and cocaine poisoning and cardiovascular disease

(F=35.34, DF=1, p=.0001). A change in the pattern of illicit drug use from injection to inhalation was detected and the resulting increase of inhalation and insufflation of illicit substances may partially explain the correlation found between herion use and asthma. This study provides supporting evidence that deliberate poisoning with illicit drugs remains a serious issue that significantly aggravates comorbidities and raises treatment costs by significantly increasing both the rate of hospitalization and hospital length of stay (LOS).

PS 1208 EVALUATION OF FLUOROPOLYMER TOXICITY FROM OUTBREAK REPORTS AND ANIMAL STUDIES.

C. Williams[1], E. C. Shay[2], K. M. Unice[2], P. K. Scott[2] and B. L. Finley[3]. *[1]ChemRisk, Inc., Tallahassee, FL, [2]ChemRisk, Inc., Pittsburgh, PA and [3]ChemRisk, Inc., San Francisco, CA.*

Fluoropolymers (FPs) are present in commercial products such as ceramic tile/grout sealants, fabric and upholstery protectors, leather impregnation sprays, and boot sealants. These products typically contain a low percentage of FP in petroleum-based solvents and/or propellants. FPs have low acute toxicity, with LC50's greater than 20 g/m3 in rats. However, there are reports dating back to the the 1980's of "outbreaks" of human respiratory symptoms (including some fatalities) associated with the use of sprays containing FPs, and in some cases the FPs have been implicated as the causative factor. To evaluate the toxicological merits of these claims, we conducted a weight-of-evidence evaluation of the relevant epidemiological and animal toxicity literature. We found more than 20 case reports of mass or single outbreaks of respiratory injury following the use of FP-containing sealants, but in each of these reports, either the FP in the commercial product was not identified, the product label or the material safety data sheet (MSDS) for the product did not list an FP as an ingredient, toxicity could not specifically be assigned to the FP (e.g., in formulations containing multiple ingredients in addition to the FP), or ingredients other than the FP were thought by the authors to be responsible for the reported illnesses. Similar limitations were present in the animal exposure studies involving FP-based sealants. For example, in some studies the FP concentrations in the test material and/or the test chambers were never characterized or even measured. In other studies, the exposures were too high to represent a realistic commercial use scenario. In short, there are currently no animal studies that indicate that FP in a commercial product, or even the FP product itself, is capable of causing respiratory injury in humans under normal use conditions. We conclude that further research would be necessary to establish a link between exposure to FP-containing sealants and serious respiratory problems in humans.

PS 1209 URINARY CONCENTRATIONS OF DIALKYL ORGANOPHOSPHATE METABOLITES IN FARMWORKERS AND NON-FARMWORKERS AND THEIR CHILDREN IN A LONGITUDINAL COHORT STUDY.

E. G. Moreira[1], G. D. Coronado[2], B. Thompson[2], E. M. Vigoren[1], W. C. Griffith[1] and E. M. Faustman[1]. *[1]Environmental and Occupational Health Sciences, U of WA, Seattle, WA and [2]Fred Hutchinson Cancer Research Center, Seattle, WA.*

In 2005–2006, we conducted a longitudinal cohort study in the Yakima Valley of Washington State of farmworker and non-farmworker households with young children ages 2–6 to look at the occupational take-home pathway for organophosphates pesticides (OP). We are reporting on median urinary concentrations of OP dialkyl metabolites during the thinning season, a time of higher pesticide usage when farmworkers are thinning trees in orchards. Farmworkers had an approximately 14-fold higher concentration of dimethylthiophosphate (DMTP) and 1.4-fold higher concentration of diethylthiophosphate (DETP) than non-farmworkers. Children of farmworkers presented an approximately 2.5-fold higher concentration of DMTP than children of non-farmworkers, but no difference was observed for DETP. Values for different segments of the US population for 2001-2002 are given in NHANES III (CDC 2005). The NHANES adults and children ages 6–11 had lower median DMTP values compared to our non-farmworkers and their children (<0.4 vs 5 ng/ml and 1.4 vs 6.4 ng/ml, respectively). Concentrations of DETP were low in both NHANES and our non-farmworker adults and children (0.8 ng/ml and below). It is noteworthy that among non-farmworkers, as in NHANES, the concentration of DMTP was higher in children than in adults. In conclusion, the present results suggest the importance of examining: 1) the take-home pathway as a source of OP exposure to farmworkers' children; 2) the occupational exposure of farmworkers to OPs during the thinning season; and 3) the higher environmental OP exposure of an agricultural population compared to the general population in the US. In order to interpret if these differences are associated with health effects, these exposures must be examined along with information about the relative potency of these agents. (Supported by grant 5P01ES009601 from NIEHS and RD83170901 and RD83273301 from EPA.)

PS 1210 POLYCYCLIC AROMATIC HYDROCARBON (PAH)-DNA ADDUCTS, CHROMOSOMAL ABERRATIONS, AND *CYP1A1* AND *GSTM1* RISK VARIANTS IN PERIPHERAL BLOOD LYMPHOCYTES FROM YOUNG ADULTS LIVING IN MEXICO CITY.

W. A. García[3], A. Chagoya[3], K. Carrasco[3], P. Petrosyan[3], L. Asenjo[2], R. Campos[2], J. Rubio[3], C. Castro[3], M. C. Poirier[1] and M. E. Gonsebatt[3]. *[1]CDI Section, National Cancer Institute, NIH, Bethesda, MD, [2]Ciencias Ambientales, Universidad de Alcalá de Henares, Madrid, Madrid, Spain and [3]MGTA, Instituto de Investigaciones Biomédicas, Universidad Nacional Autónoma de México, MÑ©xico, DF, Mexico.*

According to the automated air quality monitoring system, the critical air pollutants in Mexico City are ozone and particulate matter < 10μm (PM10) and <2.5 μm (PM2.5). Particulate matter increases during the dry season (winter) and decreases during the rainy season (summer). PAHs adsorbed in respirable PM2.5 in urban air are mainly derived from the incomplete combustion of organic materials, and bioactivation of some PAHs produces reactive metabolites that bind to DNA resulting in mutagenesis and cancer. We compared levels of PAH-DNA adducts and chromosomal aberration frequencies using peripheral blood lymphocytes from non-smoking young adults (n=98) obtained during one winter and the following summer. PAH-DNA adducts were analyzed using a chemiluminescence immunoassay with antiserum elicited against DNA modified with r7,t8-dihydroxy-t-9,10-oxy-7,8,9,10-tetrahydro-benzo[*a*]pyrene (BPDE). Chromosomal aberration frequencies were determined in metaphases of cultured lymphocytes, and *Cytochrome P450 (CYP)1A1* and *Glutathione-S-transferase M1 (GSTM1)* allelic variants were also evaluated. Smoking status was confirmed by urinary cotinine. The levels of DNA adducts determined in winter (11.8 ± 2.6 per 109 nucleotides) were slightly higher than those in summer (10.4 ± 2.8 per 109 nucleotides) (p<0.036). The frequency of chromosomal aberrations was essentially the same in winter and summer, and the presence of at-risk alleles for *CYP1A1* and *GSTM1* was associated with higher levels of PAH-DNA adducts only in those samples obtained during winter (p<0.044). The study demonstrates that PAH-DNA adducts are modulated by level of external exposure, which, in Mexico City, varies by season. This work was supported by CONACYT grant 46341-M

PS 1211 PILOT STUDY OF PERCHLORATE EXPOSURE IN LACTATING WOMEN IN AN URBAN COMMUNITY IN NEW JERSEY.

M. Borjan[1], B. C. Blount[2], S. Marcella[1] and M. G. Robson[3]. *[1]UMDNJ - School of Public Health, Piscataway, NJ, [2]Centers for Disease Control and Prevention, Atlanta, GA and [3]Rutgers University, New Brunswick, NJ.* Sponsor: L. White.

Perchlorate is most widely known as a solid oxidant for missile and rocket propulsion systems and has been detected in drinking water, fruits, vegetables, and milk throughout New Jersey and most of the U.S. In New Jersey, the FDA detected perchlorate in romaine lettuce (3.70-21.60 ppb), tomatoes (0.38-6.48 ppb), spinach (6.02-40.90 ppb), broccoli (3.60-6.96 ppb), and whole milk (3.40-4.85 ppb); these levels were below the U.S. average. Water sampling by the EPA found that numerous sites in New Jersey exceeded the Minimal Reporting Level of 5.00 ppb with levels ranging from 5.00-21.00 ppb. Perchlorate interferes with the uptake of iodine into the thyroid and may interfere with the development of the skeletal system and central nervous system of infants who are exposed to perchlorate through breast milk. Increased perchlorate in breast milk leads to a decrease in iodine uptake by the infant, which is why iodine supplementation is encouraged among lactating women. The main objective of this study is to estimate total perchlorate exposure for lactating women and infants based on perchlorate levels in maternal milk and urine. Over 100 lactating mothers have provided consent to participate in this study. Demographic data shows that over 90% of the subjects are Hispanic and range in age from 18-38. The primary sources of drinking water are filtered, municipal tap water (54%) and bottled water (30%). Further analyses of the data will be done when urine, water, and breast milk samples are analyzed. Subjects are asked to provide a urine and breast milk sample on three separate occasions along with a sample of their primary source of drinking water. At each sample collection, the subjects are required to complete a 24-hour dietary recall. Perchlorate, thiocyanate, nitrate, and iodide excretion in breast milk and urine will be analyzed using ion chromatography and tandem mass spectrometry.[Funding: NJDEP Contract # SR06-044]

1212 A TALE OF ONE CITY: AIR POLLUTION AND THE BEIJING OLYMPICS.

L. Chen[1], J. Hwang[2], X. Guo[3], M. Zhong[1], Q. Qu[1], J. Zhang[4] and Q. Sun[5]. *[1]Environ Med, NYUSOM, Tuxedo, NY, [2]Inst Statistical Sci, Academia Sinica, Taipei, Taiwan, [3]Occup and Environ Health Sci, Peking U School of Public Health, Beijing, China, [4]Environ and Occup Health, UMDNJ, Piscataway, NJ and [5]Environ Health Sci and Cardiology, OSU, Columbus, OH.*

Because air pollution can affect the health and performance of athletes participating in this summer's Olympics, the Chinese government imposed drastic measures by closing industries and clearing road traffic during the Olympics in an attempt to improve the air quality in Beijing. In anticipating that these measures would reduce ambient particulate matter (PM) concentrations as well as alterations in the constituents of PM, we set up an animal exposure facility in Peking University School of Public Health to evaluate the health consequences of this targeted reduction in PM as a "natural, real-world" experiment. C57/B6 mice were exposed to fine ambient PM (PM2.5) for 23 hr/d, 7d/wk, for 4 months beginning on July 30th, 2008. PM2.5 mass concentrations, black carbon (BC) levels, as well PM2.5 components were measured daily. Electrocardiogram (ECG) based Heart Rate (HR), deep body temperature, and activity counts data were constantly sampled for 20 sec/5 min throughout the experiment using implanted DSI telemetry transmitters. Heart Rate Variability (HRV) analysis was conducted using conventional methods (SDNN; RMSSD; PSD, power spectral analysis). Preliminary data indicated that the PM2.5 concentrations in Beijing during the Olympics were 2 to 3 times higher than those in New York City (NYC), and rose to levels at least 5 fold greater after the Olympic Games was completed. Concentrations of BC, primary emissions from vehicle traffic, were 3-5 times those in the NYC during the Olympics, and rose to levels more than 10 times greater after the Olympics. We also found that, in the first two months of this study, corresponding to a period of reduced air pollution, there were strong negative correlations between HR and BC in the early morning and positive correlations in the late afternoon. Ongoing trace element analysis will provide data to correlate source components with changes in cardiac endpoints.

1213 TOXICITY OF AMBIENT PM COLLECTED IN BEIJING AND TIANJIN DURING AND AFTER THE 2008 OLYMPICS.

T. Gordon[1], L. Chen[1], J. Zhang[4], J. Wang[2], Z. Bai[2], Y. Shang[3], F. Tian[3] and T. Zhu[3]. *[1]NYU School of Medicine, Tuxedo, NY, [2]Nankai University, Tianjin, China, [3]Peking University, Beijing, China and [4]UMDNJ, Piscataway, NJ.*

Understanding the toxicity of complex ambient pollutants presents challenging research issues. Intervention of air pollution sources can present a unique opportunity to study how changes in air pollution affect human health. In this study, we collected size-segregated ambient PM at 2 locations which were close in proximity to 2008 Olympic events: Tianjin and Beijing. Coarse, fine, and UF PM fractions were collected with a 900 LPM ChemVol sampler at both locations during the Olympics when interventions significantly reduced point source and traffic emissions and after the Olympics when pollution emissions returned to previous levels. Additional samples were collected during the 48 hr period surrounding National Day which is a time of celebration and numerous firework displays. In general, ambient PM2.5 and NO2 concentrations during the Olympics were half of what they were prior to the Olympics and rose to pre-Olympic levels after the Olympics were completed. Particles were tested for toxicity and reactive oxygen species (ROS) production in human-derived BEAS-2B airway epithelial and HPMEC-ST1.6R pulmonary vascular endothelial cell lines. Clear particle size differences in ROS production were observed in both cell lines. Additionally, there was some evidence of dose-dependent differences in ROS production between the 2 sampling sites and the samples taken during the 'fireworks' period. Ongoing trace element analysis will provide data to correlate source components with differential oxidative stress outcomes in both epithelial and endothelial cell lines.

1214 USE OF MULTIPLE LINES OF EVIDENCE FOR EVALUATING A VAPOR INTRUSION SCENARIO – CASE STUDIES.

S. Roy-Semmen[1], C. Y. Jeng[1] and G. A. Pollock[2]. *[1]Department of Toxic Substances Control, California Environmental Protection Agency, Cypress, CA and [2]Department of Toxic Substances Control, California Environmental Protection Agency, Sacramento, CA.*

A multifaceted approach was used to evaluate vapor intrusion scenarios at two distinct sites (A and B). Site A is an oil refinery, with elevated levels of methane and gasoline vapors beneath adjacent residential and commercial properties. Site B is a former chemical manufacturing facility with a chlorinated volatile organic compound (VOC) plume extending from beneath a commercial building (located on Site B) to offsite areas immediately adjacent to residential properties. Preliminary review of subsurface data suggested that residents/workers in these buildings may be exposed to VOCs emanating from the subsurface. A step-wise approach was taken to determine if mitigation measures were warranted to prevent indoor air exposures: (1) Shallow soil vapor data from residential and commercial buildings were compared to health-based screening criteria to identify, for further study, candidate buildings with the potential for subsurface vapor intrusion; (2) Indoor and outdoor air monitoring and/or sub-slab soil vapor data were collected from these candidate commercial and residential buildings; and (3) Potential for other sources of organic vapors (e.g., household products, building materials, background ambient air) as confounding variable(s) were assessed using multiple data analysis techniques. Based on the multiple lines of evidence from these analyses, it was determined that subsurface vapor intrusion did not have a significant effect on indoor air quality in the residential and commercial buildings at Site A. At Site B, soil gas, sub-slab vapor, and indoor/ambient air data indicated that VOCs had migrated from the subsurface into two of the offices and a break room in the commercial building, but not into the warehouse area. Vapor intrusion was not of concern in residences located immediately adjacent to Site B.

1215 THE ROLE OF PM SIZE AND COMPOSITION ON THE CELLULAR TOXICITY INDUCED BY SAMPLES FROM AN ARID REGION CITY.

A. R. Osornio-Vargas[1], J. Serrano[2], L. Rojas Bracho[3], G. Flores[1], M. Zuk[3], J. Miranda[4], I. Vazquez[1], Y. Sanchez[1], C. Garcia[1], M. A. Reyna[6], M. Quintero[6], T. Lopez[3] and I. Rosas[5]. *[1]Inv Basica, I Nal Cancerologia, SSa, Mexico, DF, Mexico, [2]Fac Ciencias, UNAM, Mexico, DF, Mexico, [3]INE, SEMARNAT, Mexico, DF, Mexico, [4]Inst Fisica, UNAM, Mexico, DF, Mexico, [5]CCA, UNAM, Mexico, DF, Mexico and [6]Inst Ingenieria, AUBC, Mexicali, Baja California, Mexico.*

Background: Discrepancies on the role of PM composition and specific health outcomes, particularly in relation to coarse particles exist. PM2.5 represents a more homogenous mixture, than PM10, probably accounting for its more consistent association with mortality worldwide. Nevertheless, neither can be considered harmless. Objective: Provide toxicological evidence on the role of PM size/composition using PM from Mexicali; a city where soil dust (aluminum-silicates) has a toxic potential and contributes importantly to air pollution. Methods: Semi-urban (SU) and urban (U) PM2.5 & PM10 were collected during six months. Pooled samples by size, site, and month were evaluated for elemental composition and its capacity to induce hemolysis, inhibition of cell proliferation, TNFα/IL-6 secretion and DNA degradation. Principal Component Analysis (PCA) was applied to reduce dimensionality of PM elements. Relationships between PM components and biological effects underwent regression analysis. Differences of components by site were tested by one-way ANOVA and toxicological differences by site and size, by two-way ANOVA. Results: PCA extracted: C1:Mg,Al,Si,P,Cl,K,Ca,Ti,Va,Cr,Fe, and C2:Cu,Zn, in both fractions/sites. C2 was significantly higher in U samples. PM10 had larger effects than PM2.5. Hemolysis was favored by PM10SU, whereas cytokine production by PM10U. Hemolysis related with C1PM10U; cytotoxicity with C1PM10SU, IL-6 with C1PM10SU/C2PM10SU; and TNFα with C2PM2.5U. Conclusions: Our data indicate the existence of size/composition differential toxicological effects induced in vitro by PM from Mexicali. PM10 retains the majority of the toxic effects. PM soil elements potentiate anthropogenic ones in complex ways. This supports the role of PM composition on toxicological patterns, particularly for larger particles.

1216 HUMAN BIOMONITORING IN THREE AGE GROUPS, RESULTS OF THE FLEMISH ENVIRONMENTAL & HEALTH SURVEY (FLESH 2002-2006).

G. Schoeters[1, 2], E. Den Hond[1], G. Koppen[1], E. Govarts[1], V. Nelen[3], K. Desager[4], M. Viaene[5, 6], G. Vermeir[6], L. Bruckers[7], N. Van Larebeke[8] and W. Baeyens[9]. *[1]Environmental Toxicology, VITO, Mol, Belgium, [2]UA, Antwerp, Belgium, [3]PIH, Antwerp, Belgium, [4]UZA, Antwerp, Belgium, [5]GPH, Geel, Belgium, [6]KUL, Leuven, Belgium, [7]UH, Hasselt, Belgium, [8]UZG, Ghent, Belgium and [9]VUB, Brussels, Belgium.* Sponsor: B. De Wever.

The Flemish Centre for Environment & Health (Belgium) has organized a human biomonitoring campaign which included the recruitment of 1196 mothers and their newborns, 1679 adolescents (14 to 15 years) and 1583 adults (50 to 65 years). Recruitment followed a stratified sampling scheme in eight geographical areas. We tested the hypotheses whether living in different areas has a measurable impact on the pollutant profile in the body and whether this was associated with signs of early health effects. We measured biomarkers of exposure and effect and collected health

information of the participants. Persistent organochlorine compounds (PCB, p,p'-DDE, HCB, dioxin-like compounds), heavy metals (Pb, Cd) and metabolites of benzene and PAHs were measured. The levels of all exposure markers were in line with those reported in other countries. Inter-regional differences in concentrations – up to a factor 2-3 – were observed. We report that inhabitants of rural areas have higher serumlevels of persistent halogenated compounds and that inhabitants of urban areas have more asthma complaints. Environmental levels of dioxins, PCBs, HCB, p,p'-DDE or lead were associated with an increased risk for fertility problems in young women, with elevated levels of fT3 and fT4 in cord blood, with deregulation of puberty in adolescents and with higher occurrence of diabetes in adults. These data serve as an input for environmental health policy in Flanders. In the next cycle of the Environmental Health Survey (2007-2011) more pollutants will be measured and we will focus on monitoring in areas at risk, so called "hot spots" . The study was commissioned, financed and steered by the Flemish Government (Department of Economics, Science and Innovation; Flemish Agency for Care and Health; and Department of Environment, Nature and Energy)

PS 1217 ISOLATION AND IDENTIFICATION OF ANTIBIOTIC RESISTANT BACTERIA FROM MANHATTAN BEACH, NY.

S. M. Jeanlouis, T. Osmundson and C. Bolnet. *Medgar Evars College, Brooklyn, NY.*

Our Group is interested in exploring the diversity of soil bacteria in different locations in Brooklyn, NY: Manhattan Beach (MB), Coney Island Beach (CIB), Down State (DS) and Prospect Park (PP). These locations represent a variety of natural and anthropogenic factors. Manhattan Beach is located on the eastern end of Coney Island in Brooklyn, bordering the Atlantic Ocean. It is one of the most visited beaches in New York. Our lab had performed previous research on diversity and antibiotic resistance (AR) patterns of culturable soil bacteria from MB. Our results showed that the highest concentration of culturable bacteria exhibiting AR was found in MB. Furthermore, one third of our samples from this location showed resistance to the antibiotic vancomycin, typically used as a second line agent in the treatment of methicilin resistant Staphylococcus aureus (MRSA) infections when the first line agents have failed. In this present study, our main purpose was to identify, using molecular techniques, these antibiotic resistant bacteria for a better estimation on their potential threat to human health. We proceeded by extracting DNA from the pure cultures and performing PCR using the universal bacterial 16S rDNA primers fD1 and rP1. We then sequenced the PCR products using Big-Dye chemistry and the ABI 13730 automated sequencer. Using the Basic Local Alignments Search Tool, the obtained gene sequences were compared to other bacterial 16S rDNA sequences in GenBank. The search results revealed isolates exhibiting a 99 % nucleotide similarity to Ralstonia species such as Ralstonia mannolilytica and Ralstonia picketsii .We confirmed the resistance to vancomycin by means of a Kirby-Bauer test. In conclusion, we have identified in MB Ralstonia species presenting AR to vancomycin. These bacteria are rarely isolated from clinical specimens; nevertheless, they have been reported in neonatal bacteremia outbreaks, in patients with cystic fibrosis and in patients using respiratory gas humidifiers or catheters. The epidemiological implications of our findings are the subject of ongoing investigation.

PS 1218 DECREASED NITRITE AND NITRATE IN BREATH CONDENSATE FOLLOWING DRASTIC REDUCTIONS IN AIR POLLUTION DURING THE BEIJING OLYMPICS.

H. Kipen[1], J. Gong[1], D. Rich[1], W. Huang[2], G. Wang[2], P. Zhu[2], Y. Wang[2], X. Shuo[2], T. Zhu[2] and J. Zhang[1]. *[1]University of Medicine and Dentistry of New Jersey, Piscataway, NJ and [2]Peking University, Beijing, China.* Sponsor: D. Laskin.

Numerous epidemiologic studies document that daily or hourly changes in air pollution levels, particularly fine particulate matter (PM2.5), are associated with cardiopulmonary morbidity and mortality. However, the precise mechanisms that underlie these associations are not well-understood, and further exploration of pollution effects on hypothesized pathogenic pathways is indicated. We present a panel study that examines changes in multiple biomarkers in response to the drastic reductions in Beijing air pollution during the 2008 Olympics. This abstract reports on changes in markers of inflammation /nitrosative stress in the lung among 130 healthy Chinese medical students, measured before the Olympics during periods of high pollution and during the Olympics during periods of low pollution. Breath condensate was collected in the morning prior to pollution reductions and then approximately one month later during the Olympics when reductions in PM2.5 and NO2 ranged from 40%-50% below the pre-Olympic levels (~100 ug/m3 and ~ 50 ug/m3, respectively). Exhaled Breath Condensate (EBC) samples were collected with an ECoScreen II Collector from each subject and then stored until analysis using an HPLC-UV technique. In the pre-Olympic period, breath condensate nitrite averaged 8.52 ± 5.39 μM and decreased to 5.41 ± 3.05 μM after approximately 2 weeks of the Olympic pollution reductions. Nitrate decreased from 3.05 ± 1.44 μM to 2.90 ± 1.65 μM during the same period. In summary, induction of pulmonary inflammation via oxidative / nitrosative stress is a prominent hypothesis invoked to explain the effects of PM. Our data show large reductions in exhaled breath levels of two molecules thought to reflect the level of inflammation and oxidative / nitrosative stress in the lung, which supports this hypothesis. Pending data will document further changes in these same markers following relaxation of the Olympic pollution controls and a return of higher levels of pollutants.

PS 1219 THE ESTROGENIC EFFECT OF ORGANIC EXTRACT FROM SOURCE WATER OF X CITY IN CHINA.

X. Wang[1, 2], W. Qu[1, 2], Y. Zhang[1, 2], G. Zhang[1, 2], L. Yin[1, 2], S. Jiang[1, 2] and H. Zhu[1, 2]. *[1]Department of environmental health, School of public health, Fudan University, Shanghai, China and [2]Key laboratory of public health safety, Ministry of education, Shanghai, China.* Sponsor: T. Zhou.

Water pollution by endocrine disruptors is one of the most critical problems concerning drinking water resources and environmental protection of water bodies. Up to now, the uterotrophic assay is still considered as the "gold standard" and as an essential component when testing for estrogenicity since it incorporates the effects of metabolism and pharmacokinetics. The present study was conducted to explore the estrogenic effect of organic extraction from water source of x city in the southern China by the typical uterotrophic assay. Furthermore, expression of proliferating cell nuclear antigen (PCNA) was detected by immunohistochemistry. The results showed that the changes of uterine wet weight and uterine gland number were insignificant among different doses, while uterine epithelial cell height increased significantly with increase of dosage. The results also showed the expression of PCNA was strong in positive control and high dosage group, while its expression was negative or weak in negative control and low dosage group. It suggested that water sample detected had estrogenic activity. Taken together, the data presented in current study suggest that incorporation of morphologic and biochemical responses as endpoints in the rodent uterotrophic bioassay did not show the high sensitivity of the test when assessing mixture and it therefore needs to be further improved in identifying potential environmental toxicants. Other endpoints and new methods need to be employed in order to increase the sensitivity, efficiency and reliability in the screening test.

S 1220 AQUATIC SPECIES AS SENTINELS FOR HUMAN HEALTH: COMPARATIVE TOXICOLOGY OF METALS, NANOPARTICLES, AND PCB'S.

J. Wise[1] and S. DeGuise[2]. *[1]University of Southern Maine, Portland, ME and [2]University of Connecticut, Storrs, CT.*

Aquatic toxicology has important implications for human health including using animals in aquatic environments as sentinels for both human health and the health of the aquatic environment and as models for human disease. Metals, nanoparticles, and organic compounds pose emerging and persistent concerns for public and aquatic health, but their full impacts are poorly understood. Given the current understanding of contaminants in the aquatic environment and the lessons that can be learned for human health it is important to address these issues. The panel of experts will highlight the emerging data that chromium may be a major pollutant in the marine environment with consideration that marine mammals are a sentinel species for human health, and also discuss potential novel adaptations in these whales to these exposures that may have implications for human health. The potential impact of metal nanoparticles using a fish model for development will be utilized to inform on how to rapidly determine which types of nanoparticles are more potent than others. The toxicity of nanoparticles will be compared and considered in human cells compared to cells from aquatic species to show how the response to these agents can be very different for various species. The impact of mercury will also be considered and its effects on development using a zebrafish model. It will consider how organochlorines impact the immune system of whales and humans and how whales may be sentinels for human health. Insight will be offered to researchers and risk assessors on the potential impacts of these chemicals, but even more importantly it reveals theories underlying these effects and thus suggests future directions in research for aquatic toxicology and aquatic models and how they relate to human health. For those currently engaged in nanotoxicology, metal toxicology, aquatic toxicology, risk assessment, regulatory management, occupational health, ecotoxicology, immunotoxicology, developmental toxicology, and toxicology education, this should be a particularly informative session.

S 1221 WHALES AS SENTINELS FOR HUMAN HEALTH: A GLOBAL ASSESSMENT OF CHROMIUM POLLUTION.

J. P. Wise[1, 2, 3], S. Kraus[2], R. Payne[3], S. S. Wise[1, 3], I. Kerr[3], C. LaCerte[1], J. Wise[1], C. Gianios[1], F. Shaffiey[1], M. Grau[1], T. Li Chen[1], C. Perkins[4], W. Thompson[1], T. Zheng[5], Y. Zhang[5], C. Zhu[5] and T. O'Hara[6]. *[1]Wise Laboratory of Environmental and Genetic Toxicology, Maine Center for Toxicology and Environmental Health, Applied Mediacl Sciences, University of Southern Maine, Portland, ME, [2]Edgerton Research Laboratory, New England Aquarium, Boston, MA, [3]Ocean Alliance, Lincoln, MA, [4]Center for Environmental Sciences and Engineering, University of Connecticut, Storrs, CT, [5]Yale University, New Haven, CT and [6]Institute of Arctic Biology, University of Alaska, Fairbanks, AK.*

Hexavalent chromium [Cr(VI)] is a known human lung carcinogen. Exposure to Cr(VI) occurs in both occupational and environmental settings. However, despite the fact that substantial amounts of Cr are released into the environment and that marine waters favor the hexavalent form, few studies have considered Cr exposure in marine settings or the consequences of exposure to marine species. The goal of this project is to understand the impacts of Cr exposure in the marine environment and its potential implications for human health. We are investigating the levels of Cr in both toothed and baleen whales using the sperm whale (Physeter macrocephalus) and North Atlantic right whale (Eubalaena glacialis) as a sentinel species for human health. We find that Cr is a major pollutant in the marine environment, with skin Cr concentrations (based on total Cr) reaching levels that are comparable to those Cr levels reported in lung tissue of occupationally exposed workers who died of Cr(VI)-induced lung cancer. In addition, the mean Cr skin level in both species was 23-28 times higher than the level reported for humans without a history of occupational Cr(VI) exposure. Both particulate and soluble Cr(VI) were genotoxic to cell lines from both species after a 24 h exposure. However, the amount of damage in whale cells was significantly lower than the amount induced in human cells. These data suggest that whale cells may have evolved novel mechanisms to reduce the toxic effects of Cr.

S 1222 RELATIVE TOXICITY OF METAL NANOPARTICLES TO DEVELOPING ZEBRAFISH.

R. L. Tanguay[2], S. L. Harper[1], L. Duong[1] and K. S. Saili[2]. *[1]Department of Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR and [2]Department of Environmental and Molecular Toxicology and the Environmental Health Sciences Center, Oregon State University, Corvallis, OR.*

Nano-sized metals and metal oxides have unique properties that will prove useful for applications in electronics, healthcare, remediation, imaging, sensor, catalysis, electronics, optics, technology and engineering industries. Rapid discovery and development of novel uses for nanoparticulate metals will undoubtedly increase the probability of human and environmental exposure. Of concern are recent reports of adverse biological effects from metal nanoparticle exposure. Since nanoparticles may interact with biological systems in unexpected ways, evaluation of nanomaterial toxicity should cover a broad range of cell types, tissues, organs and systems. This study employed embryonic zebrafish as a whole animal assay to delineate metal nanoparticles that are biologically active from those that are not. The embryonic zebrafish model is a dynamic in vivo system that offers the power of whole-animal investigations (e.g. intact organism, functional homeostatic feedback mechanisms and intercellular signaling) with the convenience of cell culture (e.g. cost- and time-efficient, minimal infrastructure, small quantities of nanomaterial solutions required) to rapidly evaluate interactions between nanomaterials and integrated living systems. We investigated the effects of nanoparticulate metal oxide dispersions, biologically-synthesized Au and Ag nanoparticles, a small congeneric library of gold nanoparticles, and a small congeneric library of zinc oxide nanomaterials. Information gained from model systems such as the embryonic zebrafish, can be used to inform the development of safer nanomaterials and nanotechnologies.

S 1223 COMPARATIVE TOXICITY OF SILVER NANOPARTICLES IN HUMAN, MARINE MAMMAL AND FISH CELLS.

S. S. Wise[1, 2], M. D. Mason[3], F. Shaffiey[1], T. Li Chen[1], B. Goodale[1], C. LaCerte[1], G. Craig[3], R. Walter[4], R. Payne[2], I. Kerr[2], S. Kraus[5] and J. P. Wise[1, 2, 5]. *[1]Wise Laboratory of Environmental and Genetic Toxicology, Maine Center for Toxicology and Environmental Health, Applied Medical Sciences, University of Southern Maine, Portland, ME, [2]Ocean Alliance, Lincoln, MA, [3]The Department of Chemical and Biological Engineering, Institute for Molecular Biophysics, University of Maine, Orono, ME, [4]Texas State University, San Marcos, TX and [5]Edgerton Research Laboratory, New England Aquarium, Boston, MA.*

Industrial application of silver nanoparticles has increased dramatically in recent years making them a new and emerging potential environmental contaminant. Many of these applications have the potential to release silver nanoparticles directly into the water stream. However, the toxicity of silver nanoparticles is unknown. The goal of this project is to determine the mechanisms of silver nanoparticle-induced cytotoxicity and genotoxicity in humans and aquatic species. We used cells from sperm whales (Physeter macrocephalus), North Atlantic right whales (Eubalaena glacialis), and medaka fish (Oryzias latipes) as model aquatic species. The data show that silver nanoparticles are cytotoxic to all four species in a concentration-dependent manner. However, the potency was greater in the whale cells and greatest in the fish cells. Silver nanoparticles were not genotoxic to human cells, but were significantly genotoxic to fish cells, with again the whale cells exhibiting a response in between the two. Most nanoparticle toxicity work so far focuses on human health effects with much less study of the effects in aquatic species. These data indicate that while nanoparticles can be of limited toxicity to human cells, they can still have dramatically more toxicity in cells from aquatic species. These observations raise important issues for how risk assessors consider the full potential impact of nanomaterials as merely considering rodent and human effects is likely to be insufficient.

S 1224 ZEBRAFISH MODEL FOR UNDERSTANDING METHYLMERCURY DEVELOPMENTAL NEUROTOXICITY.

M. J. Carvan[1, 2], Q. Liu[1], D. N. Weber[2] and M. L. Rise[3]. *[1]Great Lakes WATER Institute, University of Wisconsin-Milwaukee, Milwaukee, WI, [2]Children's Environmental Health Institute, University of Wisconsin-Milwaukee, Milwaukee, WI and [3]Memorial University, St. John's, NF, Canada.*

Methylmercury (MeHg) affects the developing nervous system, and the children of women that consume high quantities of wild-caught fish during pregnancy may be at risk for neurological impairment. Data suggest that certain maternal dietary components (selenium and others) may reduce the embryotoxic effects of MeHg. The goal of this project is to identify neural and molecular biomarkers as predictors of MeHg exposure and deficits in specific neurobehavioral endpoints, and to explore the effect of Se on toxicity. Specifically, we are investigating the effects of sublethal MeHg exposure (either direct or via maternal diet of wild-caught fish) on developing zebrafish by analyzing early life stage (ELS) toxicity, changes in global gene expression by microarray analysis, and neurobehavioral dysfunction. Developmental exposure to MeHgresults in ELS toxicity and neurodevelopmental alterations persist into adulthood as visual and learning deficits. Interestingly, selenium co-treatment reduced the uptake of methylmercury, ameliorated the resultant ELS toxicity, and improved the performance of exposed individuals in our visual assay. Gene expression analysis in exposed embryos was performed using an 8,000 element zebrafish cDNA microarray and revealed changes in the expression of a number of genes primarily associated with neurological structure and function, mitochondrial function, and immune system function, consistent with our findings of learning and neurobehavioral deficits. These results show that maternal exposure to moderate levels of MeHg can have dramatic developmental and behavioral effects in their offspring by disrupting numerous molecular pathways involved in the growth and development of multiple organ systems and that selenium may reduce some of the neurotoxicological effects of developmental methylmercury exposure.

S 1225 IMMUNOTOXICITY OF PCBs, AN EXAMPLE OF MARINE MAMMALS AS SENTINELS FOR HUMAN HEALTH?

S. De Guise. *University of Connecticut, Storrs, CT.*

This talk will discuss the recent advances in comparative immunotoxicology of PCBs, and how they apply to human and environmental risk assessment. A new approach will be examined, using in vitro systems to qualify and quantify toxicity in species such as humans and marine mammals, for which traditional in vivo approaches present significant logistical and ethical problems. Current efforts to translate in vitro findings to assessment of risk at the population level will be presented. The concept of marine mammals as potential sentinels for early detection and quantification of the likely effects of ubiquitous environmental pollutants on ecosystem and human health will be discussed.

S 1226 MAMMALIAN RETROTRANSPOSITIONAL ELEMENTS: EPIGENETIC REGULATION, SPECIES DIFFERENCES, AND POTENTIAL ROLES AS MEDIATORS OF CELLULAR RESPONSES TO TOXIC STRESS.

R. D. Storer and C. Qin. *Laboratory Sciences and Investigative Toxicology, Merck Research Laboratories, West Point, PA.*

Epigenetic regulation of gene expression is being extensively investigated. However, approximately 38 to 47% of the mouse and human genomes respectively are composed of mobile elements (DNA transposons and retrotransposons) whose potential roles in susceptibility to toxicity and disease upon epigenetic dysregulation have

not been fully explored. The retrotranspositional elements are the most numerous and complex, having promoter/enhancer activity, protein coding ability, and mutagenic potential and are subject to epigenetic control. Due to their structure and locations, often within, or proximate to genes and their regulation by DNA methylation, these elements can modify gene expression and serve as epigenetic mediators of phenotypic variation in a species and strain-specific manner. In addition, some classes of retrotransposons remain active as mobile elements with the potential to create new somatic mutations involved in cancer and germline mutations with the potential to drive genome evolution and modulate disease susceptibility. In humans, long interspersed nuclear elements (LINE-1) and Alu elements are the two classes of retrotransposons that remain active (mobile) while the less numerous endogenous retrovirus (ERV) LTR retrotransposons have mostly lost this capacity. In contrast, in mice, members of the class of retroviral LTR retrotransposons, in particular intracisternal A particles (IAPs), have retained retrotransposon activity. Germline IAP transpositions in certain mouse strains such as in the Agouti and Axin genes have provided fascinating examples of phenotypic variation mediated by epigenetic mechanisms, namely diet- and/or chemically-induced changes in DNA methylation. Given the large number of these genetic elements, and the species differences in their sequences, activity, and distribution in the genomes, further investigation of their potential role(s) in mediating disease processes and cellular responses to endogeneous chemicals and xenobiotics is warranted.

S 1227 MAMMALIAN L1 RETROTRANSPOSONS ARE POTENTIAL MUTAGENS IN HUMANS.

H. H. Kazazian. *Department of Genetics, University of Pennsylvania School of Medicine, Philadelphia, PA.* Sponsor: C. Qin.

LINE-1 (L1) sequences are present in 520,000 copies and make up 17% of the human genome. They constitute 20% or more of other mammalian genomes. Most of these sequences are truncated or otherwise defective, but the human genome has ~7000 full-length 6 kb elements and the average human being carries about 80-100 active L1s. These L1s have an internal promoter, two ORFs, and end in a poly A tail. The first ORF has nucleic acid chaperone activity, and the second ORF has reverse transcriptase and endonuclease activity. Reverse transcription and integration of L1s are coupled. The endonuclease nicks genomic DNA, and the reverse transcriptase uses the free 3' end at the nick as a primer and the L1 RNA as template. Both ORFs are critical for retrotransposition in cultured cells. L1s have contributed further to genome expansion by providing the reverse transcriptase for Alu, SVA (another small retrotransposon), and processed pseudogene mobility. These other sequences, mostly Alus, make up ~10% of the genome. L1 has driven genome evolution in many other ways besides through their own mobility and that of other sequences. L1 can transduce or carry sequences from either its 5' or 3' end to other genomic locations, thus providing the possibility of exon shuffling. Homologous recombination can occur between mispaired L1s leading to deletion or duplication of sequences between the L1s. L1s can alter gene expression by providing splice sites and poly A signals in introns, and producing transcriptional pausing. In our recent work, we have found that the bulk of L1 retrotransposition occurs in early embryonic development, not in the germ line, suggesting that L1 mobility may be even more frequent than has been previously thought. We are also developing genomic techniques to locate all new L1 insertions in any human genome. These techniques should provide important new insights into L1 biology, including the frequency and timing with which retrotransposition occurs in the human genome.

S 1228 MECHANISMS OF EPIGENETIC REGULATION OF L1 ELEMENTS IN HUMAN AND MURINE CELLS.

K. S. Ramos, D. E. Montoya, T. Kalbfleisch, V. Stribinskis, I. Teneng and M. E. Lacy. *Department of Biochemistry and Molecular Biology, University of Louisville School of Medicine, Louisville, KY.*

Long interspersed nuclear element-1 (L1) is an abundant retrotransposon in mammalian genomes that remains silent under most conditions and is reactivated by cellular stress signals. Of relevance is the ability of benzo(a)pyrene (BaP), a genotoxic carcinogenic hydrocarbon, to increase L1 retrotransposition rates in human and murine cells. Increased retrotransposition in BaP-treated cells is mediated by up-regulation of L1 RNA levels, increased L1 cDNA synthesis, and stable genomic integration. Thus, mutagenesis and genomic instability in human populations exposed to genotoxic hydrocarbons may involve epigenetic activation of mobile elements dispersed throughout the human genome. Recent evidence has established that E2F-Rb family complexes participate in L1 epigenetic regulation via nucleosomal histone modifications and recruitment of histone deacetylases (HDACs) 1 and 2. Reciprocal interactions between histone and DNA modifying complexes on the L1 promoter are also extensively regulated by BaP in mammalian cells. On the basis of these findings a model is proposed in which L1 reactivation is caused by modulation of DNA/histone modifications and failure of co-repressor protein recruitment leading to loss of histone epigenetic marks.

S 1229 GENETICS AND EPIGENETICS OF ENDOGENOUS RETROVIRUSES.

D. Mager[1, 2], Y. Zhang[1, 2] and D. Reiss[1, 2]. *[1]Terry Fox Laboratory, BC Cancer Agency, Vancouver, BC, Canada and [2]Medical Genetics, University of British Columbia, Vancouver, BC, Canada.* Sponsor: R. Storer.

Mammalian genomes are littered with sequences related to retroviruses. These endogenous retroviral elements (ERVs) are likely the result of ancient retroviral infections of the germ line that are now inherited as normal constituents of chromosomal DNA. Similar fractions of the human and mouse genomes are derived from ERVs, but there is a striking difference in the current activity of these elements in the two species. While there is little evidence for recent ERV activity in humans, several families of ERVs are active in inbred mice and cause 10% of all spontaneous mouse mutations through insertional mutagenesis. The first part of the presentation will compare human and mouse ERVs and will summarize our genome-wide studies to document polymorphic mouse ERVs. The remainder of the talk will focus on epigenetic studies of ERVs. Stochastic epigenetic silencing of some ERV insertions in mice has been shown to cause phenotypic variability between individuals. However, the prevalence of this phenomenon as well as its temporal dynamics are unknown. We have studied ERV DNA methylation patterns in mice and have observed that DNA methylation goes from stochastic to stable as insertions age. Variable methylation is frequent among randomly chosen recent ERV insertions, whereas older insertions are stably and heavily methylated. In contrast, our studies on one human ERV family have shown that the DNA methylation pattern for a given insertion is stable, but can vary widely between copies depending on genomic context. A model will be presented to explain these observations.

S 1230 INTRACISTERNAL A-PARTICLE (IAP) GENES: DISTRIBUTION IN THE MOUSE GENOME AND POTENTIAL ROLES AS SPECIES-SPECIFIC MEDIATORS OF CELLULAR RESPONSES TO TOXIC STRESS.

C. Qin and R. D. Storer. *Laboratory Sciences and Investigative Toxicology, Merck Research Laboratories, West Point, PA.*

Mice and rats have been the species of choice for the evaluation of chemical toxicity. However, different species and strains often respond differently. This has complicated human risk assessment for species- and strain-specific effects. To explore the basis of these species- and strain-specific effects, we examined the distribution of intracisternal-A particles (IAP) sequences, endogenous retroviral (ERV) elements, in the mouse genome and explored the possibility that IAP sequences embedded in genes may serve as mouse-specific genetic susceptibility factors for expression of disease phenotypes. We concluded that IAPs with LTR subtypes 1 and 1a are a class of young and active IAP elements. We found them located within, or in close proximity (<10kb) to, 550 genes in the C57BL/6 mouse genome. Functional (gene ontology) analysis revealed highly statistically significant associations of subsets of these genes with defined biological processes, most notably cell growth and signaling. For instance, 83 genes are involved in cell signaling ($p<2.33E-32$), 50 genes in cell death or apoptosis ($p<2.02E-17$), 38 genes in cancer development ($p<2.11E-12$), 36 genes in cell growth and proliferation ($p<2.11E-10$). To test the activity and inducibility of IAP LTRs embedded in the genes, LTRs from 4 genes were cloned into luciferase reporter plasmids; all were transcriptionally active in transient transfection assays, with enhanced activity with the LTRs in the unmethylated versus methylated state. Consistent with the presence of a glucocorticoid response element in the LTRs, dexamethasone treatment modestly enhanced activity. Different inbred strains and outbred CD-1 mice had different IAP insertion patterns for 3 genes tested. Similar strain polymorphisms have been reported for IAP insertions by other investigators. These data suggest that these epigenetically regulated IAP elements have the potential to affect cellular responses to xenobiotics and disease processes in a species- and strain-specific manner.

S 1231 INFLAMMASOME ACTIVATION IN PULMONARY DISEASE.

M. E. Poynter. *University of Vermont, Burlington, VT.*

Microbial products and endogenous molecules elaborated following tissue damage can activate cells through pattern recognition receptors. While Toll-Like Receptor (TLR) agonists can induce the expression of IL-1b, IL-18 and IL-33, these cytokines require further proteolytic processing by caspase-1 to be secreted. Caspase-1 is activated when in a multi-protein complex containing intracellular pattern recognition receptors of the NOD-like family, in particular Nalp3, which are stimulated by "danger signals". Assembly of this complex, termed the inflammasome, relieves the autoinhibitory state of caspase-1 and facilitates the proteolysis of IL-1b, IL-18 and IL-33 into secreted forms capable of orchestrating innate and adaptive immune responses. In support of these roles, asbestos fibers and silica, contact sen-

sitizers, and the adjuvant aluminum hydroxide all activate the inflammasome in their mechanisms of action. Inhalation of a TLR ligand (LPS) and a Nalp3 ligand (ATP or muramyl dipeptide) induces IL-1b and IL-33 mRNA expression, IL-1b cleavage, and the release of mature IL-1b protein. In vitro studies demonstrated that inhibition of caspase-1 or reactive oxygen species generation prevents IL-1b secretion. The role of the inflammasome in a model of nitrogen dioxide (NO2)-promoted allergic sensitization will be discussed.

S 1232 PHYSIOLOGY AND IMMUNOLOGY OF CHOLINERGIC ANTIINFLAMMATORY PATHWAY.

K. J. Tracey. *Feinstein Institute for Medical Research, New York, NY.* Sponsor: K. Sarlo.

Cytokine production by the immune system contributes importantly to both health and disease. The nervous system, via an inflammatory reflex of the vagus nerve, can inhibit cytokine release and thereby prevent tissue injury and death. The efferent neural signaling pathway is termed the cholinergic anti-inflammatory pathway. Stimulation of the vagus nerve prevents the cytokine mediated damaging effects including those resulting from lung inflammation. Research that explores this physiological, functional and anatomical mechanisms for neurological regulation of cytokine-dependent disease that begins to define an immunological homunculus will be discussed.

S 1233 INTRODUCTION OF PROINFLAMMATORY AND IMMUNOSUPPRESSIVE IMMUNE RESPONSES BY CIGARETTE SMOKE ALDEHYDES.

B. M. Freed. *School of Medicine, University of Colorado, Aurora, CO.*

The effects of cigarette smoke on pulmonary immunity are complex. The acute effects of smoking are largely restricted to the lungs, although chronic smoking is also a significant risk factor for autoimmune diseases, such as rheumatoid arthritis. Cigarette smoke suppresses acquired immunity by inhibiting gene expression associated with T cell and B cell activation, but induces innate immunity by up regulating Cox-2, MCP-1 and IL-8. The immunotoxic effects of cigarette smoke can be reproduced by a single unsaturated aldehyde, acrolein. Acrolein inhibits expression of IL-2 by adducting arginine and cysteine residues in the DNA-binding domain of NF-kB p50, preventing it from binding to the IL-2 promoter. Saturated aldehydes, such as acetaldehyde, do not react with these residues and do not inhibit DNA binding. In contrast, acrolein induces expression of IL-8 by activating NF-kB p65. Current research is focused on testing the hypothesis that NF-kB serves as a biological smoke detector that switches pulmonary innate immunity on and acquired immunity off.

S 1234 EXACERBATION OF PULMONARY TOXICITY BY PRO-INFLAMMATORY CYTOKINE HMGB1 IN HYPEROXIA-INDUCED ACUTE LUNG INJURY.

L. L. Mantell. *St John's University College of Pharmacy, Queens, NY/The Feinstein Institute for Medical Research, North Shore-Long Island Jewish Health System, Manhasset, NY.*

Supraphysiological concentrations of oxygen (hyperoxia) are routinely used to prevent or treat hypoxemia and acute respiratory failure. However, prolonged exposure to hyperoxia can result in tissue damage in many organs, especially lungs, and lead to the development of lung injury and suppressed innate immunity. Hyperoxia-induced lung injury is a product of direct oxygen toxicity and the indirect effects from activated resident and recruited inflammatory cells. HMGB1, an emerging key player in systemic inflammation, mediates the recruitment of inflammatory cells and suppresses innate immunity in response to bacterial infection under hyperoxic conditions.

S 1235 INHALED CARBON MONOXIDE AS THERAPEUTIC MODALITY IN HUMAN INFLAMMATORY LUNG DISEASES.

A. K. Choi. *Brigham and Women's Hospital, Harvard University, Boston, MA.* Sponsor: K. Sarlo.

Carbon monoxide (CO) arises endogenously from heme degradation, catalyzed by the heme oxygenase enzymes. In cell culture, CO exerts potent anti-inflammatory, anti-apoptotic and anti-proliferative effects by modulating intracellular signaling pathways. In vivo, CO confers tissue protection in animal models of lung disease, including those with oxidative and inflammatory lung injury and ischemia/reperfusion injury. Whether CO offers potential therapeutic avenues in the treatment of lung inflammatory disorders will be discussed.

S 1236 THE GOOD, THE BAD, AND THE UGLY OF TOXICANT-INDUCED PULMONARY INFLAMMATION.

L. L. Mantell[1] and J. T. Zelikoff[2]. *[1]St. Johns University College of Pharmacy, Queens, NY/The Feinstein Institute for Medical Research, North Shore-Long Island Jewish Health System, Manhasset, NY and [2]New York University School of Medicine, Tuxedo Park, NY.*

A well-orchestrated lung inflammation induced by cytokines is critical to optimizing host defense capabilities, while avoiding or minimizing potential damage to lung tissues. Normally, pulmonary inflammation plays a pivotal role during positive immune responses against microbial and small particle pathogens. Unfortunately, certain inhaled toxicants, such as cigarette smoke and prolonged hyperoxia, can non-specifically induce dysregulated chronic and acute inflammation within the respiratory tract. Therefore it is important to examine the types of immunomodulatory events that occur in the lungs in response to environmental agents and to pathogens, and to demonstrate how similar effects induced by those disparate challenges can lead to distinctly different (i.e., helpful vs. harmful) outcomes. Our panel of experts will present cutting edge studies on the regulation of inflammatory responses by the inflammasome, the nervous system and carbon monoxide. An important outcome of this session is to have attendees be able to recognize the major putative mediators involved in induction of pulmonary inflammation, describe signaling pathways that mediate inflammatory responses to inhaled toxicants and pathogens, better understand the regulation of inflammatory response and identify potential targets and therapeutic strategies for further development for the amelioration of acute lung inflammatory injury and chronic diseases.

W 1237 IMPROVED SAFETY BIOMARKERS FOR MONITORING KIDNEY INJURY.

F. D. Sistare[1] and F. Dieterle[2]. *[1]Merck and Co., Inc., West Point, PA and [2]Novartis Pharmacology AG, Basel, Switzerland.*

A number of accessible biomarkers are becoming available to toxicologists and to clinicians as qualified tools that have demonstrated their ability to out-perform BUN and serum creatinine for monitoring the early onset of certain drug induced kidney pathologies. These tools are beginning to positively impact the development of drug candidates that may present with low grade kidney toxicities in first-in-human enabling GLP animal toxicology studies, especially when observed in a single species, and human irrelevance cannot otherwise be adequately assured. The biomarkers are showing utility not only for monitoring drug safety, but also for interrogating kidney disease progression and regression. Animal toxicology studies designed to assess the biological performance of these new safety biomarkers are providing new insights into fundamental aspects of kidney function, and are supporting potential opportunities to establish a positive response to intervention where kidney disease is a target for new therapies. With the positive response received recently from the U.S. FDA and EMEA regarding the acceptability and utility of certain qualified renal safety biomarkers for targeted regulatory applications, the challenge now is to expand the tool box and to define broader uses. Therefore, we should begin by understanding the performance strengths and limitations of the more robust kidney safety biomarkers established across numerous animal toxicology studies, understanding the molecular, cellular, and anatomical bases for kidney biomarker responses observed to chemical toxicities, and describing the research progress to fill the critical research and regulatory gaps and questions that remain. By fully grasping this information we should be able to present the strategy and progress made to bridge from animal studies to human clinical trials where establishing the performance attributes of these biomarkers is far more challenging and finally present clinical data of biomarker responses to disease and drug-induced kidney injury matching the pre-clinical data and supporting the clinical qualification and utility of these and additional promising clinical biomarkers.

W 1238 ONE YEAR AFTER THE FIRST REGULATORY QUALIFICATION OF RENAL BIOMARKERS –LIMITATIONS, OPPORTUNITIES, ADVANCES AND IMPACT ON TOXICOLOGY AND TRANSLATIONAL MEDICINE.

F. Dieterle[1], S. Chibout[1], E. Perentes[1], A. Cordier[1], J. Vonderscher[3], G. Maurer[1], J. Ozer[4], D. Gerhold[2], S. Troth[2], F. Sistare[2] and P. Nephrotoxicity Working Group[5]. *[1]Translational Sciences, Novartis, Basel, Switzerland, [2]Safety Assessment, Merck Research Laboratories, West Point, PA, [3]Molecular Medicine Labs, Roche, Basel, Switzerland, [4]PGRD, Pfizer, Chesterfield, MO and [5]PSTC, C-Path Institute, Tucson, AZ.*

The Critical Path Institute's Predictive Safety Testing Consortium (PSTC) has submitted data on 7 renal safety biomarkers to the FDA/EMEA in a Voluntary eXploratory Data Submission (VXDS) to seek a first-ever formal regulatory qualification decision on safety biomarkers appropriate for regulatory decision making.

These 7 urinary biomarkers – Kim-1, Clusterin, Albumin, TFF3, Total Protein, Cystatin C and b2-Microglobulin – were accepted by regulatory authorities for monitoring acute drug induced tubular or glomerular injuries in rat GLP studies and on a case-by-case basis under specific conditions for monitoring renal safety in early clinical trials. The feedback of health authorities on this first-ever approval of biomarkers independent from the use of a specific drug will be reviewed, in particular, the lessons learned and best practices for the qualification and submission of data supporting the use of new safety biomarkers. It will be shown, how these new tools should be used to enhance safety assessment and to prepare an application to bring a drug candidate into human clinical trials to address cause for concern and guard kidney safety. This includes a discussion of the application of thresholds, appropriate statistical considerations, and the design of pre-clinical and early clinical studies. In addition, the most recent efforts will be presented, which are aimed at extending the currently agreed upon fit for purpose qualification context by cross-qualifying the biomarkers, by conducting specially designed recovery studies, and by preparing the qualification of additional biomarkers such as serum Cystatin C, which can be shown to be a better functional biomarker than BUN and serum creatinine.

W 1239 PRECLINICAL QUALIFICATION OF NOVEL URINARY MARKERS OF RENAL INJURY.

D. Ennulat. *Preclinical Development, GlaxoSmithKline, King of Prussia, PA.*
Sponsor: F. Sistare.

Preclinical studies offer a unique opportunity for both identification and biologic qualification for novel markers of renal injury. Simultaneous evaluation of kidney histopathology and urinary marker changes in controlled preclinical studies provide an initial insight on the utility of novel markers identified in toxicogenomic studies. Immunohistochemistry (IHC) can be used to further characterize marker biology by identification of marker localization in normal and diseased kidney, and for segment-specific markers of renal injury, to confirm specificity of the novel marker for discrete manifestations of nephrotoxic injury. Finally, the use of histopathology and/or IHC as a reference standard provides a more robust or stringent assessment of diagnostic performance of novel markers than current markers of renal injury such as serum creatinine and urea. In addition to phenotypic anchoring of novel markers through morphologic characterization, biologic qualification requires clarification of the relationship between changes in novel markers and onset, progression or resolution of renal injury, generally achieved through use of time-course and recovery studies. Furthermore, characterization of preanalytic variables such as inter- and intra-individual variability, and knowledge of effects of age, sex, diet or circadian rhythym are critical for biologic characterization and integrated assessment of diagnostic performance of novel urinary markers in preclinical studies. Morphologic and biochemical data from preclinical studies will be presented to illustrate these perspectives on biologic qualification of novel urinary markers of renal injury.

W 1240 INTEGRATING ANIMAL WITH CLINICAL DATA TO BEST UNDERSTAND KIM-1 AS A KIDNEY SAFETY BIOMARKER.

J. V. Bonventre. *Brigham and Women's Hospital, Harvard Medical School, Boston, MA.* Sponsor: F. Sistare.

The gene encoding kidney injury molecule-1 (Kim-1/TIM-1/HAVCR-1) is conserved across species in zebrafish, rodents, dogs, primates and humans. Urinary Kim-1 has been shown to be a sensitive and early diagnostic indicator of renal injury across a variety of acute and chronic preclinical and clinical kidney injury models. In a number of rodent models of nephrotoxicity urinary Kim-1 elevation has been shown to be much more sensitive and specific than other biomarkers and standard methods of detecting nephrotoxicity. The FDA and EMEA have worked together to encourage the submission of Kim-1 results during animal studies of new drugs. The utility of KIM-1 has also been shown in a number of clinical studies in humans with acute kidney injury associated with ischemia and/or sepsis in adults and children, subjects administered nephrotoxic drugs such as cisplatin and gentamicin, and in transplant recipients that develop graft dysfunction. Levels of urinary KIM-1 can predict regression of proteinuria in patients with diabetes mellitus and can predict outcome in a critically ill population. Urinary KIM-1 levels correlate well with histological and functional injury in patients with a variety of kidney diseases. Urinary KIM-1 levels have also been shown to be elevated in a subpopulation of patients who were previously thought to have no active kidney dysfunction and this has important implications for patient selection for drug studies as well as therapeutic intervention. We have recently found that KIM-1 is a phosphatidylserine receptor which is very active in taking up apoptotic cells as well as oxidized lipids in the damaged kidney. In conclusion clinical data comparing KIM-1's performance against a number of other urinary biomarkers in a number of populations support the conclusions from animal toxicology studies. The use of KIM-1 as a urinary biomarker has the potential to transform safety monitoring and the design of clinical trials of therapeutic agents.

W 1241 ACUTE KIDNEY INJURY NETWORK (AKIN): ADVANCING CLINICAL APPLICATIONS OF PROMISING RENAL BIOMARKERS.

R. L. Mehta. *Medicine, University of California San Diego, San Diego, CA.*
Sponsor: F. Sistare.

As acute kidney injury (AKI) is associated with a 40-60% mortality rate, there has been an explosion of research into finding ways to improve care for patients with this condition. AKIN is an international multidisciplinary collaborative research network focused on improving outcomes from AKI. AKIN's activities are designed to facilitate the acquisition of evidence through well designed and conducted clinical trials, dissemination of information via multidisciplinary joint conferences and publications and improve the translation of knowledge from pre-clinical research. AKIN has developed a consensus recommendation for the terminology, diagnostic criteria and staging of AKI and has suggested a research agenda for AKI. One of the research priority areas is the discovery, assessment and validation of unique renal biomarkers that can characterize the course of a patient with AKI. It is anticipated that renal biomarkers would significantly modify our ability to identify patients with AKI early in the course, define the nature and extent of damage, provide guidance for targeted intervention and provide prognostic information on renal recovery and development of progressive kidney disease. Additionally, it is necessary to distinguish renal functional markers from those identifying the injury and repair process. While preclinical studies have identified several potential candidates, no single biomarker has all these attributes. Several biomarkers are now being assessed in clinical studies. This presentation will provide an overview of the conceptual framework for AKI, describe the novel serum and urinary biomarkers currently being evaluated in clinical settings and provide a framework of reference for the translation of preclinical data to human application.

W 1242 IMPROVED SAFETY BIOMARKERS FOR MONITORING CLINICAL RENAL INJURY.

W. Baer. *ClinXus, Grand Rapids, MI.* Sponsor: F. Sistare.

There has been tremendous progress made in understanding the molecular mechanisms of renal diseases, in particular, acute kidney injury. However, translation of these findings to diagnostic and therapeutic use in clinical practice remains a challenge. Despite significant advances in therapeutics, the morbidity and mortality rates associated with acute kidney injury remain significantly elevated. These rates have not appreciably improved over the last few decades in light of these advances. The lack of significant progress in the prevention and management of acute kidney injury has been attributed, in part, to the failure to identify suitable physiologic surrogate endpoints for use in research study testing and the efficiency of new interventions. In fact, very few acute kidney injury studies have demonstrated a beneficial effect on the most commonly used physiologic surrogate endpoints, the serum urea nitrogen and creatinine concentrations. The diagnosis of acute kidney injury is typically based on either the elevation of serum creatinine or the detection of oliguria. Our goal is to identify thresholds on several pre-identified biomarkers using a classical nephrotoxic agent, IV contrast dye, in hospitalized diagnostic cardiac catheterization patients who develop nephrotoxicity compared to those who do not. This information will then be validated in a maintenance study with an agent known to cause renal tubular injury, cisplatin or gentamicin. Clinically current renal injury may be present with little to no significant change in serum creatinine making this marker imprecise. Therefore our current gold standard surrogate marker is far from perfect. Our current clinical needs mandate the assessment of these newer biomarkers and how they perform in this translational setting. With the positive response from the FDA and EMEA recently received and the efforts of the PSTC regarding the acceptability and utility of certain qualified renal safety biomarkers for targeted regulatory applications, the challenge for further research is now to define and support expanded use from prospective outcome based clinical trials.

W 1243 OXIDATIVE STRESS AS A REGULATOR OF NORMAL FUNCTION AND MEDIATOR OF TOXICANT-INDUCED DAMAGE WITH IMPACTS ON REPRODUCTION AND DEVELOPMENT.

S. P. Darney. *ORD, U.S. EPA, Research Triangle Park, NC.*

Exposures to certain chemicals and environmental factors are known to induce oxidative stress, either directly or indirectly, resulting in complex responses at the molecular level in cells and tissues. With respect to reproduction, high levels of en-

dogenous antioxidants such as glutathione (GSH) as are normally present in gonads and embryos are suggestive of both regulatory and protective roles. Interestingly, endogenous reactive oxygen species may be beneficial by stimulating the signaling pathways necessary for gamete development and function and embryonic development. On the other hand, excess reactive oxygen species, including those resulting from exposure to certain pharmaceuticals or environmental contaminants may impair reproductive cells by depleting endogenous antioxidants and inducing membrane lipid peroxidation and DNA damage. In turn, such damage may induce untimely apoptosis resulting in reduced numbers of healthy gametes and embryos. Indeed, environmental exposures that induce oxidative stress have been postulated to be a contributing factor in human infertility and abnormal pregnancy outcomes. Furthermore, recent evidence indicates that long term, low level oxidative stress may impair Leydig cell function with consequent decreases in testosterone secretion, thus contributing to declines in reproductive function with aging. To convey this message recent research findings on the relationship between oxidative stress and reproductive function with emphasis on specific reproductive and developmental toxicants that act in this manner, and whether polymorphisms in genes involved in the oxidative stress pathway that contribute to differential susceptibility will be addressed.

W 1244 SHIFTING CONCEPTS OF OXIDATIVE STRESS: FROM A GLOBAL IMBALANCE TO DISRUPTION OF SPECIFIC REDOX PATHWAYS; FROM FREE RADICAL TO NON-RADICAL MECHANISMS.

D. P. Jones. *Medicine, Emory University, Atlanta, GA.*

The major thiol/disulfide couples, consisting of thioredoxins, GSH/GSSG and cysteine/cystine (Cys/CySS), are maintained at stable non-equilibrium conditions in cells, organelles and extracellular fluids. The lack of equilibration between these central redox couples illustrates the concept of oxidative stress as a global imbalance is fundamentally incorrect. The thioredoxins are more reduced than GSH/GSSG pools and the latter are more reduced than the Cys/CySS pools. The compartmental redox states vary from most reduced in mitochondria to sequentially more oxidized in nuclei, cytoplasm, secretory pathway and extracellular space. Accumulating evidence shows that each of these systems differentially regulates different cell functions, presumably through specific redox control of different proteins. Methods are now available to measure oxidative stress in specific compartments and in terms of oxidation of specific proteins. Results indicate that disruption of specific thiol redox signaling and control circuits underlie much of the pathophysiology attributed to oxidative stress. Importantly, thiol systems are oxidized and modified by non-radical species, such as peroxides, peroxynitrite, conjugated aldehydes and quinones. The relative contributions of free radical mechanisms and non-radical mechanisms remain poorly defined. However, the emerging concepts of oxidative stress support the interpretation that reproduction and development have unique susceptibilities and that novel antioxidant strategies, other than free radical scavengers, will be needed to effectively prevent or correct related dysfunctions.

W 1245 OXIDATIVE STRESS AND OVARIAN FOLLICULAR ATRESIA.

P. J. Devine[2] and U. Luderer[1]. [1]*Medicine, University of California Irvine, Irvine, CA and* [2]*INRS-Institut Armand-Frappier, Laval, QC, Canada.*

Multiple chemicals are known to destroy ovarian follicles in rodents and humans, with adverse impacts on reproductive success. However, the mechanisms are not fully understood. Our recent data suggest that the mechanisms of follicular destruction differ depending on the stage of follicular development. Studies in cultured neonatal rodent ovaries show that multiple reactive chemicals and ionizing radiation induce double-stranded DNA breaks in oocytes and induce loss of primordial follicles via a caspase-independent pathway. In vivo exposures support such a mechanism of toxicant-induced primordial follicle loss. In the adult ovary, most spontaneous follicular atresia occurs in antral follicles and appears to be driven by apoptotic death of the granulosa cells. Using cultured antral follicles and a human granulosa cell line, we have shown that an increase in reactive oxygen species is an early event in the initiation of apoptosis induced by gonadotropin withdrawal, several chemical toxicants, and ionizing radiation. Depletion of the antioxidant glutathione sensitizes antral follicles and granulosa cells to these apoptotic stimuli. Supplementation of glutathione and other antioxidants or overexpression of the rate-limiting enzyme in glutathione synthesis prevents the rise in reactive oxygen species and protects against apoptosis induced by these stimuli. Accumulating evidence from several laboratories also suggests that the anti-apoptotic effects of gonadotropin hormones in antral follicles are mediated in part by upregulation of antioxidants. These results suggest that reactive oxygen species mediate apoptotic destruction of antral follicles by various stimuli. In contrast, destruction of primordial follicles by some of the same stimuli does not appear to involve classical apoptotic pathways and the role, if any, of reactive oxygen species remains unresolved. Supported by NIH ES10963 and NSERC.

W 1246 OXIDATIVE STRESS AND TESTICULAR FUNCTION.

B. Robaire[1, 2], H. Chen[3], G. Delbes[1, 2], B. F. Hales[1, 2] and B. R. Zirkin[3].
[1]*Pharmacology and Therapeutics, McGill University, Montreal, QC, Canada,*

[3]*Biochemistry and Molecular Biology, Johns Hopkins University, Baltimore, MD.*

Two major testicular functions, testosterone (T) synthesis by Leydig cells and sperm production, are responsive to oxidative stress. In aging Leydig cells, cAMP and T production in response to luteinizing hormone (LH) are reduced. When cultured with dbcAMP, aged Leydig cells produce T at the high levels of young cells, suggesting inefficiency in the coupling of the LH receptor to adenylyl cyclase. There is an age-related down-regulation of the antioxidants SOD1 & 2, MGST1, GSTM2, GPX-1 and GSH. Long-term vitamin E administration delays age-related decreases in steroidogenesis, while long-term vitamin E deficiency has the opposite effect. The steroidogenic function of Leydig cells from young animals is reduced by depletion of glutathione; antioxidants, vitamin E, N-tert-butyl-alpha-phenylnitrone and Trolox, protect against this reduction. Together, these observations support the hypothesis that reactive oxygen plays an important role in age-related reductions in Leydig cell T production. The ability of germ cells undergoing spermatogenesis to respond to oxidative stress may determine their quality and thus impact on progeny outcome. Exposure of adult male BN rats to the drug combination used to treat testicular cancer (bleomycin, etoposide, and cis-platinum, BEP) affects sperm chromatin integrity. The glutathione S-transferases (GSTs) detoxify reactive electrophiles, including lipid peroxide products of oxidative stress. BEP treatment increased the expression of 8 of 16 GST family members detected in the expression profiles of round spermatids (GST a2, a4, m1, m2, m3, p1, p2; mGST1). The increased expression of GSTp and GSTm was confirmed by RT-PCR; Western blots showed that the proteins were also induced. These results suggest that GSTs play a prominent role in the response of germ cells to insult. We hypothesize that BEP induction of GST expression may lead to the survival of damaged cells and production of abnormal sperm. Supported by NIH, CIHR, The Cole Foundation.

W 1247 OXIDATIVE STRESS IN THE MALE GAMETE: THE YING-YANG OF SPERM FUNCTION.

R. J. Aitken. *ARC Centre of Excellence in Biotechnology and Development, University of Newcastle, Newcastle, NSW, Australia.* Sponsor: U. Luderer.

Mammalian spermatozoa are redox-regulated cells. The generation of low levels of reactive oxygen species (ROS) is a key component of capacitation, a post-insemination maturation event that prepares spermatozoa for union with the oocyte. If ROS production is prevented, then capacitation is suppressed and fertilization cannot occur. Despite the physiological significance of these ROS intermediates, the excessive production of ROS is extremely detrimental to spermatozoa. The major reasons for this are that these cells possess a limited repertoire of antioxidant enzymes as a consequence of the restricted volume and distribution of their cytoplasmic space and these cells are replete with substrates for free radical attack including abundant unsaturated fatty acids and DNA. Exposure to oxidative stress results in a loss of sperm motility mediated by lipid peroxidation and oxidative DNA damage, reflected by an increase in the DNA base adduct, 8-OH 2'-deoxyguanosine. Since the presence of DNA damage in spermatozoa is associated with poor fertility, high rates of miscarriage and increased incidence of disease in the offspring, determining the causes of oxidative stress in the male germ line is a matter of some urgency. A variety of environmental factors have been implicated in this process including electromagnetic radiation (heat and radiofrequency EMR), redox cycling xenobiotics (quinones) metabolites (catechol estrogens) metals (iron copper, manganese) and compounds that target the mitochondrial electron transport chain including unesterified, unsaturated fatty acids and pharmaceuticals. Susceptibility to oxidative stress in the germ line may be dictated by polymorphisms in key metabolic enzymes such the cytochrome P450s and glutathione-S-transferases. Attention is also being given to the use of antioxidants as a means of ameliorating oxidative damage to spermatozoa. Although initial results are promising, some antioxidants were found to damage sperm DNA via a cross linking mechanism to which these cells are uniquely susceptible, given the unusually compacted nature of their chromatin.

W 1248 REDOX REGULATION DURING DEVELOPMENT AND EARLY EMBRYONIC ORGANOGENESIS.

J. M. Hansen. *Pediatrics, Emory University, Atlanta, GA.* Sponsor: U. Luderer.

Development is a specific, coordinated series of events that lead to timely functional and morphological changes. Disruption of these events can have serious outcomes that may result in malformation and/or function deficits in the newborn.

Data show that the cellular transition from a proliferating to a differentiating state coincides with an oxidation of the intracellular biothiol, glutathione (GSH), while other couples, such as thioredoxin (Trx), are not affected. Independent regulation of particular redox couples may provide rationale for the specificity of redox control during differentiation and also relate to oxidant-induced malformation. In human mesenchymal stem cells, undifferentiated cells are more reduced than differentiated (osteocytes or adipocytes) cells. With oxidant exposure, redox couples, both GSH and Trx, rebounded more quickly and to a greater degree and were less disposed to undergo apoptosis in undifferentiated cells than in differentiating cells, suggesting that the susceptibility to oxidative insult and redox misregulation is greater in differentiating cells than in undifferentiated/proliferating cells. In organogenesis-staged embryos, redox changes occur concomitantly with mitochondrial maturation, an increased need for oxygen and a subsequent increase in reactive oxygen species generation. Interestingly, antioxidant enzyme activities, such as GSH peroxidase, GSSG reductase, superoxide dismutase (SOD) and catalase increase as development progresses and thus provide a compensatory mechanism capable of correcting redox balance during periods of oxidative stress. The natural oxidative shift in GSH and the regulation of Trx in a reduced state suggests that these couples are tightly regulated and may control different aspects of differentiation. Thus, untimely oxidative stress and misregulation of specific couples may disrupt redox-sensitive pathways to cause dysmorphogenesis.

W 1249 PESTICIDES AND PARKINSON'S DISEASE: IMPLICATIONS OF NEW EPIDEMIOLOGY AND EXPOSURE DATA TO RISK ASSESSMENT.

T. Levine[1] and A. A. Li[2]. *[1]Health Effects Division, EPA Office of Pesticides Program, Arlington, VA and [2]Health Sciences, Exponent, Inc., San Francisco, CA.*

Numerous animal and epidemiological studies have suggested a relationship between pesticide exposure and the development of Parkinson's Disease (PD). Frequently, scientists and the media question whether regulatory processes are sufficiently protective of this potential risk factor. However, there has been relatively little attention paid to the exposure side of the risk equation in the research to date. Furthermore, there is a tremendous need for an improved interface between toxicology and epidemiology. Thus, it is important that we focus our attention on new epidemiology and animal research with an emphasis on the exposure question and the implications of the findings for human health risk assessment. To adequately address these topics, speakers from government, academia and industry with knowledge of different aspects of pesticide risk assessment: toxicology, epidemiology, neurology, pharmacokinetics, and exposure assessment. The session will present new results of two important epidemiological studies on Parkinson's Disease that evaluate exposure of humans to pesticides, and an animal study that uses PBPK modeling to relate animal models of PD to estimated human exposure levels. The two epidemiological studies that will be presented are the Honolulu-Asia Aging study (HAAS) and the Farm and Movement Evaluation (FAME) Study of the Agricultural Health Study (AHS). In addition, the results of the Farm Family Exposure Study, which focused on exposure assessment to pesticides, will be discussed in relation to the practice of exposure assessment in agricultural worker epidemiologic studies. This session will end in a panel discussion that will be stimulated by two discussants representing industry and government who have specialized expertise in pesticide exposure assessment and have an understanding of the risk assessment process.

W 1250 A NEUROLOGIST'S BIRD'S EYE VIEW OF KEY RISK FACTORS OF PARKINSON'S DISEASE.

J. Langston. *Director and CEO, Parkinson's Institute and Clinical Center, Sunnyvale, CA.* Sponsor: A. Li.

Although there is no known cause of Parkinson's Disease, there are a number of risk and protective factors that have been suggested based on analytical epidemiological studies. Proposed risk factors include environmental exposures (i.e. pesticides and certain metals), genetic (i.e. mutations in the genes for alpha-synuclein, parkin, and LRRK2), dietary (i.e. milk, iron), hormonal (i.e. low estrogen status), occupation and place of residence. There are also protective factors that have been reported, such as cigarette smoking, coffee consumption, and non-steroidal antiinflammatory drugs (NSAIDS). Broader perspective on the relative contributions of these different factors and the strength of the scientific evidence supporting the association with PD will aid in developing new hypothesis, prioritizing research, and designing studies that consider interactions among multiple factors. A multidisciplinary and interactive approach (i.e. genetics, molecular biology, epidemiology, pharmacology and toxicology) involving both scientists and clinicians is needed to make progress toward the overall goal of understanding the natural history of Parkinson's disease, finding its cause and developing better treatments.

W 1251 HONOLULU-ASIA AGING STUDY (HAAS): RELATIONSHIP OF ORGANOCHLORINE LEVELS WITH PARKINSON'S DISEASE RISK.

W. Ross[1], E. Pellizzari[2], Q. He[3], D. Miller[4], J. P. O'Callaghan[4], H. Petrovitch[3], R. Abbott[5], C. Tanner[6] and L. White[2]. *[1]Veterans Affairs Pacific Islands Health Care System, Pacific Health Research Institute, Honolulu, HI, [2]Research Triangle Institute International, RTP, NC, [3]Pacific Health Research Institute, Honolulu, HI, [4]Centers for Disease Control and Prevention, NIOSH, Morgantown, WV, [5]University of Virginia School of Medicine, Charlottesville, VA and [6]The Parkinson's Institute, Sunnyvale, CA.*

The Honolulu Heart Program / Honolulu-Asia Aging study (HAAS) is a community based, long term, prospective study of dementia and Parkinson's disease (PD) in a cohort of 8006 Japanese-American men living on the island of Oahu and born between 1900 and 1919. Interest in the association of neurotoxicants and PD was stimulated by the fact that many of the HAAS participants worked on sugar and pineapple plantations in Hawaii and would have been exposed to numerous agricultural chemicals. In order to further explore the possible relationship of pesticide exposure with PD risk, organochlorine levels were obtained on previously frozen occipital lobe brain samples from 445 cohort decedents. Twenty-one organochlorines were measured using gas chromatography. The presence of incidental Lewy bodies (i.e. found in brains of decedents without a history of PD during life) is thought to represent a preclinical stage of PD in persons who died before the classic motor features of the disease were manifest. New data on the association of brain organochlorine levels with neuropathologically confirmed Parkinson's Disease and with the presence of Lewy bodies in the substantia nigra or locus coeruleus will be presented.

W 1252 FARMING AND MOVEMENT EVALUATION STUDY (FAME): PARKINSON'S DISEASE IN PESTICIDE APPLICATORS AND THEIR SPOUSES.

F. Kamel[1] and C. M. Tanner[2]. *[1]National Institute of Environmental Health Sciences, RTP, NC and [2]Parkinson's Institute and Clinical Center, Sunnyvale, CA.*

FAME is a case-control study of PD nested within the Agricultural Health Study (AHS), a cohort of ~89,000 pesticide applicators and their spouses recruited in North Carolina and Iowa in 1993-1997. Suspect PD cases from the AHS were evaluated with medical records, an in-person neurologic exam, and a videotaped movement evaluation, and diagnosis was verified by consensus of two neurologists (N=115). Controls were a stratified random sample of the remaining cohort, frequency matched to cases by age, gender, and state (N=384). We evaluated exposure based on questionnaires completed at enrollment in the AHS; extensive telephone interviews conducted for the FAME study; and biological and environmental samples, including blood samples collected for measurement of persistent organochlorine pesticides. The FAME interviews collected complete occupational histories including detailed information on cumulative lifetime use of 31 pesticides previously implicated in PD by human, experimental, or mechanistic studies. We are presently evaluating associations of PD with pesticide exposure based on these multiple sources of information. Previous studies have indicated that farmers report pesticide use accurately and that exposure assessment based on the AHS questionnaires is consistent with data obtained from environmental and biological measurements made based on intensive sampling during pesticide application. Thus the FAME study has more detailed and reliable information on pesticide exposure in verified PD cases and matched controls than any study to date. Further, the focus of the study on an agricultural cohort, which is likely to have more frequent and greater pesticide exposures than the general population, will allow us to better characterize exposures associated with PD.

W 1253 FARM FAMILY EXPOSURE STUDY: BIOMONITORING AND EXPOSURE ASSESSMENT IN AGRICULTURAL POPULATIONS.

B. H. Alexander. *Division of Environmental Health Sciences, University of Minnesota School of Public Health, Minneapolis, MN.* Sponsor: A. Li.

The Farm Family Exposure Study evaluated pesticide exposure in ninety-five farm families in Minnesota and South Carolina to compare self-reported and observed exposure metrics to biomarkers of exposure. Exposure was based on 24 hour urine samples collected 24 hours before through 96 hours after a pesticide application that was part of the usual farm operation. Three widely used chemicals 2,4-D, glyphosate, and chlorpyrifos were the focus of the study and represent pesticides with differing chemical and physical properties. Urine concentrations of the chemical or metabolite were used to determine exposure from the application. Application practices and potential exposure to family members were ascertained by direct observation and questionnaire. The background and application related

exposure varied by chemical, the individual, and the potential for direct contact with the chemical. Background concentration was minimal for glyphosate but universal for chlorpyrifos. Compared to glyphosate and chlorpyrifos the magnitude of 2,4-D exposure was much higher. Applicators and children assisting in the application had the most pronounced exposure. Application practices were inconsistently related to the exposure intensity of different chemicals and were not reliable predictors of exposure for the single application. Exposure to spouses and children not present during the application were low, but did vary by the measured exposure in the applicator. This study demonstrates the complexity of measureing pesticide exposure in agricultural populations. Modeling of pesticide exposure for epidemiologic investigations of diseases with long latency, including Parkinson's disease, may be improved if chemical specific information and potential routes of exposure are considered. Studies relying on individual recall should consider these sources of exposure uncertainty and their influence on inter- and intra-individual exposure variability over time.

W 1254 PESTICIDE RISK ASSESSMENT AND ANIMAL MODELS OF PD.

A. A. Li[1], G. L. Kedderis[2], S. Warren[3] and L. J. McIntosh[4]. [1]*Health Sciences, Exponent, San Francisco, CA,* [2]*Independent Consultant, Chapel Hill, NC,* [3]*Exponent International Ltd, Moorestown, NJ and* [4]*Health Sciences, Exponent, Menlo Park, CA.*

Whole animal models of Parkinson's Disease (PD) using pesticides can contribute to our understanding of underlying mechanisms of degeneration that may be relevant to PD or other neurologic diseases. Human health risk assessment based on these pesticide animal models of PD requires evaluation of the relationship between routes and levels of exposures used in these animal studies with estimated human exposures. Qualitative and quantitative comparisons between animal doses used in animal models of PD and estimated or allowable human exposures levels will be presented. In one representative case study, a mouse PBPK model for paraquat (PQ) will be presented based on C57Bl/6 mouse blood and brain data following different routes of exposure. Specifically, blood and brain levels of PQ were measured at 6 timepoints (n=3 per timepoint) within 24 hours of a single i.p. (10 mg/kg bwt), oral (10 mg/kg bwt), dermal (40 mg/kg bwt) or intranasal (3 mg/kg bwt) exposure. Using appropriate human and chemical-specific parameters, this PBPK model was used to extrapolate experimental mouse exposures to human oral, dermal and inhalation exposures. Field studies of exposed workers have shown that the predominant route of exposure is dermal. Utilizing worker exposure conditions described in the the UK risk assessment for PQ (UK draft assessment report, 1996), the human PQ PBPK model was used to estimate the brain dosimetry of PQ in farm workers and gardeners exposed under various conditions. Model simulation of dermal exposure of workers to PQ under field conditions to PQ indicated that the internal dose of PQ to the brain corresponds to an IP dose of PQ in mice that is 6-8 orders of magnitude below the dose used in PQ or PQ/Maneb animal models of PD. The PBPK study was sponsored by the UK Department of Environment, Food and Rural Affairs.

W 1255 SAFETY OF HIGH-INTENSITY SWEETENERS: BITTERSWEET CONTROVERSY.

M. G. Soni[1] and D. Thompson[2]. [1]*Vero Beach Hematology Oncology, Vero Beach, FL and* [2]*CDER/OND, U.S. Food & Drug Administration, Silver Spring, MD.*

The quest for the perfect high-intensity sweetener with a clean, sweet taste, no off-flavor, non-caloric, and no adverse health effects continues. To date, the U.S. Food and Drug Administration (U.S. FDA) has approved five artificial sweeteners: aspartame, acesulfame-K, neotame, and sucralose, in addition to saccharine. Currently, cyclamate is pending FDA approval/re-approval. The agency regulates high-intensity sweeteners as food additives, which must be approved as safe for their intended use before they can be marketed. Although these approved sweeteners have whetted the palates of millions of Americans over the years, the one problem common to all of them has been the controversies over their safety, which have been anything but sweet. Saccharin has been marketed for more than 100 years and represents a good example of how the shifting requirements of the law and the progress of science can change a substance's status from 'safe' to 'unsafe.' Both the products' manufacturers and the FDA maintain that the currently approved intense sweeteners are safe for their intended uses. Nevertheless, there are accusations in both the scientific literature and in the popular media about risks posed by these sweeteners. Is there really a cause for concern? To fully understand the issues, it is important to provide the current 'state of the science' as it relates to safety of the approved sweeteners; discuss the safety of certain sweeteners currently in development and/or approved outside the U.S., explore the evolving regulatory requirements for safety testing of sweeteners. The session will begin with a brief overview of the basic toxicological requirements for sweeteners in general, followed by presentations on specific controversial issues, lessons learned from previously approved sweeteners, concerns related to obesity, and a look at some possible future sweetener developments.

W 1256 WHY IS THERE CONCERN ABOUT ALTERNATIVE SWEETENER SAFETY?

R. Kava. *American Council on Science & Health, New York, NY.* Sponsor: M. Soni.

A decrease in caloric intake is a prime mode of dealing with the explosion of obesity in the United States. Nearly one third of adults in a recent survey admitted to being on a diet. The popularity of alternative sweeteners, particularly intense sweeteners, to replace the calories from sugar in a variety of foods and beverages is great. In 2007, nearly 200 million adults used low-calorie, sugar-free foods and beverages. Despite this popularity and the fact that the FDA has approved 5 such compounds as food additives, and their approval is seconded by a variety of professional groups, doubts are repeatedly raised over their safety for a variety of reasons. First, human carcinogenic risk is inappropriately extrapolated from high-dose animal studies, as in the case of saccharin and bladder cancer. Second, poorly designed experimental designs are used to provide grist for anti-sweeteners' mills (e.g., the recent European Ramazzini Foundation studies). Third, media reports often exaggerate the relevance and meaning of individual studies, and the concepts of dose and duration of exposure are ignored. Fourth, the concept that "natural" compounds are by definition more healthful than anything produced in a lab is widely accepted, and is a valuable marketing tool. Finally, for some activists, proclaiming the supposed "dangers" of such products yields media attention and perhaps financial support from consumers. The common thread in all these types of attacks is a lack of attention to sound science.

W 1257 TOXICOLOGY AND PHARMACOLOGY OF REBAUDIOSIDE (REB A).

J. A. Thomas[2] and S. M. Tarka[1]. [1]*The Tarka Group, Inc., Carlisle, PA and* [2]*Pharmacology & Toxicology, Indiana U Sch Med, Indianapolis, IN.*

Rebaudioside A (Reb A) and stevioside (S) (a closely related structural analogue) are steviol glycosides (SG) identified as the principal sweeteners in S. rebaudiana (Bertoni). They are natural non-caloric, high intensity sweeteners (~ 200 x sucrose sweetness equivalence. A resurgence in interest in SG has been driven by the search for an alternative natural high intensity sweetener. Rebiana is the common name for high purity Reb A (> 97% Reb A), and has been determined GRAS as a general purpose use sweetener. The Joint FAO/WHO Expert Committee on Food Additives (JECFA) (JECFA, 2008)allocated a permanent Acceptable Daily Intake (ADI) of 0-4 mg/kg bw/day, expressed as steviol, for SG. Reb A and S demonstrated a lack of genotoxic activity for SG in vitro and in vivo. The metabolism and pharmacokinetic profile for SG has been reported. Rat and human metabolism studies using high-purity Reb A and S affirm their metabolic equivalence. Studies conducted with S support the safety assessment of rebiana. Orally, SG are not readily absorbed from the upper small intestine of the rat or human. Human digestive enzymes are not capable of hydrolyzing β-glycosidic bonds, hence, SG are expected to escape digestion in the upper GI-tract. Microbes of the Bacteroidaceae family (predominantly Bacteroides) transform Reb A and S to steviol in the large intestine in the rat and human. There are no concerns for rebiana with respect to allergenicity or toxicity associated with metabolites or impurities.The safety of Reb A is supported by published studies using purified SG, including rebiana, consisting of studies of metabolism, pharmacokinetics, and animal toxicology. Human studies with Reb A and S assessed glucose homeostasis in subjects with type 2 diabetes, and hemodynamics in subjects with normal to low-normal blood pressure. SG are safe and well-tolerated in normotensive or hypotensive individuals and subjects with type-2 diabetes following acute- or long-term consumption at doses of up to 1.5 g/day (~ 25 mg/kg bw/day;~ 10 mg steviol equivalents/kg bw/day).

W 1258 CONTROVERSIES SURROUNDING ASPARTAME.

B. Magnuson. *Nutritional Sciences, University of Toronto, Toronto, ON, Canada.*

The safety of aspartame has been questioned in both the lay and scientific press, despite hundreds of studies on the low calorie sweetener. The major controversies of aspartame safety continue to be focus on allegations of neurotoxicity and carcinogenicity. Recently a group of experts assessed all available data on aspartame, including premarket toxicology studies, post-market in vitro and animal studies, human clinical reports, and epidemiological studies. In addition, current consumption of aspartame in the US was evaluated. The findings from these assessments with specific focus on the neurotoxicity and carcinogenicity studies that fuel the controversy illustrate that the consumption of aspartame remains well below levels shown to

have no adverse effects in well designed studies. Poorly designed studies and inappropriate extrapolation of data play a major role in anti-aspartame messages, creating unwarranted concern regarding the safety of this well studied sweetener.

W 1259 TASTE AND BEHAVIORAL EFFECTS OF HIGH POTENCY SWEETENERS.

D. E. Walters. *Biochemistry and Molecular Biology, Rosalind Franklin University of Medicine and Science, North Chicago, IL.* Sponsor: M. Soni.

Genetics has experienced dramatic progress in recent years and genome sequencing has tremendously helped in the understanding of the sweet taste reception. A diverse range of chemical substances can induce sweet taste, even though there is a single sweet taste receptor. Current health and wellness concerns related to obesity are leading consumers and manufacturers to search for great-tasting foods and beverages with reduced caloric content. The current state of knowledge on sweet taste chemoreception and its role in obesity will be discussed. Notably, sweet taste receptors have been found in the intestine as well as in taste buds on the tongue. It remains to be determined whether a diet high in artificial sweeteners contributes to sweetness liking and preference with the same result as a diet high in sugar. The effects of high potency sweeteners on ingestive behavior in humans are extremely complex and will be discussed. The role of these findings in the developments of new sweeteners from safety and obesity perspective needs to be addressed.

W 1260 FDA'S SWEETENER (FOOD ADDITIVE) APPROVAL PROCESS: SAFETY ASSURANCE BASED ON SCIENTIFIC ASSESSMENT.

A. M. Rulis. *Center for Chemical Regulation and Food Safety, Exponent, Inc., Washington, DC.* Sponsor: C. Thompson.

Controversy often surrounds sweeteners in both the scientific community and in the popular media. Often there are challenges to FDA's decisions, but time and again the agency's original judgments have successfully withstood these challenges over the years. This presentation provides a look into FDA's safety evaluations of a number of sweetener applications filed over the years in the U.S., with historical reflections on some of the more notable policy and scientific controversies. This talk will frame the current FDA safety requirements for new sweeteners, including chemical identity, purity and specifications; estimates of probable consumer daily intake; toxicological information (usually built around an array of animal feeding studies) and other information of potential public health significance. Given the controversies that often surround safety judgments about sweeteners, it is helpful to understand, for example, how FDA approached the body-weight-gain decrement effect in test animals fed sucralose; the arguments FDA used for not requiring further carcinogenicity testing on the acesulfame-K hydrolysis product, acetoacetamide, relative to potential thyroid tumorigenesis; and issues surrounding the safety of aspartame. These and other sweetener issues will be discussed in the context of FDA's time-tested safety assessment methods for new sweetener approvals.

PL 1261 ABSORPTION, DISTRIBUTION AND ELIMINATION OF BROMATE IN FEMALE F344 RATS.

X. Zhang[1], N. Kolisetty[1], S. Muralidhara[1], R. J. Bull[2], O. Quinones[3], S. A. Snyder[3], J. A. Cutruvo[4], J. Fisher[5] and B. S. Cummings[1]. *[1]Pharmacology and Biomed. Sci., University of Georgia, Athens, GA, [2]MoBull, Richland, WA, [3]Water Quality Research and Developoment, Southern Nevada Water Authority, Henderson, NV, [4]Joseph Cutruvo & Associates, LLC, Washington, DC and [5]Environment Health Sci., University of Georgia, Athens, GA.*

Bromate is a common by-product of ozone disinfection of water containing bromide, and a possible human carcinogen. Absorption, distribution and elimination of bromate (BrO_3^-) in female F344 rats were studied after oral and I.V. treatments. Concentrations of BrO_3^- used were 0, 0.02, 0.1, 0.5, 1.0, 2.5, 5.0 and 20 mg/kg and blood levels were assessed after 0, 5, 10, 20, 40, 60, 120, 240, 480, and 720 minutes. BrO_3^- levels were determined by liquid chromatography (LC) with tandem electrospray ionization-mass spectrometry detection (MS/MS). Isotope dilution using [^{18}O] bromate, incorporated prior to extraction, was used to correct for any decay or matrix suppression of the bromate ion in biological extract. Levels of BrO_3^- in blood following both I.V. and oral exposure were dependent on the dose administered. In IV treated rats BrO_3^- levels rapidly declined in a distribution phase, but displayed evidence of saturation in the terminal half-life at doses > 2.5 mg/kg. BrO_3^- levels peaked 10 minutes after oral administration, followed by a rapid distribution phase during which >90% was eliminated within 2 hours. Analysis of the area under the curve for similar I.V. and oral doses resulted in an absolute bioavailability of approximately 30%. These data indicate a significant first pass effect for BrO_3^- metabolism and that BrO_3^- is rapidly eliminated from the blood of rats. These kinetic data are part of an ongoing project to evaluate the dose-response characteristics of bromate for eventual use in risk assessment of bromate in drinking water supplies. This work was supported by the Awwa RF 4042, IOA, MWD, NWRI, Calleagas Water, Long Beach Water, SNWA, and the Georgia Cancer Coalition.

PL 1262 A DIETARY DOSE RANGE-FINDING AND TOXICOKINETIC (TK) STUDY OF 2, 4-DICHLOROPHENOXYACETIC ACID (2, 4-D) IN ADULT CRL:CD(SD) RATS AND THEIR OFFSPRING: II. TOXICITY.

M. S. Marty[1], S. A. Saghir[1], C. L. Zablotny[1], A. J. Clark[1], A. W. Perala[1], B. L. Yano[1], J. S. Bus[1] and B. H. Neal[2]. *[1]Toxicology & Environmental Research, The Dow Chemical Company, Midland, MI and [2]The Weinberg Group, Washington, DC.*

TK and toxicity data from a range-finding one-generation study were used to determine appropriate doses for an extended one-generation dietary toxicity study of 2,4-D in rats (based on Cooper et al., Crit. Rev. Toxicol. 36:69, 2006). Groups of 10 male (M) and female (F) CD® rats were treated with 0, 100, 200, 400, 600, 800, 1200 and 1600 ppm 2,4-D in diet from pre-breeding through weaning (M, 71; F, 95 days). A satellite group was included to evaluate 2,4-D effects from gestation day (GD) 0-17. Adult F given ≥1200 ppm 2,4-D had significantly decreased body weights/body weight gains and feed consumption during the pre-breeding period. Satellite F showed decreased body weight gain through GD 17, which was compensated by GD 21 in main study animals. Feed consumption in parental F was markedly decreased throughout lactation at 800, 1200 and 1600 ppm. Litter size was decreased at concentrations ≥1200 ppm and pup body weights were significantly decreased at concentrations ≥800 ppm during lactation until termination on PND 35. Dams in the 1600 ppm group and litters in the 1200 and 1600 ppm groups were removed from study at or before lactation day (LD) 21 due to excessive toxicity. Adult test day (TD) 71 M had slight kidney histopathology at doses ≥400 ppm. TD 95 F had slight kidney histopathology at higher doses (≥800 ppm). There were no effects on reproduction, fertility, gestation length, litter size at birth, birth weights or pup sex ratio. There was no evidence of increased susceptibility in pups. The NOAELs were 100 ppm (M) and 400 ppm (F and pups). If the high dose level for the definitive study was selected based only on traditional toxicity endpoints, this dose would clearly have been in the nonlinear range with respect to TK. (Sponsored by the Industry Task Force II on 2,4-D Research Data)

PL 1263 TOXICOKINETICS OF EPHEDRINE AND CAFFEINE FOLLOWING ADMINISTRATION OF EPHEDRINE, CAFFEINE, OR MA HUANG.

T. Fennell[1], N. L. Gaudette[1], B. L. Fletcher[1], S. D. Cooper[1], R. Fernando[1], J. Dunnick[2] and B. J. Collins[2]. *[1]RTI International, Research Triangle Park, NC and [2]National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

Both Ma Huang and Ephedrine (EPH), found in Ma Huang are incorporated in a number of dietary supplements containing caffeine, which have been shown to cause cardiac toxicity in rats following a single dose at lower concentrations than each component administered singly. Whether caffeine and ephedrine interact at the pharmacokinetic level or the pharmacodynamic level is not known. This study was conducted to compare the pharmacokinetics of ephedrine administered alone, or in combination with caffeine, and Ma Huang alone or in combination with caffeine. Jugular-vein cannulated male Fischer 344N rats were administered EPH by i.v. injection (6.25 mg/kg), p.o. (6.25, 12.5, and 25 mg/kg), EPH + caffeine by gavage (12.5 and 30 mg/kg), Ma Huang by gavage (312.5 mg/kg, equiv. to 12.5 mg/kg EPH) and Ma Huang + caffeine by gavage (312.5 and 30 mg/kg). Blood was collected at 5, 10, 15, 30 min, 1, 2, 4, 8, and 12 h following dosing. EPH, pseudoephedrine, and caffeine were measured using an LC-MS/MS method. Pharmacokinetic parameters were determined using non-compartmental analysis. The mean elimination half-life of ephedrine on i.v. dosing was 42 min, whereas after gavage, the mean $t_{1/2}$ ranged from 132 – 165 min for ephedrine alone. EPH bioavailability was 48%. The area under the curve (AUC) increased disproportionately in a sublinear manner with dose of EPH. In combination with caffeine, EPH AUC increased slightly (1.2-fold). EPH in Ma Huang was 90 % bioavailable. EPH AUC in animals administered Ma Huang + caffeine was approximately 20% higher compared with Ma Huang alone. This study indicates that the administration of caffeine in combination with Ma Huang or EPH has only slight impact on the pharmacokinetics of EPH, and suggests toxicity of caffeine in combination with Ma Huang or EPH may result from pharmacodynamic interactions.

1264 METABOLISM OF DI(2-ETHYLHEXYL)PHTHALATE (DEHP) IN NEONATAL MALE RHESUS MONKEYS AFTER INTRAVENOUS AND ORAL DOSING.

D. R. Doerge[1], N. C. Twaddle[1], J. J. James[1], P. H. Siitonen[1], L. Camacho[1], S. Moon[1], J. Vostal[2] and K. Delclos[1]. *[1]NCTR, FDA, Jefferson, AR and [2]Office of Blood Research and Review, CBER, FDA, Rockville, MD.*

DEHP, long the major plasticizer used in multiple polyvinylchloride medical devices, has been clearly established as a male reproductive toxicant in rodents, particularly when exposure occurs in developing animals. High exposures, primarily via the iv route, of male infants in neonatal intensive care units (NICU) have thus raised concern, but existing human data are inadequate to resolve the issue. Oral dosing of juvenile or adult nonhuman primates (NHP) with doses higher than those used to produce adverse effects in rodents has not caused testicular toxicity. However, there are no data available on NHP exposed to DEHP during the sensitive perinatal period. We monitored the formation of DEHP metabolites in blood samples over 48 hours in male rhesus monkeys after single iv or oral doses at 1, 5, 9, and 10 weeks of age. The hypothalamic-pituitary-testicular axis is active in this time period and the design attempts to mimic the human NICU exposure. Deuterated DEHP was utilized due to high and variable background levels of DEHP and was administered at 5 mg/kg body weight in 10% Intralipid emulsion. The analytes, both aglycone and glucuronidated, monitored by liquid chromatography-tandem mass spectrometry included DEHP, mono(2-ethylhexyl)phthalate (MEHP), mono(2-ethyl-5-hydroxyhexyl)phthalate (MEHHP), mono(2-ethyl-5-oxohexyl)phthalate (MEOHP), and mono(2-ethyl-5-carboxypropyl)phthalate (MECPP). Detailed data analyses are on-going, but it is clear that MEHP and its oxidized metabolites are formed throughout the dosing period after both iv and oral dosing and that a substantial proportion of these metabolites circulate in the aglycone form. Metabolite patterns are similar in rhesus monkeys of Indian and Chinese origin, and comparison with urinary metabolite profiles reported from NICU infants suggests that this is a relevant model for the evaluation of DEHP toxicity. Supported by Interagency Agreement 224-07-007 between FDA and NIEHS.

1265 PBPK MODELING OF BENZENE METABOLITES IN BONE MARROW OF HUMANS WITH VARIED WORKPLACE EXPOSURE PATTERNS AND CYP2E1 ACTIVITY.

J. S. Knutsen[2], B. D. Kerger[1], J. R. Kuykendall[2] and D. J. Paustenbach[3]. *[1]Health Science Resource Integration, Tallahassee, FL, [2]ChemRisk, Boulder, CO and [3]ChemRisk, San Francisco, CA.*

A 6-compartment physiologically based pharmacokinetic (PBPK) model of benzene in the mouse was modified to include a bone marrow compartment and calibrated to provide good fit with human studies of benzene excretion via breath. The resulting human PBPK model was then used to determine whether differences in exposure rates (intermittent peak vs. uniform) for similar cumulative workday benzene exposures of 8, 80, or 800 ppm-hr produced biologically significant differences in benzene metabolism in persons with and without CYP2E1 induction. The predicted bone marrow dose of benzene and its major metabolites (benzene oxide, phenol) within 24 hours did not vary appreciably with exposure rate or induction status at 8 ppm-hrs, consistent with expected impacts of physiologic damping on deep tissue compartments. At 80 ppm-hrs the predicted bone marrow dose showed no appreciable impacts of exposure rate on major metabolites, but a paradoxical trend of disproportionately higher benzene fraction and a lower fraction of hydroquinone, catechol, and benzenetriol was observed at the highest peak exposures. Similar trends, but of greater magnitude, were seen at 800 ppm-hr for all exposure rates, and induction tended to attenuate the trend where uniform exposures corresponded to the highest bone marrow dose. This paradoxical trend is explained by model-predicted metabolic saturation leading to higher blood benzene levels, enhanced exhalation losses of unchanged benzene, and a consequently lower fraction of metabolite production that prominently affects benzoquinone precursor metabolites, hydroquinone and catechol. The model predictions suggest that it may be important to consider interactions between benzene exposure patterns, CYP2E1 induction, and capacity-limited metabolism when evaluating dose-response trends for benzene hematotoxicity.

1266 IMPROVED ANALYSIS OF TRICHLOROETHYLENE (TCE) METABOLITES BY GAS CHROMATOGRAPHY (GC).

S. Muralidhara and J. V. Bruckner. *PBS, University of Georgia, Athens, GA.*

TCE and several haloacetic acids [e.g., dichloroacetic and trichloroacetic acid (DCA and TCA)] are common contaminants of drinking water in the U.S. Our objective was to develop a GC method of analysis of these and other TCE metabolites in biological samples, with improved separation of GC peaks, simplicity and sensitivity. Measurement of DCA and TCA by headspace analysis required their esterification with a mixture of distilled water, concentrated sulfuric acid and alcohol (6:5:1). Methanol, ethanol, 1- and 2-propanol, t-butanol and 1-octanol were evaluated for their ability to provide good separation with a short retention time. Ethanol proved to be superior. TCE, chloral hydrate and trichloroethanol can be analyzed concurrently with DCA and TCA in blood, tissue and urine samples. The LOD and LOQ for these analytes were 5 ng /ml and 20 ng ml respectively. Toxicokinetic and metabolism studies of low levels of TCE, perchloroethylene and related halocarbons can be conducted using this procedure. Supported in part by U.S.DOE cooperative agreement DE-FC09-02CH111090

1267 TOXICOKINETICS OF THE STEREOISOMER SPECIFIC FLAME RETARDANT HEXABROMOCYCLODODECANE (HBCD) GAMMA: EFFECT OF DOSE, TIME, AND REPEATED EXPOSURE.

D. T. Szabo[1], J. J. Dilliberto[2], J. Huwe[4] and L. S. Birnbaum[3]. *[1]Toxicology, University of North Carolina, Chapel Hill, NC, [2]ORD/NHEERL/ETD, U.S. -EPA, RTP, NC, [3]ORD/NCEA, U.S. -EPA, RTP, NC and [4]ARS, USDA, Fargo, ND.*

Hexabromocyclododecanes (HBCDs) are high production volume brominated aliphatic cyclic hydrocarbons used as flame-retardants in foams, plastics and textiles. Commercial HBCD is a mixture of three main stereoisomers, alpha (α), beta (β) and gamma (γ). A shift from the high percentage of γ in the mixture and environment to a dominance of α in biota is observed. In predicting human health risk posed by HBCD, there's a need to understand the disposition and elimination kinetics of the major commercial stereoisomer γ. Methods: Adult female C57BL/6 mice were gavaged with [C14] HBCD-γ (0.2uCi/mouse) at 10ml/kg and held in metabolism cages. Radioactivity in tissues and excreta were determined by combustion followed by liquid scintillation spectrometry. Metabolite profiles were examined using an Ultra Performance LC (UPLC) with a radiodetector. For the dose/response study, a single dose (3, 10, 30, or 100 mg/kg) was administered and mice held for 4 days. For the effect of time, mice were treated with a single 3mg/kg dose and held up to 14 days. For the repeated study, mice were dosed daily at 3mg/kg with non-radiolabed γ for 9 days followed by [C14] HBCD-γ on the 10th day and held for 4 days. Results: Tissue disposition is dose-independent and HBCD's behavior appears to be linear across all doses measured including the repeated exposure. Tissue concentrations were highest in liver followed by blood and then fat. A large percentage of the administered dose is excreted in urine (23%) and feces (50%) by day 1. Preliminary results suggest none of the HBCD-derived radioactivity in the urine is parent chemical. Conclusions: HBCD-γ demonstrates a lack of tissue-specific sequestration. Considering levels in fat are lower than blood and liver, and the rapid elimination in urine and feces, the biological persistence of HBCD-γ in mice appears limited. This finding may help explain the low levels of γ in biota.(This abstract does not reflect USEPA policy)

1268 ALTERED DISPOSITION OF ACETAMINOPHEN IN NRF2-NULL AND KEAP1-KNOCKDOWN MICE.

S. A. Reisman, I. L. Csanaky and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

Acetaminophen (AA) is a widely-used antipyretic drug that causes hepatotoxicity at high doses. Nuclear factor erythroid 2-related factor 2 (Nrf2) is a transcription factor that mitigates electrophilic stress from AA by inducing genes, such as NAD(P)H:quinone oxidoreductase 1 (Nqo1), multidrug resistance-associated proteins (Mrps), and glutathione (GSH) synthesis enzymes. To determine whether Nrf2 activation alters the biotransformation, excretion, and in turn, the hepatotoxicity of AA, male wild-type, Nrf2-null, and Keap1-knockdown (Keap1-kd) mice (which have increased activation of Nrf2) were administered a subtoxic dose of AA (50 mg/kg, iv), after which, AA and its metabolites (AA-glucuronide, AA-GLUC; AA-sulfate, AA-SULF; AA-glutathione, AA-GSH) were quantified in plasma, bile, and liver. AA-GLUC concentrations were reduced in plasma and elevated in livers of Nrf2-null mice due to decreased glucuronidation activity and lower expression of the basolateral efflux transporter Mrp3. In contrast, Keap1-kd mice had higher plasma and lower hepatic AA-GLUC concentrations, due to higher Mrp3 expression. Lower glucuronidation activity of Nrf2-null mice increased the proportion of AA available for sulfation, resulting in elevated AA-SULF concentrations in plasma, bile, and liver. Decreased AA sulfation activity in Keap1-kd mice resulted in lower AA-SULF concentrations. In general, GSH-derived AA conjugates were increased in Nrf2-null mice and decreased in Keap1-kd mice. Furthermore, Nqo1, an enzyme capable of detoxifying the reactive intermediate of AA metabolism, NAPQI, had 85% lower activity in Nrf2-null mice and 415% higher activity in Keap1-kd mice relative to wild-type. In addition, hepatotoxicity 6 h after AA (600 mg/kg, ip) was most severe in Nrf2-null mice and absent in Keap1-kd mice. In conclusion, lack of Nrf2 decreases AA glucuronidation, leading to increased NAPQI formation

and hepatotoxicity, whereas activation of Nrf2 enhances detoxification of NAPQI by Nqo1 and elimination of AA-GLUC via Mrp3. (Supported by NIH grants ES09716, ES07079, ES013714, ES09649, and RR021940).

PL 1269 USE OF PHARMACOKINETIC MODELING TO EVALUATE GENETIC POLYMORPHISMS IN CARISOPRODOL METABOLISM.

T. A. Lewandowski. *Health and Nutrition Sciences, Brooklyn College/CUNY, Brooklyn, NY.*

The muscle relaxant carisoprodol is one of the most commonly abused drugs in the U.S. and other Western Countries. We previously presented a pharmacokinetic model of carisoprodol metabolism based on first order rates of absorption, metabolism and elimination. The model was able to accurately predict plasma concentrations of carisoprodol and its primary metabolite meprobamate in individuals displaying the metabolic profile observed in the general population. We now present a revised model to address individuals who are poor metabolizers of carisoprodol due to a CYP2C19 polymorphism (Bramness et al., 2005). The revised model is able to correctly predict blood concentrations of carisoprodol and meprobamate in these individuals. To do so, the model's first order rate constant for carisoprodol metabolism (km) is reduced from 0.95 to 0.24 per hour and the percentage of carisoprodol metabolized to meprobamate (consistent with a shift in metabolic pathways) is reduced from 0.79 to 0.67. We found it was also necessary to reduce the absorption rate constant for carisoprodol, suggesting that GI uptake of this drug may be saturable in these individuals even in the therapeutic dose range. We have also developed an alternative pharmacokinetic model that describes carisoprodol metabolism as a saturable Michaelis-Menten (MM) process. Our intent is to use the MM model to predict the time course of blood concentrations in overdose situations. Preliminary analyses show the MM model fits the available data with a Vmax value of 1850 mmol/hr and a km value of 28mM. The presentation will also contrast the fit of the two models to blood concentration data obtained at therapeutic and toxic doses.

PL 1270 COMPARATIVE TOXICOGENOMIC ANALYSIS OF PCB 126 REPS DERIVED FROM PRIMARY HUMAN AND RAT HEPATOCYTES.

E. Carlson[1], T. R. Sutter[2], M. Colin[1], S. Goodwin[2] and J. Silkworth[1]. *[1]General Electric Company, Niskayuna, NY and [2]W. Harry Feinstone Center for Genomic Research, University of Memphis, Memphis, TN.*

Relative potency (REP) measurements of individual "dioxin-like" compounds (DLCs), such as co-planar polychlorinated biphenyls (PCBs), are often estimated using the toxic equivalency factor (TEF) approach. An international World Health Organization committee has established the PCB126 TEF at 0.1, based primarily on in vivo rat studies. Recent studies in our laboratory and elsewhere have demonstrated that the PCB126 REP for human cells /cell lines is at least an order of magnitude lower than the rodent-derived PCB126 TEF. The current microarray study sought to extend these findings by investigating dose response changes in gene expression induced by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and PCB 126 in primary hepatocytes from either human donors or female Sprague-Dawley rats. Nonlinear mixed-effects models, which directly estimated PCB126 REP, were generated for 47 unique human and 79 unique rat genes using an automatic model selection scheme. Only five orthologs were commonly modeled in both species. The geometric mean maximum likelihood estimates of the PCB126 TEF for all human and rat genes were 0.002 and 0.06, respectively. This species difference in sensitivity was also extended to significantly enriched categories for gene ontology and KEGG pathways. Closer examination of the data revealed that while many rat genes possessed PCB 126 EC50s below -8 logM, the PCB 126 EC50s for most humans genes were above –8 logM. In addition, the human genomic response was found to be less sensitive to TCDD exposure compared to rats. Thus, to be accurate, any standardized risk value based on animal studies but used for human health risk assessment must account for species differences in sensitivity to both the reference TCDD and the DLC. Overall, the current study raises serious questions about the suitability of rat-derived REP estimates for use in human health risk assessment.

PL 1271 PAH ANALYTICAL TECHNIQUES AND IMPACTS ON RISK ASSESSMENT.

E. J. Martin, G. O'Sullivan and C. D. Sandau. *TRIUM Environmental Solutions Inc., Cochrane, AB, Canada.*

Polycyclic aromatic hydrocarbons (PAHs) constitute a large group of chemicals that are formed during incomplete combustion of organic substances. They can be anthropogenic in origin – burning of coal, oil & gas, tobacco – or form naturally in the environment – volcanoes, forest fires. Due to the numerous sources, PAHs are ubiquitous in the environment. PAHs are often found at contaminated sites. They are a contaminant of concern at 749 National Priorities List (NPL) sites (approximately 60% of sites) and are ranked sixth on the CERCLA priority list of hazardous substances. A number of standard laboratory techniques are available to determine the composition, distribution, and abundance of PAHs in various environmental media including EPA method 8720C which uses gas chromatography/mass spectrometry. However, more sensitive techniques for measurement of PAHs have also been developed including high-resolution isotope dilution mass spectrometry (ID/MS). We have conducted a study to compare a standard analytical method (EPA 8720C; often used in the environmental industry) to a more sensitive method (ID/MS) for monitoring PAHs in soil. Our results indicated that the frequently used standard laboratory method (EPA 8720C) consistently overestimated PAH concentrations in soil as compared to the more sensitive ID/MS technique which was found to be more accurate and more precise. Using the benzo(a)pyrene toxic equivalency (BaP TEQ) scheme, it was found that the BaP TEQ values generated using the standard laboratory technique were significantly greater that those from the more sensitive technique. These findings may have important implications for contaminated site risk assessment. Risks associated with exposures to PAHs in soil (via inadvertent ingestion, dermal contact and inhalation of soil/dust) are directly proportional to measured PAH concentrations. Any error in the determination of PAH concentrations will consequently impact the calculation of risk. Thus, use of more sensitive laboratory techniques for PAH measurements will reduce uncertainty and provide for a more accurate understanding of site conditions and liability.

PL 1272 SPECIES DIFFERENCES IN HUMAN AND RAT RELATIVE POTENCY VALUES FOR DIOXINS, FURANS AND PCBs ARE CONGENER-SPECIFIC.

C. Sutter[1], S. Bodreddigari[1], T. R. Sutter[1], E. A. Carlson[2] and J. B. Silkworth[2]. *[1]Feinstone Center for Genomic Research, University of Memphis, Memphis, TN and [2]General Electric Company, Niskayuna, NY.*

In 2005, Silkworth et al reported that the EROD-based REP value for PCB126 in human hepatocytes was 100-fold less than the REP value in rat hepatocytes. To confirm the lower REP value of PCB126 in other human cells and to determine whether this observation held for other dioxin-like compounds with 0.1 TEFs, we tested normal human epidermal keratinocytes (NHEKs) and calculated EC50-based REP values for CYP1A1 mRNA induction for PCB126, TCDD, 2,3,7,8-tetrachlorodibenzo-p-furan (TCDF), 1,2,3,6,7,8-hexachlorodibenzo-p-dioxin (HxCDD) and 1,2,3,6,7,8-hexachlorodibenzo-p-furan (HxCDF). Chemical concentrations were analytically determined. Our results demonstrated that in NHEKs, PCB126 had a REP value of 0.002, compared to 1 of TCDD. This value is 50 times less than the TEF value of 0.1 assigned to it by WHO2005 and the same as the value reported earlier for human hepatocytes. The REPs for TCDF and HxCDD were 0.07 and 0.19, respectively, similar to their assigned value of 0.1. HxCDF had a REP value of 1.19, which is 12 times its assigned value. For direct comparisons to responses in rats, the same stocks of TCDD, PCB126 and HxCDF were used to treat the rat cell line, H4IIE, resulting in REP values of 0.06 for PCB126 and 0.05 for HxCDF, similar to the assigned value of 0.1, confirming our chemical concentrations. Importantly, the EC50 value for TCDD in H4IIE cells was 20 times less than the value obtained in NHEKs, as has been shown in other human cells. In conclusion, our preliminary data indicate that the differences in REP values between rat and human are congener-specific. A complete study of congeners in human cells is warranted and these results should be incorporated into TEFs by risk assessors.

PL 1273 APPLICATION OF NONLINEAR DOSE-RESPONSE METHODS BASED ON MODE OF ACTION FOR POLYCHLORINATED BIPHENYLS (PCBs).

R. E. Keenan[1], P. O. Gwinn[1], J. D. Schell[2], E. A. Carlson[3] and J. B. Silkworth[3]. *[1]AMEC Earth & Environmental, Inc., Portland, ME, [2]Entrix, Houston, TX and [3]General Electric Global Research, Niskayuna, NY.*

A mode-of-action (MOA) for PCB-promoted rat liver tumors that fulfills the Hill Criteria and the comprehensive requirements of strength, consistency, specificity, temporality, dose-response and biological plausibility, was used as the basis for deriving a set of preliminary Tolerable Daily Intakes (TDIs) for four different PCB mixtures using a nonlinear dose-response model. Nonlinear approaches are suitable for this investigation because none of the MOA elements shows linearity at low doses. The derived TDIs were then compared to allowable intake levels calculated using the linear default extrapolation approach as currently used by EPA. The statistical dose-response analysis was conducted using EPA Benchmark Dose Software, which was initialized to employ a dichotomous multi-stage procedure to model dose

response in the observable region of the data in order to extrapolate to a point-of-departure (POD) at or near the fringe of the observable region. In this preliminary evaluation of a nonlinear dose response model for PCBs, the application of conservative toxicological uncertainty factors (UFs) was used as the simplest method for extrapolating below the POD to the threshold dose anticipated by the MOA. This resulted in the determination of a preliminary set of TDIs, one for each PCB mixture, that were approximately 3,000 to 5,000 times greater than the corresponding values for the risk-specific dose (10^{-6}). This nonlinear dose-response assessment indicates that much higher levels of PCBs can be tolerated without subjecting individuals to unreasonable excess cancer risks. Further refinements to the nonlinear approach may include the application of probabilistic methods to estimate the changing shape of the dose-response curve as it flattens from the POD to the unobservable region where it approaches a threshold consistent with the PCB MOA.

PL 1274 WEIGHT OF EVIDENCE EVALUATION OF THE MODE OF ACTION FOR PCB-PROMOTED RAT LIVER TUMORS USING THE HUMAN RELEVANCE FRAMEWORK.

R. Golden[1], E. Carlson[2] and J. Silkworth[2]. *[1]ToxLogic LLC, Potomac, MD and [2]Global Research Center, General Electric, Niskayuna, NY.*

While it is well established that sufficient exposure of rodents to PCB mixtures (i.e., Aroclors) can promote liver tumors the mode of action (MOA) has been elusive. A recent publication described the likely MOA by which PCBs promote hepatic tumors in Aroclor-dosed S-D rats. Numerous biochemical measurements taken over the course of a chronic bioassay with Aroclors 1016, 1242, 1254 and 1260 showed that liver tumors were closely, consistently, and predictably correlated with the net hepatic cytosolic activity of redox-cycling quinones (RCQ) acting as catalysts for the production of reactive oxygen species (ROS). This indicated a tumorigenic MOA whereby (1) tissue PCB/TEQ accumulations induce expression of mixed function oxidases (MFOs) and (2) MFOs convert endogenous substrates to RCQs, eventually resulting in ROS-mediated promotion via H2O2 mitotic signaling of spontaneously initiated liver cells. These findings are corroborated by the results of other bioassays with TCDD, individual PCB congeners and binary PCB mixtures based on the results of bioassays conducted by the National Toxicology Program (NTP). Because a well-defined MOA can be described for PCB promoted rat liver tumors, the totality of the data can be used in a systematic weight of evidence (WOE) evaluation of the relevance of these tumors to human health and for risk assessment. This evaluation follows EPA's Guidelines in conjunction with the methodology of ILSI/IPCS which provides a decision-logic based approach for determining the relevance of PCB-promoted liver tumors in animal studies to humans. The WOE supporting the postulated MOA fulfills the Hill Criteria and the comprehensive requirements of strength, consistency, specificity, temporality, dose-response and the key criterion of biological plausibility. Since the MOA fulfills the rigorous ILSI/IPCS Human Relevance Framework and none of the elements show linearity at low doses a non-linear approach is justified for cancer risk assessment of rodent liver tumors for humans.

PL 1275 THE RELATIONSHIP BETWEEN THE IC50, TOXIC THRESHOLD, AND THE MAGNITUDE OF STIMULATORY RESPONSE IN BIPHASIC (HORMETIC) DOSE-RESPONSES.

M. A. Nascarella[1, 2] and E. J. Calabrese[2]. *[1]Gradient Corporation, Cambridge, MA and [2]Environmental Health Sceinces, University of Massachusetts Amherst, Amherst, MA.*

Hormesis is a dose-response relationship characterized by a biphasic (U- or inverted U-shaped) response. We present the results of a study designed to assess the relationship between toxic potency (as measured by the IC50) and the magnitude of the hormesis stimulation. We describe a new parameter (ΔX), which we define as the difference between the concentration (or dose) that inhibits 50% of the growth of the organism under study (IC50), and the concentration (or dose) of the respective toxicological threshold (e.g., benchmark dose (BMD) or zero equivalent point (ZEP)). Our analysis includes a subset of data from a previously published report describing a National Cancer Institute study that exposed 13 strains of yeast to over 2,100 putative anticancer agents (representing over 28,000 dose-responses). The toxic threshold used in this Calabrese et al. (2008) paper was the BMD5 (Crump, 1984). Thus, the ΔX in this presentation (in uM) is defined as: ΔX = IC50 – BMD5. We have found that the ΔX and the magnitude of stimulation above the control response are inversely related. For example, the Calabrese et al. (2008) paper reports model mean estimates for the aggregate response of yeast growth below the BMD5. When the mean estimate of response for were segregated into 5 approximately equal quintiles (n ~79, mean responses of 99, 102, 104, 111, and 131% of the control response, quintiles 1-5, respectively), and compared to the mean ΔX values (56, 50, 43, 36, and 21 μM, quintiles 1-5, respectively), it was observed that as the magnitude of stimulation (or evidence of hormesis) increases, the ΔX decreases. These findings describe the first known relationship between toxic potency and the magnitude of hormetic response and warrant further inquiry.

PL 1276 HEALTH RISK ASSESSMENT OF MELAMINE IN DRINKING WATER.

V. S. Bhat, C. J. McLellan, L. L. Bestervelt and G. L. Ball. *NSF International, Ann Arbor, MI.*

Acceptable levels of melamine in drinking water were determined based on NSF/ANSI 61 Annex A (2007a). Melamine is detected in the extract water of products that convey drinking water, since it is used as an ingredient in some materials used to make these products. In Fall 2008, melamine was implicated in as many as 50,000 acute renal failure cases in infants that consumed contaminated milk in China. The complex of melamine and cyanuric acid was implicated in many cases of renal failure resulting from renal obstruction with melamine cyanurate crystals in domestic dogs and cats that consumed contaminated pet food in the U.S. in Spring 2007. Limited quantitative data for melamine exposure in humans were identified, such as data from the milk adulteration. Both renal and bladder precipitation of melamine crystals were observed in domestic and laboratory animals after dietary melamine intake. Although crystals were generally seen in both organs, species-specific differences were observed with respect to the predominate organ. Renal precipitation of melamine predominates in non-rodent species, such as dogs and cats, while bladder precipitation predominates in rodents. Most of the data in dogs and cats were from a mixture of melamine and cyanuric acid, which likely affected the target organ. Repeated dietary melamine intake was associated with bladder stones with a male predisposition in rodents. Upon chronic dietary exposure, these stones progressed to bladder tumors in male, but not female rats or male or female mice. The bladder tumors were considered to arise from a threshold mechanism secondary to urinary melamine precipitation that lead to bladder stone formation. Kinetics data support the lack of melamine metabolism. Since insufficient quantitative data were available to identify a NOAEL for renal or urinary calculus formation in non-rodent species exposed to melamine alone, the RfD of 0.1 mg/kg-day melamine was based on the 10% benchmark dose level of 38 mg/kg-day for urinary calculus formation in laboratory rats. The RfD of 0.1 mg/kg-day was used to determine the Total Allowable Concentration in drinking water of 0.9 mg/L.

PL 1277 ARSENIC BIOAVAILABILITY IN SOIL: EVIDENCE FROM *IN VITRO* AND MICROPROBE STUDIES.

J. M. LaVelle. *CDM, Green Valley, AZ.*

Bioavailability of arsenic in soil is a continuing issue for appropriate human health risk assessment associated with arsenic exposure. Recent results of in vitro and microprobe analysis of arsenic at a former secondary lead smelter and two former mining/milling sites provide some additional perspective on this issue. In vitro analysis of arsenic bioavailability at a former lead smelter site was entirely consistent with low or zero assessability of arsenic in soils from non-contaminated areas, and increasing content of highly assessable arsenic in contaminated soils closer to the former location of the smelter stack. Results of the in vitro assay between to independent laboratories were consistent, demonstrating the reproducibility of the methods. Estimates for possible remediation goals for arsenic at this site for a given risk target were perhaps an order of magnitude higher than typical default values, when bioavailability information was taken into account. In vitro analysis of arsenic bioavailability at two former mine/mill sites suggested that, regardless of soil concentrations, the amount of available arsenic was small. Results ndicate that potential arsenic-related exposure may be only a fraction of exposure estimated using default assumptions. Electron microprobe analysis of soils indicated that arsenic was observed within the soil matrix and in forms typically non-assessable in the in vitro assay. Iron content of soils at these site was high (25,000 mg/kg or higher), and arsenic was likely associated with insoluble iron species. The current results re-confirm that knowledge of information on bioavailability of arsenic is critical to risk assessment at sites with arsenic soil contamination. Quantitative use of information on bioavailability of arsenic may provide the risk manager with addition options for remediation and/or mitigation.

PL 1278 CREATING CONTEXT FOR THE USE OF DNA ADDUCT DATA IN RISK ASSESSMENT.

L. Pottenger, A. Jarabek, M. Himmelstein, L. Andrews, P. Boogaard, D. Casciano, J. Cadet, M. Embry, P. Farmer, J. Kim, J. Preston, E. Martin, V. Reddy, R. Schoeny, J. Skare, J. Swenberg, G. Williams and E. Zeiger. *DNA Adducts Project Committee, ILSI Health and Environmental Sciences Institute, Washington, DC.*

Assessments of human cancer risk require the integration of diverse types of data. Advancing technologies for quantitative measurements at the sub-cellular domain raise the critical issue of interpretation and use of DNA adduct data in context with

current understanding of cancer as a multifaceted process. A HESI Committee is developing a framework for the use of DNA adduct data in risk assessment. The approach includes: 1) defining a preliminary framework for data organization, 2) assessing available methods for quantitative measurement of adducts; 3) using case studies to refine the framework and draw inferences. Conclusions to date include: DNA is not pristine; DNA adducts cannot be used in isolation to determine mode-of-action (MOA); and DNA adducts (biomarkers of exposure) are not equivalent to mutations (biomarkers of effect). The framework stresses the consideration of a variety of adduct data in context with traditional toxicology data to inform MOA characterization. Conclusions on the relevance and applicability of DNA adduct data to quantitative risk assessment will be further refined by subsequent review of selected case studies. The strategy for selection and evaluation of case studies of known DNA-reactive carcinogens is discussed. A complementary effort summarizes the methods used to identify and quantify DNA adducts, focusing on reliability and validation. That effort describes sensitivity and specificity as key factors for method selection, as is sample type. The reliability of oxidative DNA damage measurement techniques is reviewed. Assay limitations are discussed along with issues that have impact on results, i.e., sample collection, processing, and storage. This framework is a critical effort to aid understanding of issues underlying DNA adducts as biomarkers and to improve the context for data inference and application in cancer risk assessment. (This abstract does not reflect U.S. EPA policy.)

PL 1279 THE TRANSLOCATION AND FATE OF CHRYSOTILE ASBESTOS IN COMBINATION WITH FINE PARTICLES FOLLOWING EXPOSURE IN A BIOPERSISTENCE STUDY.

D. M. Bernstein[1], K. Donaldson[2], D. Schuler[3], S. Gaering[3], P. Kunzendorf[4], J. Chevalier[5] and S. E. Holm[6]. *[1]Consultant in Toxicology, Geneva, Switzerland, [2]University of Edinburgh, Edinburgh, United Kingdom, [3]RCC, Itingen, Switzerland, [4]GSA, Ratingen, Germany, [5]EPS, Basel, Switzerland and [6]Georgia-Pacific, LLC, Atlanta, GA.*

To evaluate the translocation, fate and clearance of chrysotile asbestos that was used as a component of a joint-compound an inhalation biopersistence study was performed using chrysotile in combination with the sanded reformulated joint-compound. A positive control of the amphibole asbestos amosite was also evaluated. Groups of Wistar rats were exposed 6 h/d for 5 d to either 7RF3 chrysotile & the aerosolized sanded joint-compound or to amosite asbestos. A control group was exposed to filtered-air. The animals were followed through 1 year post exposure. The initial results through 30 days after cessation of exposure are reported. The chrysotile used in the Ready Mix joint compound is rapidly removed from the lung. In the chrysotile & sanded exposure group the T1/2 of fibers L>20 μm was 4.8 days. The WT1/2 for amosite for fibers L>20 μm = 266,000 days. Histopathological examination showed that the chrysotile & sanded material exposed lungs had the same appearance as the filtered-air controls. The amosite exposed group showed an intense inflammatory response and developed interstitial fibrosis within 30 days post exposure. The lungs from sub-groups of rats were evaluated by confocal microscopy with the size and distribution of fibers in airways, parenchyma and macrophages quantified at each time point. In addition, a separate time course study addressed mechanisms of cell-associated transport of amphibole amosite and chrysotile fibers through parietal pleural lymphatics and evaluated any associated inflammatory cell reaction. The initial results of this study confirm that the chrysotile and sanded joint compound is quickly cleared from the lung, that there is no sustained inflammatory response. In contrast, the amphibole amosite following short-term bronchial clearance remains in the lung, produces an intense inflammatory response leading quickly to interstitial fibrosis.

PL 1280 VASCULAR EFFECTS OF A SUBCHRONIC INHALATION EXPOSURE TO CONCENTRATED AMBIENT AIR PARTICLES IN ATHEROSCLEROSIS SUSCEPTIBLE MICE.

K. Dreher, H. Floyd, R. Snyder, M. Daniels, R. Jaskot, A. Ghio, L. Walsh and I. Gilmour. *U.S. EPA, Research Triangle Park (RTP), NC.*

Several studies have reported the adverse effects of particulate air pollution on cardiovascular function/disease. The causal physiochemical properties of particles and their mechanisms of action/injury remain unknown. This study examined the vascular effects in 15 wk old male ApoE knockout mice fed normal chow and exposed by inhalation for 3 months (Nov. 2007 – Feb. 2008, 5d/wk, 6 hr/d) to either filtered air (FA), fine (F) (ave. conc. 219 μg/m3, range 55 – 780 μg/m3; ave. size ~680 nm), or ultrafine (UF) (ave. conc. 365 μg/m3, range 46 – 680 μg/m3; ave. size ~95 nm) RTP concentrated ambient air particles (CAPs). Mice were examined for vascular effects at 0 hr, 72 hrs and 1 month post-exposure. Histopathology performed at 72 hrs post-exposure showed a lack of significant pulmonary inflammation/injury in mice exposed to either F or UF CAPs vs. FA and an increased frequency of pulmonary arterial atherosclerosis occurred only in mice exposed to UF CAPs vs. FA. A 2-fold and 1.7-fold increase in aortic plaque size was observed in mice exposed to F or UF CAPs vs. FA, respectively, and this effect persisted at 1 month post-exposure. Elevated plasma CRP, fibrinogen, iron, and UIBC levels were observed in mice exposed to UF or F CAPs vs. FA immediately after their last exposure. These plasma endpoints were highest in the UF CAPs exposed mice and returned to FA control levels for both exposure groups by 72 hrs post-exposure. Decreased circulating white blood cell and lymphocyte cell counts were only observed in UF CAPs vs. FA exposed mice at 0hr post-exposure and modest decreases in blood platelet counts were observed in mice exposed to UF or F CAPs vs. FA at 72 hrs post-exposure. These data demonstrate F and UF CAPs exposure enhance atherosclerosis without overt lung injury. They also suggest that UF particulate air pollution may be more effective in producing atherosclerosis in smaller arteries and systemic inflammation immediately following exposure to these particles. (This abstract does not necessary reflect US EPA policy)

PL 1281 VASCULAR LIPID PEROXIDATION AND INDICES OF PLAQUE REMODELING ARE PROMOTED BY INHALATION EXPOSURE TO VEHICULAR EMISSIONS, BUT NOT HARDWOOD SMOKE OR A SIMULATED COAL COMBUSTION ATMOSPHERE.

M. J. Campen, A. K. Lund, J. D. McDonald, M. D. Reed and J. L. Mauderly. *Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM.*

The source emissions that contribute to cardiovascular morbidity and mortality have not been compared in a head-to-head manner. Using an established animal model of hypercholesteremia and atherosclerosis, we conducted 7- and 50-day whole body inhalation exposures to emissions from a gasoline engine, a diesel engine, hardwood combustion, and coal combustion. To address the long range transport of coal combustion emissions, this atmosphere was modified by addition of several gases (NOx, SO_2). Additionally, we produced a "traffic" atmosphere with combined gasoline and diesel engine emissions. For the 50-day exposures, apolipoprotein E-null mice were exposed to one of four levels of each pollutant atmosphere, or a high level with particles removed by filtration. Following exposures, aortas from exposed mice were harvested and probed for indies of lipid peroxidation and mRNA for matrix metalloproteinases (MMPs), endothelin-1 (ET-1) and several other markers. While strong responses to gasoline and diesel engine emissions were observed (along with the combined emissions), minimal to no effect could be determined from the woodsmoke and coal atmospheres. Furthermore, removal of particles from the whole exhaust atmospheres resulted in no difference from the responses to the whole exhaust, indicating that the gaseous portion of emissions contained the driver(s) of these effects. In 7-day studies, results were consistent with those from 50-day studies, and we found that several changes in PCR markers could be recreated by exposures to nitric oxide and carbon monoxide. However, lipid peroxidation could not be replicated by any individual gas, and was only upregulated by gasoline and/or diesel engine emissions. These studies confirm that complex pathophysiological responses are likely to arise from exposure to complex mixtures. Supported by the National Environmental Respiratory Center with funds from multiple government and industry sponsors.

PL 1282 MECHANISTIC INSIGHTS INTO THE RELATIONSHIP BETWEEN LUNG AND VASCULAR RESPONSES TO AMBIENT PARTICULATE MATTER (PM).

R. F. Thomas[1], A. A. De Vizcaya-Ruiz[2], A. Osornio-Vargas[3], M. C. Schladweiler[1], J. McGee[1] and U. P. Kodavanti[1]. *[1]ETD, NHEERL, U.S. EPA, Durham, NC, [2]Toxicology Section, CINVESTAV-IPN, Mexico City, Mexico and [3]Investigación Básica, INCan, SSA, Mexico City, Mexico.*

The mechanisms by which inhaled ambient PM induces vascular response are not well understood. We examined lung and aortic response of rats to three ambient PM. Chemically characterized PM10 and PM2.5 from the north and PM10 from the south of Mexico City were tested for in vivo acute lung and vascular toxicity. Male Wistar Kyoto rats (14 weeks) were intratracheally instilled with either saline or one of three PM at 3 mg/kg. All three PM induced inflammation (day 1>day 3) as evidenced by the increases in bronchoalveolar lavage fluid (BALF) protein and neutrophils with small differences between PM types. Gene expression for markers of inflammation, oxidative stress, vasoconstriction, thrombosis, metalloproteases, and receptors which recognize oxidatively modified proteins and lipids (RAGE and Oldlr-1) were analyzed in the lung and aorta. Pulmonary HO-1, TNF-α, MIP-2, tissue factor and PAI-1 but not tPA mRNA increased with all three PM. Maximum response occurred at day 1 but diminished by day 3. Endothelin-1 was induced

slightly at day 3 but not MMP-2. The most remarkable induction occurred with iNOS in the lung at day 1. RAGE expression decreased in lung at day 1, while Oldlr-1 increased slightly at day 3. Although the effects on the aorta were milder than what was observed in lung, the response was significant and occurred at day 3 with most markers. Aorta MMP-2, HO-1, endothelin-1, iNOS and eNOS were induced up to 3-fold by all three PM at day 3. PAI-1 and tPA were not induced consistently or significantly. Unlike lung, both Oldlr1 and RAGE expressions were increased in the aorta. We provide the evidence of delayed vascular effects from ambient PM exposure that are reflective of oxidative stress, vasoconstriction, matrix abnormalities and increased thrombosis likely mediated via upregulation of RAGE and Oldlr-1. (Does not reflect US EPA policy). Supported by EPA SEE Program, and EPA/UNC co-op #CR83346301.

PL 1283 ARSENIC INDUCES ENDOTHELIAL ACTIVATION, INFLAMMATION AND ATHEROSCLEROTIC LESION FORMATION.

S. E. D'Souza[1], S. D. Sithu[1], M. A. Siddiqui[2], E. N. Vladykovskaya[2], P. Haberzettl[2], J. States[3] and S. Srivasyava[2]. *[1]Physiology, University of Louisville, Louisville, KY, [2]Medicine, University of Louisville, Louisville, KY and [3]Pharmacology and Toxicology, University of Louisville, Louisville, KY.*

Exposure to arsenic increases cardiovascular disease, especially atherosclerosis in humans and experimental animals. However, little is known about the biochemical mechanisms by which arsenic exacerbates atherogenesis. In the present study we show that in vitro, sodium arsenite (5-20 μM), significantly ($P<0.05$) induces the surface expression of adhesion molecules ICAM-1, VCAM-1 and increases the expression of MT-1 MMP in vascular endothelial cells. Incubation of endothelial cells with sodium arsenite (5-20 μM) increased the transmigration of activated monocytic (THP-1) cells in a concentration dependent manner and anti-MT-1 antibodies (10 μg/mL) attenuated the arsenic-induced transmigration of monocytes. Moreover, we also observed that in bone marrow derived macrophages, sodium arsenite (5 μM) increased the foam cell formation by 1.8 fold and expression of the mRNA of cytokine, IL-6 by 7 fold. In vivo, sodium arsenite (1, 4.9 and 49 ppm) feeding to three week old apoE-/- mice for 13 weeks increased the lesion formation ($P<0.01$), accumulation of macrophages in lesions ($P<0.01$) and expression of chemokine, MCP-1 in the proliferative area of the lesion. Moreover, circulating levels of soluble ICAM-1 and MCP-1 were also significantly higher in the arsenic-fed mice. These data suggest that exposure to arsenic stimulates endothelial activation, inflammation and exacerbates plaque formation.

PL 1284 EXPOSURE TO PARTICULATE AIR POLLUTION IN CHILDHOOD INCREASES SUSCEPTIBILITY TO DIABETES/INSULIN RESISTANCE DEVELOPMENT IN ADULTHOOD.

M. Verdin[1], Z. Yavar[1], G. Mihai[1], Z. Ying[1], T. Kampfrath[1], X. Hong[3], A. Wang[1], T. R. Williams[1], M. Zhong[2], L. Chen[2], S. Rajagopalan[1] and Q. Sun[1]. *[1]The Ohio State University, Columbus, OH, [2]New York University, Tuxedo, NY and [3]Dongfang Hospital, Fuzhou, China.*

Background: Obesity has become a leading cause of preventable morbidity and mortality worldwide, and its rapid increase in genetically stable population points at the importance of environmental factors, such as fine particulate matter (diameter <2.5μm, $PM_{2.5}$). We hypothesized that exposure to $PM_{2.5}$ during childhood increases the susceptibility to type 2 diabetes mellitus (T2DM) and insulin resistance (IR) development in adulthood. Methods: Male C57BL/6 mice at 3-4 weeks old were randomly exposed to either concentrated ambient $PM_{2.5}$ or filtered air (FA) in a whole-body exposure system "OASIS-1" in Columbus, OH for 10 weeks (6 hours/day, 5 days/week). During the exposure period, mice were fed either normal chow (NC, 13% calories from fat) or high fat chow (HFC, 60% calories from fat). Results: The mean (SD) daily $PM_{2.5}$ concentration was 15.8 (6.1) $\mu g/m^3$ at the study site in Tuxedo, 111.0 $\mu g/m^3$ in the exposure chamber (approximately 7-fold concentration from ambient Tuxedo levels). Intraperitoneal glucose tolerance tests indicated glucose metabolic abnormality and IR in the $PM_{2.5}$ exposed mice fed with either chow. The $PM_{2.5}$ exposed mice exhibited increased constriction response to phenylephrine and decreased relaxation response to endothelium dependent vasodilator acetylcholine in aortic segments when compared to the FA groups. Magnetic resonance imaging (MRI) indicated visceral adipose tissue increase in the $PM_{2.5}$-HFC mice compared to the FA-HFC mice while no difference was detected between $PM_{2.5}$-NC and FA-NC. Via intravital microscopy, $PM_{2.5}$ exposure induced marked increase in adherent and rolling monocytes in the cremaster circulation when compared to the FA treated mice, and HFC exaggerated the $PM_{2.5}$ effects. Conclusion: Exposure to ambient $PM_{2.5}$ in childhood potentiates T2DM, vascular and systemic IR in adulthood. High fat diet significantly worsens the effects of $PM_{2.5}$.

PL 1285 INTERSTRAIN VARIATION IN CARDIAC AND RESPIRATORY ADAPTATION WITH ACUTE PARTICULATE MATTER (PM) AND OZONE (O3) EXPOSURES.

A. Hamade[1], R. Rabold[2] and C. G. Tankersley[2]. *[1]Gradient Corporation, Cambridge, MA and [2]Johns Hopkins University, Baltimore, MD.*

OBJECTIVES: Increased ambient PM and O3 are associated with adverse cardiac and respiratory events in humans. However, the mechanisms by which PM and O3 affect cardiac function remain uncertain. It is accepted that physiological adaptation to acute O3 exposures involves the cardiac and respiratory systems. We hypothesize that adaptation to PM and O3 is strain dependent in mice. In addition, the adaptation to O3 is an integrated response involving cardio-respiratory coordination. STUDY DESIGN: Heart Rate (HR), HR variability (HRV), respiratory rate (RR), and core temparature were assessed by implanted telemeters and plethysmography in 3 inbred mouse strains; C57Bl/6J (B6), C3H/HeJ (HeJ) and C3H/HeOuJ (OuJ). Mice were exposed for 3 consecutive days to either filtered air (FA), carbon black particles (CB), or O3 and CB sequentially (O3CB). RESULTS: Time-dependent changes in response to O3CB and O3FA exposures were observed in each strain relative to FAFA. These changes were most prominent in HeJ and OuJ mice. For example, HeJ and OuJ mice demonstrated dramatic increases in HRV with reductions in HR during O3CB exposure. In contrast, depressed HR occurred in B6 mice with only slight changes in HRV. Moreover, each mouse strain show distinct adaptation profiles to repeated O3CB exposures. The B6 mice were either unresponsive or rapidly adaptive. In contrast, HeJ mice generally showed marked responsiveness and adapted after 2-days of exposure; and the OuJ mice showed marked responsiveness with only modest adaptation over the 3-day O3CB exposure. Likewise, HeJ and OuJ mice demonstrated rapid breathing with O3CB exposure, whereas B6 mice showed no change in RR. CONCLUSIONS: These findings suggest that genetic factors determine the magnitude of the response to acute co-pollutant exposures, which may determine susceptibility to air pollutant morbidity and mortality. Moreover, physiological adaptation to O3 exposure may involve a coordinated integration among the cardiovascular and respiratory systems.

PL 1286 RAT MODELS OF CARDIOVASCULAR DISEASE DEMONSTRATE DISTINCTIVE PULMONARY GENE EXPRESSIONS FOR VASCULAR RESPONSE GENES: IMPACT OF OZONE EXPOSURE.

W. O. Ward, M. C. Schladweiler, A. D. Ledbetter and U. P. Kodavanti. *NHEERL, U.S. EPA, Research Triangle Park, NC.*

Comparative gene expression profiling of tissues from rat strains with genetic diverse cardiovascular diseases (CVD) can help decode the transcriptional program that governs organ-specific functions. We examined expressions of CVD genes in lungs of rat models at baseline and following ozone exposure to reveal mechanisms of susceptibility. Gene lists for heart failure, obesity, hypertension and stroke were compiled from literature. Each list was distinct with a maximum overlap of 19% between two lists. Using rat 230A Affymetrix GeneChips, lung expression was measured for male 12-14 week Wistar Kyoto (WKY, healthy), Spontaneously Hypertensive (SH), Stroke-Prone SH (SHRSP), Heart Failure SH (SHHF) and Diabetic (JCR) rats following air or 1.0 ppm ozone exposure for 4 hrs. Principle component analysis for each gene list identified clusters for each of the rat strains. For hypertension genes there were three clusters with similar gene expression: 1) JCR; 2) WKY, SHR, and SHRSP; and 3) SHHF strain. Those regulating vasoconstriction were induced in JCR but down-regulated in other strains. Vasodilation genes were suppressed in JCR but upregulated in other strains. For heart failure and stroke genes there were three clusters: 1) JCR; 2) WKY; and 3) SHR, SHHF and SHRSP strains. For obesity genes, there were three clusters: 1) JCR; 2) SHR, SHRSP, and WKY; and 3) SHHF strain. The similarity of expression response among the SHR, SHRSP, and WKY rats could be attributable to known similarity among their genomes. Ozone caused minimal pulmonary response (few genes changed) in JCR but marked response in other strains (WKY>SHRSP>SHR>SHHF>>JCR). Based on analysis of functional categories, heart failure genes appeared most affected by ozone in JCR, SHRSP and WKY, while stroke genes were altered in the SHR. Our study demonstrates how pulmonary expression patterns are influenced by cardiovascular disease and provides insights into the mechanisms of ozone susceptibility differences among disease models. (Does not reflect US EPA policy.)

PL 1287 A SINGLE TRANSITION METAL-RICH PARTICULATE INHALATION EXPOSURE ELICITS CONCENTRATION-DEPENDENT CARDIOVASCULAR TOXICITY IN HYPERTENSIVE RATS.

A. Farraj[1], D. Winsett[1], N. Haykal-Coates[1], M. Hazari[1], A. Carll[2], A. Ledbetter[1] and D. Costa[3]. *[1]Experimental Toxicology Division, U.S. Environmental Protection Agency, Research Triangle Park, NC, [2]School of Public Health, University of North Carolina, Chapel Hill, NC and [3]Office of Research and Development, U.S. Environmental Protection Agency, Research Triangle Park, NC.*

Recently, investigators in the CALFINE study demonstrated an association between the fine particulate matter (PM)-associated metals, Ni and Fe, in ambient air in nine California counties and increased cardiovascular mortality (Ostro et al. 2007). Residual oil fly ash (ROFA), a waste product of fossil fuel combustion from boilers, is rich in the transition metals Fe, Ni, and V, and when released as a fugitive particle, is an important contributor to ambient fine particulate air pollution. We hypothesized that a single acute inhalation exposure to transition metal-rich particulate matter will cause concentration-dependent cardiovascular toxicity in Spontaneously Hypertensive (SH) rats. Rats were exposed once by nose-only inhalation for 4 hours to 3.5 mg/m3, 1.0 mg/m3 or 0.45 mg/m3 of a synthetic particulate matter (dried salt solution) consisting of Fe, Ni and V sulfates and that is similar in composition to a well-studied ROFA sample. Twenty-four hours after exposure, only the high dose caused an increase in plasma Angiotensin Converting Enzyme (ACE), an enzyme that stimulates vasoconstriction and increased blood pressure, and serum myoglobin, a muscle protein released by injured cardiac myocytes. Only rats exposed to 1.0 mg/m3 of ROFA had increased heart fatty acid binding protein (HFABP), a marker of myocardial infarction in humans. Thus, metal particulate exposure increased circulatory markers of cardiac injury and disease in rats with hypertension suggesting that metal components of PM may be acutely toxic in individuals with pre-existing cardiovascular disease. Heart rate, core body temperature, activity, and electrocardiogram data are currently being analyzed to assess the physiological effects of metal sulfate particle exposure (This abstract does not reflect EPA policy).

PL 1288 RESVERATROL (TRANS-3, 5, 4'-TRIHYDROXYSTILBENE) PROTECTS THE FETUS FROM THE IMMUNOTOXIC EFFECTS OF TCDD FOLLOWING PERINATAL EXPOSURE BY BLOCKING AHR ACTIVATION.

N. Singh, M. Nagarkatti and P. Nagarkatti. *Pathology, Microbiology, and Immunology, Univ of South Carolina School of Medicine, Columbia, SC.*

TCDD, an environmental pollutant that causes thymic atrophy and immunotoxicity, severely affects both maternal and fetal immune system during pregnancy. TCDD mediates its toxic effects primarily through activation of aryl hydrocarbon receptor (AhR). Resveratrol, a natural phytoalexin present in plant products including grapes and nuts, exhibits anti-cancer, anti-oxidant, and anti-inflammatory properties. It is also known to act as an AhR antagonist. In the current study, we investigated whether resveratrol when administered into pregnant (C57BL/6) mice can reverse the immunotoxicity of TCDD in the mother and the fetus. Resveratrol at lower concentrations (1-5 μM) acted as an AhR antagonist and blocked TCDD-induced upregulation of Fas and FasL expression in T cells and consequent apoptosis in T cells. Moreover, resveratrol protected the pregnant mothers and their fetuses from TCDD-induced thymic atrophy, phenotypic changes and apoptosis. Also, there was significantly reduced expression of CYP1A1 in thymus and liver when resveratrol was used in vivo post-TCDD exposure. Significant reduction in luciferase expression under the control of CYP1A1 promoter was observed when resveratrol was added in culture with TCDD. Together, these studies demonstrate that consumption of resveratrol, a natural plant product during pregnancy can protect fetus from TCDD-mediated immunotoxicity (This work was supported in part by NIH grants P01AT003961-01A1, R01AI053703, R01ES09098, R01AI058300, R01DA016545, and R01HL058641).

PL 1289 ROLE OF NF-κB/REL PROTEINS IN MODULATING THE 3′IgHRR BY LPS AND TCDD.

R. Salisbury and C. Sulentic. *Wright State University, Dayton, OH.*

Transcriptional regulation of the immunoglobulin heavy chain (IgH) gene involves several regulatory elements including the 3′IgH regulatory region (3′IgHRR). The 3′IgHRR is composed of at least four enhancers (hs3A; hs1,2; hs3B; hs4) and contains binding sites for several transcription factors including NF-κB/Rel proteins. The dioxin responsive element (DRE) may also contribute to 3′IgHRR regulation. 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD), a known disrupter of B-cell differentiation, induces binding of the aryl hydrocarbon receptor (AhR) to a DRE motif within both the hs1,2 and hs4 enhancers. Interestingly, in transient luciferase reporter studies TCDD profoundly inhibited the activation of a 3′IgHRR by the B-cell activator lipopolysaccharide (LPS) but enhanced LPS-induced activation of the hs4 enhancer. Within the hs4 enhancer, the DRE overlaps an NF-κB/Rel binding site (κB) and site-directed mutational analysis demonstrated a cooperative interaction between proteins binding to these motifs. The objective of the current studies was to evaluate the expression of NF-κB/Rel proteins including their negative regulator IκBα following LPS stimulation and TCDD treatment and to compare these results to 3′IgHRR activity under the same treatment conditions. For these studies we utilized the CH12.LX B-cell line and its variant, CH12.IκBαAA, which expresses an inducible IκBα super repressor (IκBαAA). Western blot analysis of LPS-stimulated CH12.IκBαAA cells demonstrated a decrease in endogenous IκBα with a reciprocal increase in nuclear RelA which appeared to be diminished when IκBαAA was expressed. Utilizing transiently expressed luciferase reporters, induction of IκBαAA expression partially attenuated both LPS-induced activation of the 3′IgHRR as well as hs4 activation following an LPS and TCDD co-treatment. Also, co-immunoprecipitation (Co-IP) assays with the CH12.LX cells have demonstrated an interaction between the AhR and NF-κB/Rel. These results suggest that NF-κB/Rel proteins, perhaps through an interaction with the AhR, are at least partially responsible for 3′IgHRR modulation by LPS and TCDD. (Supported by NIEHS R01ES014676)

PL 1290 GENERATION OF NOVEL "REGULATORY" DENDRITIC CELLS *VIA* AHR ACTIVATION.

J. Bankoti[1, 2], T. Simones[1, 2] and D. M. Shepherd[1, 2]. *[1]Ctr for Environ Hlth Sci, University of Montana, Missoula, MT and [2]Department of Biomedical & Pharmaceutical Sciences, University of Montana, Missoula, MT.*

Dendritic cells (DCs) are key antigen presenting cells governing T cell activation and differentiation. TCDD, the prototypical AhR ligand, has been shown to affect the differentiation of murine bone marrow-derived dendritic cells (BMDCs). Previous studies have also demonstrated that TCDD and 6-formylindolo[3,2-b]carbazole (FICZ), an endogenous AhR ligand, can induce Tregs or Th17 cells, respectively. Induction of indoleamine 2,3–dioxygenase (IDO) has been implicated in AhR-mediated immune suppression. However, the effects of AhR activation on two DC subpopulations - inflammatory (GM-CSF-derived) DCs and steady-state (Flt-3-derived) DCs - have not been investigated. We hypothesize that AhR activation induces novel regulatory DCs from both inflammatory and steady-state DCs. To test this hypothesis, inflammatory or steady-state BMDCs were generated in the presence of vehicle, TCDD, or FICZ. Both TCDD and FICZ decreased expression of CD11c but increased MHC class II and CD86 expression on inflammatory BMDCs. TCDD increased levels of both IDO and IDO2 mRNA in inflammatory BMDCs by 18 and 24-fold, respectively. TCDD also upregulated LPS-and CpG-induced TNF-α and IL-6 production by these BMDCs. Previous studies have shown that AhR activation can alter NF-kB signaling. TCDD downregulated LPS- and CpG-induced p65 levels and induced a trend towards upregulation of RelB levels in inflammatory BMDCs. In contrast, steady-state DCs treated with TCDD expressed lower levels of CD11c but increased CD86 expression. Following stimulation with CpG or LPS, TCDD decreased TNF-α and IL-6 production by steady-state BMDCs. TCDD induced a 7-fold increase in IDO2 mRNA levels in steady-state DCs but had no effect on IDO. Overall, our results suggest that AhR activation differentially affects inflammatory and steady-state DCs thereby contributing to the generation of regulatory DCs that may ultimately direct the production of Tregs or Th17 cells. This research was supported by grants from NIEHS (ES013784) and NCRR (RR17670).

PL 1291 PATHWAYS OF PFOA-MEDIATED IMMUNOSUPPRESSION.

J. DeWitt[1], C. Copeland[2] and R. Luebke[2]. *[1]Pharmacology and Toxicology, East Carolina University, Greenville, NC and [2]Immunotoxicology Branch, ETD/NHEERL/ORD/U.S. EPA, RTP, NC.*

Perfluorooctanoic acid (PFOA) is an environmentally persistent industrial chemical that is present in human and wildlife populations worldwide and has been reported to suppress T cell-dependent antibody responses (TDAR) after 10 to 28 days of exposure. Various modes of action have been proposed, including activation of the peroxisome proliferator activated receptor alpha (PPARa), generalized systemic toxicity leading to excess corticosterone release, or other, as yet undetermined, pathways. To evaluate the role of PPARa, we exposed female C57BL/6 PPARa null and wild-type mice to 3.75 to 30 mg/kg PFOA in drinking water for 15d. On d11 of dosing, mice were immunized with sheep red blood cells (SRBCs). Serum was collected for IgM titers 1d after dosing ended. Relative to controls, IgM titers were suppressed ($p < 0.05$) in both wild-type and PPARa null mice exposed to 30 mg/kg. At this dose, spleen weights were reduced by approximately 30% in wild-type mice

and were unchanged in null mice; thymus weights were unaltered in both wild-type and null mice and liver weights were elevated in both. The role of elevated glucocorticoids in immunosuppression was addressed by exposing adrenalectomized (adx) and sham-operated female C57BL/6 mice to 7.5 or 15 mg/kg PFOA in drinking water for 10d. Mice were immunized and bled as in experiments with PPARa null mice. Suppression ($p < 0.05$) of IgM titers was similar in sham-operated and adx mice. These studies suggest that the mechanisms by which PFOA affects TDAR are not mediated by PPARa receptor activation or by excess corticosterone release. Additional work with T cell-independent antibody responses and with adrenalectomized PPARa null mice are planned to further elucidate the mechanism of PFOA-induced antibody suppression (This abstract does not reflect EPA policy and was supported by UNC/EPA Cooperative Training Agreement CT829472.)

PL 1292 MECHANISMS OF ETHANOL MEDIATED INHIBITION OF TOLL-LIKE RECEPTOR SIGNALING IN MACROPHAGES.

K. von Maltzan[2] and S. Pruett[1]. [1]*Department of Basic Sciences, Mississippi State University, Mississippi State, MS and* [2]*Cellular Biology & Anatomy, LSU Health Sci. Center, Shreveport, LA.*

The mechanisms underlying the effects of alcohol on host defense are still poorly understood. Previous studies indicate that ethanol interferes with LPS induced TLR4/CD14 complex formation and receptor clustering, thus inhibiting effective signaling. TLR3 is not known to cluster or to be recruited to lipid rafts like TLR4. As ethanol still seems to inhibit the poly I:C-induced cytokine production by macrophages, it may act by other mechanisms. In an ELISA-type assay, binding of poly I:C to TLR3 protein was tested. No inhibiting effect of ethanol on poly I:C binding to TLR was found, but butanol seemed to increase binding, suggesting that inhibition of ligand binding is not a mechanism of ethanol action. ELISA assay studies on cell culture supernatants indicated that alcohols from methanol through pentanol were tested for their ability to inhibit the LPS and poly I:C induced cytokine response. The macrophage like cell line RAW 264.7 was activated with 50 ng/ml LPS, or with 50 μg/ml poly I:C. It was found that the efficiency of the tested alcohols in decreasing the cells pathogen induced TNF production positively correlates with their carbon chain length. Interestingly, the effect of isopropanol was in between the effects of ethanol and 1-propanol. The mechanism behind these phenomena will be subject to further evaluation. To determine whether the effects of ethanol on TNF production is mediated at the post-transcriptional rather than the transcriptional level, RAW 264.7 cells were treated with the translation inhibitor cycloheximide together with LPS or poly I:C challenge. Cells were treated with 5 μg/ml cycloheximide, and at the same time point with 50 ng/ml LPS, or 50 μg/ml poly I:C. The TNF response completely vanished. Even when applied 20 min after challenge with LPS or poly I:C, cycloheximide almost completely abrogated the TNF response. If TNF protein had been stored in the cell, this would not have occurred. This work was funded by grant AA009505 from NIAAA.

PL 1293 15D-PGJ2-G, A PUTATIVE METABOLITE OF 2-ARACHIDONYL GLYCEROL, ACTIVATES PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR γ

P. Raman[1], B. L. Kaplan[1], J. T. Thompson[2], J. P. Vanden Heuvel[2] and N. E. Kaminski[1]. [1]*Pharmacology and Toxicology, Center for Integrative Toxicology, Michigan State University, East Lansing, MI and* [2]*Veterinary Science and Biomedical Sciences, Center for Molecular Toxicology and Carcinogenesis, Pennsylvania State University, University Park, PA.*

Previous published results from our laboratory demonstrated that 2-arachidonyl glycerol (2-AG), an endocannabinoid, suppressed IL-2 secretion in activated T cells by the activation of peroxisome proliferator activated receptor γ (PPARγ) independent of the cannabinoid receptors, CB1 and CB2. 2-AG is structurally similar to arachidonic acid and a comparison of the eicosanoid pathway of arachidonic acid and 2-AG predicts that the potential metabolites of 2-AG are glycerol esters of various prostaglandins and thromboxanes produced from arachidonic acid. One of the putative metabolites of 2-AG is a glycerol ester of a prostaglandin, 15d-PGJ2-G. Treatment of Jurkat T cells with increasing concentrations of 15d-PGJ2-G followed by activation with phorbol ester and ionomycin demonstrated that 15d-PGJ2-G suppressed IL-2 secretion in activated T cells in a concentration-dependent manner. Since one of the known ligands for PPARγ is 15d-PGJ2, it was investigated if 15d-PGJ2-G served as a ligand for PPARγ. Cotransfection of HEK293T cells with PPARγ-LBD plasmid and pFR-luc reporter plasmid followed by treatment with 15d-PGJ2-G demonstrated that 15d-PGJ2-G transcriptionally activated PPARγ-LBD in a concentration-dependent manner. In addition, the increase in luciferase activity caused by increasing concentrations of 15d-PGJ2-G was inhibited in the presence of a PPARγ antagonist, T0070907. We hypothesize that 15d-PGJ2-G is a metabolite of 2-AG and is responsible for IL-2 suppression by acting in a CB1/CB2 independent manner through the activation of PPARγ. (Support in part by NIH RO1 DA12740)

PL 1294 SHORT-TERM SODIUM TUNGSTATE EXPOSURE REDUCES THE QUANTITY OF CYTOTOXIC AND HELPER T-CELLS IN C57BL6 MICE AFTER IMMUNE CHALLENGE.

A. Osterburg[2], D. Carson[2], M. Sun[2], D. Wagner[1], A. Olabisi[1], M. Stockelman[1], S. Schwemberger[1], P. G. Gunasekar[1], G. Chapman[1] and G. Babcock[2]. [1]*Department of Navy, Naval Health Research Center Detachment Environmental Health Effects Laboratory, Dayton, OH and* [2]*Shriners Hospitals for Children, University of Cincinnati, Cincinnati, OH.*

Tungsten as the water-soluble tungstate (WO4-) has been identified as a water contaminant and can be absorbed by ingestion. In this study, we examined the effect of 28-day sodium tungstate (Na2WO4-2H2O) exposure in drinking water on murine leukocytes after immune challenge. Drinking water included weight adjusted tungstate concentrations of 0, 62.5, 125 and 200 mg/kg/day. Additionally, mice were given a specialized molybdenum free diet (0 ppm). After 28 days of tungstate exposure, and 24 hr prior to sacrifice, mice were given (i.p.) saline, lipopolysaccharide (LPS) (5 mg/kg), or Staphylococcus aureus enterotoxin B (SEB) (20 μg). Following sacrifice, splenocytes and blood were isolated and cells were surface stained with a panel of lymphocyte (CD3, CD4, CD8, CD19, CD71) and myeloid (CD11b, Ly-6C, Ly-6G, F4/80) antibodies. Flow cytometric analysis revealed that cytotoxic T-cells (CD3+CD8+) and helper T-cells (CD3+CD4+) from spleens had a dose dependent reduction in activation/proliferation as measured by CD71 positivity. In SEB treated mice the CD71 positive cytotoxic T-cells in 0 and 200 mg/kg/d treatment groups were 12.87% ± 2.05 SE vs 4.44% ± 1.42 ($P<0.001$), respectively. Helper T-cells were reduced 5.85% ± 1.23 vs. 2.76% ± 0.51 ($P<0.001$), respectively. There was also a trend toward reduced numbers of CD71 positive NK cells (CD161c+) cells in LPS treated mice. The effects of tungstate were only observed in the spleen and not blood. Myeloid cells appeared not to be affected by tungstate exposure. Reduced numbers of activated/proliferating cytotoxic and helper T-cells in response to challenge may result in susceptibility to infections. These data suggest that tungstate exposure may have a detrimental effect on the adaptive immune response.

PL 1295 ACTIVATION OF THE TRANSCRIPTION FACTOR, NUCLEAR FACTOR ERYTHROID 2-RELATED FACTOR 2 (NRF2), INHIBITS IFN GAMMA PRODUCTION BY MURINE T CELLS.

C. E. Rockwell and C. D. Klaassen. *Pharmacology, Toxicology, & Experimental Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Nrf2 is a transcription factor that upregulates numerous cytoprotective genes in response to electrophilic and oxidative stimuli. Although best characterized for its role in the regulation of detoxification and antioxidative genes, Nrf2 also plays an anti-inflammatory role in macrophages and other myeloid cells. The purpose of the present studies was to determine the expression and function of Nrf2 in mature murine T cells. Nrf2 mRNA is detectable in mature CD3+ T cells and is upregulated by the Nrf2 activator, tert-butylhydroquinone (tBHQ). In addition, tBHQ induces expression of the Nrf2 target genes, Ho-1, Nqo1, and Gclc in wild-type, but not Nrf2-null CD3+ T cells, suggesting the induction is Nrf2-dependent. Furthermore, tBHQ, as well as another Nrf2 activator, butylated hydroxyanisole (BHA), markedly inhibit IFNγ transcription and secretion in wild-type CD3/CD28-activated splenocytes. In contrast, tBHQ and BHA have little effect upon IFNγ transcription in Nrf2-null splenocytes. Consistent with the effects on IFNγ transcription, tBHQ inhibits binding to both the AP-1 and NFκB response elements in wild-type CD3+ cells, but only modestly inhibits AP-1/NFκB binding in Nrf2-null CD3+ cells, suggesting the effects on the AP-1 and NFκB binding sites are partially Nrf2-dependent. Interestingly, Nrf2-null T cells produce markedly higher levels of IFNγ than wild-type T cells in the absence of any exogenous activators. Collectively, the present studies demonstrate Nrf2 is expressed and functional in CD3+ T cells as evidenced by the Nrf2-dependent upregulation of Nrf2 target genes, including Ho-1, Nqo1, and Gclc. Moreover, the current studies suggest Nrf2 activation markedly inhibits IFNγ transcription, which is likely due in part to decreased binding to the AP-1 and NFκB response elements. Overall, the present studies suggest Nrf2 represents a novel regulatory mechanism in mature murine T cells. (Supported by NIH grants ES09716, ES07079, ES013714, ES09649, and RR021940.)

PL 1296 TRICLOSAN GLUCURONIDATION AND SULFONATION IN CHANNEL CATFISH LIVER FRACTIONS.

M. O. James and C. J. Marth. *Medicinal Chemistry, University of Florida, Gainesville, FL.*

The personal care product and antibacterial agent Triclosan has been found in wastewater and sediments from sewage treatment plants. As a lipophilic compound with log P of >4, Triclosan would be expected to bioaccumulate in exposed fish. However, the phenolic hydroxyl group in Triclosan's structure suggests the possibility that this substance will be glucuronidated or sulfonated, resulting in reduced bioaccumulation. We therefore examined microsomal glucuronidation and cytosolic sulfonation of Triclosan in channel catfish liver using 14C-UDPGA or 35S-PAPS to follow the conjugation reactions. Subcellular fractions were prepared from livers of five control fish and assays were conducted at 20°C. To obtain kinetic parameters for each pathway, linear conditions for product formation were established with respect to protein concentration and incubation time, then incubations were conducted with varying concentrations of triclosan and saturating concentrations of UDPGA or PAPS. Reaction rates were fit to the Michaelis-Menten equation or the equation for substrate inhibition, as appropriate. Glucuronidation followed classic Michaelis-Menten kinetics: the Km for hepatic glucuronidation was 41 + 15 μM (mean + S.D., n=5 samples) and Vmax was 968 + 385 pmol/min/mg protein. Sulfonation exhibited substrate inhibition at triclosan concentrations above 10 μM. The Km was 3 + 1 μM Vmax was 831 + 190 pmol/min/mg protein and Ki was 86 + 48 μM. Compared with other halogenated phenolic xenobiotics, Triclosan was efficiently sulfonated and glucuronidated in catfish liver, suggesting this compound will be rapidly eliminated from exposed fish.

PL 1297 TOXICITY AND BIOTRANSFORMATION OF POLYBROMINATED DIPHENYL ETHERS IN AVIAN EMBRYOS.

B. A. Rattner[1], M. A. McKernan[1], R. C. Hale[2] and M. Ottinger[3]. [1]*Patuxent Wildlife Research Center, U.S. Geological Survey, Beltsville, MD,* [2]*Department of Environmental and Aquatic Animal Health, Virginia Institute of Marine Science, Gloucester Point, VA and* [3]*Department of Animal and Avian Sciences, University of Maryland, College Park, MD.*

Concentrations of polybrominated diphenyl ethers (PBDEs) in eggs of wild birds have increased dramatically over the past 25 years, yet only limited data are available to interpret toxicological consequences of exposure. Embryonic survival, pipping and hatching success, and sublethal biochemical, endocrine, and histological endpoints were examined in chicken (Gallus gallus), mallard (Anas platyrhynchos), and American kestrel (Falco sparverius) hatchlings following in ovo (air cell) administration of the commercial penta-BDE mixture DE-71 (0.01-20 μg DE-71/g egg). Environmentally realistic concentrations of DE-71 induced ethoxyresorufin-O-dealkylase activity, and reduced bursa of Fabricius follicle size and number in chicken hatchlings, but not in other species. Pipping and hatching success decreased in American kestrels receiving 10 and 20 μg DE-71/g egg, but these endpoints were unaffected in other species. Absorption of air cell administered DE-71 (dose = 11.1 μg/g egg) into the contents of eggs varied among species and uptake rate tended to increase during the latter half of development (dose absorbed by pipping: chicken 29.6%, kestrel 18.8%). Several PBDE congeners and two metabolites were detected in DE-71 dosed eggs that were not present in the dosing solution, providing some evidence of debromination and methoxylation. Uptake of the commercial octa-BDE mixture DE-79 (dose = 15.4 μg /g egg) following air cell administration to avian eggs was found to be low (dose absorbed <6.5%). Based on the DE-71 uptake rate in kestrels, the lowest observable effect level on pipping and hatching success may be 1.8 μg total PBDE/g egg, which approaches concentrations detected in eggs of free-ranging birds. As some PBDE congeners are still increasing in the environment, the embryotoxic effects observed following DE-71 administration are cause for concern.

PL 1298 MARINE BIOCIDE COPPER PYRITHIONE (COPPER 2-PYRIDINETHIOL-1-OXIDE) ALTERS GILL MORPHOLOGY AND INCREASES OXIDATIVE STRESS IN JUVENILE BROOK TROUT, *SALVELINUS FONTINALIS.*

D. Borg and L. D. Trombetta. *Pharmaceutical Sciences, St. Johns University, New York, NY.*

Copper Pyrithione (CuPT) is currently a leading candidate to replace globally banned tributyltin although studies have been limited concerning its effects on other aquatic life. CuPT exposure on juvenile brook trout, *Salvelinus fontinalis*, was investigated. Morphologic changes,copper bioaccumulation, and markers of oxidative stress in several organ systems were studied. Trout were divided into groups of 10 and exposed to CuPT (dissolved in DMSO) in separate aquaria for a duration of 2 hours. Concentrations of CuPT ranged from 2ppb to 64ppb. Trout were sacrificed and tissue was collected and preserved according to the method of analysis. Results from histological analysis demonstrate the formation of club shaped lamella, significant epithelial lifting and edema, and the fusion of secondary lamella at CuPT concentrations of 16, 32 and 64ppm. ICPAAS analysis demonstrates significantly increased levels of copper in the liver($P < 0.001$) brain ($P < 0.005$) and gill arches ($P < 0.001$)as compared to matched controls. Transmission electron microscopy revealed the presence of altered mitochondrial morphology within the chloride cells of gill tissue. They displayed a swollen appearance with disruption of internal cristae, accumulation of electron dense bodies, and lipid membrane disruption. TBARS demonstrated increased levels of lipid peroxidation products in both gill and brain tissue at CuPT levels of 32ppb ($P < 0.001$) and 64ppb ($P < 0.001$). Assays for the total antioxidant capacity of gill tissue homogenates revealed significantly lowered antioxidant levels at 64ppb CuPT. Scanning electron microscopy of gill tissue revealed epithelial exfoliation, fusion of adjacent lamella, and a loss of microridge structure. Preliminary data indicates that the use of CuPT could be potentially harmful to non-target aquatic organisms. Further study will be needed to elucidate a mechanism of action, but these results indicate that CuPT alters gill tissue morphology and increases oxidative stress in both gill and brain tissue

PL 1299 ENDOCRINE DISRUPTION IN A NORTHERN CALIFORNIA WATERSHED: THE RESPONSE OF A RESIDENT FISH SPECIES.

S. M. Brander and G. N. Cherr. *Bodega Bay Marine Laboratory, Environmental Toxicology, U.C. Davis, Bodega Bay, CA.*

Endocrine disrupting compounds (EDCs) are widespread in the environment and are known to damage the reproductive systems of fishes. Deleterious effects of EDCs include the production of female reproductive proteins and malformed or tumorous testes in adult male fish, reduced egg production in adult females, and altered mating behavior in both sexes. Recent findings suggest that these effects may extend beyond individual fish to influence population declines. Research has also shown that water samples from a number of locations in and near the San Francisco Bay (SF) / Sacramento-San Joaquin (SSJ) watershed in Northern California produce estrogenic responses in adult male rainbow trout. However, rainbow trout are not found throughout this entire estuary and thus may not be representative of the many threatened and endangered native estuarine species that are found across a range of salinities in this watershed. To address this gap in knowledge, our work utilizes a ubiquitous euryhaline resident fish species (*Menidia beryllina*) as an indicator of exposure to reproductive contaminants. Investigations include determining whether specific sites within the SF Bay / SSJ Delta estuary that differ in contaminant inputs (treated wastewater effluent and/or pyrethroid pesticide run-off) cause male *M. beryllina* to express choriogenin, an egg coat protein normally found only in females that is a well-established biomarker of endocrine disruption. Initial work confirms that commercially available salmonid antibodies cross-react with *M. beryllina* choriogenin, permitting rapid assessment tissue and plasma samples. Initial sampling will establish a pattern of EDC distribution at these sites and will be followed by confirmatory laboratory exposures to environmentally relevant concentrations of specific pyrethroid pesticide(s) and the wastewater effluent component ethinylestradiol.

PL 1300 EFFECTS OF CHLORPYRIFOS AND ALDICARB ON FLIGHT ACTIVITY AND RELATED CHOLINESTERASE INHIBITION IN HOMING PIGEONS (COLUMBA LIVIA): POTENTIAL FOR MIGRATION EFFECTS.

J. K. Moye[2] and C. A. Pritsos[1, 2]. [1]*Nutrition, University of Nevada, Reno, NV and* [2]*Environmental Sciences Program, University of Nevada, Reno, NV.*

Since the banning of the organochlorine pesticides in the US, cholinesterase (ChE) inhibiting compounds have become widely used on agricultural and residential areas to control insect infestations. Two of the most widely used cholinesterase inhibiting insecticides in California and the nation are chlorpyrifos, an organophosphate, and aldicarb, a carbamate. There is limited information describing the effects of low-level, environmentally relevant concentrations of ChE inhibitors on the flying ability of avian species. In this study, homing pigeons (Columba livia) were used as a model to assess the effects of chlorpyrifos and aldicarb on flight times at sublethal, environmentally relevant concentrations (0.0, 3.0, 5.0 mg/kg for chlorpyrifos; 0.0, 0.25, 0.5 mg/kg for aldicarb). The results indicated that there was a significant increase in flight times in birds dosed with aldicarb and with 3.0 mg/kg chlorpyrifos but not 5.0 mg/kg. Subsequently, we correlated ChE inhibition with

increases in flight times from pesticide exposure. Blood samples were collected and plasma ChE activity was measured over time following exposure to either chlorpyrifos at 1.0, 2.5, 5.0, and 7.5 mg/kg or aldicarb at 0.1, 0.25, 0.5, and 1.0 mg/kg. The results indicated that chlorpyrifos dosed birds exhibited a dose dependent decrease in activity at the initial time measurements after dosing with full recovery at all dosage levels by 48 hours. All aldicarb dosage groups showed extreme plasma ChE depression at the first post-dose measurement (1 hour) with full recovery by 24 hours. The time of peak inhibition would correlate with migratory flight activity after exposure to a contaminated food or water source. In total, the results of these studies show that low-dose exposure to carbamate and organophosphate pesticides can be detrimental to the flying ability of non-target avian species. These studies were funded in part by Nevada Agricultural Experiment Station Hatch Grant 0731.

PL 1301 HYPOXIA EXACERBATES TOXICITY OF AN ARRAY OF PAHS AND PAH MIXTURES.

C. R. Fleming and R. T. Di Giulio. *Nicholas School for the Environment, Duke University, Durham, NC.*

Previous work in our laboratory revealed that hypoxia interacts with the polycyclic aromatic hydrocarbon (PAH) fluoranthene (FL) and the model PAH α-naphthoflavone to induce pericardial edema and, in the case of FL, spinal deformities in larval zebrafish; exposure to hypoxia and PAH benzo[a]pyrene was found not to induce overt embryotoxicity. In this study, zebrafish were exposed to hypoxia (7.4% O2) or normoxia (21% O2) and PAHs singly (BaP, benzo[k]fluoranthene (BkF), 2-aminoanthracene (AA), Carbazole (CZ), phenanthrene (PH), pyrene (PY)), in combination (BaP/AA, BaP/CZ) or in complex mixtures (coal tar extract (CT), Elizabeth River sediment extract (ERSE)) from 24hpf to 96hpf. Embryos were observed for developmental abnormalities. Hypoxia exacerbated BkF toxicity, inducing pericardial edema and mortality at doses of BkF that are nontoxic in normoxia. Conversely, coexposures to BaP, AA, and CZ did not reveal signs of hypoxia interactions. Preliminary results suggest that PH and PY also do not interact with hypoxia. Hypoxia exacerbated the toxicity of binary mixtures of BaP/AA and BaP/CZ, inducing pericardial edema in both and mortality in BaP/AA. Exposure to CT or ERSE revealed that hypoxia exacerbated the pericardial edema caused by these mixtures and induced mortality. The effect of hypoxia on the toxicity of these real world mixtures indicates that current regulations on PAHs in hypoxia-prone waterways may not be sufficiently protective. PAHs that share known molecular mechanisms did not share patterns of interactions with hypoxia (AhR agonists—BaP and BkF; CYP1A inhibitors—FL, ANF, AA, CZ). Additionally interactions with hypoxia were observed in binary mixtures of compounds that did not interact with hypoxia singly (BaP with AA or CZ). Further research is necessary to understand the mechanism(s) of PAH-hypoxia interactions and why some PAHs interact and others do not. Funded by NIEHS Duke Superfund Basic Research Center (P42 ES10356), NIEHS-supported ITEHP (T32 ES07031), and EPA STAR Fellowship to C. Fleming.

PL 1302 DEVELOPMENTAL AND GROWTH EFFECTS ASSOCIATED WITH ACUTE EXPOSURE OF EGGS TO BISPHENOL A IN RAINBOW TROUT.

N. Aluru[1], J. F. Leatherland[2] and M. M. Vijayan[3]. *[1]Biology, Woods Hole Oceanographic Institution, Woods Hole, MA, [2]Biomedical Sciences, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada and [3]Biology, University of Waterloo, Waterloo, ON, Canada.*

Effect of maternal exposure to xenoestrogens on embryonic development and growth in fish is poorly understood. The objective of this study was to determine the effect of maternal exposure to Bisphenol A (BPA), a xenoestrogen, on development and growth in rainbow trout (Oncorhynchus mykiss). Trout oocytes were exposed to 0, 30 and 100 micro grams/ml of BPA for 3 h in the ovarian fluid to mimic in utero exposure, and this was followed by fertilization. The BPA levels in the embryos showed a declining trend after exposure and was completely eliminated by 21 and 35 d post-fertilization in low and high BPA groups, respectively. Despite the elimination of the contaminant during embryogenesis, high BPA treatment delayed hatching, yolk absorption, time to first feed and growth rate compared to the other two groups. This BPA-treated developmental abnormality correlated with lower insulin-like growth factor (IGF)-2 but not IGF-1 mRNA levels. The deleterious effects on growth rate post-hatching in high BPA group persisted for a longer time (400 days) and corresponded with a suppressed IGF-1, IGF-1 receptor and growth hormone receptor mRNA abundances. Also, juvenile fish from the BPA exposed group showed an abnormal cortisol and glucose response to an acute stressor exposure. Taken together, the results demonstrate that maternal exposure to BPA affects development and leads to growth and performance defects that persist even in juvenile trout.
Acknowledgements: Funding for this study was provided by Natural Sciences and Engineering Research Council, Canada, discovery grant (MMV and JFL) and post-doctoral fellowship (NA).

PL 1303 INFLUENCE OF ORGANOCHLORINE PESTICIDES ON STEROID HOMEOSTASIS AND REPRODUCTIVE INDICES IN LARGEMOUTH BASS (*MICROPTERUS SALMOIDES*).

N. J. Doperalski[1], M. S. Prucha[2], N. D. Denslow[1] and D. S. Barber[1]. *[1]Department of Physiological Sciences, University of Florida, Gainesville, FL and [2]Department of Pharmacology and Therapeutics, University of Florida, Gainesville, FL.*

Organochlorine pesticide (OCP) exposure has been linked to altered plasma sex hormone levels and poor reproductive performance in largemouth bass (LMB). Possible mechanisms for disruption of hormone homeostasis include direct effects on gonadal steroid synthesis or altered hormone metabolism. In this study, effects of *in vivo* and *ex vivo* OCP exposure on ovarian steroidogenesis were investigated. Incubation of ovarian tissue with methoxychlor (MXC) decreased both basal and human chorionic gonadotropin (hCG)-stimulated estradiol (E2) and testosterone (T) synthesis by up to 46 and 92%, respectively. Incubation with toxaphene (TOX) had no effect on basal E2 or T synthesis, but reduced hCG-stimulated synthesis by up to 65 and 74%, respectively. To investigate the influence of *in vivo* exposure to OCPs on gonadal steroidogenesis, E2 production was measured in ovarian explants from LMB after 2 months in a mesocosm containing OCPs. Basal and hCG-stimulated E2 production by control explants was 3.1 ± 0.4 and 4.3 ± 0.6 pg/mg tissue, respectively. Similar production was observed in tissue from exposed LMB (3.3 ± 0.3 and 4.8 ± 0.5 pg/mg, respectively). However, gonadal somatic index (GSI) was significantly lower in exposed LMB (38% of control). In further studies, LMB were administered TOX, MXC, *p,p'*-DDE or dieldrin in the diet for 2 months. While a reduction in ovarian E2 synthesis was observed only in LMB exposed to ethinylestradiol (EE2, positive estrogenic control), curtailed GSIs were induced in females exposed to EE2 and TOX (25 and 53% of control) and *p,p'*-DDE exposure increased hepatosomatic index vs all other groups. Exposure to *p,p'*-DDE or dieldrin had no effect on hepatic estrogen sulfotransferase activity. These findings suggest that OCPs are capable of perturbing gonadal steroidogenesis directly, however compensatory mechanisms may ameliorate this effect when exposure occurs *in vivo*. These studies were supported by NIH R01ES015449.

PL 1304 IMPACT OF THIAMETHOXAM ON GLYCOLYTIC AND GLUCOGENIC ENZYMES OF A FRESH WATER FISH, CHANNA PUNCTATUS.

V. R. Chintalapani. *Biochemistry, Chaitanya Degree and P.G. College (Autonomous), Warangal, Andhrapradesh, India.* Sponsor: C. Chetty.

Thiamethoxam (TMX) is the first commercial neonicotinoid insecticide and is widely used both for foliar/soil applications. It provides excellent control of a broad range of commercially important pests. The recent studies reported that TMX is hepatotoxic and hepatocarcinogenic and induce tumors in mouse liver. The present study investigated in vivo toxic effects of TMX on glucose metabolism in freshwater edible fish, Channa punctatus. The fish were exposed to sublethal concentration (38.26 ppm) of TMX for different time period (24, 48, 72 and 96 hours) to assess the levels of glycogen, glucose, pyruvate and lactate and specific activities of selected enzymes of glucose metabolism in liver, brain, gill, muscle and kidney tissues. The data show a decrease in glycogen and pyruvate levels and an increase in glucose and lactate levels. The specific activities of phosphoglucoisomerase (PGI), phosphofructokinase (PFK), glucose-6-poshphate dehydrogenase (G6PDH), pyruvate carboxylase (PC) and PEP carboxykinase (PEPCK) were significantly increased where as lactate dehydrogenase (LDH), isocitrate dehydrogenase (ICDH), succinate dehydrogenase (SDH), and malate dehydrogenase (MDH) exhibited a decrease as consequence of exposure to TMX. The data suggest that TMX enhanced the mobilization of glucose through increased breakdown of glycogen and reduced the oxidation of glucose to meet the increased energy demands during induced toxic stress condition. The altered enzyme activities could be attributed to the differential effect of TMX resulting in the modulation of glucose metabolism in tissues of fish.

R 1305 CHARACTERIZATION AND APPLICATION OF PBPK MODELS IN RISK ASSESSMENT.

B. Meek[1], U. Gundert-Remy[2], H. Barton[3], H. Clewell[4] and K. Krishnan[5].
[1]McLaughlin Centre for Population Health Risk Assesment, University of Ottawa, Ottawa, ON, Canada, [2]Federal Institute for Risk Assessment, Berlin, Germany, [3]Pfizer Inc, Groton, CT, [4]The Hamner Institutes for Health Sciences, Research Triangle Park, NC and [5]University of Montreal, Montreal, QC, Canada.

Physiologically-based pharmacokinetic (PBPK) models are part of a broader continuum of increasingly data-informed approaches to dose response analysis ranging from default based on external dose to more biologically-realistic models. By facilitating the incorporation of dose measures of relevance to the mode of action of chemicals, and quantitative physiological scaling taking into account relevant chemical-specific physical chemical properties and biological constants, PBPK models provide a representation of biologically effective dose as a basis for conducting more informed extrapolations across studies, species, routes, and dose levels. Resultingly, they increase precision and reduce uncertainty in risk estimates. Despite the availability of PBPK models for a number of chemicals incorporating significant additional biological data over default and the potential of such models to contribute more broadly to the development of additionally informative testing strategies, their adoption in regulatory risk assessment has been limited. This limited uptake is being addressed in a project undertaken as part of the World Health Organization/International Programme on Chemical Safety project on harmonization. The initiative includes preparation of guidance and case studies on the characterization, documentation, evaluation and communication of PBPK models for risk assessment. Aspects being addressed include the need for early and continuing communication between risk assessors and modellers, greater consistency in consideration of mode-of-action as a basis for relevant PBPK models and sufficiently transparent documentation of model development to support potential application. More consistent and transparent consideration of the basis for and output of PBPK models relative to default approaches in risk assessment is also being addressed.

IS 1306 NOVEL TRANSLATIONAL SAFETY BIOMARKERS AND SAFETY FIRST AT THE FDA.

F. D. Sistare. *Safety Assessment, Merck and Co., Inc., West Point, PA.*

The U.S. Food and Drug Administration has initiated a program called "Safety First" that increases focus on the safety evaluation of medical products throughout their life cycle. The safety of therapeutics is extensively evaluated prior to product approval; however, even the most extensive preapproval testing cannot ascertain a safety profile of a product that is used in all possible combinations of genetic backgrounds and health conditions in the population. The goal of Safety First is to bolster continued oversight of drugs already on the market as well as newly emerging products. The Office of Surveillance and Epidemiology at CDER is developing the infrastructure and tools to achieve the goals of Safety First. They will utilize records of large healthcare organizations and electronic medical record databases, coupled with appropriate statistical techniques, to monitor safety signals. The Agency also is accessing new databases listing possible side effects of drugs and their continuing dialog on safety questions. In addition, Translational Safety Biomarkers are important tools both for the development of safer drugs as well as for effective surveillance of marketed drugs. These biomarkers provide a continuous metric with which to measure safety through nonclinical and clinical development. This session will outline how Safety First will be implemented and how novel translational safety biomarkers are needed for its success.

EC 1307 TOXICOLOGISTS: THE NEXT GENERATION.

J. B. Tarloff. *Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA.*

An important component of the Society of Toxicology 2008-2011 Strategic Plan is the priority to build for the future of toxicology. In addition to ongoing K-12, graduate, and postdoctoral fellow educational activities, undergraduate educators have been meeting regularly to exchange ideas and teaching strategies. Principles and applications of toxicology can enter curricula through a variety of mechanisms, from dedicated programs that lead to baccalaureate degrees to single, stand-alone courses that satisfy intellectual curiosity. It is logical that college students who have positive experiences in toxicology courses will be more likely to enter graduate programs and become our next generation of toxicologists. The Undergraduate Educators Forum hopes to establish a repository for course materials and to open the lines of communication for individuals involved in teaching undergraduate students. College-level education in toxicology demands different skills and approaches than those used for graduate or K-12 education. Developing critical thinking and analytical skills is particularly challenging for college students, who are more accustomed to accepting information without critique. In order to foster communication among educators it is important that we illustrate strategies that engage critical thinking and improve student learning and involvement. Several undergraduate college educators will present classroom-based exercises or assessments designed to stimulate student-based learning. Through this forum we will learn what has been developed for upper-level high school students and how these exercises and experiences may be modified for college students. This session will provide a venue for educators to discuss classroom experiences and educational philosophies.

S 1308 FROM MECHANISMS TO BIOMARKERS: BASIC AND APPLIED METABOLOMICS IN TOXICOLOGY.

F. J. Gonzalez. *Laboratory of Metabolism, National Cancer Institute, Bethesda, MD.*
Sponsor: D. Robertson.

The use of metabolomics in the discovery of biomarkers and elucidating mechanisms of human disease is a rapidly expanding field. While nuclear magnetic resonance (NMR) has historically been used in mammalian metabolomics studies, LC/MS and GC/MS, with new and powerful chemometric software, makes this technology more widely available to individual academic laboratories. Metabolomics can also be used to study the metabolism of drugs, toxins and carcinogens and to find biomarkers for drug efficacy and toxicities. Preview studies from both academic and industrial laboratories will be highlighted to show the value of this burgeoning technology.

S 1309 INTRODUCTION TO METABOLOMICS: METABOLITE PROFILING IN TOXICOLOGY.

O. Fiehn. *Department of Molecular and Cellular Biology & Genome Center, University of California, Davis, Davis, CA.* Sponsor: D. Robertson.

Metabolomics is a demanding challenge, for which sophisticated analytical methods, (e.g. GC/MS and LC/MS) are required. Currently, we hold mass spectra, retention indices, structures and links to external metabolic databases for a large number of compounds which are routinely screened by gas chromatography – time of flight mass spectrometry. In addition we develop and apply metabolomic and metabolic fingerprinting methods by high resolution LC/MS and by direct infusion – mass spectrometry. Metabolomics applications follow a two-tiered approach: they can be used for sample discrimination and classification (e.g. for clinical diagnostics or GMO substantial equivalence), or for biochemical and mechanistic studies (e.g. for understanding the onset and progression of human diseases, or for detailing regulatory modules in cells or subcellular compartments). Therefore, we use several biological models on organismal, tissue or cellular levels. Current applications include the linking of metabolic aberrations in fetal, newborn and young adult rat lungs to establish links between the type and amount of transported environmental tobacco smoke components and the magnitude and timing of metabolic aberrations and dysfunction during fetal lung development.

S 1310 FROM DRUG METABOLISM TO DRUG METABOLOMICS.

J. Idle. *Institute of Pharmacology, Charles University, Prague, Czech Republic.*
Sponsor: D. Robertson.

Metabolism is perhaps the single biggest contributor to the systemic toxicity of small organic molecules. The rate and extent of biotransformation of xenobiotics determines not only the delivery to target organs but also the overall toxicity profile at the target organs. Both presystemic and systemic metabolism play a role in modulating the toxicity of xenobiotics and they do so by the processes of detoxication and metabolic activation. In extreme cases, a xenobiotic may display organotropism simply because of the selective expression of enzymes than can metabolically activate that xenobiotic in those organs. Moreover, chemically reactive metabolites may represent small increments of the total exposed dose of toxicant. It is therefore crucial to understand in detail the metabolic map of toxicants to which humans may be exposed. Xenobiotic metabolism has its origins in the mid-1800s and for almost a century its practice involved isolation, purification and simple chemical investigation of urinary constituents. The advent of UV/visible and fluorescence spectroscopy, radiolabeled compounds, and partition chromatography catalyzed a major expansion of activities in the field. But, perhaps the biggest single advance of benefit to xenobiotic metabolism was the development of biomedical mass spectrometry, at first GCMS and subsequently the range of LCMS technologies that we are familiar with today. Drug metabolism may now be conducted by what may be called drug metabolomics. During its short history, metabolomics has generally been thought of as a tool for either discovering cellular responses to external stimuli such as toxicant administration, or cataloging metabolic pathways in health and

disease. In addition to examining endogenous molecular changes in response to stimuli, metabolomics can equally be applied to the examination of xenobiotic metabolites, the footprints of cellular metabolism that are left on compounds foreign to living systems. This presentation will discuss the application of UPLC-ESI-QTOFMS based metabolomics protocols to the reexamination of the metabolism of Aminoflavone, areca alkaloids, PhIP, melatonin and acetaminophen.

S 1311 METABONOMICS IN PHARMACEUTICAL DISCOVERY AND DEVELOPMENT.

D. Robertson. *Applied and Investigative Metabonomics, Bristol-Myers Squibb, Princeton, NJ.*

Metabonomics has emerged as a key technology in pharmaceutical discovery and development, evolving as the small molecule counterpart of transcriptomics and proteomics. A critical component of any toxicology study is a thorough characterization of the experimental models employed in our investigations and the biochemical ramifications of the interaction of the employed model with the compound under study. Metabonomics engenders such understanding at a much broader level than traditional toxicity endpoints. This presentation will focus on recent developments in the pharmaceutical application of metabonomics technology emphasizing its use in model characterization, mechanistic toxicology and biomarker discovery.

S 1312 METABONOMICS AND TRANSCRIPTOMICS: A SYNERGISTIC APPROACH TO BIOMARKERS AND MECHANISMS OF TOXICITY.

L. Lehman-McKeeman. *Bristol-Myers Squibb, Princeton, NJ.*

Metabonomic profiles can provide important leads for identifying key events underlying toxicologic responses. Furthermore, as a likely phenotypic consequence of altered gene expression, metabonomic changes are important complementary data for determining the systemic relevance or significance of induction or repression of specific gene pathways. Although many investigations have utilized either metabonomic or transcriptomic data to evaluate adverse effects or develop mechanistic hypotheses, the integration of both types of data has not been routinely accomplished. Efforts to integrate these platforms indicate that each can inform the other and augment the identification of the major systemic effects of a xenobiotic. For example, agents such as phenobarbital and diallylsulfide, which induce numerous xenobiotic metabolizing enzymes through activation of the constitutive androstane receptor (CAR), affect hepatic transcriptional changes in rats of a wide variety of recognized CAR-dependent genes. However, the urinary metabonomic profile indicated that the major change in endogenous intermediates was a marked increase in the excretion of gulonic acid, a precursor in ascorbate biosynthesis. With evidence for alterations in Vitamin C metabolism, the transcriptional profiles were re-evaluated, and dose- and time-dependent transcriptional changes in enzymes regulating ascorbic acid biosynthesis and reutilization were identified. Although these transcriptional changes did not represent those that changed to greatest extent, the urinary metabonomic data confirm that they were the most significant with respect to systemic effects on intermediary biochemistry. Similar analyses integrating transcriptional profiles from skeletal muscle with metabolites in urine or tissue extracts have helped to identify to possible biomarkers of skeletal muscle toxicity. Concerted efforts to exploit the relationship between metabonomic and transcriptional profiling data should be pursued in order to advance the use of these technologies for determining mechanisms of toxicity and human safety evaluation.

S 1313 INCORPORATING 'OMICS IN THE STUDY OF REPRODUCTION AND DEVELOPMENT.

S. J. Sumner[1] and T. B. Knudsen[2]. *[1]Metabolomics/Biomarkers, RTI International, Research Triangle Park, NC and [2]National Center for Computational Toxicology, U.S. Environmental Protection Agency, Research Triangle Park, NC.*

In recent years, ground breaking research in genomic applications in the area of reproductive and developmental toxicology have been successful in linking changes in the expression of specific genes and their higher-level biological processes to effects induced by drugs or chemicals in developing tissues. While gene expression profiling has demonstrated the ability to provide mechanistic insight into the cellular mechanisms of drug and chemical-induced effects, proteomics provides advantages in areas beyond the genome. For example, post-translation modifications of proteins that are known to be involved in cell-cell signaling cascades for developmental pathways, the flux-balance in signaling molecules themselves, or the metabolic intermediates connecting to these pathways are important parts of our ability to understand the pathogenesis of fetal malformations. These higher-level operations can be inferred, but not directly evaluated through measurement of mRNA or DNA sequencing. In recent years, the application of proteomics in the study of reproduction and development has rapidly increased, while such studies that incorporate metabolomics approaches are at their infancy. A summary of the recent advances in genomic, proteomic, and metabolomic methodologies that demonstrate the successful use of these technologies in the study of reproduction and development will be provided. Finally, an illustration of how these data may be integrated by multi-scale models of dynamical systems will be highlighted that can serve to improve our understanding of reproductive and developmental toxicities.

S 1314 METABOLOMICS IN THE STUDY OF REPRODUCTION AND DEVELOPMENT.

S. J. Sumner, R. Snyder, J. Burgess, R. Tyl, C. Sloan and T. Fennell. *Metabolomics/Biomarkers, RTI International, Research Triangle Park, NC.*

Our group conducted studies in animal models to demonstrate the use of metabolomics to draw correlations between early life exposures and reproductive or developmental outcomes. Male and female CD rats were fed AIN76A (devoid of genistein)or AIN76A with genistein added (250 or 500 ppm) through breeding. Female rats were maintained on these diets through gestation (gd), lactation, and weaning (postnatal day, pnd, 21). Offspring were maintained on the mothers' diet following weaning. Metabolomics of endogenous compounds in urine could differentiate dams that received the three diets, and could differentiate the pups based on gender, diet, and pre- or post-pubertal age. Studies were also conducted in pregnant CD rats exposed daily during gestation (gd 14-20) to vehicle and effect or no effect levels of butyl benzyl phthalate (BBP), and phenotypic anchors (e.g., anogenital distance, retained nipples) were measured for pups during development. Metabolomics of urine collected from dams (gd 18, pnd 21) and from pups (pnd 25) exhibited differences in levels of endogenous metabolites in urine based on age, gender, dose, and phenotypic anchor. In general, urine from BBP exposed dams collected on gd 18 showed an increase (relative to controls) in Kreb's cycle metabolites, tyrosine, and tryptophan. Urine from BBP exposed dams on pnd 21 showed an increase in nicotinamide, and decrease in trigonelline. Female pups born to dams receiving BBP had increased levels of methyl nicotinamide, and decreased levels of quinolinate, tryptophan, and glutamate. Male pups born to BBP exposed dams, showed a decrease in quinolinate, tryptophan, and glutamate, but did not show an increase in methyl nicotinamide. Urine from male (but not female) pups had an increase in Krebs Cycle metabolites for both dose groups. Alanine,cytidine, and aminolevulinate were decreased (relative to controls) for the male pups born to BBP-exposed dams. Atnecropsy, the offspring males(but not the females)at the high BBP dose exhibited reproductive tract malformations,as anticipated. This research was supported by RTI International.

S 1315 APPLICATION OF TRANSCRIPTOMICS TO ASSESS CHEMICALS WITH ESTROGENIC ACTIVITY.

J. M. Naciff and G. P. Daston. *Procter & Gamble Company, Cincinnati, OH.*

There is a growing concern about the potential adverse health effects to humans and wildlife resulting from exposure to chemicals with the ability to interfere with the normal function of the endocrine system. These chemical have been referred to as "endocrine disrupters", of which the most abundant are chemicals with estrogenic activity. Since these chemicals may interfere with the production or activity of hormones of the endocrine system, and have the potential to affect multiple cellular pathways, the use of transcriptomics (global analysis of gene expression) for their characterization offers a great opportunity to significantly improve the process of assessing their safety and risk. We have used this approach with model chemicals, to identify molecular fingerprints that are indicative of estrogenicity, both in females as well as in the males. These molecular fingerprints show clear similarities in this response between females and males, but also demonstrate gender-specificity of the estrogenic responses. We have also determined that the transcriptional program elicited by exposure to chemicals with estrogenic activity, at equipotent doses, clearly indicate differences in the response of an organism at different life stages (fetal vs. juvenile), can be detected very early on during the exposure phase (hours vs. days), and is more sensitive than traditional assays (i.e. the uterotrophic assay). Further, we have determined the genomic response of an estrogen-sensitive cell line (Ishikawa cells) to estrogen exposure in a time and dose dependent manner. Comparing the estrogenic response of this in vitro system versus the in vivo response (human vs. rat), we determined that the Ishikawa cells are capable of mounting a proper estrogenic response and they offer a robust in vitro system to evaluate the potential estrogenicity of chemicals of interest. By determining quantitative relationships between changes in gene expression and manifestations of estrogenicity, our data clearly supports the use of transcript profiling as an endpoint in quantitative assessments of estrogenicity for any given chemical.

S 1316 IDENTIFYING MOLECULAR MECHANISMS OF GENE EXPRESSION IN MAMMALIAN GAMETES AND EMBRYOS USING FUNCTIONAL GENOMICS APPROACHES.

E. Memili. *Animal and Dairy Sciences, Mississippi State University, Mississippi State, MS.* Sponsor: R. Carr.

Spermatozoa and oocyte are produced through gametogenesis, and the union of these two haploid gametes at the fertilization sets the stage for the fascinating event of mammalian development. Gametogenesis and embryogenesis are both developmentally regulated and right set of transcripts and proteins must be synthesized at the right time and levels. While mostly maternal RNAs and proteins support early embryogenesis, new messages and proteins are synthesized soon after fertilization, a critical event known as Embryonic Genome Activation. Environmental toxicants, stress factors and in vitro culture conditions are all known to affect the gamete and embryo development, and fertility. Molecular dynamics of both transcriptome and proteome can be analyzed using high throughput methods of transcriptomics and proteomics, generating hypothesis for mechanisms of gene regulation. This presentation will review the advances in functional genomics and its applications in identifying genome wide analyses of bovine gametes and embryos, a review of applications in other mammalian species, and provide future prospects.

S 1317 VIRTUAL TISSUE MODELS IN DEVELOPMENTAL TOXICITY RESEARCH.

T. B. Knudsen[1], I. Shah[1], M. R. Rountree[1], A. V. Singh[2] and R. J. Kavlock[1]. *[1]ORD / NCCT, U.S. EPA, Research Triangle Park, NC and [2]NCCT, Lockheed Martin contractor, Lockheed Martin, Research Triangle Park, NC.*

Prenatal exposure to drugs and chemicals may perturb, directly or indirectly, core developmental processes in the embryo (patterning, morphogenesis, proliferation and apoptosis, and cell differentiation), leading to adverse developmental outcomes. Because embryogenesis entails a genomic program that orchestrates aggregate cell behaviors across time and space, a challenge for systems biology is to integrate data and knowledge from the genomic sciences into multi-scale models of developmental toxicity that can be translated into a regulatory context. Computational models of embryonic systems can be used to improve understanding of how the core developmental processes are wired together into genetic regulatory networks (GRNs) and cellular reaction networks (CRNs), and to progressively unravel the changes in these complex systems caused by toxicant exposure. The virtual embryo project (v-Embryo™) at the US EPA aims to build, over the long-term, a working computer model of an embryo through knowledgbase and simulation of toxicity pathways that are important for development (http://www.epa.gov/ncct/v-Embryo/). In the short-term, the technology focuses on specific virtual tissue prototypes to formulate hypotheses about how mechanisms at one scale (molecular) interact to produce higher level (tissue) phenomena, thus guiding research to build quantitative dose-response models that connect to the dynamics of the subtendant GRNs and CRNs. The v-Embryo™ aligns with high-throughput screening assays and systems biology research initiatives at the National Center for Computational Toxicology (NCCT), including ACToR, ToxCast™, and the Virtual Liver. [This work has been reviewed by EPA and approved for publication but does not necessarily reflect official Agency policy].

S 1318 INTERACTOMES AND THEIR APPLICATION IN TOXICOLOGY.

J. N. Meyer. *NSOE, Duke University, Durham, NC.*

A major challenge in the analysis of microarray data in toxicology and other fields is taking full advantage of the large and often very complex datasets that are obtained. A variety of tools are available for such analysis. The use of interactomes as an especially powerful systems biology tool applicable to the analysis of the transcriptomic response to toxicant exposure will be highlighted. Interactomes are networks of protein-protein, protein-DNA, and other interactions that occur in organisms. They are derived both from careful curation of decades of biological research on such interactions, and via higher-throughput assays designed to detect such interactions (e.g., yeast two-hybrid screens). By overlaying gene expression data on these interactomes, it is possible to analyze large, complex microarray datasets in a statistically robust and biologically meaningful fashion. Our panel of experts, who are foremost researchers in toxicological research utilizing interactomes, will discuss both the important toxicological findings and applications of this cutting-edge technology.

S 1319 SYSTEMS BASED APPROACHES FOR THE IDENTIFICATION OF CELLULAR RESPONSES TO TOXICANTS.

T. Begley[1], R. Cunningham[2], A. George[1], J. Rooney[1], F. Joseph[2] and A. Patil[1]. *[1]Biomedical Sciences, University at Albany, SUNY, Renssekaer, NY and [2]Biological Sciences, University at Albany, Albany, NY.*

The toxic effects of chemical exposures can be dramatically influenced by the collection and coordination of cellular proteins and pathways. There are over 30,000 gene-products found in human cells, thus allowing cells to initiate complicated protein-based responses to toxicants. Fast and cost effective approaches are therefore needed to methodically analyze the contribution that specific gene-products and the collection of gene-products (i.e. networks) make towards toxicity modulating pathways. We have developed high throughput screening approaches using gene-deletion libraries from bacteria and yeast to identify conserved responses to DNA damaging agents. We have tethered our high-throughput output to computational mapping and homology based approaches, to identify functional pathways and protein networks that respond to damage, and to identify novel human proteins that coordinate translational responses to damage. Our hightrouhput and computational pipeline is amenable for mass screening of drug libraries and the resulting data has great potential for both toxicity predication and mechanistic studies.

S 1320 PATHWAY MAPPING OF CHEMICAL-PERTURBED REGULATORY NETWORKS.

I. Rusyn. *Environmental Sciences and Engineering, School of Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Signaling networks are altered, either permanently or transiently, in response to chemical exposure. Such alterations may occur on various scales and the activation of nuclear receptors and downstream networks and pathways is a good example of the complex responses to chemical exposure. In common among most nuclear receptors is that they transcriptionally regulate a number of proteins involved in xenobiotic metabolism and that their ligands are frequently causing liver cancer in rodents through non-genotoxic mechanisms. The genome-wide view of gene expression that microarrays offer is a suitable research paradigm to unravel the paucity of events evoked by activation of the nuclear receptors. Pathway mapping is now used frequently to provide more biological relevance to the analyses. This presentation will illustrate the utility of pathway-based interpretation of the genomics data in mechanistic toxicology by considering time- and dose-dependent effects of activators of PPARalpha and CAR. Key nodes responsible for the effects of these agents in rodent liver, the temporal shift in responses, and the concordance/differences between agents may be easily observed when networks, rather than individual genes, are compared.

S 1321 IDENTIFICATION OF NEW BIOLOGICAL PATHWAYS AFFECTED BY TRANSITION METALS.

J. H. Freedman. *Laboratory of Molecular Toxicology, NIEHS, NIH, Research Triangle Park, NC.*

Exposure to transition metals and metalloids (copper, cadmium, mercury, copper, zinc, silver, and arsenic) is correlated with the progression of a variety of human pathologies ranging from cancer to cognitive dysfunction. To avoid metal-induced cytotoxicity, sophisticated mechanisms for regulating the intracellular concentrations of metals and repairing metal-induced damage have evolved. Microarray studies have shown that metals affect the transcription of hundreds of genes that apparently have unrelated functions. We applied multi-species (yeast, C. elegans, mouse, and human) comparative genomics to identify novel pathways that are responsible for the activation or repression of transcription. Gene Ontology analyses of microarray data groups differentially expressed genes in to functional categories. Applying gene expression data to previously defined pathways and interaction networks using Cytoscape, Ingenuity Pathway Analysis and GenMAPP, however, allows for the identification of metal responsive signal transduction pathways. Using this approach, microarray data from metal-treated C. elegans, yeast, HepG2 cells, and mice has been analyzed. In addition to the previously characterized metal responsive signal transduction pathways; NRF2, MAPK, NF-κB; new pathways have been identified. These pathways include those regulated by retinoic acid, calcium, HNF4α, and cAMP-dependent protein kinase. The consequence of inhibiting the expression of genes in these pathways using gene deletions or RNA interference technologies has provided insights into the role of metals in intermediate metabolism, translation, as well as development.

1322 IDENTIFYING MOLECULAR PATHWAYS THAT MODULATE ENVIRONMENTAL AND GENETIC COMPONENTS OF COMPLEX DISEASES.

J. M. Gohlke[1], R. Thomas[1], Y. Zhang[2], M. C. Rosenstein[3], A. P. Davis[3], C. Murphy[3], C. J. Mattingly[3], K. G. Becker[2] and C. J. Portier[1]. *[1]Laboratory of Molecular Toxicology, NIEHS, Research Triangle Park, NC, [2]Gene Expression and Genomics Unit, NIA, Baltimore, MD and [3]Department of Bioinformatics, MDIBL, Salisbury Cove, ME.*

Identifying relationships between phenotype, genotype, and environmental factors using traditional experimental approaches is particularly challenging. Using novel bioinformatics approaches to synthesize information from genetic association studies and mechanistic environmental health research, we have developed an efficient method for the identification of molecular pathways associated with both genetic and environmental contributions to several complex diseases. Consistent with other work using protein interaction datasets, we have found signal transduction pathways versus highly conserved metabolic pathways are more often linked to disease phenotypes. For example, PPAR and adipocytokine signaling define a metabolic syndrome subnetwork and identify natural and synthetic retinoids, antipsychotic medications, Omega 3 fatty acids, and a bisphenol A derivative as potential environmental modulators. To validate our predictions using independent datasets and methodology, we define transcription factor regulation from gene expression datasets for several environmental factors and phenotypes identified in the metabolic syndrome subnetwork. Through utilization of pathways as the unifying concept for linking current knowledge on environmental factors, genes and disease we have identified apoptosis, p53 signaling, PPAR signaling and steroid metabolism as key pathways associated with complex diseases having strong environmental components. Further validation of hypotheses generated will define disease associated targets with both environmental and genetic support, allowing for efficient screening of environmental factors, screening that could set priorities for further research and guide public health decisions.

1323 IRON TOXICITY IN THE MITOCHONDRIA: UNDERSTANDING NETWORK RESPONSES IN FRIEDREICH'S ATAXIA.

B. Van Houten. *Department of Pharmacology and Chemical Biology, Hillman Cancer Center, University of Pittsburgh, Pittsburgh, PA.* Sponsor: J. Meyer.

Frataxin, a conserved mitochondrial protein involved in iron homeostasis, is reduced in patients with Friedreich's ataxia (FRDA) due to a triplet repeat expansion in the first intron. Transcription profiling and DNA damage assays were performed on blood cells from FRDA patients. Altered expression patterns identified using gene set analysis, GoMINER, DAVID, Ingenuity Pathway Analysis, included: immune response; signaling pathways; oxidative phosphorylation, proteins synthesis, transcription; apoptosis; and genotoxic stress response pathways. FRDA patients had significantly more mitochondrial and nuclear DNA damage than a control population. Frataxin mRNA levels correlated with age of onset and displayed unique sets of gene alterations involved in oxidative phosphorylation and protein synthesis. Thus analysis of blood in FRDA patients yields insight into the nature and progression of the disease.

1324 TRANSCRIPTIONAL CHANGES IN IMMUNOTOXICOLOGY: TRANSCRIPTION FACTORS, SIGNAL TRANSDUCTION, AND EPIGENETICS.

N. Kerkvliet[1] and K. Nohara[2]. *[1]Environmental & Molecular Toxicology, Oregon State University, Corvallis, OR and [2]Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Ibaraki 305-0053, Japan.*

Numerous pioneering studies have taken advantage of innovative genomics technologies to demonstrate that various chemicals cause toxic effects by inducing transcriptional changes. These changes are induced by the activation or inactivation of various transcription factors by the direct binding of chemicals or indirectly through modulation of signal transduction pathways. Epigenetics has been recognized as another pivotal mechanism to regulate transcription particularly in development and cellular differentiation that has been found in response to environmental factors. The latest studies are shedding light on the relationship between transcription factor functions and epigenetic alterations. Particular focus will be given to several transcription factors or signal transduction pathways which are highly expressed in immune cells and/or closely related to immune suppression, such as the NF-kB family, E2F, AhR and p53-activating ATM and ATR kinases, and also on the epigenetic regulation of immune reactions. Taking a broad as well as an up-close view of these up-to-date studies on how chemicals induce transcriptional changes and cause adverse effects in immune cells will advance our understanding of the characteristics of immunotoxicity and give insights into the mechanisms of transcription-mediated toxicity in general.

1325 THE E2F FAMILY IS A SENSITIVE TARGET OF ARSENITE IN THE THYMUS: A CHARACTERISTIC DOWN-REGULATION OF E2F-RELATED GENES REVEALED BY IMMUNOTOXICOGENOMICS.

K. Nohara. *Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Japan.*

A variety of environmental chemicals are reported to induce thymus atrophy and cause adverse effects on immune system. We adopted a toxicogenomics approach to identify the pathways that mediate the atrophy induced by arsenite. C57BL/6 mice were administered arsenite at doses that reduce thymus weight by approximately 30%, and gene expression changes in the thymus 24 hours after the administration were analyzed using microarrays. The microarray analysis showed that arsenite down-regulates a variety of E2F target genes, including *Ccnb2* and *Ccne2*, that are involved in cell cycle progression. These changes were not detected in the course of thymus atrophy by 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) or estradiol (E2). Cell cycle analyses of the thymocytes from arsenite-exposed mice showed arrest in the G1 phase. Among various tissues, expression of *Ccnb2* and *Ccne2* was found to be especially high in the thymus of the control mice and relatively high in their spleens, and expression of these genes in the thymus and spleen was significantly suppressed by arsenite exposure. Thus, the arsenic-induced down-regulation of E2F target genes is a characteristic feature of lymphoid cells. Our further studies suggest that a kinetics change in a pocket protein by arsenite is key to regulate the E2F function. The results of these studies illuminate a unique mechanism of arsenite insults to immune system.

1326 ROLE OF P53 AND ATM/ATR IN DMBA-INDUCED IMMUNOTOXICITY.

S. W. Burchiel[1], J. Gao[2], L. Mitchell[1] and F. Lauer[1]. *[1]College of Pharmacy, University of New Mexico, Albuquerque, NM and [2]Los Alamos National Lab, Los Alamos, NM.*

We have shown that 7,12-Dimethylbenz(a)anthracene (DMBA) immunotoxicity is CYP1B1 and microsomal epoxide hydrolase (EPHX1) dependent in C57BL/6 mice, suggesting that DMBA-3,4-dihydrodiol-1,2-epoxide, a known genotoxic agent, is responsible for immune suppression. ATM/ATR and p53 pathways are sensors of genotoxicity. In the present studies, we found that p53 was activated (phosphorylated) in WT mice. WT mice were immunosuppressed by DMBA, whereas p53 null mice were resistant. ATM, ATR, and phospho-ATM levels were increased by DMBA in both WT and p53 null mice, but not in CYP1B1 null or EPHX1 null mice. Therefore, ATM and ATR appear to detect DMBA metabolite-induced genotoxicity producing p53 activation and immunosuppression.

1327 NF-KB PLAYS A MAJOR ROLE IN THE MATURATION OF DENDRITIC CELLS INDUCED BY CHEMICAL SENSITIZERS.

M. J. Pallardy, N. Ade, D. Antonios, A. Larange and S. Kerdine-Romer. *school of Pharmacy, University Paris-Sud 11, Chatenay-Malabry, France.*

Application of low-molecular-weight chemicals (haptens) on the skin may result in allergic contact hypersensitivity. During in vivo immune responses, the role of antigen-presenting cells is played primarily by dendritic cells (DC) acting as initiators of the immune response. Considering similarities between immunity to simple chemicals and that to infectious agents, it is reasonable to speculate that hapten itself stimulates DC maturation. The establishment of human in vitro models of dendritic cell (DC) offered the possibility to demonstrate that haptens were able to directly activate cultured human DCs derived from peripheral blood monocytes or from human CD34+ hematopoietic progenitors. Indeed, DC phenotype was extensively modified after addition of NiSO4 or DNCB (dinitrochlorobenzene) with up-regulation of co-stimulatory molecules (CD86,CD80,HLA-DR) and cytokines (IL-12p40,IL-6,IL-8). Signal transduction pathways such as NFKB and Mitogen-activated protein kinase (MAPK) have been described to play a major role in DC maturation in response to Toll-like receptor agonists. We and others have shown that both DNCB and NiSO4 activated MAPKs but only NiSO4 was able to activate NFKB. NiSO4 induced the degradation of IKB-alpha and the binding of the p65 subunit on DNA probe. Using a specific pharmacological inhibitor of NFKB we found that this pathway was central to the maturation of DC by by regulating CD40, HLA-DR, CCR7, IL-8, IL-6 and IL-12p40 expression. These results suggested a causal relationship between activation of NFKB by chemical sensitizers and alteration of DC phenotype.

S 1328 IMMUNE PROGRAMMING BY THE ARYL HYDROCARBON RECEPTOR.

B. Lawrence[1, 2]. [1]*Environmental Medicine, University of Rochester, Rochester, NY and* [2]*Microbiology and Immunology, University of Rochester, Rochester, NY.*

Despite mounting evidence that prenatal and early post-natal environmental exposures adversely impact immune function later in life, our understanding of how this occurs is limited. The aryl hydrocarbon receptor (AhR) is an important modulator of the development and function of the immune system; however, the mechanism by which AhR regulates the immune system remains poorly understood. We have obtained evidence that developmental exposure to the AhR-specific ligand TCDD affects epigenetically-regulated events important for generating a response to respiratory viral infection. Specifically, developmental exposure to TCDD causes long-lasting defects in the offspring's response to influenza A virus infection, including reduced expansion and differentiation of virus-specific CD8+ T cells and production of the important antiviral cytokine interferon (IFN)g. These changes occurred as a result of developmental exposures that did not affect overall cellularity of immune organs. Although there were defects in the offspring's immune response, the exposed dams did not exhibit impaired immune function. Also, impaired CD8+ T cell responses were inherent to bone marrow cells of the developmentally-exposed offspring, as defects could be transferred to unexposed mice. Epigenetic mechanisms such as DNA methylation and histone modifications regulate IFNg expression and T cell clonal expansion, supporting the idea that AhR modulates programming of the immune system via epigenetic mechanisms, and point to known epigenetically-regulated pathways as targets. These findings are of considerable interest because poorer CD8+ T cell responsiveness and reduced IFNg production correlate with an impaired ability to combat viral infection and to detect and destroy tumor cells. Moreover, although epigenetic mechanisms are known to regulate gene expression in immune cells, the idea that inappropriate AhR activation during development causes permanent functional changes in lymphocytes via epigenetic regulatory mechanisms is a novel paradigm. Supported by NIH grants K02-ES012409 and R21-ES013863.

S 1329 EPIGENETIC CHANGES IN T HELPER GENES AFFECTING IGE PRODUCTION *IN VIVO* FOLLOWING COMBINED INHALED DIESEL EXHAUST PARTICLES AND ALLERGEN EXPOSURE.

R. L. Miller[1, 3], J. Liu[1], M. Ballaney[1], U. Al-alem[1], C. Quan[2], X. Jin[2], F. Perera[3] and L. Chen[2]. [1]*Medicine, Columbia University, New York City, NY,* [2]*Environmental Health Sciences, New York University, Tuxedo, NY and* [3]*Mailman School of Public Health, Columbia University, New York City, NY.*

Changes in methylation of CpG sites at the interleukin (IL)-4 and interferon (IFN)γ promoters are associated with T helper (Th) 2 polarization in vitro. No previous studies have examined whether air pollution or allergen exposure alters methylation of these two genes in vivo. In this talk, we will review our recent findings that inhaled diesel exposure and intranasal A. fumigatus mold allergen induced hypermethylation at CpG-45, CpG-53, CpG-205 sites of the IFNγ promoter and hypomethylation at CpG-408 of the IL-4 promoter. Altered methylation of promoters of both genes was correlated significantly with changes in IgE levels. This study is the first to demonstrate that inhaled environmental exposures influence methylation of Th genes in vivo, supporting a new paradigm in asthma pathogenesis.

W 1330 DEVELOPING BRAIN: SAFETY ASSESSMENT FOR PEDIATRIC USE OF PHARMACEUTICALS.

M. J. Kallman. *Investigative Toxicology, Eli Lilly & Company, Greenfield, IN.*

With the recent enactment of the EU pediatric regulation as well as the reenactment of the Pediatric Research Equity Act and the Best Pharmaceuticals for Children Act in the US, increased expectations from a number of regulatory agencies for nonclinical support of pharmaceuticals for pediatric use have lead to an increased need for testing in juvenile animals. One area of particular focus is on the developing central nervous system (CNS). Since development of the CNS continues through adolescence it is one organ system thought to be at high risk for drug toxicity. Safety assessment of the CNS is generally evaluated through functional assays including cognitive tests; however, histopathologic changes are also possible. Our panel of experts will discuss the relevant considerations when designing juvenile toxicity studies to evaluate potential effects on the developing CNS that will allow the most useful risk assessment for the intended clinical population.

W 1331 WORKSHOP OVERVIEW.

M. J. Kallman. *Investigative Toxicology, Eli Lilly & Company, Greenfield, IN.*

A brief review of the latest regulations on pediatric clinical requirements and associated regulatory expectations for nonclinical support will be presented. Reasons for the increased interest in providing pediatric evaluations for drug approval will be considered.

W 1332 THE POSTNATAL DEVELOPING BRAIN: A TARGET OF TOXICITY.

G. D. Cappon. *Department of Safety Sciences, Pfizer Global Research and Development, Groton, CT.*

To design nonclinical safety studies evaluating the potential effects on the brain, an understanding of CNS development is needed. Juvenile toxicity studies are designed case-by-case. The timing of dosing in the animal should reflect the intended pediatric population such that the phase of growth and development of the organ system to be evaluated are similar. This presentation will provide an overview of postnatal brain development and a high level comparison across species.

W 1333 ENDOCRINE ENDPOINTS: INTERACTIONS DURING POSTNATAL CNS DEVELOPMENT.

D. R. Mann. *Department of Physiology, Morehouse School of Medicine, Altanta, GA.* Sponsor: M. Kallman.

The endocrine system undergoes tremendous development during adolescence. Not only is this system a potential target for toxicities during this period, but because it plays a substantial role in CNS development, alterations in normal endocrine development can have a profound impact on CNS function. This presentation will provide an overview of postnatal endocrine development, its influence on CNS development, and potential consequences that could confound interpretations of juvenile toxicity studies.

W 1334 TESTS TO EVALUATE COGNITIVE AND EMOTIONAL FUNCTION IN RODENTS.

C. V. Vorhees. *Division of Neurology, Children's Hospital Research Foundation, Cincinnati, OH.* Sponsor: M. Kallman.

Much discussion has occurred regarding the need for more sensitive tests of learning and memory for safety assessment for pediatric use of a pharmaceutical and how these compare to those employed for pre- and postnatal development studies. Furthermore, many regulatory agencies have raised concern for potential effects on emotional development. This presentation will consider advantages/disadvantages of currently available tests for learning and memory as well as endpoints considered to reflect emotional behavior in rodents.

W 1335 INDUSTRY PERSPECTIVE: START WITH THE END IN MIND.

L. L. Morford. *Nonclinical Safety Assessment, Eli Lilly and Company, Greenfield, IN.*

Many considerations are needed when designing a juvenile toxicity study to address concerns regarding potential effects on the developing CNS. These include dosing period, endpoints to evaluate, dose levels, and species. Behavioral response may be affected by systemic toxicity, motivation, activity levels, and stress which are often related to dose levels and design specifics. This presentation will discuss how study designs can impact risk assessment.

W 1336 HISTOLOGICAL CHANGES IN ANIMALS: IMPLICATIONS FOR USE IN PEDIATRIC PATIENT POPULATIONS.

R. Mellon. *Division of Anesthesia, Analgesia, and Rheumatology Products, Food and Drug Adminstration, Silver Spring, MD.* Sponsor: M. Kallman.

Animal studies suggest that some drugs, such as anesthetic agents, have the potential to produce widespread neuroapoptosis of the brain during what appears to be the synaptogenesis period of development. Several of these animal studies also sug-

gest that the histopathological changes may be associated with possible cognitive sequelae. These observations in animals have raised concerns regarding the use of these agents in pediatric patients. This presentation will provide a historical overview that outlines the challenges faced by FDA on this topic in determining the potential clinical significance.

W 1337 TOXICOLOGY OF UNINTENTIONAL AND INTENTIONAL DISASTERS.

A. J. Harris[1] and M. Ottlinger[2]. *[1]CTEH, North Little Rock, AR and [2]Office of Emergency Management, U.S. Environmental Protection Agency, Cinncinati, OH.*

There is no greater challenge in toxicology than making decisions concerning public health under extreme circumstances with limited data. Yet, with the ever increasing risk of terroristic activities, the occasional accidental release of chemicals during transport and manufacture, and the unpredictable occurrence of natural disasters such as volcanic activity, hurricanes and wild fires; toxicologists from a wide range of governmental agencies and companies are faced with making decisions that affect the health of impacted communities. Such responses to emergency situations is where the rubber meets the road in putting toxicological principles into public health practice. To address these issues tropical disasters will be used to initiate discussion about the challenges faced during catastrophic events involving toxic agents in order to develop better strategies to address the toxicological impact on public health. We will consider the need for toxicological assessment and support during unintentional and intentional disasters with examples from recent events including Hurricanes Katrina and Rita, the California wild fires, and the collapse of the World Trade Center. A brief roundtable discussion will follow to identify the idiosyncrasies and commonalities of dealing with unintentional and intentional disasters.

W 1338 INTRODUCTION.

M. Ottlinger. *Office of Emergency Management, U.S. Environmental Protection Agency, Cincinnati, OH.*

Environmental and industrial accidents or natural disasters may result in discharges of toxic materials into the environment in a wide variety of settings. Such events may create conditions that do not always fall within the existing regulatory contexts, although it may be necessary to provide information to the public about exposure hazards and health risks. The topics and speakers in this workshop are meant to illustrate recent disasters, and prompt a discussion of the issues which toxicologist face after these events and how to plan for future responses.

W 1339 DHS ROLE AND RESPONSIBILITIES UNDER THE NEW NATIONAL RESPONSE FRAMEWORK.

M. A. Kirk. *Office of Health Affairs, U.S. Department of Homeland Security, Washington, DC.* Sponsor: A. Harris.

The role of the Department of Homeland Security is becoming increasingly involved in a variety of disaster response scenarios, be they intentional acts of terrorism, natural disasters, or industrial accidents. Under the new National response Framework (NRF), DHS will be integrated into a full spectrum of government response beginning at the local and state levels and possibly involving multiple federal agencies. Appointing experienced physicians with emergency medicine and/or medical toxicology board certifications to senior level posts at DHS, and elsewhere in the government, recognizes the value of having such depth of expertise both in planning for, as well as, in responding to, and coordinating, such events. This talk will discuss DHS' planning and contemplated response activities across a range of potential toxicological events.

W 1340 PUBLIC IMPACT OF VOLCANIC ACTIVITY.

P. Nony. *CTEH, North Little Rock, AR.*

Volcanic activity can produce air quality impacts from volcanic ash as well as volcanic smog (a.k.a. vog), a phenomenon that produces high ambient air concentrations of the respiratory irritant sulfur dioxide. The impact of vog on air quality in communities near active volcanoes, such as large parts of the State of Hawai'i, is a public health concern that can vary greatly both in magnitude and severity of resulting health problems. Because of variations in the occurrence and duration of vog releases as well as variation in meteorological conditions, health departments and other authorities often struggle to warn communities of vog impacts before they reach human receptors. Unfortunately in many cases, public health impacts cannot always be predicted because vog releases and resulting areas of impact cannot always be predicted accurately. In contrast, because of the size of the area of potential impact, more broad public impacts from volcanic ash and vog may result from catastrophic volcanic eruptions, even though these events can be more predictable. Despite the advance of technologies available to assess ambient air quality impacts in real time, the recent threat of eruption of Mt. St. Helens in Washington State presented new challenges to emergency responders tasked with monitoring ambient air quality in areas impacted by volcanic ash and vog. First and foremost is the challenge presented by the immense size of the area of potential impact of a large eruption with regard to proper placement and maintenance of air monitoring equipment and manpower. Second is the logistical challenge presented by the timely collection and transmission of real-time air quality data, often in rural and remote areas, for use by communities, government entities, and industries impacted by volcanic ash and vog. Finally, determining how to divert resources based on changing meteorological conditions presents an extreme challenge given the vast area to be covered and limited resources. This presentation will address these issues and encourage discussion of public health impacts of volcanic activity and approaches to monitoring changes in ambient air quality in impacted areas.

W 1341 RISK ASSESSMENT AND PUBLIC HEALTH IMPLICATIONS OF WTC DUST CONTAMINATION TOPIC:.

P. Goad. *CTEH, North Little Rock, AR.*

The collapse of the WTC resulted in unprecedented environmental contamination which directly impacted nearby buildings. Massive quantities of dust combined with emissions from the longest-burning commercial fire in US history created a complex mixture of chemical contaminants that were dispersed directly into severely damaged buildings. The nature and extent of contamination was initially unknown. Emerging data regarding the unique composition and morphology of WTC Dust precluded any reliable prediction of risks to the health of individuals potentially reoccupying such buildings in the absence of further study of conditions in affected buildings. This talk will address the extent and results of testing, and the implications of the presence of these contaminants to public health.

W 1342 MONITORING AND SURVEILLANCE OF DISASTER RESPONDERS: TRACKING OF THE HEALTH OF WTC CLEAN UP AND RECOVERY WORKER.

A. S. Geyh. *Environmental Health Services, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.* Sponsor: A. Harris.

Hundreds of workers responding to the WTC disaster, participated in the clean up and recovery effort. Seven years after the cleanup operation came to a conclusion, the health of these workers continues to be of significant concern. Inhalation of the complex mixture of airborne contaminants at the disaster site has resulted in an "after disaster" for hundreds of workers who still suffer from the harmful effects of that exposure. The nature of the contaminate mixture and the harm it has caused continue to be the focus of the exposure assessment, epidemiological and clinic communities. This talk will address the questions that continue to be outstanding for these workers and discuss what should be done to prepare for a future event.

W 1343 TOXICOLOGICAL RISKS OF URBAN WILDFIRES: ANALYSIS OF FIRE ASH AND DEBRIS FOLLOWING THE SOUTHERN CALIFORNIA WILDFIRES.

S. DuTeaux. *Environmental Health Hazard Assessment, U.S. Environmental Protection Agency, Sacramento, CA.* Sponsor: A. Harris.

The 2007 Southern California wildfires burned more than 350,000 acres in populated and open space areas, consuming some 3200 structures and 2000 vehicles. The destruction left in the wake of the fires resulted in the potential for wide-spread public exposure to toxic materials. Residents were warned of the risk of exposure to contaminants in burn ash and debris upon reentry to destroyed neighborhoods and properties. In addition, there were concerns of off-site migration of hazardous substances into sources of drinking water. Results from the sampling and analysis of ash show that concentrations of lead (mean = 1075 mg/kg), arsenic (mean = 11.4 mg/kg), cadmium (14.7 mg/kg), and copper (4458 mg/kg) were significantly above California background levels and exceeded both California and federal health-based screening levels. Also highlighted in the presentation will be recovery efforts that had a direct impact on reducing public health threats post-fire, efforts which are now regularly applied in the wake of California firestorm events.

RI 1344 BIOFUELS AND THE BAY: CHARACTERIZING HEALTH AND ECOSYSTEM IMPACTS IN THE CHESAPEAKE.

M. C. Madden. *ORD, NHEERL, HSD, Clinical Research Branch, U.S. EPA, Chapel Hill, NC.*

The Chesapeake Bay Commission has evaluated alternative fuel development efforts in the Chesapeake Region. Already under stress from anthropomorphic factors, the Chesapeake Bay Region could be adversely impacted by the wide spectrum of use of the region for biofuels production, transport, storage, and combustion. This Regional-Interest session will characterize the potential adverse effects on public health and ecological degradation from the production and use of biofuels in the Bay, an uncertain and complex challenge. There are multiple types of biofuels that are derived from various feedstocks and production processes. The amount of land use devoted to biofuels in this region will vary tremendously in part by the biofuel stock in economic demand, the advances made in the growth rate and energy content of plant stocks, and whether it can be imported. Domestic corn planting in the Bay Region increased 11,000 acres from 2005 to 2006, primarily for use in ethanol production with consequences for decreased food availability, soil loss, and nutrient runoff. In contrast, a biodiesel production plant in Baltimore will import soybeans as the raw material due to ecomonic incentives, thereby avoiding issues with domestic corn production. Potential human health effects will occur through exposure to the fuels, inhalation of combustion products, and fallout into water supplies. Algal blooms due to increased nitrogen deposition in the estuarine environment from biofuel production would impact public and environmental health. Air quality could be impacted from combustion, as could water quality through deposition of the fuel products into the Bay. Estuarine and marine organisms, some with commercial importance, could be adversely impacted. Ethical issues over the displacement of crops for food to energy for mobile sources have arisen and will be considered. Both the public health and ecological problems posed by the wide spectrum of biofuels being considered for use in the Bay will be addressed. [This abstract of a proposed presentation may not reflect US EPA policy.]

RI 1345 OVERVIEW: BIOFUELS AND POTENTIAL EFFECTS IN THE BAY.

A. Swanson. *Office, Executive Director, Chesapeake Bay Commission, Annapolis, MD, MD.* Sponsor: M. Madden.

In the Chesapeake Bay region, the demand for biofuel feedstocks potentially may change forestry practices and the amounts and types of crops grown. This demand could bring about profound changes to the region's agricultural practices, and possibly have major effects on the health of the Bay and prospects for restoration. Production of ethanol can degrade water quality without best management practices. However, cellulosic and other advanced biofuels use plant material for feedstock, such as perennial grasses, which can potentially help meet the nation's fuel needs and helping to protect water. In 2007, the Pennsylvania Governor and the Chesapeake Bay Commission proposed the Chesapeake Cellulosic Biofuels Project. This project and its associated efforts used regional expertise to derive proposed goals of maximizing the economic opportunities of this emerging technology and protecting natural resources. Three areas of action were identified to make the Bay region a leader in the evolution of cellulosic and advanced biofuels: 1) Feedstocks- The Chesapeake region is blessed with the land and climate to produce a significant amount of cellulosic biomass throughout the year; 2) Natural Resource Protection- the production of certain biomass crops has the potential to not only sustain water quality but improve it; and 3) Marketing and Infrastructure- there are opportunities and challenges for production capacity, distribution, and marketing of feedstocks, biofuels, and their co-products. The Chesapeake Bay region is well positioned to take leadership in the shift to renewable fuels with economic and environmental benefits. A large number of universities and research institutes in the region are already working on cellulosic biofuels, and many private companies are willing to partner and develop competitive technologies. These Project recommendations have been made to policy makers, opinion leaders, energy providers and consumers for consideration and adoption, so that biofuels in the Bay will be one of economic prosperity, environmental sustainability with minimal environmental health issues, and foster resource restoration.

RI 1346 HEALTH EFFECTS OF EXPOSURE TO BIOFUELS.

M. L. Witten. *Pediatrics, University of Arizona, Tucson, AZ.*

The energy crisis has highlighted the emerging uses of biofuels for transportation. The sources of the biofuels range from corn to saltwater plants. Consequently, the toxicity of these biofuels is largely unknown and will be complicated by the numerous plant sources as well as the distillation techniques used for biofuel generation. This talk will focus on the health effect(s) of jet fuel exposure and extrapolate these findings to potential toxcity issues with biofuels.

RI 1347 BIOFUELS: POTENTIAL IMPACTS OF PRODUCTION, STORAGE, AND USE ON ESTUARINE WATERS.

J. E. Baker. *Environmental Science, University of Washington Tacoma, Tacoma, WA.* Sponsor: M. Madden.

Production, transportation, and use of energy resources has historically been fraught with unintended or unanticipated environmental consequence, ranging from acid mine drainage near coal mining operations to alteration of the global mercury and atmospheric carbon dioxide budgets. Combustion products clearly impact natural waters, including estuaries, as atmospheric deposition is a significant source of nutrients, trace metals, and persistent organic pollutants. For example, approximately one-third of the nitrogen entering the Chesapeake Bay is derived from the atmosphere, much of which is emitted as NOx from fossil fuel combustion. As "biofuels" technologies are developed and expanded, it is important to consider holistically the impacts on the environment. Estuaries may be affected by biofuels in a number of ways. Changes in land use practices if agricultural crops are used as source materials for biofuels may alter nutrient and sediment run-off. Altered emission rates and chemical compositions by stationary and mobile sources burning biofuels may alter the magnitudes of nutrient and chemical pollutant loadings from the atmosphere. By-products and waste emissions from biofuel production facilities may add to these regional pollutant loads. Finally, alterations to engines to allow for biofuel consumption may introduce novel chemicals or catalysts into the environment. On balance, these potential impacts must be evaluated in the context of continued emissions from petroleum-based fuels.

RI 1348 BIOFUELS: ESTUARINE ECOTOXICOLOGICAL IMPACTS.

C. Menzie. *Ecosciences, Exponent, Alexandria, VA.* Sponsor: M. Madden.

The increased use of biofuels within the Chesapeake Bay region will likely result in accidental releases to the Bay, atmospheric inputs at, and runoff from the extensive watershed. The composition of fuels influences the fate and effects of these mixtures in estuarine ecosystems. Biofuels are variable and also differ in hydrocarbon composition from fossil fuels and these differences can influence their fate and effects within the estuary. Long-term exposures and effects will depend both on the loading of chemicals to the Bay as well as the persistence of these chemicals. This presentation will examine these
characteristics in comparison to those associated with conventional fossil fuels. In addition, because some viscous biofuels can exert adverse effects as a result of physical modifications of sediments, this aspect of exposure will also be examined. A conceptual model that
illustrates the sources, loadings, and fate of biofuel constituents as these relate to the estuarine biota will be presented along with a framework for considering the variable toxicological implications of the various fuels.

RI 1349 ETHICS AND BIOFUELS: DISTRIBUTIVE AND INTERGENERATIONAL JUSTICE.

T. M. Powers. *Philosophy & Delaware Biotechnology Institute, University of Delaware, Newark, DE.* Sponsor: M. Madden.

Current overlapping markets in feedstocks for biofuels, food staples, and cropland work to the disadvantage of the poorest consumers—those who are not in the market for transportation fuel. Further, the interests of participants in future markets—i.e., future generations—might be harmed by current practices of consumption of resources (especially fuels) and the production of negative externalities (especially greenhouse gas pollution). Hence various food, fuel, and land-use distributions appear to be Pareto non-comparable both within and across generations; we cannot make some people better off without making others worse off. These issues will be analyzed from several theoretical standpoints of ethics to suggest a framework of a solution.

PL 1350 CALCIUM-DEPENDENT VASODILATION IS IMPAIRED IN CORONARY ARTERIOLES AFTER NANOPARTICLE INHALATION.

A. J. LeBlanc[1], J. Cumpston[2], B. Chen[2], D. Frazer[2], V. Castranova[2] and T. Nurkiewicz[1]. *[1]Center for Interdisciplinary Research in Cardiovascular Sciences, West Virginia University, Morgantown, WV and [2]National Institute for Occupational Safety and Health, Morgantown, WV.*

Epidemiological studies have shown that exposure to particle pollution is associated with an increased risk for myocardial infarction (MI). This laboratory has shown in skeletal muscle that nanoparticle exposure produces significantly greater microvas-

cular dysfunction than larger particles of the same composition. However, it remains unclear if coronary microvascular endothelial function is affected to a similar degree. Rats were exposed to filtered air (control) or TiO_2 nanoparticles (primary particle diameter, ~21 nm) via inhalation at concentrations relevant to ambient air pollution (9.5 μg measured pulmonary deposition). Coronary arterioles (~150 μm in diameter) were isolated from the left anterior descending artery distribution and responses to flow (FID) (5-25 μL/min), acetylcholine (ACh, 10^{-7} – 10^{-5} M), and the Ca^{2+} ionophore, A23187 (10^{-8} – 10^{-6} M), were assessed. Endothelium-dependent FID was preserved in coronary arterioles from rats exposed to nano-TiO_2 compared to control rats. Conversely, a profound vasoconstriction (16±14, % constriction) resulted from cumulative additions of ACh in arterioles from rats exposed to nanoparticles, whereas control rats responded by vasodilation (73±4, % dilation). Similarly, nanoparticle exposure impaired arteriolar dilation to A23187 as compared to control rats. Sodium nitroprusside (10^{-3} M) produced comparable arteriolar dilation in both groups, indicating that vascular smooth muscle NO responsiveness remains intact after nanoparticle exposure. These results suggest that nanoparticle exposure significantly impairs Ca^{2+}-dependent microvascular responses to ACh and A23187, whereas responsiveness to shear stress is preserved. It is probable that such disturbances in coronary microvascular function contribute to the cardiac events associated with particle pollution exposure.
Support: NIH RO1-ES015022 and HEI #4730 (TRN)

PL 1351 TIME COURSE OF SYSTEMIC EFFECTS FOLLOWING A SINGLE EXPOSURE TO CARBON NANOTUBES.

A. Erdely, T. Hulderman, R. Salmen, A. Liston, P. C. Zeidler-Erdely and P. P. Simeonova. *NIOSH, Morgantown, WV.*

Pulmonary exposure to carbon nanotubes (CNT), in a mouse model, causes aortic mitochondrial DNA damage and enhanced thrombogenicity, prerequisites of atherosclerosis. The link between endpoint systemic effects and pulmonary exposure is unknown. We hypothesized that blood cell gene expression and serum protein analysis will provide insight into the relationship between CNT-induced lung and cardiovascular effects. C57BL/6 mice were exposed to 40ug of multi-walled CNT (MWCNT) and sacrificed at 4hr, 24hr, 7d and 28d post single exposure. We evaluated serum proteins and blood cell gene expression of biomarkers related to potential cardiovascular effects. Furthermore, the CNT effects on lung and cardiovascular tissues were characterized by a coordinated gene expression analysis. At 4hr, a marked systemic inflammatory response was evidenced by increased inflammatory serum proteins (e.g. IL-6, CXCL1) and upregulated blood cell gene expression of inflammatory mediators. Cardiovascular tissue, including heart and aorta, showed a generalized stress and inflammatory response. In addition, the expression of specific endothelial related genes was elevated in the aorta (e.g. E-selectin). The systemic effects at 4hr were mostly a reflection of the ongoing lung response. At 24hr, inflammatory serum proteins and blood cell gene expression had returned to baseline and the systemic tissue response had diminished. In exchange, serum acute phase proteins (e.g. C-reactive protein, serum amyloid P) and accompanying liver gene expression were increased. Furthermore, at both 4 and 24hr increased serum levels of the prothrombotic protein plasminogen activator inhibitor-1 were found. The late blood response (7 and 28d) was characterized by increased serum osteopontin levels in conjunction with increased lung expression of genes coding for a macrophage related response (e.g. arginase I, galectin-3, osteopontin). In conclusion, our data suggests a link between MWCNT-induced pulmonary toxicity and potential systemic effects related to cardiovascular dysfunction through alterations in blood parameters.

PL 1352 NANOPARTICLE INHALATION INCREASES MICROVASCULAR OXIDATIVE STRESS AND COMPROMISES NITRIC OXIDE BIOAVAILABILITY.

T. R. Nurkiewicz[1], A. Hubbs[2], A. Mosely[2], B. Chen[2], D. Frazer[2], M. Boegehold[1], K. Dreher[3] and V. Castranova[2]. *[1]Center for Interdisciplinary Research in Cardiovascular Sciences, West Virginia University, Morgantown, WV, [2]National Institute for Occupational Safety and Health, Morgantown, WV and [3]U.S. EPA, Research Triangle Park, NC.*

We have shown that pulmonary nanoparticle exposure impairs endothelium dependent dilation in systemic arterioles. However, the mechanism(s) through which this effect occurs are unclear. The purpose of this study was to identify alterations in the production of oxidative stress and endogenous nitric oxide (NO) after nanoparticle exposure, and determine the relative contribution of hemoproteins and oxidative enzymes in this process. Rats were exposed to TiO_2 nanoparticles via inhalation (primary particle diameter ~21 nm) at depositions of 4-90 μg/rat. The spinotrapezius muscle was prepared for intravital microscopy 24 hrs after exposures. Intraluminal infusion of the Ca^{2+} ionophore A23187 was used to evaluate endothelium-dependent arteriolar dilation. Endogenous microvascular NO production was measured with an electrochemical sensor. Oxidative stress in the microvascular wall was quantified via dihydroethidium fluorescence (O_2^- probe). Histological sections of pulmonary tissue revealed nanoparticle uptake by alveolar macrophages, and migration to nearby lymph tissue. TiO_2 nanoparticles quenched spontaneous NO signals generated in vitro by S-Nitroso-N-acetyl-D,L-penicillamine (550 mM). As in previous experiments, A23187 produced dose-dependent arteriolar dilations (10-69% of maximum response). Nanoparticle exposure robustly attenuated this to 6-16% of the maximum response. Nanoparticle exposure also increased microvascular oxidative stress by ~60%, and decreased NO production. Inhibition of either myeloperoxidase (4-aminobenzoic hydrazide, 10 μm) or NADPH oxidase (apocynin, 10^{-4} M) partially restored NO production and normal microvascular function. These results indicate that in conjunction with microvascular dysfunction, nanoparticle exposure also increases local oxidative stress and decreases NO bioavailability.
Support: R01-ES015022 and HEI#4730 (TRN).

PL 1353 MECHANISTIC LINKS BETWEEN THE LUNG AND THE SYSTEMIC MICROCIRCULATION AFTER NANOPARTICLE EXPOSURE.

T. R. Nurkiewicz[1], M. Donlin[2], A. Hubbs[2], A. Goodwill[1], J. Frisbee[1], B. Chen[2], D. Frazer[2] and V. Castranova[2]. *[1]Center for Interdisciplinary Research in Cardiovascular Sciences, West Virginia University, Morgantown, WV and [2]National Institute for Occupational Safety and Health, Morgantown, WV.*

Previous studies in our laboratory have shown that pulmonary nanoparticle exposure causes peripheral microvascular dysfunction. This dysfunction is characterized by impaired endothelium-dependent arteriolar dilation and venular leukocyte adhesion. The mechanisms that produce these effects remain poorly understood. The purpose of this study was to determine if neurological mechanisms and/or circulating leukocytes play a fundamental role between pulmonary exposure and peripheral microvascular dysfunction. Rats were exposed to TiO_2 nanoparticles via inhalation (primary particle diameter ~21 nm) at depositions of 4-90 μg/rat. Some rats received a bolus dose of cyclophosphamide (200 μg/g, i.p.) 3 days prior to nanoparticle exposure to deplete circulating neutrophils. The spinotrapezius muscle was prepared for intravital microscopy 24 hrs after exposures. Intraluminal infusion of the Ca^{2+} ionophore A23187 (10^{-7} M, pipette concentration) was used to evaluate endothelium-dependent arteriolar dilation. Histological sections of the spinotrapezius muscle and lung were prepared, and plasma was sampled from each rat for multiplex analyses. Following nanoparticle exposure, plasma IL-1, 2, 13 and ICAM-1 were altered. Consistent with previous experiments, nanoparticle exposure significantly limited arteriolar dilation (in response to A23187) to 0-7% of the normal maximum response. Co-incubation with the fast Na^+ channel antagonist tetrodotoxin (TTX, 10^{-6} M) restored dilation by as much as 54%. Neutrophil depletion similarly resored dilation by as much as 42%. These mechanistic data support prominent hypotheses that suggest peripheral vascular effects associated with particle exposure are due to neurogenic and/or inflammatory mechanisms.
Support: NIH RO1-ES015022 and HEI#4730 (TRN)

PL 1354 CARDIOVASCULAR EFFECTS OF ULTRAFINE PARTICULATE MATTER ON SPONTANEOUSLY HYPERTENSIVE RATS.

K. Salazar, G. Gookin, P. Willett, D. Meacher and M. T. Kleinman. *Department of Medicine, University of California, Irvine, Irvine, CA.*

Exposure to particulate air pollution has been associated with increased cardiovascular morbidity and mortality. A suggested mechanism for this association is the development of oxidative stress and inflammation with exposure to ambient particulate matter. Exposure to ultrafine particles may result in greater oxidative stress and inflammation than exposure to larger particles due to a larger surface area to mass ratio and greater ability to translocate to other areas of the body. Spontaneously hypertensive rats, an animal model of arterial hypertension, were implanted with telemetry devices to measure heart rate and blood pressure. The rats were exposed to concentrated ultrafine particles or filtered air for 5 hours per day, 4 days per week for 12 weeks in Riverside, CA. Rats exposed to ultrafine particles showed greater serum levels of the inflammatory cytokines IL-1β, IL-6, IL-12, TNF-α, and IFN-γ, the anti-inflammatory cytokine IL-10, monocyte chemoattractant protein-1, and eotaxin. Cell differential counts from bronchoalveolar lavage fluid showed higher levels of mononuclear cells and neutrophils in the ultrafine particle exposed rats. Analysis of telemetry data from exposed animals showed a depression in blood pressure during exposure periods compared to non-exposure periods. In addition, rats exposed to ultrafine particles showed a decrease in heart rate compared to the control animals. These results indicate a change in cardiovascular function with exposure to ultrafine particulate matter. Further analysis is needed to determine the mechanistic relationship between the increase in inflammatory biomarkers and change in cardiac parameters.

PL 1355 FINE PARTICULATE MATTER EXPOSURE DEPRESSES PULMONARY FUNCTION IN THE DEVELOPING MOUSE LUNG.

G. R. Gookin, K. I. Salazar, P. Willett, D. Meacher and M. T. Kleinman. *University of California, Irvine, Irvine, CA.*

Evidence is increasing that ambient air pollution has chronic negative effects on pulmonary function in the developing lungs of children. In this study, a mouse model was used to test whether exposure to ambient particulate matter delays or stunts lung growth. Mice undergo a rapid period of growth between birth and 6 weeks of age. After lung remodeling and alveolarization is complete normal lung growth occurs from 4 weeks into adulthood. C57BL/6 mice were exposed to concentrated ambient fine particulate matter less than 2.5 μm or purified air for 8 weeks starting at either 4, 6, or 8 weeks of age. An invasive lung function measurement was utilized using parameters that are considered to be classical methods for accurate and specific determination of pulmonary mechanics (e.g., pulmonary resistance and dynamic compliance) Analysis of the data shows a depression of pulmonary function in particle-exposed animals compared to purified-air exposed animals, 1 wk post 8 wk exposure. At the end of their lung growth period particle-exposed mice had a significant decrease in dynamic compliance compared to purified-air exposed mice. The particle-exposed animals also displayed increased pulmonary resistance as well as a depression in maximum inspiratory and expiratory flow compared to purified-air exposed animals. Histopathological analyses of the lung tissue will be performed to determine if the functional decrements are accompanied by morphological changes.

PL 1356 ACTIVATION OF ENDOTHELIAL CELLS AFTER EXPOSURE TO AMBIENT ULTRAFINE PARTICLES: THE ROLE OF NADPH OXIDASE.

Y. Mo, R. Wan, D. J. Tollerud and Q. Zhang. *Environmental and Occupational Health Sciences, University of Louisville, Louisville, KY.*

Ultrafine particles(UFPs)may pass from the lungs to the circulation because of their very small diameter. The direct effects of UFPs on vascular endothelium remain unknown. We hypothesized that exposure to UFPs leads to endothelial cells O2.- generation via NADPH oxidase and results in activation of endothelial cells. Our results show that ROS generation was inhibited when mouse pulmonary microvascular endothelial cells(MPMVEC) were pre-treated with the ROS scavengers, or the NADPH oxidase inhibitor, diphenyleneiodonium chloride(DPI), but not with the mitochondrial inhibitor, rotenone. This was further confirmed by studies showing that UFP-induced ROS generation in MPMVEC was abolished by p67phox siRNA and UFPs did not cause ROS generation in MPMVEC isolated from gp91phox -/- mice. ROS generation in endothelial cells was also determined in vivo by using lung image. Gp91phox -/- endothelial cells did not generate ROS when they were exposed to UFPs. We demonstrated by western-blot and immunofluorescence staining that MPMVEC treated with UFPs resulted in the translocation of cytosolic protein p67phox, p47phox and rac 1 to the plasma membrane. Our results demonstrate that DNAPH oxidase in the pulmonary endothelium is involved in ROS generation following exposure to UFPs. To investigate the activation of endothelial cells due to UFP-induced oxidative stress, we determine the mitogen-activated protein kinases(MAPKs) in MPMVEC after exposure to UFPs. Our results showed that exposure of MPMVEC to UFPs causes increased expression of phosphor-p38 and phosphor-ERK1/2 MAPKs. However, these increase were blocked by pretreatment with DPI and p67phox siRNA. Moreover, exposure of MPMVEC obtained from gp91phox -/- mice to UFPs did not cause increased expression of phosphor-p38 and phosphor-ERK1/2 MAPKs.Our findings confirm that UFPs can affect endothelial cells directly to generate ROS via activation of NADPH oxidase. This can further lead to up-regulation of phospho-p38 and phosphor-ERK1/2 MAPK expression that may result in the endothelial dysfunction.

PL 1357 PERSISTENCE OF GENE EXPRESSION CHANGES IN LUNGS OF MICE AFTER INHALATION OF COMBUSTION-DERIVED NANOPARTICLES HAS ENDED.

A. Penn, D. Paulsen, Z. Perveen and W. Polk. *LSU School of Vet.Med., Baton Rouge, LA.*

Inhalation of PAH-rich soot nanoparticles produced during incomplete combustion of the high-volume petrochemical, 1,3-butadiene initiates the following immediate changes: up-regulation of Phase I biotransformation enzymes, oxidative stress and inflammatory genes, plus induction of pulmonary inflammation. One day after exposures end, all these changes are still evident, but at reduced intensity. We are investigating whether and how long these changes are retained after exposures end. 8-week old female Balb/c mice inhaled freshly-generated butadiene soot (BDS; 5 mg/m3, 4 hr/day, 3 weeks) mixed with HEPA-filtered air (AIR) or AIR alone and were allowed to rest 10 days before sacrifice. qRT-PCR was carried out on RNA from 1 lung/mouse for each of 10 genes previously shown to be up-regulated 1 day after BDS exposures end. Bronchoalveolar lavage fluid (BALF), lung inflammation and presence of alveolar macrophages containing BDS particles also were assessed. Ten days after exposures ended the Phase 1 biotransformation enzymes Cyp1a1, Cyp 1b1 and AhRR were up-regulated 1.5-2.3-fold. The oxidative stress response gene Nqo1 was up-regulated 1.8-fold as was Ptgs2, which is partially responsible for prostanoid synthesis involved in inflammatory responses. No significant increases in lung inflammation or BALF differentials were noted; however, particle-laden alveolar macrophages were still present in all BDS-exposed mice vs. none in controls. The results indicate the possibility of delayed lung effects well after relatively brief exposures to soot nanoparticles have ended.

PL 1358 ADIPOSE DEPOSITION REGULATION THROUGH EPIDERMAL GROWTH FACTOR RECEPTOR SIGNALING.

M. Weed[1, 2] and D. W. Threadgill[2, 1]. [1]*Toxicology, University of North Carolina, Chapel Hill, NC and* [2]*Genetics, University of North Carolina, Chapel Hiill, NC.*

The balance between food intake and energy expenditure is regulated through a highly integrated multi-organ system. Satiety and adiposity signals from the intestines and adipose tissue are sent to the central nervous system (CNS) where they, along with other neuronal signals, are used to maintain this balance. Obesity results from taking in more calories than required for this energy homeostasis or from resistance to anorexogenic signals, and can lead to prolonged exposure to lipophilic toxicants. As a result of the worldwide rise in obesity and obesity-related complications such as diabetes, stroke, and cardiovascular disease, understanding the mechanisms associated with this disease and determining treatment options is necessary. The epidermal growth factor receptor (EGFR) is involved in adipogenesis and therefore may contribute to this regulation of energy homeostasis in the body. Using a diet-induced obesity mouse model, we found that inhibition of EGFR either genetically with the *Egfr*^{wa2} hypomorphic allele or pharmacologically with a small molecule inhibitor against the EGFR tyrosine kinase (AG1478) slows adipose mass deposition. Therefore, to determine EGFR's role in energy homeostasis, particularly adipose deposition, we deleted *Egfr* specifically in peripheral tissues (i.e., intestines and adipocytes) and in the CNS using the *Egfr*^{tm1Dwt} conditional allele and the *Villin-Cre*, *aP2-Cre*, and *GFAP-Cre*, transgenic lines, respectively. All mice were fed a high-fat diet over three months. Body weight and MRI measurements were collected monthly and upon sacrifice, heart, liver, and fat depots were dissected, weighed, and stored at -80 °. Ablation of EGFR within the intestinal epithelium with *Villin-Cre* showed no effect on adipose deposition. However, deletion specifically within the CNS caused a significant reduction in adipose mass while ablation within adipocytes caused an increase in adipose mass. These experiments show that adipose deposition is under complex regulation by EGFR signaling involving both the CNS and adipocytes.

PL 1359 EXPOSURE OF NEONATAL MALE RATS TO ENDOCRINE DISRUPTER BISPHENOL A, AFFECTS ONTOGENIC EXPRESSION PATTERN OF TESTICULAR STEROID RECEPTORS AND THEIR COREGULATORS.

S. S. Salian, T. Doshi and G. Vanage. *National Center for Preclinical Reproductive and Genetic Toxicology, National Institute for Research in Reproductive Health (ICMR), Mumbai, Maharashtra, India.* Sponsor: V. Vasiliou.

Bisphenol A (BPA), an endocrine disrupter has the propensity to leach from various consumer products. Detection of BPA in human amniotic fluid, cord blood indicated its capability to transverse the placental barrier thus highlighting a need to investigate its effect during critical "windows" of development. Present study was undertaken to determine the effect of exposure of neonatal male rats to environmentally relevant dose of BPA on the testicular expression pattern of steroid receptors (ERα, ERβ, AR) and their coregulators(corepressor viz. NCoR; coactivator viz.SRC-1, GRIP-1, p/CIP) during development. Neonatal male rats were s.c injected with 2.4μg/kg bw/day of BPA in sesame oil from postnatal day 1-5 and controls received vehicle. Animals were sacrificed on PND 15, 30, 45, 60, 75, 90, 125, and testes were dissected out. One testis from each animal was used for gene expression studies using Real time PCR and another for protein expression profile using immunohistochemistry. Expression pattern of steroid receptors was studied at gene and protein level whereas expression of steroid receptor coregulators was studied only at the protein level. The results obtained were compared with their respective age matched controls. Significant decrease in the expression profile of ERα, ERβ and AR at both the gene and protein level was seen in the treated group. Coregulator viz. NCoR and SRC-1 showed a significant decrease in expression, whereas GRIP-1and p/CIP showed a significant increase in their protein expression

profile in the treated animals. These results demonstrated that exposure of neonatal male rats to BPA lead to impairment in expression pattern of steroid receptors and coregulators which play a crucial role in modulating the steroid hormone action during critical period of differentiation and development of male reproductive organs and their function.

PL 1360 ESTRADIOL IS INVOLVED IN THE UPREGULATION OF GLUTATHIONE SYNTHESIS BY FSH IN OVARIAN FOLLICLES.

Y. D. Hoang[1], B. N. Nakamura[1] and U. Luderer[1, 2]. *[1]Medicine, University of California Irvine, Irvine, CA and [2]Developmental and Cell Biology, University of California Irvine, Irvine, CA.*

The antioxidant tripeptide glutathione (GSH) detoxifies electrophilic metabolites and reactive oxygen species. Our previous studies showed that treatment with gonadotropin hormones enhanced ovarian GSH synthesis. In the present studies, we evaluated the effects of follicle-stimulating hormone (FSH) and estradiol (E2) on the expression of glutamate cysteine ligase (GCL), the rate-limiting enzyme in GSH synthesis, in ovarian granulosa cells (GC) and follicles. Primary GC or small antral follicles were isolated from ovaries of 25-day old female E2-primed Sprague-Dawley rats and were cultured with 0 or 20ng/ml FSH plus or minus 100 ng/ml 17β-E2. In isolated GC, GSH concentrations increased significantly after 48h, but not 24h, of FSH treatment, and this effect was enhanced by E2. FSH alone increased GCL subunit protein levels at 48h without affecting mRNA levels. In contrast, FSH with E2 induced mRNA and protein expression of both GCL subunits as early as 24h; levels remained elevated at 48h. E2 alone had no effects. Luteinizing hormone receptor mRNA levels also increased after 48h of FSH treatment, consistent with GC differentiation. The PKA inhibitors, H89 and PKI, abolished the effect of FSH on GCLM protein, whereas only PKI blocked the effect on GCLC. These results suggest that the effects of FSH alone on GCL are mediated by PKA signaling. Small antral follicles cultured with FSH showed a 35-fold increase in E2 secretion at 24h versus controls. FSH-treated follicles had a 2-fold increase in total GSH and a 2-fold increase in the ratio of reduced to oxidized GSH versus controls at 24h, indicating that untreated controls were more oxidized. This coincided with a significant rise in GCL subunit mRNA and protein levels. Taken together these data show that FSH and E2 interact to maximally stimulate GCL subunit expression and GSH synthesis in GC. The data further suggest that E2 mediates the pronounced stimulation of GCL expression/GSH synthesis by FSH in small antral follicles. Supported by NIH ES10963.

PL 1361 HORMONAL SUPPRESSION RESTORES FERTILITY IN IRRADIATED MICE FROM BOTH ENDOGENOUS AND DONOR-DERIVED SPERMATOGENESIS.

G. Wang, S. H. Shao, C. Weng and M. L. Meistrich. *Experimental Radiation Oncology, M.D. Anderson Cancer Center, Houston, TX.*

Irradiation reduces sperm production and causes male sterility in rodents and humans. Suppression of testosterone was able to restore spermatogenesis in irradiated rats, but not in mice or humans. Recently, we showed that testosterone suppression with a GnRH antagonist, acyline, and flutamide (A+F), given to mice after irradiation, improved the recovery of endogenous spermatogenesis and enhanced colonization of transplanted stem spermatogonia. Here we further explore the restoration of fertility from endogenous or donor-derived germ cells in irradiated mice by hormone suppression. All mice were irradiated, with or without spermatogonial transplantation (ST) 3-4 wk later from GFP-marked donors, and followed by spermatogenic evaluation and fertility testing. For endogenous recovery, testes of mice were irradiated (10.5 Gy) and subjected to either 10-wk A+F or sham treatment. Hormone suppression enhanced recovery of endogenous spermatogenesis as indicated by increased testis weights (1.3-fold) and sperm count (2-fold) at 21 wk after irradiation. In the hormone-suppressed group 12 out of 15 mice recovered fertility at about 22 wks after irradiation, while all sham-treated mice remained infertile as of 30 wk. For donor-derived spermatogenesis, mice were irradiated (13.5 Gy) and were either treated with: 1) sham A+F & sham ST; 2) A+F & sham ST; 3) ST and sham A+F; or 4) A+F and ST. Testis weights were also significantly higher in mice treated with both A+F and ST than those in mice treated with either A+F or ST at 21 wk. Furthermore, in the transplanted, hormone-suppressed group, 2 out of 20 mice were fertile from donor-derived spermatogenesis at 18 wk after irradiation, but no mice from the other groups regained fertility within 28 wk. Thus hormone suppression successfully restores spermatogenesis and fertility from both endogenous and transplanted spermatogonial stem cells in irradiated mice. The combination of ST with hormonal suppression should be investigated to restore fertility in young men after cytotoxic therapy for cancer.

PL 1362 INSULIN RESISTANCE IN SPRAGUE-DAWLEY RATS CHRONICALLY TREATED WITH ETHANOL.

T. M. Badger[1, 3], M. Ferguson[1] and M. J. Ronis[1, 2]. *[1]Arkansas Children's Nutrition Center, University of Arkansas Medical Sciences, Little Rock, AR, [2]Pharmacology & Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR and [3]Physiology & Biophysics, University of Arkansas for Medical Sciences, Little Rock, AR.*

We have previously demonstrated that hepatic insulin signaling is disrupted in Sprague-Dawley (SD) rats fed EtOH-containing diets by total enteral nutrition (TEN). To determine if whole body insulin resistance could be demonstrated in the TEN model, we conducted euglycemic-hyperinsulinemic clamp studies in adult (age 90 days) rats chronically (4 weeks) fed ethanol-containing diets (10-13 g/kg/d EtOH). Rats were fed either control diets formulated to meet the National Research Council recommended daily nutrient intake for rats, or an isocaloric diet containing 10-13 g/kg/d EtOH (EtOH calories replaced a portion of the carbohydrate calories). The glucose infusion rate (GIR) of rats chronically fed >10 g/kg/d ethanol was lower ($P<0.05$) than control rats receiving the same isocaloric diet without ethanol. Because blood ethanol concentrations (BECs) of rats in the TEN model are pulsatile (i.e., EtOH concentrations occur as large pulses over a 6 day period), insulin clamp studies were conducted at different stages of the pulse (i.e., different BECs), and preliminary data suggest that insulin sensitivity does not vary with differences in BECs. We conclude that chronic ethanol intake causes whole body insulin resistance and while consistent with previous data demonstrating disruption of hepatic insulin signaling, these data suggest that overall insulin sensitivity does not vary throughout the EtOH pulse and therefore does not drive EtOH metabolism as previously predicted. Supported in part by NIAAA008645.

PL 1363 LOW DOSE ETHANOL CONSUMPTION IMPROVES INSULIN SENSITIVITY IN RATS.

L. He[1, 3], M. Ferguson[1], M. Blackburn[1, 3], J. Badeaux[1], M. J. Ronis[1, 2] and T. M. Badger[1, 3]. *[1]Arkansas Children's Nutrition Center, University of Arkansas Medical Sciences, Little Rock, AR, [2]Pharmacology & Toxicology, University of Arkansas for Medcial Sciences, Little Rock, AR and [3]Physiology & Biphysics, University of Arkansas for Medcial Sciences, Little Rock, AR.*

While chronic consumption of high doses of ethanol is well known to have adverse health consequences, intake of low doses have been reported to improve several markers of health outcomes. Published results from our laboratory using total enteral nutrition (TEN) in rats, in which ethanol-containing diets are infused directly into the stomach, have clearly demonstrated that chronic ethanol intake results in disruption of hepatic insulin signaling. Based upon previous literature reports we posited that using the same TEN model, but with chronic low EtOH doses, insulin sensitivity would increase. Young adult male Spraque-Dawley rats (age 60 days) were surgically fitted with an intragastric cannula and fed a high fat diet plus low dose EtOH (4 g/kg/d). After 4 weeks of this diet, rats had gained weight equal to control rats that were fed the same isocaloric diet (except EtOH calories were replaced with carbohydrate calories). Rats were fasted over night and a standard oral glucose tolerance test was administered. Rats fed low doses EtOH had a greater ($P<0.05$) whole body insulin response than control rats fed a diet with no ethanol. Moreover, hepatic Akt-GSK3beta-SREBP-1 signaling was enhanced ($P< 0.05$) and expression of the gluconeogenic enzyme PEPCK was suppressed in low dose EtOH vs. control animals ($P<0.05$). We conclude that chronic intake of a diet containing low dose EtOH can improve insulin sensitivity. Supported in part by NIAAA008645.

PL 1364 TRICLOSAN MODULATES ESTROGEN-DEPENDENT RESPONSES IN THE RAT UTEROTROPHIC ASSAY.

T. Stoker[1], L. Zorrilla[2, 1], J. Pregenzer[3] and E. Gibson[1]. *[1]U.S. EPA, Research Triangle Park, NC, [2]NCSU College of Veterinary Medicine, Raleigh, NC and [3]CEETOX, Kalamazoo, MI.*

Our previous studies in the juvenile rat indicated that the biocide triclosan may alter steroid hormone levels. Here, we hypothesize that triclosan possesses estrogenic activity. First, we evaluated triclosan using the immature rat uterotrophic assay. Female Wistar rats (19 days old) were gavaged for 3 days with corn oil, 3 ug/kg ethinyl estradiol (EE) or 1.17 to 300 mg/kg triclosan either alone or in combination with EE. Six hours after the last dose, the uteri were weighed and processed for subsequent histological evaluation. Uterine weight was increased in the EE group as compared to the control, but was not affected by triclosan alone. However, there was a significant dose-dependent increase in the triclosan 4.69 to 300 mg/kg co-treated with EE as compared to the EE alone, indicating a potentiation of the estrogen response on uterine weight. In addition, this result was correlated with a dose response increase in degree of columnar differentiation of the luminal epithelium of the uteri in the females receiving co-treatment with EE. In a

second study, an in vitro estrogen receptor (ER) transcriptional activation (TA) assay using the T47D-Bluc cell line was used to determine if triclosan altered estrogen receptor activation. Triclosan concentrations of .003 to 10μM were evaluated in this assay. Triclosan were completely soluble and cytoxicity was not observed after 24 hour incubation. Triclosan alone did not have agonistic activity in the ER TA assay. In addition, co-incubations of triclosan and various concentrations of estradiol resulted in a response comparable to estradiol alone, indicating that the parent compound does not antagonize or potentiate ER TA. It is possible that one of the metabolites of triclosan may be responsible for the observed effect. In conclusion, there appears to be a potentiating effect of triclosan on estrogen mediated uterine response in the weanling female rat. Current studies are evaluating other potential modes of action for this effect. This abstract does not reflect EPA policy.

PL 1365 EFFECTS OF A MODEL INDUCER, PHENOBARBITAL, ON THYROID HORMONE GLUCURONIDATION IN RAT HEPATOCYTES.

V. M. Richardson[1, 2] and M. J. DeVito[1]. *[1]ORD/NHEERL/ETD/PKB, U.S. EPA, Research Triangle Park, NC and [2]Curriculum in Toxicology, UNC at Chapel HilL, Chapel Hill, NC.*

In vivo, hepatic enzyme inducers such as phenobarbital (PB) have been shown to decrease circulating thyroid hormone (TH) concentrations. This decrease in circulating TH occurs in part through extrathyroidal mechanisms. Specifically, through the induction of hepatic xenobiotic metabolizing enzymes such as uridinediphosphate-glucoronosyltransferases (UGTs), thyroid hormones are catabolized and cleared through biliary elimination. This study further examines the catabolism and clearance of THs by analyzing the formation of T4-glucuronide (T4G) using rat cryopreserved hepatocytes. Hepatocytes were plated in a monolayer and treated for 72 hours in serum-free media with or without 1mM PB. After removal of media, 0.05, 5.0, 25.0, or 50.0uM T4I125 was added to cells and incubated for up to 24 hours at 37C. After 24 hours, 3.3, 4.3, 4.5, and 5.7 % T4I125 accumulated within hepatocytes exposed to 0.05, 5.0, 25.0, or 50.0uM T4I125, respectively. In hepatocytes pretreated with 1mM PB, 2.1, 2.8, 3.2, and 4.3% T4I125 accumulated within hepatocytes to 0.05, 5.0, 25.0, or 50.0uM T4I125, respectively. In controls, Vmax was 0.85pM T4G/min/million cells, while in PB treated hepatocytes, Vmax increased to 1.94pM T4G/min/million cells. The Km for T4G formation following PB pretreatment was 112.4uM whereas the Km without PB was 44.7uM. These data suggest that pretreatment with PB increased the elimination of T4I125 through an increase in T4 catabolism and clearance. This study also demonstrates that rat hepatocytes are a valuable tool for evaluating the effects of xenobiotics on extrathyroidal mechanisms of T4 elimination. (This is an abstract of a proposed presentation and does not necessarily reflect USEPA policy.)

PL 1366 ARYL HYDROCARBON RECEPTOR EXPRESSION AND FUNCTION IN NORMAL ENDOMETRIUM AND ENDOMETRIOSIS.

E. V. Hestermann[1], J. Wise[1], B. Lessey[2], A. Houwing[2] and S. Young[3]. *[1]Biology Department, Furman University, Greenville, SC, [2]Reproductive Endocrinology, Greenville Hospital System University Medical Center, Greenville, SC and [3]Obstetrics and Gynecology, University of North Carolina Health Care, Chapel Hill, NC.*

The aryl hydrocarbon receptor (AHR) has been suspected to play a role in the development of endometriosis. Using human tissue samples and an endometrial carcinoma cell line, we investigated the interactions between AHR and hormonal pathways involved in endometrial physiology. Expression of mRNA for AHR and it's target genes cytochromes P4501A1 (CYP1A1) and P4501B1 (CYP1B1) were all significantly higher in endometriosis samples than in normal controls. Because endometriosis is associated with progesterone resistance during the secretory phase of the menstrual cycle, we next measured expression of AHR in normal endometrial samples from different stages of the cycle. Expression of AHR, CYP1A1 and CYP1B1 were typically highest during the proliferative phase and significantly lower by the mid-secretory phase. Hypothesizing that expression of these genes was regulated by hormones important in the control of the menstrual cycle, we treated ECC-1 endometrial adenocarcinoma cells with diethylstilbestrol, epidermal growth factor, or medroxyprogesterone 1-acetate (MPA). Expression of AHR and its target genes was decreased in cells exposed to MPA as compared to vehicle controls. Finally, we examined the effects of AHR ligands on expression of the progesterone receptors (PR) A and B in ECC-1 cells. The AHR agonists beta-naphthoflavone and 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) both significantly decreased expression of total progesterone receptors but not PR-B, suggesting that AHR agonists selectively decrease the expression of PR-A. A combination of TCDD and the AHR antagonist CH-223191 modestly increased PR expression versus the control. Taken together, these data suggest that AHR and its target genes are part of a larger program of gene regulation during the menstrual cycle, and that AHR activity may play a role in the progesterone resistance characteristic of endometriosis.

PL 1367 MULTIPOTENT NEURAL STEM CELLS ARE TARGETS FOR TCDD TOXICITY: POTENTIAL ROLES FOR AH RECEPTOR DURING NEUROGENESIS.

S. E. Latchney and L. A. Opanashuk. *Environmental Medicine, University of Rochester, Rochester, NY.*

Neurogenesis is a multi-step process that includes proliferation and differentiation of neural stem cells (NSCs). Pluripotent NSCs abundantly express the aryl hydrocarbon receptor (AhR), which mediates dioxin toxicity. Therefore, we hypothesized that dioxin exposure impedes AhR-mediated signaling events during NSC maturation. In this study, 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD), a pervasive environmental toxicant and a potent AhR ligand, was used to test this hypothesis. We previously determined that the C17.2 cell line contained abundant AhR levels and exhibited a multipotent NSC-like phenotype, as characterized by the expression of nestin, a NSC marker. Our studies revealed that TCDD exposure suppressed NSC proliferation by interfering with the G1 to S cell cycle transition. Under defined conditions, we determined that C17.2 cells adopted a neuronal fate, as evidenced by reduced nestin expression, elevated βIII-tubulin levels and absence of glial markers. AhR protein levels declined but remained detectable following NSC differentiation, suggesting a role for this receptor during NSC maturation to a neuronal lineage. When C17.2 cells were cultured in TCDD under non-depolarizing conditions, AhR expression was not downregulated, as would be expected. Additionally, AhR remained in the nucleus and the expression patterns of nestin, βIII-tubulin and GFAP proteins were consistent with reduced neural differentiation in response to TCDD. When C17.2 cells were exposed to TCDD in depolarizing conditions, AhR expression was reduced and NSC differentiation was not altered. Our data suggest that AhR activation by TCDD disrupted early NSC differentiation into neurons but that TCDD had distinct actions during activity dependent maturation. These observations suggest that the inappropriate or sustained activation of AhR by TCDD during neurogenesis can interfere with multiple signaling pathways during NSC proliferation and differentiation, which could adversely impact brain cytoarchitecture and function.

PL 1368 COMPARING GENE EXPRESSION ALTERATIONS IN MOUSE EMBRYOS UNDERGOING NEURULATION; DOSE AND TIME DEPENDENT EFFECTS OF CADMIUM AND ARSENIC EXPOSURES.

J. F. Robinson, X. Yu, S. Hong and E. M. Faustman. *Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.*

Initiated by known and unknown genetic and environmental factors, Neural Tube Defects (NTDs) represent the second most common birth defect in the human population. When exposed during neurulation, the C57 is more sensitive to metals than other inbred mouse strains, displaying a higher incidence of metal-induced NTDs. In limited studies, cadmium (Cd) and arsenic (As) impact biological processes (i.e. cell cycle) associated with increased toxicity and NTD formation. However, these studies do not account for comparative analyses across dose and time which may be important 1) to develop sensitive indicators of toxicity, 2) to characterize common and unique mechanisms of NTD formation between environmental teratogens and 3) to determine potential application for risk assessment. In this study, we examined dose- and time-dependent effects of As and Cd on gene expression using microarray and qRT-PCR in C57 embryos exposed in utero (GD8) across dose (As, 0-10mg/kg; Cd, 0-4mg/kg) and time (0-12h). We identified significantly altered genes due to metal exposure by ANOVA and corresponding enriched Gene Ontology (GO) functional categories using MAPPFinder. Using GO-Quant, we calculated the average impact on gene expression (As/Con or Cd/Con) for genes within enriched GO categories. Our results suggest As and Cd induce dose and time-dependent gene expression alterations, representing common (cell cycle) and unique (glycolysis, one-carbon metabolism (As only)) gene expression-linked GO biological processes. These observations correlate with common and differential impacts on specific genes of interest involved in cell cycle regulation (Cdkn1a), ion regulation (MT1), hypoxia signaling (Ndrg1) and methylation (Tyms). In summary, we have identified As and Cd induced gene expression responses in mouse embryos undergoing neurulation and associated quantitative changes within GO categories across dose and time to developmental toxicity and strain sensitivity. NIEHS:2P01ES09601, U10ES11387

PL 1369 LEAD DISRUPTS DEVELOPING HIPPOCAMPAL NEURON SYNAPSES *VIA* NMDA RECEPTOR INHIBITION.

A. P. Neal and T. R. Guilarte. *Env. Hlth. Sci., Johns Hopkins School of Public Health, Baltimore, MD.*

Lead (Pb^{2+})is a ubiquitous neurotoxicant that impairs hippocampal-mediated learning. $Pb^{2+}$is a potent N-methyl-d-aspartate receptor (NMDAR) antagonist and developmental exposure to Pb^{2+} alters NMDAR subunit mRNA and protein ex-

pression in the rat brain. Further, Pb^{2+} exposure alters glutamatergic and GABAergic transmission both *in vitro* and *in vivo*. We used a primary hippocampal cell culture system to assess the effects of Pb^{2+} in both the pre-synaptic active zone (PAZ) and the post-synaptic density (PSD). Previously, we reported that Pb^{2+} exposure (0.01-1.0 μM) altered NMDAR (NR1 subunit) targeting to the PSD, reduced levels of Synaptophysin (Syn) and increased the expression of the pre-synaptic scaffolding protein Bassoon. We now report that Pb^{2+} exposure results in decreased levels of Synaptobrevin ($p<0.05$), a PAZ protein essential for exocytic release. Based on these findings, we hypothesized that Pb^{2+} was increasing the number of pre-synaptic "silent" synapses. To test this hypothesis, we used FM1-43 dye to determine if vesicular release was impaired in Pb^{2+}-exposed cultures. Live imaging showed a significant decrease in the number of boutons actively releasing dye ($p<0.05$). The rate constants from individual release sites and the averaged rate of release were significantly different after exposure to Pb^{2+} ($p<0.05$), indicating a shift towards slower rate constants. To determine if both pre- and post-synaptic effects Pb^{2+} were mediated by NMDAR inhibition, we chronically exposed DIV7 neurons to 100 μM of the NMDAR antagonist APV, 1.0 μM Pb Pb^{2+}, or a co-exposure. As observed with 1.0 μM Pb^{2+}, exposure to 100 μM APV resulted in decreased Syn expression and increased targeting of NR1 to the PSD ($p<0.05$). These data suggest that both pre- and post-synaptic effects of chronic Pb^{2+} exposure are due to NMDAR inhibition and putative disruption of retrograde signaling to alter pre-synaptic elements. This is the first report to show that both pre- and post-synaptic effects of Pb^{2+} exposure are mediated by NMDAR inhibition [Supported by ES06189 to TRG, APN supported by T32ES07141]

PL 1370 PERSISTING EFFECTS OF DEVELOPMENTAL COPPER EXPOSURE IN WILDTYPE AND METALLOTHIONEIN KNOCKOUT MICE.

A. Petro[1], N. Pollard[1], H. Sexton[1], C. Miranda[1], A. Rastogi[1], J. Freedman[2] and E. D. Levin[1]. *[1]Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC and [2]National Institute of Environmental Health Sciences, NIH, Research Triangle Park, NC.*

Developmental exposure to heavy and transition metals such as lead and mercury have been shown to cause persisting neurobehavioral toxicity. Metllothioneins are small proteins, which are crucial for the distribution of heavy and transition metals. Previously we found that knockout of MT 1 and 2 potentiated the cognitive impairment caused by development mercury exposure. The current study examined the neurocognitive effects of developmental copper exposure. Wildtype and MT 1 and 2 knockout mice (MTKO) were given 10 or 50 mg/l of copper during gestation and until weaning. Mice of both genotypes with no added copper served as controls. When the mice were young adults they were trained for 18 sessions on the win-shift 8-arm radial maze test of spatial learning and memory. MTKO mice with no added copper were significantly impaired on radial-arm maze choice accuracy relative to wildtype controls. This MTKO-induced impairment was significantly attenuated by addition of 10 mg/l of Copper to the drinking water during development. Interestingly, Copper had a non-monotonic dose effect function. The addition of 50 mg/l of Copper to the drinking water during development was not effective in reversing the MTKO-induced impairment. Modest but not high doses of Cu supplementation given during development can effectively reverse the cognitive impairment seen in the radial-arm maze of mice with knockouts of MT 1 and 2. (Supported by NIH ES10356 and Autism Speaks)

PL 1371 MODERATE MATERNAL IRON INADEQUACY WORSENS NEUROBEHAVIORAL OUTCOMES OF DEVELOPMENTAL ETHANOL EXPOSURE.

E. S. Rufer[1], T. Tran[2] and S. M. Smith[1]. *[1]Nutritional Sciences, Molecular & Env. Toxicology, University of Wisconsin - Madison, Madison, WI and [2]Psychology, East Carolina University, Greenville, NC.*

Prevention of alcohol use is difficult, thus therapies that ameliorate alcohol's damage are desirable. The severity of fetal alcohol spectrum disorders (FASD) increases with parity, implying the depletion of a protective maternal factor. Iron deficiency is the most common nutritional deficiency in women and causes neurodevelopmental deficits in the offspring that parallel FASD. We hypothesized that moderate maternal iron inadequacy (ID) exacerbates alcohol's effects upon the developing brain and tested this in rat pups reared by dams fed iron-sufficient (IS) or ID diets. We exposed pups to 0, 3.5 or 5 g/kg alcohol during the brain growth spurt period via gastric gavage (postnatal days 4-9; P4-9). Peak blood alcohol levels for 3.5 and 5 g/kg doses were ~250 and ~400 mg/dl, respectively. Dams of the ID pups modeled a Stage I iron inadequacy without anemia, common in women. At P10, ID pups fed 0, 3.5 or 5 g/kg alcohol (ID-0, ID-3.5, ID-5) were slightly smaller and had lower indicators of iron status including moderate anemia. At ~P33 we evaluated the pups' associative learning using delay eyeblink classical conditioning (ECC). The frequency or amplitude of conditioned responses (CR) in the ID-0, IS-0, IS-3.5, and IS-5 groups did not differ reflecting the test's simplicity. In contrast, ID-5 pups had a dramatically reduced frequency and strength of CR; values were ~50% and 28%, respectively, of control values. Main effects for pup iron status and alcohol dose and a significant iron status x alcohol dose interaction were seen for CR frequency, $F[2, 47]=6.44$, $p<0.005$, and strength, $F[2, 47]=3.23$, $p<0.05$. Analyses of brain morphology and other behavioral outcomes are underway. This is the first study to show that maternal iron inadequacy profoundly exacerbates alcohol's effects upon learning in the offspring. We propose that maternal iron status is an important modulator of fetal neurobehavioral outcome following alcohol exposure. (Funded by NIH award T32 ES07015, R32 AA11085 & the Palmer fund)

PL 1372 DEVELOPMENTAL NEUROTOXICITY OF SILVER IN ZEBRAFISH AND PC12 CELLS.

C. M. Powers[1], J. Yen[2], E. Linney[2], S. Donerly[2], F. J. Seidler[1] and T. A. Slotkin[1]. *[1]Pharmacology & Cancer Biology, Duke Univ Med Ctr, Durham, NC and [2]Molecular Genetics & Microbiology, Duke Univ Med Ctr, Durham, NC.*

Silver (Ag+) accumulates in soft tissues and impairs CNS function after prolonged periods of high exposure in adults. Furthermore, Ag+ accumulates in fetal tissues to higher levels than those found after birth, raising concerns about developmental neurotoxicity, especially in light of the nearly 10-fold increase in the number of consumer products incorporating silver nanoparticles (AgNPs). Biological systems can accumulate both Ag and Ag+ from AgNP exposure. We are therefore exploring the role of Ag+ as a developmental neurotoxicant to serve as a baseline for comparison with AgNPs. We used zebrafish (Danio rerio) as a model organism that allows for evaluation of Ag+ effects in the context of both human health and the environment. Zebrafish embryos were exposed to Ag+ starting at 4h post fertilization (hpf). We then measured mortality and hatch rate through 5 days post-fertilization (dpf). We found increased mortality and severe morphological defects at concentrations above 3 uM. Concentrations as low as 1 uM decreased the number of embryos hatched by 72 hpf, when hatching is normally completed. We then examined neurodevelopmental effects at a lower exposure that did not impair hatchability or morphology. After embryonic (0-5 dpf) exposure to 0.3 uM Ag+, larvae showed impaired motor function at 5-10 dpf. We went on to determine potential mechanisms of neurotoxicity using neuronotypic PC12 cells; Ag+ impaired cell replication and altered neurodifferentiation. These studies thus point to the likelihood that Ag+ is a developmental neurotoxicant. Our future work will evaluate effects of AgNPs in both these in vivo and in vitro models, since AgNPs may be more toxic than Ag+ due to endocytotic uptake of the AgNPs. Support: NIH ES10356, GM007105.

PL 1373 METHYL MERCURY INDUCED GENE EXPRESSION CHANGES IN CEREBELLUM AND CEREBRUM OF PERINATALLY EXPOSED FEMALE WISTAR RATS.

R. Stierum[1], A. Wolterbeek[2], D. de Groot[2] and M. Radonjic[1]. *[1]Physiological Genomics, TNO Quality of Life, Zeist, Netherlands and [2]Toxicology and Applied Pharmacology, TNO Quality of Life, Zeist, Netherlands.* Sponsor: B. Blaauboer.

A developmental toxicity study was performed on the effects of perinatal exposure to methyl mercury (MeHg) (0, 0.1, 0.4, 0.7, 1.0, 1.5, 2.0 mg MeHg/kg BW; p.o.; gestation day 6 to lactation day 10). Off-spring was studied until post natal day (PND) 70, with attention to the developing immune, hormonal and neural systems. For selected dose groups, in vivo imaging, in vitro long term potentiation, toxicokinetics and toxicogenomics were performed. For toxicogenomics, rats were sacrificed on PND21 and PND70. Parts of cerebrum and cerebellum were collected. RNA was isolated using Trizol/NucleoSpin RNA II, labelled and hybridized to Affymetrix GeneChip® Rat Genome 230 2.0 arrays. For selected dose levels, microarrays were performed on RNA obtained from 5 individual animals, yielding a 68 microarray experiment. Quality control and GCRMA (slow) normalization was performed. Preliminary data analysis (principal component analysis) indicated clear differences between the two different brain regions. Gene expression patterns were distinct between PND21 and PND70, suggesting that neural biochemical changes concur with development. The effects of methyl mercury on gene expression in cerebellum were modest: a union of 159 genes changed significantly in any of the dose groups on PN21 and PN70. For most of these genes, the effect of methyl mercury was opposite on PN70 in comparison to PN21. The differentially expressed genes were associated with GO terms and functions that are relevant for brain development, including synaptic transmission, neuron projection and nervous system development. Together, toxicogenomics proved to be a sensitive method to detect, within the context of developmental toxicity studies, persistent chemically-induced mechanistic changes in neurological target tissues, even long after cessation of the actual exposure.

PL 1374 INTERFERON-GAMMA CAUSES DENDRITE RETRACTION IN SYMPATHETIC NEURONS *IN VIVO*.

It is hypothesized that environmental chemicals modulate neurodevelopment via activation of inflammatory processes. Further, inflammation is implicated in the pathogenesis of a diverse group of neurological diseases. However, the mechanisms by which inflammation causes adverse effects on neural development and function are not well understood. We demonstrate that a peripheral inflammatory event, induced by viral infection and restricted to airways, causes a decrease in dendritic complexity and tertiary length sympathetic neurons of the superior cervical ganlia (SCG). Systemic exposure to the proinflammatory cytokine γ-interferon (IFNγ), also causes dendrite retraction and synapse loss in the SCG. IFNγ-induced loss of receptive surface in the SCG occurs in the absence of reduced neuronal cell viability or decreased trophic interactions between SCG neurons and their target tissues. Decreased dendritic complexity and synapse loss is coincident with impaired ganglionic neurotransmission as evidenced by an attenuation of the baroreflex in animals treated with IFNγ. Based on these observations we propose a novel pathogenic mechanism of neuroinflammatory disease in th wich IFNγ disrupts neuronal connectivity via selective retraction of dendrites, leading to decreased neuronal excitability.

PL 1375 BUILDING A DATABASE OF DEVELOPMENTAL NEUROTOXICANTS: EVIDENCE FROM HUMAN AND ANIMAL STUDIES.

W. Mundy[1], S. Padilla[1], T. Shafer[1], M. Gilbert[1], J. Breier[1,2], J. Cowden[1], K. Crofton[1], D. Herr[1], K. Jensen[1], K. Raffaele[3], N. Radio[4] and K. Schumacher[5]. EPA's program for the screening and prioritization of chemicals for developmental neurotoxicity (DNT) necessitates the generation of a list of chemicals that are known mammalian developmental neurotoxicants. This chemical list will be used to evaluate the sensitivity, reliability, and predictive power of alternative DNT assays. A literature review was conducted for >400 compounds that have been suggested as developmental neurotoxicants. Compounds were assigned to one of three groups based on the strength of the evidence for DNT: (1) **no evidence**: no reports meeting our criteria for evidence or reports showing no DNT; (2) **minimal evidence**: one report or multiple reports from a single laboratory; or (3) **substantial evidence**: reports from more than one laboratory. Evidence was defined as (a) mammalian (laboratory animal or human) studies published in the peer-reviewed literature and/or (b) studies submitted to the EPA. Studies on chemical mixtures, *in vitro* studies, reports where ≥5 g/kg of the chemical was administered, and reports with inappropriate statistical analyses were excluded. The definition of neurotoxicity was broad, encompassing gross structural changes (*e.g.*, reduced brain weight, spina bifida, exencephaly) to more subtle indices of DNT (*e.g.*, changes in brain morphometry, neurochemical imbalances, and behavioral impairments). Of the chemicals examined, ~50% were assigned to the **no evidence** of developmental neurotoxicity group; ~25% had **minimal evidence**; and the remaining 25% had **substantial evidence** of toxicity to the developing nervous system. The chemicals in the latter group will be especially useful for vetting protocols that have been proposed as screens for develomental neurotoxicity. (*This abstract does not necessarily reflect Agency policy*)

PL 1376 HEXABROMOCYCLODODECANE (HBCD) INHIBITS THE DEPOLARIZATION-EVOKED INCREASE IN INTRACELLULAR CALCIUM LEVELS AND NEUROTRANSMITTER RELEASE IN PC12 CELLS.

M. M. Dingemans[1], H. J. Heusinkveld[1], A. de Groot[1], √. Bergman[2], M. van den Berg[1] and R. H. Westerink[1]. [1]*Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands and* [2]*Department of Environmental Chemistry, Stockholm University, Stockholm, Sweden.*

Neurotoxic effects have been described for several brominated flame retardants (BFRs). The BFR hexabromocyclododecane (HBCD) has been shown to cause adverse effects on learning and behavior in mice, as well as on dopamine uptake in rat synaptosomes and synaptic vesicles. As other BFRs have previously been demonstrated to alter the intracellular Ca^{2+} homeostasis, the aim of this study was to investigate whether the technical HBCD mixture and individual HBCD-stereoisomers (α-, β- and γ-HBCD) affect the intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) in a neuroendocrine *in vitro* model (PC12 cells). $[Ca^{2+}]_i$ and vesicular catecholamine release were measured using respectively imaging of the fluorescent Ca^{2+}-sensitive dye Fura-2 and amperometry. Exposure of PC12 cells to HBCD did neither affect basal $[Ca^{2+}]_i$ nor the frequency of basal neurotransmitter release. However, the number of cells showing depolarization-evoked release was markedly reduced following exposure to 20 μM HBCD. Exposure to HBCD (0-20 μM) caused a dose-dependent reduction of the depolarization-evoked increase in $[Ca^{2+}]_i$. This effect was apparent only when HBCD was applied at least 5 min before depolarization, while the maximum effect was observed after 20 min exposure. Additionally, using specific blockers of L-, N- or P/Q-type voltage-gated Ca^{2+} channels (VGCCs), it was shown that the inhibitory effect of HBCD is VGCC-a-specific. Interestingly, the effects of α- and β-HBCD were similar to that of the technical mixture, whereas the inhibitory effect of γ-HBCD on evoked $[Ca^{2+}]_i$ was larger. Summarizing, HBCD inhibits depolarization-evoked $[Ca^{2+}]_i$ and neurotransmitter release. As increasing HBCD levels are not unlikely, these findings justify additional efforts to improve (isomer-specific) exposure, hazard and risk assessment.

PL 1377 THE ROLES OF CHONDROMODULIN I AND NQO1 IN THE INHIBITION OF TUBE FORMATION INDUCED BY THE BENZENE METABOLITE HYDROQUINONE IN HUMAN BONE MARROW ENDOTHELIAL CELLS.

H. Zhou[1], J. Kepa[1], D. Siegel[1], S. Miura[2], Y. Hiraki[2] and D. Ross[1]. [1]*Department of Pharmaceutical Sciences, University of Colorado Denver, Aurora, CO and* [2]*Department of Cellular Differentiation, Institute for Frontier Medical Sciences, Kyoto University, Kyoto, Japan.*

Bone marrow is one of the major targets of benzene toxicity and NAD(P)H:quinone oxidoreductase (NQO1), a protective enzyme against benzene toxicity, is present in human bone marrow endothelial cells which form the hematopoietic stem cell vascular niche. Therefore, we have employed a transformed human bone marrow endothelial cell (TrHBMEC) line to study the adverse effects of the benzene metabolite hydroquinone (HQ) at the level of bone marrow endothelium. In this study, HQ (10μM) inhibited TrHBMEC tube formation at concentrations which were not overtly toxic as demonstrated by trypan blue exclusion or MTT analysis. HQ up-regulated chondromodulin I (ChMI), a protein that promotes chondrocyte growth and inhibits endothelial cell growth and tube formation. We also showed that recombinant human ChMI protein could inhibit TrHBMEC tube formation. Anti-ChMI siRNA was used to deplete ChMI mRNA and block the induction of ChMI by HQ. Pretreatment with anti-ChMI siRNA abrogated HQ induced inhibition of tube formation in TrHBMEC. Overexpression of NQO1 in TrHBMEC inhibited the up-regulation of ChMI and abrogated the inhibition of tube formation induced by HQ. Similar up-regulation of ChMI and inhibition of tube formation by HQ treatment was also observed in human umbilical vein endothelial cells (HUVEC) demonstrating that the effects observed are not cell line specific. In summary, HQ treatment up-regulated ChMI and inhibited tube formation in both TrHBMEC and HUVEC. The inhibition of tube formation in TrHBMEC occurred at least in part, through up-regulation of ChMI. The protective enzyme NQO1 inhibited HQ induced up-regulation of ChMI in TrHBMEC and protected cells from HQ induced inhibition of tube formation. This study provides a mechanism that may contribute to benzene induced toxicity at the level of bone marrow endothelium. (Supported by NIH grant ES09554)

PL 1378 GENOTOXICITY AND CELL CYCLE EFFECTS OF A CHICAGO AIRBORNE POLYCHLORINATED BIPHENYL MIXTURE AND AROCLORS IN LUNG FIBROBLASTS.

S. Pk, S. Flor, H. Lehmler, L. W. Robertson and G. Ludewig. *Interdisciplinary Graduate Program in Human Toxicology, The University of Iowa, Iowa, IA.*

Polychlorinated Biphenyls (PCBs) are environmental pollutants that produce various toxicities in humans and animals. Research till now has focused on the commercial mixtures (Aroclors) and individual PCB congeners and no work has been done on the toxicities of Airborne PCB mixtures, to which humans are exposed directly. To study the effects of Chicago air PCBs, a similar synthetic "Airborne mixture" was produced. This study is undertaken to determine cytotoxicity, DNA damage and cell cycle effects of this Chicago Airborne PCB mixture and compare it with Aroclor 1242 and Aroclor 1254. Chinese Hamster lung fibroblasts (V79) were exposed for 24 h to the mixtures at concentrations from 1 to 100 μM. Cytotoxicity increased dose-dependently between 10-100 μM concentrations, with Aroclor 1254 >> Airborne PCBs > Aroclor 1242. Micronuclei levels were significantly increased in all groups at 10 and 25 μM concentration, with Aroclor 1254 showing the highest effect and two thirds of the micronuclei being produced by the

loss of a chromosome fragment, not due to whole chromosome loss. Micronuclei could not be counted at 50 and 100 μM due to the high cytotoxicity and damaged nuclei. In the cell cycle phase distribution study, control cells had 32% of cells in G0-G1 phase, 8% in G2-M phase and 60% in S phase. None of the mixtures changed this phase distribution from 1 to 25 μM, but cells started to accumulate in S-phase at 50 μM concentration with the highest percentage in Aroclor 1254 treated samples. In conclusion, Aroclor 1254, which contains higher chlorinated PCB congeners, had the most potent toxic effects suggesting that the Airborne PCBs in our inner cities may not be as directly harmful as feared. However, studies with metabolically competent lung cell lines should be performed to exclude specific organ toxicity due to metabolic activation of the lower chlorinated congeners present in the Airborne mixture. (Supported by NIEHS P42ES013661, DOD DAMD17-02-1-0241, and CHEEC)

PL 1379 TOXICOGENOMIC EVALUATION OF PCB153-ELICITED HEPATIC EFFECTS IN C57BL/6 MICE.

A. K. Kopec[1, 2], L. D. Burgoon[1, 2], D. Ibrahim-Aibo[2, 3], J. R. Harkema[2, 3], C. Tashiro[4], B. Chittim[4] and T. R. Zacharewski[1, 2]. Polychlorinated biphenyls (PCBs) are ubiquitous contaminants found as complex mixtures of coplanar and non-coplanar congeners. Since non-coplanar PCBs do not elicit dioxin-like effects, their toxicity cannot be equated to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). The hepatic temporal and dose-dependent effects of the most abundant non-dioxin-like congener, 2,2',4,4',5,5'-hexachlorobiphenyl (PCB153), were examined in the immature ovariectomized C57BL/6 mice. Animals were gavaged once with 600 mg/kg PCB153 or sesame oil vehicle and sacrificed 2, 4, 8, 12, 18, 24, 72, 120 or 168 h after dosing. In the dose-response study, mice were treated by gavage with 1, 3, 10, 30, 100, 300 and 600 mg/kg PCB153 or sesame oil for 24 h. Significant increases in relative liver weights were noted at 72, 120 and 168 h (600 mg/kg) and at 24 h (300 and 600 mg/kg), accompanied by slight vacuolization. PCB153 altered the hepatic expression of 587 and 177 genes using Agilent 4 x 44 K microarrays (|fold change|≥1.5, P1(t)≥0.99) in the time course and dose-response studies, respectively. Prototypical constitutive androstane and pregnane x receptor (CAR/PXR) regulated genes including Cyp2b10, Cyp3a11, Ces2, Abcc transporters and Slco1a4 were induced. Functional annotation associated differential gene expression with drug metabolism, DNA damage and growth arrest, transport and lipid metabolism. Computational promoter analysis of the highest induced gene, Cyp2c55 (~60 fold) identified putative CAR/PXR response elements. Moreover, hepatic PCB153 levels paralleled differential gene expression. Preliminary examination suggests that PCB153 elicits a unique gene expression profile when compared to TCDD that may be mediated by CAR/PXR. Funded by SBRP P42ES04911.

PL 1380 THE *PARA* SUBSTITUTION IS A KEY DETERMINANT OF ACTIVITY OF BROMINATED DIPHENYL ETHERS TOWARD THE TYPE 1 RYANODINE RECEPTOR.

K. Kim[1], G. Marsh[2], √. Bergman[2], J. M. LaSalle[3] and I. N. Pessah[1]. [1]*Department of Molecular Biosciences: VM and Center for Children's Environmental Health, University of California, Davis, Davis, CA,* [2]*Department of Environmental Chemistry, Stockholm University, Stockholm, Sweden and* [3]*Department of Medical Microbiology and Immunology, the school of Medicine, University of California, Davis, Davis, CA.*

Polybrominated diphenyl ethers (PBDEs) are widely used flame retardants that bioaccumulate in human and animal tissues. Structurally similar non-coplanar polychlorinated biphenyls (PCBs) sensitize microsomal Ca^{2+} channels known as ryanodine receptor (RyRs). In this study, we investigated the structure activity relationship for select PBDEs and their respective methoxy metabolites towards the RyR type1 (RyR1) using [^{3}H]Ryanodine ([^{3}H]Ry) binding analysis and measurements of Ca^{2+} efflux. *Para*-bromo substitution(s) of were found to critically influence activity toward RyR1. BDE-49 (2,2'4,5'-tetrabromo) showed similar activity to BDE-17 (2,2'4-tribromo), whereas BDE-42 (2,2'3,4'-tetrabromo) showed 1.5 fold higher potency but 2.5 fold lower efficacy. Addition of a methoxy group to the free *para*-position reduced the potencies and efficacies of the corresponding parent congener. BDE-49 and its metabolite elicit release of Ca^{2+}- from microsomal vesicles and these effects are completely abolished with the RyR1 blocker ruthenium red. BDE-47 (2,2'4,4'-tetrabromo) had a minimal effect on RyR1 activation. Collectively these results indicated that *para*-substitution diminishes the activity of PBDEs toward RyRs. Considering RyRs are broadly expressed in excitable and non-excitable cells, these data provide a structure-activity to study how PBDEs influence cellular Ca^{2+} signaling and Ca^{2+}-dependent processes. Supported by ES11269, ES04699 and ES015171

PL 1381 METABOLISM OF PBDE 47, 99, AND 153 BY HUMAN LIVER MICROSOMES.

S. J. Lupton[1], B. McGarrigle[2], J. Olson[2], T. D. Wood[1] and D. S. Aga[1]. [1]*Chemistry, University at Buffalo, Buffalo, NY and* [2]*Pharmacology and Toxicology, University at Buffalo, Buffalo, NY.*

Polybrominated diphenyl ethers (PBDEs) 47 (2,2',4,4'), 99 (2,2',4,4',5) and 153 (2,2',4,4',5,5') are three of the most abundant congeners that bioaccumulate in humans and biota. The metabolism of PBDEs may contribute to their relative persistence and toxicity, which may in part be due to the formation of metabolites with endocrine-disrupting effects. However, the metabolism of BDEs in humans has not been well documented. This study determined the degree of BDE 47, 99, and 153 metabolism in human liver microsomes and identified specific metabolites formed. Radiolabelled or non-radiolabelled BDE 47, 99, or 153 were incubated for 2 hrs with a pooled specimen of human liver microsomes and specimens from 3 individual donors (A,B,C). After liquid-liquid extraction, radiolabelled samples were analyzed using HPLC/radio-chemical detection (RCD) while non-radiolabelled samples were analyzed before and after derivatization using GC/MS. The metabolism of BDE 47 and 99 was found to be linear for up to 2 hrs, while no detectable metabolites were observed for BDE 153. Specimen A had the highest activity, with 31% of BDE 47 and 52% of BDE 99 converted to metabolites over 2 hrs. Lower activity was observed for specimens B and C, with only 9% and 12% of BDE 47 and 12% and 13% of BDE 99 converted to metabolites by the respective specimens. Metabolism of BDE 47 produced two brominated metabolites, one dibrominated compound indicating a cleavage of the ether bond and one dihydroxylated tetra BDE. BDE 99 produced three brominated metabolites, two tribrominated metabolites, an epoxide and monohydroxylated compound, as well as a dihydroxylated penta BDE. This initial study further indicates that there are marked inter-individual differences in the ability of human liver microsomes to metabolize BDE 47 and 99, which could contribute to individual difference in the resulting retention and the potential toxicity of these agents.

PL 1382 TOXICITY OF HIGHLY PURIFIED PCB 180 IN RATS.

R. Roos[1], P. Heikkinen[2], L. van der Ven[3], M. Korkalainen[2], S. Lensu[2], M. Niittynen[2], S. Sankari[4], K. Savolainen[5], H. Schmitz[1], P. L. Andersson[6], D. Schrenk[1] and M. Viluksela[2]. [1]*Food Chemistry and Toxicology, University of Kaiserslautern, Kaiserslautern, Germany,* [2]*Department of Environmental Health, National Public Health Institute, Kuopio, Finland,* [3]*Laboratory for Toxicology, Pathology and Genetics, National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands,* [4]*Department of Equine and Small Animal Medicine, University of Helsinki, Helsinki, Finland,* [5]*ISLAB Laboratory Centre, Kuopio, Finland and* [6]*Environmental Chemistry, Umeå University, Umeå, Sweden.*

PCB 180 is a non-dioxin-like polychlorinated biphenyl (NDL-PCB) abundantly present in food and the environment. Risk characterisation of NDL-PCBs has been confounded by the presence of highly potent dioxin-like (DL) impurities. We used, therefore, highly purified PCB 180 (DL impurities 2.7 ng TEqWHO/g PCB 180) for a 28-day toxicity study in young adult rats. Groups of 5 males and 5 females were given total doses of 3, 10, 30, 100, 300, 1000 or 1700 mg/kg PCB 180 by gavage. Total dose was divided into 6 daily loading doses and 3 weekly maintenance doses. No increase in serum ALAT or APHOS activity was found, while increased liver weight and centrilobular hepatocellular hypertrophy were observed at >10 and >300 mg/kg bw in males and females, respectively. A significant increase in liver pentoxyresorufin O-dealkylase (PROD) was found in males at >10 mg/kg bw and in females at >30 mg/kg bw. In both genders, a significant induction of hepatic 7-ethoxyresorufin O-deethylase (EROD) activity was also observed. The CYP induction pattern indicates that PCB 180 acts as an agonist of the constitutive androstane receptor (CAR) and may also have some agonistic activity at the Ah receptor. Plasma T4 and to some extent also T3 were dose-dependently decreased in association with thyroid follicle depletion. Red blood cell parameters were dose-dependently decreased in both genders. Thymus weight was not affected. The results demonstrate a distinct toxicological profile of PCB 180 with some similarities with that of DL compounds, but clearly lower potency.
Funded by the European Commission (ATHON, FOOD-CT-2005-022923).

PL 1383 INTESTINAL PERMEABILITY AND DISPOSITION OF CHLORPYRIFOS AND CHLORPYRIFOS-OXON IN THE SINGLE-PASS INTESTINAL PERFUSION IN THE RAT.

T. J. Cook[1], S. Agrawal[2,6], J. Desiderio[2], T. Poet[3], M. Bartels[4] and J. Mattson[5]. *[1]Department of Pharmaceutical and Biomedical Sciences, Touro College of Pharmacy, New York, NY, [2]Department of Pharmaceutics, Rutgers University, Piscataway, NJ, [3]Center for Biological Monitoring and Modeling, Battelle, Pacific Northwest Division, Richland, WA, [4]Toxicology & Environmental Research and Consulting, The Dow Chemical Company, Midland, MI, [5](Retired), Dow AgroSciences, Indianapolis, IN and [6]Current Affiliation: Discovery Medicine and Clinical Pharmacology, Bristol-Myers and Squibb Company, Princeton, NJ.*

Chlorpyrifos (CPF), a common organothiophosphate pesticide, is metabolized in mammals to the active metabolite chlorpyrifos-oxon (CPF-O), which is primarily responsible for the observed toxicity. As part of our efforts for more accurate exposure modeling, we evaluated the intestinal permeabilities of CPF and CPF-O at environmental levels using the single-pass intestinal perfusion technique with mesenteric vein sampling in rats. Tritiated CPF (25, 250 and 2500 ng/ml) and CPF-O (25 and 2500 ng/mL) were perfused through the rat ileum for 30 min, after which the perfusate was switched to blank buffer. Outlet perfusion samples and mesenteric blood samples were collected over the entire perfusion period of 60 min. Radioactivity was determined by liquid scintillation counting. The lumenal, effective permeabilities (P_e), based on perfusate concentrations, and blood permeabilities (P_{blood}), based on mesenteric blood concentrations, were calculated. CPF and CPF-O exhibited P_e values > 10^{-4} cm/s, which are correlated to high fractions of dose absorbed (i.e., > 90%) in humans. P_{blood} values were approximately 10% of P_e values. After switching the perfusate to the blank buffer system, CPF and CPF-O unexpectedly continued to appear in the blood, which suggests that the intestine was acting as a reservoir for the compounds under these experimental conditions. The high lumenal and blood permeability values and the apparent sequestering of CPF and CPF-O have implications for exposure modeling and risk assessment. Financial support (TJC): Dow AgroSciences and NIH R03CA105465, R03CA121403.

PL 1384 EARLY-LIFE ORGANOPHOSPHATE EXPOSURE DISRUPTS LIPID METABOLISM IN ADULTHOOD.

T. Lassiter, E. D. Levin, F. J. Seidler and T. A. Slotkin. *Pharmacology & Cancer Biology, Duke Univ Med Ctr, Durham, NC.*

Organophosphate pesticides are developmental neurotoxicants but new findings point to lasting effects on metabolism, abnormal weight gain and prediabetes. We gave parathion to rats on postnatal days 1-4, using doses straddling the threshold for barely-detectable cholinesterase inhibition and the first signs of systemic toxicity (0.1 or 0.2 mg/kg). In adulthood, we evaluated serum adipokines, leptin and adiponectin, as well as standard lipid markers. Parathion decreased adiponectin and β-hydroxybutyrate in males, while decreasing cholesterol, nonesterified fatty acids and β-hydroxybutyrate in females. When animals were fed a high-fat (HF) diet for 7 weeks, further abnormalities emerged. In controls, there were increases in adiponectin, leptin and all serum lipid markers, verifying the metabolic effect of the HF diet. Males who had received the low neonatal dose of parathion showed an exaggerated increase in adiponectin and leptin on the HF diet, whereas females in the high dose group displayed a decrease in leptin relative to controls fed the HF diet. The sex differences were also apparent in the weight gain elicited by the dietary change: parathion-exposed males gained the same additional weight as controls on the HF diet, whereas females showed enhanced weight gain in the low dose group and suppressed weight gain in the high dose group. These results are consistent with long-lasting perturbations of lipid metabolism even at neonatal parathion exposures that produce minimal signs of exposure. Decreased adiponectin is associated with increased insulin resistance, diabetes, and cardiovascular disease. Further, changes in leptin and adiponectin are likely to play key roles in the weight gain caused by increased dietary fat intake, as these signals are responsible for communicating metabolic status to brain areas that control diet and metabolism. Our findings thus provide further evidence that early-life toxicant exposures may play a contributory role in the explosive increase in the incidence of metabolic dysfunction, obesity, and diabetes. (NIH ES10356, Leon Golberg Fellowship)

PL 1385 METABOLISM AND CHOLINESTERASE INHIBITION IN LUNGS OF RATS FOLLOWING *IN VITRO* CHLORPYRIFOS EXPOSURE.

C. Timchalk[1], R. M. Fox[3], K. M. Meyer[2], S. Lee[1], J. N. Smith[1], A. L. Busby[1] and T. S. Poet[1]. *[1]Biological Monitoring and Modeling, Pacific Northwest National Laboratory, Richland, WA, [2]Trinity Western University, Langley, BC, Canada and [3]Gonzaga University, Spokane, WA.*

Chlorpyfios (CPF) is an organophosphorous insecticide that is routinely applied to crops as an aerosol spray, hence there is potential for workers and bystanders to be exposed via inhalation. Though inhalation represents a primary occupational route of exposure, little is known about lung metabolism or cholinesterase (ChE) response following a CPF exposure. Hence, this study evaluated the in vitro metabolism and ChE response following exposure to CPF or its active metabolite CPF-oxon in rat lung tissue. Rat microsomes were prepared from naïve S-D rat lungs and liver. The comparative metabolism of CPF to the major metabolite trichloropyridinol (TCPy) was evaluated over a range of CPF concentrations (50 – 500 μM), and the amount of TCPy generated was analyzed by GC/MS. The maximum velocity (Vmax) of lung metabolism was ~44% of the liver (0.72 vs. 1.62 μg/min/mg protein) and the predicted Km for the lung and liver microsomes were 5.9 and 21 μM. For in vitro ChE determination, whole lung from naïve S-D rats were homogenized and optimally diluted for the Ellman assay. Substrates for the assay included acetylthiocholine (ATC) and butyrylthiocholine (BTC). The lung homogenates were then incubated with a broad range of CPF-oxon concentration (1 – 1E4 nM). Overall, the BTC substrate was ~43% of the ATC response, suggesting that butyrylcholinesterase (BuChE) represents ~40% of the lung ChE activity. The estimated IC50 for CPF-oxon ChE inhibition in lung for ATC and BTC were 76.5 and 52.7 nM, respectively. These in vitro studies confirm that the rat lung has the capacity to metabolize CPF, and CPF-oxon can readily inhibit lung ChE activity. Future in vivo studies will be conducted to quantify the lung pharmacokinetic and pharmacodynamic dose-response. Finally, these data will then be utilized to further refine the CPF PBPK/PD model to accommodate inhalation exposure. (Funded by CDC/NIOSH grants R01 OH008173 & OH003629)

PL 1386 SEX SPECIFIC CIRCADIAN VARIATION IN PHYSIOLOGICAL AND MOLECULAR RESPONSES TO PESTICIDES.

L. A. Hooven, K. Sherman and J. Giebultowicz. *Zoology, Oregon State University, Corvallis, OR.*

Circadian clocks synchronize internal biochemical and physiological rhythms to daily light/dark cycles. Many genes, including many involved in xenobiotic metabolism, reveal circadian expression rhythms. Many of the same genes exhibit sex-dependent induction after xenobiotic exposure. Utilizing Drosophila melanogaster as a model organism, we describe crosstalk between the circadian clock, sex, and xenobiotic metabolism. Flies were maintained in 12h:12h light/dark conditions, or moved to constant darkness or light prior to testing. Flies were acutely exposed to a series of doses of propoxur, malathion, deltamethrin, or fipronil by moving them to scintillation vials coated on the interior with chemical for one hour. Exposures or collections were every four hours for 24 hours. Mortality was scored two days later. Collected flies were processed for qRT-PCR, or to assay enzyme activity. Comparing dose responses at different times of day, we have established sex-specific daily susceptibility profiles. Females were generally less sensitive than males, and in the case of propoxur, LC50 was 100 fold that of males at ZT4. Similar rhythms were found in enzyme activities associated with xenobiotic metabolism, including ECOD, esterase, and GST activity. Mortality and enzyme activity rhythms continue in constant darkness and are lost in constant light, as has been observed in other clock-controlled rhythms. Using qRT-PCR, we are currently comparing daily expression profiles of clock genes, nuclear receptors, and xenobiotic metabolizing genes in males and females. Our previous work has indicated that defects in the central clock genes Pdp1 and CLK/CYC lead to increased susceptibility to pyrethroids in male flies. Our future work includes comparing daily susceptibility, expression, and enzyme activity profiles of these flies to wild-type males and females. This work will detail how the circadian clock modulates sex differences in xenobiotic metabolism in Drosophila. This will in turn lead to further understanding of how circadian disruption affects health in humans.

PL 1387 STRUCTURAL INSIGHT INTO INHIBITION/AGING OF NEUROPATHY TARGET ESTERASE (NTE) FROM X-RAY CRYSTAL STUDIES OF ITS CATALYTIC DOMAIN HOMOLOGUE, PATATIN-17 (PAT17).

S. J. Wijeyesakere[1], J. A. Stuckey[2] and R. J. Richardson[1]. *[1]Environmental Health Sciences/Toxicology, University of Michigan, Ann Arbor, MI and [2]Life Sciences Institute, University of Michigan, Ann Arbor, MI.*

NTE is a neuronal protein of unknown structure whose inhibition/aging by organophosphorus compounds (OPs) is linked to OP-induced delayed neurotoxicity, OPIDN. We hypothesized that NTE inhibition/aging results in toxic gain of function via conformational change. To test this hypothesis, we solved the crystal structure of the NTE catalytic domain homologue, pat17, inhibited/aged with diisopropylphosphorofluoridate (DFP). We purified his-tagged pat17 via affinity and size-exclusion chromatography and determined the 20-min I50 of DFP against its phenyl valerate hydrolase activity to be 172μM. We grew cubic crystals of DFP-inhibited pat17 within one week via vapor-diffusion at 4°C in 0.1M Na-acetate (pH

4.6)/46% (v/v) polyethylene glycol-400/75mM $(NH_4)_2SO_4$. We collected diffraction data at 0.97626Å at the Advanced Photon Source (Argonne, IL) and solved the crystal structure to 2.6Å in space group P4(3)2(1)2 (a=b=52.99Å, c=242.77Å; $\alpha=\beta=\gamma=90°$) via molecular replacement using PHASER with the structure of native pat17 (PDB ID 1OXW) as the search model. We did subsequent refinements of the structure by simulated annealing using the Crystallography and NMR System. The structure of DFP-aged pat17 showed that the negatively charged phosphoryl oxygen moiety was stabilized by the oxyanion hole. We also found that the pat17 active site lies at the end of a 16Å tunnel formed by Pro191, Ala190, Glm288, Ala217, Val218, Thr 291, and Asp 292. Comparisons of the pat17 native and aged states revealed no significant conformational changes (root-mean square deviation, RMSD = 0.98 Å). The results suggest that the toxic gain of function model for pathogenesis of OPIDN is not valid, and a new model for initiation of this condition is needed (Funded by NIH ES07062 and MEDC; plasmid encoding pat17 provided by Monsanto Company).

PL 1388 A C60 POLYHYDROXYFULLERENE DECREASES PARAOXON-INDUCED ACETYLCHOLINESTERASE (ACHE) INHIBITION *IN VITRO*.

M. Ehrich[1], K. Fuhrman[1] and R. Van Tassell[2]. [1]*Virginia Maryland Regional College of Veterinary Medicine, Blacksburg, VA and* [2]*Luna Innovations, Inc., Blacksburg, VA.*

In vitro methods are useful for initial identification (screening) of potential neuroprotectants. Such tests have demonstrated that polyhydroxyfullerenes can protect from excitotoxic neuronal cell death [Dugan, Neurobiol Dis 3, 1996], but they have not previously been examined for capability to decrease cholinergic toxicity induced by AChE-inhibiting organophosphorus compounds (OPs). This possibility was examined by incubating the active AChE-inhibiting OP paraoxon (4.2 – 17 nM) with an aqueous soluble hydroxylated fullerene with 60 carbons, C60(OH)n. Following 15 min incubation at room temperature, the paraoxon-fullerene was added to hen brain homogenate, which provided the source of AChE. AChE in the presence of 4.2 - 17 nM paraoxon was inhibited in a concentration-related manner (64% at 4.2 nM, 87% at 8.3 nM, >94% at 17 nM). When 8.3 uM C60(OH)n was included, AChE inhibition was markedly less, being 26% at 4.2 nM, 52% at 8.3 nM and 71% at 17 nM paraoxon. Increasing the C60(OH)n concentration to 16 uM further decreased paraoxon-induced AChE inhibition, with only 51% inhibition at 17 nM. However, if hen brain AChE was already inhibited with opportunity to 'age' by 15 min pre-exposure to an OP compound, addition of this C60(OH)n fullerene was not able to reverse OP-induced AChE inhibition in the in vitro system. Extrapolation to in vivo situations cannot be made when neither delivery of toxicant nor delivery of neuroprotectant is a feature of the in vitro experiments, so further experimentation is needed to evaluate therapeutic potential to act against cholinergic and noncholinergic toxicities following OP exposure in more relevant situations. (Supported by the NINDS CounterACT Program)

PL 1389 DIFFERENTIAL SENSITIVITY OF HUMAN AND RAT NAV1.3 VOLTAGE-GATED SODIUM CHANNELS TO THE PYRETHROID INSECTICIDE TEFLUTHRIN.

D. Soderlund and J. Tan. *Cornell University, Geneva, NY.*

Voltage-gated sodium channels are important sites for the neurotoxic actions of pyrethroid insecticides in mammals. The pore-forming α subunits of mammalian sodium channels are encoded by a family of 9 genes, designated Nav1.1 - Nav1.9. Native sodium channels in the adult central nervous system (CNS) are heterotrimeric complexes of one of these 9 α subunits and two auxiliary (β) subunits. Here we compare the functional properties and pyrethroid sensitivity of the rat and human Nav1.3 isoforms, which are abundantly expressed in the developing CNS and are potential targets for developmental neurotoxic effects of pyrethroids. Coexpression of the rat Nav1.3 and human Nav1.3 α subunits in combination with their conspecific β1 and β2 subunits in Xenopus laevis oocytes gave channels with markedly different inactivation properties and sensitivities to the pyrethroid insecticide tefluthrin. Rat and human Nav1.3 channels channels differed in their kinectis of fast inactivation and their voltage dependence of steady-state inactivation. Exposure of rat and human Nav1.3 channels to 100 μM tefluthrin in the resting state produced populations of channels that activated, inactivated and deactivated more slowly than unmodified channels. Application of trains of depolarizing prepulses enhanced the extent of tefluthrin modification of both channels approximately twofold; this result implies that tefluthrin may bind to both the resting and open states of the channel. Modification of rat Nav1.3 channels by 100 μM tefluthrin was four-fold greater than that measured in parallel assays with human Nav1.3 channels. Human Nav1.3 channels were also less sensitive to tefluthrin than rat Nav1.2 channels, which are considered to be relatively insensitive to pyrethroids. These data demonstrate that orthologous channels with a high degree of amino acid sequence conservation differ in both their functional properties and their sensitivities to pyrethroid insecticides.

PL 1390 DO PESTICIDES CAUSE PARKINSON'S DISEASE? SYNERGISTIC EFFECTS OF PESTICIDES ON CELL DEATH AND PROTEASOME ACTIVITY IN A DOPAMINERGIC CELL LINE.

A. Dreiem, G. Coccaro, V. M. Miller and R. F. Seegal. *Wadsworth Center, New York State Department of Health, Albany, NY.*

According to epidemiological and laboratory studies, pesticide exposure is a risk factor for Parkinson's disease (PD). People are usually exposed to mixtures of pesticides rather than to individual chemicals, but the toxicity of complex pesticide mixtures (i.e. more than binary combinations) is not well understood. We hypothesized that commonly used pesticides would cause more than additive effects on PD associated endpoints.

We examined the effects of chlorpyrifos (CPF), 2,4-D, dieldrin, atrazine, trifluralin (TFL), glyphosate, paraquat, maneb and mancozeb on cell viability, proteasome activity, and superoxide ($O_2^{\bullet -}$) formation (assessed with XTT, suc-LLVY-AMC, and hydroethidine, respectively) in a dopaminergic rat midbrain cell line (N27). Using an effect addition approach, we tested combinations of the most toxic pesticides (CPF, TFL, 2,4-D and dieldrin). Three of six binary combinations synergistically reduced proteasome activity and caused cell death, but had no effect on $O_2^{\bullet -}$ formation. Tertiary combinations: CPF + TFL + dieldrin and 2,4-D + TFL + dieldrin were synergistic in all three assays. Finally, the combination of all four pesticides was synergistic in all assays. The PD type cell death was confirmed by immunocytochemistry showing loss of cell and nuclear integrity, and ubiquitinated protein inclusion bodies in exposed cells. Our results show that complex pesticide mixtures have synergistic effects on PD related endpoints in dopaminergic cells in vitro. These results will provide a better foundation for risk assessment, and elucidate the mechanisms responsible for the epidemiological association between pesticide exposure and PD. In future studies we will use a complex pesticide mixture with a ray design to determine which pesticides cause more than concentration additivity, and the magnitude of the interactions. Supported in part by NIH grant 1 R01 ES014675-01 to RFS.

PL 1391 DICHLORVOS- AND METHOMYL-INDUCED RESPIRATORY TOXICITY RESULTS FROM CENTRAL MUSCARINIC EFFECTS.

F. J. Baud[2], P. Houzé[1, 2], G. Lévy[1] and A. David[1]. [1]*University Paris 7, Paris, France and* [2]*Toxicological Laboratory, Faculty of Pharmacy, Paris, France.*

Objective: We previously showed atropine (A) but not methylatropine (MeA) induced the correction of paraoxon-induced respiratory toxicity. The aim of this study was to assess the peripheral or central origin of respiratory toxicity induced by dichlorvos (D), and a carbamate, methomyl (M). Methods: male Sprague-Dawley rats were poisoned using D (5.76 mg.Kg-1; i.e. 45% of the sc MLD) or M (2.3 mg.Kg-1; i.e. 50% of the ip MLD). Poisoned rats were treated with A (base: 10 mg.Kg-1) or equimolar MeA (base: 5.42 mg.Kg-1) by intramuscular injection at the time of maximal respiratory effects, 5 min post injection of D or M. Respiratory function was assessed using whole body plethysmography and central temperature using infra-red telemetry. Results are expressed as mean +/- SEM. Statistical analysis used parametric tests with $p< 0.05$. Results: In rats with intraperitoneal telemetry, greater dose of D or M than about 50% of the MLD resulted in death. M but not D induced a significant decrease in core temperature. D and M induced a decrease in respiratory rate resulting from an increase in expiratory time. M but not D increased the tidal volume. The onset of respiratory toxicity occurred 5 min after injection for both D and M. The decrease in respiratory rate induced by M and D lasted 20 and 30 min, respectively. A (10 mg.Kg-1) completely reversed the D- and M-induced respiratory toxicity while an equimolar dose of MeA (5.42 mg.Kg-1) was without significant effects. Discussion: A crosses the blood-brain barrier and induces peripheral and central muscarinic effects. In contrast, MeA does not cross the blood-brain barrier only resulting in peripheral effects. In addition to paraoxon, our study showed that A resulted in the complete correction of D- and M-induced respiratory toxicity. In contrast, MeA did not induce any significant effect. We conclude the respiratory toxicity induced by anticholinesterasic insecticides including paraoxon, dichlorvos, and methomyl at dose about half the MLD results from effects mediated by central muscarinic receptors.

PS 1392 HAPLOTYPE ANALYSIS OF THE FULL *XPC* GENOMIC SEQUENCE REVEALS A CLUSTER OF VARIANTS ASSOCIATED WITH SENSITIVITY TO THE GENOTOXIC EFFECTS OF TOBACCO SMOKE.

C. M. Rondelli[1], J. K. Wickliffe[1], R. A. El-Zein[2], C. Etzel[2] and S. Z. Abdel-Rahman[1]. *[1]PMCH-ET/NCB, UTMB, Galveston, TX and [2]Epidemiology, MD Anderson Cancer Center, Houston, TX.*

The *Xeroderma pigmentosum* complementation group C protein, encoded by the *XPC* gene, plays a key role in the nucleotide excision repair process. *XPC* is highly polymorphic, but only a few single nucleotide polymorphisms (SNPs) have been studied as modifiers of cancer risk. To date, the phenotypic effects of these SNPs have not been characterized, nor has their impact on DNA damage-response and DNA repair capacity been determined. In this study, we constructed a comprehensive haplotype map encompassing the common SNPs in the *XPC* gene, and evaluated their effect on DNA damage associated with smoking, using chromosome aberrations (CA) as a biomarker. We hypothesized that if certain haplotypes have phenotypic effects, there would be a correlation between these haplotypes and CA in smokers. Our results indicate that out of 92 SNPs identified, 35 had a minor allele frequency ≥0.05. A haplotype-tagging (ht) approach was used to identify 12 htSNPs representing these 35 SNPs. We used these htSNPs to genotype a population of smokers matched to non-smokers (n=123), and to construct corresponding haplotypes. Out of 48 haplotypes we identified 20 that existed with a frequency ≥0.05. Phylogenetic analysis revealed that these 20 haplotypes segregate into 5 distinct phylogenic groups of haplotypes (PGHs A to E). When we evaluated the relationship between these PGHs and CA, we observed that smokers with PGH-E had double the mean CA frequency (mean CA/100 cells ±SEM=1.25±0.257) compared to smokers with other haplotypes (0.568±0.137). We also observed significant interactions between smoking and PGH-B (P=0.042). Among those negative for PGH-B, CA was 1.35 times higher in smokers compared to non-smokers; whereas among those who were positive for PGH-B, CA was 41% less in smokers compared to non-smokers. Given the strong association between CA and cancer, our data suggest that *XPC* haplotypes could significantly affect the risk of smoking-related cancers.

PS 1393 GENETIC INSTABILITY IN THE PERIPHERAL LYMPHOCYTES AND BUCCAL CELLS OF HEAD AND NECK CANCER PATIENTS AND THEIR FIRST DEGREE RELATIVES: INFLUENCE OF XRCC1 ARG399GLN POLYMORPHISM ?

S. Burgaz[1], N. A. Kocabas[1], E. Coskun[1], G. D. Cakmak[1], F. Cetindag[2], O. Sunter[2] and H. Edinsel[2]. *[1]Toxicology, Gazi University, Ankara, Turkey and [2]Abdurrahman Yurtaslan Oncology Hospital, Ankara, Turkey.* Sponsor: M. Iscan.

It may be important to know the influence of genetic polymorphisms on chromosome damage with respect to the improvement of cytogenetic biomarkers and also to the identification of at-risk groups. We studied the baseline micronucleus (MN) and radiation-induced micronucleus (Ind-MN) frequencies in lymphocytes and the buccal cell MN frequencies and influence of XRCC1 gene polymorphism (Arg399Gln) both for head and neck cancer (HNC) patients (n=59) and their first degree relatives (FDRs) (n=34) as well as controls (n=31).The XRCC1 alleles were detected using PCR-RFLP technique. For the Ind-MN assay, blood samples were exposed in vitro to 2 Gy gamma rays (60Co) at a dose rate of 0.62 Gy/min. The mean(SD)MN and Ind-MN frequencies(‰)in lymphocytes of HNC patients, FDRs and controls were 27.1(9.5), 172.7(44.8),14.1(5.2),169.5(47.1)and 9.0 (6.9), 150.9(43.3),respectively. Significant differences in baseline MN frequencies between studied groups were found ($p<0.05$), however, there were no differences in Ind-MN frequencies between all groups ($p>0.05$).Significant differences in buccal MN frequencies between HNC patients and FDRs as well as controls were found ($p<0.001$).Number of subjects with wild genotype (Arg/Arg), heterozygous subjects (Arg/Gln) and mutant subjects (Gln/Gln) are 23, 12, 12; 21,13,14 and 8,5,5 for patients, FDRs and controls, respectively. Our data suggest that MN frequencies in lymphocytes and buccal cells may be predictive for cancer risk. It might be possible to identify high risk family members by analyzing background MN frequencies in lymphocytes but not in buccal cells. XRCC1 variant genotypes did not significantly modulate the frequency of MN in studied groups. Further work is needed to resolve the importance of other polymorphisms of XRCC1 including codon 194, as well as other DNA repair systems.

PS 1394 CYP1A1 (ILE462VAL) POLYMORPHISM, RESPONSE TO CHEMOTHERAPY AND SURVIVAL IN ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS: IS THERE ANY ASSOCIATION ?

M. Iscan[1], A. O. Ada[1], S. Bilgen[1], S. C. Kunak[2], F. Hancer[1], S. H. Suzen[1], S. Alpar[3] and M. Gulhan[3]. *[1]Toxicology, Ankara University, Faculty of Pharmacy, Ankara, Turkey, [2]Pharmacology, University of Giresun, Faculty of Medicine, Giresun, Turkey and [3]Pulmonary Diseases, Ankara Pulmonary Diseases and Thoracic Surgey Hospital, Ankara, Turkey.*

Lung cancer is an increasing worldwide public health problem particularly in men. Recently, the mutations in CYP1A1 gene have been suggested to be responsible for decreasing of the survival rates of patients with non-small cell lung cancer (NSCLC) by forming aggressive tumors by P53 inactivation and thereby altering sensitivity to chemotherapy. However, the limited studies, which either did not provide data with respect to their relation to response to therapy, had contradictory results. In this study, the association between CYP1A1 (Ile462Val) polymorphism, and response to platinum based chemotherapy and survival rates in 138 (126 men and 12 women) NSCLC patients who are treated with platinum based drugs have been investigated.. The polymorphism of CYP1A1 (Ile462Val) did not significantly influence the responses to platinum based chemotherapy. No significant associations were noted between the responses of genotypes to chemotherapy and age, sex, smoking status, chemotherapy treatment status, tumor stage and histology. Significant survival was not observed in patients with CYP1A1 genotypes (median survival of 18 months for wild type (Ile/Ile) genotype and 16 months for variant (Ile/Val or Val/Val) genotype; p=0.523). Multivariate analysis, (after adjustment for age, gender, tumor histology, disease stage, smoking status and response to chemotherapy) also revealed no significant hazard ratio (HR)s of death associated with CYP1A1 genotypes (HR, 1.46; 95 % CI, 0.69-3.08, p=0.318). These results show that there is no association between CYP1A1 genotype and response to chemotherapy or survival in advanced NSCLC patients (Supported by Research Fund of Ankara University, Grant No: 20070803005HPD).

PS 1395 ROLE OF POLYMORPHIC HUMAN CYTOCHROME P450 ENZYME IN ESTROGEN METABOLISM AND BREAST CANCER RISK IN THAI WOMEN.

S. Sangrajrang[1], T. Khuhaprema[1], P. Brennan[2], P. Boffetta[2] and T. Yoshida[3]. *[1]National Cancer Institute, Bangkok, Thailand, [2]International Agency for Research on Cancer, Lyon, Thailand and [3]National Cancer Center Research Institute, Tokyo, Japan.*

Estrogen and its metabolites are believed to play important roles in breast cancer and its determinant include both genetic and lifestyle factors. The objective of the study is to investigate association of breast cancer risk in Thailand with genetic polymorphisms in several genes involved in estrogen synthesis and metabolism. Five hundred and seventy patients with histopathologically confirmed breast cancer and 497 controls were included in the present study. Forty single nucleotide polymorphisms (SNPs) in the CYP1A1, CYP1A2, CYP1B1, CYP17, CYP19, CYP2C9, CYP2C19, AhR, ESR1, PGR, ERRG, COMT, HSD17B1, HSD17B2, EPHX1, and NQO1 genes were genotyped. Association of genotypes with breast cancer risk were evaluated using multivariate logistic regression. Heterozygote carriers of SNPs in CYP2C19 (rs4917623), AhR (rs2066853), ERRG (rs1857407) and homozygote carriers of SNPs in CYP1A2 (rs762551), CYP2C19 (rs4917623), ERRG (rs945453) had altered risk of developing breast cancer. In addition, a stratified analysis by menopausal status indicated that the association of the CYP1A2 (rs762551) and CYP17 (rs743572) polymorphisms with breast cancer risk were mainly evident in premenopausal, while those of CYP1B1 (rs162556) and ERRG (rs1857407) significant in postmenopausal women. These findings suggest that CYP1A2, CYP2C19, AhR, ERRG, CYP17 and CYP1B1 polymorphisms may play an important role in estrogen metabolism and modify individual susceptibility to breast cancer in Thai women.

PS 1396 UNEXPECTED DEATH DUE TO METHADONE OVERDOSE MAY BE ASSOCIATED WITH GENETIC POLYMORPHISM(S) OF THE CYP3A4 GENE.

L. L. Richards-Waugh[1], D. A. Primerano[2], Y. Dementieva[3], J. C. Kraner[4] and G. O. Rankin[1]. *[1]Pharmacology, Physiology & Toxicology, Marshall University, Huntington, WV, [2]Biochemistry and Microbiology, Marshall University, Huntington, WV, [3]Mathematics & Integrated Science, Marshall University, Huntington, WV and [4]WV Office of the Chief Medical Examiner, Charleston, WV.*

Methadone usage can lead to unexpected death due to inter-individual variability in its pharmacokinetics. CYP3A4 is a key P450 involved in the metabolism of methadone to 2-ethyl-1,5-dimethyl-3,3-diphenylpyrrolidine (EDDP). The methadone/EDDP ratio was higher in individuals who had overdosed on

methadone compared to those successfully undergoing maintenance treatment in a retrospective study of methadone-only deaths (WV Office of the Chief Medical Examiner). A high methadone/EDDP ratio may be associated with a poor-metabolizer phenotype for methadone due to a genetic defect associated with one or more single nucleotide polymorphisms (SNPs) in the CYP3A4 gene. To assess this possibility, 93 individuals who had died of a methadone-only overdose were genotyped at four different SNP sites on the CYP3A4 gene. Genomic DNA was isolated from blood collected during autopsy, and SNP genotypes were determined by Taqman Allelic Discrimination Analysis. All loci studied were within Hardy-Weinberg Equilibrium. The observed genotype frequencies were not significantly different from those expected based on population statistics for the rs2246709, rs3735451, and rs4646437 SNP loci. The genotype frequency was significantly different than the frequency for the general population ($p<0.001$) for the rs2242480 SNP. Western blotting for CYP3A4 protein was performed on nine different human liver microsomal samples from overdosed individuals. Three of the samples with the highest methadone/EDDP ratio did not appear to have detectable amounts of CYP3A4 and five samples with the lowest methadone/EDDP ratio had detectable amounts of CYP3A4. These initial findings indicate that a genetic polymorphism on the CYP3A4 gene may contribute to unexpected death from methadone due to decreased function and/or production of CYP3A4.

PS 1397 DETECTION OF SINGLE NUCLEOTIDE POLYMORPHISMS IN CYTOCHROME B5 PROMOTER.

T. T. Hoang[1, 2], J. C. Sacco[1] and L. A. Trepanier[1]. *[1]Medical Sciences, University of Wisconsin-Madison, Madison, WI and [2]Biochemistry, University of Illinois at Urbana-Champaign, Champaign, IL.*

Cytochrome b5 (CYB5A) and cytochrome b5 reductase (CYB5R) catalyze the detoxification reaction of hydroxylamine metabolites of arylamine drugs, specifically sulfamethoxazole hydroxylamine (SMX-HA) to its amine parent sulfamethoxazole (SMX). In the absence of this reaction, the SMX-HA intermediate metabolite is spontaneously transformed to sulfamethoxazole nitroso (SMX-NO). Consequently, SMX-NO is thought to lead to sulfonamide hypersensitivity reactions due to formation of a hapten. The effectiveness in detoxifying the SMX-HA metabolite mainly depends on the variability in gene expression and catalytic activity of CYB5A and CYB5R. The aim of this study was to screen individual human liver samples with outlying high or low activity for SMX-HA reduction or outlying CYB5A protein expression, for single nucleotide polymorphisms (SNPs) in the promoter region of CYB5A, specifically from +1 bp to -551 bp. Among 55 individuals, we found 5 novel promoter SNPs and 1 known promoter SNP (rs3764506). Four of the SNPs were located in the silencer region (-302 bp to -449 bp). Two of these SNPs may be important in the regulation of CYB5A gene expression at the transcriptional level. First, rs3764506 (-363 C/A) was associated with high protein expression and median activity. Secondly, the -389 G/A SNP was associated with both low protein expression and activity. Finally, an individual who had high protein expression and moderately high activity was heterozygous for a -458 C/T SNP. In addition, we also found two cases of linkage disequilibrium. One was the SNP at -382 C/T linked to SNP at -214 C/T and the other one was rs1051236 in cDNA also linked to SNP at -214 C/T.

PS 1398 GENOTPYPE DETERMINES SUSCEPTIBILITLY TO MERCURY TOXICITY: STUDIES IN TRANSFORMED CELLS EXPRESSING COPROPORPHYRINOGEN OXIDASE (CPOX) AND ITS GENETIC VARIANT CPOX4.

T. Li and J. S. Woods. *Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.*

CPOX catalyzes the 2-step decarboxylation of coproporphyringen-III (Cp) to proto-porphyrinogen-IX (Pp) with the intermediate formation of harderoporphyrinogen (Hp) in the heme biosynthetic pathway. Previously, we identified a polymorphism (A814C) in exon 4 of the human CPOX gene (CPOX4) and showed that the catalytic activity of cloned CPOX4 was ~50% that of the wild type (WT) enzyme in vitro. We obtained comparable findings in human liver samples from CPOX WT, Het and CPOX4 homozygous (Mut) subjects. We also showed that mercury (Hg2+) specifically inhibits the second step of Cp decarboxylation (Hp to Pp) in a dose dependent manner both in vitro and in liver human fractions. Here, we established a CPOX expression cell model using Epstein Barr virus (EBV) transformed lymphocytes from human subjects to further study the consequences of CPOX genotype on cell viability and the effects of Hg2+ on this process. Consistent with findings in vitro and in liver samples, Hg2+ (5 or 10μM for 24 hrs) promoted excess Hp accumulation in WT, Het and Mut cell lines in a concentration-dependent manner. In cell viability studies as determined by AlamarBlue assays, treatment of cells concomitantly with Hg2+ and the heme synthesis inhibitor succinyl acetone (0.5 mM) for 24 hrs impaired cell viability in a genotype (WT, Het, Mut)- and Hg2+ concentration-dependent manner, with CPOX4 (Mut) cells undergoing 40% loss of viability compared with 27 and 21% of Het and WT, respectively, at 5μM Hg2+. These results suggest that CPOX4 increases the susceptibility of cells to Hg2+ toxicity and that this effect is modulated by heme deficiency. Additionally, these studies demonstrate the utility of EBV transformed cells as an alternative to transgenic animal models for studying the effects of genetic variation on chemical-mediated changes in cell functions. Supported by NIH grants ES04696 and ES07033.

PS 1399 GENETIC POLYMORPHISMS ON ACTIVATION AND DEACTIVATION ENZYMES OF ORGANOPHOSPHATE PESTICIDES ARE INVOLVED IN THEIR NEUROTOXICITY.

M. Sánchez-Guerra[1], N. Pérez-Herrera[1], E. Rojas-García[2], V. H. Borja-Aburto[3], I. Hernández-Ochoa[1], J. Alvarado-Mejía[4], O. Reyes-Hernández[1], M. López-González[1], G. Elizondo-Azuela[1] and B. Quintanilla-Vega[1]. *[1]Toxicology Section, CINVESTAV-IPN, Mexico City, Mexico, [2]Dirección de Fortalecimiento de la Investigación, Universidad Autónoma de Nayarit, Tepic, Nayarit, Mexico, [3]Coordinación Nacional de Salud en el Trabajo, IMSS, Mexico City, Mexico and [4]Facultad de Medicina, Universidad Autónoma de Yucatán, M√©rida, Yucat√°n, Mexico.*

Recent studies have suggested that polymorphisms of enzymes involved in the metabolism of environmental contaminants may confer susceptibility to their toxicity. It is the case of some organophosphate pesticides (OP) that require bioactivation by CYP450 and are deactivated by paraoxonase 1 (PON1). CYP1A2*1F polymorphism increases OP activation, while OP deactivation is reduced by PON1-108C/T and PON1- 162A/G polymorphisms and is substrate-dependent for PON1 192Q/R polymorphism; therefore, these polymorphisms may be involved in OP toxicity. The aim of this study was to determine the role of CYP1A2*1F and PON1 polymorphisms on the neurological damage in agricultural workers exposed to OP. A cross-sectional study was conducted in Yucatan, Mexico in 80 subjects (43±12 years old). Information about lifestyle, health status, pesticide exposure and symptoms of neurological damage was obtained from a questionnaire and a chronic OP exposure index was constructed. Genetic polymorphisms were determined by RT-PCR or RFLP. Sixty-nine percentage of participants reported adverse neurological symptoms associated with pesticides exposure. Workers with *1F/*1F (73%), -108CT/TT (86%), -162GG (74%) or 192QR/RR (77%) genotypes and with the genotype combinations *1F/*1F/-108CT/TT (63%), *1F/*1F/192QR/RR (54%) and -108CT/TT/192QR/RR (64%) showed higher risks of having more than 10 adverse symptoms and/or have presented an intoxication episode associated with OP exposure. This suggests that CYP and PON1 polymorphisms confer elevated risk for neurological damage and carrying the combination of some unfavourable genotypes further increases this risk (Supported by CONACYT, Grant CO-134).

PS 1400 ASSOCIATION OF GENETIC VARIATIONS IN THE ALPHA1-ANTITRYPSIN AND MATRIX METALLOPROTEINASE GENES WITH LUNG FUNCTION DECLINE IN A GROUP OF FIREFIGHTERS.

B. Yucesoy[1], M. Kurzius-Spencer[2], V. J. Johnson[1], K. Fluharty[1], D. R. Germolec[3], M. I. Luster[1] and J. L. Burgess[2]. *[1]Health Effects Laboratory Division, NIOSH/CDC, Morgantown, WV, [2]Environmental and Occupational Health, University of Arizona, Tucson, AZ and [3]Toxicology Branch, NTP, NIEHS, Research Triangle Park, NC.*

The measurement of forced expiratory volume in 1 second (FEV_1) and its decline over time are prognostic indicators of early chronic airflow obstruction. Although α1-antitrypsin (AAT) deficiency (Z allele) was shown to be a risk factor for rapid decline in lung function, individuals with the same AAT genotype may differ in their phenotypes suggesting the presence of other genetic modifiers. Matrix metalloproteinases (MMPs) are a group of proteolytic enzymes that play an important role in connective tissue remodeling and repair. The aim of this study was to investigate whether polymorphisms within genes encoding for AAT and MMPs may be associated with the age-related rate of FEV_1 decline. Genetic variations in the AAT (Z, S and 3'), MMP-9 (IVS4+3G/T and 2003A/G) and MMP-12 (1082A/G and -82A/G) genes were investigated in 374 active firefighters with at least five or more annual pulmonary function tests over a period of five or more years. Genotyping was performed using multiplex polymerase chain reaction (PCR) and 5' nuclease

real-time PCR assays. Rate of decline in FEV_1 was calculated for each subject by running a simple linear regression of FEV_1 over age. After adjusting for covariates, the AAT Z and 3' variants (both p=0.048) and the MMP12 -82A/G (p=0.009) polymorphism were associated with a more rapid rate of FEV_1 decline. No association was observed between the rate of FEV_1 decline and other variations. These data suggest that genetic variations within genes involved in tissue remodeling and repair may influence susceptibility to progressive decline in FEV_1.
This work was supported in part by an Interagency Agreement with the Intramural Research Program of the NIEHS (Y1-ES-0001)

PS 1401 GENETIC VARIATION IN ISOGENIC STRAINS OF LABORATORY MICE ALTERS THE DISPOSITION AFTER ACUTE EXPOSURE TO [14C] BENZENE.

G. A. Knudsen[1], R. K. Kuester[1], M. L. Cunningham[2] and I. G. Sipes[1]. *[1]Medical Pharmacology, University of Arizona, Tucson, AZ and [2]Chemical Toxicology, National Institutes of Environmental Health Sciences/National Institutes of Health, Raleigh/Durham, NC.*

Many of the variations in human susceptibility to chemical toxicities may be linked to genetic diversity in their disposition. Thus, understanding how the genetic diversity affects the disposition of chemicals in various mouse strains may better define the effects of genetic variability on human susceptibility. Initial studies focused on searching for differences in AUC(0-2h), Cmax or Tmax of [14C] benzene equivalents in whole-blood from genetically diverse murine strains (based on degree of single nucleotide polymorphisms) selected from the NTP-Perlegen Mouse Genome Resequencing Project. Mice (5 per time point) were administered a single oral dose of [14C] benzene, (0.1 mg/kg, 75 μCi/kg). Blood and bladder urine were obtained at 5-120 min post dose for analysis of total [14C] content. In addition, expression levels of CYP2e1 & UGT1a6 in hepatic microsomes were determined for each of the strains. The AUC(0-2h), Cmax and Tmax of [14C] equivalents in blood ranged from 23 to 75 min*μmol/mL min, 0.2-0.4 μmol-eq/mL and 5-20 min, respectively. Differences were observed in the quantitative profile of benzene metabolites present in bladder urine among the various mouse strains. Additionally, a unique metabolite of benzene appeared to be present in the urine of male BALB/cJ mice. Preliminary results suggest inter-strain differences in the expression of benzene metabolizing enzymes (CYP2e1 & UGT1a6). Based on these studies, strains showing notable differences in these parameters will be selected for detailed pharmacokinetic/metabolic studies. This research was supported in part by the NIEHS NTP Grant No. N01-ES-45529 and NIEHS-sponsored Southwest Environmental Science Center Grant Number P3-ES-06694.

PS 1402 MODIFYING EFFECT OF GENE POLYMORPHISMS IN THE RELATION BETWEEN LEAD AND BLOOD PRESSURE.

F. Scinicariello[1], A. Yesupriya[2], M. Chang[2] and B. A. Fowler[1]. *[1]ATSDR/DTEM, Atlanta, GA and [2]CDC/NOPHG, ATLANTA, GA.*

Background: Environmental lead exposure has been associated with an increased risk of developing hypertension. Few studies have addressed the role of genetic polymorphisms in influencing the effect of lead exposure on hypertension.
Methods: We examined the genetic effects of five previously characterized single nucleotide polymorphisms (NOS3 rs2070744, VDR rs731236, VDR rs2239185, PON1 rs662, and PON1 rs854560) on the relationship between blood lead levels and hypertension using nationally representative data from the Third National Health and Nutrition Examination Survey (NHANES III) DNA bank, 1991-1994 (n=6016).
Results: The prevalence of hypertension was 22.8% .Among persons with and without hypertension, the mean blood lead was 3.72 and 2.78 μg/dl, respectively. Multivariate regression analysis stratified by lead tertile showed that in the highest lead tertile (>3.3 μg/dl) individuals carrying the PON1 rs662 G allele had a significantly lower prevalence of hypertension compared to those with the AA genotype (OR: 0.41; 95%CI; 0.24-0.68; p <0.01). In addition, predicted diastolic blood pressure was 2.23 mmHg lower for PON1 rs662 G allele carriers in this tertile (p =0.004). There was no effect modification by the other genotypes on the relations of lead dose with blood pressure.
Conclusion: In a nationally representative sample of the U.S. population, the prevalence of hypertension and estimated diastolic blood pressure was significantly lower for carriers of the PON1 rs663 G allele compared to individuals homozygous to the PON1 AA genotype at the highest tertile of blood lead. These data, also, provide no evidence that the NOS3 rs2070744, VDR rs731236, VDR rs2239185, and PON1 rs854560 genes modify the association of lead dose with blood pressure.

PS 1403 ABNORMALLY DECREASED LEVELS OF NON-STEROIDAL ANTI-INFLAMMATORY DRUG-ACTIVATED GENE (NAG)-1 AND H6D POLYMORPHISM IN LUNG CANCER PATIENTS' SERA.

H. Kim[1, 2], A. Joiakim[1], D. J. Kaplan[1], K. Onofrey[1], R. Hadad[1] and D. G. Beer[3]. *[1]Detroit R&D, Inc., Detroit, MI, [2]Institute of Environmental Health Sciences, Wayne State University, Detroit, MI and [3]Department of Thoracic Surgery, University of Michigan Medical School, Ann Arbor, MI.*

NAG-1 has anti-tumorigenic and anti-inflammatory activities. There are inconsistent reports on expression/secretion of NAG-1 in various human tissues and serum/plasma obtained from cancer patients and controls. This is due to lack of reagents and methodology to measure only cleaved mature forms and/or to distinguish NAG-1 proteins from H6D polymorphism. Antibodies specific for human NAG-1 or H6D polymorphism have been produced using KLH conjugates of a synthetic peptide unique to NAG-1 or H6D protein. Form-specificity of the antibodies was characterized using synthetic NAG-1 and H6D peptides conjugated to BSA and native NAG-1 and H6D proteins in normal human serum samples. NAG-1 polyclonal antibodies recognized the NAG-1 peptide-conjugated BSA but almost no cross-reactivity was detected with the H6D peptide-conjugated BSA. H6D polyclonal antibodies recognized the H6D peptide-conjugated BSA but almost no cross-reactivity was detected with the NAG-1 peptide-conjugated BSA. The results demonstrated that the NAG-1 and H6D antibodies are form-specific. Western blot analyses using the NAG-1 and H6D antibodies were carried out with 4 human control serum samples and found that the pattern of cleaved ~40 kDa dimer (active form) NAG-1 protein levels among the 4 serum samples differed from the pattern of H6D protein levels. Western blot analyses using the NAG-1 and H6D antibodies carried out with 4 serum samples obtained from lung cancer patients revealed that levels of the ~40 kDa NAG-1 and H6D dimers dramatically decreased compared with the levels of NAG-1 and H6D dimers detected in 4 control serum samples (significantly different with p<0.04 and p<0.06, respectively). The results suggest that decreased serum NAG-1 or H6D levels may serve as a serum biomarker of lung cancer patients. (Supported by NIEHS SBIR Phase I Contract HHSN273200700012C).

PS 1404 INTER AND INTRAINDIVIDUAL VARIABILITY OF GLUCURONIDATION OF SELECTED PHTHALATE METABOLITES IN HUMANS.

M. J. Silva, J. Preau, L. L. Needham and A. M. Calafat. *National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, GA.*
Sponsor: B. Fowler.

Glucuronidation is a major detoxification pathway in humans for all metabolites of phthalate diesters. Genetic polymorphisms and physiological conditions can affect each person's ability for glucuronidation. Furthermore, the extent of glucuronidation of phthalates varies depending on the solubility of the metabolite in aqueous media. Although the concentrations of total (i.e., free plus glucuronidated) species of phthalate metabolites are typically reported in exposure assessment studies, the free form of the phthalate metabolites is thought to represent the bioactive dose. We investigated in eight adults with no documented phthalate exposure, the extent of glucuronidation of six phthalate metabolites in urine: monoethyl phthalate, monobutyl phthalate, monobenzyl phthalate, mono(2-ethyl-5-oxohexyl) phthalate, mono(2-ethyl-5-hydroxyhexyl) phthalate, and mono(2-ethyl-5-carboxypentyl) phthalate. The conjugated species concentrations were determined indirectly from the concentrations of the free and the total species in urine. The observed intraindividual differences in glucuronidation did not change significantly between days of sample collection or the urine void volume. Furthermore, our findings suggest that intraindividual variability of glucuronidation also exist. Nevertheless, the significant associations (p<0.01) between total and free phthalate metabolite urinary concentrations suggest that, in large epidemiological studies, total phthalate metabolite concentrations may be used to represent the free bioactive dose.

PS 1405 BROMINE VAPOR SKIN STUDIES IN WEANLING PIGS.

R. C. Kiser[1], F. M. Reid[1], M. R. Perry[1], J. Mann[1], A. Simmons[1], M. C. Babin[1], J. A. Blank[1] and J. S. Graham[2]. *[1]Battelle Biomedical Research Center, Columbus, OH and [2]U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Due to continued public concern for safety from chemical attacks, the Battelle Biomedical Research Center (BBRC) and the U.S. Army Medical Research Institute of Chemical Defense (USAMRICD) have aligned research efforts to establish an anesthetized weanling pig model of superficial dermal (2nd degree) and deep dermal (3rd degree) cutaneous injuries induced by bromine vapor. A bromine

vapor exposure system was fabricated and characterized to evaluate female Yorkshire-cross pigs with four lesion sites (each 3 cm in diameter) between the axillary and inguinal areas of the ventral abdomen. Injury was produced by modifying exposure length to various concentrations of bromine vapor and evaluating the sites after 24 and 48 h. Lesion assessment included clinical observations, digital photographs, size measurements, modified Draize scoring, reflectance colorimetery, and evaporimetry. Infrared thermographic images were also collected. Histopathologic evaluation of skin collected at 48 h post-exposure included wound severity, wound depth, and percent of the total area involved. Different exposure lengths and vapor concentrations were explored during model development. The injuries induced by controlled bromine vapor concentrations of 85,000 to 175,000 ppm and exposure durations of 5 to 30 minutes were characterized histologically and ranged from superficial dermal to deep dermal in severity. Follow-on efforts will address efficacy testing of therapeutic compounds to improve wound healing by preventing/reducing the erythema, edema and deep tissue damage to the skin caused by exposure to bromine vapor. This work was supported by the U.S. Army Medical Research and Materiel Command under Contract W81XWH-05-D-0001, Task Order 0010.

PS 1406 BROMINE VAPOR CUTANEOUS EXPOSURE SYSTEM FOR WEANLING PIGS.

M. R. Perry[1], B. Reed[1], G. Sparks[1], R. C. Kiser[1], F. M. Reid[1] and J. S. Graham[2]. *[1]Battelle Biomedical Research Center, Columbus, OH and [2]U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Due to the concern that bulk industrial chemicals could be used in terrorist attacks, the Battelle Biomedical Research Center (BBRC) and the U.S. Army Medical Research Institute of Chemical Defense (USAMRICD) have aligned research efforts to test medical treatments for chemical burns. To test these treatments a bromine vapor exposure system that produces both superficial dermal (2nd degree) and deep dermal (3rd degree) cutaneous injuries in an anesthetized weanling pig model was developed. A dermal exposure system capable of dosing four skin areas (each 3 cm in diameter) between the axillary and inguinal areas of the ventral abdomen to controlled bromine vapor concentrations was fabricated and characterized. Controlled bromine challenge concentrations were generated by mixing saturated bromine vapor with dried dilution air. Once the bromine vapor concentration had stabilized at the desired target level and the exposure cups were securely positioned on the anesthetized animal, the exposure was initiated. Each set of 2 exposure cups were independently controlled to permit 2 exposure durations for each test. Initial tests indicated that extremely high vapor concentrations of bromine were required to illicit the desired lesions. Due to the high vapor concentrations, a direct vapor concentration monitoring approach was not used. Time weighted bromine vapor concentration was determined from the consumed mass of liquid bromine over the total air volume. This exposure system successfully delivered controlled bromine vapor concentrations from 85,000 to 175,000 ppm with exposure durations between 5 and 30 minutes. This range of exposure conditions was sufficient to induce superficial dermal and deep dermal skin lesions, as verified by histopathologic evaluations.
This work was supported by the U.S. Army Medical Research and Materiel Command under Contract W81XWH-05-D-0001, Task Order 0010.

PS 1407 GÖTTINGEN MINIPIGS AS THE NONRODENT SPECIES IN THE IND FOR KNS-760704.

S. W. Frantz[1], E. J. Popke[1], E. J. Tasker[1], J. A. Dalton[1], D. R. Demady[2], E. W. Ingersoll[2] and V. K. Gribkoff[2]. *[1]MPI Research Inc., Mattawan, MI and [2]Knopp Neurosciences, Pittsburgh, PA.*

Although the beagle dog remains a pharmaceutical industry standard for many nonrodent toxicology studies, adverse pharmacodynamic responses can necessitate the use of an alternative nonrodent species. During pre-IND studies with KNS-760704, a CNS drug in Phase II clinical trials for the treatment of ALS, single doses of KNS-760704 administered to dogs produced significant exposures after gavage administration of 2.5, 7.5, or 25 mg/kg but also produced dose-limiting toxicity (emesis) immediately following dosing; the single-dose no-observed-adverse-effect-level (NOAEL) in dogs was 2.5 mg/kg. A no-observed-effect-level (NOEL) could not be identified due to emesis at all dosages, suggesting that dogs were not an acceptable nonrodent species. In minipigs, the single-dose NOAEL was 25 mg/kg (AUC_{0-t} of 18.5 μg*hr/mL), with little emesis noted, while 7.5 mg/kg (AUC_{0-t} of 3.0 μg*hr/mL) was the NOAEL. A lower incidence and severity of clinical signs following single doses of KNS-760704 supported minipig selection for further toxicology testing and 75 mg/kg was selected as the high dose level for a 2-week IND-enabling toxicity study. The definitive minipig studies employed a combined acute (MTD, single doses up to 300 mg/kg) and 2-week multiple dose (doses of 0, 7.5, 25, or 75 mg/kg/day) study design with a 2-week recovery period. KNS-760704 was well tolerated in pigs, with only moderate clinical signs (decreased activity, inappetence, salivation, and mild emesis) that were not present during the recovery phase and no adverse treatment-related anatomic or clinical pathology findings. The NOAEL was considered ≥75 mg/kg/day (Day 13 AUC_{0-24} of 128.6-197.7 μg*hr/mL); 7.5 mg/kg/day (Day 13 AUC_{0-24} of 9.0-9.9 μg*hr/mL) was the NOEL in this 2-week study. Finally, a cardiovascular study in Göttingen minipigs (3/sex) at 0, 7.5, 25, or 75 mg/kg showed only minor effects, with a NOAEL of 75 mg/kg. Thus, multiple toxicology studies using Göttingen minipigs have successfully supported first-in-human and ongoing Phase II clinical trials for KNS-760704.

PS 1408 TRANSCRIPT PROFILING OF PXR AND CAR KNOCK-OUT AND HUMANIZED MOUSE LIVER PROVIDES INSIGHT INTO ENDOGENOUS ROLES OF THE HUMAN PXR/CAR ISOFORMS.

S. Plummer[1], J. Ross[1], C. R. Elcombe[1], N. Scheer[2] and C. Wolf[1]. *[1]CXR Biosciences, Dundee, United Kingdom and [2]TaconicArtemis GmbH, Cologne, Germany.*

Simon Plummer1, Jillian Ross1, Nico Scheer2, Cliff Elcombe1 and Roland Wolf1. 1 CXR Biosciences Ltd, Dundee, Scotland and 2TaconicArtemis GmbH, Koln, Germany.

We have created mouse lines in which the murine pregnane X receptor (PXR) and constitutive androstane receptor (CAR) genes have been removed (PXR KO, CAR KO mice) and/or replaced with human PXR or CAR (huPXR, huCAR mice). To investigate PXR- and CAR-regulated endogenous and species specific functions we performed transcript profiling and pathways analysis on RNA extracted from the livers of these mice compared to C57BL/6J wild type mice (WT) using Agilent whole mouse genome expression microarrays and Ingenuity Pathways Analysis software, respectively. Upregulation (~2-7-fold) of several genes involved in xenobiotic/fatty acid metabolism (24 genes) and cholesterol biosynthesis (7 genes), e.g. Cyp3a11, Ugt1a1, Acox1 and Hmgcr was observed in PXR KO mice but these changes were reversed in huPXR mice. Thus huPXR may function as a repressor of genes in these pathways. Induction of Cyp isoforms in the PXR KO mouse liver was accompanied by upregulation of genes involved in redox homeostasis (7 genes) and endoplasmic reticulum stress (3 genes), some of which are regulated by Nrf2. This effect was not observed in huPXR mouse liver, reflecting the lack of Cyp induction in huPXR mice.
Fatty acid metabolism and xenobiotic metabolism genes were also overrepresented in the list of altered genes in CAR KO and huCAR mice. However, these genes tended to be altered with similar polarity in the CAR KO and huCAR mice relative to WT mice. The fold changes observed were generally lower in huCAR mice than CAR KO mice, suggesting partial functional substitution of the mouse CAR gene by its human homologue. Repression of CAR-regulated genes in the CAR KO mice and the moderation of this by huCAR is consistent with the constitutive activity of this receptor in rodents and humans.
This work was supported by ITI Life Sciences, Scotland.

PS 1409 COMPARISON OF A HEPARIN-LOCK PROCEDURE TO CONTINUOUS MAINTENANCE SOLUTION ADMINISTRATION FOR INTERMITTENT INTRAVENOUS INFUSION STUDIES.

A. M. Brooks, S. Pawl, J. Agate and A. N. Alexander. *Covance Laboratories Inc., Madison, WI.*

The purpose of this study was to determine the feasibility of using a heparin-lock procedure during nondosing intervals on intermittent intravenous infusion studies in surgically catheterized rats fitted with Instech Solomon's Vascular Access Harness™. Feasibility assessment was based on maintenance of catheter patency, ease of dosing, and labor and technical demands. Animal tolerance of procedures was also evaluated using clinical signs, body weights, and macroscopic findings. The heparin-lock procedure was employed between dosing cycles and consisted of disconnecting the external tether assembly from the harness and injecting a heparin dextrose solution (0.11 mL 50% dextrose with 500 IU heparin/mL) directly into the self-sealing port on the harness. A variety of heparin-lock/infusion dosing scenarios were conducted to identify the optimal timing and duration of the heparin-lock method. The duration between dosing was 1 to 3 weeks; during nondosing intervals, the heparin lock procedure was repeated daily or once every 2, 3, 4, 5, 6, or 7 days. On dosing days, animals received 5% dextrose at 10 mL/kg/hour for 0.5 hours or 1 mL/kg/hour for 24 hours to test short and long-duration intermittent dosing cycles. Body weight changes, clinical signs, and pathology findings were comparable across groups. The incidence of catheter patency-related observations with the heparin lock/infusion procedure was similar to that seen with traditional intermittent infusion studies. Ultimately, it was determined that the heparin-lock procedure was feasible for intermittent intravenous infusion studies in rats fitted with the Vascular Access Harness, although it was most advantageous for twice weekly or less frequent dosing. Use of the heparin-lock procedure for intermittent

infusion with doses administered more frequently than twice weekly was not beneficial; labor and technical demands were comparable to those in traditional tethered infusion studies with rats administered a maintenance solution during nondosing intervals.

PS 1410 PRELIMINARY TRIAL FOR THE PREDICTION OF MECHANISM-BASED INHIBITION IN HUMAN USING PXB MICE® WITH HIGHLY REPOPULATED HUMANIZED LIVER.

M. Kakuni[1], Y. Ishida[1], A. Tachibana[1], Y. Yoshizane[1], T. Horie[1], K. Ubukata[2], T. Takanohashi[2] and R. Mihara[2]. *[1]Study Service Department, PhoenixBio Co., Ltd., Higashi-hiroshima, Hiroshima, Japan and [2]Pharmaceutical Research Laboratories, Ajinomoto Co., Inc., Kawasaki, Kanagawa, Japan.* Sponsor: S. Fukushima.

To predict the extent of mechanism-based inhibition (MBI) in human, a model system which reflects *in vivo* human is required. The PXB-mouse is a humanized chimeric mouse model where the liver has been repopulated by more than 70 % with human hepatocytes. We therefore anticipated that the PXB-mouse would be a potentially useful model for predicting MBI in human. PXB-mice and control mice were administered 500 mg/kg of erythromycin, mechanism-based inhibitor of CYP3A4, thrice a day for 3 days as an oral gavage dose. To measure the enzyme activity of CYP3A4, a single oral gavage dose of midazolam as a probe compound was administered 3 days before the start of the erythromycin administration at Day -3 and one day after the end of the erythromycin administration at Day 3. The plasma concentration of midazolam was determined by LS-MS/MS, the mRNA and protein expression levels of CYP3A4 were measured using RT-PCR and western blotting, respectively. $AUC_{0\text{-}4h}$ of midazolam was 257.0 ngh/mL at Day -3 and 1369.8 ngh/mL at Day 3 (5.3-fold) in PXB-mice, and 49.7 ngh/mL at Day -3 and 89.4 ngh/mL at Day 3 (1.8-fold) in control mice. The mRNA and protein expression levels of CYP3A4 increased rather than decreased in PXB-mice. These findings strongly suggest that the PXB-mouse is a valid *in vivo* model system for estimating and predicting mechanism-based inhibition in humans.

PS 1411 COMPARATIVE MAMMALIAN GASTROINTESTINAL ABSORPTION: THE INFLUENCE OF VARIOUS GASTROINTESTINAL FACTORS.

A. L. Williams and J. M. DeSesso. *Noblis, Falls Church, VA.*

Absorption of ingested materials through the gastrointestinal (GI) system is an important process. The physicochemical properties of drugs and chemicals (e.g., molecular size, aqueous solubility, lipophilicity) are influential, but do not vary during exposure in different animals. By contrast, factors that characterize the barrier between the lumen and the GI tube, such as the absorptive surface areas and secretions that contribute to the luminal milieus, are greatly affected by species-specific GI anatomy and physiology. These differences can result in disparities in the rate and extent of absorption. To determine which animal best models human GI absorption, data from seven mammalian species (dog, rabbit, mouse, rat, pig, monkey and human) were evaluated. Parameters examined include intestinal tract lengths and surface areas, GI transit times, and pH of GI segments. With the exception of the rabbit and possibly the mouse, the proportions of small to large intestinal lengths were similar to those found in humans. The relative surface area of the small intestine (luminal surface area compared to total body surface area) is highest in the human and monkey due to the presence of extensive surface modifications (e.g., folds of luminal epithelium [plicae circulares], villi and microvilli) that are notable especially in the cranial portion of the small intestine. Transit times are generally longer in species with larger body sizes, such that humans have the longest transit times followed by the pig and monkey. The stomach pH in rodents (rats and mice) is nearly neutral, allowing the presence of a rich microflora. In the remaining species, most of which are omnivores, stomach pH is quite acidic. The rabbit, (a lagomorph and strict herbivore) exhibits luminal pH in intestinal tract segments that differs greatly from that of other species, including humans. Our analysis finds rabbit to be most different and monkey, followed by pig and dog, to be the closest models of human GI absorption; however, appreciating and accounting for interspecies absorptive factors allows the other species to also be useful.

PS 1412 ESTABLISHMENT OF A LINE OF SPORTS (SPONTANEOUSLY-RUNNING-TOKUSHIMA-SHIKOKU) RATS THAT FORM LEFT ATRIAL THROMBI.

T. Ohnishi[1, 2]. *[1]Pathology, Nishi-Kobe Medical Center, Kobe, Japan and [2]Molecular and Environmental Pathology, The University of Tokushima, Tokushima, Japan.*

We report a new model leading to a high incidence of thrombus formation in the left atrium. This new rat model was named SPORTS (Spontaneously-Running-Tokushima-Shikoku) rat, with high wheel-running activity in this male rat. We found that some of the SPORTS rats died after losing body weight after the age of one year. At autopsy, formation of thrombi in the left atrium was recognized in SPORTS rats. The objective of this study was to clarify the autopsy results in the SPORTS rats related to thrombus formation in the left atrium. The incidences of atrial organized thrombosis were 57% in male SPORTS rats and 38% in female SPORTS rats. Systolic blood pressures were 134 ± 16 mmHg (control rats 115 ± 11 mmHg) and heart rates were 459 ± 21 beat/min in male SPORTS rats. Arrhythmias, such as atrial fibrillation, were not recognized by electrocardiogram in SPORTS rats. In conclusion, we established a line labeled SPORTS rats that form spontaneous thrombi in the left atrium. It is thought that the SPORTS rat might contribute to development of new anti-thrombotic approaches for human atrial thrombosis or familial thrombophilia.

PS 1413 A NON CLINICAL TOXICITY AND BIODISTRIBUTION STUDY IN CYNOMOLGUS MONKEY WITH A NEW LIVE ATTENUATED JAPANESE ENCEPHALITIS VACCINE.

G. Ravel[1], C. Meric[2] and S. Gould[1]. *[1]Non Clinical Safety, sanofi pasteur, Marcy L'etoile, France and [2]R & D, sanofi pasteur, Marcy l'etoile, France.*

Japanese Encephalitis (JE) vaccine (JE-CV) is a new live attenuated vaccine, which has been constructed using the yellow fever 17D vaccine (YF 17D) and recombinant technology. The YF genes for the pre-membrane/membrane and envelope (prM/M and E) proteins were replaced with those of an attenuated JE virus. The remainder of the construct contains the non-structural and core elements of YF 17D vaccine which provides the replication engine for producing viruses that display the prM/M and E antigens of JE virus on their surface.

As part of the safety assessment of the JE vaccine, a combined toxicity and biodistribution study was conducted in the cynomolgus monkey. The study assessed the general and local toxicity, immunogenicity, biodistribution and the persistence of the vaccine in both target and non-target tissues/organs and its shedding from injection site and body fluids. Cynomolgus monkeys were given a single subcutaneous dose of either the JE-CV or control, and were observed for 3 or 21 days. The study design included standard clinical observations, body temperature measurements, body weight, food consumption, clinical pathology, ophthalmology and full examination at necropsy with organ weights and histopathological examination of a full range of tissues. In addition, the distribution and persistence of JE-CV, as well as its shedding, were evaluated by qRT-PCR analysis. One subcutaneous administration of the vaccine was well tolerated in cynomolgus monkeys. There were no vaccine-related adverse signs of general and local toxicity of JE-CV. All vaccinated animals seroconverted. Half the animals developed low viremia 3 days after immunization, and the biodistribution and the shedding of JE-CV were limited. These results, as well as those from previous neurovirulence and toxicology studies, confirm the absence of any major safety concerns with JE-CV.

PS 1414 A NEW IN VITRO METHOD FOR IDENTIFYING SKIN SENSITIZERS AND PREDICTING LLNA EC3 VALUES.

J. M. McKim, B. D. Jeffy, M. E. Steffey and H. N. Wagner. *CeeTox Inc., Kalamazoo, MI.*

The purpose of this study was to develop a novel *in vitro* human cell-based model to detect chemicals and finished products that are skin sensitizing agents. In vitro alternatives to animal testing are needed to support REACH and the European Cosmetics Directive initiatives. The present study describes the use of human (HaCaT) cells in culture and a 3D human skin model to identify skin sensitizers and predict LLNA EC3 values by utilizing concentration response, exposure time, and expression of genes controlled by the antioxidant response element (ARE). The model was developed using a set of 14 chemicals previously classified as non-, very weak-, weak-, moderate-, strong-, and extreme-sensitizers. A prevalidation study with more than 100 compounds is currently underway. The standard HaCaT cell culture model is efficient, but is limited to chemicals with high solubility. In contrast, the human 3D skin models commercially available from SkinEthic and MatTek provide a test system that can be used to test finished products and chemicals with low solubility. Test chemicals were applied at concentrations that ranged from 0.01 μM to 1 mM. Exposures were for 24 hr at 37°C in a 96-well format. Viability was monitored with MTT or histology. Total RNA was isolated with Trizol and changes in the expression of quinone reductase (NQO1), interleukin 8 (IL-8), and aldoketo reductase (AKR) were measured by RT-PCR. The strong sensitizer 1-chloro-2,4 dinitrobenzene produced significant increases in IL-8 and AKR at an exposure of 10 μM. In comparison, the non-sensitizer benzoic acid had no effect at an exposure concentration of 1 mM. An algorithm based on an analysis of the magnitude of gene expression, concentration response, the number of genes responding, and time provides a single value of response, the in vitro toxicity index (IVTI). Comparison of the IVTI to known LLNA EC3 values by exponential re-

gression analysis resulted in an R value of 0.92 in both cell models. This in vitro system provides a useful tool for identifying sensitizers and predicting LLNA EC3 values without the use of animals.

PS 1415 PROTECTIVE EFFECT OF ASCORBIC ACID SUPPLEMENTATION ON LEAD TOXICITY IN RAT BLOOD.

B. P. Patlolla and L. M. Turner. *Department of Biological Sciences, Alcorn State University, Alcorn State, MS.* Sponsor: A. Patlolla.

It is well known that lead is an environmental toxicant that can have long-term adverse health effects on humans. Lead has been evident, used, and consumed in many faucets of human life. This study focused on a possible alternative method of using ascorbic acid supplementation in the treatment of lead poisoning. Sprague-Dawley rats, weighing 100-124g, were exposed to 0.1% lead acetate in drinking water for 2 and 4 week periods. They were then allowed to recover for 5 days with 3.5g/ml ascorbic acid supplementation. Rats were sacrified and blood was collected via cardiac puncture. Blood samples were wet digested using nitric acid and analyzed using optical emission spectrophotometry. Results indicated that the 2 weeks treated animals showed an approximate 25% reduction in blood lead levels. In addition, the 4 weeks treated animals showed a reduction in blood lead levels of approximately 50%. This study illustrates the potential of ascorbic acid supplementation on lead toxicity.

PS 1416 COMMON NEOPLASTIC LESIONS IN THE WISTAR HANNOVER RCCHANTM: WIST RAT.

K. Weber[1, 2], T. Thio[1, 2], H. Iwata[1, 2], A. Piersigilli[1, 2] and M. Josten[1, 2]. [1]*Harlan Laboratories, Indianapolis, IN and* [2]*RCC Ltd, Itingen, Switzerland.* Sponsor: S. Corney.

Differing data on strains, depending on their source, feed and housing conditions have been published. Generally, before starting a toxicology program in rodents it should be considered that oncogenicity studies will be performed for a majority of compounds successfully completing development. The incidence, type and time of onset of age-dependent lesions and neoplasms and some special considerations of rat strain selected may be decisive. Therefore, knowledge of the historical background data is needed. The use of a rat strain should be carefully considered at the beginning of the toxicology program. This paper deals with the occurrence of neoplasms that were recorded in 50 oncogenicity studies performed during 25 years at RCC Ltd Switzerland at incidences ≥ 1.0 % (3748 males and 3751 females planned for terminal sacrifice: 104 to 130 weeks) including brain: granular cell tumor; pituitary gland: adenoma; adrenal cortex: adenoma; adrenal medulla: pheochromocytoma; thyroid: follicular and C-cell neoplasms; parathyroid: adenoma; pancreas: islet cell tumors; liver: hepatocellular adenoma; skin: papilloma, keratoacanthoma, fibroma, lipoma; mammary glands: adenoma, fibroadenoma, adenocarcinoma; testes: Leydig cell tumor; ovaries: granulosa cell tumor, theca-granulosa cell tumor; uterus: endometrial and stromal polyps, adenocarcinoma; vagina: stromal polyp; systemic tumors: lymphoma; mesenteric lymph node: hemangioma and hemangiosarcoma; thymus: thymoma. The onset of tumors in 460 males and 450 females scheduled for sacrifices at study periods between 52 and 78 weeks is rare. At these ages, neoplasms consisted mainly (more than 2 tumors per entity within control data) of pituitary gland adenomas, C-cell and follicular cell tumors of the thyroids, mammarian fibroadenoma and adenocarcinoma, stromal polyps of the uterus and vagina, malignant lymphoma, hemangioma of the mesenteric lymph nodes, and lipoma in body cavities. Over a period of 25 years, the Wistar Hannover RccHanTM: WIST Rat showed a robust stability in its tumor profile regarding the incidences and tumor entities.

PS 1417 DEVELOPMENT OF A RODENT MODEL OF INFLUENZA A INFECTION IN F344 RATS.

M. Wolf[1], A. Kajon[1], T. March[1], D. Baden[2] and J. Benson[1]. [1]*Lovelace Respiratory Research Institute, Albuquerque, NM and* [2]*Center for Marine Science, University of North Carolina, Wilmington, NC.*

The purpose of this study was to develop a model of influenza pulmonary infection in rats to facilitate examination of the abilities of environmental agents to induce immune suppression and to assess potential new drugs/vaccines for efficacy against influenza infection. Stocks of non-adapted influenza A, strain HKX-31 (H3N2)were prepared and titered by plaque assay in MDCK (Madin Darby Canine Kidney) cell monolayers. Groups of 8 male F344 rats were administered 100, 10,000, or 1,000,000 plaque forming units (PFU) by intratracheal instillation. Six rats served as vehicle controls. Half of the rats in each group were euthanized 48 hours (expected time of peak viral growth) and 7 days (period where virus was expected to be cleared from the lung) post dosing. The left lung from each rat was fixed for histological evaluation. The right apical lung lobe was collected for assessment of infectious virus load by plaque assay. The remaining right lobes were collected in RNA later for RT-PCR-based analysis of viral load. Infected animals displayed no clinical signs of disease or toxicity. Overall histology lesion scores (based on severity of parenchymal inflammation, as well as changes in the vasculature and conducting airway epithelium) were increased in a dose dependent manner. However, only high dose group scores at both 48 hr and 7 days post infection were significantly increased compared to the controls. In each dose group, lesion scores at 48 hours post infection were not different from corresponding group scores at 7 days. Infectious virus loads at 48 hr post infection ranging from 1000 PFU/100 mg of tissue (~ 13000 PFU/lung) for the low dose to 100,000 PFU/100mg tissue (1,300,000 PFU/lung) for the medium dose. Virus was not detected in the lung at day 7. Results suggest that F344 rats are permissive for HKX-31 infection and that the model may prove useful for assessing immune competence and therapeutic agent efficacy. Research conducted under NIEHS P01 ES10594.

PS 1418 ACUTE AND SUBCHRONIC STUDIES FOR EVALUATION OF HALOACETAMIDE IN MINI PIGS: CLINICAL PATHOLOGY AND HISTOPATOLOGY ASPECTS.

L. C. Sá-Rocha[1], J. G. Júnior[3], J. R. Mariano[5], C. Massoco[2], R. P. Foz[3], M. Mariano[4] and J. E. Kalil[5]. [1]*Pathology, Faculty of Veterinary Medicine of São Paulo University, SÃ£o Paulo, SÃ£o Paulo, Brazil,* [2]*Research, Mini Pigs Research and Development, Campina do Monte Alegre, SÃ£o Paulo, Brazil,* [3]*Animal Toxicology, Ciallyx Labs & Consultants, SÃ£o Paulo, SÃ£o Paulo, Brazil,* [4]*Immunology, Faculty of Medicine of São Paulo Federal University, SÃ£o Paulo, SÃ£o Paulo, Brazil and* [5]*Immunolology and Allergy, Faculty of Medicine of São Paulo University, SÃ£o Paulo, SÃ£o Paulo, Brazil.*

Scope: For evaluate the possible toxic effect caused by the acute and subchronic oral administration of the Haloacetamido, a new molecule to be used in the combat of Leishmaniose, we use mini-pigs like non-rodent animal model. Experimental procedures: Acute oral toxicity test and chronic studies, 4 and 13 weeks, had been carried through using mini pigs, males and females, between 25 and 32 kg, with about 12 and 14 months of age. The animals had been acclimatized by a minimum period of seven days. Daily clinical evaluations and weekly measures of the weight and the alimentary consumption had been carried through. To the end of the 4 and 13 weeks studies hematology, clinical pathology, pathology and histopathology examinations had been carried through in all the animals. Results: The doses of 10,0; 30,0 and 100,0 mg/kg used in the acute oral study had not evidenced of clinical or pathological signals of toxicity. In the 4 and 13 weeks studies the used doses had been of 1,0; 3,0 and 10,0mg/kg. In the two studies significant serum glucose reduction was verified, as much in males as in female. The gross pathology and the histopathology analysis had shown discrete hepatic and renal alterations only in the high dose (10,0mg/kg). Principal conclusion: Haloacetamido revealed sufficiently safe in the carried through tests and we considered NOEL the dose of 3,0mg/kg in mini pigs. Mini pigs had revealed excellent to animal models for the study of new medicines and a good alternative to the use of dogs as not rodent species for toxicology and safety studies.

PS 1419 "ARTHRITIS-ASSOCIATED MYOPATHY", A CHARACTERISTIC PATHOLOGY OF PRIMATE MODELS.

N. Horai[1, 2], T. Nagaoka[1], H. Kasai[1], R. Kodama[1], M. Matsuda[1], T. Izumi[1], T. Sukamoto[1], K. Fukuzaki[1], R. Nagata[1] and K. Abeyama[2]. [1]*Shin Nippon Biomedical Laboratories (SNBL), Ltd., Kagoshima, Kagoshima, Japan and* [2]*Department of Preventive Medicine, Kagoshima University, Kagoshima, Kagoshima, Japan.*

We have established a collagen-induced arthritis (CIA) model in cynomolgus monkeys (CM) to assess the effectiveness of new therapeutics in preclinical development (e.g., candidate compounds for anti-rheumatic drugs). Based on similarities in human and CM drug metabolism, primate models have been considered to be predictive of drug effects in clinical applications. In this study, we introduce an additional advantage in the employment of primate CIA models in pre-clinical; demonstrating our finding that "arthritis-associated myopathy" appears frequently in CIA models of CM. CIA was induced in 22 female CM by two immunizations with bovine type II collagen in the presence of Freund's complete adjuvant. Symptoms of arthritis were monitored with arthritis score, and food intake, body weight, and serum biochemical parameters (CPK, Creatinine, CRP, serum IL-6 and cortisol) were measured sequentially. The animals were sacrificed in stages, 5 to 6 animals per timepoint (Day 11, 21, 35 and 63 after the first immunization) for histopathology. Necrosis of muscle fiber at quadriceps femoris was observed only on Day 11.

The most significant findings such as atrophy, degeneration and/or regeneration of muscle fiber were most frequently observed on Day 35. A marked decrease in body weight was reproducibly observed in this model, which positively correlated with serum creatinine at all timepoints. CPK increased markedly on Day 11, and thereafter CRP and IL-6 rose and peaked on Day 28. These suggested that the procedure of CIA targets skeletal muscle tissues as well as joints independently of systemically-induced inflammatory reaction. In this context, a biphasic increase in serum cortisol was observed on Days 11 and 35, thus indicating that cortisol withdrawal might be associated in the development of "arthritis-associated myopathy".

PS 1420 COOPERATIVE DEVELOPMENT OF AN AUTOMATED SYRINGE INFUSION PUMP FOR PRECLINICAL TOXICOLOGY.

R. Haas[1], A. Jacobson[2], J. Sommers[2], S. Pawl[1], J. Agate[1], A. Brooks[1] and A. Alexander[1]. *[1]Covance Laboratories, Inc., Madison, WI and [2]Solomon Scientific, San Antonio, TX.*

Historically, preclinical infusion studies have used syringe pumps designed for laboratory or human use; often requiring extensive manual documentation and pump manipulation to meet regulatory requirements for GLP studies. Infusion experts at Covance have co-developed with Solomon Scientific the Orchesta™ syringe infusion pump with wireless communication incorporating input from a variety of regulatory and technical stake-holders, to meet the specific needs of preclinical toxicology. The pump features a magnesium splash-proof case and fully enclosed drive mechanism to prevent contamination; these features will extend the life of the pumps over that of those currently available. Pumps may be programmed and operated individually or numerous pumps may be operated in tandem wirelessly (IEEE 802.15.4 WAPN standard) from a single host PC. Tandem operation allows the infusion setup to be entered once on the host PC at the beginning of the study, a significant improvement over the current paradigm of manually programming each pump for each dose. This pump accommodates syringes of 1 to 140 mL, can deliver infusion rates of 0.01 mL to 3 L per hour, and is therefore scalable for small or large animal infusion studies for a variety of study designs. The pump software interfaces with commercially available data collection systems to query for animal ID, body weight data, and dose parameters and to facilitate reporting of infusion-related data and can be upgraded to interface with a variety of data collection systems. The system features robust electronic documentation which meets GLP Part 11 requirements, facilitating reporting of infusion data and eliminating the need for paper documentation. A unique user code is required for all pump or system interventions and each action is automatically documented by time and user identification. The Orchesta™ syringe infusion pump with wireless communication will improve the accuracy, reproducibility, and regulatory compliance of preclinical toxicology infusion studies.

PS 1421 FEASIBILITY OF REPEATED INTRA-ARTICULAR ADMINISTRATION IN THE MARMOSET MONKEY (CALLITRIX JACCHUS).

S. Korte and G. F. Weinbauer. *Covance Laboratories GmbH, Muenster, Germany.*

S Korte, G.F. Weinbauer
Covance Laboratories GmbH, Muenster, Germany

The common marmoset (Callitrix jacchus) provides an alternative species to macaques in preclinical safety testing (1) and has also been used as a model for induced Parkinson's disease, multiple sclerosis and rheumatoid arthritis. For the latter indication, administration of specific testis items such as biopharmaceuticals directly into joints is required in some instances, and for some biopharmaceuticals the marmoset represents the only relevant animal model. This work investigates, therefore, the feasibility of repeated intra-articular dosing into the knee joint in this animal model in the context of toxicity studies. Male and female marmosets (n = 6/group), weighing 278–455 gram and 1-9 years old, were fasted and slightly anesthetized with 0.2 mL/animal ketamine hydrochloride. Knees were shaved and intra-articular administration was done under aseptic conditions using sterile NaCl. Based upon consideration of the complete synovial fluid volume, maximal injection volume was determined as 0.20 mL/kg. Four bolus doses were injected into the same knee in weekly intervals in every animals. The contralateral knee served as control. Post dosing observations were performed 3 and 5 hours after administration during the first 3 days after dosing. Macroscopic and histopathology evaluation after last dosing did not reveal inflammatory reactions in comparison with the control knee. Post dosing observation did not indicate any procedure related swellings. Activity and movement patterns appeared unaffected in all animals. Body weights and clinical pathology parameters did not indicate any adverse findings. For single injection, intra-articular dosing volumes of 0.35 mL/kg have also been reported (2). In conclusion, repeated intra-articular administration of dose volumes up to 0.2 mL/kg is feasible in the marmoset model, thus adding another route of administration for this species in toxicity studies. 1. Korte et al. (2004) Toxicologist, 78:S-1; 2. Hunneyball (1983) Rheumatol Int. 3:69.

PS 1422 SENSITIVITY OF TELEMETRY TO PREDICT QT INTERVAL PROLONGATION IN DOG TOXICITY STUDIES: ASSESSMENT OF EFFECTS OF MOXIFLOXACIN BY INVASIVE AND NON-INVASIVE METHODS.

A. Breidenbach, M. Festag, G. Andrea, H. Holzgrefe, G. Schmitt and W. Thomas. *Non-Clinical Drug Safety, F. Hoffmann-La Roche, Basel, Switzerland.*
Sponsor: M. Stephan-Gueldner.

ECG assessment in repeat-dose toxicity studies offers important information that complements cardiovascular studies using invasive telemetry. However, the acquisition of conscious ECGs employing physical restraint may transiently alter the fundamental electrophysiology of the subject, resulting in potentially misleading results. Therefore, a variety of non-invasive jacketed telemetry systems for use in freely moving animals are available. The purpose of this study was to compare the sensitivity to detect moxifloxacin-mediated (MOX) QT prolongation in 2 groups of dogs equipped with either EMKA jacket (n=5) or ITS invasive telemetric system (n=6). QT was corrected for the effects of heart rate employing Van de Waters' correction (QTcV for the EMKA system), or the probabilistic method (QTca for ITS data). All dogs received vehicle and MOX (30 mg/kg, p.o.) and continuous L-II ECGs were obtained. To mimic the design of a toxicity study, ECGs were measured in EMKA dogs at pretest and for 6 h postdose. Dogs instrumented with ITS telemetry implants (Konigsberg) (3 male, 3 female) were dosed in a crossover design (vehicle and MOX) and ECGs were acquired for 20 h. Plasma MOX levels were measured 4 h postdose to confirm exposure and were comparable in both studies (approx. 5.9 ± 0.6 ug/ml). MOX maximally increased QTcV by 28 ms (threshold for significance 18 ms; $p \leq 0.05$) and QTca by 33 ms (threshold for significance 8 ms; $p \leq 0.05$). These data demonstrate that while the sensitivity to detect significant QT prolongation was slightly lower with the EMKA jacket system, both systems detected a qualitatively similar response to MOX. Thus, the EMKA jacket system is a sensitive method to detect QT prolongation which may provide high quality ECG signals in repeat-dose toxicity studies while avoiding the confounding effects of restraint.

PS 1423 AN AMBULATORY METHOD OF INTRAVENOUS INFUSION FOR USE IN PRECLINICAL STUDIES IN THE DOG.

V. Hélène, C. Gerhardy and J. Briffaux. *MDS Pharmacology Services, St Germain sur l'Arbresle, France.*

A feasibility study was performed to assess the suitability of an ambulatory method of intravenous infusion for use in preclinical studies in the dog. Three male and 3 female beagle dogs were infused with sterile physiological saline at a rate of 15 ml/kg/day for six weeks. A Silastic catheter was surgically implanted into the jugular vein with the tip protruding into the anterior vena cava. The distal portion of the catheter was tunnelled subcutaneously to exit at the nape of the neck and was connected to a peristaltic pump (Pegasus Light, LAB). The total weight of the pump was approximately 200g. The pump and 300-ml reservoir were protected by a polystyrene case contained within a jacket worn by the dog. Standard observations and measurements were performed as in a routine toxicology study. The integrity of the infusion lines and the rate of infusion were verified 3 times per day. The reservoir and batteries were replenished daily. The dogs were allowed to socialise in groups of 3 of the same sex for 2 hours per day, under constant supervision by a technician. There were no adverse reactions in any dog. Some improvements were made regarding the housing of the pump and reservoir in the jacket in order to avoid kinks in the tubing. Following this, the accuracy of the infused volume was within +/- 10%. This experiment demonstrated the feasibility and advantages of the ambulatory method of intravenous infusion for use in regulatory safety studies in dogs.

PS 1424 SEMI-AUTOMATED ELECTROCARDIOGRAPHY (ECG) DATA ANALYSIS USED TO DETECT QTC PROLONGATION IN MONKEYS.

J. J. Kremer, H. Fan, E. Robinson, T. W. Beck, C. Foley, M. A. Osinski, D. Gumpf and R. Sarazan. *Covance Labs, Madison, WI.*

Moxifloxacin, a fluoroquinolone antibiotic, is widely used as a positive reference drug in human Thorough QT/QTc studies. This study determined the sensitivity to detect QTc prolongation in cynomolgus monkeys following administration of

moxifloxacin using semi-automated analysis software to evaluate electrocardiography (ECG) data. Methods: Four male and four female cynomolgus monkeys were implanted with telemetry devices and administered moxifloxacin at 0 (control), 10, 50, or 175 mg/kg in separate Latin Square designs. ECG, heart rate, body temperature, and blood pressure data were collected continuously for 48 hours following each dose. ECG data were analyzed using ECG PRO (Data Sciences International). At least 100,000 waveforms were analyzed per animal following each dose. Plasma was collected at 5 and 29 hours postdose and moxifloxacin levels were measured using liquid chromatography/mass spectrometry (LCMS). Results: Moxifloxacin induced QT and QTc interval prolongation in male and female monkeys. When males and females were analyzed separately in four animal Latin Square designs, significant QTc interval prolongation was detected from 12 to 47 msec for hourly averages and 30 msec for an analysis block (defined by day/night). Data were combined across sex into a double Latin Square, which detected significant QTc interval prolongation from 5 to 39 msec for hourly averages and 13 to 30 msec for an analysis block. Power analysis demonstrated that QTc interval changes using semi-automated ECG analysis software in these study designs can be detected at 16 (4 animals) and 10 msec (8 animals) with 80% power. Moxifloxacin plasma levels at 5 and 29 hours postdose were 760 and 50 ng/ml (10 mg/kg), 3700 and 290 ng/ml (50 mg/kg), and 6500 and 2200 ng/ml (175 mg/kg). Conclusions: This study demonstrates that semi-automated ECG analysis software can be used to detect QTc prolongation in monkeys with sensitivities of 16 (n=4) or 10 msec (n=8). This approach allows researchers to analyze large sets of ECG data with comparable sensitivity as conventional methods.

PS 1425 VALIDATION OF THE AUDITORY STARTLE REFLEX IN RATS.

R. Forster, S. Bentz, S. Frary, L. Basset, J. Legois, A. Bétat and G. Chevalier. *CIT, Evreux, France.*

The auditory startle test is a test required during pre- and post-natal development studies. The auditory startle reflex is a protective reaction in rodents which consists of a very fast contraction of muscles provoked by a sudden and intense sound stimulus. In order to validate the auditory startle test system, two pharmacological reference molecules, kanamycine and clonidine, known to modify this reflex, were used as positive controls in adult and/or young Sprague Dawley rats. The auditory startle test consists of three minutes of acclimation to the arena followed by two consecutive stimuli performed with a one minute interval. The first stimulus was composed of a sound at 107 dB, 10 kHz, 137 ms and the second stimulus had a higher intensity (119 dB). The test was performed on 5- and 11-week old rats which had been treated 15 minutes previously with clonidine (0.4 mg/kg) by intraperitoneal injection and on 5-week old rats which had been treated with kanamycine (400 mg/kg) from post-natal days 9 to 16, also by intraperitoneal injection. The data showed that treatment with clonidine or kanamycine decreased significantly the amplitude of the reflex and disturbed the reflex whatever the intensity of the stimulus. In addition, treatment with clonidine increased the latency of the response. Thus, the auditory startle test system is now fully validated and is used in routine preclinical reproductive toxicology studies at CIT.

PS 1426 PUPILLOMETRY OF ALERT AND KETAMINE-SEDATED NON HUMAN PRIMATES UNDER VARIOUS STATES OF ILLUMINATION.

T. M. Streit[1], J. VerHoeve[2], C. J. Murphy[2] and T. T. Lam[1]. *[1]Covance Laboratories, Inc., Madison, WI and [2]Comparative Ophthalmic Research Labs, Madison, WI.*

Pharmacological agents, such as tricyclic antidepressants, which do not have the eye as a target organ, but have side effects on the eye including mydriasis, may elicit adverse effects such as photophobia and cycloplegia. Therefore, for some drugs, it is important to determine their drug-mediated effects on pupil diameter changes and to this end pupillometry can be a valuable tool. This in vivo non-human primate study evaluated two methods of determining pupil diameter under various illumination conditions in conscious animals, and also evaluated the effect of ketamine. Pupil diameters were determined by manual measurements and by evaluation of videographic recordings under illumination of (1) room light, (2) darkness, and (3) direct exposure to a pen light (to elicit maximal light-mediated constriction) in conscious and properly restrained animals. An infrared video camera, modified to serve as a photorefractor, allowed the determination of pupil diameter in the dark. Cyclopentolate was used as a positive control. The mean measurements using the manual method under room lighting on conscious and restrained animals were comparable to those values obtained by videographic analysis. Videographic analysis indicated a maximum papillary constriction of 29.5% and 43.6% when exposed to room light and muscle light, respectively, when compared to total darkness. Measurements under sedation with ketamine showed a moderate decrease in pupil dilation when results were compared with the values obtained in the conscious and restrained state. The results of this study suggest that pupil measurements of animals under the effects of ketamine can be compromised due to ketamine's pupil-dilating effect. Furthermore, videographic analysis of pupil diameter is of added value compared to manual measurements due to its ease in capturing pupil diameter under a variety of illuminations, and its ability to determine additional parameters such as percent constriction of maximum dilation.

PS 1427 HOW TO INTEGRATE SAFETY PHARMACOLOGY END-POINTS DURING TOXICOLOGICAL STUDIES IN NON HUMAN PRIMATES FOR BIOLOGICS ?

H. Ficheux, G. Froget and J. Legrand. *CIT, Evreux, France.*

Existing guidance ICH M-3; S6; S7A; S7B, provide requisites for the conduct of appropriate safety pharmacology and toxicology assessment. However, inherent differences between biologics and small molecular entities support different approaches in non clinical safety assessment. As a result, opportunities exist for alternative strategies for the integration of safety pharmacology end-points in general toxicological studies.

Based on our own experience, we describe an approach in non human primates to explore a new biologic that matches not only toxicological criteria, but also meets guideline criteria. Requirements from the ICH S7A core battery were met by the following: Respiratory function is evaluated by the use of a facial mask. Respiratory volumes, flows and bronchoconstriction index are recorded on different occasions; Cardiovascular functions are assessed by measurements of blood pressure using tail/leg cuff while the ECGs are recorded on separate occasions by external telemetry,; and, finally, some aspects of CNS are investigated during the study, including detailed clinical observation, social behavior and body temperature - TK measurements are also made at the most appropriate time-points. The sequence of evaluation of these different parameters is a critical issue in order to avoid interferences between the different measurements. Since ECG is considered as the most critical end-point, it has been decided to perform it on days when no other parameters are to be assessed. Blood pressure, respiratory function as well as body temperature are monitored every other day under light anesthesia and can be associated with TK samplings. Such a design while fulfilling most regulatory compliances presents not only the additional benefit of reducing quantities of compound, time of development and cost but also meets the ethical constraints of reducing the number of animals used.

PS 1428 COMPARISON OF BACKGROUND DATA FROM NORMAL (NON-CANNULATED) *VERSUS* DATA FROM SURGICALLY-CANNULATED, INTRAVENOUSLY INFUSED, RATS, DOGS, MONKEYS AND PIGS.

G. Washer, S. Authier and E. Lebel. *LAB Research Inc., Laval, QC, Canada.*

Extended IV infusion, employing surgically implanted catheters, continues to be critical in non-clinical development of many IV pharmaceuticals (e.g. anti-cancer agents, large molecules), or for certain pharmaceuticals that cannot achieve high systemic exposure by other routes. To reliably undertake such non-clinical studies, confidence in the methods and appreciation for procedure-related changes are critical. To that end, establishing background ranges, and understanding how parameters may be temporarily or permanently altered by the procedures, is essential. Having conducted many continuous intravenous studies in all major laboratory species, we have established the data sets required to compare to normal animals. In all rodent and non-rodent laboratory species evaluated, the methodology was very similar and involved cannulation of the vena cava, via a femoral vein, followed by exteriorization of the catheter via a jacket and tether which permitted connection to an infusion pump. Patency was maintained, during non-treatment periods, by continuously infusing normal saline at a low rate (varied depending on species and catheter size). During the studies the infusion rates were adjusted, at least weekly, based on individual body weight. Despite the jacket and tether, specialized handling procedures facilitated routine clinical examinations, body weight and food intake measures, blood and urine collections, as well as specialized examinations (e.g. ECG, ophthalmology). At termination, particular attention to gross and histopathological evaluation of the infusion site (i.e. catheter tip) and certain key tissues (e.g. lungs), was critical to proper evaluation of procedure-related effects. Evaluation of data collected from these vehicle-treated animals has demonstrated only minor, transient post surgical effects on limited parameters (e.g. post surgical weight loss; slight increase in white cells), and minor, local microcopic changes consistent with presence of a catheter.

PS 1429 BIOMARKERS PROVIDE IMPORTANT PHOTOTOXICITY DATA BUT ARE NOT YET SUFFICIENT FOR PHOTOCARCINOGENIC RISK ASSESSMENT.

C. P. Sambuco[1], D. P. Forbes[1], D. B. Learn[1], S. Eldridge[2] and A. M. Hoberman[1]. *[1]Charles River Laboratories, Horsham, PA and [2]Charles River Laboratories, Frederick, MD.*

The photosafety guidances promulgated by American and European regulatory agencies indicate that the use of biomarkers to evaluate the consequences of combined drug and ultraviolet radiation (UVR) exposure will be considered, based on a thorough evaluation of the scientific data. Potentially, these alternative approaches (which currently provide essential repeat-dose phototoxicity data) could substitute for the standard hairless mouse photocarcinogenesis bioassay. For this approach to be viable, a substantial data base from mechanistic studies would be required. Demonstration of key relationships between biomarkers and verifiable carcinogenesis require substantial verification data before a study design may be considered adequate for risk assessment and serve as a photocarcinogenesis bioassay surrogate. The use of varying UVR exposure regimens and selected biomarkers (thymine dimers, TUNEL, p53, MSH2, DNA synthesis, histopathological changes) was investigated in several studies with known photocarcinogens in hairless albino mice (e.g., retinoids, fluoroquinolone antibiotics), the phototoxic but not photocarcinogenic agent anthracene and the human photocarcinogen 8-methoxypsoralen. The data from recent studies has not proven to be predictive of experimental photocarcinogenesis. For example, thymine dimers from two levels of UVR doses that cause differences in time to tumor in mice did not show such difference at the times evaluated; furthermore, anthracene caused the highest change in p53 values, even though it is not photocarcinogenic in mice. Therefore, the use of these biomarkers in alternative assays is not yet ready to replace the accepted hairless mouse photocarcinogenesis bioassay. Recent studies have, however, provided leads on in the further development of abbreviated tests.

PS 1430 CEREBROSPINAL DELIVERY AND SAMPLING IN RATS.

C. Copeman, M. Mus and Y. Trudel. *Toxicology, Charles River, Senneville, QC, Canada.* Sponsor: M. V√©zina.

Intrathecal (IT) injection and infusion in rats were validated as routes of cerebrospinal drug delivery. Intracerebroventricular (ICVS) injection or infusions in rats were previously validated and IT injections or infusions in non-rodents are well-established methods in our laboratories. Validation of the IT methods in rats, permits conduct of regulatory compliant efficacy or toxicity assessments of neuroactive compounds. The use of the cerebrospinal routes allows for an effective way of bypassing the blood-brain barrier when administering compounds that would not otherwise reach their desired target. This directed administration also avoids potential toxicity that could arise from systemic exposure to therapeutic concentrations of neurologically active drugs. In addition to dose administration procedures, we evaluated the feasibility of serial sampling of cerebrospinal fluid (CSF) in additional populations of rats. For IT infusion, rats were instrumented with a catheter, entry via the cisterna magna and tracked to the lumbar (L) region with placement of the tip targeted at L2 to L4. The animals were maintained on infusion for up to 20 to 22 days and were thereafter euthanized and post-mortem examinations performed. At necropsy, catheters were confirmed to be in the IT space, at the lumbar level. Presence of the catheter in the IT space resulted in expected histopathological changes consisting primarily of inflammation. IT injections were performed by direct puncture through the exposed dura between the L4/L5 vertebrae above the cauda equina. Intrathecal placement was verified by flick of the tail upon entry of the needle. Up to 40 μL was successfully injected into this space. The feasibility of serial sampling of CSF (30 μL/sample) at 4 time points over 24 hours in rats was investigated. Sampling was performed via an implanted cannula in the cisterna magna. Intrathecal and ICVS infusion or injection in rats together with serial collection of cerebrospinal fluid was concluded to be successfully performed in our laboratories to be used for conduct of efficacy or toxicity testing.

PS 1431 EVALUATION OF THE FEASIBILITY OF JUVENILE TOXICITY STUDY IN THE GöTTINGEN MINIPIG.

R. Forster, G. Chevalier and C. Bouchez. *CIT, Evreux, France.*

The Göttingen minipig is a potential non-rodent model for the assessment of pediatric toxicity. The present study was undertaken to evaluate the zootechnical requirements and specificities of pregnant, lactating and juvenile animals and to validate the sensitivity of this species by treating the piglets with reference compounds during their neonatal period (first month of life). Three sows were received at CIT in their last month of gestation and were allowed to deliver normally. In the first days after parturition, the piglets were randomized by cross-fostering (litters were mixed and reattributed to the sows). The 20 newborn piglets were then allocated to groups treated with different compounds and submitted for tests in order to collect specific data on juvenile animals for blood chemistry, electrocardiography, neurological evaluation and ophthalmology. All the piglets were sacrificed on day 34 and submitted for macroscopic and microscopic examination. One group of piglets was treated with enalapril (Angiotensin II Converting Enzyme Inhibitor) by oral gavage from day 7 to day 33. Another group was treated with purified water under the same conditions and acted as a control group. Increased uremia and creatininemia associated with increased renal weight and macroscopic and microscopic lesions in the kidneys were observed in the piglets given enalapril. A third group of piglets received sotalol (antiarrhythmic agent) on the day of electrocardiography, inducing decreased heart rate, PQ and QT interval prolongation. This study supports the interest of the Göttingen Minipig model for the assessment of toxicity in the pediatric population.

PS 1432 ACTIVATION OF ENDOPLASMIC RETICULUM-STRESS IN HEPATIC ALCOHOL DEHYDROGENASE-DEFICIENT DEER MICE IS ASSOCITED WITH NONOXIDATIVE METABOLISM OF ETHANOL.

B. S. Kaphalia[1], S. Kondraganti[2], K. K. Bhopale[1] and G. Ansari[1]. *[1]Pathology, The University of Texas Medical Branch, Galveston, TX and [2]Biochemistry & Molecular Biology, The University of Texas Medical Branch, Galveston, TX.*

In previous studies, we reported ethanol-induced pancreatic injury in hepatic alcohol dehydrogenase (ADH)-deficient (ADH-) deer mice model. To further elucidate the mechanism of alcoholic chronic pancreatitis (ACP), a dose-dependent study was conducted in ADH- and hepatic ADH-normal (ADH+) deer mice fed 1, 2 and 3.5% ethanol via liquid diet daily for 2 months. Metabolism of ethanol and pancreatic injury and endoplasmic reticulum (ER)-stress were evaluated. The blood alcohol levels (BAL) and nonoxidative metabolism of ethanol as measured by quantitating fatty acid ethyl esters (nonoxidative metabolites of ethanol) in the plasma and pancreata were several folds higher in ADH- vs. ADH+ deer mice fed 3.5% ethanol. However, the blood acetaldehyde levels were not significantly altered in both strains. ADH- deer mice fed 3.5% ethanol also showed significant pancreatic injury (edema and increases in trypsinogen activation peptide and cytoplasmic cathepsin B). The most prominent ultrastructural change observed in the ADH- deer mice fed 3.5% ethanol was endoplasmic reticulum (ER)-stress. This was further confirmed by analyzing the glucose-regulated protein 78 (GRP78; a marker of unfolded protein response) using Western blot analysis and immunohistochemistry. About 9-fold increase in the expression of GRP78 was estimated in the pancreata of ADH- vs. ADH+ deer mice fed 3.5% ethanol. These results suggest that increased nonoxidative metabolism of ethanol is an important determinant for the activation of ER-stress in the pancreas and that the observed pancreatic injury could be a down stream effect of ER-stress.

PS 1433 AN ALTERNATE DESIGN FOR THE EXTENDED ONE GENERATION REPRODUCTION STUDY.

P. M. Foster. *Toxicology, DHHS, NIH, NIEHS, Research Triangle Park, NC.*

EPA has proposed a protocol to replace the current multigeneration reproduction study based on an original proposal from ILSI/ACPA. This extended 1-generation study has now been submitted to OECD. The drivers for replacement were to reduce animal numbers on reproduction studies and the testing demands of REACH for reproductive toxicity. Some surveys had indicated that the F2 generation may add little extra information to hazard characterization, although this inference is disputed. The NTP recently modified its default approach for the rat cancer bioassay by incorporating a perinatal exposure period (gestation, lactation and puberty) into the 2-year design that starts treatment with animals at 5-6 weeks of age. A cancer bioassay would normally require a prior sub-chronic toxicity study with the same exposure paradigm, for basic toxicity information and dose level setting that can stand alone, or be adapted for a reproductive study. This new NTP design focuses evaluations on the F1 animals with continuous exposure during the study. It commences with timed pregnant females exposed from implantation through lactation, to weaning of their offspring. Various offspring cohorts are then selected to include one for standard toxicity assessments with exposure continuing to sexual maturity (2 males and females/ litter). A second cohort designated for breeding on reaching maturity (1 male and female/litter) and a third cohort (1 male and female/litter) would be bred, and a teratology exam on pregnant females conducted just prior to term. The second cohort of pregnant females could be terminated in

mid-gestation and implants assessed, or allowed to litter their offspring and raise them to weaning. This approach would maximize the use of animals produced, maintain a 10 week pre-breed period, to ensure that male germ cell effects could be noted as a functional change, and increase the power to detect potential developmental effects on the reproductive system. The total number of animals used would be considerably less than a multigeneration study and similar to the EPA proposal, but produce more information on developmental outcomes.

PS 1434 TESTING THE UTEROTROPHIC ACTIVITY OF PERFLUOROOCTANOIC ACID (PFOA) IN THE IMMATURE CD-1 MOUSE.

E. P. Hines[1], E. A. Gibbs-Flournoy[3], J. P. Stanko[2], R. Newbold[4], W. Jefferson[4] and S. E. Fenton[2]. *[1]NCEA, EMAG, ORD, U.S. EPA, Research Triangle Park, NC, [2]NHEERL, RTD, ORD, U.S. EPA, Research Triangle Park, NC, [3]BBSP/IMSD Programs, UNC, Chapel Hill, NC and [4]Reproductive Medicine Group, NIEHS, Research Triangle Park, NC.*

The uterotrophic assay is an in vivo screening tool used to determine the estrogenic or anti-estrogenic potential of an exogenously administered compound. Recent studies reported that PFOA increased activity of estrogen-responsive genes in fish. Thus, we explored the effect of PFOA on the immature mouse uterus using a standardized uterotrophic assay. Timed-pregnant CD-1 dams (N=17) delivered litters that were equalized to 10 female pups. On postnatal day (PND) 18, pups were weaned, weighed, and assigned to treatment groups of equal weight. That same day, pups were treated by oral gavage with PFOA (0, 0.01, 0.1, or 1 mg PFOA/kg body weight (BW)) with or without 17-B estradiol in corn oil (E2, 500 ug/kg, s.c.). All mice not receiving E2 received a corn oil vehicle s.c. injection. The mice (N=16/non-E2 group, N=8/E2 group) were weighed and dosed for 3 consecutive days and killed on PND 21. BW and uterine wet weights (UWW) were recorded, and uteri were fixed in buffered formalin for future histopathology. BW was unchanged by PFOA treatment. There was a significant increase in the UWW and UWW:BW ratio (% BW) at 0.01 mg PFOA/kg ($p<0.05$) that is most likely due to enlargement of the uterine cervix junction, visibly enlarged in >75% of the PFOA-animals regardless of E2 status. UWW and % BW ratios for 0, 0.01, 0.1, and 1 mg/kg PFOA were 13+/-1, 20+/-1, 16+/-2, and 16+/-2 mg, and 0.11+/-0.01, 0.16+/-0.01, 0.14+/-0.01, and 0.13+/-0.01, respectively. E2 induced a significant increase in UWW in all groups (mean % BW 0.86+0.06). No anti-estrogenic effects were found by co-administration of PFOA with E2. PFOA produced a unique effect at the utero-cervical junction that was distinct from the uterine effect of estrogen. Histological analysis will be required to determine the specific cell types affected by PFOA exposure. These data do not necessarily reflect EPA policy.

PS 1435 COMPARISON OF THE EFFECTS OF GENISTEIN AND ETHINYL ESTRADIOL (EE_2) IN SPRAGUE-DAWLEY (SD) RATS IN MULTIGENERATIONAL REPRODUCTIVE AND CHRONIC TOXICITY STUDIES.

K. Delclos[1], C. C. Weis[1], G. R. Olson[2], T. J. Bucci[2], P. W. Mellick[2], J. R. Latendresse[2], N. Sadovova[2], B. Thorn[1] and R. R. Newbold[3]. *[1]NCTR, FDA, Jefferson, AR, [2]Toxicologic Pathology Associates, NCTR, FDA, Jefferson, AR and [3]NIEHS, Research Triangle Park, NC.*

The complexity of estrogen signaling and/or interaction with non-estrogen receptor targets leads to distinct but overlapping patterns of effects from compounds interacting with estrogen receptors. Genistein, a soy isoflavone, and EE_2, which differ in potency and receptor selectivity, were studied in multigenerational reproductive and chronic toxicity studies with different treatment intervals among generations. SD rats were exposed to genistein (0, 5, 100, or 500 ppm) or EE_2 (0, 2, 10, or 50 ppb) in a low phytoestrogen diet. Both produced similar effects in female rats exposed continuously, including decreased body weights, accelerated vaginal opening, and altered estrous cycles. Litter size was reduced in generations directly exposed to genistein. Chronic studies involved treatment from conception to 2 years (F_1C), from conception to PND 140 followed by control diet to 2 years (F_1T140), or exposure of the offspring of three exposed generations (F_0, F_1, and F_2) until weaning at PND 21 followed by control diet to 2 years (F_3T21). EE_2, but not genistein, significantly increased the incidence of uterine lesions (atypical focal hyperplasia, squamous metaplasia) in F_1C and F_3T21, but not F_1T140, animals. High dose genistein, but not EE_2, reduced mammary fibroadenomas (F_1C) and increased adenomas/adenocarcinomas (F_1C and F_3T21) in females. Both compounds resulted in increasing trends in preputial gland tumors in males only in F_3T21. High dose genistein, but not EE_2, induced early onset of aberrant estrous cycles in all exposure intervals, and all dose levels produced early onset of aberrant cycles in F_3T21 animals. Thus, there was apparent increased sensitivity in offspring of prior exposed generations (F_3T21) for several endpoints. Supported by Interagency Agreement 224-07-007 between FDA and NIEHS.

PS 1436 CONTROL DATA OF REPRODUCTIVE TOXICITY STUDIES IN THE WISTAR HANNOVER RCCHANTM: WIST RAT.

K. Weber[1, 2], S. Whitlow[1, 2], R. Gerspach[1, 2] and M. Josten[1, 2]. *[1]Harlan Laboratories, Indianapolis, IN and [2]RCC Ltd, Itingen, Switzerland.* Sponsor: S. Corney.

A Segment I male fertility study allows detection of effects of spermatogenesis and fertility. Stable data were obtained. In the segment III studies, the reproductive success was comparable in the P and the F1 generation. It can be expected that any latent effect in a substance would lower the reproductive success of the F1 generation and would result in high pre-and post-implantation loss. The mean duration of gestation of the P generation was 21-22 days. Post-implantation loss affected up to 6.3% of implantations. No dead pups were found at the first check of the litter. During the first 4 days of lactation, pup loss was up to 3.8% of the pups born. Loss between days 5-21 was up to 11.8% of the pups born. The percentage of males and females was close to 50% in all litters. The pup weights at birth ranged from 6.1 - 6.3 grams, the male pups being slightly heavier than the female pups. On day 21 of lactation, pup weights were 39.4 - 52.0 grams. Developmental landmarks included the unfolding of the pinna on day 3 - 4 of lactation and the opening of the eyes on day 14-15. In the F1 generation, there was an average of 13.2 corpora lutea per dam and a pre-implantation loss of 5.1% of all corpora lutea. Post-implantation loss was up to 8.3% of all implantation sites. No dead fetuses were noted. In two-generation studies, the loss of pups after birth is low in the Han Wistar rat in both the P and F1 generations and there is little difference between the generations. Organ and body weights are slightly higher in the F1 than the P generation but are comparable. Pathology data revealed no major differences in females compared to animals in other study types at similar ages, except of higher incidences of hepatocellular hypertrophy as well as physiological changes in the cycle after birth. These studies suggest that the Han Wistar rat has a high fecundity and there is little variation in reproductive success between the generations. Thus, it is a strain well suited for reproductive toxicity studies.

PS 1437 COLLABORATIVE WORK ON EVALUATION OF OVARIAN TOXICITY:EFFECTS OF 2- OR 4-WEEK REPEATED DOSE STUDIES AND FERTILITY STUDY IN FEMALE RATS.

A. Sambuissho[1], M. Yoshida[2], S. Hisada[3], F. Sagami[4], M. Takahashi[5], S. Kudo[6], T. Kumazawa[7], M. Ube[8], S. Komatsu[9] and Y. Ohno[2]. *[1]DAIICHI SANKYO CO., LTD, Fukuroi, Shizuoka, Japan, [2]National Institute of Health Sciences, Setagaya, Tokyo, Japan, [3]Aska Pharmaceutical Co., LTD., Kawasaki, Kanagawa, Japan, [4]Eisai Co., LTD., Tsukuba, Ibaragi, Japan, [5]Pathology Peer Review, Shinagawa, Tokyo, Japan, [6]Kyorin Pharmaceutical Co., LTD, Nogi, Tochigi, Japan, [7]Sanwa Kagaku Kenkyusyo Co., LTD., Inabe, Mie, Japan, [8]Mitsubishi Tanabe Pharmacology Corporation, Kisarazu, Chiba, Japan and [9]GlaxoSmithKline K.K., Shibuya, Tokyo, Japan.*

The National Institute of Health Sciences and 18 pharmaceutical companies of the Japan Pharmaceutical Manufacturers Association (JPMA) have conducted a validation study intended to evaluate whether a 2-week repeated dose period with ovarian histopathological examinations is enough to detect ovarian toxicity. The current repeated dose general toxicity study has been considered insufficient in terms of evaluating female reproductive function due to a lack of evidence indicating the appropriateness. Evaluation of ovarian toxicity by precise histopathological examination were performed.

In this study, 2- or 4-week repeated dose studies with ovarian histopathological examinations were conducted. Female fertility study was also conducted to compare the results to those of ovarian histopathological findings. A total of 17 test substances was evaluated and categorized into hormone analogues, primordial follicle damaging agents, metabolic imbalance inducers, and endocrine imbalance inducers. At the end of treatment, the reproductive organs were prepared the histopathological specimens and stained with hematoxylin and eosin (HE). To the ovaries, immunohistochemistry using Dako anti-Proliferation cell nuclear antigen (PCNA) antibody was also performed. The prepared histopathological specimens were examined under a light microscope. In conclusion, ovarian toxicity could be detected by a detailed histopathological examination. A 2-week dosing period may be sufficient for the evaluation of ovarian toxicity, except for cytotoxic compounds such as alkylating agents. Pathological findings of ovarian toxicity reflected female fertility parameters.

PS 1438 COLLABORATIVE WORK ON EVALUATION OF OVARIAN TOXICITY: EFFECTS OF INDOMETHACIN IN 2- AND 4-WEEK REPEATED DOSE STUDIES AND FERTILITY STUDY IN FEMALE RATS.

K. Tsubota, K. Kushima, K. Yamauchi, S. Matsuo, T. Saegusa, S. Ito, M. Fujiwara, M. Matsumoto, S. Nakatsuji, J. Seki and Y. Oishi. *Toxicologic Pathology, Astellas Pharmacology Inc, Osaka, Japan.* Sponsor: J. Yanase.

The 2- and 4-week general toxicity studies in rats were perfomed with indomethacin. A female fertility study was also conducted to compare the study results with ovarian histopathological findings obtained in general toxicity studies. Indomethacin is a well-known nonselective inhibitor of cyclooxygenase 1 & 2, and has been reported to inhibit ovulation by acting directly on the ovary. The main purposes of present studies are to assess whether a precise histopathological examination, taking account of morphological changes in the female reproductive organs in each estrus phase, can evaluate ovarian toxicity and to determine an optimal dosing period for detecting ovarian toxicity. Female Sprague-Dawly rats were orally given indomethacin at doses of 0.3, 1.3 or 4 mg/kg (10 rats/ group) in all studies. In the general toxicity studies, luteinized follicular cyst was observed in 3 and 2 animals at 4 mg/kg in the 2- and 4-week studies respectively, and atretic follicular cyst was noted in 1 animal at 4 mg/kg of the 4-week study. There was no abnormal finding in the uterus, vagina, or pituitary at any dosage group. In the fertility study, effects of indomethacin on the female fertility parameters could not be evaluated at the top dose, since 8 rats at 4 mg/kg died or were sacrificed moribund before completion of the mating period, whereas no effect on any fertility indexes was detected at 1.3 or 0.4 mg/kg. In conclusion, ovarian toxicity induced by indomethacin could be detected at 4 mg/kg in the 2-week and 4-week general toxicity studies. In the fertility study, although toxic effect on female fertility could not be evaluated at 4mg/kg due to over-dosing because of animal death, no effects were detected at lower doses. These results suggest that the dosing period of 2 weeks is sufficient to detect the ovarian toxicity induced by indomethacin.

PS 1439 COLLABORATIVE WORK ON EVALUATE OF OVARIAN TOXICITY: EFFECTS OF 2- OR 4-WEEK REPEATED DOSE STUDIES AND FERTILITY STUDY OF BROMOCRIPTINE IN FEMALE RATS.

A. Nakajima, T. Ishiguro, Z. Jiuxin, T. Tanaharu, H. Nishitani, S. Harada, Y. Inoue, Y. Tagawa and T. Kumazawa. *Pharmaceutical Research Laboratories, SANWA KAGAKU KENKYUSHO CO., LTD., Inabe-shi, Mie, Japan.* Sponsor: M. Takahashi.

The main focus of this study is to determine the optimal administration period concerning toxic effects on ovarian morphological changes in a general toxicity study. To assess morphological and functional changes induced in the ovary by bromocriptine, the compound was administered to female rats at dose levels of 0, 0.08, 0.4 and 2 mg/kg for the 2- or 4-week general toxicity study, and for the female fertility study from 2 weeks prior to mating to day 7 of gestation. In the 2-week general study, increase of ovarian weights was observed at 2 mg/kg. In the 4-week general study, ovarian weights were increased at 0.4 and 2 mg/kg. The number of corpora luteum was increased in the 0.4 and 2 mg/kg groups of the 2- and 4-week general toxicity studies by the histopathological examination of the ovaries. Bromocriptine did not affect estrous cyclicity in the 2- and 4-week repeated dosing. In the female fertility study, although animals in any groups mated successfully, no females in 0.4 and 2 mg/kg groups were pregnant. There were no adverse effects on the reproductive performance in the 0.08 mg/kg group. Based on these findings, the histopathological changes in the ovary are considered important parameters for evaluation of drugs including ovarian damage. We conclude that a 2-week administration period is sufficient to detect the ovarian toxicity of bromocriptine in a general toxicity study.

PS 1440 DEVELOPMENT AND VALIDATION OF MULTIPLEX HORMONE PANELS TO EVALUATE RAT PITUITARY, STRESS AND THYROID HORMONES.

R. Kuk and D. J. Stanislaus. *Reproductive Toxicology, Safety Assessment, GlaxoSmithKline, King of Prussia, PA.* Sponsor: S. Lerman.

Hormone multiplexing allows the analyses of multiple hormones in one single assay. This method enables the investigator to reduce sample volume by over 90% and still obtain quality data. Furthermore, this methodology realizes two goals of the 3R philosophy. Reduction in sample volume enables reduction in animal use. Refinement of analytical technique means low bleed volumes and hence better animal welfare. In addition, hormone multiplexing allows for faster data turnaround at a lower cost. For example, for analyses of LH, FSH and PRL, radioimmunoassay (RIA) requires 300 uL of sample, takes 7 working days and costs $2500, compared to the hormone multiplex which requires 25 uL, takes 1 day and costs $1125.
We have evaluated the Linco Diagnostics (now Millipore) 3 hormone multiplex panel [rat pituitary, rat thyroid and rat stress hormone panels]. All validations were performed side by side with conventional RIA or enzyme linked immunosorbent assay (ELISA) using the same rat serum samples from hypophysectomized, adrenalectomized, castrated or intact rats. Hormone concentration results showed pituitary and thyroid hormone panels had very good correlation with RIA/ELISA($R^2 > 0.8$), had excellent reproducibility ($R^2 > 0.9$) and was capable of detecting biologically relevant hormonal changes. The stress hormone panel is still under evaluation.

PS 1441 VINCLOZOLIN (V) TREATMENT INDUCES REPRODUCTIVE MALFORMATIONS AND INFERTILITY IN F1 MALE RATS WHEN ADMINISTERED DURING SEXUAL BUT NOT GONADAL DIFFERENTIATION. THE EFFECTS ARE NOT TRANSMITTED TO THE SUBSEQUENT GENERATIONS.

J. Furr and L. E. Gray. *ENDOCRINOLOGY BRANCH, NHEERL, U.S. EPA, Research Triangle Par, NC.*

V produces adverse reproductive effects in male rats when administered during sexual differentiation by acting as an androgen receptor-antagonist. It was recently reported that four generations of SD rats, derived from dams dosed via ip injection GD8-15 with 100 mg V/kg/day, displayed prostate, testis, kidney and immune pathologies and infertility. The authors also reported that these abnormalities were transmitted via epigenetic mechanisms. Our study was designed to determine if such effects could be induced by oral treatment with V. Two groups of SD rats were dosed with 100 mg V/kg/d during either gonadal (GD8-15) or sexual (GD13-17) differentiation. Vehicle controls were dosed GD8-17. GD13-17 V treatment demasculinized F1 male rats, however none of the effects were transmitted to the F2 or F3 generations. In F1 males, GD13-17 V treatment reduced anogenital distance at birth and androgen-dependent tissue weights, and induced female-like nipples, undescended testes, histopathological lesions in the testis, hypospadias and infertility. The effects of V on AGD, nipple and fertility were not transmitted to the F2 generation. In contrast, GD8-15 V treatment did not reduce fertility, induce reproductive tract malformations, or reduce epididymal sperm numbers in the F1 or F2 generations. F3 males will be examined at middle age and the histology of the testes and other endpoints measured in F3 males to determine if V treatment of P0 dams affected any of these measures in this generation. In summary, oral V treatment during gonadal differentiation did not affect reproductive morphology, sperm numbers or the fertility in the F1 or F2 generations. In contrast, clear adverse reproductive effects were seen in the F1 group exposed to V during androgen-dependent sexual differentiation, however these effects were not transmitted to the F2 generation. This abstract does not necessarily reflect US EPA policy.

PS 1442 A COMPARISON OF THE GLOBAL GENE EXPRESSION IN RAT GRANULOSA CELLS WHEN CHALLENGED BY METHOXYCHLOR AND ITS METABOLITE 2, 2-BIS-(P-HYDROXYPHENYL)-1, 1, 1-TRICHLOROETHANE, HPTE, *IN VITRO* .

C. Harvey[1], M. Esmail[2], R. Zachow[3, 4] and M. Uzumcu[1, 2]. *[1]Joint Graduate Program of Toxicology, UMDNJ/Rutgers University, Piscataway, NJ, [2]Department of Animal Sciences, Rutgers, The State University of New Jersey, New Brunswick, NJ, [3]Department of Physiology and Biophysics, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ and [4]College of Medicine, Touro University, Hackensack, NJ.*

Previous studies have examined the effects of methoxychlor [1, 1, 1,-tri-chloro-2, 2,-bis-(p-methoxyphenyl) ethane; MXC] within the female reproductive system. The active toxicant for this mechanism of action is thought to be its estrogenic metabolite, 2,2-bis-(p-hydroxyphenyl)-1,1,1-trichloroethane (HPTE). The role of MXC and HPTE on gene expression changes within the ovary is unclear. In order to further investigate this effect, granulosa cells were cultured in the presence or absence of follicle-stimulating hormone (FSH, 3 ng/ml)) or dibutyryl cAMP (cAMP, 1 mM) for 48 h and challenged with either MXC (0,1,3,10 μM) or HPTE (0,1,5,10 μM) during this 48 h period. Microarray analysis using Affymetrix Rat Genome 230 2.0 arrays were used to determine changes in gene expression. Estradiol-17β was also measured in cell-conditioned media using radioimmunoassay. HPTE appeared to have a more potent effect on gene expression changes than did MXC. MXC and HPTE significantly ($P \leq 0.05$) altered 2943 and 3633 genes, respectively, of which 826 genes were commonly affected. Enrichment analysis suggested that MXC affects genes regulating the ribosome, cell cycle, DNA polymerase, biosynthesis of steroids and PPAR signaling pathways. In contrast, HPTE

affects genes regulating focal adhesion, regulation of actin cytoskeleton, extracellular matrix receptor interaction, adherens junction, and glutathione metabolism. MXC and HPTE each induce differential gene expression activities in rat granulosa cells, and this marked difference in effect provides insight as to the mechanisms by which these environmental endocrine disruptors can impede female reproductive function.

PS 1443 CYNOMOLGUS MONKEY FERTILITY ASSESSMENTS IN A REPEATED DOSE TOXICOLOGY STUDY: TESTOSTERONE LEVELS, SEMEN ANALYSIS AND TESTICULAR VOLUME.

S. Oneda[1], N. Makori[1], N. Lalayeva[1], D. Carwin[1], J. Kenfield[1], S. Herrin[1], L. Lennox[1], W. Congdon[1], R. Eyre[1], B. Baker[1], J. Klaassen[1], S. Meyer[1] and R. Nagata[2]. *[1]SNBL USA, Ltd., Everett, WA and [2]Shin Nippon Biomedical Laboratories, Ltd., Kagoshima, Japan.*

The Cynomolgus monkey (*Macaca fascicularis*) male reproductive function assessments are included in chronic preclinical studies in lieu of stand-alone fertility studies. For minimum selection criteria, background reference data is provided as a guide. Sexually mature animals (4-10 years and 3.6-10.2 kg) were evaluated. Testicular volume (TV) was measured twice for each animal (total of 76 animals, 7 to 18 days interval). Testicular volume (right plus left sides) was calculated using the formula: volume (mL) =(πxLxW^2)/6. Semen was collected by penile electro-stimulation for 2 or 3 times/animal (total 76 animals, minimum one week interval). Total ejaculate volume (EV) was measured. Computer-assisted sperm analyzer (CASA) was used for sperm motility (SM) and concentration (SC). Total sperm count per ejaculation (TSC) was calculated. Testosterone levels were measured using an ELISA assay. The mean TV was 36.6±9.5 mL at the first measurement (min. - max. = 18.5 - 62.8 mL). At the second measurement, % difference from the first measurement was 10.0±10.1% (0.6-45.6%) indicating good reproducibility. Semen analysis parameters notably varied inter-animal and between samples. Average SM, SC, EV and TSC of 2 or 3 measurements were 76±11% (33-93%), 918.6±674.7 x10^6/mL (68.1-3302.4 x10^6/mL), 0.3665±0.4036 mL (0.0200-2.5960 mL) and 164.56±115.27 x108/ejaculation (27.24-602.53 x10^6/ejaculate). The % differences between the 1st and 2nd analyses were 18.7, 60.3, 62.2 and 62.1% for SM, SC, EV and TC, respectively. Testosterone level (mean of three samples/animal) range was 3.8-26.6 ng/mL, mean 7.9. Based on these data, testicular volume shows greater accuracy in reproducibility. Semen analysis parameter varies between samples. Multiple time-points are required to establish each animal's baseline data.

PS 1444 ESTRADIOL PROTECTS OVARIAN ANTRAL FOLLICLES FROM PHTHALATE ESTER-INDUCED GROWTH INHIBITION AND ATRESIA.

R. K. Gupta, S. Meachum, M. Deppert, J. A. Flaws and H. H. Yao. *Veterinary Biosciences, University of Illinois, Urbana, IL.*

Phthalate esters (PEs) are synthetic plasticizers used in a wide range of consumer and industrial products. Di-(2-ethylhexyl) phthalate (DEHP) decreases serum estradiol (E_2) levels, prolongs estrous cycles, and blocks ovulation in rats. Monoethylhexyl phthalate (MEHP), the active metabolite of DEHP, decreases aromatase levels in cultured rat granulosa cells. Our previous studies shows PEs inhibit growth and reduce the levels of E_2 of antral follicles *in vitro*. This study tested the hypothesis that E_2 protects antral follicles from DEHP and MEHP- induced growth inhibition and atresia. Antral follicles from CD-1 mice were mechanically isolated and cultured in α-minimal essential media ± DEHP (100μg/ml), MEHP (10μg/ml), or E_2 (1 or 10nM) for 96 hr. Dimethyl sulfoxide (DMSO) was used as vehicle control. Follicles without any treatment were also included to monitor the culture conditions. Follicle size, as a measurement of growth, was obtained every 24hr and presented as percent change compared to that of 0hr. After culture, follicles were processed for histological evaluation and were rated for atresia on a scale from 1-4 (1-healthy follicle, 2 ≤ 10%, 3 ≤ 10 to 30%, and 4 ≥ 30% pyknotic bodies/follicle). The results indicate that DEHP and MEHP significantly inhibit follicle growth compared to DMSO treated controls, and E_2 partially restores growth of these follicles. (DEHP: DMSO=148.8±2.0, DEHP =102.2±2.4, DEHP+$E_2$1nM=127.6±1.5; DEHP+$E_2$10nM=123.3±1.49; MEHP: DMSO=144.41±1.51, MEHP =100.47±0.8, MEHP+$E_2$1nM=125.4±0.6; MEHP+$E_2$10nM =126.3±1.1; n=3; p≤0.05). Further, DEHP and MEHP induced atresia in cultured follicles and E_2 treatment protected these follicles from PE-induced atresia (DEHP: DMSO=1.3±0.3, DEHP =4.0±0.1, DEHP+$E_2$1nM=2.0±0.1; DEHP+ $E_2$10nM=1.7±0.3; MEHP: DMSO=1.3±0.3, MEHP =4.0±0.1, MEHP+ $E_2$1nM=1.0±0.1; MEHP+$E_2$10nM =1.3±0.3; n=3; p≤0.05). Collectively, these data indicate that E_2 partially restores growth in DEHP and MEHP treated follicles and fully protects against DEHP and MEHP-induced atresia. Support: NICHD46861

PS 1445 COLLABORATIVE WORK TO EVALUATE OVARIAN TOXICITY: (17) EFFECTS OF 2- OR 4-WEEK REPEATED DOSE AND FERTILITY STUDIES OF SULPIRIDE IN FEMALE RATS.

M. Ube[1], S. Ishii[1], M. Okada[1], T. Adachi[2], J. Sugimoto[1], Y. Inoue[1], Y. Uno[1] and M. Mutai[1]. *[1]Safety Research Laboratory (Kazusa), Mitsubishi Tanabe Pharmacology Corporation, Kisarazu, Japan and [2]Safety Research Laboratory (Kashima), Mitsubishi Tanabe Pharmacology Corporation, Osaka, Japan.* Sponsor: S. Mariko.

The National Institute of Health Sciences and 18 pharmaceutical companies of the Japan Pharmaceutical Manufacturers Association (JPMA) have conducted collaborative validation studies on ovarian toxicity. Our company selected sulpiride, a D2 antagonist, as test substance. To find the appropriate dosing period to detect ovarian toxicity, sulpiride was orally dosed to female rats at the dose levels of 1, 10 and 100 mg/kg/day daily for 2 or 4 weeks in the general toxicity study. Additionally, sulpiride at the same dose levels was given to female rats daily for pre-mating period, for mating period, and for Days 0-7 of gestation to assess its effect on fertility, and the results were compared with the ovarian toxicity detected in the general toxicity study. In the ovarian histology in the 2-week study, increase of atretic follicle was seen at 1 mg/kg or more, and increase of follicular cyst was at 10 mg/kg or more. In the 4-week study, these findings were seen at 1 mg/kg or more, and decrease of large follicle was seen at 10 mg/kg or more. Increased body weight gain was observed at 10 mg/kg or more in the 2- and 4-week studies. The females in these groups indicated development of mammary alveolus. In the fertility study, sulpiride-treated females showing persistent diestrus resulted in successful mating, and almost all females got pregnant. However, increased implantation loss was observed at 10 mg/kg or more, which were considered to be caused by the adverse effect of sulpiride on oocyte development. From these results, sulpiride-induced ovarian toxicity was seen at 1 mg/kg or more in the 2- and 4-week repeated dose toxicity studies, and observed ovarian histological changes were considered to be related with adverse effect on female fertility.

PS 1446 THE EFFECTS OF A SINGLE DOSE OF ALPHA-CHLOROHYDRIN ON SPERM MOTION, MORPHOLOGY AND GONADAL PATHOLOGY ON THE MATURE MALE SPRAGUE-DAWLEY RAT.

C. M. Carruthers, W. B. Lawrence, K. S. Bendler, M. Turner, D. Hoover, J. Kosco and B. Fisher. *Covance Laboratories Inc, Vienna, VA.*

Alpha-chlorohydrin (3-chloro-1,2-propanediol or U-5897), a chlorinated propanediol, is a proven male rat chemosterilitant that directly targets spermatozoa and has been shown to produce no impairment to libido while significantly reducing the number of successful matings and pups. In previous studies, alpha-chlorohydrin produced toxic effects on sperm in the epididymis and at low doses (33mg/kg/day for 4 days and 5mg/kg/day for 2 weeks) has been shown to impair sperm motion. Chemosterilization has been shown to occur due to the production of lesions in the initial segment of the caupt epididymis at repeated doses of 35 mg/kg or following a single 45 mg/kg dose. Contrary to the present findings, previous studies have shown a reduction in the percentage of motile sperm without a decrease in sperm velocity. Here we characterized the toxic effect of alpha-chlorohydrin on sperm motion, and testicular staging following a single oral dose of 40 or 80 mg/kg to mature male Crl:CD(SD) rats. A single dose of alpha-chlorohydrin at 80 mg/kg/day resulted in test article-related decreases in food consumption that resulted in slight mean body weight decreases. Additionally, a single dose of alpha-chlorohydrin at 40 or 80 mg/kg produced dose dependent decreases in average path velocity and curvilinear velocity, an increased incidence of head abnormalities and increased testis weight. Microscopic findings in the testes and epididymides included seminiferous tubule dilatation, seminiferous epithelial degeneration, multinucleated spermatocytes/spermatids, and inspissation of seminiferous tubule contents in the testes and luminal cellular debris, oligospermia, sperm granulomas, acute inflammation, and epithelial degeneration of the ductus epididymis in proximal portions of the epididymis. These findings demonstrated that a decrease in sperm velocity without a concomitant reduction in the percentage of motile sperm occurs with an acute, low dose of alpha-chlorohydrin.

PS 1447 VINCLOZOLIN: F1-EXTENDED ONE-GENERATION REPRODUCTION TOXICITY STUDY IN WISTAR RATS.

S. Schneider, W. Kaufmann, V. Strauss and B. van Ravenzwaay. *Product Safety, BASF SE, Ludwigshafen, Germany.* Sponsor: C. Hastings.

In 2006, ILSI - HESI published a strategy for agricultural chemical safety assessment (ACSA) that included an adapted design for reproductive and developmental toxicity evaluation (Cooper et al, 2006). The ACSA testing proposal was designed

in the context of an intelligent testing strategy for the evaluation of agrochemicals, aimed at addressing the inefficient development of data (Carmichael et al, 2006). The extended one-generation study is the centerpiece of the life stages paradigm, which has three specific purposes: (1) to determine effects on reproduction, (2) to determine the effects on organ systems of developing animals, and (3) to determine the effect of developmental exposure on the young adult (postnatal day 70/90) offspring. The aim of the presented work was to obtain information on the technical feasibility to conduct an F1-extended one-generation study. This is the first of a series of studies using model (positive control) compounds. Vinclozolin as endocrine modulating (antiandrogenic) model compound was administered at doses of 4, 20 and 100 mg/kg bw/d. Effects include reduced anogenital distance and retained areolae at an oral dose of 20 mg/kg and above, hypospadias, hypoplastic penis, vagina-like orifices, reduced testicular size, aplasia/agenesia or reduced size of male accessory glands at 100 mg/kg. The overall NOEAL is 4 mg/kg bw. The complexity of the study triggered a number of minor modifications of the ACSA-protocol, particularly in terms of the specific timing of samplings/investigations around PND 21. Despite the challenging logistics the F1-extended one-generation study is technically feasible in a well-trained laboratory. The results of this study prove that the F1-extended one-generation study design is sufficiently sensitive to detect endocrine effects on organ systems of developing animals. At least for this endpoint, it is a scientifically robust approach to reduce and refine the studies required for registration of agrochemicals.

PS 1448 INTRAVAGINAL ADMINISTRATION OF 17-β ESTRADIOL TO OVARIECTOMIZED RATS AS A POSITIVE CONTROL FOR UTEROTROPHIC ASSAYS.

T. D. Thullen[1], A. K. Remick[2], C. Abolin[3], D. G. Stump[1], A. Workman[1], P. M. Jones[1], T. Jerussi[3], Y. Schwartz[3] and M. D. Nemec[1]. *[1]DART, WIL Research, LLC., Ashland, OH, [2]WIL-Biotechnics, LLC., Hillsborough, NC and [3]Hygeia Therapeutics, Inc., Holden, MA.*

The uterotrophic assay (UA, OECD Guideline 440) is used to test compounds for potential estrogen receptor agonism or antagonism. 17-β Estradiol (estradiol), the most potent naturally-occurring estrogen, has been used as a positive control for UA in rodents and is typically administered either orally or subcutaneously. Recommended rodent models include the prepubertal female or ovariectomized young adult female rat. In the case of compounds that are to be administered intravaginally, only ovariectomized young adult female rodents are relevant models due to the age at vaginal patency (31-37 days in the Crl:CD[SD] rat). In order to develop a positive control of uterotrophic activity for intravaginal applications, estradiol in sesame seed oil was administered intravaginally to 60-day old rats (ovariectomized at 41 days) at 0, 0.6, 2, 6, 10 and 20 μg/kg/day once daily for 3 consecutive days. Detailed clinical observations, body weights and food consumption were collected throughout the treatment period and, 24 hours after the last dose administration, wet/blotted uterine weights were measured. At 6, 10 and 20 μg/kg/day, estradiol treatment resulted in dose-related increases in wet and blotted uterine weights. Histopathology performed on uterine and vaginal tissues in 10 μg/kg/day-treated rats compared to vehicle-treated rats demonstrated uterine epithelial hypertrophy, mitotic figures, epithelial necrosis, and smooth muscle hypertrophy; vaginal cornification; and cervical cornification and neutrophil infiltrates. The uterine weight increases and histological changes in 10 μg/kg/day-treated rats are indicative of expected estrogenic effects, and demonstrate that intravaginal administration of 17-β Estradiol can be used as a positive control in the rat UA for compounds intended for intravaginal administration.

PS 1449 EFFECTS OF FENVALERATE ON CELL PROLIFERATION, APOPTOSIS AND COLLAGEN I PRODUCTION IN HUMAN UTERINE LEIOMYOMA CELLS AND UTERINE SMOOTH MUSCLE CELLS.

X. Gao, L. Yu, M. Klippel, L. Castro, T. Hermon, A. B. Moore and D. Dixon. *Cellular and Molecular Pathology Branch, NTP, National Institute of Environmental Health Sciences, National Institutes of Health, Department of Health and Human Services, Research Triangle Park, NC.*

Fenvalerate (Fen; CAS # 51630-58-1), widely used for its high insecticidal potency and low mammalian toxicity, is classified as an environmental disruptor chemical. Recently, Fen has received great attention for its adverse effects on human reproductive health. To determine whether Fen could influence the growth of hormonally responsive uterine leiomyoma (UtLM) cells and normal uterine smooth muscle cells (UtSMC), MTS colorimetric and bromodeoxyuridine (BrdU) uptake assays were done. FACS was used to examine the impact of Fen on cell cycle and apoptotic distribution. Also, real-time PCR and western blotting were employed to determine the expression of Collagen I, a major uterine leiomyoma (fibroid) extracellular matrix component. Fen (10 μM) had a stimulatory effect on the growth of both cell lines at 24 hrs compared with controls by MTS ($p<0.01$) and BrdU ($p<0.01$) assays. Cell cycle analysis showed that Fen enhanced the escape of cells from the G0-G1 checkpoint and promoted progression from G2 to mitosis phase. Annexin V assay illustrated that Fen had an anti-apoptotic effect on both cell lines. By Real-time PCR, we found that Collagen I mRNA expression increased ($p<0.05$) in Fen-treated cells compared to controls, although it was greater in UtLM tumor cells. Accordingly, Fen increased ($p<0.05$) Collagen I protein level in both cell lysate and supernatant when compared to controls. Our data show that Fen can stimulate the growth of both uterine leiomyoma and myometrial cells, which involves a combination of enhanced cell-cycle progression and apoptosis inhibition. Additionally, we found this compound can increase Collagen I expression, at both mRNA and protein levels. Our results indicate Fen exposure should be considered a novel risk factor for uterine fibroids.

PS 1450 COLLABORATIVE WORK ON EVALUATION OF OVARIAN TOXICITY: (5) EFFECTS OF 2- OR 4-WEEK REPEATED DOSE STUDIES AND FERTILITY STUDY OF BUSULFAN IN FEMALE RATS.

Y. Sakurada, S. Kudo, S. Iwasaki and Y. Masumoto. *Research Center, Kyorin Pharmaceutical Co., LTD., 1848 Nogi, Nogi-Machi, Japan.* Sponsor: M. Shirota.

This study aimed to validate the usefulness of histopathology in a 2- or 4-week general toxicity study as a first-tier screening method for risk assessment of female reproduction. Busulfan, an antineoplastic alkylating agent known to target small follicles (primordial, primary follicle), was given to female SD rats orally (0, 0.1, 0.5, and 1.5 mg/kg/day, n=10 in each group) for 2 or 4 weeks, and ovaries were excised, weighed and fixed. Ovarian histopathology and follicle counts were performed in the greatest cross-sectional area of bilateral ovaries to assess optimal administration period concerning toxic effects on ovarian morphology. In addition, a female fertility study was conducted by dosing the same levels of Busulfan from 2 weeks prior to mating to Day 7 of gestation to compare the Non-toxic doses for female reproduction with those in 2- or 4-week general toxicity studies. In the 2-week study, Busulfan treated rats showed normal estrous cyclicity and no toxicological changes in weights and histopathology of ovaries. In the 4-week study, a decrease in small follicles was observed histopathologically in 1 rat in the 0.5 mg/kg group and in 4 rats in the 1.5 mg/kg group. The follicle counts indicated a decrease in small follicle number in the 1.5 mg/kg group immunohistochemically, although there were no changes in ovarian weight. In the female fertility study, reduced body weight gain, increase in dead embryos and post-implantation loss were observed in Busulfan treated groups, thus Non-toxic doses of Busulfan for reproductive functions and early embryonic development were determined as 1.5 and 0.5 mg/kg, respectively. In conclusion, a 4-week administration period and appropriate assessment of follicle number are needed to detect small follicle depletion in general toxicity study. Moreover, histopathological examination is useful to detect ovotoxicity; however, due to developmental toxicity, careful examination is needed to assess the risk of alkylating agents in female reproduction.

PS 1451 AN ASSESSMENT OF THE REPRODUCTIVE AND DEVELOPMENTAL TOXICITY POTENTIAL OF THE ANTIMICROBIAL 7-ETHYL BICYCLOOXAZOLIDINE.

R. Rasoulpour, C. Zablotny, K. Brooks, B. Tornesi, J. Thomas, K. Stebbins, N. Berdasco and E. Carney. *The Dow Chemical Company, Midland, MI.*

7-ethyl bicyclooxazolidine (EBCO), a broad-spectrum bactericide registered for use in consumer and industrial applications, was evaluated in developmental and reproductive toxicity studies. In the rat developmental toxicity study, groups of 25 time-mated Crl:CD BR® rats were gavaged with 0, 50, 250, or 650 mg/kg/day (mkd) EBCO on gestation days (GD) 6-15. Maternal toxicity consisted of significantly decreased body weight gain (GD 6-15) limited to the 650 mkd group. Fetal examination revealed treatment-related findings only in the high dose group, with 18 malformed fetuses from four litters with abdominal wall defects and/or cleft palate; however, 15 of these fetuses were clustered in two litters. The no-observed-adverse-effect-level (NOAEL) for maternal and developmental toxicity was 250 mkd. In the rabbit study, groups of 26 time-mated NZW rabbits were administered 0, 15, 50, or 150 mkd EBCO by gavage on GD 7-27. Maternal toxicity was limited to the high dose group with mean body weight losses at the start of treatment (GD 7-10), decreased feed consumption (GD 7-13), and decreased fecal output. There were no treatment-related developmental effects at any dose level. The maternal and developmental toxicity NOELs were 50 and 150 mg/kg/day, respectively. The reproduction study evaluated Crl:CD(SD) rats given 0, 5, 25, and 150 mkd EBCO by gavage for two generations. Parental toxicity consisted of decreased lactation body weight gains, increased liver weights, and stomach irritation effects in the majority of animals given 150 mkd. Point of contact stomach irritation of lesser severity and incidence were seen at 25 mkd. There were no effects on any pa-

rameter of reproductive performance or offspring survival at any dose level. The NOELs for parental toxicity and reproductive toxicity were 5, point of contact irritation only, and 150 mkd, respectively. The NOELs from these studies were greater than those used for the risk assessment, which indicated sufficient margins of exposure for all detailed exposure scenarios.

PS 1452 REPRODUCTIVE AND DEVELOPMENTAL TOXICITY SCREENING TEST OF POTASSIUM PERFLUOROHEXANESULFONATE IN SPRAGUE-DAWLEY RATS.

R. G. York[1], J. Butenhoff[2], S. Chang[2] and D. J. Ehresman[2]. *[1]Charles River Preclinical Services, Horsham, PA and [2]3M Company, St. Paul, MN.*

This study was undertaken to evaluate the potential reproductive and developmental toxicity of perfluorohexanesulfonate (PFHxS), a surfactant found in sera of the U.S. population. In a modified OECD 422 guideline-based design, 15 rats per sex and dose group (control, 0.3, 1, 3, and 10 mg/kg/day) were dosed by gavage with potassium PFHxS or vehicle 14 days prior to cohabitation, during cohabitation, and until the day before sacrifice (21 days of lactation or gestation day 25 (if not pregnant) for females and minimum of 42 days of treatment for males). F1 pups were not dosed by gavage but were exposed in utero and during lactation. Evaluations were made for reproductive success, clinical signs, body weight, feed consumption, estrous cycling, neurobehavioral effects, gross and microscopic anatomy of selected organs, sperm, hematology, clinical pathology, and concentration of PFHxS in serum and liver. An additional 3 rats per sex and group were added for toxicokinetic sampling. No reproductive or developmental effects were observed. There were no treatment-related effects in females or offspring. Parental males experienced: 1) reductions in weight gain and serum total cholesterol (all PFHxS doses); 2) decreased prothrombin time (0.3, 3, and 10 mg/kg/day); 3) increased liver-to-body weight and liver-to-brain weight ratios, centrilobular hepatocellular hypertrophy, hyperplasia of thyroid follicular cells, and decreased hematocrit (3 and 10 mg/kg/day); 4) decreased triglycerides and increased albumin, BUN, ALP, Ca++, and A/G ratio (10 mg/kg/day). Serum and liver concentrations of PFHxS are reported for parents, fetuses, and pups. PFHxS was not a reproductive or developmental toxin under study conditions.

PS 1453 PERCUTANEOUS UTEROTROPHIC ASSAY OF LAVENDER OIL IN IMMATURE FEMALE RATS.

V. T. Politano[1], J. Scognamiglio[1], E. M. Lewis[2], A. M. Hoberman[2], M. S. Christian[3], R. M. Diener[3] and A. Api[1]. *[1]Research Institute for Fragrance Materials, Inc., Woodcliff Lake, NJ, [2]Charles River Laboratories Preclinical Services, Horsham, PA and [3]Argus International, Inc, Horsham, PA.*

The estrogenic potential of lavender oil was evaluated in a percutaneous uterotrophic bioassay in immature female rats by measuring uterine weights at sacrifice. From the use of multiple cosmetic products containing lavender oil as a fragrance ingredient, the maximum daily human skin exposure has been calculated to be 0.2 mg/kg for a 60 kg high-end user of these products. Correcting for 14.4% skin exposure, the maximum daily exposure is 0.03 mg/kg/day. Four groups of ten immature female rats were randomly selected on postpartum day 16. Three groups of immature rats were administered the vehicle control article (corn oil) or lavender oil at 20 or 100 mg/kg/day in a volume of 5 ml/kg on the shaved back during the 3-day treatment period, days 19, 20, and 21 postpartum. The positive control group was gavaged twice daily with 2.5 mcg/kg/day of 17α-ethinyl estradiol on days 19, 20, and 21 postpartum. All rats were euthanized 24 hours after the third and final treatment, the uteri and ovaries were removed, and the paired ovaries and wet and blotted uterine weights were recorded. No unscheduled deaths occurred. No skin reactions were observed. Both dosages of lavender oil significantly reduced body weight gains after the third day of treatment, but terminal body weights and mean uterine weights did not differ significantly from vehicle control values. Positive controls produced significant increases in body weight and mean uterine weights. Based on the above data, dosages of 20 and 100 mg/kg of lavender oil equivalent to greater than 3000 times the human maximal daily exposure of 0.03 mg/kg/day were not active in the uterotrophic assay and are not considered to be estrogen agonists.

PS 1454 PLEIOTROPIC EFFECT OF AKT1 DEFICIENCY ON FEMALE FERTILITY.

C. Brown, M. Ota, L. Anderson and M. Hixon. *Brown University, Providence, RI.*

The majority of ovarian follicles including oocytes undergo atresia through a mechanism involving apoptotic cell death. The purpose of this study was to understand the basis of reduced fertility in mice deficient for the Akt1 gene. Akt1-deficient females exhibit a reduced body size and have decreased ovarian and uterine horn weights. Akt1 deficiency led to a delay in both the age at first litter and onset of estrous and a reduction in average litter size relative to Akt1 wild type and Akt1 heterozygous females. Histological analyses revealed fewer healthy mature follicles in Akt1-deficient females with a significant decrease in the number of follicles at the preantral stage. Primary and secondary oocyte diameter measurements revealed larger primary and secondary oocytes in Akt1-deficient females relative to Akt1 wild type females suggesting defects in the communication between granulose cells and the oocyte. In addition, multiple oocytes per follicle were observed in Akt1-deficient ovaries. Hormonal analyses indicated that Akt1-deficiency has a deleterious effect on FSH and LH levels, as Akt1-deficient females had significantly lower FSH serum levels and significantly higher LH serum concentrations relative to Akt1 wild type females. We found a trend for increased expression of Fas mRNA in Akt1-deficient ovaries. These findings indicate an in vivo role for Akt1 in promoting both follicle and oocyte growth and maturation.

PS 1455 THE ARYL HYDROCARBON RECEPTOR MAY REGULATE GENE EXPRESSION IN THE NEONATAL MOUSE OVARY.

B. Karman and J. Flaws. *Department of Veterinary Biosciences, University of Illinois, Urbana, IL.*

The aryl hydrocarbon receptor (AHR) is a ligand activated transcription factor known mainly for its role in mediating the toxic effects of numerous environmental contaminants. Recent data also indicate that the AHR plays a role in normal ovarian physiology. Specifically, previous studies have shown that Ahr deletion results in slow follicular growth, decreased estradiol synthesis, and reduced fertility in adult female mice. However, the role of the AHR in early neonatal reproductive function is unknown. Normally, just after birth, the mouse ovary contains a finite number of oocytes available for follicle formation. These oocytes are organized in clusters called oocyte nests that will break apart and form primordial follicles. This study tested the hypothesis that on postnatal day (PND) 3, when oocyte nests are breaking apart to form primordial follicles, differences in global gene expression exist between aryl hydrocarbon receptor null (AhRKO) and wild type (WT) mouse ovaries. To test this hypothesis, ovaries were collected from AhRKO and WT mice on PND3 and subjected to Affymetrix™ Mouse Genome 430 2.0 arrays to compare the expression of more than 20,000 genes. A comparative analysis revealed differential expression of 147 genes: 123 genes were up-regulated, whereas 24 genes were down-regulated in the AhRKO ovaries compared to WT ovaries. Interestingly, a gene essential for initiation of X chromosome inactivation, inactive X specific transcripts (*Xist*), was decreased by 2 fold in the AhRKO ovary compared to the WT ovary. This finding was confirmed by quantitative RT-PCR (AhRKO=0.68±0.04, WT=1.10±0.12 relative expression levels, n=5, $p \leq 0.05$). Collectively, these data suggest that the AhR regulates genes involved in neonatal ovarian function. Further, the down-regulation of *Xist* in the AhRKO ovaries compared to the WT ovaries suggests that the AHR may be involved in chromosomal regulation during meiosis in the developing oocyte. Supported by NIH R01 HD 047275 and NIEHS ES07326.

PS 1456 VINCLOZOLIN—THE LACK OF A TRANSGENERATIONAL EFFECT AFTER INTRAPERITONEAL MATERNAL EXPOSURE DURING ORGANOGENESIS.

V. Strauss, S. Schneider, W. Kaufmann and B. van Ravenzwaay. *Product Safety, BASF SE, Ludwigshafen, Germany.* Sponsor: C. Hastings.

This is the second study which was performed to investigate a reported transgenerational effect of Vinclozolin on the integrity and performance of the male reproductive system. Pregnant Wistar rats (F0 generation) were treated with doses of 0, 4 and 100 mg/kg bw/day by intraperitoneal (ip) administration from gestational day (GD) 6 to GD 15. All subsequent generations (F1-F4) were not exposed to the test compound. Fifty male pups per group were selected to become F1 parental male animals to generate F2 pups with untreated female rats. Subsequent breeding was continued in the same manner for 3 generations. F1, F2 and F3 generation male rats were observed for mating behavior and success as well as ability to generate healthy offspring. F1-F4 generation male gonads were examined on postnatal day (PND) 130 (sperm evaluation, detailed histopathology of testes, epididymides and accessory sexual glands, as well as quantification of apoptotic cells in testes). IP administration of 100 mg/kg bw/day to F0 gestating mothers resulted in minimal anti-androgenic effects. One male offspring was affected by a hypospadia and the average sexual maturation was slightly (by 1 day) delayed exclusively in the F1-generation. In spite of these findings, the F1, F2 and F3 generations of male offspring, derived from Vinclozolin-exposed dams, developed normally to sexual maturity and were able to mate and to generate healthy progeny. Spermatid/Sperm count,

sperm morphology and sperm motility were not affected in F1 and F2 generation male offspring. At present, after the investigation of F1 and F2 pups, the study gives no indication of a transgenerational effect of Vinclozolin on the integrity and performance of the male reproductive system, in particular spermatogenic capacity and sperm viability. There were no effects noted at 4 mg/kg bw at any of the investigated generations. Thus, this is the second study which fails to confirm the reported transgenerational effects with Vinclozolin. This ip study confirms the absence of such effects as reported earlier following oral treatment.

PS 1457 COLLABORATIVE WORK TO EVALUATE OVARIAN TOXICITY BY REPEATED DOSE AND FEMALE FERTILITY STUDIES IN RATS: MORPHOLOGICAL CHARACTERISTICS OF NORMAL CYCLING OVARY IN RATS AND THEIR VIEWPOINTS FOR OVARIAN TOXICITY DETECTION.

M. Yoshida[1], A. Sanbuissho[2], S. Hisada[3], M. Takahashi[4], Y. Ohno[1] and A. Nishikawa[1]. *[1]National Institute of Health Sciences, Tokyo, Japan, [2]Daiichi-Sankyo Co., Ltd., Shizuoka, Japan, [3]Aska Pharmaceutical Co. Ltd., Kanagawa, Japan and [4]Pathology Peer Review Center, Tokyo, Japan.*

Detection of ovarian toxicities is very important for safety assessment of chemicals including drugs. The detection, however, is very hard without underlying normal ovarian morphology based on reproductive physiology. This study was focused on practical analysis of ovarian morphology in each estrous cycle stage and guides of morphological viewpoints to detect the toxicities. Single ovary sections transversely dissected in maximum area in 143 rats with normal cycling were examined microscopically. The classification of follicles was referred to Pedersen and Peters (1968). The growing follicles are functionally divided into follicular stimulating hormone (FSH)-independent and dependent ones. The former small and medium follicles relevant to primordial/primary and preantral ones, respectively, were constantly distributed in all sections and easy to detect with immunohistochemical staining for proliferating cell nuclear antigen (PCNA). The latter large follicles relevant to antral or Graafian ones, and atresia showed synchronous histological changes depending on estrous cycle stage. Regarding to corpora lutea (CL), most recently formed CL underwent remarkable changes in their appearance by each cycle, reflecting ovulation and progesterone production. Combined observation of follicle and CL alterations enhanced reliability of the analysis. These results indicate that qualified morphological analysis in the ovary enables us to classify each estrous cycle. Notification of morphological deviation in follicles and CL from normal estrous cycle is the first tier to detect ovarian toxicities. PCNA immunohistochemical staining is useful to detect follicular loss. Vaginal cytology is also informative to predict the ovarian toxicity.

PS 1458 GENISTEIN AND ETHINYL ESTRADIOL DIETARY EXPOSURE IN MULTIGENERATIONAL AND CHRONIC STUDIES INDUCE SIMILAR PROLIFERATIVE LESIONS IN THE MAMMARY GLAND OF MALE SPRAGUE-DAWLEY RATS.

J. R. Latendresse[1], G. R. Olson[1], T. J. Bucci[1], P. W. Mellick[1], B. Thorn[2], C. C. Weis[2], R. R. Newbold[3] and B. K. Delclos[2]. *[1]Toxicologic Pathology Associates, NCTR, Jefferson, AR, [2]NCTR, Jefferson, AR and [3]NIEHS, Research Triangle Park, NC.*

Genistein, a soy isoflavone and phytoestrogen (PE), and ethinyl estradiol (EE2), a potent pharmaceutical estrogen, were examined in multigenerational reproductive (multigen) and chronic toxicity studies with differing exposure windows across generations (F0-F4). Sprague-Dawley rats were exposed to genistein (0, 5, 100, and 500 ppm) or EE2 (0, 2, 10, and 50 ppb) in a low PE diet. In the multigen studies, animals were exposed to dosed feed from wk 6 in the F0 to weaning of the F3. The F3 was then placed on control feed and mated to produce unexposed F4. All generations were terminated at postnatal day (PND) 140. In the chronic studies there were three exposure windows: continuous from conception to 2 yr (F1C); conception to PND 140, followed by control diet to termination (F1T140); conception until weaning at PND 21 of the offspring of three exposed generations (F0, F1, and F2) followed by control diet to 2 years (F3T21). In the EE2 and genistein multigen toxicity studies, there was a dose-responsive mammary gland (MG) hyperplasia, evident even at the lowest dose of EE2 (2 ppb). There was no amplification across generations or significant carry over into unexposed F4. The lower incidence of MG hyperplasia in the chronic studies likely resulted from regression, not progression to neoplasia, because there was no proportionate increase in neoplasms. Sexual dimorphism of MG was retained with no observed feminization in F1 or F2 compared to control for high dose genistein or EE2. Furthermore, the morphology of MG hyperplasia did not appear appreciably different across generations in the multigen studies, nor was it different from the low background hyperplasia observed in controls. Supported by Interagency Agreement 224-07-007 between FDA and NIEHS.

PS 1459 EFFECTS OF ETHYLENE GLYCOL MONOETHYL AND MONOBUTYL ETHERS ON THE REPRODUCTIVE AND HEMATOGENOUS SYSTEMS IN MICE.

R. Wang[1], K. Ohtani[1], T. Kawamoto[2] and T. Nakajima[3]. *[1]Japan National Institute of Ocuupational Safety and Health, Kawasaki, Japan, [2]University of Occupational and Environmental Health, Kitakyushu, Japan and [3]Nagoya University, Nagoya, Japan.* Sponsor: N. Mei.

Ethylene glycol monoethyl ether (EGEE) can cause damage to the reproductive and hematogenous systems in animals and in occupationally exposed workers. Ethylene glycol monobutyl ether (EGBE), another member in the family of ethylene glycol ethers, is much less toxic compared with EGEE, and therefore it is used in some cases as an alternative solvent. In this study we investigated the effects of the two ethylene glycol ethers on the reproductive and hematogenous systems when administrated separately or in combination. Wild-type and Aldh2 knockout male mice were orally treated with 600 mg/kg/day of EGEE, EGBE or both compounds for 14 consecutive days. In wild type mice, the motility of sperm in the spermaducts was significantly damaged in EGEE group, and to the same extent also in the group of co-administration. In addition, the ratio of testes to body weight in the two groups was smaller than controls, indicating the testicular atrophy. However, EGBE had no such effects and exerted little influence on the reproductive effects of EGEE. In Aldh2 knockout mice, the effect on the reproductive system was not observed in any group, implying a critical role of the enzyme. On the other hand, EGBE treatment caused damage in hematogenous system, such as remarkable decrease in red blood cell count, hemoglobin content and hematocrit value. Furthermore, Calculus was found in the bladder of mice receiving EGBE administration, and its occurrence was 75% in wild and 50% in Aldh2 knockout mice. EGEE did not induce the decrease in blood cells and the formation of calculus, and had no interaction with EGBE on these effects. These results showed that although EGEE and EGBE are similar in molecular structure and chemical properties, these two ethylene glycol ethers have different targets of toxic effects in vivo.

PS 1460 EVALUATION OF ACUTE TOXICITY OF NOVEL SELECTIVE ET_A- RECEPTOR ANTAGONISTS THAT CONTROL PRETERM BIRTH IN A MOUSE MODEL.

N. S. Olgun, H. J. Patel, R. Stephani and S. E. Reznik. *Department of Pharmaceutical Sciences, Saint John's University, Jamaica, NY.*

Preterm Birth (PTB), for which the single most common cause is intrauterine infection, is defined as any birth occurring before the completion of 37 weeks of gestation and is a leading cause of perinatal morbidity and death (Rush et al, 1976). Endothelin-1 (ET-1) is a potent vasoconstrictor peptide that is both regulated by inflammatory cytokines and also capable of increasing myometrial smooth muscle tone (Yanagisawa, 1988). We have synthesized a novel series of 1-3-6-trisubstituted-2-carboxy-qunol- 4-one's that act as selective Endothelin A receptor antagonists (ET_A–RA) *in vitro*. Our overlying hypothesis is that these compounds will control inflammation-associated PTB *in vivo* without having significant toxic effect. Several different analogues of our compound are tested for an effect on PTB. Briefly, C57Bl/6 mice at E15.5 are injected intraperitoneally (i.p.) with lipopolysaccharide (LPS) and then treated with the compound being tested. Control mice are injected with LPS and then treated with vehicle. In addition, the LD_{50} of the compound is determined by the "Acute Toxic Class" method with slight modifications as per OECD 423 guidelines and with Probit analysis. Neurotoxicity is evaluated further with the rotorod test. Our results show that these novel compounds have a significant effect on the timing of PTB and on the number of pups prematurely delivered ($p < 0.001$). Furthermore, the estimated LD_{50} range for at least one of the analogues (n-propyl) is 200-1000 mg/kg, which is several-fold higher than the therapeutic dose range. Rotorod results confirm that the n-propyl analogue causes neurotoxicity at doses several-fold higher than therapeutic doses. Finally, blood was assayed and organs were taken from mice receiving the n-propyl analogue for tissue histology in order to assess organ specific toxicity. We conclude that the novel ET_A-RA's control PTB at doses that do not have significant toxic effect. These results may impact on a very important clinical problem for which there is currently no satisfactory therapy.

PS 1461 METHYL-PARAOXON, THE ACTIVE METABOLITE OF THE ORGANOPHOSPHATE PESTICIDE METHYL-PARATHION, ALTERS SPERM QUALITY IN MICE.

P. Espiritu-Gordillo[1], M. Solís-Heredia[1], W. Maldonado-Vázquez[2] and B. Quintanilla-Vega[1]. *[1]Toxicology Section, CINVESTAV-IPN, Mexico City, Mexico and [2]Universidad Autónoma de Nayarit, Tepic, Nayarit, Mexico.*

Methyl-parathion (Me-Pa) is an organophosphate pesticide (OP) forbidden in developed countries but still widely used in Mexico. Hepatic and extrahepatic metabolism of Me-Pa generates methyl-paraoxon (Me-Pox), an extremely reactive compound that is responsible for the anticholinesterase activity. Studies in human

populations and animal models have shown that occupational exposure to OPs, including Me-Pa, alters sperm quality parameters. Nevertheless, little is known about the contribution of oxons to sperm quality effects. Therefore, the aim of this study was to evaluate the ability of Me-Pox to alter sperm quality in mice as a new mechanism of toxicity. To achieve this purpose, male ICR-CD1 mice (10-12 weeks old) were administered with single (1, 2 and 3 mg/kg bw, i.p, corresponding to ¼, ½ and ¾ of the LD50) or repeated (1 mg/kg bw/5 days, i.p.) doses of Me-Pox. Before and 1 h after Me-Pox administration, peripheral blood was obtained to measure erythrocyte acetylcholinesterase (AChE) activity as a biomarker of toxicity. Then, 24 h after the last administration, animals were euthanized to obtain sperm cells from cauda epididymis-vas deferens and evaluate sperm concentration, viability, motility and morphology in cells that were at epididymal maturation at the time of exposure. All doses, single and repeated generated a significant inhibition of AChE (40-60%). Single low doses of Me-Pox did not alter sperm quality parameters, but the highest dose decreased 40% sperm motility. While repeated doses of Me-Pox significantly decreased sperm motility and normal morphology (25 and 10%, respectively). In conclusion, spermatozoa at epididymal maturation, a key stage in the acquisition of progressive motility and fertilization ability, are sensitive to the exposure of the active metabolites of OP, the oxons, which may represent a mechanism of OP male reproductive toxicity. Project supported by Conacyt-Grant #58213.

PS 1462 EFFECTS OF CYP2E1 DEFICIENCY ON MALE REPRODUCTIVE SYSTEM IN MICE.

A. Okamura, M. Kamijima, Y. Ito, Y. Yanagiba and T. Nakajima. *Department of Occupational and Environmental Health, Nagoya University Graduate School of Medinice, Nagoya, Japan.*

Cytochrome P450 2E1 (CYP2E1), a drug-metabolizing enzyme, is localized not only in liver but in epididymal epithelium and testicular Leydig cells where testosterone is produced. It is possible that different expression levels of CYP2E1 can increase the testicular toxicity risks of chemicals which are metabolically activated by CYP2E1, such as trichloroethylene and acrylamide which reportedly decreased testosterone concentration and reduced sperm counts in animal studies. This hypothesis can be clearly tested after addressing the physiological role of CYP2E1 in the reproductive system. This study aimed to clarify the effects of CYP2E1 deficiency on the male reproductive system during the growing stages. Body and reproductive organ weights, sperm counts, sperm head morphological abnormality and plasma testosterone concentrations were compared between cyp2e1+/+ and cyp2e1-/- mice at 6, 8, and 12 weeks of ages (n=7-8/group). Tissue sections of the testes of the 8-week-old mice were stained with periodic acid Schiff's reagent and hematoxylin. Plasma testosterone concentrations were significantly higher in the cyp2e1-/- mice than in the cyp2e1+/+ mice at 8 and 12 weeks of ages but not at 6 weeks. Body weights and absolute weights of the epididymides and the prostates-seminal vesichles were also significantly higher in the cyp2e1-/- mice of the ages, but testicular absolute weights were not changed. Sperm counts were also not significantly different between the genotypes in all ages, whereas sperm head abnormality was significantly higher in the cyp2e1-/- mice. Stage VII seminiferous tubules did not show increased degeneration or abnormal spermatogenic cells in the cyp2e1-/- mice. The present study revealed that the CYP2E1 expression was related to the function of male reproductive organs in mice. It was also suggested that the physiological role of CYP2E1 in the organs changed in the course of growth since the significant differences in the testosterone concentrations were observed at 8 and 12 weeks of ages but not at 6 weeks.

PS 1463 REPRODUCTIVE AND DEVELOPMENTAL EFFECTS OF MOTORCYCLE EXHAUST IN RATS.

T. Ueng, C. Chen, H. Hsueh and S. Lu. *Institute of Toxicology, National Taiwan University, Taipei, Taiwan.*

Fossil fuel combustion products are potential health hazard and environmental hazards. Engine emissions from two-stroke and four-stroke motorcycles create a major environmental burden in urban areas where motorcycles are a popular means of transportation. Motorcycle exhaust (ME) contains higher levels of benzene and butadiene than diesel and gasoline exhaust from passenger cars. Carcinogenic aromatic hydrocarbons such as benzo(a)pyrene and benz(a)anthracene are present in organic extracts of ME particulates. The major purpose of the present study was to determine the reproductive and developmental effects using male rats exposed to 1:10 diluted ME 2 hr daily and 5 days a week for 7 weeks. ME exposure markedly decreased testicular and epididymal sperm counts and increased testicular lipid peroxidation and interleukin-1β mRNA expression. The ME-exposed male rats were mated with unexposed female rats and their offspring were used to determine the effects of ME on the parameters of reproductive system development. The ME exposure caused decreases of anogenital distance in male offspring on postnatal day (PND) 1 and anovaginal distance in female offspring on PND 14. The exposure resulted in an earlier vaginal opening in the female offspring. The ME exposure increased organ weights of prostate, levator ani bulbocavernosous, and bulbourethral glands in the male offspring on PND 56. The exposure also decreased cytochrome P450 content and 7-ethoxycoumarin O-deethylase activity of female rat liver microsomes on PND 56. These present results suggest that ME inhalation exposure of male rats has the ability to produce reproductive toxicity and to cause effects on the parameters of reproductive development in their male and female offspring.

PS 1464 EVALUATION OF THE EFFECTS OF MDMA ("EXTASY") ON THE FERTILITY AND REPRODUCTION OF THE MALE RAT.

M. Barenys[1], N. Macia[1], L. Camps[2], J. de Lapuente[2], J. Gonzalez[2], J. Gomez-Catalan[1], M. Rodamilans[1], M. Borras[2] and J. M. Llobet[1]. *[1]University of Barcelona, Barcelona, Catalonia, Spain and [2]Scientific Park of Barcelona, Barcelona, Catalonia, Spain.*

3,4-Methylenedioxymethamphetamine (MDMA, "ecstasy") is an illicit drug that has become increasingly popular in Europe and North America over the past 20 years. As consumption mainly occurs among young population, it is relevant to take into consideration the effects of MDMA on the reproductive system. The impact of MDMA on the health has been repeatedly documented in the past, but its effects on reproduction have not yet been deeply studied. MDMA consumption affects several neurotransmitter systems such as serotoninergic, dopaminergic and norepinephrinergic which are implied in the neuroendocrine control of reproductive functions. In this study the influence of MDMA on the fertility and reproduction of the male rat was assessed.
MDMA was administered (sc) to Sprague-Dawley male rats once a day, three consecutive days a week, simulating human week-end associated consumption. MDMA doses: 10mg/kg, 5mg/kg, 0.5 mg/kg or saline (control) during 12 weeks, (from 5 to 17 PNW) covering the puberty onset and the sexual maturity achievement. The highest dose was calculated as 1/5 LD50 and the lowest was in the same order of magnitude of human exposure. Hormonal (LH, FSH and testosterone), haematological, biochemical, histological, genotoxicological (Comet test in sperms) and, testicular and sperm parameters (mobility, morphology and quantification of spermatozoids and spermatids, epididymis and teste weigh), were evaluated in half of the animals. The remaining animals were mated with untreated sexually receptive females to evaluate the mating and pregnancy rates and sexual behaviour
No biologically significative differences were found in the studied parameters except in genotoxicity, food and water consumption in all treated groups, and total weigh in the high dose group. In conclusion, these results show the lack of important effects in male rat fertility after MDMA subchronic exposure.

PS 1465 ASSESSING THE CUMULATIVE IMPACTS OF CHEMICAL EMISSIONS AND DISCHARGES.

G. V. Alexeeff[1], J. Faust[1], A. Kyle[2], R. Morello-Frosh[2], M. Jerrett[2] and L. Zeise[1]. *[1]OEHHA, Cal/EPA, Oakland, CA and [2]School of Public Health, UC Berkeley, Berkeley, CA.*

California legislation to address environmental justice has required the transformation of the risk assessment process to address cumulative impacts in communities. The state's definition of cumulative impact requires consideration of the combined emissions and discharges from all sources in a geographic area, on public and environmental health, taking into account sensitive populations and socio-economic factors. In a collaborative project involving Cal/EPA and academic partners, we are developing better analytical tools to identify cumulative impact, reviewing existing statutory authorities and regulatory requirements, developing case studies and concept papers and creating a framework for analysis to support decision making. While U.S. EPA adopted a very specific interpretation of cumulative risk which requires consideration of chemicals that act by a "common mechanism of toxicity," our focus has been to identify how community exposure disparities contribute to health disparities for environmentally mediated diseases. Further, in addition to exposure, toxicity, and health status the process considers increased vulnerabilities that result from non-intrinsic factors such as race, ethnicity and SES. We found that existing exposure disparities contribute to community health disparities. We considered the California Air Toxics Hot Spots program as a case study to examine these concepts in a specific decision context. While the current hot spots program focuses on the cumulative risk of chemical emissions from individual facilities, it does not take into account emissions from other facilities located in the community or incorporate community health status or vulnerabilities. We conclude that a mixture of these methods, including those drawn from toxicology and other disciplines, are needed to address cumulative impacts.

1466 A NOVEL ALGORITHM FOR COMPUTING INTERACTION-BASED HAZARD INDEX FOR THE HEALTH RISK ASSESSMENT OF CHEMICAL MIXTURES.

S. S. Isukapalli[1], A. F. Sasso[1], P. G. Georgopoulos[1] and K. Krishnan[2, 1]. [1]*DEOM, UMDNJ RWJ Medical School, Piscataway, NJ and* [2]*GRIS, University of Montreal, Montreal, QC, Canada.*

Health risk assessment of chemical mixtures is frequently conducted on the basis of exposure and toxicity information for individual components. Routine application of physiologically-based toxicokinetic (PBTK) and toxicodynamic (PBTD) models in mixture risk assessment is limited by the number of parameters that need to be specified for the full model for mixtures. Since human exposures to environmental chemicals frequently lead to steady-state conditions, it is pragmatic to develop a tool that provides the steady-state solutions of full PBTK models of mixtures by accounting for the nature and magnitude of interactions. A steady-state solution was developed for computing dose metrics (i.e., blood concentration and metabolism rate) during mixture exposures and applied for computing interaction-based hazard index for mixtures. The algorithm is based on critical determinants of the internal dose during chronic exposure to VOCs (i.e., alveolar ventilation rate, blood flow rate to liver, blood:air partition coefficient, maximal velocity of metabolism, Michaelis constant, inhibition constants, and free concentration of chemical at the site of interaction and metabolism). This algorithm, developed as a spreadsheet program, is an iterative procedure for estimating an intermediate term representing sum of ratios of liver concentrations of individual components to the Michaelis parameter (or inhibition constant). Case studies demonstrating the application of this tool were conducted for human inhalation exposure to toluene, xylene, ethylbenzene, carbon tetrachloride and tetrachloroethylene. The results demonstrate that the algorithm appropriately accounts for the saturable metabolism and competitive inhibition among the chemicals in mixtures, as a function of exposure concentration. This risk assessment tool should be of use in establishing interaction thresholds for environmental contaminants, as well as for conducting interaction-based risk assessment for populations exposed to chemical mixtures.

1467 THE CUMULATIVE DIETARY EXPOSURE TO ORGANOPHOSPHOROUS INSECTICIDES IS PROBABLY OVERSTATED.

R. Krieger[2], J. H. Ross[3] and R. Cochran[1]. [1]*California EPA, Sacramento, CA,* [2]*U C Riverside, Riverside, CA and* [3]*risksciences.net LLC, Carmichael, CA.*

Organophosphorous insecticides (OPs) continue to be an extremely important class of insecticides used on food crops consumed in the US. Since 2002, residential uses of OPs are limited to malathion garden products and to public health applications of mosquito adulticides. Thus, diet constitutes the overwhelming majority of OP exposure for the general public. Several investigators have attempted to vet USEPA's OP cumulative dietary exposure estimate through utilization of data from various biomonitoring surveys that have reported levels of OP metabolites, dialkyl phosphates (DAPs), in human urine. It is generally recognized that biomonitoring represents the most accurate estimates of actual exposure. However, these estimates rely on a number of assumptions, including the supposition that all urinary DAPs were derived from ingested OPs. A recent study has indicated that OP residues on produce form DAPs on and in that same produce at levels equal to or exceeding the parent OP on a molar basis. Oral bioavailability of DAPs has been measured in the range of 30-95%. This suggests that dietary ingestion of DAPs on produce may contribute 15% to greater than 50% of the DAPs measured in the urine. The implication of these findings is that the OP "risk cup" is not nearly as full as previously postulated. The exposure estimates from biomonitoring are substantially below USEPA's current estimate of cumulative dietary exposure. If the biomonitoring data are "inflated" by misattributing pre-hydrolyzed OPs as parent compounds, then the true estimate is significantly less than even the biomonitoring indicates. Consequently, the present USEPA cumulative OP estimate should be revisited to reflect the more accurate estimates of exposure provided by biomonitoring tempered by the reality of preformed OP biomarkers in foods.

1468 SPECIATION PROFILING AND SIZE FRACTIONING OF TOTAL PARTICULATE MATTER EMITTED FROM STATIONARY, MOBILE AND AREAWIDE SOURCES IN CALIFORNIA.

D. HaMai and M. Suh. *Toxicology and Mechanistic Biology, Exponent Engineering and Health Sciences, Irvine, CA.*

The California Air Resource Board (CARB) collects emissions data from various stationary sources, which include power plants and factories, and mobile sources, which include on- and off-road motor vehicles and engines. Areawide source categories comprise human activities and emissions occurring over a wide geographic area such as unpaved road dust and waste burning. In this study, emissions inventory for stationary, mobile and areawide sources were analyzed for chemical composition and size fractions in total particulate matter (PM) to develop a more comprehensive understanding of the physical and chemical characteristics of air pollution generated by human activities. The weighted percentages of particle size fractions of 2.5 μm and 10 μm were considered for each source category and each metal to calculate particle size multipliers, and to identify occurrences of fine particle enrichment. Particle size and elemental speciation of emissions were found to vary widely by area sources and industrial processes. Areawide source categories had the highest frequency of fine particle enrichment compared to mobile and stationary source categories; fine particle enrichment was observed in most chemical species profiled in dust related to road, construction, and agricultural operations. Stationary sources such as mineral processing, and paper and pulp industries were associated with fine particle enrichment of metals and metalloids. Fine particle enrichment did not occur in the emissions released by secondary metal production and sources related to fuel combustion and fires. Biologically active constituents of particulate air pollution, specifically metals, are of toxicological concern. Ascertaining the respirable fraction and bioavailability of specific chemical constituents will facilitate attribution of risk and is critical to the refinement of exposure and risk assessments of particulate emissions.

1469 IMPACT OF CLIMATE CHANGE AND MIGRATION ON TOXICOLOGICAL RISK ASSESSMENT.

H. A. Abadin, F. Scinicariello, H. R. Pohl and H. E. Murray. *ATSDR/DTEM, Atlanta, GA.*

The 2006 Stern report predicted that global climate will result in "greater resource scarcity, desertification, risks of droughts and floods, and rising sea levels could drive many millions of people to migrate". One of the most cited estimates is up to 200 million climate migrants (mostly Asians) by 2050. There is a steady increase in migration as a result of economic globalization. Migration enables gene flow which could impact toxicological risk assessments via the inter-individual variability factor, addressed not only by the genetic polymorphism, but also by other factors, such as age, gender, and disease status. The ALDH2 enzyme converts the acetaldehyde in acetate. The ALDH2*2 null allele is highly represented in Asians. As an example of the impact of changes in genetic frequency in population, we used data on blood acetaldehyde levels after alcohol intake based on the ALDH2 genotype status (Mizoi et al. 1994) combined with the estimated frequencies of the ALDH2 genotype in the US population until 2050 to generate a Monte Carlo population distribution of blood acetaldehyde levels after alcohol intake. Using the released US projected population estimates until 2050 (US Census Bureau, 2008), the contribution of the genotype frequencies of Asian-origin individuals to the total U.S. population is steadily captured in the upper 99th percentile of the distribution of blood acetaldehyde levels. These levels are 3.15 and 3.58-fold higher than their median (2040 and 2050 US population estimates, respectively), and the latter is slightly higher than the 3.16-fold default UF representing toxicokinetics. For states with higher Asian populations, this effect may even be greater. If we add the estimate of the climate migration, the ratios may further change. In addition, immigrants tend to adopt the lifestyles, (e.g. nutritional behavior, alcohol consumption, tobacco use) of the hosting country, resulting in a potentially greater impact on chronic disease incidences that have also a genetic composition. The example emphasizes how migration may influence the dynamics of risk assessment evaluations.

1470 ENVIRONMENTAL PREDICTORS OF U.S. COUNTY MORTALITY PATTERNS ON A NATIONAL BASIS.

M. P. Chan[1], R. S. Weinhold[2], R. Thomas[1], J. M. Gohlke[1] and C. J. Portier[1]. [1]*Environmental Systems Biology, NIEHS, Research Triangle Park, NC and* [2]*Independent researcher and journalist, Colorado City, Colorado City, CO.*

A growing body of evidence has found that mortality rates are positively correlated with social inequalities, air pollution, elevated ambient temperature, age and availability of medical care. This study develops a model to predict the mortality rates for different diseases by county across the US. The developed model is then applied to predict changes in mortality caused by changing environmental factors. A total of 1, 514 counties from the continental US, excluding Hawaii, were studied and divided into five geographical regions. A subset of samples from the total counties was chosen by using systematic random sampling and these samples were used to validate our model. Principal component analysis and step-wise regression analysis were used to evaluate the ability of environmental pollutants, socio-economic factors, climate and median age to explain variations in county-specific mortality rates for heart disease, cancer, stroke, chronic obstructive pulmonary disease (COPD) and all causes combined. Generally the estimations of the models of all diseases for all regions were considered reasonable. This study suggests the need for a better understanding of the pathways through which these factors and mortality are related

at the community level, thus providing policy-makers at local, state, and federal levels with more explicit and feasible targets for policy intervention at the community level. Predictions of changing mortality with changing climate are used to illustrate the predictive value of the model.

PS 1471 HYPOTHESIS-BASED WEIGHT OF EVIDENCE (HBWOE) – A TOOL FOR EVALUATING THE ENTIRE BODY OF LITERATURE IN CONSIDERING HUMAN RELEVANCE AND POTENTIAL CARCINOGENIC MODE OF ACTION – NAPHTHALENE AS AN EXAMPLE.

L. Bailey and L. Rhomberg. *Gradient Corporation, Cambridge, MA.*

Human health risk assessment consists of bringing to bear a large body of in vitro, animal, and epidemiologic studies on the question of whether environmental exposures to a substance are a potential risk to humans. However, the body of scientific information is typically unclear, often contains apparent contradictions; and therefore, often only possible conclusions about potential human risks may be surmised from the data and may vary from very strong to tenuous. The task, therefore, is to also effectively communicate the uncertainties within the data, giving proper consideration to contrary data and alternative scientifically plausible interpretations. We propose an approach, HBWoE, to organize, evaluate, and communicate all of the available data on a given chemical exposure, using naphthalene as an example. The National Toxicology Program (NTP) inhalation bioassay data for naphthalene showed an increased risk for nasal tumors in rats and lung tumors in mice, and although cytotoxicity and hyperplasia were observed in mouse nasal and to some extent in rat lung tissue, tumors were not observed in these tissues. CYP2F metabolism of naphthalene to its epoxide and cytotoxicity has been invoked as a potential carcinogenic mode of action (MOA) for naphthalene, and there is CYP2F activity in both tissues and species. We evaluate the available data for naphthalene, through the HBWoE approach, considering potential key events (end-points) in the MOA in each species and tissue: metabolism by CYP2F, cytotoxicity, chronic inflammation, potential genotoxicity, regenerative hyperplasia, and tumor formation. We evaluate the weight of evidence in support of a cytotoxic MOA, in addition to alternative MOAs that have also been offered in the scientific community, noting the explanatory power of the proposed hypotheses, considering consistencies, inconsistencies, and contradictions within the data set, and how compelling each end-point is as evidence of a similar MOA in humans from low levels of naphthalene exposure.

PS 1472 AN ASSESSMENT OF THE IMPACT OF EXPOSURE ROUTE ON THE INTERINDIVIDUAL VARIABILITY FACTOR (IVF) FOR DRINKING WATER CONTAMINANTS (DWCS).

M. Valcke[1, 2] and K. Krishnan[1]. *[1]Santé environnementale et santé au travail, Université de Montréal, Montr√©al, QC, Canada and [2]Institut national de santé publique du Québec, Montr√©al, QC, Canada.*

An IVF of 10 or two multiplicative factors of 3.16 representing pharmacokinetic (PK) and pharmacodynamic (PD) variability are frequently used in risk assessment, independently of the exposure route and sensitive subpopulation. The objective of this study was to evaluate the impact of exposure route on the magnitude of IVF-PK for two frequently identified/presumed sensitive subpopulations (pregnant women and infants (age 1-3 years)). A multiroute PBPK model framework was obtained from the literature and used for computing the dose metrics (DM, i.e., area under the blood concentration vs time curve (AUC) and the amount metabolized/L liver/24 hr (MET)) in adults, infants and pregnant women following four exposure scenarios to three DWCs – chloroform (CHL) trichloroethylene (TCE) and bromoform (BRO). The exposure scenarios were: (i) ingestion of drinking water, (ii) dermal contact (15 min/day), (iii) inhalation for 24 hr, and (iv) an oral dose (μg/kg-day). Distributions for body weight (BW), height (H) and hepatic CYP2E1 content were obtained from the literature or from P3M software whereas body surface area, blood flows and tissue volumes were calculated from BW and H. The magnitude of IVF-PK was calculated as the ratio of the 95th percentile value of DM in sensitive subpopulation to the 50th percentile value in adults, obtained by Monte Carlo simulations. In neonates, the magnitude of IVF-PK for CHL-AUC was 2.59, 1.25, 1.42 and 1.43 for drinking water ingestion, inhalation, dermal and oral dose, respectively. For CHL-MET, the values were 1.36, 1.14, 1.34 and 0.76. In pregnant women, the corresponding values were 0.41, 2.12, 1.61 and 0.39 for CHL-AUC; and 0.87, 0.47, 0.42, and 0.83 for CHL-MET. Comparable values were obtained for TCE and BRO. Overall, these results indicate that the chemical-specific IVF-PK is route-dependent for the DWCs investigated and the PBPK model-derived values for all three routes were below the default value of 3.16.

PS 1473 YOUR RESULTS MAY VARY: EXPLORING THE SENSITIVITY OF TITANIUM DIOXIDE RISK ESTIMATES TO DIFFERENT MODELING ASSUMPTIONS.

D. A. Dankovic, E. D. Kuempel and M. W. Wheeler. *Risk Evaluation Branch, CDC/NIOSH, Cincinnati, OH.*

Risk analysts typically make a number of decisions during the conduct of a quantitative risk assessment, and these decisions may have significant impact on the final risk estimate. In this analysis we explore the sensitivity of risk estimates for titanium dioxide (TiO_2) to pooling of data, dose-response model selection, animal-to-human extrapolation method, and the choice of a human dosimetry model. The goal was to estimate the occupational exposure concentration of TiO_2 associated with a 0.1% lifetime excess risk of lung tumors, based on long-term bioassay data for both fine (pigment-grade) and ultrafine (UF) TiO_2. The method used was benchmark dose (BMD) modeling, estimating either the model-based 0.1% exposure concentration in rats, or a 10% "point of departure" coupled with linear extrapolation. Potential modeling decisions included use of the best-fitting model, the most health-protective model, or a model average, and whether to use the central BMD estimate or a 95% lower-bound (BMDL). Extrapolation issues include the choice of dose metric – either particle surface area/g-lung or particle surface area/lung surface area – and the choice of a human lung particle dosimetry model. The BMD estimates vary by a factor of 29 between the most health-protective dose-response model and the best-fitting, while the BMDLs differ by 2.7. The BMD and BMDL differ by factors of 1.3–14, depending on the choice of dose-response model. Pooling fine and UF TiO_2 data has little impact on the risk estimates for fine, but does affect the risk estimates for UF. The choice of dose metric for rat-to-human extrapolation impacts the risk estimate by roughly 3-fold, and the choice of dosimetry model alters it by approximately 2-fold. Overall, the estimated occupational exposure associated with a 0.1% excess risk of lung tumors may vary more than 100-fold, depending on the specific assumptions which are made.
The findings and conclusions in this report are those of the authors and do not necessarily represent the views of the National Institute for Occupational Safety and Health.

PS 1474 VERIFICATION AND SENSITIVITY ANALYSIS OF THE JOHNSON-ETTINGER MODELS.

C. Liu, N. Luke, C. Julias and M. Watt. *CDM, Edison, NJ.*

Assessment of the potential for subsurface volatile organic contamination on indoor air quality is widely relied on the Johnson-Ettinger Model (J&E). However, depending on the availabilities and types of site-specific data, using the J&E to estimate subsurface vapor intrusion into buildings generally is a very conservative approach that tends to overestimate actual risks. Therefore, it is essential to fully understand the behavior of each J&E with different medium data sets and the response of the model to various input parameters. The study site contains a large industrial building in an urban area. The contaminants include chlorinated organics such as 1,1,1-trichloroethane, tetrachloroethene, methylene chloride, and trichloroethene which were released into shallow soil and groundwater from past operations. These volatile organics pose potential concern to indoor air quality of the overlying building. Four suites of data including soil, groundwater, soil gas, and sub-slab soil gas were collected from the site. Potential risks from subsurface vapor intrusion are evaluated using the J&E soil, groundwater, and soil gas models. Results of the J&E risk evaluations are verified by indoor air samples. This verification analysis provides a guide for selecting data sets when using the J&E and the ranking of the data sets to be used. Sensitivity analysis will be conducted on each J&E to evaluate uncertainties generated by individual parameters. Fully understanding the behavior of each J&E M and the response of the model to individual parameters will provide a more representative estimate of risks.

PS 1475 CONSIDERATION OF IN VITRO BIOACCESSILITY OF INDOOR DUST WHEN ASSESSING RISKS IN SMELTER COMMUNITIES.

E. Sigal, G. Ferguson and C. Bacigalupo. *Intrinsik, Mississauga, ON, Canada.*

In smelter communities, one of the most important pathways to consider in Human Health Risk Assessments (HHRA) is potential exposures to relevant chemicals (i.e., metals) in indoor dust. Wet and dry deposition causes atmospheric emissions from smelters to settle onto local soils and other surfaces. Both the settled material and the airborne chemicals may be transferred into residential homes via human and local meteorological activity. Outdoor yard soil can be transported indoors by wind, household pets, or on clothing or shoes of humans. These outdoor sources, combined with numerous indoor, anthropogenic sources, form typical household dust. Studies have reported that between 20 and 30% of indoor contamination comes from outdoor soil sources. This is an important pathway of exposure in human health risk assessments, especially for sensitive individuals.

The bioaccessibility of a contaminant is the portion that is soluble in the gastro-intestinal environment, and is available for uptake into the blood stream. This soluble fraction can be measured in an in vitro laboratory setting, and can be used as a surrogate for bioavailability. The use of bioaccessibility in risk assessment is considered to be valid and applicable, provided that some basic data requirements are fulfilled to permit regulatory groups (e.g., U.S. EPA, Health Canada) to ascertain the validity and defensibility of such measurements. While in vitro assays are commonly used to evaluate soil, evaluation of bioaccessibility of metals in dust is not routinely undertaken. In a recent community-based HHRA, consideration was give to the bioaccessibility of metals present in indoor dust collected from within homes in the community. Comparison of the dust bioaccessiblity to soil for the same community provides some insight to its utility and necessity of collecting this type of data at other locations. Not surprisingly given its ultrafine characteristics, bioassessibilty for dust was slightly higher than for soil. The soil and dust bioaccessibility data for six smelter-related metals will be discussed and compared.

PS 1476 WHEN BACKGROUND RISKS ARE IMPORTANT: METALS IN SOIL.

T. Behrsing, B. Davis, M. Wade and J. Eichelberger. *Department of Toxic Substances Control, CalEPA, Sacramento, CA.*

Naturally occurring metals in soils can be significant in risk assessment and risk management. USEPA has recommended including naturally occurring metals in risk assessments. Background issues are to be addressed in risk characterization, rather than in selecting chemicals of potential concern. This new approach presents a more thorough picture of risks and encourages transparency. However, it may generate confusion by reporting risks which will generally not be addressed in remediation because they stem from background. For some sites it is important to portray total risks from both anthropogenic and natural sources. Sites A, B, C, and D illustrate areas affected by mineralized soils, dredged material used to create land, drainage from mine tailings, or agricultural drainage. Site A was created by filling wetlands with sediments dredged from a bay. The sediments were impacted by drainage from mine tailings carried through a river system. Metal concentrations in original soils are generally much less than those detected in artificial fill soils. Arsenic (As) concentrations in original soils ranged from 2 to 21 mg/kg compared to 0.7 to 49 mg/kg in artificial fill. Manganese (Mn) ranged from 156 to 628 mg/kg in original soils and 27 to 13,559 mg/kg in artificial fill. Potential risks to human and ecological receptors from exposure to these fill soil metals can be significant. The cancer risk and hazard quotient (HQ) for future residents are 6E-4 and 1.6 based on the 95th percentile As concentration, and 8E-4 and 2.2 assuming the maximum concentration. The Mn HQ for future residents is 0.9 based on the 95th percentile and 7.5 based on the maximum. Ecological receptors may suffer harm from exposure to local background concentrations that are toxic. For example transport of fill material containing serpentine to areas where ecological receptors are adapted to lower metal concentrations can be deleterious. Addressing high risk estimates can be problematic through traditional remediation because of large areas. Awareness of the potential risk can suggest alternate mitigation measures such as land use restrictions.

PS 1477 LEAD TESTING WIPES CONTAIN MEASURABLE BACKGROUND LEVELS OF LEAD.

J. Keenan, M. H. Le, D. J. Paustenbach and S. H. Gaffney. *ChemRisk, San Francisco, CA.*

Lead is registered under the California Safe Drinking Water and Toxic Enforcement Act of 1986 (Proposition 65) as both a carcinogen and reproductive hazard. As part of the process to assess whether consumer products satisfy Proposition 65 with respect to lead, various wipe sampling strategies have been utilized coupled with analytical methods with very low limits of detection (LOD). A method developed by the Consumer Products Safety Commission recommends using Ghost™ Wipes, a commercially available wipe designed for surface lead testing. In this study, four commonly used wipe materials (cotton gauze, cotton balls, ashless filter paper, and Ghost Wipes) were tested for background lead. A total of 33 samples were collected. Each sample included three units of wipe material that were removed from their packaging, digested together, and analyzed using inductively coupled plasma-mass spectrometry (ICP-MS) (LOD = 0.1 μg /sample). Lead was not found in cotton ball (n=3) or filter paper (n=3) samples. One of three cotton gauze samples was found to have 0.2 μg of lead. Every Ghost Wipe sample (n=24) contained measurable amounts of lead. On average, Ghost Wipe material was found to have 0.43 ± 0.11 μg lead/sample (0.14 μg/wipe). Therefore, wipe testing for lead using Ghost Wipes and analyzing them with ICP-MS may result in measurable concentrations of lead regardless of whether or not the consumer product has leachable lead. These results may falsely lead one to conclude that the product causes lead exposures in excess of the Proposition 65 Safe Harbor Levels. Therefore, special attention needs to be paid to the choice of wipe material and the importance of field blank controls. Our research indicates that when using a commercially available lead wipe such as Ghost Wipes, a minimum of eight field blanks should be collected to characterize the distribution of lead in the wipes and that, in general, the 95th percentile of the distribution be used as the value for the background concentration.

PS 1478 USING THERAPEUTIC DATA TO ASSESS POTENTIAL HUMAN HEALTH RISKS FROM EXPOSURE TO ORGANIC NITRATES.

H. Choudhury and A. J. Weinrich. *ORD/NCEA, U.S. EPA, Cincinnati, OH.*

Pentaerythritol tetranitrate (PETN) and nitroglycerine are organic nitrates that have been found as contaminants at several Superfund sites. These organic nitrates are explosives with military and commercial applications. However, they also are used therapeutically as vasodilators to treat angina pectoris by reducing venous pressure, cardiac preload and cardiac output. Because of this therapeutic application, a rich database is available in the pharmacutical literature. Additionally, these organic nitrate vasodilators tend to reduce arterial pressure, myocardial oxygen demand, and tissue edema. However, several of these therapeutic effects can also cause undesirable consequences in some peole. For example, the maximum therapeutic doses of 38 mg/day for nitroglycerine and 160 mg/day for PETN have been reported to cause headache and postural hypotension due to cerebral vasodilation. More severe consequences might result if already hypotensive people are exposed to these organic nitrates. This presentation discusses whether effects from lower doses that are therapeutic in people with angina pectoris should be considered as critical effects for assessing health risks to the general population.

PS 1479 STUDY OF THE EFFECT OF CONCOMITANT INGESTION AND INHALATION EXPOSURE TO THE INTERNAL DOSE OF N-HEXANE (HEX) OR CYCLOHEXANE (CYCLO) IN RATS.

M. Gagné, G. Charest-Tardif, K. Krishnan and R. Tardif. *GRIS - Santé environnementale et santé au travail, Université de Montréal, Montr√©al, QC, Canada.*

The potential contribution of dermal and inhalation routes of exposure to volatile organic chemicals (VOCs) in drinking water is increasingly drawing attention. The objective of this study was to evaluate, in an animal model (rat), the contribution of multiroute exposures to the total internal dose of HEX and CYCLO in drinking water. Initial experiments showed that the contribution of the dermal route was insignificant for the two compounds. Subsequently, groups of 5 male Sprague-Dawley rats were either given a single dose of HEX (5.5 or 22.3 mg/kg) by oral ingestion (ING) or exposed to 50 or 200 ppm (2 hr) by inhalation (INH). For CYCLO, ING doses were 27.9 and 108.9 mg/kg whereas INH concentrations were 300 and 1200 ppm (2 hr). Additional groups were exposed by the two routes simultaneously (INH and ING) at the high doses for HEX, and both at the high and low doses for CYCLO. Blood samples (25 μl - 200 μl) were collected for up to 6 hr after treatments and HEX and CYCLO concentrations were measured. Overall, the blood concentrations measured after multiroute exposure to the high dose of HEX were higher (~ 1.45 - 1.70 - fold) than the sum of the blood levels obtained after administration of HEX by each route. In contrast, results for CYCLO after multiroute exposure were similar to the sum of the blood levels obtained for single route exposures to CYCLO (~1.0 - 1.2 - fold), suggesting additivity of the internal dose associated with individual exposure routes. These results suggest that the additivity of internal dose arising from multiple routes is not only determined by the route-specific kinetic characteristics but also by the degree of saturation during aggregate exposures. Supported jointly by ExxonMobil and NSERC, Canada.

PS 1480 NASAL OLFACTORY EPITHELIAL LESIONS IN F344 AND SD RATS FOLLOWING A 5-DAY INHALATION EXPOSURE TO NAPHTHALENE.

D. E. Dodd[1], M. W. Marshall[1], E. A. Gross-Bermudez[1], R. A. Miller[2] and B. A. Wong[1]. [1]*The Hamner Institutes for Health Sciences, Research Triangle Park, NC and* [2]*Experimental Pathology Laboratories, Inc., Research Triangle Park, NC.*

Naphthalene was shown to be carcinogenic, causing respiratory epithelial adenoma in the nasal cavity of male F344 rats and olfactory epithelial neuroblastoma in the nose of female F344 rats at an exposure concentration of 10 ppm in a two-year inhalation study. To explore the exposure-response relationship and threshold for nasal epithelial effects in F344 and SD rats, we conducted a 5 day, 6 hr/day inhalation exposure to naphthalene vapor at 0, 0.1, 1, and 10 ppm. Group sizes were 10 per sex per strain. An additional 10 per sex per strain were assigned to the 10 ppm group to evaluate post exposure recovery. There were no clinical observations or al-

terations in body weights related to naphthalene exposure throughout the study. At necropsy, rat heads were fixed in buffered formalin, decalcified, cross-sectioned at six standard levels, embedded in paraffin, sectioned (five microns), and stained (H&E) for microscopic examination. Naphthalene concentration was measured by gas chromatography, and aerosol testing was performed to verify that solid naphthalene particles were not present. Degeneration of the olfactory epithelium was observed in both F344 and SD strains, both sexes, with increasing incidence and severity that correlated with naphthalene exposure concentration. Lesions were minimal to moderate in severity. At 0.1 ppm, minimal olfactory lesions were observed in female SD rats only. Fourteen-day recovery animals exposed to 10 ppm also had olfactory epithelium lesions, though at a lower severity, showing evidence of recovery. Minimal to mild nasopharyngeal goblet cell hyperplasia/hypertrophy was related to exposure to 10 ppm naphthalene in all groups of rats.

PS 1481 METHYL TERTIARY BUTYL ETHER (MTBE): ONE-YEAR TOXICITY DRINKING WATER STUDY IN WISTAR RATS.

E. Bermudez, H. Parkinson and D. E. Dodd. *The Hamner Institutes for Health Sciences, Research Triangle Park, NC.*

The environmental presence of MTBE, particularly in groundwater, underscores the need for information on the toxicology of this compound when administered in drinking water (DW). The current study is part of a 2-yr study designed to examine the toxicity and carcinogenicity of MTBE administered in DW. Male Wistar rats were exposed to 0, 0.5, 3, 7.5 and females to 0, 0.5, 3, and 15 mg/ml MTBE in DW for 12 mo, based on the results of a 90-d pre-chronic study. Body weights, clinical signs, and food and water consumption were monitored. Urinalysis was performed on males at study weeks 25, 38, and 52 and on females at study weeks 25 and 52. A complete necropsy was performed at 6 mo (males) and 12 mo (males and females), including the collection of blood for clinical pathology and hematology. Blood levels of tert-butyl alcohol (TBA), the major metabolite of MTBE, were determined for males and females at 12-mo. Body weight and food consumption were the same as control and water consumption was less than control ($p<0.01$), for MTBE-treated males and females. There were no significant changes in hematology or serum chemistry parameters for males or females. Blood levels of TBA increased with dose in males and females. Urine osmolality (OSM) and specific gravity (SG) were increased in males (7.5 mg/ml MTBE) and females (15 and 3 mg/ml MTBE). Creatinine (CRE) was increased in male (3 mg/ml MTBE) and female (3 and 15 mg/ml MTBE) urine. There was a trend in males and females of increasing urine protein with dose. Increases in OSM and SG indicate increased concentration of urine as a response to reduced intake of water and suggest that the apparent increase in protein is due to a concentration effect. The relative weights of kidneys and testes were significantly increased in males at 12 mo of exposure. A treatment-related increase in nephropathy, of minimal to mild severity, was observed in males. No treatment-related histopathologic changes in testis were observed. In summary, effects were limited to reduced water intake in males and females and an increase in nephropathy in males.

PS 1482 PATHOLOGY AND GENOTOXICITY IN F344 RATS IN A TWO WEEK INHALATION EXPOSURE EXPOSED TO AEROSOLIZED FT JET FUEL.

B. A. Wong[1], C. U. Parkinson[1], S. Sharma[1], G. A. Willson[2], D. J. Wagner[3], D. R. Mattie[4] and D. E. Dodd[1]. *[1]The Hamner Institutes for Health Sciences, Research Triangle Park, NC, [2]Experimental Pathology Laboratories, Research Triangle Park, NC, [3]Naval Health Research Center, Environmental Health Effects Laboratory, Wright-Patterson AFB, OH and [4]AFRL/711 HPW/RHPB, Wright-Patterson AFB, OH.*

Fischer-Tropsch (FT) jet fuel is produced by a synthetic process from natural gas and may be used to augment or replace petroleum-derived JP-8 jet fuel for the US military. During operations and maintenance, personnel may be exposed to jet fuel vapors and aerosols. An inhalation study was conducted in which F-344 rats were exposed to 0, 500, 1000, and 2000 mg/m^3 of an aerosol/vapor mixture of jet fuel. Animals were exposed for 6 hours per day, 5 d/wk for two weeks. After the last exposure, animals were euthanized and selected tissues examined for histopathology. Bone marrow from the femur was taken, stained, and examined for micronucleus formation to assess the genotoxic potential of inhaled FT jet fuel. In the lungs of males and females at the highest concentration, we observed multifocal areas of inflammatory cell infiltration. In the nasal airways of males and females exposed to the intermediate and high concentrations, olfactory epithelial degenerative changes were observed. Male rats exposed to jet fuel exhibited an increased accumulation of hyaline droplets in the proximate convoluted tubular cells, characteristic of alpha-2u globulin induction. There was no statistically significant induction of micronuclei observed in the exposed groups.

PS 1483 INTRAVENOUS- AND INHALATION-ROUTE PHARMACOKINETICS OF PROPANOL AND ITS METABOLITE, PROPIONIC ACID.

J. J. Soelberg[1], T. S. Poet[1], A. L. Busby[1], L. M. Sweeney[2] and W. Faber[3]. *[1]Battelle, Pacific Northwest Division, Richland, WA, [2]The Sapphire Group, Dayton, OH and [3]Willem Faber Toxicology Consulting, LLC, Victory, NY.*

n-Propanol is widely used in many industrial applications, potentially leading to inhalation exposures in the workplace . Extrapolation between observed effects in animals and potential human effects requires detailed route-specific pharmacokinetic analyses. Inhalation and intravenous (iv) exposure studies were conducted in rats to determine the blood pharmacokinetics of propanol and its major metabolite, propionic acid. Inhalation-route studies included constant exposures to 500 or 3500 ppm 13C-propanol with concurrent measurement of respiratory rates using plethysmography and measurement of 13C-propanol and 13C-propionic acid in blood. Radiolabeled material was used to isolate the metabolite from endogenous propionic acid. Respiratory rates were steady for the 2 hr inhalation exposures. The average minute volume for 4 rats exposed to 3500 ppm propanol over 2 hr was 116 ± 22 ml/hr. Blood propanol and propionic acid peaked within the 2 hr exposure and dropped immediately post exposure. For 3500 ppm exposures, peak propanol was 360 ± 67 nmol/ml, several fold higher than observed after a 25 mg/kg iv dose. Propionic acid however was proportionally less than after the iv dose, most likely indicating saturable metabolism of propanol. The iv exposures included a 30 minute infusion to achieve steady state with analysis for 13C-propanol and 13C-propionic acid in blood and urine. Rats were also dosed iv with 13C-propionic acid to determine the acid kinetics independent of propanol metabolism. The Cmax and AUC of 13C- propionic acid were ~6x higher following a propionic acid dose than following an equimolar dose of propanol. The rate of elimination of propionic acid in blood post iv dosing was the same following a propanol dose as for a propionic acid dose. Propanol in urine was close to detection limits. These studies show that propanol is readily absorbed via inhalation and metabolized to propionic acid. (ACC Oxo Panel Sponsored)

PS 1484 INHALATION KINETICS OF PENTAFLUOROPROPANE IN HUMANS.

L. Ernstgård[1], M. Andersen[2], W. Dekant[3], S. Juran[1], B. Lind[1], B. Sjögren[1] and G. Johanson[1]. *[1]Karolinska Institutet, Stockholm, Sweden, [2]The Hamner Institute for Health Sciences, Research Triangle Park, NC and [3]University of Wuerzburg, Wuerzburg, Germany.*

1,1,1,3,3-Pentafluoropropane (HFC245fa) is one of the hydrofluorocarbon (HFC) replacers of the ozone-depleting chlorofluoro- and hydrochlorofluorocarbons. Human kinetic data on HFCs, and in particular on HFC245fa, are sparse. Five healthy volunteers of each sex were exposed in random order to 0, 100 or 300 ppm HFC245fa for 2 h during light physical exercise in an exposure chamber. Capillary blood, urine and exhaled air were sampled before, during and after exposure and analyzed for HFC245fa by head space gas chromatography. Urinary fluoride and trifluoropropionic and trifluoroacetic acid were analyzed by ion selective electrode and GC/MS, respectively. Symptoms of irritation and central nervous system effects were rated in Visual Analogue Scales (VAS). Biochemical (ASAT, ALAT, ALP, GGT, urate, creatine kinase (CK), and CK-MB) and inflammatory markers (SAA protein, fibrinogen, D-dimer, C-reactive protein, and IL-6) in plasma/serum were analyzed, based on sporadic findings after exposure to other HFCs. The initial increase in blood was fast and average levels of 1.9 and 5.7 μM were reached within a few minutes of exposure to 100 and 300 ppm HFC245fa, respectively. The biphasic post-exposure decrease in blood was fast as well and parallel to that in exhaled air. The respiratory uptake could not be determined, as inhaled and exhaled air had similar concentrations of HFC245fa. On average, about 0.7% and 0.001% of the total amount of inhaled HFC245fa was excreted in breath and urine, respectively, after exposure. trifluoropropionic acid was not detected in urine (LOD 0.1 μM) and no increase in trifluoroacetic acid or fluoride above background was seen, suggesting minimal metabolism. The VAS ratings revealed no HFC245fa-related effects, except a slight increase of dubious significance in headache 2 h after the exposure at 300 ppm. None of the biochemical or inflammatory markers was affected. The study was financed by Honeywell International and approved by the regional ethical review board.

PS 1485 ASSESSMENT OF THE IRRITATION POTENTIAL OF SWEDISH SNUS INGREDIENTS USING THE EPIORAL™ TISSUE MODEL.

L. R. Neilson[1], S. P. Faux[2], S. J. Hinchliffe[2], T. S. Jai[2] and C. Meredith[1]. *[1]Group R&D, British American Tobacco, Southampton, United Kingdom and [2]Toxicology Group, Advanced Technologies (Cambridge) Limited, Cambridge, United Kingdom.*

Our risk assessment for ingredients used in Swedish style pouched snus differs significantly from that used for traditional combusted tobacco products. Prolonged contact of the snus pouch with the oral mucosa may allow certain ingredients to

exert an irritant potential on mucosal tissue. As part of our risk assessment, we have utilized an *in vitro* screen for irritancy in order to define non-irritant levels of ingredients for use in snus products. The EpiOral™ tissue model consists of cultured human epidermal keratinocytes in a differentiated multilayer with a buccal phenotype. The irritant effects of topically applied chemicals are measured using the MTT cell viability assay. Ingredients for use in snus were tested in duplicate up to a maximum concentration of 5000 μg/ml using exposure periods of both 1h and 20h. Triton X-100 and SDS were included as positive controls and DMSO as a negative control. None of the ingredients tested at concentrations up to 5000 μg/ml affected the tissue viability at either time point. Actual tissue viabilities relative to controls were: benzyl carbinol (118.6% & 114.5%), cinnamaldehyde (99.1% & 93.3%), citronellol (124.2% & 118.4%) and menthol (121.3% & 122.7%) for 1h and 20h exposure respectively. In contrast, exposure for 1h to 1% Triton X-100 or 1% SDS gave tissue viabilities relative to controls of 40.3±11.4% and 34.4±9.2% respectively, reducing to 7.1±1.8% and 7.6±1.3% respectively after 20h exposure. A reduction of ≥25% tissue viability relative to the negative controls was used to define irritancy within our model. These data demonstrate the utility of the EpiOral™ model for assessing irritation potential to the oral mucosa. In our hands, ingredients for use in snus that may possess an irritation potential are screened using this model at an early stage in our risk assessment paradigm. This assists in defining a level of ingredient use in pouched snus that is without irritant effect.

PS 1486 HOW DO ANIMAL STRAINS AND VEHICLES IMPACT ON LLNA RESULTS.

W. Wang-Fan and L. G. Ullmann. *Business Unit Pharmacology, RCC Ltd, Itingen, Switzerland.*

The murine local lymph node assay (LLNA) is a stand-alone method for objective and quantitative determination of skin sensitizing potential of chemicals. However, various factors, e.g. animal strains and vehicle-effects, may have an influence on the LLNA in different ways and by a variety of mechanisms and sometimes even elicit unreliable results. To quantitatively evaluate such influences we made various measurement: (1) the total disintegrations per minute per node (dpm/LN) of 3H-methyl thymidine incorporated in draining lymphocytes, using CBA/CaOlaHsd, CBA/CaHsdRcc(SPF), CBA/Ca(CruBR), CBA/Jlbm(SPF), CBA/JNCrj, Balb/c and NMRI mice. The methods were identical with those described in the OECD Guideline 429. The results obtained demonstrated that the background dpm/LN in these strains of mice were different. CBA/CaOlaHsd and NMRI mice of those tested presented the lowest and the highest dpm/LN (130 to 554), respectively; (2) dpm/LN derived from CBA/CaOlaHsd and CBA/CaHsdRcc(SPF) mice, following topical exposure to dimethyl sulphoxide (DMSO). It was found that CBA/CaHsdRcc(SPF) mice presented a significantly higher response to DMSO than CBA/CaOlaHsd mice; (3) dpm/LN derived from CBA/CaHsdRcc(SPF) mice following topical exposure to acetone/olive oil (4/1, v/v) (AOO), ethanol/water (7/3, v/v) (EtOH70%), dimethylformamide (DMF), 2-butanone (BN), propylene glycol (PG) and DMSO, separately. It was shown that DMSO caused a significantly higher dpm/LN than the other five vehicles in CBA/CaHsdRcc(SPF) mice; (4) the allergenic potential, expressed by dpm/LN and stimulation index (SI), of alpha-hexylcinnamaldehyde (HCA) in six vehicles, at concentrations of 5%, 10% and 25% (w/v) using CBA/CaOlaHsd mice. Our results demonstrated that the magnitude of SI of HCA with DMSO was clearly decreased due to a high dpm/LN level in the vehicle-control when using CBA/CaOlaHsd mice. The EC3 values were 1.76 (BN), 5.71 (DMF), 6.36 (EtOH70%), 7.35 (PG), 11.72 (AOO) and 16.21 (DMSO). In conclusion, both animal strain and the choice of vehicle can affect the background dpm/LN, which may directly impact on the results of the LLNA.

PS 1487 TSCA 8(E)/FYI INITIAL SCREEN DATABASE, A PRIORITIZATION TOOL.

E. Cohen[3], J. Von Runnen[3], V. Houck[1], W. L. Richards[3], A. Blaschka[2], A. Kennedy[2] and M. Townsend[2]. *[1]Environmental Science, SRC, N. Syracuse, NY, [2]Risk Assessment Division, OPPTS/U.S. EPA, Washington, DC and [3]Environmental Science, SRC, Arlington, VA.*

Under TSCA section 8(e), persons who manufacture/import a chemical must inform EPA of any new information regarding substantial risk of injury to health or the environment. Data received under section 8(e) generally report findings of toxic effects in laboratory animals, incidents of environmental release, toxic effects in aquatic species, or reports of human exposure. FYI (for your information) submissions are voluntarily submitted and generally consist of studies with negative results. EPA's Risk Assessment Division (RAD) screens these 8(e)/FYI submissions to identify chemicals to determine priority for follow-up activity. In April 2006, SRC began to assist EPA in the development of the TSCA 8(e)/FYI Initial Screen Database to store the screening information derived from 8(e) and FYI submissions. Each database record contains a link to an electronic version of the corresponding 8(e) or FYI submission. The database is searchable by chemical name, CAS number, submitter name, date range, key words within text, document number, and submission description. Other fields in the database indicate whether or not the document contains confidential business information (CBI), study information/description, and priority level for follow up. The current prototype of the TSCA 8(e) Initial Screen Database contains data from 2000 to present and supplements the data within the original TSCATS database, which includes the evaluation of chemicals up to the year 2000. A parallel version of this database has been created which contains CBI information in addition to all the information that is present in the non-CBI version.

PS 1488 HORMESIS KNOWLEDGE AND OPINION SURVEY RESULTS.

A. Jones, A. L. Douglas, S. J. Edward and C. J. Edward. *School of Public Health, University of Massachusetts, Amherst, MA.*

Studies and review articles about hormesis are being published at an increasing rate by researchers from a variety of disciplines. Due to increased publication interest, we conducted an opinion survey to assess knowledge and attitudes about the hormesis dose response.
Research objectives were to 1) assess the respondent's general knowledge about dose response models, including hormesis, 2) determine characteristics of people who would, if allowed by regulation, take potential for hormesis into account when designing or interpreting risk assessments, and 3) compare the characteristics of those who would consider hormesis to those who would not by identifying variables affecting acceptance/rejection.
Methodology: The survey was administered in August and September of 2008. It consisted of 44 questions covering basic demographics, knowledge and attitudes about dose response, knowledge and attitudes hormesis, and knowledge and attitudes about risk assessment principles and practice. The survey was pre-tested and pilot tested by 25 toxicologists and risk assessors representing diverse backgrounds and employers.
The survey was distributed via email to 9,500 potential respondents, all of whom were members of either the Society of Toxicology or the Society for Risk Analysis. Respondents were offered an opportunity to decline participation and to ask questions of the researchers. Survey responses were analyzed in the aggregate using SAS statistical software. QA/QC techniques were used to assure duplicate responses were eliminated from analysis and to evaluate survey reliability and validity.
Conclusion: The survey had an overall response rate of 20% and a completion rate of 73%. The poster presents results of the detailed analysis and identifies the characteristics of those who would employ hormesis in a risk assessment and those who would not. In general the survey indicated 65% of respondents felt hormesis justified a change in hazard assessment protocols and that 87% of respondents felt risk assessments should accommodate the hormesis dose response.

PS 1489 A PROBABILISTIC CANCER RISK ASSESSMENT MODEL OF KEY SMOKELESS TOBACCO CONSTITUENTS.

Z. S. Naufal[1], S. Kathman[2], J. Bodnar[2], M. Borgerding[2] and C. Wilson[2, 1]. *[1]Integrated Toxicology and Environmental Health Program, Duke University, Durham, NC and [2]Research and Development Department, RJ Reynolds Tobacco Co., Winston-Salem, NC.*

Smokeless tobacco (ST) use is common worldwide, with a potential increase in consumption in coming years. This report describes a probabilistic cancer risk assessment model of key ST constituents. The model includes a wide range of ST products obtained from the US market in 2006-2007: moist and dry snuff, loose leaf and plug tobacco, and a dissolvable tobacco pellet. Products assessed varied considerably in chemical composition and moisture content. The constituents included in the risk analysis were selected based on their detection in ST products, evidence of being known or suspected carcinogens, and availability of oral cancer potency data. Such compounds fell into a range of chemical classes including polycyclic aromatic hydrocarbons (PAHs), *N*-nitrosamines, heavy metals, carbonyls and other organic chemicals. Distributions incorporated in the probabilistic model included: analyte concentration (built from quantitative chemical analysis data collected in triplicate for each product), daily ST consumption (based on market surveys and the peer-reviewed literature), frequency of use and body weight (based on data from the 1999-2006 National Health and Nutrition Examination Surveys) and duration of use (based on U.S. Census Bureau life expectancy data). Cancer slope factors were included as point estimates and potency equivalency factors were used to estimate potency of individual PAHs where slope factors did not exist. In summary, probabilistic models provide significant improvements over deterministic models in health risk assessments with highly variable and uncertain input parameters such as those associated with ST use. To our knowledge, the present work is the first application of probabilistic approaches in estimating cancer risk linked to ST use.

PS 1490 EFFECTS ON EXPRESSION OF APOPTOSIS AND INFLAMMATORY GENES OF THE COMBINATION ARSENIC AND FLUORIDE-EXPOSURE.

M. Salgado-Bustamante[1], B. Estrada-Capetillo[2], D. P. Portales-Pérez[2] and R. González-Amaro[3]. *[1]Biologia Molecular y Bioquimica, Universidad Autonoma de San Luis Potosi, San Luis Potosi, San Luis Potosi, Mexico, [2]Inmunología Celular y Molecular, Universidad Autonoma de San Luis Potosi, San Luis Potosi, San Luis Potosi, Mexico and [3]Facultad de Medicina, Universidad Autonoma de San Luis Potosi, Seattle, WA.*

Arsenic (As) and Fluoride (F) are considered important environmental elements widely distributed in nature around the world through drinking water. The estimates indicate that more 100 million people worldwide are exposed and often result in adverse health effects. There are reports about several effects of arsenic on inflammatory and apoptosis process. However the groundwater contains combination arsenic and other elements like fluoride. The effects and mechanism of arsenic and fluoride combination exposure at human are unknown. To investigate molecular targets of inflammatory and apoptosis pathways, we conducted an exploratory study cDNA macroarrays to identify differential profiles expression in arsenic and fluoride-exposed yet apparently healthy individuals selected of areas exposure-different of Mexico. The effect due to F in co-exposition with As was observed when gene expression was significantly down in several apoptotic genes and up-regulated in anti-apoptotic gene (survivin). The results of this gene expression study indicate that the combination-exposed may be have effects on expression of apoptosis molecules may be decrease in subjects after prolonged exposure to combination arsenic and fluoride. Our study demonstrates different profiles of gene expression in PBMC from subjects co-exposed to As and F, although it remains to be determined whether or not the simultaneous exposure of humans to As and F has less deleterious effects than the exposure to As alone. Further studies are needed to elucidate the exact mechanism of interaction of arsenic and fluoride toxicity and their implication in human population exposed to both.

PS 1491 CONTRIBUTION OF TRICHLOROACETIC ACID TO LIVER TUMORS OBSERVED IN PERCHLOROETHYLENE (PERC)-EXPOSED MICE.

L. M. Sweeney[1], C. R. Kirman[2], M. L. Gargas[1] and P. H. Dugard[3]. *[1]The Sapphire Group, Dayton, OH, [2]The Sapphire Group, Cleveland, OH and [3]Halogenated Solvents Industry Alliance, Arlington, VA.*

Perchloroethylene (perc) is a solvent used in dry cleaning operations and industrial applications such as metal degreasing. Perc has been found to produce increases in hepatocellular carcinomas and/or adenomas in male and female mice in chronic inhalation bioassays. Perc is metabolized primarily to trichloroacetic acid (TCA), which is also a mouse hepatocarcinogen. The fractional conversion of perchloroethylene to TCA by mice was determined from physiologically based pharmacokinetic (PBPK) modeling of TCA in mouse blood at the conclusion of inhalation exposure of male and female B6C3F1 mice to 10, 50, 100, or 200 ppm perc for 6 hrs/day for 5 days. The dose-dependent bioavailability of TCA in male and female B6C3F1 mice exposed to TCA in drinking water was estimated by optimizing the fit of time course blood, plasma, and liver TCA concentrations for TCA doses ranging from 12 to 800 mg/kg/day to predictions of a previously published TCA PBPK model. Using the PBPK models, the area under the liver TCA concentration vs. time curve (liver TCA AUC) was calculated for TCA and perc bioassays. Benchmark dose analyses were conducted to determine the dose-response relationship between liver TCA AUC and the additional risk of hepatocellular adenomas or carcinomas (combined) in mice ingesting TCA. Using the dose-response relationships derived for the TCA-exposed mice, the contribution of TCA produced by metabolism to the additional risk of liver adenomas and carcinomas in mice exposed to perchloroethylene by inhalation was computed. The analysis indicated that the levels of TCA observed in perchloroethylene-exposed mice are sufficient to explain the incidence of liver adenomas and carcinomas.

PS 1492 ESTABLISHING A MUTAGENIC MODE OF ACTION: CASE STUDIES.

M. Anatra-Cordone, M. Odin, H. Carlson-Lynch, P. McClure and P. McGinnis. *Syracuse Research Corp, N. Syracuse, NY.*

Current U.S. EPA guidelines for cancer assessment place emphasis on establishing mode of action (MOA) as a key step in determining the choice of low-dose extrapolation model and whether early life-stage exposure is considered to result in additional risk. Case studies were developed for 2 chemicals: 2-naphthylamine (2NA) and 3,3′-dimethylbenzidine (33DMB). 2NA is known to cause bladder cancer in humans and 33DMB is likely to cause bladder cancer in humans. A mutagenic mode of action for each of these chemicals is proposed based on a review of the literature and application of U.S. EPA's Framework for Determining a Mutagenic Mode of Action for Carcinogenicity. For both chemicals, the proposed MOA entails: metabolism to DNA-reactive metabolites, covalent binding with DNA, mutation, and proliferation of mutated cells. For 2NA, key evidence includes: observation of mutagenicity and genotoxicity following metabolic activation in a variety of organisms and tests; identification of metabolites that form DNA adducts in the bladder in humans and animals and cause mutations in bacteria; formation of tumors following less than one year of exposure; and similarity to benzidine, which is recognized by EPA to have a mutagenic MOA. Additional support comes from findings that 1-naphthylamine, a 2NA analog, is neither mutagenic nor extensively transformed to a DNA reactive metabolite and does not cause bladder cancer in animals or humans. Evidence in support of a mutagenic MOA for 33DMB includes: mutagenicity and genotoxicity in a variety of organisms and tests; mutations in oncogenes found in rat tumors induced by 33DMB; demonstration of specific activated oncogenes in 81% of benign and malignant tumors in rats treated with 33DMB, compared with only 2.5% of spontaneous tumors in controls; and similarities to benzidine. Key determinants for a mutagenic MOA for these chemicals included similarities to another mutagenic agent in structure and response, and strong associations between tumor occurrence and occurrence of specific DNA adducts or mutations within target tissues in exposed humans or animals.

PS 1493 FACTORING PRE-EXISTING, TUMOR-ASSOCIATED MUTATIONS AND POLYCLONAL TUMOR DEVELOPMENT INTO THE REGULATORY RISK ASSESSMENT PARADIGM.

B. L. Parsons, F. Meng and P. B. McKinzie. *Division of Genetic and Reproductive Toxicology, FDA/National Center for Toxicological Research, Jefferson, AR.*

In quantitative cancer risk assessment, genotoxic and non-genotoxic carcinogens may be regulated differently. It is generally assumed there is no safe dose of a genotoxic carcinogen, based on the idea that the induction of a single mutation is potentially carcinogenic. If a chemical has a mode of action that is not directly genotoxic, some regulatory groups will use a nonlinear approach to quantitative cancer risk assessment. This is based on the idea that non-genotoxic carcinogens may operate through a mechanism that has a dose-related threshold. The realizations that many or most tumors are polyclonal in origin [B.L. Parsons (2008) *Mutation Research/Reviews in Mutation Research* 659: 232-247] and tumor-associated mutations pre-exist in normal tissues have not been factored into the development of this risk assessment paradigm. A review of data from several studies, obtained using Allele-specific Competitive Blocker-PCR (ACB-PCR), indicates tumor-associated mutations (*ras* and *p53*) are measureable in tissues (colon, liver, lung, nasal mucosa, and skin) of control animals (rats and mice), as well as in human colonic mucosa. The observed spontaneous mutant fractions (MFs) range from below the level of accurate ACB-PCR quantitation (10^{-5}) up to 10^{-3}, with the majority of spontaneous MFs above 10^{-3}. Further, a literature review identified studies which support the idea that pre-existing mutations within a tissue are involved in initiating carcinogenesis. The hypothesis that tumor initiation involves the spatial interaction between cooperating clones of cells with complementing genetic and/or epigenetic lesions implies that polyclonal tumors may be initiated through mixed modes of action. Together, this information raises the question of whether the mutagenic effects of chemicals seen at high doses in rodents accurately model mode of action relevant to human exposures and whether chemically-induced epigenetic effects have a larger role in human cancer development than previously realized.

PS 1494 INDUCTION OF TUNICA VAGINALIS MESOTHELIOMAS IN RATS BY XENOBIOTICS.

R. R. Maronpot[1], E. Zeiger[2], E. E. McConnell[3], H. Kolenda-Roberts[1], H. Wall[1] and M. A. Friedman[4]. *[1]Experimental Pathology Laboratories, Inc., Research Triangle Park, NC, [2]Errol Zeiger Consulting, Chapel Hill, NC, [3]Tox Path, Inc., Raleigh, NC and [4]Kennesaw State University, Marietta, GA.*

The relevance to human cancer risk assessment of treatment-associated tunica vaginalis mesothelioma (TVM) in rat cancer bioassays has been questioned. Hormone imbalance brought about by perturbations of the endocrine system has been proposed as a key factor leading to both spontaneous and treatment-associated TVM in rats. Tunica vaginalis mesotheliomas commonly occur in F344 male rats and are causally associated with an altered hormonal milieu attributable to the high background incidence of Leydig cell tumors of the testes of these animals. Twenty-one chemicals were found that produced a treatment-associated TVM response primarily in F344 rats; of these, 11 had a robust TVM response (maximum incidence ≥24%), 7 were judged to have a non-significant to marginal response (maximum incidence 10-18%), and 3 were excluded due to early mortality from other induced

tumors. The background frequency of this tumor in rats is 2-5%. No TVM were seen in mice. Of the 10 chemicals with robust responses that also had mutagenicity test results, 8 (80%) were mutagenic in Salmonella. In contrast, only 2 of the 7 (29%) with non-significant to marginal TVM responses were positive. TVM responses are F344-rat-specific, their incidence can be exacerbated by treatment, and their causal association with F344 rat Leydig cell tumors indicates that when this rat bioassay tumor response is not robust, it may not be relevant to other species or pose a risk for human cancer.

PS 1495 ASSESSMENT OF THE RODENT CARCINOGENICITY TESTING REQUIREMENTS FOR PESTICIDES.

M. Manibusan, R. Mitkus, P. Shah, J. Rowland, B. May, G. Akerman, K. Baetke and V. Dellarco. *Office of Pesticide Programs, U.S. EPA, Washington, DC.*

The Office of Pesticide Programs (OPP), United States Environmental Protection Agency (US EPA), requires a two sex, two species rodent carcinogen bioassay for the registration of all food use pesticides. To date, the results of approximately 500 such studies have been reviewed by OPP. The common rat and mouse strains used in carcinogenicity studies for pesticides were Fischer, Sprague-Dawley, and Wistar rats and CD-1 or Swiss and B6C3F1 mice. The most common tumor types observed in studies with male or female rats were liver, thyroid and testes; in studies with male and female mice, evidence of increased incidences of liver tumors was by far the most common tumor type. The positive carcinogens generally induce tumor responses only in male and/or female mice. Most of these mouse only tumor responses were detected using a Swiss strain of mouse and a few were detected using B6C3F1 mice. The majority of the mouse only carcinogens induced tumors in both sexes of mice. The most common tumor type reported for the mouse specific carcinogens was liver tumors. These mouse specific carcinogenic pesticides generally did not appear to be DNA reactive. Some mode of action data are available on these mouse specific carcinogens that indicate they generally induce tumors either by promoting the clonal expansion of preneoplastic cells by stimulating cell proliferation or by persistent cell killing which in turn may result in a persistent regenerative proliferative response in the damaged tissue. This assessment includes a summary of the tumor profile data from the standard rodent carcinogen bioassays for pesticides which may provide insights into the value of these studies. An analysis will be presented for each rodent study and its overall impact on human health risk assessment. The views expressed in this abstract are those of the authors and do not necessarily reflect those of the U.S. EPA.

PS 1496 OXYFLUORFEN: EVALUATION OF THE MODE OF ACTION FOR LIVER TUMORS IN MALE MICE.

N. J. Stagg[1], M. J. LeBaron[2], H. L. Kan[2], W. Stott[2], B. L. Yano[2], B. Gollapudi[2], D. L. Eisenbrandt[1] and J. Klaunig[3]. *[1]Human Health Assessment, Dow AgroSciences, Indianapolis, IN, [2]TERC, The Dow Chemical Company, Midland, MI and [3]Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Oxyfluorfen (2-chloro-1-(3-ethoxy-4-nitrophenoxy)-4-(trifluoromethyl) benzene) is a diphenyl ether herbicide. A carcinogenicity study with oxyfluorfen resulted in a minimal increase in the incidence of combined hepatocellular adenomas and carcinomas in male CD-1 mice following chronic exposure at the highest dose tested, 200 ppm (33 mg/kg/day). The increase in liver tumors was within the range of appropriate historical controls and only statistically significant for one of the two control groups. No increases in liver tumors in female mice or male or female rats were seen, nor were there any increases in any other types of tumors in either species. A dose-related toxic response in the livers was most pronounced in males and included: cytomegaly, karyomegaly and individual cell necrosis. Oxyfluorfen is not genotoxic. Non-genotoxic modes of action (MOAs) evaluated include: peroxisome proliferation receptor alpha (PPARα) activation, hepatotoxicity and porphyria. Mechanistic studies with male CD-1 mice fed oxyfluorfen up to 800 ppm for up to 28 days showed increased liver weights, increased hepatocellular S-phase DNA synthesis, and histologic changes consistent with a degenerative and regenerative response in the liver. Peroxisomal acyl-CoA oxidase was increased in the oxyfluorfen-treated animals, but electron microscopy provided no evidence of peroxisome proliferation. A PPARα transactivation assay was negative for oxyfluorfen. Additional mechanistic studies include gene expression in male mice fed increasing doses of oxyfluorfen and measurements of liver enzymes and liver porphyrin content. High doses of oxyfluorfen in male mice for 10 days (2500 ppm) or 3 months (2000 ppm) are known to cause hepatic porphyrin accumulation and increased liver weights (Krijt et al., 1993, 1994). Overall, these mechanistic data provide further definition of the MOA in the livers of male mice fed oxyfluorfen.

PS 1497 OPPORTUNITIES FOR PROGRESS IN USING MECHANISTIC INFORMATION IN RISK ASSESSMENT: THE PPAR-α MODE OF ACTION HYPOTHESIS REVISITED.

K. Z. Guyton, W. A. Chiu, T. F. Bateson, J. Jinot, C. Siegel Scott, R. C. Brown and J. C. Caldwell. *Office of Research & Development, U.S. EPA, Washington, DC.*

Data on a chemical's mode of action (MOA) can be critical to decisions in evaluating human health risks. However, there are several challenges in evaluating and applying MOA data for carcinogen risk assessment purposes. These challenges include determining whether a MOA causes cancer, and estimating the likely human sensitivity to a MOA. These issues are elaborated in our present review of the PPAR-α MOA for hepatocarcinogenesis. PPAR-α receptor agonism has been posited as a sole, causative factor for hepatocarcinogenesis. In addition, based on a hypothesized reduction in human sensitivity to this MOA, it has been concluded that rodent hepatocarcinogenesis by PPAR-α agonists is irrelevant to human carcinogenic risk. Herein we review recent studies that experimentally challenge these suppositions, including evidence that the plasticizer di(2-ethylhexyl) phthalate is hepatocarcinogenic in PPAR-α-null mice and other data that PPAR-α activation in hepatocytes does not alone evoke liver tumors. We conclude that 1) the hypothesized PPAR-α MOA is no longer tenable as a sole explanation for rodent liver tumors; 2) for most PPAR-α agonists, chemical-specific data are insufficient to characterize the relative human sensitivity to the rodent MOA or to hepatocarcinogenesis; and 3) the available epidemiologic data for PPAR-α agonists are inadequate to provide sufficient information to inform conclusions of human relevance. These findings have broad implications for the assessment of the human health risks of the diverse rodent hepatocarcinogens that are PPAR-α agonists, including many environmental contaminants. They also suggest opportunities for progress in how MOA hypotheses are developed, tested, and applied in human health risk assessment. Disclaimer: These views are those of the authors and do not necessarily reflect US EPA policy or opinion.

PS 1498 USE OF TOXICOGENOMIC DATA AT THE U.S. EPA CANCER ASSESSMENT REVIEW COMMITTEE.

N. E. McCarroll[1], E. Reaves[1], M. Manibusan[1], D. Wolf[2], S. Hester[2], J. Allen[2], S. Thai[2], J. Ross[2], Y. Ge[2], W. Winnik[2], L. King[2], C. Blackman[2], W. Ward[2] and S. Nesnow[2]. *[1]Office of Pesticide Programs, U.S. EPA, Washington, DC and [2]Office Of Research and Development, U.S. EPA, Research Triangle Park, NC.*

The Office of Pesticide Programs' (OPP), Cancer Assessment Review Committee (CARC) routinely utilizes mode of action (MOA) data when available for pesticides whose cancer risk assessment is being considered. Typically, an MOA analysis incorporates data from required toxicology studies and supplemental mechanistic data. The CARC has considered genomic data in the weight-of-the-evidence (WOE) for support of an MOA. As part of this effort, standard approaches are being developed for the inclusion of toxicogenomic data, and other new technologies, into the risk assessment process. The Office of Research and Development has developed toxicogenomic datasets for several regulated conazoles. Members of this class of fungicides induce mouse liver tumors via an undetermined MOA. Toxicogenomic data, supplemental tissue response information, molecular and biochemical studies, and traditional registration studies were used to determine the value of applying genomic data to the MOA analysis. Postulated key events based on genomic and experimental studies are: nuclear receptor activation, CYP induction, cholesterol inhibition, oxidative stress, effects on retinoic acid and mevalonic acid levels, and in vivo mutagenicity. These key events are being synthesized into MOAs that help to explain the toxicological effects of conazoles. EPA Cancer Risk Assessment Guidance approaches will be used to develop a process whereby genomic data can be integrated into our risk assessments. The CARC sees this as an opportunity to bring new approaches that inform our understanding of cancer and increase the efficiency and accuracy of our risk assessment process. The views expressed in this abstract do not necessarily reflect those of the U.S. EPA.

PS 1499 INTERPRETATION OF DERMAL ABSORPTION FOR PESTICIDES AND BIOCIDES IN THE EU: A LIMITED CRITIQUE OF EU GUIDANCE.

S. Warren. *Food & Chemicals Practice, Exponent, International, Harrogate, United Kingdom.*

Risk assessments for agrochemicals and biocides within the EU require an assessment of dermal absorption; a statement of "percentage dermal absorption" is a required regulatory endpoint. Harmonsiation and consistency of data evaluation by the various Member States of the EU has been assisted by the "Guidance Document on Dermal Absorption", a working document of the European Commission. The "Guidance Document" was established with a primary aim of es-

tablishing default assumptions in cases where no data, or very little data, are available for a chemical. The document also describes how data from in-vitro or in-vivo dermal absorption studies may be interpreted in order to derive the "percent dermal absorption" value. Use of this guidance document since 2004 has however indicated further areas where better use of additional data can refine the procedures described in this guidance. Circumstances in which additional data could be incorporated in dermal penetration assessments, while remaining appropriately precautionary, are discussed for the following three areas: - Interpretation of in-vivo and in-vitro studies, considers only penetration of radiolabel, without assessment of the toxicological relevance of the radiolabel; There is limited consideration of the time course of absorption. The degree of dermal penetration is assessed against an "Acceptable Exposure Level" cited as mg/kg bw/day, but the potentially absorbed dose may be the result of multiple days of absorption; and, There is no adequate consideration of relative toxicity by oral and dermal routes. Comparison of oral and dermal LD50s is expressly discouraged, but there is no discussion of the merits of No Effect Levels from comparable oral and dermal toxicity studies. In conclusion, a dermal absorption value should not be derived without consideration of all relevant data, particularly comparable oral and dermal no effect levels (where these are available). This would help avoid unnecessary conservatism based on data which sometimes is less appropriate than toxicity data.

PS 1500 PROTECTING EMERGENCY RESPONSE PERSONNEL FROM CHEMICALS OF HIGH PRIORITY BY DERIVING IMMEDIATELY DANGEROUS TO LIFE OR HEALTH (IDLH) VALUES USING REFINED METHODOLOGY.

A. Maier[1], A. L. Parker[1] and G. Dotson[2]. *[1]Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH and [2]The National Institute for Occupational Safety and Health (NIOSH), Center for Disease Control and Prevention (CDC), Cincinnati, OH.*

The National Institute for Occupational Safety and Health (NIOSH) has been investigating methods to improve the derivation of Immediately Dangerous to Life or Health (IDLH) values. IDLH values are 30-minute atmospheric concentrations of any toxic, corrosive, or asphyxiant substance that, via inhalation exposure, poses an immediate threat to life or would cause immediate or delayed irreversible adverse health effects or would interfere with an individual's ability to escape from a dangerous atmosphere in the event of a respirator failure. We developed a process to prioritize IDLH development for high priority chemicals of specific interest to emergency response personnel (i.e., chemical terrorism agents or industrial chemicals subject to emergency or uncontrolled releases). The prioritization process included weighted scores to account for metrics of exposure potential, toxicity, and a variety of secondary considerations (such as toxicity data availability and existence of other acute exposure guidance values). We evaluated the impact of a refined weight of evidence approach described in our prior work on methods for developing IDLH values. The refined approach was applied to 20 case study chemicals from the list of agents identified by the prioritization process. The resulting preliminary IDLH values and the rationale for their derivation is presented and contrasted to the IDLH values that would have been developed using a default IDLH calculation approach. Lessons learned from these case studies are used to inform further refinements in the IDLH derivation methods as they apply to chemicals of interest to homeland security applications and emergency preparedness.

PS 1501 DRAFT REVISIONS TO THE GUIDELINES FOR AUTHORS OF DRINKING WATER HEALTH ADVISORIES.

S. S. Kueberuwa[1] and L. T. Haber[2]. *[1]Office of Water, U.S. Environmental Protection Agency, Washington, DC and [2]Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH.*

The EPA's Office of Water is updating the Guidelines for Agency authors for writing Drinking Water Health Advisories (HA). EPA's Office of Water develops HAs to identify non-regulatory concentrations of drinking water contaminants at which adverse health effects would not be anticipated to occur over specific exposure durations in children and adults. EPA develops 1-day and 10-day HAs for a 10 kg child, Longer-term HAs for a 10-kg child and for adults, and a Lifetime HA for adults. The draft updated Guidelines reflect new developments in risk assessment methods, including benchmark dose modeling, updated approaches to uncertainty factors (including chemical-specific adjustment factors), and the 2005 cancer guidelines. In addition, the draft updated Guidelines provide information on data sources and quality, guidance on key decision points, and references to other relevant EPA guidelines. Additional information is provided in the Guidance on consideration of life stages and endpoints relevant to the 1- and 10-day HAs. It is expected that the guidance, when finalized, will result in a more scientifically robust and consistent approach to the development of HAs. [The opinions herein are those of the authors and do not necessarily reflect the opinions of the U.S. Environmental Protection Agency (USEPA)].

PS 1502 EFFECT OF THE IMMUNOSTIMULANT γ-D-GLUTAMYL-L-TRYPTOPHAN ON THE EFFECTOR PHASE OF ASTHMA IN A GUINEA PIG MODEL.

J. F. Regal[1], C. Tuthill[2] and M. Mohrman[1]. *[1]Biochemistry & Molecular Biology, University of Minnesota Medical School Duluth, Duluth, MN and [2]SciClone Pharmaceuticals, Inc., Foster City, CA.*

The dipeptide γ-D-Glu-L-Trp (SCV-07) is being tested as an immunostimulant in clinical and animal studies of cancer and infectious disease. Previous studies suggest that it stimulates Th1 immunity and reduces Th2 immunity. We hypothesized that this pattern of immunomodulation would be of benefit in controlling asthma. Objective: Determine if γ-D-Glu-L-Trp inhibits the effector phase in a guinea pig model of asthma. Animals were sensitized with ovalbumin(OVA) i.p. on day 0. On day 17-21, animals received daily i.p. injections of 1 or 10 μg/kg γ-D-Glu-L-Trp or vehicle phosphate buffered saline (PBS). On day 21 all animals were pre-treated with antihistamine to reduce the acute histamine component of the immediate bronchoconstrictor response that can be fatal. Animals were challenged with 1% OVA or saline (NSS) aerosol for 5 min. During OVA aerosol challenge, animals administered γ-D-Glu-L-Trp experienced significantly reduced cough, labored breathing and distress compared to PBS treated animals given OVA aerosol. γ-D-Glu-L-Trp did not affect the OVA specific IgG1 concentration in serum. Cell infiltration and lung injury were assessed 18 hours after OVA challenge. In animals challenged with NSS aerosol, γ-D-Glu-L-Trp significantly reduced total lung eosinophil peroxidase, suggesting that dipeptide treatment reduced the number of resident eosinophils and modulated eosinophil distribution. The OVA-induced increase in eosinophil infiltration into the lung was not inhibited by γ-D-Glu-L-Trp treatment. OVA challenge significantly increased red blood cell number in the BAL indicating lung injury occurred, and γ-D-Glu-L-Trp treatment markedly reduced this OVA-induced lung injury. Thus, these studies indicate that γ-D-Glu-L-Trp does not prevent eosinophil movement into the allergic lung, but significantly reduces the immediate allergic reaction and subsequent lung damage and may decrease the number of resident eosinophils in the lung. (Research supported by SciClone Pharmaceuticals, Inc.)

PS 1503 ASSESSMENT OF PROTEIN ALLERGENIC POTENTIAL IN MICE : RELATIONSHIPS BETWEEN IMMUNOGENICITY AND ALLERGENICITY.

R. J. Dearman and I. Kimber. *Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom.*

Assessment of the potential allergenicity of novel proteins is an important issue, particularly in the context of the safety of genetically modified crop plants. We have shown previously that the measurement of specific IgE production induced by systemic (intraperitoneal; ip) administration of proteins to BALB/c strain mice correlates with allergenic potential. In the current experiments, IgG and IgE antibody responses following ip exposure to a range of proteins have been measured by enzyme-linked immunosorbant assay (ELISA) and homologous passive cutaneous anaphylaxis (PCA) assay, respectively. Intraperitoneal administration of proteins not associated with allergic responses such as potato lectin and purified potato protein stimulated vigorous IgG antibody responses but failed to stimulate IgE antibody production, even at relatively high doses (10%). Exposure of BALB/c strain mice to protein enzymes such as lipolase and termamyl that cause IgE-mediated respiratory allergy induced relatively low titer IgG antibody responses, but comparatively vigorous IgE antibody production. Similarly, ip administration of the major cows' milk allergen β-lactoglobulin and the peanut allergen Ara h 1 stimulated weak IgG antibody responses and detectable specific IgE antibody production. In contrast, exposure to the peanut allergen Ara h 2 failed to provoke detectable IgG or IgE antibody. The relatively poor immunogenicity of both of the peanut proteins may reflect prior exposure to cross-reactive soy proteins in the diet. These data demonstrate the importance of monitoring IgG antibody responses, such that only the failure to observe detectable IgE antibody in the presence of a robust IgG antibody response is interpreted as a secure negative. Furthermore, respiratory sensitizing proteins may also be characterized as a function of induced IgE antibody responses following systemic ip exposure. Experience to date is encouraging that this method may represent a useful approach for the prospective identification of protein allergens.

PS 1504 CIRCUMVENTING THE HYPERSENSITIVITY LIKE REACTION ASSOCIATED WITH REPEAT DOSING OF A HUMANIZED MONOCLONAL ANTIBODY IN TRANSGENIC MICE.

T. Magee, M. M. Flaherty, M. Troutt, C. A. Rogers, T. K. MacLachlan, L. Andrews and R. D. Garman. *Genzyme Corporation, Framingham, MA.*

GMA161, an aglycosyl humanized monoclonal antibody that binds to hCD16A and hCD16B Fc-receptors, has been examined in models for treatment of idiopathic thrombocytopenic purpura. A human double transgenic (Tg) mCD16-/-,

hCD16A+, hCD16B+ mouse was used for preclinical studies due to appropriate receptor expression and distribution. Following repeated doses of GMA161, or its murine surrogate aglycosyl 3G8, an acute and severe hypersensitivity like reaction was observed. The first study conducted to evaluate the mechanism of action behind the hypersensitivity like reaction involved repeat dosing of aglycosyl-3G8 to double and both single Tg mice. Double Tg mice exhibited a severe reaction following repeat dosing, whereas single Tg mice displayed minor reactions, supporting that both transgenes are required for a severe hypersensitivity like reaction. Anti-GMA161 antibody titers were significantly higher in the double Tg mice compared to the single Tg mice, suggesting the severity of the reaction may be associated with the antibody response. A second study further investigated the possible mechanism of action by blocking two of the known pathways mediating murine systemic anaphylaxis: IgE – characterized by histamine release, and IgG – characterized by platelet activating factor (PAF) release. Double Tg mice were pretreated with an antihistamine [diphenhydramine (DPH)], a PAF antagonist (CV-6209), or both DPH and CV-6209 prior to repeat dosing with GMA161. Double Tg mice were tolerant of repeat dosing of GMA161 when pretreated with CV-6209 with no adverse clinical signs observed. DPH administration did not reduce the hypersensitivity like reaction, suggesting that the response to GMA161 is not histamine mediated but may be PAF mediated. Together these studies indicate that the hypersensitivity-like reaction following repeat dosing of GMA161 or aglycosyl 3G8 correlates with anti-GMA161 antibody titers, and may be alleviated by inhibiting IgG mediated hypersensitivity mechanisms in Tg mice.

PS 1505 LYMPHOCYTE GENE EXPRESSION CHARACTERISTIC OF IMMEDIATE AIRWAY RESPONSES (IAR) AND METHACHOLINE (MCH) HYPERRESPONSIVENESS IN MICE SENSITIZED AND CHALLENGED WITH ISOCYANATES.

M. Selgrade[1], C. Pucheu-Haston[2], E. Boykin[1] and S. Hester[1]. *[1]Nat'l Health & Environmental Effects Research Labora, U.S. EPA, Research Triangle Park, NC and [2]Curriculum in Toxicology, University of NC, Chapel Hill, NC.*

Exposure to isocyanates has been associated with occupational airway diseases, including asthma. Previously we reported on respiratory and immune responses following dermal sensitization and intranasal challenge of BALB/c mice with 6 different isocyanates. The purpose of this study was to determine whether differences in gene expression in the draining lymph node could be related to phenotypic differences that were observed in responses to the different isocyanates. RNA was extracted from lymph nodes of mice exposed to 2% dicyclohexylmethane-4,4'diisocyanate (HMDI), 1% toluene diisocyanate (TDI), and 1% meta-tetramethylene xylene isocyanate (TMXDI) following the intranasal challenge. IAR were observed in mice treated with TDI and HMDI, but not TMXDI. Increased MCH hyperresponsiveness was observed in mice treated with HMDI and TMXDI, but not TDI. Affymetrix chips were used to analyze treatment-associated changes in gene expression RNA. A statistical filter was used to assess difference from vehicle control ($p<0.05$) corrected for multiple observations. A Venn diagram was generated showing changes in expression of 2475 genes in common with HMDI and TDI, hence possibly associated with the IAR, and in expression of 88 genes in common with HMDI and TMXDI, hence possibly associated with the MCH response. Amongst the 2475 genes pathway analysis revealed a number of genes associated with the T-cell receptor and T-cell activation. In contrast, amongst the 88 genes, pathway analysis identified genes associated with cell cycle and tight junctions, but T-cell activation genes were notably absent. These genes (and/or pathways) could potentially be used to predict airway responses to other isocyanates and possibly other low molecular weight chemicals. This abstract does not reflect EPA policy.

PS 1506 A MODIFIED LOCAL LYMPH NODE ASSAY (LLNA) DOSING THE EAR CANAL FOR THE CHARACTERIZATION OF INDUSTRIAL ENZYMES.

N. W. Berg, U. Festersen, T. R. Kjaer, N. K. Soni, K. M. Bidstrup, G. Lindemann and E. L. Roggen. *Toxicology & Pharmacology Protein Development, Novozymes A/S, Bagsvaerd, Denmark.*

Industrial enzymes are proteinacous water soluble test materials, known to be potential respiratory allergens in case of occupational exposure to dust or aerosols. There is a high need for a test model to be able to discriminate such sensitizers from contact sensitizers. We have assessed the potential of a modified LLNA for this purpose. The effects of dosing selected test materials using an aqueous vehicle into the ear canal have been investigated by analyzing the proliferative response of the draining lymph nodes. The OECD protocol 429 was used; however, the difficulties associated with the skin application of aqueous solutions in the traditional model were overcome by using 1% Pluronic in PBS as vehicle and by the dosing into the ear canal instead of on the ear dorsum. The following test materials were tested: The skin sensitizer hexyl cinnamic aldehyde, normally used as positive control substance, the chemical respiratory sensitizer ammonium hexa chloro-platinate, a standard protein ovalbumin, tuberculin purified protein derivative and two industrial enzymes, a protease and an amylase. Proliferative responses in terms of stimulation indexes were established both *in vivo* and *in vitro*, 5 hours after pulse with H3-thymidin, followed by a cytokine profiling with and without re-stimulation.
The aqueous vehicle worked very well with all test substances and the various allergens showed a clear increase in the total amount of proliferating cells in comparison to the solvent control-treated mice. The *in vitro* and *in vivo* stimulation indexes showed a strong correlation, indicating that refining the model by using the *in vitro* pulsing alone is feasible. In addition, the cytokine phenotyping of the proliferating cell populations provided information with regard to discrimination between a Th1- and a Th2-type response. The present LLNA approach offers an easy to perform, significantly refined method for the assessment of sensitizers and the influence on the proliferation and production of cytokines *in vitro*.

PS 1507 TOLUENE DIISOCYANATE (TDI)-SPECIFIC MONOCLONAL ANTIBODIES: PRODUCTION AND EPITOPE MAPPING.

T. B. Ruwona[1, 2], D. Schmechel[1], J. M. Hettick[1], E. Janotka[1], F. M. Blachere[1], D. H. Beezhold[1], R. H. Simoyi[2] and P. D. Siegel[1]. *[1]ACIB, NIOSH/CDC, Morgantown, WV and [2]Chemistry, Portland State University, Portland, OR.*

Toluene diisocyanate (TDI) is a commonly used diisocyanate (dNCO). TDI is a reactive low molecular weight chemical that is widely used in industry, especially in the manufacture of polyurethane foams and adhesives. Diisocyanate exposure is one of the most commonly reported causes of occupational asthma. The production of well characterized TDI-specific monoclonal antibodies (mAbs) will allow for the development of standardized immunoassays for exposure and biomarker assessment. Such mAbs may also be useful to isolate and study dNCO protein targets. BALB/c mice were immunized with 2,4- or 2,6-TDI conjugated keyhole limpet hemocyanin (KLH), spleen cells isolated and hybridomas made. Resultant mAbs produced by these hybridomas were screened for their ability to bind TDI conjugated human serum albumin (HSA) by ELISA. MAbs were further characterized by ELISA and western blot against various monoisocyanate (mNCO) and dNCO and diisothiocyanate conjugated proteins to identify reactivity toward urea, amide or thiourea linkages. A total of 35 mAbs were produced (25 IgG1, 8 IgG2a, 2 IgG2b) were obtained against 2,4-TDI-KLH sensitized mice. Seven mAbs were found to recognize 2,4-TDI-HSA and 28 mAbs reacted with both 2,4- and 2,6-TDI-HSA. mAbs specific for only 2,4-TDI-conjugated protein did not recognize 2,6-TDI-HSA, mNCO-HSA or other dNCO–HSAs. Other cross-reactive mAbs reacted with 2,4-TDI-HSA, 2,6-TDI-HSA, and other dNCO protein conjugates like methylene diphenyldiisocyanate- and hexamethelene diisocyanate-HSA, but not mNCO-HSA. All mAb reactivities were carrier protein independent. The mAbs produced can differentiate between specific dNCO in a carrier independent fashion and may be useful as hapten-specific reagents for immunoassay development and research into dNCO related diseases. Funded in part by NIEHS-NIOSH IAG#Y1-ES-0001

PS 1508 IDENTIFYING THE LOW DOSE CHEMICAL-INDUCED RESPIRATORY ALLERGIC RESPONSE IN MICE.

T. Fukuyama, Y. Tajima, H. Ueda, K. Hayashi, Y. Shutoh, K. Ebino, T. Harada and T. Kosaka. *The Institute of Environmental Toxicology, IBARAKI, Japan.*

The inhalation of many types of chemicals, including pesticides, perfumes, and other low-molecular-weight chemicals, is a leading cause of allergic respiratory diseases. We attempted to develop a new test protocol to detect environmental chemical–related respiratory hypersensitivity at low and weakly immunogenic doses. We used long-term dermal sensitization followed by a low-dose intratracheal challenge to evaluate sensitization by the well-known respiratory sensitizers trimellitic anhydride (TMA) and toluene diisocyanate (TDI) and the contact sensitizer 2,4-dinitrochlorobenzene (DNCB). Female Balb/c mice aged 8 week were divided into five subgroups for each chemical: Subgroup A-C (sensitized and challenged with solvent or test solution); Subgroup D1-D2 (sensitized with test solution and challenged with low or high dose of test solution). On days 1 to 3, 8 to 10, and 15 to 17, a 25-μL aliquot of test solution was applied to the dorsum of each ear for dermal sensitization. Two weeks after the last sensitization, mice were intratracheally challenged with a 50-μL aliquot of test solution. After topically sensitizing and challenging them intratracheally, we assayed differential cell counts and chemokine levels in bronchoalveolar lavage fluid (BALF); lymphocyte counts, surface antigen expression of B cells, and local cytokine production in lung-associated lymph nodes (LNs); and antigen-specific IgE levels in serum and BALF. TMA induced marked increases in antigen-specific IgE levels in both serum and BALF, proliferation of eosinophils and chemokines (MCP-1, eotaxin, and MIP-1β) in BALF, and prolifer-

ation of Th2 cytokines (IL-4, IL-10, and IL-13) in restimulated LN cells. TDI induced marked increases in levels of cytokines (IL-4, IL-10, IL-13, and IFN-γ) produced by restimulated LN cells. In contrast, DNCB treatment yielded, at most, small, nonsignificant increases in all parameters. Our protocol thus detected respiratory allergic responses to low-molecular-weight chemicals and may be useful for detecting environmental chemical–related respiratory allergy.

PS 1509 4-OXOPENTANAL IDENTIFIED AS A POTENTIAL INDOOR AIR IRRITANT AND ALLERGEN.

J. L. Franko, A. E. Munson, J. Ham, L. Jackson, R. Wells, L. Butterworth and S. E. Anderson. *CDC/NIOSH, Morgantown, WV.*

Over the last two decades, there has been an increasing awareness regarding the potential impact of indoor air pollution on human health. People working in an indoor environment often experience symptoms such as eye, nose and throat irritation, headache, and fatigue. Investigations into these complaints have ascribed the effects to volatile organic compounds (VOC) emitted from building materials, cleaning formulations or other consumer products, and indoor chemistry. The dicarbonyl 4-Oxopentanal (4-OPA) is generated through the ozonolysis of squalene and several high volume production compounds that are commonly found indoors. Measureable levels of 4-OPA have been detected in simulated indoor air environments. 4-OPA was tested in a combined local lymph node assay (LLNA) and identified to be an irritant and extreme sensitizer with an EC3 value of 0.08%. Significant increases were observed in the B220+ and IgE+B220+ cell populations in the draining lymph nodes after exposure to 4-OPA concentrations of 6.25% and higher. Total serum IgE levels were also significantly elevated after exposure to 25% 4-OPA. These results suggest that 4-OPA may function as an IgE-mediated sensitizer. The identification of this compound as an irritant and sensitizer may help to explain some of the adverse health effects associated with indoor air exposure.

PS 1510 *ORTHO*-PHTHALALDEHYDE INHALATION INDUCES IMMUNE ACTIVATION IN THE NASAL MUCOSA AND DRAINING LYMPH NODES IN MICE.

V. J. Johnson, J. S. Reynolds, W. Wang, K. Fluharty and B. Yucesoy. *Health Effects Laboratory Division, NIOSH/CDC, Morgantown, WV.*

ortho-Phthalaldehyde (OPA) is increasingly being substituted for glutaraldehyde as a high-level disinfectant for sensitive medical devices, however, toxicological data on OPA safety is lacking. Concerns regarding the safety of glutaraldehyde include acute nasal toxicity and sensory irritation as well as sensitization leading to occupational rhinitis and asthma. Since OPA is a dialdehyde like glutaraldehyde and functions as a disinfectant due to its high reactivity for biological macromolecules, it is reasonable to hypothesize that OPA may pose similar respiratory hazards. Several case reports have been published supporting this hypothesis showing development of respiratory hypersensitivity reactions in healthcare workers and patients exposed to OPA. The purpose of this study was to determine the respiratory toxicity of OPA using a murine model. A nose-only vapor inhalation system was used to expose mice to OPA vapor for 4 hours/day for 3 consecutive days followed by sacrifice on day 5. The lungs, nasal mucosa and head-draining lymph nodes were collected and processed for cytokine gene expression analysis. Expressions of TNFα and IL-1β, cytokines important for activation and migration of dendritic cells, were increased in the draining lymph nodes as well as the nasal mucosa. Increased IL-4 and IL-10 expression was observed in the draining lymph nodes as well as increased IL-4 expression in the nasal mucosa. In contrast, the expression of IFNγ was not changed in either tissue following OPA inhalation. Lung cytokine expression was also examined; however, no changes were evident. These data demonstrate that OPA inhalation induces an immune response locally in the nasal mucosa. Importantly, OPA inhalation induced activation of lymphocytes in the mandibular lymph nodes that drain the nasal mucosa, thus supporting the potential for sensitization to this chemical. The Th2-dominant expression pattern in the draining lymph nodes suggests that OPA may have the potential to cause respiratory sensitization.

PS 1511 IDENTIFICATION OF INDOOR AIR CONTAMINATES USING AN *IN VITRO* EXPOSURE SYSTEM.

L. Jackson, R. Wells, A. E. Munson and S. E. Anderson. *CDC/NIOSH, Morgantown, WV.*

On average, U.S. citizens spend 80% or more of their daily lives indoors whether at home, work, or in other commercial buildings. Over the last two decades, there has been increasing awareness regarding the potential impact of indoor air pollution on health. These studies use an in vitro monitoring system called the VitroCell which utilizes the air/cell interface allowing for direct contact between cells and components of a test atmosphere to assess chemicals found in the indoor air environment. The structurally similar dicarbonyls diacetyl, 4-oxopentanal, gluteraldehyde and methylglyoxal were selected for use in this system. Exposure to these compounds, which are found in the indoor environment, has been suggested to contribute to adverse health effects. The VitroCell module was used to evaluate immune-related gene and protein expression generated after a non-immune (pulmonary epithelial A549) and immune (alveolar macrophage) cell line were exposed to these aerosolized chemicals. A low density real time PCR gene array, screening 84 immune-related genes, was used to investigate the exposure effects of these compounds. Alterations in the inflammatory cytokines IL-8 and TNF-alpha were identified after exposure to these compounds. The identified cytokines can potentially be used as biomarkers to screen contaminated indoor air environments. These studies may provide an in vitro method for the identification and characterization of chemical hazards including indoor air pollutants in work environments such as office buildings, allowing for the reduction of worker illness and more specifically reducing respiratory consequences of exposures to allergens and irritants.

PS 1512 TH17 INVOLVEMENT IN PENICILLAMINE-INDUCED AUTOIMMUNITY.

J. Li, X. Zhu and J. Uetrecht. *Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada.*

Rationale: At present idiosyncratic drug reactions (IDRs) are impossible to predict, largely because the mechanisms involved are poorly understood. The most recently identified subtype of helper T cells, Th17 cells, are characterized by the production of proinflammatory cytokine, IL-17, and have been shown to be involved in the pathogenesis of many types of autoimmune syndromes. This study investigated the involvement of Th17 cells in penicillamine-induced autoimmunity in Brown Norway (BN) rats. Experimental Procedures: BN rats were given penicillamine (1.0 mg/ml in drinking water). Serum IL-6 and TGF-beta concentrations were determined by ELISA. At the end of the experiment, spleen CD4+ T cells were purified via an immunomagnetic column from 3 treated and 3 control animals and cytokine mRNA levels were determined. Results: 4/7 treated rats developed autoimmunity. A significant increase of serum IL-6 was detected only in sick animals and did not occur until shortly before animals developed signs of autoimmunity. Serum TGF-beta was found to go up by the 2nd week in nonsick animal compared to a decease in the two sick animals. In addition, a two-fold increase of IL-17 mRNA was observed only in sick rats. Moreover, in preliminary experiments we detected a marked increase in IL-17 and IL-6 in several patients with idiosyncratic drug-induced liver injury. Conclusions: IL-6 is known to favor the development of Th17 cells and the elevation of IL-6 only in animals that develop autoimmunity is consistent with the involvement of Th17 cells in this animal model. The increase in IL-17 mRNA further supports this hypothesis. The finding of an increase in IL-17 in patients with idiosyncratic drug-induced liver failure suggests that Th17 cells may also be involved in drug-induced liver injury. This work was supported by a grant from the Canadian Institutes of Health Research.

PS 1513 GENISTEIN INCREASES BLOOD GLUCOSE LEVELS IN STREPTOZOTOCIN-TREATED FEMALE B6C3F1 MICE.

T. L. Guo, J. F. Zheng and K. L. White. *Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA.*

Previously, we have reported that oral exposure to phytoestrogen genistein (GEN), a major isoflavone in most soy products, protected female NOD (non-obese diabetic) mice from developing type 1 diabetes when fed a soy- and alfalfa-free diet. When given in multiple low doses (MLD), administration of streptozotocin (STZ, a selective β-cell cytotoxin) can cause type 1 diabetes with an autoimmune pathology in mice that do not develop diabetes spontaneously. The objective of present study was to determine if exposure to GEN by gavage had any effects on blood glucose levels in the MLD-STZ-induced diabetic female B6C3F1 mice. Adult mice were administered GEN (2, 6, and 20 mg/kg; 0.1 ml/10 g body weight) for two weeks before STZ injection (5 X 50 mg/kg, i.p.) was performed to induce diabetes. GEN administration was continued to the end of study. Vehicle mice (25 mM Na2CO3) had moderate levels of blood glucose (250 - 350 mg/dL) in the 13 weeks of dosing period, and treatment with GEN produced increases in blood glucose levels. In the 2 mg/kg GEN group, significant increases were observed at weeks 7, 8, 9, 10, 11 and 12 following STZ injection. In the 6 mg/kg GEN group, significant increases were observed at weeks 7, 9, and 12 following STZ injection. In the 20 mg/kg GEN group, significant increases were observed at weeks 3, 5, 7, 10, 11 and 12 following STZ injection. When the percentages of mice with blood glucose levels over 650 mg/dL (the detection limit of our Accu-Chek Diabetes monitoring kit) were plotted against time, there were significant decreases at week 7 for the 2 mg/kg GEN group and at week 12 for the 6 mg/kg GEN group, and a significant increase at week 13 for the 2 mg/kg GEN group; however, the overall differences were minimal. Taken together, GEN exposure had no protective effect in MLD-STZ-induced diabetes in female B6C3F1 mice. These results suggest that the mechanism

of GEN protection of diabetes development in female NOD mice is complex, and more studies are needed to identify the immune components that are targeted by GEN (Supported in part by NO1-ES05454).

PS 1514 ACETAMINOPHEN REVEALS IMMUNE-SENSITIZATION IN ORAL EXPOSURE MOUSE MODEL.

I. S. Ludwig, L. Kwast, D. Fiechter and R. Pieters. *Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands.*

Many drugs are known to induce adverse immune reactions in susceptible individuals and may result in clinical diseases. The reporter antigen popliteal lymph node assay (RA-PLNA) is assessing this immune-sensitization capacity of low molecular weight compounds. However this assay only assesses local responses and does not include oral exposure. Therefore systemic effects are missed and furthermore, when metabolism is required compounds may test false negative in this assay. Preclinical systemic exposure models with a predictive value do not exist.
In this study the immune-sensitization of acetaminophen (APAP) was investigated when orally administered to mice. Trinitrophenyl-ovalbumin (TNP-OVA) was used as a reporter antigen (RA) to assess the capacity of the drugs to stimulate systemic immune responses to a bystander antigen. Female C3H/HeOuJ mice were exposed to 30, 100 or 300 mg/kg APAP daily for 7 days and co-exposed to TNP-OVA at day 1. 15 days after the start of the exposure delayed type hypersensitivity was determined by a challenge with the RA. A vigorous response to the RA was detected in animals exposed to APAP. RA-specific IgG1 and IgG2a antibodies could be detected in the serum at day 21. Furthermore, isolated LN cells from APAP treated animals displayed a higher IFN-γ, IL-4 and TNF-α production than cells from control animals upon restimulation in vitro. In conclusion, APAP, with a known capacity to induce immune mediated adverse reactions in patients, displays in this oral exposure mouse model a mixed TH1/Th2 response. Combined with results from other studies in which ofloxazine, diclofenac and D-penicillamine, all known immune-sensitizing drugs and induced antibody responses in this mouse model, this experimental set up could be useful for preclinical assessment of sensitizing potential of new chemical entities.

PS 1515 EXAMINATION OF POTENTIAL CHEMICAL INTERACTIONS IN SKIN SENSITIZATION : ACTIVITY OF CLOVE BUD OIL ADMIXED WITH OXAZOLONE IN THE LOCAL LYMPH NODE ASSAY.

J. Lalko[1], I. Kimber[2], R. J. Dearman[2], G. Gerberick[3] and A. Api[1]. *[1]Research Institute for Fragrance Materials Inc., Woodcliff Lake, NJ, [2]The University of Manchester, Manchester, United Kingdom and [3]Procter & Gamble Co., Cincinnati, OH.*

The potential for interaction between contact allergens during the induction phase of skin sensitization has rarely been investigated. Understanding of the potential for additive and/or synergistic effects might prove relevant and inform risk assessment strategies. In order to explore the potential for interactions between chemicals during the acquisition of skin sensitization a series of local lymph node assays (LLNA) were conducted with a well-characterized sample of clove bud oil - an essential oil containing multiple contact sensitizers – alone, and in combination with a constant amount of the strong sensitizer oxazolone. Clove bud oil was tested at five concentrations ranging from 1.0% to 25% w/v in a vehicle of 1:3 ethanol:diethyl phthalate (EtOH:DEP), both with and without 0.005% oxazolone. Two vehicle controls were included, one containing 0.005% oxazolone and one without. The concentration of oxazolone was selected based on a known EC3 value of <0.001% in EtOH:DEP. Stimulation indices (SI) were calculated for each dose level with an SI ≥ 3 compared with the relevant vehicle control being considered positive. Theoretical dose response curves based upon summation of the individual responses to clove oil and the oxazalone containing vehicle controls were also generated. Comparison of the theoretical with experimentally derived dose responses revealed that the combination of clove bud oil and oxazolone had a slightly greater than additive effect, particularly at higher doses. These results are consistent with other reports of additive effects in the LLNA. Further work is needed to determine if these effects translate into increased levels of sensitization to the individual materials.

PS 1516 INDUCTION OF SENSITIZATION AND CYTOTOXICITY TO TRICHLOROETHYLENE IN MICE: ROLE OF METABOLITES.

D. Yufei, L. Haishan, L. Qing, S. Yaofeng, N. Yong, B. Ping and Z. Yuxin. *Key laboratory, National institute for occupational health and poison control, Chinese center for disease control and prevention, Beijing, China.* Sponsor: Z. Yuxin.

Trichloroethylene (TCE) is an important industrial chemical and is widely used. The severe allergic skin damage induced by TCE has been described. The aim of the study was to explore role of metabolites of TCE in the process of allergic skin damage in mice using a combination of *in vivo* and *in vitro* endpoints. Female BALB/c mices pretreated with ethanol or phenobarbital (PB) were administered TCE for 6 weeks, followed by challenge onto the ears to evaluate delayed-type hypersensitivity (DTH) response. After the mice were sacrificed, activities of aspartate aminotransferase and alanine aminotransferase in serum were measured as markers of hepatic damage. The TCE-specific lymphocytes proliferation and cytotoxicity of TCE and its metabolites were determined in cultured spleen lymphocytes exposed to TCE and SKF-525A (CYP450 inhibitor) or aminooxyacetic acid (AOAA, cysteine conjugate β-lyase inhibitor) *in vitro*. The results showed that no DTH response could be observed in 3 groups of mice treated by TCE, TCE+PB and TCE+ethanol. However, a significant proliferation of spleen cells from TCE-treated mice was evidenced following incubation with TCE *in vitro*, it was interesting that this proliferation disappeared when AOAA was added and cytotoxicity of TCE decreased when SKF-525A was added. In mice treated by TCE+PB and TCE+ethanol, no significant proliferation of spleen cells was found in culture with TCE *in vitro*, but hepatoxicity of TCE *in vivo* was promoted by PB and ethanol through increasing the CYP450-dependent oxidation metabolic flux. This study provides an indirect evidence that Glutathion-dependent pathway might play an important role in allergic reaction induced by TCE, and dichlorovnyl thiol-metabolite catalyzed by cysteine conjugate β-lyase is responsible for proliferation of hapten- specific lymphocytes in TCE-sensitized mice. The CYP- dependent oxidation cause cytotoxicity of spleen cells *in vitro*, and hepatotoxicity *in vivo* as well.

PS 1517 INCREASED CELL PROLIFERATION IN SPLEEN AND LYMPH NODES PERIPHERAL TO CONTACT ALLERGEN APPLICATION SITE.

I. Chipinda, S. E. Anderson, L. F. Butterworth, D. H. Beezhold and P. D. Siegel. *HELD/ACIB, CDC/NIOSH, Morgantown, WV.*

The local lymph node assay (LLNA) is widely used to identify chemicals that are contact sensitizers. The assay involves dosing mice with the chemical on both ears and pooling the cervical lymph nodes for assessment of lymphocyte proliferation as a marker of sensitization. The present study explored potential reduction in animal usage by dosing one ear with the allergen and the other with vehicle only. The respective draining lymph nodes were processed separately for quantification of cell proliferation. Cell proliferation in axillary and renal nodes, and in the spleen was also assessed. Cross contamination of the chemicals from the dosed ears to other parts of the body via preening was prevented by dosing restrained animals and washing off the residual chemical with saline after 4 hours. Dosing the left ear with 0.02% oxazolone (OX) on unrestrained animals resulted in marked cell proliferation in its draining lymph node (Stimulation index, SI = 12.8) and in the lymph node draining the contra-lateral vehicle dosed ear (SI = 6), and the axillary lymph nodes (SI = 3.3). Increased tritiated thymidine (^{3}H-TdR) incorporation was not observed in the renal lymph nodes (SI = 1.1). Similar stimulation of cells was observed in the lymph node draining the ear contra-lateral to the allergen dosed ear when 30% hexylcinnamaldehyde (HCA) was applied. Increased proliferative activity was observed in non-directly draining lymph nodes of restrained mice demonstrating that these results can not be attributed to cross-contamination of adjacent skin. A significant increase in proliferation of splenocytes was observed. It is concluded that epicutaneous application of a contact allergen, as exemplified by OX and HCA, may induce cell proliferation in the neighboring lymph nodes and spleen indicative of hapten and/or haptenated proteins diffusing through the skin to peripheral nodes and the blood to produce systemic sensitization. Thus the node draining the contra-lateral ear can not be used as a control for application of contact allergen to a single ear in a modified LLNA.

PS 1518 COMPARISON OF GLOVE CONTACT ALLERGEN CONTENT AND CLINICAL PATCH TEST.

P. D. Siegel[1], F. J. Storrs[2], D. Sasseville[3], M. Pratt[4], T. A. Bledsoe[1], B. F. Law[1], D. H. Beezhold[1] and J. F. Fowler[5]. *[1]NIOSH/CDC, Morgantown, WV, [2]Oregon Health Sciences University, Portland, OR, [3]McGill University, Montreal, QC, Canada, [4]Ottawa Hospital, Ottawa, ON, Canada and [5]University of Louisville, Louisville, KY.*

Irritant dermatitis, allergic contact dermatitis (ACD) and urticarial reactions have been associated with chemical rubber accelerators present in latex and nitrile/synthetic rubber gloves. In this study, patients reporting to a dermatology clinic with glove associated ACD were allergy patch tested with the North American Contact Dermatitis Group standard rubber allergen series, medical history taken and asked to identify and supply "problem gloves" which they associated with their ACD and if possible "non-problem gloves". Medical exam, surgical and industrial-type rubber and nitrile gloves from patients were assessed for chemical content including: zinc dithiocarbamates, thiurams, mercaptobenzothiazole (MBT) and its disulfide, dimorpholine, diphenylguanidine, thiourea, and phenylene diamine. Only zinc di-

ethyl - (ZDEC) and zinc dibutyl dithiocarbamate (ZDBC), MBT and dimorpholine were found in glove extracts. Considerable discordance was found between clinical patch test results and glove chemical content. Approximately 37% of patients had no discordance. However, similar percents of patients identified "problem gloves" that did not contain their patch test positive allergen or provided "non-problem gloves" containing the patch test positive allergen. The lowest glove allergen levels associated with a patch test-confirmed ACD were 584, 283 and 590 μg/g glove of ZDEC, ZDBC and MBT, respectively. Discordance between the allergy patch test and glove chemical accelerator content may be in part attributed to both false positive/negative allergy patch test rates and misidentification of problem/non-problem gloves due to the delay between glove usage and clinical ACD manifestation.

PS 1519 TRICHLOROETHYLENE INGESTION ENHANCES PROLIFERATION RATE OF T CELLS AND CYTOKINE PRODUCTION ON MICE.

R. Kobayashi[1], S. Watanabe[1], T. Nakanishi[1], M. Satoh[2] and H. Nagase[1]. *[1]Gifu Pharmaceutical University, Gifu, Japan and [2]School of Pharmacy, Aichi Gakuin University, Nagoya, Japan.*

Trichloroethylene (TCE) contamination of groundwater has been a social problem because of its toxicity and persistency. We reported that TCE ingestion from drinking water enhanced passive and active cutaneous anaphylaxis (PCA and ACA) reaction on mice. In this study we investigated a mechanism on the enhancement of allergic reaction. We first measured the proliferation rates of the naive mouse splenocytes and lymphocytes exposed to TCE (1 pM- 1 μM) in vitro. The proliferation rates of the splenocytes and lymphocytes were increased by TCE exposure. BALB/c mice were treated with 0.03 mg/L and 3 mg/L TCE dissolved in drinking water for 2 weeks, and immunized twice with ovalbumin (OVA) on the first day and a week after. On the final day of the TCE treatment period, we collected mice spleens and prepared splenocytes. The proliferation rates of splenocytes and cytokine levels of the conditioned medium were measured. The proliferation rates of splenocytes were enhanced by TCE ingestion. IL-2, IL-3, IL-4, IL-10,IFN-γ and TNF-α levels in the conditioned medium of splenocyte increased in TCE treated group. These results show that TCE ingestion enhances T cell proliferation and cytokine production. Therefore, TCE ingestion from drinking water may lead to increase patients of allergic diseases.

PS 1520 MITOGEN-ACTIVATED PROTEIN KINASES CONTROL NRF2 ACCUMULATION IN HUMAN DENDRITIC CELLS IN RESPONSE TO THE CHEMICAL SENSITIZERS.

S. Kerdine-Romer[1], D. Antonios[1], M. Damiens[1], J. Ourlin[2] and M. Pallardy[1]. *[1]University Paris Sud - INSERM UMR-S 749, Faculté de Pharmacie, 5 rue J.B.Clément, Ch¢tenay-Malabry, France and [2]AFSSAPS DLC/BCM 635 rue de la Garenne F-34740, Vendargues, France.*

Exposure of dendritic cells (DC) to skin contact sensitizers, such as nickel (NiSO4) or dinitrochlorobenzene (DNCB), induce an up-regulation of phenotypic markers and cytokine secretion that are regulated by mitogen-activated protein kinases (MAPKs). Our current hypothesis is that chemical sensitizers generate a chemical stress that is perceived by DCs as a danger signal leading to DC maturation. Among signalling pathways known to be
redox-sensitive, the Keap1/Nrf2 pathway is central for the detection of endogenous or exogenous electrophiles. Briefly, in the absence of electrophile, Keap1 associates with Nrf2 and targets Nrf2 for degradation. In the presence of an electrophilic compound, Keap1 conformation is modified, Nrf2 is released and translocates to the nucleus to act as a transcription factor.
Because sensitizers activate both MAPKs and Nrf2, we address the question whether Nrf2 accumulation by contact sensitizers depends on MAPK pathways. Human monocytes derived DC (Mo-DC) were obtained from peripheral blood and cultured in the presence of GM-CSF and IL-4 for 5 days. Mo-DCs were preatreated with MAPKs inhibitors and then treated with nickel sulfate (500 μM) or DNCB (20 μM). Our results showed that NiSO4 and DNCB induced an accumulation of the Nrf2 protein in Mo-DC. The mRNA expression of target genes of Nrf2, such as *hmox 1* (heme-oxygenase 1) and *nqo1* (NADPH quinone oxydoreductase), were up-regulated after treatment in response to NiSO4 and DNCB. Furthermore, an inhibitor of P38MAPK, SB203580, reduced the accumulation of Nrf2 protein in NiSO4-treated MoDC whereas an ERK inhibitor (PD98059) induced the accumulation of Nrf2 in NiSO4-treated MoDC.
These results suggest that accumulation of Nrf2 in MoDC is controlled by P38MAPK and ERK, two kinases involved in DC maturation. We are currently investigating the role of Nrf2 in DC maturation.

PS 1521 ANALYSING DISCORDANT LOCAL LYMPH NODE ASSAY DATASETS: IMPLICATIONS FOR REACH.

D. A. Basketter[1], N. Ball[2], S. Cagen[3], J. Carrillo[4], H. Certa[5], D. Eigler[6], H. Esch[7], C. Garcia[8], C. Graham[9], C. Haux[10], R. Kreiling[11] and A. Mehling[12]. *[1]DABMEB Consultancy Ltd, Sharnbrook, United Kingdom, [2]Dow Europe GmbH, Horgen, Switzerland, [3]Shell Health, Houston, TX, [4]Shell International BV, The Hague, Netherlands, [5]SASOL Germany GmbH, Marl, Germany, [6]Evonik Goldschmidt GmbH, Essen, Germany, [7]BASF AG, Ludwigshafen, Germany, [8]SEPPIC, Castres, France, [9]Huntsman Corporation, The Woodlands, TX, [10]Akzo Nobel Surface Chemistry, Stenungsund, Sweden, [11]Clariant Produkte (Deutschland) GmbH, Sulzbach, Germany and [12]Cognis GmbH, Dusseldorf, Germany.*

The local lymph node assay (LLNA) is the assay of choice in European regulatory toxicology. As with other toxicology/sensitisation assays, it has a potential for false results, the anionic surfactant sodium lauryl sulphate (SLS) representing a classic example. In the work reported here, examples of false positives in the LLNA are compared to published "benchmarks" such as SLS. Clear false positives (eg oleic acid) are also contrasted with examples where data interpretation is more challenging. As the LLNA will be applicable to >30,000 chemicals under REACH, and in the light of animal welfare considerations to do no more than the absolute minimum of animal testing, results from a single LLNA often represent the only available data on sensitisation. This reinforces the need to ensure data from this assay are interpreted intelligently, using scientific analysis of results and considering the weight of evidence, before decisions are made on which substances should be classified as representing a skin sensitisation hazard. In chemical classes where the LLNA has been shown to be an inappropriate assay other standardised methods (e.g. the Buehler or Magnusson and Kligman guinea pig tests [OECD 406]) should be employed as the first choice assays.

PS 1522 THE MURINE LOCAL LYMPH NODE ASSAY WITH NON-RADIOACTIVE ALTERNATIVE ENDPOINTS.

A. Karakaya, O. C. Ulker and I. Ates. *Department of Toxicology, Ankara University Faculty of Pharmacy, Ankara, Turkey.* Sponsor: A. Karakaya.

The murine local lymph node assay (LLNA) is a predictive test for detection of contact allergens. The LLNA has been endorsed by the US Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) and European Centre for the Validation of Alternative Methods (ECVAM) as a stand-alone method for skin sensitization testing. Although the validity of the LLNA, attention was drawn to two disadvantages; radioactive in vivo measurement of lymph node cell proliferation (3H-thymidine labeling) and possibility of false positive results caused by non-specific cell activation as a result of inflammatory processes in the skin (irritation). In the present study, we investigated the development of non-radioactive endpoint of LLNA based on 5-bromo-2'-deoxyuridine (BrdU)(NR-LLNA) and compared in vivo and ex vivo BrdU incorporation by enzyme-linked immunosorbent assay (ELISA) to improve animal welfare. Female BALB/c mice were treated by the topical application of strong sensitizer 2,4-dinitrochlorobenzene (DNCB) in acetone:olive oil (4:1 v/v) and dimethylsulfoxide at the concentrations of %0.025, %0.05, %0.01, %0.25. Ear thickness was also measured to determine the differentiation index and by this modification it was aimed to determine the proportion of non-specific activation due to irritating properties of test compound. For all concentrations, irritation effect was not observed. At the concentration of %0.05, stimulation index value was found 3 for DNCB. In vivo NR-LLNA and ex vivo NR-LLNA results were good agreement with previous radioactive LLNA data. The study was supported by The Scientific and Technological Council of Turkey, Project number: 107S365

PS 1523 REDUCING THE NUMBER OF ANIMALS IN THE LOCAL LYMPH NODE ASSAY BY USING A COMMON VEHICLE FOR THE TEST MATERIAL AND ALPHA-HEXYLCINNALDEHYDE.

D. Hoban, P. Bennet, M. Golt, M. Fallers, S. Gude, M. Wilford and S. E. Loveless. *DuPont Haskell Global Centers for Health and Environmental Sciences, Newark, DE.*

The Local Lymph Node Assay (LLNA) requires the inclusion of a known sensitizer as a positive control as described in the OPPTS 870.2600 EPA Health Effects Test Guidelines. Historically, a 21% solution of the commercially available alpha-hexylcinnamaldehyde, tech., 85% (HCA, CAS 101-86-0) has been diluted in an acetone-olive oil (4:1 v/v) solution (AOO) and applied to the dorsum of the ears of a group of mice. This approach worked well when the test substance was also soluble

in AOO. However, many times another solvent/vehicle was selected for the test material on the basis of maximizing the test concentration while producing a solution/suspension suitable for application. When a solvent/vehicle other than AOO was selected, an additional group of mice was added to the assay. This additional group served as the positive control vehicle group, since AOO was used to prepare the positive control (21% HCA in AOO), and increased the number of animals required per assay. This study evaluated 21% and 30% alpha-hexylcinnamaldehyde, tech., diluted in various common vehicles; AOO, N,N-dimethylformamide, methyl ethyl ketone, propylene glycol, and dimethyl sulfoxide to demonstrate their use as routine vehicles for the positive control to produce dermal sensitization in mice using the LLNA. The mice dosed with 30% HCA in the various vehicles resulted in SI values (range 5.61-15.78) similar to those achieved with 21% HCA (range 4.36-8.85). Therefore, these vehicles are suitable to use as a solvent/vehicle for preparing 21% HCA, thereby reducing the number of animals per assay.

PS 1524 ICCVAM TEST METHOD RECOMMENDATIONS FOR THE REDUCED LLNA (RLLNA): AN ALTERNATIVE TEST METHOD USING FEWER ANIMALS TO ASSESS THE ALLERGIC CONTACT DERMATITIS POTENTIAL OF CHEMICALS AND PRODUCTS.

M. Wind[1], J. Matheson[1], A. Jacobs[2], R. Tice[3] and W. Stokes[3]. *[1]U.S. CPSC, Bethesda, MD, [2]U.S. FDA, Silver Spring, MD and [3]NICEATM, NIEHS, Research Triangle Park, NC.*

Based on recommendations by ICCVAM in 1999, U.S. regulatory agencies that require the submission of skin sensitization data accepted the LLNA, with identified limitations, as an alternative to guinea pig tests for assessing allergic contact dermatitis (ACD). In January 2007, the CPSC nominated several activities related to the LLNA for evaluation by ICCVAM and NICEATM. One of the nominated activities was an assessment of the usefulness and limitations of the rLLNA. In the rLLNA, each substance is tested at one dose level only (the high dose), whereas in the traditional LLNA, a minimum of three dose levels is tested. NICEATM and ICCVAM conducted a retrospective review of traditional LLNA data from 11 different sources that included 457 unique substances tested in 471 traditional LLNA studies. The ability of the rLLNA to correctly identify potential skin sensitizers was compared to traditional LLNA results. Based on the available data, the rLLNA has an accuracy of 99% (465/471), a false positive rate of 0% (0/153), and a false negative rate of 2% (6/318) when compared to the traditional LLNA. Based on these data, ICCVAM concluded that the rLLNA is sufficiently accurate to distinguish between skin sensitizers and non-sensitizers. Therefore, ICCVAM recommends that the rLLNA test method should be routinely used for determining the ACD potential of chemicals and products. ICCVAM has also made recommendations for a standardized rLLNA protocol, future studies to potentially improve the usefulness and applicability of the rLLNA, and the use of LLNA performance standards for modified rLLNA test methods. The comprehensive ICCVAM evaluation of the rLLNA should facilitate regulatory agency decisions on the acceptability of the method. Use of the method by industry can then be expected to significantly reduce animal use for ACD testing while continuing to support the protection of human health. ILS staff supported by NIEHS contract N01-ES-35504.

PS 1525 LYMPH NODE CELL COUNT AS A USEFUL ALTERNATIVE FOR EVALUATING LLNA RESULTS.

B. van Ravenzwaay, A. O. Gamer and R. Landsiedel. *BASF SE, Ludwigshafen, Germany.* Sponsor: A. Doi.

Alternative endpoints have been evaluated to replace the use of radioactivity or the injection of toxic chemicals such as BrdU, following the initial development of the local lymph node assay based on lymph node cell proliferation measured by ^{3}H-Thymidine incorporation into the lymph node cells. Authors have recommended that the evaluation of cell proliferation be based on measuring the number of cells in the single cell suspensions produced from the ear lymph nodes. Cell count proved to be useful for evaluation of LLNA results in a multi center study if the cut off stimulation index (SI) for positive tests was adjusted to reflect the overall range of cell count increase. We have integrated measurements of cell count into the process of cell preparation for the radioactive LLNA in the conduct of our routine testing. The comparison of both endpoints in a project examining the skin sensitizing potency of 13 epoxy resin constituents (epoxides and amines) showed very good congruence of test evaluation. Data from more than 50 additional studies with a variety of compounds of different chemical classes, as well as mixtures, showed a non linear correlation between ^{3}H-thymidine incorporation and lymph node cell count. When using a SI of 1.5 for cell count as the cut off to predict a positive response in CBA/J mice, equivalent estimated concentrations (ECs) for the prediction of skin sensitizing potency are obtained in the majority of cases with both measurements.

PS 1526 ALLERGEN-INDUCED INTERLEUKIN 2 EXPRESSION : CELLULAR SOURCE AND FUNCTION.

C. Portsmouth[1], M. Cumberbatch[1], C. E. Griffiths[2], I. Kimber[1] and R. J. Dearman[1]. *[1]Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom and [2]Dermatological Sciences, University of Manchester, Manchester, United Kingdom.*

Prolonged (13 day) exposure of BALB/c strain mice to the contact allergen 2,4-dinitrochlorobenzene (DNCB) or to the respiratory sensitizer trimellitic anhydride (TMA) preferentially activates T helper (h) 1 and Th2 cells, respectively. In the current investigations, early events that may initiate the polarization of these responses have been examined. BALB/c strain mice were exposed to a single topical dose of either 1% DNCB or 25% TMA, or to vehicle alone, for 6 and 16h. Draining auricular lymph nodes were excised and cytokine production by draining lymph node cells (LNC) measured by cytokine multiplex bead array. DNCB exposure provoked rapid production of interleukin (IL)-2, and, with somewhat delayed kinetics, IL-17 and interferon (IFN)-γ. Relatively low levels of these cytokines were recorded after similar treatment with TMA or vehicle at these early time points. Prior to culture, LNC preparations were depleted of various cell populations using magnetic bead separation and the effect on cytokine production was analyzed. Removal of cells expressing B220, a B cell marker, was without effect on IL-2, IL-17 or IFN-γ expression. Depletion of cells expressing CD25, the high affinity IL-2 receptor expressed primarily by activated T cells and natural killer (NK) cells, reduced IL-2 expression and abrogated secretion of IL-17 and IFN-γ. Removal of cells expressing the NK cell marker CD49b also resulted in reduced production of these three cytokines. Finally, depletion of cells expressing the dendritic cell (DC) marker CD11c inhibited IL-2 expression completely as well as reducing IL-17 and IFN-γ secretion. These data suggest that there are complex interactions between DC, NK and T cells in DNCB-activated LNC that result in the observed cytokine secretion profile and subsequent Th1 polarization of the immune response. DNCB-activated DC are the likely source of the IL-2 that serves to stimulate the production of IL-17 and IFN-γ by other skin draining LNC, probably NK and activated T cells.

PS 1527 MECHANISTIC APPROACH TO DEVELOPING AN *IN VITRO* SKIN SENSITIZATION TEST "HUMAN CELL LINE ACTIVATION TEST (H-CLAT)".

Y. Nukada, T. Abo, Y. Ito, M. Miyazawa, H. Sakaguchi and N. Nishiyama. *Safety Science Research Laboratories, Kao Corporation, Tochigi, Japan.* Sponsor: A. Javier.

We have been developing the "human Cell Line Activation Test (h-CLAT)", an in vitro skin sensitization test, based on augmentation of CD86/CD54 expression in THP-1 cells. From the examination of 100 chemicals, 83 chemicals were identified correctly. Inter-laboratory studies have found the h-CLAT to be reliable and reproducible. Thus, the h-CLAT is thought as a useful in vitro skin sensitization test. While both CD86 and CD54 expression are important to form the skin sensitization, we previously showed that some allergens augmented only CD86 or CD54 expression. Moreover, most allergens augmented these expressions at subtoxic concentrations. The purpose of this study is to clarify these phenomena. First, we investigated why some allergens induce only CD86 or CD54 expression. We hypothesized that exposure time is not enough for strong augmentation of the expression in these allergens. Presently exposure to some chemicals causes induction of only CD54 in h-CLAT after 24h. When exposure time was increased, both CD54 and CD86 were induced. Next, we investigated the relationship between CD86/CD54 expression and cytotoxicity induced by allergen stimulation. We first investigated whether dead cells induced by allergens effect the augmentation of CD86/CD54 expression. But dead cells did not have much influence to CD86/CD54 expression. We next examined how cytotoxicity is induced by allergens. Since allergens strongly induced apoptotic cell death, we therefore performed the inhibition assay using caspase inhibitors. Treatment with inhibitor suppressed apoptosis and almost recovered cell viability at 24h after treatment with allergens. These result indicated that allergens induced both CD86/CD54 expression and cytotoxicity respectively. In conclusion, most allergens have a potential for inducing both CD86 and CD54 expression in THP-1 cells. Moreover, CD86/CD54 expression and cytotoxicity are both induced by allergens respectively. These results suggest that the criterion of h-CLAT is accurately based on the specific response of allergens.

PS 1528 ACCEPTABILITY OF THE MOUSE LOCAL LYMPH NODE ASSAY FOR PESTICIDE FORMULATION HAZARD ASSESSMENT.

S. C. Gehen[1], C. M. Wiescinski[2], M. Woolhiser[2] and R. Billington[3]. *[1]Dow AgroSciences, LLC, Indianapolis, IN, [2]The Dow Chemical Company, Midland, MI and [3]Dow AgroSciences, LLC, Abingdon, United Kingdom.*

The LLNA is widely regarded as a sensitive skin sensitization test and provides animal welfare benefits relative to guinea pig (M&K, Buehler) tests. For these reasons, the LLNA is now the preferred test for hazard assessment of substances and formu-

lated products, particularly in the EU. Recently, the acceptability of testing 'mixtures' via the LLNA has been questioned by U.S. agencies; subsequent evidence indicates such data are reliable (Boverhof et al. ToxSci, 2008). Due to animal use practices, the same formulations are not typically tested in multiple assays, precluding direct comparison for this evaluation. Thus, to further assess the validity of the LLNA for testing pesticide formulations, a retrospective analysis was performed on LLNA (n=52), M&K (n=31) and Buehler (n=32) data for Dow products. The positive response rate was 63.5 %, 58.1% and 19.4% respectively. Considering the sensitization potential for these formulations' active ingredients, 78% of formulations tested in the LLNA with sensitizing active ingredients were positive. With the M&K assay, 82% of the formulations containing a sensitizing active were positive while only 42% were positive with the Buehler assay. In cases where the same formulation was tested using multiple methods (n = 6), there has been good agreement. Four such products were evaluated in an interlaboratory comparison (Boverhof et al., 2008); 2 positive Buehler results were confirmed using the LLNA (EC3 = 26.8% and 1.1%), and 2 borderline negative results (one M&K and one Buehler) were positive in an LLNA. Lastly, two recent Buehler studies confirmed negative LLNA findings. These results substantiate the widely held belief that the LLNA is as sensitive as the M&K and superior to the Buehler test for hazard assessment of pesticide formulations.

PS 1529 A PLASMACYTOID DENDRITIC CELL-BASED ASSAY TO SCREEN THE ALLERGENICITY POTENTIAL OF CHEMICALS.

S. Ayehunie, M. Klausner, J. E. Sheasgreen and P. J. Hayden. *MatTek Corporation, Ashland, MA.*

An in vitro assay system that utilizes human cells to predict the allergenicity potential of chemicals will have utility throughout industry to monitor products for contact sensitization. Development of such a non-animal alternative assay system for hazard assessment is within the provisions of the European Union chemicals policy known as REACH (Registration, Evaluation, and Authorization of Chemicals). In this study, we investigated whether the CD86 expression level in plasmacytoid dendritic cells (pDC) could be used as a non-animal alternative to test for contact allergens. To achieve this goal, human DC were generated from CD34+ progenitor cells and the pDC fraction (CD123+/CD11c-) was harvested using FACS sorting. The pDC were exposed to chemical allergens (n=23) or irritants (n=18). Sub-toxic concentrations of each chemical were determined using FACS analysis of propidium iodide stained cells. Allergens were identified based on stimulation index (SI) calculated by the fold increase in CD86 expression. A material that had an SI ≥ 1.5 in at least 50% of the pDC donors (n = 2-5 donors) was considered an allergen. Using this methodology, allergens increased expression of CD86 ≥ 1.5 fold in 23 of 23 allergens (100%) but not for 78% of non-allergens (n=18). Based on these results, a preliminary prediction model was developed to identify chemical allergens (sensitivity = 100%, specificity = 78%, and accuracy = 89%). In conclusion, CD86 expression in pDC appears to be a sensitive and specific predictor of allergenicity of chemicals. The assay is advantageous because high throughput screening of chemicals is possible, donor-to-donor variation can be monitored, the cells are of human origin, and the assay is cost effective.

PS 1530 APPLICATION OF TRYPTOPHAN FLUORESCENCE TO ASSESS SENSITIZING POTENTIALS OF CHEMICALS.

T. Pham, T. Oyama, T. Isse and T. Kawamoto. *environmental health, university of occupational and environmental health, Kitakyushu, Japan.*

We aimed to develop a simple in vitro method to quantitatively predict the sensitizing potentials of chemicals by measuring the fluorescence of chemical-HSA complexes. Human serum albumin (HSA) was treated with test chemicals and then analyzed by tryptophan fluorescence and protein concentration measurement. Four strong sensitizers (toluene 2,4-diisocyanate (TDI), phthalic anhydride, glutaraldehyde, bisphenol A diglycidyl ether), two weak sensitizers (bisphenol A, 4,4'-diamindiphenyl ether designated by only one organization), and two non-sensitizers (2,5' hexandione, phthalic acid) were examined by using the tryptophan fluorescence assay. HSA fluorescence at 280 nm of excitation and 340 nm of emission was reduced by TDI, dose-dependently. The addition of TDI immediately reduced the fluorescence and was stable 6 h to 21 days after treatment, with a slight decrease. The reduction of HSA fluorescence by chemicals was in the order: strong sensitizers > weak sensitizers > non-sensitizers. Chemical treatment at 0.05 and 0.5 mM leads to an optimal separation among the three groups. Ortho-phthalaldehyde (OPA), which has not been evaluated regarding its sensitization potential by any of the authorized organizations, reduced HSA fluorescence as much as the strong sensitizer at final concentrations of 0.05 and 0.5 mM of the chemical. According to our method, OPA is evaluated as a strong sensitizer. The treatment of all test chemicals did not cause obvious differences in the total protein concentration by either the Lowry or Bradford method. The assay utilizing tryptophan fluorescence loss of HSA after chemical treatment is a promising method to evaluate the sensitizing potentials of chemicals.

The study was supported partly through a grant of LRI by JCIA.

PS 1531 EXPOSURE TO ULTRAFINE PARTICLES DURING ALLERGIC SENSITIZATION YIELDS AN ALTERED LUNG EPITHELIAL STRUCTURE.

C. M. Carosino[1], J. R. Harkema[2] and K. E. Pinkerton[1]. *[1]University of California, Davis, Davis, CA and [2]Michigan State University, East Lansing, MI.*

Particulate matter (PM) has been shown to exacerbate allergic airway diseases. Exposure to high PM air is a common occupational and often atmospheric hazard. Recent studies demonstrate ambient ultrafine particles (UFP) may act as an adjuvant in Ovalbumin-induced allergic sensitization via the addition of small quantities of intranasally instilled UFPs with Ovalbumin (Ova). The objective of this study was to investigate the effect of ultrafine particles via inhalation and/or instillation during the sensitization phase of an allergic mouse model. Male eight week old Balb/c mice were sensitized with 10μg Ova on days 2, 3, and 4, challenged with 40mg/m3 Ova for 1 hour on days 12 and 13, and sacrificed on day 14. Some animals additionally received collected UFP instilled with the Ova, inhalation exposure to UFP for 5 hours/day for days 1-5 following Ova instillation or both treatments combined. The UFPs are generated and collected on-site with an average concentration of 224.6μg/m3 and an average size of 53.5 ± 3.8nm. Histology of the fixed lung revealed significantly increased mucin content in the animals sensitized with UFP and Ova than in animals primed with Ova alone. Previous studies have shown no increase in mucin content with UFP alone or in the challenge phase. Interestingly, total IgE appears that it may be lower in UFP and Ova exposed animals than Ova alone, though not statistically significant. This study indicates with the addition of UFP during the priming phase, an altered allergic response results and this could further explain some of the epidemiological trends we witness in asthmatic patients living and working in high PM areas.

PS 1532 RAT SERUM ANTIBODIES INDICATE OXIDATIVE STRESS AND RENAL TOXICITY, BUT NOT NEUROTOXICITY FOLLOWING SUBCHRONIC ORAL EXPOSURE TO SODIUM TUNGSTATE.

W. C. McCain[1], T. M. Henson[2], K. Mozzachio[3], G. Leach[1] and H. A. El-Fawal[4]. *[1]Toxicology, U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD, [2]Mercy College, Dobbs Ferry, NY, [3]Biotechnics, Hillsborough, NC and [4]Albany College of Pharmacy and Health Sciences, Albany, NY.*

The health effects of tungsten are of concern to both the public and military personnel. Exposure via groundwater contamination is of particular interest near military installations. The present study assessed the effects of oral tungsten in 120 day old male (n=10/exposure) and female (n=10/exposure) Sprague-Dawley rats administered tungsten as sodium tungstate dihydrate at 0, 10, 75, 125 or 200 mg/kg for 90 consecutive days. Toxicity was assessed by measuring autoantibodies against nervous system and renal proteins using ELISA. Neither IgM, nor IgG antibodies against neurofilament triplet or gliotypic proteins (glial fibrillary acidic protein and myelin basic protein) were detected in rat sera. However, sera of both male and female rats had IgG titers against glomerular basement membrane protein (GBM), with titer levels being significantly higher in female rats. Renal involvement was consistent with the histopathology in some animals that manifested chronic progressive nephropathy with lymphocytic infiltrates. In this gender, anti-GBM was highest at 75 and 125 mg/kg tungsten, but lower at 200 mg/kg. This was also seen with the significant decline in total IgG seen in this group and suggestive of immunological effects. In addition, all exposed rats had detectable titers of IgM and IgG against the mitochondrial phospholipid cardiolipin (CL), indicative of oxidative stress and cell injury. These results indicate that oral tungsten exposure results in serological and pathological changes indicative of renal insult. This may be associated with the induction of oxidative stress at the doses used. This is surprising in light of tungstens use in renal therapy. In addition, the study confirms that antibody detection may be useful in defining toxic effects of environmental exposures in human populations.

PS 1533 REACTIVITY AND TOXICITY OF ENDOGENOUS ALDEHYDES GENERATED *VIA* DOPAMINE CATABOLISM.

L. L. Eckert, J. N. Rees, V. R. Florang and J. A. Doorn. *Medicinal and Natural Products Chemistry, The University of Iowa, Iowa City, IA.*

Over 1 million Americans are currently affected by Parkinson's disease (PD). The cause of PD hallmark dopaminergic neuronal death is currently unknown, but recent research implicates oxidative stress leading to increased levels of an endogenous

neurotoxin, 3,4-dihydroxyhenylacetaldehyde (DOPAL). DOPAL is generated from DA by monoamine oxidase (MAO) and oxidized to 3,4-dihydroxyphenylacetic acid by aldehyde dehydrogenase. DA and metabolites are methylated at the 3-hydroxy position by catechol-O-methyltransferase (COMT) to generate 3-methoxytyramine (3-MT), 3-methoxy-4-hydroxyphenylacetaldehyde (MOPAL), and 3-methoxy-4-hydroxyphenylacetic acid (homovanillic acid). MOPAL can also be generated through oxidative deamination of 3-MT by MAO. DOPAL has been shown to modify protein amines (e.g. lysine), but the reactivity of MOPAL toward amino acids is currently unknown. MOPAL was biosynthesized by oxidative deamination of 3-MT catalyzed by mouse liver MAO. A novel synthesis of MOPAL was also devised and used. N-Acetyl Lysine (NAL) and other individual amino acids were reacted with MOPAL and the kinetics of these reactions were measured by HPLC. It was determined that MOPAL is reactive toward NAL, but 6-fold less reactive than DOPAL, based on measured rate constants. Also, the NAL-MOPAL adducts are considerably less stable than DOPAL adducts, and the reducing agent, sodium cyanoborohydride, must be included in the reaction mixture to stabilize the modification. Also, MOPAL minimally competes with DOPAL for protein binding, shown by a co-incubation of the aldehydes at various ratios with protein and staining for the presence of catechol adducts with nitro blue tetrazolium. These results suggest methylation activity by COMT on DOPAL as a route of detoxification. The ability of MOPAL to modify proteins is of significant interest, as PD patients are frequently administered COMT inhibitors as a part of their therapy, and inhibition of MOPAL formation could lead to increased levels of DOPAL and increased toxicity.

PS 1534 THE MECHANISM OF TOXICITY OF 3, 4-DIHYDROXYPHENYLACETALDEHYDE, AN ENDOGENOUS NEUROTOXIN.

J. N. Rees, V. Florang and J. A. Doorn. *Medicinal and Natural Products Chemistry, The University of Iowa, Iowa City, IA.*

Parkinson's disease is a neurodegenerative disorder characterized by cell death of dopaminergic neurons. Previous and current studies indicate that cell death may originate from increased oxidative stress leading to augmented levels of an endogenous neurotoxin. Within dopaminergic neurons, dopamine (DA) is metabolized to 3,4-dihydroxyphenylacetaldehyde (DOPAL) through oxidative-deamination catalyzed by monoamine oxidase. DOPAL is then primarily oxidized to 3,4-dihydroxyphenylacetic acid by mitochondrial aldehyde dehydrogenase. Previous work demonstrated DOPAL to be highly toxic to dopaminergic cells, and the mechanism of toxicity is hypothesized to involve protein modification as DOPAL contains two reactive functional groups, i.e. catechol and aldehyde. Oxidation of the catechol yields a cysteine-reactive quinone, which is known to occur for DA; however, the aldehyde may form adducts with lysine residues. In addition, the stability of each adduct under physiologic conditions is of question, especially for lysine as Schiff base products often require reduction for stability. The goal of this work is to determine if protein modification by DOPAL occurs via cysteine or lysine residues. Results demonstrate that at pH 7.4 and 37 deg C, the order of DOPAL reactivity is: N-acetyl lysine (NAL) >> N-acetyl cysteine. The kinetics of NAL modification by DOPAL were measured, and it was found that the product of NAL and DOPAL was stable in the absence of reducing agent. Moreover, DOPAL will react with model proteins, but in the presence of the lysine modifier citraconic anhydride or 2-iminothiolane hydrochloride, a modifier that converts amines to thiols, the reactivity of DOPAL towards the proteins is diminished. In addition, it has been established, through mass spectrometry, that DOPAL will form a stable, Schiff base adduct with amine containing model peptides. These results indicate that DOPAL has a unique structure that leads to protein modification via amine residues.

PS 1535 OXIDATION AND REACTIVITY OF THE DOPAMINERGIC METABOLITE 3, 4-DIHYROXYPHENYLACETALDEHYDE.

D. Anderson, V. Florang and J. A. Doorn. *Medicinal and Natural Products Chemistry, University of Iowa, Iowa City, IA.*

Parkinson's disease involves progressive neurodegeneration and loss of dopaminergic neurons. It currently afflicts over a million patients in the U.S. The disease pathology is known to involve multiple factors, one of which is the inherent toxicity of the neurotransmitter dopamine (DA). The ability of DA to auto-oxidize to an ortho-quinone plays a role in its cytotoxicity, resulting in increased protein reactivity, thiol depletion, and redox cycling. In the presence of transition metals, DA-quinone formation can also trigger reactive oxygen species production. Certain metabolites of DA such as 3,4-dihydroxyphenylacetaldehyde (DOPAL) may also be involved in PD and act as endogenous neurotoxins. However, little is known about DOPAL's ability to similarly undergo auto-oxidation to a reactive quinone. If confirmed, DOPAL-quinone formation would help explain the high levels of toxicity associated with this aldehyde metabolite. NaIO4 and Tyrosinase, which are known to induce DA-quinone formation, were investigated for their ability to oxidize DOPAL. Experimental evidence indicates that DOPAL is susceptible to oxidation, as these methods induced oxidative rearrangement of DOPAL both colorimetrically and spectrophotometrically. Such species demonstrated selective reactivity toward glutathione and N-acetyl cysteine, which is a strong indicator of protein reactivity. A direct quantitative method that may be useful for determining the stoichiometry of thiol addition relevant to oxidized DOPAL by measuring N-acetyl cysteine concentrations was also demonstrated. Furthermore, DOPAL was found to be sensitive to transition metal catalyzed oxidation. Treating DOPAL with Cu2+ in solution resulted in UV-Vis absorption spectra increases also observed with tyrosinase oxidized DOPAL. Such experiments elucidate the potential of DOPAL to undergo auto-oxidation and participate in redox cycling, similar to DA. Ultimately, determining the biological relevance of such oxidized species will reveal their role in Parkinson's disease.

PS 1536 MODIFICATION OF TYROSINE HYDROXYLASE BY 3, 4-DIHYDROXYPHENYLACETALDEHYDE, A REACTIVE INTERMEDIATE OF DOPAMINE CATABOLISM.

L. M. Mexas, V. Florang, J. Yunden and J. A. Doorn. *Medicinal and Natural Products Chemistry, University of Iowa, Iowa City, IA.*

Parkinson's disease (PD) is a neurodegenerative disease that affects the dopaminergic neurons of the substantia nigra, causing a variety of motor disabilities. Dopamine (DA) is a neurotransmitter that undergoes catabolism to form 3,4-dihydroxyphenylacetaldehyde (DOPAL). DOPAL is structurally analogous to DA, but is a reactive intermediate; therefore, it has the potential to interact with proteins containing DA-binding sites. There is evidence that DOPAL, at pathological levels, modifies proteins in dopamine neurons; however, the identity of the protein targets and effect on protein function are not known. It is hypothesized that DOPAL modifies and inhibits enzymes important for dopamine biosynthesis and trafficking. Tyrosine hydroxylase (TH) is the enzyme that catalyzes the formation of L-3,4-dihydroxyphenylalanine (L-DOPA) from tyrosine, and it is the rate-limiting step in dopamine synthesis. Isolated mice striatal synaptosomes and nerve growth factor differentiated PC6-3 cells containing TH, were obtained and treated with varying concentrations of DOPAL. HPLC-ECD was used to show tyrosine hydroxylase activity (i.e. the linear increase in L-DOPA formation over time). Using Western blotting, it was found that the treatment of cell lysate with DOPAL (10-100μM) for 4 hours yielded a decrease in TH signal, indicating a loss of antibody recognition and protein modification. Such a result suggests that the reactive and toxic intermediate DOPAL may adversely affect TH and DA biosynthesis.

PS 1537 DISRUPTION OF CATECHOLAMINE HOMEOSTASIS PROMOTES OXIDATIVE DAMAGE AND NEURODEGENERATION.

T. N. Taylor[1, 2], K. R. Shepherd[1, 2] and G. W. Miller[1, 2]. [1]*Environmental and Occupational Health, Emory University, Atlanta, GA and* [2]*Center For Neurodegenerative Disease, Emory University, Atlanta, GA.*

Previously, we have shown that mice with reduced vesicular monoamine storage (VMAT2 LO) display behavioral deficits associated with Parkinson's disease (PD) and progressive neurodegeneration in the substantia nigra (SNpc) and locus coeruleus (LC). Traditional chemical models of PD rely on oxidant-mediated mechanisms to cause neuronal cell death, resulting in the rapid onset of symptoms as opposed to the slow degeneration seen in VMAT2 LO mice. These models typically utilize the unique ability of dopamine (DA) and norepinephrine (NE) to auto-oxidize and form deleterious cysteinyl adducts. VMAT2 normally sequesters catecholamines, protecting against neuronal damage; however, when VMAT2 is reduced, cytosolic DA and NE are increased, potentially leading to cellular damage. Here, we examined the generation of oxidant species in catecholaminergic cellular degeneration. In VMAT2 LO mice, we observe a marked reduction in total DA and NE in the striatum and hippocampus, presumably due to increased turnover. When postnatal SN or LC neurons were cultured and exposed to physiological concentrations of either DA or NE, cells from VMAT2 LO mice undergo increased oxidative stress via formation of H2O2 and other oxidants, as measured by DCF fluorescence; whereas, WT cells were unaffected. Similarly, SN or LC cells from VMAT2 LO mice were susceptible to catecholamine-induced cell death. In order to study the subcellular redox consequences of alterations in VMAT2 expression, we used HEK293 cells stably transfected with the DA transporter (DAT) and VMAT2.

However, we failed to reproduce the same cytosolic oxidative stress seen in primary culture. This may be due to the lack of a catecholaminergic phenotype or the absence of glial cells, suggesting the HEK293 cells may be inappropriate to study DA and NE toxicity. Overall, our data suggest that catecholamine-rich brain regions other than the SNpc display similar vulnerability to neurodegeneration and likely contribute to the overall presentation of symptoms.

PS 1538 DOPAMINERGIC TOXICANT (MPTP) EFFECTS ON THE STRIATAL AND NIRGAL MITOCHONDRIAL PROTEOMES: IMPLICATIONS FOR PARKINSON'S DISEASE.

R. B. Pringle[1], T. Pechan[2], J. Tang[2] and N. M. Filipov[1, 3]. *[1]CEHS, Basic Sci., Mississippi State University, Mississippi State, MS, [2]LSBI, Mississippi State University, Mississippi State, MS and [3]Physiol. & Pharmacology, University of Georgia, Athens, GA.*

Mitochondrial dysfunction has been linked to several neurodegenerative diseases, including Parkinson's Disease (PD). Environmental toxicants, including pesticides, PCBs, and certain metals (Mn, Fe), are known to have harmful effects on the nervous system, and are also mitochondrial disrupters. Studies linking neurodegeneration to toxicant exposure at a whole mitochondrial proteome level are lacking. Hence, our goal is to establish profiles of global quantitative differences in the mitochondrial proteome of brain regions affected by dopaminergic toxicant exposure, using MPTP, a known dopaminergic toxicant, as our initial model. Adult, male C57BL/6 mice were treated with MPTP and sacrificed 7 days later. Brain tissues from the substantia nigra (SN) and striatum (STR) were used for proteomic analyses utilizing iTRAQ (multiplexed isobaric tagging technology). Neurochemistry detection (HPLC-ECD) and standard western blot techniques were also used. Dopamine, its metabolites, and tyrosine hydroxylase were significantly decreased in MPTP treated mice. Additionally, GFAP levels were significantly elevated by MPTP. Proteomic analyses identified 449 and 331 proteins in the STR and SN, respectively, and about 30% were mitochondrial. Overall, MPTP treatment altered the expression of more proteins in the STR compared to the SN. Interestingly, a number of proteins (i.e., ADP/ATP carrier protein 1, creatine kinase, hexokinase, cytochrome c) were decreased by MPTP in the STR, while increased in the SN. This finding suggests that either terminal fields (STR) are damaged first, or that following insult, energy is repartitioned to allow the cell bodies (SN) to stay functional longer. Our methods seem capable of detecting quantitative mitochondrial proteome changes, and this technique may establish a tool to screen potential basal ganglia or mitochondrial toxicants. (Support: LSBI/USDA Pi-lot Grant and NIEHS ES11654)

PS 1539 PRE-TREATMENT WITH NEAR-INFRARED LIGHT ATTENUATES THE CYTOTOXIC EFFECTS OF MPP+ IN SH-SY5Y HUMAN NEUROBLASTOMA CELLS.

K. D. DeSmet[1], M. Henry[2], E. V. Buchmann[2], H. T. Whelan[2, 1] and J. T. Eells[1, 2]. *[1]Clinical Laboratory Sciences, University of Wisconsin-Milwaukee, Milwaukee, WI and [2]Neurology, Medical College of Wisconsin, Milwaukee, WI.*

A large body of evidence supports a central role for mitochondrial dysfunction in the pathogenesis of Parkinson's Disease (PD). PD patients express systemic defects in mitochondrial complex I activity and complex I inhibitors have been shown to produce PD. There are also inherited forms of PD that result from mutations in genes that code for α-synuclein. The underlying pathological feature in both genetic and environmentally induced forms of PD is mitochondrial dysfunction resulting in increased production of reactive oxygen species followed by subsequent cell death of dopaminergic neurons in the substantia nigra. Photobiomodulation by far-red to near-infrared (630 to 1000 nm) light has been shown to enhance mitochondrial energy production and promote cellular survival following a mitochondrial insult. The present studies were undertaken to test the hypothesis that pre-treatment of human neuroblastoma cells engineered to stably overexpress the A30P mutant form of α-synuclein with near-infrared (NIR) light emitting diode (LED) treatment will attenuate the toxic effects of MPP+, a complex I inhibitor. Cells received a total of 4 LED pretreatments, consisting of irradiation at 670 nm for 5 minutes resulting in a power intensity of 50 mW/cm2 and an energy density of 8 J/cm2. Cells were then exposed to increasing concentrations of MPP+ (0 – 5 mM) for 12 hours. Cellular proliferation, lactate dehydrogenase (LDH) release, superoxide production, glutathione concentrations as well as protein expression of BCL-2, BAX, alpha-synuclein, and complex IV were assessed. Results demonstrate that pre-treatment with 670 nm LED light in SH-SY5Y A30P cells exposed to MPP+ reduces LDH release and superoxide production while increasing glutathione production. Pre-treatment with 670 nm LED light can also alter the expression of apoptotic and mitochondrial linked proteins resulting cell survival after MPP+ exposure.

PS 1540 EXPRESSION OF ALPHA-SYNUCLEIN IN RAT DOPAMINERGIC CELLS INCREASED SUSCEPTIBILITY TO MANGANESE LINKED TO OXIDATIVE STRESS, MAP KINASES AND NF-κB MEDIATED NEURONAL INJURY.

K. Prabhakaran, G. D. Chapman and P. G. Gunasekar. *Naval Health Research Center Detachment Environmental Health Effects Laboratory, Wright-Patterson AFB, Dayton, OH.*

Researchers have reported that Navy personnel who are exposed to dust and fumes from welding, thermal cutting, and boiler maintenance may be at risk of manganese (Mn) poisoning. Inhalation exposure to high levels of Mn can lead to a disabling neurological syndrome "manganism" which resembles Parkinson's disease. Understanding pathogenic mechanisms of Mn exposure is important to provide effective treatment modalities. We proposed recently that nuclear factor kappaB (NF-κB) and oxidative stress are major factors in Mn exposure-induced neurodegeneration. To further clarify the roles of oxidative stress and redox signaling response in neuronal injury, we over- expressed alpha-synuclein (a pre-synaptic protein implicated in neurodegenerative disorders including PD) in rat dopaminergic cells (Mes 23.5 cell line) and explored the involvement of this protein in conjunction with oxidative stress, NF-κB induction, p38-MAPK and c-Jun N-terminal kinase, following Mn exposure. We found that over-expression of wild-type human alpha-synuclein significantly enhanced the cell death due to Mn as evidenced through apoptosis. Mn exposure-induced cell death was characterized by significant increased NF-κB nuclear translocation as shown by nuclear binding activity. Pretreatment with anti-oxidants, p38-MAPKs (SB239063) and c-Jun N-terminal kinase (SP600125) inhibitors significantly reduced NF-κB activation, supporting the role of oxidative stress and MAPKs in NF-κB induction. Furthermore, nitric oxide (NO) generation in association with NF-κB was blocked by SN-50 and p38-MAPK inhibitor. These events are accompanied by decreased apoptosis by SN-50 and iNOS specific inhibitor (1400W). Hence, these data suggest that alpha-synuclein regulates ROS and associated MAP kinases signaling, NF-κB and NOS in dopaminergic neurons. As a result, changes in the response of these cells to Mn make dopaminergic neurons vulnerable to Mn toxicity.

PS 1541 GLIAL ACTIVATION-MEDIATED DOPAMINERGIC NEUROTOXICITY INDUCED BY MANGANESE AND LIPOPOLYSACCHARIDE: ROLE OF FREE RADICALS.

B. Liu[1, 2], K. M. Lokuta[1], D. E. Turner[1] and P. Zhang[1]. *[1]Pharmacodynamics, University of Florida, Gainesville, FL and [2]McKnight Brain Institute, University of Florida, Gainesville, FL.*

Excessive exposure to manganese can lead to damage to the basal ganglial neurons and the development of Parkinsonian movement disorder. Inflammation in the brain, in the mean time, has been increasingly associated with the pathogenesis of Parkinson's disease (PD) that is resulted from the degeneration of the nigrostriatal dopaminergic (DA) pathway. In this study, we aimed to determine the combined effects of elevated exposure to manganese and the occurrence of inflammation on the degeneration of DA neurons and the potential mechanism of action in the primary mesencephalic neuron-glia cultures. Manganese chloride (MnCl2, 10-300 μM) was significantly more effective in inducing a preferential degeneration of DA neurons in the neuron-glia cultures than in the neuron-enriched and microglia-depleted cultures. This enhancement of DA neurotoxicity was attributed to, at least in part, the activation of glial cells by MnCl2 and the increased production of free radicals. On the other hand, activation of glia, especially microglia with bacterial endotoxin lipopolysaccharide (LPS, 1-10 ng/ml) induced a time- and concentration-dependent DA neurodegeneration. When cultures were treated with combinations of minimally effective concentrations of MnCl2 and LPS, the magnitude of DA neurodegeneration induced by the combinations was significantly greater than that induced by either toxicant alone. Mechanistically, MnCl2 was found to be capable of augmenting the production of proinflammatory and cytotoxic cytokines and free radicals that are particularly deleterious to the oxidative damage-prone DA neurons. Neutralization of free radical reactivity by antioxidants or inhibition of microglial activation afforded significant protection of DA neurons against damage induced by MnCl2 and LPS. These results may be of relevance not only to the understanding of the neurotoxicity induced by over exposure to manganese but also to the determination of potential multi-factorial etiology of idiopathic PD.

PS 1542 PHARMACOGENETIC AND BIOCHEMICAL ANALYSIS OF PARKINSON'S DISEASE-, MANGANISM, AND DOPAMINE NEURON-ASSOCIATED PROTEINS IN C. ELEGANS: EFFECTS ON MITOCHONDRIA FUNCTION AND DOPAMINE NEURON VULNERABILITY.

R. Settivari, J. LeVora and R. Nass. *Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Manganese (Mn) neurotoxicity resembles a number of aspects of the dopamine (DA) neuron degenerating disorder Parkinson's disease (PD). Both PD and manganism is characterized by motor deficits and damage to substantia nigra and other basal ganglia nuclei, and dopamine or its metabolites are believed to contribute to the disorder. The molecular pathways involved in the neuropathology in both disorders are ill defined. Here we describe our expression and biochemical investigations of WT and mutant PD- and DA neuron-associated proteins, and their effects on mitochondria function and DA neurons under basal conditions and following exposure to neurotoxins in PD and manganism C. elegans models. Expression of a number of stress response genes including the C. elegans homologue of GSTpi, is increased in response to several PD-associated toxicants. Gene knock-down (RNAi) of GSTpi increased the susceptibility of DA neurons to the toxicants.. DA neuron vulnerability to Mn is partially dependent on the divalent metal transporter-1 (DMT-1) orthologues Smf-1-3, since knockdown or deletion of the transporters partially protects against the neurodegeneration. Furthermore, expression of the smf genes following Mn2 exposure is dramatically increased in young animals relative to controls, consistent with its putative role in the toxicity. Biochemical analysis show that mutations within some of the PD-associated genes in C. elegans affect mitochondrial membrane potential, respiration capacity, and dopamine and glutathione concentrations. We have also generated antibodies to over 40 C. elegans proteins, including PD-associated orthologues, DA- and putative DAT-associated proteins, and stress response proteins, and we are analyzing protein expression and localization patterns under basal conditions and in response to PD-relevant toxins. Initial results from our genetic screens will also be described.

PS 1543 SUSTAINED STRIATAL IL-1β OVEREXPRESSION AND THE PARKINSON'S DISEASE (PD) PHENOTYPE.

J. Frasca[1], D. A. Cory-Slechta[1], M. K. O.Bannion[2], M. Thiruchelvam[3] and L. A. Opanashuk[1]. *[1]Environmental Medicine, University of Rochester Medical School, Rochester, NY, [2]Neurobiology and Anatomy, University of Rochester Medical School, Rochester, NY and [3]EOSHI, Piscataway, NJ.*

Glial activation-induced inflammatory processes are known to be operative in Parkinson's disease (PD) and suggested to play a role in nigrostriatal dopaminergic cell death, the pathological hallmark of this disease. Such inflammatory cascades include the release of various cytokines, including IL-1β which may contribute to neurodegeneration associated with PD. This study sought to determine whether striatal overexpression of IL-1β, i.e., inflammation at the dopamine (DA) terminal, would enhance the PD phenotype associated with exposure to the herbicide paraquat (PQ). For this purpose, a GFAP IL-1βXAT transgenic young adult male mouse model was used that specifically overexpresses IL-1β in astrocytes. IL-1β was activated via unilateral intra-striatal FIV-cre mediated excision (IL-1βXAT; n=6); two weeks later, a timeframe designed to allow significant glial activation, IL-1βXAT and wild-type (WT; n=4) mice were injected i.p. twice weekly with 5.0 mg/kg of PQ for 6 weeks, and sacrificed 2 weeks following the final PQ injection. IL-1βXAT mice tended to show higher levels of both ambulatory and vertical activity measured immediately after PQ injection and 24 hr later. For both groups, changes in GFAP, a marker of glial activation, and of tyrosine hydroxylase (TH), a measure of DA terminal integrity, were compared histologically, for each animal, across hemispheres; thus each animal served as its own control. Viral activation in IL-1βXAT mice resulted in an approximate 30% increase in GFAP on the activated side, as expected. Moreover, while TH density did not differ between groups, lesions were observed in IL-1βXAT mice in the activated but not the non-activated hemisphere, consistent with fiber loss. Such lesions were not observed in the brain of an IL-1βXAT mouse that did not receive PQ. Collectively, these findings suggest that striatal IL-1β upregulation could enhance striatal DA terminal vulnerability to neurotoxic damage.

PS 1544 MITOCHONDRIAL MECHANISMS OF ROS PRODUCTION AND OXIDATIVE STRESS BY REDOX CYCLING HERBICIDES IMPLICATED IN PARKINSON'S DISEASE.

D. Drechsel and M. Patel. *School of Pharmacy, University of Colorado Denver, Aurora, CO.*

Exposure to environmental pesticides causes significant brain damage and has been linked with the etiology of Parkinson's disease (PD). Bipyridyl herbicides, such as paraquat (PQ) and diquat (DQ) and benzyl viologen (BV), are redox cycling agents (RCAs) known to exert cellular damage through the production of reactive oxygen species (ROS) leading to oxidative stress. However, the site and mechanism of action within the brain of these compounds has not been resolved. The goal of this study was to determine the mechanisms by which redox cycling compounds exert neurotoxicity. Previous work in our laboratory has shown that mitochondria are a major cellular site for PQ-induced H2O2 production. Here, we further characterized the role of mitochondria in redox cycling-induced ROS production and determined if in vivo treatment with PQ results in mitochondrial oxidative stress. Following treatment with redox cycling agents, H2O2 production was attenuated in respiration-deficient SH-SY5Ydopaminergic cells compared to controls. In isolated rat brain mitochondria, DQ and BV stimulated H2O2 production at rates significantly greater than PQ at similar concentrations. RCA-induced ROS production was inhibited by antimycin A suggesting a role for Complex III of the mitochondrial respiratory chain. Additional mechanistic studies further identified the Qi site of cytochrome b within Complex III as the potential site of ROS production by these RCAs. Administration of 10 mg/kg PQ bi-weekly for three weeks significantly increased mitochondria DNA damage assessed by qPCR in PQ-treated mice. Additionally, reduced coenzyme A, an index of the mitochondrial redox status was significantly decreased in the ventral midbrain of PQ-treated mice in comparison with saline-treated mice. These data provide evidence that bipyridyl herbicides are capable of using mitochondria as a site for redox cycling to generate ROS and emphasize the importance of further identifying mitochondrial mechanisms by which environmental agents produce oxidative stress and parkinsonism.

PS 1545 EFFECTS OF MIXED TOCOPHEROLS IN ANIMAL MODELS OF PARKINSON'S DISEASE.

C. Becker, M. Thiruchelvam, J. Kochar and C. Yang. *Joint Graduate Program in Toxicology, Rutgers University, UMDNJ-RWJMS, Environmental & Occupational Health Science Institute, Ernest Mario School of Pharmacy, Piscataway, NJ.*

Parkinson's disease (PD) is a progressive neurodegenerative disorder that affects more than 1.5 million people in the United States alone. An abundance of evidence indicates that oxidative stress leads to the loss of the dopaminergic neurons. Vitamin E (α-tocopherol, αT) has been tested both in animal models of PD as well as in human clinical trials, but with equivocal results. Although αT is the biologically most active form of vitamin E, γ-tocopherol (γT) is the most abundant form found in the U.S. diet and is also a better antioxidant and anti-inflammatory agent. Thus, to determine the efficacy of γT to protect against dopaminergic cell death, animals were pre-treated for 2 months with either a 0.3% mixed tocopherol diet (containing about 60% γT) or control diet and subsequently treated with either saline or 10mg/kg paraquat (PQ) + 30 mg/kg maneb (MB) twice a week for 6 weeks or 20 mg/kg MPTP everyday for 5 days. Both MPTP and PQ+MB exposure caused a significant decrease in striatal dopamine (DA) and metabolite levels in mice on the control diet. However, mice on the mixed tocopherol diet treated with either PQ+MB or MPTP were partially protected against decreases in striatal DA and metabolite levels. In a subsequent experiment, however, mice that were pretreated for only 1 month with 5 different tocopherol enriched diets were not protected against decreases in striatal DA levels from exposure to 20 mg/kg MPTP everyday for 5 days. Interestingly, the diet with the highest tocopherol concentration tested (0.5% mixedT) proved to be neurotoxic, with saline-treated mice showing significantly decreased striatal DA levels compared to mice on the control diet. This data suggests that a diet enriched with γT may prove useful in protecting dopaminergic neurons against oxidative stress generated by exposure to dopaminergic neurotoxicants.

PS 1546 DIFFERENTIATION OF BONE MARROW-DERIVED STEM CELLS INTO DOPAMINERGIC PROGENITOR CELLS INCREASES THEIR SENSITIVITY TO PARAQUAT.

J. P. Gray[1], K. A. Trzaska[2], J. R. Richardson[3], D. E. Heck[4], P. Rameshwar[2] and J. D. Laskin[3]. *[1]Science, United States Coast Guard Academy, New London, CT, [2]Medicine Hematology/Oncology, UMDNJ - The New Jersey Medical School, Newark, NJ, [3]Environmental & Occupational Medicine, UMDNJ-RWJMS, Piscataway, NJ and [4]Environmental Health, New York Medical College, Valhalla, NY.*

Dopaminergic neurons of the substantia nigra are known to be sensitive to paraquat, an herbicide associated with increased risk of Parkinson's disease in humans. Several animal studies have demonstrated that dopaminergic neurons are particularly vulnerable to paraquat. However, the mechanism responsible for this selective vulnerability is unknown. Paraquat is known to undergo redox cycling to generate reactive oxygen intermediates (ROI) that are thought to mediate its toxicity. Thus, it is possible that differences in enzymatic generation of ROI may play role in this selective vulnerability. In the present studies we utilized human adult-derived mesenchymal stem cells (MSCs) that were differentiated into dopaminergic progenitor cells to determine how differentiation affects the neurotoxicity of paraquat. Following differentiation, cells progressively display characteristics of

dopaminergic neurons. Little or no caspase-3 activation was observed in undifferentiated (day 0) or partially differentiated (day 6) MSC treated with paraquat (100 or 400 μM). However, like cells of the substantia niagra, cells differentiated for 12 days showed significant caspase-3 activation. Differences in the generation of ROI were responsible for the increased toxicity in differentiated cells; MSC lysates from 6 day- and 12-day differentiated cells produced 2.4- and 5.3-fold more hydrogen peroxide than non-differentiated cells in the presence of paraquat (100 μM) when supported by the reducing agent NADPH. Taken together, these data demonstrate that differentiation of MSCs into dopaminergic progenitor cells increases their susceptibility to paraquat and suggest that this is due in part to enhanced expression of NADPH-dependent oxidoreductase activity and paraquat redox cycling.

PS 1547 FYN KINASE DEPENDENT PROTEOLYTIC ACTIVATION OF PROTEIN KINASE C-DELTA PHOSPHORYLATES ANTI-APOPTOTIC KINASE PKD1 DURING OXIDATIVE INSULT IN CELL CULTURE MODELS OF PARKINSON'S DISEASE.

A. Asaithambi, A. Kanthasamy, A. Kanthasamy and V. Anantharam. *Biomedical Sciences, Iowa State University, Ames, IA.*

Oxidative stress is a prominent pathophysiological mechanism contributing to neurodegenration in Parkinson's disease (PD) and therefore, unraveling cell signaling mechanisms underlying oxidative neuronal damage will provide new insights into mechanisms of nigral degeneration as well as foster development of newer treatment modalities in PD. We previously showed that PKCδ proteolytic activation mediates oxidative stress-induced apoptosis in dopaminergic neuronal cells (N27). In the present study, we identified that Protein kinase D1 (PKD1) functions as a key anti-apoptotic kinase to protect dopaminergic cells against oxidative insult. Treatment of N27 cells with H2O2 (100-300μM) or MPP+ (300μM) induced phosphorylation of PKD1 activation loop in a dose- and time-dependent manner. Inhibition of PKCδ with rottlerin or siRNA significantly attenuated H2O2-induced PKD1 phosphorylation, suggesting that PKCδ regulates PKD1 activation. Treatment with Z-VADfmk or overexpression of cleavage-resistant PKCδ mutant effectively attenuated PKD1 activation, indicating that the PKCδ proteolytic activation contributes to PKD1 phosphorylation. Overexpression of PKCδ catalytic fragment, but not regulatory fragment, also increased PKD1 phosphorylation. Additionally, Fyn kinase inhibitors block both PKCδ activation and PKD1 phosphorylation, indicating that FYN kinase is an upstream regulator of the PKCδ-PKD1 signaling. RNAi mediated PKD1 knockdown augmented oxidative stress-induced apoptosis, suggesting an anti-apoptotic role for PKD1 during oxidative injury. Collectively, our results suggest that Fyn-PKCδ-dependent PKD activation represents a key intrinsic protective response in counteracting early stages of oxidative damage in dopaminergic cells. A positive modulation of PKD1 signaling may prove to be a novel neuroprotective strategy against oxidative damage in PD (support NIH grants ES10586 & NS45133).

PS 1548 ELEVATED HISTAMINE AS A VULNERABILITY FACTOR IN THE PARKINSON'S DISEASE PHENOTYPE.

J. Allen[1], M. Thiruchelvam[2] and D. A. Cory-Slechta[1]. *[1]Environmental Medicine, University of Rochester Medical School, Rochester, NY and [2]EOHSI, Piscataway, NJ.*

Brain histamine levels are elevated in Parkinson's disease (PD) patients. There is a significant interaction between brain histamine and dopamine (DA) systems. Given the inflammatory processes evoked by histamine, and the presumed role of inflammation in PD, this study sought to generate a mouse model of increased brain histamine that could be used in subsequent experiments to determine its ability to enhance risk in PD animal models. Male C57Bl6 mice were fed standard lab chow that was fortified with 0, 6 or 10% (n=2, 3 and 3, respectively) of the histamine precursor l-histidine for a period of 3 weeks. The l-histidine diet did not change body weights nor produce any overt clinical manifestations. Measurement of locomotor activity over the course of dietary l-histidine feeding revealed increases in horizontal and ambulatory activity in the 10% group. L-histidine also modified novel object recognition performance, with the 10% dietary group exhibiting both fewer approaches and the absence of an increase in time spent with the novel object. Differential changes in locomotor activity in response to 3 mg/kg of the H3 antagonist thioperamide, hindlimb splay and inverted screen performance were not observed. Although based on a limited sample size to date, both trends and significant changes in brain catecholamines were evident in all brain regions examined. These included increases in DA turnover in midbrain and a similar trend in striatum, coupled with a significant decrease in DA turnover in frontal cortex. Trends towards increased levels of DA and DOPAC were found in striatum and frontal cortex, whereas decreases were noted in midbrain. Increases in both DOPAC and 5-HIAA were evident in olfactory bulb. Collectively, these findings demonstrate that elevated dietary l-histidine can modify brain catecholamines and associated motor function, as well as resulting in potential learning impairments. As such the dietary l-histidine protocol shows utility for evaluation as a risk factor modifying the PD phenotype in animal models.

PS 1549 MITOCHONDRIA-TARGETED TRIPHENYLPHOSPHONIUM CONJUGATED NITROXIDE FUNCTIONS AS A RADIOPROTECTOR.

J. Jiang[1], D. Stoyanovsky[2], N. A. Belikova[1], Q. Zhao[1], Y. Y. Tyurina[1], M. A. Tungekar[1], V. Kapralova[1], J. S. Greenberger[3] and V. E. Kagan[1]. *[1]Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA, [2]Surgery, University of Pittsburgh, Pittsburgh, PA and [3]Radiation Oncology, University of Pittsburgh, Pittsburgh, PA.*

Removal of intracellular reactive oxygen species (ROS), particulary mitochondrial ROS, by antioxidants emerges as a promising strategy to dampen the detrimental effects of oxidative stress induced by chemical and physical factors, including radiation exposure. Here we exploited triphenylphosphonium (TPP) cation as a means to target nitroxide radicals to mitochondria. We synthesized a library of TPP-conjugated nitroxides and tested their radioprotective effects in γ-irradiated mouse embryonic cells and human epithelial BEAS-2B cells. Cells were incubated with conjugates either before or after irradiation. We found that hydroxyl vinyl TPP conjugated TEMPO (HVTP-TEMPO) significantly blocked irradiation induced apoptosis as revealed by externalization of phosphatidylserine on cell surface. Using electron paramagnetic resonance, we showed that HVTP-TEMPO effectively integrated into cells and mitochondria where it underwent reduction to hydroxylamines. Notably, the cellular integration efficiencies of non-radioprotective TPP-conjugates, including Mito-TEMPO (Alexis, San Diego, CA) were markedly lower, although they integrated into succinate-energized isolated mitochondria to a similar extent as HVTP-TEMPO. This indicates that the presence of positive charge in TPP moiety is not sufficient for the successful delivery of TPP-conjugates into mitochondria of cells. Further, radioprotective effect of HVTP-TEMPO is likely due to its ability to act as an electron scavenger, prevent superoxide generation and cardiolipin oxidation in mitochondria, and hence inhibit release of proapoptotic factors from mitochondria. Most importantly, HVTP-TEMPO increased the clonogenic survival rate of irradiated cells. We conclude that mitochondria targeting of TPP-conjugated nitroxides is a promising approach for the development of novel radioprotectors. Supported by NIAID U19-AI068021, HL-70755.

PS 1550 PEROXIDASE-ACTIVATED MITOCHONDRIA-TARGETED NO-DONOR PROTECTS MOUSE EMBRYONIC CELLS AGAINST IRRADIATION-INDUCED INJURY.

N. A. Belikova[1, 2], J. Jiang[1, 2], V. Kapralova[1, 2], Y. Y. Tyurina[1, 2], J. S. Greenberger[3, 2], D. A. Stoyanovsky[4, 2] and V. E. Kagan[1, 2]. *[1]Environmental and Occupational Helath, University of Pittsburgh, Pittsburgh, PA, [2]Center for Free Radical and Antioxidant Health, University of Pittsburgh, Pittsburgh, PA, [3]Radiation Oncology, University of Pittsburgh, Pittsburgh, PA and [4]Surgery, University of Pittsburgh, Pittsburgh, PA.*

Mitochondria play crucial role in irradiation-induced apoptosis. Generation of reactive oxygen species (ROS) by damaged respiratory chain followed by the formation of cytochrome c-cardiolipin complex (cyt c/CL) with peroxidase activity specific towards polyunsaturated CL are early events in the cascade of events leading to cell death. Inhibition of CL peroxidation is associated with the protection of cells and tissues from apoptotic death. This suggests that mitochondria-targeted prodrugs capable of preventing/inhibiting CL oxidation, particularly those activated by cyt c/CL peroxidase reaction, are promising radioprotectants/mitigators. We report protective effect of (2-hydroxyamino-vinyl)-triphenyl-phosphonium (HVTP) against irradiation-induced apoptosis of mouse embryonic cells. Incubation of cells with HVTP resulted in effective accumulation of the drug in mitochondria. Consequently, irradiation induced CL peroxidation, caspase activation, PS externalization were inhibited in cells pre-incubated with HVTP. Colony-formation assay demonstrated marked protective effects of HVTP against radiation injury of cells. HVTP did not display radiomitigating activity. Based on in vitro studies, it is likely generation of NO due to its bioactivation by cyt c/CL complexes resulting in inhibition of lipid oxidation are the major contributors to radiation protection. Supported by NIH U19-AI068021 and HL 70755.

PS 1551 CYCLOSPORIN A POST-TREATMENT PROTECTS FROM DICLOFENAC-INDUCED SMALL INTESTINAL INJURY IN MICE.

A. LoGuidice, V. Ramirez-Alcantara and U. A. Boelsterli. *Department Pharmaceutical Sciences, University of Connecticut, Storrs, CT.*

Diclofenac (DCF) and other NSAIDs are a frequent cause of small intestinal inflammation, ulceration, and perforation of the mucosa in both acutely and chronically treated patients. The underlying mechanisms of enteropathy are poorly understood, but DCF acyl glucuronides have been implicated in causing enteropathy as a

result of their chemical reactivity and/or because these biliary metabolites are the major transport form of the drug to the small intestine where the aglycone is released. Because DCF induces mitochondria-mediated apoptosis in other cell types including hepatocytes, we hypothesized that drug-induced mitochondrial permeabilization may be involved in intestinal mucosal damage induced by DCF. To test this hypothesis, we first developed a mouse model of DCF enteropathy. Male C57BL/6 mice (fed) were injected with a single dose of DCF (60 mg/kg, ip) or vehicle (10% solutol HS-15 in PBS), and the extent of injury to the jejunum and ileum was quantified at various time points by estimating the number and size of ulcers, as well as by determining decreases in serum alkaline phosphatase (ALP) activity and total protein levels. Next, to explore the role of mitochondrial permeabilization, mice were post-treated (1 h) with low doses (≤10 mg/kg, ip) of cyclosporin A (CsA), a well-known inhibitor of the mitochondrial permeability transition pore. Post-treatment was chosen to minimize possible interactions of CsA with the hepatobiliary transport of DCF. Treatment with CsA greatly reduced both the number and size of small intestinal ulcers, indicating significant protection from DCF-induced enteropathy. Also, ALP activity and total serum protein levels were restored to normal values. These results are compatible with our concept that diclofenac causes enteropathy via a topical effect involving mitochondrial permeabilization and cell death.

PS 1552 KNOCKDOWN OF SUPEROXIDE DISMUTASE 2 IN BRL3 CELL AND RAT TO EVALUATE THE DURG-INDUCED HEPATOTOXICITY.

T. Yokoi, Y. Yoshikawa, H. Hosomi, M. Morita and M. Nakajima. *Drug Metabolism and Toxicology, Kanazawa University, Faculty of Pharmaceutical Sciences, Kanazawa, Japan.*

Drug-induced hepatotoxicity is a major problem in drug development, and oxidative stress is known as one of this causes. Superoxide dismutases (SODs) are important antioxidant enzymes against reactive oxygen species (ROS). Mitochondria are the major source of superoxide production, and SOD2 is mainly localized in mitochondria, suggesting that SOD2 plays an important role for scavenging superoxide among other SODs. In this study, we established SOD2 knockdown-cells and -animal models. An adenovirus vector with short hairpin RNA against rat SOD2 (AdSOD2-shRNA) was constructed, and infection of AdSOD2-shRNA to rat hepatic BRL3A cells resulted in significant decrease of SOD2 activity by 50% after 3 days infection. We previously constructed an adenovirus expressing CYP3A4 (AdCYP3A4). Co-infection of AdSOD2-shRNA and AdCYP3A4 to BRL3A cells was performed to evaluate the superoxide- and CYP3A4-mediated formation of active metabolites, and MTT reduction and ROS and superoxide radical production were selected to assess the cell viability. Expression of CYP3A4 was not affected by the co-infection of AdSOD2-shRNA. Dapsone and troglitazone demonstrated the significant increase of cytotoxicity, compared with that of rosiglitazone. As to investigate the in vivo animal model, infection of AdSOD2-shRNA to F-344 rat demonstrated the significant decrease of SOD2 activity by 60% after 7 days infection. Serum AST and ALT were significantly increased by single orally administered acetaminophen (1,000 mg/kg) to these SOD2-knockdown rats without fasting condition, compared with the control adenovirus infected groups. In conclusion, we established useful SOD2 knockdown-cells and -animal models to evaluate the drug-induced hepatotoxicity with high sensitivity.

PS 1553 IDENTIFICATION OF SMALL MOLECULE INDUCERS OF HEAT SHOCK RESPONSE.

S. Sakamuru[1], K. Bi[2], M. K. Hancock[2], R. Huang[1], S. Shukla[1], S. C. Miller[1], C. P. Austin[1] and M. Xia[1]. *[1]NIH Chemical Genomics Center, Rockville, MD and [2]Invitrogen –Discovery Sciences, Madison, WI.*

Heat shock response (HSR) is triggered by cellular and environmental insults such as increased temperature, oxidative stress and chemical exposure, which results in the over expression of heat shock proteins (HSPs). As an integral component of HSR, HSPs function as molecular chaperones that assist in protein folding and protein homeostasis during cellular stress. HSP expression is regulated by heat shock regulated transcription factors (HSF), such as HSF1, which can serve as prognostic indicators of several diseases associated with misfolded/aggregated proteins, such as neurodegenerative disorders or cancer. This study was designed to identify novel small molecule inducers of HSR that promote the activation of HSF1 and subsequent up-regulation of HSPs. A HeLa cell line that stably expresses a β-lactamase reporter gene under the control of a heat shock response element (HSE) was developed, optimized and miniaturized into a 1536-well plate format for quantitative high-throughput screening (qHTS). Thus far, approximately 2000 approved drugs from the NCGC Pharmaceutical Collection (NPC) have been screened with this assay. Several known HSR inducers, such as 17-AAG (via HSP90 inhibition), bortezomib (via proteasome inhibition) and curcumin (via Keap1/Nrf2/ARE pathway) were identified, as well as several novel HSR inducers. Mechanistic and pathway specificity associated with identified compounds were further studied in other stress related pathways including NFκB signaling. Identification of novel HSR inducers from the NPC using our qHTS approach sheds new light on the mechanism of action of these drugs and their potential for producing both toxicological and novel therapeutic effects.

PS 1554 LOW-LEVEL LIGHT THERAPY ENHANCES RENAL FUNCTION AND ANTIOXIDANT DEFENSE SYSTEM IN STREPTOZOTOCIN-INDUCED DIABETIC RAT MODEL.

J. Lim[1], T. E. Balestri[2], R. A. Sanders[2], A. C. Snyder[3], J. T. Eells[3], D. S. Henshel[1] and J. B. Watkins[2]. *[1]SPEA, Indiana University, Bloomington, IN, [2]Medical Sciences, Indiana University, Bloomington, IN and [3]Health Sciences, University of Wisconsin, Milwaukee, WI.*

Hyperglycemia-induced oxidative damage contributes to the progression and severity of diabetic complications. Levels of oxidative stress are controlled by antioxidant defense systems. However, diabetes generates excessive oxidative stress in tissues and consequently results in renal damage. Low level light therapy in the range of 630-1000 nm has been shown to accelerate wound healing, thereby increasing the recovery rate from ischemic injury in heart tissue and attenuating degeneration in the injured retina and optic nerve. The present study tests the hypothesis that 670 nm light therapy increases antioxidant defense capabilities against renal oxidative stress in the streptozotocin-treated rat model of type I diabetes. Male Wistar rats were made diabetic with streptozotocin (50 mg/kg, ip), and subsequently exposed to 670 nm light at a dose of 9 J/cm2 daily for 15 weeks. Kidneys were harvested, flash frozen, and assayed for markers of oxidative stress, including glutathione reductase, glutathione peroxidase, superoxide dismutase, catalase, reduced/oxidized glutathione, lipid peroxidation, cytochrome c oxidase, and 8-hydroxy-2′-deoxyguanosine. Markers of renal function (Na+ K+ ATPase, blood urea nitrogen, and creatinine levels) were also evaluated. Both renal antioxidant defense systems and kidney function were enhanced by light therapy compared to diabetic groups, while the levels of oxidative stress in diabetic animals showed no significant changes compared to control groups. Our findings suggest that low-level light therapy may attenuate the effects of diabetes on renal function and stimulate antioxidant protective pathways in the diabetic rat model.

PS 1555 ANTIOXIDANT ACTIONS OF TAURINE AND STRUCTURALLY-RELATED SULFUR-CONTAINING COMPOUNDS IN THE BRAIN OF DIABETIC RATS.

S. N. Patel and C. A. Lau-Cam. *Pharmaceutical Sciences, St. John's University, College Of Pharmacy, Jamaica, NY.* Sponsor: B. Billack.

This work has assessed the ability of taurine (TAU) and of the structurally-related compounds aminomethanesulfonic acid (AMSA), homotaurine (HMTAU) and pantoyltaurine (PTAU) to protect the brain against diabetes-induced oxidative stress in male Sprague-Dawley rats. The rats were divided into three groups: control group, diabetic group, and diabetic group treated with a sulfur compound. Diabetes was induced using a single, 60 mg/kg, intraperitoneal (i.p.) dose of streptozotocin (STZ). A sulfur compound was administered as two 1.2 mM/kg i.p. doses, 75 min and 45 min before STZ. Control animals received only physiological saline. At 24 hr post-STZ, animals were sacrificed and their brain removed. Enzymatic (catalase, glutathione peroxidase, superoxide dismutase) and nonenzymatic (malondialdehyde, reduced and oxidized glutathione, nitric oxide) indices of oxidative stress were measured in brain stem, cerebellum, cortex and spinal cord. While diabetes lowered the values of all enzymatic parameters and of the reduced/oxidized glutathione ratio, it increased those of malondialdehyde and nitric oxide. Without exceptions, all the aminosulfonic acids tested here were found to effectively protect the brain against oxidative stress due diabetes. In general, the magnitude of the protective effect was found to vary in a rather consistent manner in the various areas of the brain, with HMTAU and AMSA usually being more potent than TAU and PTAU. The only exception was the nitric oxide values, for which TAU and PTAU appeared more protective than HMTAU and AMSA in all brain areas but the spinal cord.

PS 1556 ALDH7A1 IS A NOVEL ALDEHYDE DEHYDROGENASE WITH MULTIPLE FUNCTIONS INCLUDING PROTECTION FROM OXIDATIVE STRESS.

C. Brocker, M. Cantore, N. Lassen, A. Pappa and V. Vasiliou. *Department of Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO.*

ALDH7A1 is a novel aldehyde dehydrogenase (ALDH) that plays a major role in lysine catabolism through the NAD+ dependent conversion of α-aminoadipic semialdehyde (AAS) to α-aminoadipic acid (AAA). In humans, deleterious muta-

tions in ALDH7A1 are responsible for Pyridoxine-Dependent Epilepsy (PDE). The continuing aim of this study is to characterize the subcellular localization, tissue distribution, biochemical properties and functions of mammalian ALDH7A1. Human ALDH7A1 protein, baculovirus expressed and affinity purified, was found to be catalytically active with various aldehyde substrates. Results from Western blot analyses revealed high expression of ALDH7A1 protein in mouse kidney, liver, brain, and tongue and low expression in the heart, stomach, and lung. Subcellular fractionation studies, immunohistochemistry and confocal microscopy revealed ALDH7A1 protein was found in the cytosol, nucleus and mitochondria. Through sequence analysis and RT-PCR we identified a second novel ALDH7A1 transcriptional variant, which was found to contain a mitochondrial leader sequence. Both ALDH7A1 transcript variants were expressed at different ratios in a tissue specific manner. The mitochondrial variant was the predominant transcript found in the liver, kidney, stomach and brain. Finally, ALDH7A1 protects against osmotic stress-induced apoptosis. In conclusion, ALDH7A1 is a novel ALDH found in the cytosol, nucleus and mitochondria, which along with its substrate specificities suggest potentially tissue- and cell-specific biological roles against oxidative damage. (Grant support: EY11490)

PS 1557 EFFECTS OF SELENOCOMPOUNDS ON THIOREDOXIN REDUCTASE-1 IN NON-TUMORIGENIC AND TUMORIGENIC HUMAN LUNG CELLS.

R. Poerschke and P. J. Moos. *Department of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

Selenium-based cancer prevention strategies have demonstrated reduced cancer mortality and efficacy for some cancer types, but the mechanisms of selenium-dependent cancer prevention are not fully understood. Considerable differences in efficacy exist among the cancer prevention activities of organoselenocompounds, and the amino acid selenomethionine is currently the favored selenocompound used in clinical trials. However, other selenocompounds have demonstrated better efficacy in the NNK murine model of lung cancer. Based on a microarray study using the NNK model and selenium sufficient mice, we found evidence of activation of genes involved in oxidoreductase activity, including the selenoprotein thioredoxin reductase-1 (TrxR1), when the mice were supplemented with selenocystine. We have also evaluated the cellular redox consequences of selenocystine in human lung cell lines and found that it had an oxidizing effect on a lung cancer cell line, A549, but minimal effect on a non-tumorigenenic lung cell line, BEAS-2B. Therefore, we set out to determine if selenocystine, as well as other organoselenocompounds, influenced the expression of TrxR1 in these human lung cell lines after 12, 24, and 48 hour treatments. Using QPCR, we found that selenocystine, methylseleninic acid, and selenocysteine prodrugs (selenazolidines) all elevate TrxR1 mRNA expression in BEAS-2B cells after treatment for 24 hours, but we did not observe this same change in expression in A549 cells. These results appear consistent with the NRF2-KEAP1 status of these cell lines, as A549 cells have a mutated KEAP1. Of interest, selenomethionine did not induce expression of TrxR1 in either cell line at 24 hours. TrxR1 protein expression and activity in the A549 and BEAS-2B cells were also evaluated following selenocompound treatment using Western blotting and an NADPH oxidation assay, respectively. These data taken together suggest that selenocystine, as well as other selenocompounds, may modulate TrxR1 as part of their mechanism of action in human lung cells.

PS 1558 MANIPULATION OF CELL GLUTATHIONE (GSH), γ-GLUTAMYL TRANSPEPTIDASE (GGT) & GLUTATHIONE S-TRANSFERASE (GST) ACTIVITY SENSITIZES NORMAL BUT NOT VITILIGO MELANOCYTES AGAINST 4-TERTIARY BUTYLPHENOL (4-TBP) TOXICITY.

R. Sarangarajan[1], I. Le Poole[2] and S. Kerr[1]. *[1]Massachusetts College of Pharmacy & Health Sciences, Worcester, MA and [2]Loyola University, Chicago, IL.*

Exposure to 4-TBP is associated with onset of occupational vitiligo (patchy depigmented skin) associated with melanocyte destruction. Current paradigm suggest that inherent deficiencies in redox cell defense systems in vitiligo melanocyte increases its sensitivity to oxidative stress induced by quinone derivatives of 4-TBP. In this study the status of cell GSH, GGT & GST activities & its influence on 4-TBP toxicity were compared between vitiligo & normal melanocytes. Cultures of immortalized human melanocytes established from normal (PIG1) and vitiligo (PIG3V) donors were maintained in M154 media with supplements (HMGS2, Cascade Biologics). GSH content and GST activities were determined in cell lysates, GGT activity was determined using intact cells. Approximately 10^4 cells/well were seeded in 96 well plates and allowed to attach overnight. Cells were exposed for 72 hours to increasing concentrations (0,100,250,500μM) of 4-TBP alone or pretreated (6 hours) with 1mM buthionine sulfoximine (BSO) or acivicin (ACV). Toxicity was assessed using the MTS cell proliferation assay and results expressed as %control±SD. GSH content and GST activities in PIG3V cells was 35% & 30% lower compared to PIG1 cells respectively. Treatment with 1mM BSO and 50μM ethacrynic acid (EA) significantly decreased GSH content and GST activities respectively in both cell lines. PIG3V has significantly lower levels of GGT activity compared to PIG1 cells. Although PIG1 and PIG3V cells were equally susceptible to toxicity of 4-TBP at all concentrations, pretreatment with BSO and ACV increased sensitivity of PIG1 cells to 250μM 4-TBP but not in PIG3V cells. Interestingly, PIG1 cells were more sensitive to GST inhibition by EA alone or in combination with 4-TBP compared to PIG3V cells. Data describe inherent deficiency in GSH content, GGT and GST activities in PIG3V compared to PIG1 cells that influence sensitivity to 4-TBP induced toxicity.

PS 1559 DETA NONOATE RESCUES HYPEROXIA-INDUCED MACROPHAGE DYSFUNCTION.

A. Pathak, T. Entezari-Zaher and L. Mantell. *St John's University, New York, NY.*

Mechanical ventilation with hyperoxia is a life-saving therapy for the management of patients with acute respiratory failure. However, it carries many potential complications including inflammatory lung injury and ventilator-associated pneumonia (VAP). Our previous studies show that elevated levels of ROS under hyperoxic conditions lead to the compromised ability to phagocytize bacteria by macrophages, thus predisposing the patient population to VAP. Despite of advances in antimicrobial therapy, VAP results in significant morbidity and mortality in patients on ventilation. Nitric oxide (NO) has been shown to be involved in vasodilation and immune modulation. In vitro studies in other laboratories have shown that NO, in various forms, has antimicrobial activity against bacteria, yeasts and mycobacteria. NONOates, as a NO donor, can spontaneously and nonenzymatically release NO. In this study, we tested the effects of DETA NONOate on hyperoxia-induced impairment of macrophage function. RAW 264.7 cells were treated with the combination of treatment of hyperoxia and varying concentrations of DETA NONOate (5 μM to 300uM). Moderate concentrations (up to 150 μM) of DETA NONOate significantly rescued hyperoxia-suppressed phagocytosis and reversed hyperoxia-induced inhibition of cell migration. However, DETA NONOate at concentrations of 300uM or higher caused the death of macrophages. These results suggest that NO at concentrations that are comparable to those used clinically for treating pulmonary hypertension may also be useful in preventing VAP.

PS 1560 RNA INTERFERENCE OF HGSTA4 IN HUMAN AORTIC VASCULAR SMOOTH MUSCLE CELLS RESULTS IN SIGNIFICANT CHANGES IN GENE EXPRESSION.

Y. Yang[1], Y. Xu[1], M. Sinha[2], B. Luxon[2] and P. J. Boor[1]. *[1]Pathology, University of Texas Medical Branch, Galveston, TX and [2]Bioinformatic Program, University of Texas Medical Branch, Galveston, TX.*

Our previous work in endothelial and smooth muscle cells showed that overexpression of glutathione S-tranferases (GSTs) protects against oxidative damage from aldehydes such as 4-hydroxynonenal (HNE) and hydrogen peroxide (H2O2). Over expression of mGSTA4-4 in endothelial cells also plays a key role in upregulation of iNOS, NF-κB.

In this study, we investigated whether knocking down hGSTA4 gene in human aortic vascular smooth muscle cells (HAVSMC) by RNAi is deleterious to the defensive mechanism of these cells against oxidative stress. Cell culture of HAVSMC, siRNA of hGSTA4 transfection, Microarray and Ingenuity data analysis, Real-time RT-PCR analysis, cytotoxicity assay, enzyme assay and Western blot were carried out. The Affymetrix GeneChip Human Genome U133A2.0 microarray chip was used in the present studies; a total of 309 genes in siRNA of hGSTA4 transfected HAVSMC were either up-regulated or down-regulated ($p<0.05$ by Ingenuity software). We focused on 15 altered genes with a possible relevance to cardiovascular disease, especially atherosclerosis and those genes related to apoptosis, lipid peroxidation, or tone of vascular wall. The up-regulated genes in this group include: AIFM1, BDKRB2, BIN3, Cytochrome c, HMOX1, ID2, PBRM1, and TFEB. The down-regulated genes include: Bcl2, CYR61, ITGB3, OPA1, POU4F1, and PSEN2. Down-regulating hGSTA4-4 by siRNA raised the basal level of lipid peroxidation products, MDA and HNE in cells. Cytotoxicity assay proved that hGSTA4-4 is a necessary defensive enzyme against oxidative stress in vascular smooth muscle cells. When the enzyme was decreased, the cells were more easily damaged by toxicants.

These results demonstrate that hGSTA4-4 is an important defensive enzyme in the vascular wall. Knocking down this gene greatly influences cellular function by altering 4-HNE levels that modulate the expression of the other genes.

PS 1561 COMPARATIVE DISTRIBUTION AND RETENTION OF ARSENIC IN ARSENIC (+3 OXIDATION STATE) METHYLTRANSFERASE KNOCKOUT AND WILD TYPE MICE.

M. F. Hughes, B. C. Edwards, K. M. Herbin-Davis and D. J. Thomas. *ORD/NHEERL, U.S. EPA, Research Triangle Park, NC.*

The mouse arsenic (+3 oxidation state) methyltransferase (*As3mt*) gene encodes a ~ 43 kDa protein that catalyzes conversion of inorganic arsenic into methylated products. Heterologous expression of *As3mt* or its silencing by RNA interference controls arsenic methylation phenotypes in cultured human cells, suggesting a critical role for the enzyme in arsenic metabolism. Because methylated arsenicals mediate some of the toxic or carcinogenic effects associated with exposure to inorganic arsenic, studies of the fate and effects of arsenicals in mice which cannot methylate arsenic could be a valuable experimental tool. The mouse *As3mt* gene was disrupted by homologous recombination and transferred into the C57BL/6 mouse strain. Homozygous *As3mt*$^{-/-}$ mice are viable and fertile. This study compared retention and distribution of arsenic in *As3mt* knockout mice and C57BL/6 mice in which expression of the *As3mt* gene is normal. Male and female mice of either genotype received an oral dose of 0.5 mg of arsenic as arsenate per kg containing [^{73}As]-arsenate as a label. Mice were radioassayed for up to 24 or 96 hours post dosing and tissues were collected at term. Whole body clearance of [^{73}As] in *As3mt* knockouts is substantially slower than in C57BL/6 mice. At 24 hours post dosing, *As3mt* knockouts retain about 90% of the dose; C57BL/6 mice retain about 6%. After 96 hours, *As3mt* knockouts still retain 20% and C57BL/6 mice retain less than 2% of the dose. At 24 hours post dosing, *As3mt* knockout mice retain significantly higher percentages of arsenic dose in liver, kidney, urinary bladder, lungs, heart, and carcass than do C57BL/6 mice. These data confirm a central role for As3mt in metabolism of inorganic arsenic and indicate that phenotypes for arsenic retention and distribution are markedly affected by the null genotype for arsenic methylation. (This abstract does not reflect US EPA policy.)

PS 1562 COMPARISON OF TOXICOGENOMIC RESPONSES TO INORGANIC AND ORGANIC MERCURY IN CAENORHABDITIS ELEGANS.

M. K. McElwee[1, 2], J. W. Chou[1], J. R. Rice[1] and J. H. Freedman[1]. [1]*Laboratory of Molecular Toxicology, NIEHS, Reserch Triangle Park, NC and* [2]*Nicholas School of the Environment, Duke University, Durham, NC.*

Humans are exposed to methylmercury through consumption of fish, and inorganic mercury through occupational exposures and dental amalgams. While the toxicity of mercury is well established, much remains to be elucidated about the mechanisms of mercury toxicity. In particular, little is known about the extent to which different species of mercury behave similarly or differently at the cellular level. In order to address this issue, we employed a toxicogenomics approach using the nematode Caenorhabditis elegans. We first established toxic responses in C. elegans to methylmercury chloride (MeHg) and mercuric chloride (HgCl2) using qPCR of stress response genes, and toxicity assays that measured growth, reproduction and feeding. Based on these results, we then exposed mixed-stage C. elegans populations to sub- (0.75 μM MeHg, 2 μM HgCl2), low- (2 μM MeHg, 7.5 μM HgCl2), and high- (7.5 μM MeHg, 20 μM HgCl2) toxic mercurial concentrations for 24 hours. RNA was isolated from 3 biological replicates from each treatment plus untreated control and was hybridized to whole genome Agilent microarrays. Using ANOVA with a Bonferroni post-hoc test ($p<0.01$) and a 2-fold change cut off we identified 8, 76, and 411 differentially expressed genes in the sub-, low- and high toxic HgCl2 exposures and 44, 424 and 2835 differentially expressed genes in the sub-, low- and high toxic MeHg exposures. Analysis of the microarray data using principal components analysis, hierarchical clustering, and self-organizing maps indicated that C. elegans have vastly different transcriptional responses when exposed to different mercury species. Additionally, comparison of significantly enriched Gene Ontologies found no overlap between low-toxic exposures, and only a ~20% overlap between high-toxic exposures. These data indicate that there are large differences in the manner in which different species of mercury affect the cell.

PS 1563 MOUSE *SLC39A8* GENE ENCODING THE ZIP8 ZINC/BICARBONATE SYMPORTER IS ESSENTIAL FOR EMBRYONIC NORMAL HEMATOPOIESIS.

B. Wang, T. P. Dalton, M. L. Miller and D. W. Nebert. *Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

The solute carrier gene (*SLC*) superfamily comprises 55 families and at least 362 putative protein-coding genes. Members within each family are evolutionarily related, whereas families in the superfamily have been assigned mostly on the basis of function: transmembrane transporters that move ions and other molecules in or out of cells, or across vesicular and mitochondrial membranes. *SLC39* genes are members of the ZIP family of metal ion transporters, which transport essential metals such as Zn, Fe, Cu and Mn. For example, mutations in the human *SLC39A4* gene are responsible for acrodermatitis enteropathica, Zn-deficiency (AEZ). Our lab has shown that ZIP8 is a $Zn^{2+}/(HCO_3^-)_2$ symporter moving both ions into the cell as an electroneutral complex. Zn is well known to be critical during embryo implantation and development. While creating a *Slc39a8* knockout construct, we inserted a neomycin-resistance gene (*neo*) into intron 2 with *loxP* sites in introns 2 and 5. Crossing *Slc39a8(+/neo)* heterozygotes produced offspring having a normal Mendelian distribution through gestational day (GD)16.5; however, all *Slc39a8(neo/neo)* homozygotes were pale, growth-retarded and succumbed between GD16.5 and postnatal day (PND)2. ZIP8 mRNA was significantly decreased in *Slc39a8(neo/neo)* embryos, yolk sac, and placenta. At PND1, *Slc39a8(neo/neo)* Zn was 60.3% (P=0.016) and Fe 46.8% (P=0.011) of littermate controls, liver showed far fewer hematopoietic islands, and hepatocytes contained much less glycogen; the RBC was 68% (P=0.06), Hgb 60% (P=0.008) and Hct 64% (P=0.003) of littermate controls. Crossing *Slc39a8(neo/neo)* with our BAC-transgenic BTZIP8-3 line (having 3 extra copies of *Slc39a8*), we successfully rescued the *Slc39a8(neo/neo)* pups. These studies indicate that ZIP8 serves an essential function of transporting Zn/Fe into the embryo, needed for normal hematopoiesis and development. —*Supported, in part, by NIH grants R01 ES010416 and P30 ES006096.*

PS 1564 ROLE OF MELATONIN IN ENZYMATIC STRESS MARKERS AND GENE EXPRESSION IN ABETAPP TRANSGENIC MICE EXPOSED TO ALUMINUM.

J. L. Domingo[1], J. L. Esparza[1], T. Garcia[1], M. Gomez[1], M. R. Nogués[2] and M. Romeu[2]. [1]*Toxicology, Rovira i Virgili University, Reus, Spain and* [2]*Pharmacology Unit, Rovira i Virgili University, Reus, Spain.*

1Laboratory of Toxicol & Environ Health, and 2Pharmacology Unit, School of Medicine, URV, 43201 Reus, Catalonia, Spain.

Aluminum (Al), a well known neurotoxic agent, induces free radicals in brain, while melatonin (Mel) can act as a free radical scavenger, or induce the expression of some genes linked to the antioxidant defence. In this study, AbetaPP transgenic (Tg2576) (Tg) and wild-type mice of 5 months of age, received a supplement of Al lactate (1 mg Al/g diet). They also received oral melatonin (Mel)(10 mg/kg)until 11 months of age. For Tg and wild-type mice, there were 4 groups: control, Al, Mel, and Al+Mel. At the end of the treatment, hippocampus was removed and processed to examine: GST, GSH, GSSG, SOD, GR, GPx, CAT and TBARS. The gene expression of Cu-ZnSOD, GR and CAT was evaluated by real-time PCR. Al concentration in hippocampus was also determined. Al levels increased in all Al-exposed groups with independence of the genotype. When all groups were compared, stress oxidative markers showed differences in GSH, SOD and GR, but not in GSSG, CAT, GPx and TBARS. GSH levels increased in Al+Mel Tg/wild-type mice, while SOD and GR decreased in Al+Mel wild-type and in Al+Mel Tg/wild-type groups, respectively. In relation to mRNA levels of Cu-ZnSOD, CAT and GR, the results show that concomitant administration of Al and Mel increases the gene expression of SOD and CAT, but not GR mainly in Tg animals. In turn, Al decreased similarly the m-RNA levels of CAT in wild-type and Tg exposed groups. Mel wild-type groups showed a decrease in the expression of GR, SOD and CAT. Catalase also decreased in all groups exposed to Al only. The biochemical changes observed in hippocampus indicate that Al acts as pro-oxidant agent, while Mel exerts an antioxidant action by increasing the mRNA levels of the antioxidant enzymes SOD and CAT in presence of Al and Mel, and with independence of the animal model.

PS 1565 BLOOD CADMIUM AND LEAD AND CHRONIC KIDNEY DISEASE IN U.S. ADULTS.

V. M. Weaver[1, 3, 5], A. Navas-Acien[1, 2, 3], M. Tellez-Plaza[2, 3, 4], E. Guallar[2, 3, 4], P. Muntner[6], E. Silbergeld[1] and B. Jaar[2, 3, 5]. [1]*Env Health Sciences, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD,* [2]*Epidemiology, JHSPH, Baltimore, MD,* [3]*Welch Center for Prevention, Epidemiology and Clinical Research, JHMI, Baltimore, MD,* [4]*Cardiovascular Epidemiology and Population Genetics, Centro Nacional de Investigaciones Cardiovasculares, Madrid, Spain,* [5]*Medicine, JHMI, Baltimore, MD and* [6]*Community and Preventive Medicine, Mount Sinai School of Medicine, NY, NY.*

Environmental exposures to cadmium and lead are widespread. Recent data indicate that environmental lead exposure increases risk for chronic kidney disease (CKD). However, few studies have evaluated associations between low-level cadmium and clinical renal outcomes, particularly with respect to joint cadmium and lead. Therefore, we calculated odds ratios for albuminuria (albumin ≥ 30 mg/g creatinine), reduced estimated glomerular filtration rate (eGFR; < 60 mL/min/1.73 m2), and both outcomes combined by quartile of blood cadmium and lead in

adults who participated in the 1999-2006 National Health and Nutrition Examination Survey (n=14,778). Models were adjusted for survey year; sociodemographic and CKD risk factors; and the other metal as a continuous variable. The geometric means of blood cadmium and lead were 0.41 μg/L and 1.58 μg/dL, respectively. The adjusted odds ratios (95% confidence interval) for albuminuria, reduced eGFR, and both albuminuria and reduced eGFR were 1.92 (1.53, 2.43), 1.32 (1.04, 1.68) and 2.91 (1.76, 4.81), respectively, comparing the highest to the lowest blood cadmium quartiles, and 1.19 (0.96, 1.47), 1.56 (1.17, 2.08) and 2.39 (1.31, 4.37), respectively, comparing the highest to the lowest blood lead quartiles. The odds ratios comparing participants in the highest quartile of both metals to those in the lowest quartile of both metals were 2.36 (1.49, 3.73) for albuminuria, 1.88 (1.24, 2.84) for reduced eGFR and 7.80 (3.04, 19.98) for both outcomes. These findings provide strong support for consideration of lead and cadmium as CKD risk factors in the general population and novel evidence of increased risk with exposure to both metals, which is common.

PS 1566 MICROARRAY ANALYSIS OF THE PULMONARY EFFECTS OF STAINLESS AND MILD STEEL WELDING FUMES IN A/J AND C57BL/6J MICE.

P. C. Zeidler-Erdely, M. L. Kashon, S. Li and J. M. Antonini. *HELD, NIOSH, Morgantown, WV.*

Our earlier studies found supportive evidence for a tumorigenic effect of carcinogenic metal-containing welding fume in A/J mice. A/J mice are genetically predisposed to spontaneous and/or chemically-induced lung tumors while C57BL/6J (B6) mice are resistant. This genetic disparity provides a unique scenario to identify molecular mechanisms associated with the lung response to welding fume at the transcriptome level. Mice were exposed four times by pharyngeal aspiration to 5mg/kg mild steel (MS) fume, stainless steel (SS) fume, or saline vehicle. Mice were necropsied 28 days after the last exposure and whole lung microarray using Illumina Mouse Ref-8 expression beadchips was done. Ingenuity pathway analysis (cutoffs: $p<0.05$; fold change >1.3) of the microarray data revealed the top global molecular network involved in the A/J response to MS fume was behavior, nervous system development and function, and gene expression. In contrast, the connective tissue disorders, immunological disease, inflammatory disease network was most significant in the B6 strain. In the A/J, 75% of the focus molecules that met the cutoff were up-regulated as compared to 40% in the B6. Six genes were common between the strains such as KLF2, KLF4 and MARCO. SS fume exposure in the A/J induced genes primarily involved in connective tissue disorders, immunological disease, and inflammatory disease. Genes regulating cellular movement, hematological system development and function, and immune response were most involved in the B6 response. Of the significant focus molecules, 88% were up-regulated in the A/J compared to 45% in the B6. Only five common genes were found between the strains such as HSPH1, MMP12 and CTSK. Overall, these data confirm our previous observation that strain-dependent differences in response to welding fume occur in the A/J and B6 lung. Also, in contrast to the B6, the A/J strain exhibited a persistent up-regulation of welding fume-induced gene transcription suggesting that chronic lung cell activation may play a role in the tumorigenic effects of welding fume.

PS 1567 EXPOSURE TO ARSENIC COMBINED WITH HIGH FAT DIET PROMOTES THE IMPAIRMENT OF GLUCOSE TOLERANCE IN C57BL/6 MICE.

D. S. Paul[1], F. S. Walton[1] and M. Styblo[1, 2]. [1]*Nutrition, University of North Carolina at Chapel Hill, Chapel Hill, NC and* [2]*CEMALB, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Obesity is the single most important risk factor for the development of insulin resistance and type 2 diabetes. However, chronic exposures to inorganic arsenic (iAs) have also been associated with an increased prevalence of type 2 diabetes mellitus. The current study examines diabetogenic effects of exposures to iAs combined with consumption of a high fat diet (HFD). Here, weanling, male, C57BL/6 mice were divided into 6 groups which drank deionized water containing arsenite (iAs^{III}) (25 or 50 ppm) or water without iAs^{III}, *ad libitum*, for 20 weeks while consuming either a HFD (58% fat) or a low fat diet (LFD) (11% fat), also *ad libitum*. Body weight, adiposity, food and water consumption were monitored throughout the study. At 20 weeks fasting blood samples were collected and oral glucose tolerance tests were administered to all mice. In general, the 25 and 50 ppm groups consumed less water than control mice. iAs^{III} intake was estimated at 57 μg/d for 25 ppm groups and 81 μg/d for 50 ppm groups. In general, HFD groups gained significantly more fat mass and had higher fasting blood glucose and serum insulin levels than did their respective LFD groups. However, these measures decreased with iAs^{III} intake in a dose dependent manner. Oral glucose tolerance tests showed an impairment of glucose tolerance for HFD groups compared to their respective LFD groups. The degree of glucose intolerance increased with iAs^{III} intake in a dose dependent manner in spite of the observed decrease in adiposity, fasting glucose and fasting insulin levels. These data suggest that the diabetogenic effects of iAs^{III} are independent of the mechanisms traditionally associated with consumption of high fat diets and/or obesity in mice.

PS 1568 CADMIUM INDUCES REDUCED PLACENTAL ENOS ACTIVATION, REDUCED UMBILICAL ARTERY BLOOD VELOCITY AND FETAL GROWTH RESTRICTION IN MICE.

N. Johnston, T. Hargest, P. Sysa, S. Pin, A. Tsoa, Y. Xu, D. Bedja and K. L. Gabrielson. *Molecular and Comparative Pathobiology, Johns Hopkins University, Baltimore, MD.*

Cadmium is an environmental toxin present in industrial wastes, road and house dust, and food crops grown in cadmium-polluted soil. The most significant route of cadmium exposure is via cigarette smoke. Women who smoke during pregnancy have a higher incidence of placental insufficiency and intrauterine growth retardation (IUGR) than their nonsmoking counterparts. We hypothesized that cadmium could induce fetal growth restriction and placental insufficiency through a reduction of placental blood vessels and reduction of blood flow through the umbilical artery. Methods: Cadmium chloride (40ppm) was administered via drinking water to female C57Bl/6 mice from 2-4 weeks prior to conception. Due to the reduction of successful pregnancies, the treatment was adjusted to 20ppm starting at day 1 until E15 of pregnancy. Umbilical artery blood velocity was assessed on E15 via ultrasound using the Doppler pulse method before euthanasia. Fetuses and placentas were weighed and evaluated by histopathology, TUNEL staining and western blotting. Results: Mice treated with cadmium chloride demonstrated a significant reduction of umbilical artery velocity with control mice having 59.67±14.15 mm/sec versus 35.84±1.89 mm/sec in the cadmium group. Mean weights for fetuses of cadmium-treated mice were reduced 0.119 ±0.007g compared to the controls 1.349 ±0.119. Placental weights were also reduced from 0.164 g ±0.009g in the controls to 0.131±0.008g in the cadmium group. Fewer blood vessels and more TUNEL positive cells were found in the placenta with cadmium treatment. Western blots determined that endothelial nitric oxide synthase, peNOS and heat shock protein 90 (chaperone of eNOS) were decreased in placentas from cadmium exposed mothers. In conclusion, cadmium compromises HSP90 and eNOS pathways leading to reduced placental blood flow with subsequent fetal growth restriction suggesting that this metal may be one of the compounds in cigarette smoke that induces IUGR in pregnant women who smoke.

PS 1569 HYPOXIA INDUCIBLE FACTOR 1 ALPHA (HIF1α) PROTECTS MICE LUNGS FROM COBALT-INDUCED INJURY.

Y. Saini[1, 2, 3], K. Y. Kim[3], J. R. Harkema[2, 4, 5] and J. J. LaPres[1, 2, 3]. Millions of American workers are exposed to cobalt, primarily through inhalation, leading to several disorders including respiratory tract hyperplasia, fibrosis, and asthma. Cobalt is a known hypoxia mimic, attributed to its ability to stabilize hypoxia inducible factor(HIFs). HIFs are oxygen-regulated transcription factors that are critical to the development of the lung and processes such as inflammation. The role of HIFs in cobalt-induced lung injury has not been determined. To address this knowledge gap, a doxycycline-inducible, lung-specific HIF1α knockout mouse model was generated. In this study, wild type(WT) and HIF1α lung-deficient male mice were treated for two weeks (5 days on, 2 days off, 5 days on, 2 days off) with saline, 5 mM CoCl2, or 10 mM CoCl2 via oropharyngeal aspiration. HIF1α-deficient mice were more prone to cobalt-induced toxicity when compared to WT controls and the severity of the lesion correlated with the level of loss of HIF1α. In comparison to WT mice, HIF1α deficient mice had greater numbers of eosinophils and macrophages in bronchoalveolar lavage fluid following cobalt exposure with greater eosinophil infiltration in affected alveolar tissues.In addition, there was greater airway mucous cell metaplasia in the bronchiolar epithelium and greater chitinase-like protein (YM1) expression in the airway epithelium and alveolar macrophages (MBP) in the lungs of HIF1α deficient mice following metal challenge, when compared to similarly treated WT mice. Finally, inflammatory cytokine profiling revealed significant induction of KC and IL-4 only in metal-treated HIF1α deficient mice. These results suggest that HIF1α regulates the cobalt-induced inflammatory response in the lung with asthma-like phenotype.

PS 1570 LYMPHOCYTE NUCLEAR CHANGES AFTER INHALED V2O5 EXPORURE. B1-LAMIN IMPLICATION.

V. Rodriguez-Lara[1], E. Garcia-Zepeda[2], G. Soldevila[2] and F. I. Teresa[1]. [1]*Cellular and Tissular Biology, School of Medicine, UNAM, Mexico City, Mexico and* [2]*Immunology, Instituto Investigaciones Biomedicas, UNAM, Mexico City, Mexico.*

It has been reported that vanadium pentoxide (V2O5) exposure produces cytotoxic effects such as genotoxicity, cell cycle modifications, apoptosis, as well as structural and functional cytoskeleton alterations. Vanadium adverse effects help to explain its potential in producing pathologies such as cancer. Previously our laboratory observed that vanadium pentoxide inhalation induced nuclear morphological changes in lymphocyte similar to those found in neoplastic cells. Owing to the fact that nuclear lamins keep nuclear structure and function integrity, and have been also associated with neoplastic transformation, we investigated the alterations in nuclear B1-lamin from spleen lymphocytes after vanadium pentoxide inhalation. CD-1 male mice were exposed twice a week for four weeks to vanadium pentoxide (0.02M). Mice were sacrificed at 1, 2, 3 and 4 weeks; spleen was removed. Changes in nuclear B1-lamin concentration in lymphocytes subpopulations were evaluated by flow cytometry. Our results demonstrated that vanadium exposure produce a decrease in B1-lamin concentration in all lymphocyte populations analyzed (CD19, CD4, CD8) compared to controls. Moreover, this effect was time dependent in all cases. Our findings explain the morphological nuclear changes observed previously in our laboratory. Additionally, these results help to elucidate the potential carcinogenic effect of vanadium pentoxide due to the decrease in nuclear lamins, as it has been observed in cancer.

PS 1571 *S. CEREVISIAE* GENOME WIDE MUTANT SCREEN FOR ALTERED SENTIVITY AND RESISTANCE TO $NiSO_4$

A. G. Arita[1, 2], X. Zhou[2], T. Ellen[2], T. Begley[3] and M. Costa[2, 1]. [1]*Pharmacology, New York University, New York, NY,* [2]*Environmental Medicine, New York University, New York City, NY and* [3]*SUNY Albany, Albany, NY.*

Although nickel compounds are extremely important commercial elements, they are also occupational and environmental pollutants classified by both the International Agency for Research on Cancer and the U.S. National Toxicology Program as carcinogens to humans. However, the mechanism(s) of nickel toxicity and carcinogenesis remains unclear. Here, we performed a systematic screen of the set of 4,733 haploid *S. cerevisiae* gene deletion strains (the entire set of nonessential genes for this organism) and have identified 111 genes whose gene deletion causes sensitivity to Nickel Sulfate ($NiSO_4$) and 72 genes whose deletion confers resistance $NiSO_4$. Cells were exposed, in triplicate, to a high dose (1.25mM) and a low dose (0.75mM) of $NiSO_4$, and the ability to recover (relative to similarly exposed wild-type) was monitored by digital imaging 48 hrs after treatment. In order to identify those genes whose gene deletion are most highly sensitive or resistant to $NiSO_4$ a validation screen of those genes that were identified in the primary screen was performed by calculating the IC_{50} of Ni^{+2} on each individual deletion strain. This analysis yielded a number of genes involved in cation homeostasis, trasporters (cation, vacuolar/lysosomal, intra Golgi, vesicle), and regulation of C-compound and carbohydrate metabolism. Interestingly, a number of target genes function in trancriptional repression, cell cycle arrest, and DNA recombination. This study takes a whole genome approach to understanding the toxicity and carcinogenesis of nickel compounds and sheds light on previously underestimated molecular mechanisms/pathways associated with the tolerance of eukaryotic cells to Ni^{+2}.

PS 1572 METAL TOXICOLOGY IN NEW ORLEANS: SOIL PB, BLOOD PB AND ACHIEVEMENT BY 4TH GRADE STUDENTS.

H. W. Mielke[1, 2], C. Gonzales[2] and E. Powell[3]. [1]*Chemistry, Tulane University, New Orleans, LA,* [2]*Center for Bioenvironmental Research, Tulane University, New Orleans, LA and* [3]*Lead Lab, Inc, New Orleans, LA.*

Rigorous attention to metal toxicology is critical to the global development of healthy and sustainable urban environments. Lead (Pb) is a well known neurotoxin that was extensively used in high volume consumer products. It was dispersed worldwide and accumulated in especially large amounts in built environments. This study examines results of a New Orleans spatially matched database of soil Pb, blood Pb of children under 6 years old, and 4th grade percent achievement rates from the 1999 Louisiana education assessment program (LEAP 21). All data reflects the pre-Hurricane Katrina condition of the city. Blood Pb is strongly associated with soil Pb ($r^2 = 0.85$, $P < 0.0001$). Blood Pb is directly and significantly (P-values < 0.0001) related to percent unsatisfactory achievement for English language arts ($r^2 = 0.58$), Math ($r^2 = 0.50$), Science ($r^2 = 0.63$), and Social Studies ($r^2 = 0.61$). Poor people of color predominantly live in the most Pb contaminated neighborhoods of New Orleans. The social burden of Pb is especially large in the inner city where children in some communities have a 20 percent plus prevalence of exposure ≥ the CDC 10 μg/dL guideline for Pb, and within the same communities, school failure rates exceed 50% in all subject matter of the LEAP 21 test. An estimated $US 76 million per year represents the costs of Pb poisoning in New Orleans. This underestimates a host of costs related to the inequities of Pb poisoning because it excludes the social stresses from excessive violence and the extraordinary price of the justice and prison system. During the recovery of New Orleans from the flood after Hurricane Katrina an opportunity exists to improve the environment for the benefit of children's health, and promote education and sustainability of the entire community. **Acknowledgements:** AMHPS/ATSDR Cooperative Agreement 5 U50 TS 473408; BLL data, Kathleen Golden & Dianne Dugas, Sect. Env. Epi. & Toxicology, LA Office Public Health, & Ngoc Huynh, LA CLPPP; LEAP data, LA Dept. Education.

PS 1573 CADMIUM (CD) EXPOSURE *IN VIVO* RESULTS IN THE UPREGULATION OF THE RATE LIMITING ENZYME IN THE PENTOSE PHOSPHATE PATHWAY, GLUCOSE 6 PHOSPHATE DEHYDROGENASE (G6PDH), AND DIRECTLY INHIBITS NADPH FORMATION IN NRK CELLS.

J. Edwards, P. Lamar and W. Prozialeck. *Pharmacology, Midwestern University, Downers Grove, IL.*

Exposure to Cd results in: oxidative stress, disruption of cell adhesion molecules and alterations in cell cycle control. Although some of the generalized cellular responses to Cd-induced injury are well known; other cellular responses are just now being elucidated. In previous studies, we showed that the NADPH-producing and rate limiting enzyme of the pentose phosphate pathway, G6PDH, is up-regulated in a sub-chronic animal model of Cd-induced nephrotoxicity. In that study, male Sprague/Dawley rats were given daily subcutaneous injections of 0.6 mg/kg of Cd in the form of $CdCl_2$ for up to 6 weeks. After 6 weeks of Cd exposure, G6PDH was upregulated in kidney tissue as indicated by western blot analysis, without signs of oxidative stress (TBARS). In the present study, we attempt to determine the etiology of the increase in the expression of G6PDH. We examined the ability of Cd to inhibit G6PDH directly in an in vitro system. Whole cell lysates from Normal Rat Kidney (NRK) cells were placed in a quartz cuvette containing 20 μM $CdCl_2$ then the conversion of $NADP^+$ to NADPH was monitored spectrophotometrically as a direct indicator of G6PDH activity. Cd had no effect on G6PDH activity. However, another NADPH-producing enzyme in the pentose pathway, 6-phosphogluconate dehydrogenase (6PGDH) was inhibited to 10% of control activity in the presence of 20 μM $CdCl_2$. In summary, we found that Cd inhibits production of the reducing agent, NADPH, in vitro. Furthermore, that G6PDH was upregulated at an early time point in a subchronic animal model of Cd nephrotoxicity, before signs of overt oxidative stress (TBARS), may indicate that G6PDH is a "sentinel" protein and part of an early cellular defense and/or stress response. Supported by Grant RO1-ES006478 from the NIEHS.

PS 1574 ARSENIC METABOLISM AND A-477G POLYMORPHISM OF AS3MT GENE.

L. M. Del Razo[1], E. Hernandez-Castellanos[1], L. C. Sanchez-Peña[1], A. Pimentel[1], O. L. Valenzuela[1, 3] and G. G. Garcia-Vargas[2]. Exposure to naturally occurring inorganic arsenic (iAs), primarily from drinking contaminated water, is considered one of the top environmental health threats worldwide. Arsenic (III) methyltransferase (AS3MT) is the key enzyme in the biotransformation pathway of iAs. AS3MT catalyzes the transfer of a methyl group from S-adenosyl-L-methionine to trivalent arsenicals resulting in the production of methylated (MAs) and dimethylated (DMAs) arsenicals. Recent studies have been focused on the iAs metabolic pathway and AS3MT polymorphisms. In this study, we evaluated the association of the SNP A-477G in the promoter region AS3MT gene between iAs metabolism and the presence of arsenic (As) premalignant skin lesions. We examined 119 residents from an As endemic area in Mexico in this study. A total of 69 individuals with skin lesions and 50 people without skin lesions were evaluated. We measured the urinary As metabolites of the individuals, differentiating the trivalent and pentavalent arsenical species, using the hydride generation atomic absorption spectrometry method. Additionally, the individuals were genotyped to analyze SNP A-477G in the AS3MT gene using real-time PCR. The arsenic trivalent species are present in greater proportion in urine samples, being DMAsIII the predominant metabolite in urine. Population studied shown a frequency of A=0.63 and G=0.37 which were similar to frequency observation in American-Caucasic population, the G allele in the -477 variant had the lowest pro-

portion of MAs and the highest proportion of DMAs, which consequently increased the DMAs/MAs ratio. The SNP A-477G was not associated with the risk of As-skin lesions. This study was supported by CONACYT grant 50097.

PS 1575 EFFECT OF DMPS AND DMSA ON THE DISPOSITION OF HG^{2+} IN MODELS OF REDUCED RENAL MASS.

C. Bridges, L. Joshee and R. K. Zalups. *Division of Basic Medical Sciences, Mercer University School of Medicine, Macon, GA.*

Chronic kidney disease affects approximately 50,000,000 adults in the United States. This disease is characterized generally by a progressive loss of functioning nephrons and subsequent compensatory cellular hypertrophy, which occurs primarily in proximal tubules. These compensatory changes may subject remaining nephrons to greater levels of toxins and toxicants. Interestingly, the primary site where inorganic mercury (Hg^{2+}) accumulates and induces toxic effects is the proximal tubule. The purpose of this study was to examine the potential increase in expression and activity of membrane transporters involved in proximal tubular secretion of Hg^{2+}. Sham-operated (SHAM) and uninephrectomized (NPX) Wistar and TR^- (MRP2-deficient) rats were injected with a non-toxic dose of $HgCl_2$ followed by treatment with saline, 2, 3-dimercaptopropane-1-sulfonic acid (DMPS) or meso-2, 3-dimercaptosuccinic acid (DMSA). The renal burden of Hg^{2+} was greater in TR^- rats than in Wistar rats. The renal burden of Hg^{2+} was also greater in NPX rats than in SHAM rats. Treatment with DMPS or DMSA reduced the renal and hepatic content of Hg^{2+} in both groups of rats and was accompanied by a significant increase in urinary and fecal excretion of Hg^{2+}. Interestingly, the change in Hg^{2+} content in the samples from TR^- rats was less than that of Wistar rats. These data indicate that MRP2 is involved in the DMPS- and DMSA-mediated elimination of Hg^{2+} from hypertrophied proximal tubular cells.

PS 1576 THIOREDOXIN AND GLUTAREDOXIN TRANSCRIPTIONAL MODULATION BY SPIRULINA IN THE LIVER OF MICE TREATED WITH ARSENITE.

C. Valdovinos, M. A. Torres-Alemán[2], B. Martínez[2], L. M. Del Razo[3] and M. E. Gonsebatt. *[1]Medicina Genómica y Toxicología Ambiental, Instituto de Investigaciones Biomédicas, Universidad Nacional Autónoma de México, M*©*xico, DF, Mexico, [2]Instituto de Farmacia y Alimentos, Universidad de la Habana, La Habana, Cuba and [3]Sección de Toxicología, CINVESTAV, Mexico, DF, Mexico.*

There is evidence suggesting that inorganic arsenic (iAs) toxicity involves oxidative damage, mainly by the interaction of iAs with protein thiols that are central components of redox-sensitive proteins in redox signaling and control pathways. Several studies have demonstrated that liver is the primary arsenic metabolizing organ and dose-repeated oral exposure of mice to sodium arsenite have shown a dose-related distribution of As and of its methylated metabolites in the liver. Spirulina (SP) a filamentous cyanobacterium used as food supplement increased the levels of the antioxidant glutathione (GSH) as well as the activity of some antioxidant enzymes. Moreover, humans exposed to iAs via drinking water showed health improvement after a treatment with a SP extract plus zinc for 16 weeks. We investigated the levels of reduced and oxidized (GSH/GSSG) and the mRNA levels of gamma-glutamylcysteine synthetase (GCS), thioredoxin (TRX) and glutaredoxin (GRX) in mouse liver. CD-1 mice were given 0, 2.5, 5 and 10 mg/kg/day of sodium arsenite orally during 9 days after receiving an oral dose of 2g/kg of SP for 30 days. Animals were killed by cervical dislocation and livers were dissected immediately and frozen in liquid nitrogen or processed for GSH determination. The levels of mRNA were determined using RT-PCR. SP by itself, induced the expression of GCS; TRX and GRX mRNA and reduced the levels of GSH. However, in those animals that received SP + iAs the expression of GCS; TRX and GRX mRNA and GSH levels were significantly lower. The putative antioxidant property of SP in iAs exposure deserves further investigation.

PS 1577 THE INCREASE IN BLOOD LEAD LEVELS IN FEMALE JAPANESE FARMERS EXPOSED TO CADMIUM.

H. Horiguchi[1], E. Oguma[1], S. Sasaki[2], K. Murakami[2], K. Miyamoto[1], Y. Hosoi[1, 2] and F. Kayama[1]. *[1]Jichi Medical University, Shimotsuke, Japan and [2]Tokyo University, Tokyo, Japan.* Sponsor: T. Yoshida.

The peripheral blood level of lead (Pb), which accumulates preferentially in bone, is influenced by bone metabolism. Another toxic heavy metal, cadmium (Cd), affects on bone metabolism, through direct actions on bone cells or indirect ones, that is, renal tubular dysfunction. Therefore, we investigated Japanese female farmers who had been orally exposed to various levels of Cd in order to clarify the relationship between Cd exposure, bone metabolism and blood Pb levels. We conducted group health examinations on female farmers more than 40 years old from 4 areas contaminated with Cd at various levels and 2 control areas in Japan, resulting in 1,568 subjects for analyses. We collected peripheral blood and urine samples from them and measured erythrocyte counts and Cd and Pb concentrations in the whole blood, luteinizing hormone (LH), bone-specific alkaline phosphatase and osteocalcin in serum, N-telopeptide cross-liked collagen type I (NTx), deoxypyridinoline, and Cd concentration in urine, which were normalized by urinary creatinine. Geometric means and ranges of blood Pb, blood Cd and urinary Cd in all subjects were 18.9 (3.2 – 85.0) μg/L, 2.7 (not detected – 13.1) μg/L and 3.7 (not detected – 27.3) μg/g cr., respectively, indicating various levels of Cd exposure without high Pb contamination, although there was no Cd nephropathy. When the subjects were stratified by urinary Cd levels, the blood Pb levels did not show significant difference between the groups. However, when they were stratified by blood Cd levels, blood Pb levels were increased blood Cd dependently. Multiple regression models for blood Pb using age, LH, blood Cd, erythrocyte counts, and each bone metabolism marker as independent variables always showed much more significant regression coefficients of blood Cd than those of other variables. These results indicate that blood Cd would increase blood Pb level in a manner independent of bone metabolism or renal function, although the mechanism is unknown yet.

PS 1578 MYOCARDIAL CONNEXIN-43 ALTERATION AFTER VANADIUM INHALATION.

T. I. Fortoul, A. Soto-Mota, C. I. Falcón-Rodriguez, N. Lopez-Valdez, L. F. Montaño and V. Rodriguez-Lara. *Cellular and Tissular Biology, UNAM, Mexico City, Mexico.*

Air pollution by suspended particles (SP) has been associated to myocardial ischemic events and arrhythmias. One of the components adhered to these particles is Vanadium (V), produced by the combustion of petroleum derivates. A structural characteristic of the myocardiocyte is presence of special intercellular communications –intercalated discs –rich in gap junctions which are integrated by connexins (Cx), mainly Cx43. Knowing that these Cx are essential for impulse conduction; we decided to explore the changes in Cx43 presence in an inhalation mice model. Male mice were exposing twice a week for 12 weeks to V2O5 (0.02M). Mice were sacrificed at 2,6,12 weeks, heart fixed and processed for standard histological evaluation and immunohistochemistry identification of Cx43. Control and exposed mice were analyzed and densitometry for Cx43 was performed with Image Pro-Plus v6. Our findings indicated that myocardiocyte in the presence of V, showed increased in nuclear size, disrupted myofibrils and a progressive decrease in Cx43 staining, as well as disorganization in its location.
These results suggest the involvement of V in cardiovascular events associated to SP air pollution, and also imply the interaction of V with Cx43 resulting in arrhythmias and other heart pathologies

PS 1579 MERCURY TOXICITY FROM MEXICAN COSMETIC SKIN REJUVENATING CREAM.

M. Fedoruk[1, 2], L. Israel[1], J. Fuller[1] and S. J. Hong[2]. *[1]University of California, Irvine, CA and [2]Exponent, Inc., Irvine, CA.*

Mercury (Hg) toxicity from nonoccupational sources has been a continuing problem in the US. Toxicity has resulted from inhalation of elemental Hg from broken thermometers and Afro-Caribbean religious practices. Some overseas consumer products may contain Hg, eg, herbal medicines, skin ointment, beauty and skin lightening creams. Despite publicity, the public and health care professionals may fail to recognize this as a source of Hg poisoning. CASE REPORT: A 51-yr-old female Latin-American had 5 months of worsening fatigue, depression, emotional lability, headaches, weakness, myalgia, and joint pains. She reported use of a Mexican laxative that prompted testing for Hg and other metals. Discontinued use of the laxative and subtherapeutic succimer chelation did not improve symptoms or reduce blood/urine Hg levels. Subsequent history revealed use of skin rejuvenating cream formulated in Mexico and shipped directly to patient. Testing revealed 6.1% Hg content in cream. A 19-day course of succimer treatment initially increased urine Hg, and decreased blood Hg, and only minimal symptom improvement was reported. In the next several months, symptoms gradually improved, and blood/urine mercury levels diminished. CASE DISCUSSION: Initial urine Hg was 192 ug/24 hr (ref 0-20 ug/24 hr) and blood Hg was 43.1 ug/L (ref 0-14.9ug/L). Following subtherapeutic chelation, blood Hg was 46.4 ug/L. Prior to next chelation course at recommended doses, urine Hg was 244 ug/24 hr and increased to 504 ug/24 hr. About 1 month after chelation, urine Hg was 147 ug/24 hr, blood Hg was 11.6 ug/L. At 3 months, symptoms improved significantly, and urine Hg was 119 ug/24 hours, blood Hg was 9.2 ug/L. Renal and hepatic function and color discrimination were normal. CONCLUSIONS: Hg-containing cosmetics may still reach US consumers. Although Hg-containing skin creams is reported in the literature to cause Hg toxicity, there is a lack of awareness among consumers and health care providers. Educational efforts could increase the potential for early case recognition and possibly prevention.

1580 EVALUATION OF A METHODOLOGY FOR CONTROLLING BERYLLIUM EXPOSURE IN LABORATORY SETTING.

C. Muller[1], S. Audusseau[2], F. Salehi[2], G. Truchon[3], G. Chevalier[4], B. Mazer[3] and J. Zayed[1]. *[1]Department of environmental and occupational health, University of Montreal, Montreal, QC, Canada, [2]Meakins-Christie Laboratories, McGill University, Montreal, QC, Canada, [3]Institut de recherche Robert-Sauvé en santé et en sécurité du travail (IRSST), Montreal, QC, Canada and [4]Department of Biological Sciences, University of Quebec in Montreal, Montreal, QC, Canada.*

Beryllium (Be) is used in several forms: pure metal, beryllium oxide, and as an alloy with copper, aluminum, or nickel. Beryllium oxide, beryllium metal and beryllium alloys are forms of Be present in the workplace with inhalation being the primary route of exposure. Cases of workers with sensitization (BeS) or chronic beryllium disease (CBD) challenge the scientific community for a better understanding of Be toxicity. Therefore, a toxicological inhalation study using a murine model was performed in our laboratory in order to identify the toxic effects related to different particle sizes and chemical forms of Be. In this paper we describe the approach developed in order to reduce the potential for exposure, of technicians and students involved in the experiments, which includes specific attention to particle migration control through intensive housekeeping and systematic airborne and surface contamination. Results show that the protective measures applied during this research have been effective. The highest airborne Be concentration in the laboratory was more than ten times lower than the Quebec TLV of 0.15 µg/m3. Considering the protection factor of 103 of a complete head cover used in this research, the average exposure level would be 0.03 x 10-4 µg/m3 which is extremely low. Moreover, with the exception of one value, all average Be concentrations on surfaces were below the guideline level of 3 µg/100 cm2 for Be contamination. Finally, all beryllium lymphocyte proliferation tests (BeLPT) on workers were no higher than unexposed controls. Overall, employing a rigorous protective and preventive approach, will allow for future research to be conducted safely in this important field.

1581 COPPER AND MERCURY INDUCED OXIDATIVE STRESS IN AQUATIC SPECIES.

U. A. Rani[1] and S. P. Reddy[2]. *[1]Zoology, Sri Venkateswara University, Tirupati, Andhra Pradesh, India and [2]Biology, National Tsing Hua University, Hsinchu, Taiwan.* Sponsor: C. Chellu.

Metals are known to influence oxidative stress resulting in patho-physiological conditions in aquatic organisms. Copper (Cu) and mercury (Hg) are the most diffused and hazardous organ specific environmental contaminants that exist in a wide variety of physical and chemical states, each endowed with unique characteristics of target organ specificity. We have studied the oxidant defense levels, lipid peroxidation (LP), and metal accumulation in the liver and hepato pancreas (hepatic tissue) of three different aquatic species with different life strategies (fish, Tilapia mossambica; snail, Pila globosa;and crab, Oziotelphusa senex senex). Animals were collected from local fresh water ponds, acclimated to laboratory conditions for one week before the test animals were exposed to sublethal concentrations of Cu (0.6 ppm for fish ;0.04 ppm for snail and 2.8 ppm for crab) and Hg (0.12ppm for fish ; 0.05 ppm for snail and 0.17 ppm for crab) . The alterations in the activities of the antioxidant enzymes glutathione-S-transferase (GST), catalase (CAT), LP levels and tissue accumulation of metals by AAS were assayed after 7 and 15 days of metal exposure. The decrease in the specific activities of GST was greater in the hepatopancreas of crab (-63.99 %) and CAT was greater in the liver of fish (-65.97%) as compared to snail . However, LP increased in all the three species with increased levels of accumulation of both the metals. Among the three species, fish liver exhibited greater accumulation of both Cu and Hg (23.4 µg / g and 8.3 µg /g). However, the accumulation was significantly decreased during depuration period of 15 days. The data indicate that Cu and Hg induced species-specific adaptive responses in these aquatic animals suggesting that the tissue antioxidants may further serve as surrogate markers of exposure to oxidant pollutants.

1582 A WEIGHT-OF-EVIDENCE EVALUATION OF THE CARCINOGENICITY OF SOLUBLE NICKEL.

R. L. Prueitt[1], J. E. Goodman[2], D. G. Dodge[1] and S. Thakali[2]. *[1]Gradient Corporation, Seattle, WA and [2]Gradient Corporation, Cambridge, MA.*

It has been known for decades that inhalation of sulfidic nickel ore refinery dust containing a mixture of soluble and insoluble nickel compounds can increase the risk of lung and nasal cancers in humans. What is less clear, however, is which specific chemical forms of nickel are associated with these cancers. IARC will be reassessing the human carcinogenicity of soluble and insoluble forms of nickel in 2009. To address the inconsistencies among studies of soluble nickel, we conducted a weight-of-evidence analysis of the relevant epidemiological, toxicological, and carcinogenic mode-of-action data. Certain epidemiological data, but not all, suggest that soluble nickel exposure leads to increased respiratory cancer risk, but only with co-exposures to high levels of insoluble sulfidic or oxidic nickel. Soluble nickel alone was not carcinogenic in the majority of animal studies, including robust inhalation and oral studies (NTP 1996; Heim et al. 2007). There is limited (although inconsistent) animal evidence that soluble nickel can act as a promoter, although it is unclear whether this mode of action is relevant to humans. Some positive *in vitro* genotoxicity results have been reported, but these results are not likely to be applicable to humans because they don't take into account processes that prevent high bioavailability of the nickel ion (the ultimate carcinogen) in the nucleus *in vivo*. Other *in vitro* studies have supported plausible non-genotoxic modes of action (cytotoxicity and induction of signal transduction pathways) for soluble nickel acting as a promoter. We considered whether the toxicological and mode-of-action data support the potential for soluble nickel to be either a complete carcinogen or a tumor promoter. We concluded that the weight of evidence does not clearly support a role for soluble nickel alone in carcinogenesis, and there is only limited evidence that it could act as a promoter.

1583 ACUTE TOXICITY OF THIN-FILM CADMIUM TELLURIDE PHOTOVOLTAICS.

J. Zayed and S. Philippe. *Department of environmental and occupational health, University of Montreal, Montreal, QC, Canada.*

In the context of the growing need for energy and the decline in oil and gas reserves, renewable energies, and photovoltaics (PV) in particular, have experienced significant growth. Cadmium-telluride (CdTe) thin-film PV has become one of the leading technologies in the solar market, but concerns have been raised about the usage of cadmium, known for its toxicity. In the absence of specific toxicological data related to CdTe, regulatory agencies usually apply Cd criteria. However, it may be that CdTe has toxicological properties that are different from those of Cd, and it would therefore be useful to determine such data. The goal of this study is to determine the lethal dose 50 (LD50) and the lethal concentration 50 (LC50) of CdTe in order to establish its acute toxicity in comparison to that of Cd. Using an animal model (rats), the method followed essentially that described in the OECD guidelines and in the US Environmental Protection Agency Health Effects Test Guidelines. The 4-hr LC50 of CdTe in rats was established at 2.71 mg/L, showing a very low variability between genders while the LD50 was determined to be greater than 2000 mg/kg. These results clearly show that CdTe is less toxic than Cd. Thus, applying Cd criteria to CdTe by the regulatory agencies does not seem appropriate and further research on CdTe's other toxicological properties appear to be warranted.

1584 RELEASE OF HEAVY METALS FROM HUMAN BLOOD AND URINE BY CYSTUS-SUD (CISTUS INCANUS SSP.PANDALIS).

C. Siegers[2, 1], R. K. Johannisson[1] and J. Traeder[1]. *[1]Toxicology, University of Luebeck, Luebeck, Germany and [2]University of applied Sciences, Luebeck, Germany.*

Heavy metals in cigarette tobacco may cause serious damage
to human health by smoking.Surveys show that the body burden of certain metals like cadmium or mercury is the consequence of active smoking habits.In a clinical trial 15 volunteers smoking about 15 cigarettes/day were included; this collective was randomly divided in two groups,blood and urine levels of cadmium,mercury and iron were measured under the influence of Cystus-Sud in a cross-over-design.Results: the enhanced levels of cadmium were reduced by 60% in blood and 45% in urine;with mercury the results were more indifferent between both groups.It was excludeed that Cystus-Sud intake does influence the iron-status in blood or urine.Our main finding was that Cystus-Sud significantly reduces the cadmium burden in smoking people,this confirms our pilot study in 8 volunteers in 1999.

1585 ARSENIC IN MEXICO: AN UP TO DATE OVERVIEW.

V. Obregón-Barboza, L. M. Del Razo and A. Albores. *Toxicology, Cinvestav-IPN, Mexico D.F., Distrito Federal, Mexico.*

An extensive part of the Mexican territory has an inorganic arsenic (iAs) rich soil substrata, in addition anthropogenic activities such as mining and smelting process contribute to increase iAs levels in groundwater and soils leading to significant exposure to this metalloid. In Mexico, iAs exposure is mainly through drinking water coming from contaminated sources and affecting to 2 millions people. Therefore, iAs intoxication is a prioritary problem of public health. The aim of this work is to

provide an up to date overview of the iAs problem in Mexico. To achieve this objective, we conducted an exhaustive literature mining focused in geological data and its relevance to human health. Arsenic concentrations exceeding the drinking water Mexican norm (0.025 mg/L) have been reported in 17 states, and up to now there are 5 towns with arsenicism reports. iAs chronically exposed populations have shown skin lesions, peripheral vascular diseases, hepatotoxicity, immunotoxicity, diabetes mellitus and genotoxicity. In addition, children living close to smelting areas showed neurological disorders. Therefore biomarkers associated with health effects by chronic exposure to iAs have been actively investigated. For example, some biomarkers like frequencies and types of chromosomal aberrations in lymphocytes, urinary COPRO/URO and COPROIII/COPROI ratios, TGF-alpha level in bladder urothelial cells, as well as micronuclei in buccal and urothelial cells have been investigated. In summary, due to the abundant presence of iAs in soil and water in Mexico, and its reported effects on human health, it is necessary to carry out systematic evaluations of the drinking water sources to identify all the high iAs areas and to develop surveillance program to detect early human effects.

PS 1586 COMPARATIVE TOXICITY AND TISSUE DISTRIBUTION AFTER REPEATED ADMINISTRATION ORALLY WITH VARIOUS TYPES OF ARSENIC INTO THE MONKEY.

J. Park[1], C. Kim[2], S. Choi[1], D. Kim[1], M. Huang[1], B. Choi[1], K. Park[3], Y. Yum[4], E. Han[4] and T. Kang[4]. *[1]Chung-Ang University, Seoul, Korea, South, [2]Korea Institute of Toxicology, Daejeon, Korea, South, [3]Korea Institute of Science and Technology, Seoul, Korea, South and [4]National Institute of Toxicological Research and Technology, Seoul, Korea, South.*

Arsenic (As) is an ubiquitous element in several forms in food and environment. The main route of As in general population is an oral exposure. However, the toxicity of As varies much by chemical forms. In this study, we compared the toxicity and tissue distribution of the various types of As after repeated administration orally into the animal. The cynomolgus monkey was used in this study. The dosage of repeated administration orally into the monkey was determined based on the previous single administration study. We prepared arsenics, such as sodium arsenite (low: 1.0 mg As/kg/day, high: 5.0 mg/kg/day), arsenocholine (low: 1.5 mg/kg/day, high: 15 mg/kg/day) and dimethyl arsenic acid (DMA, 15 mg/kg/day). Animals were administered with chemical in each group for 4 weeks except the sodium arsenite high-dosed group. We terminated the administration of As on day 6th, because observed died or abnormal positioned animals in the high dose sodium arsenite group. Where, the lethality was 60% (3/5). In DMA (15 mg As/kg/day) group, one animal showed abnormal position on day 23rd. No significant change was not observed in the low-dose sodium arsenite and in the low- or high-dose arsenocholine administered animals during experimental period. The total As in the liver and kidney were increased with dose-dependent pattern. The level of As was higher in the liver than in the kidney in sodium arsenite or arsenocholine administered animals, while was higher in the kidney than in the liver in DMA group. These results from monkey support the previous studies that inorganic As is much more toxic than DMA and organic As, and As is accumulated in the tissue.

PS 1587 EFFECTS OF ARSENITE IN DRINKING WATER ON MOUSE LUNG IN A 30 DAY EXPOSURE.

J. Chilakapati[1, 2], K. Wallace[2], D. Thomas[2], T. Moore[2], H. Ren[2], W. Ward[2] and K. Kitchin[2]. *[1]Curriculum in Toxicology, UNC, Chapel Hill, NC and [2]ECD, NHEERL, U.S. EPA, RTP, NC.*

Humans in Taiwan, Chile and Argentina exposed to inorganic arsenic in their drinking water have demonstrated elevated risks of lung cancer deaths. Since, the carcinogenic mode of action of arsenicals is unknown; we investigated the effects of inorganic arsenic (iAsIII) in female C3H mice, exposed to 0, 0.05, 0.25, 1, 10 and 85 ppm arsenite in drinking water for 30 days. As traditional rodent diets contain arsenic, both inorganic and seafood derived arsenicals, we reduced food arsenical exposure by using a purified diet (AIN-93M). Arsenite-treated mice drank less water at all doses (significantly lower at 85, 10 and 1 ppm (66, 49 and 42 % respectively). Only mice in the 85 ppm group weighed considerably lower (12 %) than the control group. Mouse lungs were analyzed for inorganic arsenic, monomethylated and dimethylated arsenicals by hydride generation atomic absorption spectroscopy. The total lung mean arsenical levels were 2.4, 22.5, 30.1, 50.9, 105.3 and 316.4 ng/g lung tissue after 0, 0.05, 0.25, 1, 10 and 85 ppm, respectively. At 85 ppm, the total mean lung arsenical levels increased 14-fold and 131-fold when compared to either the lowest non-control dose (0.05 ppm) or the control dose, respectively. Gene expression analysis was conducted using Affymetrix Mouse Genome 430A 2.0 GeneChips®. Differentially expressed genes (DEG) were determined using a one-way ANOVA ($p<0.05$) by Rosetta Resolver®, a Benjamini-Hochberg FDR multiple testing correction (<0.05) and a + 1.5 fold change cut-off. Surprisingly, we found that arsenic exposure caused minimal numbers of DEGs (57, 9, 3, 22, and 17 DEGs after 0.05, 0.25, 1, 10 and 85 ppm respectively). Thus, from 0.05 to 85 ppm arsenite, we observed monotonic increases in mouse lung arsenical concentrations but no clear dose- related increases in DEGS. Increasing the dose above the current doses might show more significant biological changes in the lungs. (This research was supported by UNC/EPA Cooperative Agreement EPA CR 833237. This abstract does not necessarily reflect EPA policy.

PS 1588 COMPARISON OF THE PERSISTENCE OF DEPOSITED PARTICLES AND THE INFLAMMATORY POTENTIAL OF STAINLESS STEEL *VERSUS* MILD STEEL WELDING FUME IN RAT LUNGS AFTER INHALATION.

J. M. Antonini, D. Schwegler-Berry, S. Stone, T. Chen, P. C. Zeidler-Erdely, D. G. Frazer and J. R. Roberts. *NIOSH, Morgantown, WV.*

Epidemiology studies have been unable to correlate chronic adverse lung effects associated with exposure to specific welding fumes generated from different processes. The objective of this study was to use an animal model to compare the persistence of deposited particles and the inflammatory potential after inhalation of stainless steel welding fume (SS WF) or mild steel welding fume (MS WF), the two most common fumes used in U.S. industry. Male Sprague-Dawley rats were exposed to 40 mg/m^3 of SS WF or MS WF for 3 hr/day for 3 days. Controls were exposed to filtered air. Generated fume was collected in the breathing zone of the animals, and particle size, morphology, and composition were determined. Bronchoalveolar lavage was done on days 1, 4, 8, 11, 22, and 43 after the last exposure to assess lung injury/inflammation and to recover lung phagocytes. SS WF and MS WF were similar in particle morphology and size with mass median aerodynamic diameters of 0.26 and 0.31 μm, respectively. Chemical composition of the fumes was different- SS WF: 57 % Fe, 20 % Cr, 14 % Mn, 9 % Ni; MS WF: 81 % Fe, 15 % Mn. There was no effect of MS WF on lung injury/inflammation at any time point compared to air control. Lung injury was elevated through 11 days after exposure to SS WF, whereas inflammation was delayed and not significantly increased until day 11 compared to control. SS WF also was associated with greater recovery of welding fume-laden cells from the lungs at all time points compared to the MS WF group. Few cells contained MS WF particles at 22 days, whereas 25 % of cells recovered from the SS WF group still contained particles at 43 days. Thus, it appears that clearance of SS WF is impaired compared to MS WF, which may explain the delayed and persistent inflammatory response. These observations could be related to the presence of insoluble carcinogenic metals in SS WF, such as Cr or Ni, which may play a role in the development of chronic lung disease.

PS 1589 WELL WATER HIGH IN TUNGSTEN, ARSENIC AND POLONIUM 210 FROM CHURCHILL COUNTY, NEVADA INDUCES OXIDATIVE STRESS IN MICE.

C. A. Pritsos[1, 2], K. L. Pritsos[1], R. Seiler[4] and L. Welniak[3]. *[1]Nutrition, University of Nevada, Reno, NV, [2]Environmental Sciences Program, University of Nevada, Reno, NV, [3]Microbiology, University of Nevada, Reno, NV and [4]U.S. Geological Survey, Carson City, NV.*

Between 1997 and 2001, 15 children were diagnosed with acute lymphocytic leukemia (ALL), in Churchill County, Nevada. A CDC investigation of the cancer cluster demonstrated elevated levels of arsenic and tungsten in the urine of study participants and tap water samples. Extremely high levels of alpha radioactivity in numerous domestic wells used for drinking water in the Fallon area were also found which could not be accounted for by naturally occurring uranium activity in the area and were subsequently determined to come from polonium-210 contamination. This study was designed to determine if consumption of drinking water from one or more sources high in one or more of these chemical from Churchill county Nevada induces oxidative stress in mice. C57BL/6 female mice were provided drinking water for up to 10 weeks from selected sources in Churchill County. Several sources of water samples were selected to provide representative ranges of naturally occurring levels of arsenic, tungsten and polonium-210. An in-depth chemical analysis of these water samples was conducted to confirm the concentration and diversity of the contaminants in these tests. The treated mice were assessed for changes in biomarkers of oxidative stress including superoxide dismutase (SOD), glutathione peroxidase (GPOX), total antioxidant capacity(TOAX), lipid peroxidation (LPO) and total DNA damage. Mice provided water high in all three chemicals showed statistically significant increases in SOD, GPOX, TOAX, LPO and DNA damage. Mice provided water high in tungsten but lower levels of polonium 210 and arsenic showed some increases in oxidative stress but not as significant as those high in all three. High tungsten levels are a common feature in the water samples which induce oxidative stress in this mouse model. This study was supported in part by a grant from the U.S. EPA, EM-96963201.

PS 1590 EVALUATION OF THE INHIBITORY EFFECT OF THIMEROSAL TOWARDS THE YEAST PLASMA MEMBRANE H^+-ATPASE.

A. R. Warren, S. M. Nicholson, J. Basaric and B. Billack. *Pharmaceutical Sciences, St. John's University, Jamaica, NY.*

Thimerosal (sodium ethylmercurithiosalicylate) is a potent antimicrobial agent extensively used as a preservative in pharmaceutical preparations such as immunogenic, ophthalmic and nasal products. The mechanism of the antimicrobial action of this organomercury compound has been ascribed to its strong affinity for sulfhydryl groups in cysteine residues of key microbial enzymes. The yeast plasma membrane H^+-ATPase (Pma1p), a vital fungal protein, represents an attractive target for thimerosal by virtue of the nine cysteine residues within its structure. In the present study, the inhibitory action of thimerosal on Pma1p was examined using three types of experiments and compared to that of its structural analog thiosalicylic acid (TSA). In one set of experiments, the antifungal activity of these two compounds was tested using strains of both *S. cerevisiae* and *C. albicans*. While thimerosal was a very potent inhibitor of fungal growth (*S. cerevisiae*: IC_{50}-0.149 μM, IC_{90}-0.741 μM; *C. albicans*: IC_{50}-0.249 μM, IC_{90}-0.826 μM), TSA was devoid of antifungal activity in concentrations up to 10 μM. Time-kill experiments in *C. albicans* revealed that thimerosal produced its fungicidal activity by 8 hr of treatment. In a second set of experiments, thimerosal, but not TSA, was found to inhibit medium acidification by growing yeast. Moreover, thimerosal, but not TSA, reduced the ATPase activity of a sample of Pma1p isolated from *S. cerevisiae*. Taken together, the present data verifies that thimerosal, but not TSA, can reduce the activity of Pma1p because of its ethylmercury component. However, since thimerosal is cytotoxic at concentrations ≤1 μM and an inhibitor of Pma1p at concentrations ≥10 μM, its antifungal activity may not be solely dependent on its propensity to inhibit proton pumping function.

PS 1591 REFERENCE VALUES OF 28 ELEMENTS (HEAVY METAL AND OLIGOELEMENTS) IN HAIR IN A CHILDREN POPULATION IN SPAIN FOR THE USE AS BIOMARKER OF ENVIRONMENTAL EXPOSURE.

E. Vilanova[1], R. Ruiz[1], J. V. Martí-Boscá[2] and C. Esteban[1]. *[1]Toxicología. Instituto de Bioingeniería, Universidad Miguel Hernández de Elche, Elche, Spain and [2]D. G. Salud Pública, Generalitat Valenciana, Valencia, Spain.*

The heavy metals in the human body cause damages to the health and the oligoelements are indispensable in small amounts for the life. Non invasive biomarkers are needed for monitoring and for that appropriate reference values are needed to be established. The study has been made in the municipality of Elche, province of Alicante Spain using children local population in the range of 3 to 12 years old that may considered a standard Spanish population from urban, rural, industrial areas. Twenty eight elements (heavy metal and oligoelements) have been measured in hair samples being used the ICP-MS technology and to establish the curves of normal distribution for each element of interest in the study population. This is an observational, descriptive cross sectional study. Sampling: 430 samples by simple random method. Methodology for sample treatment and measuring with ICP-MS were improved and validated. The distribution curves were asymmetric. Values of reference for the heavy metal concentrations of the potentially toxic elements were established as the value in μg of the element by gram of dry hair smaller than the 75 percentiles. For the oligoelements the reference value were established as the values between the percentiles 25 and 75. Acknoledgment: Work supported by regional government (D. G. Public health Generalitat Valenciana)

PS 1592 MYOSIN LIGHT CHAIN-1: EXTENDING THE DIAGNOSTIC WINDOW FOR DRUG-INDUCED CARDIAC AND SKELETAL MUSCLE TOXICITY IN VETERINARY SPECIES.

M. L. Pritt, D. Sun, K. A. Runnels, K. Rodocker, D. Hall, H. W. Smith and D. E. Watson. *Eli Lilly and Company, Indianapolis, IN.*

Myosin light chain-1 (Myl3) has been used as a biomarker of cardiac injury in humans to evaluate the severity and prognosis of patients with acute myocardial infarction and congestive heart failure. Current biomarkers of muscle injury in veterinary species appear quickly in blood and correlate well with injury. However, their rapid elimination from blood decreases their diagnostic value. Myl3 has the added advantage of a wide diagnostic time window, remaining elevated in the blood for hours or days longer than many other markers. We evaluated serological Myl3 as a biomarker of muscle injury in veterinary species by studying tissue distribution in rats, serum concentrations after drug-induced muscle toxicity in rats, dogs and monkeys, and serum pharmacokinetics following IV infusion in monkeys. Myl3 gene expression and protein concentration are most abundant in heart and type-1 skeletal muscle. Treatment with cardiac and type 1 SKM toxicants (isoproterenol & PPAR) induced higher and/or more sustained serum concentrations of Myl3 than other biomarkers of muscle toxicity. PK of Myl3 in monkeys revealed rapid elimination of Myl3 from blood, suggesting prolonged treatment-induced increases in serum Myl3 are due to persistent release from injured tissue, not slow elimination from blood. Earlier publications found that a cytosolic pool of "unassembled" myosin light chain is released quickly from injured tissue while ischemia-induced acidosis and proteolytic degradation are possible mechanisms for subsequent dissociation of additional Myl3 from the myofibril enabling persistent release from injured myocytes. These data indicate that Myl3 is a sensitive and predictive biomarker of cardiac and skeletal muscle injury in veterinary species and adds value to a myopathy biomarker panel by extending the diagnostic window.

PS 1593 CHARACTERIZATION OF GLUTATHIONE CONJUGATES OF 1-BROMOPENTANE AND ITS HEPATOTOXICITY.

T. Jeong, S. Lee, J. Kim, Y. Seo, S. Shin, J. Choi and M. Kang. *Pharmacy, Yeungnam University, Gyeongsan, Gyeongbuk, Korea, South.*

Glutathione (GSH) conjugation and hepatotoxicity induced by 1-bromopentane (1-BPT) were investigated in female BALB/c mice. S-Bromopentyl GSH, S-bromopentyl cysteine, and mono-hydroxypentyl mercapturic acid were identified in liver isolated from the mice treated orally with 1-BPT by liquid chromatography-electrospray ionization tandem mass spectrometry. Oral treatment of mice with 1-BPT at 1500 mg/kg produced maximum GSH conjugates at 6 h after treatment. For hepatotoxicity tests, the animals were treated orally with 1-BPT at 375, 750, or 1500 mg/kg in corn oil once for a dose response study or at 1500 mg/kg for 6, 12, 24, or 48 h for a time course study. 1-BPT dose-dependently increased serum activity of ALT and AST and decreased hepatic GSH levels, peaking at 6 and 12 h after treatment. 1-BPT (750 and 1500 mg/kg) also significantly increased the hepatic content of malondialdehyde. Thus, 1-BPT could cause hepatotoxicity and depletion of GSH content by forming GSH conjugates, presenting a toxicity mechanism and potential biomarkers for low molecular weight haloalkanes. (Supported by a grant from NITR, Korea)

PS 1594 NOVEL TOXICOLOGY DATABASE ALLOWING FOR CROSS-COMPANY, MULTI-STUDY DATA MINING AND ANALYSIS FOR THE QUALIFICATION OF PREDICTIVE BIOMARKERS.

P. G. Rossi[1], W. Mattes[1], E. Walker[1], M. Cooper[3, 1] and A. Hoover[2]. *[1]PSTC, the Critical Path Institute, Rockville, MD, [2]Product Development, Rosetta Biosoftware, Seattle, WA and [3]Roche, Pao-Alto, AZ.*

The integration of genomics data with traditional toxicology data remains a work in progress despite the positive strides taken by several members of industry. The needs of the Predictive Safety Testing Consortium (PSTC), revolving around the qualification of predictive biomarkers, demand that traditional toxicology data including histopathology be brought together in one database and associated with biomarker data. The PSTC Rosetta Resolver database (PRD) is not only a storehouse of biomarker and toxicology information but also a centralized cross-company resource from which multiple teams can extract data for mining and analysis exercises. The end result is a robust tool with the potential to decrease the time and effort spent qualifying biomarkers and thus accelerating investigative compounds through the early phases of development. As a proof of concept we examined the responsiveness of serum creatinine (SCr) to tubular kidney damage as measured by kidney histopathology. Data exported from the PRD represented two companies and 23 studies containing approximately 1600 samples. For tubular damage, samples with a histopathology severity score of one (five point scale) did not correspond to any samples with a SCr level exceeding the ULN. Samples with a score of two (minimum to moderate damage) correlated to only a small number samples with a SCr level above the ULN (2.5%). Samples with a score of three (moderate damage) correlated with the most number of samples with a SCr level above the ULN, but even still, the number of corresponding samples was a modest one (30%). This data confirms the common knowledge that SCr is not responsive to mild kidney damage and underscores the importance of PSTC successful efforts to qualify more sensitive biomarkers of kidney injury. Further examples of data analysis for novel biomarkers of kidney, liver, and vascular injury will be discussed.

PS 1595 DEVELOPMENT AND VALIDATION OF A MULTI-ANALYTE PROFILE (MAP) OF PUTATIVE BIOMARKERS OF HUMAN KIDNEY DAMAGE.

K. Hepfer, K. Tatro, D. Eisinger, J. Mapes and L. Stephen. *RBM Inc., Lake Placid, NY.* Sponsor: J. Stevens.

Introduction – In June 2008, the FDA and EMEA issued a joint framework allowing submission of a single application for 7 new urinary biomarkers of drug-induced kidney damage in rats. Based on our previous experience in developing both

assays and analyzing samples for the FDA/EMEA submission by the C-Path Predictive Safety Testing Consortium (PSTC), we developed and validated a human kidney MAP corresponding to the rat biomarkers. Experimental Procedures – Utilizing the Luminex xMAP platform, we developed multipled immunoassays to quantify the following 15 human protein analytes from urine: KIM-1, Albumin, Beta-2-Microglobulin, Clusterin, Cystatin C, TreFoil Factor-3, CTGF, GST- alpha, VEGF, Calbindin, Osteopontin, Tamm-Horsfall Protein, Timp-1, NGAL, alpha-1-Microglobulin. The assays were validated to clinical laboratory standards that include the standard parameters of lowest detectable dose, normal range, dynamic range, imprecision, spiked recovery, linearity, cross reactivity and matrix interference. Results: - Assay development and validation efforts starting with multiple antibody reagents and standard calibrators lead to a robust panel of assays with the appropriate sensitivity and assay range. Multiplex assay performance was assessed with human urine samples from normal individuals and patients treated with the chemotherapeutics fluorouracil, cisplatin, gemcitabine, or the bisphosphonate, zoledronic acid. The results obtained from the assay validation effort meet the specifications for using the human kidney MAP in a CLIA certified laboratory for analyzing human samples. Conclusions – A new human kidney MAP is a highly useful tool to further qualify and monitor biomarkers of kidney damage for use in human studies.

PS 1596 NGAL EXPRESSION IN KIDNEY OF SPONTANEOUS HYPERTENSIVE RATS (SHR) TREATED WITH DOXORUBICIN ALONE OR WITH DEXRAZOXANE: A COMPARISON WITH KIM-1 EXPRESSION.

J. Zhang[1], J. Ohm[2], V. S. Vaidya[3], P. Espandiari[1], A. Knapton[1], P. L. Goering[4], R. P. Brown[4], J. V. Bonventre[3] and E. H. Herman[1]. *[1]CDER, FDA, Silver Spring, MD, [2]BioPorto Diagnostic A/S, Gentofte, Denmark, [3]Department of Med., Brigham & Women's Hosp, Harvard Medical School, Boston, MA and [4]CDRH, FDA, Silver Spring, MD.*

Neutrophil gelatinase-associated lipocalin (NGAL) has shown promise as a novel next-generation nephrotoxicity biomarker. The present study was undertaken to examine changes in NGAL expression following acute drug-induced renal injury. Four groups of male SHR (5/group) were treated once with 10 mg/kg doxorubicin (Dox) (iv), 50 mg/kg Dex (ip) given 30 min before Dox, 50mg/kg dexrazoxane (Dex) (ip) or saline (ip, iv). Rats were euthanized and necropsied 14 days after treatment. Dox-induced acute kidney injury (AKI) which was characterized by glomerular vacuolization, proximal and distal tubular epithelial cell degeneration (cytoplasmic vacuolization and accumulation of hyaline droplet formation in the cytoplasm) and apoptosis identified by TUNEL assay in the proximal tubular epithelia and glomerular cells. Renal damage was attenuated in SHR pretreated with Dex. Immunoperoxidase staining with anti-rat NGAL mAb (BioPorto Diagnostics) and mouse anti-rat kidney injury molecule-1 (Kim-1) ectodomain mAb (Harvard Medical School) showed (1) NGAL expression was elevated in the proximal tubular cells of Dox-treated SHR compared with that observed in kidneys of saline- or Dex-treated SHR; (2) pretreatment with Dex attenuated increases in renal NGAL expression compared to the intensity of expression observed in SHR given Dox alone; (3) the intensity of NGAL expression correlated with the severity of renal lesion scores; (4) the immunolocalization of renal NGAL in Dox-treated SHR was similar to that observed for Kim-1 as determined in the present and in previous studies; and (5) the immunostaining intensity of NGAL in the kidney of Dox-treated rats is comparable to that of Kim-1. These findings suggest that NGAL can be used as a new biomarker to identify drug-induced AKI in the rat.

PS 1597 ASSESSMENT OF OSTEOPONTIN INDUCTION IN VIVO AND IN VITRO TO PREDICT ITS POTENTIAL AS A SAFETY BIOMARKER OF HEPATIC INFLAMMATION AND LIVER INJURY.

J. Lee and S. K. Ramaiah. *Pathobiology, Texas A&M University, College Station, TX.*

Osteopontin (OPN) is a phosphorylated glycoprotein associated with a variety of pathologic events including inflammation and this laboratory has previously reported the involvement of OPN in a rodent model of alcoholic liver disease (ALD). Also, recent reports have shown the role of OPN during hepatic injury caused by selected hepatotoxic chemicals *in vivo*. Based on this, hepatobiliary OPN induction following well-known hepatotoxicants, acetaminophen (APAP) and thioacetamide (TAA) was investigated *in vitro* and *in vivo*. The objective of this study was to evaluate the usefulness of hepatic OPN expression as a potential biomarker of liver inflammation and injury in the rat and mouse liver *in vivo* and in cell cultures of hepatocytes and biliary epithelium following exposure to these selected hepatotoxicants. Treatment of rats and mice with both TAA and APAP showed hepatic inflammation and injury coinciding with hepatic OPN induction. Serum levels of OPN as measured by ELISA revealed significantly higher levels in the treated groups compared to the controls and the OPN protein appeared to originate from the liver based on the significantly lesser expression of OPN mRNA and protein in the non-hepatic organs compared to the liver. Also, biliary epithelium and HepG2 cells exposed to these chemicals resulted in increased OPN mRNA and protein expression. $OPN^{-/-}$ mice showed significantly decreased liver injury following TAA and APAP treatment. In conclusion, OPN can be potentially employed as a safety biomarker of hepatic inflammation both *in vitro* and *in vivo* to assess chemically mediated liver injury and further supports the involvement of OPN in the pathogenesis of hepatic inflammation. (Supported by funds from SOT-Colgate Palmolive Alternate Research Grant Award).

PS 1598 EVALUATION OF NEPHROTOXICITY BIOMARKERS IN GENTAMICIN-TREATED RATS.

E. Wang[1], I. Knemeyer[2], R. Snyder[1], S. Brunnert[1], R. Casale[2], R. Smith[1], A. Ingrassia[1], R. Andrukiewicz[1], K. Prevete[1], E. Evans[1], N. Collins[1] and Y. Z. Gu[1]. *[1]Toxicology, Schering-Plough, Summit, NJ and [2]DMPK, Schering-Plough, Kenilworth, NJ.*

Nephrotoxicity is a recurring impediment in drug development. The objective of the present study was to examine the utility of some novel genomic and protein nephrotoxicity biomarkers, as well as the ToxFX platform in a rat model. Male SD rats were dosed subcutaneously once daily with corn oil or gentamicin (5, 34 or 267 mg/kg/day for 5 days; or 5, 25 or 50 mg/kg/day for 14 days). Histopathology confirmed that acute necrosis of proximal tubules was present in the high-dose group treated for 5 days. Multifocal accumulations of lymphocytes in the renal cortex associated with tubular basophilia were identified mainly in the mid- and high-dose groups treated for 14 days. Marked increase in BUN and CRE were found in only the high-dose group of the 5-day treatment and not in any of the 14-day treatment groups. A list of highly-induced genes was identified after 5 or 14 days treatment. Among these genes were KIM1, SPP1, LCN2, A2M and CLU, with KIM1 being the most sensitive correlate with renal damage. ToxFX Analysis Suite is a microarray data analysis platform that utilizes drug signatures and other relevant data to provide toxicity risk assessment for chemicals. To evaluate the performance of the ToxFX platform for renal toxicity prediction, total RNA was extracted from kidneys and run on ToxFX chips to generate gene expression data. The predictions of nephrotoxicity by ToxFX platform matched well with the renal histopathological findings in rats treated for either 5 or 14 days, signifying the usefulness of the gene expression analysis in renal toxicity detection. Furthermore, the performance of a set of potential urinary protein nephrotoxicity biomarkers including KIM1, LCN2, SPP1, ALB, and GSTs was evaluated. KIM1 again showed best correlation with renal damage among the proteins tested. In summary, the present study confirmed that novel genomic and protein biomarkers outperformed the traditional biomarkers BUN and CRE in detection of gentamicin-induced nephrotoxicity in rats.

PS 1599 CHANGES IN URINARY CREATINE AND GENE EXPRESSION IN TESTIS TISSUE OF RATS TREATED WITH TESTICULAR TOXICANT.

M. Sonee[1], A. Collins[1], G. C. Leo[2], E. Taylor[1] and M. McMillian[1]. *[1]GPCD, Johnson & Johnson PRD, Raritan, NJ and [2]Research and Early Development, Johnson & Johnson PRD, Spring House, PA.*

Testicular toxicity is one of the target organ toxicities that are observed during preclinical development. Published literature discusses some biomarkers to monitor testicular changes following drug administration. This study focused on evaluating urinary creatine and gene expression changes as potential biomarkers of testicular toxicity. Groups of 8 SD male rats were treated once orally with the known testicular toxicant 2,5-hexanedione (2500mg/kg). Blood and testis were collected at day1. Urine was collected on ice before dosing and then at day1. Gene expression studies using testicular tissue showed a pronounced repression of IGFBP3 (insulin growth factor binding protein-3) mRNA with treatment as compared to control. Decreases in serum IGFBP3 were also observed with the testicular toxicant. Based upon NMR analysis, urinary creatine levels were below detection levels in the predose and control samples, but shown to be elevated in the hexanedione treated rats. Serum Inhibin B levels will also be measured in this study to evaluate changes relative to the other markers. Further studies will be conducted with other testicular toxicants to confirm the use of urinary creatine in combination with IGFBP3 gene repression to assess testicular toxicity.

PS 1600 PLASMON-ENHANCED FLUORESCENT MICROARRAY ANALYSIS OF TOXICOLOGICAL SIGNATURES.

D. V. Donaldson[1], J. Rice[2], E. Guignon[2], D. A. Lawrence[3] and M. A. Lynes[1]. *[1]Molecular and Cell Biology, University of Connecticut, Storrs, CT, [2]Ciencia, Inc., E. Hartford, CT and [3]Wadsworth Laboratory, Albany, NY.*

The ability to detect biologically relevant levels of toxicants and immune responses to toxicants presents a significant challenge. Currently available assay methods are often limited by sensitivity or by the number and/or types of analytes that can be

detected in parallel. Grating-Coupled Fluorescent Plasmonics (GCFP) may enable us to overcome these limitations. This microarray-based approach builds upon the established Grating-Coupled Surface Plasmon Resonance Imaging (GCSPRI) platform, but incorporates enhanced fluorescent detection. By coupling fluorescent emission from antibody-conjugated fluorophores to surface plasmons generated at the biosensor chip surface, fluorescent detection can be increased by 14-fold. This greatly expands the range of concentrations that can be detected for many analytes including toxicants, cytokines, enzymes, and other biomarkers. By utilizing a microarray format on a gold biosensor chip, we can simultaneously quantify hundreds to thousands of biomarkers reaching femtomolar sensitivity to generate unique signatures associated with disease states and toxicant exposure. For example, we can detect TNF-α, IL-5, IL-6, and IL-10 to a limit of less than 28 fM.
Our preliminary experiments with GCFP have included quantifying cytokine secretion from differentially activated immune cells to generate unique biosignatures of activation. The GCFP technology permits cells to be captured using either antibodies or MHC monomers, separated by phenotype, and then characterized by secretion in parallel; all in one assay. Detected biomarkers can also include transcription factors, measures of enzyme specific activity, and other small molecules whose presence or change in concentration might be indicative of a disease state. The ability to define complex biological signatures may lead to earlier diagnosis and more effective treatments of disease and toxicant exposure. Supported by NIH grants ES07408, DK77291, and ES016014.

PS 1601 A NOVEL TOXICOPROTEOMIC/TOXICOGENOMIC METHOD FOR THE IDENTIFICATION OF MOLECULAR BIOMARKERS.

M. E. Gillespie. *PHS, St. John's University, Jamaica, NY.*

Chronic low-level lead toxicity takes a silent toll on those it effects, driving cognitive and behavioral alterations that are not apparent for years after exposure. Here genomic and proteomic approaches are used in parallel to identify gene expression and functional protein interaction responses to low-level lead intoxication. The result is a set of candidate molecular biomarkers of chronic low-level lead intoxication.
Initial proteomic screens utilized a modified two-hybrid proteomic system to identify a number of potential in vivo protein-protein interactions disrupted by the neurotoxin lead (Pb2+). The proteomic search centered on the neuronal SNARE protein SNAP-25b and identified proteins within the SNARE complex including Syntaxin1A and Vamp-2. The neuronal SNARE proteins are the minimal membrane fusion machinery required for vesicle fusion and calcium dependant neurotransmitter release. This method also identified proteins beyond the SNARE complex, including HGS, involved in vesicle transport and sorting pathways and EEF1A2 a protein family that contains a mutant form associated with neuronal wasting in mice. In the second phase of this project the proteomic set of molecular markers was compared with microarray data, global gene expression patterns observed in offspring of time-pregnant Long Evans rats subject to chronic low-level lead exposure vs. control groups. Both genomic and proteomic methods described are subject to artifacts, but when the data from each method is overlaid, elements present in both data sets identify a subset of molecular biomarkers. To date we know of no reliable biomarkers for low-level lead toxicity in man, nor is there a satisfying model for how chronic low-level lead toxicity effects the neuronal systems of mammals. This work provides a glimpse at these mechanisms, identifies a candidate protein network of biomarkers for chronic low-level lead exposure, and describes a novel platform for de novo biomarker discovery for poorly characterized toxicant/organism systems.

PS 1602 TRANSCRIPTOMIC CHANGES INDUCED BY LIPOPOLYSACCHARIDE TREATMENT IN RAT WHOLE BLOOD: OPTIMIZATION OF A NOVEL COLLECTION PROCEDURE.

A. C. Ditewig[1], M. M. Grudzien[2], M. J. Liguori[1], E. A. Blomme[1], P. M. Jung[2] and Y. Yang[1]. *[1]Cellular, Molecular and Exploratory Toxicology, Abbott Laboratories, Abbott Park, IL and [2]Gene Expression Analysis, Abbott Laboratories, Abbott Park, IL.*

Blood is an easily accessible tissue that can be used to identify biomarkers for a wide range of tissue injuries using transcriptomic profiling. Using blood for transcriptional profiling presents significant technical challenges, particularly because of the presence of large quantities of globin mRNA transcripts that prevent acceptable signal collection. PAXgene™ blood RNA collection tubes have been the traditional method for blood collection. However, they are not ideal for rat toxicology studies because they require large amounts of blood (2.5mL). We have developed a reproducible method of RNA stabilization and isolation from small quantities of whole blood to be used for transcriptional profiling. To confirm the validity of this technique, male, Sprague-Dawley rats (n=3) were treated with vehicle or 5 mg/kg of lipopolysaccharide (LPS; IV) for 2h, 6h and 24h. Two blood collection methods were used: collection of blood in PAXgene™ tubes, or collection of 500µl of blood in 2mL of Qiazol®. Both techniques yielded abundant, high quality RNA. Total RNA (50 ng) was processed using the NuGEN Ovation™ RNA Amplification System, and cDNA was hybridized to Affymetrix RG 230 2.0 microarrays. Similar genes and pathways were disregulated in both techniques following LPS treatment. In particular, genes associated with LPS-induced inflammatory response, LPS and IL-1 mediated inhibition of RXR function and IL-10 signaling were differentially expressed. In conclusion, this novel and cost-effective blood preparation technique yields accurate results, requires less input than the traditional method, and can also be used in preclinical toxicology and pharmacology studies to identify novel biomarkers.

PS 1603 PERFORMANCE OF NOVEL KIDNEY BIOMARKERS IN PRECLINICAL TOXICITY STUDIES.

D. Hoffmann[1], M. Adler[1], E. Rached[1], L. Mulrane[2], W. L. Gallagher[2], J. J. Callanan[2], J. Gautier[3], K. Matheis[4], F. Staedler[5], F. Dieterle[5], A. Walijew[6], P. Hewitt[6], H. Ellinger[7], V. S. Vaidya[8], M. Clement[8], J. V. Bonventre[8], W. Dekant[1] and A. Mally[1]. *[1]University of Wuerzburg, Wuerzburg, Germany, [2]University College Dublin, Dublin, Ireland, [3]Sanofi-Aventis, Paris, France, [4]Boehringer Ingelheim, Biberach, Germany, [5]Novartis Pharmacology AG, Basel, Switzerland, [6]Merck KGaA, Darmstadt, Germany, [7]Bayer Healthcare, Wuppertal, Germany and [8]Harvard Medical School, Boston, MA.*

The kidney is one of the main targets of drug-induced toxicity, but early detection of renal damage is often difficult. As part of the InnoMed PredTox project, a collaborative effort by 15 pharmaceutical companies, 2 small- and mid-sized enterprises and 3 universities aimed at assessing the value of combining –omics technologies with conventional toxicology methods for improved safety assessment, we evaluated the performance of a panel of novel kidney biomarkers in preclinical toxicity studies. Rats (Han Wistar) were treated with either the reference nephrotoxin gentamicin or one of several proprietary compounds that were dropped from drug development in part due to renal toxicity. Animals were dosed at two dose levels for 1, 3 and 14 days. Putative kidney markers, including Kim-1, lipocalin-2 and clusterin, were analyzed in kidney, serum and urine using qRT-PCR, ELISA and immunohistochemistry. Changes in gene/protein expression generally correlated well with renal histopathological alterations and were frequently detected at earlier timepoints or at lower doses than traditional clinical parameters. Overexpression of Kim-1 was often one of the earliest responses and might be seen as the most sensitive tissue marker of kidney injury. Urinary Kim-1 and clusterin reflected changes in gene/protein expression and histopathological alterations in the target organ, confirming clusterin and Kim-1 as early and sensitive, non-invasive marker of renal injury. In contrast, urinary lipocalin-2 was found to be less sensitive and not specific for kidney toxicity. The InnoMed Project is supported by partial funding by the 6th Research Framework Program of the European Union (LSHB-CT-2005-518170).

PS 1604 MECHANISM-BASED BIOMARKER GENE SETS FOR GLUTATHIONE-DEPLETION RELATED HEPATOTOXICITY IN RAT LIVER.

W. Gao[1], Y. Mizukama[2], H. Yamada[1], N. Nakatsu[1], Y. Minowa[1], Y. Ohno[3] and T. Urushidani[2, 1]. *[1]Toxicogenomics Informatics Project, National Institute of Biomedical Innovation, Osaka, Japan, [2]Faculty of Pharmaceutical Sciences, Doshisha Women's College of Liberal Arts, Kyoto, Japan and [3]National Institute of Health Sciences, Tokyo, Japan.*

Two types of toxicological mechanisms are reported regarding Chemical-induced glutathione (GSH) depletion, i.e., GSH-conjugation with chemicals such as phorone (PHO) or diethyl maleate (DEM), or inhibition of GSH synthesis by chemicals such as L-buthionine-sulfoximine (BSO). To identify mechanism-based biomarker gene sets for GSH depletion related hepatotoxicity in rat liver, male SD rats were treated with various chemicals including PHO, DEM or BSO, Bromobenzene (BBZ), etc. Liver samples were taken 3, 6, 9, and 24 hr after administration and examined for hepatic GSH content, physiological and pathological changes, and for gene expression changes by Affymetrix GeneChip. Differentially expressed probe sets responsive to GSH-depletion were extracted according to the following two courses relating to GSH-depletion: gene expression changes simultaneously in response to GSH-depletion and shortly after GSH-depletion. The extracted probe sets were refined and verified by gene expression data from rat liver samples treated with 17 compounds, resulting in 21 probe sets responsive to GSH-depletion induced by GSH-conjugation, 14 probe sets responsive to both types of GSH-depletion, but specifically altered probe sets were not found in response to GSH-depletion induced by inhibition of GSH synthesis. Some known GSH-depletors, PHO, DEM, BBZ, BSO, nitrofurazone, acetaminophen, coumarin, methapyrilene were well distinguished from the GSH-depletion negative compounds and the controls by principal component analysis using gene expres-

sion data of the 14 probe sets from rat liver samples collected 24 hr after treated with 17 compounds. The 14 probe sets would be promising biomarker gene sets for further understanding of GSH-depletion and identification of GSH-depletion related hepatotoxicity in drug safety evaluation.

PS 1605 NOVEL BIOMARKERS FOR RISK OF PROSTATE CANCER. RESULTS FROM A CASE-CONTROL STUDY.

L. Yang[1], E. G. Rogan[1], E. L. Cavalieri[2], P. Muti[5], B. Trock[4] and J. Meza[3]. *[1]Department of Environmental, Agricultural and Occupational Health, University of Nebraska Medical Center, Omaha, NE, [2]Eppley Institute for Research in Cancer and Allied Diseases, Omaha, NE, [3]Department of Biostatistics, University of Nebraska Medical Center, Omaha, NE, [4]Brady Urological Institute, The Johns Hopkins School of Medicine, Baltimore, MD and [5]Department of Cancer Epidemiology, Italian National Cancer Institute, Rome, Italy.*

Even though the estrogens estrone and estradiol are recognized to play a very important role in the risk of developing prostate cancer (Pca), the molecular mechanism by which estrogens initiate and/or promote Pca is still largely unknown. Substantial evidence supports the idea that specific metabolites of estrogens, reactive catechol estrogen quinones can react with DNA to form depurinating estrogen-DNA. Apurinic sites that are formed by depurination can induce mutations leading to cancer. Once released from DNA, the depurinating estrogen-DNA adducts are shed from cells into the bloodstream and excreted into the urine. By analyzing the estrogen metabolite profiles in the urine from men with and without prostate cancer, potential biomarkers of Pca can be detected. The goal of this case-control study is to detect and identify a potential biomarker of Pca.
Urine samples from fourteen cases, men diagnosed with Pca, and one hundred and twenty-five controls, men who had not been diagnosed with Pca, were partially purified by solid phase extraction and analyzed by ultra-performance liquid chromatography/tandem mass spectrometry. The urinary levels of androgens, estrogens, estrogen metabolites, conjugates and depurinating DNA adducts were measured. The median levels of 4-OHE1(E2)-1-N7Gua, 4-OHE1(E2)-1-N3Ade and 2-OHE1(E2)-N3Ade, which reflect the oxidative pathway of estrogen metabolism, are higher in the Pca group than those in the control group ($p=0.0004$, $p=0.056$, $p=0.0014$, respectively), suggesting that the oxidative pathway that leads to DNA adduct formation is more active in the Pca group than in the control group. The ratio of depurinating estrogen-DNA adducts to the sum of the corresponding estrogen metabolites and conjugates was significantly higher in cases (57.34) compared to controls (23.39) ($p<0.001$). This study suggests that the depurinating estrogen-DNA adducts could serve as a potential biomarker to predict risk of Pca. They also could be useful tools for early clinical diagnosis and development of suitable strategies to prevent Pca.

PS 1606 INVESTIGATIONS TO IDENTIFY PROLIFERATING SINUSOIDAL ENDOTHELIAL CELLS IN B6C3F1 MOUSE SPLEEN.

A. Shen, S. Zhao, C. Huang and S. A. Sokolowski. *Drug Safety Research and Development, Pfizer Global Research and Development, Groton, CT.*

The purpose of this study was to investigate and establish methods for the identification of proliferating sinusoidal endothelial cells in mouse spleen by multicolor flow cytometry. B6C3F1 mouse splenocytes were isolated and stained with CD31 (PE-CAM1), CD45, Flk-1 (VEGFR-2), CD105 (Endoglin), CD71 and CD146 (LSEC) antibodies to characterize the spleen cell populations in normal animals. Extracellular or intracellular Flk1 staining was not observed. The CD105 and CD71 antibodies labeled populations separate from the EC population. Results from these studies demonstrate the spleen cell endothelial cell population to be CD31+ CD146+ CD45-. To develop appropriate methods to identify proliferating endothelial cells, traditional (BrdU) and novel (EdU) proliferation markers were compared in studies designed to induce EC proliferation. Using 2-butoxyethanol (2-BE) as a positive control compound, male B6C3F1 mice were dosed by oral gavage once daily for 7 consecutive days with either 900 mg/kg 2-BE or vehicle. For EdU and BrdU evaluations, mice were implanted with osmotic pumps containing either 20 mg/mL 5-bromo-2′-deoxyuridine (BrdU) or 5-ethynyl-2′-deoxyuridine (EdU). Total nucleated spleen cell counts increased approximately 2 fold in 2-BE treated mice. Evaluation with EdU demonstrated a several fold increase of proliferating endothelial cells in 2-BE treated animals compared to vehicle control. Analysis of BrdU samples revealed extensive cell loss possibly due to the harsh processing method required for detection of proliferating cells with BrdU. The EdU proliferation marker was shown to be superior to BrdU for the identification of proliferating endothelial cells in mouse spleen by flow cytometry.

PS 1607 IDENTIFICATION AND QUANTITATION OF PROLIFERATING LIVER SINUSOIDAL ENDOTHELIAL CELLS BY FLOW CYTOMETRY IN MICE AFTER TREATMENT WITH 2-BUTOXYETHANOL.

C. Huang, S. Eddy, A. Shen, S. Zhao and S. A. Sokolowski. *Drug Safety Research and Development, Pfizer Global Research and Development, Groton, CT.*

Induction of liver sinusoidal endothelial cells (LSEC) may be related to hepatotoxicity, hepatic injury, development of hemangiosarcomas and hepatic carcinomas. It is critical to develop methods to identify and quantify proliferating LSEC to evaluate drug induced hepatotoxicity during non-clinical drug development. Here we describe a method to identify proliferating LSEC from B6C3F1 mouse liver tissue by using multicolor flow cytometry techniques. Mice were euthanized and liver perfusions were performed by injecting HBSS buffer with EGTA(38mg/100ml) and HEPES(230mg/100ml)), followed by Collagenase II solution (60mg/100ml) through the inferior vena cava. Livers were removed and further digested in the Collagenase II buffer for an additional 15 minutes. Liver non-parenchymal cells were enriched by centrifugation. To identify LSEC, cells were stained with exclusion markers CD45, CD3, B220, and CD11b and inclusion markers CD31, Flk1 and CD105. The results indicate that the CD31+/CD45- phenotype accurately identifies the LSEC. To assess cellular proliferation, male B6C3F1 mice were dosed by oral gavage once daily for 7 consecutive days with either 900 mg/kg 2-butoxyethanol (2-BE) or vehicle. Mice were implanted with osmotic pumps containing 5-ethynyl-2′-deoxyuridine (EdU). Proliferating CD45+/EdU+ and CD31+/CD45-/EdU+ cells were quantitatively measured and absolute counts were calculated by using BD TruCOUNT Tubes. In this study, we observed a 1.2 fold increase of the proliferating LSEC population and a 0.5 fold reduction of the leukocyte (CD45+) population after 2-BE treatment. These results suggest that 2-BE treatment (900mg/kg) may have a proliferating effect on LSEC and a detrimental effect on other cell types in the liver.

PS 1608 BLOOD GENE EXPRESSION MARKERS FOR TARGET ORGAN TOXICITY.

P. Joseph, C. Umbright, R. Sellamuthu, M. Kashon and M. Luster. *Health Effects Laboratory Division, NIOSH, Morgantown, WV.*

The purpose of this study was to investigate whether peripheral blood gene expression can be used as non-invasive, surrogate marker(s) to detect and distinguish target organ toxicity. Rats were intraperitoneally administered a single, acute dose of either a hepatotoxic (acetaminophen) or a neurotoxic (methyl parathion) chemical. Administration of acetaminophen (AP) in the rats resulted in hepatotoxicity as evidenced from elevated blood transaminase activities. Similarly, administration of methyl parathion (MP) resulted in neurotoxicity in the rats as evidenced from the inhibition of acetyl cholinesterase activity in their blood. Microarray analysis of the global gene expression profile in rat blood identified distinct gene expression markers which were capable of detecting and distinguishing hepatotoxicity and neurotoxicity induced by the chemicals. Differential expressions of the marker genes, for hepatotoxicity and neurotoxicity, were detectable in the blood much earlier than the appearance of the widely used clinical markers corresponding to the respective toxicities. The hepatotoxicity and neurotoxicity marker genes were further validated using additional hepatotoxic (thioacetamide, dimethylnitrobenzene and carbon tetrachloride) or neurotoxic (ethyl parathion, chlorpyrifos and malathion) chemicals. The blood gene expression markers detected and distinguished hepatotoxicity and neurotoxicity induced by the chemicals with significant accuracy and specificity. In summary, our results demonstrated that blood gene expression may be used as markers to detect and distinguish target organ toxicity. Furthermore, it appears that the blood gene expression markers are more sensitive than the traditional toxicity markers. Disclaimer: The findings and conclusions in this abstract have not been formally disseminated by the National Institute for Occupational Safety and Health and should not be constructed to represent any agency determination or policy.

PS 1609 IDENTIFICATION OF NOVEL GENOMIC BIOMARKERS OF SKELETAL MUSCLE TOXICITY IN RAT BY CORRELATION ANALYSIS OF GENE EXPRESSION AND HISTOPATHOLOGY DATA.

U. Hemmann[1], A. Bube[1], K. Lindauer[2], I. Stammberger[1], G. Troschau[1] and K. Kotlenga[1]. *[1]Drug Safety Evaluation, sanofi-aventis, Frankfurt, Germany and [2]Biological Sciences Department, sanofi-aventis, Frankfurt, Germany.*

Skeletal muscle toxicity is of particular interest in preclinical testing of PPAR agonists, which are developed as drug candidates for type II diabetes and dyslipidemia. CK and AST are conventionally used to monitor skeletal muscle toxicity in preclinical animal species. However, these markers often lack sensitivity, especially when

measured outside their optimum diagnostic window. In addition, they do not allow the differentiation of type I versus type II muscle fiber damage. Thus, there is a need for new predictive and sensitive markers of myotoxicity, which identify damage early in its progression and allow discrimination of adverse events in type I and type II fibers. In this study, phenotypic anchoring of the expression data to individual animal histopathology or clinical chemistry parameters was applied in order to identify novel genomics biomarkers for skeletal muscle toxicity in rats. In a 14-day rat study, the potent PPAR delta agonist GW501516 was used as a model compound to induce lesions in type I (M soleus) and type II (M quadriceps) skeletal muscles. Transcripts that correlate with the microscopic findings observed in the respective muscle were identified and used to characterize adverse effects in type I or type II muscles. Among the genes with high correlation with histopathology and significant regulation in M quadriceps were Sln (sarcolipin), Ankrd1 (ankyrin repeat domain 1) and Tpm3 (tropomyosin 3). Relevant transcripts in M soleus included for example the scavenger receptor Scarb1. Gpnmb (osteoactivin), Sfrp4 (secreted frizzled-related protein 4) and Spp1 (osteopontin) showed high correlation and induction in both muscles. Several transcripts are proposed as potential genomic biomarkers for myotoxicity. The identified set of transcripts could further provide insights into the potential mechanism of PPAR-induced skeletal muscle damage.

PS 1610 DEVELOPMENT AND VALIDATION OF A GENE EXPRESSION SIGNATURE FOR SKELETAL MUSCLE INJURY IN RAT.

G. H. Searfoss[1], J. Gollub[2], C. I. Pearson[2], M. Fielden[2] and C. Thomas[1]. [1]*Investigative Toxicology, Eli Lilly & Co., Indianapolis, IN and* [2]*Entelos, Inc., Foster City, CA.*

Skeletal muscle fiber injury is a sporadic but recurrent event that has been seen both preclinically and clinically (e.g. statin-induced rhabdomyolysis) during drug development. Early identification of molecules that may induce muscle injury during preclinical safety studies in the rat would be advantageous. However, established serum biomarkers of skeletal muscle injury in the rat (e.g., creatine kinase, alkaline phosphatase) become elevated only in response to injury, limiting their value as predictive tools. Recently, biomarkers based on gene expression profiles have been shown to have utility as sensitive diagnostic and, in some cases, predictive markers of both pharmacologic and toxicologic end points. Consequently, we sought to develop a gene expression signature to detect generalized skeletal muscle injury in short term rat toxicology studies. Seven proprietary compounds directed across several drug target classes were administered daily by oral gavage to Sprague Dawley rats at doses that produced microscopic injury at or before day 14. RNA was extracted from muscle tissue at days 1 and 5 and changes in gene expression were determined using Affymetrix RG 230 2.0 arrays. A sparse linear programming machine learning approach was used to derive a signature comprised of 27 genes that demonstrated excellent performance metrics in cross validation. The signature achieved a sensitivity of 99% and a specificity of 95%. Independent validation testing with 8 compounds demonstrated that the signature accurately diagnosed muscle injury for each of the 6 compounds that caused injury. Furthermore, 4 day tissue samples were sufficient to predict the extent of muscle toxicity resulting in evident histologic changes after 14 days, suggesting the signature has predictive potential. The signature performed well across different compound target classes, in different rat strains, and for injury occurring in different muscle fiber types.

PS 1611 NON-INVASIVE BIOMARKER DEVELOPMENT FOR AIRWAY DISEASE AND EXPOSURE.

K. Bloemen[1], R. Van Den Heuvel[1], G. Koppen[1], E. Govarts[1], K. Desager[3], E. Witters[1, 2] and G. Schoeters[1, 2]. [1]*Environmental toxicology, VITO, Mol, Belgium,* [2]*UA, Antwerp, Belgium and* [3]*UZA, Antwerp, Belgium.* Sponsor: B. De Wever.

Exhaled breath condensate (EBC) is a biological fluid that contains trace amounts of secreted pulmonary proteins, and is emerging as a potentially valuable and non-invasively obtained source of disease or exposure biomarkers. We developed a protocol for proteome analysis of these samples*, which leads to the selection of a biomarker pattern for airway disease or exposure. In short, proteins in 1 ml EBC (about 1 μg/ml) are concentrated on POROS R2 beads and digested with trypsin. Resulting peptides are separated and analyzed by nano-LC/MSMS. Protein patterns are selected by performing Support Vector Machine analysis (Weka software). In a first pilot study, samples from 6 smokers and 6 non-smokers were analyzed and compared. Proteins such as calgranulin A, calgranulin B, hemoglobin, lysozyme and cytokeratins 1, 2, 9 and 10 were identified. Calgranulin B was uniquely present in samples from smokers. To investigate the predictiveness of the protein profile towards clinical endpoints, the protocol was also applied on EBC samples from another study including 40 children with asthma, and 30 healthy children (age 6-12 years). A pattern based on 16 peptides was able to differentiate correctly between asthmatic and healthy individuals. Two of those peptides were identified as a part of cytokeratins 1 and 9. The other peptides are still under investigation. The developed procedure led to the identification of new proteins in EBC. Furthermore, it makes it possible to select biomarker patterns for disease or exposure. Manuscript accepted for publication in Proteomics – Clinical Applications. This study was partly supported by the Belgian Science Policy (Contract number SD/HE/05A: ANIMO project).

PS 1612 PRELIMINARY FINDINGS OF THE LIVER TOXICITY BIOMARKERS STUDY: ENTACAPONE AND TOLCAPONE.

W. M. Hines[1], J. C. Fuscoe[2], L. S. VonTungeln[2], L. K. Schnackenberg[2], R. D. Beger[2], C. L. Moland[2], J. J. Chen[2], T. Han[2], C. Chang[2], Z. Su[2], X. Fan[2], W. Tong[2], S. A. Booth[1], R. Balasubramanian[1], P. L. Courchesne[1], J. M. Campbell[1], A. Graber[1], Y. Guo[1], T. Y. Li[1], M. D. Lynch[1], N. M. Morel[1], T. N. Plasterer[1], C. Zeng[1], F. A. Beland[2] and R. N. McBurney[1]. [1]*BG Medicine, Waltham, MA and* [2]*National Center for Toxicological Research, U.S. Food and Drug Administration, Jefferson, AR.*

Drug Induced Liver Injury (DILI) represents a challenge for new therapeutics despite extensive preclinical efforts to identify hepatotoxic drugs prior to introduction into the clinic. The Liver Toxicity Biomarker Study (LTBS) was conceived to better predict drug candidates likely to produce idiosyncratic DILI. LTBS compares pharmacologically similar drug pairs; with one drug being associated with DILI in humans though not predicted by preclinical studies. A broad spectrum of molecular profiling measures in liver, plasma, urine, and serum clinical chemistries provides the foundation for the comparisons. The first drug pair comparison—entacapone(clean) and tolcapone(DILI)—is reported. Ten study cohorts containing 12 male Sprague-Dawley rats per cohort were dosed with vehicle or drug for 3 or 28 days. 3-Day dosing was limited to the high dose while 28-Day dosing included low, medium and high (E 30, 110, 400, T 15, 55, 200 mg/Kg) doses. Urine was collected predosing through day 4 and on day 27 for the 28 day study. Plasma and liver samples were collected at sacrifice. 1H NMR metabolomic analysis was performed on all urine samples. Plasma samples analysis platforms included proteomics (discovery iTRAQ and targeted) and metabolomics (lipid LC/MS, derivatized polar LC/MS and targeted amino acid analysis). Liver sample analysis included transcriptomics, discovery proteomics, and the same metabolic platforms as plasma. The results show high analytical quality data from 240 primary liver and plasma samples, greater than 800 urine samples, with CVs generally less than 20%. Over 2500 significant changes were found. These include differences in drug metabolizing enzymes and transcripts as well as off target effects synchronized between transcriptomics, proteomics, and metabolomic findings.

PS 1613 NATRIURETIC PEPTIDES AS BIOMARKERS OF CARDIAC HYPERTROPHY IN RATS.

S. K. Engle[1], M. J. Berna[1], M. L. Pritt[1], B. Ackermann[1], A. Schultze[1], V. Reynolds[1], P. F. Solter[2] and D. E. Watson[1]. [1]*Eli Lilly and Company, Indianapolis, IN and* [2]*University of Illinois, Urbana-Champaign, IL.*

Serological biomarkers of cardiac hypertrophy would be beneficial for drug development, but are not currently available for use in veterinary species or humans. Natriuretic peptides are important in the regulation of plasma volume and related phenomena that can lead to cardiac hypertrophy. We therefore evaluated the utility of NTproANP and NTproBNP as biomarkers of cardiac hypertrophy caused by PPAR α/γ dual agonist LY510929 in Sprague-Dawley rats. Heart-to-brain weight ratios were increased 51%, 50%, or 78% after 28 days of treatment with 0.5, 5, or 50 mg/kg LY510929. Transcripts for Nppa (natriuretic peptide precursor A), Nppb (natriuretic peptide precursor B) and Myh7 (myosin heavy chain β) were measured in left atria and ventricles by TaqMan. In left atria, Nppa, Nppb, and Myh7 were induced 1.6, 1.7, and 2.0 fold at 0.5 mg/kg, 1.6, 2.0, and 3.0 fold at 5 mg/kg, and 1.6, 1.8, and 3.4 fold at 50 mg/kg, respectively. In left ventricles, transcription of Myh7 was not increased; Nppa and Nppb were induced 4.2, and 4.0 fold at 0.5 mg/kg, 17.0, and 4.4 fold at 5 mg/kg, and 35.0, and 8.4 fold at 50 mg/kg respectively. Increases in Nppa and Nppb transcripts in left ventricles were correlated with absolute heart weight (r = 0.73 and 0.83). NTproANP measured in serum by ELISA was 0.9 ± 0.1, 2.0 ± 0.2, 2.3 ± 0.4, and 3.6 ± 0.4 nM at 0, 0.5, 5, and 50 mg/kg, respectively. These values were correlated with absolute heart weight as well (r=0.73). NTproBNP was measured in serum by mass spectrometry and was 0.18 ± 0.03, 0.30 ± 0.03, 0.27 ± 0.04, and 0.22 ± 0.03 ng/mL, and was not correlated with absolute heart weight (r=0.24). Transcription of Nppa was well-correlated with NTproANP in serum (r=0.84); whereas transcription of Nppb was not correlated with NTproBNP in serum (r=0.14). After 1, 3, and 7 days of treatment with 50 mg/kg LY510929, NTproANP in serum was increased 2-5 fold from control. These results suggested that NTproANP may be a predictive biomarker of cardiac hypertrophy induced by PPAR agonism in rats.

1614 EXPLORATION OF NEW LIVER-SPECIFIC MRNAS DETECTABLE IN PERIPHERAL BLOOD FROM RATS WITH DRUG-INDUCED LIVER DAMAGE FOR HEPATOTOXICITY BIOMARKERS.

M. Miyamoto, S. Okubo, M. Yanai, N. Awasaki, K. Takami and R. Imai. *Development Research Center, Takeda Pharmaceutical Company Limited, Osaka, Osaka, Japan.*

If organ/tissue-specific mRNAs leaking from drug-damaged organs/tissues could be detected in peripheral blood, such mRNAs are expected to be toxicological biomarkers for identification of the target organs for drug toxicity. Recently, we reported that α1-microglobulin/bikunin precursor (Ambp) and albumin mRNAs, which are specifically expressed in the liver, were detectable in peripheral blood from rats with chemical-induced hepatotoxicity by a reverse-transcription polymerase chain reaction (RT-PCR) [Miyamoto et al, Tox Sci, in press]. In order to identify the target organs for drug toxicity, evaluation with several marker mRNAs would be valuable to enable the acquisition of more reliable results and to avoid false-positive findings. Therefore, we explored new liver-specific mRNAs other than Ambp and albumin mRNAs. Peripheral blood was collected from rats receiving D-galactosamine HCl and total RNA was extracted. Based on several reference databases for gene expression analysis, we selected 31 candidate genes which were considered to be expressed exclusively and at high levels in normal liver. Of their transcripts, 9 mRNAs were detected by RT-PCR in peripheral blood from the rats with hepatotoxicity but not from normal rats. Their expression levels were examined for a total of 9 major organs/tissues from rats and finally Apoh (apolipoprotein H), Slco1b2 (solute carrier organic anion transporter family 1b2), Plg (plasminogen) and GC (group specific component) mRNAs were judged to be liver-specific. In conclusion, 4 new liver-specific mRNAs were found in the present study. A total of 6 liver-specific mRNAs, including the previously explored Ambp and albumin mRNAs, are expected to allow more accurate detection of hepatotoxicity when they are used in combination.

1615 PORCINE-TO-MURINE TESTICULAR XENOGRAFTS AS NOVEL BIOMARKERS FOR PREPUBERTAL EXPOSURE TO ENDOCRINE DISRUPTORS.

T. J. Evans, E. M. Walters, V. K. Ganjam and Y. Agca. *University of Missouri-Columbia, Columbia, MO.*

There is increasing concern about the potential adverse effects of endocrine disruptors (EDs) on human fertility. Relatively little is known about the effects of EDs on prepubertal reproductive development in non-rodent mammals. Swine share many anatomic and physiologic similarities with humans and are likely to provide an accurate model for human risk assessment involving exposures to EDs. However, there are financial and logistical concerns associated with the use of porcine models in comparative research. The recent development of testicular tissue xenografting techniques using immunodeficient murine recipients addresses some of those concerns. Using the antiandrogenic fungicide vinclozolin (VCZ) as a model ED, it was hypothesized that oral exposure to VCZ would adversely affect the development of spermatogenically and steroidogenically competent porcine-to-murine testicular xenografts. Two, 8-week-old boars were orally exposed to either 0 or 100 mg VCZ/kg body weight for 5 weeks. Portions of the testes from each animal were xenografted into castrated and vasectomized immunodeficient mice (n=6 for each boar; 6 xenografts per mouse), and xenograft development was evaluated at 10 or 21 weeks post-surgery. Porcine-to-murine testicular xenografts originating from the control boar were larger at both 10 and 21 weeks post-implantation and appeared to have more "functional' seminiferous tubules at 21 weeks, as compared to xenografts of tissue collected from the VCZ-treated animal. In addition, both testosterone and immunosayable estrogens were detected in serum samples from recipient mice xenografted with testicular tissue from the control animal, but the serum from mice with xenografted tissue from the VCZ-treated boar contained essentially undetectable concentrations of immunoassayable estrogens. The results of this preliminary study demonstrate that altered development of porcine-to-murine testicular xenografts can be used as a novel biomarker for the effects of prepubertal exposures to EDs on porcine spermatogenesis and steroidogenesis.

1616 EARLY METABOLIC BIOMARKERS OF DRUG-INDUCED NEPHROTOXICITY.

K. M. Weinberger. *Biocrates Life Sciences, Innsbruck, Austria.* Sponsor: G. Bode.

Nephrotoxicity is still one of the most frequent reasons for late-stage drug failures but there are no biomarkers monitoring the early pathophysiological events involved in glomerular and tubular dysfunction. In this longitudinal study, a targeted metabolomics approach quantifying several hundred endogenous metabolites in plasma and urine has been applied to study dose- and time-dependence of biochemical alterations associated with puromycin-induced nephropathy in Sprague-Dawley rats. Metabolites such as amino acids, biogenic amines, polyamines, glycerophospho- and sphingolipids, reducing sugars, acylcarnitines, polyunsaturated fatty acids, eicosanoids, etc. were analyzed by multiple reaction monitoring on tandem mass spectrometers, and concentrations were determined by stable isotope dilution. The quantitative data were then statistically analyzed and mapped onto biochemical pathways for a mechanistic understanding of the observed deviations from healthy homeostasis. By systematically assessing the intra-individual time-courses and the significant differences between the controls and three dose-groups (10, 20, and 40 mg/kg/day)we could identify a set of biomarker candidates for crucial events in nephropathy such as tissue damage, mitochondrial leakage, phospholipase activation, lipoxygenase and cyclooxygenase activation (i.e. the orchestration of the inflammatory response), tubular dysfunction as shown by impaired resorption of specific metabolite classes, oxidative stress, regulation of immune cell activity, and various other accompanying phenomena. Most interestingly, some of the markers were able to indicate significant biochemical alterations even in the low-dose group which was previously characterized as showing no histopathological changes at all. This clearly demonstrates that targeted metabolomics is ideally suited as a sensitive tool for early detection of nephrotoxicity, and it also grants mechanistic insight into the underlying biochemical pathways.

1617 DETECTION OF THE MITOCHONDRIAL AND CATALYTICALLY ACTIVE ALANINE AMINOTRANSFERASE (ALT2) IN HUMAN TISSUES AND PLASMA.

B. Glinghammar[1], I. Rafter[1], L. Anna-Karin[2], H. Jesper[1] and C. Ian[1]. *[1]Molecular Toxicology, Safety Assessment, S√∂dert√§lje, Sweden and [2]Pathology, Safety Assessment, S√∂dert√§lje, Sweden.*

Serum alanine aminotransferase (ALT) is used as a clinical marker of hepatotoxicity. Two forms of ALT have been identified in the genome of most species studied, ALT1 and ALT2. A shorter form of ALT2 also exists due to alternative splicing (ALT2_2). The standard ALT activity assay does not discriminate between ALT from different organs, or which isoform being measured in plasma. Here, we show that ALT1 and ALT2 possess similar enzymatic activity for alanine and pyruvate but with different Km and kcat values, while recombinant ALT2_2 protein does not possess any enzymatic activity. We developed an antibody that specifically detected catalytic form of ALT2 to distinguish it from ALT2_2. Isolation of organelles from cultured human skeletal muscle cells, showed localisation of ALT2 to the mitochondrial fraction and endoplasmatic reticulum (ER), but not to the cytosol. In human hepatocytes, on the other hand ALT1 was only localised to the cytosol and ER, with no detection in mitochondria. ALT2 was not detected in cultured human hepatocytes, liver extract or liver tissue using western blotting or immunohistochemistry. Skeletal muscle, the islet of Langerhans and cardiomyocytes were other examples of cells with high expression of catalytic ALT2. A clinical method for selective measurement of ALT1 and ALT2 in human plasma is described, and both ALT1 and ALT2 were immunoprecipitated from human plasma and structurally detected using western blotting techniques.

1618 IDENTIFICATION OF GLUTATHIONE-DNA ADDUCTS INDUCED BY FORMALDEHYDE.

K. Lu, W. Ye, A. Gold, L. M. Ball and J. A. Swenberg. *Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC.*

Formaldehyde (HCHO) is a known human and animal carcinogen. Previous studies have demonstrated that inhaled HCHO causes nasal cancers in rats and humans. However, determining whether or not distant site effects of HCHO occur remains a critical issue for understanding HCHO toxicity, carcinogenicity and epidemiology. Limited epidemiology data suggest that leukemia may be associated with HCHO exposure, however, there are no experimental data which demonstrate that HCHO can reach distant sites in an active form. This has been attributed to the rapid metabolism of HCHO by glutathione (GSH)-dependent enzyme systems. Among the intermediates in the pathway of HCHO detoxification, *S*-hydroxymethylgultathione is a reactive species that has the potential to further conjugate with DNA bases. To test this hypothesis, a physiologic concentration of GSH (5mM) was incubated with HCHO, followed by the addition of deoxyguanosine or DNA. The coupling product eluted at 11.87 min on a C18 column and gave an UV absorbance maximum at 260nm. The exact mass of the protonated adduct was 587.1896 Da, consistent with the expected elemental composition $C_{21}H_{30}N_8O_{10}S$. The HCHO-derived methylene linkage between the methylene carbon of the Cys residue and exocyclic $N^2$of dG was established by NMR spectroscopy. The amount of adduct rose with increasing HCHO concentration from 0.1mM to 5mM *in vitro*. At higher HCHO concentrations, adduct formation was limited by availability of GSH as a result of the conjugation of *S*-hydroxymethylgultathione with a second HCHO molecule. Demonstration of the formation of HCHO-induced *S*-[1-(N^2-deoxyguanosinyl)-methyl]GSH adduct between GSH and DNA is unique

because of the involvement of *S*-hydroxymethylgultathione, a key player during the detoxification of HCHO. This adduct may serve as a promising biomarker to understand HCHO toxicity and carcinogenesis at contact and distant sites if coupled with the application of isotope-labeled HCHO to differentiate the endogenous and exogenous HCHO.

PS 1619 INTERPRETING TRIHALOMETHANE BIOMONITORING DATA IN A PUBLIC HEALTH RISK CONTEXT USING BIOMONITORING EQUIVALENTS.

S. M. Hays[1], L. L. Aylward[2], J. S. LaKind[3, 4] and B. C. Blount[5]. *[1]Summit Toxicology LLP, Lyons, CO, [2]Summit Toxicology LLP, Falls Church, VA, [3]LaKind Associates LLC, Catonsville, MD, [4]School of Medicine, University of Maryland, Baltimore, MD and [5]National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, GA.*

Biomonitoring Equivalents (BEs) provide a useful tool for interpreting human biomonitoring data in a public health risk context. Interpretation of biomonitoring data for compounds with short half-lives in humans, however, poses challenges for the BEs construct. This paper presents the derivation of BE values for trihalomethane compounds (THMs) and recommendations for evaluation of biomonitoring data for short-lived compounds using BEs for THMs. THMs commonly form as byproducts during drinking water disinfection, leading to episodic exposures to THMs from drinking, showering or bathing in disinfected water. THMs have short half-lives in humans. Variations in population biomonitoring data for THMs will reflect the variabilities associated with, 1) the concentration of THMs in water, 2) the extent of exposures, 3) the rate of metabolism and elimination of THMs in individuals, and 4) the timing between exposures and collection of a blood sample. However, the BE values for THMs correspond to the steady-state concentrations of THMs in blood consistent with the current USEPA RfDs for these compounds. This disconnect influences the interpretation of exceedances of the BE in population based biomonitoring data sets. The BE values were derived using currently available physiologically based pharmacokinetic models for THM compounds and analysis of the underlying toxicity data used as the basis for the RfD values. BE values corresponding to current USEPA RfDs for chloroform, dibromochloromethane, bromodichloromethane, and tribromomethane are 230, 80, 20, and 130 pg/ml in blood, respectively. Interpretation of CDC biomonitoring data for these compounds using the BE values is discussed.

PS 1620 MEASURING 1, 4-DIOXANE IN BLOOD AS A BIOMARKER OF EXPOSURE.

R. Y. Wang, B. C. Blount, D. M. Chambers, D. O. McElprang and C. G. Skinner. *Division of Laboratory Sciences, Centers for Disease Control and Prevention, Atlanta, GA.* Sponsor: B. Fowler.

1,4-Dioxane is a relatively polar ether that is a rodent carcinogen and has potential toxicity to the central nervous system, liver and kidneys. 1,4-dioxane has many industrial uses as an aprotic solvent and can also form in consumer products as a synthesis byproduct. Potential human exposure to 1,4-dioxane in personal care products has led to concerns about internal dose and health effects. Based on the chemical characteristics of 1,4-dioxane, dermal exposure may not lead to increased internal dose because 1,4-dioxane is unlikely to partition through skin at a significant rate. Therefore internal dose measurements are required to best interpret the potential exposure and health relevance of 1,4-dioxane in dermally-applied consumer products. To meet this need we developed a method for measuring 1,4-dioxane in human blood. This method uses solid phase microextraction coupled with gas chromatography and mass spectrometry to quantify 1,4-dioxane concentrations as low as 0.400 ng/mL in a 3 mL human blood specimen. We applied this method to human blood specimens collected in 2007 – 2008 from a geographically-diverse population of U.S. residents ages 12 years and older. No detectable concentrations of 1,4-dioxane were found in 2053 human blood specimens analyzed. Despite the potential for exposure to 1,4-dioxane from dermally-applied consumer products, we found no measurable internal dose. These data appear to be consistent with the low dermal permeability of 1,4-dioxane.

PS 1621 USING BLOOD MEASUREMENTS TO ASSESS EXPOSURE TO DIOXIN/FURANS: POTENTIAL INFLUENCE OF ELEVATED DETECTION LIMITS.

L. F. Scott[2], J. Keenan[1], B. L. Finley[1] and S. H. Gaffney[1]. *[1]ChemRisk, San Francisco, CA and [2]ChemRisk, Houston, TX.*

Exposure to polychlorinated dibenzo-p-dioxins and dibenzofurans (PCDD/Fs) is frequently estimated by measuring congener levels in blood. Total toxic equivalent (TEQ) concentrations are often used to characterize blood levels of the PCDD/F congeners. In this study, blood PCDD/F levels of 11 residents (ages 37-79 years) of a community situated in close proximity to a wood treatment plant were compared to the 2003-2004 National Health and Nutrition Examination Survey (NHANES) serum concentration data for participants 37 years and older (n=661). Average limits of detection (LODs) were 5-27 times higher for the community cohort than the corresponding LODs for the NHANES data. Additionally, on average, only ~3 of 17 congeners were detected for the community cohort, with the percentage of congeners not detected (ND) in the blood of these 11 individuals ranging from 65 to 94%, whereas an average of 8 congeners were detected for NHANES participants. When congeners reported as ND were assumed to have a concentration equal to the LOD/$\sqrt{2}$, higher average total TEQ concentrations (stratified by age) were observed in the blood of the community cohort relative to the NHANES population (~3 to 5 times higher). However, when total TEQ levels were calculated using a value of zero for non-detected congeners, the average total TEQ in blood was, generally, lower in the community cohort than the NHANES population. Therefore, the observed difference in total blood TEQ may simply be the result of 1) the higher percentage of congeners not detected in the blood of the community cohort and 2) the much higher analytical LODs for these 11 individuals compared to the NHANES data. In conclusion, when comparing blood PCDD/F levels of a population to NHANES, it is important to carefully analyze the congener detection frequencies and LODs before drawing conclusions, and in some cases, a comparison of congener concentrations for those congeners with a high detection frequency may be more appropriate than calculating total TEQs.

PS 1622 INFLUENCE OF THE UNIT OF EXPRESSION OF BIOMONITORING DATA ON THE ASSESSMENT OF PYRETHROID EXPOSURE.

M. C. Fortin, G. Carrier and M. Bouchard. *Department of Environmental and Occupational Health, Universite de Montreal, Montreal, QC, Canada.*

Human exposure to non-persistent pesticides such as pyrethroids is often based on urinary biomarker measurements. These are usually expressed in volume-weighted or creatinine-adjusted concentrations measured in spot urine samples. This research aimed at studying the effect of the unit of expression of biomonitoring results (volume-weighted or creatinine adjusted concentrations or 24-h amounts) on the assessment of pyrethroid absorbed doses at individual and population levels. Using population data from previous studies, intra-individual (void-to-void) and inter-individual variations in the urinary flow rate and creatinine excretion rate were assessed. Individual daily absorbed doses of permethrin were then reconstructed from volume-weighted and creatinine-adjusted concentrations of urinary biomarkers, according to published approaches, and compared to a benchmark dose estimate obtained from amounts of biomarkers in timed collections. The effect of the units of measurements on results of comparisons of biomarker levels between two populations was also assessed. There were large void-to-void variations in the urinary flow rate and creatinine excretion rate (%CV of up to 101% and 48%, respectively) as well as large between-individual variability (%CV of up to 48% and 45%, respectively). Estimation of individual absorbed doses of permethrin from volume-weighted or creatinine-adjusted concentrations of biomarkers was thus found to potentially lead to substantial under or overestimation when compared to doses reconstructed directly from amounts excreted in urine during a given period of time (–70 to +573% and –83 to +167%, respectively). It was also shown that the variability in creatinine excretion rate and urinary flow rate may introduce a bias that limits the validity of between population comparisons. The unit chosen to express biomonitoring data may thus influence the validity of estimated individual absorbed dose as well as the outcome of between population comparisons.

PS 1623 EVALUATION OF A TEST METHOD FOR THE MEASUREMENT OF URINARY CYCLOPHOSPHAMIDE, 4-KETOCYCLOPHOSPHAMIDE AND IFOSFAMIDE.

C. B'Hymer and K. L. Cheever. *BHAB, NIOSH, Cincinnati, OH.*

High-Performance Liquid Chromatography-Mass Spectrometric (HPLC-MS) conditions were developed and validated for use to detect and quantitate urinary levels of cyclophosphamide (CP), 4-ketocyclophosphamide (4-ketoCP) and ifosfamide (IF). CP and IF are common antineoplastic drugs used for the treatment of many types of cancer. These compounds have known toxicity and are carcinogenic; thus, workers in the health care field, including nurses and pharmacists who prepare or dose patients, have potential exposure risk. 4-KetoCP is the primary urinary metabolite of CP and is a good potential biomarker of exposure to the parent drug. Spiked urine specimens were extracted with ethyl acetate, and then the liquid volume was reduced by evaporation. A triple quadrupole mass spectrometer (MS/MS) was used as detector with gradient reversed-phase HPLC conditions to measure the target analytes. Recovery studies using 1, 2, 4 and 15 ng/ml CP and IF spiked urine samples, and 25, 50, 100 and 375 ng/ml 4-keto-CP spiked urine samples, demon-

strated good accuracy and precision. Recovery of the three compounds averaged between 97 to 105% of theory with precision [measured as percent relative standard deviation (%RSD)] as high as 8.4% for 4-ketoCP. Linearity of response was verified for concentrations of 0.5 to 25 ng/ml CP and IF in urine, and from 10 to 625 ng/ml 4-ketoCP in urine. Correlation coefficients of 0.99 or greater were obtained for all standard curves. This method offers a valid test for the determination of the urinary levels of CP, 4-ketoCP and IF as demonstrated by the accuracy and precision of the recovery studies. Disclaimers: Mention of company names and/or products does not constitute endorsement by the National Institute for Occupational Safety and Health (NIOSH). The findings and conclusions in this abstract have not been formally disseminated by NIOSH and should not be construed to represent any agency determination or policy.

PS 1624 URINARY PROTEIN/PEPTIDE ADDUCTS AS MARKERS OF REACTIVE NAPHTHALENE METABOLITE FORMATION IN MALE MICE.

N. T. Pham and A. Buckpitt. *Molecular Biosciences, University of California, Davis, Davis, CA.*

Naphthalene (NA), a ubiquitous polyaromatic hydrocarbon in the environment, has shown dose dependent cytotoxicity in the murine respiratory epithelium and in the rat and murine nasal epithelium. The relevance of these animal studies to human health is not clear due to several factors, including species differences in NA susceptibility and a high background of lung diseases in the human population. Previous work has shown that metabolism of NA in target tissues of rodents to reactive metabolites leads to their covalent binding to potentially critical proteins, which may result in cytotoxicity. Although the formation of covalent adducts with hemoglobin and albumin has been used as surrogates for the generation of reactive metabolites, their measurement has not led to a clearly established relationship between adduct levels and toxicity. The urine is a relatively unexplored site for the measurement of protein adducts generated from the interaction of reactive metabolites with proteins. The current work focuses on methodology development for the separation, detection, and identification of urinary protein/peptide adducts as markers of key processes associated with NA toxicity. Both radiolabeled and label-free methods will be applied, including the development of an antibody specific for the naphthyl-cysteine moiety of adducts. Preliminary data showed that 24-hour urine collected from male mice following ip administration of 14C-NA revealed specific activities of covalent adducts exceeding those observed in critical tissues, like the lung and nose. In addition, we have tentatively identified a few urinary protein adducts similar to ones previously identified in the lung and nasal epithelium following naphthalene exposure. Resolution of urinary proteins by high performance liquid chromatography and 2D electrophoresis and their subsequent identification by mass spectrometry is ongoing. We conclude that adducted proteins eliminated in the urine may be excellent markers of processes critical to target tissue toxicity. Supported by NIEHS 04311 and 04699.

PS 1625 INCREASED MALONDIALDEHYDE LEVELS IN EXHALED BREATH CONDENSATE OF RETIRED COAL MINERS WITH DECREASED LUNG FUNCTION.

J. Lee[1], J. Shin[1], B. Choi[1], K. Lee[1], J. Lee[1], W. Lee[1] and J. Lee[2]. [1]*Center for Occupational Lung Diseases, K-medi, Ansan, Korea, South and* [2]*Aansan Choongang General Hospital, K-medi, Ansan, Korea, South.* Sponsor: I. Yu.

Inhaled coal mine dusts can cause inflammation and fibrosis in the lung called coal worker's pneumoconiosis. Chronic inflammatory process in the lung is associated with reactive oxygen species (ROS) formation. Disturbance of the balance between ROS and antioxidant defenses produces oxidative stress, which leads to tissue damage. The aim of the present study was to compare malondialdehyde in exhaled breath condensate (EBC-MDA) as a biomarker of lipid peroxidation resulted from pulmonary oxidative stress in retired coal miners. In this study, we measured EBC-MDA, pulmonary function test, radiological findings, and urinary cotinine, and analyzed the difference among indices. The study population contained 69 retired coal miners. EBC-MDA level of retired workers with decreasing lung function (%FVC<80, %FEV1<80, FEV1/FVC<70) was higher than those of subjects with normal lung function (8.5+/-3.9 nmol/L vs. 6.5+/-3.3 nmol/L, p<0.05). EBC-MDA level (7.4+/-3.1 nmol/L) was increased in no medication for pneumoconiois as compared with other subjects (4.3+/-2.4 nmol/L) in those with normal lung function (p<0.05). Among non-smokers with normal lung function, MDA level (7.5+/-3.4 nmol/L) was increased in no medication for puemoconiosis as compared with subjects with medication for pneumoconiosis (4.0+/-2.8) (p<0.05). But, there was no significant correlation between EBC-MDA levels and the profusion of radiological findings, age, BMI, urinary cotinine, and work duration. In this study, there was significant difference between the EBC-MDA levels and decreased lung function. It was supposed that increased MDA levels were resulted from pulmonary oxidative stress, but, it was necessary to evaluate reliable variables for the effects of oxidative stress in the lung such as aldehydes, hydrogen peroxide, leukotriene B4, and 8-isoprostane in EBC, lung tissue or bronchoalveolar lavage fluid.

PS 1626 A MULTI-ANALYTE PROFILE OF SERUM PROTEINS TO SCREEN FOR TOXICOLOGICAL EFFECTS OF ANTICHOLINESTERASE INSECTICIDES IN THE RAT.

C. Gordon[1] and W. O. Ward[2]. [1]*Neurotoxicology, U.S. EPA, Research Triangle Park, NC and* [2]*Environmental Carcinogensis Division, U.S. EPA, Research Triangle Park, NC.*

The development of high throughput biochemical screens could be useful to assess the broad spectrum of physiological effects of environmental toxicants. To explore the prospect of using a screen in an in vivo exposure scenario, we applied a commercially available multianalyte profile (MAP) of 58 serum biomarkers to rats exposed acutely to two anticholinesterase insecticides, chlorpyrifos (CHP) and carbaryl (CAR). Male, Long-Evans rats were dosed orally to 30 mg/kg CHP, 75 mg/kg CAR or the corn oil vehicle. Doses were selected based on their equivalent physiological effects (hypothermia and reduced motor activity). The animals were terminated 24 hours or 7 days after dosing. Serum was collected and analyzed for 58 biomarkers consisting primarily of cytokines, chemokines, and a few hormones. There were changes in six analytes (4 up, 2 down) following CHP and eight analytes (5 up, 3 down) following CAR at 24 hours. There were significant changes in only two biomarkers when measured 7 days after dosing with CHP. Overall, the MAP detected a broad spectrum of unique effects for CHP and CAR. It is concluded that the MAP is a useful tool to screen for in vivo effects of environmental toxicants and its use could lead to the discovery of novel mechanisms of action. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy

PS 1627 MICRORNA EXPRESSION CAN BE SIGNIFICANTLY ALTERED ONE DAY AFTER CANCINOGEN TREATMENT.

Z. Li[1], L. Shi[2], M. Pearce[1], Y. Wang[3] and T. Chen[1]. [1]*Division of Genetic and Reproductive Toxicology, National Center for Toxicological Research, Jefferson, AR,* [2]*Division of Systems Toxicology, National Center for Toxicological Research, Jefferson, AR and* [3]*SABiosciences Corporation, Frederick, MD.*

Dysregulated expression of microRNA (miRNA) has been extensively detected in human cancers and has shown promise in defining tumor status. It, however, is little known whether expression of miRNAs can be changed in non-cancerous tissues after carcinogen exposure. To explore whether changes of miRNA expression can be utilized as a short-term biomarker for carcinogen exposure, we treated five mice per group with one dose of 120 mg/kg model genotoxic carcinogen N-ethyl-N-nitrosourea (ENU) and vehicle control. The miRNAs were isolated from the liver of ENU-treated and control mice one day after the treatment. The miRNA expression profiles were determined using RT2-mouse miRNA PCR Array. There are significantly difference between miRNA expression profiles of control and treated samples. Among the 376 mouse miRNAs, 18 miRNAs were found upregulated and 10 miRNAs were down-regulated ($p < 0.05$). Primary analysis of the altered miRNAs demonstrates that most of them are involved in cell growth, apoptosis and other functions related to carcinogenesis. These results suggest that miRNAs might have the potential to be exploited as a biomarker for early prediction of chemical carcinogenicity.

PS 1628 A REVIEW OF THE METHODS FOR LIPID CONTENT IN HUMAN SERUM AND THE IMPACT ON SERUM LEVELS OF PERSISTENT ORGANIC POLLUTANTS.

P. K. Scott and M. L. Kreider. *ChemRisk, Inc., Pittsburgh, PA.* Sponsor: L. Sweet.

Because many persistent organic pollutants (POPs), such as polychlorinated dibenzo-p-dioxins and furans (PCDD/Fs), are adsorbed to fat, serum concentrations are often reported on a lipid basis instead of a whole weight or volume basis. Thus, the method used to estimate the lipid content in a particular serum sample is important because the accuracy of the lipid analysis method can impact the accuracy of the associated serum concentrations. The two methods for determining serum lipid are the gravimetric and the enzymatic methods. We compared these methods to understand the differences in lipid contents for split samples using two data sets. Data collected in 2006 and 2008 as part of the Arctic Monitoring and Assessment Program (AMAP) inter-laboratory comparison for certain POPs were used along with lipid content data from 10 people from Mills et al. (2007). For these data, the absolute relative difference between the actual lipid content of the sample and the measured lipid content was significantly lower for the samples analyzed using the enzymatic method versus those analyzed using the gravimetric

method (p=0.002), indicating that the enzymatic method produced more accurate lipid content estimates than the gravimetric method. Also, the relative differences for the enzymatic data were significantly less than zero while the relative differences for the gravimetric data were significantly greater than zero, which indicates that the enzymatic method consistently overestimates lipid content while the gravimetric consistently underestimates lipid content. For the Mills et al. (2007) data, the gravimetric lipid contents were, on average, 55.8%, and ranged from 39.2% to 64.4% of the enzymatic lipid contents. Applying this range to the 2001/2002 NHANES results for 2,3,7,8-PCDD/Fs, the gravimetric method would produce serum lipid concentrations that are a factor of 1.55 to 2.55 times those for the enzymatic method. Due to these differences, it is critical that the method used for lipid content be consistent between any potentially exposed population and background population.

PS 1629 EVALUATION OF BIOMARKERS OF EXPOSURE IN CLINICAL SAFETY ASSESSMENTS.

H. Leslie, A. Wong and K. Musa-Veloso. *Cantox Health Sciences International, Mississauga, ON, Canada.*

Biomarkers of exposure are an important consideration when designing clinical trials intended to assess product safety or efficacy. Without proper biomarkers of exposure, interpreting study findings and drawing conclusions about safety is difficult because the proportion of the test compound that reaches systemic circulation and/or target tissues is unknown. When selecting biomarkers of exposure, it is essential to consider several factors such as route of administration or, for food additives and ingredients, the matrix in which the compound is delivered. Additionally, biomarkers should address not only the absorption of the test compound from the GI tract into the circulation, but also distribution to target tissues, although this may be difficult to achieve in humans. Levels of known metabolites of the test compound also should be measured to avoid underestimating absorption and distribution. Finally, the biomarker must be measured at an appropriate time point, when sufficient time has elapsed after administration to allow for steady-state levels to be achieved. As a case study, clinical trials conducted with phytosterols that included measurements of safety endpoints were examined to determine the prevalence of appropriate biomarker selection in clinical research in this area of study. Phytosterols have recently been reviewed by various regulatory bodies (e.g., FDA, EFSA, and JECFA) with the goal of deriving safe and efficacious levels of intake. Based on these evaluations, phytosterols are expected to become more prevalent in the food supply; however, the relevance of conclusions drawn on their safety is dependent upon the measurement of suitable exposure biomarkers. Generally, tissue levels of phytosterols were measured in the studies identified; however, some inconsistencies were noted with respect to the selection of individual phytosterols considered reflective of the test product composition. This case study illustrates the necessity for investigators to consider biomarkers of exposure in clinical trial design.

PS 1630 OPTIMIZATION OF A PROTOCOL TO ISOLATE GENOMIC MATERIAL FROM BUCCAL CELLS.

Z. Guerrette, X. Yu, H. Kim, S. Hong and E. M. Faustman. *Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.*

Buccal cells have been used as sources for genomic DNA in a variety of settings and are an attractive potential source of RNA since they can be collected in noninvasive manners that cause little to no discomfort to subjects. Recent studies have shown reproducible and quantifiable gene expression signatures in exfoliated buccal cells from human subjects. In the present study, we optimize a protocol for extraction of RNA using samples from a pooled set of buccal cells consisting of 770,000 cells per sample to isolate high yield (~1 μg /sample) and high quality (260/280 and 260/230 ratios=~2.0) RNA for gene expression analysis. We compared three different protocols: an RLT mini protocol using Qiagen's RLT buffer in combination with proteinase K incubation, a Fibrous Tissue protocol using the same buffer but with different incubation and centrifugation parameters, and a Trizol method with column cleanup. We also employed mouse fibroblast cells (500,000 per sample) for comparison. The highest yields of RNA (mean, standard deviation) from buccal cells were obtained using the Fibrous Tissue protocol (1.5 μg, 0.1), followed by the RLT (0.2 μg, 0.03) and Trizol (0.1 μg, 0.1) protocols. The fibroblast cells provided a similar trend in the results between the Fibrous Tissue (28 μg, 3), RLT (20 μg, 1.6), and Trizol (16 μg, 2.5) protocols. For buccal cells, no differences were seen in the 260/280 values, but the 260/230 value were greater for the Fibrous Tissue method compared to the RLT and Trizol methods: 1.1 (0.5), 0.3 (0.1), and 0.4 (0.3), respectively. No significant differences in the absorbance ratios were observed in the fibroblast samples, which were near the optimum value of 2.0. The total amount of RNA and quality isolated using this protocol will enable us to further explore the gene expression differences in field samples obtained from farmworkers and non-farmworkers as part of a longitudinal study during pesticide spray and non-spray seasons. This project was supported by NIEHS grant 2-P01-ES009601 and EPA grants RD-8370901-0 and RD-83273301-0.

PS 1631 QUANTIFICATION OF BUTADIENE-MONOEPOXIDE AND DIEPOXIDE N-TERMINAL VALINE ADDUCTS IN RODENTS AT LOW EXPOSURES.

N. Bordeerat[1], N. I. Georgieva[1], G. Boysen[1], L. Collins[1], V. Walker[2] and J. A. Swenberg[1]. *[1]ESE, University of North Carolina at Chapel Hill, Chapel Hill, NC and [2]Lovelace Respiratory Research Institute, Albuquerque, NM.*

Butadiene (BD) is an industrial chemical used in the production of synthetic rubber and found in gasoline and combustion products. It is a multisite and multispecies carcinogen in rodents with mice being much more sensitive than rats. BD is metabolized mainly by P450 2E1 to 1,2-epoxy-3-butene (EB), 1,2;3,4-diepoxybutane (DEB) and 1,2-epoxy-3,4-butanediol (EB-diol). For risk assessment, the in vivo dose of each epoxide can inform their relative risks because they show significantly different mutagenicity. The internal formation of EB can be measured indirectly by analysis of the 2-hydroxy-3-butenyl-valine (HB-Val) adduct. In this study, the formation of the HB-Val was evaluated in globin samples (40-50 mg) from female mice and rats exposed to 1, 1.5, 6.25, and 62.5 ppm BD by inhalation for 10 days. An immunoaffinity nano-UPLC-MS/MS assay was developed for HB-Val analysis. In addition, the cyclic adduct N, N-(2,3-dihydroxy-1,4-butadiyl)-valine (pyr-Val), a biomarker for DEB, was simultaneously determined. Utilizing this assay increased the sensitivity and allowed detection of both adducts in mice and rats exposed to BD as low as 1 ppm. The amounts of HB-Val in mice were about 12-fold higher than rats at the same exposure. In both species, the amount of pyr-Val was about 1.5-fold higher than HB-Val. These data show that mice are much more efficient at forming EB and DEB than rats, particularly at low exposures. The data are in accordance with the observed carcinogenic effects of BD in mice and rats. Overall, the analyses of adducts derived from 1,3-butadiene metabolites provided valuable insight for cross species comparison at low exposures which will be readily comparable with similar data from molecular epidemiology studies on 1,3-butadiene-exposed workers.

PS 1632 THE ASSESSMENT OF ENDOTHELIAL CELL PROLIFERATION BY FLOW CYTOMETRY WITH PROLIFERATION MARKERS BRDU AND EDU IN MOUSE BONE MARROW AFTER TREATMENT WITH 2-BUTOXYETHANOL.

S. Zhao, A. Shen, C. Huang and S. A. Sokolowski. *Drug Safety Research and Development, Pfizer Global Research and Development, Groton, CT.*

The purpose of this study was to identify proliferating endothelial cells (EC) and monocytes in mouse bone marrow by flow cytometry. Studies were designed to identify endothelial cell markers and compare proliferation markers BrdU and EdU. Bone marrow cell suspensions were evaluated by staining with inclusion markers CD45, CD31, Flk1 and CD105 and exclusion markers CD71, B220, and CD3. To compare proliferation markers BrdU and EdU male B6C3F1, mice were dosed by oral gavage once daily for 7 consecutive days with either 900 mg/kg 2-butoxyethanol (2-BE) or vehicle. Mice were implanted with osmotic pumps containing either 20 mg/mL 5-bromo-2′-deoxyuridine (BrdU) or 5-ethynyl-2′-deoxyuridine (EdU). In proliferation experiments, the bone marrow cell suspensions were stained with antibody panels containing the CD45, CD31, Flk1, EdU and BrdU markers. Results indicated the CD31+CD45- and Flk1+CD45- phenotypes identified EC's in bone marrow cell suspensions. In each study, total nucleated cell counts from vehicle control and 2-BE treated animals were comparable. Although absolute cell counts of CD31+CD45- and Flk1+CD45- increased approximately 1.5 fold with 2-BE treatment, the total number of proliferating EC's recovered after processing samples for BrdU was 4 fold less than for EdU. These results also indicated that the harsh treatment required for detection of proliferating EC's with BrdU might result in significant sample cell loss. Our results suggest that EdU is the preferred proliferation marker for identification of proliferating EC's in bone marrow by flow cytometry. Overall, these results provide important and useful information for future mechanistic and toxicity studies in the bone marrow of mice.

PS 1633 COMPARATIVE MICROARRAY STUDY OF GENE EXPRESSION IN CULTURED RAT LUNG CELLS FOLLOWING JET FUELS EXPOSURE.

M. Stockelman[1], A. Olabisi[1], H. Fullenkamp[1], T. Doyle[1], D. Wagner[1], C. Garrett[2], M. Kadakia[2], P. G. Gunasekar[1], G. Chapman[1], M. Markey[2], S. Berberich[2] and J. McDougal[2]. *[1]Department of Navy, Naval Health Research Center Detachment Environmental Health Effects Laboratory, Dayton, OH and [2]Wright State University, Dayton, OH.*

Each year over 2 million military and civilian personnel are occupationally exposed to jet fuels including jet propulsion fuel-8 (JP-8)and its civil aviation equivalent Jet A. Jet fuels are among the most common sources of military and nonmilitary occu-

pational chemical exposures. Standard commercial and military jet fuels consist of kerosene fractions of petroleum with additives. A new synthetic jet fuel, designated synthesized paraffinic kerosene (SPK), is being phased into military use. To assess the effects of exposure to jet fuels and to compare the synthetic SPK to the petroleum based standard fuels, we analyzed gene expression patterns of cultured L-2 rat pulmonary epithelial cells following exposure in vitro to equitoxic concentrations of Jet A, JP 8, JP 4 and SPK. Total RNA was extracted and mRNA was processed for analysis and placed on the Affymetrix rat genome 230-2 microarray. The main biological functions affected by these fuels were similar, and related to gene expression, growth and proliferation, cell cycle, cell development and cell death. Two (2) hr functional changes were related primarily to cell death and lipid metabolism. At 4 hr lipid metabolism, cellular development and small molecule biochemistry were the most changed functions. One signaling pathway related to vitamin D metabolism (VFR/RXR) was significantly changed at both 2 and 4 hr post-exposure. The results suggest that these fuels have significant functional effects in these cells.

S 1634 GENE-ENVIRONMENT INTERACTIONS: EPIGENETIC PATHWAYS IN CHRONIC DISEASE PROMOTION AND PROGRESSION.

H. Floyd[1], C. Guerrero-Bosagna[2], W. Tang[3], A. Dosunmu[4], D. Ray[5] and S. A. Martin[6]. *[1]Alcon Laboratories, Ft. Worth, TX, [2]School of Molecular Biosciences, Washington State University, Pullman, WA, [3]University of Cincinnati College of Medicine, Cincinatti, OH, [4]Department of Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI, [5]University of Michigan Medical School, Ann Arbor, MI and [6]Environmental Health Sciences Department, University of Georgia, Athens, GA.*

The study of gene-environment interactions has become increasingly more common as it relates to disease susceptibility and chronic disease development. These studies aid in the characterization of environmental exposures and development of targeted prevention/treatment regimens. Traditional genetic endpoints can be expanded to include epigenetic modifications related to altered DNA methylation patterns, histone modifications, and germ-line reprogramming. Heritable alterations in the expression of particular genes or gene clusters and transgenerational effects that are linked to environmental exposures, such as gonadal sex determination and tumor development, are of particular interest. Alterations that result in chronic conditions present in early to mid-life stress the importance of ongoing research efforts to characterize molecular mechanisms associated with these conditions. Gene-environment interactions resulting in the promotion of autoimmune or neurodegenerative diseases serve to highlight current public health issues with an epigenetic basis. This is an important platform that will highlight toxicologically relevant epigenetic alterations with accompanying disease states and showcase trainee achievements. This session is brought to you through the collaborative efforts of the Post-Doctoral Assembly and the Student Advisory Council.

R 1635 PRECLINICAL EVALUATION OF CANCER HAZARD AND RISK OF BIOPHARMACEUTICALS.

J. Cavagnaro[2] and M. D. Todd[1]. *[1]Drug Safety R&D, Pfizer, Inc, San Diego, CA and [2]Access BIO, LC, Boyce, VA.*

The carcinogenicity testing of biopharmaceuticals may not always be possible by conventional means due to factors such as species specificity and immunogenicty. However, cause for concern for tumorigenicity of biopharmaceuticals is heightened based on knowledge and plausibility of particular mechanisms of action. Mitogenicity is a concern for exogenously administered biopharmaceuticals such as hormones and growth factors and may also be a concern for pharmaceuticals designed to stimulate their endogenous production. In an attempt to address the potential risks of these agents, investigators have explored the ability of growth factors to influence the growth of tumor cells expressing their receptors in *in vitro* and *in vivo* models. However, the value of these models to adequately address the clinical risk of enhanced tumor growth with therapeutically administered growth factors is not clear. Special issues of concern following chronic treatment of immunomodulatory pharmaceuticals and biopharmaceuticals include the potential for immune impairment leading to opportunistic infections and/or lymphoproliferative disorders. Experimental data will be presented from approaches that have been used in an attempt answer the central question of the role of exogenous growth factors and immunomodulatory agents in tumor progression *in vivo*; these approaches include rodent tumor xenograft, and alternative short-term and traditional carcinogenicity models. This material will also provide an overview of the current practices in the assessment of carcinogenic risk of biopharmaceuticals including the challenges in assessing human derived proteins in animals and developing waivers of carcinogenicity assessments and labeling considerations.

IS 1636 KINASE INHIBITORS AS TARGETED THERAPEUTICS IN INFLAMMATION AND ONCOLOGY – APPROACHES TO PREDICT AND MANAGE TOXICITIES.

M. A. Breider[1], K. Kolaja[3] and P. Zarrinkar[2]. *[1]Preclinical Development, Ambit Biosciences, Inc., San Diego, CA, [2]Technology Development, Ambit Biosciences, Inc., San Diego, CA and [3]Discovery and Investigative Safety, Roche Palo Alto, LLC, Palo Alto, CA.*

Targeted therapy with either monoclonal antibodies or small molecules has been a major focus of recent pharmaceutical research efforts in the inflammation and oncology disease areas. In particular, cell surface and cytoplasmic kinases have been targeted with varying degrees of clinical success in human oncologic disease. Although targeted therapy does provide an opportunity for more predictable and manageable toxicity based on anticipated and characterized exaggerated pharmacology of kinase inhibition, there have been considerable safety surprises with the various kinase inhibitor therapies in man. Therefore, it is important to address the pharmacologic rationale of targeted therapeutics in inflammation/oncology and provide an overview of kinase inhibitor toxicity in preclinical and clinical settings to demonstrate the importance of kinase activity profiling. To highlight these various issues participants will be provided with an overview of kinase biology and the use of high-throughput kinase profiling as a drug development tool and the correlation of kinase-inhibitor cardiotoxicity to kinase specificity profiles using in vitro tools to predict toxicological liabilities of kinase inhibitors with an emphasis on cardiac injury. The on and off-target toxicity for currently marketed kinase inhibitors of observed toxicities of currently marked kinase inhibitors will be provided to gain a broader understanding of the complexities of kinase inhibitor pharmacology and toxicology. Finally, the tools to be better prepared to assess the possible toxicity of kinase inhibitors through systematic kinase target analysis and will be addressed that will unable us to ultimately devise an early identification of safety and derisking strategies.

PS 1637 THE ROLE OF OXIDANTS IN ETHANOL-INDUCED HEPATIC DNA SYNTHESIS.

S. M. Corthals, C. L. Walker and L. M. Kamendulis. *Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Ethanol increases the risk of hepatocellular cancer in humans and rodents following chronic consumption; however, the mechanism(s) involved are not known. A common finding following ethanol exposure is an increase in reactive oxygen species (ROS) and oxidative stress in both rodents and humans. The present studies examined whether oxidative stress induction participated in ethanol-induced hepatocellular growth. We first performed a dose response study (0-5% ethanol (w/v) in liquid diet (LD), 7 days) in male C57Bl mice to characterize the growth response characteristics of ethanol in liver. Ethanol at non-hepatotoxic doses (2% and 3% ethanol) increased hepatic DNA synthesis (~2-fold over control); while ethanol at hepatotoxic doses (4% and 5%, evidenced by increased serum ALT and AST) failed to increase DNA synthesis. To determine whether increased DNA synthesis by ethanol was mediated by oxidative stress, mice were exposed to 3% ethanol (w/v) in the presence or absence of the antioxidant polyphenon-60 (3g/L, in LD). Exposure to ethanol (3%) produced the expected increase in DNA synthesis (~2-fold over control), while co-treatment with polyphenon reduced DNA synthesis to basal levels. CYP2E1 levels were increased (~2-fold) by 3% ethanol. Ethanol also increased the expression of the ROS-sensitive transcription factor, nuclear factor E2-related factor (Nrf2; ~2-fold over control), supporting that ethanol increases ROS. Similarly, ethanol (10, 25, or 50mM; 24 h) increased Nrf2 protein expression in a dose dependent manner in primary cultured hepatocytes. Increased ROS following ethanol exposure may arise from CYP2E1 metabolism or Kupffer cell activation. Depletion of Kupffer cells reduced ethanol-induced increases in Nrf2 while CYP2E1 levels remained elevated in Kupffer cell depleted mice. These data suggest that the enhanced growth and survival seen following non-toxic doses of ethanol may arise through mechanisms involving Kupffer cell-mediated ROS production and enhanced Nrf2 expression.

PS 1638 ROLE OF KUPFFER CELL IN TUMOR PROMOTION CAUSED BY NON-GENOTOXIC CARCINOGENS WYETH 14, 643 AND PHENOBARBITAL IN DIETHYLNITROSAMINE INITIATED C3H MICE.

T. J. Peat, B. K. Philip and J. E. Klaunig. *Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Kupffer cells (KC), the resident macrophages in the liver, play an important role in normal physiology and homeostasis. Upon activation, KC release inflammatory mediators, growth factors, and reactive oxygen species, which may modulate acute and chronic liver responses including hepatic cancer. Wyeth 14,643 (WY) and

Phenobarbital (PB) are non-genotoxic hepatic carcinogens in rodents. This study examined the role of the KC on tumor promoting effects of WY and PB in initiated C3H mice. Male 21 day old C3H mice were injected with DEN (50 mg/kg, ip, 1X/wk for 4 wks). After focal lesions were apparent, mice were treated with WY (0.1% in diet) or PB (500ppm in drinking water) for 28 days. Lipopolysaccharide (1 mg/kg, ip, 2X/wk), a known activator of the KC, was used as a positive control. Liposome encapsulated clodronate (10 ml/kg, iv, 3X/wk) was given to animals to deplete the KC. Osmotic pumps containing BrdU (20 mg/ml) were surgically implanted 7 days prior to sacrifice to evaluate DNA synthesis. Treatment with PB increased the relative focal volume of both basophilic and eosinophilic lesions and depletion of the KC decreased the focal volume. The volume of basophilic lesions in WY treated mice increased, and with depletion of the KC, focal volume decreased while eosinophilic lesion volume was unchanged. WY and PB increased DNA synthesis in both basophilic and eosinophilic lesions, similar to LPS. Upon KC depletion, a decrease in DNA synthesis was seen in PB treated mice. In the surrounding normal (non-lesion) tissue, PB produced a marginal increase in DNA synthesis (two-fold over control) and decreased with the depletion of the KC compared to control. DNA synthesis increased greatly (ten-fold over control) when treated with WY. These results show that the KC participates in the tumor promoting effects of PB and Wyeth 14,643 in preneoplastic mouse liver (Supported in part by NIH CA100908 (JEK)).

PS 1639 KUPFFER CELL INVOLVEMENT IN PHENOBARBITAL AND WYETH-14, 643 INDUCED CLONAL EXPANSION OF PRENEOPLASTIC HEPATIC LESIONS.

B. K. Philip, T. J. Peat, L. M. Kamendulis and J. E. Klaunig. *Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Non genotoxic tumor promoters, phenobarbital (PB) and Wy-14,643 selectively induce the growth of preneoplastic focal lesions via increasing cell proliferation and/or decreasing apoptosis. In the present study, we have examined the role of KC in the clonal expansion of preneoplastic lesions induced by these compounds in diethylnitrosamine (DEN)-initiated F344 rats. In addition, lipopolysaccharide (LPS) a known KC activator was examined as a positive control. After lesions were histologically apparent (5 months), rats were treated with LPS, PB, Wy-14,643 or control diet/water and sampled after 28 d. KC were depleted/inactivated using clodronate liposomes or with dietary glycine respectively. Growth of GSTp positive focal lesions and various focal lesion phenotypes (H&E staining) were evaluated using stereological methods. Focal lesion volume was increased by LPS, PB, and WY. However, each chemical exhibited differential effects on lesion phenotype; LPS increased the volume of GSTp and basophilic foci, PB increased the volume of GSTp positive and eosinophilic focal lesions, while WY increased eosinophilic and basophilic lesion volume. KC depletion/inactivation reduced PB- and LPS-induced increases in lesion volume. Rates of DNA synthesis (labeling index) in focal lesions was increased by PB, WY, and LPS (1.7 to 2.8 fold over control). KC depletion/inactivation decreased PB- and LPS-induced increases in DNA synthesis. The non-focal hepatic labeling index remained elevated in the WY treatment group but was reduced by KC depletion/inactivation. The labeling index in normal liver of PB and LPS groups were similar to control. While each non-genotoxic chemical produced a different phenotypic profile for lesion growth, our data provide evidence supporting a role of the KC in tumor promotion (Supported in part by NIH CA100908(JEK)).

PS 1640 MECHANISMS FOR POLYHEXAMETHYLENE BIGUANIDE (PHMB) CARCINOGENICITY.

L. M. Kamendulis[1], X. Pu[1], S. J. Barbee[2] and Z. Wang[1]. *[1]Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN and [2]Arch Chamicals Inc., Cheshire, CT.*

Chronic dietary exposure to polyhexamethylene biguanide (PHMB) resulted in an increased incidence of liver hemangiosarcomas in C57/Bl6 mice (4/55 in control, 20/55 in 4000 ppm group). The mechanism for liver hemangiosarcoma induction is not understood, but since PHMB does not induce mutations or produce genotoxicity, these tumors are produced through non-DNA reactive mechanisms. The present studies evaluated the dose-response profile of PHMB on endothelial cell growth. C57/Bl6 mice were exposed to 0, 100, 200, 400, 1200, and 4000 ppm PHMB for 7, 14, and 28 days. PHMB did not induce hepatotoxicity (evidenced by ALT and AST) at any dose or time evaluated. Rates of DNA synthesis, quantified using BrdU immunohistochemistry, showed that 4000 ppm PHMB decreased DNA synthesis after 7 and 14 days, a finding that may be related to the decreased bodyweight, food utilization, and thinning of the intestines seen at this dose. At 28 days, PHMB increased DNA synthesis in a dose-responsive manner (~1.5- and 1.6-fold over control at 1200 and 4000 ppm), with no increases in this endpoint at or below 4000 ppm. In vitro, PHMB (0-1ppm) did not increase endothelial cell DNA synthesis. Concomitant with the increased liver tumors in the 2-year study was an increase in Kupffer cell pigmentation, suggesting that this cell type may be activated and participate in the carcinogenic response. To test this, DNA synthesis was measured in endothelial cells co-cultured with macrophages. PHMB (0-1ppm) did not increase DNA synthesis in endothelial cells co-cultured with macrophages. Accompanying the gastrointestinal effects caused by PHMB in vivo was an increase in plasma endotoxin, a known activator of macrophages, by 1200 and 4000 ppm PHMB for 28 days. Collectively, these results suggest that PHMB does not produce a direct effect on endothelial cell growth, but rather through an indirect effect, perhaps involving endotoxin-mediated activation of macrophages.

PS 1641 THE AH RECEPTOR PLAYS AN ANTI-APOPTOTIC ROLE IN DEN-INDUCED LIVER CARCINOGENESIS.

Y. Fan, E. Knudsen and A. Puga. *Environmental Health, University of Cincinnati, Cincinnati, OH.*

In previous work, we have characterized an interaction between the aryl hydrocarbon receptor (AHR) and the transcription factor E2F1 that results in attenuation of E2F1-mediated apoptosis. Whereas loss of AHR expression causes a significant elevation of oxidative stress, DNA damage and E2F1-dependent apoptosis, AHR activation represses the transcriptional induction of E2F1-dependent pro-apoptotic genes Apaf1 and p73 and the induction of apoptosis resulting from E2F1 stabilization. These results suggested that the AHR might have an anti-apoptotic function that is likely to play a role in tumor progression. To test this hypothesis, we developed a strain of mice with a double knockout liver genotype resulting from the mating of knockout Ahr-/- mice with mice bearing a liver-specific Rb ablation. Mice of the four homozygous genotypes were challenged with a single I.P injection of 20 mg/kg of DEN or with control vehicle. Livers of control double knockout mice showed a higher proliferative index at 3-weeks of age, significantly higher levels of polyploidy and higher levels of liver apoptosis at 28 weeks than mice of the other genotypes. Nine months after DEN challenge mice were sacrificed and scored for liver tumors and expression of genetic markers. Regardless of Rb genotype, Ahr-/- mice had highly elevated levels of liver DNA damage and apoptosis, while the incidence of hepatocellular carcinoma was higher in Ahr+/+ mice. A real-time RT PCR screen of liver tumors and surrounding tissues of these mice for expression of a battery of genes involved in proliferation, apoptosis and differentiation was also consistent with an anti-apoptotic role for the AHR. These results indicate that the Ah receptor plays an important role in tissue and organ homeostasis that is independent of its activation by xenobiotic ligands. (Supported by NIH R01ES6273, NIH R01ES10807, and NIH P30 ES06096).

PS 1642 ESTROGEN RECPTOR-ALPHA IS PROTECTIVE AGAINST LIVER TUMOR DEVELOPMENT AND IS CRITICAL FOR SEXUAL DIFFERENTIATION OF HEPATIC GENE EXPRESSION.

M. H. Feld[1, 2] and N. R. Drinkwater[1]. *[1]McArdle Laboratory for Cancer Research, University of Wisconsin, Madison, WI and [2]Department of Biology, Boston University, Boston, MA.*

In mice, androgens promote hepatocarcinogenesis while ovarian hormones are known to be protective. Estrogen has been suggested to be responsible for this protection. Following perinatal treatment with N,N-diethylnitrosamine, we found that female Estrogen Receptor-α Knockout (ER-α KO) mice had a 5-9 fold increase in tumor multiplicity compared to wild-type and heterozygous littermates ($p < 10\text{-}6$). Because sex-hormones affect susceptibility to liver tumor development, we examined the effects of sex-hormones on hepatic gene expression. Gene expression in the ER-α KO females did not resemble the pattern seen in ovariectomized mice but was similar to the pattern seen in male mice. This masculined hepatic gene expression profile may account for their susceptibility to liver tumor development. Sex-dependent gene expression differences were dramatic, with several genes differing over 100-fold between sexes. For genes that were regulated by ER-α in female mice, and were also sex-dependent, most of these genes differed to a similar degree between sexes and between the wildtype and ER-α KO females. For example, the male predominant cytochrome P450 4a12 and members of the hydroxysteroid dehydrogenases 3β family varied to a similar degree between sexes and between the wildtype and ER-α KO females. Female-predominant cytochrome P450 3a44 was expressed higher in ER-α KO females, compared to wildtype littermates, and the degree of this difference was similar to the difference seen between the sexes. Other genes, such as sulfotransferase 3a1 and flavin-containing monooxygenase 3, also differed between ER-α KO females and wildtype littermates, but these changes were much less extreme than seen for the sex-dependent differences in transcription of these genes. These studies implicate the importance of hepatic ER-α in protecting against hepatocarcinogenesis and suggest that regulation of hepatic gene expression in the ER-α knockout females occurs in a multihormonal manner.

PS 1643 HISTOLOGIC AND IMMUNOHISTOCHEMICAL CHARACTERIZATION OF CYP1C1 AND CYP1A EXPRESSION IN PAH-INDUCED *FUNDULUS* HEPATIC LESIONS.

L. Wang[1], W. Dong[1], C. Thornton[1], M. W. Thornton[1], A. Camus[2] and K. L. Willett[1]. [1]*Pharmacology and Environmental Toxicology, University of Mississippi, University, MS and* [2]*Pathology, College of Veterinary Medicine, University of Georgia, Athens, GA.*

Mammalian CYP1B1 has been recognized for its role in tumorgenesis not only by its ability to activate polycyclic aromatic hydrocarbons (PAHs), but also by its increased expression in a variety of human tumors relative to normal tissues. CYP1C1 is the newest member of the cytochrome P450 family 1 identified in teleost. Amino acid analysis suggests CYP1C1 may be structurally and/or functionally more similar to mammalian CYP1B1, rather than CYP1A. However, its physiological role and full significance in tumor development is unclear. We have hypothesized that CYP1C1 genes may be involved in the molecular mechanisms of PAH carcinogenesis. In a previous study, we initiated hepatic lesions in *Fundulus heteroclitus* by exposing them to 5 mg/L BaP or dimethylbenzanthracene (DMBA). Eight months after the PAH exposure, livers from 20 fish per treatment were sectioned and stained for microscopic evaluation. Histopathologic findings included the presence of nonneoplastic proliferation (nodular hyperplasia), preneoplastic foci of cellular alteration (eosinophilic and basophilic foci) and hepatocellular carcinoma. Inflammatory changes including mild perivascular lymphocytic infiltration and hepatic granulomas were also observed. Immunohistochemistry (IHC) was performed with CYP1A and CYP1C1, as well as PCNA antibodies. Intense CYP1A staining was present diffusely in hepatocyte cytoplasm, both in areas of nodular hyperplasia and foci of cellular alteration. In hepatocelluar carcinomas, an intense CYP1A signal was detected at the border of the tumors (invading cancer cells), while a lower amount was seen in the remainder of the neoplasm. In contrast, CYP1C1 was detectable and highly expressed only in granulomas involving cells suggestive of bile duct epithelium. Our results suggest a important role of CYP1C1, as well as CYP1A, in carcinogen bioactivation and tumor formation. This project is supported by NIEHS (R01ES012710).

PS 1644 MODULATION OF ACRYLONITRILE ON MITOCHONDRIAL GENE EXPRESSION AND MEMBRANE POTENTIAL.

S. Zhou, Z. Wang, X. Pu and J. E. Klaunig. *Pharmacology and Toxicology, Indiana University, Indianapolis, IN.*

Acrylonitrile (ACN) causes increased glial cell tumors in rats following chronic exposure. Oxidative stress induced by ACN is proposed to be a mechanism underlying ACN carcinogenesis. Previous studies demonstrated that ACN induces a dose-related increase in oxidative DNA damage in rat astrocytes. This study determined whether ACN treatment in cultured rat astrocytes interferes with mitochondrial genomic expression and membrane potential resulting in oxidative stress. The mitochondrial DNA content was evaluated by mitochondrial gene COXII expression level detected by RT-PCR, and membrane potential determined by flow cytometer using JC-1 as a probe. Treatment of astrocytes with ACN (0 to 0.5 mM) for 2 days suppressed mitochondrial membrane potential. Determination of mitochondrial DNA content revealed a 2-fold increase in cells treated with ACN. To determine if this ACN induced mitochondrial effects are involved in oxidative DNA damage, we determined ROS production in cells treated with ACN. We found 0.25 mM ACN at 2 d induced increase in ROS generation determined by fluorescent probe DHR123. These data indicate that ACN affects mitochondrial biogenesis and bioenergetics, and causes increased ROS generation. Whether this modulation of mitochondrial functions contributes to increased oxidative DNA damage induced by ACN remains further investigated.

PS 1645 IMPACT OF LIFE STAGE AND DURATION OF EXPOSURE ON ARSENIC-INDUCED PROLIFERATIVE LESIONS, NEOPLASIA, AND GENE EXPRESSION IN MALE C3H MICE.

G. Nelson[1], G. Ahlborn[1], D. Delker[1], H. Ren[1], K. Kitchin[1], C. Corton[1], M. Waalkes[2], B. Diwan[3] and J. Allen[1]. [1]*NHEERL, ORD, U.S. Environmental Protection Agency, RTP, NC,* [2]*National Cancer Institute at NIEHS, RTP, NC and* [3]*Basic Research Program, SAIC, Frederick, MD.*

Previous studies have demonstrated increased liver and adrenal tumor incidence in male mice exposed gestationally to 85 ppm inorganic arsenic via the dams' drinking water. To further characterize age susceptibility to arsenic carcinogenesis we have administered 85 ppm sodium arsenite to C3H mice during gestation, prior to pubescence, and post-pubescence to compare proliferative lesions, tumor outcomes, and global liver gene expression patterns at the age of one year. Incidence of urinary bladder hyperplasia was increased in continuously exposed mice compared to in utero only exposed mice. In contrast, the incidence of liver and adrenal tumors in male mice continuously exposed to arsenic was significantly decreased compared to control and in utero only exposed mice. This apparent protective effect of continuous arsenic exposure was accompanied by expression changes for many genes known to be involved in liver cancer including cell growth and proliferation, cell death, and oxidative stress genes. In addition, overlap was noted between genes affected by chronic arsenic exposure and those reported in the literature to be associated with caloric restriction and the metabolic syndrome. In particular, the gene for stearoyl-CoA desaturase (Scd1), which catalyzes the synthesis of monounsaturated fatty acids, was down-regulated by continuous arsenic treatment but up-regulated by in utero only treatment. Because Scd1 is important in the metabolic regulation of body weight, this response may explain the decrease in body weight gain seen in continuously exposed pups despite normal food consumption. Scd1 is implicated in hepatocarcinogenesis due to both environmental and genetic factors in rodents. Therefore, Scd1 and the genes it interacts with may be of key importance in the treatment-dependent tumor responses reported here. (This abstract does not necessarily reflect EPA policy.)

PS 1646 DOSE EFFECTS OF ARSENITE ON RODENT BLADDER UROTHELIUM.

S. Suzuki[1], L. L. Arnold[1], K. L. Pennington[1], B. Chen[2], X. Le[2] and S. M. Cohen[1]. [1]*Pathology and Microbiology, University of Nebraska Medical Center, Omaha, NE and* [2]*Environmental Health Sciences, University of Alberta, Edmonton, AB, Canada.*

Inorganic arsenic (arsenate and arsenite) is a known human carcinogen, inducing tumors of the skin, urinary bladder and lung. In short-term experiments in rats, treatment with 100 μg/g arsenite in the diet or drinking water induced cytotoxicity and necrosis of the urothelial superficial layer, with increased cell proliferation and hyperplasia. These phenomena might be involved in the development of arsenic-induced bladder cancer in humans. Therefore, the objectives of this study were to determine if the arsenic-induced urothelial effects are dose responsive and to determine the dietary dose of arsenic at which no urothelial effects are detected. We treated female F344 rats with arsenic (as sodium arsenite) in the diet at doses of 0, 1, 10, 25, 50, and 100 μg/g for 5 weeks. We detected hyperplasia in the urothelium at the high doses by light microscopy with superficial necrosis detected by scanning electron microscopy. No hyperplasia or necrosis was detected at the lower dose. The majority of arsenic present in the urine of arsenite-treated rats was in the form of the organic arsenical dimethylarsinic acid (DMA^V). However, arsenite and trimethylarsine oxide (TMAO) were also present. Interestingly, the ratio of DMA^V/TMAO in the urine was different between the low dose and high dose treatments. These data suggest that arsenite-induced urothelial cytotoxicity and proliferation are dose responsive and the urothelial effects have a threshold. Further investigation of the dynamic metabolism of arsenicals is needed to fully understand the urothelial effects of arsenite *in vivo*.

PS 1647 ALTERATION OF H4K16 ACETYLATION *VIA* SAS2 IN YEAST AND MYST1 IN HUMANS IS ASSOCIATED WITH INCREASED SENSITIVITY OF ARSENIC TOXICITY.

X. Ren[1], W. Jo[2], M. Aleshin[1], H. Wintz[2], M. Smith[1], C. Vulpe[2] and L. Zhang[1]. [1]*Division of Environmental Health Sciences, University of California, Berkeley, Berkeley, CA and* [2]*Department of Nutritional Sciences and Toxicology, University of California, Berkeley, Berkeley, CA.*

Arsenic is a human carcinogen commonly found in drinking water. An important mechanism of arsenic carcinogenesis is through alterations in gene expression, which has been correlated to epigenetic changes. Recently, we found that genes which encode subunits of the heterotrimeric something about silencing (SAS) complex, are required for the optimal growth of yeast in arsenite (AsIII) -containing medium. Within the SAS complex, the catalytic subunit Sas2 and its human homolog, MYST1, are orthologous acetyltransferases responsible for the acetylation of histone 4 lysine 16 (H4K16). To further explore their roles in arsenic toxicity, we used short hairpin RNA (shRNA) to silence endogenous levels of MYST1 in the human uroepithelial cell line (UROtsa cells) and subsequently exposed the cells to AsIII and its toxic metabolite monomethylarsonous acid (MMAIII). Silencing of MYST1 in UROtsa cells significantly increased their sensitivity to both AsIII and MMAIII treatment. The observed increased sensitivity to arsenic treatment correlated with reduced acetylated H4K16 resulting from silencing of MYST1 in UROtsa cells. Further, we found that the H4K16→R yeast mutant strain, which

contains a non-acetylatable arginine residue instead of the regular lysine, was sensitive to high doses of AsIII. Together, these data suggest that the alteration of H4K16 acetylation affects arsenic toxicity in both yeast and human cells. Acetylation of H4K16 is known to regulate the transcription of genes and promote DNA repair; therefore, aberrant gene expression induced by changes of H4K16 acetylation may be involved in the resistance of human cells to arsenic. Funding: This work was supported by the National Institute of Environmental Health Sciences [P42 ES04705].

PS 1648 HUMAN SKIN CARCINOMAS - ANALYSIS OF GENE MUTATION DIFFERENCES.

X. Li[1], I. A. Lea[1], S. Bailey[1], M. Jackson[1] and J. K. Dunnick[2]. [1]*Information Sciences, ILS, Inc., RTP, NC and* [2]*NTP, NIEHS, RTP, NC.*

Cutaneous basal cell carcinomas (BCC), squamous cell carcinomas (SCC), and malignant melanomas (MM) related to UV exposure occur commonly in humans. These tumors display different clinical characteristics: BCC grow slowly and rarely metastasize, SCC develop more aggressively, and MM are the most aggressive skin cancer and do metastasize. Data from the NIEHS Genetic Alterations in Cancer Knowledge System* were analyzed to determine if the mutation incidence and spectra in genes from human BCC, SCC and MM provide further insight into the process of tumor development in skin cancer. MM were more active in the MAPK pathway: BRAF and RAS gene mutations occurred more frequently compared to the non-melanomas (BRAF: 48% vs. 0%; NRAS 21% vs. 1%; $P<0.05$). But the mutation incidence in the TP53 cell cycle gene was lower in MM than in the non-melanomas (14% vs. 33-34%; $P<0.05$). Furthermore the UV signature mutation, the CC>TT dipyrimidine transition, was not seen in any of the MM compared to a 10-17% incidence observed in the non-melanomas. MM had a higher incidence of AT>TA transversions compared with non-melanomas ($P<0.05$). Comparison of mutations in BCC vs. SCC showed that SCC had a higher incidence of mutations in the Ras and p16 genes compared to BCC ($P<0.05$). No mutations in the p16 gene were reported for BCC but 15% of the SCC examined had p16 mutations. Overall, CC>TT transitions occurred more frequently in SCC than in BCC (17% vs. 10%, $P<0.05$). The TP53 mutation spectrum for BCC and SCC showed that GC>TA transversions also were more frequent in SCC than in BCC (19% vs. 8%; $P<0.05$) while GC>AT transitions were more frequent in BCC (60% vs. 37%, $P<0.05$). The results of this analysis indicate that different gene pathways and types of mutations give rise to the different human skin cancers.

PS 1649 PHARMACOLOGICAL INHIBITION OF TGFBETA1 SIGNALING ENHANCES MALIGNANT PROGRESSION.

L. Mordasky Markell, R. Pérez-Lorenzo and A. B. Glick. *Center for Molecular Toxicology and Carcinogenesis, Penn State University, University Park, PA.* Sponsor: G. Perdew.

Transforming growth factor β1 (TGFβ1) is an important cytokine in the regulation of development, inflammation and carcinogenesis. Small molecule inhibitors of the TGFβ1 type 1 receptor kinase (ALK5) such as SB431542 (SB) have been developed to block the TGFβ1 signaling pathway, showing potential as anti-fibrotic and anti-cancer agents. However, the duality of TGFβ1 signaling in cancer as both a tumor suppressor and oncogene suggests that long term pharmacological intervention in this pathway could provoke rather than inhibit tumor formation. To test the role of TGFβ1 in the development of skin tumors, we treated Balb/c mice with SB in a 2-stage chemical carcinogenesis assay. ALK5 inhibition accelerated malignant progression, although there was no change in tumor number or volume compared to 12-O-tetradecanoyl phorbol 13-acetate (TPA) alone. To test if ALK5 inhibition altered the cutaneous response to tumor promoters, we examined the response to TPA promotion in the presence of SB. There was a significant increase in hyperplasia and a 4-fold inhibition of TPA-induced neutrophil infiltration by SB, with no differences in proliferation or apoptosis. To determine a mechanism for enhanced malignant progression *in vitro*, keratinocytes that conditionally expressed oncogenic human rasV12G were treated with SB. SB by itself had little effect on keratinocytes in the absence of ras. However, SB caused ras expressing keratinocytes to increase levels of terminal differentiation proteins and to form cornified envelopes, the end product of epidermal differentiation. Following this cell death, a resistant premalignant population with properties of immortalized cancer cells remained. In contrast to the primary keratinocytes, these cells were stimulated to proliferate by the combination of oncogenic ras and SB, and no cornification was observed. These data suggest that pharmacological inhibition of ALK5 enhances malignant conversion possibly through effects on inflammatory cells and changes in epidermal differentiation.

PS 1650 TARGETED DISRUPTION OF BCL-X_L IN MOUSE KERATINOCYTES INHIBITS BOTH UVB- AND CHEMICALLY-INDUCED SKIN CARCINOGENESIS.

D. J. Kim[1], K. Kataoka[1], S. Sano[2] and J. DiGiovanni[1]. [1]*Carcinogenesis, The University of Texas M.D. Anderson Cancer Center, Smithville, TX and* [2]*Dermatology, Osaka University, Osaka, Japan.*

Bcl-x_L, one of the members of the Bcl-2 family, is an antiapoptotic protein that has been found to play a role in a wide variety of human malignancies including skin cancer. Bcl-x_L is one of several antiapoptotic proteins regulated by signal transducer and activator of transcription 3 (Stat3). We have recently shown that Stat3 is required for both chemically-induced as well as UVB-induced skin carcinogenesis. In this study, the functional role of Bcl-x_L in skin carcinogenesis was investigated using skin-specific Bcl-x_L-deficient mice. In this model, Bcl-x_L expression is disrupted in the basal compartment of mouse epidermis using the bovine keratin 5 (K5) promoter to drive expression of Cre recombinase (i.e., K5.Cre × Bcl-$x_L^{fl/fl}$ mice). A significant increase in apoptosis induced by either UVB irradiation or 7,12-dimethylbenz[a]anthracene (DMBA) treatment was observed in the epidermis of skin specific Bcl-x_L-deficient mice. Furthermore, an increase in apoptotic cells was noted in the bulge region of hair follicles. In contrast, cell proliferation was not affected by Bcl-x_L deficiency following exposure to either UVB or 12-*O*-tetradecanoylphorbol-13-acetate (TPA). In skin carcinogenesis experiments using UVB or two-stage DMBA/TPA protocols, Bcl-x_L-deficient mice were more resistant than wild-type controls to skin tumor development with delayed onset and reduced number of tumors. Moreover, Bcl-2, Mcl-1, and survivin protein levels were increased in the epidermis of Bcl-x_L-deficient mice in the absence of stimuli. Furthermore, levels of these antiapoptotic proteins were also high in skin tumors from Bcl-x_L-deficient mice that developed in response to either UVB or two-stage carcinogenesis protocols, indicating partial compensation for the loss of Bcl-x_L. Collectively, these studies demonstrate that Bcl-x_L plays a role early in skin carcinogenesis through its antiapoptotic functions to enhance survival of keratinocytes, including those found in the bulge region, following DNA damage.

PS 1651 HIGHER EXPRESSION OF P63 AND LOWER INDUCTION OF P53 AND APOPTOSIS LED TO BENZO(A)PYRENE AND DIMETHYLBENZ(A)NTMHRACENE INDUCED SKIN TUMORS IN NQO1-/-/NQO2-/- DOUBLE KNOCKOUT MICE.

J. Shen[1], R. Barrios[2] and A. Jaiswal[1]. [1]*Pharmacology and Exp.Therapeutics, University Maryland Sch.Medicine, Baltimore, MD and* [2]*Department .Pathology, Methodist Hospital, Houston, TX.* Sponsor: B. Moorthy.

Quinone oxidoreductases are cytosolic proteins that detoxify quinones, prevent redox cycling and protect cells against oxidative stress and neoplasia. We crossed NQO1-null mice with NQO2-null mice and generated double knockout(DKO) mice. C57BL/6 wild type and DKO mice were used to investigate the relative susceptibility of DKO mice to DMBA and BaP induced skin carcinogenesis and metastasis. The dorsal skin of wild type and DKO mice were shaved and exposed to a single dose of dimethylbenz(a)anthracene (DMBA) or benzo(a)pyrene (BaP) followed by twice weekly application of phorbol 12-myristate 13-acetate (TPA) for twenty weeks. Mice were analyzed for development of skin tumors. In related experiments, wild type and DKO mice were exposed to acetone (control) or BaP or DMBA for 6, 12 and 24 hours and analyzed for alterations in growth, differentiation and proliferation factors by Western blot and immunohistochemical analysis. DKO mice exposed to DMBA showed significantly higher skin tumor frequency and multiplicity. One hundred percent DKO mice showed DMBA-induced tumor and average tumor multiplicity was greater than 15 per mouse. In contrast, only 30% of wild type mice got tumor and average tumor multiplicity was less than 3. DKO mice also showed significantly higher skin tumor multiplicity than single knockout mice that showed tumor multiplicity lower than 4 per mouse. BaP showed 100% incidence of tumors in DKO mice, as compared to none in wild type mice. Western blot and immunohistochemical analysis revealed that the treatment with BaP and DMBA induced higher levels of p63 but failed to significantly increase p53 and apoptosis in the skin of DKO mice. The results led to the conclusion that BaP and DMBA-mediated higher expression of p63 and lower induction of p53 and apoptosis led to significantly increased sensitivity of DKO mice to BaP and DMBA induced skin carcinogenesis, as compared with wild type and single knockout mice.

PS 1652 GASTROESOPHAGEAL REFLUX LEADS TO ESOPHAGEAL CANCER IN A SURGICAL MODEL WITH MICE.

J. Hao[1], B. Liu[1], C. Yang[1] and X. Chen[2]. [1]*Chemical Biology, Rutgers, The State University of New Jersey, Piscataway, NJ and* [2]*Julius L. Chambers Biomedical/Biotechnology Research Institute, North Carolina Central University, Durham, NC.*

Esophago-gastroduodenal anastomosis (EGDA) with rats mimics the development of human Barrett's esophagus (BE) and esophageal adenocarcinoma (EAC) by introducing mixed reflux of gastric and duodenal contents into the esophagus. However, use of this rat model for mechanistic and chemopreventive studies is limited due to lack of genetically modified rat strains. A mouse model of BE and EAC is needed. We performed EGDA on wild-type, p53A135V transgenic, and INK4a/Arf+/- mice of A/J strain. Some mice were also treated with omeprazole (1,400 ppm in diet), iron (50 mg/kg/m, i.p.), or gastrectomy plus iron. Mouse esophagi were harvested at 20, 40 or 80 weeks after surgery for histopathological analysis. At week 20, we observed metaplasia in wild-type mice (5%, 1/20) and p53A135V mice (5.3%, 1/19). At week 40, metaplasia was found in wild-type mice (16.2%, 6/37), p53A135V mice (4.8%, 2/42), and wild-type mice also receiving gastrectomy and iron (6.7%, 1/15). Esophageal squamous cell carcinoma (ESCC) developed in INK4a/Arf+/- mice (7.1%, 1/14), and wild-type mice receiving gastrectomy and iron (21.4%, 3/14). Among 13 wild-type mice which were given iron from week 40 to 80, twelve (92.3%) developed ESCC at week 80. None of these mice developed BE or EAC. Surgically induced gastroesophageal reflux produced ESCC, but not EAC, in mice. Dominant negative p53 mutation, heterozygous loss of INK4a/Arf, antacid treatment, iron supplementation, or gastrectomy failed to promote EAC in these mice. Further studies are needed in order to develop a mouse model of EAC. (This study was supported by NIH grants R01 CA75683, R03 CA125804, and U56 CA092077)

PS 1653 TUMOR SUPPRESSOR MEL-18 IS A NOVEL GLOBAL SUMOYLATION INHIBITOR.

J. Zhang[1, 4], M. L. Goodson[2], Y. Hong[3] and K. D. Sarge[4]. [1]*Graduate Center of Toxicology, University of Kentucky, Lexington, KY,* [2]*Section of Microbiology, University of California, Davis, CA,* [3]*Department of Biology, University of Dayton, Dayton, OH and* [4]*Department of Molecular and Cellular Biochemistry, University of Kentucky, Lexington, KY.*

Small Ubiquitin-like Modifier (SUMO) pathway is an important modifier in the carcinogenesis, as well as of toxicity in the neurodegenerative diseases. The sumoylation generally requires E3 ligases to specifically recognize substrate, however little study showed the existence of the anti-E3 ligase. Here we show that tumor suppressor Mel-18 can function like a novel anti-E3 ligase to down-regulate cellular sumoylation globally, which may give clues to the further studies in its tumor suppressor activities. In this study, extracts of HEK 293 cells transfected with GFP-Mel-18 or GFP, along with Myc-SUMO-1 were subjected to Western blotting using anti-Myc and anti-SUMO-1 antibodies, and the results indicate that increased expression of Mel-18 is associated with a detectable decrease in conjugation of SUMO-1 to cellular proteins. Consistent with this hypothesis, we found that Mel-18 can interact with at least two sumo substrates (HSF2 and RanGAP1) and that overexpression and RNA interference-mediated reduction of Mel-18 also result in decreased and increased HSF2/RanGAP1 sumoylation, respectively. In the study of the underlying mechanism, we found that Mel-18 can interact with UBC9 and inhibit UBC9 activity by blocking its ability to transfer the SUMO group from its active site to the target protein. This was tested by transfection of GFP-Mel-18 or GFP alone, and then extracts of the transfected cells were subjected to Western blotting with anti-UBC9 antibodies, the results indicate that expression of GFP-Mel-18 results in increased levels of the SUMO-containing form of UBC9 compared with cells expressing the GFP-alone construct. In the summary, tumor suppressor Mel-18 can function like a novel anti-SUMO ubiquitin-protein isopeptide ligase (E3), interacting both with substrates and the SUMO E2 UBC9 but acting to inhibit UBC9 activity to decrease sumoylation of a target protein.

PS 1654 GENETIC AND EPIGENETIC EFFECTS OF FORMALDEHYDE ON HUMAN BLOOD STEM AND PROGENITOR CELLS.

L. Zhang, Z. Ji, W. Guo, M. Azuma, Y. Bai and M. T. Smith. *School of Public Health, University of California at Berkeley, Berkeley, CA.*

Formaldehyde, an economically important industrial chemical, is a human carcinogen that causes nasopharyngeal cancer, and is also a suspected leukemogen (IARC, 2006). The impact of formaldehyde on the human cancer burden would increase considerably if it was found to cause leukemia in addition to nasopharyngeal cancer, which is relatively rare. Our recent meta-analysis of the epidemiological studies to date on this topic corroborates the association between formaldehyde exposure and leukemia, especially for myeloid leukemia at high levels of exposure (Zhang, et, al., 2008, Mut Res Rev). Leukemia originates in the pluripotent stem and progenitor cells that are located mainly in the bone marrow, but a portion circulate in the peripheral blood where they constitute up to 0.05% of total nucleated cells and can be cultured in vitro. To further examine whether the observed association between formaldehyde and leukemia is biologically plausible, we investigated the effects of formaldehyde on DNA-protein crosslinks (DPCs), chromosome alterations (CAs) and DNA methylation in CD34+ cells and blood myeloid progenitor cells cultured and harvested in colony-forming assays using growth factor enriched semi-solid media. We found that formaldehyde induces DPCs in a dose-dependent manner in CD34+ cells. We also examined metaphase and interphase cells from the cultured CFU-GM colonies and CD34+ cells using classical and molecular cytogenetics, and found that formaldehyde caused an increase in structural and numerical CAs. Further, we demonstrated that formaldehyde altered global DNA methylation and caused hypo- and hyper-methylation of specific cancer genes measured using an Illumina methylation array. These results show that formaldehyde can cause significant genetic and epigenetic changes in human hematopoietic stem and progenitor cells, and add further weight to the biological plausibility of an association between formaldehyde exposure and leukemia.

PS 1655 BENZENE-INHALATION ENHANCED THE INCIDENCE OF HEMATOPOIETIC NEOPLASMS IN P53-DEFICIENT MICE WITH RESPECT TO STRAIN-DIFFERENCES BETWEEN C57BL/6 AND C3H/HE.

T. Inoue[1], Y. Kawasaki[2], Y. Hirabayashi[2], B. Yoon[2, 3], Y. Kodama[2], O. Uchida[2], T. Umemura[2], Y. Matsushima[2], M. Saitoh[2], K. Sekita[2], J. Kanno[2] and T. Kaneko[2]. [1]*Center for Biological Safety & Research, National Institute of Health Sciences, Tokyo, Japan,* [2]*Division of Cellular & Molecular Toxicology, Center for Biological Safety & Research, National Institute of Health Sciences, Tokyo, Japan and* [3]*Laboratory of Histology & Molecular Pahtogenesis, School of Veterinary Medicine, Kangwon National University, Chuncheon, Korea, South.*

The dose-range of benzene exposure for induction of the hematopoietic neoplasms including leukemia is narrow, and the relevancy between benzene-exposure and the hematopoietic neoplasms is not clear but remained to be elucidated, specifically on; a low incidence, like a threshold, of hematopoietic neoplasms at low dose exposure, despite of Ames test-negative, known genotoxicity in its metabolites; a reason of its unlikely linear dose-response relationship, specifically at high dose; its strain/species differences in disease spectrum, specifically in incidences of myelogenous leukemias among the experimental animals and human. In this study, to resolve such questions in in vivo-studies after benzene exposure, we chose p53-knockout mice because of high sensitivity in tumorigenicity for elucidating underlying background mechanism of the threshold-like low incidence at a low dose and an unlikely linear dose-response curve at a high dose for experimental hematopoietic neoplasms; and compare C3H/He mice, a myelogenous leukemia prone, with C57BL/6, a prone for lymphoid neoplasms, focusing on the strain differences. As results, an increased number of benzene-exposure induced a high frequency of hematopoietic neoplasms up to 62 % including myelogenous leukemias (38%) with plateau forming incidence at the high dose of benzene exposure in p53-heterozygous deficient C3H/He mice. There were nonthreshold hematopoietic neoplasms observed in p53-heterozygous deficient mice, whereas it was not clearly defined in wild-type mice because of only limited incidence of hematopoietic neoplasms in wild-type mice; thus, possible threshold in wild-type mice might be false.

PS 1656 COMPARISON OF HEPG2 AND HEPARG CELL LINES EXPOSED TO DIFFERENT CARCINOGENS BY GENE EXPRESSION ANALYSES.

D. Jennen[1, 2], H. Ketelslegers[1], M. Van Herwijnen[1], J. Kleinjans[1, 2] and J. Van Delft[1, 2]. [1]*Department of Health Risk Analysis and Toxicology, Maastricht University, Maastricht, Netherlands and* [2]*Netherlands Toxicogenomics Centre, Maastricht, Netherlands.* Sponsor: H. Van Loveren.

The demand for toxicogenomics-based tests assessing the carcinogenicity of chemicals as an alternative to current rodent bioassays has resulted in the investigation of potential in vitro models. Two such models are the human hepatoma cell lines HepG2 and HepaRG. HepG2 cells are metabolically competent with respect to biotransformation of mutagens and carcinogens and carry no p53 mutations. HepaRG is a cell line that under specific conditions can be highly differentiated and quiescent, and in contrast to HepG2 cells expresses various CYP450s enzymes and exhibits other metabolic functions comparable to those in cultured human primary hepatocytes. The purpose of this study was to investigate the effect on gene expression of HepG2 and HepaRG after exposure to different carcinogens. Both cell lines

were exposed to the genotoxic carcinogens BaP and AFB1 and to the non-genotoxic carcinogens TCDD, CsA and Estradiol for 48 h. Gene expression analysis was carried out using Affymetrix Human Genome U133 Plus 2.0 Arrays. PCA showed that the expression data of all exposures were grouped together with the exception of TCDD in HepG2 and CsA in HepaRG. Gene expression was highest for BaP and TCDD in HepG2 and for AFB1 and CsA in HepaRG. The same compounds revealed the most pathways using MetaCore. Furthermore, the largest overlap in pathways between the two cell lines was found for the TCDD treatment.
Further analyses were conducted to examine whether HepG2 as well as HepaRG can be used to predict genotoxicity by gene expression profiling. First results indicated that both cell lines perform equally well. The HepaRG cell line was kindly provided by Biopredic International, Rennes, France.

PS 1657 THE INFLUENCE OF DIETARY FAT ON BENZO(A)PYRENE (BAP)-INDUCED DNA ADDUCT CONCENTRATIONS AND COLON TUMORS IN APC^{MIN} MICE.

D. L. Harris[1], M. K. Washington[2], L. Roberts II[3] and A. Ramesh[1]. *[1]Cancer Biology, Meharry Medical College, Nashville, TN, [2]Pathology, Vanderbilt University, Nashville, TN and [3]Pharmacology, Vanderbilt University, Nashville, TN.*

Studies conducted in our laboratory have shown that consumption of chemically contaminated food rich in fat, leads to a greater retention of toxicants in the body. These findings have relevance to human health in that in US alone around 60,000 lives is lost every year to colon cancer. Diet and environmental toxicants contribute to the development of sporadic colon tumors. Therefore, the objective of this study was to determine how dietary fat accelerates the development of colon tumors induced by benzo(a)pyrene (BaP), an environmental toxicant. Benzo(a)pyrene was administered to Apc^{Min} mice in unsaturated- (peanut oil) and saturated- (coconut oil) fats at doses of 50 and 100 μg/kg via oral gavage over a 60-day period. Blood, jejunum, colon and liver, were collected at 60 days post-BaP exposure; adenomas in colon and jejunum were counted and subjected to histopathology. Samples were analyzed by reverse phase-HPLC for BaP metabolites. DNA was isolated from the tissues and analyzed for BaP-induced DNA adducts by the ^{32}P-postlabeling method using a four-directional thin-layer chromatography system. BaP exposure through dietary fat induced adenomas and adducts in colon in a dose-dependent manner, with 100 μg/kg dose group registering more adenomas and adducts compared to the 50 μg/kg dose group ($p < 0.05$) for the fat categories tested. The number of adenomas, concentrations of BaP metabolites and adducts showed a statistically significant increase ($p < 0.05$) for saturated fat-treatment group compared to unsaturated fat group. These findings clearly demonstrate that the high residence time of BaP when given through saturated fat allows extensive metabolism, resulting in formation of reactive metabolites that bind with DNA and contribute to neoplastic transformation of adenomas in a long-term exposure scenario (supported by the NIH grants S11ES014156, 5T32 HL007735-14 and RO3CA130112-01).

PS 1658 REQUIREMENT FOR METALLOPROTEINASES-DEPENDENT ERK AND AKT ACTIVATION IN UVB-INDUCED G1-S CELL CYCLE PROGRESSION OF HUMAN KERATINOCYTES.

Y. He and W. Han. *Medicine/Dermatology, University of Chicago, Chicago, IL.*

Ultraviolet B (UVB, 280-315 nm) in natural sunlight represents a major environmental challenge to the skin and is clearly associated with human skin cancer. Here we demonstrate that low doses of UVB induce keratinocyte proliferation and cell cycle progression of human HaCaT keratinocytes. Different from UVA, UVB irradiation induced ERK and AKT activation and their activation are both required for UVB-induced cell cycle progression. Activation of EGFR was observed after UVB exposure and is upstream of ERK/AKT/cyclin D1 pathway activation and cell cycle progression following UVB radiation. Furthermore, metalloproteinase inhibitor GM6001 blocked UVB-induced ERK and AKT activation, cell cycle progression, and decreased the EGFR phosphorylation, demonstrating that metalloproteinases mediates the EGFR/ERK/AKT/cyclin D1 pathways and cell cycle progression induced by UVB radiation. In addition, ERK or AKT activation is essential for EGFR activation because ERK or AKT inhibitor blocks EGFR activation following UVB radiation, indicating that EGFR/AKT/ERK pathways form a regulatory loop and converge into cell cycle progression following UVB radiation. Identification of these signaling pathways in UVB-induced cell cycle progression of quiescent keratinocytes as a process mimicking tumor promotion in vivo will facilitate the development of efficient and safe chemopreventive and therapeutic strategies for skin cancer.

PS 1659 CENTROSOMAL AMPLIFICATION IN XPA/P53 TRANSGENIC MICE EXPOSED TO ZIDOVUDINE (AZT).

T. A. Nostrand, M. C. Poirier and O. A. Olivero. *Carcinogen-DNA Interactions, National Cancer Institute, NIH, Bethesda, MD.*

In cultured cells, exposure to the highly-effective nucleoside reverse transcriptase inhibitor (NRTI) Zidovudine (AZT) induces genomic instability, causing cell cycle arrest, micronuclei, sister chromatid exchanges, and shortened telomeres. In previous studies, we demonstrated for the first time that AZT induced centrosomal amplification (defined as > 2 centrosomes /cell), a novel manifestation of genotoxicity. Here, bone marrow cells from transgenic C57BL/6 mice with the genotypes XPA/p53 wild type, XPA null/p53 wild type, and XPA null/p53 heterozygote, were cultured in vitro to obtain homogeneous populations of mesenchymal-derived fibroblasts. Cells grown from mice (n=3/group) of the above genotypes were exposed to AZT for 24 hr, and centrosomal amplification was examined by immunohistochemical (IHC) staining with an anti-pericentrin antibody. Values for centrosomal amplification (% of cells with ≥2 centrosomes/cell) were 4.6, 11.2, 12.1 and 17.0 % in XPA/p53 wild type cells exposed to 0, 10, 100 or 200 μM AZT, respectively. Values for centrosomal amplification were 20.9, 33.3, 49.2, and 41.1% for XPA null/p53(+/+) cells exposed to 0, 10, 100 and 200 μM AZT, respectively. For XPA null/p53(+/-) cells exposed to 0, 10, 100 and 200 μM AZT, centrosomal amplification values were 20.9, 28.1, 40.6 and 41.9 %, respectively. The data suggest that loss of both XPA alleles confers genomic instability, but that additional loss of one p53 allele does not further enhance instability. Whereas nucleotide excision repair is not considered to impact NRTI intracellular processing, these data would argue that lack of intact nucleotide excision repair (XPA null status) enhances genomic instability in AZT-exposed cells.

PS 1660 OGG1 SER326CYS AND P53 ARG72PRO POLYMORPHISMS IN A TURKISH POPULATION WITH GASTRIC CARCINOMA.

A. E. Karakaya[1], A. Engin[1], B. Karahalil[1] and A. Engin[2]. *[1]Department of Toxicology, Gazi University, Faculty of Pharmacy, Ankara, Turkey and [2]Department of General Surgery, Gazi University, Faculty of Medicine, Ankara, Turkey.*

Initiating factors that damage the gastric cell DNA leading to gastric carcinoma has still been poorly understood. Constantly generated reactive oxygen and nitrogen species may contribute to the process of carcinogenesis by interacting with DNA. 8-oxoguanine DNA glycosylase-1 (OGG1) is an enzyme involved in the base excision repair of 8-hydroxyguanine (8-OHG). Deletion or functional loss of the p53 tumor suppressor gene contributes to the oncogenic transformation. Thus, polymorphisms of DNA repair gene OGG1 Ser326Cys and tumor suppressor gene p53 Arg72Pro were assessed in eligible 100 gastric cancer patients. One hundered and ten matched controls were included to the study. Genotypes were determined by Polymerase Chain Reaction-Restriction Fragment Length Polymorphism (PCR-RFLP) using DNA extracted from peripheral blood cells. Homozygote variant alleles Cys; of OGG1 at codon 326, Pro; of p53 at codon 72 were found to be not associated with increased risk of gastric carcinoma (OR=0.694, 95% confidence interval; (0.291-1.657), 1.282 (0.581-2.831), respectively). (Supported by The Scientific & Technological Research Council of Turkey, SBAG-3820, 107S363)

PS 1661 ATM DEFICIENT MICE DEMONSTRATE AN EXACERBATED RESPONSE TO DEXTRAN SULFATE SODIUM-INDUCED COLITIS CHARACTERIZED BY ELEVATED DNA DAMAGE AND A CHRONICALLY ACTIVATED IMMUNE RESPONSE.

A. M. Westbrook and R. H. Schiestl. *Molecular Toxicology, UCLA, Los Angeles, CA.*

The deficiency of Atm, a DNA damage recognition and repair protein, is recognized to lead to high levels of oxidative stress and increased susceptibility to cancers, however its role in inflammation is largely unknown. To determine the effect of Atm deficiency in inflammation, we induced experimental chronic colitis in Atm deficient and WT mice with dextran sulfate sodium (DSS) treatment. The immune response and systemic DNA damage were then characterized by repeated draws of peripheral blood throughout cycles of treatment. Atm deficient mice had higher levels of DNA single and double strand breaks than WT mice throughout each cycle of treatment, demonstrating lack of repair of damage during remission periods. Micronuclei formation in normochromatic erythrocytes was also markedly increased in Atm deficient mice, illustrating the clastogenicity of treatment on erythroblasts. DNA damage was elevated in Atm deficient mice even up to four weeks after end of treatment. Although Atm deficient mice had lower counts of CD4+ and CD8+ T cells in peripheral blood than WT mice, higher percentages were activated at all points of treatment. Finally, both a Th1 and Th2 inflammatory response were seen in both genotypes, with Atm deficient mice showing greater upregulation

of both Th1 and Th2 cytokines in the latter chronic phase of treatment. In conclusion, Atm deficient mice mounted a stronger immune response characterized by both pro-inflammatory and anti-inflammatory cytokines towards the chronic phase of treatment, which may have been both a cause and an effect of the larger amount of DNA damage to peripheral lymphocytes and erythroblasts. Atm therefore may be a critical factor in dampening the deleterious effects of chronic DSS-induced inflammation, necessary for genomic stability and homeostasis of the gut epithelial barrier.

PS 1662 MESOTHELIOMA DIAGNOSIS: SHOULD GENETIC SCREENING BE USED TO EVALUATE PRIMARY SITE AND PLAUSIBILITY OF ASBESTOS CAUSATION?

B. D. Kerger[1], J. Britt[2], L. Barfield[2] and R. C. James[2]. *[1]Health Science Resource Integration, Tallahassee, FL and [2]TERRA Inc, Tallahassee, FL.*

Some epidemiologic observations suggest that the incidence of mesothelioma (meso) caused by asbestos exposure may have peaked in the 1990s because the highly potent amphibole exposures were largely curtailed in the 1960s and the typical latency period of 20 to 50 years has now transpired. Epidemiologic observations also suggest a much lower or zero potency for the more prominent chrysotile exposures from various sources and products in subsequent years. If this is true, then a larger proportion of future meso cases may be due to causes other than asbestos. While some 80% of recent pleural meso cases may be caused by asbestos, the risk factors for peritoneal meso are far more diverse with less than half of the cases explained by heavy amphibole exposures. Routine genetic screening of meso patients may assist in more definitive identification of tissue/cell type of origin, risk factors, and more effective treatment regimens for the underlying cancer. First, extragonadal germ cell tumors may present as diverse tumor types, including peritoneal or pleural meso, that can be distinguished by specific mutations (iso12p) of chromosome 12 in tumor tissue. Second, apparent meso can sometimes represent misdiagnosed synovial sarcoma that is confirmed by observation of the specific translocation t(x;18) producing SYT-SSX1 or SSX2 fusion genes in tumor tissues. Additionally, we hypothesize that persons with certain inherited disorders leading to multiple cancers and chromosomal instability may present as late or disseminated tumors with meso characteristics. Thus, we suggest that it is important to collect and more thoroughly evaluate genetic evidence, particularly for meso in individuals with little known amphibole asbestos exposure. Such screening may help to identify alternative etiologies when the tumor is difficult to confirm as a primary meso. Moreover, such genetic testing may improve estimates of primary meso incidence and help to better define the dose-response relationship associated with low-level asbestos exposure.

PS 1663 THE MOLECULAR BASIS OF REVERSIBLE AND IRREVERSIBLE ANCHORAGE-INDEPENDENT GROWTH.

T. Weber, K. Waters, R. D. Quesenberry and R. Tan. *Pacific Northwest National Laboratory, Richland, WA.*

We have established an experimental model that reflects the reversible phenotypic characteristics regulated by basic fibroblast growth factor (bFGF) during normal wound healing and irreversible phenotypic characteristics associated with carcinogenesis regulated by phorbol ester (TPA). In this context, bFGF induces 1) persistent activation of the ERK pathway that is characterized by prominent ERK oscillations, 2) efficient cell migration and 3) reversible AIG in JB6 mouse epidermal cells. In contrast, TPA induces 1) persistent activation of the ERK pathway without oscillations, 2) negligible cell migration and irreversible AIG in side-by-side comparisons. Using this newly developed model, we have undertaken a genomics approach to identify biomarkers of anchorage-independent growth. Distinct gene expression profiles are associated with anchorage-independent colonies arising from bFGF-stimulated JB6 cells, relative to colonies arising from fully tumorigenic JB6 RT101 cells. 43 differentially expressed genes were common to colonies arising from bFGF-treated JB6 cells and TPA-treated JB6 cells (RT101 genetic variants). The majority of genes exhibited comparable patterns of regulation in terms of increased or decreased expression, while 12 genes exhibited reciprocal regulation patterns. Hepatic leukemia factor (HLF) and D-site albumin promoter-binding protein (DBP) expression were increased in both bFGF and RT101 colonies. Ectopic expression of DBP and HLF dramatically enhanced tumor promoter (12-O-tetradecanoyl phorbol-13-acetate, TPA; epidermal growth factor, EGF)- and low dose X-ray radiation (10 cGy)-induced AIG responses. In a preliminary screen, we observed an increase in HLF and DBP mRNA expression in human basal cell carcinoma, relative to paired non-tumor tissue. Collectively, our approach has identified candidate biomarkers of AIG.

PS 1664 INCREASED FORMATION OF MDA-DNA ADDUCTS IN ANILINE-INDUCED SPLENIC TOXICITY.

H. Ma, J. Wang, P. J. Boor and M. Khan. *Pathology, UTMB, Galveston, TX.*

Malondialdehyde (MDA), one of the most abundant lipid preoxidation-derived aldehydes, is known to be mutagenic and carcinogenic. MDA can transfer oxopropenyl group to guanine residues of DNA to yield pyrimodopurinone (M1G) adducts. M1G is a biologically important adduct that serves as a useful dosimeter of MDA-induced DNA modifications. The focus of this study was to evaluate if aniline-induced increased lipid peroxidation also leads to increased formation of MDA-DNA adducts in the spleen. To accomplish that, male SD rats were subchronically exposed to aniline (0.5 mmol/kg/day via drinking water for 30 days), while controls received drinking water only. Quantitation of M1G in the DNA samples from control and aniline-treated rats was done using an enzyme-linked immunosorbent assay (ELISA) and by using an anti-MDA-DNA monoclonal antibody. M1G levels in the spleen of aniline-treated rats showed remarkable increases which were 4.1 fold or 315% greater than the controls. To further validate our M1G ELISA results, immunohistochemistry of MDA-DNA adducts was also performed. MDA-DNA adduct-specific immunostaining showed more nuclear staining in the red pulp areas of the spleens of aniline-treated rats compared to the controls. Our study clearly shows that aniline treatment leads to significant increases in MDA-DNA adduct formation in the spleen, suggesting greater DNA base modification by MDA. Formation of MDA-DNA adducts may serve as a biomarker of DNA damage by MDA, and also presents a potential mechanism in the pathogenesis of aniline-induced fibrosarcomas in the spleen.

PS 1665 PHOSPHORYLATION OF CYCLIN-DEPENDENT KINASES AND RETINOBLASTOMA PROTEIN IN RAT SPLEEN FOLLOWING ANILINE EXPOSURE.

J. Wang and M. Khan. *pathology, UTMB, Galveston, TX.*

Aniline exposure is associated with toxicity to the spleen leading to splenomegaly, hyperplasia, and a variety of sarcomas of the spleen on chronic exposure. In earlier studies, we have shown that aniline exposure leads to iron-overload, oxidative stress and activation of redox-sensitive transcription factors, which could regulate various genes leading to a tumorigenic response in the spleen. This study was focused on evaluating the expression of cell cycle proteins (cyclins) and cyclin-dependent kinases (CDKs) associated with phosphorylation of the retinoblastoma protein (Rb) in the spleen, in an experimental condition preceding a tumorigenic response. Male SD rats were treated with aniline (0.5 mmol/kg/day via drinking water) for 30 days (controls received drinking water only), and splenocyte proliferation, expression of cyclins, and phosphorylation of cell cycle-related proteins were measured. Western blot analysis of splenocyte proteins from aniline-treated rats showed significantly increased expression of cyclin D2, cyclin D3, cyclin E and cyclin A as compared to the controls. The overexpression of these cyclins was associated with significant increases in the expression of CDK2, CDK4, as well as phosphorylation of CDK2 and Rb proteins. Aniline treatment also resulted in significant increases in splenocyte proliferation, based on cell counts and MTT assay. Our data suggest that changes in the expression of cyclins, and phosphorylation of CDK2 and Rb proteins could be critical in cell proliferation, and may contribute to aniline-induced tumorigenic response in the spleen.

PS 1666 HIGHER LEVELS/AGGREGATION OF MICROTUBULES/MICROFILAMENTS AND GLOBAL DISRUPTION OF GENE EXPRESSION IN NI-TRANSFORMED 10T1/2 MOUSE EMBRYO CELL LINES.

A. T. DeSilva[2,3], H. S. Lee[1,3] and J. R. Landolph[1,2,3]. *[1]Department of Molecular Microbiology and Immunology, University of Southern California, Los Angeles, CA, [2]Department of Pathology, University of Southern California, Los Angeles, CA and [3]USC Cancer Center, University of Southern California, Los Angeles, CA.*

Inhaling Ni-containing sulfidic ore dusts and cigarette smoke in Ni refineries induces human lung cancer. Inhalation of Ni3S2/green NiO induces respiratory cancer in rats. Ni3S2 and green/black NiO were phagocytosed into/ induced morphological/A. I./neoplastic transformation in 10T1/2 mouse embryo cells. 130 genes were differentially expressed between non-transformed and two MCA/four Ni-transformed 10T1/2 cell lines. Mutations in 15 genes likely led to differential expression of 130 genes. Ni/MCA-transformed cell lines displayed a) ect-2 gene amplification/higher levels of ect-2 mRNA/protein; higher levels of b) calnexin mRNA/protein and c) Wdr1 gene mRNA; and d) decreased levels of DRIP/TRA80, β-2-centaurin, and FAD synthetase gene mRNAs. We hypothesized Ni+2-induced 1) amplification of ect-2 gene/higher levels of rhoA-GTP led to higher levels of microtubules, and 2) silencing of β-2-centaurin gene, causing higher levels/aggregation of microfilaments in Ni-transformed 10T1/2 cell lines. We

stained cells with fluorescent phalloidin to decorate microfilaments, and fluorescent antibody to α-tubulin/β-tubulin to decorate microtubules, then examined cells by fluorescent confocal microscopy. In non-transformed 10T1/2 cells, microfilaments/microtubules were arranged homogeneously in long fibers. In three NiS transformed/one green NiO transformed cell lines, microfilaments and microtubules were over-expressed/aggregated in some areas, absent in other areas, changing shapes of transformed cells, rounding them/altering their contact with extracellular matrix. This likely leads to differential expression of eight [(130-15)/15] genes in transformed cell lines, contributing to induction/maintenance of transformed states. Supported by grants R01 ES0-3341/NIEHS (PI, JRL) and 5 T32 AI07078/NIAID, USC Discretionary Funding.

PS 1667 ALTERATIONS OF DIURNAL EXPRESSION RHYTHM OF CIRCADIAN GENES AND HORMONE RECEPTOR GENES BY CHEMOPREVENTIVE DOSE OF SELENIUM IN RAT MAMMARY TISSUE.

M. Fang[1], X. Zhang[2] and H. Zarbl[1, 2]. *[1]Department of Environmental Occupational Medicine, University of Medicine and Dentistry of New Jersey, Piscataway, NJ and [2]Division of Human Biology, Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA.*

To further define the molecular basis for methylselenocysteine (MSC)- mediated chemoprevention, we compared global gene expression profiles in normal mammary tissues from rats maintained on a diet supplemented with MSC (3 ppm Se) or a control diet (0.1 ppm Se), with and without exposure to N-nitroso-N-methylurea (NMU). The results of this analysis indicated that the most dramatic effect of Se diet was the coordinated change in the expression of genes that regulate circadian rhythm. Our results further demonstrated that a single carcinogenic dose of NMU ablated and that dietary MSC supplementation restored the coordinated diurnal expression of circadian genes Per1, Per2, and RevErbAα in mammary tissues, suggesting that normal circadian rhythm suppresses mammary carcinogenesis. We also found that neither carcinogen exposure nor dietary MSC altered blood melatonin levels, indicating that neither treatment had an effect on light mediated regulation of melatonin through the Suprachiasmatic Nucleus. By contrast, MSC induced a dramatic increase in the expression of the melatonin receptor 1α in mammary tissues, suggesting that increased melatonin signaling contributed to or affected by the MSC-mediated restoration of circadian rhythm in NMU treated mammary tissues. More importantly, we demonstrated that MSC induced a 7-fold increase in the circadian expression of Estrogen Receptor beta (ERβ) in the mammary tissues. These findings suggest that dietary MSC might prevent mammary carcinogenesis through enhanced rhythmic expressions of circadian genes, induced melatonin signaling, and ERβ-mediated differentiation and growth inhibition in mammary epithelial cells. Further studies are needed to elucidate the mechanistic associations between these tumor-inhibition pathways. Supported by the NIEHS grants, U19ES011387, P30ES007033, and P30ES005022.

PS 1668 A CB1 SPECIFIC AGONIST, JWH-133 ACCELERATES TUMOR GROWTH IN A XENOGRAFT MODEL OF ESTROGEN RECEPTOR NEGATIVE BREAST CANCER.

A. Alexander, J. Baek, E. C. Stuart, S. Taurin, P. F. Smith and R. J. Rosengren. *Pharmacology & Toxicology, Univeristy of Otago, Dunedin, New Zealand.*

Natural and synthetic cannabinoids have shown anti-cancer actions in a variety of *in vitro* and *in vivo* cancer models. However, there is limited information regarding their actions in breast cancer. Therefore, we investigated two synthetic cannabinoids in an ER- breast cancer model. Athymic nude female mice were implanted subcutaneously with MDA-MB-231 cells ($2x10^6$) and left to form palpable tumors. The mice were then treated with JWH-133 (a selective CB1 agonist), WINN 55,212-2 (a mixed CB1 and CB2 agonist) at 50, 25 or 12.5 μg/mouse or vehicle control, ip for 70 days. Tumor volume was measured weekly with electronic calipers. At necropsy, tumors and organs were weighed and blood was collected to determine plasma ALT activity. Tumors extracts were also prepared. The results demonstrated that JWH-133 (50 μg/mouse) significantly increased tumor volume (tumor volume of 662 ±305 and 832 ± 283 mm^3, for vehicle and 50 μg, respectively, $p<0.03$). This correlated to tumor weights of 415 ± 142 and 281 ± 135 mg for 50 μg and control, respectively. In contrast, WINN 55,212-2 (25 μg/mouse) decreased tumor volume 70% compared to control. Importantly, both cannabinoids were non-toxic to the mice, as ALT activity, weight gain and gross organ weights were all normal. Western blotting of tumor extracts demonstrated that the tumors expressed CB1 and CB2 receptors, but their expression was unchanged following cannabinoid treatment. The angiogenic factor VEGF and its receptor VEGFR-1 were also unchanged following cannabinoid treatment. The results from this study demonstrate that JWH-133 accelerates tumor growth in an MDA-MB-231 xenograft model of ER- breast cancer, but this did not occur following treatment with WINN 55,212-2. The mechanism for this effect is not clear, but it does not involve up-regulation of VEGF or VEGFR-1. Therefore, further research is required on the anti-cancer effects of synthetic cannabinoids, as we are the first to demonstrate that low doses of a selective CB1 agonist accelerates tumor growth *in vivo*.

PS 1669 INHIBITION OF MAMMARY DNA ADDUCTS AND TUMORS INDUCED BY XENOESTROGENS.

S. R. Kondraganti and B. Moorthy. *Pediatrics, Baylor College of Medicine, Houston, TX.*

Breast cancer is a leading cause of cancer-related death among American women. The etiology of majority of breast cancers is multifactorial, of which 95% is environmental and hormonal. Xenoestrogens are present in the environment, includes PAHs, and range from natural plant-derived phytoestrogens to man-made substances, such as pharmacological agents and organochlorine pesticides. Exposure to xenoestrogens leads to adverse health effects such as reproductive dysfunction, developmental disorders, malignancies etc. 3-Methyl-cholanthrene (3-MC) represents a novel subclass of xenoestrogenic compounds that activates both ER-α and AhR signaling pathways. The formation of depurinating estrogen-DNA adducts appear to be a critical step in the initiation of cancer by estrogens. CYP19 or aromatase is involved in the biosynthesis of estrogens. Phytochemicals have the advantage of being dietary compounds that are less toxic to animals, abundant, and inexpensive. Many molecular and cellular studies have revealed the ability of dietary phytochemicals in vegetables and fruits to reduce the risk of cancer. The major mechanisms of chemoprevention involve induction of phase II detoxification enzymes and/or inhibition of phase I enzymes that are involved in the activation of certain carcinogens. In the present study, we evaluated the chemopreventive and chemotherapeutic potencies of dietary phytochemicals to suppress xenoestrogen induced mammary DNA adduct and tumor formation in female mice. Our studies show that in mammary tissues of mice exposed to 3-MC, EROD activities, CYP1A1 (phase I enzyme) and NQO1 (phase II enzyme) gene expressions increased when compared to controls. Significant reduction of phase I enzymes along with elevation of several phase II enzymes was observed in female mice treated with dietary phytochemicals. Thus, the dietary phytochemicals could modulate the Phase I/Phase II enzymatic systems, a critical mechanism involved in the formation of cancers. These studies will result in improved prevention or treatment methodologies in endocrine therapy for hormonally induced breast cancer.

PS 1670 THE RAT HOMOLOG OF THE DROSOPHILA FRY GENE ENCODES A PUTATIVE MAMMARY CANCER SUSCEPTIBLITY LOCUS.

J. Graham[1], X. Ren[3, 2], M. Fang[1], L. Jing[3], A. Mikheev[3], Y. Gao[3], H. Xie[3], J. Lew[3], A. Kim[3], X. Zhang[3], B. Trask[3], V. Li[3], R. Sullivan[3], C. Friedman[3] and H. Zarbl[1, 2, 3]. *[1]Department of Environmental and Occupational Medicine, RWJMS-UMDNJ, EOHSI, Piscataway, NJ, [2]Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA and [3]Division of Human Biology, Fred Hutchinson Cancer Research Center, Seattle, WA.*

Rat strains vary in their susceptibility to mammary carcinogens. Using a genetic backcross between the resistant Copenhagen (Cop) and sensitive Fischer 344 (F344) strain, we mapped a Mammary carcinoma susceptibility (Mcs) locus to the centromeric region on the long arm of rat chromosome 12. The locus is contained within a ~5 centimorgan region whose synteny is conserved on human chromosome 13. Rat BRCA2, along with several other candidate genes within this interval, were examined for polymorphisms and differences in expression levels in the mammary tissue of the two rat strains. Our results revealed two non-synonymous mutations within the rat ortholog of the Drosophila furry gene in the Fisher 344. Comparative genomic analysis indicated that these F344 specific mutations occur within a region of the coding sequence that is highly conserved (>90%) in eutherial mammals. One of these mutations results in a serine residue at codon 2170 of the mutant Fry protein in the F344 rat. This amino acid substitution creates a consensus sequence that has a high probability of being a substrate for various cancer related protein kinases, suggesting altered activity or regulation of the mutant Fry protein. Examination of Fry gene expression indicated a reduction in the majority of rat mammary tumors, as well as several human breast carcinoma cell lines. In an effort to further examine Fry protein expression as well as perform functional studies, we have developed a polyclonal anti-peptide antibody against a conserved sequence within the predicted human and rat furry protein. We are also conducting functional studies using shRNA to functionally "knock out" the Fry gene in mammary cells.

PS 1671 ESTROGENIC STATUS MODULATES THE EFFECT OF SOY ON HEPATIC RESPONSES TO 7, 12-DIMETHYLBENZ(A)ANTHRACENE (DMBA).

R. Singhal[1, 2], T. M. Badger[1, 3] and M. J. Ronis[1, 2]. [1]*Arkansas Children's Nutrition Center, University of Arkansas Medical Sciences, Little Rock, AR,* [2]*Department of Pharmacology & Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR and* [3]*Department of Physiology & Biophysics, University of Arkansas for Medical Sciences, Little Rock, AR.*

We examined the influence of estradiol (E2) status and soy protein isolate (SPI) intake on the hepatic responses altered by 7,12-dimethylbenz(a)anthracene (DMBA, a polycyclic aromatic hydrocarbon [PAH]). Sprague-Dawley rats were ovariectomized (OVX) at PND50 and infused with E2 or vehicle for 14d and gavaged with 50mg/kg DMBA or vehicle 24 h before sacrifice at PND64. Rats were fed an AIN-93G diet made with SPI or casein as sole protein source throughout the study. Basal AhR protein levels were reduced (P<0.05) by SPI feeding irrespective of the E2 status. However, DMBA increased (P<0.05) AhR-induced CYP1A1 gene expression in OVX, SPI-fed rats, but reduced (P<0.05) CYP1A1 in OVX+E2, SPI-fed rats. Chromatin-immunoprecipitation demonstrated lower (P<0.05) DMBA-mediated recruitment of estrogen receptor alpha to the CYP1A1 promoter by SPI feeding in the presence of E2, suggesting an estrogen-like action of SPI on DMBA-mediated signaling in the absence of E2. Further, microarray analysis (Rat 230-2.0 Affymetrix-GeneChip™) revealed 231 genes common to SPI + DMBA and SPI + E2 + DMBA (normalized to E2) treatments. AhR-activated genes (CYP1A1, CYP1A2, and NQO1) were down-regulated by SPI + E2 + DMBA compared to SPI + DMBA. Unique interactions among SPI, DMBA and E2 altered the expression profile of 316 genes, not observed by either treatment alone. Our data suggest that although E2 status does not effect soy-mediated AhR degradation, it modulates the effects of soy on many genes, including CYP1A1. Supported in part by USDA CRIS 6251-51000-005-02S.

PS 1672 EFFECT OF CAFFEIC ACID PHENETHYL ESTER AND QUERCETIN ON N-7-ETHYLGUANINE ADDUCT FORMATION INDUCED BY N-DIETHYLNITROSAMINE IN RAT LIVER DNA.

R. Mácias-Pérez[1], O. Beltrán-Ramírez[1], V. Vásquez-Garzón[1], M. L. López-González[2], A. Sierra-Santoyo[2] and S. Villa-Treviño[1]. [1]*Cell Biology, Cinvestav-IPN, Mexico City, D.F, Mexico and* [2]*Toxicology Section, Cinvestav-IPN, Mexico City, D.F, Mexico.*

Caffeic acid phenethyl ester (CAPE) and quercetin (Q) have shown anti-carcinogenic properties in the modified resistant hepatocyte model when they are administered on initiation stage. In this model, N-diethylnitrosamine (DEN) cytochrome P450 (CYP)-dependent bioactivation, the ion ethyldiazonium and ROS are generated to produce ethylated and oxidized DNA adducts. N-7-ethylguanine (N7-EtG) is one of the most important adducts formed by DEN treatment. The information about the action mechanism of CAPE and Q in initiation stage is limited. The aim of this study was to determine the effect of CAPE and Q on the formation of N7-EtG in DNA induced in rat liver after DEN administration. F344 male adult rats were administered with a CAPE i.p. dose (20 mg/kg) 12 h or a Q p.o. dose (10 mg/kg) 2 h before DEN i.p. administration (200 mg/kg). Animals were sacrificed at different times after DEN administration and liver was removed and processed to obtain DNA. N7-EtG was determined in hydrolyzed liver DNA in 1 N HCl by HPLC/MSD. A maximum of N7-EtG adduct formation was observed at 18 h after DEN administration and decreased gradually after. CAPE and Q pretreatment decreased the N7-EtG formation. In the CAPE treated animals the peak of N7-EtG formation occurred at 12 h, in addition, at 6, 12 and 18 h, N7-EtG concentration decreased 50, 43 and 89%, respectively, in comparison to the DEN treated animals. Q treatment produced a decreasing from 35 to 65% at all determined times, showing a similar trend to CAPE. These results suggest that CAPE and Q reduce the formation of ethylated-DNA adducts and support the proposal that their chemopreventive effects may be by altering CYP-dependent DEN bioactivation in chemical carcinogenesis (Project supported by Conacyt-Grant 48,774).

PS 1673 CAFFEIC ACID PHENETHYL ESTER INHIBITES CYP 1A1 ACTIVITY IN HEPA 1C1C-7 CELLS.

J. Park, E. Han and H. Jeong. *BK21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South.*

Caffeic acid phenethyl ester (CAPE), a natural component of propolis, is known to antioxidant, anti-inflammatory, antiviral, and anticancer activity. However, CAPE is unknown to effects of metabolism of xenobiotics and endogenous compounds. The present study, we investigated effect of CAPE on CYP1A1 related to metabolism of xenobiotics and 7, 12-dimethylbenzanthracene (DMBA)-DNA adduct in Hepa1c1c7 cells. CYP1A1 catalyzes the metabolic activation of procarcinogenic polycyclic aromatic hydrocarbons (PAHs), such as DMBA. CAPE inhibits DMBA induced DNA adduct formation. There upon we examined the effect of CYP1A1 enzyme activity by CAPE using a 7-ethoxyresorufin O-deethylation (EROD) assay. CAPE suppresses DMBA-induced CYP1A1 enzyme activity. However, CAPE was not changed DMBA-induced XRE promoter activity. Moreover, CAPE also was not changed to protein level. Subsequent studies we confirmed by measuring direct EROD the effect of DMBA-induced CYP1A1 activity, and we known to CAPE directly suppress DMBA induced CYP1A1 enzyme activity. Taken together, these results suggest that CAPE has chemoprevention effect through inhibition of DMBA induced CYP1A1 activity and of DMBA induced DNA adduct formation, as well as a direct inhibitor of CYP1A1 enzymes.

PS 1674 EFFECTS OF DIETARY FISH OIL ON THE DECREASE OF CARCINOGENIC PAH-DNA ADDUCT LEVELS IN THE LIVER OF B6C3F1 MALE MOUSE.

G. Zhou, S. S. Wang and K. C. Donnelly. *Environmental & Occupational Health, Texas A&M University System Health Science Center, College Station, TX.*

Genotoxic complex mixtures are released into the environment from a variety of sources. Many carcinogenic PAHs and their metabolites can bind covalently to DNA. The formation of covalent DNA adducts is known to be a key event in the initiation of neoplasia and, also, contributes significantly to the progression of tumors. It has been reported that fish oil (Omega-3, FO), compared to corn oil (CO), may play a role as an apoptosis inducer, and thus be protective against formation of DNA adducts. In this study we tested hypothesis that fish oil could decrease the levels of PAH-DNA adducts by removing damaged cells. B6C3F1 male mice were fed a FO or CO diet for one month. The animals were then treated with seven carcinogenic PAHs including BaP with two doses via intraperitoneal injection. Animals were terminated at 7d after treatment. The levels of DNA adducts were analyzed by the nuclease P1-enhanced 32P-postlabeling assay. Our results showed that the levels of total DNA adducts in the livers of mice fed with FO were significantly decreased compared to CO mice. The mean RAL values for total DNA adducts in the liver of mice treated with the high dose PAHs were 52.34±8.07 and 89.11±9.89 in 109 nucleotides (P=0.028), respectively, for the FO and CO groups. The levels of BP-dG adduct were also diminished in FO group (23.35±3.60) compared to CO group (33.76±2.02), P=0.045. Animals treated with the low dose (2.5 fold lower) PAHs displayed similar trends. Total RAL values of hepatic DNA adducts were 21.52±3.53 in FO group and 34.46±2.82 in CO group, P=0.029. The levels of BP-dG adduct were 7.76±1.74 and 13.27±0.90 in 109 nucleotides, respectively, for FO and CO diet group (P=0.031). Our results suggest a possible mechanistic link between cellular apoptosis and DNA adduct formation. In conclusion, these results help furthering our understanding of the mechanisms of carcinogenesis, especially in relation to the chemopreventive properties of nutritional apoptosis inducers. (Supported by P30-ES09106)

PS 1675 TRANSPLACENTAL CHEMOPREVENTION BY CHLOROPHYLLIN, PURIFIED CHLOROPHYLLS AND FREEZE-DRIED SPINACH: CONFIRMATION OF THE COMPLEXATION THEORY FOR CHL.

D. J. Castro[1, 2] and D. E. Williams[1, 2, 3]. [1]*Environmental & Molecular Toxicology, Oregon State University, Corvallis, OR,* [2]*Linus Pauling Institute, Oregon State University, Corvallis, OR and* [3]*Environmental Health Sciences Center, Oregon State University, Corvallis, OR.*

The carcinogenic potential of dibenzo[*a,l*]pyrene (DBP) has been well characterized in numerous animal models. We have previously documented that a single dose of 15 mg/Kg DBP to pregnant mice late in gestation (GD 17) produces an aggressive T-cell lymphoma as well as lung and liver cancer in offspring. The current study examines the chemopreventative properties of chlorophyllin (CHL) and chlorophyll (Chl) in this transplacental carcinogenesis model. Pregnant B6129SF1 females, bred to 129S1/SvIm males, received purified diets incorporated with either 2000 ppm CHL, 2000 ppm Chl, or 10% freeze-dried spinach beginning at gestation day 9. Lymphoma-dependent mortality was not significantly altered by maternal consumption of any of the diet and little effect on lung tumor burden in mice surviving to 10 months of age was observed. However, co-administration of CHL at 380 mg/Kg with DBP by gavage (molar ratio of 10:1, CHL:DBP) provided significant protection against DBP initiated carcinogenesis. Offspring born to dams receiving CHL co-gavaged with DBP exhibited markedly less lymphoma-dependent mortality (p< 0.001). The degree of protection by CHL, compared to controls dosed with DBP in tricaprylin (TCP) as the vehicle, was less marked, but still significant. Co-administration of CHL (TCP as vehicle) also reduced lung tumor multiplicity in mice by approximately 50% and this was observed throughout the study (p< 0.005). This is the first demonstration that CHL can provide potent

chemoprotection in a transplacental carcinogenesis model and supports a mechanism involving complex-mediated reduction of carcinogen uptake. The work reported here was supported by PHS grants CA90890, ES07060 and ES00210.

PS 1676 SAPONINS DERIVED FROM ROOTS OF PLATYCODON GRANDIFLORUM INHIBIT 4-(METHYL NITROSAMINO)-1-(3-PYRIDYL)-1-BUTANONE (NNK)-INDUCED NF-KB TRANSACTIVATION AND CELL TRANSFORMATION IN BEAS-2B HUMAN BRONCHIAL EPITHELIAL CELLS.

H. Park and H. Jeong. *BK21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South.*

Epidemiological data suggest that consumption of fruits and vegetables has been associated with a lower incidence of cancer. Platycodon grandiflorum is a traditional oriental herbal medicine that is known for its immunostimulatory and antitumor effects. In this study, we investigated effects of Changkil saponins (CKS) derived from roots of Platycodon grandiflorum on 4-(methyl nitrosamino)-1-(3-pyridyl)-1-butanone (NNK)-induced NF-kB transactivation and cell transformation in BEAS-2B human bronchial epithelial cells. We found that CKS significantly blocked NNK-induced cell transformation in a concentration-dependent manner. CKS significantly attenuated NNK-induced NF-kB activation, and transcription factor. CKS inhibited the NNK-induced phosphorylation of extracellular-signal regulated protein kinases Akt and p38 kinases, which NF-kB regulate activation. Taken together, our results suggest that inhibition by CKS of NNK-induced neoplastic transformation in BEAS-2B cells is related to blocking of Akt and p38 activation, and also attenuation of NF-kB activation. These results indicated that CKS has potent anticancer-promoting activity.

PS 1677 EFFECT OF CELASTROL ON SPECIFICITY PROTEIN TRANSCRIPTION FACTORS IN PANCREATIC CANCER CELLS.

I. Jutooru[1], G. Chadalapaka[1] and S. Safe[1,2]. *[1]Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX and [2]Institute of Biosciences & Technology, Texas A&M Health Science Center, Houston, TX.*

Specificity protein (Sp) transcription factors Sp1, Sp3 and Sp4 are overexpressed in multiple tumor types and negative prognostic factors for survival. Since Sp transcription factors regulate genes associated with survival (survivin), angiogenesis [vascular endothelial growth factor (VEGF) and its receptors] and growth (cyclin D1), research in this laboratory has focused on development of anticancer drugs that decrease Sp protein expression. Celastrol, a naturally occurring triterpenoid acid from an ivy-like vine exhibits anticancer activity and treatment of Panc28 and L3.6pl pancreatic cancer cells with 0.5 – 2.5 μM celastrol decreased cell survival and IC50 values for inhibition of cell proliferation were 1.4 and 1.1 μM, respectively. Celastrol also induced apoptosis and decreased expression of survivin, cyclin D1, epidermal growth factor (EGFR1), and VEGF in Panc28 and L3.6pl cells, suggesting that decreased expression of these genes may be due to downregulation of Sp proteins. Treatment of Panc28 and L3.6pl cells with 1 – 5 μM celastrol decreased Sp1, Sp3 and Sp4 protein expression in both cell lines and cotreatment with the proteosome inhibitor MG132 did not inhibit downregulation of Sp proteins. The mechanism of celastrol-induced repression of Sp proteins was associated with downregulation of microRNA-27a (miR-27a). Decreased miR27a results in the induction of ZBTB10, a zinc finger protein that acts as an Sp-repressor by competitive interaction with Sp proteins bound to GC-rich promoter elements. At a dose of 4 mg/kg every second day, celastrol also inhibited pancreatic tumor growth in athymic nude mice bearing L3.6pl cells as xenografts, and Sp proteins were also decreased in tumors from treated mice. This study demonstrates that the anticancer activity of celastrol in pancreatic cancer due to celastrol-miR27a interactions resulting in ZBTB10-dependent repression of Sp and Sp-dependent genes.

PS 1678 1, 1-BIS(3'-INDOLYL)-1-(P-BROMOPHENYL)METHANE AND RELATED COMPOUNDS DECREASE PANCREATIC AND COLON CANCER CELL SURVIVAL AND EXPRESSION OF SURVIVIN.

S. Sreevalsan[1], I. Jutooru[1], G. Chadalapaka[1] and S. Safe[1,2]. *[1]Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX and [2]Institute of Biosciences & Technology, Texas A&M Health Science Center, Houston, TX.*

1,1-Bis(3'-indolyl)methane (DIM),a metabolite of indole-3-carbinol which is expressed in brassica vegetables, exhibits anticancer activity in a wide variety of tumors. 1,1-Bis(3'-indolyl)-1-(substituted aromatic)methanes (C-DIMs) are structurally related to DIM and are potent anticancer agents. The para-bromo-substituted analog (DIM-C-pPhBr) and a 2-methyl indole ring derivative (2-methyl-DIM-C-pPhBr) were used in this study to investigate their anticancer activity in Panc28 (pancreatic cancer) and SW480 (colorectal cancer) cell lines. Inhibition of Panc28 and SW480 cell proliferation was observed after treatment with 5-15 μM concentrations of both compounds. IC50 values for DIM-C-pPhBr in Panc28 and SW480 were 5.29 and 4.9 μM, respectively, and values of 4.75 and 6.6 μM were observed after treatment with 2-methyl-DIM-C-pPhBr. In addition, both compounds induced caspase-dependent cleavage of poly (ADP-ribose) polymerase (PARP) which is indicative of apoptosis. Since, survivin negatively regulates apoptosis, we further investigated the effects of DIM-C-pPhBr and 2-methyl-DIM-C-pPhBr on survivin expression in Panc28 and SW480 cell lines. Both compounds induced a concentration- and time-dependent decrease in survivin protein and mRNA levels. In addition, we also investigated the effects of DIM-C-pPhBr and 2-methyl-DIM-C-pPhBr on survivin promoter activity. SW480 cells were transfected with pSurvivin 269, a construct containing the -269 to +49 GC-rich region of the survivin promoter linked to the luciferase gene, and after treatment with 10, 15 and 20 μM DIM-C-pPhBr and 2-methyl-DIM-C-pPhBr, there was a decrease in luciferase activity of 30, 80 and 95% and 40, 90 and 95%, respectively. Similar results were obtained in cells transfected with pSurvivin 150 which contains the -150 to +49 GC-rich region of the survivin promoter linked to the luciferase gene.

PS 1679 PREGNANE X RECEPTOR SUPPRESSES PROLIFERATION AND TUMORIGENICITY OF COLON CANCER CELLS THROUGH REGULATING RB/E2F1 PATHWAY.

N. Ouyang, S. Ke, N. Eagleton, Y. Xie and Y. Tian. *VTPP, Texas A&M University, College Station, TX.*

Pregnane X receptor (PXR) is nuclear receptor that coordinately regulates the metabolism and disposition of various xenobiotics and endobioitics. In the present study, we report a novel tumor suppressor function of PXR in cell culture and xenograft models. We demonstrated that expression of PXR through stable transfection of human PXR in human colon epithelium cancer cell line (HT29) significantly inhibited cell proliferation as determined by MTT assay ($p<0.01$). Colony growth of the PXR-transfected HT29 cells was suppressed in soft agar assay. In the xenograft assay, the tumor size formed in nude mice was significantly suppressed with PXR gene stable-transfection (310 mg±6.2 v.s. 120 mg±6, $p<0.01$). The Ki-67 positive cells were significantly decreased in PXR-transfected HT29 xenograft tumor tissue comparing to the vector-transfected HT29 controls ($p<0.01$) as determined by immunohistochemistry suggesting that PXR inhibits the proliferation of colon cancer cells. Results of flow cytometry analysis indicated that PXR-transfection in HT29 cells caused G0/G1 arrest in PXR-HT29 cells. The cell growth inhibitory effects of PXR are likely mediated through the E2F/Rb-regulated check point as the E2F1 nuclear expression was significantly inhibited by PXR overexpression. Taken together, these results suggest that PXR directly inhibits the proliferation and tumorigenicity of colon cancer cells in vitro and in vivo. Our results indicate that the evolutionarily conserved PXR protects organisms from carcinogenesis by inhibiting tumor growth as well as eliminating carcinogenic substances. (The research is supported by ES09859 to YT).

PS 1680 INHIBITION OF EPIDERMAL GROWTH FACTOR RECEPTOR (EGFR) IN BLADDER CANCER CELLS BY CURCUMIN AND BETULINIC ACID.

G. Chadalapaka[1], I. Jutooru[1] and S. Safe[1,2]. *[1]Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX and [2]Institute of Biosciences & Technology, Texas A&M Health Science Center, Houston, TX.*

The epidermal growth factor receptor 1 (EGFR1) is overexpressed in multiple tumor types and is an important drug target for cancer chemotherapy using either neutralizing antibodies or tyrosine kinase inhibitors. Research in this laboratory has characterized betulinic acid (BA) and curcumin as anticancer drugs that act by repressing specificity factor (Sp) transcription factors and Sp-dependent genes associated with cancer cell growth, survival and angiogenesis. Treatment of 235JB-V and KU7 bladder cancer cells with curcumin and BA decreased cell survival, whereas the tyrosine kinase inhibitor gefitinib differentially inhibited growth of these cells since KU7 cells are gefitinib-resistant. Curcumin and BA also decreased expression of Sp1, Sp3 and Sp4 proteins and the Sp-dependent genes survivin and vascular endothelial growth factor (VEGF) and induced caspase-dependent PARP cleavage in both cell lines. We hypothesized that curcumin and BA would also decrease EGFR1 in bladder cancer cells since EGFR1 expression is Sp-dependent in some cancer cell lines. Curcumin and BA decreased EGFR1 protein and mRNA levels and also inhibited EGFR1- dependent downstream kinase activity including phosphatidyli-

nositol 3-kinase (PI3K)-dependent phosphorylation of AKT in both cell lines. In addition, BA and curcumin also decreased expression of sodium/glucose co-transporter 1 (SGLT1) which is also regulated by EGFR1 (kinase-dependent). Conformation that EGFR1 is an Sp-dependent gene was determined in RNA interference studies where knockdown of Sp1, Sp3 and Sp4 decreased EGFR1 protein. Thus, BA and curcumin specifically target downregulation of EGFR1 in bladder cancer cells and also in tumors (xenografts), demonstrating that these agents and other drugs that decrease Sp protein expression can be used in cancer chemotherapies that specifically target EGFR1.

PS 1681 A NOVEL ANTI-CANCER DRUG DERIVED FROM GLYCYRRHETINIC ACID DECREASES LNCAP CELL SURVIVAL BY INDUCTION OF A DUAL PHOSPHATASE, MKP5.

S. Papineni[1], S. Chintharpalli[2], S. Lee[2] and S. Safe[1, 2]. *[1]Veterinary Physiology & Pharmacology, Texas A & M University, College Station, TX and [2]Institute of Biosciences & Technology, Texas A&M Health Science Center, Houston, TX.*

Methyl 2-cyano-3,11-dioxo-18β-olean-1,12-dien-30-oate (CDODA-Me) was synthesized from glycyrrhetinic acid, a triterpenoid acid that is the principal active component of licorice root extracts. CDODA-Me is a potent inhibitor of LNCaP prostate cancer cell survival (IC50 ~ 1 μM) and induces caspase-dependent PARP cleavage (apoptosis) in this cell line. Mechanistic studies initially showed that CDODA-Me activated two pathways associated with growth inhibition and decreased cell survival, namely, decreased phosphorylation of a translation initiation factor, the eukaryotic initiation factor 4E (eIF4E), and decreased expression of specificity protein (Sp) transcription factors, Sp1, Sp3 and Sp4. In addition CDODA-Me also decreased several Sp-dependent genes including survivin and VEGF and also affected the expression of eIF4E-dependent target genes c-myc and Mcl-1. Cotreatment of LNCaP cells with Phosphatase Inhibtior cocktail II and specific phosphatase inhibitor, sodium orthovanadate, completely blocked CDODA-Me-dependent dephosphorylation of eIF4E and also reversed proteasome dependent degradation of Sp1, Sp3 and Sp4. The effects of the phosphatase inhibitors on CDODA-Me-dependent modulation of phospho-eIF4E and Sp proteins suggested that this compound activated a phosphatase in LNCaP cells. Several candidate phosphatase genes were screened and we demonstrated that CDODA-Me induced mitogen-activated protein kinase phosphatase-5 (MPK5) expression in LNCaP cells. Similar results were recently reported for curcumin and other chemoprotective phytochemicals in prostate cancer cells. However, in contrast to previous studies, MKP5 had minimal effects on stress kinases, whereas overexpression of this gene decreased eIF4E phosphorylation and expression of Sp 1, Sp3 and Sp4 proteins. Thus, the anticancer activity of CDODA-Me in LNCaP cells and in tumors (xenografts) is due, in part, to induction of a dual phosphatase MKP5.

PS 1682 TCDD AND THE SELECTIVE ARYL HYDROCARBON RECEPTOR (AHR) MODULATORS INDOLE-3-CARBINOL (I3C) AND 3, 3'-DIINDOLYLMETHANE (DIM) REGULATE PROSTATE TUMORIGENESIS IN TRAMP MICE.

T. M. Lin[1], W. A. Fritz[1], S. Safe[2] and R. E. Peterson[1]. *[1]Sch. of Pharmacy, University Wisc., Madison, WI and [2]Vet. Physiol. Pharmacology, Texas A&M University, College Station, TX.*

In utero and lactational (IUL) TCDD exposure increased precancerous cribriform lesion incidence in dorsolateral prostates (DLP) of senescent wild-type mice, while AhR acts as a prostate tumor suppressor in TRAMP mice. We therefore hypothesized that perinatal AhR signaling pathway activation would increase susceptibility to prostate cancer while AhR activation during adulthood would be protective. Pregnant TRAMP mice were given 1 μg TCDD/kg or vehicle on embryonic day 13.5; macroscopic prostate tumor incidence in male offspring was determined at 140 days of age. IUL TCDD exposure significantly elevated prostate tumor incidence (30% versus 10% in controls). All tumors had neuroendocrine (NE) characteristics. In adult AhR activation studies, TRAMP mice were gavaged 3 times/week with vehicle, 10 or 100 mg/kg DIM or I3C starting at 56 days of age. Other TRAMP mice were given 5 μg TCDD/kg and weekly 1.8 μg TCDD/kg maintenance doses. Tumor development was examined weekly by palpation. TCDD and 5 mg I3C/kg significantly increased the median age for prostate tumor-free survival, and the other three treatments also appeared to be protective. All vehicle-dosed TRAMP mice developed NE-characteristic prostate tumors in the ventral prostate (VP). Papillary adenomas were also found in the DLP and anterior prostate (AP) in I3C-, DIM-, and TCDD-treated TRAMP mice. Tumors in younger mice were predominantly NE tumors located in the VP, while older mice typically developed papillary adenoma in DLP and to a lesser extend in AP. These results suggest that adult exposure of TRAMP mice to I3C, DIM, and TCDD protects against NE tumor development, increasing tumor-free survival and allowing prostate adenomas to be manifested. In summary, perinatal AhR activation enhances prostate tumor development in TRAMP mice while adult AhR activation is protective. (Supported by NIH grants CA095751, ES01332, and ES12352).

PS 1683 A NOVEL NUTRIENT MIXTURE INHIBITS MMP EXPRESSION, INVASION AND APOPTOSIS IN CHONDROSARCOMA CELL LINE SW 1353.

M. Roomi, N. Roomi, M. Rath and A. Niedzwiecki. *Dr. Rath Research Institute, Santa Clara, CA.*

Introduction: Chondrosarcoma, a malignant tumor of cartilaginous origin, is the second most frequent primary malignant tumor of bone, representing approximately 25% of primary osseous neoplasms. Incidence of tumors in children is low. Most tumors occur in patients older than 40 years. Cancer mortality usually results from tumor invasion of local tissues and metastases to vital organs. A novel nutrient mixture (NM) containing ascorbic acid, lysine, proline and green tea extract has exhibited significant anticancer activity against a number of cancer cell lines, including inhibition of invasive parameters.
Objective: We investigated the effect of NM on human chondrosarcoma cell line SW 1353 for viability, MMP expression, invasion, apoptosis and morphology.

Methods: Human chondrosarcoma cell line SW1353 (ATCC) was grown in DEM media with 10% FBS and antibiotics and treated with NM at 0, 10, 50, 100, 500 and 1000 μg/ml in triplicate at each dose. Cells were also treated with phorbol 12-myristate 13-acetate (PMA) 100 ng/ml for MMP-9 induction. Cell proliferation was assayed by MTT assay, MMPs by zymography, invasion through Matrigel, apoptosis using live green caspase detection kit, and morphology by H&E staining.
Results: NM was not toxic to chondrosarcoma cell line at 100 μg/ml, but exhibited 10% and 40% toxicity at 500 and 1000 μg/ml. Zymography demonstrated two bands corresponding to MMP-2 and MM-9. PMA treatment enhanced MMP-9 secretion. NM inhibited the secretion of both MMP-2 and MMP-9 by 50% at 100 μg/ml and by 100% at 500 μg/ml. Invasion through Matrigel was inhibited by 40%, 50%, 70% and 100% at 50, 100, 500 and 1000 μg/ml respectively. NM induced slight apoptosis at 250 μg/ml, moderate at 500 μg/ml and significant at 1000 μg/ml. H&E showed slight changes at the highest concentration.
Conclusions: NM significantly inhibited MMP secretion, invasion through Matrigel and apoptosis, important parameters for cancer prevention, suggesting NM has the potential for therapeutic use in treatment of chondrosarcoma.

PS 1684 ROLE OF NF-KB IN THE CHEMOPREVENTIVE ACTIVITIES OF CITRUS AND GINGER COMPOUNDS AGAINST SKIN CANCER DEVELOPMENT.

H. E. Kleiner[1, 2], A. Remeika[1, 2], V. Batra[1, 2], N. Gill[3, 2], Z. Syed[3, 2], T. Terry[4, 2], P. Adegboyega[5, 2], J. DiGiovanni[7], M. Mathis[6, 2] and J. Clifford[3, 2].
[1]Pharmacology, LSUHSC, Shreveport, LA, [2]Feist-Weiller Cancer Center, Shreveport, LA, [3]Biochemistry, LSUHSC, Shreveport, LA, [4]Animal Resources & Imaging, LSUHSC, Shreveport, LA, [5]Pathology, LSUHSC, Shreveport, LA, [6]Cellular Biology & Anatomy, LSUHSC, Shreveport, LA and [7]Carcinogenesis, UTMD Anderson Cancer Center, Smithville, TX.

NF-kB is a survival signaling transcription factor involved in the malignant phenotype of many cancers, including Squamous cell carcinomas. The citrus coumarin, auraptene (AUR), and the ethno-medicinal ginger (Alpinia galanga) phenylpropanoid, 1-acetoxychavicol acetate (ACA), were previously shown to suppress 12-O-tetradecanoylphorbol-13-acetate (TPA) induced mouse skin tumor promotion. The goal of the present study was to determine whether AUR and ACA could suppress NF-kB activation and advanced stages of skin carcinogenesis in mouse models. First, we found that orally administered ACA (100 mg/kg bw) and AUR (200 mg/kg bw) suppressed lipopolysaccharide-induced NF-kB activation in NF-kB-RE-luc (Oslo) luciferase reporter mice by 65% and 76%, respectively. Next, dietary administration of AUR (1000 ppm) and ACA (500 ppm) was evaluated in a xenograft model. Female SCID-bg mice were fed the test diets, injected with 1 million human squamous cell carcinoma cells (SRB12) s.c., palpated and weighed twice a week for 28 days following injection. AUR and ACA modestly suppressed tumor volume by 30% and 50%, respectively. In a third study, ACA (340 nmol, topical) suppressed TPA-induced skin tumor promotion by 43% in K5.Stat3C transgenic mice. These mice, which possess a constitutively active Stat3, are highly susceptible to skin carcinogenesis. TPA increased the phosphorylation of the p65

NF-kB subunit compared to control skin, indicating that TPA activates NF-kB signaling. ACA suppressed the level of phospho-p65 almost to the control level in TPA treated mouse skin. The aforementioned data suggest promising potential for chemopreventive action through dietary administration of AUR and ACA by inhibiting the downstream effects of NF-kB activation.

PS 1685 BHAS42 CELL TRANSFORMATION ASSAY FOR INVESTIGATION OF ANTI-TUMOURIGENIC EFFECTS OF CHEMICAL COMPOUNDS.

A. Poth[1, 2], A. Heppenheimer[1, 2], A. Schaefer[3], S. Bohnenberger[1, 2] and D. Pollet[3]. *[1]Harlan Laboratories, Indianapolis, IN, [2]RCC Cytotest Cell Research GmbH, Rossdorf, Germany and [3]Hochschule Darmstadt, Fachbereich Chemie und Biotechnologie, Darmstadt, Germany.*

The rodent bioassay is used to detect complete genotoxic carcinogens and tumour promoters and co-carcinogens. Cell transformation assays detect morphological changes that provide the earliest phenotypic sign in carcinogenicity. For the improvement of the experimental conditions Sasaki et al. (1988) developed a cell line, Bhas42, established from Balb/c3T3 cells transfected with v-Ha-ras oncogene for detection of carcinogens and tumour promoters. The purpose is to identify the potential use of the Bhas42 system for the detection of tumour protective effects of chemical compounds. The Bhas-system was established and validated by using the reference carcinogen 3-methylcholanthrene as an initiator and TPA and insulin as promoters. Increasing concentrations led to a dose-dependent increase in transformed foci. To investigate whether the Bhas42 system can detect tumour-protective compounds, 4 substances, a-Tocopherolacetate, b-Naphtoflavone, Asthaxantine and Ellagic acid, known as potentially anti-tumourigenic, were tested. Both, Astaxantine and Ellagic acid showed tumour protective effects by reducing the number of foci induced by Methyl-Cholanthrene (MCA). Astaxanthine showed the highest tumour-protective effect after a simultaneous 24 hour treatment with MCA. The protective mechanism is assumed to be its antioxidative properties and the increased intercellular gap junctional communication. The treatment of Ellagic acid 24 hours before treatment showed the highest tumour-reductive response. The supposed mechanism is the covalent binding of the compound to DNA which may lead to protection of DNA to initiating compounds like MCA. No tumour-protective effects were observed with the remaining two compounds, a-Tocopherolacetate and b-Naphtoflavone. Overall, our results indicate the Bhas-system is not only useful for the investigation of carcinogens and tumour promoters but can also be used for determining tumour-protective effects of compounds.

PS 1686 EARLY POSTNATAL KETAMINE ANESTHESIA CAUSES PERSISTENT BEHAVIORAL EFFECTS IN RHESUS MONKEYS.

M. G. Paule[1], M. Li[1], X. Zou[1], C. Hotchkiss[2], J. Hanig[3], W. Slikker[1] and C. Wang[1]. *[1]Division of Neurotoxicology, National Center for Toxicological Research/FDA, Jefferson, AR, [2]Bionetics Corportation, National Center for Toxicological Research, Jefferson, AR and [3]Center for Drug Evaluation and Research/FDA, Silver Spring, MD.*

Our earlier studies in developing monkeys showed that ketamine exposure (24 hours of clinically relevant anesthesia) causes significant increases in neuronal cell death. Sensitivity to the neurotoxicity of ketamine in monkeys was observed on gestational days 122-124 (in utero exposure via maternal anesthesia) and on PNDs 5-6, but not on PND 35. In the present study, subjects were exposed on PND 5 or 6 to 24 hrs of ketamine anesthesia, intravenously (n = 6); controls were unexposed (n = 6). At 7 months of age all animals were weaned and began training via successive approximation to perform a series of cognitive function tasks as part of the National Center for Toxicological Research (NCTR) Operant Test Battery (OTB). The OTB tasks used here included those for assessing aspects of learning, motivation, color discrimination, and short-term memory. Subjects responded for banana-flavored food pellets by pressing response levers and press-plates during daily (M-F) test sessions (50 min) and were assigned training scores based upon task performance. After approximately 60 training sessions (3 months of testing), control animals began to outperform the ketamine exposed animals as evidenced by higher training scores: one month later (80 test sessions) control animals were outperforming the ketamine exposed group by more than 10% and this difference was maintained for another 4 months (animals at about 15 months of age). These observations suggest that, in primates, a single 24 hr episode of ketamine anesthesia occurring during a sensitive period of brain development results in long-lasting deficits in brain function. Whether this effect represents a developmental delay or a permanent alteration remains to be determined.

Supported by NICHD, CDER/FDA and NCTR/FDA

PS 1687 STRUCTURAL AND FUNCTIONAL DIFFERENCES IN RAT LUNGS DUE TO POST-NATAL OZONE OR PARTICLE EXPOSURE.

D. Lee[1], E. Schelegle[2], C. Wallis[1], M. Fanucchi[2], L. Van Winkle[2], C. Plopper[2] and A. Wexler[1, 3, 4]. *[1]Department of Mechanical and Aeronautical Engineering, University of California, Davis, CA, [2]Department of Anatomy, Physiology and Cell Biology, University of California, Davis, CA, [3]Department of Civil and Environmental Engineering, University of California, Davis, CA and [4]Department of Land, Air and Water Resources, University of California, Davis, CA.*

Inhaled pollutants cause various lung diseases such as asthma, COPD, and emphysema, but chronic effects of gas and particle pollutants are not nearly as well explored as the acute effects, due to the longer-term nature of chronic effects and the lack of reliable physiological indicators. We measured alterations in airway architecture and lung function due to ozone or particle exposure during development. To analyze alteration of all conducting airways, we developed a computer technique that can automatically extract geometric information of each airway from CT-imaged rat airways enabling quantitative analysis of airway structure; for example, diameter, length, branching angle, asymmetry. Male Sprague Dawley rats were exposed to 0.2, 0.5 ppm ozone or 80 μg/m3 flame-generated soot particles from 7 days to 28 days postnatal, 8 hrs/day, 5 days/week. Lung function tests and lung casting for CT-scan were conducted 56 days post-exposure. While there was no significant difference in lung architecture between control and exposed groups, TLC and dynamic compliance changed.

PS 1688 PRENATAL TCDD EXPOSURE AND POSTNATAL IMMUNE MODULATION IN A 36-WEEK-OLD LUPUS-NEPHRITIS STRAIN.

R. M. Gogal[1, 2], A. Mustafa[1], S. Witonsky[1], R. Kerr[1], K. Zimmerman[1], C. M. Reilly[3] and S. D. Holladay[2]. *[1]Biomedical Science & Pathobiology, Virginia Tech, Blacksburg, VA, [2]Radiology and Anatomy, University of Georgia, Athens, GA and [3]Biomedical Sciences, Virginia College of Osteopathic Medicine, Blacksburg, VA.*

The developmental stage is a highly sensitive period for exposure to environmental contaminants, including 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Adverse effects associated with prenatal TCDD exposure can affect multiple sites in the body (e.g., immune system, endocrine system, integument) and persist into adulthood. Previous studies in our laboratory found that prenatal TCDD exposure altered adaptive immunity differently across sex in lupus–nephritis SWR X NZB F1 (SNF1) mice, exacerbating the disease in the females and accelerating it in the males. The extent to which prenatal TCDD may affect immunity and immune-mediated renal pathology during aging is unknown. In this study, 36-week-old low-affinity AhR SNF1 mice prenatally-exposed to TCDD (0, 40 or 80 μg/kg) at gestational day 12 were evaluated for changes in T cell and B cell maturation and function, and for progression of immune-mediated renal disease. TCDD-treated males displayed decreased thymic weight while females displayed altered CD4/CD8 thymocyte antigen expression. The TCDD-treated offspring also had increased percentages of autoreactive CD4+Vβ17+ TcR spleen T cells. Alterations in bone marrow B cell lymphopoiesis were seen in both sexes. Splenic B transitional-1 cells (T1) (CD23neg CD1neg) were increased in treated females while marginal zone (MZ) B cells (CD24intCD21hi) (CD23neg CD1hi) were increased in males. Anti-IgG and anti-C3 immune complex renal deposition were visibly enhanced in TCDD-treated mice in both genders. These results show that prenatal TCDD exposure in an autoimmune–prone strain permanently alters adult immune function, including immune signatures that differ across sex and may underly immune-mediated nephritis.

PS 1689 REPROGRAMMING OF MATERNAL DIET IN RAT AFFECTS BODY WEIGHT AND AUDITORY STARTLE RESPONSE IN THE OFFSPRING.

D. M. De Groot, J. Van Esterik, C. De Esch, H. Hendriks, L. Van der Horst, J. Lammers, M. Otto, I. Waalkens and A. Wolterbeek. *TNO Quality of Life, Zeist, Netherlands.* Sponsor: V. Feron.

People from Dutch Famine studies have been found more obese and at higher risk for chronic diseases like diabetes, but also neurodegenerative diseases. Obesity is thought to be linked to reprogramming of (neuro)physiological set points during early development of the nervous system. In the present study it is hypothesized that maternal diet determines bodyweight (BW) and (neuro)development in the offspring and, with that, the vulnerability for environmental exposure to toxic substances. Three groups of female Wistar rats (n=24) were kept on a semi-synthetic control diet (n=24), a high-caloric diet (15% butter oil, n=48) or a caloric restricted (deficient) diet (75% of control diet, n=38) during 6 weeks premating, mating (1 week) and gestation (3 weeks) period. Pups were cross-fostered immediately after

birth to obtain 5 diet groups, i.e. (gestation/LACTATION): cont/CONT; high/HIGH; def/DEF; def/HIGH and high/DEF. The reprogrammed def/HIGH diet group mimics the situation of the Dutch Famine. A selection of male (n=100) and female (n=100) pups was additionally dosed sc. with saline (control) or MeHg (3 mg/kg BW) from PN2 to 21. In time, BW was measured and an auditory startle response (ASR) was performed. The ASR measures anxiety over-time; disability to habituate in the ASR test is considered indicative of neurodegeneration. Results: 1) BWs of the offspring differed significantly between the diet groups; effects were slightly exacerbated by exposure to MeHg and maintained during adulthood, especially for the def/HIGH group. 2) Dietary effects on ASR appeared causally related to the BW changes. Additional effects of MeHg, i.e. a disability to habituate to the ASR, were also seen especially in the female def/HIGH diet group suggesting similar neural deficits as found in the Dutch Famine casualties. The findings support the hypothesis that maternal diet may increase the vulnerability of the developing offspring to (subtle) environmental exposure like MeHg, ultimately resulting in neurodegenerative diseases.

PS 1690 MATERNAL BENZENE EXPOSURE CAUSES PERSISTENT STRAIN AND GENDER DEPENDENT CHANGES IN THE HEMATOPOIETIC SYSTEM OF OFFSPRING.

H. Badham and L. M. Winn. *Queen's University, Kingston, ON, Canada.*

Chronic exposure to benzene is associated with an increased risk of developing leukemia in adults. Furthermore, epidemiological studies show that in utero exposure to benzene is correlated with an increased incidence of childhood leukemia. Our overall objective is to determine if maternal benzene exposure in mice causes prolonged changes in the hematopoietic system of the offspring. We have previously shown that C57Bl/6N gestational day (GD)16 fetuses exposed in utero to benzene (200 mg/kg) had significantly increased BFU-E and CFU-G (male and female), CFU-E (male only), and CFU-GM (female only) colonies. A higher dose of benzene (400 mg/kg) elicited a significant increase in male CFU-E colonies only. Conversely, the only effect observed in CD-1 GD16 fetuses was in females exposed in utero to 200 mg/kg of benzene, showing a significant increase in CFU-E colonies. This current study evaluated the hematopoietic system of mice exposed in utero to benzene 6 months after birth to determine if strain and gender differences were still present. Pregnant C57Bl/6N and CD-1 dams were injected i.p. on GD 8,10,12, and 14 with either corn oil (vehicle) or benzene (200 mg/kg, or 400 mg/kg). Six months postpartum, colony formation assays on bone marrow cells and flow cytometric analysis of blood cell parameters in the spleen and bone marrow were performed. C57Bl/6N male mice exposed to 400 mg/kg had significantly increased bone marrow BFU-E and CFU-M colony numbers. Blood cell parameters in C57Bl/6N females revealed a significant decrease in bone marrow myeloid cells and splenic T-helper cells in both the 200 and 400 mg/kg groups. CD-1 mice had no significant changes in colony number; however, females in the 200 mg/kg group had significantly lower numbers of bone marrow myeloid cells. No malignancies were detected. Together these results support the hypothesis that in utero benzene exposure significantly alters the hematopoietic system of mice and these alterations are strain and gender specific. [Support: CIHR]

PS 1691 GESTATIONAL EXPOSURE TO THE TYPE II PYRETHROID DELTAMETHRIN RESULTS IN INCREASED EXPRESSION OF NEUROTROPHINS 3 AND 4 IN THE DEVELOPING HIPPOCAMPUS AND CORTEX.

B. Laffin and M. Pine. *Veterinary Integrative Biosciences, Texas A&M University, College Station, TX.*

Due to concerns over the neurotoxicity of organophosphate and organochlorine pesticides in children, use of pyrethroid pesticides has increased greatly in recent years. The type II pyrethroid deltamethrin (DM) is one of the most commonly used pyrethroids as well as one of the most neurotoxic. DM has been shown to have lasting toxic effects in rats, such as learning deficits and inappropriate induction of apoptosis and Brain Derived Neurotrophic Factor (BDNF) expression. However, there is little information on the consequences of low level, in utero DM exposure on brain development. To examine the neurodevelopmental impact of DM exposure, adult female Sprague Dawley rats were dosed by oral gavage with DM (1.0 or 0.5 mg/kg) or corn oil vehicle beginning on gestational day 1 (as evidenced by a vaginal plug) and continuing until parturition. Offspring of treated rats were sacrificed on postnatal days 14 and 21, and brain tissue was analyzed by histology and ICC. Preliminary studies revealed that rats treated with 1 mg/kg DM exhibited increased immunoreactivity for active caspase 3 in purkinje cells, as well as increased expression of neutrotrophins 3 and 4 in the hippocampus and cortex. Decreased Purkinje cell number was observed in the posterior lobe of the cerebellum (control 2.69±0.15 cells/100 μm, 1mg/kg DM 2.025±0.22 cells/100μm, $p<0.05$), while no significant effect was observed in the anterior lobe despite a similar trend. No significant effects were observed in the 0.5mg/kg treated animals. Intriguingly, hippocampal BDNF expression, which has been reported previously to be induce by DM treatment, was decreased at 14 days but elevated at 21 days in the 1mg/kg DM group, suggesting that DM may delay the normal rise in BDNF expression during postnatal neurodevelopment. These results suggest that DM may have adverse effects on mammalian neurodevelopment at or below the current NOAEL.

PS 1692 PBPK MODELING OF ALKYLBENZENE MIXTURES IN NEONATES: EVALUATION OF THE RELATIVE CONTRIBUTION OF INHALATION AND LACTATIONAL TRANSFER TO THE INTERNAL DOSE.

T. Adamou[2], S. Haddad[1] and K. Krishnan[2]. *[1]sciences biologiques, TOXEN, Université du Québec à Montréal, Montr√©al, QC, Canada and [2]santé environnementale et santé au travail, Université de Montréal, Montr√©al, QC, Canada.*

Lactational transfer of environmental contaminants is of prime importance in consideration of internal dose to neonates. The objective of this study was to simulate the internal dose of alkylbenzenes (toluene (T), m-xylene (X) and ethylbenzene (E)) in neonates exposed via inhalation alone or by both inhalation and mother's milk. A validated mixture PBPK model for alkylbenzenes previously validated in adult humans was adopted for pregnant women and neonates, by accounting for physiological differences. The lactational transfer was described as a function of the frequency of lactation, suckling rate and volume of milk. The simulated scenarios consisted of (i) 24-hr exposure of mother and child to the ambient air containing alkyl benzenes at their reference concentrations (RfCs) and (ii) the exposure of infants via lactational transfer when the mother is exposed for 8-hr to a-third of the current threshold limit values (TLVs) of the alkylbenzenes. When considering inhalation as well as lactational exposures (associated with maternal occupational exposures) in the PBPK model, the maximal venous blood concentration (Cvmax) of T in infants are simulated to be 16.5 fold higher than when the infant is exposed by inhalation route to TEX mixture at the RfC level. When area-under-curve of venous concentrations over a 24 hr-period was used as the dose surrogate, this factor, however, was 2.9. Similar values were obtained when considering single chemical exposures as well. This study demonstrates the feasibility of using PBPK models to simulate multiroute exposures of infants to chemical mixtures as well as to evaluate the relative contribution of occupational maternal exposure to the internal dose of chemical mixtures in infants.

PS 1693 PERINATAL EXPOSURE TO A MIXTURE OF ENVIRONMENTAL CONTAMINANTS WHEN ASSOCIATED WITH POSTNATAL STRESS ALTERS THE GLUCOCORTICOID STRESS RESPONSE DURING ADULTHOOD IN THE RAT.

D. Desaulniers and G. Xiao. *HECSB, Hazard Identification Division, Health Canada, Ottawa, ON, Canada.* Sponsor: G. Bondy.

Rodent studies suggest that perinatal events could reprogram the expression of the glucocorticoid receptor for the entire lifespan, creating abnormal hormone levels and predispositions to diseases. As part of a larger study, we tested the hypothesis of a link between perinatal exposure to environmental contaminants and abnormal corticosterone (CS) stress response (CSR) in rats. The experiment included 9 treatment groups. From gestation-day 0 (day of vaginal plug) and until postnatal day (PND) 20, dams were fed daily cookies laced with corn oil (control) or Mixture-A (MA: polychlorinated biphenyls, organochlorine pesticides, and methylmercury) at 0.5 or 1.0 mg/kg/day (0.5MA, and 1MA). At birth, some control (C) and 1MA litters were crossfostered to create 4 groups of pups with the following in utero/postnatal exposure: C/C, C/1MA, 1MA/C, 1MA/1MA. Other dams received cookies with a dose of 1.7 ng/kg/day of a mixture of aryl hydrocarbon receptor (AhR) agonists (AhR: non-ortho PCBs, dibenzodioxins and furans) without or with 0.5MA. A CSR was induced in male offspring at PND85 (10 min exposure to a heating lamp to induce vasodilation and 5 min bag-restraint to facilitate the collection of 500 microliter of blood from the tail vein). The CS decay was assessed from the trunk blood collected at decapitation 30 min later (T30). The concentrations of CS returned to normal at T30 in the group C, 0.5MA, 1MA, C/C and 1MA/C, but it remained elevated in the group AhR, AhR+0.5MA, C/1MA, and 1MA/1MA. The most important finding is that 1MA had no effect on its own but it prevented the CS drop in adulthood only when perinatal exposure was associated with the postnatal stress created by the crossfostering, suggesting that rats can tolerate exposure to 1M with no consequences unless they are subjected to early postnatal stress. This result is important in our understanding of the perinatal influence of contaminant exposure on stress-induced diseases.

PS 1694 THE EFFECTS OF THE PESTICIDES MANEB AND PARAQUAT ON THE DEVELOPING DOPAMINERGIC SYSTEM.

D. Gaines, B. K. Barlow and M. Thiruchelvam. *Environmental & OccupationalMedicine, University of Medicine and Dentistry of New Jersey - RWJMS, Piscataway, NJ.*

Parkinson's disease (PD) is a neurodegenerative disorder characterized pathologically by the loss of nigral dopaminergic neurons, and environmental factors have been widely implicated in the etiology of sporadic PD. Previous studies have shown that exposure to maneb (MB) and paraquat (PQ) (two agrichemicals used on various crops) in mice induces a PD phenotype. Additionally, recent data suggests that exposure to environmental factors early in life can predispose or cause nigral dopaminergic neurodegeneration. The mechanism(s) responsible for this increased risk remains unknown and thus, was the focus of this study. Pregnant dams were treated with either saline, 0.6 mg/kg PQ, 2 mg/kg MB or PQ+MB from gestational day (GD) 10 - 15. The effects of these pesticides on the developing dopaminergic system where determined on GD16 and GD18 mouse embryos, 24hrs and 72hrs after the last exposure. The end-points that were analyzed include PQ toxicokinetics, proteasomal function, and catecholamine levels. Observable paraquat levels were measured in brain of embryos from dams treated with either PQ or PQ+MB, both at GD16 and GD 18, with higher levels observed at the earlier age. Embryos from dams treated with Mb showed an increase in proteasomal activity at GD18. A decrease in serotonin occurred in embryos from MB and PQ+MB treated dams at GD16 and GD 18, while a decrease in dopamine, DOPAC, and HIAA was observed only in GD18 embryos. It was also determined whether there were gender-related differences due to exposure. These studies will give us additional mechanistic insight into how exposure to environmental factors can alter neurodevelopment, and subsequently increase the risk of PD onset later in life. Furthermore, future studies may identify specific targets, which can eventually be used or manipulated with specific interventions that can alter disease progression.

PS 1695 AKT1-DEPENDENT GENE CHANGES ARE ASSOCIATED WITH BLOOD-TESTIS-BARRIER FORMATION FOLLOWING EXPOSURE TO A POSTNATAL GOITROGEN.

M. Hixon[1], J. Santos Ahmed[1], A. Delong[2] and Z. Wu[2]. *[1]Pathology, Brown University, Providence, RI and [2]Statistics, Brown University, Providence, RI.*

Transient postnatal hypothyroidism induced by exposure to the goitrogen, 6-N-propylthiouracil, extends cell proliferation and differentiation leading to a subsequent increase in adult testis size. Akt1 has been implicated in the regulation of apoptosis in the testis. We sought to determine if Akt1 modulates germ and/or Sertoli cell proliferation and/or apoptosis following exposure to PTU. We exposed wild type, heterozygous, and Akt1-deficient mice to PTU (0.01% w/v) via the dams milk. At postnatal day 90, exposed wild type and heterozygous male mice exhibited a 23% and a 15% increase in testis weight, respectively. A trend of increased testis size was observed in Akt1-deficient males. Sperm production was increased in exposed wild type and heterozygous males by 20 and 16%, respectively. No increase in DSP was observed in Akt1-deficient males. Consistent with the hypothesis that Akt kinase activity is important to circumvent apoptosis, TUNEL analyses revealed a significant increase in apoptosis in the testes of exposed Akt1-deficient males. To elucidate Akt1-dependent gene changes mediating these phenotypic effects, we monitored changes in testicular gene expression in wild type, heterozygous, and Akt1-deficient testes following exposure. Postnatal exposure significantly altered 23,930 transcripts in Akt1-deficient males relative to exposed wild type and heterozygous males. Prominent functional categories were integrin signaling, germ cell maturation, and junction dynamics. Elucidation of regulatory networks was conducted using Ingenuity Pathways Analysis software. Analyses revealed that PTU targets proteins that make up the testicular tight junctions, including several members of the claudin gene family. In summary, the altered developmental pattern of expression of a number of testis related genes reflects a delayed maturation of Sertoli cells in postnatal hypothyroid animals and points to Akt1 as a critical early regulator of BTB development.

PS 1696 ACUTE AND LONG-TERM EFFECTS FOLLOWING *IN UTERO* EXPOSURE TO DI-(N-BUTYL) PHTHALATE IN P53-NULL MICE.

C. Saffarini, N. Heger, S. J. Hall, H. Yamasaki and K. Boekelheide. *Department of Pathology and Laboratory Medicine, Brown University, Providence, RI.*

Testicular dysgenesis syndrome (TDS) suggests that in utero exposure from endocrine-disrupting chemicals can lead to abnormalities of the male reproductive tract, such as cryptorchidism and hypospadias, and is proposed to be the precursor of male germ cell cancer. Previous studies demonstrate that exposure to di (n-butyl) phthalate (DBP) during a critical window of gestation results in TDS-like effects. The present study investigated in utero exposure of DBP in the apoptotic resistant p53-null mouse model, evaluating both acute and long-term effects. Dams were treated with 250 or 500 mg/kg DBP by oral gavage from gestational day (gd) 12 until birth. Acute effects were assessed on gd 19 and postnatal days (PND) 1, 4, 7, and 10; long-term time-points ranged from 85 – 200 days. As expected, DBP exposure induced multinucleated gonocytes in the seminiferous cords. In wildtype and heterozygous mice these abnormal gonocytes were eliminated soon after birth; however, in p53-null pups the multinucleated gonocytes persisted as large multinucleated cells adjacent to the seminiferous tubule basement membrane. Immunohistochemical staining of these abnormal cells was negative for a gonocyte marker (Oct-3/4) and for a marker characteristically found in testicular germ cell tumors (PLAP). This unique model identifies a role for p53 in the perinatal apoptosis of DBP-induced multinucleated gonocytes, and gives insight into the behavior and appearance of these abnormal cells in the p53-null environment.

PS 1697 INTERSPECIES APPROACH TO THE ASSESSMENT OF HUMAN SUSCEPTIBILITY TO PHTHALATE-INDUCED ENDOCRINE DISRUPTION.

N. Heger[1], K. Gaido[2], K. J. Johnson[3], S. J. Hall[1] and K. Boekelheide[1]. *[1]Pathology and Laboratory Medicine, Brown University, Providence, RI, [2]The Hamner Institutes for Health Sciences, Research Triangle Park, RI and [3]Nemours Biomedical Research, Alfred I. duPont Hospital for Children, Wilmington, DE.*

A "testicular dysgenesis syndrome" has been suggested to explain the temporal increases in congenital malformations (cryptorchidism, hypospadias) and adult-onset diseases (testis germ cell cancer, decreased sperm counts) over the past 50 years, possibly resulting from exposure to endocrine disruptive chemicals during critical periods of development. Previous experiments of in utero exposure to the plasticizer di-(n-butyl) phthalate (DBP) revealed suppression of fetal testicular steroidogenesis in rats, with mice remaining relatively unaffected. To examine this species-specific sensitivity, a rodent host bioassay consisting of human and rodent fetal testicular grafts was developed to examine toxicant-induced alterations of testicular development. Human fetal testes (gestational weeks 10-23, n=10) were cut into mm3-sized fragments, implanted into the renal subcapsular space of nude rat hosts, exposed to 250mg/kg DBP for 3 days, and removed 6 hours following the last dose. Histopathological analysis revealed a significant increase in multinucleated gonocytes (MNGs; $p<0.05$, one-way t-test), and a non-significant increase in the number of nuclei per MNG and diameter of seminiferous cords. Quantitative RT-PCR of steroidogenic genes revealed no DBP-induced alterations. Using a similar exposure paradigm, gestational day 16 rat testes were syngeneically implanted and processed for the same endpoints. Like the human, a significant increase in MNGs ($p<0.05$, n=7) and non-significant increase in the number of nuclei per MNG and diameter of seminiferous cords was seen. Unlike the human, a non-significant decrease in steroidogenic gene expression was observed, suggesting that humans may be resistant to the developmental anti-androgenic effects of phthalates.

PS 1698 DEVELOPMENTAL SEX DIFFERENCES IN MYELINATION, ASTROCYTIC AND DOPAMINERGIC DENSITY: IMPLICATIONS FOR INCREASED RISK OF ADHD IN MALES.

V. M. Miller[1, 2], T. Khanke[2], S. Sanchez-Morrissey[1] and R. F. Seegal[1, 2]. *[1]DEDP, Wadsworth Center, Albany, NY and [2]School of Public Health, State University of New York, Albany, NY.*

Developmental neurological diseases such as Attention Deficit Hyperactivity Disorder (ADHD) are four-six times more likely to affect males than females. ADHD symptoms are present by 2years of age, involve cerebellar and dopaminergic dysfunction and are associated with abnormal inflammatory responses. Exposure to toxicants and infections are implicated in ADHD suggesting sensitivity of the developing male brain immunogens and toxicants. We hypothesized latency in inflammatory cerebellar and dopaminergic protein synthesis in developing male brains compared with female brains. We obtained brain tissue from 7, 14, 21, and 42 post natal day (PND) old Long Evans rats. Using a combination of ELISAs, western blotting, and digital immunohistochemistry, we quantified markers for astrocytes (GFAP), microglia (Iba-1), myelin (MBP), dopamine (Tyrosine Hydroxylase:TH) and oligodendrocyte precursor cells (T.Lectin) in the cerebellum and caudate. We found increased astrocytic density in the cerebellum of PND14, PND21 and PND42 females ($p<0.05$) compared with males. PND7 males had increased TH in the caudate compared with females. We also found increased cerebellar MBP in the PND 14 and PND21 females compared with males. We suggest that increased astrocytic density may protect the female brain against infiltration of immunogenic agents through the blood brain barrier. Increased dopamine in

PND7 males suggests the developing male brain may be particularly sensitive to dopamine associated toxicants. Dopamine differences may be associated with sexual differentiation and the conversion of estrogen to testosterone in the basal ganglia. In the future we aim to characterize the response of developing male and female brains, exposed in utero to dopamine associated toxins; PCBs and PBDEs. This will help us better understand the functional relationship between developmental gender differences in dopaminergic and glial cells, and an increased prevalence of ADHD in males. NIH grant #ESO1568803

PS 1699 AKT1 MEDIATES EPIGENETIC REGULATION *VIA* HISTONE MODIFCATIONS IN THE POSTNATAL TESTIS.

B. Moyer[1], A. DeLong[2], Z. Wu[2], C. Schorl[3] and M. Hixon[1]. *[1]Department of Pathology and Laboratory Medicine, Brown University, Providence, RI, [2]Department of Community Health, Brown University, Providence, RI and [3]Center for Genomics and Proteomics, Brown University, Providence, RI.*

Chromatin structure plays an important role in the regulation of gene expression in the testis. Recently, the PI3K/Akt signaling pathway has been implicated in the regulation of chromatin remodeling. The methylation of lysine residues on histone tails is an epigenetic mark that influences chromatin repression when specifically imparted on lysines 9 and 27 of histone H3, and on lysine 20 of histone H4. Our recent work indicates that Akt1 plays a role in a testicular stress response to mono-2-ethylhexyl-phthalate-induced injury. To gain further insight into the regulation of gene expression during postnatal development of the testis, we examined global gene expression changes in postnatal day 28 Akt1 wild type and postnatal day 28 Akt1-deficient testes using Affymetrix oligonucleotide microarrays (mouse 430 2). A total of 2,619 genes were significantly different in Akt1-deficient testes compared to Akt1 wild type testes (adj p-value < 0.05). Among these differentially expressed genes, 45% were down regulated and 55% were up regulated in the Akt1-deficient testes. Functional classification based on selected gene ontology terms indicated that over represented terms in genes up regulated in Akt1-deficient testes grouped with chromatin modification, chromatin binding, transcription regulator activity and heterochromatin. To corroborate the microarray data, we detected abnormalities in vivo in the heterochromatin markers, heterochromatin protein 1 beta (HP1β), dimethyl histone K9 (H3K9) and trimethyl histone K27 (H3K27) indicating aberrant chromatin packaging in Akt1-deficient mice. In summary, our results suggest a role for Akt1 in the epigenetic control of spermatogenesis and infer chromatin state as an important component in the response to injury.

PS 1700 DEVELOPMENTAL EFFECTS OF PERFLUORONONANOIC ACID ARE DEPENDENT ON PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR-ALPHA.

C. J. Wolf, C. Lau and B. D. Abbott. *Reproductive Toxicology Division, U.S. EPA, ORD, NHEERL, Research Triangle Park, NC.*

Perfluorononanoic acid (PFNA) is one of the predominant perfluoroalkyl acids in the environment and in tissues of humans and wildlife. PFNA strongly activates the mouse and human peroxisome proliferator-activated receptor-alpha (PPARα) in vitro and negatively impacts development and survival in offspring of mice exposed during pregnancy. In the current study, we use PPARα-knockout mice (KO) and 129S1/SvlmJ wild type mice (WT) to investigate the role of PPARα in mediating the in vivo effects. KO and WT females were mated with males of the same strain overnight and plug positive mice were dosed orally with water (vehicle control; 0.01 ml/g), 0.83, 1.1, 1.5, or 2 mg/kg PFNA on gestational day (GD) 1-18 (day of plug = GD 0). Dams and pups were monitored daily. Dam weight gain was unaffected in either strain. The number of uterine implantation sites was unaffected in KO and WT, but the total number of pups at birth (live and dead) was reduced in the 2 mg/kg group in the WT. Pup weight at birth was unaffected although pup weight at weaning (postnatal day 21) was reduced in WT females at 2 mg/kg. Eye opening was delayed (mean delay = 2.1 days) in WT pups at 2 mg/kg. Survival of offspring to weaning was reduced to 28% and 21% of control in the 1.1 and 2 mg/kg groups in WT. Liver-body weight ratio at weaning was increased in a dose-dependent manner in WT dams and pups, but only slightly in the highest dose group in KO dams and pups. In dams, this was a 1.1 fold increase over controls at 2 mg/kg in KO compared to a 2 fold increase over controls at 2 mg/kg in WT. In summary, the only response to PFNA found in KO mice was a slight increase in relative liver weight of dams and pups at 2 mg/kg, in contrast to the effects on liver weight, pup eye opening and pup survival in the WT. These results suggest that PPARα is a primary mediator of PFNA effects on pup development and survival to weaning. This abstract does not necessarily reflect USEPA policy.

PS 1701 NEONATAL AMPHETAMINE EXPOSURE AND CEREBELLAR GRANULE CELL NUMBER IN RATS: A STEREOLOGY STUDY.

D. Pappalardo, R. Morrow, M. Files, A. Smith and W. Chen. *NEXT, Texas A&M Health Science Center College of Medicine, College Station, TX.* Sponsor: S. Maier.

The use of amphetamine (AMPH) is rising globally. Among AMPH abusers, women of reproductive age are of particular concern due to the potentially harmful effects of AMPH on their fetuses. In this study, we examined the long-term effects of AMPH exposure during the brain growth spurt on cerebellar cytoarchitecture by estimating the granule cells in cerebellar lobules I and VII. On postnatal day (PD) 4, Sprague-Dawley rat pups were assigned to four groups: AMPH 5, 15, 25 (5, 15, and 25 mg/kg/day AMPH) and IC (intubation control; 0 mg/kg/day). Animals received intragastric intubation twice a day with a 2-hr inter-intubation interval from PD 4-9. A normal control was also introduced. The cerebelli of the animals were removed on PD 68 and processed for stereological cell counting. Cerebellar granule cells of lobules I and VII were counted to examine the effects of early postnatal AMPH and to determine whether the detrimental effects of AMPH were lobule-specific. The data showed that the estimated granule cell number and the area (three-dimensional) where the granule cells were located were not affected significantly by the AMPH treatment, and there were no lobule specific effects, indicating that amphetamine exposure during the brain growth spurt did not exert long-term effects on the granule cell numbers in both anterior (lobule 1) and posterior (lobule VII) portions of the cerebellum. Although the cell number and size of the granule cell layer of these adult cerebelli did not result in significant changes statistically, the density of the granule cells in the AMPH 5 showed a marginally significant increase compared with those of other groups. Taken together with findings of other studies evaluating the effects of neonatal AMPH exposure, it suggests that neonatal AMPH treatment has limited effects on cell loss and the ultimate fate of a cell, and that other measures, such as molecular or electrophysiological approaches, are needed to reveal the presence of detrimental AMPH-induced neurotoxicity on developing brains. (Supported by NIH grant DA018809)

PS 1702 EMBRYO-FETAL DEVELOPMENT IN CYNOMOLGUS MACAQUE: EVALUATION FOR TERATOLOGY BY ULTRASONOGRAPHY.

N. Makori[1], S. Oneda[1], J. Kenfield[1], S. Herrin[1], C. Adair[1], W. Congdon[1], R. Eyre[1], B. Baker[1], J. Klaassen[1], S. Meyer[1] and R. Nagata[2]. *[1]Safety Assessment, SNBL USA, Ltd., Everett, WA and [2]Shin Nippon Biomedical Laboratories, Ltd., Kagoshima, Kagoshima Prefecture, Japan.*

Assessment for teratology (Segment II) and F1 (Segment III) preclinical studies in cynomolgus macaque (Macaca facsicularis) is presented, with fetal and infant data obtained using a single maternal animal (N = 36). The end-points for Segment II are measured without fetal evaluations at Caesarean section. Embryo-fetal ultrasound imaging measurements included crown-rump length (CRL, at gestation day [GD] 25, GD31, GD37, GD45); femur length (FL, at GD79, GD93, GD107, GD121, GD135); biparietal diameter (BPD, at GD53, GD70, GD90, GD110, GD130); and heart rate (HR, at GD44, GD51, GD65, GD93, GD121, GD150).The newborn infant was examined for external morphology, at 30 days for skeletal development by radiography, and at six months for organ development at necropsy. Embryos between GD25 and 31 were measured for the greatest length (GL). In embryos greater than GD31, CRL excluded tail measurement. The mean GL at GD25 was 4.5 mm and 8.5 mm at GD31. The mean CRL was 14.3 mm at GD37 and 23.5 mm at GD45. For BPD, correct positioning of the cursor for measurement is based on the developing brain anatomical landmarks, with the caliper cursors being positioned from the outer margin of the skull line on one side to the inner margin of the far one (Tarantal and Hendrickx, 1988). Mean BPD was 12.9 mm by GD53, 21.3 mm by GD70, 30.2 mm by GD90, 36.9 mm by GD110, and 41.2 mm by GD130. Mean heart rate ranged from 177 to 181 bpm between GD53 and GD150. The longest view of the ossified portion of the femur was measured with the linear internal clipper cursors. Mean FL was 9.2 mm by GD70, 17.4 by GD90, 25 by GD110, and 30.4 by GD130. Infant weight mean was 341.1 grams. In conclusion, data from the measurements combined with adequate infant examination adequately assesses teratology without resorting to fetal evaluations thus negating the need for Caesarean section and minimizing the number of non-human primates required for stand-alone Segment II and III studies.

PS 1703 THE DEVELOPMENTAL TOXICITY OF ALCOHOL OR NICOTINE: A ZEBRAFISH (DANIO RERIO) MODEL.

A. Leal and W. A. Chen. *Neuroscience & Experimental Therapeutics, Texas A&M HSC College of Medicine, College Station, TX.* Sponsor: S. Maier.

One major challenge for researchers in the field of Development Toxicology is to identify the mechanisms for perinatal drug-induced toxicity on the developing brain. It has been hypothesized that microRNA (miRNA) may play a role in mediating drug-induced developmental toxicity. miRNAs are noncoding transcripts that

are thought to be involved in patterning and differentiation of the central nervous system, post-transcriptionally modulate the expression of mRNAs, and the maintenance of cell fate identity. In this study, a zebrafish (Danio rerio) model system was used to explore the morphological changes of the zebrafish in response to alcohol, nicotine or the combination of the two. Zebrafish embryos were exposed to 2% (w/v) alcohol, 40 μM nicotine, the combination of alcohol/nicotine or 2% artificial salt water (control) beginning at 4 hours post-fertilization (hpf). The treatment lasted for 3.5 hours during gastrulation. The developing embryos were evaluated for morphological changes at 72 hpf and sacrificed for miRNA analysis. The results showed that the zebrafish assigned to the alcohol and the alcohol/nicotine groups exhibited significant morphological changes, such as cardiac edema and a curved vertebral column. However, the zebrafish in the nicotine group did not show significant changes compared with the control group. The miRNA microarray analysis between the alcohol and the control group identified a number of miRNAs that were sensitive to alcohol with a significant down-regulation in the alcohol group compared with the control. These miRNAs include let-7h, let-7i and miR-456 which are involved in axonal guidance, cell migration and angiogenesis in the development of the nervous and the cardiovascular systems, and miR-129 which is involved in the cell cycle and nervous system development. These findings provide direction for future studies to evaluate the role of these targeted miRNAs as the underlying mechanisms for alcohol-induced developmental toxicity. (Supported in part by Texas A&M HSC Summer Research Program)

PS 1704 SPONTANEOUS ABORTIONS, PREMATURE BIRTHS AND STILLBIRTHS IN EMBRYO-FETAL AND POST-NATAL REPRODUCTIVE TOXICITY STUDIES IN CYNOMOLGUS MONKEY.

N. Lalayeva[1], T. Matsuyama[2], A. Arima[2], S. Oneda[1], N. Makori[1], Y. Ooshima[2], R. Eyre[1], B. Baker[1], J. Klaassen[1], S. Meyer[1], K. Fukuzaki[2] and R. Nagata[2]. *[1]Safety Assessment, SNBL USA, Ltd., Everett, WA and [2]Shin Nippon Biomedical Laboratories, Ltd., Kagoshima, Japan.*

The cynomolgus monkey (*Macaca fascicularis*) is a valuable animal model for preclinical embryo-fetal and post-natal reproductive toxicity studies. For accurate study data interpretation, it is essential to continually update, as a reference, background incidences of spontaneous abortions (AB), premature births (PB) and stillbirths (SB). Loss of embryos or fetuses on or before gestation day 130 (GD130) i.e. AB, delivery (live or dead neonate) between GD131 and GD145, i.e. PB, and delivery of dead neonate on or after GD146, i.e. SB data were compared between two GLP facilities. Total fetal loss ratios combining all AB, PB and SB were 16.7% at SNBL USA and 12.9% at SNBL Japan. Incidences at SNBL USA / SNBL Japan were 14.8% / 9.6% for AB, 4.5% / 2.0% for PB and 7.1% / 9.0% for SB. Approximately 50% of the abortions occurred on or before GD30. In the case of early embryo losses (on or before GD30), there were no notable differences in maternal age (all 3 to 10 years old), maternal body weight (aborted / normal = 3.40 ± 0.96 kg / 3.56 ± 0.84 kg) and menstrual cyclicity (28.8 ± 2.1 days / 30.9 ± 4.5 days) at mating between aborted animals and maternal animals which maintained pregnancy. For stillbirths, there were no notable differences in maternal age (all 3 to 10 years old) and maternal body weight (stillbirth / normal birth = 5.12 ± 0.91 kg / 4.92 ± 0.74 kg) at delivery between maternal animals with stillbirth birth and normal birth. In addition, F1 neonate body weights at birth were comparable between stillborn neonates (380.5 ± 38.1 g) and live born neonates (348.7 ± 41.7 g). The stillbirth ratios in the two facilities were lower than that of an outdoor breeding colony reported in the literature. In conclusion, study procedures, such as frequent restriction for dosing and blood collection or sedation, do not affect the rate of spontaneous embryo-fetal losses or natural birth.

PS 1705 TERATOGENIC EFFECT AND TESTICULAR CHANGES INDUCED BY DI-N-BUTYL PHTHALATE ADMINISTERED ORALLY TO RATS.

A. H. Abou Hadeed, A. M. Alklech, G. G. Moustafa and S. R. El sayed. *Forensic Medicine and Toxicology, Faculty of Veterinary Medicine, Zagazig University, Zagazig, Egypt.* Sponsor: A. Kadry.

Di- n- butyl phthalate (DBP) is one of the commonly used plasticizers. It can enter the environment and organisms through various routes and has been shown to affect reproductive and developmental processes of the organism. Therefore, the present study was carried out to explore the teratogenic and testicular effects of DBP in rats after gavage administration. In the first of two experiments, thirty adult pregnant female albino rats were divided into three dose groups including controls receiving corn oil, DBP at a dose of 1/10 LD50 (800 mg/kg.), and DBP at a dose of 1/20 LD50 (400 mg/kg.) from day 6th-15th of gestation. Incidence of resorptions and dead fetuses were significantly increased in both DBP treated groups. In addition, there was a significant decrease in fetal body weight and length and a significant increase in the incidence of fetuses with visceral and skeletal malformations, especially incomplete ossification of cranial bones, open wide fontanale, absence of ossification center of vertebrae, absence of strenbrae & xiphistrenbrae, absence of phalanges of both limbs and absence of coccygeal vertebrae. In the second experiment, twenty adult male rats were administered either corn oil or 1/20 LD50 (400 mg/kg.bwt) DBP daily for 65 days via gastric intubation. DBP induced a significant decrease of sperm motility and sperm cell count and a significant increase in sperm abnormalities including detached head, bent tail, looped sperm, and stunted sperm. Also, a significant decrease in the level of testosterone hormone accompanied with increase of LH hormone was observed in treated groups compared with controls. Thus, DBP may affect fertility and epididiymal spermatozoal characteristics in males. In addition, teratogenic data demonstrate that DBP also appears to have an adverse effect on the developing fetus.

PS 1706 ULTRASOUND-BASED DETECTION AND MONITORING OF THALIDOMIDE-INDUCED FETAL MALFORMATIONS IN THE CYNOMOLGUS MONKEY (MACACA FASCICULARIS)MODEL.

A. Fuchs[1], G. F. Weinbauer[1], M. Christian[2], L. Latriano[3], J. Hui[3], O. Laskin[3] and R. P. Amin[3]. *[1]Covance Laboratories GmbH, Muenster, Germany, [2]Argus International, Horsham, PA and [3]Celgene Corporation, Summit, NJ.*

Recent developments including the increased demand for nonhuman primates in (biopharmaceuticals) drug development have led to consideration of modified designs for embryofetal and pre-/postnatal studies, e.g. advanced imaging (i.e. Doppler-ultrasound-based) of embryonic and fetal development as a surrogate for Caesarean section followed by sophisticated evaluation of the infant. It is crucial to evaluate the sensitivity of ultrasound for detection of abnormalities during embryofetal development. This study evaluates the feasibility of ultrasound-based embryofetal development monitoring. Thalidomide (thal), a well established teratogen, was used as a positive control. Five female cynomolgus monkeys received 15 mg/kg thal on gestational days (GD) 26 to 28. Five controls received vehicle only. Animals were housed individually and studies were conducted in accordance with the German Animal Welfare Law and were approved by IACUC. Ultrasound evaluations were performed on GD 20, 30, 44, 58, 72, and 86. Caesarean section was performed on GD 100 in both groups. In the control group, no prenatal loss and malformations were observed. In the thal-exposed group, in two females early caesarean sections were performed on GD 41 and 49 due to intra-uterine death. Three live fetuses were available at Caesarean-section. For one fetus, polydactyly was recorded by ultrasound on GD 58. For the second fetus, abnormalities of the upper extremities were detected from GD 72 onwards. The ultrasound-based findings were confirmed at Caesarean-section for both fetuses. In the third fetus, no malformations were detected by ultrasound and at external examination the only finding was a shift of preputium to the left. In conclusion, advanced ultrasound enables early detection (prior to Caesarean-section) and precise monitoring of embryofetal development and abnormalities in this relevant nonhuman primate model.

PS 1707 THE CHICKEN EMBRYOTOXICITY SCREENING TEST (CHEST) AS PUTATIVELY METABOLICALLY ACTIVE *IN VITRO* TEST SYSTEM FOR TERATOGENICITY/ EMBRYOTOXICITY.

B. van Ravenzwaay, S. Boehn, T. Bernshausen, A. Noss, E. Fabian, H. Kamp, T. Kaufmann, M. Koch, P. Wessa and R. Landsiedel. *Experimental Toxicology and Ecology, BASF SE, Ludwigshafen, Germany.* Sponsor: A. Van Cott.

The chick embryo has been described to provide a useful test system for the determination of teratogenic/ embryotoxic effects. Within this study, the chicken embryotoxicity screening test (CHEST) was evaluated for its predictive value for teratogenicity/ embryotoxicity of exogenous chemicals. The CHEST is performed using fertilized hen eggs during early developmental stages which by legislation are not considered to be an animal. Therefore, the CHEST can be considered as a replacement method. In contrast to other embryotoxicity assays (e.g. whole embryo culture), the CHEST is easier to conduct and does not require the use of embryonic stages from mammalian species. Additionally, it has been demonstrated that xenobiotic metabolizing enzyme activities are present in hen eggs and that testing and evaluation of proteratogens should be possible. We have tested teratogens (e.g. retinoic acid, hydroxyurea, valproic acid, thalidomide), non-teratogens and proteratogens in this in vitro assay. The results show a good correlation with the teratogenic potential of these substances in vivo. Specifically, we confirm that proteratogens are detected as being "positive" in this assay. Investigations on the metabolic capacity of the CHEST indicate the presence of metabolic capacity. Therefore, the CHEST assay has confirmed its potential to serve as a replacement study and may significantly reduce the numbers of animals needed for teratogenicity/ embryotoxicity testing.

PS 1708 EMBRYOPROTECTIVE ROLE OF ENDOGENOUS CATALASE IN WILD-TYPE (C3HEB/FEJ) AND ACATALASEMIC (C3GA.CG-CATB/J) MICE.

J. Perstin[1] and P. G. Wells[1, 2]. [1]*Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada and* [2]*Pharmacology and Toxicology, University of Toronto, Toronto, ON, Canada.*

Low activities of antioxidative enzymes including catalase, which detoxifies hydrogen peroxide (H2O2), leave the embryo highly susceptible to pathogenic reactive oxygen species (ROS). Although treatment with exogenous catalase is embryoprotective, little is known about endogenous embryonic catalase expression, inter-individual variability or protective importance, which we investigated in wild-type (C3HeB/FeJ) and acatalasemic (C3Ga.Cg-Catb/J) mice. Acatalasemic mice exhibited substantially lower catalase activity in all organs ($p < 0.05$), with the largest 82% decrease in brain. Conversely, the activity of glutathione peroxidase (GPx), which also detoxifies H2O2, was modestly elevated in all organs but one in acatalasemic mice ($p < 0.05$), with an increase of only 14% in brain. Untreated acatalasemic mice were more susceptible than wild-type controls to both in utero and postnatal death, with a 3-fold greater incidence of resorptions and preweaning lethality ($p < 0.05$). On the other hand, when treated with the ROS-initiating anticonvulsant drug phenytoin, acatalasemic dams did not differ in embryonic DNA oxidation or fetal death. These results provide direct evidence that the relatively low level of endogenous embryonic and fetal catalase provides important protection against physiological but perhaps not drug-enhanced oxidative stress. Catalase deficiencies constitute a risk factor notwithstanding the small compensatory increase in GPx activity. This protective importance of catalase against endogenous oxidative stress is similar to that observed for a more highly expressed antioxidative enzyme, glucose-6-phosphate dehydrogenase, except the latter also protects against drug-enhanced oxidative stress. (Support: Canadian Institutes of Health Research)

PS 1709 EMBRYO-FETAL DEVELOPMENT STUDY (ICH-3) DATA FOR CD-IGS RATS TREATED BY INHALATION.

H. Devine, M. Adamo, L. Pouliot, A. Viau and K. Robinson. *Toxicology, Charles River, Senneville, QC, Canada.* Sponsor: M. Vezina.

Inhalation is becoming a more common clinical route of treatment for a variety of pharmaceuticals and biopharmaceuticals. For embryo-fetal development studies (ICH-3), nose-only inhalation exposure can be utilized to mimic the clinical route. Data from studies treated by oral gavage, subcutaneous and intravenous injection as well as room controls were compared to the vehicle controls from a number of inhalation studies. Time-mated rats Crl:CD(SD), 10 to 12 weeks of age at the start of treatment, were housed individually and were provided a standard certified pelleted commercial laboratory diet and water ad libitum. The animal room environment and photoperiod were controlled. For nose-only inhalation studies, the females were acclimated to the restraint tubes for increasing periods of time for a minimum of 3 consecutive days prior to the initiation of treatment. Animals were exposed to atmospheres (aerosols, typically of dry powders, generated by EDPDS or metered dose inhalers) on a nose-only flow-through chamber for up to 2 hours daily from Days 6 to 17 of gestation, inclusive. Comparison of in-life data, showed no effect from the acclimation or dosing procedures for the inhalation studies when compared to other routes. Maternal, ovarian and uterine findings also showed no difference between inhalation and other routes of administration. No differences were noted for fetal weights or external, visceral/skeletal findings. In conclusion, the nose-only inhalation route of dosing in Crl:CD(SD) rats does not affect embryo-fetal development when compared to other routes of administration.

PS 1710 ASSESSING THE POTENTIAL DEVELOPMENTAL TOXICITY OF THE RED TIDE TOXIN, BREVETOXIN, IN CD-1 MICE.

G. Chavez[1], J. Hutt[1], M. Wolf[1], G. Chavez[1], D. Baden[2] and J. Benson[1]. [1]*Lovelace Respiratory Research Institute, Albuquerque, NM and* [2]*Center for Marine Science, University of North Carolina, Wilmington, NC.*

Brevetoxins are produced by Karenia brevis, the algae causing Florida Red Tide. Previously, brevetoxin 3, or its metabolites were detected in fetuses of dams administered the compound via the lung, or systemically. The purpose of this study was to begin evaluation of the potential developmental toxicity of brevetoxin. Pregnant CD-1 mice were administered brevetoxin (50 ng/kg/hr) via osmotic minipump beginning on gestational day (GD) 6. The total deposited dose in these mice is estimated to be 200 times higher than that deposited in a pregnant human during a single 2 hour visit to a beach where brevetoxin concentrations are 50 ng/L air. Mice were euthanized on GD19. Numbers of implantations, resorption sites, live and dead fetuses, and fetal sex were recorded. Fetuses were weighed, crown to rump length measured and external malformations recorded. Pups were fixed for examination of soft tissue and skeletal abnormalities. Brevetoxin-exposed dams exhibited no clinical signs of toxicity. To date there were 16.2 ± 0.5 fetuses/dam (n = 4). Fetal viability was 98%; 49.5 ± 8.7% were females. Pup weights were similar for females (1.44 ± 0.11 g; n = 33) and males (1.51 ± 0.11 g; n = 32), as were crown to rump lengths (24.1 ± 1.5 mm for females; 24.6 ± 1.10 mm for males). By comparison, female and male pup weights from saline control dams were 1.33 ± 0.19 g and 1.38 ± 0.18 g, respectively. There were no incidences of exencephaly, eye, limb, digit, or tail abnormalities in pups from either brevetoxin exposed or control dams. These preliminary data suggest that brevetoxin, administered throughout the period of organogenesis, does not adversely affect implantation, fetal viability, fetal growth, or cause obvious external malformations. Further studies, including examination of visceral and skeletal changes, are in progress. Research funded by Florida Fish and Wildlife Conservation Commission, FWC/FWRI Red Tide Control and Mitigation Grant Program Number: 68A-2.015.

PS 1711 ONTOGENY OF GLUTATHIONE S-TRANSFERASES IN MOUSE LIVER.

T. House-Knight, S. Choudhuri and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

Cells have developed a number of defense mechanisms to prevent or minimize the accumulation of various xenobiotics and the potential toxicity they may cause. Membrane transport, biotransformation, and repair mechanisms comprise the various arms of the cellular defense systems against xenobiotics. Glutathione S-transferase (Gst) enzymes are instrumental in protecting cellular macromolecules against electrophiles by conjugating them with glutathione. Of primary interest to pharmacologists and toxicologists, is the ability of these enzymes to detoxify cancer chemotherapeutic drugs, insecticides, herbicides, and carcinogens. Constitutive expression of Gsts in a tissue at various ages can determine the tissues susceptibility to electrophilic stress. Accordingly, the present study was designed to investigate the ontogenic expression of 19 known Gst isoforms in mouse liver from 2 days before birth to postnatal day 45. The results indicate that at all developmental time points examined, multiple isoforms of Gst were constitutively expressed in both male and female livers. Most Gst isoforms showed a progressive increase in postnatal mRNA expression, however Gstm5 and MGst2 were the only two isoforms showing a progressive decline in postnatal mRNA expression, whereas Gsto1, Gstt2, and MGst3 were similarly expressed at all ages. For the majority of Gst isoforms, the adult levels of mRNA expression were reached by 22 days of age. Marked gender differences in the expression of Gstp1/2 were observed on day 30 and 45, and MGst2 on day 0, with higher expression in males than females. The present study provides insight into the expression of the various isoforms of Gst(s) in livers of fetuses and young mice at different stages of development. (Supported by NIH grants ES-09649, ES-013714, ES-07079, ES-09716, and RR-021940.)

PS 1712 CHANGES IN BLOOD PARAMETERS AND COAGULATION-RELATED GENE EXPRESSION DURING GESTATION AND LACTATION IN RATS.

M. Ikeya[1], Y. Urasoko[1], X. He[2], M. Takano[1], T. Ebata[1], Y. Kinoshita[1], J. Kobayashi[1], M. Mochizuki[1] and Y. Katsumata[1]. [1]*Gotemba Laboratory, Bozo Research Center Inc., Gotemba-shi, Shizuoka, Japan and* [2]*Department of veterinary pathology, Graduate School of Agricultural and Life Sciences, The University of Tokyo, Tokyo, Japan.* Sponsor: Y. Asano.

Although rats are commonly used in studies for embryology and reproductive toxicology, there are no sufficient data regarding changes in maternal blood parameters. We carried out to examine changes in maternal blood parameters, especially those related to blood coagulation, as well as alterations in blood coagulation-related gene expression in the liver during gestation and lactation in rats. Crl:CD(SD) rats were used. Blood sampling was done on 10 animals on gestation day (GD) 7, 13, 17 and 20 and postpartum days (PPD) 1, 7, 14 and 21, respectively, for analysis of blood parameters. In addition, DNA microarray analysis was done on 5 animals on GD13 and 19, and PPD 0 and 14, respectively. Non-pregnant animals were used as controls. In pregnant rats, FIB and PLT increased with the progress of pregnancy, and PT and thrombo test were shortened before delivery, suggesting a physiological reaction to avoid prolongation of bleeding at parturition. Conversely, APTT was prolonged before delivery and antithrombin time was higher during fetal organogenesis and thereafter, indicating a mechanism to prevent thrombosis in dams. In the DNA microarray analysis of blood coagulation-related gene expression in the liver, there were no changes on GD13, whereas the expression of fibrinogen-related factors, coagulation factors (FII and X) and anti-coagulation factor-related gene, leuserpin-2, were elevated on GD19. The above-mentioned changes tended to recover after delivery. The data obtained in the present study were considered to be the basic data for effective evaluation of reproductive toxicology in rats, and they suggest that the rat is a useful animal model for investigating the mechanisms of disorders in the blood coagulation system which are reported to occur in perinatal period in women.

PS 1713 EVALUATION OF PHYSICAL, SENSORY AND SEXUAL LANDMARKS IN AN EXTENDED ONE GENERATION REPRODUCTION STUDY: A COMPARISON BETWEEN A CLASSICAL NOAEL AND A BENCHMARK APPROACH.

D. M. De Groot[1], M. De Groot[1], C. De Esch[1], I. Tonk[2], J. Lammers[1], L. Van Loveren[2], A. Piersma[2], I. Waalkens[1], A. Wolterbeek[1] and R. Woutersen[1]. *[1]TNO Quality of Life, Zeist, Netherlands and [2]RIVM, Bilthoven, Netherlands.*

The study was designed to investigate in a rat model the changes in developmental landmarks associated with prenatal exposure to methylmercury (MeHg). The landmarks comprised a series of tests establishing the phase of development from postnatal day (PN) 1 to PN 46. A comparison was made between a statistical analysis using the classical NOAEL approach and the benchmark approach. Female F0-animals were dosed with MeHg (GD6-LD10; 0 (corn oil vehicle), 0.1, 0.4, 0.7, 1.0, 1.5, or 2.0 mg/kg BW/day; oral gavage). F1-animals were used for evaluation of physical, sensory and sexual landmarks from PN 1 to PN 46. In addition to the classical approach, data were analyzed by the benchmark approach using PROAST 16.4 running on Splus. For each landmark, a dose-response model was fitted to the data. From this fitted model, a critical effect dose (CED or benchmark dose (mg MeHg/kg BW)) was derived, for a predefined critical effect size (CES) of 10%. The CED's found for the different landmarks on a specific postnatal day all showed a dose response relationship, except for pinna unfolding and hair growth which could not be fitted to a model. Tooth eruption showed a maximal response of <10% and could not be analyzed with a CES of 10%. Body length showed a CED>2 which is outside the dose range. No dose-response relationship was observed with the classical NOAEL approach and, except for pinna unfolding, hair growth and tooth eruption; not any significance was observed compared to the vehicle control group. So, using identical group sizes, the statistical power of the benchmark approach is stronger than that of the NOAEL approach since a dose response relationship is demonstrated for most parameters. More research with lower numbers/group and reliable CES descriptions is needed and e.g. introduction of corrections for litter size, mortality etc, to exclude false positive and false negative findings.

PS 1714 INFLUENCE OF AGE ON SUB-CHRONIC TOXICITY OF AQUEOUS LEAVES EXTRACT OF CALOTROPIS PROCERA IN RABBITS.

G. Pouokam[1], H. Ahmed[2], C. Dawurung[3] and A. Atiku[3]. *[1]Biochemistry, University of Yaounde 1, Yaounde, Centre, Cameroon, [2]Forensic toxicology Laboratory, Unviversity of Cairo, Cairo, Egypt and [3]Biochemistry, National Veterinary Research Institute, Vom, Plateau, Nigeria.*

Calotropis procera is a major browse toxic plant for grazing animals. Animals undergo different changes throughout their developmental stages and this affects their susceptibility to drugs inducing injury. The aim of this study was to investigate the influence of age on sub-chronic toxicity of aqueous leaves extract of Calotropis procera in rabbits. The twenty five rabbits used during the study were classified in five groups of identical ages; each experimental group had his own controls. Extract was administered every morning by gavage at the dosage of 200mg/kg body weight for 42 days; food and water were given ad libitum. Liver biomarkers (ALT, ALP, AST, Total protein) and kidney parameters (serum creatine and Urea) were assessed. PCV, Hb, WBC, RBC and differential leucocytes count were determined for hematological analysis. Necropsy, gross and histopathology were performed. All rabbits gained weight during the treatment period, with an appreciable gain for smaller animals. There was a significant decrease ($p<0.005$) of ALT and RBC for the youngest rabbits. A significant increase ($p<0.005$) of serum creatinine level and lymphocytes were also observed within the group of juvenile rabbits. Necropsy revealed lesions in kidney, liver, lung, small intestine and brain; these lesion were further confirm by histopathology that revealed more pronounced tissue lesion with the youngest animals compare to the control and the adults rabbits. Extract had no significant effect on rabbit's weight. Major target organs were liver; kidney; brain and haematopoietic system with the youngest animals being more sensitive. This study was made possible by grants from The Africa Education Initiative (www.nef3.org).

PS 1715 A PRACTICAL SIMPLE ANALYSIS OF LYMPHOCYTE SUBSET WITH A 6-COLOR ANALYTICAL FLOW CYTOMERTRY USING HEMATOLOGY SAMPLES FROM CYNOMOLGUS MONKEYS.

M. Kurata, Y. Hirasawa, K. Otabe, T. Koizumi and M. Nomura. *Safety Research Center, Ina Research Inc., Ina-shi, Nagano, Japan.*

(Purpose) Lymphocyte subset analysis using peripheral blood has been incorporated into the toxicity studies for immuno-toxicological evaluation. The present study was conducted to establish a practical simple analysis of lymphocyte subset in cynomolgus monkeys, which enables one-round analysis using small quantities of hematology samples. (Method) Blood was collected from cynomolgus monkeys. The blood was stained with the antibodies (anti-human CD3-PE-Cy7, CD4-APC, CD8-APC-Cy7, CD20-FITC, CD16-PE and CD56-PE), and then was treated with a hemolytic agent. The analysis requires only 100 micro L of EDTA-anti-coagulated blood using BD FACSCanto II with 6 analytical colors. To calculate the absolute counts, an internal standard (TruCOUNT Tubes, BD) or ADVIA 120 was also used. (Results) The subset analysis [T cells (CD4, CD8), B cells and NK cells] was not affected by (1) dilution of antibody up 2 or 5 times, (2) dilution or concentration of the samples, (3) formaldehyde fixation and (4) storage for 6 hours at room temperature or 24 hours at approximately 4 degree C. Acceptable CV was confirmed in repeated analyses including pre-analytical procedure. The NK cell ratio appeared to be lower when using the internal standard than using lymphocyte counts determined by ADVIA 120. The subset analysis for three origins (monkeys from the Philippine, Vietnam and Indonesia) will also be introduced. (Conclusion) The present method allows a practical simple analysis of lymphocyte subset using small quantities of blood from hematology samples of cynomolgus monkeys, and will be useful as a routine method. This method also supports the concept of the 3R's by reducing the blood sample, and a biomarker strategy of immunotoxicity in drug development.

PS 1716 VALIDATION OF METHOD FOR DETERMINATION OF ANTI-KLH ANTIBODIES IN RAT SERUM USING ENZYME LINKED IMMUNOSORBENT ASSAY.

W. Koh, W. Choi and Y. Ryu. *Korea Institute of Toxicology, Daejeon, Korea, South.*

To assess the influence of a test substance administration on the immune system, especially producing specific antibodies against the T-cell dependent antigen, Keyhole Limpet Haemocyanin (KLH), we developed and validated a method for detecting anti-KLH antibodies in KLH-treated rat sera using indirect ELISA. The parameters taken into consideration in assay development and validation were precision, sensitivity, immunodepletion, drug interference, and stability. Rat blank sera from 20 individual lots were analyzed for determination of negative cut off and cut point factor. The % CV for intra-assay and inter-assay precision were analyzed with positive control samples and ranged from 0.7 to 8.5 and 15.3 to 21.4, respectively. The sensitivity of this assay was 100 ng/ml at which the OD value was greater than the normalized negative cut off value. Immunodepletion assay was developed for further confirmation of the positive samples during the in-study analysis. Drug interference was observed from 1 ng/ml of KLH at low positive control. Results from stability assessment indicated that anti-KLH antibodies in rat serum were stable at least for 6 hours at room temperature, for 4 weeks in a deep freezer, and during three freeze and thaw cycles. In conclusion, we have validated a method for analyzing anti-KLH antibodies in rat serum. All the results met the preset acceptance criteria suggesting that this method is suitable to assess the immunomodulating potential of a test article through detecting the antibodies elicited by KLH-treatment in rats using ELISA method.

PS 1717 OPTIMIZATION OF LENTIVIRAL VECTOR PRODUCTION FOR USE IN GENERATION OF B LYMPHOCYTE MODELS.

J. Suarez[1] and N. Kaminski[2]. *[1]University of Puerto Rico at Cayey, Cayey, PR and [2]Michigan State University, East Lansing, MI.*

The term dioxin is used for members of the polyhalogenated aromatic hydrocarbons that are structurally related and have a common spectrum of biologic responses mediated via binding to a specific intracellular receptor. The prototype chemical for this class is 2,3,7,8-tetrachlorodibenzo-para-dioxin(TCDD).TCDD is a potent suppressant of adaptive immune responses.The aryl hydrocarbon receptor(AHR) is a ligand-activated transcription factor involved in the altered gene expression and toxicity produced by TCDD. To characterize the molecular mechanism by which TCDD alters human B cell differentiation and function, a major obstacle to doing so is a convenient renewable source of human B cells and genomic material from donors. One way to overcome this obstacle is to utilize human cell lines such as the SKW6.4,which are immortalized human B cells. However, these cells lack the AHR, the receptor to which dioxin and dioxin like compounds bind to produce their biological and toxic effects.A way to circumvent this problem is to stably introduce the gene that codes for the AHR into the genome of SKW6.4 cells. To achieve this we use a lentiviral-based approach with the long-term goal of introducing the AHR gene into SKW6.4 in order to create a stable AHR expressing SKW6.4 line for mechanistic studies.The specific purpose of this research was to optimize viral production in host HEK293 cells as well as transduction of genes,using GFP as a surrogate, in the human SKW6.4 B cells.We found that incubation of HEK293 at 32oC had no effect on viral production as opposed to 37oC incubation.Also, sodium butyrate treatment inhibited production of lentivirus-

based vectors.In addition,we found that polybrene at a concentration of 4ug/mL improved gene transduction by the virus into the SKW6.4 cells.Infection by centrifugation in comparison to mere incubation with virus at 37oC significantly increased the viral transduction. In summary, using polybrene and infection by centrifugation resulted in maximal viral transduction of SKW6.4 cells.(Supported by McNair/SROP Program and NIH ES04911)

PS 1718 ESTABLISHMENT OF AN IGM ANTIBODY FORMING CELL RESPONSE MODEL FOR EVALUATING IMMUNOTOXICITY IN HUMAN PRIMARY B LYMPHOCYTES.

H. Lu, R. B. Crawford and N. E. Kaminski. *Pharmacology and Toxicology, Center for Integrative Toxicology, Michigan State University, East Lansing, MI.*

Historically, identification and characterization of immunotoxicants has been conducted in rodent models, most often using mice. The IgM antibody forming cell (AFC) response developed in rodents, in combination with other immune function assays, has been effective for identifying rodent immunotoxicants. In spite of the similarities between the mouse and human immune systems, uncertainties still arise concerning whether results derived from rodent models are predictive of human toxicity. Therefore, the objective of this study was to establish an in vitro IgM AFC response model employing human peripheral blood B lymphocytes. CD40 ligand (CD40L) mimics the cognate T cell-B cell interaction occurring in vivo in lymphoid germinal centers. Thus, a mouse fibroblast line stably transfected to express human CD40L (CD40L-L cell) was utilized to provide the CD40L stimulus for B cells. Human B cells were isolated from leukocyte packs obtained commercially. Initial experiments were conducted to optimize various aspects of the model including, but not limited to, cell culture conditions, magnitude of CD40L stimulation, and identification of critical T cell cytokines. Co-culture of $CD19^+$ human B cells with CD40L-L cells in the presence of interleukin-2 (IL-2), IL-6, and IL-10 induced a robust IgM AFC response as measured by both ELISPOT and ELISA. Of the donors assayed thus far, the magnitude of response has been remarkably consistent, ranging between 4,000 to 6,000 IgM AFC/106 B cells. $CD19^+CD27^-$ Naive B cells, more closely reflective of B cells obtained from laboratory animals, could also be driven into AFC. We have also adapted the human AFC response into a 96 well format, which allows the assessment of multiple agents at multiple concentrations using B cells from one single donor. Collectively, a novel human IgM AFC response model has been established for evaluating immunotoxicity in human primary B lymphocytes. (Supported in part by the Dow Chemical Company/NIH ES02520/NIH ES04911)

PS 1719 DEVELOPMENT AND VALIDATION OF A HUMAN LYMPHOCYTE ACTIVATION (HULA) ASSAY.

S. H. Cole, P. Schneider, C. Kamperschroer, M. Collinge and T. Kawabata. *Immunotoxicology, Pfizer Global R&D, Groton, CT.*

In vitro assays to assess human antigen-specific responses are needed to evaluate potential immunosuppressive effects and rank order compounds during the drug development process. To address these needs, a human lymphocyte activation (HuLA) assay was optimized and validated. Peripheral blood mononuclear cells (freshly isolated or frozen) from donors immunized with influenza vaccine are first incubated for 1 hour with test compound, after which influenza antigen (Fluzone®) is added. Seventy two hours later, cultures are pulsed with BrdU. After 18-20 hours, cell viability is determined with trypan blue exclusion and BrdU incorporation is measured by a 96-well plate-based method. Assay conditions were optimized by evaluating different incubation times, donor cells, influenza antigen concentrations and BrdU staining procedures. Assay sensitivity and performance was evaluated by testing known immunosuppressive drugs. Cyclosporine A (Neoral®) was tested at dose ranges from 3-3000 ng/mL and found to have an IC50 of approximately 100 ng/ml or 83 nM (n=7 donors). Methotrexate was tested at 0.15-20 nM and found to have an IC50 of 4.5 nM (n=7 donors). At the concentrations of cyclosporine or methotrexate tested, decreases in proliferative responses were not associated with cytotoxicity. The recommended clinical therapeutic range for cyclosporine is 100-300 ng/mL or 83-250 uM. Methotrexate blood concentrations of approximately 20 nM is recommended for low dose therapy. Based on the initial findings with this assay, IC50's appear to correlate well with the desired therapeutic ranges of cyclosporine or methotrexate. In addition, there is only moderate variability in IC50 differences between donors and little variability between assays for individual donors. An advantage of this assay is that a frozen cells can be used such that multiple drugs on multiple assay dates may be evaluated with minimal variability. Studies to characterize the cells involved in the proliferative response and measure anti-influenza antibodies will be conducted.

PS 1720 COMPARISON OF BOVINE *VERSUS* HUMAN PRIMARY EPITHELIAL CELLS IN AN IN VITRO MODEL FOR TESTING PARTICLE TOXICITY ON INNATE IMMUNE RESPONSES OF AIRWAY EPITHELIUM.

L. K. Ryan[1], A. M. Pavlosky[2] and G. Diamond[3]. *[1]Medicine, Public Health Research Institute, NJ Medical School, UMDNJ, Newark, NJ, [2]Graduate School of Biomedical Sciences, UMDNJ, Newark, NJ and [3]Oral Biology, NJ Dental School UMDNJ, Newark, NJ.*

Primary human lung cells are often hard to obtain or they are expensive for utilization for high volume toxicity testing *in vitro*. Primary bovine tracheal epithelial cells (BTE) are easy and inexpensive to obtain and were hypothesized to be a suitable model for determining toxicity of particulate matter targeting innate immune responses in normal human bronchial and tracheal epithelium (NHBE). The purpose of this study was to compare the ability of stimulators to induce innate immune mediators in BTE and NHBE and to examine the ability of an air pollutant particle component, vanadium, to modulate these responses in each species. Cells were sham-exposed or exposed to 0.145μg/cm^2-2.32 μg/cm^2 $VOSO_4$ for 6 hr, washed twice, and then stimulated with LPS or IL-1β for 24 hr. Total RNA was extracted, treated with DNase, and both semi-quantitative and quantitative RT-PCR was performed using primers for either human or bovine β-defensin-2, lactoferrin, lysozyme, IL-8, IL-6, iNOS, ICAM-1, endothelin-1, and matrilysin. The innate immune response that vanadium affected similarly in these two species was LPS or IL-1β-induced β-defensin-2, where the induction of mRNA was inhibited by even the lowest [$VOSO_4$]. IL-6, IL-8, lactoferrin, endothelin-1, ICAM-1 and iNOS responses were differentially affected by vanadium in BTE and NHBE, suggesting that the pathways for IL-1β and LPS induction of these responses may diverge in humans and cattle. Use of BTE for modeling *in vitro* responses in human trachea is ideal for some specific innate immune responses—in this case, β-defensin-2. This may be an important biomarker for immunotoxicity of air pollutants, for evidence is growing that β-defensins are responsible for early innate immune pulmonary defense against both viruses and bacteria.

PS 1721 COMPARISONS OF THE IN VITRO IMMUNOMODULATORY EFFECTS OF ELASTIN AND COLLAGEN NANO-FIBROUS BIOMATERIALS BLENDED WITH POLYDIOXANONE.

M. J. Smith[1, 2], D. C. Smith[1, 3], G. L. Bowlin[2] and K. L. White[1]. *[1]Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA, [2]Biomedical Engineering, Virginia Commonwealth University, Richmond, VA and [3]Altria Client Services, Richmond, VA.*

Nano-fibrous biomaterials, which can be produced utilizing electrospinning, are of particular interest in tissue engineering for many potential applications including vascular replacement. While electrospun blends of polydioxanone with both soluble elastin (PDO-ELAS) and collagen type I (PDO-CI) have each demonstrated significant potential uses, minimal evaluations of the potential effects of these materials on the immune system have been completed previously. This study investigated the immunosuppressive effects of electrospun PDO-ELAS and PDO-CI on humoral immunity following culture with splenocytes from female B6C3F1 mice. Endpoints examined included: lipopolysaccahride (LPS)-stimulated B-cell proliferation, $F(ab')_2$ antibody fragment-mediated B-cell proliferation, and the Mishell-Dutton T-dependent antibody-forming cell (AFC) response to sheep erythrocytes. Results indicated that PDO-ELAS blends are more immunosuppressive *in vitro* than blends of PDO-CI. Specifically, PDO-CI blends were not suppressive of LPS-stimulated B-cell proliferation, while $F(ab')_2$-mediated proliferation was suppressed by no more than 50% and the *in vitro* AFC response by as much as 80%. In contrast, PDO-ELAS blends suppressed B-cell proliferation in both proliferation assays as much as 99.8%, while the AFC response was reduced by up to 70% of control. Based on these results, electrospun elastin may not be suitable for use in regenerative medicine applications, however it is necessary that additional testing of these materials be completed in order to determine if these results correlate with any potential *in vivo* effects. Funded in part by the American Heart Association Mid-Atlantic Affiliate (0555407U) and NIEHS Contract ES 05454.

PS 1722 ANIMAL EXPOSURE IN EARLY LIFE IS ASSOCIATED WITH DECREASED TNF-α RESPONSES IN INFANCY.

M. H. Lappalainen[1, 2], K. Huttunen[1], M. Roponen[1], J. Pekkanen[1, 2] and M. Hirvonen[1, 2]. *[1]Department of Environmental Health, National Public Health Institute, Kuopio, Finland and [2]University of Kuopio, Kuopio, Finland.* Sponsor: M. Viluksela.

Growing body of evidence suggests that the immunological development in humans is affected by animal exposure in early life. Because exposure to furred domestic and production animals is very common, the focus of our study was to investigate if animal contact during pregnancy and during the first year of life is

associated with the cytokine responses of children at birth and at the age 1 year. Cord blood (n=228) and peripheral venous blood (n=200) samples at the age 1 year were collected. Ethical permission was granted by the Research Ethics Committee, Hospital District of Northern Savo. Whole blood samples were stimulated with Staphylococcal enterotoxin B (SEB), lipopolysaccharide (LPS) and the combination of phorbol 12-myristate 13-acetate and ionomycin (P/I) for 48h. The production of TNF-α, IFN-γ, IL-5, IL-8 and IL-10 were measured using sandwich ELISA. Information about animal exposure was collected with prospective questionnaires starting already from pregnancy and the obtained data was compared with stimulated cytokine patterns. We found that especially LPS and P/I -stimulated production of TNF-α was decreased in cord blood and/or blood collected at the age 1 year if mothers had animal contact during gestation. This effect was seen in infants whose mothers either lived at a farm or were in contact with dogs or horses during the pregnancy. In conclusion, maternal contact to pets and domestic animals during pregnancy may be associated with reduced immune responses of their offspring. This attenuation of cytokine production may aid in preventing exaggerated immune responses to harmless antigens later in life. Thus, the exposure to furred animals during pregnancy and during the first year of life may be an important factor in immunological development.

PS 1723 INDEPENDENT EVALUATION OF CRITICAL WINDOWS IN IMMUNE SYSTEM DEVELOPMENT MAY BE NECESSARY TO ACCURATELY PREDICT DEVELOPMENTAL IMMUNOTOXICITY (DIT).

K. L. White[1], D. M. Roesh[1], T. L. Guo[1], W. Auttachoat[1] and D. R. Germolec[2]. *[1]Pharm/Toxicology VCU, Richmnd, VA and [2]NTP, NIEHS, RTP, NC.*

DIT is a major area of investigation and several DIT testing paradigms have been proposed. One approach begins dosing on gestation day 7 (GD7), continuous dosing of the dams through weaning post natal day (PND) 21. Unless it can be determined that the test compound or its metabolites are present in milk, dosing of the pups begins on PND3 and continues until PND42. This approach encompasses the critical periods during which immune cells and tissues develop and mature. The objective of these studies was to determine the effect of dibenzanthracene (DBA) on the developing immune system and to ensure effects on specific periods of immune development were captured. A study in adult female B6C3F1 mice assessed effects of DBA on antibody (Ab) responses to establish doses for the DIT studies. A dose-related decrease in Ab production was observed following 28 days of sc treatment with 250, 793, or 2500 μg/kg DBA. Suppression occurred at all doses. Following the DIT paradigm, mice were exposed in utero at 0.25, 2.5 and 25 μg/kg DBA starting on GD7 and continuing through PND42. As DBA metabolites were detected in milk, pups were not directly treated until weaning. Ab suppression was observed at the 25 μg/kg dose, suggesting the developing immune system was approximately 10 times more sensitive than adults. When pups were exposed in utero, through lactation and evaluated on PND22, no significant effects were observed at doses as high as 2500 μg/kg. In contrast, juvenile mice treated from PND21 - PND49 demonstrated decreases in Ab production with a LOEL of 2.5 μg/kg. Thus during the juvenile period, PND21-PND49, mice were 10 time more sensitive then when evaluated throughout development and 100 time more sensitive than adult animals treated with DBA. These data suggest the developing immune system is a sensitive target following toxicant exposure, and independent assessment of specific windows of immune system development may be necessary to establish accurate safety levels. Supported in part by NIEHS Contract ES 054554.

PS 1724 PRENATAL EXPOSURE TO CIGARETTE SMOKE SUPPRESSES ANTITUMOR CYTOTOXIC T-LYMPHOCYTE ACTIVITY POSSIBLY *VIA* CHANGES IN T-REGULATORY CELL NUMBER AND TGF-β LEVEL.

S. P. Ng[1], A. E. Silverstone[2], Z. Lai[2] and J. T. Zelikoff[1]. *[1]Nelson Institute of Environmental Medicine, New york University School of Medicine, Tuxedo, NY and [2]Department of Microbiology & Immunology, SUNY Upstate Medical University, Syracuse, NY.*

Epidemiological studies suggest that prenatal cigarette smoke (CS) exposure increases the incidence of some childhood cancers. Our previous study has demonstrated that male mice, exposed prenatally to mainstream CS (MCS), had a higher incidence of transplanted tumors and reduced cytotoxic T-lymphocyte (CTL) activity. In the current study, mouse dams were exposed to MCS (4h/d, 5d/wk) during gestation at a particle concentration of 15mg/m^3. Juvenile male pups were subsequently injected with EL4 lymphoma cells and the spleen and thymus recovered before injection (d 0) and at 1, 8, and 15 d post-injection to determine effects of prenatal smoke exposure on CTL activity, lymphoid organ subpopulations, and TGF-β levels. Whole splenocyte CTL activity against EL4 cells were significantly suppressed by prenatal CS exposure prior to, and at 8 and 15 d post-tumor cell injection; isolated CD8$^+$ T-lymphocytes demonstrated similar suppression. Percentages of thymic T-regulatory (T-reg, CD4$^+$CD25$^+$FoxP3$^+$) cells, which regulate/suppress effector T-cells, were increased in pups exposed prenatally to CS at 0, 1, and 8 d post-injection; increases in splenic T-reg cells were observed, but only on d 8. Prenatal CS exposure increased levels of TGF-β released from both phorbol myristateacetate- and tumor cell-stimulated splenocyte cultures. Given that T-reg cells and TGF-β can suppress anti-tumor CTL activity, these findings suggest a possible mechanism by which fetal insult by CS could result in reduced CTL activity in the offspring during tumor development. These data suggest that children of smoking mothers may be unable to mount an appropriate immune response to tumors, thus, increasing their risk for developing cancer later in life. [SOT Novartis Graduate Fellowship]

PS 1725 IMMUNOTOXIC EFFECT OF PRENATAL CADMIUM EXPOSURE ON MURINE OFFSPRING.

M. L. Hanson, K. M. Brundage, R. Schafer, R. A. Brundage and J. B. Barnett. *Microbiology, Immunology, and Cell Biology, West Virginia University, Morgantown, WV.*

Cadmium (Cd) is an environmental pollutant due to its widespread and continual use. Cd is generally found in low concentrations in food, air, and water, while its concentration in cigarette smoke is high. Although there is evidence demonstrating that adult exposure to Cd causes changes in the immune system, there are no reports of immunomodulatory effects of prenatal exposure to Cd. The thymus, which is the site of T cell development, is a target organ of Cd-induced toxicity. T cell development is essential for the establishment and maintenance of the adaptive immune system. Thymocytes mature through a series of stages defined by expression of cell surface markers CD4 and CD8. The most immature thymocytes are CD4-CD8- double-negative (DN). In this study, pregnant C57Bl/6 mice were given free access to 10 ppm Cd water during pregnancy. At day 0 of birth, three pups from each litter were euthanized and thymi were removed. Thymocytes were analyzed by flow cytometry for specific cell surface markers. There was a significantly higher incidence of CD4+ and DN4 cells among Cd-treated mice as compared to non-treated controls. In addition, the CD4+/CD8+ SP ratio was significantly higher in Cd-treated mice. At 14 and 49 days of age, thymi and spleens were analyzed from the remaining litters to demonstrate that prenatal Cd exposure leads to immunomodulatory effects throughout adulthood. There was a significantly lower total number of splenocytes in Cd-treated than controls at both ages. Preliminary results suggest splenocyte phenotypic changes that may be sex-specific. Following splenocyte stimulation with concanavalin A, cytokine release was analyzed and the IFN-γ and TNF-α levels were significantly decreased in prenatal Cd exposed mice. These results demonstrate that prenatal exposure to Cd results in phenotypic alterations in thymocyte development ultimately leading to immunomodulatory effects evident at adulthood. Supported by NIH grant ES015539.

PS 1726 CHLORPYRIFOS INDUCES APOPTOSIS IN HUMAN T CELLS.

Q. Li, M. Kobayashi and T. Kawada. *Hygiene and Public Health, Nippon Medical School, Tokyo, Japan.*

We found previously that organophosphorus pesticides significantly inhibited cytotoxic T lymphocyte (CTL) activity. To explore the mechanism of organophosphorus pesticide-induced inhibition of CTL activity, we investigated whether organophosphorus pesticides can induce cell death/apoptosis in T cells in the present study. Jurkat human T cells were treated with chlorpyrifos at 0-100ppm for 2 and 4 hrs at 37°C in 5% CO2 in vitro. We first found that chlorpyrifos induced cell death of human Jurkat T cells in a dose- and time-dependent manner, as shown by LDH and MTT assays. Then, we investigated if chlorpyrifos -induced cell death consisted of apoptosis, as determined by analyses of FITC-Annexin-V staining and the intracellular level of active caspase-3 by flow cytometry, and DNA fragmentation analysis. We found that chlorpyrifos induces apoptosis in Jurkat T cells in a dose- and time-dependent manner, as determined by analysis of Annexin-V staining. DNA fragmentation was detected when cells were treated with 50 and 100 ppm chlorpyrifos for 4 and 6 hrs. Chlorpyrifos also induces an increase of intracellular active caspase-3 in Jurkat T cells in a dose-and time-dependent manner, and a caspase-3 inhibitor, Z-DEVD-FMK, significantly inhibited the chlorpyrifos -induced apoptosis. These findings indicate that chlorpyrifos can induce apoptosis in human Jurkat T cell cells, and this effect is partially mediated by activation of intracellular caspase-3. This work was supported by a grant from the Ministry of Education, Culture, Sports, Science, and Technology (No. 19590602).

PS 1727 GENE EXPRESSION PROFILING OF MOUSE THYMOCYTES UPON *IN VITRO* EXPOSURE TO BIS(TRI-N-BUTYLTIN)OXIDE (TBTO).

S. W. van Kol[1], A. A. Peijnenburg[2], P. J. Hendriksen[2] and H. van Loveren[3]. *[1]Department of Health Risk Analysis and Toxicology (GRAT), Maastricht University, Maastricht, Netherlands, [2]RIKILT-Institute of Food Safety, Wageningen University and Research Centre, Wageningen, Netherlands and [3]Department of Toxicology, Pathology and Genetics (Toxicology, National Institute of Public Health and the Environment (RIVM), Bilthoven, Netherlands.*

Bis(tri-n-butyltin)oxide (TBTO) has been widely used as biocide and belongs to the class of organotins. Immunosupression is the most important endpoint of TBTO and it causes a reduction of thymus weight by depletion of cortical thymocytes. To get a better insight in the mechanism of action of TBTO, in this study primary thymocytes of C57BL6 mice were exposed in vitro to different concentrations of TBTO for 3, 6 and 11 hours. The applied concentrations were non-cytotoxic as deduced from WST-1 experiments. Subsequently, gene expression profiles were determined using Agilent 4x44k whole mouse genome microarrays and subjected to gene set enrichment analysis (GSEA). Using Gene Ontology gene sets representing various physiological processes, GSEA showed a clear upregulation of cell cycle genes after exposure to 0.5 μM TBTO for 3 and 6 hours. Longer exposure time and higher TBTO concentrations showed a down regulation of cell cycle related gene sets. Also genes involved in apoptosis and the unfolded protein response appeared to be affected after exposure to TBTO. Comparison of the data from this study with various lymphocyte-related gene sets obtained from literature provided evidence for the involvement of different transcription factors like NFkB, NFAT and FoxP3. Particularly, gene sets derived from studies on activated T cells showed an overlap with the gene expression data from our TBTO experiment. On the basis of these results it can be hypothesized that one of the effects of TBTO on primary mouse thymocytes is the release of Ca2+ from the endoplasmatic reticulum which leads to activation of transcription factors, a Ca2+ influx into the cell and subsequently to activation and nuclear translocation of NFAT. Current experiments are directed toward testing this hypothesis.

PS 1728 STAPHYLOCOCCAL ENTEROTOXIN B INDUCES VASCULAR LEAK AND ACUTE LUNG INJURY THROUGH DIRECT ACTIVATION OF NATURAL KILLER T CELLS.

S. A. Rieder, P. Nagarkatti and M. Nagarkatti. *Pathology Microbiology and Immunology, University of South Carolina, Columbia, SC.*

Staphylococcal enterotoxin B (SEB) is a highly toxic superantigen that can activate 5 to 30% of the T cell population and unlike conventional antigens; it directly binds to the MHC Class II molecules and activates T cells expressing variable TCR beta chains such as Vbeta8. Such activation triggers massive cytokine release that leads to rash, fever, and can often lead to acute respiratory distress, multi-organ failure, coma and death. This study focuses on the precise role of NKT cells in SEB-induced acute lung injury. We demonstrate that the intranasal administration of SEB triggered Vascular Leak Syndrome (VLS) in the lungs of wild-type (WT) mice while VLS was significantly decreased in Cd1d-/- and Jalpha18-/- mice lacking NKT cells. In addition, mice deficient in NKT cells had significantly less amounts of IL-2, IFN-γ and TNF-alpha in the serum and bronchial alveolar fluid when compared to WT mice. Decreased infiltration of lymphocytes was observed in the lungs of Cd1d-/- and Jalpha18-/- mice, correlating with decreased cytokine production. When purified NKT cells were co-cultured with bone marrow-derived dendritic cells (DC), SEB was shown to directly activate NKT cells and lead to IL-2 production. This study, for the first time, demonstrates that NKT cells can be activated not only by glycolipids but also by a protein. Thus, the plethora of cytokines produced following SEB can also be attributed to initial NKT cell activation (Supported in part by NIH grants: AI053703, ES09098, AI058300, DA016545, HL058641 and P01AT003961).

PS 1729 TRIBUTYLTIN: A DUAL BONE MARROW STROMAL CELL AND LYMPHOCYTE TOXICANT?

J. Schlezinger, A. Haas and D. Sherr. *Environmental Health, Boston University School of Public Health, Boston, MA.*

Tributyltin (TBT) has been a contaminant of concern in the marine environment due to its use as an anti-fouling agent; however, measurement of organotins in stormwater runoff suggests land-based sources of these contaminants, likely resulting from their use as stabilizers in the manufacture of plastics and in wood preservatives. Recent studies have shown that TBT, uniquely, is a highly potent PPARγ/RXRα dual agonist. We have shown that bone marrow B cells are susceptible to apoptosis induced by structurally diverse PPARγ agonists. We show here that TBT suppresses thymidine incorporation in primary pro-B cells (EC_{50} 150 nM), a non-transformed pro/pre-B cell model (BU-11; EC_{50} 15 nM), and an immature B cell lymphoma line (WEHI-231; EC_{50} 185 nM) at levels comparable to those measured in humans (0.1-500 nM). Reduced thymidine incorporation largely results from an increase in apoptosis, indicated by the formation of a population of cells with a sub-G_0/G_1 DNA content in BU-11 cultures treated with TBT (≥ 40 nM). The concentrations of TBT required to induce apoptosis correspond with those required to stimulate PPARγ/RXRα-mediated gene transcription in a Cos7 transactivation assay. Studies are underway to determine if the TBT-induced apoptosis pathway requires PPARγ/RXRα-dependent gene transcription and if it differs from that which we have mapped for other PPARγ agonists. Interestingly, TBT (10-50 nM) induces adipocyte differentiation, reduces granulocyte/macrophage colony formation, and alters cytokine profiles in human long term bone marrow cultures. We hypothesize that TBT may suppress B lymphopoiesis by two mechanisms, by inducing apoptosis in early B cells directly and by altering the bone marrow microenvironment that supports lymphopoiesis in general. Current studies are addressing the latter question using the B cell-supportive bone marrow stromal cell line BMS2.

PS 1730 IMMUNOTOXICOLOGICAL EFFECTS OF ASBESTOS ON HUMAN T CELLS.

T. Otsuki[1], M. Maeda[1], S. Murakami[1], Y. Miura[1], N. Kumagai[1], Y. Chen[1], H. Hayashi[1], T. Nakano[2], K. Fukuoka[2], T. Kishimoto[3] and Y. Nishimura[1]. *[1]Hygiene, Kawasaki Medical Shool, Kurashiki, Okayama, Japan, [2]Respiratory Medicine, Hyogo Medical College of Medicine, Nishimomiya, Hyogo, Japan and [3]Internal Medicine, Okayama Rosai Hospital, Okayama, Okayama, Japan.* Sponsor: S. Pruett.

To analyze the possibility that immunolotoxicological alteration in asbestos-related diseases (ARDs) such as asbestosis (ASB) and malignant mesothelioma (MM) may affect the progression of cancers, a human adult T cell leukemia virus-immortalized T cell line (MT-2Org) was continuously exposed to 10 μg/ml of chrysotile-B (CB), an asbestos. After at least 8 months of exposure, the rate of apoptosis in the cells became very low and the resultant subline was designated MT-2Rst. The MT-2Rst cells were characterized by (i) enhanced expression of bcl-2, with regain of apoptosis-sensitivity by reduction of bcl-2 by siRNA, (ii) excess IL-10 secretion and expression, and (iii) activation of STAT3 that was inhibited by PP2, a specific inhibitor of Src family kinases. These results suggested that the contact between cells and asbestos may affect the human immune system and trigger a cascade of biological events such as activation of Src family kinases, enhancement of IL-10 expression, STAT3 activation and Bcl-2 overexpression. This speculation was partially confirmed by the detection of elevated bcl-2 expression levels in CD4+ peripheral blood T cells from patients with MM compared with those from patients with ASB or healthy donors. Further studies will be required to verify the role of T cells with enhanced bcl-2 expression in tumor progression induced by asbestos exposure. In addition, high plasma concentrations of interleukin (IL)-10 and transforming growth factor (TGF)-β, and multiple over-representation of T cell receptor (TcR)-Vβ in peripheral CD3+ T cells found in MM patients. We also detail an experimental long-term exposure T-cell model. Analysis of the immunotoxicological effects of asbestos may alter the occurrence of asbestos-related malignant tumors.

PS 1731 LOW-DOSE MERCURY TARGETS MACROPHAGE ACTIVATION IN HUMAN CELLS *IN VITRO* .

R. M. Gardner[1], J. F. Nyland[2] and E. K. Silbergeld[1]. *[1]Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD and [2]Department of Pathology, Microbiology, and Immunology, University of South Carolina School of Medicine, Columbia, SC.*

There is growing recognition that exposure to both inorganic and organic mercury (Hg) compounds can affect the human immune system, in addition to the nervous system, with potential consequences for host resistance to infection and the risks of autoimmune disease. We have investigated the human response to inorganic Hg using an in vitro system composed of LPS-stimulated human peripheral blood mononuclear cells (PBMCs), a cell population which includes T cells, B cells, monocytes, and macrophages. We have previously reported that we saw no changes in markers of activation or cell populations in both T and B cells, but that we did observe a consistent increase in pro-inflammatory cytokines in response to Hg. These inflammatory signals prompted us to examine the responses of monocytes and macrophages more closely. We recruited six volunteers (3 males, 3 females) to donate blood. PBMCs were isolated and cultured with LPS and low levels of HgCl2 (up to 200nM). After 48 hours in culture, the cells were stained and analyzed by flow cytometry. While we did not observe a change in the number of CD11b+ cells over the concentration of Hg used, we did observe subtle but consistent changes in markers of macrophage maturation and activation. The percentage of CD11b+ cells that were CD80+/CD86- cells significantly increased, as did the percentage of CD11b+ cells that were CD80+/TLR4-. The percentage of

CD86+/TLR4+ significantly decreased. These results indicate that Hg can exert significant effects on the human immune system at very low levels, and that macrophages may be the cell population that is primarily affected by Hg exposure. The observed increases in pro-inflammatory cytokines also support this hypothesis. Hg is also known to disrupt immune signaling pathways and cytokine release by microglia, affecting neuronal migration. These results provide evidence that the immune response to Hg is related to the neurotoxic effects of Hg.

PS 1732 POTENTIAL IMMUNOTOXICITY BY 2, 3 BUTANEDIONE IN BALB/C MICE.

R. P. Frawley[1], J. Painter[2], W. G. Lieuallen[3], T. Masinde[1], Y. Rebolloso[1], G. Hurlburt[1], N. Clayton[1], K. L. White[4], W. Auttachoat[4], D. L. Morgan[1] and D. R. Germolec[1]. [1]*National Institute of Environmental Health Sciences, Research Triangle Park, NC,* [2]*Integrated Laboratory Systems, Research Triangle Park, NC,* [3]*Pathology Associates, Inc., Research Triangle Park, NC and* [4]*Virginia Commonwealth University, Richmond, VA.*

Occupational exposure to high concentrations of 2, 3 butanedione (diacetyl)-containing butter flavor seasoning has been associated with an increased prevalence of airway obstruction. Previous studies in our laboratory to investigate potential immune-mediated mechanisms of diacetyl-induced toxicity have demonstrated that BALB/c mice exposed to diacetyl in a modified local lymph node (LN) assay exhibited an increase in cervical lymph node cell proliferation at ≥2.5 mg/kg/d, and in absolute number of CD3+, B220+, CD4+, CD8+, and Mac3+ cells in LN and spleen at 25 mg/kg/d. CXCL10 protein expression was increased at 25 mg/kg/d in LN, spleen and serum, and CXCL9 was upregulated at ≥10 mg/kg/d in LN. As CXCL9 and CXCL10 and their common receptor, CXCR3, have been associated with inflammation and obstructive pulmonary disease in humans and animal models, we examined expression of these inflammatory markers in immune tissues from BALB/c mice following diacetyl exposure. Enhanced histopathological evaluation revealed limited adverse pathology; 2 out of 5 mice in the 25 mg/kg/d group exhibited lymphoid hyperplasia in lymph nodes. Spleen and thymus of all mice were histologically normal and there was no evidence of apoptosis. Immunohistochemical staining confirmed an increase in CXCL9+ cells within the interfollicular, paracortical, and medullary sinus regions of the cervical LN at 25 mg/kg/d. Similar CXCL9+ cells were found in the thymic medulla and splenic white pulp, but there were no treatment related differences in positive cell numbers in either organ. Collectively these data suggest that exposure to diacetyl induces changes in leukocyte populations and inflammatory mediators that may contribute to observed pathology in diacetyl-exposed individuals.

PS 1733 COVALENT BINDING OF NEVIRAPINE *IN VIVO* AND *IN VITRO* .

Y. Li and J. P. Uetrecht. *Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada.*

Background: Nevirapine (NVP) is associated with a high incidence of idiosyncratic skin rash and liver toxicity. We have developed a Brown Norway rat model in which nevirapine causes a skin rash that has characteristics similar to the reaction that occurs in humans. We demonstrated that oxidation of the methyl group was required in order to cause a rash. Most idiosyncratic drug reactions are due to reactive metabolites. Method: We produced an anti-nevirapine antibody by injection of a NVP-modified Keyhole Limpet Hemocyanin into New Zealand White Rabbits and it was characterized by ELISA. With this antibody the covalent binding of the nevirapine reactive metabolite to liver and skin was studied using immunohistochemistry and immunoblotting. Result: The anti-NVP serum recognized NVP and some metabolites/derivatives, specifically 12-OH-NVP, and 12-Cl-NVP. Binding could still be detected at an antiserum dilution of 1/106. Hepatic covalent binding was greatest in the centralobular area. Cotreatment with aminobenzotriazole changed this pattern. Several hepatic protein bands were observed at 83, 65, 48, and 40 kD. Using expressed rat CYP2C11 and CYP3A1, covalent binding to P450 was observed. Replacing the methyl hydrogens with deuterium decreased covalent binding to hepatic microsomes and the major protein that was modified had a molecular mass of 48 kD. The rat skin homogenate was incubated with 12-OH-NVP sulfate; the major protein that was modified had a molecular mass of 25 kD. When aryl sufatase was incubated with 12-OH-NVP sulfate; the major protein that was modified had a molecular mass of 37 kD. Conclusion: Oxidation of the nevirapine methyl group by P450 lead to direct formation of a reactive metabolite, presumably a quinone methide. In addition, sulfation of the benzylic alcohol formed by oxidation of this methyl group also forms a reactive metabolite. Combined with previous data that demonstrated that oxidation of the NVP methyl group is required to cause a skin rash establishes the pathway that is responsible for the idiosyncratic reactions associated with NVP.
This work was supported by grants from CIHR.

PS 1734 DANGER SIGNALS IN NEVIRAPINE-INDUCED SKIN RASH.

X. Zhang and J. Uetrecht. *The faculty of pharmacy, University of Toronto, Toronto, ON, Canada.*

Background: Nevirapine (NVP) is used to treat HIV infections. However, its use is associated with a high incidence of hypersensitivity reactions, specifically, skin rash and liver toxicity. We have developed an animal model in which Brown Norway (BN) rats develop a NVP-induced skin rash with characteristics very similar to the skin rash in humans. The rash is clearly immune-mediated. We have shown that the rash is dependent on oxidation of NVP to the 12-hydroxyl metabolite (12-OH-NVP). It is unknown how this pathway leads to a skin rash. The objective of this study was to test the "danger hypothesis" in which cell damage leads to a danger signal that initiates the immune response. Methods and Results: BN rats were treated with NVP (150 mg/kg, ip) and 6 or 12 hours later the animals were sacrificed, skin was removed from the ears, and mRNA was isolated. Changes in gene expression were determined with an Affymetrix gene chip. Already at these early time points 122 and 156 genes were upregulated at 6 and 12 hr, respectively. Potential danger signals such as S100 A15 mRNA increased more than 4 fold. Western blot analysis also demonstrated that S100 A15 expression level was increased in skin 12, 48 and 72 hr after NVP treatment. 12-OH-NVP treatment results in a rash at a lower dose than NVP. The number of genes upregulated after 6 or 12 hrs after 12-OH-NVP treatment (159 mg/kg, ip) was similar to that of NVP treatment: 238 and 193, respectively. Genes that were upregulated more than 2 fold at 6 hours in both NVP and 12-OH-NVP treatment were: kruppel-like factor 5, nuclear receptor subfamily 4, group A, member 3, CEBPδ, FK506 binding protein 5, metallothionein 1a & II. Genes that were upregulated more than 2 fold at 12 hours in both treatments were: 3-hydroxy-3-methylglutaryl-coenzyme A, synthase 2, metallothionein 1a & II. Conclusions: These results are consistent with the danger hypothesis. It now remains to further test the involvement of these genes by finding methods to modify their expression and determine the effects of this modification on the incidence/severity of the rash. This research was supported by grants from CIHR.

PS 1735 A STUDY OF LYMPHOCYTES SPECIFICITY IN NEVIRAPINE-INDUCED SKIN RASH.

X. Chen and J. Uetrecht. *Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada.*

Background: The mechanisms by which drugs cause idiosyncratic drug reactions (IDRs) are unknown. A novel animal model for studying IDRs developed by us is nevirapine (NVP)-induced skin rash in the Brown Norway (BN) rats. NVP is used to treat AIDS but is associated with a high incidence of skin rash and liver toxicity. The characteristics of the animal model are very similar to those of the rash that occurs in humans. For example, a low CD4+ T cell count decreases the risk of rash in both rats and humans. Furthermore, CD4+ T cells can transfer the sensitivity from sensitized animals to naïve animals. The NVP-induced skin rash in BN rats is clearly immune-mediated and we believe the mechanism is similar to that in humans. **Methods and Results:** To study the specificity of lymphocytes in this model we used a modified lymphocyte transformation test. Female BN rats were treated with NVP (150 mg/kg/day) in food for 21 days and rechallenged for 5 days after 4 wks off drug. Cells from auricular lymph nodes were isolated and cultured with various concentrations of NVP and NVP metabolites for 3 days at 37°C in 5% CO2. The production of cytokines and cell proliferation were measured by Luminex and Alamar Blue assays, respectively. With the stimulation by NVP the proliferation rate of lymphocytes was increased and cytokines including IFN-γ and IL10 were produced. The response to NVP was greater than to its 12-hydroxy metabolite even though we know that 12-hydroxylation is required to induce a rash. In order to determine which cells respond to NVP, we depleted CD4+ and/or CD8+ T cells; ELISA showed that both T cells are involved in producing IFN-γ, which is consistent with real-time PCR results. **Conclusions:** Lymphocytes from sensitized animals respond to NVP with both proliferation and cytokine production. There is a disconnect between what induces the rash and what the T cells respond to. With these studies we have developed a better understanding of which cells are involved in the mechanism of NVP-induced skin rash and, in turn, this may provide possible ways to prevent and/or treat IDRs. This work was supported by grants from CIHR.

PS 1736 SODIUM METHYLDITHIOCARBAMATE AS A PROBE FOR MECHANISMS OF LETHALITY IN SEPSIS.

W. Tan, P. Crittenden, D. Liu, T. Sebastian and S. Pruett. *Department of Basic Sciences, Mississippi State University, Mississippi State, MS.*

As the third most abundantly used agricultural pesticide in the U.S., Sodium Methyldithiocarbamate (SMD) has been reported that can cause adverse health effects in humans. SMD oral administration decreases IL-12 production and in-

creases IL-10 production induced by lipopolysaccharide (LPS) in mice, indicating suppression of innate immunity. However, the mechanism of this effect and the scope of effects in infections are not known. Studies were conducted using SMD treatment in B6C3F1 mice challenged with non-pathogenic E.coli in a mouse model for sepsis. Body temperature was monitored and immunological parameters, including IL-1β, IL-6, IL-10, IL-12, MIP-1α/β, were evaluated at different time points (2, 4, 12 and 24 hr). A decrease in IL-12 and increase in IL-10 were observed in SMD treated mice. Other cytokines were decreased at early time points and increased at 24 hr, compared with the group treated with E.coli only. This suggests inhibition of pro-inflammatory cytokines early by SMD leads to outgrowth of bacteria, which then induce higher than normal levels of cytokines after the SMD is cleared. Microarray analysis of peritoneal macrophages also indicates that IL-10 was upregulated in SMD treated mice challenged with LPS (as a non-replicating surrogate of E. coli). Numerous other changes consistent with suppressed innate immunity were also observed. Correlation analysis indicates body temperature was highly related to survival and the levels of cytokines. The result of differential counts on cells from peritoneal fluid shows that phagocytosis by macrophages and neutrophils and trafficking of neutrophils to the peritoneal cavity were not affected by SMD. However, clearance of bacteria was adversely affected. Microarray analysis indicated that cathepsin and NADPH oxidase were upregulated, as expected due to increased numbers of neutrophils, so it is unlikely that decreased expression of these key effector proteins is a mechanism of SMD action. This work was supported by NIH grant R01ES013708.

PS 1737 TARGETING CANNABINOID RECEPTORS AS A NOVEL APPROACH TO PREVENT DONOR T CELL-MEDIATED INFLAMMATION DURING GRAFT-*VERSUS*-HOST DISEASE.

R. Pandey, M. Nagarkatti and P. Nagarkatti. *Pathology, microbiology and Immunology, University of South Carolina, Columbia, SC.*

Inflammation plays a critical role in the pathogenesis of a wide range of diseases. Marijuana cannabinoids activate cannabinoid receptors on immune cells and mediate immunomodulation including anti-inflammatory properties. Graft-versus-host disease (GVHD) is a major challenge to transplantation owing to associated morbidity and mortality. It is caused by activation of the donor-derived mature T cells that recognize the recipient's alloantigens and mount a strong inflammatory and immmunotoxic reaction. In the current study, we tested the hypothesis that activation of cannabinoid receptors on donor-derived T cells may help prevent GVHD. To this end, we tested an acute model of GVHD by transferring parental C57Bl/6 (B6) spleen cells into (C57B1/6 X DBA/2) F1(BDF1) mice. Transfer of B6 cells into BDF1 mice produces lymphoid hyperplasia followed by immunosuppression, weight loss, a Thl pattern of cytokines and mortality. In this model, we tested the efficacy of natural cannabinoid (Tetrahydrocannabinol, THC) on the development of acute GVHD. THC treatment suppressed the expansion of donor-derived T cells and blocked the decrease in the number of host cells. THC administration led to early recovery from body weight loss, reduced tissue injury in the liver and increased survival. Impaired haematopoiesis seen during GVHD was rescued by treatment with THC. Moreover, the donor derived T cells from THC-treated GVHD mice failed to proliferate and mediate cytotoxicity against the recipient's cells. The ability of THC to reduce the clinical GVHD was reversed by administration of CB1 and CB2 antagonists thereby demonstrating that THC-mediated suppression of GVHD was cannabinoid receptor-dependent. Our results demonstrate for the first time that targeting cannabinoid receptors may constitute a novel treatment modality against acute GVHD (Supported in part by NIH R01-DA016545, R01-ES09098, R01-AI053703, R01-AI058300, R01-HL058641, and P01-AT003961).

PS 1738 DELTA^9-TETRAHYDROCANNABINOL (Δ^9-THC) SUPPRESSION OF CD40 LIGAND (CD40L) EXPRESSION IN ACTIVATED CD4$^+$ T CELLS.

T. Ngaotepprutaram[1,2], B. L. Kaplan[1,2], R. B. Crawford[1] and N. E. Kaminski[1,2]. [1]*Pharmacology and Toxicology, Michigan State University, East Lansing, MI and* [2]*Center of Integrative Toxicology, Michigan State University, East Lansing, MI.*

Δ^9-THC, a plant-derived cannabinoid, possesses immunomodulatory properties. As demonstrated by this laboratory, treatment with Δ^9-THC selectively inhibits T cell function including T cell-dependent humoral immune responses, T cell proliferation, and production of T cell-derived cytokines. The mechanism of immune suppression involves at least in part, the impairment of the nuclear factor of activated T cells (NFAT). Even though Δ^9-THC binds both known cannabinoid receptors, CB1 and CB2, the role of these receptors in immune regulation remains poorly understood. CD40L, a member of the tumor necrosis factor ligand superfamily, plays a major role in the generation of appropriate T cell-dependent humoral immune responses. Furthermore, optimum expression of CD40L on activated T cells requires the activation of the transcription factors NFAT and early growth response-1 (Egr-1). In light of the above, the objective of this study was to investigate whether Δ^9-THC impairs the up-regulation of CD40L expression in T cells activated with different stimuli. Time course studies demonstrated that peak cell surface CD40L expression after either anti-CD3/CD28 or phorbol ester plus calcium ionophore (PMA/Io) was at 8 h post stimulation on activated CD4$^+$ T cells, as determined by flow cytometry. Pretreatment with Δ^9-THC significantly suppressed the anti-CD3/CD28-induced, but not the PMA/Io-induced up-regulation of the cell surface CD40L expression on CD4$^+$ T cells. Furthermore, pretreatment with Δ^9-THC also attenuated anti-CD3/CD28-induced CD40L expression on CD4$^+$ T cells derived from CB1$^{-/-}$/CB2$^{-/-}$ mice, but to a lesser extent. Studies are currently underway to further characterize the role of CB1 and CB2 on Δ^9-THC-mediated impairment of anti-CD3/CD28-induced CD40L and the involvement of NF-AT and Egr-1 signaling pathways. PS 1739 IMMUNOLOGICAL CONSEQUENCES OF SUSTAINED *VERSUS* TRANSIENT AHR ACTIVATION DURING INFLUENZA VIRUS INFECTION.

J. Head[1], A. Moore[1] and B. Lawrence[1,2]. [1]*Environmental Medicine, University of Rochester, Rochester, NY and* [2]*Microbiology & Immunology, University of Rochester, Rochester, NY.*

The immunomodulatory effects of aryl hydrocarbon receptor (AhR) activation have been demonstrated in a variety of *in vivo* models of disease. The majority of these studies have used the environmental contaminant 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) to activate the AhR because it is poorly metabolized *in vivo* and has a high affinity for the receptor. Our laboratory has demonstrated that TCDD-mediated AhR activation during influenza virus infection causes significant modifications in both the innate and adaptive immune responses, however the mechanism by which AhR activation causes these alterations remains unclear. An important factor that may influence the underlying mechanism of AhR immunomodulation is the duration in which the receptor is activated. Due to TCDD's long half-life *in vivo*, AhR activation is sustained over the course of influenza virus infection. To directly test whether sustained AhR activation is required for immune modulation, we compared the impact of TCDD with that of the tryptophan photoproduct 6-formylindolo [3,2-b] carbazole (FICZ). FICZ has a higher affinity for the AhR than TCDD and is thought to cause transient activation of the AhR. Our laboratory has demonstrated that TCDD treatment causes significant suppression of influenza specific CD8$^+$ T-cell clonal expansion and differentiation; however FICZ treatment had no effect on these endpoints. Moreover, while TCDD treatment increases neutrophil recruitment and iNOS expression in the lungs of infected mice, treatment with FICZ failed to mimic these effects. The immunological endpoints we have studied require AhR activation in different tissues. Specifically, AhR is required in hematopoietic cells to see effects on CD8$^+$ T-cell response but is not required in these cells for excessive neutrophil recruitment and enhanced iNOS levels. Therefore, failure of FICZ to modulate these endpoints suggests that differences in the duration of AhR activation may play a broad role in AhR-mediated immunomodulation.

PS 1740 DEVELOPMENT OF A HUMAN MODEL FOR 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) DISRUPTION OF LPS-INDUCED B CELL DIFFERENTIATION.

C. M. North[1], R. B. Crawford[1], M. Manzan[1], S. Simmons[2], R. Ramabhadran[2] and N. E. Kaminski[1]. [1]*Center for Integrative Toxicology, Michigan State University, East Lansing, MI and* [2]*ORD/NHEERL/Neurotoxicology Division, U.S. EPA, Durham, NC.*

Rodent models have established TCDD as suppressing the primary IgM antibody response. To better understand potential human health risks posed by dioxins, it would be useful to verify data from rodents in human models; however, donor-to-donor variation in human primary cell models has posed problems for establishing human immunotoxicity models. An attractive alternative has been human cell line models with homogeneity in genotype and stimulus response. To that end, the human lymphoblast cell line SKW 6.4 was established as a model to study dioxin immunotoxicity. LPS (100 μg/mL) increased SKW 6.4 IgM secretion, but was not impaired by TCDD concentrations up to 310 nM. Western Blot and rt-qPCR demonstrated that SKW 6.4 cells do not express aryl hydrocarbon receptor (AHR). To establish a cell line model for mechanistic studies hAHR was cloned into a plasmid vector, phCMV-CGFP, generating both native and C-terminal GFP fused forms of AHR for establishing AHR-expressing SKW 6.4 cells. Both AHR forms were validated by TCDD-induced CYP1A1 expression in transiently transfected HEK 293 cells. Cells stably expressing AHR were detected by rt-qPCR in G418-resistant SKW 6.4 cells. AHR-GFP was subcloned into the plasmid pTRED and

packaged into a lentiviral vector, then transduced into SKW 6.4 cells to generate stable AHR-GFP expression. GFP fluorescence was verified by FACS, AHR expression was detected by rt-qPCR, and AHR-GFP function established by TCDD-induced CYP1A1 gene expression. Future studies will assess TCDD effects on LPS-activated IgM secretion in AHR$^+$ SKW 6.4 cells in comparison to murine models to validate cross-species mechanism conservation. This work was supported in part by the Dow Chemical Company, Superfund Basic Research Program (P42 ES004911), and NIH (RO1 ES002520, T32 ES007255). This is an abstract of a proposed presentation and does not necessarily reflect U.S. EPA policy.

PS 1741 DECREASED IN VITRO CYTOTOXIC T LYMPHOCYTE (CTL) EFFECTOR RESPONSES IN MICE LACKING CANNABINOID RECEPTORS 1 AND 2.

W. Chen[1, 2], P. W. Karmaus[1, 3], B. L. Kaplan[1, 4] and N. E. Kaminski[1, 4]. *[1]Center for Integrative Toxicology, Michigan State University, East Lansing, MI, [2]Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI, [3]Cell and Molecular Biology Program, Michigan State University, East Lansing, MI and [4]Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

Cannabinoid compounds have been established as modulators of host immune responses, and exhibit affinity for cannabinoid receptors 1 (CB1) and 2 (CB2). CB1 is highly expressed in the central nervous system, while CB2 is highly expressed in the periphery, including the immune system. From studies using antagonists or CB1$^{-/-}$/CB2$^{-/-}$ (KO) mice, immune modulation by the marijuana derived compound, Δ^9-tetrahydrocannabinol (Δ^9-THC), has been found to be mediated only in part through CB1 and CB2. In addition, it has been demonstrated that CB1 and CB2 play a critical role in generation of the *in vitro* antibody response. Thus, the objective of the present study was to investigate the role of CB1 and CB2 in the generation of functional CTL effectors *in vitro*. In an allogeneic model, the kinetics of CTL activity resulting from co-culture of splenocytes (SPLC) with major histocompatability complex (MHC)-mismatched P815 (DBA/2) cells showed a peak response on day 5 after elicitation using a standard 51Cr-release assay. The ability to lyse P815 target cells was reduced in CTLs derived from KO mice compared to WT mice. In a syngeneic model, CTLs were elicited in response to an immunodominant peptide from influenza ($PB_{1703\text{-}711}$) presented in the context of MHC I. The PB1 peptide was loaded onto antigen presenting RMA-S cells and co-cultured with SPLC. Five days after elicitation, the resulting population was assayed for CTL activity using IFN-γ ELISPOT to enumerate peptide specific CTLs. Lower numbers of IFN-γ producing cells were observed in peptide-specific CTL populations elicited from SPLC of KO mice compared to WT mice. Collectively, these results suggest that CB1 and CB2 are involved in the regulation of CTL responses (supported by NIH DA07908 and MSU Respiratory Research Initiative).

PS 1742 TCDD INHIBITS TRANSCRIPTIONAL ACTIVATION OF THE 3'IgHRR AND HS3A/HS1, 2 ENHANCERS IN A TRANSGENIC B-CELL LINE.

D. Ellis, T. Fernando and C. Sulentic. *Wright State University, Dayton, OH.*

2,3,7,8,-tetrachlorodibenzo-p-dioxin (TCDD) is a ubiquitous environmental toxin and potent prototype for aryl hydrocarbon receptor (AhR) ligands. The ligand-activated AhR can bind dioxin responsive elements (DRE) and affect transcription of sensitive genes. Immunoglobulin (Ig) gene expression is inhibited by AhR ligands including TCDD in both in vivo and in vitro animal models and human cellular models. In mouse models, Ig inhibition correlates with AhR expression and function. Ig heavy chain (IgH) gene expression involves a complex interaction between several regulatory elements including the 3'IgH regulatory region (3'IgHRR) which is typically associated with four enhancers (hs3a; hs1,2; hs3b; hs4). We have demonstrated in a mouse B-cell line, CH12.LX, that TCDD inhibits LPS activation of luciferase reporters regulated by the 3'IgHRR or the hs1,2 enhancer alone. Surprisingly, a luciferase reporter regulated by the hs4 enhancer was synergistically activated by LPS and TCDD. The objective of this study was to determine if the inhibitory effect of TCDD is mediated through the hs1,2 enhancer. CH12.LX cells were stably transfected with constructs containing an LPS-inducible γ2b reporter regulated by the 3′IgHRR with LoxP sites flanking either the hs3b/hs4 or the hs3a/hs1,2 enhancer pairs. The hs3b/hs4 enhancer pair was removed by CRE-LoxP recombination, creating a cell line with LPS-inducible γ2b regulated by hs3a/hs1,2. TCDD inhibited LPS-activation of both the parental 3'IgHRR and the hs3a/hs1,2 variant, suggesting that the hs3a/hs1,2 enhancer pair plays an important role in the inhibitory effect of TCDD on the 3'IgHRR. Efforts to generate the hs3b/hs4 variant are underway. Notably, the 3′IgHRR has been associated with several human diseases including Burkitt's lymphoma, IgA nephropathy, and Celiac disease. Since the mouse and human hs1,2 and hs4 have several trancription factor binding sites in common, including a DRE-like site, TCDD may modulate the human 3′IgHRR and potentiate the occurrence and/or severity of diseases associated with the 3'IgHRR. (Supported by NIEHS R01ES014676)

PS 1743 TCDD MODULATES THE TRANSCRIPTIONAL ACTIVITY OF THE HS1, 2 ENHANCER IN THE 3'IgH REGULATORY REGION.

T. Fernando and C. Sulentic. *Wright State University, Dayton, OH.*

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is a potent environmental toxin known to inhibit immunoglobulin (Ig) gene expression in animal studies. Transcriptional regulation of the Ig heavy chain (IgH) involves the 3'IgH regulatory region (3'IgHRR) and its enhancers (i.e., hs3; hs1,2; and hs4), which contain DNA binding sites for several transcription factors, including NF-κB/Rel and the aryl hydrocarbon receptor (AhR). TCDD induces binding of the AhR nuclear complex to a dioxin responsive element (DRE) in both the hs1,2 and hs4 enhancers and inhibits murine 3'IgHRR activation in a well characterized mouse B-cell line (CH12.LX). In humans, a polymorphism of the hs1,2 enhancer, resulting in varying numbers of a 53 bp sequence tandemly repeated, has been correlated with autoimmune diseases like IgA nephropathy and Celiac disease. The repeated sequence contains κB and DRE binding sites. The objective of this study was to comparatively evaluate the effect of TCDD and LPS on human and mouse hs1,2 enhancers in the CH12.LX model. In transient luciferase studies, an increased number of repeats in the human hs1,2 enhancer increased the sensitivity to LPS. Interestingly, TCDD also markedly enhanced human hs1,2 activity and even augmented LPS-induced activation. TCDD-induced activation positively correlated with the number of repeats. This starkly contrasted with TCDD-induced inhibition of the mouse hs1,2 and 3'IgHRR in LPS-stimulated CH12.LX cells. Through sequence analyses, we verified that the human hs1,2 enhancer retains the κB and DRE binding sites but lacks binding sites for B-cell specific activator protein and NF-αP, which are both important to mouse hs1,2 regulation. Mutational analyses are underway to evaluate the significance of these binding sites in TCDD-induced modulation of both the human and mouse hs1,2 enhancer. Since TCDD represents a large class of chemicals found in the environment, diet, and pharmaceuticals, understanding chemical-induced modulation of the 3'IgHRR enhancers may provide a clue to the etiology of certain autoimmune diseases. (Supported by NIEHS R01ES014676)

PS 1744 INVESTIGATION OF THE IMMUNOMODULATORY EFFECTS OF PERFLUORINATED FATTY ACIDS (PFCA) *IN VITRO* .

V. Ahuja[1], M. Eisenblätter[2], V. Ahuja[1], R. Ignatius[2] and R. Stahlmann[1]. *[1]Institute of Clinical Pharmacology & Toxicology, Charite University, Berlin, Germany and [2]Institute of Microbiology & Hygiene, Charite University, Berlin, Germany.*

Perfluorinated fatty acids (PFCAs) are commonly used as plasticizers, corrosion inhibitors, and fire extinguishers. We studied the immunomodulatory potential of various PFCAs, ammonium perfluorooctanoate (APFO), perfluorooctanesulfonic acid (PFOS), perfluoroheptanoic acid (PFHA), perfluorononanoic acid (PFNA) and perfluorodecanoic acid (PFDA) in in vitro models. Firstly, lymphocytes isolated from spleens of BALB/c mice were incubated with PFOS, APFO, PFHA, PFNA and PFDA at 0.1, 1, 10 and 100 μM concentrations for 24, 48, and 72 hr, and changes in percentages of lymphocytes (CD4+, CD8+, CD45+) were monitored by FACS. We found significant modulation in expression of all the studied lymphocyte markers at a concentration of 0.1 μM for PFNA after 24 hr of incubation. At higher concentrations, effects were more pronounced and were also present with the other PFCAs studied. In another set up, the effects of APFO on dendritic cells (DCs) were studied. DCs were prepared from PBMCs isolated from buffy coats of healthy blood donors by density gradient centrifugation, followed by CD14+ magnetic cell sorting. Immature DCs were obtained by culturing CD14+ cells in the presence of GM-CSF and IL-4 for 6 days and simultaneously activated by the addition of pro-inflammatory cytokines for 2 days. APFO (200 μM) was added during differentiation and maturation stages. The phenotypic expression of CD25, CD80, CD83, CD86 and HLA-DR, cytokine (IL-10 and IL-12) secretion of the cells and their capacity to simulate allogeneic T cell-proliferation in mixed leukocyte reaction (MLR) were studied. We found that APFO significantly affected the expression of CD86 marker, and secretion of IL-10 and IL-12 cytokines. The capacity to stimulate allogeneic T-cell proliferation was not affected. Our results show the immunomodulatory effects of PFCAs on mouse lymphocytes and human monocyte derived DCs. Further studies are ongoing.

PS 1745 IMMUNOSUPPRESSIVE EFFECTS OF 1, 2:5, 6-DIBENZANTHRACENE ARE MEDIATED PRIMARILY BY CYP1B1 AND NOT CYP1A1 OR AHR.

D. Smith[1, 2], M. J. Smith[2] and K. L. White[2]. *[1]Altria Client Services, Richmond, VA and [2]Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA.*

The mechanism of polycyclic aromatic hydrocarbon (PAH) immunotoxicity is not completely understood. Because PAHs are agonists of the aryl hydrocarbon receptor (AhR) and they are metabolized by cytochrome P450 enzymes, there are two

competing yet complimentary hypotheses on the mechanism. In these studies, a pharmacological approach was devised to determine if the mechanism of action of 1,2:5,6-Dibenzanthracene (DBA) immunotoxicity is mediated by direct action of the AhR or by metabolism of DBA to metabolites that may subsequently intercolate into DNA and exert their effects. Utilizing the Mishell-Dutton in vitro antibody forming cell assay, it was possible to show that resveratrol (RSV; an AhR antagonist) had no effect on the immunosuppressive potency of DBA and that α-naphthoflavone (ANF; an inhibitor of both CYP1A1 and CYP1B1) and 2,3',4,5'-tetramethoxystilbene (TMS; a CYP1B1-specific inhibitor) both significantly reduced the immunosuppressive effects of DBA in Mishell-Dutton culture. While ANF may have effects on the AhR and CYP1A1 as well as on CYP1B1, the results suggest that TMS is a competitive inhibitor of CYP1B1 with greater specificity for CYP1B1 than ANF. These results suggest that the immunosuppressive effects of DBA are not receptor-mediated, but instead are mediated by the metabolism of the parent compound to more toxic metabolites by the P450 system. Funded in part by NIEHS Contract ES 05454.

PS 1746 DIFFERENTIAL EFFECTS OF ACUTE ETHANOL ADMINISTRATION ON THE POLY I:C-INDUCED IMMUNE RESPONSE: IS ALL POLY I:C CREATED EQUAL?

M. Glover[2] and S. Pruett[1]. [1]*Department of Basic Sciences, Mississippi State University, Mississippi State, MS and* [2]*Cellular Biology & Anatomy, LSU Health Sci. Center, Shreveport, LA.*

Acute ethanol exposure inhibits the proinflammatory cytokine response to many pathogens. Double-stranded RNA (dsRNA) and its synthetic analog, polyinosinic-polycytidylic acid (poly I:C) are molecular patterns associated with viral infection which are recognized by the pattern recognition receptor, TLR3. This recognition sets off a signaling cascade culminating in the production of proinflammatory cytokines. Poly I:C has been used extensively both in vivo and in vitro to mimic viral effects on the immune response. Unfortunately, literature searches to shed light on its effects often prove to be frustrating, due to variability in results. The likely culprit for this variability is endotoxin contamination. Endotoxin is a potent stimulator of the TLR4 pathway, a pathway which also culminates in the production of proinflammatory cytokines. Like many agents used in research laboratories, poly I:C is available from a variety of sources. The purpose of this study was to compare and contrast results from experiments utilizing poly I:C from two of these sources, Sigma and Invivogen. The effects of these agents were assessed in female B6C3F1 mice treated first by oral gavage with ethanol (32% in water at 6 g/kg body weight). The Invivogen poly I:C is considered to be endotoxin-free (< 0.125 EU/mg), whereas Sigma poly I:C has been shown to have some level of contamination. Most parameters tested yielded comparable results with the two poly I:Cs, but a few of the parameters, including IL-10 secretion and NF-kappaB activation showed marked differences. This work was supported by NIH grant AA009505.

PS 1747 A GENOMIC APPROACH TO AN INNATE IMMUNO-REGULATORY MECHANISM MODULATED BY ETHANOL: MICROARRAY AND PATHWAY ANALYSIS.

T. Sebastian[1], M. Glover[2] and S. Pruett[1]. [1]*Department of Basic Sciences, Mississippi State University, Mississippi State, MS and* [2]*Cellular Biology & Anatomy, LSU Health Sci. Center, Shreveport, MS.*

Ethyl alcohol diversely affects intracellular signaling events and gene expression of innate immune system leading to altered inflammatory responses. Our previous studies clearly demonstrated that some of the effects of EtOH on the innate immune system mediated through TLR signaling pathways, and this could suppress cytokine expression depending on which transcription factor inhibited. Through microarray and pathway analysis we made an attempt to analyze the transcriptional profile to study the mechanism of action of EtOH on the innate immune response. MA analysis showed that EtOH can affect cellular signaling events such as activation of MAPK, NF-kappaB mediated by toll like receptors leading to altered inflammatory responses. A number of genes are affected by treating B6C3F1 mice with ethanol. We analyzed 45101 genes, of which 3525 candidate genes showed 2 fold changes in expression level with untreated naïve. Among the genes that mediate inflammation, IFN-α, IFN-β, CCL20 and CXCL2 are significantly changed by EtOH. Based on the present study and earlier results it is evident that there is a common mechanism by which EtOH regulates inflammation, and we propose a model explaining how EtOH control signaling and cytokine production. Viral infection results in the activation and phosphorylation of IRF3 and IRF7 which form a complex with p300 and CBP in the cytoplasm and undergo conformational change. As a result the complex translocates to the nucleus and allows binding to the ISRE sequence of the DNA. Pathway analysis showed that DHX 58, an RNA helicase upregulated by EtOH prevents serine/threonine phosphorylation of IRF3 and complex formation with IRF7 there by inhibit the translocation of IRF3-IRF7 complex to the nucleus and activates the transcription of IFN α and β and other interferon induced genes. This work was funded by NIH grant AA009505.

PS 1748 THE ROLE OF PPAR-ALPHA ON MACROPHAGE FUNCTION FOLLOWING PFOS EXPOSURE IN THE MOUSE RAW264.7 CELL LINE.

M. Mollenhauer[1], P. Fair[2] and M. Peden-Adams[1]. [1]*Medical University of South Carolina, Charleston, SC and* [2]*NOAA/NOS, Charleston, SC.*

Although numerous toxicological endpoints have been linked to perfluorooctane sulfonate (PFOS), its effects on inflammation, specifically, macrophage function are not well understood. Understanding these effects and the role of PPAR-alpha in them are important to fully comprehend the consequences PFOS has on immune function. The current study assessed cellular proliferation, cytokine production and PPAR-alpha activity following in vitro exposure to PFOS in murine RAW264.7 macrophages. All three endpoints were measured after a 24 hr. exposure to 0, 0.03, 0.1, 0.3, 1, 3 or 300 ug PFOS/mL and stimulation with 0.1 ug/mL LPS. Significant results included an increase in cellular proliferation at 1 and 3 ug PFOS/mL but decreased proliferation at 300 ug PFOS/mL. IL-6 secretion was reduced by exposure to 0.1, 0.3 and 300 ug PFOS/mL while TNF- alpha production was reduced by exposure to 300 ug PFOS/mL. PPAR-alpha activity was significantly increased at 0.1 - 300 ug PFOS/mL, but this was not dose-responsive. Evidence for the involvement of PPAR-alpha in these effects was indicated by co-exposure to PFOS and the PPAR-alpha inhibitor MK886. Not only was PPAR-alpha activity significantly decreased with co-exposure to PFOS and MK886, but this also resulted in the elimination of cellular proliferation at 1 and 3 ug/mL and recovery of the observed reduction in TNF- alpha production at 300 ug/mL that was observed with PFOS alone. Alternatively, culture with MK886 did not change the effects of PFOS on IL-6 production in this cell line. Overall these data indicate that PFOS exposure can alter macrophage functions and begins to elucidate the complex role of PPAR-alpha in PFOS modulated inflammatory effects suggesting both PPAR-alpha-dependant and -independent modes of action.

PS 1749 EFFECTS OF PERFLUOROOCTANE SULFONATE (PFOS) ON MACROPHAGE FUNCTION AND SPLENOCYTE SUBPOPULATIONS IN B6C3F1 MICE.

D. E. Keil[1], M. Mollenhauer[2], J. Berger-Ritchie[1], M. Lutman[1], M. Morse[1] and M. Peden-Adams[2]. [1]*UNLV, Las Vegas, NV and* [2]*Medical University of South Carolina, Charleston, SC.*

Perfluorinated hydrocarbons have recently generated much interest as some of these compounds (i.e., perfluorooctane sulfonate (PFOS)) are persistent in the environment and are detectable in blood samples of both wildlife and humans. Of the toxicological effects identified, antibody production seems to be a highly sensitive target. This study builds on previous work examining the immunotoxicity of PFOS and potential mechanisms attributing to suppression in humoral immunity. Specifically, we report splenic cell populations (B220/CD40, CD4/CD154, and F4/80) and macrophage function. Macrophage parameters assessed included phagocytosis and the ability to generate nitric oxide. Of these measures, phagocytosis was suppressed only at 5.0 mg/kg total administered dose (TAD) of PFOS for a duration of 28 days. Numbers of B220+/CD40- and B220+/CD40+ cells were not altered but numbers of B220-/CD40+ were increased at the 5 mg/kg treatment. However numbers of F4/80 (macrophages) were not altered. Numbers of CD4+, CD154+ and CD4+/CD154+ cells were also not altered. These data suggest that activation and expression of CD40 on B-cell (B220+/CD40+) and CD154 on T-cell (CD4+/CD154+), which are both important in humoral immune production of IgM, are not modulated by PFOS exposure at concentrations where PFOS-induced IgM suppression is noted. Based on our previous reports, it is clear that humoral immunity is suppressed following exposure to PFOS at serum concentrations that fall below occupationally measured levels. What is not clear, however, is the mechanism of immunosuppression. Based on these data, it appears that deficits in expression of CD40 and CD154 following antigen challenge are not a factor. Although macrophage phagocytosis was suppressed at 5.0 mg/kg TAD, no alterations were detected at 0.5 mg/kg TAD the LOEL in this strain/gender. Additional studies are in progress examining the cytokine network that supports IgM production to further characterize the mode of immunosuppression.

PS 1750 COMPARATIVE IMMUNOLOGICAL RESPONSES BETWEEN WILD-TYPE AND PPAR-ALPHA NULL MICE FOLLOWING EXPOSURE TO PFOS.

M. Morse[1], M. Mollenhauer[2], J. Berger-Ritchie[1], M. Lutman[1], D. E. Keil[1] and M. Peden-Adams[2]. [1]*Medical University of South Carolina, Charleston, SC and* [2]*CLS, UNLV, Las Vegas, NV.*

The cause for concern for perfluorinated hydrocarbons is not only driven by the environmental persistence of these compounds, but by the fact that the toxicity of these chemicals have not been extensively studied while substantial levels have been

detected in blood samples of humans and wildlife. This study builds on previous work examining the immunotoxicity of PFOS and potential mechanisms attributing to suppression in humoral immunity. It is known that perfluorooctane sulfonate (PFOS), along with other compounds of this class, cause peroxisomal proliferation. Since lymphocytes express peroxisome proliferator activated receptor-alpha (PPAR-alpha) it has been suggested that the immunotoxicity of PFOS may be related to PPAR-alpha activation. Previous studies from this laboratory have demonstrated that to PFOS suppresses IgM humoral immune responses in adult B6C3F1 mice. To elucidate potential mechanisms of PFOS-induced immunosuppression, this study compared the immunotoxicity profile in PPAR-alpha null mice with respect to the wild type control (C57Bl/6 mice). C57 +/+ and -/- mice were exposed to PFOS (0, 0.5, or 5 mg/kg total administered dose [TAD]) orally for 28-days. Sheep red blood cell (SRBC)-specific IgM production along with macrophage phagocytosis, pinocytosis and nitric oxide production was assessed. No effect on macrophage function was observed for any of the parameters in either strain. IgM suppression was observed in the wild-type mice at both 0.5 and 5 mg/kg TAD but was not observed in the PPAR-alpha null mice. This suggests a role for PPAR-alpha in the observed suppression of IgM production by PFOS. However, further studies are required to completely characterize the mechanism of action of PFOS on humoral immunity.

PS 1751 DIFFERENTIAL DISRUPTION OF HEMATOPOIESIS IN BONE MARROW BY BENZO(A)PYRENE AND 7, 12-DIMETHYLBENZ(A)ANTHRACENE: EFFECTS ON BLOOD, SPLEEN, AND THYMUS.

A. U. N'jai[1, 2], M. Larsen[3], C. Czuprynski[1, 2] and C. Jefcoate[2, 3]. *[1]PBS, UW, Madison, WI, [2]METC, UW, Madison, WI and [3]Pharmacology, UW, Madison, WI.*

Benzo(a)pyrene (BP) and 7, 12-dimethylbenz(a)anthracene (DMBA) are carcinogenic polycyclic aromatic hydrocarbons (PAHs), that selectively target bone marrow (BM) cells through local activation by Cyp1b1. We have previously shown that, in C57BL/6J mice, total BM cellularity decreased two-fold following IP DMBA but not BP treatment. Here, we further characterize the temporal response in the BM, blood, spleen, and thymus compartments to IP or oral gavage of DMBA or BP (50 mg/kg). Progenitor B cell colony forming units (CFU-preB) were decreased to a greater extent than myeloid progenitors (CFU-GM) following IP or oral BP and DMBA treatments. The preB response to BP and DMBA were similarly decreased at 6 h, but BP treated mice displayed a recovery. In contrast, CFU-GM decrease more slowly in response to DMBA, while BP had no effect. The acute (6-48 h) effects of DMBA and BP on blood leukocytes were similar, but differed substantially by 168 h. Decreased spleen and thymus weights, indicative of lymphocyte depletion paralleled decreases in BM cells. DMBA produced significant reduction in spleen and thymus weights, while BP was more potent in thymus than spleen. In congenic AhRd mice where PAH induction of the AhR (BP>>DMBA) is minimal, BP responsiveness in BM cells is fully restored. Similar amounts of BP and DMBA reach the BM in wild-type and AhRd mice, suggesting that AhR activation protect against BM responses to BP. BM responses were lost in Cyp1b1 -/- mice and therefore dependent on Cyp1b1 PAH metabolism. Overall, oral administration of BP or DMBA caused marked early (6h) effects, that diminished substantially by 48 h compared to IP, consistent with more rapid hepatic clearance. Blood levels of DMBA were six fold higher for oral than IP administration at 6 h, but the magnitude of blood cell depletion was surprisingly similar. The observations in the BM and immune compartments shed light on role of AhR and Cyp450 metabolism on the differential effects of PAHs on BM hematopoiesis.

PS 1752 IDENTIFICATION AND CHARACTERIZATION OF INFILTRATING MACROPHAGES IN ACETAMINOPHEN-INDUCED LIVER INJURY.

M. Holt, L. Cheng and C. Ju. *Pharmaceutical Sciences, University of Colorado Denver, Denver, CO.*

The role of macrophages in the pathogenesis of acetaminophen (APAP)-induced liver injury remains controversial, as it has been demonstrated that these cells display pro-toxicant and hepato-protective functions. This controversy may stem from the heterogeneity and/or plasticity of macrophages and the difficulty in distinguishing and differentially studying subpopulations of macrophages in the liver. In the present study, using flow cytometric analysis and fluorescence-labeled antibodies against specific cell surface macrophage markers, we were able to, for the first time, identify an APAP-induced macrophage (IM) population distinct from resident Kupffer cells. The data demonstrated that the IMs were derived from circulating monocytes that infiltrated the liver following APAP-induced liver injury. The IMs exhibited a phenotype consistent with that of alternatively activated macrophages and demonstrated the ability to phagocytize apoptotic cells and induce apoptosis of neutrophils. Furthermore, in the absence of the IMs, the resolution of hepatic damage following APAP-induced hepatotoxicity was delayed in $CCR2^{-/-}$ mice compared with wild-type mice. These findings likely contribute to the role of the IMs in the processes of tissue repair, including counteracting inflammation and promoting angiogenesis. The present study also demonstrated the ability of separating populations of macrophages and delineating distinct functions of each group in future studies of inflammatory disease in the liver and other tissues.

PS 1753 EICOSANOIDS MEDIATE GALLERIA MELLONELLA CELLULAR IMMUNE RESPONSE TO VIRAL INFECTION.

E. Buyukguzel[1], H. Tunaz[2], D. Stanley[3] and K. Buyukguzel[1]. *[1]Faculty of Arts and Sciences, Biology Department, Zonguldak Karaelmas University, Zonguldak, Turkey, [2]Faculty of Agriculture, Department of Plant Protection, Kahramanmaras-Sutcuimam University, Kahramanmaras, Turkey and [3]Biological Control of Insects Research Laboratory, USDA/Agricultural Research Service, Columbia, MO.*

Nodulation is the predominant insect cellular immune response to bacterial and fungal infections and it can also be induced by some viral infections. Treating seventh instar larvae of greater wax moth *G. mellonella* with Bovine herpes simplex virus-1 (BHSV-1) induced nodulation reactions in a dose-dependent manner. Because eicosanoids mediate nodulation reactions to bacterial and fungal infection, we hypothesized that eicosanoids also mediate nodulation reactions to viral challenge. To test this idea, we injected G. mellonella larvae with indomethacin, a non-steroidal anti-inflammatory drug immediately prior to intrahemocoelic injection of BHSV-1. Relative to vehicle-treated controls, indomethacin-treated larvae produced significantly reduced numbers of nodules following viral infection (down from approximately 190 nodules/larva to <50 nodules/larva). In addition to injection treatments, increasing dietary indomethacin dosages (from 0.01% to 1%) were associated with decreasing nodulation (by 10-fold) and phenoloxidase activity (by 3-fold) reactions to BHSV-1 injection. We infer from these findings that cyclooxygenase products, prostaglandins, mediate nodulation response to viral infection in *G. mellonella.*

PS 1754 CHRONIC LOW-DOSE ARSENIC IN DRINKING WATER ALTERS IMMUNE RESPONSES TO RESPIRATORY VIRAL INFECTION *IN VIVO* .

C. D. Kozul[1], K. H. Ely[2], R. I. Enelow[3] and J. W. Hamilton[1]. *[1]Pharmacology/Toxicology, Dartmouth Medical School, Hanover, NH, [2]Medicine, Dartmouth Medical School, Lebanon, NH and [3]Medicine and Microbiology, Dartmouth Medical School, Lebanon, NH.*

Arsenic (As) exposure is a significant worldwide environmental health concern. Through mechanisms that have yet to be elucidated, chronic As exposure via the drinking water has been associated with an increased incidence of pulmonary disease. We have recently found that environmentally relevant levels (10 and 100 ppb) of chronic As exposure significantly alters inflammatory cytokine production in mouse lung. Our findings led us to investigate the effect of chronic As exposure on respiratory Influenza A infection, a common and potentially fatal disease. In this study, C57BL/6J mice (9 wk, n=6 per treatment group) were housed on a casein-based AIN-76A diet and exposed to 100 ppb As in the drinking water for 5 wk. Following As exposure, mice were inoculated intra-nasally with a sub-lethal dose of Influenza A/PuertoRico/8/34 (H1N1) virus. Morbidity (measured by weight loss) was monitored over the course of infection. Multiple endpoints were evaluated post infection (p.i.). Mice exposed to As had a significant increase in morbidity over the entire course of infection and significantly higher pulmonary influenza virus titers on day 7 p.i. The As exposed mice also displayed a significant decrease in total cell infiltration and inflammatory cytokine production at day 3 p.i. Respiratory infections with influenza virus and the looming potential of an influenza pandemic are major worldwide health concerns. Our data indicate that chronic As exposure may be a significant contributor to the susceptibility and pathogenesis of respiratory viral infections. Moreover, these results suggest that chronic arsenic exposure, even at low levels commonly found in drinking water in the U.S., and throughout the world, may compromise immune responses to various infectious challenges, leading to or exacerbating disease risk. (NIH-NIEHS SBRP P42 ES007373 P2)

PS 1755 METALLOTHIONEIN EXPRESSION AFFECTS THE FUNCTIONAL IMMUNE RESPONSE OF MURINE MACROPHAGES.

G. Marusov[1], X. Yin[1], R. Emeny[2], D. A. Lawrence[2] and M. A. Lynes[1]. *[1]Molecular and Cell Biology, University of Connecticut, Storrs, CT and [2]Wadsworth Laboratory, Albany, NY.*

Metallothioneins (MTs) are small cysteine-rich proteins with a wide range of functions including reactive oxygen species scavenging, chemotactic activity, immunomodulation, essential cation management and toxic metal sequestration.

Listeria monocytogenes is a Gram-positive bacterium that can be pathogenic in humans and is used as a model of intracellular infection. We have used an in vivo model of listeriosis to evaluate the effects of MT gene dose during the course of Listeria infection in three strains of mice: C57BL/6 wild-type (WT), congenic MT knock-out (MTKO), and congenic MT-I transgenic (MTTG). Our results suggested that either overexpression of MT-I or a lack of functional MTs significantly altered the course of intravenous listeriosis. Both MTTG and MTKO mice had significantly lower Listeria burdens in liver and spleen. A time course study showed this difference was most prominent in the first 48 hours of infection, during the innate immune response, after which Listeria clearance occurred at comparable rates in all three strains. Listeria infection resulted in decreased IL-6 and TNF-α levels in both MTTG and MTKO mice compared to WT. Macrophages from MTTG and MTKO mice exhibited an increased oxidative burst compared to WT macrophages, suggesting a possible mechanism by which these strains maintained a lower Listeria burden. We have used grating-coupled surface plasmon resonance imaging (GCSPRI) and grating-coupled fluorescent plasmonics (GCFP) to identify components of a biomarker signature of inflammation for each of three strains of mice. Analysis of LPS-stimulated peritoneal cells from the three strains reveal that MT gene dose can significantly affect the secretion of cytokines and other inflammatory mediators. Moreover, these patterns are reflected in mRNA microarray studies of resting and activated cells. These results indicate that MT levels can dramatically influence the innate immune response to infection. Supported by NIH grants ES07408 and ES016014.

PS 1756 A NOVEL *IN VITRO* SYSTEM (MIMIC™) FOR THE ASSESSMENT OF THE IMMUNOTOXIC EFFECTS OF DRUGS ON THE HUMAN IMMUNE CELLS.

M. Fort[1], Y. Ma[2], V. Wittman[2], R. Higbee[2], E. Mishkin[2] and P. Narayanan[1].
[1]Investigative Toxicology, Amgen Inc., Seattle, WA and [2]VaxDesign Corp., Orlando, FL.

Assessment of immunotoxic potential of novel therapeutics traditionally involves utilizing a series of in vitro assays in which PBMC are stimulated in a manner quite different from how they are activated in an animal. In vivo, antigen is picked up by antigen-presenting cells (APC), traffics to the lymph nodes, is presented to T cells, and then the T cells migrate to B cell follicles to activate antibody (Ab) secretion. In order to more closely mimic the in vivo situation, a novel in vitro system (MIMC™) has been developed using human PBMC. In this model, lymphocyte activation is broken down into a "peripheral tissue" module where PBMC are activated to become mature dendritic cells (DC) by crossing through an endothelial cell layer, and a "lymphoid tissue equivalent" module where these activated DC are co-cultured first with autologous T cells, and subsequently with autologous B cells. We tested the MIMIC™ system for its ability to detect and characterize effects of 8 well-known immunomodulatory compounds, including imiquimod, CpG, cyclosporine A, methotrexate, anti-TNFalpha mAb, anti-CD154 mAb, OKT3, and CTLA4-Ig, from 8 human donors. Read-outs included: assessment of DC numbers and DC maturation, detection of 22 cytokines/chemokines, T and B cell proliferation and cell viability, and antigen-specific Ab production. The MIMC™ system was able to detect both immunostimulatory (e.g. imiquimod) as well as immunosuppressive compounds (e.g. CsA). In addition, the MIMC™ system was able to characterize the varied effects of OKT3: stimulatory on T cells but inhibitory for Ab production. The results seen with these compounds in the MIMC™ system are in agreement with the published literature on the effects of these drugs' in humans. The MIMIC™ system may be an effective method for predicting the immunomodulatory effects of novel therapeutics on human immune cells.

PS 1757 ELUCIDATION OF CYTOKINE STORM: THE EFFECT OF IN VITRO ANTIBODY IMMOBILIZATION METHODS ON CYTOKINE SECRETION IN A CELL-BASED ASSAY.

J. Mulligan, R. Shively and C. L. O'Day. *Cell Biology, MDS Pharmacology Services, Bothell, WA.* Sponsor: J. Briffaux.

In 2006, the phenomenon of cytokine storm was grimly demonstrated in the phase 1 clinical trial of TGN1412, a CD28-specific monoclonal antibody. In the trial, six healthy subjects were dosed with this therapeutic agent, and all six subjects rapidly suffered a life-threatening proinflammatory cytokine response. Subsequent analyses of the TGN1412 used in the study found no errors in formulation or administration, and a review of all preclinical studies indicated that the dose given in the human trial was far below the upper limit of safety as determined by studies in Cynomologous macaque (Cyno). The reason for the unexpected adverse events in the human trial was eventually determined to be caused by differences in antibody presentation and mode of action in Cyno v. human cells.
Here we compare methods of CD28 antibody immobilization in a cell-based assay, and the effects on the secretion of 22 cytokines as well as lymphocyte proliferation in peripheral blood mononuclear cells (PBMC). Cytokine secretion was analyzed via Luminex technology, and lymphocyte proliferation was assessed through BrdU incorporation into PBMC. Immobilization methods include direct binding onto tissue culture plates, direct binding on high bind plates, and binding through a protein G intermediate. We find dramatic differences in the secretion of several proinflammatory cytokines, most notably IL-6, MIP-1α, and TNFα, when antibody is prebound onto the assay plate rather than free in solution. For example, we find that MIP-1α is secreted at a level over 100-fold higher when αCD28 is bound onto the assay plate v. unbound. We also compare various binding methods of αCD28 and the effects on cytokine response and cell proliferation in both human and Cyno PBMC. Through these studies we offer a tool to help predict adverse immunological events in antibody therapeutics.

PS 1758 STREAMLINED PREDICTION OF COMPOUND EFFICACY AND SAFETY INDEX IN AN INFLAMMATION MODEL THROUGH MULTIPLEXING, QUANTITATIVE, CELL-BASED IMAGING AND CYTOKINE ARRAYS.

K. K. Opperman, E. Hommema, B. Webb and R. N. Ghosh. *Thermo Fisher Scientific, Rockford, IL.* Sponsor: A. Barchowski.

Ideally, assessment of compound toxicity should occur concurrently with assessment of its effectiveness and mechanism of action. Frequently, toxicity is detected only after significant time and effort has been spent on determining the mechanism and action of the compound in relation to the disease state. In this study, we have tested multiplexing, quantitative, cell-based imaging with cytokine arrays in an inflammation model for compound screening. Ten commercially available compounds were assessed in RAW 264.7 macrophages for anti-inflammatory activity. Cytokine production was measured by multiplexed cytokine antibody arrays and confirmed by ELISA. Both mechanism of action and toxicity were determined through quantitation of changes in target fluorescence by quantitative cell-based imaging assays. Minimal effort was required for transfer of cell culture supernatants to the antibody arrays or ELISA format, while cells were simultaneously stained for intracellular target changes or toxicity. In total, twelve cytokines, ten intracellular signaling targets, and six toxicity parameters were assayed. Compound EC50 values were determined for each intracellular target (phospho-p38, phospho-ERK, phospho-JNK, NF-κB, phospho-CREB, phospho-c-Jun, PKA, COX-2, iNOS, MnSOD), for cytokine inflammatory cytokine production (TNFα, IL-6), and for toxicity. Therapeutic safety windows were calculated for each compound. The results indicate that multiplexing the two assay platforms could successfully predict safety windows for each compound and differentiate relative toxicities from mechanisms of action. Quantitative cell-based imaging when combined with antibody cytokine arrays provides a powerful, streamlined approach for assessing anti-inflammatory compound activity, mechanism of action and toxicity, all with only two assay platforms.

PS 1759 IMMUNOTOXICITY OF EMISSION PARTICLES FROM FOSSIL- AND BIODIESEL-FUELED NON-ROAD DIESEL ENGINE.

M. Tapanainen[1, 2], P. I. Jalava[1, 2], R. O. Salonen[1], A. S. Pennanen[1], M. S. Happo[1, 2], K. Kuuspalo[2], M. Ihalainen[2], J. Jokiniemi[2] and M. Hirvonen[1, 2].
[1]National Public Health Institute, Kuopio, Finland and [2]University of Kuopio, Kuopio, Finland. Sponsor: M. Viluksela.

Immunotoxicity of fine particulate emissions of fossil diesel fuel (EN590), first generation biodiesel (rapeseed methyl ester, RME) and 2nd-generation renewable diesel fuel (hydrotreated vegetable oil, HVO) were investigated. Particulate samples were collected from diluted exhaust gas of a non-road Euro II IDI diesel engine, which was operated with and without a catalytic converter. During sample collection engine was employed according to previously chosen ISO 7178-4:1996 C1 test cycle modes. Mouse RAW264.7 macrophages were exposed for 24 hrs to four doses (15, 50, 150 and 300 μg/ml) of the emission particles. The production of cytokines (TNFα, MIP-2) was measured by ELISA immunoassay, and the intracellular formation of reactive oxygen species (ROS) as well as cytotoxicity (MTT, live gate, PI-exclusion, apoptosis and cell cycle) were analyzed by flow cytometric or spectrophotometric methods. Particulate mass emission was the largest with EN590, followed by RME and HVO. The catalytic converter decreased the emissions with all the fuels. All the exposures triggered cytokine production, cytotoxicity and formation of ROS in a dose-dependent manner in macrophages. The cytokine responses to the EN590 and HVO particles were slightly increased after catalyst treatment. PI-exclusion or MTT test did not reveal any major differences in cytotoxicity between the three diesel fuels with or without the catalytic converter. Before the catalytic converter the largest ROS production was measured after exposure to the HVO particles, followed by RME and EN590. The catalytic converter increased this response induced by the EN590 and HVO particles, but not that by

RME particles. Thus, the HVO emission particles without the catalyst treatment were the most potent inducers of ROS and cytokine production, but the overall effect was not regarded as the most harmful, due to the smallest emitted mass.

PS 1760 INHIBITION OF HUMAN DENDRITIC CELL ACTIVATION BY CIGARETTE SMOKE EXTRACT.

S. M. Castro, T. Ivanciuc, R. P. Garofalo and A. Guerrero-Plata. *Pediatrics, University of Texas Medical Branch, Galveston, TX.*

The innate immune system is the first line of host defense and recognizes pathogens via effector molecules, including type-I interferon (IFN-α/β) and recognition Toll-like receptors (TLRs). Plasmacytoid dendritic cells (pDC) and monocyte-derived DC (moDC) are potent producers of IFN in response to viruses and provide a critical link between the innate and adaptive immune responses. Exposure to second hand smoke (SHS) is associated with an increase in the frequency and severity of respiratory infections. However, the mechanisms by which SHS alters anti-viral immune responses have not fully characterized. In this project, we investigate the ability of pDC and moDC to respond to respiratory syncytial virus (RSV) or human metapneumovirus (hMPV) and Toll-like receptor (TLR) agonists in the presence of cigarette smoke extract (CSE). In viral infected pDC and moDC, CSE led to a significant dose-dependent decrease in IFN-α production, measured by ELISA. In viral infected pDC treatment with CSE (1%) also significantly decreased levels of IL-10 and IP-10, determined by Bio-Plex. Apoptosis or cell death were not responsible for the decreased production of cytokines since pDC viability was marginally affected by exposure to CSE. In contrast, CSE had no significant effect on the production of other cytokines and chemokines in viral infected moDC. The stimulation IFN-α prodcution in pDC and moDC by respective agonists TLR7 (Loxoribine) and TLR9 (ODN-CpG D19); TLR3 (ICLC) was significantly decreased in cells treated with CSE. Quantitative Real-Time PCR revealed that CSE also significantly decreased TLR7 and TLR9 gene expression in viral infected pDC. These findings provide evidence to support that cigarette smoke extract alters the immune capacity of pDC and moDC. Therefore, exposure to SHS may potentially exacerbate the severity of respiratory infections by impeding the innate ability DC to respond to viral pathogens.

PS 1761 TOXIC EFFECTS OF MERCURIC SULFIDE ON THE LIVER AND IMMUNE ORGANS IN MICE.

H. Son, S. Park, S. Lee, M. Kim and S. Kim. *Pharmacology, Kyungpook National University Medical school, Daegu, Korea, South.*

Mercuric sulfide (HgS) is a major component of cinnabar, which has been used as a sedative in Chinese mineral medicine for more than 2000 years. Because its toxicological effects are still unclear, we attempted to verify what are the specific toxic effects of HgS. ICR male mice were administered by gavage with HgS (0.02, 0.2, 2.0 g/kg/day) for 4 weeks. During the administration period, HgS-treated mice did not reveal overt signs of clinical toxicity. HgS had no significant effect on body weight, food consumption, water consumption, and various organ (liver, kidney, spleen, and thymus) weights. In spite of its insolubility, HgS was significantly absorbed by the gastrointestinal (GI) tract and then accumulated in the liver, kidney, spleen, thymus and brain in a dose-dependent manner. The dose range of HgS used did not cause hepatotoxicity as indicated by circulating alanine aminotransferase and aspartate aminotransferase levels. Circulating blood leukocytes were elevated in mice treated with the highest dose of HgS. Interestingly, HgS increased significantly both CD8+ T lymphocytes and double-positive CD4+/CD8+ lymphocyte populations in spleen in a dose-dependent manner. A dose of 0.2 g/kg/day of HgS increased CD4+ T lymphocytes, whereas decreased CD4+/CD8+ T lymphocytes in thymus. Our results demonstrate that insoluble HgS was absorbed by the GI tract, accumulated in spleen and thymus, and then could affect immune systems.
This work was supported by Brain Korea 21 Project in 2008.

PS 1762 LYMPHOCYTE IMMUNOPHENOTYPING AND RED BLOOD CELL ONTOGENY IN FETAL AND NON-VACCINATED AND KLH-IMMUNIZED INFANT CYNOMOLGUS MONKEYS.

T. L. Warren[1], N. Makori[1], J. Stewart[1], L. Brown[1], S. Oneda[1], R. Klein[1], R. Grant[1], R. Eyre[1], J. Klaassen[1], S. Meyer[1] and R. Nagata[2]. *[1]SNBL USA, Everett, WA and [2]Shin Nippon Biomedical Laboratories, Ltd., Kagoshima, Japan.*

Preclinical in vivo models for drug development are predictors of fetal outcomes after drug administration to pregnant mothers. Many drugs cross the placental barrier leading to potential embryo-fetal exposure. Developmental immunotoxicity is one of the possible outcomes of the embryo-fetal drug or metabolite exposure. The cynomolgus monkey (Macaca fascicularis) is a well characterized model for developmental toxicity. The aim of this study is to present the expression patterns of specific lymphocyte surface markers in fetuses and infants (non-vaccinated and KLH-immunized). Data on nucleated red blood cell to non-nucleated transition from Gestation Day (GD) 100 and 140 cord blood, and neonates (F1) is presented. On average, the relative percentage (when gated on lymphocytes) of CD3+ T cells is 74% at GD100, 77% at GD140, and 68% in infant (30 days old) compared to 64% in adult females. The percentage of CD20+ B cells is 17% at GD100 and GD140, and 25% in neonates (30 days old) compared to 27% in adult females. CD3+CD4+ T cells is 67% at GD100, 68% at GD140, and 52% in neonates (30 days old) compared to 34% in adult females. The relative percentage of CD3+CD8+ T cells is 11% at GD100, 15% at GD140, and 16% in neonates compared to 30% in adult females. The nucleated red blood cell (RBC) population accounts for approximately 150 cells per 103 non-nucleated RBCs at GD100, approximately 16 cells per 103 non-nucleated RBCs at GD140, and approximately 5 cells per 103 non-nucleated RBCs in neonates (30 days old). The percentage of CD71+ cells in peripheral blood in infants did not change significantly between blood samples obtained prior to KLH vaccinations and following KLH immunization and boosts. KLH immunization does not upregulate CD71 expression in lymphocytes in monkey infants in peripheral blood and lymphoid tissues.

PS 1763 ARSENIC PREDISPOSES SKIN KERATINOCYTES TO UV-INDUCED OXIDATIVE DNA DAMAGE YET ENHANCES THEIR SURVIVAL.

Y. Sun[1], C. Kojima[1], C. Chignell[2], R. Mason[2] and M. P. Waalkes[1]. *[1]ICS, LCC, NCI at NIEHS, Research Triangle Park, NC and [2]LP, NIEHS, Research Triangle Park, NC.*

Inorganic arsenic and ultraviolet (UV) irradiation are known human skin carcinogens that may act together as cocarcinogens. Oxidative DNA damage (ODD) is a possible mode of action in arsenic carcinogenesis although we find it only occurs in cells that bio-methylate the metalloid. However, oxidative damage is a hallmark of UV-induced epidermal carcinogenesis. We have developed a model of skin carcinogenesis using a human skin keratinocyte (HaCaT) cell line which has been malignantly transformed by arsenic (100 nM, 30 weeks) and is fully adapted to arsenic toxicity. Prior work indicated these cells (termed As-TM) may be resistant to UV-induced apoptosis but not UV-induced ODD, although the measurement of ODD used a technique prone to significant artifacts. Thus, in this study As-TM were acutely irradiated with UV (UVA, 25 J/cm^2), incubated for a further 18 hrs, harvested and subjected to flow cytometry for apoptosis, immuno-spin trapping method for ODD and gene expression analysis by RT-PCR. Elevated ODD was not observed in As-TM cells during the 30-weeks malignant transformation process with arsenic, likely because HaCaT cells poorly methylate arsenic. However, although acute UV irradiation markedly increased ODD in control cells, in As-TM cells UV-induced ODD was actually further increased by over 50%. Additionally, As-TM cells were resistant to apoptosis induced by UV compared to control despite the enhanced ODD seen with UV in these cells. Various oxidative stress responses were reduced in As-TM cells after UV compared to control, including expression of nuclear factor E2-related factor 2 (Nrf2) and several of its target genes, like heme oxygenase-1 (HO-1) and glutamate-cysteine ligase catalytic subunit (GCLC). Thus, the potential synergy between UV irradiation and arsenic for skin cancer could be due to arsenic adaptation and enhanced survival even in the face of enhanced UV-induced ODD.

PS 1764 ARSENITE AND HUMAN LUNG CELL CULTURES – GENOTOXICITY AND EFFECTS ON MRP-TRANSPORTERS.

F. Glahn, J. Wiese, A. Torky and H. Foth. *Environmental Toxicology, Martin Luther University, Halle / Saale, Germany.*

Chronic exposure to low doses of organic as well as inorganic arsenicals eventually leads to resistance mediated by different mechanisms. One of them being increased expression of multidrug resistance associated proteins (MRP). We investigated the effects of As(III) on human lung cell cultures using the tumor cell line H322 and normal human bronchial epithelial cells (NHBEC). To elucidate whether MRP-transporters protect lung cells from arsenite toxicity we used the MTT-assay to measure their viability in the presence or absence of the MRP-inhibitor MK571. H322 cells showed significantly increased sensitivity to As(III) when pre-treated with MK571 in 24h and 72h-experiments. We also analysed genotoxic effects of As(III) on H322 cells with the alkaline comet-assay. While As(III) (2.5 and 5 μM) alone did not lead to significant DNA-damage after 24h, cells pre-incubated with MK571 showed significantly increased olive tail moment (OTM) 135% and 155%, respectively. Five days of treatment with As(III) (5 μM) lead to significant DNA-damage (OTM 750% of control). Again, pre-treatment with MK571 in-

creased genotoxic effects of As(III); at 2.5 and 5 μM As(III) OTMs where increased 824% and 1000%, respectively. Additionally we investigated the influence of As(III) on the expression of different MRPs in NHBEC using real-time RT-PCR. Treatment of NHBEC from two different donors with 1 and 2.5 μM As(III) for 5 days lead to up-regulation of MRP3 (1.4 to 1.5 fold), MRP4 (1.6 to 2.1 fold) and MRP5 (1.6 to 2.3 fold). Interestingly additional 5 days with As(III) repressed MRP1, 3, 4 and 5 (0.4 to 0.5 fold) only in the cultures from donor II. Further 5d of As(III) down-regulated MRP3 (0.4 fold). Another 5d of As(III) increased MRP3 (2.2 fold). Our results demonstrate a contribution of MRP-transporter to the detoxification of As(III) in human lung cell cultures, as inhibition of MRPs increased their sensitivity to As(III). Primary cultures from different donors do not show uniform reactions upon As(III) treatment.

PS 1765 STABLE OVEREXPRESSION OF HUMAN MT-IIA GENE IN A HEART-DERIVED CELL LINE CONFERS OXIDATIVE PROTECTION.

W. Feng, W. Xue, Q. Liu, L. Cai and Y. Kang. *University of Louisville, Louisville, KY.*

Metallothionein (MT) is a low-molecular-mass cysteine-rich protein. Numerous studies have suggested that MT plays an important role in essential metal homeostasis and confers resistance of cells against heavy metal toxicity and oxidative stress. Previous studies using an animal model that overexpressing MT specifically in the heart have shown that MT protects heart against multiple insults. Albeit the protective function of MT has been attributed to its anti-oxidant properties, the precise mechanism remains elusive and needs to be studied using different strategies. Cultured cell systems are now considered indispensable powerful tools in studying the molecular and cellular mechanism. In present study, a stable MT-IIA over-expressing cardiac cell line was established, and its anti-oxidatant properties were evaluated. Rat heart-derived H9c2 cell line, which is immortalized cardiac fibroblast cell line and has been well characterized and widely used in culture owing to the ability to proliferate and differentiate, is stably transfected with a plasmid in which human MT-IIA gene was placed under control of the constitutively active β-actin promoter. The transfected cell line (H9c2MT) exhibited similar growth kinetics and morphology. Western blotting analysis showed that H9c2MT had a remarkably increased MT protein level compared with the parent cell line H9c2. Addition of 25 μM ZnSO4 had an undetectable effect on the induction of endogenous MT, but it likely stabilized MT protein that is expressed only in H9c2MT cells. H9c2MT cells showed marked reduction in ROS production when exposed to hydrogen peroxide or subjected to hypoxia/reoxygenation challenge, as evaluated by dihydroethidium staining. In addition, transfection of MT showed cellular resistance to cadmium toxicity. In summary, we have established a stable human MT-IIA overexpressing cardiac cell line; and this cell line showed a markedly increased oxidative protection and would be useful for dissection of the mechanisms of MT in the cardiac protection.

PS 1766 EFFECTS OF CHRONIC LOW DOSE ARSENIC EXPOSURE ON HORMONE-REGULATED GLOBAL GENE EXPRESSION IN NORMAL HUMAN LUNG FIBROBLASTS.

J. A. Gosse[1, 2, 4], E. R. Macari[1], C. D. Kozul[1, 2], T. H. Hampton[1, 2], M. Wungjiranirun[1], J. E. Bodwell[3, 2] and J. W. Hamilton[1, 2, 5]. *[1]Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH, [2]Center for Environmental Health Sciences, Dartmouth Medical School, Hanover, NH, [3]Physiology, Dartmouth Medical School, Lebanon, NH, [4]Biochemistry, Microbiology, and Molecular Biology, University of Maine, Orono, ME and [5]Bay Paul Center, Marine Biological Laboratory, Woods Hole, MA.*

Chronic exposure to arsenic (As) is associated with many diseases including cancer, cardiovascular disease, and developmental/reproductive disorders. As is a potent endocrine disruptor of transcriptional regulation by all five steroid receptors. Many of the As-associated toxic effects may result from this endocrine disruption. We have examined the global gene expression effects of chronic (5 weeks), low dose (20 ppb) As exposure prior to a short-term (8 hour) exposure to the synthetic glucocorticoid hormone dexamethasone (Dex) in normal, telomerase-immortalized, human lung fibroblasts (WHTBF-6 cells), using Affymetrix GeneChip U133 Plus 2.0 whole genome microarrays. We used R software packages in Bioconductor to perform RankProd analysis, followed by pathways analysis using Ingenuity software. Our results demonstrate As-induced endocrine disruption at the transcriptional level for glycoprotein hormones alpha subunit (CGA), a gene containing a negative glucocorticoid response element (GRE), as well as for other Dex-regulated genes. Chronic As exposure caused decreased expression of numerous putative tumor suppressor genes and altered expression of multiple cancer biomarkers. Affected pathways include NRF2-mediated oxidative stress response, Wnt/beta-catenin signaling, and cell cycle checkpoint regulation. Soft agar assays confirmed that these cells were not transformed by 5 or 10 weeks of 20 ppb As exposure, indicating that these gene expression changes precede, and may, therefore, contribute to As-induced transformation. This study demonstrates As's disruption of hormone-regulated gene expression and suggests molecular mechanisms underlying As's possible role as a co-carcinogen in normal human lung cells.

PS 1767 ARSENITE INDUCES APOPTOSIS OF HUMAN UMBILICAL VEIN ENDOTHELIAL CELLS THROUGH MITOCHONDRIAL PATHWAYS.

Y. Wei[1] and R. Li[2]. *[1]Department of Community Medicine, Mercer University School of Medicine, Macon, GA and [2]Key Laboratory of Pathobiology, Jilin University, Changchun, China.*

Background and Objective: Inorganic arsenic is widely distributed in nature and its contamination in drinking water remains a major public health problem. It was found that exposure to arsenic leads to degenerative peripheral vascular diseases. To clarify the molecular mechanisms through which arsenic causes injuries of blood vessel, we analyzed effects of sodium arsenite on the apoptosis of human umbilical vein endothelial cells (HUVECs), mitochondria membrane potential (MMP), intracellular reactive oxygen species (ROS), and the expression of the related genes. Methods: HUVECs apoptosis, MMP and intracellular ROS were determined by flow cytometry, after incubation with Annexin V-PI, rhodamine 123 (RH123), and DCFH-DA, respectively. Real time quantitative RT-PCR was used to analyze gene expression. Results: HUVECs apoptosis increases and MMP decreases following arsenite treatment (5 - 40 μM) in a dose-dependent manner. Intracellular ROS showed 2 phase alterations: a slight decrease with low levels of arsenite (5 and 10 μM) treatment; but a sharp increase at higher concentrations (≥ 20 μM). The expression of superoxide dismutase 2 (SOD2) and NAD(P)H quinone oxidoreductase 1 (NQO1) genes increased strikingly when cells were treated with as low as 5 μM of sodium arsenite. Both SOD2 and NQO1 play very important roles in the reduction of intracellular ROS with their functions occurred in the mitochondria and in the cytoplasm, respectively. Conclusion: The decreases of MMP and the alteration of intracellular ROS level caused by arsenite and the resulted cell apoptosis could play very important roles in the injuries of blood vessel in arsenism. The decrease of intracellular ROS and the increase of SOD2 and NQO1 expressions, when HUVECs were treated with a low concentration (5 μM) of sodium arsenite, suggest a role of the two enzymes in protecting cells from injuries by exposure to arsenite.

PS 1768 DISTINCT ROLES OF THE MAPKS IN Cr(VI) TOXICITY.

L. Chen[1], J. L. Ovesen[2], A. Puga[1, 2] and Y. Xia[1]. *[1]Environmental Health, University of Cincinnati, Cincinnati, OH and [2]Interdisciplinary Graduate Program in Cancer and Cell Biology, University of Cincinnati, Cincinnati, OH.*

Chromium (Cr) is widely distributed in the environment and used in various industrial processes. Exposure to Cr, especially to Cr(VI), is associated with higher risk of diseases such as asthma, skin ulcerations, developmental defects and cancer of the respiratory tract. At the cellular level, Cr(VI) causes DNA instability, oxidative stress and apoptosis, which are attributed, at least in part, to the activation of signal transduction pathways. It has been reported that Cr(VI) induces the activation of mitogen-activated protein kinases (MAPKs), including c-Jun N-terminal kinase (JNK), p38 and the extracellular signal-regulated kinase (ERK); however, the roles of each MAPK in Cr(VI) toxicity have not been well characterized. We show that Cr(VI) activates all three MAPKs in HaCaT human keratinocytes and mouse embryonic stem (ES) cells. Activation of MAPKs depends on their upstream MAPK kinases (MAP2Ks), of which MAP2K4 and MAP2K7 are responsible for JNK activation. We find ablation of MAP2K7 in ES cells prevents JNK activation by Cr(VI), while ablation of MAP2K4 prevents both JNK and p38 activation. Using specific MAPK inhibitors and MAP2K4- and MAP2K7-deficient ES cells, we show that JNK decreases Cr(VI) cytotoxicity, p38 potentiates it and ERK has no effect on it. In contrast to its role in preventing Cr(VI) cytotoxicity, the JNK pathway appears to contribute to Cr(VI) developmental toxicity. During embryoid body (EB) differentiation, Cr(VI), at concentrations as low as 0.1 μM, causes 90% inhibition of beating cardiomyocyte development in WT EBs, but only 50% inhibition in Map2k7 (-/-) EBs. Consistent with this observation, Cr(VI) significantly reduces the expression of cardiomyocyte-specific markers, such as MhcA and MhcB, in the differentiating wild type EB, but it does not cause such reduction in the Map2k7(-/-) EB. Our data show that Cr(VI) induces the activation of JNK, p38 and ERK. JNK prevents and p38 potentiates cytotoxicity, whereas MAP2K7-mediated JNK pathways may contribute to Cr(VI) developmental toxicity.

PS 1769 MICROTUBULES AS A MAJOR CELLULAR TARGET FOR ARSENIC TOXICITY.

W. Li, Y. Zhao and P. Toselli. *Biochemistry, Boston University School of Medicine, Boston, MA.*

Arsenic (As) is an abundant element of the earth's crust. Its compounds are widely used in industries, agricultures, and medicines. Trivalent As (As^{3+}), the major chemical form in contaminated drinking water, targets protein sulfhydryls (-SH) affecting on the health of an estimated 700 million people around the world. Prolonged exposure to As in drinking water induced cell injuries and malignancies in multiple organs. Microtubules (MT) are a major cytoskeletal element critical for regulation of cell division. The principal protein of MT is a heterodimer consisting of tightly linked α and β tubulins, which polymerize into long, hollow, cylindrical filaments in the cytoplasm. To understand mechanisms for cellular toxicity of As, we examined As^{3+} effects on MT assembly *in vitro*, cellular MT organization, and levels of free and polymer tubulins as well as MT associated proteins (MAPs) in the rat lung fibroblast model (RFL6). Exposure of RFL6 cells to sodium m-arsenite (As^{3+}) at 20 μM induced disassembly of MT. Western blot analysis indicated that cells exposed to As^{3+} exhibited a dose-dependent decrease in polymer MT and increase in the free tubulin pool, consistent with morphological loss of MT in these cells as revealed by fluorescent microscopy. As^{3+} (50-200 μM) also inhibited MT polymerization *in vitro* as monitored by turbidity and EM examinations. Dithiothreitol (DTT) (1 mM) fully abolished As^{3+} inhibitory effects on MT assembly *in vitro*. As^{3+} decreased the binding of [^{3}H] N-ethylmaleimide (NEM), an -SH group-directed reagent, to tubulin suggesting As^{3+} action upon tubulin through –SH groups. [^{35}S] Methionine labeling of cell MT proteins and 2D-gel analysis further showed that MAPs 50/6.6, 53/6.5, 60/6.4, 62/6.3 and 86/6.5 (MW in kDa/isoelectric point) were markedly reduced leading to MT instability in cells treated with As^{3+}. These results strongly support MT as a major cellular target for As insult (Supported by NIH grant R01-ES11340 and Philip Morris ERP).

PS 1770 MECHANISM OF ARSENATE REDUCTION BY PHOSPHOROLYTIC ENZYMES. II. REDUCTION OF THE ARSENYLATED PRODUCTS BY THIOLS.

Z. Gregus[1], B. Nemeti[1] and G. Roos[2]. [1]*Univ of Pecs, Pecs, Hungary and* [2]*Vrije Universiteit Brussel, Brussels, Belgium.*

Enzymes catalyzing the phosphorolytic (or arsenolytic) cleavage of their substrates reduce arsenate (AsV) to the more toxic arsenite (AsIII) in a manner dependent on the arsenolytic reaction and presence of a thiol compound, such as glutathione or DTT. We have shown this for purine nucleoside phosphorylase (PNP), glyceraldehyde-3-phosphate dehydrogenase (GAPDH), glycogen phosphorylase (GP), and phosphotransacetylase (PTA; poster of Németi and Gregus). We now used these enzymes to explore the mechanism whereby they mediate AsV reduction. It is known that PNP cleaves inosine with AsV to form ribose-1-AsV (R1AsV). In presence of inosine, AsV and DTT, PNP mediates AsIII formation, which is completely blocked by BCX1777, a PNP inhibitor. In this study, we incubated PNP first with inosine and AsV, allowing the arsenolytic reaction to run for 2 min, then stopped this reaction with BCX1777 and promptly added DTT to continue the incubation for 2 more min in presence of the thiol. Despite inhibition of PNP, large amount of AsIII was formed in these incubations, indicating that PNP does not reduce AsV directly but forms a product (i.e., R1AsV) that is reduced to AsIII by DTT. Such studies with the other arsenolytic enzymes yielded similar results. Various thiols that differentially supported AsV reduction when present during PNP-catalyzed arsenolysis (DTT > DMPS > mercaptoethanol > DMSA > GSH) similarly supported AsV reduction when added only after a transient PNP-catalyzed arsenolysis, which preformed R1AsV. Experiments with progressively delayed addition of DTT after BCX1777 indicated that R1AsV is short-lived (half-life ~ 4 min). In conclusion, phosphorolytic enzymes, such as PNP, GAPDH, GP, and PTA, promote thiol-dependent AsV reduction because they convert AsV into arsenylated products reducible by thiols more readily than AsV. In support of this view, reactivity studies using conceptual density functional theory reactivity descriptors (local softness, electrophilicity, nucleofugality) indicate that reduction by DTT of R1AsV is favored over AsV.

PS 1771 MECHANISM OF ARSENATE REDUCTION BY PHOSPHOROLYTIC ENZYMES. I. THE ROLE OF ARSENOLYSIS.

B. Nemeti and Z. Gregus. *Univ of Pecs, Pecs, Hungary.*

The environmentally prevalent arsenate (AsV) is reduced in the body to the more toxic arsenite (AsIII). We have shown that three mammalian phosphorolytic enzymes, i.e., purine nucleoside phosphorylase (PNP), glyceraldehyde-3-phosphate dehydrogenase (GAPDH), and glycogen phosphorylase mediate thiol-dependent AsV reduction with unknown mechanism. In presence of AsV instead of phosphate, these enzymes catalyze arsenolysis of their substrates into an arsenylated product. Therefore, we tested yet other phosphorolytic-arsenolytic enzymes and the role of arsenolysis in AsV reduction. It was found that two structurally different bacterial phosphotransacetylases (PTAs) that arsenolytically cleave acetyl-CoA into acetyl-AsV and CoA reduce AsV to AsIII in presence of acetyl-CoA and glutathione (GSH) or other thiols. Interestingly, mammalian GAPDH, like PTA, also forms acetyl-AsV by catalyzing arsenolysis of acetyl-phosphate, a non-physiological reaction. When GAPDH was incubated with AsV and acetyl-phosphate in presence of GSH or other thiols, AsIII was produced. Importantly, AsV reduction by either acetyl-AsV-forming enzyme (i.e., PTAs and GAPDH) depended on the arsenolysis and thiol supply, and exhibited similar responsiveness to various thiols. Arsenolysis of inosine into ribose-1-AsV and hypoxanthine (HX) is catalyzed by both bacterial and mammalian PNP. Although these are structurally diverse enzymes, both mediated AsV reduction with similar responsiveness to different thiols. We examined the effect of five thiol compounds on the stoichiometry of the PNP-catalyzed arsenolysis of inosine (measured by HX formation) and the coupled AsV reduction (measured by AsIII formation). While HX formation was not influenced by the thiols, AsIII formation was increased dissimilarly by various thiols. Collectively, these findings suggest that neither the arsenolytic enzymes nor their arsenolytic reactions are directly involved in the arsenolytic enzyme-mediated thiol-supported AsV reduction, and raise the notion that the arsenylated products of these enzymes become reduced by thiols. The poster of Gregus and Németi supports this hypothesis.

PS 1772 ARSENIC ALTERS THE DIFFERENTIATION OF MOUSE MUSCLE CELLS THROUGH THE REPRESSION OF TRANSCRIPTION FACTORS.

A. A. Steffens[1] and L. J. Bain[2, 1]. [1]*Environmental Toxicology Program, Clemson University, Pendleton, SC and* [2]*Biological Sciences, Clemson University, Clemson, SC.*

Arsenic is a contaminant of drinking water in many parts of the world. A number of epidemiological studies have correlated arsenic exposure with cancer, skin diseases, cardiovascular diseases, and adverse developmental outcomes such as stillbirths, spontaneous abortions, neonatal mortality, low birth weight, and delays in the use of musculature. Previous studies using a model fish species termed mummichogs have shown that offspring exposed to 230ppb arsenic during gametogenesis have an upregulation of genes involved in the musculature, such as myosin light chain 2, tropomyosin, and parvalbumin. The current study used C2C12 mouse myoblast cells to examine whether low concentrations of arsenic could alter their differentiation into myotubes. Expression of the muscle-specific transcription factor myogenin, along with the expression of myosin light chain 2, tropomyosin, and DNA methyltransferases (DNMT) 1, 3a, and 3b were investigated using real time PCR and immunoblotting. Exposing C2C12 cells to 20nM arsenic delayed the differentiation process, which was correlated to a time-dependant decrease in myogenin expression in the arsenic exposed cells, as compared to the control cells. Arsenic reduced myogenin expression by 1.4-fold on day 2, by 2.4-fold on day 3, and by 3.2-fold on day four of differentiation. However, this did not result in changes in tropomyosin expression in the C2C12 cells nor was it caused by altered DMT1 expression. Additional mechanisms for the repression of myogenin by arsenic are being investigated.

PS 1773 EPIGENETIC CONTROL OF MT-3 EXPRESSION IN NORMAL BREAST AND BLADDER CELL LINES.

S. Somji, S. H. Garrett, M. Sens and D. A. Sens. *Pathology, University of North Dakota, Grand Forks, ND.*

Metallothioneins (MT) are cysteine rich intracellular proteins that bind transition metals with high affinity and have a wide pattern of tissue distribution However the third isoform of metallothionein, MT-3 is shown to have a restricted pattern of tissue distribution with expression confined to the neural tissue. Previous work done by this laboratory has shown that MT-3 is not expressed in the normal bladder or normal breast epithelial cells but is over-expressed in bladder and breast cancer with levels correlating to the type and grade of tumor. This lack of expression of MT-3 in normal tissue indicates that there must be a transcriptional induction event in the MT-3 promoter that occurs at some point in the tumorigenic process. Attempts to study MT-3 over expression have been plagued with difficulties due to the inability to express this gene at the protein level in many non-tumorigenic cells and the difficulty of modeling transcriptional regulation with transient transfection-reporter systems. This suggested that the mode of transcriptional control of MT-3 during the formation of cancer may be at the level chromatin structure regulation. To test this hypothesis normal bladder UROtsa cells and breast MCF-10 cells were exposed to the common histone deacetylation inhibitor MS-275 or the commonly utilized CpG island demethylating agent 5-aza-cytidine (AZC). Growth of these cells for several days (estimated three cell divisions) in the presence of 3 μM MS-275 or 1.5

μM AZC resulted in the expression of MT-3 mRNA as assessed by real-time PCR. This treatment also allowed for the further increase in expression elicited by 24 hr exposure to 100 μM zinc. These results indicate that the over expression of MT-3 during bladder and breast cancer involve chromatin structural changes that may involve changes in histone modifications and/or DNA methylation patterns.

PS 1774 EFFECT OF EGF AND INSULIN ON THE EXPRESSION OF KERATIN 6 IN ARSENITE AND CADMIUM TRANSFORMED UROTSA CELL LINES.

L. Cao, S. H. Garrett, D. A. Sens, M. Sens, X. Zhou and S. Somji. *Pathology, University of North Dakota, Grand Forks, ND.*

Arsenite (As^{+3}) and cadmium (Cd^{+2}) are carcinogens that have been implicated in the development of bladder cancer. Previous work from this laboratory has shown that normal urothelial cells (UROtsa) do not express keratin 6, however malignant transformation of these cells by the heavy metals As^{+3} and Cd^{+2} results in an over expression of keratin 6 mRNA as well as protein. Tumor heterotransplants generated from these cells also express keratin 6 as determined by immuno-histochemistry. Growth factor deletion and addition studies in the normal UROtsa cell line indicated that the level of keratin 6a expression was regulated by the presence of both insulin and epidermal growth factor (EGF). The purpose of this study was to determine if EGF and insulin had an effect on the expression levels of keratin 6 in UROtsa cells malignantly transformed by As^{+3} and Cd^{+2}. For this purpose six independent As^{+3} transformed urothelial cell lines and seven independent Cd^{+2} transformed cell lines were exposed to EGF, insulin or EGF and insulin for 24 hr. The level of keratin 6 mRNA expression was determined by real time PCR and protein levels were measured by western analysis. The data obtained indicates that the process of transformation of the urothelial cells by As^{+3} and Cd^{+2} induces the expression of keratin 6 in some of the transformed cell lines. Furthermore exposure to EGF, insulin or EGF plus insulin only had a modest effect on the expression of keratin 6 in some of the transformed cell lines whereas all the tumor heterotransplants generated from these transformed cell lines over expressed keratin 6. This suggests that the in-vivo environment may be necessary for the up regulation of keratin 6.

PS 1775 THE ROLE OF CYTOKINE SIGNALING IN ARSENIC INDUCED DIABETES.

I. Druwe, J. J. Sollome and R. R. Vaillancourt. *Department of Pharmacology & Toxicology, The University of Arizona, Tucson, AZ.*

Diabetes mellitus is a metabolic syndrome characterized by inappropriate production of insulin or the inability of cells to respond to insulin. Insulin is the principal hormone involved in lowering blood glucose and functions by suppressing gluconeogenesis and glycogenolysis in the liver and by stimulating the uptake of glucose into skeletal muscle and adipocytes. Interestingly, recent epidemiological studies both in the USA and abroad have linked chronic ingestion of low levels of arsenic, an environmental toxicant, to the onset of diabetes mellitus. Arsenic-induced diabetes in mice is characterized by insulin resistance [insensitivity] and not a deficiency in insulin secretion. In a previous in vivo study, we demonstrated that chronic administration of 10 ppb (0.13 μM) NaAsO3 in drinking water resulted in dysregulation of glucose metabolism. The purpose of the current study was to determine if arsenic could induce cytokine production and contribute to insulin resistance and hyperglycemia in our model system. Cytokine array analysis of sv40 MES 13 cells treated with 50 ppb (0.67 μM) NaAsO3 resulted in an induction of a cytokine response in treated cells versus control. Upregulation of various interleukins included IL-2, IL-4, and IL-6. IL-6 is known to be involved in the inflammatory response and has also been implicated in atypic insulin signaling. Studies are on-going to investigate the role of IL-6 and other potential cytokines on the deactivation of the insulin receptor. This work was supported by ES004940.

PS 1776 DEPLETED URANIUM INDUCED OXIDATIVE STRESS ACTIVATES DNA REPAIR IN HUMAN BRONCHIAL EPITHELIAL CELLS.

M. Yellowhair[1], L. A. Henricksen[2], A. Hossain[2], K. Dixon[2, 3] and C. R. Lantz[3]. *[1]Department of Pharmacology & Toxicology, The University of Arizona, Tucson, AZ, [2]Department of Molecular & Cellular Biology, The University of Arizona, Tucson, AZ and [3]Department of Cell Biology & Anatomy, The University of Arizona, Tucson, AZ.*

Cellular oxidative stress has been implicated in the genotoxicity of many heavy metals. The aim of this study is to evaluate the toxicity of depleted uranium (DU) in its soluble and insoluble forms in human bronchial epithelial cells (16HBE14o-). 16HBE14o- cells were exposed to 30 ppb of soluble depleted uranium (uranyl acetate - UA) and insoluble depleted uranium (uranium trioxide - UO3) for 2 – 24 hr. Oxidative stress was assessed in vitro by 5(6)-carboxy-2',7'-dichlorofluorescein diacetate (H2DCFDA) staining and visualized by live cell fluorescent microscopy. DNA damage response was assessed in vitro via Western immunoblotting to determine phosphorylation of histone H2AX and RPA levels. Results indicate that 16HBE14o- cells treated with UA and UO3 induced oxidative stress compared to untreated cells at 3 – 4 hr time points. 16HBE14o- cells treated with UA and UO3 induced phosphorylation of histone H2AX. These results are consistent with previous studies that indicate DU induces DNA damage via strand breaks and uranium-DNA adducts in treated cells. Interestingly, there was no increase in RPA phosphorylation levels of DU treated cells compared to untreated cells. These results suggest that: (1) cellular oxidative stress may be a pathway of particulate DU genotoxicity, and (2) induced DNA damage by DU may activate base excision repair in vitro. We are currently examining additional DNA repair targets to better understand the DNA repair pathway(s) stimulated by exposure to DU.

PS 1777 ARSENIC SYNERGISTICALLY INCREASES ZINC CHROMATE-INDUCED ANEUPLOIDY AND SPINDLE ASSEMBLY CHECKPOINT BYPASS IN HUMAN LUNG CELLS.

A. Holmes[1, 2], D. Buehler[1, 2], J. Young[1, 2], S. S. Wise[1, 2], A. Jeevaragen[3], W. Wallace[3], D. Hammond[3] and J. P. Wise[1, 2, 4]. *[1]Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME, [2]Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME, [3]NASA Johnson Space Center, Houston, TX and [4]Department of Applied Medical Science, University of Southern Maine, Portland, ME.*

Hexavalent chromium (Cr(VI)) and arsenic are dangerous environmental pollutants, because they are known human lung carcinogens and exposure is widespread. Since the potential for co-exposure to Cr(VI) and arsenic is high, it is important to understand the mechanisms involved in its carcinogenic potential and their potential interactions. Previous studies show that chronic exposure to Cr(VI) alone induces chromosome instability. Therefore, the objective of this study was to determine if arsenic can potentiate Cr(VI)-induced chromosome instability. We investigated the effects of arsenic on zinc chromate-induced cytotoxicity and found that co-exposure to arsenic and zinc chromate induced a less than additive increase in cytotoxicity after a 120 h exposure. However, chronic co-exposure to arsenic and zinc chromate induced an additive increase in chromosome damage and a synergistic increase in aneuploidy and spindle assembly checkpoint bypass. Co-exposure to arsenic and zinc chromate for 120 h specifically increased the percentage of hyperdiploid metaphases. For example, exposure to arsenic and zinc chromate alone induced 2 and 7% hyperdiploid metaphases while co-exposure induced 22.5% hyperdiploid metaphases. In addition, chronic exposure to arsenic or zinc chromate alone induced 7 and 12% of cells with evidence of spindle assembly checkpoint bypass, but co-exposure to zinc chromate and arsenic induced 65% of cells with evidence of spindle assembly checkpoint bypass. Therefore, arsenic synergistically increases zinc chromate-induced aneuploidy and spindle assembly checkpoint bypass.

PS 1778 LUNAR DUST AND ITS COMPONENTS ARE CYTOTOXIC TO HUMAN LUNG CELLS.

J. L. Young[1, 2, 3], J. P. Wise[1, 2], J. Wise[1, 2], A. Jeevaragen[4], W. Wallace[4], D. Hammond[4], T. Shehata[5] and J. P. Wise[1, 2, 3]. *[1]Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME, [2]Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME, [3]Department of Applied Medical Science, University of Southern Maine, Portland, ME, [4]NASA Johnson Space Center, Houston, TX and [5]Maine Space Grant Consortium, Augusta, ME.*

NASA plans to develop a permanent manned space station on the Moon with the intent of exploring and colonizing its surface, which is covered in lunar dust. Currently the potential toxic effects of the dust are poorly understood and need to be determined in order to safely establish the moon base. One approach is to establish exposure limits for lunar dust by comparison with toxic particles with established occupational health standards. We used NASA lunar dust simulant JSC-1AVF to test the cytotoxicity of lunar dust on human bronchial epithelial cells (HBEC-2) and human lung fibroblasts (WHTBF-6). We compared this toxicity to the cytotoxicity of titanium dioxide and silica. In HBEC-2 cells, a 24 h exposure to JSC-1AVF induced a concentration-dependent decrease in relative survival from 89 to 46 percent after exposure to 200 $\mu g/cm^2$ and 400 $\mu g/cm^2$ JSC-1AVF, respectively. Silica was more cytotoxic to HBEC-2 cells than JSC-1AVF, while titanium dioxide was not cytotoxic at the doses considered. JSC-1AVF was also cytotoxic to

WHTBF-6 cells with 50 μg/cm^2 and 200 μg/cm^2 inducing 54 and 8 percent relative survival, respectively. However, in these cells both silica and titanium were less cytotoxic than the JSC-1AVF. These data indicate that lunar dust may be more toxic to fibroblasts than epithelial cells. Furthermore, while occupational health standards for silica may be protective for epithelial cells, they may not sufficiently protect lung fibroblasts. Future studies will include looking at other occupationally encountered dusts as possible standards. This work was supported by NASA EPSCoR grant through the Maine Space Grant Consortium (JPW), the Graduate School of Biomedical Sciences (JLY) and the Maine Center for Toxicology and Environmental Health.

PS 1779 DEFINING THE DURATION OF CHRONIC, LOW-LEVEL MONOMETHYLARSONOUS ACID EXPOSURE REQUIRED TO INDUCE THE MALIGNANT TRANSFORMATION OF UROTSA CELLS.

S. M. Wnek, T. J. Jensen, M. K. Medeiros and A. J. Gandolfi. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

Arsenic is a known human bladder carcinogen; however, the exact molecular mechanisms underlying arsenical-induced bladder carcinogenesis are unknown. The human bladder urothelial cell line, UROtsa, has been shown to be malignantly transformed following low-level exposure to both arsenite [AsIII] and monomethylarsonous acid [MMAIII]. Previous research has demonstrated that continuous exposure to 50 nM MMAIII for 52 wk resulted in the malignant transformation of UROtsa cells. Transformation was demonstrated by the ability of these cells to grow in soft agar at 24 wk, and the ability to form tumors in SCID mice at 52 wk. In order to focus research efforts on the biological changes occurring to arsenic-exposed UROtsa cells prior to malignant transformation, the goal of this research was to evaluate the minimum duration of 50 nM MMAIII exposure necessary to induce transformation of UROtsa cells. UROtsa cells were cultured in the presence/absence of 50 nM MMAIII, and the following time points were assessed for colony growth in soft agar: 12, 16, 20, 24, and 52 wk in the presence of MMAIII; and 12, 16, and 20 wk exposure to MMAIII carried out to 24 wk in the absence of MMAIII exposure. Cellular transformation assessed through anchorage-independent growth demonstrated that UROtsa cells exposed to MMAIII for 12 wk begin to form colonies in soft agar. To further substantiate that transformation occurs prior to 52 weeks MMAIII exposure, UROtsa cells were tested for the ability to form tumors in SCID mice. Tumorigenicity in SCID mice was observed after UROtsa cells were exposed to 50 nM MMAIII for 24 wk followed by 24 wk in the absence of MMAIII exposure. This data provides evidence that MMAIII is capable of transforming UROtsa cells prior to 24 wk exposure, and validates future mechanistic studies focused on the biological changes occurring during these critical times points, which result in arsenic-induced malignant transformation.

PS 1780 PGE2 FACILITATES HIF-1α SIGNALING IN HUMAN LUNG FIBROBLASTS TO AMPLIFY NI- AND VANADIUM-INDUCED VEGF AND CXCL8 RELEASE.

K. A. Brant and J. P. Fabisiak. *Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Air particulate matter pollution (PM) stimulates inflammation of the lower airways, linking PM exposure to numerous lung diseases including fibrosis and cancer. Recent evidence shows that the transcription factor HIF-1α participates in various inflammatory-like processes and may contribute to the pathogenesis of pulmonary fibrotic disorders. It is widely considered that in the lung, the extent of inflammatory responses is limited by Prostaglandin E2 (PGE2). However, studies have indicated that fibrotic lung fibroblasts may lose PGE2 responsiveness. The purpose of this study was to examine the role of HIF-1α in mediating the release of pro-fibrotic and pro-inflammatory factors from human lung fibroblasts (HLF) in response to metals commonly found in PM and how this pathway may be altered by PGE2. HLF were stimulated with $NiSO_4$ or $VOSO_4$ in the presence or absence of 100 nM PGE2 for 48 h. Following exposure, cells were harvested for protein and conditioned medium was collected for ELISA analysis of VEGF and CXCL8. $NiSO_4$ and $VOSO_4$ both stimulated HIF-1α protein expression in HLF in a concentration-dependent manner. Binding of HIF-1α to the HRE was also induced following exposure to $NiSO_4$ and $VOSO_4$, indicating the HIF-1α to be transcriptionally active. Although PGE2 alone was without effect, PGE2 enhanced the induction of HIF-1α protein observed with metal exposure. Moreover, PGE2 synergized with $NiSO_4$ and $VOSO_4$ to release VEGF and CXCL8 from HLF. Transient transfection of HLF with HIF-1α siRNA attenuated both the stabilization of HIF-1α as well as VEGF and CXCL8 release by $NiSO_4$ and $VOSO_4$ alone or with PGE2 compared with cells transfected with a non-targeting siRNA. In conclusion, these data highlight a novel role for HIF-1α in mediating chemical-induced alterations in PGE2 responses that depart from its typical anti-inflammatory (inhibitory) role, imparting a susceptibility to fibrotic changes and the development of a pro-angiogenic environment in the lung. Supported by RO1-ES011986 and F32ES015966.

PS 1781 LOW DOSE ARSENIC EXPOSURE POTENTIATES A PRO-ATHEROGENIC PHENOTYPE IN MACROPHAGES AND LIVER.

K. K. Mann[1], A. M. Padovani[1], W. H. Miller[1], A. Straub[2] and A. Barchowsky[2]. *[1]Lady Davis Institute for Medical Research, McGill University, Montreal, QC, Canada and [2]Occupational and Environmental Health, University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA.*

Arsenic exposure increases risk of cardiovascular disease, in particular atherosclerosis. Atherosclerosis develops, in part, due to dysregulated cholesterol levels in macrophages and other cell types, resulting in localized vascular inflammation and monocyte adhesion. We have previously described that μM concentrations of arsenic inhibit the transcriptional activation of the liver X receptor (LXR), which controls genes involved in reverse cholesterol efflux from macrophages. Here, we present evidence that low arsenic levels (at or below maximal EPA limits for drinking water) potentiate a pro-atherogenic environment both in vitro and in vivo. Macrophages cultured in low dose arsenic (50 nM arsenic trioxide = 20 ppb arsenic) exhibited a decreased response to oxysterol challenge after 1 week, as measured by induction of the LXR target genes ABCA1 and SREBP-1c, compared to macrophages cultured in media not supplemented with arsenic. This phenotype persisted throughout the 25 weeks of exposure to low level arsenic. In addition, LXR target protein expression decreased in C57BL/6 mice given 10-100 ppb arsenic in the drinking water for 5 weeks as compared to controls. While arsenic inhibited LXR, it potentiated the induction of inflammatory molecules by LPS, such as iNOS and Cox-2. Arsenic also enhances LPS induction of IL-1β, as well as monocyte adhesion to VCAM-1 coated plates at doses as low as 2 ppb. Together, these data suggest that prolonged exposure to low arsenic levels can alter nuclear receptor function, increase inflammation, and increase vascular adhesion of mononuclear cells, in a manner that can increase susceptibility to atherosclerosis. Supported by the CIHR (WHM) and R01 ES10638 (AB).

PS 1782 STAT1 IS ESSENTIAL FOR CHROMIUM SILENCING OF NICKEL-INDUCED VEGF EXPRESSION IN HUMAN AIRWAY EPITHELIAL CELLS.

A. A. Nemec and A. Barchowsky. *Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Hexavalent chromium (Cr(VI)) promotes lung injury and pulmonary diseases through poorly defined mechanisms that often involve silencing of inducible protective genes. The current study investigated the hypothesis that Cr(VI) actively signals through a signal transducer and activator of transcription 1 (STAT1)-dependent pathway to silence nickel (Ni)-induced expression of vascular endothelial cell growth factor (VEGF), an important mediator of lung injury and repair. In human bronchial airway epithelial (BEAS-2B) cells, Ni induced VEGF transcription by stimulating a complex Erk signaling cascade that involved increased hypoxia-induced factor-1α (HIF) stabilization and DNA binding, as well as a Src kinase-activated cascade involving Sp1 transactivation. Exposing the cells to Cr(VI) prior to the addition of Ni silenced Ni-induced VEGF transcript levels. During this exposure, Cr(VI) also decreased Ni-stimulated Erk phosphorylation, HIF stabilization, and the induction of a hypoxia response element-driven reporter construct. We previously demonstrated that Cr(VI) stimulated STAT1 which has been implicated as a negative regulator of VEGF expression. Therefore, we tested the effect of Cr(VI) on VEGF expression in BEAS-2B cells stably expressing siRNA that eliminated STAT1. In the absence of STAT1, Cr(VI) increased VEGF transcript levels and did not block Ni-stabilized HIF protein levels. In addition, Cr(VI) and Ni co-exposures positively interacted to further increase VEGF transcripts. This study demonstrates that the different signaling pathways stimulated by metals interact to influence transcriptional regulation of adaptive responses in airway cell injury and repair. In addition, the data implicate STAT1 as an essential mediator of Cr(VI)-stimulated gene silencing and suggest that cells lacking STAT1, such as many tumor cell lines, have opposite responses to Cr(VI) relative to normal cells. *Supported by NIEHS R01ES10638.*

PS 1783 HEXAVALENT CHROMIUM IS MORE CLASTOGENIC TO NORTHERN RIGHT WHALE CELLS THAN HUMAN CELLS.

T. L. Chen[1, 2, 3], S. S. Wise[1, 2, 3], F. Shaffiey[1, 2], H. Xie[1, 2, 3], A. L. Holmes[1, 2, 3], S. D. Kraus[4] and J. P. Wise[1, 2, 3]. *[1]Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME, [2]Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME, [3]Applied Medical Sciences, University of Southern Maine, Portland, ME and [4]Edgerton Research Laboratory, New England Aquarium, Boston, MA.*

It has been suggested that longer-lived species have better DNA repair than shorter-lived species. Some whales, such as the Northern right whale are thought to have much longer lifespans than humans suggesting that these animals may have better

DNA repair than humans. To test our hypothesis we compared the genotoxic effects of hexavalent chromium, a well known human carcinogen, in Northern right whale and human cells. Our results show that at the same intracellular concentration, hexavalent chromium induces less chromosome damage and in whale cells compared to human cells after a 24 h exposure. For example, an intracellular chromium level of 250 μM, damaged 43 chromosomes in human cells compared to only 26 in the whale cells. We considered the possibility that this damage was due to Cr(VI)-induced apoptosis, but found little apoptotic cell death with these treatments. These data are consistent with a hypothesis that whales may have better DNA repair than humans. Future experiments will consider DNA double strand breaks and DNA repair. This work was supported by Grant number NA03NMF4720478 from the United States Department of Commerce, NOAA (J.P.W.), NIEHS grant ES10838 (J.P.W.) and the Maine Center for Toxicology and Environmental Health.

PS 1784 PERMEATION OF ARSANILATE AND ARSACETIN IN CACO-2 CELLS IS ADEQUATE TO STIMULATE CELL PROLIFERATION.

G. S. Bayse[1], L. P. Hammonds-Odie[2], K. M. Jackson[1], K. G. Ward[3] and D. K. Robinson[1]. *[1]Chemistry, Spelman College, Atlanta, GA, [2]Biology, Dillard University, New Orleans, LA and [3]Pharmacology and Toxicology, Morehouse School of Medicine, Atlanta, GA.*

Arsanilate is an organoarsenical feed additive used in swine, with USDA approval, to control microbial infections and to improve feed efficiency. Current farming practices allow waterways to annually receive undetermined amounts of Arsanilate and its metabolites, in the tons of swine waste from concentrated animal farm operations. These contaminants have increased exponentially in this country since the 1980s. In major swine-growing states such as Iowa and North Carolina, the waste has usually been stored in open pits and recycled as fertilizer. Although efforts are underway to change this practice, leaching into ground water will likely cause continuing contamination. Our laboratory has been concerned with possible effects on humans of Arsanilate and its' N-acetylated metabolite Arsacetin. The literature indicates that swine dosed with ^{14}C-Arsanilate excrete an average of 28% unchanged Arsanilate and 22% of the N-acetylated metabolite Arsacetin. Our study of the potential human impact of these compounds employed the adenocarcinoma Caco-2 cell line, an accepted model for intestinal absorption. The cells exhibited significantly increased proliferation, as measured by ^{3}H thymidine uptake into DNA, when dosed with Arsanilate and Arsacetin at the μM level for 24 hours. In our additional experiments, cells were grown to confluency on collagen-coated Transwells before dosing on the apical side. After removal of FBS, basolateral and apical media were separately analyzed by HPLC. Preliminary results at a 10μM dose for 24 hours reveal permeation to basolateral side of 3.3μM (33%) for Arsanilate and 3.8μM (38%) for Arsacetin. Thus, permeation occurs at a concentration capable of stimulating cell proliferation, in agreement with our previously reported results for the poultry feed additive Roxarsone and its metabolites. Support:NIGMS/NIH1SC3GM 083747-01 and 028248; 2P20MD000215-06; RCMI RR033032.

PS 1785 HEXAVALENT CHROMIUM IS MORE CLASTOGENIC TO BOWHEAD WHALE (BALAENA MYSTICETUS) CELLS THAN HUMAN CELLS.

S. S. Wise[1, 2, 3], C. LaCerte[1, 2, 3], T. L. Chen[1, 2, 3], J. Martino[1, 2, 3], A. Doering[1, 4], P. Martin[1, 4], D. McGovern[1, 4], A. Sample[1, 4], M. Bickford[1, 4], T. Goodwin[5], T. O'Hara[6] and J. P. Wise[1, 2, 3]. *[1]Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME, [2]Maine Center of Toxicology and Environmental Health, University of Southern Maine, Portland, ME, [3]Department of Applied Medical Sciences, University of Southern Maine, Portland, ME, [4]Windham High School, Windham, ME, [5]NASA Johnson Space Center, Houston, TX and [6]University of Alaska, Fairbanks, AK.*

Chromium is a common marine and atmospheric pollutant. Hexavalent chromium is a known human carcinogen which has been shown to damage DNA and cause chromosomal breaks. Few studies have considered the effect of chromium in marine mammals despite their exposure. We have begun investigating the effects of chromium in bowhead whales and comparing these effects with those seen in humans. Hexavalent chromium was only weakly clastogenic to whale cells. Concentrations of 0, 0.5, 1, 2, 4 and 5 μg/cm^2 lead chromate induced chromosome damage in 6, 11, 9, 12, 13 and 11 percent of metaphase cells in bowhead lung cells; 4, 4, 16, 12, 8, and 14 percent of cells in bowhead skin cells; and 8, 6, 10, 15, 15 and 17 percent of metaphases in bowhead testes cells. These results indicate that the potency of hexavalent chromium in bowhead lung and testes is similar and lower than in bowhead skin cells. By contrast, hexavalent chromium is potently genotoxic to human cells. Lead chromate damaged chromosomes in 2, 23 and 34 percent of metaphase cells after exposure to 0, 0.5 and 1 μg/cm^2 respectively. Higher concentrations induced cell cycle arrest and no metaphases were seen. These data indicate that a given dose of lead chromate will induce 2-4- fold more damage in human cells compared to whale cells. These data suggest that bowhead whale cells may have a protective mechanism against genotoxic damage. This work was supported the Maine Center for Toxicology and Environmental Health.

PS 1786 CADMIUM-INDUCED PROLIFERATION OF BREAST CANCER CELLS IS MEDIATED BY GPR30.

X. Yu[1], E. J. Filardo[2] and Z. A. Shaikh[1]. *[1]Department of Biomedical & Pharmaceutical Sciences, University of Rhode Island, Kingston, RI and [2]Department of Medicine, Rhode Island Hospital and Brown University School of Medicine, Providence, RI.*

Cadmium (Cd) is a nonessential metal that is dispersed throughout the environment. It is considered as an endocrine-disrupting element because it tightly binds to estrogen receptor. As a xenoestrogen, Cd mimics estrogen and promotes breast cancer cell proliferation. Estrogen receptor plays an important role in this process. G-protein coupled receptor 30 (GPR30) is a recently discovered membrane estrogen receptor. The purpose of the present study was to investigate whether GPR30 plays a role in Cd-induced cell proliferation. Two human breast cancer cell lines, SK-BR-3 (GPR30 positive, vector transfected) and SK-BR-3 HA-Δ154 (GPR30 negative), were utilized. Incubation with Cd promoted proliferation of GPR30 positive cells, but not of GPR30 negative cells. Intracellular cAMP levels increased about 1.7-fold in GPR30 positive cells upon treatment with 0.5 μM Cd, but not in GPR30 negative cells. Also, in GPR30 positive cells, Cd activated Raf kinase, mitogen-activated protein kinase kinase, extracellular signal regulated kinase, ribosomal S6 kinase, and E-26 like protein kinase about 4-fold. In comparison, in GPR30 negative cells, Cd activated these signaling molecules by only about 1.4-fold. Taken together, these results demonstrate that Cd increases cAMP level, activates ERK kinase pathway, and stimulates breast cancer cell proliferation through GPR30. (Supported in par by a fellowship from INBRE grant #P20RR016457)

PS 1787 ALUMINUM IS MORE CYTOTOXIC THAN LUNAR DUST IN HUMAN SKIN AND LUNG FIBROBLASTS.

J. Martino[1, 2, 3], J. P. Wise[1, 2], J. Wise[1, 2], A. Jeevaragen[4], W. Wallace[4], D. Hammond[4], T. Shehata[5] and J. P. Wise[1, 2, 3]. *[1]Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME, [2]Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME, [3]Department of Applied Medical Science, University of Southern Maine, Portland, ME, [4]NASA Johnson Space Center, Houston, TX and [5]Maine Space Grant Consortium, Augusta, ME.*

NASA plans to build a permanent space station on the moon to explore its surface. The surface of the moon is covered in lunar dust, which consists of fine particles that contain silicon, aluminum and titanium, among others. Because this will be a manned base, the potential toxicity of this dust has to be studied. Also, toxicity standards for potential exposure have to be set. To properly address the potential toxicity of lunar dust we need to understand the toxicity of its individual components, as well as their combined effects. In order to study this we compared NASA simulant JSC-1AVF (volcanic ash particles), that simulates the dust found on the moon, to aluminum, the 3rd most abundant component in lunar dust. We tested the cytotoxicity of both compounds on human lung and skin fibroblasts (WTHBF-6 and BJhTERT cell lines, respectively). Aluminum oxide was more cytotoxic than lunar dust to both cell lines. In human lung fibroblasts 5, 10 and 50 μg/cm^2 of aluminum oxide induced 85%, 61% and 30% relative survival, respectively. For human skin fibroblasts the same concentrations induced 58%, 41% and 58% relative survival. Lunar dust was also cytotoxic to both cell lines, but its effects were seen at higher concentrations: 50, 100, 200 and 400 μg/cm^2 of lunar dust induced a 69%, 46%, 35% and 30% relative survival in the skin cells and 53%, 16%, 8% and 2% on the lung cells. Overall, for both compounds, lung cells were more sensitive than skin cells. This work was supported by a NASA EPSCoR grant through the Maine Space Grant Consortium (JPW), the Maine Center for Toxicology and Environmental Health., a Fulbright Grant (JM) and a Delta Kappa Gamma Society International World Fellowship (JM).

PS 1788 EXPRESSION OF ZINC TRANSPORTERS IN THE HUMAN KIDNEY AND CULTURES OF HUMAN PROXIMAL TUBULE CELLS.

S. H. Garrett, T. Botsford, R. Zahn, S. Somji and D. A. Sens. *Pathology, University of North Dakota, Grand Forks, ND.*

The kidney is a major organ of systemic zinc regulation and is capable of efficient re-absorption over a large range of dietary zinc intakes. The kidney also accumulates other heavy metals especially cadmium, a metal with similar electronic configuration to that of zinc. The regulation of cellular zinc transport is now known to involve the deployment of two large families of transport proteins (ZnT or SLC30a

and ZIP or SLC39a) which control the transport across lipid membranes, thereby controlling zinc into and out of the cell or between sub-cellular compartments. This study was a part of the program for Short Term Educational Experiences for Research (STEER) in Environmental Sciences for Undergraduates, and the purpose was to characterize the expression of nine ZnT transporter genes and ten ZIP transporter genes in renal cortical tissues specimens and in cultures of human proximal tubule cells. The overall goal was to define the genetic regulation of zinc transport in the human kidney as well as its potential interaction with toxic heavy metal transport. For this purpose, total RNA was purified from cultures treated with and without 100 μM zinc or from renal cortical tissue and subjected to RT-PCR using real-time quantitative detection. Expression of ZnT-1, -2, -4, -5, -6, and -7 was detected in both tissue and cultures with ZnT-1 and -2 mRNA being induced by zinc. The expression of ZIP-1, -3, -5, -7, -8, and 14 was also detected in both cultures and tissue with little if any regulation by zinc exposure. These results suggest that there is a high level of complexity in the control of zinc transport within the kidney.

PS 1789 HISTOLOGICAL CHARACTERISTICS OF SUBCUTANEOUS AND INTRAPERITONEAL TUMORS PRODUCED BY CLONES OF ARSENITE AND CADMIUM TRANSFORMED HUMAN UROTHELIAL CELLS.

X. Zhou, M. Sens, S. Somji, S. H. Garrett and D. A. Sens. *Pathology, University of North Dakota, Grand Forks, ND.*

Arsenite (As^{+3}) and cadmium (Cd^{+2}) are carcinogens that cause bladder cancer. Previous work from this laboratory has shown that both As^{+3} and Cd^{+2} can directly malignantly transform the UROtsa cell line and that the tumor heterotransplants produced have histologic features consistent with human bladder cancer. In this laboratory, six As^{+3} and seven Cd^{+2} transformed cell lines were generated independently from the parent UROtsa cells, and they formed tumors when injected subcutaneously in nude mice. This work was further extended and in this study, these lines were injected into the intraperitoneal (IP) cavity of nude mice. All lines formed tumors IP, with some of them forming single and others forming multiple tumor nodules. These tumors were further grouped into superficial tumors (IP-S) and deep tumors (IP-D), according to its location. The morphological features observed for the IP tumors were compared with the subcutaneous tumor (SC) produced by the same line with emphasis on squamous differentiation of the tumors. Histologically, tumors generated by these cell lines demonstrated varying degree of squamous differentiation. The SC tumors and IP-S tumors had similar level of squamous differentiation, but the IP-D tumors were consistently less differentiated than both SC tumor and IP-S tumor. Comparison of the squamous markers between the tumors indicated no significant difference between IP-S and SC tumors, but the IP-D tumors were significantly different from SC and IP-S tumors. In conclusion, these transformed urothelial cell lines can produce intraperitoneal tumor heterotransplants in nude mice; however, the deeply located IP tumors have a lesser degree of squamous differentiation compared to the superficial intraperitoneal and subcutaneous tumors.

PS 1790 METALLOTHIONEIN EXPRESSION IN CADMIUM- AND ARSENITE-TRANSFORMED UROTHELIAL CELLS.

K. L. Carlson, C. Johnson, S. Somji, R. Johnson, D. A. Sens and S. H. Garrett. *Pathology, University of North Dakota, Grand Forks, ND.*

Cadmium (Cd^{+2}) and arsenite (As^{+3}) are known bladder carcinogens that can directly malignantly transform the urothelial cell line (UROtsa). The expression of the cystein rich metal binding protein metallothionein in bladder cancer is potentially significant because some bladder cancers over express metallothionein, and the expression of this protein can confer resistance to chemotherapeutic agents. Previously, this laboratory has established a bladder carcinogenesis model by continuous exposure of the normal, non-tumorigenic urothelial cell line, UROtsa to low levels of cadmium or arsenite over several months of continued cell passage. Each of the transformed cell line formed a tumor when injected subcutaneously in nude mice. The goal of this study was to determine the expression of metallothioneins in these transformed lines as part of the program for Short Term Educational Experiences for Research (STEER) in Environmental Sciences for Undergraduates. Specifically, real-time PCR was utilized to measure the mRNA expression pattern of the ten human metallothionein genes in seven cadmium- and six arsenite-transformed cell lines. The expression of MT-1X, -1E, and MT-2A was high, whereas the expression of MT-1F and MT-3 was variable. There was very little difference between the transformed and parent UROtsa line in terms of metallothionein expression with the exception of MT-3 being expressed in some of the transformed isolates. In conclusion, the expression patterns of metallothioneins do not get altered during the transformation of the normal bladder cell line by heavy metals.

PS 1791 RESPONSE OF HEMOPOIETIC AND OSTEOGENIC CELLS FOLLOWING EXPOSURE TO TUNGSTEN AND TUNGSTEN ALLOYS *IN VITRO* .

A. Olabisi[1], D. Wagner[1], V. Mokashi[1], M. Stockelman[1], P. G. Gunasekar[1], G. Chapman[1] and J. Damen[2]. [1]*Naval Health Research Center Detachment Environmental Health Effects Laboratory, Wright-Patterson AFB, Dayton, OH and* [2]*Stem Cell Technologies, Inc., Vancouver, BC, Canada.*

Bone marrow is a target of many environmental, chemical and therapeutic agents. As such, hemopoietic and osteogenic toxicity is a common, dose-limiting factor for xenobiotics. Here we examined the in vitro toxicity of tungsten (W), 2 tungsten alloys, one containing nickel (Ni) and cobalt (Co) (WA1) and the other Ni and iron (Fe) (WA2), and 2 metal salts, sodium tungstate dihydrate and lead (II) nitrate, on human and mouse hematopoietic and mesenchymal progenitors. For 14 days, cells were exposed to W, WA1 or WA2 at 0.02-20 mg/mL, or metal salts at 0.001-10 mM. The effects on myeloid and erythroid progenitor proliferation was also assessed using human and mouse bone marrow cells in a methylcellulose-based in vitro colony forming assay and mesenchymal proliferation was assessed using freshly isolated human and mouse bone marrow cells in a liquid-based in vitro culture assay. The impact of 3 metal compounds on human and mouse hematopoietic and stromal progenitors revealed that toxicity of tungsten was either similar to or less than levels observed for both tungsten alloys.

PS 1792 LOW-LEVEL INORGANIC ARSENITE IMPAIRS GLUCOSE-STIMULATED INSULIN SECRETION IN PANCREATIC BETA-CELLS: INVOLVEMENT OF NRF2-MEDIATED ANTIOXIDANT RESPONSE.

J. Fu, C. G. Woods, E. Shnaidman, Q. Zhang, M. E. Andersen, S. Collins and J. Pi. *The Hamner Institutes fro Health Sciences, RTP, NC.*

There is growing evidence that chronic exposure of humans to inorganic arsenic, a potent environmental oxidative stressor, is associated with the incidence of type 2 diabetes (T2D). A key driver in the pathogenesis of T2D is the impairment of pancreatic beta-cell function, the hallmark of which is decreased glucose-stimulated insulin secretion (GSIS). In contrast to what has been a prevailing beneficial view of antioxidants in preventing beta-cell dysfunction in diabetes, this study proposes that in response to arsenic exposure, transcription factor Nrf2-mediated adaptive induction of endogenous antioxidant enzymes plays a pathophysiological role in beta-cell function. Exposure of INS-1(832/13) cells or isolated mouse islets to low-levels of arsenite (up to 1 μM for 24-96 hr; non-cytotoxic) led to decreased GSIS in a dose- and time-dependent manner. The impaired GSIS was associated with increases in a battery of endogenous antioxidant enzymes that are regulated by the transcription factor Nrf2. In addition, intracellular glutathione and total antioxidant potential was significantly increased in the arsenite-treated cells. The increased antioxidant activity significantly inhibited net glucose-stimulated intracellular H2O2 accumulation, which is involved in GSIS. In addition, the effects of arsenite exposure on the genes/proteins that are associated with glucose transport and metabolism, classical GSIS pathway, insulin synthesis, mitochondrial function, and inflammatory response were also evaluated in the beta-cell models. Taken together our studies suggest that low-level of arsenite triggers a cellular adaptive oxidative stress response to impair ROS signaling that is involved in GSIS, and thus disturbs beta-cell function. (This research was supported by NIEHS-ONES-R01ES016005 and NIDDK-K01DK076788).

PS 1793 ALTERED GRAVITY EXACERBATES CHROMATE-INDUCED GENOTOXICITY.

J. P. Wise[1, 2], S. S. Wise[1, 2, 3], J. Wise[1, 2], J. McKay[1, 2], A. Courtemanche[1], B. Freedman[4], M. Brown[4], C. Gianios[1, 2, 3], M. Mason[4], T. Shehata[5], D. Hammond[6] and J. P. Wise[1, 2, 3]. [1]*Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME,* [2]*Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME,* [3]*Department of Applied Medical Sciences, University of Southern Maine, Portland, ME,* [4]*Department of Chemical and Biological Engineering, University of Maine, Orono, ME,* [5]*Maine Space Grant Consortium, Augusta, ME and* [6]*NASA Johnson Space Center, Houston, TX.*

NASA plans to build a permanent manned space station on the Moon. A challenge for personnel stationed on the moon will be the potential for altered gravity to potentiate the toxicity of exposures to metals and dusts on the Moon. Microgravity is known to causes changes in the morphology of cells, and results in the loss of muscle and bone mass. Based on these observations, we hypothesized that altered gravity will cause genotoxic chemicals to have a greater damaging effect on cells and DNA. To test this hypothesis, we studied human lung cells treated with a known carcinogen (sodium chromate) and exposed to microgravity. Cells were then ex-

posed to altered gravity on NASA's C-9B plane with parallel run simultaneously on the ground. Cells were exposed to sodium chromate for four hours including time in flight and on ground. Our data show that altered gravity increased the amount of chromate-induced chromosome damage two-fold. Specifically, 5 and 10 μM sodium chromate damaged chromosomes in 40 and 70 percent of metaphases, respectively in cells exposed to altered gravity compared to 18 and 38 percent in cells on the ground. These data suggest that altered gravity can potentiate the genotoxicity of metals. This work is currently supported by a NASA EPSCoR grant through the Maine Space Grant Consortium (JPW,Sr), and the Maine Center for Toxicology and Environmental Health., the Maine Space Grant Consortium and NASA's Microgravity University.

PS 1794 MMA^{III} MAY BE THE ARSENIC METABOLITE RESPONSIBLE FOR DECREASED HBD1 EXPRESSION FOLLOWING ARSENIC EXPOSURE.

N. Dangleben, C. Skibola and M. Smith. *School of Public Health, University of California, Berkeley, Berkeley, CA.*

Arsenic (As) is a major drinking water contaminant and is associated with numerous adverse health effects. Thus, it is critical to develop biomarkers of response for prevention strategies and to elucidate its mechanism of toxicity. Proteomic analysis recently conducted by our laboratory identified lower levels of β-defensin-1 (hBD1) peptides in urine of individuals from two independent human populations exposed to As in drinking water (Hegedus *et al.*, 2008). Subsequent *in vitro* analysis demonstrated that As decreases hBD1 mRNA levels, providing evidence that hBD1 may be a biomarker of response to As. To further validate these findings, we examined the effect of As on *hBD1* gene expression in HOK-16B and UROtsa cells, derived from human skin and bladder, respectively, both of which are target tissues for As toxicity. Real-time PCR analysis was performed to quantify *hBD1* mRNA following exposure to arsenite (iAs^{III}) or its methylated metabolite, MMA^{III}, for 48 hours. UROtsa cells demonstrate a dose-dependent decrease in *hBD1* mRNA following exposure to MMA^{III}, but appear to be resistant to As^{III}, while HOK-16B cells demonstrate a dose-dependent decrease in *hBD1* mRNA in response to As^{III}, and MMA^{III} suppresses *hBD1* mRNA only at the highest dose. UROtsa cells do not express the enzyme AS3MT and cannot metabolize As^{III} to MMA^{III}, which is more toxic *in vitro*. Without AS3MT, UROtsa cells also cannot metabolize MMA^{III} to the less toxic metabolite DMA^{V}. Thus, our preliminary data suggest that MMA^{III} may be the As species responsible for decreased hBD1 expression. hBD1 is a cationic antimicrobial peptide constitutively expressed in epithelia of the skin and urogenital system. Renal cell carcinomas have decreased hBD1 expression, suggesting that hBD1 may be a tumor suppressor for urological cancers. Thus, it is plausible that decreased hBD1 caused by the toxic metabolite MMA^{III} may play a role in As-associated cancers. *Supported by NIH grant P42ES04705.*

PS 1795 THE IKKBETA CROSSTALKS WITH THE TGFBETA PATHWAYS IN ARSENIC TOXICITY.

Z. Peng and Y. Xia. *university of cincinnati, cincinnati, OH.*

Arsenic compounds are environmental hazards, causing diverse health problems in exposed humans and animals. We have previously shown that IκB kinasebeta(IKKbeta), through activation of nuclear factor κB (NF-κB) and up-regulation of anti-oxidant genes, plays a crucial role in antagonizing arsenic-induced death. Thus, the Ikkbeta (-/-) fibroblasts have increased susceptibility to arsenic toxicity. In genome-wide expression study, we unexpectedly find that the Ikkbeta (-/-) fibroblasts have elevated expression of the TGFbeta pathway target genes, such as insulin-like growth factor binding protein (Igfbp), transgelin and connective tissue growth factor (Ctgf). We hypothesize that the elevated TGFbeta pathway activation may contribute to arsenic toxicity of the Ikkbeta (-/-) cells. Using real-time polymerase chain reaction (PCR), we show that the expression of Tgfbeta2/3 and their receptor transforming growth factor, beta receptor II and III (Tgfbr2/3) are markedly increased in the Ikkbeta (-/-) than in wild type fibroblasts. The TGFbetaR directly interacts and activates the SMAD transcription factors. Using Smad-binding element driven luciferase (SBE-luc) reporter, we indeed find higher SMAD activation in the Ikkbeta (-/-) cells. Interestingly, inhibition of the TGFbeta pathway by pre-treatment the Ikkbeta (-/-) fibroblasts with a TGFbetaR inhibitor, SB505124, and by overexpression of the inhibitory SMAD7, significantly reduces cell death induction by arsenic. Conversely, pre-treating the wild type cells with TGFbeta caused approximately 10 times more cell death in response to arsenic. Moreover, the higher TGFbeta pathway activation may be responsible for the lower growth rate and higher motility observed in the Ikkbeta (-/-) fibroblasts. Taken together, our results suggest that IKKbeta may negatively regulate the TGFbeta pathway thereby protecting cells against arsenic toxicity.

PS 1796 HUMAN INDIVIDUAL VARIATION IN SUSCEPTIBILITY TO ARSENIC-INDUCED CYTOTOXICITY.

A. M. Bolt, P. Severson and W. Klimecki. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

A frequent observation in human environmental toxicology is the scenario of a relatively uniform toxicant exposure that is associated with a variable response in toxicant-associated human disease. In an effort to develop a practical in vitro model of this population-level effect we exposed human lymphoblastoid cell lines (LBLs) derived from 30 individuals to 0.75μM sodium arsenite for two weeks in culture, measuring net doubling time for the arsenic-exposed cells and their arsenic-naïve counterparts. Expressed as a ratio to the doubling time of the naïve line, we observed doubling time elevations ranging from 1.10 to 3.54, suggesting that there was significant inter-individual variation in arsenic-induced toxicity. To further characterize this phenotype we used annexinV/ propidium iodide labeling and dual-labeling with bromodeoxyuridine (pulsed) and propidium iodide to investigate chances in cytotoxicity induction and cell cycle kinetics. The data suggests that arsenic-induced cytotoxicity and an increased s-phase transit time largely explain the arsenic induced doubling time increase. Interestingly, we also observed that arsenic induced cytotoxicity does not involve classical apoptosis in these cell lines. These 60 samples were also analyzed by genome-wide RNA expression microarray analysis. Analysis of the most affected against the least affected individuals' LBLs identified several cell cycle regulatory genes that are differentially expressed in relatively arsenic-resistant lines compared to arsenic-sensitive LBLs. We conclude that there is substantial variability in the effect that arsenic has on cell doubling time. Differences in cell cycle doubling times also correlate with the extent to which arsenic can induce cell death. Human LBLs exposed to arsenic appear to be a promising model of individual variability in resistance to non-apoptotic cytotoxicity.

PS 1797 ARSENIC BIOMETHYLATION IS OBLIGATORY FOR OXIDATIVE DNA DAMAGE BUT NOT FOR MALIGNANT TRANSFORMATION.

C. Kojima[1], E. Tokar[1], D. Ramirez[2], Z. Drobná[3], M. Styblo[3], R. Mason[2] and M. Waalkes[1]. *[1]ICS, LCC, NCI at NIEHS, Research Triangle Park, NC, [2]LPC, NIEHS, NIH, Research Triangle Park, NC and [3]Department of Nutrition, UNC, Chapel Hill, NC.*

Inorganic arsenic is a human carcinogen that acts by undefined mechanisms. Studies indicate reactive oxygen species, possibly formed during arsenic biomethylation (AsBM), lead to oxidative DNA damage (ODD), and presumably genotoxicity. ODD measured by common methods, such as oxidized bases, is confounded due to a high artifactual background. Thus, the role of AsBM in arsenic-induced ODD was studied with the recently developed, highly reliable immuno-spin trapping method, which directly traps DNA radicals and measures them as stable nitrone derivates. The AsBM-capable rat liver epithelial line, TRL1215, and the AsBM-deficient human prostate cell line, RWPE-1, were exposed to low-levels of arsenite that induce malignant transformation (< 5.0 μM). A remarkable, but delayed (>5 wks), increase in ODD occurred with arsenic only in AsBM-capable cells prior to malignant transformation (18 wks), whereas the AsBM-deficient cells were devoid of increased ODD despite being exposed past a point that induced transformation (30 wks). In fact, peak ODD in AsBM-competent cells directly correlated with signs of malignant phenotype, including tumors upon inoculation into mice and increased matrix metalloproteinase-2 secretion. Selenite, which blocks AsBM, abolished arsenic-induced ODD and signs of malignant phenotype in TRL1215 cells. The human bladder cell lines UROtsa, which does not methylate arsenic, and its stable arsenic methyltransferase transductant, UROtsa/F35, similarly showed that arsenic-induced ODD occurred only in AsBM-competent cells and that ODD levels also directly correlated with biomarkers of malignant transformation. Thus, although neither arsenic-induced ODD nor AsBM are obligatory for malignant transformation, they likely hasten the process. However, mechanisms not requiring ODD are operative in target cells not biomethylating arsenic, and arsenic has multiple carcinogenic mechanisms.

PS 1798 AUGMENTATION OF CISPLATIN CYTOTOXICITY ASSOCIATED WITH ALTERED DNA DAMAGE RESPONSE AND CELLULAR PLATINUM ACCUMULATION.

C. S. Muenyi, A. A. Pandit, T. Fan, C. Helm and J. States. *Pharmacology and Toxicology, University of Louisville, Louisville, KY.*

Resistance to cisplatin is associated with enhanced DNA repair and decreased cellular platinum accumulation. In vitro data from our laboratory suggest that combined sodium arsenite (NaAsO2) and hyperthermia have the potential to reverse

cisplatin resistance in ovarian cancer cells. We hypothesized that NaAsO2 and hyperthermia would enhance cisplatin cytotoxicity by modifying DNA repair proteins and altering cellular platinum accumulation. Cisplatin-sensitive (A2780) and -resistant (CP70) ovarian cancer cells were treated with cisplatin, with or without 20 uM NaAsO2 at 37 or 39°C (hyperthermia) for 1 h. A2780 and CP70 cells expressed basal levels of XPC and DDB2, key lesion recognition proteins in global genomic repair, subpathway of nucleotide excision repair. Cisplatin increased the levels of these proteins. CP70 cells maintained higher levels of XPC and DDB2 with increasing concentrations of cisplatin. NaAsO2 destabilized XPC, whereas, hyperthermia stabilized it. A2780 cells accumulated ~2-fold more Pt than CP70 cells. Unlike NaAsO2, hyperthermia increased the cellular accumulation of Pt. Cell cycle analysis revealed G2/M accumulation of cells 36 h after treatment. NaAsO2 and hyperthermia stabilized p21CIP1/WAF1 over time, which correlated with decreased pRB phosphorylation at Ser807/811, suggesting cell cycle arrest. Cyclins A & B and Cdc2 proteins were stabilized following cisplatin treatment, suggesting G2 arrest. NaAsO2 decreased the expression of cyclin A and stabilized cyclin B & Cdc2, suggesting that the cells accumulating in the G2/M compartment are mitotic cells. PARP cleavage which is an early indicator of apoptosis was also evident at 36 h. In summary, these data suggest that CP70 cells have a more efficient lesion recognition system than A2780 cells. Hyperthermia increased cellular Pt accumulation and NaAsO2 altered DNA repair by decreasing the expression of XPC and causing cells to accumulate in the M phase of the cell cycle. Supported in part by NIH grants 1P30ES014443 and 5R01ES011314.

PS 1799 THE ROLE OF PKC CONSENSUS SITES IN MTF-1 TRANSCRIPTIONAL ACTIVATION.

E. K. Braithwaite. *Laboratory of Molecular Toxicology, NIEHS, Research Triangle Park, NC.*

Elena Braithwaite, Amy Treece, Min Ok Song, Jonathan H. Freedman, National Institute of Environmental Health Sciences, RTP, NC 27709

Metallothioneins (MTs) belong to a superfamily of intracellular proteins that sequester environmentally toxic metals and are thought to regulate their intracellular concentration. MT expression is transcriptionally regulated by the metal-regulatory transcription factor 1 (MTF-1). MTF-1 acts by binding to short DNA sequences called metal responsive elements (MREs) found in the enhancer/promoter regions of target genes including MT-I, MT-II and ZnT1, a Zn efflux transporter. Two models exist to describe how metals regulate MTF-1 mediated transcription: One proposes that MTF-1 functions as zinc sensor, and the other that phosphorylation of MTF-1 via protein kinase C (PKC) signaling pathways controls its transcriptional activity. To examine the role of phosphorylation in MTF-1 transcriptional activation, PKC consensus sites were identified within MTF-1 using Prosite analysis and each site was systematically mutated. Lentiviruses were developed for each mutant, transduced into MTF-1 knockout mouse embryonic fibroblasts (dko7 cells) and stable cell lines expressing each construct were isolated. We exposed these cells to cadmium or zinc, and measured changes in expression of three marker genes: MT-I, MT-II and ZnT1, by real time qPCR. dko7 cells transduced with wild type MTF-1 demonstrated significant levels of metal-inducible transcription of all three marker genes examined. Surprisingly, the MTF-1-T224A mutant had MTF-1 mRNA levels similar to cells transduced with wild-type MTF-1, but did not show metal-inducible transcription of the marker genes examined. Additionally MTF-1 -/- cells expressing MTF-1-T224A are hypersensitive to cadmium exposure. These data confirm that mutation of this PKC phosphorylation site prevents metal inducible MTF-1-mediated transactivation and has detrimental effects on cell survival after exposure to metal.

PS 1800 ROLE OF DIVALENT METAL IONS IN AMINOACYLASE 3 MEDIATED CATALYSIS.

K. Tsirulnikov[1], N. Abuladze[1], T. Wolak[1,2], D. Newman[1], S. Que Hee[1], J. Abramson[1], I. Kurtz[1] and A. Pushkin[1]. *[1]UCLA, Los Angeles, CA and [2]Ben-Gurion University of the Negev, Beer Sheva, Israel.* Sponsor: W. Dekant.

Aminoacylase 3 (AA3) is highly expressed in renal proximal tubules. The AA3 mediated deacetylation of N-acetyl-1,2-dichlorovinyl-L-cysteine (Ac-DCVC), a metabolite of a xenobiotic trichloroethylene (TCE), is involved in acute renal failure induced by TCE. Despite of ~40% identity of AA3 with the zinc containing aspartoacylase, there is no data on the metal-dependence of AA3. In this study we determined whether mouse AA3 contains a metal ion(s) and whether this metal ion(s) is necessary for the catalysis. In the absence of a high-resolution 3D structure of AA3, we performed modeling of its 3D structure to determine putative amino acid residues involved in metal binding in or near the active site. Based on the 3D model of mouse AA3, His21, Glu24 and His116 were hypothesized to be involved in the coordination of a metal ion in a putative active site. In agreement with this hypothesis, the H21A, E24A and H116A mutants of mouse AA3 were inactive. Using inductively coupled plasma mass spectrometry, 0.01-0.05 atoms of Mn, Cu, Fe or Ni, and 0.35-0.5 atoms of Zn per monomer of wild type (wt) AA3 was determined. Incubation with Co^{2+} activated several times wt-AA3 and the Co^{2+}-activated wt-AA3 contained 1-2 atoms of Co per monomer and no Zn indicating that Co^{2+} replaced Zn^{2+} in the enzyme. Incubation with zinc did not change the activity of wt-AA3 despite the fact that it bound up to 4 zinc atoms per monomer. The amount of the specific metal bound to wt-AA3 was dependent on its concentration in the growth media. The H21A, E24A and H116A mutants had decreased metal content in comparison with wt-AA3. In addition to drastic increase of the rate of deacetylation of Ac-DCVC, Co^{2+} significantly increased the toxicity of Ac-DCVC in the mouse proximal tubule mPCT cells expressing mouse wt-AA3. The results indicate that AA3 is a metalloenzyme and suggest that divalent metal ions may play an important role in mediating the toxicity of TCE.

PS 1801 PROTECTIVE ROLE OF FERROUS SULFATE IN CHROMIUM TOXICITY.

R. Sellamuthu, C. Umbright, S. Leonard, R. Chapman, S. Li, M. Kashon and P. Joseph. *Health Effects Laboratory Division, NIOSH, Morgantown, WV.*

In the US, approximately 1.5 million construction workers are occupationally exposed to cement each year. Allergic contact dermatitis (ACD) is a major skin problem reported among cement workers. Hexavalent chromium [Cr(VI)], present as a contaminant in the cement, is believed to be responsible for cement ACD. A significant reduction in the incidence of cement ACD has been reported in certain European countries where the addition of ferrous sulfate (FeSO4) to cement has been mandated. However, the actual involvement of FeSO4 in counteracting the Cr(VI)-mediated cement ACD has been questioned. Presently, we have conducted in vitro cell culture experiments to investigate whether FeSO4 is capable of protecting cells of human dermal origin against Cr(VI)-induced toxicity. Human dermal fibroblasts and keratinocytes were treated with potassium dichromate alone or with potassium dichromate and FeSO4. Cytotoxicity, apoptosis, and oxidative stress were determined by MTT assay, TUNEL assay, and by electron spin resonance (ESR) analysis, respectively, in the treated cells. Exposure of the cells to potassium dichromate alone resulted in concentration-dependent cytotoxicity, apoptosis, and oxidative stress. The Cr(VI)-induced cytotoxicity, apoptosis, and oxidative stress in the dermal cell lines were significantly blocked by the addition of FeSO4 to the cell culture medium. Analysis of the global gene expression profile in the cells further confirmed the protective role of FeSO4 in Cr(VI) toxicity and provided novel insights regarding Cr(VI) toxicity as well as the protective role of FeSO4. In summary, our results demonstrated a protective role for FeSO4 in Cr(VI) toxicity suggesting that the addition of FeSO4 to cement may be helpful to prevent or at least reduce the incidence of cement ACD among construction workers in the US.
Disclaimer: The findings and conclusions in this abstract have not been formally disseminated by the National Institute for Occupational Safety and Health and should not be constructed to represent any agency determination or policy.

PS 1802 3'-OH-GENISTEIN IN THE TREATMENT OF ACUTE PROMYELOCYTIC LEUKEMIA.

Z. Drobna[1], C. S. Tarraga[2], F. S. Walton[1], L. D. Bennie[1], R. Marcos[2] and M. Styblo[1,3]. *[1]Nutrition, University of North Carolina, Chapel Hill, NC, [2]Department of Genetics and Microbiology, Universitat Autonoma de Barcelona, Barcelona, Spain and [3]CEMLB, University of North Carolina, Chapel Hill, NC.*

Acute promyelocytic leukemia (APL) is caused by a unique gene translocation t(15;17), involving the promyelocytic leukemia (PML) gene that encodes a growth suppressing transcription factor and the retinoic acid receptor alpha (RARα) gene that regulates myeloid differentiation. This translocation creates a chimeric PML/RARα protein which is the key player in APL leukemogenesis. This highly lethal disease has been successfully treated with all-trans retinoic acid (ATRA). APL patients who have relapsed or who have failed to respond to standard therapy are treated with arsenic trioxide (ATO). While ATRA induces myeloid differentiation, ATO triggers apoptosis of APL cells. A recent study showed that a complete remission of APL can be achieved faster with a combined ATRA/ATO therapy as compared to monotherapy. Notably, nearly 30% of APL patients treated with ATRA and/or ATO develop a life-threatening complication known as "APL syndrome". Thus, identification of more effective drugs with fewer side effects would significantly improve the outcomes of APL therapy. Several studies have demonstrated that genistein, a soybean isoflavonoid, induces differentiation and apoptosis in human leukemia cells. Results of our preliminary studies demonstrate synergistic effects of genistein and ATRA and/or ATO on the viability of APL cells and on PML/RARα degradation. In humans, CYP1A2, CYP1A1 and CYP2E1 metabolize genistein to hydroxylated metabolites. We found that the primary metabolite of genistein, 3'-OH-genistein, is more effective than the parental compound as an inducer of cell death and PML/RARα degradation in NB4 culture. In addition, our results show that both CYP1A1 and CYP2E1 are expressed in NB4 cells and are inducible by treatment with ATO. Thus the metabolites of genistein may play a significant role in the outcomes of APL therapy.

PS 1803 HERG VS APD/QT RESULTS OFTEN DISCORDANT: FAST AND ACCURATE REPOLARIZATION SCREEN A NECESSITY EARLY IN DEVELOPMENT.

J. W. Kramer, J. Brimecombe, T. Yang, G. E. Kirsch and A. M. Brown. *ChanTest Corporation, Cleveland, OH.*

Many drugs are screened early in development for hERG effects. We compared the effects of 118 drugs on hERG, action potential duration (APD) and the QT interval. Of the drugs that were hERG+ (IC50≤1μM), only 35% prolonged the APD or the QT. 65% of the hERG+ drugs did not prolong the APD or QT, most likely due to mixed ion channel effects. These results demonstrate the importance of performing a repolarization screen early in development. To meet this need, we have validated a paced isolated heart screen called QTScreen. It provides fast, accurate QT measurements and multiple hearts can be tested simultaneously to increase throughput. Sensitivity and variability of the screen was determined using power/sample size analysis; in control a 2% increase in QT change was detected with 80% power and n as small as 5. Sensitivity to moxifloxacin was also determined because of its use as a positive control in TQT studies. Perfusion of paced hearts with 3 μg/mL (~Cmax in TQT studies), 15 μg/mL and 90 μg/mL moxifloxacin increased the QT by 5±1%, 11±2% and 35±4%. In the moxifloxacin studies, a 4% change was detected with 80% power and n=6. QTScreen provides a fast, inexpensive, accurate and sensitive screen of QT effects that can be performed early in the drug development process, making it a natural companion to the hERG screen.

PS 1804 NEUROPROTECTIVE EFFECT OF SILDENAFIL AGAINST AMYLOID-BETA INDUCED TOXICITY.

S. Uthayathas, S. S. Karuppagounder, B. Shonesy, T. Kariharan, K. Parameshwaran, V. Suppiramaniam and M. Dhanasekaran. *Pharmacal Sciences, Auburn University, Auburn, AL.*

Background: Amyloid beta (Aβ) plays a crucial role in the pathology and progression of Alzheimer's disease (AD). AD is characterized by Aβ containing plaques, neurofibrillary tangles, and synaptic or neuronal loss. Choline esterase inhibitors like donepezil are being primarily used to improve memory, mood and behavior of AD patients. Recent studies have shown sildenafil to enhance memory. However, the memory enhancing mechanism of sildenafil is not well established. Objective: Establish the neuroprotective mechanism of sildenafil against Aβ-induced neurotoxicity. Experimental Procedures: Aβ (1-42, human) was infused intracerebroventricularly (icv), 4 nmol, to three month old Sprague Dawley rats. Administration of sildenafil (1 or 2 mg/kg, i.p.,) was started 24 hours after the Aβ lesioning and continued for 10 days. Effect of sildenafil against Aβ-induced behavioural and biochemical changes were evaluated after the last sildenafil administration. Y-Maze and Object Recognition Task were performed to assess the differences in memory performance. Rats were sacrificed and different brain regions were dissected out. Choline acetyl transferase and acetyl cholinesterase activity were analyzed using spectrophotometric method. The statistical significance was evaluated by the one-way ANOVA using Sigma-Stat version 2.03. Results: Novel arm entries in the Y-maze and discrimination index in the object recognition task were significantly low in Aβ infused rats compared to controls. Administration of sildenafil (1mg/kg) to Aβ infused animals effect a significant increase in the novel arm entries and discrimination index. Sildenafil had no effect on the cholinesterase and choline acetyltransferase activity in various brain regions. Conclusion: These results indicate that icv administration of Aβ produce a memory dysfunction most likely through inducing neurotoxicity. Selective phosphodiesterase 5 inhibitor sildenafil prevented the cognitive impairment induced by Aβ. Support: Auburn University Bio-grant program.

PS 1805 C. ELEGANS MITOCHONDRIAL UNCOUPLING PROTEIN 4: ROLE IN REDOX BALANCE, AGING, AND MITOCHONDRIAL SUBSTRATE UTILIZATION.

M. E. Pfeiffer[1], C. A. Ungles[1], E. Abramson[1], P. Morgan[2] and E. Mills[1]. *[1]University of Texas at Austin, Austin, TX and [2]University of Washington, Seattle, WA.*

Mitochondrial uncoupling proteins (UCPs) are highly conserved members of the mitochondrial anion carrier superfamily that transport protons across the inner mitochondrial membrane. Humans express multiple homologs (UCP2 – 5) in diverse tissues, but their physiologic functions remain unknown. We have recently shown that UCP3 mediates the lethal and hyperthermic toxicities to amphetamine psychostimulants. To better understand the mechanisms by which UCPs may regulate metabolic processes related to thermoregulation, we chose to use the simple organism C. elegans, which expresses only one UCP (ceUCP) ortholog. Consistent with its potential for conserved function as a regulator of mitochondrial uncoupled respiration, compared to wild type (WT), UCP-null worms consume less oxygen, express greater adiposity, and show increased markers of oxidative stress. Surprisingly, when UCP-null worms were crossed with the Mev-1 strain carrying a mutation in complex II that renders them short lived and oxidatively stressed, lifespan was extended compared to Mev-1 controls. Biochemical analyses show that UCP-deficient worms have lower GTP-sensitive respiration, a biochemical marker of uncoupling, and a failure to utilize the mitochondrial complex II substrate succinate. Consistent with an essential role for UCP in complex II function, UCP-null worms are hypersensitive to the lethal effects of the complex I toxin rotenone compared to WT, and UCP-null animals crossed with complex I (gas-1) mutants fail to survive. In support of a role for C. elegans UCP in substrate access to mitochondria and not respiratory enzyme functions, no changes in electron transport activities of enzymes in complexes I-IV were observed. Together, these observations point to novel metabolic regulatory functions of mitochondrial uncoupling proteins, and suggest that their roles in substrate access in C. elegans mitochondria shed possible mechanistic light on the actions mammalian UCPs.

PS 1806 ESTABLISHING A HISTORICAL DATABASE FOR A MULTI-PHASED INTERNATIONAL VALIDATION STUDY OF A STABLY TRANSFECTED ESTROGEN RECEPTOR (ER) TRANSCRIPTIONAL ACTIVATION (TA) TEST METHOD.

R. Tice[1], F. Deal[2], P. Ceger[2], D. Allen[2], J. Gordon[3], J. de Lange[4], S. Bremer[4], M. Nakamura[5], H. Kojima[6], A. Ono[6] and W. Stokes[1]. *[1]NICEATM, NIEHS, Research Triangle Park, NC, [2]ILS, Inc./NICEATM, NIEHS, Research Triangle Park, NC, [3]XDS, Inc., Durham, NC, [4]ECVAM, Ispra, Italy, [5]Hiyoshi Corp., Omihachiman, Japan and [6]JaCVAM, Tokyo, Japan.*

The LUMI-CELL® ER assay is a stably transfected ER TA method developed for the detection of ER agonists and antagonists. Based on an ICCVAM recommendation, NICEATM, ECVAM, and JaCVAM initiated a validation study, using three laboratories (one each in the United States, Japan, and Europe), to evaluate the reproducibility and accuracy of the LUMI-CELL® ER assay. This four-phased study will ultimately evaluate all of the 78 reference substances recommended by ICCVAM for validation of in vitro ER test methods (http://iccvam.niehs.nih.gov/methods/endocrine/endocrine.htm). During Phase I, multiple testing of reference standards and controls was conducted using standardized LUMI-CELL® agonist and antagonist protocols to demonstrate proficiency, establish historical databases to be used as quality controls for subsequent testing, and provide measured or calculated reference standard and control data for an evaluation of intra- and inter-laboratory reproducibility. Phase I also included an evaluation at the U.S. laboratory for "edge" effects on the 96-well plate used for testing, which resulted in a redesign of the plate layout to include all 96 wells. Additional testing was also conducted at the European and Japanese laboratories to demonstrate proficiency with a visual observation method of assessing cell viability. Results of Phase I testing demonstrated the ability of the three laboratories to conduct the assay in a reproducible manner and supported modifications made to the protocols to increase testing efficiency. The three laboratories also established a historical database to use as quality controls when testing coded reference substances in the subsequent phases of the validation study. Supported by NIEHS Contract N01-ES-35504.

PS 1807 ASSESSMENT OF THE PHOTOTOTOXICITY USING 3T3 MOUSE FIBROBLAST NEUTRAL RED UPTAKE ASSAY.

J. Ju, J. Lee, K. Sohn, C. Lim, S. Hong, T. Kwon, M. Chang and K. Park. *immunotoxicology, NITR/KFDA, Seoul, Korea, South.* Sponsor: J. Ju.

Phototoxicity is defined as toxic response from a substance applied to the body which is either elicited or increased after substance exposure to light, or that is induced by skin irradiation after systemic administration of a substance. When substances are developed in the aim to be a constituent of personal care products, and to be applied on the skin, it is necessary to carry out an assessment of potential phototoxicity hazard. Most phototoxic compounds absorb energy particularly from UVA light leading to the generation of activated derivatives which can induce cellular damage. In the present study, We investigated photo-irritation potential of 15 chemicals using the 3T3 NRU PT(3T3 Neutral red Uptake Phototoxicity Test). The basis of this test is a comparison of the cytotoxicity of the chemical when in the present and in the absence of exposure to a non-cytotoxic dose of UVA light. The phototoxic potential of the chemicals was evaluated the prediction model in which

either the photo irritation factor (PIF) or the mean photo effect (MPE) were determined. Both PIF and MPE of the chemicals were highly reproduced. The non-phototoxic chemicals were determined a negative result, phototoxic chemicals showed clear positive results except one chemical. These results suggest that 3T3 NRU PT is a good alternative method for assessing the phototoxic potential.

PS 1808 COLIPA PROGRAM ON OPTIMIZATION OF EXISTING *IN VITRO* EYE IRRITATION ASSAYS FOR ENTRY INTO FORMAL VALIDATION: TECHNOLOGY TRANSFER AND INTRA/INTER LABORATORY EVALUATION OF SKINETHIC' HUMAN CORNEAL EPITHELIUM (HCE) ASSAY FOR CHEMICALS.

N. Alépée[1], B. Le Varlet[2], M. Marrec-Fairley[3], A. De Brugerolle[4] and P. McNamee[5]. *[1]L'Oréal, Aulnay sous bois, France, [2]Link Ingénierie, Mont√©lier, France, [3]Colipa, Brussels, Belgium, [4]SkinEthic, Nice, France and [5]Procter & Gamble, Egham, United Kingdom.* Sponsor: E. Dufour.

The European Union will ban in vivo eye irritation tests on ingredients tested for cosmetic purpose after March 2009. COLIPA, (European Cosmetics Association) is actively working to bring in vitro eye irritation tests to formal validation with ECVAM. This poster details the Colipa program on technology transfer and reproducibility of the Human Corneal Epithelium (HCE), SkinEthic assay as one of the two human reconstructed tissue assays currently submitted. Two exposure times (10 min and 1 hr + 16 hrs post-exposure incubation) were applied in the present work to predict the eye irritating potential of test substances. An optimized SkinEthic' HCE protocol was established on a set of more than 200 chemicals. The prediction Model was based on a 50 % viability cut off, which allowed 2 prediction classes (irritants and non irritants). Inter-batch and intra-batch reproducibility was assessed by using a specific batch control, positive control and negative control. It has been demonstrated in the present work that chemical reactivity criteria enabled to choose the most appropriate exposure treatment time assay of the HCE protocol using 90 chemicals. Predictive capacities based on these data were analyzed and discussed. The biological eye irritancy SkinEthic' HCE assay (1 protocol including two exposure times), was able to discriminate irritants from non irritants with an overall accuracy of 81% and well balanced sensitivity and specificity performances, thus demonstrating the robustness of the protocol when applied to significant very large set of chemicals representative of industrial needs. Using these data, a formal submission was sent to ECVAM in support the SkinEthic HCE protocol's entry into a formal validation study.

PS 1809 AN ALTERNATIVE METHOD FOR SKIN IRRITATION TESTING USING AN OPTIMIZED "42BIS" PROTOCOL: SKINETHIC' RECONSTRUCTED HUMAN EPIDERMIS (RHE) MODEL.

C. Tornier[1], C. Amsellem[2], M. Pelleter[2], J. Meunier[3], A. De Brugerolle[1] and N. Alépée[3]. *[1]SkinEthic, Nice, France, [2]EPISKIN SNC, Lyon, France and [3]L'Oréal, Aulnay sous Bois, France.* Sponsor: E. Dufour.

ECVAM launched a formal validation study on in vitro EpiSkin, EpiDerm reconstituted human epidermis models. In 2007, the EpiSkin model was scientifically validated to fully replace the regulatory Draize skin irritation test (EU B. 4 method; OECD TG 404), according to the EU classification system (R38/no label). A performance standard document was developed describing the basis by which a new test method (Me-too) can determine its relevance (predictive capacity) and reliability (reproducibility within and between laboratories). The purpose of the present study was to develop a new test method able to discriminate skin irritancy potential of chemicals, using the Reconstructed Human Epidermis (RHE) system commercialized by SkinEthic. In phase I, twenty reference test substances (10 irritants and 10 non irritants) were tested to determine if the validated protocol (15 min chemical exposure with a post incubation period of 42 hours) was appropriate using the RHE model. For RHE, both sensitivity and specificity were 70%. The predictive ability of the RHE was considered as inadequate therefore, suitable protocol improvements were envisaged. The RHE test protocol was further refined by extending the topical application period (42 and 60 minutes chemical exposure). Applying those two protocols, an overall accuracy of 85% was observed (specificity: 80%, sensitivity: 90%). Due to its highest intra-laboratory reproducibility (>90%), further evaluation was performed only with the "42 bis" protocol (42 min exposure followed by 42 hrs post incubation period). In Phase II, testing performed on 19 liquid/solids additional substances resulted on a similar overall accuracy compared to the recognized validated models using the MTT as endpoint and a threshold of 50% viability. Currently a new test system with an optimized protocol to handle test substances spanning skin irritants vs. non irritants has been developed. This protocol was chosen for entering formal validation study.

PS 1810 VALIDATION OF THE RECONSTRUCTED HUMAN EPIDERMIS (RHE) SKIN IRRITATION ASSAY FOR FULL REPLACEMENT OF THE DRAIZE TEST.

A. De Brugerolle[1], C. Tornier[1], C. Amsellem[2], I. Goulet[2], J. Meunier[3] and N. Alépée[3]. *[1]SkinEthic, Nice, France, [2]EPISKIN SNC, Lyon, France and [3]L'Oréal, Aulnay sous Bois, France.* Sponsor: E. Dufour.

Efforts to fully replace the in vivo Draize skin irritation test, according to Directive 67/548/ECC or OECD TG 404, was reinforced with the 7th Amendment of the Cosmetic Directive and the REACh regulation. Two reconstructed human epidermis models, EpiDerm and EpiSkin were scientifically validated with the reliability for EpiSkin to discriminate skin irritants (R38) from non-irritants (no label) as defined with EU risk phrases. A performance standard document was developed describing the basis by which a new test method (Me-too) can evaluate its accuracy and reliability (ECVAM SIVS, 2007). The model used in the present study was the in vitro Reconstructed Human Epidermis (RHE) system, commercialized by SkinEthic Laboratories. A multicentric study was performed with three independent laboratories (L'Oréal, Coty and Oroxcell) under blind conditions (coded by Vitroscreen). The twenty reference test substances were selected to give a broad coverage of physico-chemical properties, and a range distribution of in vivo irritancy scores. RHE Skin Irritation Test protocol consisted to apply topically test substances on 3 tissues for 42 minutes followed by rinsing and a 42 hrs post-incubation. The main endpoint was cell viability (MTT reduction), with a threshold of 50% viability. An independent statistical analysis was performed to assess intra and inter-laboratory reproducibility. Regardless the measure, good reproducibility was achieved in the three laboratories. Correct predictions of the skin potential for those twenty substances were assessed with 90% sensitivity and 80% specificity (MTT only). Overall accuracy was 85% and was not improved by IL-1 a release measurement. Conducting the same calculations for the full replacement stand alone validated method EpiSkin with the two combined endpoints, the overall is very similar. The method was submitted to ECVAM for scientific review. Therefore the present RHE assay is a promising in vitro toxicity test to replace the Draize skin irritation test.

PS 1811 *IN VITRO* TOOLS TO ASSESS THE MYELOTOXICITY OF KINASE INHIBITORS.

M. Brughera, G. Pennella, M. Magistrelli, P. Rossi and A. Giusti. *Preclinical Development, Accelera - Nerviano Medical Sciences srl, Nerviano, Milano, Italy.*

Nowadays, pharmacological research for new anticancer therapeutic strategies is mainly directed towards "target specific" drugs, identified through a detailed molecular understanding of changes underlining cancer development. In this respect, protein kinases are considered attractive targets for the treatment of cancer. The interest for these proteins is based on their key role in processes like proliferation, differentiation and cellular apoptosis, activities that are controlled under physiological conditions. However, deregulation of these activities can lead to cellular transformation. Among several inhibitors of protein kinases that are currently under investigation, we focused our attention on a few small molecules exhibiting activity against PLK1 (Polo-Like Kinase); the key role of these proteins in the process of development of different type of cancers is widely described PLK1 is a mitotic kinase protein that plays a critical role in the transition G2/M during the cell cycle and cells that are blocked during mitosis are characterized by phosphorylation of histone H3 at Ser 10. We investigated the myelotoxic potential of some PLK1 inhibitors using a validated HALOTM technology and their effects on cell cycle progression and histone H3 phosphorylation at Ser 10 with flow cytometry analysis. The results obtained demonstrated that the myelotoxic effect of several PLK1 inhibitors on human bone marrow and on bone marrow from different animal species (rat and mouse) correlated well with the percentages of cells arrested during the G2/M transition phase of the cell cycle. In vitro cross-species myelotoxicity studies coupled with mechanistic investigations allows to correlate (in vitro/in vivo) toxic findings in preclinical animal settings, to select the most appropriate species for preclinical studies, to understand the mechanism of toxicity (on-target vs off-target) and to predict potential toxic effects in humans. Therefore, these tools are considered to improve overall the safety assessment of compounds.

PS 1812 IL-1α MEASUREMENT AS A USEFUL ADJUNCT TO VIABILITY ASSAYS IN RECONSTRUCTED EPIDERMIS: HOW TO ENSURE STANDARDIZATION AND REPRODUCIBILITY?

D. Lelièvre, F. Amaral, N. Li, L. Martin and J. Cotovio. *L'Oréal Research, Aulnay sous Bois, France.* Sponsor: E. Dufour.

The reconstructed human epidermis EpiSkinTM model was validated by the ESAC in 2007 as a stand alone replacement test for the prediction of acute skin irritation. The validated test is mainly based on viability assessment (MTT test). During vali-

dation, IL-1α release was demonstrated as a potentially useful adjunct for the detection of irritants (sensitivity increase from 75% to 91%). But some questions remained regarding standardization and variability of the marker. The purpose of this study was to investigate the possibility of standardizing the IL-1α measurements whatever the ELISA kit supplier and to clarify reproducibility aspects of the marker. IL-1α was expressed as pg/ml and its quantification during the validation was performed by using the R&D Systems ELISA kit. We investigated the linearity response of the assay system by using WHO/NIBSC IL-1α international standard. Good linear responses were observed for all kits evaluated. IL-1α quantification in test samples revealed sensitivity differences related to the ELISA kit used. Standardization of the data was obtained by using International Unit (IU) values following a proposed 3 steps procedure: 1-check R&D Systems kit calibration (converting factor) with the reference IL-1α standard in the laboratory working conditions and convert pg/ml to IU/ml, 2- measure IL-1α in the test samples with the R&D Systems kit and the ELISA replacement kit to evaluate, 3-calculate the converting factor between both kits and express results as IU (R&D/IL-1α standard calibration conditions). 20 chemicals were evaluated by using the combined approach [viability + IL-1α]. Intra and inter-batch variability was measured in order to clarify the use of the additional marker as a relevant end point able to reinforce the ability of the EpiSkinTM model protocol to detect irritant chemicals. In conclusion, IL-1α evaluated in standardized and controlled conditions is a helpful adjunct to viability assays, thus strengthening the detection of irritants when using the validated EpiSkinTM model.

PS 1813 EXPRESSION OF MAJOR PHASE 1 ENZYMES IN HACAT CELLS.

J. Hennen, M. Kalmes and B. Blömeke. *Department of Environmental Toxicology, University Trier, Trier, Germany.*

A delayed-type hypersensitivity reaction induced by small reactive chemicals may be mediated by metabolic conversion of the compounds. Skin cells especially keratinocytes play a major role in this process. A total replacement of animal experiments for the endpoint skin sensitization will only be possible when we have well characterized in vitro test systems developed. Thus, it is necessary to understand the metabolic capacities of relevant cells under in vitro conditions. This knowledge will help elucidating whether in vitro metabolism adequately represent human skin metabolism in predicting toxicity. Thus, we evaluated the human keratinocyte cell line HaCaT regarding their metabolic potentials. In this study we studied the expression of major cytochrome P450 (CYP) enzymes by RT-PCR and activities were evaluated for CYP1A1. Interestingly, HaCaT showed comparable basal activities as found for primary keratinocytes, and chemical-induced enzyme activities were even slightly higher compared to in vitro cultured primary keratinocytes (1.5-3.0 fold). These findings demonstrate that a permanent epithelial cell line from adult human skin exhibits CYP expression and CYP1A1 enzyme activities. In sum, HaCaT cells provide a promising tool for studying metabolism of common chemicals whose exposure may occur via skin.

PS 1814 CIGARETTE SMOKE INDUCES GOBLET CELL HYPERPLASIA IN *IN VITRO* CULTURES OF PRIMARY HUMAN BRONCHIAL EPITHELIAL CELLS.

L. E. Haswell, K. Hewitt, D. Thorne and M. D. Gaca. *Group R&D, British American Tobacco, Southampton, United Kingdom.* Sponsor: C. Meredith.

Cigarette smoke is associated with chronic obstructive pulmonary disease (COPD), which encompasses chronic lung inflammation, chronic bronchitis and emphysema. Goblet cell hyperplasia (GCH) is a feature of the lung epithelium in hypersecretory diseases such as chronic bronchitis and contributes to overproduction of airway mucus. We have developed a potential in vitro model of epithelial mucociliary differentiation to investigate the effects of cigarette smoke on development of GCH, in particular expression of the gel-forming mucin MUC5AC. Primary human bronchial epithelial cells (HBECs) were cultured at the air-liquid interface (ALI) for 28 days to induce differentiation. During this period, cells were repeatedly exposed to 0.3-20 μg/ml cigarette smoke total particulate matter (TPM) or 1:900-1:300 (smoke:air) dilutions of whole mainstream smoke. Cell viability and membrane integrity were measured by neutral red uptake and trans-epithelial electrical resistance, respectively. Expression of MUC5AC was investigated using flow cytometry. HBECs cultured for 28 days at the ALI underwent epithelial mucociliary differentiation producing a pseudostratified columnar epithelium containing goblet, ciliated and basal cells, clearly observed by light microscopy and electron microscopy. Non-cytotoxic doses of TPM (5 μg/ml) and whole cigarette smoke (1:300) resulted in significant increases in MUC5AC expression compared to controls (3.1 and 3.0-fold, respectively). In conclusion, epithelial mucociliary differentiation of HBECs could be used as an in vitro model to investigate GCH in response to cigarette smoke, and potentially cigarette smoke constituents and other lung toxicants.

PS 1815 COMPARATIVE EVALUTATION OF COSMETIC FORMULATIONS WITH DIFFERENT ALTERNATIVE METHODS FOR EYE IRRITATION.

A. Poth[1,2], A. Heppenheim[1,2], R. Fautz[3] and A. Fuchs[3]. [1]*Harlan Laboratories, Indianapolis, IN,* [2]*RCC Cytotest Cells Research GmbH, Rossdorf, Germany and* [3]*KPSS-Kao Professional Salon Services GmbH, Darmstadt, Germany.*

Eye corrosion and irritation testing seeks to determine the adverse effects from a single exposure of the eye to a chemical compound. Under the REACH regulation (440/2008 EC) all chemical substances produced in or imported into the EU in quantities greater than 1 tonnage per annum, will have to be assessed for their eye irritation potential. For chemicals in quantities between 1 and 10 tonnes per annum, only in vitro testing is permitted for the assessment of eye irritation. For cosmetic ingredients animal experiments will be forbidden for all acute toxicity endpoints, including eye irritation, from March 2009, as stipulated in the 7th Amending Directive 2003/15/EC to Cosmetic Directive 76/768/EEC and cosmetic formulations have to be investigated only by in vitro methods.
In this work, the eye irritating potential of 5 cosmetic formulations were determined by 5 different alternative methods for eye irritation. In particular the test methods were: Hens-Egg-Chorio-Allantoic Membrane (HET-CAM), Bovine Cornea Opacity and Permeability Test (BCOP), Isolated Rabbit Eye (IRE), an in vitro method using a human cornea model (EpiOcularTM from MatTek), and the Red Blood Cell Test (RBC). The cosmetic formulations were chosen to cover the whole range of irritating effects: non, mild, moderate, and severe/very severe. The results of this study indicate that the eye irritation models, HET-CAM, BCOP, IRE, and EpiOcularTM are able to discriminate between the above mentioned irritating effects. The RBC method had limitations because only soluble and liquid test items can be tested but this may relate to its anticipated use as a test system for the evaluation of surfactants. This study shows that existing alternative methods are able to discriminate between non, mild, moderate, and severe/very severe irritants and may substitute the in vivo Draize Rabbit Eye Irritation test. Nevertheless, the Draize test will still have to be used to confirm the classification of industrial chemicals.

PS 1816 *IN VITRO* PHOTOTOXICITY TESTING: A TASK INVOLVING MULTIPLE ENPOINTS.

L. Marrot, J. Belaidi, C. Jones, A. Labarussiat, P. Perez and J. Meunier. *L'Oréal, Aulnay sous Bois, France.* Sponsor: E. Dufour.

Today's lifestyle is often associated with frequent exposure to sunlight. In this context, some chemicals used in drugs, cosmetics or food sometimes produce adverse biological effects when irradiated. There is thus a need for appropriate methodologies aiming at obtaining relevant data at the molecular and cellular levels for such compounds. For ethical and practical reasons, in vitro models have got an increasing importance in safety screening. Here, we propose a strategy based on complementary tests for assessment of the photocytotoxic and photogenotoxic potentials. First, the use of a light source that mimics environmental solar UV is presented as an essential requirement: in this regard, solar simulators appear to be most appropriate available equipment. Then, complementary methods with increasing complexity are implemented in order to get a rational evaluation of the phototoxic risk: (i) supercoiled circular DNA for in tubo assessment of photoreactivity, (ii) yeast Saccharomyces cerevisiae for evaluation of photocytotoxicity and photomutagenicity in realistic exposure conditions, (iii) in addition to the validated 3T3 NRU test, use of normal cultured human skin cells where photogenotoxicity can be detected using the comet assay (iiii) and finally reconstructed skin where cell death as well as DNA damage can be measured after either systemic or topical application of the studied chemical. Such a strategy allows the evaluation of compounds with very different physico-chemical properties, and it is thus particularly well adapted to rigorously ensure the safety of products likely to undergo environmental sunlight exposure.

PS 1817 QUANTITATIVE ASSESSMENT OF GENOTOXICITY INDUCED BY SIMULATED SOLAR UV ON EPISKIN RECONSTRUCTED SKIN MODEL.

E. Planel, L. Marrot, J. Belaïdi, C. Jones and J. Meunier. *L'Oréal, Aulnay sous Bois, France.* Sponsor: E. Dufour.

Even though cultured normal human keratinocytes constitute a relevant model for photogenotoxicity studies, it is also important to get information on epithelial tissue conditions where these cells form a structural network closer to that of human skin. In this regard, reconstructed skin model such as Episkin are very convenient. Numerous studies on photobiology have been already reported using these models. But, in most cases, data are obtained using immuno-histochemistry techniques

which are generally qualitative. The goal of this study was thus to develop approaches aiming at quantify markers related to photogenotoxicity. Here, the Episkin reconstructed skin model (including dermis with fibroblasts embedded in collagen) was exposed to simulated solar UV radiation similar to zenithal sunlight in terms of spectral power distribution. Biological endpoints related to genotoxicity were then quantitatively assessed. A dose dependent induction of DNA breaks and pyrimidine dimers in the genome of keratinocytes was shown using an adapted protocol of the single cell gel electrophoresis (comet assay). Thanks to an ELISA approach, we observed that p53 accumulation, at 24 hours post UV exposure reached a plateau for exposure times longer than 15 minutes. Finally, expression of genes controlled by p53 was measured by quantitative RT-PCR showing that (i) p21 and GADD45 were induced; (ii) a clear induction of MDM2 required exposure to relatively high UV doses. This study shows that reconstructed skin can be a useful tool as part of in vitro strategies aiming at assessing photoprotection and photogenotoxicity.

PS 1818 PROMISING ALTERNATIVE METHOD FOR THE EVALUATION OF PERCUTANEOUS ABSORPTION USING RECONSTRUCTED EPIDERMIS MODELS.

A. Garrigues-Mazert, S. Grégoire, W. Wargniez, C. Patouillet and J. Meunier. *L'Oréal, aulnay sous Bois, France.* Sponsor: E. Dufour.

In human risk assessment, cutaneous bioavailability needs to be considered to predict the exposure and the risk of cosmetic ingredients. To date the OECD guildelines n° 428 recommend the use of ex vivo human skin for dermal absorption studies. However, it is time consuming and requires numerous replicates due to the variability of the donors. Reconstructed skin models could be a promising alternative approach, as they are highly reproducible, suitable for screening and risk assessment purposes. The aim of the present study was to determine the absorbed dose of chemical ingredients using human epidermis Episkin model. A new in vitro test was developed. A very good correlation between ex vivo and in vitro data (r=0.902) was observed with 18 tested chemicals. 3 different classes were defined determining the low, medium or high ability of a chemical to penetrate through human skin. Enlarged to 34 chemicals, 91% were well classified according to human skin data. In conclusion, this study demonstrates the promising capabilities of reconstructed epidermis to give relevant information according to human skin. The applicability domains of this in vitro test would need to be refined and expanded but could be a promising suitable method to evaluate the penetration potential of chemicals in REACH purpose.

PS 1819 A SCORING TOOL TO ASSESS INHERENT QUALITY OF TOXICOLOGICAL DATA.

A. Kinsner-Ovaskainen[1], K. Schneider[2], M. Schwarz[2] and S. Hoffmann[1]. *[1]IN VITRO Toxicology Unit - ECVAM, E.C. Joint Research Centre, Institute for Heath and Consumer Protection, Ispra, Italy and [2]Forschungs- und Beratungsinstitut Gefahrstoffe GmbH (FoBiG), Freiburg, Germany.* Sponsor: T. Hartung.

The assessment of inherent quality of toxicological information is receiving renewed attention, especially within the REACH programme of the EU, where the use of existing information is emphasised. Also the US Society of Toxicology recently published an opinion, where concern that differences in data quality may counteract the efforts to harmonise classification of substances were expressed (1). Moreover, data quality assessments are highly relevant for the validation process of alternative test methods. Validation depends on the reference in vivo data that should be of highest possible quality to allow an evaluation accurate of the performance of the in vitro test under validation. To evaluate the quality of toxicological studies the so-called Klimisch criteria (2) have been widely used. Recently, ECVAM and the contractors FoBiG/DKFZ, with the support of a group of European experts, have completed a project intended to develop a more comprehensive and detailed scoring tool to assess the quality of toxicological data in an unambiguous and transparent way. The tool was developed by expanding on existing approaches of reliability assessment, by identifying about 25 variables related to quality. The main focus was on the determination of data reliability of experimental toxicological data, both in-vivo and in-vitro (independent of the relevance for the evaluation purpose). Toxicological data mainly come from peer-reviewed publications and studies undertaken for regulatory purposes, and the tool should be equally applicable to data from these sources. The scoring tool will facilitate and harmonise this first pivotal step of data evaluation and will increase its transparency. The project is one of the activities towards an evidence-based toxicology (EBT). 1. Society of Toxicology (2007) http://www.toxicology.org/AI/NEWS/GHS_Comments.pdf and 2. Klimisch, HJ. (1997) Reg. Tox. Pharm., 25, 1-5.

PS 1820 IN SILICO PREDICTION OF SKIN PENETRATION FOR VOLATILE CHEMICALS FROM COSMETIC AND DERMATOLOGICAL FORMULATIONS.

S. Grégoire, A. Garrigues-Mazert and J. Meunier. *L'Oréal, Aulnay sous Bois, France.* Sponsor: E. Dufour.

The accurate prediction of dermal uptake and exposure of topically applied chemicals is relevant for formulation development and risk assessment. Refinement of usual predictive model has been recently done [1]. This model is able to predict the amount of chemical into the skin and in the receptor fluid after the topical application of cosmetic or dermatological formulations. The aim of this study was to take into consideration the vapor pressure of volatile chemicals to predict the absorbed dose. In the in silico model developed by Kasting [2], the volatility of chemicals was considered. Recently, the impact of evaporation on skin uptake of volatile chemicals was evaluated [3]. The model of L'Oréal was recently refined. Measurements of skin bioavailability of 6 volatile chemicals were compared to the predictive data from the L'Oréal model. We demonstrated that the consideration of the vapor pressure improves the in silico prediction of dermal uptake for volatile molecules. Many cosmetic ingredients are highly volatile, like fragrance components. Without correction for evaporation, great overestimation of skin exposure could be done. When evaporation is taken into account, cumulative amount penetrated into the skin can decrease by a factor of two for most volatile chemicals. Thus, using this improvement gives more relevant and consistent results with typical exposure scenario. [1]Grégoire S. and al. British Journal of Dermatology, 2008 Sep 20., [2]Kasting, G.B.; Miller, M.A. Journal of Pharmaceutical Sciences 2005, 95, 268-280., [3]Mohlin P. and al. 11th Perspectives in Percutaneous Penetration, La Grande Motte, France, 2008, [4]Saiyasombati, P.; Kasting, G.B. PS 1821 TOWARDS THE USE OF BIOCHIP TECHNOLOGIES FOR THE PREDICTION OF *IN VIVO* ACUTE TOXIC POTENTIAL.

R. Note, J. Eilstein, M. Thomas, D. Duché, G. Ouedraogo-Arras and J. Meunier. *L'Oréal, Aulnay sous Bois, France.* Sponsor: E. Dufour.

Developing alternative methods to animal testing is critical based on ethical reasons, the REACh regulation and the 7th Amendment of the European Cosmetic Directive which has called for a broad replacement of animal experiments for the testing of cosmetic products. With regards to the acute toxicity, considerable efforts have been gathered over the last years to develop robust in vitro methods. The rationale behind derives from observations, notably arising from the Multi-centre Evaluation of In Vitro Cytotoxicity study, that basal cytotoxicity can be used as a surrogate endpoint for predicting lethal systemic toxicity in vivo. Because of their strong commitment to alternative to animal testing, l'Oréal and Solidus Biosciences Inc. have completed a proof of concept study of the Solidus biochips as an alternative to acute toxicity tests. Solidus researchers have developed a high-throughput, automatable technology which can help revealing toxicity potentially mediated by metabolic activation. Such a technology, integrating a cell-based (Datachip) and enzymatic systems (Metachip), provides mechanistically-based information. In the current study, 50 chemicals representative of L'Oreal's chemical space and cosmetic application have been collated and tested. These compounds ranged in their degree of in vivo toxicity, as defined by the LD50 values and also in their mechanisms of toxic action. Other selection criteria relate to the target species and the route of administration: data generated in rats treated by gavage have been used to assess the correlation between the experimentally derived IC50 and LD50 values. Preliminary statistical analysis has led to encouraging results, with sensitivity and specificity values over 85%. This is an exploratory work and further investigations such as assessing the relevance of such an approach in an Integrated Testing Strategy (ITS) workflow, are still in progress.

PS 1822 PREDICTION OF OCULAR IRRITANT POTENTIAL OF SURFACTANTS-BASED FORMULATIONS AT DIFFERENT CONCENTRATIONS USING THE EPIOCULAR MODEL.

J. Yin[1], A. Dang[1], A. Gill[1], C. Rodriguez[2], H. Pham[2], W. Armbrister[2], J. Harbell[2] and B. Jones[1,2]. *[1]Product Safety, Mary Kay Inc., Dallas, TX and [2]Clinical and Consumer Evaluation, Mary Kay Inc., Dallas, TX.*

Evaluating ocular irritation is essential to the safety assessment of facial and eye-area cosmetics. The EpiOcularTM tissue construct model has been developed and used extensively to predict the traditional eye irritation potential endpoints of those products used around the eye area. Sensory discomfort to the mucus membranes and skin tissues around the eye is also an important factor in consumer acceptance of these products. The current study investigated whether the concentration tested

in the tissue construct model affects the ability to distinguish the degree of sensory discomfort potential to the eye area. Two surfactants-based cosmetic formulations (Fd and Fm) were tested at different concentrations using the EpiOcularTM assay. No significant difference was found in ET50 (time to reduce tissue viability to 50%) between the two formulations when tested at a concentration of 10%. However, when the formulations were tested at 3% formula Fm was shown to have a notably shorter ET50 than Fd, indicating a higher potential for ocular irritation. No matter which concentration tested, the two formulations were classified to have "non-irritating, minimal" irritation potential to the eye based on the existing prediction model (for the standard 4-hour exposure protocol). These results were compared with data obtained from clinical discomfort and clinical use studies. A significant difference in sensory discomfort responses to the two formulations was observed in both clinical and consumer use studies. Formula Fm induced appreciable sensory discomfort in human subjects in both studies, while Fd was well tolerated. These results indicate that use of relatively low test article concentrations for eye area products, may allow the EpiOcularTM assay to better distinguish the degree of ocular irritation and sensory discomfort of surfactants-based formulations.

PS 1823 IMPLEMENTATION OF IN SILICO MODELS IN THE COSMETIC INDUSTRY TO FACE THE 7TH AMENDMENT OF THE EUROPEAN COSMETICS DIRECTIVE.

A. Trotier-Faurion, S. Ringeissen, R. Note, C. Dochez, S. Imbert, N. Flamand, G. Ouedraogo-Arras and J. Meunier. *L'Oréal, Aulnay sous Bois, France.* Sponsor: E. Dufour.

The 7th Amendment to the EU Cosmetics Directive has made in vitro and in silico approaches to warrantee the safety of products a key issue to support regulatory dossiers and future innovation. A ban on animal testing for chemicals to be used in cosmetics comes into effect in the EU in March 2009 for acute toxicity, genotoxicity, and skin or eye irritation. For repeat-dose (or systemic exposure) toxicity, the EU ban is subject to the 2013 deadline. Over the past years there have been considerable efforts to develop alternative methods, including in silico methods that would comply with regulatory constraints (OECD principles). In this context, transparent and mechanism-based approaches are needed. A number of commercial or free software integrate global models targeting the 2009 endpoints. From the cosmetic industry prospective, the predictive performance of such models has to be evaluated on chemical series of interest for: Chemical prioritization; Mechanistic understanding; and, Elaboration of regulatory dossiers by providing additional information. The purpose of the present study was to use data generated on "real-life" chemicals from the cosmetic industry to challenge some of the global models available today. Historical in-house data obtained from the in vivo skin irritation, bacterial mutagenicity and in vivo oral acute toxicity tests, have been curated in collaboration with in-house experts for this purpose. Global models available in the Derek, MC4PC and TIMES software were evaluated for mutagenicity (Derek, MC4PC and TIMES), acute toxicity (Derek, MC4PC) and skin irritation (Derek). Applicability domains and predictive performance were compared in order to identify potential gaps and assess the complementarities of these tools and their relevance in Integrated Testing Strategy (ITS) workflows.

PS 1824 USE OF THE EPIOCULAR™ TISSUE MODEL FOR TESTING OF ULTRA-MILD EYE CARE COSMETICS.

J. Kubilus[1], P. J. Hayden[1], M. Klausner[1] and J. McDonnell[2]. *[1]MatTek Corporation, Ashland, MA and [2]BioScience Laboratories, Inc., Bozeman, MT.*

Eye care cosmetics (ECC) need to be non-irritating in order to be successful in the marketplace. In addition, in order to avoid complaints by customers with sensitive eyes, many ECCs are formulated to be ultra-mild. However, testing of, and discrimination between ultra-mild formulations is difficult since traditional Draize rabbit eye testing is insensitive to the low levels of irritation caused by ECCs. Furthermore, animal testing is not possible due to animal rights concerns and due to current European legislation banning cosmetics that have been tested using animals. Human clinical testing can be performed but because only a low level response is expected, large numbers of subjects would be necessary and hence testing costs would be high if not prohibitive. Cells in monolayer culture could be used for testing however the test materials would need to dissolved in aqueous media which for many non-water soluble cosmetics is not possible. The current study investigated use of the organotypic EpiOcular tissue model as a means of discriminating between ultra-mild formulations. Ten (10) commercially available mascara products were purchased and tested using EpiOcular with an extended time exposure protocol. Because the tissue model is cultured at the air-liquid interface (apical tissue surface left dry), both water soluble and water insoluble test materials could be applied neat to the apical tissue surface. Exposure times between 8 and 24 hours were used after which the tissue viability was determined using the MTT assay. Dose response curves were constructed and the exposure time that reduces tissue viability to 50% (ET-50) was determined by mathematical interpolation. For the 10 mascaras tested, a broad range of ET-50s was obtained from 8.7 hours to > 24 hours. Other studies with low levels of surfactants known to be irritating at higher concentrations could also be discriminated by ET-50s. As such, the extended time exposure protocol appears to be a facile, cost effective means to screen ultra-mild ECCs and other materials.

PS 1825 FOLLOW-UP VALIDATION OF THE EPIDERM SKIN IRRITATION TEST.

M. Liebsch[1], A. Gamer[2], R. Curren[3], J. Frank[4], E. Genschow[1], J. Tharmann[1], M. Remmele[2], B. Bauer[2], H. Raabe[3], N. Barnes[3], A. Hilberer[3], N. Wilt[3], M. Lornejad-Schäfer[4], C. Schäfer[4], P. Hayden[5] and H. Kandarova[5]. *[1]Unit 37 (ZEBET), Federal Institute for Risk Assessment (BfR), Berlin, Germany, [2]Experimentelle Toxikologie und Oekologie, BASF SE, Ludwigshafen, Germany, [3]Institute for IN VITRO Sciences, Inc., Gaithersburg, MD, [4]zet–LSL; Centre for Alternative and Complementary Methods to Animal Testing, Linz, Austria and [5]MatTek Corporation, Ashland, MA.*

In April 2007, ECVAM endorsed 2 alternative methods (EPISKIN and EpiDerm Skin Irritation Tests (SIT)) as replacements of the in vivo rabbit skin irritation test. While EPISKIN assay was recognized as a stand alone method, EpiDerm SIT was endorsed for use in a tiered testing strategy (OECD TG 404), where irritating results are accepted and non-irritating results may require further testing by another method. Based on results published by Faller and Bracher (2002), and analysis of results of the ECVAM validation study, there was evidence that differences in the barrier properties between the 2 models were responsible for the lower sensitivity of EpiDerm SIT when using an identical protocol as used for EPISKIN. Therefore, modifications of the exposure conditions were introduced to the EpiDerm protocol: a) exposure time was increased from 15 min to 60 min; b) the temperature during the exposure was increased to 37°C. With these modifications, when testing chemicals from the pre-validation and validation studies, a significant increase in sensitivity (84%) was obtained, while maintaining an acceptable specificity of the method. In autumn 2007, an international validation study between 4 laboratories was performed to evaluate reproducibility and confirm the predictive ability of the modified EpiDerm SIT. Results of the study are presented here. Overall, sensitivity and specificity of 80% were obtained, which is comparable to results for the EPISKIN SIT for the same set of chemicals (sensitivity of 70%, specificity 80%). The inter-laboratory reproducibility of the modified EpiDerm SIT and its concordance with the in vivo rabbit data was also very good. The method was submitted to ECVAM for scientific review in April 2008.

PS 1826 DEVELOPMENT OF AN EPIDERM™ *IN VITRO* SKIN IRRITATION TEST (SIT) FOR THE GLOBALLY HARMONIZED SYSTEM (GHS) OF CLASSIFICATION AND LABELING OF CHEMICALS.

P. J. Hayden, H. Kandarova, A. Armento, J. Kubilus and M. Klausner. *MatTek Corp., Ashland, MA.*

Determination of skin irritation potential is an international regulatory requirement to ensure safe handling, packaging, labeling and transport of chemicals and evaluation of cosmetics and household products. Recent legislation and a ban on animal testing for cosmetics have heightened the need for validated in vitro SITs. A UN treaty endorsed by the US, EU, China, Japan, Australia and others has outlined a GHS of Classification and Labeling of Chemicals. The GHS classifies skin irritancy of chemicals into three categories: non-irritant (corresponding to in vivo Draize skin irritation scores < 1.5), slight irritant (Draize score 1.5 – 2.3) or irritant (Draize score > 2.3). The EpiDerm model has been validated for in vitro skin corrosion testing worldwide, and in vitro SIT in the EU in studies sponsored by the European Center for the Validation of Alternative Methods (ECVAM). However, the EU SIT system distinguishes only 2 classifications – skin irritant (R38) and non-irritant (no label), and thus will not satisfy the worldwide GHS SIT system. Therefore, additional efforts are underway to validate an EpiDerm SIT for GHS. In results reported here, 15 test chemicals with known in vivo Draize skin irritation scores, chosen to avoid borderline classifications, were applied to EpiDerm to identify in vitro skin irritation biomarkers and establish a preliminary EpiDerm-GHS-SIT prediction model. Biomarker endpoints evaluated include EpiDerm viability (MTT assay) and inflammatory mediator release by ELISA and/or Multiplex (Bio-Rad BioPlex) assays. Among the mediators investigated, significant levels of IL-1α, IL-1ra, IL-8, IL-18, GROα and PGE2 were produced by EpiDerm tissues. The MTT viability response was the most predictive and least variable biomarker, providing 80% concordance with the in vivo Draize classification (i.e. 80% sensitivity and specificity for assigning GHS classifications). This preliminary prediction model will be further tested and refined to form the basis for formal multi-laboratory EpiDerm-GHS-SIT validation studies.

PS 1827 EVALUATING THE CONSISTENCY OF THE MEDIUM THROUGHPUT C. ELEGANS GROWTH ASSAY FOR TOXICITY.

M. Smith[1], W. A. Boyd[2], J. R. Rice[2], J. H. Freedman[2, 3] and C. J. Portier[3]. [1]*SRA International, Durham, NC,* [2]*National Toxicology Program, RTP, NC and* [3]*National Institute of Environmental Health Sciences, RTP, NC.*

The National Toxicology Program and Environmental Protection Agency are developing alternative toxicological methods to prioritize and screen chemicals using high- and medium-throughput assays. Contributing to that effort, several assays have been developed using C. elegans as an alternative animal model. Measurements are made using the COPAS Biosort, a flow cytometer adapted to C. elegans. In the 48 h growth assay, L1 hatchlings are loaded into 96 well plates containing the tested chemicals and incubated for 48 h before being aspirated. In this study, we investigate the reliability and consistency of both the assay and the analyses of the results. Eight chemicals were chosen from the 320 phase I chemicals of the U.S.E.P.A. ToxCast program, four of which are known to be toxic at 200 uM and 4 of which are not (Parathion, Dichlorvos, Diazinon, Lindane, Mehtyl-isothiocyanate, Carbaryl, Isoxaben, and Ethephon). The growth assay was applied in triplicate at eight concentrations of each chemical. In addition, the assay was replicated for each compound an additional six times at 200 uM. The data can be analyzed either by a test for toxicity, yielding a yes/no answer, or by estimated toxicity measures to be used together with other information on the compound. Thus, we tested six replicate assays at the highest dose for all eight chemicals using the Mann-Whitney test. As a toxicity measure, we estimated the average growth rate of the nematodes by adapting a growth model developed earlier. The high number of observations led to the toxicity tests being extremely sensitive: out of 24 tests (4 chemicals x 6 replicates) on toxic compounds, all were rated as toxic. However, the specificity suffered with only 5 out of the 24 tests on the non-toxic compounds failing to reject toxicity. Using the estimated growth rates the toxic and non-toxic chemicals were consistently separated, with only a few order changes within the groups of toxic and non-toxic compounds.

PS 1828 CHEMICAL REACTIVITY: A PHYSICAL-CHEMICAL PROPERTY OF GREAT INTEREST FOR *IN VITRO* EYE IRRITATION PREDICTION WITH SKINETHIC'S HUMAN RECONSTRUCTED CORNEA EPITHELIUM (HCE).

C. Rousseau, D. Duché, J. Eilstein, G. Lereaux, E. Arbey, J. M. Ovigne, N. Alépée and J. R. Meunier. *L'Oréal Recherche, Aulnay sous Bois, France.* Sponsor: E. Dufour.

Chemical reactivity is a physical-chemical parameter of interest to define the intrinsic molecular behavior of chemicals. With the raise of in vitro tests in the toxicology field, this molecular fingerprint is a powerful tool in the protocol orientation, result interpretation and subsequent decision (McKinney, 1996).
The importance of chemical reactivity parameter is particularly well demonstrated in the field of In vitro Eye Irritancy prediction. For this purpose, a protocol based on two exposure times using the SkinEthicTM HCE model has been developed and optimized to predict irritant versus non irritant potential. The measure of molecular reactivity of these chemicals is used as criteria to orientate the tested item towards the suitable time exposure. The resulting performances of the testing battery combining chemical reactivity measurement and HCE biological assay, and the applicability domain of the HCE assay were consequently greatly enhanced.
Chemical reactivity was determined by measuring the depletion of peptides such as glutathione (GSH) and a synthetic peptide containing a cystein (CYS) residue (Gerberick et al, 2007). HPLC-MS and HPLV-UV analytical methods were developed for assaying reduced&oxidized glutathione (GSH&GSSG) and CYS peptide, respectively. Depletion rates for the sum of GSH&GSSG and the CYS peptide were determined in the aim of defining the reactivity status of chemicals.
A Multicentric study is under way in order to prevalidate these chemical reactivity assays (transferability and reproducibility). The results of this multicentric study will be presented.

PS 1829 ANALYSIS OF CELL TOXICITY USING TOXREPORTER™ TECHNOLOGY.

J. Hwang, R. Wiese, J. Mistry and D. Hayes. *R&D Immunoassays, Millipore Corp, St. Charles, MO.* Sponsor: S. Sarang.

Abstract : The most common cause of drug failures is poor ADME properties. New technologies allow for the failure of "bad" compounds sooner in the development pipeline by identifying potential toxicity issues. When compounds interact with cells in a deleterious way, a wide spectrum of adaptive response systems are induced. These toxic responses are inititated by a variety of factors, such as oxidative stress, DNA damage, apoptosis, hypoxia, etc. However, when a cell is exposed to toxic agents subsequent to initiating toxic events, a whole plethora of metabolic changes occurs. This makes investigations into the actual underlying mechanism of chemical toxicity and toxic liabilities extremely difficult to determine. There is, therefore, a need for a high throughput system for the real-time assessment of metabolic change that occurs when cells are exposed to potentially toxic agents. We have developed proprietary technology which will facilitate such an assessment. A reporter-type cell based assay that translates each toxic event into a specific protein which is excreted into the tissue culture medium. The excreted product is identified by a traditional sandwich based ELISA assay. A portfolio of 10 reporter gene assays has been developed to access the potential toxicity of compounds or chemicals. Each cell line has been engineered with a specific response element that, upon activation, switches on the expression of a unique reporter protein. The response elements selected represent common mechanisms of toxicity, for example, oxidative stress, DNA damage, apoptosis, hypoxia, etc. These cell based toxicity assays offer new solutions for the early identification of toxic lead compounds.

PS 1830 *IN VITRO* MODULATION OF BCNU TOXICITY BY O4 BENZYLFOLIC ACID IN HUMAN BONE MARROW CFU-GM AND TUMOR CELL LINES.

H. P. Behrsing[1], M. Furniss[1], K. A. Robillard[1], J. E. Tomaszewski[2] and R. E. Parchment[1]. [1]*Predictive Toxicology Section, Laboratory of Human Toxicology and Pharmacology, SAIC-Frederick/NCI-Frederick, Frederick, MD and* [2]*Division of Cancer Treatment & Diagnosis, National Cancer Institute, Bethesda, MD.*

2-Amino-O4-benzylpteridine derivatives are inactivators of the human DNA repair protein O6-alkylguanine-DNA alkyltransferase (alkyltransferase) and have been tested as possible modulators of alkylating agent chemotherapy. Recently, a new highly water-soluble and potent analog O4 Benzylfolic Acid (O4FA) became available and its therapeutic potential in modulating bis-chloroethylnitrosourea (BCNU) toxicity to human colony forming unit – granulocyte/macrophage (CFU-GM) was evaluated in a validated clonogenic assay. Donor bone marrow cells were pre-incubated (5 hr) with O4FA, followed by BCNU for an additional 42 hrs, after which drug was removed and CFU-GM colony formation was measured in semi-solid agarose cultures. O4FA at 2 or 5 μM progressively lowered the IC values for BCNU, but further increases in O4FA concentrations did not, suggesting a plateau effect. Human CFU-GM could not tolerate >10 μM BCNU at any O4FA concentration. Two human carcinoma lines, HT-29 and KB, representing low and high levels (respectively) of the α-folate receptor required for O4FA transport, have been used to assess the anti-tumor effectiveness of maximally tolerated O4FA/BCNU combinations. As a positive control, 2-hr pretreatment with O4FA (0-100 μM) prior to adding BCNU for 2 more hours confirmed that both cell lines are responsive and that an ATPLite assay can substitute for tumor clonogenic assays. These two cell lines are being used to evaluate the effectiveness of increasing O4FA concentrations in BCNU fixed at 10 μM, which represents the regimen tolerated by the neutrophil stem cells, and to obtain insight into the potential therapeutic index of this new modulator of alkylator chemotherapy. Funded by NCI Contract N01-CO-12400.

PS 1831 EYE AND SKIN IRRITATION IN 3-D TISSUE CONSTRUCTS USING MTT AND ATP ENDPOINTS.

H. Raabe[2], J. Burdick[1], E. Hanlon[2], A. Hilberer[2], M. Hyder[2], H. Inglis[2], A. Kong[2], S. Majewski[1], M. McNamara[1], G. Mun[2], J. Nash[2] and N. Wilt[2]. [1]*Beauty Avenues, Reynoldsburg, OH and* [2]*Institute for IN VITRO Sciences, Inc., Gaithersburg, MD.*

The irritation potential of formulations and ingredients for industrial screening and product development is often conducted using *in vitro* 3-D human ocular and epidermal tissue constructs. To predict irritation potential after chemical exposure, tissue viability is typically determined by the ability of live cells to reduce MTT. Toxic exposures result in decreases in relative MTT reduction. However, two issues may contribute to inaccurate viability assessment: subtoxic exposures that induce metabolic rates greater than controls (i.e., hormesis) and chemicals that directly reduce MTT causing an overestimation of tissue viability (e.g., NaOH, α-tocopherol (α-t), ascorbic acid). Chemical residues on the tisues may increase the total MTT signal, so freeze-killed tissues are used to estimate chemical-mediated reduction of MTT. However, alternative methods of measuring tissue viability, such as amount of adenosine triphosphate (ATP) may be used. We compared these two methods by testing a series of model mild skin care formulations in 3-D human eye and skin constructs. The formulations were spiked with various concentrations of Triton™ to induce a range of toxic effects, and were prepared with and without α-t, a MTT reducer. The inclusion of freeze-killed, test article-treated controls resulted in the same irritancy predictions for the 4 formulations containing α-t as for the 4 control formulations without α-t (e.g., formula with highest Triton conc.: ET_{50} eye = 172 and 157 min, ET_{50} skin = 778 and 772 min, with and w/o α-t). The ATP assay

provided the same rank order of irritancy as did the MTT assay although the relative viability values from the ATP assay at each exposure were overall lower (e.g., formula with highest Triton conc.: ET_{50} eye = 14.5 and 12.9 min, ET_{50} skin = 202 and 231 min, with and w/o α-t). In summary, the MTT assay of formulas capable of MTT reduction should include freeze-killed tissues, and the ATP assay can confirm the relative rank order of the irritancy predictions.

PS 1832 *IN VIVO* VISUALIZATION OF ESTROGENIC ACTIVITY IN XENOPUS LAEVIS TADPOLES.

S. Mukhi and D. D. Brown. *Department of Embryology, Carnegie Institution, Baltimore, MD.*

Endocrine disrupting chemicals including those that mimic estrogen have raised concern due to their wide spread presence in the ecosystem and their deleterious effect at very low concentrations to wild-life and humans. Early detection and screening of the these compounds in the environment for their estrogenic activity is very important. In principle an estrogen disruptor can bind to the estrogenic response element (ERE) in the genomic DNA and subsequently interfere with transcription of ertrogenic-responsive genes. We have developed a transgenic Xenopus laevis model where the estrogenic nature of a compound can be visualized in vivo by a fluorscent reporter. Five concatamers of ERE (5XERE) were fused to a Green Fluorescent Protein (GFP) reporter gene and this plasmid construct (p5XERE-GFP) was used to create transgenic Xenopus laevis tadpoles. These transgenic premetamorphic tadoples were exposed to [10-100 ppb) estradiol in 0.1MMR rearing water. After four days of exposure we observed a robust induction of GFP in various parts of the animals including heart, liver, brain, tail and jaw muscles and kidneys. We are also developing another transgenic line where 5XERE will be attached to luciferase as a reporter gene, which could be easily quantified by spectrophotometer. We are assaying for ERE-reporter activity with different types of estrogenic compounds. We propose that by increasing the number of EREs (5X) that drive the reporter the assay becomes more sensitive, and the animals will sense the presence of estrogenic compounds at very low but physiologically relevant levels in water. This system also can be used for high throughput screening of industrial and pharmaceutical chemicals that might be estrogenic in nature.

PS 1833 THE APPLICATION OF ALGINATE SCAFFOLDS FOR THREE-DIMENSIONAL CELL CULTURE.

A. Sams, Z. Li and M. J. Powers. *Primary and Stem Cell Systems R&D, Invitrogen Corporation, Frederick, MD.*

We have developed a well-defined porous alginate matrix (AlgiMatrix™) to establish a three-dimensional cell culture environment that facilitates the formation of more in vivo-like tissue structures. The addition of divalent cationic salts (e.g. calcium, barium) to a sodium alginate solution produces a highly porous (>90%) and highly interconnected biocompatible scaffold. Using multiple cell types including C3A human hepatocyte cell line, primary hepatocytes, C6 glioma cell line, and mesenchymal stem cells we have shown that the matrix pores (89.19 ± 30μm diameter) act as localized compartments in which cells form reproducible spheroidal aggregates of similar diameter. Non-enzymatic spheroid recovery is simplified by the addition of a Dissolution Buffer that dissolves the alginate matrix within a few minutes while the cell structures remain intact. Phase contrast microscopy revealed that spheroid formation is faster and more efficient in AlgiMatrix™ cultures compared to 2D cultures maintained on collagen-coated polystyrene. The MTT viability assay confirmed that the AlgiMatrix™ cultures retain a high viability through at least 7 days in culture. AlgiMatrix™ cultures of C3A human hepatocytes demonstrate enhanced CYP1A2 gene expression and enzyme induction per cell compared to 2D cell culture. Additional data demonstrating the recapitulation of numerous morphological and/or functional features indicates that AlgiMatrix™ is a platform for creating more physiologically relevant models. We conclude that the 6-well, 24-well, and 96-well AlgiMatrix™ format represents a powerful new tool in toxicology research.

PS 1834 DEVELOPMENTAL EXPOSURE TO A DOPAMINERGIC TOXICANT PRODUCES ALTERED LOCOMOTOR ACTIVITY IN LARVAL ZEBRAFISH.

T. D. Irons[1, 2], R. C. MacPhail[2], D. L. Hunter[2], B. Padnos[2] and S. Padilla[2]. [1]*Curriculum in Toxicology, UNC-CH, Chapel Hill, NC and* [2]*Neurotoxicology Division, U.S. EPA, Research Triangle Park, NC.*

In an effort to develop a rapid in vivo screen for EPA's prioritization of toxic chemicals, we are characterizing the locomotor activity of zebrafish (Danio rerio) larvae after developmental exposure to various classes of prototypic drugs that act on the central nervous system. MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine) is a neurotoxicant that destroys dopaminergic neurons, causing parkinsonian signs in mammals. Our hypothesis was that exposure of zebrafish embryos/larvae to MPTP would produce locomotor changes reminiscent of the decreased activity seen in studies of MPTP in developing mammals. Zebrafish were exposed to 0.08-50 μM MPTP in a 96-well microtiter plate from 5 hours to 5 days post-fertilization, followed by one washout day. On the sixth day, larvae were evaluated for teratogenic effects (structural alterations); locomotor activity was also assessed during alternating periods of light and darkness (infrared) using video tracking. Developmental exposure to the highest dose of MPTP (50 μM) produced teratogenic changes, as well as hypoactivity. In contrast, a lower non-teratogenic dose of MPTP produced hyperactivity. Therefore, larvae that had been exposed to high doses of MPTP during development showed decreases in motor activity similar to changes noted in mammals and zebrafish; however, the unique finding in the current study is that zebrafish larvae exposed to lower doses of MPTP manifested with hyperactivity.
(T.D. Irons is supported by the NIH NIGMS Initiative for Maximizing Student Diversity and the NIEHS National Research Service Award (T32 ES007126). This is an abstract of a proposed presentation; the information does not necessarily reflect Agency policy.)

PS 1835 DEVELOPMENT OF INTEGRATED TESTING STRATEGY IN THE FRAME OF THE 7TH AMENDMENT TO THE EUROPEAN COSMETIC DIRECTIVE.

J. Clouzeau[1], R. Note[2], J. M. Ovigne[2], G. Ouedraogo[2], S. Ringeissen[2], E. Dufour[1], M. A. Levebvre[1], S. Thornback[1], S. Loisel-Joubert[1], J. R. Meunier[2], V. Belin[1] and P. Berthe[1]. [1]*L'Oréal, Asnieres cedex, France and* [2]*L'Oréal, Aulnay Sous Bois, France.* Sponsor: E. Dufour.

The 7th Amendment to the EU Cosmetics Directive implies a shift to alternative ways of assessing the safety of cosmetic ingredients. Over the past decade there have been great efforts in the industry or academic laboratories to develop alternative methods either in silico or in vitro that would comply with regulatory constraints. A multidisciplinary team at L'Oréal worked to develop integrated testing strategies (ITS) based on the existing in vitro and in silico predicting models and tools available so far. These Integrated Testing Strategies have been then confronted and used for routine assessment of cosmetic ingredient's safety. Such strategies need to fulfill two major issues: i) fitting to the chemical-physical diversity of the chemicals currently used in the industry ii) to be predictive of the considered targeted endpoints (Ocular and skin irritancy, genotoxicity, acute toxicity) in order to predict the human safety risk of the chemical. From the cosmetic industry prospective, the predictive performance of such models has to be evaluated on chemical series of interest for: Chemical prioritization; Mechanistic understanding; and, elaboration of regulatory dossiers by providing additional information. The example of two Integrated Strategies developed and in routine use at L'Oréal for Genotoxicity assessment, Ocular or Cutaneous tolerances will be presented. References: S. Hoffmann et al., 2008, Toxicology Letters, 180, 9-20 and C. Grindon et al., 2006, ATLA, 34, 407-427.

PS 1836 TO DEVELOP AN IN VITRO (EFT-300) SKIN MODEL FOR WOUND HEALING STUDIES.

M. S. Sachdeva[1], R. R. Patlolla[1], R. Mallampati[1], P. Vashi[1], M. Klausner[2] and P. Hayden[2]. [1]*Pharmacy, Florida A&M University, Tallahassee, FL and* [2]*MatTek Corporation, 200 Homer Avenue, Ashland, MA.*

Introduction: Wound healing is a natural process, which involves the regeneration of epidermal and dermal tissue. The objective of the present study was to evaluate the epiderm full thickness (EFT-300) skin culture as an in-vitro wound healing model. Methods: In the present study, a strong base 32N KOH and 2 strong acids, concentrated H2SO4 and 100% acrylic acid (AA), were selected for making chemical wounds. Initially, the dose and exposure time required to create a significant wound were determined. Immediately after wounding, cultures were washed thoroughly with distilled water (for KOH wounds) or with phosphate buffered saline, pH 8 (for H2SO4 and AA wounds). Cultures were then returned to incubator (37°C) and the culture medium and tissues were collected every other day over a 6-day period. Histology of the tissue and the release of cytokines, chemokines, and growth factors into culture medium were evaluated. Results: Histological sections of KOH treated tissues, immediately after treatment (4ul for 3minutes) showed damage to stratum corneum and no damage was observed in the dermis.However, treatment with H2SO4 (2ul for 1minute) showed deeper wounding without significant damage to the stratum corneum. AA (5ul for 3minutes) only damaged the dermis but did appear to damage the stratum corneum or epidermis. Histological sections showed regeneration of epidermis, fibroblasts and collagen was observed following treatment with strong base and acids. In the culture medium, both KOH

and H2SO4 treatment resulted in significant release of IL-6 and IL-8 compared to control, but as the post-wounding time progressed there was a decline in biomarkers release. Furthermore, the levels of growth factors EGF (KOH and H2SO4) and FGF (AA) increased followed by increased levels of GMCSF in the culture medium. Conclusion: These results strongly support that the EFT-300 cultures could be a good in-vitro model for studying wound healing process. Acknowledgements: Supported by international foundation for ethical research (IFER).

PS 1837 ALTERNATIVE SAFETY EVALUATION ON "2009" ENDPOINTS IN THE FRAME OF THE 7TH AMENDMENT TO THE EUROPEAN COSMETIC DIRECTIVE: A STUDY CASE.

J. Meunier[1], A. Staropoli[1], J. Clouzeau[2], J. M. Ovigne[1], J. Cotovio[1], V. Belin[2] and P. Berthe[2]. *[1]L'Oréal, Aulnay sous Bois, France and [2]L'Oréal, Asni√®res, France.* Sponsor: E. Dufour.

The 7th Amendment to the European Cosmetic Directive is imposing a ban on animal testing from March 2009 for the genotoxicity, acute toxicity, ocular and skin irritancy toxicological endpoints. This European regulation implies a shift to alternative ways of assessing the safety of cosmetic ingredients on these endpoints.
Over the past decade there have been huge efforts in industry's and academic laboratories to develop alternative methods either in silico or in vitro that would comply with these new regulatory requirements. The Episkin method for skin irritancy has been scientifically validated by ECVAM (European Center for Validation of Alternative Methods) in 2007. Scientifically the replacement of animal data can only be considered through a combination of tests and using a battery of predicting tools.
A multidisciplinary team at L'Oréal has worked out the development of appropriate integrated testing strategies (ITS) based on existing in vitro and in silico predicting models and tools available so far. These ITS have been used to simulate a comprehensive "alternative" safety evaluation of some cosmetic ingredients which fulfill the "2009" ban of the 7th amendment to the European Cosmetic Directives.
One example of an "alternative" safety evaluation performed on a new and innovative cosmetic ingredient in development will be presented. This evaluation relies on the combination of chemical-physical characterization, in silico prediction, in vitro assays for genotoxicity, ocular and skin irritancy and acute toxicity, database mining and read across and in vitro skin bioavailability measurements.

PS 1838 DEVELOPMENT AND IMPLEMENTATION OF ALTERNATIVE SAFETY EVALUATION STRATEGIES IN THE FRAME OF THE 7TH AMENDMENT TO THE EUROPEAN COSMETIC DIRECTIVES.

P. Berthe[1], J. R. Meunier[2] and V. Belin[1]. *[1]L'Oréal, Asnieres cedex, France and [2]L'Oréal, Aulnay sous Bois, France.* Sponsor: E. Dufour.

The 7th Amendment to the European Cosmetic Directive will impose a ban on animal testing from March 2009 for the genotoxicity, acute toxicity, ocular and skin irritancy toxicological endpoints. A sustained and massive investment in the research and development for predictive methods and tools for Human safety assessment can be acknowledged from academics, industries in Europe and worldwide. The resulting scientific progresses remain driven in an industry perspective by realism and the only objective of perpetuating the innovation and insuring the Consumer Safety in the regulatory context of the 7th amendment to the European Cosmetic Directive. The formal validation process as defined by ECVAM, ICCVAM or JaCVAM is a necessity to warrantee the scientific robustness, transferability and reproducibility of the methods developed. But to translate these predictive methods into Safety Evaluation Procedures other steps are required. A multidisciplinary team at L'Oréal has worked to develop and implement the new Safety Evaluation procedures required by the 2009 deadline. This effort went through a stepwise process which will be presented and illustrated: Step 1: Evaluation of the performances of the predictive methods available on a significant number of cosmetic ingredients (>400) representative of the chemical-physical diversity of an industry portfolio. Aim: identifying the applicability domains of the methods and refining the protocols to fit the chemical diversity that the cosmetic industry is facing; Step 2: definition of the most suitable combinations of these predictive tools is enabled and customized (Database mining, Read Across, In silico models, Physical-chemical characterization and In vitro biological models and assays); and, Step 3: Implementation of these Integrated Testing Strategies through training and daily use for routine safety assessment of new ingredients and / or proposal to the validation agencies for formal validation. The outcome of this strategy will be illustrated in a series of posters submitted.

PS 1839 PREDICTIVE *IN VITRO* CYTOTOXICITY ASSAYS: THE "HOLY GRAIL" OF THE MODERN-DAY TOXICOLOGIST.

J. Haskins, A. Peters, D. Miller, S. Sanford, B. Samson and C. Vasudevan. *Thermo Fisher Scientific, Pittsburgh, PA.* Sponsor: A. Barchowsky.

Toxicology safety assessments have long been a challenging hurdle that potential therapeutic candidates must clear prior to introduction into a clinical setting. In recent years, late-stage candidate attrition has lead to a renewed interest in implementing assays that can reduce the number of candidates that fail during preclinical animal studies and early-stage clinical trials. By providing more relevant toxicity data earlier in the drug development process, potential liabilities can be identified prior to committing significant resources towards GLP animal studies and clinical trials. In recent years, several high-content imaging assays have been designed and implemented to generate critical toxicology information for use in the identification, selection, and prioritization of potential therapeutic candidates. They also have the added benefit of revealing mechanistic information that can be critical to understanding toxic effects. In vitro cytotoxicity assays have the potential to directly impact candidate attrition if they can be validated as being predictive of adverse effects seen in humans. In this study, we explored the applicability of two fluorescence-based, in vitro assay panels for the evaluation of toxicity. These panels were designed to evaluate effects on cell viability and proliferation, membrane permeability, mitochondrial activity, cell cycle and apoptosis. Each of these assay panels was cross-validated with an appropriate alternative format assay. Representative cell lines for liver and kidney (HepG2 and HK-2 cells, respectively) were grown in 96-well microplates and exposed to several compounds with known effects in humans. A dose response of each compound was evaluated at both 24 and 72 hours. Following exposure, microplates were analyzed using a fully automated high-content imaging system with integrated analysis software. The results of this study demonstrate that these assay panels show promise for creating a turn-key platform for predictive cytotoxicity assessment.

PS 1840 NRK-52E CELLS AS A MODEL TO STUDY TIGHT JUNCTION AND PARACELLULAR PERMEABILITY PROPERTIES.

L. Arreola-Mendoza[1], J. L. Reyes[2], E. I. Sanchez[2], J. Ortiz[2] and L. M. Del Razo[1]. *[1]Toxicology, Cinvestav-IPN, Mexico D.F., Mexico and [2]Physiology & Biophysics, Cinvestav-IPN, Mexico D.F., Mexico.*

Tight junctions (TJ) proteins are the apical-most intercellular structure in epithelial cells, playing a role in cell-cell adhesion, polarity and permeability barrier to paracellular transport of solutes across the epithelial tissue. Physiopathology implies the alteration of permeability properties are associated with the TJ disruption. On the other hand, several studies have show that the proximal tubule is the main target of nephrotoxics, affecting their paracellular permeability properties. NRK-52E is a rat renal proximal tubular cell line recently used to explore some feature of TJ. Our aim was to evaluate the expression and location of occludin, claudin (cld) 2, 3, 7, 8, & 16, as well as transepithelial electrical resistance (TER) and unidirectional 10 kDa FITC-dextran flux, as epithelial barrier functions. These parameters were performing along 3, 7, 10, & 14 days of cultivated cells. TJ location was attempted by immunofluorescence microscopy; quantity by immunoblot analysis; unidirectional FITC-dextran flux by fluorescence measure and TER using a Millicell-electrical resistance system. Results of immunofluorescence and immunoblot analysis showed a direct relationship between time of grown and expression of occludin. Only few cells cultivated by 3 days expressed occludin, this increased to days 7, & 10 post-seeding, where practically all the monolayer was positive to occludin label. A positive label for cld-2 was observed 10 days post-seeding. Cld-3, cld-7, and cld-16 expressions were present 7 days post-seeding. However, this was only in few groups of cells and lower than cld-2. TER values were variable before to 7 day, after this time TER values were similar to the described for the proximal tubule. This TER value was stable for the rest of growing time. Likewise, FITC-dextran flux was more stable after 7 days of seeding. This study support that conditions such as time of grown could affect the location and expression of TJ, and these should be considered for toxicology studies.

PS 1841 HISTOLOGICAL EVALUATION OF THE EFFECTS OF TRANSPORT ON BOVINE CORNEAS FOR OCULAR SAFETY ASSESSMENTS.

J. R. Nash, R. Curren, E. Hanlon, A. Hilberer, M. Hyder, G. Mun, N. Wilt and H. Raabe. *Institute for IN VITRO Sciences, Inc., Gaithersburg, MD.*

The bovine corneal opacity and permeability (BCOP) assay, originally developed by Gautheron (1992) and Sina (1995) has been used as an *in vitro* eye irritation screen for industrial hygiene, product development and safety testing. It has re-

cently been validated as a screen for corrosive or severe irritation by ICCVAM and ECVAM. The assay measures changes in corneal opacity, and increases in permeability to fluorescein after chemical exposure. Since Curren and Evans (2000) proposed the use of histopathology to detect potential corneal injury, where the mode of chemical action might not induce opacity and permeability changes, histopathology has been used in BCOP studies for nearly a decade. Although the state of the negative control corneas at the end of the BCOP assay has been characterized histologically, no studies have been conducted to determine if there are artifactual changes in the cornea associated with the collection and storage of the enucleated eyes, or the BCOP methodology. Corneas were excised and fixed at various steps in the assay process, at the time of collection of freshly enucleated eyes, after refrigerated transport, and at the end of the BCOP assay. Corneas were fixed in 10% buffered formalin, embedded in paraffin, H&E stained and the corneas evaluated using light microscopy. Stromal thickness was measured primarily at the central cornea. No remarkable artifacts were observed in the corneal epithelium and endothelium as a result of the various conditions, and the corneal stroma appeared very similar histologically in all cases. The thickness of the corneas collected immediately after enucleation were approx. 600 to 650 μm; corneas collected after the refrigerated transport prior to the BCOP assay were approx. 675 to 775 μm, and typical negative control corneas at the end of the BCOP assay range from 680 to 800 μm. These results show that the corneas undergo minimal artifactual changes as a result of refrigerated transport and the BCOP assay procedures.

PS 1842 DECREASED VEGF EXPRESSION IN ZEBRAFISH (*DANIO RERIO*) EMBRYOS EXPOSED TO METHYL *TERT* BUTYL ETHER (MTBE) CORRELATES WITH DISRUPTED ANGIOGENESIS AND DECREASED POST HATCH SURVIVAL.

J. A. Bonventre[1], S. M. Bugel[2], L. A. White[2] and K. R. Cooper[2]. *[1]Joint Graduate Program in Toxicology, Rutgers University, New Brunswick, NJ and [2]Department Biochemistry & Microbiology, Rutgers University, New Brunswick, NJ.*

MTBE is a gasoline additive frequently found in ground and surface waters throughout the United States. Previous studies in our laboratory have shown that exposure to MTBE during development disrupts angiogenesis. Zebrafish (Danio rerio) embryos exposed to MTBE (0.625mM to 10mM) exhibited hemorrhages in the yolk sac and brain, dysfunctional intersegmental vessels, and a reduced number of circulating blood cells. Exposure to the primary metabolite, tertiary butyl alcohol (TBA), at 0.625mM to 10mM, did not result in lesions, suggesting either the parent compound or a minor metabolite causes the developmental defects. In a second study, zebrafish exposed to 1.25mM (n=15) or 10mM (n=17) MTBE until hatch were allowed to mature in fresh system water (n=18 for control). After only 3 days, 65% of the 10mM group died. Mortality at the end of 30 days was 5.6% for control, 46.7% for 1.25mM, and 76.5% for 10mM. Therefore, embryological affects of MTBE on angiogenesis lead to a significant reduction ($p \leq 0.05$) in survival. In a third set of studies, we hypothesized that MTBE exposure decreases expression of two isoforms of vascular endothelial growth factor (VEGF), a signaling protein that promotes the migration and proliferation of endothelial cells lining blood vessels. Zebrafish were exposed to 5mM MTBE and were collected every 12 hours for 48 hours, which corresponds to the initiation phase of angiogenesis. Both VEGF-A and VEGF-C were down regulated compared to the controls. At 24 h post exposure (14-19 somite stage), VEGF-A and -C were significantly decreased (0.5 fold for both, $p \leq 0.05$), and at 48 h post exposure (Prim-25 stage), VEGF-A and -C were also significantly decreased (0.7 fold for both, $p \leq 0.05$). Down regulation of both VEGF isoforms at critical periods in blood vessel development may be the mechanism by which MTBE is disrupting normal angiogenesis. *Funding: NIEHS-ES07148 and NJAES 01201*

PS 1843 STAGE-SPECIFIC GENE PROFILING DURING NEURAL DIFFERENTIATION OF MOUSE EMBRYONIC STEM CELLS.

H. Akanuma, R. Nagano, S. Imanishi, H. Toyoshiba and H. Sone. *National Institute for Environmental Studies, Tsukuba, Japan.*

Exposure to chemicals during gestation may influence developmental programming and later health as an adult, by impacting on disease susceptibility. In vitro screening using embryonic stem (ES) cells is the most promising alternative assay to in vivo testing because ES cells are sensitive to developmental toxicants during their differentiation into various cell types. To evaluate the effects of chemical at the cellular level in a quantitative manner, we have developed protocols for mouse ES cell differentiation into neural lineages. Here, we present multivariate bioinformatic approaches for processing data from gene profiling during neural differentiation from mouse ES cells. B6G-2 cells, a mouse ES cell line were exposed to titrated doses of retinoic acid for 4 days during embryonic body formation from ES cells. The differentiated cells were cultured for a total of 29 days. Microarray analysis was performed with total RNA extracted 0, 2, 8 and 29 days after initiating ES differentiation. Sets of 70 genes termed "Neural development" or "Neural disease" was selected by gene ontology and hierarchical clustering approaches. Unique genes which categorized differentiation stage could be detected with principal component analysis at a statistically significant level. Next, optimal gene sets were further selected from the "Neural development" and "Neural disease" sets by self-organized map analysis to choose genes with different expression patterns allowing comprehensive gene interaction network analysis. Of note, the differentiation stage was reflected in the network analysis, which could be used to predict a critical regulator of neural differentiation. Applying such a gene interaction network analysis to neural differentiation of ES cells will allow the determination of the differentiation stages from ES cells to neurons. This system will be valuable for assessing the consequences of fetal exposure to many types of chemicals and to estimate their effects on fetal programming.

PS 1844 AN ATTEMPT TO ESTABLISH THE NOVEL ASSAY SYSTEM FOR EMBRYOTOXIC POTENTIAL USING MOUSE EMBRYONIC STEM CELLS.

N. Koseki, J. Deguchi, T. Yamada, H. Funabashi and T. Seki. *Safety Research Laboratories, Dainippon Sumitomo Pharmacology Co., Ltd., Osaka, Japan.*

As embryotoxic potential is one of the most severe adverse effects, *in vitro* screening for embryotoxic potential is very important in drug discovery and developmental processes. The embryonic stem cell test (EST) is one of the validated methods to assess embryotoxic potential of compounds and is a promising tool for drug screening. On the other hand, EST lacks quantitative and throughput performances because EST needs the microscopic evaluation of beating in differentiated cardiomyocytes as an endpoint assay. To improve the above problems, we tried to establish the endpoint assay using the field potential measurement in differentiated cardiomyocytes instead of the evaluation of beating. Mouse embryonic stem cells were differentiated into cardiomyocytes in the hanging drop and suspension culture, and treated with embryotoxic (valproic acid, verapamil and 5-fluorouracil) or non-embryotoxic (penicillin G, d-camphor and isoniazid) reference compounds. After differentiation process, microscopic observation of beating cardiomyocytes or measurement of the field potential by MED 64 system (Alpha MED Sciences Co., Ltd.) was performed as the differentiation index to cardiomyocyte. Embryotoxic compounds, valproic acid, verapamil and 5-fluorouracil, inhibited the field potential and myocardial beating in differentiated cells, while non-embryotoxic compounds, penicillin G, d-camphor and isoniazid, had no similar effects. These results indicated that the field potential measurement can be used as an endpoint assay instead of the microscopic observation of beating. Based on these results, we concluded that this assay system was superior to conventional EST in terms of quantitative and throughput performances and useful for assessment of embryotoxic potential of compounds.

PS 1845 EVALUATION OF EMBRYO AND MATERNAL CYTOTOXICITY OF ARSANILIC ACID USING MOUSE EMBRYONIC STEM CELL, CARCINOMA CELL AND GERM CELL AND DIFFERENTIATED CELLS.

S. Jeong, E. Kim, J. Cho, Y. Lee, H. Shin, B. Choi, J. Kang and G. Chung. *Toxicology Division, National Veterinary Research & Quarantine Service, Anyang, KyungGi, Korea, South.*

Arsanilic acid is a pentavalent organic arsenic chemical used as a growth promotant for pigs and poultry. It is known to induce neurotoxicity but the mechanism has not been well elucidated. To evaluate embryo and maternal toxicity and to clarify the target cell of arsanilic acid at specific stage of development, we performed comparative cytotoxicity test using mouse embryonic stem (NVRQS-ES), mouse embryonic carcinoma (NVRQS-EC), mouse embryonic germ (NVRQS-EG) cells and mouse differentiated cell lines representing endodermal (hepatoma cell), mesodermal (embryonic fibroblast cell, muscle cell and myeloma cell) and ectodermal cells (neuroblastoma cell). Cells were treated with arsanilic acid (2pM~20mM) for 4 hours. Digitonin (300μg/ml) was used for positive control of cytotoxicity. After treatment with arsanilic acid, dead cell protease activity and live cell MTT activity were measured as indicators of cytotoxicity and the values of EC200 (protease) and IC50 (NTT) were calculated by sigmoidal fitting. In protease activity, EC200s were 7.6mM for muscle cell line, 19.8mM for myeloma cell and higher than 100mM for the rest of the cells. In MTT activity, IC50s were 4.1mM for myeloma cell, 15mM for muscle cell, 23.4mM for neuroblastoma cell, 31mM for NVRQS-EG cell line and higher than 100mM for the rest of the cells. The NVRQS-EG cell was more sensitive to arsanilic acid than NVRQS-ES and NVRQS-EC cell in MTT assay. The cytotoxic potency of arsanilic acid on each cell types were ranked in the following order: myeloma cell > muscle cell > neuroblastoma cell > NVRQS-EG > the

rest of cell lines. These results suggest that arsanilic acid may impact on germinal cells at embryo development stage and affects more on myeloid, muscle and neuroblast cells after maturation.

PS 1846 INVESTIGATING THE MECHANISMS OF CARDIOTOXICITY WITH TYROSINE KINASE INHIBITORS USING PRIMARY HUMAN CARDIOMYOCYTES.

D. Puppala[1], H. Uppal[1], P. Dhawan[1], D. Goldstein[2], D. Misner[1] and K. L. Kolaja[1]. [1]*Discovery and Investigative Safety, Roche Palo Alto LLC, Palo Alto, CA and* [2]*Medicinal Chemistry, Roche Palo Alto LLC, Palo Alto, CA.*

Cardiotoxicity can be a side effect for many tyrosine kinase inhibitors (TKI's). The underlying mechanism(s) of cardiotoxicity is not clearly understood, although hypotheses include diverse events ranging from kinase dependent inhibitory sequelae, mitochondrial toxicity, lipid peroxidation, endoplasmic reticulum stress and so on. A model of human primary cardiomyocytes was developed and characterized for its ability to reflect TKI mediated cardiotoxicity. In our initial study, the in vitro toxicity profile of certain marketed TKI's were assessed and revealed that Sunitinib exhibited cytotoxicity to primary human cardiomyocytes at concentrations as low as 12.5 uM. Cytotoxicity was assessed using multiple in vitro toxicity assays by monitoring different aspects of cell health (e.g., ATP levels, GSH levels, LDH levels). At 12.5uM, Sunitinib depleted ATP by 50%, depleted GSH by 40%, and increased LDH release by 30 %. The kinase inhibitory profile for Sunitinib indicates many kinases are inhibited at 1 uM and 10uM, including AMP-activated kinase (AMPK). Since AMPK is a critical regulator of cellular energy status, the role of AMPK activation in our model of cardiomyocyte toxicity was examined. The approach employed was pretreatmetn with the AMPK activator AICAR followed bySunitinib treatment at a range of concentrations. Our results demonstrate that concentration of Sunitinib that decrease ATP are inhibited 40% by AICAR pretreatment. Similarly, AICAR pretreatment also attenuated cell death by ~30% of Sunitinib alone. Our results suggest via in vitro models, that cardiotoxicity may be attenuated by up regulating kinases such as AMPK.

PS 1847 THE ROLE OF MITOCHONDRIAL TOXICITY IN THE CARDIOTOXICITY OF SMALL MOLECULE KINASE INHIBITORS.

P. Dhawan[1], S. Yaung[4], H. Uppal[1], D. Puppala[1], M. Sweeney[1], J. Murray[3], P. Hajek[3], E. Oquendo[3], C. Wilson[3], N. Priedigkeit[3], D. Goldstein[2], D. Misner[1], S. Platz[1], R. Capaldi[3] and K. Kolaja[1]. [1]*Non Clinical Safety, Roche Palo Alto LLC, Palo Alto, CA,* [2]*Medicinal Chemistry, Roche Palo Alto LLC, Palo Alto, CA,* [3]*Mitosciences Inc, Eugene, OR and* [4]*MIT, Cambridge, MA.*

The development of selective kinase inhibitors (KIs) can, and often does result in toxicity due to off-target inhibition of other kinases and/or various ATP utilizing enzymes. To assess the extent of this unwanted toxicity we have evaluated a set of >100 compounds with known kinase inhibition but cardiotoxicity profiles. This cardiotoxicity was hypothesized to be due to mitochondrial dysfunction and energy depletion. Primary cultured human cardiomyocytes were employed to generate a compendium of data on mitochondrial physiology including overall cellular toxicity, the reduction in ATP levels, mitochondrial membrane potential dissipation, mitochondrial respiration, alterations in expression of a wide range of OXPHOS and other metabolic enzyme changes, oxidative stress effects including changes in superoxide, glutathione levels as well as protein modifications to a range of metabolic enzymes, and finally, induction of caspase-dependent or -independent apoptosis by a variety of protocols including monitoring movement of apoptotic factors and transcription factors to and from the mitochondrion. Our analyses of cardiotoxicity, kinase inhibition and mitochondrial metabolism revealed significant changes in the bioenergetic state of cells after various kinase inhibitor perturbations. The studies confirm that mitochondria can be a primary target of many KIs including sorafenib, imatinib and sunitinib and implicate mitochondrial dysfunction and subsequent energy depletion as a crucial factor in the cardiotoxicity. The approach described here can provide an effective screen of clinical candidates during drug development and, correspondingly, can drive the structure-activity and kinase inhibition-activity studies needed to circumvent cardiac impairment.

PS 1848 EFFECTS OF TCDD ON DIFFERENTIATION OF HUMAN EMBRYONIC STEM CELLS.

E. A. Bolterstein[1] and B. Allen-Hoffmann[1, 2]. [1]*Department of Pathology, University of Wisconsin - Madison, Madison, WI and* [2]*Molecular and Environmental Toxicology, University of Wisconsin - Madison, Madison, WI.*

The pluripotent nature and unlimited proliferative ability of hES cells have potential to provide a renewable, consistent cell source, in which to more accurately study toxicity in early human development. However, a relatively small number of published reports study toxicological endpoints and pathways in hES cells. Investigations of responses to xenobiotic exposure in animal models have been wrought with interspecies differences that have complicated data interpretation and therefore cannot be relied upon to effectively model toxic responses in humans. The aryl hydrocarbon receptor (AhR)/aryl hydrocarbon receptor nuclear translocator (Arnt) pathway is central to xenobiotic toxicity observed in various tissues and critical to proper developmental progression. When exposed in utero to 2, 3, 7, 8-tetrachlorodibenzo-ρ-dioxin (TCDD), an environmental contaminant and potent AhR/Arnt pathway agonist, rodents exhibit developmental abnormalities such as cleft palate. Futhermore, TCDD toxicity has been shown to result in regenerative growth deformities, possibly due to changes in expression of extracellular matrix remodeling genes and subsequent alterations in epithelial to mesenchymal transition (EMT). Previous work in our lab has shown that the AhR/Arnt pathway is functional in human embryonic stem (hES) cells in both undifferentiated and differentiated monolayer culture, as well as in highly differentiated embryoid bodies (EBs) derived from hES cells. Current work focuses on examination of TCDD exposure on the differentiation status of hES cells and EBs using PCR analysis. TCDD treatment appears to inhibit differentiation, as evidenced by lower mRNA expression of early differentiation markers in hES cells and greater expression in EBs. Additionally, localization of EMT-related proteins, as visualized through indirect immunofluorescence, suggests that TCDD may enhance progression of EMT in EBs. These findings support use of hES cells as a tool for exploring mechanisms in developmental toxicology.

PS 1849 A ROLE FOR THE CONSTITUTIVE ANDROSTANE RECEPTOR IN HEPATIC DIFFERENTIATION OF HUMAN EMBRYONIC STEM CELLS.

S. M. Zamule, D. M. Weyant and C. J. Omiecinski. *Veterinary and Biomedical Sciences, Pennsylvania State University, University Park, PA.*

The constitutive androstane receptor (CAR) is expressed primarily in the liver and regulates expression of genes whose products act at all three phases of hepatic metabolism and transport, thus playing a key role in the metabolism and disposition of exogenous compounds such as drugs, xenobiotics, and carcinogens, as well as endogenous substances including bile acids, thyroid hormone, heme, and steroids. Considering the importance of CAR in hepatic function, we hypothesized that CAR plays a role in hepatic differentiation. To this end, we cultured human embryonic stem cells (hESCs) on a collagen substrata in hepatocyte media (William's E Media supplemented with 25 nM dexamethasone, 10 nM insulin, 5 ng/ml selenium, 5 μg/ml transferrin, and 1% linoleic acid) for 10 days in order to induce hepatic differentiation. Using quantitative RT-PCR analyses, we demonstrated that hESCs cultured under these conditions exhibited a significant decrease in expression of alkaline phosphatase (a "stemness" marker) and significant increases in expression of FOXA1, HNF1α, and CEBPα (hepatic-enriched transcription factors), as well as CAR, RXRα, and PPARα (hepatic-enriched nuclear receptors). Expression levels of AFP (a fetal liver marker) and transthyretin, transferrin, and albumin (hepatic secretory/transport proteins) were also increased. Remarkably, CAR expression was induced ~1,000-fold, to levels only ~5-fold less than those found in human hepatocytes. We next employed a lentivirus system to stably express CAR in hESCs. Preliminary findings indicate that compared to hepatic culturing conditions alone, a 4-fold increase in CAR expression in conjunction with hepatic culturing conditions led to a 2-fold increase in expression of AFP, FOXA1, HNF1α, and transthyretin, and a 3-fold increase in expression of transferrin. Taken together, these results suggest a unique and important role for CAR in hepatic differentiation and contribute to our understanding of the regulatory networks governing differentiation of hESCs along a hepatic lineage.

PS 1850 AGING ARYL HYDROCARBON RECEPTOR NULL ALLELE MICE ARE PRONE TO HEMATOPOIETIC DISEASE CHARACTERISTIC OF LEUKEMIA.

K. P. Singh, F. L. Casado and T. A. Gasiewicz. *Environmental Medicine, School of Medicine and Dentistry, University of Rochester, Rochester, NY.*

The aryl hydrocarbon receptor (AhR) is a highly conserved, developmentally-regulated and ligand-activated gene regulatory protein. Despite extensive studies, the normal physiological function of the AhR is not known. Only a limited characterization of the immune system in Ahr null-allele (KO) mice has been performed and this has not been examined in old mice. No studies have delineated hematopoietic stem cell (HSC) function in these mice. Earlier studies indicated that bone marrow (BM) from KO mice has increased numbers of functionally-defined multipotential hematopoietic progenitors (HPP-CFC) and HSCs. In addition, these cells have high rates of proliferation and cell division. We hypothesized HSCs from aging KO mice may undergo premature senescence and/or be involved in the development of hematopoietic disease. We examined the characteristics and numbers of immune

cells in two-year old Wild Type and KO mice. There was a significant increase in total BM cells, and lymphocyte count in the blood of KO mice. Phenotype analysis of BM cells showed higher numbers of HSCs, primitive multipotent progenitor cells, and common lymphoid progenitors, but lower numbers of common myeloid progenitors. Functional analysis of KO BM cells showed an increase in HPP-CFC and colony-forming units for pre-B and decrease in erythroid and myeloid progenitors. Histological examination of KO Spleen sections from KO mice showed a decrease area of the periarteriolar lymphocyte sheet and increased lymphocyte infiltration in the red pulp area. Immunohistochemical staining of spleen sections from KO mice indicated the presence of increased numbers of highly proliferating B-and T-lymphocytes. Increased leukocyte infiltration in hepatic periportal areas was also observed. Together these data suggest that during aging HSCs function abnormally in mice lacking AhR leading to hematopoietic disease showing characteristics of leukemia. (Funded by NIH grants ES04862, ES07026, and ES01247.)

PS 1851 RELIABLE AND PREDICTIVE *IN VITRO* ASSAYS FOR MYELOTOXICITY AND CARDIOTOXICITY OF KINASE INHIBITORS.

E. Clarke[1], S. Schwengberg[2], R. Kettenhofen[2], G. dos Santos[1] and H. Bohlen[2]. *[1]ReachBio LLC, Seattle, WA and [2]Axiogenesis AG, Koln, Germany.* Sponsor: R. Schnellmann.

Kinase inhibitors (KIs) represent a new class of rationally designed drugs. The success of Imatinib, targeting the ABL tyrosine kinase in CML, has prompted the development of other KIs for the treatment of various cancers and inflammation. Although more successful than conventional therapies, myelotoxicity and cardiotoxicity are often major side effects of KIs. Using in vitro models for myelotoxicity and cardiotoxicity, we determined the IC50 values of 6 KIs (Imatinib, Lapatinib, Erlotinib, Dasatinib, Sorafenib and Sunitinib) and compared them to the degree of clinical myelotoxicity and cardiotixicity reported in the literature. For the hematopoietic colony-forming cell (CFC) assays, human bone marrow cells and KIs were mixed with methylcellulose-based media, plated in 35 mm dishes (n=3), and the progenitor cell colonies were enumerated on day 14. For the in vitro cardiotoxicity assay, mouse ES cell-derived cardiomyocytes (Cor.AT®) were plated at 20,000 cells per well (n=6), the KIs were added on day 2 (short-term effects), or 14 (long-term effects) and cell death was measured by neutral red uptake 48 hours later. Mouse embryonic fibroblasts were used as non-specific control cells. There was a direct correlation between clinical myelotoxicity and the IC50 values derived from the in vitro CFC assays, with lower IC50 values associated with increased neutropenia (IC50 range: 0.008 ug/mL (Dasatinib) -> 100 ug/mL (Lapatinib)). There was also a strong correlation between published clinical cardiotoxicity (e.g. myopericarditis, ischemia, pericarditis, myocardial infarction) and the effect of the KIs on Cor.At® cells. Imatinib was the most toxic KI where as Erlotinib and Lapatinib demonstrated the least toxicity (between 1 nM and 0.1 μM). Cor.At® cells pre-cultured for 2 days were less susceptible than those pre-cultured for 14 days. These results demonstrate that both the in vitro human CFC and Cor.At® cardiomyocyte assays are reliable and useful for accurately predicting the myelotoxic and cardiotoxic ranking of KIs.

PS 1852 THE ARYL HYDROCARBON RECEPTOR MODULATES ERYTHROPOIESIS IN MICE.

F. L. Casado-Pena, K. P. Singh and T. A. Gasiewicz. *Environmental Medicine, University of Rochester, Rochester, NY.*

The aryl hydrocarbon receptor (AhR) mediates the toxic, carcinogenic and teratogenic effects of environmental pollutants such as dioxins; exposure to humans has been correlated with blood malignancies. No physiological role of this evolutionarily conserved receptor has been established. Recently, we reported that activation of AhR by its exogenous ligand 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) produces major changes in numbers and functions of murine hematopoietic stem cell and primitive progenitor cells. Erythrocytes differentiate from stem cells through a series of intermediate stages, but any role of AhR in murine erythropoiesis is unknown. The first committed erythrocyte precursors are the burst-forming unit cells (BFU-E) that differentiate into colony-forming units (CFU-E). Fetal liver cells (FL) from embryos of E14D pregnant mice were exposed to TCDD (5 nM) in vitro. E14D pregnant mice were also dosed with TCDD (30 microg/kg) for 1 d and FL was collected. In both cases, TCDD produced a significant decrease in BFU-E and CFU-E. C-Kit+ cells sorted from FL exposed to TCDD in vivo demonstrated lower proliferation rates as determined by 3H-thymidine incorporation, and had lower numbers of cells at the G2M cell cycle stage. When young adult mice were exposed to TCDD (30 microg/kg), there was increased BFU-E in BM after day 1, 3 and 5 of treatment, but decreased numbers at proerythroblast and basophilic erythroblast stages of differentiation. In addition, there were lower numbers day 8 CFU-spleen colonies that are formed by erythromyeloid progenitors. Studies conducted in young and two years old Ahr-/- mice also showed lower BFU-E and CFU-E in BM. Hematological analysis of blood smears from older Ahr-/- mice showed erythroid cells with altered shape and size consistent with a defect in the maturation of erythroid progenitors into red blood cells. These results suggest that the AhR plays a direct or indirect role in murine erythropoiesis. (Funded by NIH grants ES04862, ES07026, and ES01247)

PS 1853 CHARACTERIZATION OF PRIMARY HUMAN CARDIOMYOCYTES AS A POTENTIAL *IN VITRO* MODEL FOR TESTING CARDIOTOXICITY.

M. D. Sweeney[1], D. Puppala[1], H. Uppal[1], N. M. Liles[2], M. W. Majdoub[2], J. Sharma[2], S. Kaushal[3], M. Fielden[1] and K. Kolaja[1]. *[1]Discovery and Investigative Safety, Roche Palo Alto, Palo Alto, CA, [2]Celprogen Inc, San Pedro, CA and [3]Division of Cardiovascular Thoracic Surgery, Children's Memorial Hospital, Northwestern University's Feinberg School of Medicine, Chicago, IL.*

A number of marketed tyrosine kinase inhibitors (TKIs) have been reported to be cardiotoxic in humans, prompting the need for better models for the preclinical assessment of cardiotoxicity. In response, we have characterized a human tissue derived primary cardiomyocyte cell model by comparing its molecular and biochemical characteristics to adult human heart tissue. Human cardiomyocytes were compared to adult heart tissue using immunohistochemistry (IHC), quantitative PCR and microarray gene expression analysis. We have used multiple antibodies to evaluate the expression of human cardiomyocyte markers and found that human cardiomycoytes in culture express tropomyosin, troponin I, actinin, ANP, desmin, NKX 2-5 and others, thus confirming they maintain the phenotypic expression of human heart tissue through multiple passages (P0, P1, P2, P4, P8 and P12). We have also evaluated the mRNA expression of 40 different cardiac specific genes including MYBPC3, MYH6, MYH7, NPPA, PLN, GATA4, and MYL7 in human cardiomyocytes. Our analysis revealed abundant expression of the cardiac gene markers over multiple passages. Using these primary cardiomyocytes, we next performed several biochemical toxicity assays including ATP depletion, ROS generation, and GSH depletion to evaluate the relative toxicity of a number of marketed TKIs. The data indicate that cardiomyocyte toxicity assays can differentiate cardiotoxic and non-cardiotoxic TKIs, thus permitting novel compounds to be effectively evaluated for relative risk of cardiotoxicity by comparison to benchmark compounds. Based on our results we propose that primary human cardiomyocytes represent a phenotypically relevant cell-based model for the early preclinical assessment of drug-induced cardiotoxicity.

PS 1854 POTENTIAL MECHANISMS OF *IN VITRO* CARDIOTOXICITY ASSOCIATED WITH TYROSINE KINASE INHIBITORS.

H. Uppal[1], D. Puppala[1], M. Sweeney[1], P. Dhawan[1], J. Jin[1], R. Varma[2], H. Bitter[2], D. Goldstein[3], D. Misner[1], S. Platz[1] and K. Kolaja[1]. *[1]Non Clinical Safety, Roche Palo Alto LLC, Palo Alto, CA, [2]Global Research Informatics, Roche Palo Alto LLC, Palo Alto, CA and [3]Medicinal Chemistry, Roche Palo Alto LLC, Palo Alto, CA.*

An in vitro model of cardiotoxicity assessment was developed using kinase inhibitors with known toxicological sequelae. A set of compounds including the kinase Inhibitors (KIs) (Imatinib, Dasatinib, Sunitinib, Sorafenib, Lapatinib, Gefitinib, Erlotinib, Vertex ERK Inhibitor (V_ERK), a cardiotoxic Roche KI (RO-459) and a Roche non-cardiotoxic KI (RO-050) (Doxorubicin, BILN-2061 controls) were used to identify mechanisms of cytotoxicity. Cultured primary human cardiomyocytes were used to generate a compendium of data across multiple time points for more than 50 parameters including ATP levels, mitochondrial membrane potential, oxidative phosphorylation complexes, respiration, cellular toxicity, oxidative stress, ER stress, apoptosis and signaling components of the energy metabolism, survival and stress pathways. Mitochondrial dysfunction and ATP depletion were a common theme in vitro for compounds that cause cardiotoxicity in vivo. ATP depletion assessed with Linear mixed effects models were ranked using the other assays (N = 28 assays) as predictor variables. This analysis yielded a set of assays (N = 13) that were highly predictive of ATP depletion and subsequent cytotoxicity. Compound toxicity, based on rank sum, using 14 of the top-ranked assays including ATP depletion, led to the ranking of potential cardiotoxicity of three distinct groups; high (Sunitinib, Doxorubicin, Sorafenib, Dasatinib & RO_459) moderate (Lapatinib, Imatinib & V_ERK) and low (Gefitinib, Erlotinib, BILN 2061 and RO_050). These data suggest that primary human cardiomyocytes assessed for key parameters are an excellent in vitro model for cardiotoxicity prediction and can be used to reveal insight into the mechanisms of kinase inhibitor mediated cardiotoxicity.

PS 1855 A QUANTITATIVE STEM CELL ASSAY FOR TESTING OF DEVELOPMENTAL NEUROTOXICITY.

D. M. De Groot[1], H. Stegeman[1], R. Kayser[1], A. Bhola[1], M. Mulderij[1], J. Bruijntjes[1], H. Wortelboer[1], J. Lammers[1], R. Westerink[2], A. Seiler[3] and J. Van Burgsteden[1]. [1]*TNO Quality of Life, Zeist, Netherlands,* [2]*IRAS, University Utrecht, Utrecht, Netherlands and* [3]*ZEBET, Berlin, Germany.* Sponsor: V. Feron.

Successful implementation of an adequate in vitro method in first tier screening of chemicals for global toxicity testing of developmental neurotoxicants on neural cell level could result in a strong reduction of animal use for regulatory testing and could reduce the time involved for testing potential developmental neurotoxicants. In the proposed assay, embryonic stem cells of the mouse are forced to differentiate into the three main cell types of the CNS (neurons, oligodendrocytes, and astrocytes) along processes like proliferation, migration and differentiation, thereby mimicking neural development in vivo. MAM and MeHgCl, well-know developmental neurotoxicants, were used to confirm the presence of the developmental phases. The final cell population was characterized on the basis of antigenic features, and quantified on the basis of H&E morphological features using stereological principles. MAM inhibited the proliferation phase of the in vitro model and MeHgCl inhibited the migration phase, both without affecting cell viability. MeHgCl exposure during the differentiation phase led to massive cell death. The presence of both mature and immature neural cells was demonstrated by specific staining with antibodies. Using morphological features after H&E staining, nine cell classes were distinguished. Using stereological principles to estimate the cell class distribution in 10 cultures collected over a period of 5 months, it appeared that the variation within and between cultures was the same even though total cell numbers might differ between cultures. Since this in vitro DNT mimics the phases of in vivo development of the CNS including differentiation into immature and mature neural cells, has a constant cell class composition and appears able to detect developmental neurotoxicity, this assay is a promising alternative for in vivo DNT studies in first tier screening settings.

PS 1856 AHR/CYP1A1 EXPRESSION IN MOUSE TROPHOBLAST ALLOGRAFTS.

J. Epple-Farmer, N. Ouyang, S. Ke and Y. Tian. *Program of Toxicology, Texas A&M University, College Station, TX.*

The placenta is an important organ for providing nutrients to the growing fetus and also serves as a barrier warding off harmful substances from maternal circulation. The placenta is an organ known to express significant levels of the aryl hydrocarbon receptor (AhR). The role of the placental AhR however, is not clear. In mammalian development, trophoblast stem cells give rise to placental tissues protecting fetal allograft in part through modulating immune response. Recent evidence indicates that AhR plays an important role in mediating immune responses through generation of regulatory T cells. In order to investigate the role of AhR in trophoblast stem (TS) cells, we utilize an allograft tolerance mouse model through injection of trophoblast stem (TS) cell through portal vein. These allografted TS cells survived up to 4 months in allogeneic female mice. We performed immune histochemistry analysis for the presence of active AhR/CYP1A1 pathway in the allograft tissues. We found significant level of cyp1a1 expression in all surviving trophoblast allografts. This finding strongly suggests the presence of active AhR/CYP1A1 pathway in trophoblast allografts and the AhR/CYP1A1 may play a role in allograft tolerance. (this work is supported in part by NIH ES 09859).

PS 1857 PREDICTING DEVELOPMENTAL TOXICITY WITH HUMAN EMBRYONIC STEM CELLS AND METABOLOMICS.

A. M. Weir[1], P. R. West[1], S. Bhattacharyya[1], A. M. Smith[1, 2] and G. G. Cezar[1, 2]. [1]*Stemina Biomarker Discovery, Inc., Madison, WI and* [2]*Animal Sciences, University of Wisconsin-Madison, Madison, WI.*

Birth defects are a prominent problem, occurring in 6% of births, nationally. Teratogens, or substances that cause one or more fetal abnormalities in development, cause 5-10% of these defects. While animal models are currently used to predict developmental toxicity of drugs, they are costly, time-consuming, and most importantly, do not adequately correlate to human response. The overall ability of animal models to predict developmental toxicity in humans is only 60%. Stemina Biomarker Discovery, Inc. (Stemina) addresses these issues by using an in vitro method that utilizes both human embryonic stem (hES) cells and metabolomics to discover metabolite biomarkers of developmental toxicity.
Stemina detects secreted extracellular metabolites from hES cells using liquid chromatography mass spectrometry (LCMS) with the hypothesis that measurable modulation of specific secreted metabolites will result due to treatment of hES cells with teratogens. Such metabolites will serve as biomarkers of developmental toxicity. Stemina has dosed hES cells with 18 drugs of known teratogenicity. Liquid chromatography electrospray ionization quadrupole time of flight mass spectrometry (LC-ESI-QTOF-MS) was performed on the hES cell spent medium in order to measure the secreted metabolites. Statistical analysis has been employed to determine abundance changes in metabolites as a result of drug treatment. We have discovered several metabolites that may serve as biomarkers of developmental toxicity and will allow for better prediction of teratogenicity.

PS 1858 ANTIOXIDANT RESPONSE ENZYMES IN PROGRESSIVE STAGES OF HUMAN NON-ALCOHOLIC FATTY LIVER DISEASE.

R. N. Hardwick, C. D. Fisher and N. J. Cherrington. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

Non-alcoholic fatty liver disease (NAFLD) encompasses various stages of liver damage ranging from steatosis (simple fatty liver) to non-alcoholic steatohepatitis (NASH), which can lead to cirrhosis. NAFLD occurs in approximately 20-25% of all Americans, while NASH affects approximately 2-5% of the population. Compromised hepatic function and oxidative stress are known characteristics occurring in NAFLD progression. The purpose of the current study was to determine whether the function of enzymes involved in the antioxidant response, NADP(H) quinone oxidoreductase-1 (NQO1) and glutathione S-transferases (GST), is altered in human liver samples diagnosed as normal, steatotic, NASH with fatty liver, and NASH no longer fatty. Immunohistochemical staining of the antioxidant responsive transcription factor Nrf2 revealed its translocation into the nucleus in all stages of NAFLD with prominent staining in the NASH (fatty) samples. NQO1 mRNA levels in the various stages of NAFLD showed a significant increase in NASH (not fatty) samples as compared to normal. Similar to mRNA, NQO1 activity was significantly increased in NASH (not fatty) samples compared to normal. Significant increases were also observed in mRNA levels of GST isozymes A1, A4, M3, and M4 in NASH (not fatty) samples compared to normal. Additionally, a significant increase from normal in both NASH disease states was observed for the GST P1 isozyme. In contrast to mRNA levels, there was a statistically significant decrease in GST activity, measured by CDNB conjugation, in both stages of NASH as compared to normal. The current data suggest that during the progression of NAFLD, increased Nrf2 activation and NQO1 activity observed in late stage NASH may provide protection against quinone-induced redox cycling. In contrast, due to a reduction in GST enzymatic activity, the ability to neutralize electrophiles may be compromised. Taken together these results demonstrate that NAFLD causes an altered capacity to manage oxidative stress-inducing events during progression of the disease.

PS 1859 HEPATIC CYTOCHROME P450 ENZYME ALTERATIONS IN HUMANS WITH PROGRESSIVE NON-ALCOHOLIC FATTY LIVER DISEASE.

L. Augustine[1], C. D. Fisher[1], A. J. Lickteig[1], J. Ranger-Moore[2], J. P. Jackson[3], S. S. Ferguson[4] and N. J. Cherrington[1]. [1]*Pharmacology & Toxicology, University of Arizona, Tucson, AZ,* [2]*2Division of Epidemiology and Biostatistics, University of Arizona, Tucson, AZ,* [3]*CellzDirect, Inc., Austin, TX and* [4]*CellzDirect, Inc., Durham, NC.*

Members of the cytochrome P450 enzyme (CYPs) families CYP1, 2 and 3 are responsible for the metabolism of approximately 75% of all clinically relevant drugs. With the increased prevalence of non-alcoholic fatty liver disease (NAFLD), patients with this disease represent an emerging population at significant risk for alterations in these important drug metabolizing enzymes. The purpose of this study was to determine whether three progressive stages of human NALFD; steatosis, non-alcoholic steatohepatitis (NASH) with fatty liver and NASH no longer fatty, alter hepatic drug metabolizing CYPs. Decreasing trends in hepatic mRNA of CYP1A2, 2D6 and 2E1 were observed with NAFLD progression, while CYP2A6, 2B6 and 2C9 mRNA tended to increase. Microsomal protein expression of CYP1A2, 2C19, 2D6, 2E1 and 3A4 tended to decrease with NAFLD progression. However, CYP2A6 protein expression increased with progression. Functional activity assays revealed decreasing trends in CYP1A2 and 2C19 enzymatic activity with NAFLD severity, and while not significant, CYP2D6 and 3A4 also tended to decrease. In contrast, activity of CYP2A6 and CYP2C9 was significantly increased with NAFLD progression. Increased expression of pro-inflammatory cytokines, tumor necrosis factor alpha (TNFα) and interleukin 1 beta (IL-1β), were implicated as factors causing decreased CYP activity. Further, elevated CYP2C9 activity with NAFLD progression was correlated to increased hypoxia identified by hypoxia induced factor 1 alpha (HIF-1α) expression and downstream target gene induction. Conclusion: Later stages of NAFLD cause significant changes in hepatic drug metabolizing CYPs. These data strongly suggest that caution should be taken when recommending standard dosing regimens of therapeutic drugs to patients with severe NAFLD.

1860 PRECLINICAL ASSESSMENT AND BIOMARKER DISCOVERY OF DRUG-INDUCED HEPATIC STEATOSIS.

M. Fielden, M. Earl, H. Uppal and K. Kolaja. *Non-Clinical Safety, Roche Palo Alto, Palo Alto, CA.*

The detection of hepatic steatosis in preclinical and clinical studies is difficult due to the lack of non-invasive biomarkers for monitoring disease appearance and progression. To address these gaps and identify new markers of compound-induced hepatic steatosis, we evaluated the concordance of histopathological diagnoses to novel biomarkers including serum lipid and lipoproteins and hepatic gene expression profiles. Test articles were administered orally to rats at toxic doses and included the mitochondrial toxicant chloroform, the LXR/PXR agonist TO-901317, and two PXR agonists mifepristone and econazole for 1 or 7 days. A non-steatotic compound and PXR activator RO-55 was dosed once daily at a maximum tolerated dose for 1, 7, 14 and 28 days and served as a negative control. With the exception of RO-55, all groups showed a compound-related increase in hepatic steatosis as early as day 1, which increased in severity and incidence by day 7. HPLC-based lipoprotein profiling indicated compound specific changes in serum lipids and lipoproteins, but no individual changes were diagnostic of hepatic steatosis. Hepatic gene expression profiling confirmed similarity between the PXR activators mifepristone, econazole and RO-55, and distinct modes of action for TO-901307 and chloroform. All compounds except chloroform induced PXR-mediated Cyp3a mRNA, however there were variable effects on CD36 fatty acid transporter suggesting that PXR-mediated lipid accumulation via CD36 may not fully explain the observed steotosis. There was a consistent up-regulation of CPT1A and other enzymes by all steatotic compounds, which function to increase mitochondrial fatty acid oxidation. However, other mitochondrial-related proteins involved in oxidative phosphorylation and energy production were consistently altered. These results suggest that compound-induced hepatic steatosis does not substantially affect detectable changes in serum lipid and lipoprotein components, yet non-invasive monitoring of mitochondrial components or activities may provide an alternate approach for biomarker identification.

1861 INVOLVEMENT OF AMP-ACTIVATED PROTEIN KINASE/ACC PATHWAY ON THE FATTY LIVER INDUCED BY OROTIC ACID.

E. Jung, Y. Lee, J. Chung and B. Lee. *Seoul National University, Seoul, Korea, South.*

Orotic acid (OA) has been known to cause fatty liver with poorly defined cellular mechanism of action. AMP- activated protein kinase (AMPK) is a critical regulator of cellular and body energy homeostasis sensing the status of the AMP:ATP ratio. The net effect of phosphorylation of AMPK by AMPK kinase in the liver is stimulation of fatty acid oxidation and inhibition of lipogenesis. The present study was aimed to investigate whether the OA-induced fatty liver is mediated by AMPK phosporylation. OA induced intracellular lipid accumulation in SK-Hep1 human hepatoma cells in a dose- and time-dependent manner. Exposure of SK-Hep1 cells to OA significantly reduced the Thr-172 phosphorylation of AMPK, and also repressed the phosphorylation of acetyl-CoA carboxylase (Acc), a well-known substrate of AMPK and decreased expression of LKB1 protein. Inhibition of AMPK phosphorylation and lipid accumulation by OA was reversed by 5-amino-4-imidazolecarboxamide riboside (AICAR). We also investigated the effects of OA on the transcriptional repression of PPAR-α and the expression of the target genes using PPRE-reporter gene assay and quantitative real-time PCR in H4IIEC3 cells. Target genes for PPAR-α include acyl-CoA oxidase (Acox), acyl-CoA dehydrogenase, short/branched chain (Acadsb), L-3-hydroxyacyl-CoA dehydrogenase, short chain (Hadhsc) and acyl-CoA dehydrogenase, very long chain (Acadvl). Treatment of H4IIEC3 cells with OA repressed the transcriptional activity of PPAR-α by 20%. Accordingly, OA inhibited the expression of Acox, Acadsb, Hadhsc, and Acadvl by 32%, 22%, 40% and 24% respectively. These results indicate that the inhibition of AMPK-dependent anti-lipogenic pathway and the inhibition of PPAR- α-dependent fatty acid oxidation mechanism contribute to the steatogenic effects of OA.

1862 PESTICIDE AND HEAVY METAL EXPOSURES ARE ASSOCIATED WITH LIVER DISEASE.

M. Patel[1], K. Falkner[1], C. McClain[1, 2], G. Brock[3], S. Appana[3] and M. Cave[1, 2]. *[1]Medicine/Gastroenterology, University of Louisville, Louisville, KY, [2]Medicine, Louisville VAMC, Louisville, KY and [3]School of Public Health, Louisville, KY.* Sponsor: D. Conklin.

Purpose: The prevalence of liver disease has risen dramatically in parallel with the obesity epidemic. The majority of these cases are thought to be due to non-alcoholic fatty liver disease (NAFLD). Occupational exposures to industrial chemicals have also been associated with NAFLD. The impact of pollutants on liver disease in the general population has not been evaluated. Materials and Methods: We analyzed data from adult participants in the National Health And Nutrition Examination Survey (NHANES) 2003-2004. We analyzed the data for an association between blood or urine levels of 196 toxicants and elevated ALT (marker of liver injury), after excluding participants with liver disease from other etiologies (hepatitis B or C, alcohol abuse or iron overload). Toxicants which were detectable in 60% of subjects were included (116 of 196). Subjects were stratified by toxicant level into quartiles and the odds ratio for abnormal ALT was determined after adjusting for confounding variables like age, sex, race, BMI, and insulin resistance (HOMA) using logistic regression analysis. Results: 4582 subjects were included in the analysis. Of these, 34.1% were found to have abnormal ALT. Several organochlorine pesticides (or metabolites) including dieldrin, oxychlordane, transnonachlor, and heptachlor epoxide were associated with a dose-dependent increased risk for ALT elevation. Among heavy metals, lead, mercury, and thallium also demonstrated a dose-dependent increased risk for ALT elevation. Conclusions: In the US population, exposures to specific organochlorine pesticides and heavy metals are associated with a dose-dependent increased risk for otherwise unexplained liver disease. Although most of these organochlorine pesticides are no longer used, they are clearly persistent pollutants which are clinically relevant. The pathogenic role of these toxicants in liver diseases such as NAFLD should be explored. Acknowledgement: NIEHS (P30ES014443-01A1), and the AASLD (Sheila Sherlock Award).

1863 TOXICANT ASSOCIATED STEATOHEPATITIS (TASH) IN AMERICAN VINYL CHLORIDE WORKERS.

M. Cave[1], M. Patel[1], K. Falkner[1], S. Joshi-Barve[1], L. Reynolds[1] and C. McClain[1, 2]. *[1]Medicine/Gastroenterology, University of Louisville, Louisville, KY and [2]Medicine, Louisville VAMC, Louisville, KY.* Sponsor: D. Conklin.

Purpose: Nonalcoholic steatohepatitis (NASH) typically develops obese patients and is believed to be the hepatic manifestation of the metabolic syndrome. Recently, NASH was described in lean individuals exposed to industrial toxicants. Here, we describe toxicant associated steatohepatitis (TASH) in American vinyl chloride (VC) workers. Next, we compare diagnostic strategies and second-hit mechanisms between TASH and NASH due to obesity. Material and Methods: Liver biopsies from 26 non-alcoholic, highly exposed, VC workers were evaluated for steatohepatitis (TASH). Serum from affected workers was analyzed and compared by ANOVA to (i) 48 unexposed, obese subjects with biopsy documented NASH, and (ii) 37 healthy controls. Analytes included: routine chemistries, cytokines, cytokeratin 18, and antioxidant capacity. Results: In VC workers, the prevalence of TASH was 78%. Affected workers had a mean BMI of 26±3.9 and an estimated mean cumulative VC exposure of 14,000±6500 PPM-Yr. The histological severity of steatohepatitis was equivalent between the TASH and NASH groups. Although ALT and AST were elevated in NASH, they were normal in TASH. While cytokeratin-18 M65 antigen was elevated in both groups, the M30 fragment was elevated only NASH. Insulin resistance and adiponectin reduction were similar between TASH and NASH. TASH was associated with markedly elevated TNFα, IL1, IL6, IL8, and IL18. Serum antioxidant capacity was reduced to a greater degree in NASH than TASH. Conclusion: TASH frequently occurs in non-obese VC workers with normal liver enzymes and high cumulative exposures. Cytokeratin-18 M65 antigen may be a useful serologic biomarker for TASH and suggests the presence of necrotic rather than apoptotic cell death. Although insulin resistance due to reduced adiponectin is common to both TASH and NASH, differences exist in pro-inflammatory cytokine levels and antioxidants. The threshold exposure and the role of other chemical agents in TASH are unknown.

1864 PROTECTIVE EFFECT OF THE AQUEOUS EXTRACT FROM THE ROOTS OF PLATYCODON RADIX ON ETHANOL-INDUCED LIVER INJURY IN RAT.

T. Khanal[1], J. Choi[1], B. Park[2], Y. Chung[3] and H. Jeong[1]. *[1]BK21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South, [2]Jangsaeng Doraji Research Institute of Biotechnology, Jangsaeng Doraji Co., Ltd., Jinju, Jinju, Korea, South and [3]Division of Food Science, International University of Korea, Jinju, Jinju, Korea, South.*

Alcoholic steatosis is the earliest and most common response to heavy alcohol intake, and may precede more severe forms of liver injury. Accumulation of fat, largely triglyceride, in hepatocytes results from the inhibition of fatty acid oxidation and excessive oxidative stress involving CYP2E1. The protective effects of an aqueous extract from the roots of Platycodon radix, Changkil (CK), on alcohol-induced liver injury in an enteral alcohol feeding model was investigated. Male Wistar rats were given control liquid diets or ethanol containing diets enterally for 4 weeks. Ethanol delivery and weight gain were not different between the CK-ethanol and ethanol groups. Pretreatment with CK prior to the administration of ethanol significantly prevented the increase in serum alanine aminotransferase (ALT), aserum spartate transaminase (AST) activities, serum albumin, necrosis and inflammation.

Moreover, ethanol elevated hepatic triglyceride content, hepatic lipid peroxidation, and induced CYP2E1. These effects were all blocked by CK treatment. Alcohol administration resulted in a decrease in AMP-activated protein kinase-alpha (AMPK-alpha) phosphorylation, which was restored by CK treatments. Recovery of AMPK activity by CK was supported by an increase in acetyl-CoA carboxylase phosphorylation. These results demonstrate that the CK effectively treats alcoholic steatosis with CYP2E1 inhibition, which may be associated with the recovery of AMPK activity, promising that the combination therapy may constitute an advance in the development of clinical candidates for alcoholic steatosis.

PS 1865 EUGENIA JAMBOLANA FRUIT EXTRACT DOES NOT ALTER CHOLESTASIS-INDUCED LIVER INJURY DESPITE DOWN REGULATION OF EFFLUX TRANSPORTER EXPRESSION IN MICE.

A. Donepudi, A. L. Slitt and N. Seeram. *Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.*

Eugenia Jambolana (Jamun) fruit is reported to contain endogenous antioxidants and is used in some cultures as a therapy to treat liver-based diseases. Because Jamun may have beneficial effects for liver, we hypothesized that Jamun fruit extract (JFE) might have a protective effect on liver injury caused by extrahepatic cholestasis. Extrahepatic cholestasis is defined as obstruction of bile flow from the liver, which occurs outside the liver. Alterations in transporter expression in liver is thought be an adaptive mechanism turned on in liver to decrease toxic bile acid levels in hepatocytes. Based on this premise, it is anticipated that downregulation of transporters that efflux bile acids would enhance cholestasis-induced hepatic injury. To determine whether administration of JFE affects the progression and severity of extrahepatic cholestasis, mice underwent either sham or bile-duct ligation (BDL) surgery. Starting the next day after surgery, sham and BDL mice were administered either JFE (100 mg/kg, po) or vehicle for 10 days once daily. Livers were collected for histopathological assessment and quantification of mRNA expression by the Branched DNA Signal Amplification Assay. Histopathological analysis revealed that JFE had no effect on BDL-induced pathological changes in liver. As anticipated, BDL increased Oatp1a4, Mrp3, and 6 and decreased Oatp1a1, Oatp1b2, and Ntcp mRNA expression. In sham controls, JFE administration increased Mrp3 and decreased expression of Oatp1a4, 1b2, Mrp2, 4 mRNA expression in liver. Treatment with JFE also decreased Mrp1, 4, and 6 after BDL, but this did not alter BDL-induced injury. In summary, administration of JFE did not protect against liver injury induced by BDL in mice. Interestingly, down regulation of efflux transporter expression during cholestasis did not increase the level of hepatic injury, indicating that Mrp1 and 6 upregulation probably do not contribute to hepatoprotection during chronic extrahepatic cholestasis. (NIH KES013782AP20RR016457)

PS 1866 DEVELOPMENT OF AN *IN VITRO* MODEL WITH THE POTENTIAL FOR DETECTION OF CHOLESTATIC COMPOUNDS.

L. Rice[1,3], E. Ainscow[1], J. Bowes[3], M. Ismair[2], J. Pilling[1], J. Valentin[3], R. Walls[1], P. Webborn[2] and M. Sullivan[1]. *[1]ASTL, AstraZeneca, Loughborough, United Kingdom, [2]DMPK, AstraZeneca, Loughborough, United Kingdom and [3]Safety Assessment, AstraZeneca, Macclesfield, United Kingdom.*

The liver transporters bile salt efflux protein, BSEP, and multidrug resistance protein, MRP2, can be inhibited by compounds leading to cholestasis and drug-induced liver injury. Early in vitro identification of compounds that inhibit transporters will help reduce attrition due to cholestasis. We describe a method for detection of compound-specific changes in expression and localisation of BSEP and MRP2 in hepatocytes using imaging technology. This data was compared to that obtained from assays for compound inhibition of BSEP and MRP2 in cell membrane vesicles. Using an automated platform, primary rat hepatocytes were treated with 65 compounds in a 96 well format. Cells were fixed and stained for BSEP and MRP2 using specific antibodies. Parallel assays were performed to detect Actin and Tubulin to determine effects on canalicular architecture. Algorithms were designed to quantify localisation and expression of the proteins. Choice of culture media proved an important factor for BSEP expression and therefore assay performance. Under defined conditions for optimal BSEP expression, Troglitazone caused BSEP internalisation. This response was significantly greater than that seen in hepatocytes cultured in standard, commercially available media. In the full compound set we observed various effects on BSEP and MRP2 expression and localisation. This may reflect the different causative mechanisms of drug-induced cholestasis. We also utilised vesicle transport assays for analysis of MRP2 and BSEP inhibition. We observed potent inhibition of BSEP-mediated taurocholate transport and MRP2-mediated carboxydichlorofluorescein (CDF) transport by cholestatic compounds. We combined the vesicle and imaging data using a statistical modeling approach. This resulted in a rank order of compounds with cholestatic potential. Statistical modeling revealed that combining information from two different assay systems shows potential for use in early detection of cholestatic compounds.

PS 1867 ASSESSING THE INHIBITION OF BILE ACID TRANSPORT AND CHOLESTATIC POTENTIAL OF DRUG CANDIDATES IN 24-WELL RAT AND HUMAN SANDWICH-CULTURED HEPATOCYTES (B-SAFE™).

J. Ansede, W. R. Smith, J. C. Clark, R. L. St. Claire, C. H. Perry and K. R. Brouwer. *Research & Development, Qualyst, Inc., Raleigh, NC.*

Drug-induced cholestasis may result from the inhibition of biliary efflux of bile acids in the liver. Inhibition of the hepatic uptake and/or the biliary efflux of bile acids will result in an increase in serum concentrations. However, it is the intracellular concentration of bile acids that may be responsible for hepatotoxicity and thus serum concentrations of bile acids may not necessarily be an appropriate indicator of hepatotoxicity. Sandwich-cultured hepatocytes (B-CLEAR®/B-SAFE™) maintain many of the structural and functional attributes of hepatocytes in vivo, and have been used as an in vitro model to predict the in vivo biliary excretion of drug candidates. The B-SAFE™ methodology maintains the expression and function of key uptake and efflux transporters and is the optimal system to evaluate and predict the potential of a compound to cause transporter based liver toxicity. The effect of test compounds on the accumulation, BEI (biliary excretion index), and $Cl_{biliary}$ (in vitro biliary clearance) of a stable isotope of taurocholate (d_8-TCA) were evaluated in 24-well B-SAFE™-RT (rat) and –HU (human) The accumulation, BEI and $Cl_{biliary}$ of d_8-TCA were 7.28 ± 1.30 pmol/mg protein, 76.9 ± 5.73 % and 8.14 ± 1.36 mL/min/kg, respectively in B-SAFE™-RT and 62.4 ± 27.5 pmol/mg protein, 65.8 ± 10.2 % and 37.7 ± 10.5 mL/min/kg, respectively in B-SAFE™-HU. Cyclosporine resulted in an increase in accumulation and decrease in the biliary efflux (BEI and $Cl_{biliary}$) of d_8-TCA in B-SAFE™-RT, however, in B-SAFE™-HU, cyclosporine resulted in a decrease in uptake (accumulation) and biliary efflux of d_8-TCA. The effects of additional cholestatic agents were evaluated and the results are presented. Furthermore, a stable isotope of glycocholate (the glycine conjugate of cholic acid and the dominant bile acid found in humans) was synthesized and evaluated along with a fluorescent derivative (cholyl-lysyl fluorescein) as alternate probes to assess the cholestatic potential of drugs in 24-well B-SAFE™.

PS 1868 TISSUE FACTOR-DEPENDENT COAGULATION CONTRIBUTES TO ALPHA-NAPHTHYLISOTHIOCYANATE-INDUCED CHOLESTATIC LIVER INJURY IN MICE.

J. P. Luyendyk[1], G. H. Cantor[2], D. Kirchhofer[4], N. Mackman[3] and R. Wang[1]. *[1]Pharmacology, Toxicology and Therapeutics, The University of Kansas Medical Center, Kansas City, KS, [2]Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ, [3]Department of Medicine, University of North Carolina, Chapel Hill, NC and [4]Protein Engineering, Genentech, Inc., South San Francisco, CA.*

Separation of concentrated bile acids from hepatic parenchymal cells is a key function of the bile duct epithelial cells (BDECs) that form intrahepatic bile ducts. Using co-immunostaining, we found that tissue factor (TF), the principal activator of coagulation, colocalized with cytokeratin 19, a marker of BDECs in the adult mouse liver. BDEC injury induced by xenobiotics such as alpha-naphthylisothiocyanate (ANIT) causes cholestasis, inflammation and hepatocellular injury. We tested the hypothesis that acute ANIT-induced cholestatic hepatitis is associated with TF-dependent coagulation, and determined the role of TF in ANIT hepatotoxicity. Treatment of mice with ANIT (60 mg/kg) caused hepatic necrosis and significantly increased serum biomarkers of cholestasis (i.e., ALP and bile acids) and hepatic parenchymal cell injury (i.e., ALT). ANIT treatment also significantly increased liver TF expression and activity. ANIT activation of the coagulation cascade was indicated by increased plasma thrombin-antithrombin levels and significant deposition of fibrin within bile infarcts. ANIT-induced coagulation was reduced in low TF mice, which express 1% of normal TF levels. Moreover, ANIT-induced liver injury was reduced in the low TF mice. The results indicate that ANIT-induced liver injury is accompanied by TF-dependent activation of the coagulation cascade, and that TF contributes to the progression of injury during acute cholestatic hepatitis.

PS 1869 INHIBITION OF BOTH BSEP AND MRP2 ACTIVITY CORRELATES WITH RISK OF DRUG INDUCED LIVER INJURY IN MAN.

J. Barber[1], S. Stahl[1], B. K. Park[2], J. R. Foster[1] and J. G. Kenna[1]. *[1]Safety Assessment UK, AstraZeneca, Cheshire, United Kingdom and [2]Pharmacology and Therapeutics, Liverpool University, Liverpool, United Kingdom.* Sponsor: R. Roberts.

To explore the relationship between inhibition of biliary efflux transporters and liver toxicity, we have assessed functional in vitro inhibition of the activities of Bsep (bile salt efflux pump; ABCB11) and Mrp2 (multi-drug resistance-associated pro-

tein 2; ABCC2) by hepatotoxic and non-hepatotoxic marketed drugs. In vitro transporter inhibition was determined by live cell high content fluorescence imaging of rat hepatocytes cultured in sandwich configuration, using selective probe substrates that accumulate into sealed canalicular pockets between the cells. The probes used were cholyllysylfluorescein (Bsep) and carboxydichlorofluorescein (Mrp2). The data obtained with cholyllysylfluorescein was quantified using a novel Cellomics ArrayscanTM algorithm. Transporter inhibition studies were also undertaken using membrane vesicles from Sf21 cell lines transfected with rat Bsep, human BSEP or rat Mrp2, to confirm the data obtained using cultured hepatocytes. Potent inhibition of Bsep activity (apparent IC50<100mM) was observed with 15/25 drugs associated with cholestatic or mixed liver injury in man (60%), 1/7 drugs associated with hepatocellular liver injury (14%) and 0/5 non or minimally hepatotoxic drugs (0%). Potent inhibition of Mrp2 activity (inhibition evident at 100mM) was observed with 10/21 drugs associated with cholestatic or mixed liver injury in man (48%), but not with 5 drugs associated with hepatocellular liver injury or with 5 non/minimally hepatotoxic drugs. The drugs that exhibited potent in vitro inhibition of both Bsep and Mrp2 activity included Troglitazone, which was withdrawn from clinical use due to severe liver toxicity. The structurally related compounds Rosiglitazone and Pioglitazone also exhibited potent inhibition of Bsep activity, but were markedly less potent inhibitors of Mrp2 activity than Troglitazone. These results indicate that a combination of potent inhibition of both Bsep and Mrp2 may confer a greater risk of drug induced liver injury than Bsep inhibition alone.

PS 1870 ROLE OF NUCLEAR FACTOR-E2-RELATED FACTOR 2 (NRF2) IN CHOLESTEROL MONOHYDRATE CRYSTAL FORMATION.

M. A. Paranjpe, Q. Cheng and A. L. Slitt. *Biomedical and Pharmaceutical sciences, University of Rhode Island, Kingston, RI.*

Cholesterol gallstone formation occurs with a high cholesterol diet and dysregulation of cholesterol handling in liver. Some populations are found to be more susceptible to gallstone formation, suggesting a genetic component to this susceptibility. Gallstones develop when cholesterol levels in bile are high resulting in cholesterol precipitation, crystallization, and gallstone formation. Nrf2 is a transcription factor that regulates the expression of many enzymes and transporters in liver that mediate metabolism and transport processes. Preliminary data demonstrate that Nrf2-null mice are resistant to gallstone formation when fed a lithogenic diet (15% fat, 1.25% cholesterol, 0.5% sodium cholate) for 9 weeks. The purpose of this study was to examine early changes in biliary cholesterol crystallization and transporter expression in wild-type (WT) and Nrf2-null mice fed a lithogenic diet for 14 days. Male littermate WT and Nrf2-null mice were fed with a lithogenic or standard diet (5% fat) for 14 days, then gallbladders and livers were collected. The lithogenic diet resulted in increased crystal formation in the gallbladder biles of WT mice as compared to Nrf2-nulls. Total RNA was isolated from liver and the mRNA expression of transporters involved in hepatic cholesterol and bile acid transport was determined using the Branched DNA Amplification Assay. The lithogenic diet increased Abca1, Abcg5/8, and Mdr2 mRNA expression equivalently in livers of WT and Nrf2-null mice. In contrast, Bsep induction by the lithogenic diet was greater in WT mice as compared to Nrf2-nulls. Mrp3 levels were significantly lower in livers of WT mice as compared to Nrf2-nulls fed either the standard or lithogenic diet. Together the lack of major differences in transport expression, other than Mrp3, between WT and Nrf2-null mice do not explain the genotype difference in crystal formation. Further studies will address how Nrf2 may regulate other molecular mechanisms that contribute to cholesterol uptake, metabolism, and excretion. (NIH KES013782A, P20RR016457)

PS 1871 ACETAMINOPHEN DISPOSITION: METABOLOMIC BIOMARKER FOR NON-ALCOHOLIC FATTY LIVER DISEASE.

M. D. Merrell[1], A. J. Lickteig[1], C. D. Fisher[1], L. M. Augustine[1], S. B. Campion[3], J. E. Manautou[3], H. H. A-Kader[2], R. P. Erickson[2] and N. J. Cherrington[1]. [1]*Pharmacology and Toxicology, University of Arizona, Tucson, AZ,* [2]*Pediatrics, University of Arizona, Tucson, AZ and* [3]*School of Pharmacy, University of Connecticut, Storrs, CT.*

Non-alcoholic fatty liver disease (NAFLD) includes a range of pathologies from simple steatosis to steatohepatitis (NASH). Researchers estimate the prevalence of NAFLD to be 20-25% and NASH at 2% of the US population. NAFLD has been linked to obesity, and with childhood obesity rates increasing drastically, the number of children with severe liver disorders continues to grow. One obstacle to proper treatment is the inability of clinicians to easily distinguish between simple steatosis and NASH. Currently, needle biopsy is the only conclusive method of diagnosing and staging NAFLD. A key concern with NASH is the possibility that altered hepatic function could interfere with proper elimination of therapeutic drugs leading to toxicity. Previous work from our laboratory using a rodent model of NASH indicated changes in the disposition of acetaminophen (APAP) metabolites, where an increase in the expression of the sinusoidal efflux transporter Mrp3 leads to elevated plasma and urinary levels of APAP-glucuronide. The current study was conducted to determine whether human NAFLD also results in altered disposition of APAP and APAP metabolites. Adolescent patients with mild and severe NAFLD and normal patients were given a single 1000 mg dose of APAP. Blood and urine samples were collected over time and the levels of APAP and APAP metabolites were determined by HPLC. As with the rodent model of NASH, patients with the more severe disease (steatosis, inflammation, fibrosis) had significantly increased plasma and urinary levels of APAP-glucuronide. Additionally, adult post-mortem NASH liver samples exhibited increased levels of Mrp3 protein. These findings corroborate the validity of the NASH animal model, and present the possibility of a non-invasive diagnostic tool for the advanced stages of NAFLD. (supported by DK068039 and ES007091)

PS 1872 EXPOSURE TO AIR POLLUTION INDUCES INFLAMMATION IN VISCERAL ADIPOSITY IN MICE.

Z. Yavar, M. Verdin, N. Kherada, A. Wang, S. Rajagopalan and Q. Sun. *The Ohio State University, Columbus, OH.*

Background: Exposure to ambient particulate potentiates an increased inflammatory response resulting in increased susceptibility to cardiovascular diseases. We hypothesized that exposure to fine particulate matter ($PM_{2.5}$) pollution at early age induces systemic inflammation and monocyte/macrophage infiltration in visceral adipose tissue through adipose tissue macrophage (ATM) activation and pro-inflammatory classically activated (M1)/anti-inflammatory alternatively activated (M2) macrophage phenotypic change. Methods: Four week old C57BL/6 mice were fed with either normal chow (NC) or high fat chow (HFC) diet, and exposed to $PM_{2.5}$ or filtered air (FA) 6 hours a day, 5 days a week for an 10 week period in a mobile trailer "OASIS-1" (Ohio's Air Pollution Exposure System for the Interrogation of Systemic Effects-1) in Columbus, OH. After mice sacrifice, subcutaneous and epididymal (regarded as visceral fat in mice) fats were collected, and monocyte chemotactic assay was performed using THP-1 cells (human monocytic cells, in the top wells) and fat tissues (in the bottom wells) via a 48 well Boyden chamber. Inflammatory biomarkers were measured by ELISA. Immunohistochemical staining of F4/80 and CD68 was preformed in the fat tissues and M1/M2 gene expression was measured in ATM through real time-PCR. Results: $PM_{2.5}$ exposure results in circulating biomarker IL-6, TNF-α, and MCP-1 increase, and significant macrophage infiltration in visceral adipose tissue. Boyden chamber assay showed that $PM_{2.5}$ exposure dramatically increased epididymal fat chemotaxis to monocytes than subcutaneous fat. M1 gene expression was upregulated and M2 gene expression dowregulated in the $PM_{2.5}$ group compared with FA group. High fat diet exaggerated the inflammatory effects and macrophage infiltration. Conclusions: Exposure to $PM_{2.5}$ pollution at early age induces systemic inflammation, macrophage infiltration in visceral adipose tissue, and M1/M2 gene changes. $PM_{2.5}$ and high fat diet has synergistic effect on macrophage infiltration and M1/M2 gene expression change.

PS 1873 EFFECTS OF SAPONINS ISOLATED FROM THE ROOTS OF PLATYCODON GRANDIFLORUM ON ALLERGIC AIRWAYS INFLAMMATION IN THE MURINE MODEL.

J. Choi and H. Jeong. *BK21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South.*

Asthma is a chronic inflammatory disorder of the airways characterized by the development of allergen-induced airway remodeling. In this study, we investigated protective effect of the saponins isolated from the roots of Platycodon grandiflorum (Changkil saponins, CKS) on airway inflammation in a mouse asthma model immunized and challenged with ovalbumin (OVA). Mice sensitized and challenged with OVA inhalation to induce chronic airway inflammation and airway remodeling. OVA had increased amounts of T-helper cell type 1 and 2 (Th1 and Th2) cytokines in bronchoalveolar lavage (BAL) fluid. CKS significantly inhibited the OVA-induced Th1 cyokines (TNF-a and IFN-gamma)and Th2 cytokines (IL-4, IL-5, and IL-13), chemokine (monocyte chemotactic protein-1) and OVA-specific IgE levels in BAL fluid. Also, total cells and eosinophils in the BAL fluid markedly decreased after CKS administration. The mice treated with CKS showed marked reductions in the infiltration of inflammation cells within the perivascular region. In addition, the lung weight was reduced compared with OVA-induced control group after CKS administration. As a result, all parameters were attenuated in a dose-dependent manner by the administration of CKS. Taken together, the results of our study provide evidence that CKS may attenuate the development of airway inflammation by reducing Th1 and Th2 cytokines.

PS 1874 INCREASED SUSCEPTIBILITY OF NEONATES TO THE INFLAMMATORY EFFECTS OF MONO-2-ETHYLHEXYL PHTHALATE.

A. M. Vetrano[1, 2], F. E. Archer[1], J. P. Gray[3], D. E. Heck[2], J. D. Laskin[1], D. L. Laskin[3] and B. I. Weinberger[1]. *[1]UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ, [2]New York Medical College, Valhalla, NY and [3]Rutgers University, Piscataway, NJ.*

Intubated neonates are exposed to higher levels of phthalate plasticizers per kg body weight than any other population. Di-2-ethylhexyl phthalate, the only plasticizer approved by the FDA for medical uses, leaches out of medical tubing into tissues where it is converted into a number of metabolites including mono-2-ethylhexyl phthalate (MEHP). Recent studies have cited a potential link between exposure to phthalates and the development of inflammatory diseases in neonates. In the present studies, we compared the effects of MEHP on neonatal and adult neutrophils. We speculated that differences in the sensitivity of these cells to MEHP may underlie disease susceptibility in neonates. Neutrophils were isolated from umbilical cord blood or adult venous blood from healthy subjects. Cells were treated with MEHP (250-500 μM), and analyzed for chemotactic activity, apoptosis and production of inflammatory cytokines. We found that MEHP inhibited chemotaxis in neonatal, but not adult neutrophils. MEHP also stimulated IL-1β and IL-8 production, 8- and 5-fold, respectively, in neonatal neutrophils, with no effects on adult cells. MEHP was also found to inhibit apoptosis, however the effects were significantly greater in neonates when compared to adults. Taken together, these data indicate that MEHP plays a pro-inflammatory role in neonates by inhibiting neutrophil chemotaxis and apoptosis, and stimulating cytokine expression. Increased sensitivity of neonatal neutrophils to the effects of MEHP may explain, in part, the increased susceptibility of neonates to inflammatory diseases. Supported by NIH HD042036, ES004738 and ES005022.

PS 1875 SILICA INDUCES LUNG INFLAMMATION, TYPE II CELL HYPERPLASIA AND ALTERED LUNG MECHANICS IN MICE.

L. B. Joseph[1], D. Laskin[1], J. Cervelli[1], D. A. Elzind[1], P. Zeidler-Erdely[3], A. J. Gow[1], J. D. Laskin[2] and V. Castranova[3]. *[1]Rutgers University, Piscataway, NJ, [2]UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ and [3]NIOHS, Morgantown, WV.*

Epidemiologic studies have demonstrated that chronic exposure to crystalline silica (quartz) leads to the development of small airway disease and decreased airflow. We speculate that early release of inflammatory mediators contributes to this process. To test this, we examined the effects of exposure of mice to silica on pulmonary inflammation and lung function. C57bl/6J mice were treated intratracheally with silica (1 mg/kg Min-U-Sil 5) or PBS control. Mice were sacrificed seven days later. Total protein and cell content in bronchoalveolar fluid (BALF) increased 2-fold following silica treatment. The cellular infiltrate consisted of neutrophils and macrophages. Both "free silica" and silica engorged macrophages were also observed in BALF. We also found that expression of cyclooxygenase-2 (COX-2), a key enzyme in eicosanoid production, and surfactant protein-D (SP-D), a collectin important in regulating lung inflammation, were upregulated in the lung following silica exposure. Proliferating cell nuclear antigen (PCNA) was also upregulated in the alveolar epithelium following silica exposure. This was correlated with increased expression of the Type II cell marker, proSP-C, suggesting that silica induces Type II cell hyperplasia. In further studies we assessed the effects of silica exposure on lung function by measuring lung responsiveness to inhaled methacholine using a SCIREQ flexiVent. In both control and silica treated mice, quasi-static compliance (Cst), which reflects the elastic static recoil pressure at the level of the alveoli, decreased upon challenge with methacholine. These effects were significantly greater in animals exposed to silica suggesting a greater loss in lung elasticity. Taken together, these data suggest that early inflammatory changes may be important in structural and functional changes in the lung induced following exposure to silica. Supported by NIH grants CA132624, ES004738, ES005022, AR055073, and HL074115

PS 1876 ANTI-INFLAMMATORY AND ANTI-ALLERGIC ACTIVITY OF PUTRANJIVAIN A IN HUMAN MAST CELLS.

S. Park and S. Kim. *Pharmacology, School of medicine, Kyunpook National University, Daegu, Korea, South.*

Activated mast cells, through their effectors and regulatory functions, play a pivotal role in immune responses and the development of chronic inflammation by releasing pro-inflammatory cytokines. Mast cell-mediated allergic inflammation is known to cause many diseases such as asthma, sinusitis, and rheumatoid arthritis. Putranjivain A, isolated from Euphorbia jolkini Bioss (Euphorbiaceae), was investigated for its anti-inflammatory and anti-allergic activity in human mast cells (HMC-1). Putranjivain A dose-dependently decreased the gene expression and production of pro-inflammatory cytokines, such as TNF-α, IL-1β, IL-6, IL-8 and IL-4 on phorbol 12-myristate 13-acetate (PMA) and calcium ionophore A23187 (PMACI)-stimulated HMC-1 cells. Putranjivain A attenuated activation of NF-κB as indicated by inhibition of degranulation of IκBα, nuclear translocation of NF-κB, and NF-κB-dependent gene reporter assay. Orally administration of putranjivain A significantly reduced IgE-mediated cutaneous reactions and gene expression of histamine H1 receptor in mice. Morever, putranjivain A dose-dependently inhibited the histamine release induced by PMACI from mast cells. These results suggest that putranjivain A attenuates the inflammatory response in activated mast cells by modulating nuclear transactivation of NF-κB and downstream cytokine production, and the allergic response by controlling histamine release and expression of histamine H1 receptor.

PS 1877 DEVELOPMENT OF A RAPID ONE-STEP METHOD USING FOUR-COLOR FLOW CYTOMETRY TO MEASURE IMMUNE CELL DIFFERENTIATION AND QUANTIFICATION IN MOUSE WHOLE BLOOD.

S. Young, M. G. Wolfarth, D. W. Porter, K. Sriram and J. M. Antonini. *NIOSH, Morgantown, WV.*

The ability to monitor changes in blood cell types is important in understanding the mechanisms and progression of allergy and immune diseases, and further may prove useful in biomarker development. In a mouse model of allergy, a rapid one-step method that uses four-color flow cytometry was developed for immune cell differentiation that requires small amounts of whole blood. Mice (male C57BL/6J) were treated by pharyngeal aspiration on days 1 and 8 to 50 μg ovalbumin or saline (vehicle control). On day 9, whole blood was recovered, and a 100 μl blood was stained with a combination of eight antibodies, incubated for 30 minutes and subsequently lysed. The antibodies consisted of the following: MHCII-FITC, CCR3-PE, CD3-PerCP, CD45R-PerCP, NK1.1-PE, Gr-1-APC, CD4-APC, and CD8a-APC. The procedure allows for identification and quantification of different white blood cells (B lymphocytes, T lymphocytes, $CD4^+$, $CD8^+$, NK, NKT, monocytes, eosinophils, and neutrophils). The Caltag counting beads were added for cell enumeration prior to analysis in FACSCalibur. Samples were acquired through a live gate without compensation. After collecting 3,500 counting beads, the data of all cells were exported to an analysis software, FlowJo. The data were then compensated and analyzed according to the following gating strategy. First, leukocytes were separated by side scattering and forward scattering into three main fractions: lymphocytes, monocytes, and eosinophils + neutrophils. Each fraction was further analyzed using cell-type specific antibodies. A significant (3- to 5-fold) increase in the percentage of monocytes, NK cells, eosinophils, and neutrophils was observed in the circulating blood of ovalbumin-treated mice compared to saline controls. In summary, a rapid four-color flow cytometric method for analyzing immune cell changes in whole blood has been developed for monitoring and assessing cellular responses during immunological and allergic disease states.

PS 1878 MULTIDRUG RESISTANCE RELATED PROTEIN (MRP) IN HUMAN LUNG CELLS IN PRESENCE OF PRO-INFLAMMATORY MEDITORS.

A. Torky, R. Gherbal, M. Ahmad, F. Glahn and H. Foth. *Environmental Toxicology, Martin Luther University, Halle / Saale, Germany.*

There are several events, which could cause inflammations, and transform the normal lung tissue into malignant tumors. Since the lung is a critical organ in oxidative stress process of either systematic or pulmonary origin, our study was to investigate possible regulatory effects of the pro-inflammatory mediators, IL6, IL-1beta, and TNF-α at physiological concentrations (25 ng/ml, 0.5 ng/ml, 0.5 ng/ml, respectively; 24h) on multi drug resistance related proteins (MRP) expression and activity in both normal human bronchial epithelial(NHBEC) and A549 human tumor cells. The results in primary bronchial cells (NHBEC) have confirmed the localization of MRP1-3 as cell membrane proteins as the case in tumor cell line A549. In cultivated normal human bronchial epithelial cells (NHBEC), MRP1 expression was minimally decreased (≤ 10% compared to control) upon treatment with IL-6, IL-1beta and TNF-α. In general, these cytokines had no effect on MRP2 and MRP3 protein expression. In A549 cells the expression of MRP1 showed slight up-regulation (20-25%) with IL-1beta. TNF-α and IL-6 had almost no effect on MRP1 protein expression. IL-6 down-regulated MRP2 protein expression to 68 % of control values and TNF-α and IL-1beta reduced MRP2 slightly. However, the MRP3 protein was induced (15-30%) by TNF-α and IL-lbeta. The strongest inductive effect was mediated by IL-6 (50%). MRPs transport activity was measured by single cell fluorometry with 5-(6-)carboxy-2',7'-dichloro-fluorescein, because

MRP function may vary from protein content. IL-1beta significantly inhibited MRP-mediated CDF efflux in both NHBEC cells and A549 cells. IL-6 showed tendency to suppress MRP activity in both cell types. TNF-α inhibited MRP transport activity only in NHBEC and not in A549 cells. In summary, major proinflammatory mediators IL-1beta, IL-6 and TNF-α can affect MRP expression and function in lung cells. The response of primary human lung cells was different between MRP protein content and functional activity, so these cytokines may act as inhibitors of MRP function.

PS 1879 EVIDENCE THAT PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR-β/δ (PPARβ/δ) IS NOT UPREGULATED BY THE APC/β-CATENIN PATHWAY OR DOWNREGULATED BY NONSTEROIDAL ANTI-INFLAMMATORY DRUGS (NSAIDS).

J. E. Foreman[1], J. M. Sorg[1], K. S. McGinnis[1], B. Rigas[2], J. L. Williams[2], F. J. Gonzalez[3] and J. M. Peters[1]. *[1]Pennsylvania State University, University Park, PA, [2]State University of New York at Stony Brook, Stony Brook, NY and [3]National Cancer Institute, Bethesda, MD.*

The role of PPARβ/δ in colon carcinogenesis remains controversial, as some studies indicate that PPARβ/δ can either attenuate or potentiate this disease. One hypothesis suggests that PPARβ/δ is upregulated by the APC/β-catenin pathway and a related hypothesis suggests that PPARβ/δ is downregulated by NSAIDS. The present study critically examined these ideas using in vivo and in vitro models. Expression of PPARβ/δ was not different in colon or intestinal polyps from wild-type or APCmin heterozygous mice. Expression of PPARβ/δ was also not significantly different in human colon cancer cell lines with different mutations in APC and/or β-catenin. Differences in the expression of either PPARα or PPARγ were also not observed in any of these colon cancer models. Expression of PPARβ/δ was also examined in vivo and in vitro following exposure to different NSAIDs. No difference in the level of PPARβ/δ was found in colonic nuclear extracts from wild-type or APCmin heterozygous mice following treatment with NO-donating aspirin. While NSAIDs inhibited cell growth of the human colon cancer cell lines, expression of PPARβ/δ was similar in RKO and DLD1 human colon cancer cell lines in response to a broad concentration range of either celecoxib, indomethacin, NS398 or nimesulide. Interestingly, expression of PPARα was increased in the human colon cancer cell lines by several NSAIDs at the highest concentration examined. Results from these studies show that PPARβ/δ is not upregulated by the APC/β-catenin pathway. Further, these studies show that PPARβ/δ is not downregulated by NSAIDs suggesting that the mechanisms underlying the chemopreventive effects of NSAIDs do not include downregulation of PPARβ/δ.

PS 1880 DIET-INDUCED OBESITY EXACERBATES INFLAMMATORY/OXIDATIVE STRESS RESPONSES IN MICE EXPOSED TO CIGARETTE SMOKE.

K. Waters[1], B. Webb-Robertson[1], N. Karin[1], R. Zangar[1], D. Bigelow[1], V. Mikheev[2], K. Lee[2], J. Pounds[1] and R. Corley[1]. *[1]Pacific Northwest National Lab, Richland, WA and [2]Battelle Toxicology Northwest, Richland, WA.*

Smoking and obesity are two of the most important, preventable risk factors for human morbidity and mortality. Our hypothesis is that oxidative stress is the unifying mechanism underlying the interaction of these lifestyle-induced risk factors with other environmental toxicants and the genome, resulting in a variety of chronic human diseases. To identify the key biological pathways that define environmental and lifestyle susceptibility factors, we performed parallel exposures of normal C57BL/6 and diet-induced obese (DIO) C57BL/6 mice to cigarette smoke, either mainstream (MS) or sidestream (SS), for 5h/d for 8 days. Blood carboxyhemoglobin levels of ≈30% were used to determine a maximum tolerated exposure for MS smoke (250ug/L WTPM) and SS smoke (85ug/L WTPM). Bronchoalveolar (BAL) cytology indicated a strong neutrophil response with MS smoke, which was 3.5-fold higher in DIO mice but absent with SS smoke exposure. Levels of inflammatory cytokines in BAL fluid also increased after MS smoke exposure in regular and DIO mice (IL-12, MCP-1, MIP-1γ) and some displayed significant increases in only DIO mice (IL-1α, TARC, VEGF). Microarray analysis revealed that DIO reprograms the lung's transcriptional response, altering both the number of genes and the specific molecular pathways induced or suppressed by smoke exposure. Despite the lack of a measureable inflammatory response with SS smoke in the BAL fluid, the microarray data demonstrate significant increases in several genes associated with SS smoke exposure, such as Cxcl5 and Cyp1b1, as well as unique gene changes that aren't seen with MS smoke. In addition, we identified more than 300 genes whose expression levels are significantly different between regular and DIO sham control animals, indicating potential susceptibility factors. These results show enhanced and unique stress responses in obese mice, which make them more sensitive to environmental exposure of lung toxicants. Supported by U54 ES016015.

PS 1881 IRON-MEDIATED PROINFLAMMATORY RESPONSE IN LUNG ENDOTHELIAL CELLS.

N. V. Gorbunov[1], D. K. Das[2], N. Gurusamy[2], Y. Y. Tyurina[1], V. E. Kagan[1] and B. R. Pitt[1]. *[1]Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA and [2]Cardiovascular Research Center, University of Connecticut, Farmington, CT.*

Activation of iron turnover in lung has been shown recently to produce oxidative stress followed by increase in leukocyte-endothelial interaction in alveolar microvessels. To clarify the iron-sensitive mechanisms mediating the proinflammatory effects we exposed rat pulmonary endothelial cells (RPAECs) to [Fe2+] pulse in the presence of the ionophore perithione and assessed (i) [Fe2+] influx, (ii) cell shape profile, (iii) relative electrical resistance of cell monolayer (REEREM), (iv) depletion of cell thiols, (v) redox-dependent nuclear translocation of NFkB and Nrf2, (vi) expression of ICAM-1 adhesion molecules, and (vii) spatial re-arrangement of the structural proteins, e.g., caveolin-1, F-actin, gelsolin, and pho-caldesmon. The produced effects were monitored with live cell imaging, EVOM endothelial voltohmmetry, immunofluorescnce confocal imaging, immunoblotting techniques, and ThioGlo-probing of thiols. Incubation of RPAECs with 30 μM [Fe2+]-nitriloacetate over 10 min resulted in depletion of cell thiols followed by nuclear translocation of Nrf2 and p50/p65 kB. Iron-induced alterations were characterized by cell polarization, formation of membrane rafts and microvilli-like membrane projections abundant with ICAM-1 adhesion molecules, pho-caveolin-1, pho-caldesmon, and F-actin proteins. The associated re-arrangements in cytoskeleton were accompanied by alterations in integrity of RPAEC monolayer measured by decrease in the REEREM values. These effects were mitigated in the presence of N,N'-bis (2-hydroxybenzyl) ethylenediamine-N,N'-diacetic acid, a polyphenol iron chelator, and Y27367, an inhibitor of Rho kinase. We have suggested that proinflammatory response of RPAECs to [Fe2+] pulse proceeds via redox-sensitive mechanisms which mediate re-arrangement of cell structural proteins, i.e., caveolin-1 and F-actin, and ICAM-1 inflammatory adhesion molecules, and increase in trans-endothelial permeability.

PS 1882 EVALUATION OF SAFETY AND EFFICACY OF TNFR1-SELECTIVE ANTAGONISTIC MUTANT TNF AS A NOVEL ANTI-INFLAMMATORY DRUG.

Y. Abe[1], H. Shibata[1, 2], T. Nomura[1, 3], H. Kayamuro[1], T. Yoshikawa[1, 3], Y. Yoshioka[1, 4], S. Nakagawa[3], H. Kamada[1, 4], S. Tsunoda[1, 4] and Y. Tsutsumi[1, 3, 4]. *[1]Laboratory of Pharmaceutical Proteomics, National Institute of Biomedical Innovation, Ibaraki, Osaka, Japan, [2]National Institute of Health Science, Tokyo, Japan, [3]Graduate School of Pharmaceutical Sciences, Osaka University, Suita, Osaka, Japan and [4]The Center for Advanced Medical Engineering and Informatics, Osaka University, Suita, Osaka, Japan.* Sponsor: Y. Abe.

Tumor necrosis factor (TNF) is a major inflammatory cytokine that plays a central role in host defense and inflammation via two receptor subtypes, TNFR1 and TNFR2. Elevated serum levels of TNF correlates with the severity and progression of the inflammatory diseases such as rheumatoid arthritis. So far, anti-TNF antibodies and soluble TNFRs have been used to treat various inflammatory diseases. However, these therapies can cause serious side effects, such as bacterial and virus infection and lymphoma development because they also inhibited the host defense function mediated by TNFR2. Therefore, we hypothesized that selective inhibition of TNF/TNFR1 could avoid undesirable side-effect of inhibiting antiviral immunity. With this in mind, we succeeded in generating PEG (polyethylene glycol)-modified TNFR1-selective antagonistic mutant TNF, designated PEG-R1antTNF as a novel anti-TNF drug candidate. In this study, we have evaluated the safety and efficacy of PEG-R1antTNF. In a murine collagen-induced arthritis model, PEG-R1antTNF clearly improved the incidence, and the clinical score of arthritis was less than half of that of the control group due to its long plasma half-life. Next, we compared the effects of PEG-R1antTNF and existing TNF-blocking drug Etanercept on antiviral immunity using a luciferase-expressing recombinant adeno virus vector. In the Etanercept-treated group, luciferase activity was significantly higher than in the control group, suggesting that the drug delayed clearance of the virus. In contrast, PEG-R1antTNF-treated group did not reactivate viral infection. These results indicate that PEG-R1antTNF might lack one of the serious side effects of existing anti-TNF drug because of its TNFR1 selectivity.

PS 1883 GENDER-DIMORPHIC INFLAMMATORY RESPONSE IN HALOTHANE HEPATITIS IN MICE.

C. M. Dugan[1], A. E. MacDonald[2], R. A. Roth[2] and P. E. Ganey[2]. *[1]Cell and Molecular Biology, Michigan State University, East Lansing, MI and [2]Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

The once widely used anesthetic halothane induces a mild hepatotoxicity in 1 in 5 patients and idiosyncratic fulminate liver injury, or halothane hepatitis, in approximately 1 in 30,000. The mechanism of the severe form of halothane hepatic injury

is thought to involve the adducts of halothane's reactive metabolite, triflouroacetyl- (TFA) chloride. Female gender is a risk factor for halothane hepatotoxicity in humans. We tested the hypothesis that the sensitivity to halothane hepatotoxicity conveyed by the female gender is due to an enhanced inflammatory response in mice. Female Balb/c mice developed severe liver injury within 12 hrs when treated with 15mmol/kg halothane (ip) as indicated by increased serum alanine aminotransferase (ALT) activity (6,000 U/L). The histopathologic lesions were consistent with those seen in postmortem liver specimens from halothane hepatitis patients. This is in contrast to male mice, which had no significant increase in serum ALT activity and minimal liver pathologic lesions at this dose. There was equivalent immunohistochemical staining of TFA-adducted proteins in the livers of male and female halothane-treated mice, suggesting that a difference in bioactivation does not explain the lack of liver injury in males. Serum tumor necrosis factor alpha (TNFα) concentration increased to 300 pg/ml by 12 hrs in halothane-treated female mice and remained elevated at 24 hrs. In contrast, males had no significant increase in serum TNFα. Hepatic neutrophil accumulation occurred sooner and to a greater magnitude in halothane-treated female mice compared to male mice. Halothane-induced hepatic injury was reduced (ALT~2000 U/L) at 12 hrs in females mice treated with CD-18 antiserum to inhibit transmigration and activation of neutrophils. These results suggest that the greater sensitivity of females to halothane hepatotoxicity may be due to a gender-dimorphic innate immune response. (Supported by NIH grant GM075865.)

PS 1884 THERAPEUTIC EFFECT OF AFGF/G-CSF/ZN ON DIABETIC ULCER HEALING AND MECHANISMS.

Y. Tan[1, 2], H. Xu[2], J. Xiao[2], X. Li[2] and L. Cai[1, 2]. [1]*Department of Medicine, University of Louisville, Louisville, KY and* [2]*Chinese-American Research Institute for Diabetic Complications, Wenzhou Medical College, Wenzhou, Zhejiang, China.*

Previous studies demonstrated that supplementation of exogenous growth factor (i.e., aFGF or G-CSF) partially improved diabetic wound healing, but the full restoration has not been obtained due to the persistent local oxidative stress in the ulcer sites. Therefore, the combined therapeutic strategies including antioxidant should be further explored. To observe the therapeutic effects of combined use of aFGF/G-CSF/ZnSO4 on diabetic ulcer healing, diabetes was induced by a single dose of streptozotocin (55 mg/kg) in Sprague Dawley (SD) rats, diabetic ulcer models were made by snipping full thickness skin at 2 month after diabetic SD rats raised. The diabetic ulcer rats were divided into six groups, and treated with aFGF, G-CSF, ZnSO4, aFGF/G-CSF/ZnSO4 and vehicle control respectively. Therapeutic effects were evaluated on 3, 6, 9, 12, 15, 18 and 21 day after treatment. We found that aFGF/G-CSF/ZnSO4 treatment group had significant better therapeutic effect in ulcer area compared with single drug treatment groups and vehicle control at different time points ($p<0.05$). Wound 50% healing time and 100% healing time for aFGF/G-CSF/ZnSO4 group were 10.88±1.85 and 20.00±1.15 days respectively, which were significantly shorter than those of the groups treated with single factor and saline ($p<0.05$). Histopathological and immunohistochemical analysis found that the capillary density, PCNA positive cell rate, and the expression of TIMP-1, MMP-1 and MMP-9 in aFGF/G-CSF/ZnSO4 treated rats were all significant higher than those of the rats treated with single drug or vehicle on 6, 15 and 21 day after treatment. Collectively, these data suggested that aFGF/G-CSF/ZnSO4 had significant diabetic ulcer curative effect, and the mechanisms of this therapeutic effect might attribute to promotion of fibroblast proliferation and differentiation, enhancement of blood vessel regeneration and up-regulation the expression of MMP-1, MMP-9, and TIMP-1 in diabetic ulcer healing process.

PS 1885 EFFECTS OF INDUCIBLE NITRIC OXIDE SYNTHASE INHIBITION ON SKIN WOUND HEALING AND MONONUCLEAR PHAGOCYTIC SYSTEM.

R. R. Bell[1], P. T. Manning[2], L. F. Branson[3] and N. K. Khan[1]. [1]*Drug Safety Research & Development, Pfizer Inc., Groton, CT,* [2]*Research & Development, VASCULOX, Inc., St. Louis, MO and* [3]*Cardiovascular Pharmacology, Pfizer, Inc., Chesterfield, MO.*

The inducible isoform of the nitric oxide (NO) synthase (NOS) enzyme (iNOS) is up-regulated by inflammatory mediators and/or other pathological stresses, generating high, sustained levels of NO. Cumulative data suggest a role for NO in the regulation of skin wound healing, although it is not clear to what extent NO generated by iNOS, and possibly endothelial NOS (eNOS), contribute to that healing process. Therefore, an in vivo incisional wound healing study was conducted to investigate the possible role of SC-842, a selective inhibitor of iNOS, in interfering with wound healing. It has been suggested that the effect of selectively modulating NO generated by iNOS may provide a balance between maintaining host defense and protecting the host from the pathological effects of sustained, high levels of NO. The relative contribution of the individual isoforms of NOS in the production of NO and the importance in the human compared to the rodent are not well understood, particularly as to date, no clinical data describing the use of selective iNOS inhibitors is published. Macrophages are among the first lines of defense in host response to immunogens; this study evaluated the potential effects of SC-842 on the functional activity of the mononuclear phagocytic system (MPS).These data indicates that iNOS inhibition does not adversely affect the healing of incisional wounds in SKH-1 mice as assessed over 28 days by wound tensile strength and histology. Importantly, phagocytosis in vivo studies are consistent with the absence of clinically significant immunotoxicological potential for selective iNOS inhibition on the mononuclear phagocytic system. Studies on other components of the immune system are needed to further explore possible immunomodulatory effects of selective iNOS inhibitors.

PS 1886 NEUTROPHIL ACTIVATION BY HIGH MOBILITY GROUP BOX-1 PROTEIN IN MICE.

D. Williams, H. Yan and H. W. Jaeschke. *Pharmacology, Toxicology & Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

High Mobility Group Box-1 (HMGB-1) is released by necrotic cells and can trigger a non-infectious inflammatory response by activating the Toll-like Receptor-4 (TLR-4). To assess if HMGB-1 activates neutrophils (PMNs) directly or indirectly through Kupffer cells, recombinant HMGB-1 protein (400μg/kg) was injected i.p. into C3HeB/FeJ (TLR-4 functional) and C3H/HeJ (TLR-4 defective) mice. Endotoxin (100 μg ET/kg) or saline (10 mL/kg) was used as a positive and negative control, respectively. Two hours after injection, peripheral blood PMNs were evaluated for PMA-induced oxidative burst and CD11b surface expression by flow cytometry. TLR-4 functional mice showed a 2-fold enhanced oxidative burst in response to both ET and HMGB-1 relative to saline controls. However, no priming for oxidative burst was observed in TLR-4 defective mice. In TLR-4 functional mice, CD11b expression increased 9.2-fold after ET but did not change after HMGB-1 treatment. The ET effect on CD11b expression was eliminated in TLR-4 defective mice. Evaluation of PMN accumulation in hepatic sinusoids showed a 13- vs 3-fold increase in liver PMNs after ET in TLR-4 functional vs defective mice, respectively. HMGB-1 increased liver PMN count 2.0-fold only in TLR-4 functional mice. To determine if Kupffer cells were responsible for the priming effect, mRNA levels of several pro-inflammatory cytokines and inducible factors were evaluated in liver tissue by realtime-PCR. ET enhanced the transcription of KC, MIP-2, IL-1β and TNF-α in TLR-4 functional mice compared to TLR-4 defective mice. HMGB-1, however, did not cause increased transcription of these cytokines (mediators) in either mouse strain. Conclusions: Both HMGB-1 and ET, in the presence of TLR-4, prime PMNs for reactive oxygen formation and hepatic accumulation in sinusoids but only ET upregulates CD11b. Whereas the ET effect on PMNs is caused by Kupffer cell-derived inflammatory mediators, HMGB-1 directly activates PMNs via the TLR-4 receptor. (Supported in part by NIH grant R01 AA12916)

PS 1887 ADMINISTRATION OF LIPOXIN ANALOG DECREASES INFLAMMATORY RESPONSES AND ENHANCES RESOLUTION PATHWAYS IN H441 CELLS TREATED WITH LPS.

R. D. Britt[1, 2], L. D. Nelin[1, 2], S. E. Welty[1] and L. K. Rogers[1, 2]. [1]*Center for Perinatal Research, The Research Institute at Nationwide Children's Hospital, Columbus, OH and* [2]*Integrated Biomedical Graduate Program, The Ohio State University, Columbus, OH.*

Background: Maternal infection and subsequent inflammation are associated with preterm birth. Prematurely born infants may lack the ability to "resolve" inflammation which contributes to the development of Bronchopulmonary Dysplasia (BPD). Lipoxin A4, a lipid-based anti-inflammatory molecule, is a high-affinity ligand for the ALX receptor (ALXR), a formyl peptide G protein coupled receptor. Clara cells, lung epithelial cells located in small airways, express ALXR and may provide important pro-resolution capabilities in the context of lung inflammation. Purpose: To test the hypothesis that the ALXR agonist, 5(S), 6(R)-lipoxin A4 methyl ester will decrease chemokine expression and increase expression of resolution molecules in H441 cells (clara-like) treated with LPS. Methods: H441 cells were pre-treated with vehicle (ethanol) or 5(S), 6(R)-lipoxin A4 methyl ester followed by administration of LPS. Cells were harvested 2 hrs post-treatment and RNA was isolated by standard techniques. Quantitative Real time PCR was preformed to measure message levels of the chemokine, CXCL-1, and the resolution molecule, Suppressor of Cytokine Signaling-2, SOCS-2. All samples were normalized to b-actin as a loading control. Results: The data indicate a 25 fold increase in CXCL-1 mRNA expression in cells treated with LPS compared to the vehicle control. However, pre-treatment of cells with 5(S), 6(R)-lipoxin A4 methyl ester, prior

to LPS treatment, ameliorated the increase in CXCL-1 expression. ALXR-mediated pro-resolution pathways include induction of SOCS-2. H441 cells treated with 5(S), 6(R)-lipoxin A4 methyl demonstrated a 0.8 fold increase in SOCS-2 expression over basal levels. Conclusions: The data suggests that activation of ALXR pathways, by administration of 5(S), 6(R)-lipoxin A4 methyl ester, decreases cytokines responses and induces expression of inflammatory resolution molecules in H441 cells.

PS 1888 CORRELATION OF TOTAL ANTIOXIDANT CAPACITY WITH NITRIC OXIDE AND NEOPTERIN IN GASTROINTESTINAL CANCER PATIENTS.

B. A. Engin[1], A. Sepici_Dincel[2] and A. Engin[3]. *[1]Department of Toxicology, Gazi University, Faculty of Pharmacy, Ankara, Turkey, [2]Department of Biochemistry, Gazi University, Faculty of Medicine, Ankara, Turkey and [3]Department of General Surgery, Gazi University, Faculty of Medicine, Ankara, Turkey.* Sponsor: A. Karakaya.

Reactive oxygen species participate in the progression of carcinogenesis by causing oxidative deterioration of membrane lipids, proteins and DNA, although, no specific biochemical marker has been identified yet. Total antioxidant capacity (TAS) and related substances, albumin, nitric oxide (NOx), neopterin, homocysteine (Hyc) are considered major circulating antioxidants which are exposed to continuous oxidative stress. High amount of NOx produced in various gastrointestinal cancers. Increased plasma Hyc level along with NOx overproduction exerts deleterious effects by peroxynitrite formation. In parallel to the enhanced oxidative stress, immune activation marker, neopterin is raised. Thus, the aim of the present study was to assess the TAS and related substances, NOx, neopterin and Hcy, in gastrointestinal cancer cases. After ethical committee approval, blood samples were collected from 36 noncancerous volunteers (Group 1) and from 70 primary gastrointestinal cancer patients (II and III clinical stages) (Group 2). Serum albumin, "high sensitivity C-reactive protein" (Sentinel-Italy), plasma cortisol, IL-6 and IL-10, (ELISA, Amb.R and D system), plasma NOx, serum TAS (Randox, UK), serum neopterin (ELISA, Demeditec) and serum HCy measurements were done in addition to routine biochemical tests. Significantly decreased serum albumin and increased cortisol might be related to the increased oxidative stress in cancer patients. Although TAS, NOx, Neopterin and Hyc levels were similar in both groups, NOx and neopterin were shown to exert significant, linear control on TAS levels of group two. We concluded that current evidence partially support the hypothesis of oxidative stress in gastrointestinal cancer patients; however, in addition to albumin, NOx and neopterin seem to contribute to antioxidant pool in response to the oxidative stress. (Supported by TUBITAK, SBAG-HD-131, 106S116)

PS 1889 REDUCTION IN THE ABILITY OF MACROPHAGES TO PHAGOCYTOSE APOPTOTOC NEUTROPHILS FOLLOWING EXPOSURE TO CRYSTALLINE SILICA.

M. Gulumian[1, 2] and N. Mbatha[1]. *[1]Toxicology, National Institute for Occupational Health, Johannesburg, Gauteng, South Africa and [2]Haematology and Molecular Medicine, University of the Witwatersrand, Johannesburg, Gauteng, South Africa.*

The role of phagocytosis of apoptotic neutrophils in the resolution of inflammation in lung diseases is now well characterized. In vitro exposure of neutrophils and macrophages to crystalline silica results in apoptosis. The present study has therefore investigated the in vitro effect of silica exposure on U937 macrophages and neutrophils and the ability of U937 macrophages to phagocytose apoptotic neutrophils. Neutrophils and U937 macrophages were treated for 2 hrs with 50 and 25 μg/ml silica, respectively. Control cells were cultured in medium alone. After each treatment cells were harvested and assessed flow cytometrically for apoptosis using Annexin V and 7-AAD. To measure phagocytosis of apoptotic neutrophils by macrophages, two-parameter flow cytometry phagocytosis assay was used in which Tracker Green labeled apoptotic, necrotic, and viable control neutrophils were incubated with U937 cells labeled with Cell Tracker Orange. Macrophages were treated with 50 ug/ml crystalline silica and thereafter co-incubated with apoptotic neutrophils and the extent of phagocytosis was quantified with flowcytometer using the FACSCaliber and Cell Quest Software. The levels of nitric oxide and different cytokines during phagocytosis were also determined. Silica induced apoptosis in neutrophils and U937 macrophages. Control U937 macrophages were able to phagocytose at least 50% of apoptotic neutrophils. On the other hand, treatment of U937 macrophages with silica resulted in a significant (70%) decrease in their ability to phagocytose the apoptotic neutrophils. A concomitant increase in the levels of nitric oxide TNF-alpha produced. Therefore, it may be suggested that silica treatment of U937 macrophages may decrease the ability of these cells to remove apoptotic neutrophils as well as increase the levels of inflammatory molecules and thus contributing to the persistent inflammation seen following exposure to crystalline silica.

PS 1890 ENHANCING ADCC IN HUMANS *VIA* NK CELLS.

R. Yafawi, Q. Zong, M. Ko, F. Sace, M. Malamant and A. John-Baptiste. *Drug Safety R&D, Pfizer Inc, San Diego, CA.* Sponsor: G. Stevens.

Antibody-Dependent Cell-Mediated Cytotoxicity (ADCC) is one of the mechanisms through which antibodies, as part of the humoral immune response, can act to limit and contain infection. Classical ADCC is mediated by natural killer (NK) cells; monocytes and eosinophils. Natural Killer cells express membrane receptors for the Fc region of antibody molecules. The Fcγ111 receptor expressed by NK cells is responsible for antibody mediated recognition and killing of tumor and viral infected cells. This study examined the interactions of human IgG1 monoclonal antibodies with enhanced Fc receptors on NK cells and the subsequent activation of ADCC. We utilized a monoclonal antibody to stimulate NK cells in normal human PBMCs to facilitate the examination of cytotoxicity and activation. Peripheral blood mononuclear cells from several healthy donors were freshly isolated by density gradient centrifugation and cell suspensions were stimulated with a human IgG1 monoclonal antibody for 24 hours at 37^{O}C. Post incubation cells were characterized by multi-parametric flow cytometry. The population of interest was CD3-CD56+ NK cells. This population was further examined for cell surface expression of lysosomal associated membrane protein-1 (CD 107a) and lymphocyte activation marker (CD69). Treatment of PBMCs with IgG1 mAb resulted in increased cell surface expression in CD69 and CD107a. A single dose treatment of 80μg/ml of IgG1 mAb increased the level of expression of CD56+/CD69+ from a baseline of 8.81% to 66.22%. In addition to NK cell activation we observed upregulation of CD107a on the surface of NK cells following stimulation. Observed expression from vehicle was 27.37% to 74.80%. The data suggests that in the presence of mAbs directed to NK cell activation receptors can be potent activators of NK cell cytotoxicity. The engagement of Fcγ receptors of effector cells in initiating ADCC, may play a large role in anti-cancer therapies. Utilizing these antibodies to trigger early steps of innate immune response against tumor cells may facilitate a method of inducing target cell ADCC for improved treatment of cancer.

PS 1891 CX3CR1 CONTRIBUTES TO OZONE-INDUCED PULMONARY INFLAMMATION IN THE MOUSE.

M. High[1, 2], H. Cho[2], R. Wilson[2], S. Kleeberger[2] and D. Cook[2]. *[1]University of North Carolina, Chapel Hill, NC and [2]NIEHS, Durham, NC.* Sponsor: D. Holbrook.

Purpose: Previous studies have shown that expression of chemokines and their receptors is elevated in human inflammatory processes. Enhanced expression of the chemokine receptor Cx3cr1 results in enhanced leukocyte adhesion. Cx3cr1 is known to play a major role in chronic pulmonary inflammation; however very little is known concerning it's role in response to sub-acute pulmonary injury. Interleukin-17 (IL-17) is linked to neutrophilic mobilization in chronic pulmonary inflammation. Previous research suggests that IL-17 is not expressed in Cx3cr1-/- mice, suggesting that IL-17 and Cx3cr1 work together in the inflammatory response. The purpose of this research was to determine the role of Cx3cr1 in ozone-induced pulmonary inflammation, and the role IL-17 plays in this response. Methods: Cx3cr1+/-, Cx3cr1-/-, Il17r+/+ and Il17r-/- mice were exposed to air or 0.3 ppm ozone (O3) for 6, 24, 48 or 72 hours. Bronchoalveolar lavage fluid (BALF) was collected after exposure and analyzed for total protein and the numbers of inflammatory cells. IL-17 expression in lung homogenate was analyzed by ELISA. Results: Relative to respective air controls, 48 and 72 hr exposure to O3 caused a significant increase in BALF total protein and numbers of inflammatory cells in all mice. However, significantly greater BALF protein content and numbers of inflammatory cells were found in O3-exposed Cx3cr1+/- mice compared to Cx3cr1-/- mice. Slight elevation of IL-17 was detected in Cx3cr1+/- mice after exposure to O3, but IL-17 was not detected in Cx3cr1-/- mice after O3 exposure. Significantly greater numbers of neutrophils were found in Il17r+/+ mice compared to Il17r-/- mice after exposure to O3 for 48 hours. Conclusions: O3-induced inflammatory cell infiltration, change in lung permeability, and IL-17 production were significantly diminished in Cx3cr1-/- mice relative to Cx3cr1+/- mice. This suggests that Cx3cr1 contributes to the pulmonary inflammatory response to O3 exposure, and it appears that IL-17 does play a role in this inflammatory response. NIH Training Grant T32-ES07126.

PS 1892 ROLE OF SURFACTANT PROTEIN-D IN OZONE-INDUCED INFLAMMATION, INJURY AND ALTERED LUNG FUNCTIONING.

A. Groves[1], A. Gow[1], C. Guo[1], P. Scott[1], M. Veleeparambil[1], J. Laskin[2] and D. Laskin[1]. *[1]Rutgers University, Piscataway, NJ and [2]UMDNJ-Robert Wood Johnson Med Sch, Piscataway, NJ.*

Ozone is a ubiquitous urban air pollutant known to induce lung damage. This is associated with macrophage accumulation in the tissue and the release of reactive nitrogen intermediates (RNIs) which we have shown contribute to tissue injury. In

these studies we analyzed mechanisms by which RNIs induce lung injury. Surfactant protein D (SPD), a pulmonary collectin, has both pro- and anti-inflammatory activities. SPD has been shown to be involved in acute lung injury and is a target for RNI. Acute exposure of mice to ozone resulted in RNI-mediated post-translational modification of SPD. This was associated with increased chemotactic activity, suggesting that nitrosylation of SPD may be one mechanism whereby RNIs induce pulmonary inflammation. To further investigate this, we analyzed the effects of ozone on SPD-/- mice. Ozone inhalation (0.8 ppm, 3 hr) resulted in increased BAL protein levels and macrophage content, markers of lung inflammation and injury in both wild type and SPD-/- mice 72 hr post exposure. These effects were more pronounced in SPD-/- mice. Greater levels of NOx were also detected in BAL from SPD-/- mice. Using a SCIREQ FlexiVent, we analyzed the effects of loss of SPD on pulmonary function. Challenging mice with methacholine resulted in increased total and central airway resistance. Whereas total resistance was reduced in SPD-/- mice relative to WT mice, central airway resistance increased. In both groups, total and central airway resistance were reduced after ozone exposure. The effects of ozone on central airway resistance were greater in SPD-/- mice when compared to WT mice. Methacholine challenge also resulted in a dose dependent decrease in total, as well as static lung compliance in both WT and SPD-/- mice, a response that was attenuated after ozone inhalation. These results suggest that SPD plays distinct roles in pulmonary inflammation and aberrations in lung function following ozone inhalation. Supported by NIH ES004738, ES005022, ES007148, AR055073, and HL074115.

PS 1893 MACROPHAGE ACTIVATION BY FACTORS RELEASED FROM NECROTIC HEPATOCYTES IN AN ACETAMINOPHEN MODEL OF HEPATOTOXICITY. POTENTIAL ROLE OF HMGB1.

A. Dragomir[1], J. D. Laskin[2] and D. L. Laskin[1]. [1]*Pharmacology and Toxicology, Rutgers University, Piscataway, NJ and* [2]*UMDNJ-RW Johnson Med Sch, Piscataway, NJ.*

Acetaminophen (APAP) is a widely used analgesic known to cause hepatic necrosis at toxic doses. Evidence suggests that activated macrophages and inflammatory mediators play a key role in the pathogenic process. In the present studies we analyzed mechanisms mediating the release of inflammatory mediators by macrophages. HMGB1 is a DNA-binding protein that is passively released from necrotic cells and is known to stimulate macrophage production of proinflammatory mediators. Treatment of mice with APAP (300 mg/kg, i.p.) resulted in a time-dependent decrease of HMGB1 expression in hepatocytes, which coincided with the development of hepatic necrosis. We speculated that hepatocyte-derived HMGB1 plays an important role in macrophage activation during APAP hepatotoxicity. To test this, primary cultures of mouse hepatocytes were treated with 5mM APAP or control. Conditioned medium was collected 24 hr later and its effects on macrophage production of inflammatory mediators analyzed. Treatment of macrophages with conditioned medium from APAP-treated hepatocytes resulted in increased mRNA expression of the proinflammatory cytokines TNF-alpha, IL-1, and IL-6, as well as COX-2, a key enzyme in prostaglandin biosynthesis. Conditioned medium from APAP-treated hepatocytes also induced oxidative stress in macrophages, as indicated by increased mRNA expression of heme oxygenase-1, an enzyme involved in antioxidant defense, and our previous studies demonstrating increased production of reactive oxygen species. Upregulation of proinflammatory and antioxidant genes in macrophages in response to hepatocyte-conditioned medium correlated with reduced expression of HMGB1 protein. These data, together with reports that HMGB1 is actively secreted by macrophages subjected to oxidative stress, suggest that HMGB1 plays a role in macrophage activation during APAP-induced hepatotoxicity. (Supported by NIH GM034310, ES005022)

PS 1894 IN VITRO PHOTOCHEMICAL FORMATION OF KOJIC ACID-DNA ADDUCTS.

J. Duan, G. M. Williams and A. M. Jeffrey. *Department of Pathology, New York Medical Collage, Valhalla, NY.*

Kojic Acid (KA) is a natural product which inhibits melanin production. Topical application of KA alone, or in combination with other compounds, is effective in reducing pigmentation in melasma patients. Based largely on a single study showing thyroid neoplasms KA was classified by the International Agency for Research on Cancer (IARC) as presenting limited evidence of carcinogenicity (group 3). More recently KA has been shown to have carcinogenic properties in rat liver, but not mouse skin. KA has produced positive and negative results in both *in vivo* and *in vitro* genotoxicity tests and was considered to be genotoxic *in vitro* by IARC. Only one report addressed potential photoactivation. KA has long been known to be photochemically unstable causing *in vitro* breakage of calf thymus DNA. Consistent with this, KA exerted weak photo-mutagenicity in bacteria and, with UV irradiation, induced chromosome aberrations in Chinese hamster lung cells although it was negative on mouse epidermis in a photo-micronucleus assay. To assess the potential relevance of the photochemical instability with respect to possible DNA adduct formation, we have investigated DNA adduct formation by irradiating KA with 320 nm light (the wavelength at the crossover from UVA to UVB) in the presence of DNA and analyzing for DNA adducts by the sensitive nucleotide ^{32}P-postlabeling (NPL) technique. The results were compared to direct chemical reaction of chloro-KA with DNA. To ascertain the reliability of this approach, we also studied photoactivation of 8-methoxypsoralen (8-MOP) and 4,5',8-trimethylpsoralen (TMP), which are photomutagenic, and 8-MOP is photocarcinogenic on mouse skin. In the NPL assay, all samples showed DNA adduct formation with one or more of the enhancement methods used: OASIS HLB chromatography or nuclease P_1 or psoralen-specific digestions. The major adducts formed photochemically with KA and directly with chloro-KA were different, as were those produced by the psoralens. In conclusion, KA may have the potential to be photoactivated to DNA-damaging products in skin.

PS 1895 ROLE OF ESTROGEN RECEPTOR ALPHA IN DECREASED HEPATIC NUCLEOTIDE EXCISION REPAIR AFTER 17α-ETHINYLESTRADIOL EXPOSURE.

E. Notch[1] and G. Mayer[2]. [1]*Biochemistry, Microbiology & Molecular Biology, University of Maine, Orono, ME and* [2]*Environmental Toxicology, Texas Tech University, Lubbock, TX.*

Estrogen is a known human carcinogen and is implicated in the etiology of human hepatocellular carcinoma. Zebrafish exposed to the strong estrogen receptor agonist 17α-ethinylestradiol (EE_2) displayed decreased mRNA expression of multiple nucleotide excision repair (NER) genes in vitro and in vivo. Additionally, liver derived zebrafish cell lines treated with estrogens were hindered in their ability to repair bulky DNA adducts. These data suggest that estrogen can act as a co-carcinogen with bulky adduct forming mutagens by hindering a cells ability to deal with DNA damage. The role of nuclear estrogen receptors in altered NER processes remains unclear. In vitro, co-exposure to EE_2 and a complete estrogen receptor antagonist (ICI 182 780) also resulted in reduced NER capacity, whereas ICI 182 780 alone did not affect the ability of ZFL cells to repair UV damage. These results indicate that estrogen exposure can decrease cellular NER capacity and that this effect can occur in the presence of the complete estrogen receptor agonist, ICI 182 780. This suggests that EE_2 can affect NER processes through mechanisms other than nuclear estrogen receptor activation.

PS 1896 FAILED BASE EXCISION REPAIR LEADS TO NECROTIC CELL DEATH THROUGH NAD+ DEPLETION.

E. M. Goellner and R. W. Sobol. *Molecular Pharmacology & Chemical Biology, Univerisity of Pittsburgh School of Medicine, Pittsburgh, PA.* Sponsor: N. Stewart.

In eukaryotic cells, DNA polymerase β (Pol β) is an essential component of the base excision repair (BER) machinery that is responsible for repairing base damage occurring from both endogenous and environmental sources. Failure to repair base damage may lead to cancer or tissue degeneration due to genomic instability or cell death; respectively. A deficiency in Pol β renders cells hypersensitive to DNA damage mediated by alkylation, oxidation and radiation. Cellular hypersensitivity in Pol β deficient cells has been attributed to aborted repair of the 5'deoxy-ribose phosphate (5'dRP) repair intermediate. We have recently propose that PARP1 acts as a sensor of aborted repair, leading to rapid synthesis of poly(ADP)ribose (PAR) and subsequent necrotic cell death. We hypothesize that the cellular mechanism behind BER mediated necrotic cell death is NAD+ depletion and cellular energy failure, exclusive of a signaling cascade initiated by PAR. NAD+ is a critical substrate for the poly(ADP)ribosylation reaction; therefore activation of PARP1 could lead to depletion of NAD+. A nontoxic 24 hour pretreatment of BER deficient cells with the NAD+ biosynthesis inhibitor FK-866 prior to methyl methanesulfonate (MMS) exposure leads to reduction of PAR synthesis to levels undetectable by immunoblot; however it also leads to a 10 fold increase in cell death. Quantitative analysis of NAD+ content shows that reduction of NAD+ to 25% of control with FK-866 leads to a more rapid and increased reduction of NAD+ after exposure to MMS. Furthermore, immunofluorescence for AIF release from the mitochondria, reported to occur due to PAR signaling, is not observed. Taken together this data suggests that necrotic cell death due to incomplete BER is due primarily from NAD+ depletion and subsequent ATP loss, not from a PAR signaling event. It also highlights the critical role NAD+ levels and overall metabolic status has on the cellular response to base damage.

1897 INCREASED FORMATION OF GLYCIDAMIDE (GA)-HGB AND GA-DNA ADDUCTS IN DIET-INDUCED OBESE MALE C57BL/6J MICE.

B. I. Ghanayem[1], M. I. Churchwell[2], K. A. Woodling[2], R. Bai[1], D. R. Doerge[2] and U. Hoffler[1]. *[1]LP, NIEHS/NIH, RTP, NC and [2]NCTR/FDA, Jefferson, AR.*

Global projections of obesity indicate that > 1 billion adults (≥ age 15) are overweight, (BMI > 25kg/m2) and at least 400 million are obese (BMI > 30kg/m2). Chronic diseases such as type 2 diabetes have also been associated with elevated BMI. In general, the etiology of most human diseases can be linked to environmental pollutants and lifestyle. We hypothesized that obese individuals may exhibit varied metabolism and responses to environmental agents. Recently, we showed acrylamide (AA) exhibited an exaggerated reproductive toxicity and germ cell mutagenicity in diet-induced obese vs. control mice. To assess AA mechanism of action, current studies compared AA metabolism in obese vs. control mice. Male C57Bl/6J mice were maintained on either a control or high fat (60% kcal fat) diet from 5 to 30 weeks of age. Mice fed the high fat diet for 30 weeks showed significantly higher body weight and % body fat. AA was administered (po) to groups of obese and control mice at 12.5, 25, or 50mg/5ml water/kg. Six hours after dosing, mice were euthanized and blood was collected to detect AA and GA in the plasma and HGB adducts in RBCs. Liver, lung, and testes were removed for DNA adducts measurement. AA and GA HGB and DNA adducts were measured using LC-ES/MS/MS analysis. In control and obese mice AAVal-PTH adducts increased in a dose-dependent manner. AAVal-PTH was a credible measure of AA internal dose and indicated exposure was similar in obese and controls. While in both groups GAVal-PTH adducts increased in a dose-dependent manner, significantly higher levels were detected at all doses in obese mice. N3-GA-Gua and N7-GA-Ade adducts in liver, lung and testes were considerably higher in obese vs. controls. In conclusion, increased AA metabolism to the epoxide intermediate, GA and increased GA-DNA adducts may explain the elevated sensitivity of obese mice to the genotoxic effects of AA and support the premise that obese individuals are more susceptible to environmental exposures.

1898 CHILD-ADULT DIFFERENCES IN EVALUATION OF *IN VIVO* GENOTOXICITY OF ACRYLAMIDE.

M. Honma[1], N. Koyama[1, 2], A. Kimura[1, 3], M. Yasui[1], S. Takami[4], M. Takahashi[4], T. Imai[4], A. Yamamoto[1], W. Kumita[1], K. Masumura[1], S. Masuda[2], N. Kinae[2], T. Matsuda[5] and T. Nohmi[1]. *[1]Division of Genetics and Mutagenesis, NIHS, Tokyo, Japan, [2]Grad. Sch. of Global Environment, Kyoto University, Kyoto, Japan.* Sponsor: M. Ema.

The recent discovery of acrylamide (AA), a potent carcinogen, in the frying or baking a variety of foods raises human health concerns, in particular, for children, because AA is relatively highly contained in snacks, cereals, and baby foods. AA is known to be metabolized by CYP2E1 to glycidamide (GA) which is responsible for AA-inducing genotoxicity and carcinogenicity. The activity of CYP2E1 varies during postnatal development implying that the genotoxic and carcinogenic risk of AA may be different between adults and children. To elucidate in vivo genotoxicity of AA and its child-adult differences, we treated adult or neonatal male rats (gpt-delta transgenic F344 rats 3w,11w or SD rats 3w,11w) with 0, 20, 40, 80 ppm or 0, 50, 100, 200 ppm of AA in drinking water for 28 days, and examined the genotoxicity in the blood, liver and testis. We observed the dose-related increases of micronuclei in peripheral blood and testis. Alkaline Comet assays in livers and testis were also significantly positive in the middle and high doses. However, there is no difference of these genotoxic responses between the adults and neonatal rats. On the other hand, the gpt mutations in livers were not induced in both the adult and neonatal transgenic rats. We are now analyzing GA-DNA adducts in these tissues of in adult and neonatal rats.

1899 DEVELOPMENT OF A CROSS-SPECIES MUTATION ASSAY BASED ON THE PIG-A GENE.

S. D. Dertinger, S. Phonethepswath, S. Bryce and J. Bemis. *Litron Laboratories, Rochester, NY.*

This laboratory has described a Pig-a gene mutation assay based on blood from Sprague Dawley rats [Bryce et al., Environ. Molec. Mutagen. 49 (2008) 256-264]. The underlying premise is that lack of glycosylphosphatidylinositol (GPI) anchored proteins on the surface of red blood cells (RBCs) should represent a reliable phenotypic marker of Pig-a mutation. Here, we extend this work to include CD-1 mice. After RBC enrichment, anti-CD24-PE was used to differentiate wildtype versus GPI anchor deficient cells (presumptive mutants). Cells were then incubated with SYTO 13 to discriminate mature erythrocytes from reticulocytes (RETs). Flow cytometry was used to score mutants in two RBC populations: RBCs irrespective of age, and RETs. Mutagen treatments (N-ethyl N-nitrosourea, 40 mg/kg/day, 3 days; or 7,12-dimethyl-1,2-benz[a]anthracene, 75 mg/kg/day, 3 days) increased the frequency of GPI anchor-deficient RBCs and RETs. Whereas the frequencies of mutant RETs were significantly elevated 1 week after the last administration, the RBC population was unchanged until the second week. Thereafter, both populations exhibited persistently elevated frequencies for the duration of the experiment (mean frequency at termination = 310 x 10^−6 and 523 x 10^-6 for RBC and RET populations, respectively). These data provide evidence that Pig-a mutation does not convey an appreciable positive or negative cell survival advantage to affected erythroid progenitors, although they do suggest that affected RBCs have a reduced lifespan in circulation. Collectively, accumulated data support the hypothesis that flow cytometric enumeration of GPI anchor deficient RBCs and/or RETs represents an effective in vivo mutation assay that is applicable across species of toxicological interest.

1900 PREDICTIVITY COMPARISON BETWEEN SCREENING ASSAYS FOR BACTERIAL MUTAGENICITY FOR NATURAL COMPOUNDS: MICRO-AMES *VS.* AMES FLUCTUATION METHOD.

G. Pappa, T. Woehrle and M. Toeroek. *R&D Human Nutrition and Health, Safety, DSM Nutritional Products Ltd, Basel, Switzerland.* Sponsor: A. Davidovich.

Aim of this study was to compare two screening assays for bacterial mutagenicity for their predictivity with respect to natural compounds for the OECD 471 guideline assay of bacterial reverse mutation. The micro-Ames uses 5 strains of S. typhimurium (TA98. TA100, TA102, TA1535 and TA1537) which are pre-incubated with the test compound in 96 well plates before being plated on agar dishes. Plating and subsequent colony counting is performed like described in the OECD 471 assay. On the other hand the Ames fluctuation method uses 2 strains (TA98 and TA100) which are pre-incubated with the test compound before reversion indicator medium containing the dye bromocresol purple is added. Subsequently, the solutions are distributed to 384 well plates and the mutagenic activity of the test item is detected by counting the number of wells shifted from purple to yellow. Both assays are run with and without metabolic activation. The big advantage of these screening assays is the low amount of compound needed, which is an eminent factor in the early stage of product development. Ten natural compounds were run in both above mentioned assays and the outcome was compared to the OECD 471 compliant assay. The micro-Ames showed a better predictivity compared to the Ames fluctuation method. One reason could be the fact that the Ames fluctuation method only uses two strains, which do not include a strain specific for detecting cross-links like the TA102. Moreover, evaluation and quantification of mutants is performed indirectly by colorimetric measurements, whereas in the micro-Ames actual colonies are counted on agar plates. However, testing of further compounds of different structural classes is needed to consolidate the results. Taken together, the Ames fluctuation method is a suitable tool for high throughput screening for mutagenicity. However, to predict the outcome of the full OECD 471 assay with low amounts of compound in early stage of product development, the micro-Ames is the preferred alternative.

1901 A MODIFIED AMES ASSAY FOR RAPID SCREENING OF CIGARETTE WHOLE SMOKE AND GAS VAPOR PHASE PREPARATIONS.

R. D. Leverette. *Lorillard, Greensboro, NC.*

The Ames Assay is frequently used to determine the mutagenicity of the particulate phase of cigarette smoke; the fraction of smoke captured on a Cambridge pad and solvent extracted (i.e. DMSO). Assessing only the particulate fraction ignores the contribution of gas vapor phase (GVP) components to the overall mutagenicity of whole smoke (WS). There are known GVP components that exhibit mutagenic activity in the Ames assay, including acrolein, formaldehyde and crotonaldehyde. Previous modifications to include GVP into the plate incorporation method have given mixed results; however, longer preincubations and an increased cell density during exposures have demonstrated the feasibility of measuring GVP mutagenicity. In order to maximize the GVP and WS responses (S9+/S9-) for rapid screening purposes, a Box-Behnken design of experiments was utilized to optimize incubation time (30 – 120 minutes), cell density (1X1010 – 1X1011 CFU/mL) and the number of cigarettes smoked through ice-cold PBS (0.2 – 1.2 cigarettes/mL). Smoke from Kentucky 2R4F reference cigarettes was passed through a Cambridge pad and subsequently bubbled through a flask containing ice-cold PBS (GVP-PBS). Removal of the in-line Cambridge pad permitted the collection of "whole smoke" bubbled PBS (WS-PBS). Different cell densities of TA98 and TA100 were preincubated with dilutions of either the fresh GVP-PBS or WS-PBS for 30 – 120 minutes, mixed with top agar and poured onto minimal glucose agar plates.

Following 48 hours of incubation (37°C), revertant colonies were counted and the activities (revertants/cigarette) were determined. The resultant optimum conditions (GVP and WS) were 120 minute preincubation, 5.5X1010 CFU/mL, and 0.2 cigarettes/mL PBS. Mutagenic activity was detected in GVP treated TA100 (S9-) only while WS elicited activity in both strains (S9+). Significant decreases in revertants/cigarette were seen with increasing cigarettes smoked per mL of PBS, indicating inefficient capture and/or saturation of the PBS with smoke components.

PS 1902 DISPOSITION KINETICS OF BENZO(A)PYRENE (BAP) METABOLITES AND BAP-DNA ADDUCTS IN OVARY OF F-344 RATS ORALLY EXPOSED TO BENZO(A)PYRENE.

A. Ramesh[1], M. S. Niaz[2] and A. E. Archibong[2]. *[1]Cancer Biology, Meharry Medical College, Nashville, TN and [2]OB/GYN, Meharry Medical College, Nashville, TN.*

Exposure to environmental toxicants has been implicated as one of the causative factors of infertility in mammals. Since the bioavailability of any xenobiotic compound is the prime driving force for toxicity, the objective of this study was to determine the amount of ingested benzo(a)pyrene (BaP), an environmental toxicant that reaches the reproductive tissues. Towards this end, the concentrations of BaP reactive metabolites and BaP-DNA adducts were measured throughout the course of BaP's residence in the body. Eight-week-old female Fisher-344 rats were administered with 5 mg of BaP/kg body weight through oral gavage. Following 1, 7, 14 and 21 days post-BaP exposure, BaP parent compound and metabolites from plasma, ovary and liver tissues were extracted using water, methanol, and chloroform. The extracts were analyzed by a reverse phase HPLC equipped with a fluorescence detector. DNA was isolated and analyzed for BaP-induced DNA adducts by the ^{32}P-postlabeling method using a four-directional thin-layer chromatography system. The BaP total metabolite concentrations in plasma, ovary and liver showed a gradual decrease from day 1 to day 21 post-BaP administration. The BaP-DNA adducts concentrations in ovary and liver tissues from the treatment group showed a trend similar to that observed for the metabolites. Ovary showed greater concentrations of DNA adducts compared to liver. However, with increase in post-cessation of exposure time, the adduct levels in liver tissue started declining rapidly, from day 1 to day 21. For ovary, the adduct levels showed an insignificant decline from day 1 to day 7 and showed a gradual decline thereafter. A concordance between BaP reactive metabolite concentrations and BaP-DNA adduct concentrations indicate that the bioavailability of reactive metabolites determine the binding with DNA and consequently the formation and persistence of adducts (research reported here is supported by the NIH grants G12 RR03032, S11ES014156 and RO3CA130112-01).

PS 1903 REMOVAL OF BULKY MITOCHONDRIAL DNA ADDUCTS FOLLOWING ULTRAVIOLET RADIATION EXPOSURE INVOLVES MITOCHONDRIAL FUSION AND AUTOPHAGY.

A. M. Smith[1], M. C. Leung[1], A. Arrant[2], A. Bernal[2], C. L. Tracey[1] and M. N. Joel[1]. *[1]Nicholas School of the Environment and Earth Sciences, Duke University, Durham, NC and [2]Integrated Toxicology and Environmental Health Program, Duke University, Durham, NC.*

Mitochondrial DNA (mtDNA) integrity is critical for human health; however, it is unclear how bulky mtDNA adducts formed after exposure to environmentally important genotoxins such as ultraviolet radiation and PAHs are handled. mtDNA may be particularly susceptible to these genotoxins due to the absence of nucleotide excision repair, the primary repair mechanism for bulky DNA adducts in nuclear DNA. We investigated the removal of bulky mtDNA adducts via mitochondrial fusion and autophagy in Caenorhabditis elegans. Larval fusion and autophagy mutant C. elegans were exposed to serial UVC doses over 48 hours. This exposure protocol allows for accumulation of mtDNA damage without lasting damage to nuclear DNA and results in measurable larval growth arrest. Strains carrying mutations in the autophagy gene atgr-18 and fusion gene fzo-1 exhibited exacerbated larval growth arrest with little to no growth recovery after 72 hours. We concluded that these proteins mediate recovery from mtDNA damage-induced larval growth arrest. In order to test directly the contribution of autophagy proteins to removal of UVC-induced DNA damage, we performed RNAi knockdown of autophagy genes (bec-1, atgr-18, unc-51) in UVC treated adult glp-1 C. elegans. Knockdown of autophagy genes inhibited removal of UVC-induced DNA damage after 72 hours, as measured by QPCR. These data suggest that autophagy and fusion processes are involved in the removal of bulky DNA damage in mitochondria. Based on the nature of these proteins, we hypothesize that UVC-induced mtDNA damage is removed via mitochondrial remodeling. This is currently being investigated in both C. elegans and cell culture. This research was supported by funding from the National Institutes of Environmental Health Sciences, 1 P30 ES-011961-01A1.

PS 1904 *IN VIVO* MUTAGENESIS INDUCED BY DIESEL EXHAUST IN THE TESTIS OF GPT DELTA TRANSGENIC MICE.

Y. Aoki[1], A. H. Hashimoto[1], K. Amanuma[1], K. Masumura[2] and T. Nohmi[2]. *[1]Research Center for Environmental Risk, National Institute for Environmental Studies, Tsukuba, Ibaraki, Japan and [2]Division of Genetics and Mutagenesis, National Institute of Health Sciences, Setagaya, Tokyo, Japan.*

Diesel exhaust is a major airborne pollutant of urban areas. Previously, we have demonstrated that typical mutagens such as benzo[a]pyrene and 1,6-dinitropyrene, as well as inhalation of diesel exhaust, caused mutations in the lungs using transgenic rodents for analyzing in vivo mutagenesis. In this study, to estimate the systemic effect of diesel exhaust inhalation, mutations in extrapulmonary organs, such as testis and liver, were determined. Gpt delta transgenic mice, carrying the guanine phosphoribosyltransferase (gpt) gene as a transgene for the detection of mutations in genomic DNA, were exposed to 3 mg m-3 of diesel exhaust (as suspended particulate matter) via inhalation for 12 or 24 weeks. Compared to the control mice, this resulted in a 2.0-fold increase in mutation frequency in the testis of the 24-week exposed mice (Inhalation group, 1.17 x 10–5; Control group 0.58 x 10–5), but not in the testis of the 12-week exposed mice (0.61 x 10–5). The mutation frequency became 2.6-fold higher than the control group in the lung, but was not elevated in the liver of the 24-week exposed mice. In testis, major mutations in the gpt gene were G:C to T:A transversions, 1 base deletions, and G:C to A:T transitions, while the only major mutations in the lung were G:C to A:T transitions. Mutations at nucleotide 402, 406, 409 and 416-418 in the gpt gene in testis seemed to be characteristic of DE inhalation. Our results suggest that inhalation of diesel exhaust is genotoxic for the testis as well as for respiratory organs.

PS 1905 MOLECULAR DOSIMETRY OF UVC-INDUCED CYCLOBUTANE PYRIMIDINE DIMERS IN DNA OF MELANOMA CELL LINES.

C. D. Sproul[1], E. Gibbs-Flournoy[3] and M. Cordeiro-Stone[1, 2]. *[1]Curriculum in Toxicology, University of North Carolina, Chapel Hill, Chapel Hill, NC, [2]Biological and Biomedical Sciences Program, University of North Carolina, Chapel Hill, Chapel Hill, NC and [3]Department of Pathology and Laboratory Medicine, Lineberger Comprehensive Cancer Center, Center for Environmental Health and Susceptibility, University of North Carolina, Chapel Hill, Chapel Hill, NC.*

Ultraviolet radiation is an established environmental carcinogen that induces DNA lesions in melanocytes, potentially promoting cancer development. It is hypothesized that reduced expression or mutations in any of the proteins responsible for DNA repair may drive UV-induced skin cancers by allowing subsequent mutations in other critical genes to be more readily acquired. One manifestation of differences in DNA repair capacities is altered UV-induced cytotoxicity. Ultraviolet-C (UVC) radiation-induced cytotoxicity was examined in different melanoma cell lines and in normal human fibroblast cells (NHF1-hTERT). These cell lines displayed differential sensitivity to UVC-induced cytotoxicity, with A375 being the most sensitive (LD_{50}=4.9 J/m^2) and closest to NHF1 (LD_{50}=4.6 J/m^2). WM2664 and VMM39 cells were less sensitive (LD_{50}=7.4 and 7.8J/m^2 respectively), and SK-MEL-28 cells the most resistant (LD_{50}=18.1 J/m^2). Because melanocytic cells may differ in their production of UV absorbing pigments, cell lines used in this study were also examined for their relative density of cyclobutane pyrimidine dimers (CPD) in DNA upon exposure to UVC (0, 2.5, 5, or 10 J/m^2). The molecular dosimetry indicated that the CPD densities in these cell lines were not significantly different from one other (ANOVA p>0.2). Equivalent molecular dosimetry of CPD following UVC irradiation indicates that the differential cytotoxicity seen in these cell lines is due to factors other than the burden of CPD. Such factors could include alterations in downstream responses to UVC, such as DNA repair, cell cycle checkpoints, or induction of apoptosis. Several of these responses are currently under investigation. Supported by NIEHS T32-ES07126 and RO1 ES015856.

PS 1906 1, N6-ETHENO-2'-DEOXYADENOSINE (εdA) IN WEANLING AND ADULT RATS EXPOSED TO 13C2-VINYL CHLORIDE BY INHALATION L. GAO, P.B. UPTON, G. BOYSEN, AND J.A. SWENBERG. ENVIRONMENTAL SCIENCES AND ENGINEERING, UNC-CHAPEL HILL, CHAPEL HILL, NC.

L. Gao, P. B. Upton, G. Boysen and J. A. Swenberg. *environmental sciences and engineering, UNC-chapel Hill, Chapel Hill, NC.*

Vinyl chloride (VC) is classified as a human carcinogen by IARC. Through metabolic activation by CYP2E1, chloroethelene oxide is formed which reacts with DNA. εdA is one of the DNA adducts that formed following VC exposure but also

formed endogenously by lipid peroxidation. In order to accurately determine the formation and repair of εdA, adult and weanling Sprague-Dawley rats were exposed to 1100 ppm 13C2-VC for 5d (6h/day). The weanling animals were sacrificed 2h post exposure. The adults were sacrificed 2h, 2, 4, and 8 weeks post exposure. A sensitive nanoUPLC-MS/MS assay was developed to detect both endogenous 12C2- εdA and exogenous 13C2-εdA in DNA. The results show that 13C2-εdA is detected in the exposed adult group and the exposed weanling group at the end of exposure, but that it was below detection levels in the exposed adult recovery groups. εdA is therefore rapidly repaired, which agrees with previous studies on the half-life of εdA (<1 day). The distribution pattern of 13C2-εdA in liver, lung and kidney clearly indicates that liver has the greatest molecular dose in adults and pups, with significantly more 13C2-εdA in the liver than in lung and kidney($p<0.05$). 13C2-εdA was significantly higher in hepatic DNA of pups (2.79±0.68/108 unmodified nucleosides) than in the adults (1.14±0.29/108 unmodified nucleosides), which suggests that young animals have greater metabolic activation of VC. The 12C2-εdA (endogenous) adducts were similar in liver DNA of adult rats with or without VC exposure, with 1.08±0.17/108 adducts in controls and 1.12±0.25/108 adducts in exposed animals. The use of stable isotope labeled VC allows the clear distinction between endogenous and exogenous εdA. This permits accurate determinations of εdA repair in cells. Our data demonstrate that εdA is rapidly repaired in rat tissues and that the steady-state endogenous amount of εdA is the result of daily formation and repair.

PS 1907 ASSESSMENT OF ULTRAVIOLET LIGHT- AND CHEMICAL-INDUCED UDS IN VARIOUS CELL LINES USING FLOW CYTOMETRY.

J. Tao, W. Newhard, D. R. Cerven and G. L. DeGeorge. *MB Research Laboratories, Spinnerstown, PA.*

UDS is a reliable assay to measure DNA damage/repair induced by genotoxins and ultraviolet (UV) radiation. Standard UDS assays detect radiolabeled nucleotides incorporated into repaired DNA. We have developed a FLow cytometry-based UDS assay (FLUDS) that measures biotin-dUTP incorporation into repaired DNA. DNA damaging agents, including direct, metabolically activated genotoxins and ultraviolet light (UVB and UVC) were exposed to cells in culture. Aphidicolin (Aph), a DNA repair enzyme inhibitor, was included in cell cultures exposed to DNA-damaging agents to temporarily inhibit repair and allow DNA damage to accumulate prior to the UDS step. The addition of Aph helps enhance the signal-to-noise (S/N) ratio. Using a human skin keratinocyte cell line, FLUDS exhibited 88% accuracy, 100% sensitivity, and 79% specificity in detecting direct-acting genotoxins, correctly categorizing 7 of 10 direct-acting genotoxins and 11 of 11 non-genotoxins. All positive responses were in a clear dose-dependent manner. In the case of Methyl methanesulfonate (MMS), a distinct population of biotin-dUTP positive cells increased from 1.8% to 61% of gated G0/1 cells in response to increasing concentrations from 10 to 100 μM. Less than 1% UDS+ cells were detected in vehicle control cultures as background. When testing bioactivation-dependent genotoxins, FLUDS detected 4 of 19 procarcinogens, which may be attributed to metabolic activation occurring in skin cell types. We successfully detected UDS by FLUDS assay in various other cell lines, HEKa, HepG2, PC3, A431, L929, 3T3, and MDA-MB-157. However,the signal to noise ratios were lower than that in human keratinocytes. In summary, the validated FLUDS assay is quantitative in nature, eliminates the need for the use of radioactive materials, is amenable to use in various cell lines, and thus obviates the need for use of laboratory animals.

PS 1908 4-ETHYLCATECHOL CAUSES DNA DAMAGE RESPONSE AT LEVELS IN WINE AND CIGARETTE SMOKE.

M. R. Knight, M. D. Aitken and J. Nakamura. *Environmental Science and Engineering, University of North Carolina-Chapel Hill, Chapel Hill, NC.*

Cigarette smoke and Brettanomyces fermented wine both contain 4-ethylcatechol (4EC). Smoking one cigarette can introduce 4EC to the lung at 0.7 μmol 4EC/kg lung. Lower quality wines can also contain 1.2 μmol 4EC/L. In addition, 4EC is a product of ethlybenzene (EB) metabolism, which is classified as a possible human carcinogen and identified in almost half of the National Priorities List sites. Little, however, is known regarding DNA damage caused by 4EC in cells. DNA damaging mechanisms may include topoisomerase II inhibition, oxidative stress, and depurinating or bulky adducts. We characterized the genotoxic profile of 4EC to elucidate types of DNA damage induced. We utilized wild type (WT) DT40 vertebrate cell line and ~40 isogenic mutants deficient in various DNA damage response pathways. After exposure to 4EC, differences in viabilities between WT and each mutant cell line indicate positive DNA damage response. Our results reveal two DNA repair pathways important for counteracting DNA damage induced by 4EC. Hypersensitivity of RAD54, KU70, and LIGIV deficient cells suggests that double strand breaks (DSB) are possibly the most serious DNA damage. These results indicate both homologous recombination and non-homologous end-joining (NHEJ) pathways play essential roles in cell survival. Also two translesion synthesis (TLS) polymerases, POLκ and REV1, appear crucial. Sensitivity of NHEJ deficient cell lines suggests topoisomerase II can be inhibited by 4EC. DNA damage responses to 4EC show similar response to hydrogen peroxide; DSB and TLS from 4EC may be explained oxidative stress. In contrast, POLβ, XPA, and XPG mutants are resistant to 4EC; depurination or bulky adducts may cause negligible DNA damage. We have shown 4EC to diminish cell viability in concentrations as low as 1.7 μM. Our DNA damage response analysis suggests that a significant impact of 4EC existing in cigarette smoke and low quality of wine on human health and implies that environmental EB may further potentiates this risk. (P30-ES10126/ P42-ES05948)

PS 1909 SUBOPTIMAL DNA REPAIR CAPACITY PREDISPOSES POLYCYCLIC AROMATIC HYDROCARBON EXPOSED WORKERS TO ACCUMULATE MORE CHROMOSOME DAMAGES IN PERIPHERAL LYMPHOCYTES.

J. Cheng[1], S. Leng[1], X. Liang[2], H. Lin[2] and Y. Zheng[1]. *[1]National Institute of Occupational Health, China CDC, Beijing, Beijing, China and [2]Institute of Industrial Health, Anshan Steel Industrial Corporation, Anshan, Liaoning, China.* Sponsor: W. Zheng.

DNA repair is an essential mechanism for cells to maintain the genomic integrity under the endogenous or exogenous assault. Reduced DNA repair capacity (DRC) is associated with increased risk for several environment-related cancers. The micronucleus in peripheral lymphocytes has been validated as a biomarker of chromosomal damage for cancer risk in human populations. We hypothesized that suboptimal DRC is associated with the increase of chromosomal damages among 94 polycyclic aromatic hydrocarbon (PAH) exposed workers and 64 controls. DRC was evaluated in isolated lymphocytes by comet assay. Chromosome damage in peripheral lymphocytes was detected by cytokinesis-block micronucleus assay. Four functional single nucleotides polymorphism in XRCC1 gene were genotyped by PCR-RFLP method. PAH exposed workers have significantly increased urinary 1-hydroxypyrene (9.0, 6.8-11.7 vs. 1.5, 1.3-1.7 μg/L; $P<0.01$) and micronucleus frequency (7.4 ± 4.3‰ vs. 3.0 ± 3.0‰; $P<0.01$) and decreased DRC (55.9 ± 16.4% vs. 63.6 ± 18.5%; $P<0.01$) compared to controls. Significant correlations between DRC and micronucleus frequency were found in PAH exposed workers ($r=-0.32$, $P<0.01$, $n=94$) and all study subjects ($r=-0.32$, $P<0.001$, $n=158$), but not in controls ($r=-0.21$, $P=0.11$, $n=64$). Variants of Arg399Gln polymorphism was associated with a decreased DRC in both PAH exposed workers (51.6 ± 16.1% vs. 60.6 ± 15.7%; $P<0.01$) and controls (59.1 ± 18.5% vs. 68.4 ± 17.5%; $P=0.04$). The complicated interrelationship of these multiple biomarkers was also identified by the path analysis. These exciting findings will be of great importance for us to understand the mechanism of the lung carcinogenesis and facilitate developing a biomarker-based risk assessment model which includes both behavioral risk factors and multiple biomarkers for this fetal disease in this occupational population.

PS 1910 EFFECTS OF CRYOPRESERVATION ON ALKALINE AND FPG-MODIFIED COMET ASSAY IN WHOLE HUMAN BLOOD AND ISOLATED LYMPHOCYTES.

X. Pu, L. M. Kamendulis and J. E. Klaunig. *Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

The Comet assay is a simple and sensitive technique for the detection of DNA damage in eukaryotic cells. Incorporation of lesion specific, oxidative DNA damage repair enzymes (i.e., Fpg, OGG1, EndoIII) in the standard alkaline Comet assay procedure provides a simple and sensitive method for the measurement of oxidative DNA damage. The Comet assay using human white blood cells (WBC) or isolated lymphocytes has proven useful in monitoring DNA damage from environmental agents in humans. A restriction in the use of this assay has been the need to perform the analysis immediately after sampling. In this study, we examined the effects of sample freezing and storage conditions on standard and Fpg-modified modified Comet assay using whole blood or isolated lymphocytes. Whole blood was stored in RPMI1640 media containing 10% FBS, 10% DMSO, and 1 mM deferoxamine at a sample to media ratio of 1:50. Samples were stored at -20°C and -80 °C for 1, 7, 14 and 28 days. Isolated lymphocytes from the same subjects were also stored under the same conditions. Direct DNA strand breakage and oxidative DNA damage in WBC and lymphocytes were analyzed using standard and Fpg-modified alkaline Comet assay and compared with freshly analyzed samples. No significant changes in either direct DNA strand breakage or oxidative DNA damage was seen in WBC and lymphocytes stored at -20°C for 1 and 7 days compared to fresh samples. However, significant increases in both direct and oxidative DNA damage were seen in samples stored at -20°C for 14 and 28 days. No changes in direct and oxidative DNA damage were observed in WBC and lymphocytes stored at -80°C for up to

28 days. These results identified the proper storage conditions for storing whole blood or isolated lymphocytes to evaluate direct and oxidative DNA damage using standard and Fpg-modified alkaline Comet assay.

1911 BIOMARKERS: NEW BREAKTHOUGHS IN THE WORLD OF AIR POLLUTION STUDIES.

M. C. Madden. *ORD, NHEERL, HSD, Clinical Research Branch, U.S. EPA, Chapel Hill, NC.*

Biomarker measurement allows better understanding of the factors that influence the health outcomes from air pollutant exposures. In this session, new biomarker strategies will be highlighted to show the use of biomarkers to study health effects derived from air pollution and to provide updates on the utility of new biomarker techniques including 'omics-type of analyses. Our panel of experts will focus on improved use of biomarkers of exposure, effects, and susceptibility are included in this session. Session highlights will include the use of select urinary PAHs to reflect exposure to petroleum-derived emissions that show similar body burdens across occupational and controlled exposure studies followed by use of suspectibility factors such as obesity and employment status to demonstrate increased biological responses (e.g., heart rate variability) and health effects (e.g., mortality). Finally, our experts will cover the use of genomics to improve the understanding of the likelihood of the development of asthma as well as proteomics to identify unique exposure biomarkers and potentially the cell types producing the markers.

1912 USE OF CARDIAC MARKERS AND SUSCEPTIBILITY FACTORS FOR EXAMINATION OF PARTICULATE MATTER INDUCED TOXICITY IN HUMANS.

D. C. Christiani. *Environmental Health, Harvard, Boston, MA.* Sponsor: M. Madden.

We investigated whether PM2.5-mediated autonomic modulation depends on individual coronary risk profiles, using as outcomes five-minute average heart rate (HR) and heart rate variability measured from 24-hour ambulatory electrocardiograms, and personal PM(2.5) exposures in a prospective study of 10 male boilermakers (aged 34.3 +/- 8.1 years). We used the Framingham score to classify individuals into low (score = 1-3) and high (score = 5-6) risk categories. Mixed-effect models revealed that each 1-mg/m(3) increase in the preceding 4-hour moving average PM(2.5) was associated with HR increase (5.3 beats/min) and HRV reduction (11.7%, confidence interval [CI] = 6.2-17.1% for SDNN). Greater responses (2- to 4-fold) were observed in high-risk than in low-risk subjects. These findings suggest that adverse autonomic responses to metal particulate are aggravated in workers with higher coronary risk profiles. We followed this study with as assessment of obesity as a potential susceptibility state to PM related autonomic (HRV) changes in 18 monitored boilermakers (39.5 +/- 9.1 years of age). Subjects with body mass index >/= 30 kg/m(2) were classified as obese. Half (50%) of the study subjects were obese. After adjustment for confounders, each 1-mg/m(3) increase in 4-hr moving average PM(2.5) was associated with HR increase of 5.9 bpm [95% confidence interval (CI), 4.2 to 7.7] and with 5-min HRV reduction by 6.5% (95% CI, 1.9 to 11.3%) for SDNN. Obese individuals had greater PM(2.5)-mediated HRV reductions (2- to 3-fold) than non-obese individuals, and had more PM(2.5)-mediated HR increases (9-bpm vs. 4-bpm increase in HR for each 1-mg/m(3) increase in PM(2.5); $p < 0.001$). Our study revealed greater autonomic cardiac responses to metal particulates in obese workers, indicating that obesity imparts greater susceptibility to acute cardiovascular effects of fine particles. We conclude that cardiac risk factors and obesity modify PM-induces autonomic cardiac responses in asymptomatic individuals of working age.

1913 COARSE PARTICULATE MATTER AIR POLLUTION AND HOSPITAL ADMISSIONS FOR CARDIOVASCULAR AND RESPIRATORY DISEASES AMONG MEDICARE PATIENTS.

F. Dominici. *Biostatistics, Johns Hopkins University, Baltimore, MD.* Sponsor: M. Madden.

The health risks of fine particulate matter (PM) (< 2.5 μm in aerodynamic diameter, PM2.5) have been studied extensively over the last decade. Evidence concerning the health risks of the coarse fraction of PM (> 2.5 and < 10 μm in aerodynamic diameter, PM10-2.5) is quite limited. Objective: To estimate the risk of hospital admissions for cardiovascular (CVD) and respiratory diseases (RESP) associated with exposure to PM10-2.5, controlling for PM2.5. Design, Setting, and Participants: We assembled a database for 108 US counties consisting of daily county-specific admission rates for CVD and RESP, temperature and dew point temperature, and PM10-2.5 and PM2.5 concentrations calculated with PM monitoring data from January 1, 1999 to December 31, 2005 as an exposure surrogate. Our study population included approximately 12 million Medicare enrollees living on average 9 miles from collocated pairs of PM10 and PM2.5 monitors. Main Outcome Measures: Daily counts of county-wide emergency hospital admissions for a primary diagnosis of CVD or RESP. Results: For the 108 counties, there were 3.7 and 1.4 million CVD and RESP admissions for the period 1999-2005. We found a positive and statistically significant association between same-day concentrations of PM10-2.5 and CVD admissions. When adjusted by same-day concentrations of PM2.5, this association was positive but not statistically significant. The associations between PM10-2.5, and RESP admissions, adjusted and unadjusted by PM2.5, were positive but not statistically significant. The effect of PM10-2.5 on CVD admissions was statistically significantly higher in more urban counties compared to less urban counties. We also found continuing evidence of a positive and statistically significant association between same day concentrations of PM2.5 and CVD admissions in the most recent Medicare data.

1914 USE OF GENE EXPRESSION CHANGES IN BLOOD TO ELUCIDATE MECHANISTIC INDICATORS OF CHILDHOOD ASTHMA (MICA).

S. Edwards[1], D. Reif[2], B. Heidenfelder[1], E. Hudgens[1], L. Neas[1], E. Hubal[2] and J. Gallagher[1]. *[1]NHEERL, U.S. EPA, Research Triangle Park, NC and [2]NCCT, U.S. EPA, Research Triangle Park, NC.*

Risk assessment increasingly relies more heavily on mode of action, thus the identification of human bioindicators of disease becomes all the more important. Genomic methods represent a tool for both mode of action determination and bioindicator identification. The Mechanistic Indicators of Childhood Asthma (MICA) Study incorporates genomics data from rodents and humans, together with phenotypic measurements, to predict the key events associated with asthma severity or symptomology and to identify human bioindicators for these key events. Gene expression was measured in blood collected from children participating in a case/control asthma study in Detroit. Transcriptional changes from blood were related to common environmental and clinical indicators to identify informative bioindicators to distinguish asthmatics with different etiologies. A parallel study using allergen sensitized Brown Norway rats included expression data from both blood and lung thereby establishing the relationship between transcriptional changes in the blood and corresponding changes in the target tissue. Systems approaches such as this are critical to realizing the National Research Council's 2007 vision of "Toxicity Testing in the 21st Century". [This abstract does not reflect EPA policy.]

1915 COMPARING URINARY BIOMARKERS OF EXPOSURE TO POLYCYCLIC AROMATIC HYDROCARBONS.

J. R. Sobus[1], M. D. McClean[2], R. F. Herrick[2], S. Waidyanatha[1], L. A. Nylander-French[1], L. L. Kupper[1] and S. M. Rappaport[3]. *[1]School of Public Health, University of North Carolina, Chapel Hill, NC, [2]School of Public Health, Harvard, Boston, MA and [3]School of Public Health, University of California, Berkeley, CA.*

Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous products of combustion that are found in numerous workplaces, including those processing hot asphalt. Because some PAHs are potent carcinogens, specifically those bound to particulate matter, it is important to assess occupational exposures. Urinary PAH analytes including naphthalene (U-Nap) and hydroxynaphthalene (OH-Nap), phenanthrene (U-Phe) and hydroxyphenanthrene (OH-Phe), and hydroxypyrene (OH-Pyr) have been independently studied as biomarkers of asphalt exposure. Here, we compare these urinary analytes to determine the most suitable biomarker(s) of exposure to particulate asphalt emissions. Our study included 20 paving workers who were observed over three consecutive workdays. Daily breathing-zone air and dermal patch measurements of 4-6 ring polycyclic aromatic compounds (PACs) were evaluated along with postshift, bedtime, and morning levels of U-Nap, U-Phe, OH-Nap, OH-Phe, and OH-Pyr. Linear mixed-effects models were used to evaluate exposure-biomarker relationships while controlling for other covariates. Measurements of PACs in the air and on the skin were significantly associated with U-Nap, U-Phe, OH-Phe, and OH-Pyr levels, with the strongest associations observed in postshift samples. Levels of OH-Nap were not associated with PAC measurements but were significantly affected by smoking status, age, day of sample collection, and urinary creatinine concentration. Overall the strongest associations were observed between PACs and OH-Phe. We conclude that OH-Phe, U-Nap, U-Phe, and OH-Pyr are useful biomarkers of exposure to particulate asphalt emissions, with OH-Phe being the most promising biomarker.

S 1916 IDENTIFICATION OF OXIDATIVELY-MODIFIED PROTEINS AS BIOMARKERS OF CHRONIC INFLAMMATORY STRESS.

J. G. Pounds and R. A. Corley. *Pacific Northwest National Laboratory, Richland, WA.*

The ultimate goal of the NIH Exposure Biology Program is to understand the development and progression of complex disease by precisely, accurately, and quantitatively assessing the individual's exposure and response to environmental stressors. Two important risk factors for human morbidity and mortality are exposure to cigarette smoke (CS) and obesity; both are associated with systemic chronic inflammation and oxidative stress. Thus, integrated high-throughput technologies are being used in both human and mouse studies to identify oxidatively modified proteins resulting from inflammatory stress. Exposures of normal and obese mice to defined conditions of CS and lipopolysaccharide (LPS) permit elucidation of biological responses to different inflammatory stresses. We find from both inflammatory cytokine levels and immune cell populations in bronchoalveolar fluid demonstrate distinct immune responses from these two stressors. In particular, obesity exacerbates the effects of CS exposure, but not of LPS. Similarly, microarray analysis of murine lung reveals that obesity reprograms the lung's transcriptional response, altering both the number of genes and the specific molecular pathways induced or suppressed by smoke exposure. Thus, complementary knowledge at gene, cytokine, and cellular levels provides fundamental biological insights regarding exposure responses to each stressor that will facilitate reliable identification of protein biomarkers in both mouse and humans. High resolution MS proteomic analyses of plasma and tissue samples from both mice and humans are ongoing. In addition, our ongoing development of ELISA microarray chips, in combination with a nanoparticle-based multiplexed Immunochromatographic / Electrochemical Biosensor, will provide validation of protein biomarkers as well as a clinic-deployable detector of individual exposure and response. Supported by U54 ES106015.

S 1917 MECHANISTIC ANALYSES OF SKIN HOMEOSTASIS AND CARCINOGENESIS.

H. Swanson[1], S. C. Smart[2], L. A. Hansen[3] and D. K. St. Clair[4]. *[1]Molecular and Biomedical Pharmacology, University of Kentucky, Lexington, KY, [2]Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC, [3]Biomedical Sciences, Creighton University, Omaha, NE and [4]Graduate Center for Toxicology, University of Kentucky, Lexington, KY.*

It is important to note the following as it relates to the significance of the studies focused on understanding skin homeostasis and carcinogenesis. Researchers know that skin cancer is currently the most common type of human cancer and the skin cancer model is a well-studied model of multistage carcinogenesis that can provide mechanistic insights. Also, the common mechanisms elucidated from these studies are highly relevant to those involved in a number of chronic human diseases. Like other epithelial cancers, skin carcinogenesis involves initiation, promotion and progression that requires activation of oncogenes and inactivation of tumor suppressor genes. Activation of oncogenes, in particular Ras, often occurs following exposure to a number of chemicals and other agents. Signaling pathways upregulated following exposure to UV light, for example, include that of the Erbb receptors. Keratinocytes that are thus initiated acquire the capabilities to bypass normal cell death pathways, such as apoptosis and proliferate and ultimately form pre-malignant lesions. Recent studies have shown redox signaling plays a key role in modulating oncogenic and tumor suppressive (i.e., p53) signals during skin carcinogenesis. In addition to p53, other proteins also thought to play important roles in suppressing epithelial tumorigenesis is C/EBP alpha that is involved in G1 checkpoint. Xenobiotics that can impinge on the regulation of skin homeostasis include dioxin, which likely exerts its tumor promoting activities, in part, via its ability to inhibit apoptosis and senescence. Thus, it is important to focus on the molecular and cellular mechanisms involved in maintaining proper skin homeostasis and how environmental factors may impinge on these mechanisms and contribute to the development of not only skin cancer, but also to the progression of chronic disease states of tissues such as the heart, esophagus, and nervous system.

S 1918 ACTIVATION OF THE AHR ALTERS CELL FATE DECISIONS AND SKIN HOMEOSTASIS.

H. Swanson. *Molecular and Biomedical Pharmacology, University of Kentucky, Lexginton, KY.*

Considerable progress has made towards understanding how activation of the aryl hydrocarbon receptor by its agonists, such as dioxin, contributes towards the development of chronic disease states in particular, cancers of epithelial cell origin. Using keratinocytes as a model of normal human epithelial cells, dioxin has been found to alter their ability of keratinocytes to proliferate, differentiate, apoptose and senesce. These events observed in cultured keratinocytes are often in contrast to those reported in other cell types. More recent in vivo studies indicate that within the context of cutaneous wound healing, activation of the AHR by dioxin accelerates wound closure, but leads to an improperly healed wound. These dioxin-induced actions are accompanied by an acceleration in TGFβ signaling and appearance of activated keratinocytes and myofibroblasts within the wounded tissue. The observations accrued using skin as a model tissue are consistent with those reporting dioxin-induced alterations in extracellular matrix remodeling and impaired morphology of the heart and kidney. These findings also have implications to other chronic disease states.

S 1919 ERBB2: A REGULATOR OF THE SKIN'S RESPONSE TO ULTRAVIOLET IRRADIATION.

L. A. Hansen. *Biomedical Sciences, Creighton University, Omaha, NE.* Sponsor: H. Swanson.

The cause of most non-melanoma skin cancer is prolonged exposure to ultraviolet (UV) irradiation, which activates cell cycle checkpoints and causes both DNA damage and mutations. UV-induced DNA damage activates the ATR checkpoint leading to degradation of Cdc25a and cell cycle arrest, which allows time for the repair of DNA damage. UV irradiation also activates members of the epidermal growth factor receptor family such as Erbb2/HER2 through an indirect mechanism involving the inactivation of protein tyrosine phosphatases. This presentation will focus on the effects of Erbb2 activation on cell cycle arrest, DNA repair and skin carcinogenesis in response to UV irradiation. UV-induced Erbb2 activation permits S-phase progression by suppressing Chk1 activation and consequent Cdc25a degradation through a phosphatidylinositol-3-kinase (PI3K)/Akt-dependent mechanism. Erbb2 also delays the repair of DNA damage and increases mutagenesis of the Trp53 tumor suppressor gene in response to UV irradiation. Blockade of Erbb2 signaling in a mouse model suppresses skin carcinogenesis in response to UV irradiation, suggesting the receptor may be an appropriate therapeutic target for the treatment or prevention of skin cancer. Observations about the role of Erbb2 in the skin have important implications for the treatment of breast and other adenocarcinomas with oncogenic activation of HER2.

S 1920 MULTIFACETED ROLES FOR C/EBPS IN THE DNA DAMAGE RESPONSE NETWORK AND SKIN TUMORIGENESIS.

R. C. Smart. *Department of Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC.*

This presentation will focus on the known and emerging roles of the basic leucine zipper (bZIP) transcription factors, C/EBPα and C/EBPβin epidermal homeostasis and skin tumorigenesis. While C/EBPα and C/EBPβ have similar DNA binding domains and bind to the same DNA consensus sequence, they have very different roles in keratinocytes and skin tumorigenesis. C/EBPα opposes oncogenic Ras via direct repression of E2F. C/EBPα has a role in the G1/S transition as well as the DNA damage induced G1 checkpoint and functions as a tumor suppressor gene in skin. In contrast, C/EBPβ is a mediator of keratinocyte survival and tumorigenesis. When C/EBPβ-/- mice are treated with carcinogens that produce oncogenic Ras mutations in keratinocytes, they respond with abnormally elevated keratinocyte apoptosis and a block in skin tumorigenesis. While this aberrant carcinogen-induced apoptosis results from abnormal up-regulation of p53, it was not known whether up-regulated p53 results from oncogenic Ras and its ability to induce p19Arf and/or activate DNA damage response pathways or from direct carcinogen-induced DNA damage. Recently we have demonstrated that C/EBPβ represses p53 levels and functions to promote cell survival downstream of DNA damage independent of oncogenic Ras and p19Arf. These findings and mechanisms will also be discussed with respect to other epithelial tissue.

S 1921 MITOCHONDRIA AND SKIN CANCER: NEW FACET IN AN OLD PARTNERSHIP.

D. K. St. Clair. *Graduate Center for Toxicology, University of Kentucky, Lexington, KY.*

Mitochondria plays an important role as a source of ROS generation as well as a source of ROS removal. The pro- or anti-oxidant function of mitochondria is regulated by the activity of the primary antioxidant enzyme, manganese superoxide dismutase (MnSOD), which is a nuclear-encoded antioxidant enzyme that localizes to the mitochondria. Using transgenic mice, we have demonstrated that MnSOD modulates tumor formation caused by the tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA) by regulation of cellular proliferation pathways. However, MnSOD deficiency lead to an enhanced apoptosis because oxidative stress in the mitochondria can modulate the p53 mediated apoptosis pathways. In

MnSOD deficient mice, TPA induces p53 translocation to mitochondria and nucleus, a response, which eventually leads to apoptosis. Translocation of p53 to mitochondria precedes its nuclear translocation after TPA application. In the mitochondria, p53 interacts with MnSOD, and reduces its superoxide scavenging activity, contributing to a transcription independent apoptosis action of p53. In addition to the immediate action on mitochondria, p53 translocation to the nucleus is accompanied by a decrease in the levels of its target gene, MnSOD, thereby amplifying the pro-oxidant conditions in mitochondria. Thus, p53 translocation to mitochondria and subsequent suppression of MnSOD explains the observed pro-oxidant function of mitochondria that leads to transcription-dependent mechanisms of p53-induced apoptosis. This work will allow for potential mechanistic based interventions of multi-stage chemical-induced skin carcinogenesis and can also be applied to a chemical-induced cardiac injury model.

S 1922 MULTIFACETED ROLES FOR C/EBPS IN THE DNA DAMAGE RESPONSE NETWORK AND SKIN TUMORIGENESIS.

R. C. Smart. *North Carolina State University, Raleigh, NC.*

This presentation focuses on the known and emerging roles of the basic leucine zipper (bZIP) transcription factors CCAAT/enhancer binding protein alpha (C/EBPα) and C/EBPβ in epidermal homeostasis and skin tumorigenesis. While C/EBPα and C/EBPβ have similar DNA binding domains and bind to the same DNA consensus sequence, they have vastly different roles in keratinocytes and skin tumorigenesis. C/EBPα has a role in the G_1/S transition, is highly inducible by UVB radiation and functions in the DNA damage-induced G_1 checkpoint. C/EBPα is a tumor suppressor gene in skin. In contrast, C/EBPβ is a mediator of keratinocyte survival and skin tumorigenesis. When C/EBPβ$^{-/-}$ mice are treated with carcinogens that produce oncogenic Ras mutations in keratinocytes, they respond with abnormally elevated keratinocyte apoptosis and a block in skin tumorigenesis. This aberrant carcinogen-induced apoptosis results from abnormal up-regulation of p53 indicating C/EBPβ is a negative regulator of p53 levels and function. Recently, we have demonstrated that C/EBPβ represses p53 levels and functions to promote cell survival downstream of DNA damage independent of oncogenic Ras and p19^{Arf}. Lastly, these findings and mechanisms will be discussed with respect to their relevance to other epithelial tissues.

S 1923 PULMONARY EFFECTS OF IN UTERO AND EARLY POSTNATAL EXPOSURE TO ARSENIC.

R. Lantz. *Cell Biology and Anatomy, University of Arizona, Tucson, AZ.*

Arsenic has long been recognized as a human lung carcinogen. In addition, the health effects of arsenic ingestion in the drinking water have also been associated with significant non-cancerous chronic pulmonary disease. It has been postulated that a significant proportion of adult lung disease originates in utero or in early infancy. Growth and development requires the temporal and spatial coordinated expression of genes and gene products. During this critical time, *in utero* and early postnatal exposure to toxicants has the potential to affect gene expression, altering organ structure and physiological function which can lead to adult disease. The effect of in utero and early postnatal arsenic exposure on lung disease and the effects of arsenic exposure during lung development on human cancer and noncancerous lung disease in adults will be presented. The adverse health outcomes associated with in utero and postnatal exposures and will demonstrate the importance of understanding the mechanisms and targets of arsenic during these developmental time points will be provided as an overview. Furthre discussions will focus on gene-environment interactions in arsenic metabolism, metabolism and distribution of arsenic during fetal development and cancerous and noncancerous animal models of *in utero* and early postnatal exposures. In order to fully understand the issues presenters, researchers will provide attendees with excellent examples and information from both population and laboratory based research that will indicate the importance of exposures during these sensitive developmental times. This symposium will be of interest to those involved in metal toxicology, developmental toxicology, public health, risk assessment, and regulatory management.

S 1924 IMPACT OF IN UTERO AND CHILDHOOD EXPOSURE TO ARSENIC IN DRINKING WATER ON MORTALITY IN YOUNG ADULTS.

A. Smith. *School of Public Health, University of California, Berkeley, CA.* Sponsor: R. Lantz.

Arsenic in drinking water is an established cause of lung cancer, and preliminary evidence suggests that ingested arsenic may also cause nonmalignant lung disease. A unique exposure scenario provided a rare opportunity to investigate the long-term mortality impact of early-life arsenic exposure. This study focused on subjects who were born during or just before a peak arsenic exposure period and who were 30–49 years of age at the time of death. For the birth cohort born just before the high-exposure period (1950–1957) and exposed in early childhood, the standardized mortality ratio (SMR) for lung cancer was 7.0 ($p < 0.001$) and the SMR for bronchiectasis was 12.4 ($p < 0.001$). For those born during the high-exposure period (1958–1970) with probable exposure *in utero* and early childhood, the corresponding SMRs were 6.1 ($p < 0.001$) for lung cancer and 46.2 ($p < 0.001$) for bronchiectasis. These findings suggest that exposure to arsenic in drinking water during early childhood or *in utero* has pronounced pulmonary effects, greatly increasing subsequent mortality in young adults from both malignant and nonmalignant lung disease.

S 1925 GENETICS, INTRINSIC ENVIRONMENT AND EXTRINSIC ENVIRONMENT INFLUENCE HUMAN VARIABILITY OF ARSENIC METABOLISM.

W. Klimecki. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

Studies characterizing human individual variation in arsenic metabolism, reflected in the speciation profile of urinary arsenic and its metabolites, suggest that variability in arsenic metabolism has a complex set of determinants that include age or developmental stage, sex, nutritional status and genetic variation. Adult women have been repeatedly shown to methylate arsenic more efficiently than do men. Variants in genes involved with arsenic metabolism (AS3MT) and one-carbon biochemistry (MTHFR) have likewise been associated in replicated studies with the efficiency of arsenic methylation. An additional layer of complexity exists in published evidence that suggests these factors can interact with each other, so that the effect of a genetic variant may be different in different age groups, or in different sexes. Exemplary in this regard is a population of arsenic-exposed individuals in Sonora, Mexico in whom we have measured urinary arsenic species as well as DNA variations in several candidate genes, testing for association with urinary arsenic species levels. In adults (>17 years) studied, females had less mean urinary arsenic as monomethylated arsenic, valence V (%MMA) than did males (4.2% Vs. 6.7%, P=0.018). Children (7-11 years) had lower mean %MMA than did adults (3.7% Vs. 4.9%, P=0.001). Polymorphisms in AS3MT were significantly associated with %MMA, but interacted with age. To complicate matters further, ancestry in this population (largely a genetic admixture between European and indigenous American ancestries) is a potential confounding factor in this study. Considering that measurements of individual variability in arsenic metabolism have provided among the best biomarkers of disease risk, it is likely that these determinants of arsenic metabolic variability have important correlates in disease likelihood. Thus, a clear understanding of how these factors collectively contribute to variability in arsenic metabolism is critical to explain their contribution to arsenic-associated disease.

S 1926 ARSENIC METABOLISM AND DISTRIBUTION IN DEVELOPING ORGANISMS.

D. Thomas. *U.S. EPA, Research Triangle Park, NC.*

A growing body of evidence suggests that exposure to inorganic arsenic during early life has long term adverse effects. The extent of exposure to inorganic arsenic and its methylated metabolites in utero is determined not only by the rates of formation and transfer of arsenicals across the placenta but also by ontogeny of arsenic metabolism in the developing organism. For example, in a mouse model for transplacental carcinogenesis of inorganic arsenic, fetuses at gestational day 18 contain inorganic, methylated, and dimethylated arsenic in placenta, liver, lung, and blood. The methylated arsenicals in fetal tissues could be transferred from the mother or formed in situ. Because concentrations of these arsenicals in fetal tissues were lower than those found in corresponding maternal tissues, there is likely a placental barrier to the transfer of arsenicals from mother to fetus or a maternal-fetal difference in the uptake, production, or retention of these arsenicals. Arsenic (+3 oxidation state) methyltransferase which catalyzes the formation of methylated arsenicals is detectable in fetal tissues by mid-gestation. However, it is unknown whether the protein is catalytically active in utero. For example, the activity of arsenic (+3 oxidation state) methyltransferase is dependent on the presence of dithiol reductants (thioredoxin, glutaredoxin) and is modulated by glutathione. Availability of these factors during development may control the ontogeny of the activity of arsenic (+3 oxidation state) methyltransferase and may affect of the levels of methylated arsenicals found in fetal tissues. In addition, developmental changes in the levels of transporters that mediate the uptake and loss of arsenicals from cells could affect accumulation in fetal tissues. Elucidating the roles of transport and metabolism in the kinetic behavior of inorganic arsenic in fetal tissues could contribute to understanding genetic and epigenetic consequences of early life exposure to this metalloid. (This abstract does not reflect US EPA policy.)

1927 FETAL ARSENIC EXPOSURE AND ADULT LUNG CANCER IN MICE; IMPLICATIONS AND POTENTIAL MECHANISMS.

J. Liu. *NIEHS, Research Triangle Park, NC.*

Inorganic arsenic has long been known as a known human carcinogen and can target the lung. More recently it has been established as a multi-site, transplacental carcinogen in mice, producing cancer in adulthood after brief fetal exposure via maternal drinking water. As a transplacental carcinogen inorganic arsenic often targets the lung as either an initiator or complete carcinogen and has show activity in a variety of mouse strains. Arsenic-induced molecular changes in fetal lung included increased estrogen receptor-alpha (ER-alpha), and overexpression of estrogen-regulated genes (trefoil factor-3, etc.) and increases in the steroid metabolism genes such as aromatase. The IGF system, which is influenced by ER and has been implicated lung cancer, and several other genes (alpha-fetoprotein, epidermal growth factor receptor, and L-myc) associated with lung cancer were overexpressed. In adult females exposed to arsenic *in utero* lung adenoma and adenocarcinoma showed widespread, intense nuclear ER-alpha expression. In contrast, normal adult lung and diethylnitrosamine-induced lung adenocarcinoma showed little evidence of ER-alpha expression. Thus, transplacental arsenic exposure at a carcinogenic dose produced aberrant estrogen-linked pulmonary gene expression. ER-alpha activation was specifically associated with arsenic-induced lung adenocarcinoma and adenoma. These arsenic-induced aberrant steroid signaling could disrupt early life stage genetic programming in the lung leading eventually to lung tumor formation much later in adulthood. These data help provide a further example of the fetal basis of adulthood disease with arsenic exposure.

1928 ALTERATION IN PULMONARY STRUCTURE AND FUNCTION FOLLOWING IN UTERO AND EARLY POSTNATAL ARSENIC EXPOSURE.

R. Lantz. *Cell Biology and Anatomy, University of Arizona, Tucson, AZ.*

In addition to cancer endpoints, arsenic exposures can also lead to noncancerous chronic lung disease. Exposures during sensitive developmental time points can contribute to the adult disease. Using a mouse model, *in utero* and early postnatal exposures to arsenic (100 ppb or less in drinking water) were found to alter airway reactivity to methacholine challenge. Removal of mice from arsenic exposure 28 days after birth did not reverse the alterations in sensitivity to methacholine. In addition, adult mice exposed to similar levels of arsenic in drinking water did not show alterations. Therefore, alterations in airway reactivity were irreversible and specific to exposures during lung development. These functional changes correlated with protein and gene expression changes as well as morphological structural changes around the airways. Arsenic increased the whole lung levels of smooth muscle actin in a dose dependent manner. The level of smooth muscle mass around airways was increased with arsenic exposure. This was associated with alterations in extracellular matrix (collagen, elastin) expression. Dietary folate supplementation reduced the arsenic induced functional alterations, indicating that methylation may be playing a role in the arsenic-induced alterations. This model system demonstrates that developmental exposure to environmentally relevant levels of arsenic can irreversibly alter pulmonary function in the adults and that dietary intervention strategies may be useful in reducing the adverse health effects caused by *in utero* and postnatal arsenic exposures.

1929 THE ROLE OF INFLAMMATION DURING METABOLIC LIVER DISEASE AND DRUG-INDUCED LIVER TOXICITY: NOVEL INSIGHTS.

S. Ramaiah[1] and H. Jaeschke[2]. *[1]Pfizer Global Research and Development, St. Louis, MO and [2]University of Kansas Medical Center, Kansas City, KS.*

Hepatic inflammation is a common finding during a variety of metabolic diseases and drug-induced liver toxicity. The inflammatory phenotype noted in the liver can be attributed to the innate immune response generated by Kupffer cells, monocytes, neutrophils and lymphocytes (T, NK and NKT cells). The adaptive immune system is also influenced by the innate immune system leading to liver damage. A major question that continues to be debated is the precise role of these immune cells to liver damage. Liver injury mediated by neutrophils has been reported in a number of animal models such as ischemia-reperfusion injury, endoxemia, alcoholic hepatitis, obstructive cholestasis and drug induced liver damage such as by ANIT and acetaminophen toxicity. Similarly Kupffer cells and lymphocytes are also implicated for hepatic pathology. The role of autoimmunity (Th17 cell) in idiosyncratic liver toxicity is also an area of intense investigation. The role of each components of both innate and adaptive immune responses during hepatic inflammation in specific metabolic diseases and idiosyncratic liver toxicity will be discussed. The issues presented will span from fundamental, mechanistic studies to clinical investigations on the role of neutrophils, lymphocytes, Kupffer cells and immune responses in liver damage during metabolic diseases and drug-induced idiosyncratic liver toxicity.

1930 ROLE OF AUTOIMMUNITY (TH17 CELLS) IN DRUG-INDUCED LIVER INJURY.

J. Utrecht. *Pharmacy and Medicine, University of Toronto, Toronto, ON, Canada.*
Sponsor: S. Ramaiah.

The clinical characteristics of liver injury caused by different drugs varies significantly. In some cases such as halothane-induced liver injury, the injury appears to be due to an immune response to a reactive metabolite. In many cases, the characteristics of the liver injury have led to the term metabolic idiosyncrasy but there is no example where polymorphisms in a metabolic pathway have been shown to be responsible for an idiosyncratic reaction. Such characteristics could also be caused by an autoimmune component to the liver injury. A "new" type of T cell called the Th17 cell, which appears to be involved in autoimmune injury such as multiple sclerosis and rheumatoid arthritis, may also be involved in some types of drug-induced liver injury. In particular, ximelagatran-induced liver injury appears to be immune-mediated because it is associated with a specific HLA genotype and yet patients who had elevated transaminases and were later inadvertently rechallenged did not have a recurrence and injury sometimes started a month after the drug was discontinued. It does not appear that ximelagatran forms a reactive metabolite

1931 IMMUNE REGULATION IN LIVER DISEASE.

D. Adams. *Hepatology, University of Birmingham, Birmingham, United Kingdom.*
Sponsor: S. Ramaiah.

Liver diseases with different pathogeneses share common pathways of immune-mediated injury. Autoreactive T cells destroy hepatocytes or cholangiocytes in autoimmune disease and virus-specific T cells destroy infected hepatocytes in viral hepatitis. In these conditions antigen-specific mechanisms can be implicated but immune-mediated injury is central to many diseases including drug toxicities where there is a less defined role for specific antigens. In all these diseases "bystander" cells" activated by the local microenvironment rather than a specific antigen are major players and amplify injury by recruiting effector cells from the circulation. Thus immune-mediated liver injury is driven by repeated cycles of inflammation and damage sustained by continuing recruitment, retention and survival of effector leukocytes within the inflamed liver. These processes are dependent on complex interactions involving epithelial cells, stromal cells and leukocytesshaped by the local cytokine microenvironment. I will present data defining some of the cellular interactions and pathways involved in these processes in humans. Understanding these mechanisms will elucidate the pathogenesis of liver disease and suggest new therapeutic approaches to regulating inflammatory liver disease.

1932 ROLE OF HEPATIC MACROPHAGES IN DRUG-INDUCED LIVER INJURY.

C. Ju and M. Holt. *SOP, UCHSC, Denver, CO.*

Drug-induced liver injury (DILI) is a major safety issue during drug development and the most common cause for drug withdrawals. Although there is growing evidence that the innate immune system is important in the pathogenesis of DILI, the exact role of hepatic macrophages remains unclear. This presentation will discuss our recent study finding and characterizing a population of macrophages that is recruited into the liver upon APAP challenge to mice. Our data demonstrated that the infiltrating macrophages (IM) were derived from circulating monocytes. The IMs exhibited a genotype consistent with that of alternatively activated macrophages and demonstrated the ability to phagocytize apoptotic cells and induce apoptosis of neutrophils. These findings very likely contribute to the role of the IMs in the resolution of inflammation and promotion of tissue repair following APAP-induced liver injury. Furthermore, our ability of separating IM from resident Kupffer cells, and delineating distinct functions of each subset of macrophages will aid future studies of inflammatory disease in the liver and other tissues.

1933 ROLE OF NEUTROPHILS IN MECHANISMS OF DRUG HEPATOTOXICITY.

H. Jaeschke. *Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Acetaminophen (APAP), a widely used analgesic, is generally considered a safe drug at therapeutic levels but can induce centrilobular necrosis and even liver failure at higher doses. Although most studies still focus mainly on the intracellular signaling

mechanisms of cell death in hepatocytes, there is an increasing interest in the role of hepatic nonparenchymal cells (Kupffer cells, NK- and NKT cells) and infiltrating leukocytes (neutrophils, monocytes) in the pathophysiology. For each cell type there is experimental evidence in the literature suggesting a contribution to the mechanism of toxicity. However, the validity of several of these conclusions has been questioned recently. The focus of our investigations is to elucidate the role of neutrophils in APAP-induced liver injury and regeneration. The presentation will address basic mechanisms of neutrophil activation and recruitment into the liver during inflammation, the signaling mechanisms that determine cytotoxicity, the mechanisms of neutrophil-induced liver injury and potential differences in neutrophil activity during regeneration. A better understanding of the role of neutrophils in host defense, aggravation of tissue injury and promotion of tissue regeneration will allow the identification of strategies that prevent the detrimental effects without negatively affecting the essential functions of these innate immune cells.

S 1934 THE CONTRIBUTION OF OSTEOPONTIN TO HEPATIC INFLAMMATION AND LIVER INJURY.

S. K. Ramaiah. *Drug Safety Research and Development, Pfizer, St. Louis, MO.*

Osteopontin (OPN) produced by cells of the immune system, epithelial tissue, smooth muscle cells, osteoblasts and tumor cells has been implicated in various pathophysiological functions such as cell binding, spreading and migration, and tumor metastasis. OPN is known to bind to integrins expressed on macrophages through the RGD motif and promote migration of cells resulting in granuloma. In the liver, it has been reported that hepatic Kupffer cells secrete OPN facilitating macrophage infiltration in necrotic areas following carbon tetrachloride liver toxicity. Recent work has underlined the importance of OPN as a pivotal cytokine/chemokine in the generated hepatic neutrophil response during early phase alcoholic liver injury. Increased hepatobiliary OPN expression correlated well with higher neutrophil infiltration in a rat model of alcoholic steatohepatitis (ASH). In the same model of ASH, higher hepatic expression of OPN in females was attributed to the higher neutrophil infiltration and consequent higher female sensitivity to liver damage. OPN as a potential biomarker for inflammatory liver disease has also been assessed recently. In this presentation, the speaker will review some of the previous findings in addition to providing new in vitro data on the role of osteopontin and the ability of other hepatotoxic chemicals to induce this protein and potentially predict liver injury and hepatic inflammation

W 1935 FOOD ALLERGY - BASIC MECHANISMS AND APPLICATIONS TO IDENTIFYING RISKS ASSOCIATED WITH PLANT INCORPORATED PESTICIDES AND OTHER GENETICALLY MODIFIED CROPS.

M. Selgrade[1] and S. Laessig[2]. *[1]U.S. EPA, NHEERL, Research Triangle Park, NC and [2]U.S. EPA, NCER, Washington, FL.*

Food allergy is a relatively new concern for toxicologists as a result of the incorporation of novel proteins into food crops in order to promote resistance to pests and other stresses, improve nutrition, or otherwise modify the phenotype. Food allergy can manifest as inflammation of the skin (hives), gut, and/or lung and in the most extreme cases can result in anaphylactic shock and death. Thus, although the technology to modify crops genetically has many advantages over more conventional approaches, there is some concern that introduction of a novel protein into the food supply could result in unintentional introduction of a new food allergen and could pose a risk to susceptible individuals. A number of potential strategies have been proposed to assess this risk, but many questions regarding basic mechanisms underlying food allergy limit our ability to provide the public with information not only about potential allergenicity of transgenic proteins, Food allergy is a relatively new concern for toxicologists as a result of the incorporation of novel proteins into food crops in order to promote resistance to pests and other stresses, improve nutrition, or otherwise modify the phenotype. Food allergy can manifest as inflammation of the skin (hives), gut, and/or lung and in the most extreme cases can result in anaphylactic shock and death. Thus, although the technology to modify crops genetically has many advantages over more conventional approaches, there is some concern that introduction of a novel protein into the food supply could result in unintentional introduction of a new food allergen and could pose a risk to susceptible individuals. A number of potential strategies have been proposed to assess this risk, but many questions regarding basic mechanisms underlying food allergy limit our ability to provide the public with information not only about potential allergenicity of transgenic proteins, but also about practices to limit the risks associated with conventional food allergens. The prevalence of food allergy is increasing, providing greater incentive to understand the process and an urgent need for better safety assessment tools. It is important to note that current regulatory approaches and recent research that has improved our understanding of host responses such as sensitization and oral tolerance, developed unique animal models of allergy, and applied structural data bases, global gene arrays, and serum screening to both explore mechanisms and develop hazard identification methods. *This abstract does not reflect EPA policy.*

W 1936 INTRODUCTION: FOOD ALLERGY-A TOXICOLOGISTS POINT OF VIEW.

M. Selgrade. *U.S. EPA, NHEERL, Research Triangle Park, NC.*

Incorporation of new proteins into crops to promote resistance to pests and other stressors, improve nutrition, or otherwise modify phenotype is a technology that has many advantages over conventional approaches. There is concern however, that introduction of a novel protein into the food supply could include a new food allergen and pose a risk to susceptible individuals. Food allergy is an immune reaction (usually IgE mediated) to an otherwise harmless protein. Clinical signs may include rhinitis, itching, hives, or gastrointestinal symptoms, and occasionally bronchoconstriction, anaphylaxis, and death. Despite constant exposure to many antigens in food, only a small percentage of individuals experience adverse immunologic reactions. The normal response to dietary proteins is the induction of oral tolerance, a state of active inhibition of immune responses to an antigen previously encountered via the oral route. The incidence of food allergy ranges from 1-2% in adults and 6-8% in children. Relatively few foods are responsible for the majority of food-induced allergic reactions suggesting that food allergens have some unique characteristics which could facilitate hazard identification. Over the past 10 years recommendations for evaluating the potential allergenicity of transgenic proteins have evolved from a systematic decision tree to a weight of evidence approach in which no single factor is recognized as an identifier for protein allergenicity. These various recommendations are based on what is known about allergens, including: the history of exposure and safety of the gene(s) source, amino acid sequence identity to human allergens, stability to pepsin digestion in vitro, protein abundance in the crop and processing effects, and when appropriate, specific IgE binding studies or skin prick testing. Several potentially useful tools for hazard identification remain under developed including rodent model(s) for hazard identification, structure activity approaches, and serum screening. New developments in these areas show promise and deserve our attention. This abstract does not reflect EPA policy.

W 1937 AN ANIMAL ORAL EXPOSURE MODEL – SENSITIZATION VS TOLERANCE.

C. Bowman and M. Selgrade. *U.S. Environmental Protection Agency, Durham, NC.*

Animal models are needed to assess novel proteins produced through biotechnology for potential dietary allergenicity. The exact characteristics that give certain foods allergenic potential are unclear, but must include both the potential to sensitize (induce IgE) as well as the capacity to avoid induction of oral tolerance (specific inhibition of IgE production). EPA has developed two complementary mouse models; one which distinguishes allergenic from non-allergenic food extracts using oral sensitization with adjuvant (cholera toxin) and another which further distinguishes highly potent allergens following oral administration without adjuvant based on the development (or not) of tolerance. For the foods tested thus far (roasted or raw peanut, Brazil nut, egg white, turkey, and spinach), the ability to sensitize and/or tolerize in these models are consistent with observed allergenicity as well as persistence and severity among allergens. *In vitro* studies of digestibility in simulated gastric fluid (pepsin) and simulated intestinal fluid (trypsin) have supported the notion that pepsin stability is associated with allergenicity and sensitization in the mouse model. However, both pepsin stability and trypsin stability appear required for oral tolerance induction. Of the foods tested only egg white exhibited this unique pattern of digestibility and was able to induce oral tolerance, consistent with the frequent resolution of egg white allergy in childhood. Varying the pH of the oral dosing solution altered both sensitization and tolerance induction for different foods, indicating that the material preparation or matrix in which the food is presented is an important consideration for test methods. This abstract does not reflect EPA policy.

W 1938 MOUSE STRAIN DIFFERENCES IN THE RESPONSE TO ORALLY ADMINISTERED ALLERGENIC AND NON-ALLERGENIC PROTEINS.

H. HogenEsch, A. Dunham and L. Hedges. *Comparative Pathobiology, Purdue University, West Lafayette, IN.* Sponsor: M. Selgrade.

With the introduction of novel proteins through genetically engineered foods, better tools are needed to predict the allergenic potential of food proteins and to understand the mechanisms underlying food allergy. Animal models that distinguish between allergenic and non-allergenic foods would be very useful. We adapted a re-

cently published protocol (Bowman and Selgrade. Toxicol. Sci.102: 100, 2008) to determine if certain mouse strains would be better able to discriminate between allergenic and non-allergenic foods. Three strains of mice (A/J, BALB/c, C3H/HeJ) were fed peanut protein extract (PPE) or spinach protein extract (SPE) with 10 μg of cholera toxin (CT) twice a week for 3 weeks. Two weeks after the last feeding, blood was collected and analyzed for the presence of PPE and SPE-specific IgG1 and IgE. The A/J mice had the highest PPE-specific IgE and this level was significantly higher than SPE-specific IgE. The levels of PPE-specific IgE were not different between BALB/cJ and C3H/HeJ. The A/J mice also had a significantly higher concentration of PPE-specific IgG1 over SPE-specific IgG1. In a subsequent experiment, A/J mice were fed PPE, ovalbumin (OVA), and potato protein extract (PoPE). The PPE and OVA induced a significantly higher food protein-specific IgE and IgG1 response than PoPE. OVA induced a stronger IgE response than PPE, but there was no difference for IgG1. These experiments indicate that feeding of A/J mice with known allergenic proteins (PPE and OVA) induced a significantly stronger IgE and IgG1 response than with non-allergenic proteins (SPE and PoPE). This model may be a useful tool to identify allergenic food proteins and to study the mechanisms of food allergy. Supported by EPA STAR R833134.

W 1939 SAFETY ASSESSMENT OF DIETARY PROTEINS FOR ALLERGENICITY USING AN ADJUVANT-FREE MOUSE MODEL.

V. Gangur. *Michigan State University, East Lansing, MI.* Sponsor: M. Selgrade.

Currently there is no validated animal model available for the assessment of allergenic potential of GE foods—a major challenge facing the regulatory agencies and the agro-biotech industry. The goal of this project is to test the validity of a novel adjuvant-free mouse model of food allergy that we have recently reported (Birmingham et al., Int Arch Allergy Immunol. 2007, 144, 3:203-210). We have been testing the hypothesis that this mouse model, which involves transdermal sensitization to food proteins followed by oral food challenge, will be highly reliable in discerning food proteins that have or do not have
intrinsic allergenic sensitization potential in humans. The two specific objectives for this project are: 1)Determine the positive predictive value (i.e., sensitivity) of the mouse-model; and 2) Determine the negative predictive value (i.e.,specificity) of the mouse model for testing allergenicity of dietary proteins. The data demonstrates that:(i) the allergenicity readouts (food specific IgE antibody response to transdermal food protein exposure, clinical signs of systemic anaphylaxis and hypothermia to oral food challenge) in this mouse model are dependent on the number of exposures to the allergenic protein; a minimum of four transdermal exposures to the allergenic food protein at 1000 ug/mouse dose is required to sensitize the mice to obtain significant readouts of systemic anaphylaxis and hypothermia to oral food challenge; ii) four human allergenic food proteins (hazelnut,cashew nut, cow's milk and chicken egg) produce all three readouts of allergenicity; (iii) two human non-allergenic food proteins (kidney bean, pinto bean) were non-allergenic based on clinical scores and hypothermia readouts but not IgE data; interestingly, Amaranth seed protein, presumably non-allergenic in humans, produced all three readouts of allergenicity in this model. Currently we are testing
additional dietary proteins for allergenicity using this adjuvant-free mouse model. Funding: US EPA STAR Grant#R833133.

W 1940 PREDICTION AND DETECTION OF CONFORMATIONAL EPITOPES OF IGE ANTIBODIES.

W. Braun[1], C. H. Schein[1], O. Ivanciuc[1], T. Midoro-Horiuti[2] and R. M. Goldblum[2]. [1]*Biochemistry & Molecular Biology, UTMB, Galveston, TX and* [2]*Pediatrics, UTMB, Galveston, TX.* Sponsor: M. Selgrade.

We created the Structural Database of Allergenic Proteins (SDAP, http://fermi.utmb.edu/SDAP/) to archive data on allergens and to provide unique bioinformatics tools to assess the potential risk of genetically modified food products for allergenicity. In this talk we demonstrate the use of 3D structures of allergens to characterize the potency of allergens, address the experimental validation of the property distance (PD) index and present a novel approach to determine conformational IgE epitopes from phage display experiments. As an example for a highly potent allergen we examined the sequence similarities and 3D structural locations of IgE epitopes from peanut and related nut allergens. Our findings indicate that the potency of peanut allergens might be due to the proteins' arrays of similar antigenic regions on opposite sides of a single protein structure. To quantitatively assess the quality of the PD index we used the previously identified epitopes of the Jun a 1 allergen from cedar pollen as a model system. Immuno dot blot assays showed that peptides with low PD indices, i.e. less than 6, relative to a given epitope are more likely to bind IgE from sera of pollen sensitive patients than those with large PD indices. We also demonstrate how 3D structures of allergens can be used to gain insights on the physical-chemical nature of conformational epitopes. We generated more than 400 reliable 3D models of allergens, considerably extending our knowledge from the 45 currently known 3D structures of allergens. Statistical analysis of surface exposed parts of experimentally determined IgE epitopes revealed a distinct distribution of residues different from that in typical protein-protein interfaces. Finally we present a new automated search method, EpiSearch that predicts the 3D location of conformational epitopes on the surface of an allergen from peptides, selected by phage display technology. We show that EpiSearch is capable to find the correct epitope locations in several cases, including one blind test. Funding: US EPA STAR grant RD 833137

W 1941 HUMAN SERUM IGE SCREENING: IDENTIFICATION OF ALLERGENS AND POTENTIALLY CROSS-REACTIVE PROTEINS.

R. E. Goodman, A. Ofori-Anti and S. N. Pramod. *Food Science & Technology, University of Nebraska, Lincoln, NE.* Sponsor: M. Selgrade.

Based on US and CODEX guidelines for assessing the potential allergenicity of foods from genetically modified (GM) crops, serum IgE binding tests are required if the gene is from a commonly allergenic source or the newly introduced protein shares greater than 35% sequence identity match over any 80 or more amino acid segment with a known allergen. Since allergy to any specific source is relatively rare and IgE binding affinity, specificity and abundance varies between subjects, serum donor selection of test and control subjects must be based on a clear history of allergy and diagnostic testing. Since IgE binding to sequential or conformational epitopes or likely irrelevant cross-reactive carbohydrate determinants (CCD) is variable, laboratory methods must be more stringent than those used in academic research, yet not as stringent as highly validated methods for commercial diagnostic assays. Examples of clinical history forms and ethical issues from a study of legume cross-reactivity (US, EU and India) will be presented. Direct IgE binding methods with native protein (dot-blot, ELISA, IgE immunoblots of native gel electrophoresis) and denatured/reduced protein (SDS-PAGE, reducing/non-reducing blots) and inhibition and verification to differentiate CCD binding and strong vs weak cross-reactivity will be presented with preliminary data evaluating IgE binding to 14 common food-legumes (peanut, chickpea, lupin, pigeon pea, soybean, lima bean, kidney bean, navy bean, blackgram, mung bean, cowpea, fava bean, lentil and pea) from five tribes of the family Fabaceae, which demonstrate that substantial cross-reactivity is rare. Methods for verification of protein identity and clinical relevance will be mentioned. Funding: US EPA STAR grant RD83313501 and the Food Allergy Research and Resource Program (FARRP, Univ. of Nebraska).

W 1942 ON THE HORIZON – EXPLORATORY RESEARCH INITIATIVE IN FOOD ALLERGY.

S. Laessig. *U.S. Environmental Protection Agency, Washington, DC.*

The U.S. Environmental Protection Agency (EPA), the National Institute of Allergy and Infectious Diseases (NIAID), the Food Allergy and Anaphylaxis Network (FAAN) and the Food Allergy Project (FAP) are partnering on an initiative to stimulate innovative research in food allergy and advance the current understanding of mechanisms of action, risk factors, and safety assessment of food allergy. The program objective is to spark new interest in food allergy research and approaches for safety assessment of potential dietary allergens including proteins introduced into food through genetic engineering. An additional major goal of the program is to encourage new investigators to move into the field of food allergy research. The initiative supports basic research on factors that contribute to the development of food allergies, the relationship between food allergies and other immune disorders, and the epidemiology and genetics of food allergy, as well as methods to predict the allergenicity of novel proteins in food. Under the initiative, EPA recently funded four projects that will develop computational models, in vitro tests, and transgenic mice to improve understanding of the initiation and susceptibility of people to dietary allergens, the importance of protein cross-reactivity, the involvement of cytokines, and the role of cell signaling. Eleven projects funded by NIAID, FAAN, and FAP are addressing key questions aimed at improving treatment, preventing food allergies, defining the genetics of human food allergy, and understanding the interactions between genes and the environment in food allergy pathogenesis. Epidemiological studies on the prenatal and maternal factors involved in oral tolerance and sensitization will help delineate sensitive populations and the probability for development of food allergy. An improved understanding of the basic immunology of food sensitization should illuminate the most important factors to consider for ensuring the safety of new bioengineered proteins or new exposures to proteins in food. This abstract does not reflect EPA policy.

W 1943 THE IMPACT OF TRANSCRIPT PROFILING IN DRUG SAFETY ASSESSMENT.

S. Pettit[1] and C. Afshari[2]. [1]*Health and Environmental Science Institute, Washington, DC and* [2]*Amgen, Inc., Thousand Oaks, CA.*

Transcript profiling technology has been around for a decade and is arguably the most developed systems biology approach that has been applied to drug safety assessment. Although there are examples where transcriptomics has been applied to

safety assessment of drug candidates, much of the data remains unpublished and reports are anecdotal. In part, the lack of publication leads to the impression that transcriptomics has had little impact. Specific examples where transcriptomics are being applied to preclinical drug safety assessment will be higlighted as will the areas of success in addition to areas where transcriptomics has had less impact. The emphasis will be on case studies outlining applications that are being integrated into safety assessment and where the technology is being reduced to practice. The impact of the technology among scientists in industry and the regulatory community will be illustrated by sharing both positive and negative experiences. Industry scientists will present case studies that illustrate the use of transcriptomics to understand issues or risks that emerge in preclinical development. Finally, the opportunities and challenges for applying transcriptomics to drug safety assessment will be summarized.

W 1944 IMPACT OF ILSI-HESI IN RESOLVING ISSUES IN DRUG SAFETY ASSESSMENT USING TRANSCRIPT PROFILING – CASE REVIEW.

C. Afshari. *Amgen, Thousand Oaks, CA.*

The rapid development and evolution of genomic, proteomic, and metabonomic based technologies has led to the development of the field of "toxicogenomics." Application of these technologies is directed toward improving the efficiency of safety and risk assessments. This is being accomplished by facilitating better understanding of the mechanisms by which compound induced injury occurs coupled with the potential for identification of early, sensitive biomarkers of toxicity. The scientific community, academic, industry and regulatory groups have all put forth efforts targeted at evaluating the development and use of genomics technologies in toxicology. Recently, a collated review of this effort was reviewed in a case-study workshop coordinated by the International Life Sciences Institute (ILSI). Members of the ILSI consortium include a large representation of pharmaceutical companies, as well as membership from academic and government institutions including the FDA. A number of industry-related case studies around predictive toxicology and issue resolution were reviewed in the context of scientific and regulatory impact/perspective. This presentation will review the efforts of ILSI-HESI in coordinating a global, cross-industry/regulatory effort to establish genomics in safety related applications and will present highlights from the recent "state of the science survey" and workshop that ILSI hosted.

W 1945 CASE STUDY: APPLYING TRANSCRIPTOMICS *IN VITRO* AND *IN VIVO* .

J. Stevens. *Toxicology, Lilly Research Laboratory, A Division of Ely Lilly and Co., Indianapolis, IN.*

Application of transcript profiling in the earliest stages of drug discovery creates opportunity to advance molecules with acceptable preclinical safety profiles into development. Using a contextual genomics database, DrugMatrix™, and a battery of gene signatures derived from both a training set and from internal compounds, we have integrated transcript profiling into a cell-based surrogate screening strategy for liver injury. Primary cultures of rat hepatocytes (RPH) were used to characterize the cytolethality of individual compounds. Transcript profiles were also collected from RPH treated with the test compounds. The combination of cytolethality data and gene signatures scores were used to predict the potential to cause liver injury in vivo in short term (4 day) rodent repeat dose studies. An initial set of performance metrics suggested that both the RPH cytolethality and the gene signature scores predicted in vivo outcomes with acceptable accuracy, sensitivity and specificity. Using this strategy, compounds synthesized in the Hit to Lead and early Lead Optimization phases were screened for hepatotoxic potential. Selected examples from project teams illustrate that early safety assessment based on in vitro cytolethality and gene expression results allows selection of Lead compounds with an improved safety profile.

W 1946 PREDICTING DRUG SAFETY USING TRANSCRIPTOMICS AND SYSTEM BIOLOGY APPROACHES.

L. Lehman-McKeeman. *Bristol-Myers Squibb, Princeton, NJ.*

Retrospective analysis of transcriptomic data collected over approximately the last 5 years has confirmed its utility as a predictive and diagnostic tool for drug discovery and development toxicology. Furthermore, there is an increasing body of literature summarizing transcriptional changes following drug or chemical insult, and databases of transcriptional profiles that can be queried as a potential tool for predicting toxic potential have been developed. In general, these efforts have focused on the liver where gene expression profiles have been used to define chemical- or target-specific changes that enable categorization and classification of potential toxicity. To date, transcriptional profiling of rodent liver or cultured hepatocytes has shown direct application to predicting toxicity, such as the identification of a battery of genes that can predict phospholipidosis or the likelihood of non-genotoxic hepatocarcinogenesis. A major strength of transcriptional profiling studies is the ability to probe the entire genome in a single experiment, and this attribute has enabled the development of cogent hypotheses for mechanisms of toxicity and directed experimental strategies and approaches in situations that might otherwise be intractable. Additional efforts to assess transcriptional profiles in other target organs such as testes have demonstrated that these data can differentiate mechanisms of toxicity in a tissue of mixed cell types. Furthermore, transcriptional profiling data readily distinguish slow and fast twitch skeletal muscle and provide the foundation for exploring mechanisms of drug-induced myopathy. Data quality and utility are influenced by fundamental elements of experimental design including dose selection, time of analysis, anchoring to histopathologic changes and integration of effects in other tissues, and these parameters must be carefully considered when executing and evaluating transcriptional profiling studies. Building on experiences with transcriptional data that address mechanism or predict toxicity will continue to enhance the application of these data to risk assessment.

W 1947 EVALUATING SAFETY ISSUES IN EARLY DRUG DEVELOPMENT WITH TRANSCRIPTOMICS.

E. Waring. *Cellular, Molecular and Exploratory Toxicology, Abbott Laboratories, Abbott Park, IL.* Sponsor: S. Pettit.

In the pharmaceutical industry, toxicity represents a major cause of failure at the costly stages of development, and reducing late-stage attrition due to toxicity can decrease overall research and development costs. The use of transcriptomics in toxicology, also known as toxicogenomics, represents one of the few recent technological advances that has improved the detection and mechanistic characterization of toxic changes in preclinical species. Published reports and our internal data have provided strong evidence that toxicogenomics is a viable and useful methodology to evaluate compounds in discovery and to develop a mechanistic understanding of toxic events at later stages in development. In the industry, toxicology has traditionally been an observational discipline that uses a limited number of endpoints with mechanistic value. In contrast, global evaluation of transcriptomic changes constitutes a rapid approach to detect abnormalities in subcellular compartments or deregulation of biological pathways. Accurate analysis and understanding of these complex data sets is largely facilitated by the use of pathway analysis software packages and by the access to repositories of reference gene expression profiles. This higher level of clarity represents a robust and efficient approach for toxicologists to rapidly formulate data-driven hypotheses regarding the mechanisms of toxic changes. These hypotheses typically need to be confirmed or refuted in follow-up functional experiments using appropriate complementary technologies. In our organization, toxicogenomics is an integrated part of the battery of toxicological endpoints used to profile or evaluate compounds in discovery and preclinical development. This presentation will provide an overview of the use of toxicogenomics at Abbott with a particular emphasis on its application to address toxicology issues in early development. Specific examples will be used to illustrate how this technology can be used to develop an understanding of the mechanisms underlying toxic changes in various tissues, such as liver, kidney, heart or testis.

W 1948 SUMMARY: OPPORTUNITIES AND CHALLENGES IN APPLYING TRANSCRIPTOMICS TO DRUG SAFETY ASSESSMENT.

F. D. Sistare. *Merck and Co., Inc., West Point, PA.*

Scientists in the pharmaceutical industry have ready access to samples from animal toxicology studies carefully designed to test the safety characteristics of a steady pipeline of agents advancing toward clinical testing. Advancing applications of toxicogenomics to the evaluation of compounds in active development could best be realized if this promising technology could be implemented in these studies fully anchored in the traditional study endpoints currently used to characterize phenotypic outcome and to support the safe conduct of clinical testing. Regulatory authorities worldwide have declared their support for toxicogenomics and related technological tools to positively impact drug development and guidance has been published. However, applications of exploratory "-omics" technologies to compounds undergoing safety testing remain inhibited. Two core data submission responsibility implications and ambiguities are contributing: 1) constraints arising from continual literature surveillance and data reanalysis burdens, under the shadow of looming subsequent reporting requirements to regulatory authorities as gene expression endpoints loosely linked to safety gain attention in the published literature, and 2) ambiguities in interpretation of validation stature remain between

exploratory, probable valid, and known valid safety biomarkers. Regulatory authorities have been engaged and a proposal has been offered with promising feedback to address these regulatory implementation barriers and open up access for exploring this technology in prospective drug development animal toxicology studies.

W 1949 THE ROAD TO PERSONALIZED MEDICINE.

D. Mendrick[1] and V. S. Vaidya[2]. [1]*Division of Systems Toxicology, NCTR/FDA, Jefferson, AR and* [2]*Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.*

To improve the safety of marketed drugs and chemicals, new biomarkers are needed to identify unsafe compounds earlier, discover patients who are at risk of adverse events to specific drugs and chemicals prior to exposure, and provide tools for the management of patients that are or will undergo adverse events. Single nucleotide polymorphisms (SNPs) and gene expression alterations provide clues into a person's response to xenobiotics thus enabling personalized medicine. Our panel of experts will highlight new approaches being used in preclinical species to understand individuals' responses and improve preclinical detection of idiosyncratic drugs, the use of translational biomarkers to enable better correlation between animals and humans, and the status of monitoring SNPs in the clinic to avoid adverse events.

W 1950 MODELING CHEMICAL TOXICITY IN THE POPULATION: MOUSE TO THE RESCUE!

I. Rusyn. *Department of Environmental Sciences and Engineering, UNC, Chapel Hill, NC.*

Rodent models have been used extensively to assess safety and investigate the mechanisms of toxicity of drugs and chemicals yet seldom do we think about a choice of a particular strain for our experiments. Significant recent breakthroughs in understanding the extent of the genetic diversity in the humans and mice show that mouse may be used to determine what genetic variants correlate with susceptibility or resistance to toxicity and disease, thus potentially helping to identify susceptible sub-populations. By using a panel of mouse inbred strains it is possible to model genetic diversity in a population which will likely provide a rationale for "individualized" assessment of risk and understanding of the variability in dose-response and mechanism. Specifically, we propose and validate a strategy using a Mouse Model of the Human Population (MMHP) to identify key mechanisms contributing to xenobiotic-induced liver injury. Whole-genome haplotype association analysis in the MMHP allows for a discovery of the candidate "susceptibility" genes which then may be validated in humans.

W 1951 TOWARDS IMPROVEMENTS IN TOXICOGENOMICS FOR UNDERSTANDING HEPATOTOXICITY.

W. Tong. *Center for Toxicoinformatics, NCTR/FDA, Jefferson, AR.* Sponsor: D. Mendrick.

Hepatotoxicity is a major reason for clinical failures and drugs being withdrawn from the market. The FDA's Voluntary Genomics Data Submission (VGDS) program has observed considerable efforts made by sponsors in exploring biomarker identification technologies to detect drug-induced liver toxicity. This presentation will discuss two FDA projects and VGDS experience on improvements of experimental design in toxicogenomics for hepatotoxicity. The FDA's Liver Toxicity Knowledge Base (LTKB) is a liver specific knowledge base which provides a resource to discover the relationship between liver toxicity, pathways/network, genes/proteins and drugs based on literature information and other public resources as well as in-house experimental data. The Liver Toxicity Biomarker Study (LTBS) is a collaborative project between the FDA and BG Medicine that is utilizing transcriptomic, proteomic, and metabolomic platforms to investigate markers of idiosyncratic hepatotoxicity. These projects and the VGDS program form the scientific basis to fill the gap in FDA regulation for hepatotoxicity.

W 1952 THE TRANSITION FROM PRE-CLINICAL TO CLINICAL SAFETY RELATED GENOMICS.

F. Frueh. *R&D, Medco Health Solutions, Inc., Darnestown, MD.* Sponsor: D. Mendrick.

Preclinical safety biomarkers have traditionally been "qualified" over a period of many years and the accumulation of such data occurred in an uncoordinated, ill-defined manner. Hence, many of the traditional markers we are using today do not have a clearly demonstrated sensitivity or specificity and lack a true definition of context for their usefulness of safety assessment. There is a need for better, well-characterized markers enabled through the availability of novel technologies and we have the opportunity to develop more sensitive and specific markers for preclinical safety evaluation studies, and to translate these markers into clinical settings. It is therefore reasonable to anticipate that these markers might be true bridging markers that will enable drug developers to move compounds into phase 1 studies in situations where the program may have been stopped otherwise. If indeed these new markers deliver on their promise, we will be able to use such a "measurable risk" approach as long as the toxicity is reversible and justified. Theoretical approaches of qualifying such new biomarkers will yield important clues as to the appropriate methodologies.

W 1953 TRANSLATIONAL BIOMARKERS FOR KIDNEY TOXICITY.

V. S. Vaidya. *Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.*

The public health impact of kidney disease is significantly high with about 20 million Americans having chronic kidney disease with a gross mortality rate for patients on dialysis being ~ 50-70 %. Drug-induced nephrotoxicity plays a major role in the high incidence and prevalence of kidney injury which may be prevented or at least minimized by effective predictive toxicity screening in preclinical drug development studies. The absence of sensitive, specific, reliable and reproducible renal injury biomarkers affects the evaluation of response to therapy and individual patient safety, especially dose monitoring decisions for important life saving drugs with potential inherent kidney toxicity risk. For the last 100 years there have been no accepted kidney injury biomarkers. The standard metrics such as serum creatinine and blood urea nitrogen are very insensitive and non-specific functional biomarkers. The urine has yielded the most promising markers for the early detection of acute kidney injury (AKI) and further characterization may qualify these markers as useful tools for earlier diagnosis, identification of mechanism of injury, and assessment of site and severity of injury. Hopefully, these biomarkers will facilitate early diagnosis, guide targeted intervention and monitoring of disease progression and resolution. Translational biomarkers have the potential to not only transform the way we do predictive nephrotoxicity

W 1954 PREDICTING TOXICITY IN PEOPLE.

M. de Mars. *Clinical Biomarkers, Critical Path Institute, Rockville, MD.* Sponsor: D. Mendrick.

The goal of personalized medicine is to deliver the right drug to the right person and at the right dose. Biomarkers may emerge as clinical tests to predict a patient's response to treatment. Among the best studied cases is warfarin. Warfarin is the most extensively utilized oral anticoagulant yet has a narrow therapeutic range with pronounced interindividual variation in response. Variants in gene underlying metabolism (CYP2C9) and the target of the therapy (VKORC1) have been shown to contribute to the unpredictability in dosing. However, it is not yet known if genetic tests could lessen the high number of potentially fatal adverse events such as hemorrhage, embolism and stroke. Several smaller scale clinical trials have been conducted to address this question, but the endpoints have differed and conclusions are mixed. C-Path is working with NHLBI on a definitive clinical trial to determine if there is clinical benefit to routine genotyping in determining warfarin dose. A 1,965 participant multicenter, double-blind, randomized, trial is in development comparing two possible approaches to guiding warfarin therapy initiation: 1) initiation of warfarin therapy based on an algorithm using clinical information and the individual's genotype relative to two genes known to influence warfarin metabolism (CYP2C9 and VKORC1 genes); 2) initiation of warfarin therapy based on an algorithm using only clinical information. Results from this trial are expected to elucidate the utility of genotyping in guiding dosing of warfarin to reduce adverse events and improve clinical outcome.

PL 1955 PHYSIOLOGICAL AND TOXICOLOGICAL TRANSCRIPTOME CHANGES IN HEPG2 CELLS EXPOSED TO COPPER.

M. Song[1], J. Li[2] and J. H. Freedman[1]. [1]*LMT, NIEHS, Research Triangle Park, NC and* [2]*Biostatistics Branch, NIEHS, Research Triangle park, NC.*

Copper is an essential trace element, however, at supraphysiological levels it can be extremely toxic. Principal components, K-means and hierarchical clustering, interactome, and pathway mapping analyses of transcriptomes of HepG2 cells exposed

to 100, 200, 400 and 600 μM copper for 4, 8, 12 and 24 h suggest that these exposure conditions induce physiological and toxicological changes. As a general trend, as the level of toxicity increases, the number and diversity of affected genes, Gene Ontology categories, regulatory pathways, and complexity of interactomes increases. Physiological responses to copper include transition metal ion binding and response to stress/stimulus; while toxicological responses include apoptosis, morphogenesis and negative regulation of biomolecule metabolism. Pathway mapping analysis indicates that copper modulates signal transduction pathways associated with MAPK, NF-κB, death receptor, IGF-1, hypoxia, IL-10, IL-2, IL-6, EGF, Toll-like receptor, protein ubiquitination, xenobiotic metabolism, leukocyte extravasation, complement and coagulation, and Sonic Hedgehog signaling. Interactome analysis using Cytoscape suggested that HNF4α (hepatocyte nuclear factor 4 α) may be a major regulator of copper-responsive transcription. We investigated the expression changes of HNF4α after exposure to copper. Our data showed that copper exposure downregulated HNF4α expression at both the mRNA and protein levels. In addition, qRT-PCR and RNAi results demonstrated that the changes in HNF4α expression, in turn, modulated expressions of its target genes (UCHL1, TXNRD1, JUNB, LIPA, APOM and APOC1). We examined the changes in HNF4α expression after p53 knock down, which clearly showed the increase in the mRNA level of HNF4α. This data suggested that p53 may have a role in copper-induced downregulation of HNF4α expression. These results may provide insights into the global and molecular mechanisms regulating the response to copper exposure.

PL 1956 CHEMICAL GENOMICS OF CANCER CHEMOPREVENTIVE DITHIOLETHIONES.

Q. T. Tran[1, 2, 6], L. Xu[2, 6], V. Phan[3, 6], S. Goodwin[1, 6], M. Rahman[1, 6], C. H. Sutter[1, 6], B. Roebuck[4], T. K. Kensler[5], E. George[2, 3, 6] and T. R. Sutter[1, 6]. *[1]Biology, The University of Memphis, Memphis, TN, [2]Mathematical Sciences, The University of Memphis, Memphis, TN, [3]Computer Science, The University of Memphis, Memphis, TN, [4]Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH, [5]Environmental Health Sciences, Johns Hopkins University Bloombrg School of Public Health, Hanover, MD and [6]W. Harry Feinstone Center for Genomic Research, The University of Memphis, Memphis, TN.*

3H-1,2-Dithiole-3-thione (D3T) and its analogs 4-methyl-5-pyrazinyl-3H-1,2-dithiole-3-thione (OLT, oltipraz) and 5-tert-butyl-3H-1,2-dithiole-3-thione (TBD) are chemopreventive agents that block or diminish early stages of carcinogenesis by inducing activities of conjugating and other detoxication enzymes. While OLT has been used in clinical trials, TBD has been shown to be more efficacious and possibly less toxic than OLT in animals. Here we describe and validate a novel, robust, and high-resolution chemical genomics procedure by examining the pharmacological structure-activity relationships of these compounds in livers of male Fischer F344 rats by microarray analyses. We identified 226 differentially expressed genes that were common to all treatments. Functional analysis identified the relation of these genes to glutathione metabolism and the Nrf2 pathway that is known to regulate many of the protective actions of dithiolethiones. OLT and TBD were shown to have similar efficacies and both were weaker than D3T. In addition, we identified 40 genes whose responses were common to OLT and TBD, yet distinct from D3T. As inhibition of cytochrome P450 has been associated with the effects of OLT on cytochrome P450 expression, we determined the IC50 values for inhibition of cytochrome P450 1A2. The rank order of inhibitor potency was OLT >> TBD >> D3T, with IC50 values estimated as 0.2, 12.8 and >100 μM, respectively. Functional analysis revealed that OLT and TBD, in addition to their effects on cytochromes P450, modulate liver lipid metabolism, especially fatty acids. Together these findings provide new insight into the actions of clinically relevant and lead dithiolethione analogs.

PL 1957 INCORPORATION OF BIOCHEMICAL INTERACTION NETWORK INFORMATION HELPS IN IDENTIFICATION OF BIOLOGICALLY-RELEVANT PATHWAYS AND IMPROVES THE TOXICITY CLASSIFICATION OF CHEMICALS.

R. Thomas, J. Gohlke, F. Parham and C. Portier. *Environmental Systems Biology, National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

With the increasing availability of molecular data collected from living systems under conditions of insult, it is imperative to focus on a smaller domain of the organism in order to understand the mechanisms by which these insults affect the organisms. Biochemical pathways are an obvious target for studying molecular data. We propose a method for finding enriched pathways relevant to a studied condition that, in addition to using the measured molecular data, would use the structural information of the pathway viewed as a network of nodes and edges. Our results demonstrate a clear improvement in the identification of biologically-relevant pathways. In the context of chemical toxicity classification, we extend the above ideas (which applied to individual pathways) to the network of pathways in the organism. Two pathways are connected to one another in the pathway network if a signal from one of the pathways initiates activity in the other pathway. Genomic data is measured at snapshots in time. We consider a pair of chemicals to have a similar toxicity profile if the pathways that they affect are mostly the same. We can take this idea a step further by assuming that chemicals have similar toxicity effects if the pathways that one of them effect are known to initiate the observed affected pathways in the others. This motivates the underlying the measure of closeness between a pair of chemicals as a distance their networks of enriched pathways (derived from their genomic data). We demonstrate the utility of these ideas in carcinogenicity classification and prediction using two sets of known liver carcinogens and non-carcinogens.

PL 1958 DEVELOPMENT OF A GENE SIGNATURE FOR NON-GENOTOXIC CARCINOGENICITY.

N. Raghavan, D. Amaratunga, A. Nie and M. McMillian. *Johnson & Johnson, Raritan, NJ.*

Genomic drug safety screens will accelerate the process for developing safer drugs and limit the failure of drugs in late stage development due to toxicity issues, by identifying potential toxicity issues early in the development process. As a result, there is now heightened interest in developing biomarkers for predictive toxicology and risk assessment using toxicogenomic technologies within pharmaceutical companies as well as from governmental agencies worldwide. A widely-recognized challenge in using high-throughput technologies, such as microarrays, has been the problem of over-fitting the data, and consequently, the irreproducibility of results. In this talk, we present a novel and carefully crafted methodology for developing a toxicogenomic signature for non-genotoxic carcinogenicity using gene expression data from 24 hour microarray experiments on rats. This is of particular interest since short-term assays for non-genotoxic carcinogenicity, which is commonly observed in long-term rodent studies, have proven difficult to develop. A performance assessment demonstrates that the gene signature has superior predictive performance to classic algorithms. In addition, it is also compact and interpretable. We also discuss the need for validating and standardizing gene signatures, to make them portable to other platforms and technologies.

PL 1959 COMPUTATIONAL MOLECULAR MODELING METHODS APPLIED TO TOXICITY SCREENING.

J. R. Rabinowitz[1], S. B. Little[1] and M. Goldsmith[2]. *[1]NCCT, U.S. EPA, Res TP, NC and [2]NERL, U.S. EPA, Res TP, NC.*

The risk to human health and the environment of chemicals that result from human activity often must be evaluated when relevant elements of the preferred data set are unavailable. Therefore, strategies are needed that estimate this information and prioritize the outstanding data requirements. The rate determining step of many relevant mechanisms of action requires the chemical or one of its biotransformation products (the toxicant) to interact with a specific biological macromolecule (the target). A library of potential protein targets for chemical toxicity has been developed from the Protein Data Bank (www.rcsb.org/pdb). Molecular modeling methods have been used to determine the interaction between these targets and two small libraries of environmental chemicals, the Laws 281 and the Toxcast 320 (www.epa.gov/ncct/dsstox). The Laws 281 contains small organic chemicals. Each chemical has been tested under the same experimental conditions for competitive binding to rat estrogen receptors. Only 15 of these chemicals bind to the estrogen receptors, 3 – 5 orders of magnitude more weakly than estrogen. Computational docking methods that would be applicable to larger chemical data bases interacting with larger numbers of targets were employed to investigate the same library of chemicals interacting with the agonist and antagonist modes of both the alpha and beta rat estrogen receptor. These methods consider the potential ligands as flexible but not the target. All active chemicals were in the top 26% of those screened. Our analysis of these results considers the importance of decreasing the false positive rate while eliminating false negatives. When a pharmacophore filter based on two hydrogen bonds was employed to restrict the space explored, a significant decrease in the false positive rate was observed. All actives are found in the top 11% of the chemicals. This approach is applicable to many of the proteins in our library of potential targets. [This work was reviewed by EPA and approved for publication but does not necessarily reflect official Agency policy.]

PL 1960 AN INTEGRATED IN VITRO AND COMPUTATIONAL APPROACH TO DEFINE THE EXPOSURE–DOSE–TOXICITY RELATIONSHIPS IN HIGH–THROUGHPUT SCREENS.

H. J. Clewell[1], F. Boellmann[1], C. Smith[2], L. Tsai[1], D. M. Rotroff[3], D. J. Dix[3], M. E. Andersen[1], S. S. Ferguson[2], E. L. LeCluyse[2] and R. S. Thomas[1]. *[1]The Hamner Institutes for Health Sciences, Research Triangle Park, NC, [2]CellzDirect, Invitrogen Corporation, Research Triangle Park, NC and [3]U.S. Environmental Protection Agency, Research Triangle Park, NC.*

Research efforts by the US Environmental Protection Agency have set out to develop alternative testing programs to prioritize limited testing resources toward chemicals that likely represent the greatest hazard to human health and the environment. Efforts such as EPA's ToxCast research program use high–throughput screening to evaluate large numbers of chemicals across a variety of *in vitro* assays. One challenge has been to provide a human exposure–dose context to the concentration values obtained in the *in vitro* assays. Organ slice cultures were established for rat liver, lung, and kidney. Cultures were exposed to 140 chemicals, a subset of the ToxCast 320, in a 5–point dose response (0.8 – 100 μM). Cytotoxicity was measured as the endpoint. Only 48 chemicals had measureable LC_{50} in at least one tissue, with kidney as the most sensitive organ (38 chemicals), followed by lung (10 chemicals), and liver (8 chemicals). For the 48 cytotoxic chemicals, intrinsic clearance was measured using primary human hepatocytes and protein binding was measured in human plasma. Using these two pharmacokinetic parameters, equivalent oral exposures were estimated using SimCyp® software that would result in steady state tissue concentrations comparable to the LC_{50} values. This integrated approach promises to provide refined exposure–dose–toxicity evaluations that will aid in interpretation of high-throughput screening results. Such context will be essential for identifying appropriate priorities for follow–up testing and risk evaluation exercises. *Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.*

PL 1961 MODULATION OF XENOBIOTIC METABOLIZING ENZYME AND TRANSPORTER GENE EXPRESSION IN PRIMARY CULTURES OF HUMAN HEPATOCYTES BY TOXCAST CHEMICALS.

D. Rotroff[1], A. Beam[2], K. Freeman[2], S. Ferguson[2], E. LeCluyse[2], K. Houck[1], R. Judson[1], R. Kavlock[1], M. Martin[1] and D. J. Dix[1]. *[1]National Center for Computational Toxicology, U.S. Environmental Protection Agency, Research Triangle Park, NC and [2]CellzDirect Inc. | Invitrogen Corp., Durham, NC.*

ToxCast chemicals were assessed for induction or suppression of xenobiotic metabolizing enzyme and transporter gene expression using primary human hepatocytes. The mRNA levels of 14 target and 2 control genes were measured: ABCB1, ABCB11, ABCG2, SLCO1B1, CYP1A1, CYP1A2, CYP2B6, CYP2C9, CYP2C19, CYP3A4, UGT1A1, GSTA2, SULT2A1, HMGCS2, and control genes ACTB, GAPDH. These genes represent 5 nuclear receptor signaling pathways: AHR, CAR, PXR, PPARa and FXR. Gene expression was quantitatively measured by nuclease protection assays at 5 concentrations, 3 time points (6, 24, 48 hr), in 4 replicate wells. Hepatocytes from 2 male donors were isolated and cultured with 6 reference chemicals and 320 ToxCast phase I chemicals. CYP1A1/2 enzymatic activity and cell morphology were assessed in each well. Concentration-response curves were generated for 13,813 chemical, time and gene combinations. EC50 (effective concentration 50%) and Emax (effective maximum) values for gene expression determined modulation of nuclear receptor pathways by ToxCast chemical exposures. Chemical potency and efficacy were determined relative to reference chemicals, and correlated with chronic hepatotoxicity endpoints from EPA's ToxRefDB database. A preliminary analysis of the 5 nuclear receptor pathways at 48 hr was conducted based on expression of a representative gene for each pathway. Of the 320 ToxCast chemicals, 3 chemicals perturbed AhR (CYP1A1/2), 35 chemicals perturbed CAR (CYP2B6), 22 chemicals perturbed PXR (CYP3A4), 15 chemicals perturbed PPARa (HMGCS2), and 28 chemicals perturbed FXR (ABCB11) at ≥40% efficacy and <40 μM EC50. Many chemicals resulted in statistically significant responses at <40% efficacy. *Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.*

PL 1962 PATHWAY-BASED CONCENTRATION RESPONSE PROFILES FROM TOXICOGENOMICS DATA.

F. Elloumi[1], R. Judson[1], D. Dix[1], I. Shah[1], T. Knudsen[1], D. Reif[1], A. Singh[2], Z. Li[3] and F. Wright[3]. *[1]NCCT, U.S. EPA, Research Triangle Park, NC, [2]Lockheed Martin, Research Triangle Park, NC and [3]Biostatistics, University of North Carolina, Chapel Hill, NC.*

Microarray analysis of gene expression of in vitro systems could be a powerful tool for assessing chemical hazard. Differentially expressed genes specific to cells, chemicals, and concentrations can be organized into molecular pathways that inform mode of action. An important parameter in this hazard assessment is the lowest observed concentration (LOC) at which a particular pathway is perturbed. We present a method to derive LOC using microarray-based pathway analysis, and assess the reproducibility of results across biological replicates. Concentration response of pathways was modeled by clustering genes across concentrations, and then calculating enrichment across pathways. Because clustering continuous gene expression data can make comparisons between replicates difficult, we discretized fold-change to one of 3 values: 0 (no change), + (increase), or - (decrease). Genes with the same ordered sequence or "signature" of discretized values across concentrations were grouped together for pathway enrichment analysis. We applied this approach to data from a concentration-response study of rat primary hepatocytes treated with Phenobarbital, RU-486, or WY-14643, which are inducers of xenobiotic metabolism pathways via nuclear receptors. Cells were exposed to 4 different concentrations of each chemical, with 5 biological replicates per concentration-chemical combination. Although a total of 3^(N-concentrations) unique signatures was possible, the observed number of pathways and concentration-response signatures observed with high reproducibility was much lower. Affected pathways included expected results on xenobiotic metabolism, and the signatures gave a direct reading of the LOC at which gene expression in these pathways was significantly perturbed. Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.

PL 1963 MODELING BIOTRANSFORMATION USING *IN VITRO* DATA ON PARENT-METABOLITE PAIRS WITHIN THE TOXCAST PHASE I CHEMICAL SET.

K. Houck, M. T. Martin, D. J. Dix, R. Judson and R. Kavlock. *ORD/NCCT, U.S. EPA, RTP, NC.*

A major focus in toxicology research is the development of in vitro methods to predict in vivo chemical toxicity. Within the EPA ToxCast program, a broad range of in vitro biochemical and cellular assays have been deployed to profile the biological activity of 320 ToxCast Phase I chemicals. Only a limited number of these assays have metabolic capacity, and it is not feasible to test all potential metabolites in the over 600 assays of ToxCast. In order to assess the magnitude of this issue and explore practical solutions, the ToxCast Phase I chemicals include 12 parent-metabolite pairs that allow comparisons of in vitro assay results between the parents and metabolites. Clear differences in cytotoxicity across several cell lines were observed when comparing these parent-metabolite ToxCast results. Some parent chemicals tested in cell-based systems with metabolic capacity, demonstrated differential cytotoxicity dependent upon assay metabolic conditions. However, comparable responses were not seen when these same parent and metabolite cytotoxicities were evaluated independently, indicating the limitations of these cell-based assays. Biochemical assay results also yielded distinct activities for certain metabolites, relative to the complementary parent chemical, emphasizing the need for development of biochemical assays with biotransformation capacity or to account for biotransformation through other approaches. A practical solution may include metabolic simulation or prediction, along with targeted testing of metabolites. Results from the wide range of assays in ToxCast, with and without metabolic capacity, are being incorporated into the data mining and interpretive process. The bioactivity profiles of parent-metabolite pairs allowed us to identify assays with the potential to recognize chemical-specific biostransformation. This will be evaluated further by the selection of assays, and parent and metabolite chemicals for Phase II of ToxCast. Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.

PL 1964 CLEAR EVIDENCE OF AHR RECEPTOR MEDIATED THRESHOLDS FOR CYP 1A1 AND 1A2 INDUCTION BY TCDD, TCDF AND 4-PECDF IN RAT AND HUMAN.

R. Budinsky[1], P. Feder[2], Z. Ma[3], J. Teeguarden[4] and C. Rowlands[5]. *[1]The Dow Chemical Co., Midland, MI, [2]Battelle, Columbus, OH, [3]Battelle, Richland, WA, [4]Battelle, Richland, WA and [5]The Dow Chemical Company, Midland, MI.*

CYP1A1 and 1A2 induction are hallmark biomarkers of the aryl hydrocarbon receptor (AHR) activation by a host of ligands with 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) being the most well-known and studied. The existence of response thresholds and rodent/human differences for TCDD mediated effects are key questions for TCDD risk assessment, yet systematic studies exploring these questions in rat and human hepatocytes, a key target tissue for effects, are limited. CYP1A1 & 1A2 induction (mRNA and protein) was measured in vitro in rat and human primary hepatocytes exposed to 0.00001-100 nM TCDD, 2,3,4,7,8-Pentachlorodibenzofuran (4-PeCDF) or 2,3,7,8-tetrachlorodibenzofuran (TCDF). The large dose range, doses (11) and replicates (N=5 donors) were selected to provide robust data set for statistical analysis and modeling. CYP 1A1 mRNA induction response thresholds for human hepatocytes identified by extrapolation from

the EC05 (Silkworth et al., 2005) were between 10 and 50 pM for TCDD; the corresponding values in the rat were ~one order of magnitude lower, demonstrating a significant reduced sensitivity in human relative to a common test species. A novel modification of the Silkworth approach that extrapolates from the first significant response dose identified by a step-down trend test was developed and also applied to the induction data. The threshold for TCDD induced CYP 1A1 expression in human hepatocytes was somewhat lower using this method (2-6 pM), as were the rat thresholds (0.06-2 pM). The lower potency TCDD analogs PcCDF and TCDF each showed thresholds much higher than TCDD, as expected. These data confirm the existence of response thresholds for early biochemical responses to TCDD and species differences in sensitivity to TCDD-like compounds.

PL 1965 ATTENUATION OF HYPEROXIC LUNG INJURY IN NEWBORN WILD TYPE AND CYTOCHROME P450 (CYP)1A2-NULL MICE EXPOSED PRENATALLY TO THE CYP1A INDUCER, BETA-NAPHTHOFLAVONE (BNF).

X. I. Couroucli, Y. W. Liang, W. Jiang, L. Wang and B. Moorthy. *Pediatrics, Baylor College of Medicine, Houston, TX.*

Supplemental oxygen administration is frequently administered to preterm and term infants having pulmonary insufficiency. However, prolonged hyperoxia contributes to the development of bronchopulmonary dysplasia (BPD) in human infants. In this study, we tested the hypothesis that pre-treatment of pregnant WT or Cyp1a2-null mice or newborn mice with BNF, followed by exposure to hyperoxia, would alleviate lung injury by mechanisms involving CYP1A-mediated detoxification of F2-isoprostanes. Pregnant WT or Cyp1a2-null mice were treated, i.p., with the vehicle corn oil (CO) or BNF (20 mg/kg) on gestational days 16, 17, and 18, and newborn mice delivered from these mothers (on gestational day 22) were exposed to hyperoxia (> than 95% O2) for up to 7 days. The WT or Cyp1a2-null newborn mice treated prenatally with CO showed increased lung injury, as determined by histology, at 4 and 7 days after hyperoxia, with Cyp1a2-null mice displaying increased susceptibility to lung injury compared to WT mice. Lung injury was significantly attenuated in WT as well as Cyp1a2-null mice that were treated prenatally with BNF. The BNF-treated mice showed increased expression of hepatic and pulmonary CYP1A1 and 1A2 protein (flourimetry/Western blotting) and mRNA (real time RT-PCR) expression, compared to those exposed to CO. These results suggest that in utero exposure to BNF induces CYP1A enzymes in the newborn mice, and that these mice are less susceptible to lung injury induced by oxygen. The extent of lung injury positively correlated with levels of F2-isoprostanes, as determined by GC/MS. Our observations support the hypothesis that BNF protects against hyperoxic lung injury by inducing CYP1A enzymes, which may act via detoxifying F2-isoprostanes. Future studies on the role of CYP1A enzymes in oxygen-mediated lung injury could lead to the development of rational strategies in the prevention/treatment of BPD in premature infants.

PL 1966 PERSISTENT INDUCTION OF CYP1A1 GENE EXPRESSION BY 3-METHYLCHOLANTHRENE (MC) IN HUMAN HEPATOMA CELLS IS MEDIATED BY SUSTAINED TRANSCRIPTIONAL ACTIVATION OF THE CYP1A1 PROMOTER.

F. S. Inayat, W. Jiang, L. Wang and B. Moorthy. *Pediatrics, Baylor College of Medicine, Houston, TX.*

3-Methylcholanthrene (MC) is one of the most potent polycyclic aromatic hydrocarbon carcinogens known to date. Metabolism of MC by cytochrome P450 1A (CYP1A) enzymes leads to the formation of chemically reactive intermediates that bind covalently to DNA, and initiate carcinogenesis. We reported previously that MC elicits a persistent induction of hepatic microsomal cytochrome P450 (CYP) 1A enzymes in rodents in vivo for several weeks after MC withdrawal. In this study, we tested the hypothesis that sustained induction of CYP1A1 gene expression by MC is mediated by persistent transcriptional activation of the CYP1A1 promoter in human hepatoma cells (HepG2). A plasmid containing the human CYP1A1 promoter (pGL3-1A1) and reporter (luciferase) gene was transiently transfected into HepG2 cells for 16 h, followed by MC (2.5 μM) or dimethylsulfoxide (DMSO) (solvent control) treatment, and luciferase expression was determined at 6, 12, 24, 48, 72 and 96 hours. MC elicited a 16-fold increase in luciferase activity at 24 hours time point in transfected cells compared to DMSO-treated controls. There was significant induction of luciferase expression even at the 96 hour time point. MC also caused sustained induction in the endogenous catalytic activity, apoprotein content and mRNA levels of CYP1A1 for up to 96 hours time point in treated cells. Electrophoretic mobility shift assays revealed that persistent CYP1A1 induction by MC may have, in part, involved Ah receptor-independent mechanisms. Pharmacokinetic experiments with radiolabeled [3H]MC revealed that the persistent induction of CYP1A1 in HepG2 cells was not due to persistence of the parent MC in the medium. In conclusion, our results support the hypothesis that persistent induction of CYP1A1 expression by MC is mediated by sustained transcriptional regulation of the CYP1A1 promoter. These observations have important implications for human carcinogenesis. (Supported by NIH grant ES 009132.)

PL 1967 CAR-NULL MICE ARE SENSITIVE TO PARATHION.

L. C. Mota and W. S. Baldwin. *Environmental Toxicology, Clemson University, Pendleton, SC.*

The Constitutive Androstane Receptor (CAR) is a key regulator of Phase I-III detoxification genes. Parathion is one of the two most potent environmentally relevant activators of CAR based on our transactivation assays. Animal studies were conducted to determine if CAR was activated by parathion in vivo. Male and female, wild-type and CAR-null mice were treated *i.p.* with 100μl of 10% DMSO/corn oil, 3mg/kg/day TCPOBOP, or parathion at either 5 or 20mg/kg/day for two consecutive days. CAR-null mice showed greater sensitivity to parathion compared to wild-type mice as determined by tear formation, lethargy, and perturbation in gross motor skills. Parathion did not induce Cyp2b expression as determined by Q-PCR or Western blots, indicating that it is not a CAR activator in vivo due to its short half-life. However, untreated CAR-null mice demonstrated lower expression of Cyp2b10 and Cyp2c29 than wild-type mice, indicating that CAR is important in the basal regulation of some CYPs. Previously published experiments indicate that Cyp2b10 preferentially forms the non-toxic metabolite p-nitrophenol instead of paraoxon (toxic metabolite). Parathion incubation of microsomes from untreated wild-type and CAR-null mice revealed differential metabolism between the genotypes. The paraoxon/p-nitrophenol ratio was higher in male CAR-null mice, indicating that parathion was preferentially metabolized to paraoxon, while the formation of p-nitrophenol was much greater in the wild-type mice. This is consistent with greater sensitivity in the CAR-null mice. We hypothesize that the drop in expression of Cyp2b10 in the CAR-null mice decreased the formation of p-nitrophenol. The formation of both paraoxon and p-nitrophenol was faster in female wild-type mice than female CAR-null mice, indicating that female wild-type mice show a slightly different strategy for protecting themselves from parathion. Because we are importing a greater percentage of our vegetable and fruit crops from Central and South America, places that still use parathion, we may be placing individuals that show repressed CAR expression, such as newborn children, at increased risk.

PL 1968 TETRAMETHOXYSTILBENE (TMS), AN INHIBITOR OF CYP1B1, DELAYS BENZO[*A*]PYRENE (BP) METABOLISM AND DOES NOT PREVENT BP-INDUCED DNA DAMAGE IN MCF-7 CELLS.

T. L. Einem, M. C. Poirier and R. L. Division . *CDI / LCBG, NCI, Bethesda, MD.*

Exposure to carcinogenic polycyclic aromatic hydrocarbons (PAHs) induces cytochrome P450 (CYP) 1A1 and 1B1, which biotransform PAHs, including BP, into metabolites that form DNA adducts. We hypothesized that TMS, an analogue of resveratrol and a potent CYP1B1 inhibitor, may modulate BP-DNA adduct levels. At 2-12 hr intervals during 96 hr of exposure, we measured BP-DNA adducts by chemiluminescence immunoassay (CIA), *CYP1A1* and *1B1* gene expression changes by relative real-time PCR, and CYP1A1/1B1 enzyme activity by ethoxyresorufin-O-deethylase (EROD) assay in MCF-7 breast cancer cells exposed to 1μM BP, with or without 1μM or 4μM TMS. Peak BP-DNA adduct levels for BP alone, BP + 1μM TMS, and BP + 4μM TMS were 1572, 1658, and 1718 adducts/10^8 nucleotides, respectively, and were observed at 16, 24, and 36 hr, respectively, showing that TMS slowed formation of BP-DNA adducts. Area under the curve ($AUC_{4\text{-}96hr}$) values for BP-DNA adducts were 76769, 94317, and 91948 adducts/10^8 nucleotides for BP alone, BP + 1μM TMS, and BP + 4μM TMS, respectively, with higher values ($p<0.05$) found in TMS-exposed groups. Fold-increase values for peak *CYP1A1* expression were 758, 1713, and 2995 for BP alone, BP + 1μM TMS, and BP + 4μM TMS, respectively, and were observed at 16, 24, and 36 hr, respectively. Similarly, fold-increase values for peak *CYP1B1* expression were 50, 69, and 83 for BP alone, BP + 1μM TMS, and BP + 4μM TMS, respectively, with peaks occurring at the same time points as maximum *CYP1A1* expression. Peak EROD activities for BP alone, BP + 1μM TMS, and BP + 4μM TMS were 2443, 3596, and 6987 fmoles/min/mg protein, respectively, and were at 24, 48, and 60 hr, respectively. Overall, addition of TMS to BP-exposed MCF-7 cells caused a delay in induction of BP-DNA adducts, *CYP1A1* and *CYP1B1* gene expression, and EROD activity. Furthermore, $AUC_{4\text{-}96hr}$ values were increased for all endpoints in groups exposed to TMS. Therefore, CYP1B1 inhibition by TMS may not reduce PAH genotoxicity *in vivo*, and TMS may not be a good chemopreventive agent.

PL 1969 CYTOCHROME P4501B1 PROVIDES A NEW LINK BETWEEN LEPTIN AND OBESITY.

M. L. Larsen[1], S. Wang[1], J. R. Bushkofsky[1], Y. Tang[2], N. Sheibani[2] and C. R. Jefcoate[1]. [1]*Pharmacology, University of Wisconsin, Madison, WI and* [2]*Ophthalmology and Visual Sciences, University of Wisconsin, Madison, WI.*

Obesity enhances Type 2 diabetes and numerous cancers. The expression of cytochrome P4501b1 (Cyp1b1), which is unique to mesenchymal cells, increases early in adipogenesis, prior to the adipogenic mediator, PPARgamma (1). Cyp1b1 deletion increases Wnt-derived intestinal adenomas (2), alters neural patterning (3), and disrupts eye development (4). Here, we report that Cyp1b1-/- C57BL/6j mice maintain basal adipose tissue levels when fed a high fat (60%) diet. MRI imaging (5) indicated uniform suppression of fat deposition. Dietary intake was unaffected in these mice, indicating enhanced fat metabolism. Improved glucose tolerance of Cyp1b1-/- mice suggested minimal oxidative damage (6). By contrast, fat deposition was not attenuated by Cyp1b1 depletion in obese leptin-deficient ob/ob C57BL/6j mice. Systemic leptin activity (7) may, therefore, be required for these Cyp1b1-mediated effects. Cultured Cyp1b1-/- pre-adipocytes differentiate normally, suggesting an extrinsic suppression mechanism in vivo. Notably, we found enhanced recruitment of adipose macrophages and associated inhibitory cytokines (8), and substantially altered pro-angiogenic function of microvascular endothelial cells, an essential component of fat development (9). Hepatic gene expression changes in Cyp1b1-/- mice suggested coordinately increased mitochondrial fatty acid oxidation (PPARgama and SCD1, suppressed; CPT1 and UCP2, stimulated) (10). Importantly, Cyp1b1 metabolizes estradiol, which is synthesized in pre-adipocytes (11), and which suppresses adipocyte maturation, in part by enhancing leptin activity (7). Cyp1b1 is potently inhibited by several common dietary flavonoids (12). Humans frequently exhibit amino acid substitutions of Cyp1b1, which sufficiently affect its activity and are considered disease risk factors (12).

PL 1970 3-METHYLINDOLE-MEDIATED CYTOCHROME P450 INDUCTION IN PRIMARY NORMAL HUMAN BRONCHIAL EPITHELIAL CELLS.

J. M. Weems and G. S. Yost. *Department of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

3-Methylindole (3MI) is a highly selective pneumotoxicant present in cigarette smoke. Several human cytochrome P450 (CYP450) enzymes, including 1A1 (CYP1A1), catalyze the dehydrogenation of 3MI to the reactive intermediate 3-methyleneindolenine (3MEIN). This metabolite has been shown to alkylate DNA and may induce apoptosis. In addition, 3MI has been observed to induce a dose dependent increase in DNA damage at low concentrations (ranging from 0.1 to 10 μM) in primary normal human bronchial epithelial (NHBE) cells. 3MI-induced DNA damage at the 10μM concentration was ameliorated following pre-treatment with the CYP450 suicide substrate inhibitor 1-Aminobenzotriazole (ABT), indicating that the observed DNA damage was CYP450 dependent. Recent literature has indicated that 3MI can induce CYP450 expression in hepatocytes. Quantitative real-time PCR analysis of 3MI-mediated CYP1A1 expression in primary NHBE cells revealed increased expression at both times (4 hour) and concentrations (0.1 to 10 μM) consistent with those observed to induce DNA damage. One of the most common pathways by which CYP1A1 becomes induced is via aryl hydrocarbon receptor (AhR) activation. Treatment with 3MI in combination with the AhR antagonist α-napthoflavone prevented 3MI-mediated CYP1A1 induction, indicating that the induction was AhR dependent. These results indicate that low concentrations of 3MI are bioactivated to intermediates that damage DNA by CYP450 enzymes and that 3MI exposure can induce the expression of these enzymes in an AhR dependent manner in normal human lung cells. Thus, 3MI at concentrations less than 10μM is a potential human lung carcinogen. Supported by NIH grant # HL13645 from The National Heart, Lung and Blood Institute.

PL 1971 A NEW VERTEBRATE CYTOCHROME P450 1 SUBFAMILY, CYP1D, AND CONSTITUTIVE EXPRESSION OF CYP1D1 IN ZEBRAFISH.

J. J. Stegeman[1], J. Goldstone[1], M. E. Jönsson[1], L. Behrendt[1], B. R. Woodin[1], M. J. Jenny[1] and D. R. Nelson[2]. [1]*Biology, Woods Hole Oceanographic Institution, Woods Hole, MA and* [2]*University of Tennessee, Memphis, TN.* Sponsor: M. Hahn.

Enzymes in the cytochrome P450 1A (*CYP1A*) subfamily oxidize polynuclear and halogenated aromatic hydrocarbons that are common environmental toxicants. We identified a new CYP1 subfamily in zebrafish, with a single gene (*CYP1D1*) that shares 45% amino acid identity with zebrafish *CYP1A*. The gene structure of *CYP1D1* is strikingly similar to that of *CYP1A*, and molecular phylogenetic analysis indicates that *CYP1D1* is paralogous to *CYP1A*. In adult zebrafish, *CYP1D1* transcript is most highly expressed in liver and appears to have a higher expression than *CYP1A* in brain. During development, *CYP1D1* transcript levels are 2-3-fold higher in 8 to 10-hour post-fertilization embryos than in later embryos or juveniles. In contrast to *CYP1A*, treatment with the potent aryl hydrocarbon receptor (AHR) agonists 3,3',4,4',5-pentachlorobiphenyl and 2,3,7,8-tetrachlorodibenzo-p-dioxin did not induce *CYP1D1* expression in embryonic or juvenile zebrafish. Morpholino oligonucleotide knockdown of AHR2, the transcription factor involved in induction of other CYP1s, did not affect expression of CYP1D1 transcript in control or PCB or TCDD-treated embryos, indicating that *CYP1D1* is not regulated by the AHR2 in developing zebrafish. Zebrafish CYP1D1 protein was expressed in yeast and exhibited ethoxyresorufin-O-deethylase activity. Polyclonal antibodies raised against a CYP1D1 peptide specifically detected a protein in zebrafish liver microsomes. The results indicate that *CYP1D1* in zebrafish is a *CYP1A*-like gene that is constitutively regulated and highly expressed early in development. This constitutive expression suggests that CYP1D1 could have metabolic functions targeting endogenous compounds. (NIH 1R01ES015912 and 5P42ES007381)

PL 1972 CYTOCHROME P450 GENES IN ZEBRAFISH DEVELOPMENT.

J. Goldstone[1], M. Jonsson[1], T. Parente[1], J. Zanette[1], A. McArthur[2], B. R. Woodin[1], D. R. Nelson[3] and J. J. Stegeman[1]. [1]*Biology, Woods Hole Oceanographic Institution, Woods Hole, MA,* [2]*Andrew McArthur Consulting, Hamilton, ON, Canada and* [3]*University of Tennessee, Memphis, TN.* Sponsor: M. Hahn.

This presentation summarizes observations on the full complement of *CYP* genes in zebrafish, a non-mammalian model for pharmacological, toxicological and carcinogenesis research. A total of 88 *CYP* genes were identified in zebrafish. Homologies between zebrafish and human CYP were inferred from amino acid sequence identity and molecular phylogeny. Functions and regulation of most zebrafish CYP are not known. For CYP that are likely involved principally in endogenous functions there is clear orthology between human genes and their zebrafish counterparts, although there are differences in numbers of genes in some families. Relative to the human CYP complement there is expansion or enhanced diversity in zebrafish CYP families 1, 2 and 3 thought to be most involved in xenobiotic metabolism. There are five *CYP1* genes, five *CYP3*s, and 42 *CYP2*s in 11 subfamilies. Only two of the zebrafish *CYP2*s (*CYP2R* and *CYP2U*) warrant the same designation as in humans based on sequence identity. However, syntenic analysis reveals that there are some 11 genes in the zebrafish *CYP2N*, *2P*, *2V*, and *2AD* subfamilies, all of which occur in tandem in a cluster that has shared synteny with the single human *CYP2J2*, indicating orthology. Studies of CYP2Ns and CYP2Ps in other species indicate functional similarity with human CYP2J2. The multiple *CYP2K*s share synteny with *CYP2W*, but the *CYP2X*s and *CYP2AA*s do not obviously share synteny with any human CYP2 genes. The five zebrafish *CYP1*s occur in four subfamilies, divided into 2 clades. Zebrafish *CYP1*s show organ, cell and developmental stage differences in transcript expression and in inducibility by aryl hydrocarbon receptor agonists. *CYP1D1*, which is most closely related to *CYP1A*, is distinctly not induced by AH receptor agonists. Oligonucleotide microarrays targeted to all zebrafish *CYP*s reveal that many *CYP*s, including 17 *CYP2*s, are expressed during early zebrafish development. (NIH 5P42ES007381 and 1R01ES015912)

PL 1973 IMPACT OF THE BIOLOGICAL ENVIRONMENT ON NANOPARTICLE COATING AND CYTOTOXICITY.

K. Phillips, L. K. Braydich-Stolle, J. J. Schlager and S. M. Hussain. *711 HPW/RHPB, AFRL, Wright-Patterson AFB, OH.*

Many studies have suggested that coating nanomaterials helps to protect cells from cytotoxicity; however, no long term exposure studies have shown the impact of the biological environment on coating stability. Previous studies from our laboratory have shown that polysaccharide coated silver nanoparticles (PS-Ag) were more compatible than hydrocarbon silver nanoparticles (HC-Ag) following a 24 h incubation in vitro. However, when the PS-Ag was kept in culture for up to one week, this biocompatibility was lost. The goal of this study was to evaluate the effects of the biological environment on the physico-chemical properties of nanomaterials. The PS-Ag 25nm and the HC-Ag 25nm were exposed to artificial alveolar, interstitial, lysosomal, and gastric fluid for 0, 6, 12, 24, and 72 h. Following exposure to the artificial fluids, the nanoparticles were washed and resuspended in sterile DI water. The average nanoparticle size in solution was then evaluated using dynamic light scattering (DLS) and biocompatibility was assessed by using the MTS assay to measure cell proliferation in the A549 cell line (type I pneumocytes) at concentrations ranging from 0-150 μg/ml. Typically, the PS-Ag 25nm is more dispersed in solution and does not agglomerate to the extent that HC-Ag 25nm agglomerates (38.9nm and 106nm respectively). Exposure to the artificial fluids increased agglomeration in both nanoparticle types at each time point and there was not much

difference in agglomeration between the two nanoparticles types. In addition, the PS-Ag is more biocompatible than the HC-Ag however exposure to the alveolar, interstitial, and lysosomal fluid had a stimulatory effect on the cells with an increase in viability observed. In contrast, over time exposure to the gastric fluid made the nanoparticles more toxic in a dose-dependent manner. This study demonstrated when addressing nanotoxicity, the effect of the aqueous biological environment not only effects the dynamics of aggregation and agglomeration but also modulates the presentation and exposure properties of nanomaterials on cellular and tissue systems.

PL 1974 DOSE AND RESPONSE METRICS IN ASSESSING *IN VITRO* AND *IN VIVO* NANOPARTICLE TOXICITY.

X. Han[1], J. N. Finkelstein[3, 1, 4], A. Elder[1], P. Biswas[2], J. Jiang[2] and G. Oberdörster[1]. *[1]Environmental Medicine, University of Rochester, Rochester, NY, [2]Energy, Environmental and Chemical Engineering, Washington University in St. Louis, St. Louis, MO, [3]Pediatrics, University of Rochester, Rochester, NY and [4]Radiation Oncology, University of Rochester, Rochester, NY.*

The increasing number and variety of new nanoparticles (NPs) calls for the development of low-cost in vitro screening assays for ranking NP toxicity. Unlike chemicals which are usually measured by mass dose, the great variety of physicochemical properties of NPs (size, shape, crystallinity, etc) means that other parameters need to be scrutinized in order to examine how useful these in vitro assays are in predicting the in vivo toxicities. We explored several dose and response metrics with the objective to predict in vivo toxicity from in vitro data. Critical to this effort are the choices of biological endpoints and cellular systems that are relevant targets in vivo. We assessed toxicity of several TiO2 NPs of sizes 3-100 nm. A rat lung Type I epithelial cell line (R3/1) was used for in vitro study; in vivo study involved intratracheal instillation of NPs to rats. In vitro endpoints were lactate dehydrogenase (LDH) release, protein carbonylation, and heme oxygenase-1 (HO-1). Number of PMNs in bronchoalveolar lavage fluid (BALF) was used as endpoint in vivo. Several metrics were used to rank the toxicity of these NPs, including ED50 and the steepest slopes in the dose-response curve calculated using two different methods. We then compared the correlations between the in vitro and in vivo ranking results. Carbonylation and HO-1 assays were good markers of oxidative stress related toxicity. The steepest slope in the dose-response curve was the best response metric for ranking NP toxicity when both dose and response were expressed in unit surface area. It was concluded that toxicity rankings by certain in vitro assays were consistent with the in vivo toxicity rankings when proper dose and response metrics were utilized. PL 1975 MECHANISMS OF INHALED MULTIWALLED CARBON NANOTUBE-INDUCED IMMUNOSUPPRESSION.

L. Mitchell[1, 2], F. Lauer[2], S. Burchiel[2] and J. McDonald[1]. *[1]Lovelace Respiratory Research Institute, Albuquerque, NM and [2]University of New Mexico, Albuquerque, NM.*

Inhalation of multiwalled carbon nanotubes (MWCNT) showed decreased systemic immune function with is modulated by the COX-2 pathway. These studies report on elucidation of this pathway. Male mice were exposed to atmospheres containing 0.3 or 1 mg/m3 MWCNT for 6 hours/day for 14 consecutive days in whole body inhalation exposure chambers. Approximately 18 hours after exposure mice were assessed for systemic immune function in the spleen. Systemic immune function was compromised after 1mg/m3 MWCNT exposure. Splenocytes from exposed animals were less able to produce antibody in response to antigenic stimuli and exhibited decreased T cell proliferation when co-cultured with a mitogen (Concanavalin A). Furthermore, splenocytes from exposed animals exhibited increased gene expression of prostaglandin synthase enzymes. Prostaglandin synthase enzymes catalyze the metabolism of arachidonic acid to prostaglandins; known T cell suppressors. Therefore an additional inhalation exposure was conducted with mice that received a Prostaglandin Synthase 2 (PTGS2 or COX-2) antagonist (ibuprofen) in their drinking water. Ibuprofen treated animals exhibited significant rescue from MWCNT-induced immunosuppression, suggesting involvement of prostaglandins in immune function alterations. Subsequent experiments showed COX-2 (PTGS2) knockout mice were resistant to inhaled MWCNT-induced immune alterations. Finally, co-culturing naïve splenocytes with protein collected from lung washes in MWCNT exposed mice showed similar responses as what was observed in vivo. This finding suggests the effects arise from a signal in the lung, not from translocation of the MWCNT to the spleen. This work was supported by NIEHS (P30 ES-012072) and EPA (RD-83252701).

PL 1976 NADPH OXIDASE REGULATES NEUTROPHILS AND FIBROSIS IN C57BL/6 MICE EXPOSED TO CARBON NANOTUBES.

A. A. Shvedova[1, 2], E. R. Kisin[1], A. R. Murray[1, 2], C. Kommineni[1], V. Castranova[1, 2, 4], B. Fadeel[3] and V. E. Kagan[1, 4]. *[1]PPRB, NIOSH, Morgantown, WV, [2]Department of Physiology/Pharmacology, WVU, Morgantown, WV, [3]Division of Biochemical Toxicology, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden and [4]Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Single-walled carbon nanotubes (SWCNT) have been introduced into a large number of new technologies and consumer products. The combination of their exceptional features with very broad applications raised concerns regarding their potential health effects. The prime target for SWCNT toxicity is believed to be the lung where exposure may occur through inhalation, particularly in occupational settings. Our previous work has demonstrated that SWCNT cause robust inflammatory responses in rodents with very early termination of the acute phase and rapid onset of chronic fibrosis. Timely elimination of polymorphonuclear neutrophils (PMNs) through apoptosis and their subsequent clearance by macrophages is a necessary stage in the resolution of pulmonary inflammation whereby NADPH oxidase contributes to control of apoptotic cell death and clearance of PMNs. Thus, we hypothesized that NADPH oxidase may be an important regulator of the transition from the acute inflammation to the chronic fibrotic stage in response to SWCNT. To experimentally address the hypothesis, we employed NADPH oxidase-deficient mice which lack the $gp91^{phox}$ sub-unit of the enzymatic complex. We found that NADPH oxidase null mice responded to SWCNT exposure with a marked accumulation of PMNs and elevated levels of apoptotic cells in the lungs, production of pro-inflammatory cytokines, decreased production of the anti-inflammatory and pro-fibrotic cytokine, TGF-β, and significantly lower levels of collagen deposition, as compared to C57BL/6 control mice. These results demonstrate a role for NADPH oxidase-derived reactive oxygen species in determining course of pulmonary response to SWCNT. Acknowledgements: supported by NIOSH OH008282, NIH HL70755, NORA 927000Y, and the 7th Program of the EC (EC-FP-7-NANOMMUNE-214281).

PL 1977 MODELING MOLECULAR INTERACTIONS BETWEEN MARCO AND NANOSILICATES.

R. Lins, B. Thrall and J. Pounds. *Pacific Northwest National Laboratory, Richland, WA.*

Airborne exposure to environmental particulates is associated with inflammation and adverse health effects, in particular increased pulmonary and cardiovascular morbidity and mortality. Scavenger receptors, expressed on the cell surface of macrophages, have been implicated as responsible for recognition and internalization of micron-sized environmental particles. However, the molecular mechanism of engineered nanoparticles recognition and uptake has not been addressed. Recently, the three-dimensional structure of the cysteine-rich domain (SRCR) of the macrophage receptor with collagenous structure (MARCO) has been determined by X-ray crystallography. The SRCR domain of MARCO was shown to be involved in cell interactions with LTA, LPS, intact bacteria, and some metal oxide particulates. In this work, the binding of silicates to MARCO is characterized through computer simulations involving its SRCR domain and a number of silicates. Molecular docking of a variety of nanowire silicates were used as screening probes to identify the putative nanosilicate binding sites on MARCO surface. Preferred binding sites involve the arginine clusters and the dimer interface. While the latter only is accessible to sub-nanoparticles, larger silicates can bind to the same region identified to bind LPS. This information has been subsequently used to model the interaction of the receptor to a fully hydroxylated (010) silica surface. Molecular dynamics simulations reveal that the binding is an energetically favorable process and involves the arginine cluster at the -sheet outer surface. Although the secondary structure of MARCO is maintained, significant rearrangement at the dimer interface was observed upon substrate adhesion slightly altering MARCO electrostatic surface potential signature. These results highlight, for the first time, potential differences between MARCO interactions between micron and nanoscale particles, and suggest potential receptor structural rearrangements that may facilitate nanoparticle induced signaling in macrophages. Supported by R01 ES016212 and the Environmental Biomarkers Initiative.

PL 1978 DIFFERENTIAL GENOTOXIC EFFECTS OF TRANSITION METAL NANOPARTICLES: THE ROLE OF OXIDATIVE STRESS.

R. Wan, Y. Mo, D. J. Tollerud and Q. Zhang. *Environmental and Occupational Health Sciences, University of Louisville, Louisville, KY.*

Nanotechnology is considered to be one the world's most promising new technologies. It directly improves our lives in areas as diverse as engineering, information technology, and diagnostics. Our current knowledge of the health effects of metal

nanoparticles (such as nano-size nickel, cobalt and titanium dioxide) is limited but suggests that metal nanoparticles may exert more adverse effects than standard-sized particles. This study addresses the overall hypothesis that transition metal nanoparticles exert genotoxic effects via alternation of cell homeostasis through a mechanism mediated by oxidative stress. In this study, we used an intratracheal instillation mouse model, and in vitro system, to study the potential genotoxic effects of transition metal nanoparticles. Our results show that exposure to Nano-Co and Nano-Ni caused reactive species species (ROS) generation in vitro and in vivo. Exposure of lung epithelial A549 cells to Nano-Co or Nano-Ni resulted in p53 protein expression, modification and down-regulation of Rad-51 protein expression, and increased formation of γH2AX foci which were abolished by pretreatment of cells with ROS scavangers or inhibitors. The results were further confirmed by in vivo studies; the concentration of 8-OHdG in mouse lungs exposed to Nano-Co and Nano-Ni significantly increased over time after exposure. Furthermore, proliferating cell nuclear antigen (PCNA) staining in mice lungs exposed to Nano-Co and Nano-Ni significantly increased over time and were greater than that caused by Nano-TiO2. Our results suggest that metal nanoparticles cause oxidative stress which is involved in nanoparticle-induced DNA damage and genotoxic effects. These findings have important implications for understanding the potential health effects of nanoparticle exposure.

PL 1979 INDUCTION OF ANEUPLOIDY BY SINGLE WALLED CARBON NANOTUBES.

L. M. Sargent, A. A. Shvedova, A. F. Hubbs, D. T. Lowry, M. L. Kashon, A. Murray, E. Kisin, S. A. Benkovic, D. B. Miller, K. T. McKinstry and S. H. Reynolds. *National Institute for Occupational Safety and Health, Morgantown, WV.*

Engineered carbon nanoparticles are newly emerging manufactured particles with potential applications in multiple fields, including electronics, computers, and aerospace. The low density and small size of these persistent particles makes respiratory exposures to workers likely during the production or use of various commercial products. To examine the potential of nanotubes to induce genetic damage in normal lung cells, primary and immortalized human small airway epithelial cells were cultured and then exposed to single walled carbon nanotubes (SWCNTs) or a positive control vanadium pentoxide. The nanotubes had an average diameter of 1.1 nanometer and a length of 50-100 microns. Cellular tubulin, mitotic spindle integrity and centriole number were determined by immunofluorescence for beta-tubulin and centrin and photographed using fluorescent and confocal laser scanning microscopy. The chromosome number was examined by fluorescent in situ hybridization. After 24 hours of exposure to either SWCNT or vanadium pentoxide, binucleate cells, bundled tubulin and fragmented centrosomes were present. Abnormalities included changes in mitotic spindles, including multiple poles that resulted in aneuploid chromosome number. Confocal microscopy demonstrated nanotubes within the nucleus that were in association with cellular and mitotic tubulin as well as the chromatin. These findings indicate that these SWCNTs can enter the nucleus, inducing mitotic spindle disruption and abnormal chromosome number. Thus, our study indicates that direct interaction between chromatin and SWCNTs may contribute to genetic changes in somatic cells. Exposure to agents that interfere with the formation and movement of the mitotic spindle apparatus and cause abnormalities in chromosome number result in a greater risk of cancer.

PL 1980 QUANTITATIVE STRUCTURE ACTIVITY MODELING OF GOLD NANOPARTICLE TOXICITY IN A ZEBRAFISH DEVELOPMENTAL SYSTEM.

A. Heredia-Langner[1], R. Lins[1], R. Tanguay[2], S. Harper[2], J. Hutchison[2], J. Teeguarden[1], J. Pounds[1], B. Webb-Robertson[1] and B. Thrall[1]. *[1]Pacific Northwest National Laboratory, Richland, WA and [2]The Oregon Nanoscience and Microtechnologies Institute, Corvallis, OR.*

Understanding how the surface physiochemical properties of nanomaterials dictate biocompatibility and potential toxicity is a central challenge in the emerging field of nanotoxicology. Although Quantitative Structure Activity Relationship (QSAR) modeling has been useful for deriving predictive relationships between the properties of chemicals and their biological effects, there has been little effort to evaluate the accuracy of QSAR methods in predicting biological response from nanomaterials. In this work, experimental results were employed to develop a generalized linear model to predict the probability of developmental toxicity in zebrafish embryos 24 hours post-fertilization. The experiment consisted of exposing zebrafish embryos to eight different concentrations of gold nanoparticles, with three different core sizes and four different surface modifications with chemical ligands. The toxicity model was statistically developed using physical and structural characteristics of the gold nanoparticles, including nine different chemical property descriptors as predictor variables. Beyond particle size and concentration, two of the QSAR variables investigated (polar surface and solvent accessible surface area) were found to be statistically significant predictors of toxicity. The model exhibits good performance and, because all the predictor variables are continuous, it can be used to point to regions in the experimental space with reduced toxicity and aid to further the understanding of the mechanisms that influence it.

PL 1981 THE EFFECT OF CADMIUM EXPOSURE ON CALCIUM HOMEOSTASIS AND SIGNALING PATHWAYS.

B. Tvermoes[1, 2], G. S. Bird[1], W. A. Boyd[1] and J. H. Freedman[1]. *[1]NIEHS, Research Triangle Park, NC and [2]Duke University, Durham, NC.*

Cadmium constitutes a threat to human health. Yet the exact molecular mechanisms involved in mediating transcriptional responses to cadmium remain unresolved. Cadmium has been shown to elevate intracellular calcium levels, which could activate multiple signaling cascades. Here we report the functional analysis of two cadmium responsive genes in the nematode Caenorhabditis elegans, numr-1 and numr-2, whose expression, in part, is regulated by alterations in intracellular calcium ([Ca2+]i) levels. In the absence of metal, constitutive expression of numr-1/-2 is developmentally regulated with maximal expression in intestinal cells during the L1 larval stage and minimal expression in adults. When adult nematodes are exposed to metal, numr-1/-2 expression increases dramatically in intestinal cells. In C. elegans the intestinal cells experience endogenous endoplasmic reticulum (ER) stress during development and cadmium is a toxicant that induces ER stress. It has been proposed that cadmium can increase intracellular calcium levels through the release of calcium from ER stores. We found that when adult nematodes carrying a NUMR-1::GFP translational fusion are exposed to thapsigargin or a calcium ionophore, numr-1 expression dramatically increases throughout the intestine, suggesting alterations in [Ca2+]i levels may regulate numr-1/-2 expression. To gain a better understanding of the effects of cadmium on [Ca2+]i we used a protein based calcium ion sensor, cameleon YC 3.60, expressed in HEK 293 cells. We found that exposing HEK 293 cells to 30uM cadmium decreased the release of intracellular calcium ions by treatment with ionomycin; suggesting that ER calcium stores had been depleted. Taken together, our data suggests that cadmium affects intracellular calcium levels, which may ultimately regulate the transcriptional response of cadmium inducible genes. These results offer insights into the effect of cadmium exposure on calcium homeostasis and signaling pathways.

PL 1982 MANGANESE TOXICITY IN CELLS THAT HYPER-ACCUMULATE PHOSPHATE INVOLVES PROTEIN TURNOVER EFFECTS OF THE PROTEOSOME.

L. Rosenfeld, E. Leung, L. Jensen and V. Culotta. *Environmental Health Sciences, Johns Hopkins School of Public Health, Baltimore, MD.*

Manganese ions are known to form tight complexes with phosphate *in vitro*, and we have investigated the effects of intracellular phosphate on manganese using the bakers yeast *S. cereviae*. Phosphate accumulation and metabolism in *Saccharomyces cerevisiae* is regulated by the cyclin dependent kinase Pho85 and the cyclin Pho80. When phosphate is abundant, they negatively regulate the transcription of phosphate uptake and metabolism genes. Cells with a genetic deletion of *pho80* accumulate increased amounts of multiple species of phosphate. The *pho80Δ* genetic deletion strain also accumulates increased levels of manganese when exposed to high manganese and is very sensitive to manganese toxicity. To investigate the mechanism of manganese sensitivity in the *pho80Δ* strain, we compared the transcriptional profile of *pho80Δ* vs WT strains exposed to manganese. As expected, a number of phosphate metabolism genes were up-regulated, including the metal-phosphate transporter *PHO84*. However, up-regulation of the metal-phosphate transporter only partially explains the sensitivity towards manganese and both *PHO84*-dependent and –independent pathways are responsible for manganese sensitivity. In a screen for multi-copy suppressors of the *pho80Δ* manganese sensitivity, we isolated *RAD23*, which encodes a proteasome-associated protein. *RAD23* does not act at the level of transcription and instead works downstream in a *PHO84*-independent fashion to reverse manganese toxicity. The reduction in manganese sensitivity is dependent on the N-terminal UbL ("ubiquitin-like") domain of Rad23p that interacts with the proteasome. We conclude that manganese toxicity in cells that hyperaccumulate phosphate involves protein turnover effects of the proteosome.

PL 1983 BIS(MALTOLATO)OXOVANADIUM ACTIVATES STAT-1 IN HUMAN LUNG FIBROBLASTS AND ANTAGONIZES IL-13-INDUCED STAT-6 SIGNALING.

P. C. Bost and J. C. Bonner. *Toxicology, North Carolina State University, Raleigh, NC.*

Bis(maltolato)oxovanadium(IV) (BMOV) is a bioavailable vanadium-based compound that has potential therapeutic value for the treatment of diabetes. We have previously shown that vanadium analogs activate signal transducer and activator of

transcription-1 (STAT-1) which is protective against fibrosis of the lungs after injury with bleomycin. Interleukin-13 (IL-13), which is a potent activator of STAT-6, is a major mediator in the progression of pulmonary fibrosis. We hypothesize that BMOV reduces the causative elements of lung fibrosis by activating STAT-1, which antagonizes IL-13 induced STAT-6 signaling. To address this hypothesis, confluent cultures of human lung fibroblasts (HLF) were rendered quiescent in serum-free medium and then dosed with both BMOV and IL-13 alone or in combination. We then collected cell lysates for Western blot analyses and cell supernatants for ELISA assays at various time points to measure STAT phosphorylation and levels of the STAT-1-regulated chemokine CXCL10, respectively. In this study we show that BMOV induced STAT-1 phosphorylation at 6 hrs post-exposure, but did not activate STAT-6. In contrast, IL-13 activated STAT-6 phosphorylation within 5 min but did not activate STAT-1. Interestingly, BMOV significantly reduced IL-13- induced STAT-6 phosphorylation. BMOV also stimulated fibroblasts to secrete CXCL10, a chemokine that inhibits angiogenesis and promotes epithelial repair. Our data suggest that BMOV inhibits pro-fibrogenic signaling pathways through a STAT-1-dependent mechanism. We propose that activated STAT-1 could reduce fibrosis in two ways; first, by antagonizing IL-13-induced STAT-6 signaling and second, by increasing CXCL10. Our data suggest that dietary BMOV could serve as a potential treatment for pulmonary fibrosis; a fatal disease for which there is currently no effective treatment strategy. Further study will test the therapeutic value of BMOV in a mouse model of pulmonary fibrosis. (Funded by NIH R21-ES015801-01).

PL 1984 SYSTEMS BIOLOGY-DEFINED CROSSTALK BETWEEN P53 AND NFκB SIGNALING AND MODULATION BY ARSENIC.

X. Yu, S. Hong, R. T. Ng, H. Kim and E. M. Faustman. *Environmental Health, IRARC, UW, Seattle, WA.*

Dept. Environmental and Occupational Health Sciences, University Of Washington

Arsenic (As) is a well-known environmental toxicant and carcinogen as well as an effective chemotherapeutic agent. The underlying mechanism of this dual capability, however, is not fully understood. In our previous study, our microarray-based gene expression analysis demonstrated that arsenic-induced cell cycle arrest and apoptosis in p53-proficient and p53-deficient cells occurred through differential gene pathways, suggesting a potential role of NFκB pathway in As-induced apoptosis in p53-/- cells. In this study, we examined the crosstalk between the p53 and NFκB pathway by applying a systems-biology-based approach. These results were verified by comparing the activation of NFκB by western blot analysis of phosphorylated NFκB p65 (p-p65) and IκBa (p-IκBα) and cytokines by cytokine protein array. In the canonical pathway-based analysis between the gene expression from p53+/+ and p53-/- cells, we found that deletion of the p53 pathway resulted in significant up-regulation of NFκB related signaling pathways, suggesting a possible inhibitory effect of p53 on NFκB. A transcriptional regulatory network analysis revealed that As treatment resulted in activation of transcription regulatory elements CAAT and NRSF in the p53+/+ cells while in the p53-/- cell As treatment seemed to reduce NFκB/Rel transcription activity. We observed significant higher level of p-p65 and p-IκBα in p53-/- cells as compared to p53+/+ cells. Treatment of As reduced p-p65 and p-IκBα in a dose-dependent manner in p53-/- cells whereas increases of the p-p65 and p-IkBα were observed in p53+/+ cells. Our study provides strong support for the existence of crosstalk between the p53 and NFκB signaling pathways, and demonstrates that As induces apoptotic processes in p53–/– cells occur through the down-regulation of NFκB, a p53-independent pathway (EPA R826886, NIEHS 1PO1ES09601, R01-ES1063, P30 ES07033, UW Royal Research Fund and CAAT Award)

PL 1985 LEAD INHIBITS BONE FORMATION THROUGH A SCLEROSTIN-DEPENDENT MECHANISM.

J. Puzas, R. Ubayawardena, D. Dao and T. Sheu. *Department of Orthopaedics, University of Rochester School of Medicine, Rochester, NY.*

Lead exposure can adversely affect the skeleton by reducing bone formation, compromising fracture healing and decreasing bone density. This last finding portends lead exposure as a risk factor for osteoporosis. Unfortunately, the mechanisms by which lead has its effect have not been well characterized. Sclerostin is an actively investigated paracrine repressor of bone formation. It is produced by bone cells and plays a role in the control of osteogenesis. Its inhibitory effect is mediated through the Wnt/beta-catenin pathway. Our recent observations indicate that bone cells and animals exposed to lead show a marked up regulation of sclerostin protein and gene expression. Mice and cells were exposed to physiologically relevant levels of lead. Protein and mRNA for sclerostin were determined with western blot analysis and RT-PCR. Sclerostin expression in vivo was assessed with immunohistochemistry. Intermediates in the TGFbeta signaling pathway (i.e. Smad2) were measured with western blot analysis. Our results show a marked dose dependent increase (over 500%) in both protein and mRNA levels for sclerostin in lead-treated osteoblasts after 24 hours. Additionally, in animals we observed a dose dependent clear-cut stimulation of sclerostin levels in osteocytes and osteoblasts. We have also identified a putative Smad repressor element in the promoter for sclerostin. Upon basal stimulation of the TGFbeta pathway, sclerostin expression is normally low. However, upon inhibition of TGFbeta signaling, sclerostin expression increases. Therefore, we investigated the effects of lead on Smad phosphorylation and found a strong blockage of the kinase responsible for its phosphorylation. We hypothesize that lead depresses bone formation through an up regulation of sclerostin and that this regulation is mediated, in part, by blocking Smad activation. The significance of this research lies in the possibility of treating patients with anti sclerostin therapies for the prevention of lead-induced osteoporosis.

PL 1986 EPIDERMAL GROWTH FACTOR RECEPTOR DEPENDENT HYPOXIA INDUCIBLE FACTOR-1α EXPRESSION BY MONOMETHYLARSONOUS ACID (MMA III) IN HUMAN BLADDER CELLS.

C. Chou, D. W. Hao, J. W. Regan and A. Gandolfi. *Pharmacology and Toxicology, University of arizona, Tucson, AZ.*

Arsenic is a human bladder carcinogen. Recent evidence showed that human bladder cells (UROtsa) are capable of biotransforming arsenite to monomethylarsonous acid [MMA(III)] and can also be transformed following long-term, low-level exposure of MMA(III). Expression of hypoxia inducible factor-1α (HIF-1α), a major regulatory protein of cellular response to hypoxia, correlates with angiogenesis and an unfavorable prognosis in bladder cancer. Acute exposure of MMA(III) [10nM, 50nM and 100nM; 6 h] induced a concentration-response HIF-1α protein expression in UROtsa cells. Inhibitors of the mitogen-activated protein kinase pathway, epidermal growth factor receptor (EGFR), and reactive oxygen species (ROS) led to attenuated expression of HIF-1α. Inhibitors of Src and ROS reduced the phosphorylation of EGFR induced by 50nm of MMA III. Elevation in HIF-1α was also observed following 52 weeks of 50 nM MMA(III) exposure. These results indicate that MMA(III) can induce HIF-1α expression by a mechanism involving Src and ROS dependent EGFR activation. This finding may provide more understanding of arsenic induced angiogenesis and its promotion of bladder tumor progression. Supported by Training Grant (ES 07091) and the Superfund (ES 04940)

PL 1987 ARSENIC PERTURBATION OF ALLERGY/ASTHMA SIGNAL TRANSDUCTION IN MAST CELLS.

L. M. Hutchinson, B. M. Trinh and J. A. Gosse. *Biochemistry, Microbiology, and Molecular Biology, University of Maine, Orono, ME.*

Millions of people worldwide are exposed to arsenic (As) via drinking water, various foods, and industrial and mining sites. Ingestion of As has been associated with increased risk of various cancers, cardiovascular disease, and reproductive/developmental abnormalities. As has been well-described as potent endocrine disruptor, which may underlie many of its toxic effects. Also, recent epidemiological studies in Bangladesh suggest that As exposure elevates asthma incidence, but the underlying mechanism(s) of action are unknown. The most common form of asthma is allergic asthma, in which mast cells are major effector cells. Antigen (Ag) or allergen crosslinking of IgE-bound receptors on mast cells leads to signaling, beginning with tyrosine phosphorylation and ending with degranulation, the release of histamine and other allergy/asthma mediators. It was recently shown that environmental estrogens can exacerbate degranulation, thereby potentiating the allergic and asthmatic response. Thus, we have tested whether As affects degranulation. Using the rat basophilic leukemia (RBL) mast cell model, we have measured degranulation in a fluorescence microplate assay based on release of beta-hexosaminidase. In assays in which RBL cells are exposed short-term to sodium arsenite, plus or minus Ag addition, we have found that As-alone has no effect on degranulation but As plus Ag perturbs degranulation. We have observed a potentiation of degranulation due to very low dose As (~2.5 ppb). Conversely, at higher As doses, we have observed inhibition of degranulation (without cell death): ~15% at 100 ppb, ~25% at 250 ppb, and ~40% at 500 ppb. We have confirmed that the interaction of beta-hexosaminidase with its substrate is unaffected by As, showing that the As effects are on mast cell signaling. Inhibition at high doses may be a mechanism underlying the traditional Chinese medicine use of As to treat asthma. As's potentiation of degranulation at low, environmentally-relevant doses may be a mechanism by which As elevates asthma incidence.

PL 1988 DISRUPTED POLYAMINE SYNTHESIS AND COBALAMIN TRANSPORT CONTRIBUTES TO ABERRANT METHYL METABOLISM DURING CHRONIC ARSENIC EXPOSURE.

J. Coppin and M. P. Waalkes. *ICS, LCC, NCI at NIEHS, Research Triangle Park, NC.*

Arsenic, a human carcinogen that may target the prostate, can be enzymatically methylated using S-adenosylmethionine (SAM) as the methyl donor. After chronic low-level arsenic exposure, the human prostate cell line RWPE-1, which cannot methylate arsenic, acquires a malignant phenotype with DNA hypomethylation. These cells show disrupted methyl metabolism with increased homocysteine (Hcy), transsulfuration pathway activation, glutathione over-production and decreased SAM as part of a complex acquired adaptive tolerance to arsenic concurrent with malignant transformation. Because cofactor deficiencies and the polyamine synthesis can cause similar changes in SAM and Hcy, we studied the effect of acquired adaptation to arsenic (5 μM arsenite; ≤ 16 weeks) on polyamine synthesis/regulation genes and cobalamin transporters. The polyamine synthesis genes ornithine decarboxylase (ODC1) and spermidine synthase, which use a SAM derivate to synthesize spermidine, showed elevated expression with arsenic. Expression of c-myc, a positive regulator of ODC1, was also elevated by arsenic while the transcription factor E2F1, which regulates the SAM synthesizing enzyme methionine adenosyltransferase, was drastically reduced. Thus, arsenic stimulates the SAM consuming polyamine synthesis pathway. Hcy remethylation depends on the cofactor cobalamin which replenishes the methionine pool required for SAM synthesis. Cobalamin deficiency causes Hcy accumulation and may play a role in carcinogenesis. Transcript levels of the cobalamin transporters, transcobalamin (TCN) 1 and 2 were either abolished (1) or strongly reduced (2) by arsenic. Cobalamin deficiency could lead to Hcy accumulation and thereby indirectly inhibit methyltransferase activity and, ultimately, DNA methylation, while activation of polyamine synthesis, often observed in cancer, could consume SAM and directly impact DNA methylation. These changes could ultimately contribute to arsenic-induced malignant transformation.

PL 1989 EFFECTS OF TUNGSTEN ON PHOSPHATE-DEPENDENT BIOCHEMICAL PROCESSES.

D. R. Johnson[1], C. Ang[1], A. J. Bednar[1] and L. S. Inouye[2]. [1]*Environmental Laboratory, U.S. Army Engineer Research & Development Center, Vicksburg, MS and* [2]*Washington State Department of Ecology, Lacey, WA.*

Tungstate, the oxidized form of tungsten (W) metal, is known to polymerize with phosphates. Extensive polymerization may deplete intracellular stores of phosphate, disrupting phosphorylation reactions in cells. A series of studies were conducted to evaluate the effect of tungsten on several phosphate-dependent intracellular functions, including energy cycling (ATP production), regulation of enzyme activity (protein tyrosine kinase (PTK)), and intracellular secondary messengers (cyclic adenosine monophosphate [cAMP]). Rat non-cancerous (Clone-9), rat cancerous (H4IIE), and human cancerous (HepG2) liver cells were used to compare rat vs. human cell response as well as cancerous vs. non-cancerous cell responses. Cells were exposed to 0, 1, 10, 100, 1000 mg/L tungsten, in the form of sodium tungstate, then analyzed for cell viability, ATP concentration, tyrosine kinase activity, and cAMP concentration. In general, tungsten significantly reduced cell viability in all three cell lines at concentrations greater than 100 mg/L; H4IIE cells were most sensitive to tungsten cytotoxicity. Tungsten did not affect ATP concentrations in all three cell types. Tungsten decreased PTK activity by 30% in Clone-9 cells but dramatically increased PTK activity by 70% in HepG2 cells. A hormetic response in PTK activity was also seen in HepG2 cells after a 24 hr exposure to tungsten, but the hormetic response was not observed after a 48 hr exposure to tungsten. Tungsten increased cAMP by 60% in Clone-9 cells. Tungsten also increased cAMP in H4IIE cells at 100 mg/L and in HepG2 cells at 1-100 mg/L, though at much lower levels than in Clone-9 cells. In conclusion, tungsten appears to increase cellular kinase activity and secondary messenger concentrations, yet the responses were species-specific and cancer-cell specific. Thus, these data indicate that tungsten produces complex results that must be carefully interpreted in the context of the respective animal model used.

R 1990 WHAT IS AN ADVERSE EFFECT IN THE AGE OF OMICS?

R. B. Conolly[2] and B. D. Beck[1]. [1]*Gradient Corporation, Cambridge, MA and* [2]*National Center for Computational Toxicology, U.S. EPA, Research Triangle Park, NC.*

Research in biology has recently been characterized by a switch in emphasis from reductionist studies that describe an organism based upon its biological components to more integrative ones that emphasize the processes through which these parts interact to produce the complex systems that form an organism. As it is applied to toxicology, this development has provided the opportunity to understand how perturbations of molecular-level signaling and regulatory pathways elicit apical toxic responses. In accord with these developments, the NRC (Toxicity Testing in the 21st Century: A Vision and a Strategy) has proposed a major paradigm shift. They believe that toxicity testing and risk assessment should involve characterization, with an emphasis on relevant levels of exposure and dose-time response surfaces for in vitro perturbation of toxicity pathways. Before this approach can become a standard practice in risk assessment, and potentially, in biomonitoring, substantial research and development is needed in the development of enhanced capabilities for characterization and prediction of both exposure and tissue dosimetry. Thus, a comprehensive set of toxicity pathways and cell culture systems that embody these pathways, delineation of adaptive responses from frankly toxic responses, and correlation of the in vitro dose-time response surfaces for perturbation of toxicity pathways with apical responses measured in vivo (i.e. responses that are either adverse or that represent critical steps on the route to adverse responses) should be specified. Finally, computational models of in vivo biology that will integrate toxicity pathway data obtained in vitro to predict in vivo dose-time response should be developed. The materials presented should enable us to consider a subset of these issues, highlighting some of the practical challenges posed by the NRC recommendation.

EC 1991 CAREER OPPORTUNITIES AND TRANSITIONS IN TOXICOLOGY.

B. Gadagbui[1] and L. M. Aleksunes[2]. [1]*TERA, Cincinnati, OH and* [2]*University of Kansas Medical Center, Kansas City, KS.*

It's never too early, or too late, to think about where your career in toxicology will lead you next. Whereas students and postdocs are typically familiar with the ins and outs of pursuing an academic research career, opportunities to investigate non-academic careers in toxicology can be few and far between. Early-career scientists often ask 'What careers are available to toxicologists? What skills and experiences do I need to be competitive for these positions?' Such questions are also relevant to established toxicologists looking to expand their work experiences or embark upon a new career path. Toxicologists that practice in various work sectors are faced with the difficult and sometimes painful task of transitioning from one sector to another as each sector often demands unique skills. Most often, guides on career transitions are not readily available for these toxicologists. The material presented will provide participants with insight into toxicology careers in diverse settings, including industry, government, consulting groups, and nonprofit organizations, and provide information about career transitions across the various sectors. Our panel of experienced toxicologists will describe the paths that their careers have taken, intentional or otherwise. Both practical and applicable advice will be offered for those participants interested in pursuing similar avenues, or for those just wishing to step off the beaten path. The presenters will highlight their motivations, challenges, success stories, and lessons learned. Be sure to bring questions to ask our panel of seasoned toxicologists during the interactive question and answer period. Whether you are a graduate student ready to jump into a job search, or an established scientist looking to move your career in an unexpected direction, join us for an interactive and informative discussion designed to expand your awareness of unique and exciting scientific career opportunities for toxicologists and more importantly, how to successfully transition between sectors.

R 1992 PHOTOTOXICOLOGY: A PASSING FANCY OR ENDURING CONCERN.

R. Osterberg[1], D. Forbes[1] and D. Hobson[2]. [1]*Aclairo, Vienna, VA and* [2]*LoneStar PharmTox LLC, Boerne, TX.*

Light is a necessary part of our existence as is air and water. Light is central to our interactions with both natural and artificial environments. Therefore we face a constant need to assess both risks and benefits, and to establish balanced guidelines for exposure in discussing this aspect of phototoxicology, which involves the influence of medications on biological responses to light (principally visible and ultraviolet radiation). Chronic phototoxicity is a proven precursor to skin cancer in human populations. Following up on earlier reports by R. Stern and others, a recent publication by Karagas and colleagues provides epidemiological evidence that reported use of photosensitizing medicine was associated with an increased risk of both basal cell carcinoma and squamous cell carcinoma. The widespread use of photosensitizing drugs and chemicals mandates adequate characterization of drug interactions and heightened counseling on sun exposure. In 2002 and 2003, the Committee for Proprietary Medicinal Products (CPMP) and the U.S. FDA published guidance documents describing their respective regulatory preferences for the testing of substances for phototoxicity and photo co-carcinogenicity. The EU has adopted an *in vitro* test method for photocarcinogenicity testing. Technical specialists generally, and the pharmaceutical industry in particular, have described problems with this regulatory guidance, particularly with regard to the over-prediction of *in vitro* tests and the duration of the *in vivo* tests. In the U.S. and other regions, the outcome of

these tests may help to determine more appropriate wording that may be used in product labels to adequately characterize the risks of excess sun exposures. Thus, it is important that strategies for providing relevant safety information and novel testing approaches to provide useful shorter-term safety data to predict phototoxicities and photo co-carcinogenicity be explored.

IS 1993 LEAD: CHILDREN'S EXPOSURES AND CURRENT REGULATORY STANDARDS.

S. Wild[1] and K. Hatlelid[2]. *[1]Amgen Inc, Thousand Oaks, CA and [2]U.S. Consumer Product Safety Commission, Bethesda, MD.*

Recent news reports raise concerns about children's exposure to lead in toys, paint, candy, and other everyday materials. While the toxicity of lead has been well studied and the use of lead in many materials has been reduced or eliminated over the past 30 years, the possibility of lead exposure in children from both past and current uses of lead remains a public health priority. While a major contributor to lead exposure in children continues to be from the home, 30% or more of children aged <6 years with lead poisoning are exposed to lead through sources other than residential lead paint such as cosmetics, folk and traditional medications, painted and metallic toys and trinkets, and ceramic food ware. Examples regarding lead exposure and risk assessments from sources such as lead based ceramics in schools and bioassessability of lead exposure in children's products will be presented. Numerous agencies are involved in controlling lead exposure and enforcing regulations including the Centers for Disease Control and Prevention (CDC), U.S. Consumer Product Safety Commission (CPSC) and the U.S. FDA. CPSC regulates more than 15,000 types of consumer products including the lead content of numerous products including paint and similar surface coatings on products and furniture intended for consumer use, including toys. The FDA is responsible for ensuring the safety of products as authorized in the Federal Food, Drug and Cosmetic Act. FDA has addressed lead issues for diverse products such as pesticides, metal food cans, lipstick and crystal baby bottles for infants. An overview of known mechanisms of lead toxicity as well as newer research on the long term effects of lead will be presented. Examples will be provided of children's exposures to lead and summarize efforts to reduce lead exposures. The session will conclude with those perspectives of regulatory agencies responsible for regulating lead-containing products, including discussion of pending legislation that could change how lead-containing consumer products are regulated and steps being taken to protect the public from excessive lead exposure.

PS 1994 MULTIPLE GENES EXHIBIT PHENOBARBITAL (PB)-INDUCED CONSTITUTIVE ACTIVE/ANDROSTANE RECEPTOR (CAR)-MEDIATED DNA METHYLATION CHANGES DURING LIVER TUMORIGENESIS AND IN LIVER TUMORS.

J. I. Goodman[1] and J. I. Goodman[2]. *[1]Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI and [2]Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

The constitutive active/androstane receptor (CAR) mediates responses to the nongenotoxic rodent liver tumor promoter phenobarbital (PB), including certain gene expression changes, hepatomegaly, and tumor formation. Aberrant DNA methylation represents epigenetic events that can play multiple roles in tumorigenesis. Previously, 146 unique PB-induced regions of altered DNA methylation (RAMs) were observed in liver-tumor susceptible CAR wildtype (WT) mice (in 23 weeks, precancerous tissue and 32 weeks, tumor tissue), as compared to the resistant knockout (KO). We believe that at least some of these might be key for tumorigenesis (Phillips et al., 2007). In this study, cloning and annotation of a subset (82%) of the unique RAMs revealed 47 genes exhibiting altered methylation; 17 are already implicated in cancer or related processes. Thus, we have identified 30 "new" candidate genes that might be involved in carcinogenesis due to an epigenetic alteration. These may contribute to tumor development through their involvement in angiogenesis, apoptosis, epithelial-mesenchymal cell transition, growth/survival, and invasion/migration/metastasis. We have also, previously, discerned unique PB-elicited RAMs in liver tumor-prone B6C3F1 mice, as compared to the relatively resistant C57BL/6 strain, at 2 or 4 weeks (Bachman et al., 2006), and identified 51 genes exhibiting altered methylation (Phillips and Goodman, 2008). Importantly, 11 of these genes were identified from identical, unique RAMs discerned in both the sensitive B6C3F1 and CAR WT mice, thus representing an initial, potential candidate "fingerprint" which might serve as a biomarker for PB-induced tumorigenesis. These 2 studies reveal "new" genes whose epigenetic statuses changed uniquely in liver tumor-susceptible mice (B6C3F1 and CAR WT), compared to their resistant counterparts (C57BL/6 and CAR KO, respectively), within a continuum of PB-induced tumorigenesis.

PS 1995 EPIGENETIC ANALYSIS OF ALDH1A2 GENE IN JAPANESE MEDAKA DEVELOPMENTALLY EXPOSED TO ETHANOL.

A. K. Dasmahapatra[1, 2, 3], Y. Hu[1, 3], K. L. Willett[1, 2, 3], B. E. Scheffler[4] and I. A. Khan[1]. *[1]National Center for Natural Product Research, University of Mississippi, University, MS, [2]Department of Pharmacology, University of Mississippi, University, MS, [3]Environmental Toxicology Research Program, University of Mississippi, University, MS and [4]USDA-ARS Mid-South Area Genomics Laboratory, USDA, Stoneville, MS.*

We have demonstrated that medaka embryos exposed to ethanol developed precocious features in craniofacial, cardiovascular and skeletal organs which are homologous to the FAS observed in human. We hypothesized that ethanol metabolism during development induces oxidative stress which is responsible for epigenetic modification in several developmentally regulated genes, in turn, promoting FAS. In this regard, we have analyzed the promoter region of aldehyde dehydrogenase 1A2 (Aldh1A2) gene, which encodes an enzyme responsible for the synthesis of retinoic acid. The information about the nucleotide (nt) sequences of 5' UTR and first exon of Aldh1A2 (-705 to +117, ATG = +1) of medaka were obtained from the web site (http://medaka.utgenome. org/) and were verified by PCR. After bisulfite treatment of the genomic DNA, a fragment of 753 nt (-636 to +117 nt) was amplified which contained 27 CpG dinucleotides. There were 173 cytosine nucleotides present in the amplified region, however, none were methylated. Medaka embryos exposed to ethanol (100-400 mM) for 48 hours post fertilization (hpf) also showed no methylation in the promoter region of Aldh1A2. Some of the ethanol treated embryos (300 mM, 0- 48 hpf) were raised to adults (breeding) and the Aldh1A2 promoter methylation was analyzed in liver, brain, heart, and eye tissues. The methylation pattern of Aldh1A2 also remained unaltered in these organs. Therefore, it was concluded that ethanol did not alter the CpG methylation pattern of Aldh1A2 gene of medaka during development [supported by NIH RO3AA016915; COBRE-P20RR021929].

PS 1996 ROLE OF EPIGENETICS IN DIOXIN-INDUCED DIFFERENTIAL REGULATION OF THE HUMAN CYP1A1 AND CYP1B1 GENES.

S. R. Beedanagari and O. Hankinson. *Molecular Toxicology, UCLA, Los Angeles, CA.*

The Aryl Hydrocarbon Receptor/ARNT heterodimer mediates carcinogenesis by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD or dioxin) and certain polycyclic aromatic hydrocarbons (PAHs) by activating gene transcription. Metabolism of PAHs by CYP1A1 and CYP1B1 plays a major role in carcinogenesis mediated by these compounds. The overall goal of this study is to understand the mechanisms involved in differential regulation of the human CYP1A1 and CYP1B1 genes. We are studying the regulation of these genes in three different human cell lines (MCF-7, MDA-MB 231, and HepG2) as the endogenous expression and induction levels of these genes upon treatment with TCDD differ significantly between these cell lines. To elucidate the mechanisms involved in the differential regulation of these genes, we studied the recruitment of AHR and RNA PolII at their enhancers and promoters, respectively. The data indicate that RNA PolII, but not AHR recruitment, correlates with CYP1A1 and CYP1B1 expression. Subsequently, we characterized the different dioxin- inducible chromatin modifications (i.e acetylation, methylation, and phosphorylation) that occur across the CYP1A1 and CYP1B1 enhancer and promoter regions using the chromatin immunoprecipitation (ChIP) assay. The results show H3K9Ac, H3K14Ac, H3K4me3 and H4Ac chromatin modifications at the CYP1A1 and CYP1B1 promoter regions strongly correlate with the TCDD-induction of the CYP1A1 and CYP1B1 genes in different cell lines. These modifications, at least in part are likely to contribute to the differential induction of these genes upon treatment with TCDD. Knock-down studies using siRNA experiments also show that the coactivator p300, but not CBP and SRC-1, play a role in the differential regulation of these genes.

PS 1997 MOUSE EPIGENOME DEFINES THE STRAIN-SPECIFIC DIFFERENCES IN SUSCEPTIBILITY TO NON-ALCOHOLIC STEATOHEPATITIS.

T. V. Bagnyukova, V. Tryndyak, B. Montgomery, J. Latendresse, F. Beland and I. Pogribny. *FDA-National Center for Toxicological Research, Jefferson, AR.*

Current trends in cancer research are moving toward the uncovering of molecular mechanisms, cellular pathways, networks, processes, and related disease states that underlie tumorigenesis. Specifically, during recent years much effort has been devoted to uncover the fundamental mechanisms of individual cancer susceptibilities. This has a great significance in identifying vulnerable subpopulations susceptible to cancer and for establishing new cancer prevention strategies. In light of these considerations, the present study was undertaken to determine whether or not the

mouse strain-specific susceptibility to non-alcoholic steatohepatitis (NASH), a pathological state that predisposes individuals to the development of hepatocellular carcinoma (HCC), is associated with differences in the epigenetic status. The initial analysis of the epigenetic status in the livers of BALB/CJ, C3H/HeJ, A/J, AKR/J, C57BL/6J, and DBA/2J mice revealed the substantial strain-to-strain differences in the degree of cytosine methylation and histone modification patterns. The most distinct strain-specific epigenetic differences were detected in DBA/2J and C57BL/6J strains. Next, we used a mouse nutritional model of NASH induced by a methyl-deficient diet that is relevant to NASH pathogenesis in humans, to study whether or not the status of the liver epigenetic phenotype indeed mediates the individual sensitivity to NASH. Inbred male C57BL/6J and DBA/2J mice were fed a methyl-adequate (control) or a methyl-deficient diet for 6, 12, and 18 weeks. Both the C57BL/6J and DBA/2J mice maintained on a methyl-deficient diet exhibited significant hepatosteatosis; however, the DBA/2J mice that were characterized by lesser amounts of histone H3 lysine 9 and H3 lysine 27 trimethylation and a lower extent of methylation of repetitive DNA elements, as compared to those in the livers of C57BL/6J mice, developed more severe hepatosteatosis. These data indicated the importance of epigenetic background in individual susceptibilities to disease.

PS 1998 ROLE OF EPIGENETIC ALTERATIONS IN FORMATION AND PROGRESSION OF GLUTATHIONE S-TRANSFERASE PLACENTAL FORM (GSTP)-POSITIVE PRENEOPLASTIC FOCI DURING RAT HEPATOCARCINOGENESIS.

V. Tryndyak, L. Muskhelishvili, S. Shpyleva, T. Bagnyukova, B. Montgomery, F. Beland and I. Pogribny. *DBT, FDA-National Center for Toxicological Research, Jefferson, AR.*

The altered expression of the GSTP in the rat liver has been routinely used as a marker of preneoplastic (initiated) cells during hepatocarcinogenesis. However, the molecular mechanisms leading to formation and progression of GSTP-positive cells are largely unknown. It has been demonstrated recently that specific mutations at the initiation step of liver carcinogenesis are not necessary for the establishment of GSTP-positive cells. Specifically, it is highly unlikely that a specific genetic change is associated with this common response to a variety of liver carcinogens. Therefore, we sought to determine the role of epigenetic changes in the formation and progression of GSTP-positive foci in the livers during carcinogenesis induced by two classic liver carcinogens – the genotoxic carcinogen 2-acetylaminofluorene (2-AAF) and the non-genotoxic carcinogen – methyl-deficient diet (MDD). Despite the different mechanisms of action, the GSTP-positive foci induced by 2-AAF or MDD are characterized by the common epigenetic alterations, such as increase of global histone H3 lysine 27 trimethylation (H3K27me3), loss of H4K20me3, and promoter hypermethylation of *Rassf1A* and *$p16^{INK4A}$* genes. These epigenetic changes gradually increased during progression of the carcinogenic process. In contrast, the methylation status of the *Socs1, Cdh1*, and *Cx26* genes in the GSTP-positive foci and tumors did not change. However, a chromatin-immunoprecipitation analysis demonstrated increased levels of H3K27me3, a known transcription silencing mark, at promoter region of *Rassf1A, p16INK4A, Socs1, Cdh1*, and *Cx26* genes. These results clearly indicate the crucial role of epigenetic mechanisms in the formation and progression of GSTP-positive initiated cells. More importantly, it demonstrates that formation of GSTP-positive foci is a result of common effects of carcinogens on cellular epigenome, rather than a specific genetic change.

PS 1999 LOW-DOSE IONIZING RADIATION ALTERS THE FETAL EPIGENOME.

A. Bernal[1,3], D. C. Dolinoy[2], D. Huang[3] and R. L. Jirtle[3]. *[1]Toxicology & Environmental Health, University Program in Genetics and Genomics, Duke University, Durham, NC, [2]University of Michigan, Ann Arbor, MI and [3]Radiation Oncology, Duke University Medical Center, Durham, NC.*

Radiation-induced bystander effect is a phenomenon where cells not directly exposed to ionizing radiation display a marked enhancement in chromosomal and genomic instability, which is thought to result in part from epigenetic changes (Kovalchuk & Baulch, 2008). There is now accumulating evidence that epigenetic dysregulation during early development is also mechanistically linked to the pathogenesis of adult-onset diseases. We sought to determine whether low doses of ionizing radiation during early gestation affect susceptibility to adult-onset diseases by deregulating DNA methylation and/or chromatin structure of the genome. Viable yellow agouti (Avy) mice were used to test this novel postulate because they are exquisitely sensitive biosensors for environmental agents that alter the epigenome (Waterland and Jirtle, 2003; Dolinoy et al. 2006; Dolinoy et al. 2007). In this study, viable yellow agouti Avy/a offspring were exposed in utero to a total dose of 8.4 cGy of low LET radiation delivered at 1.2 cGy/day from gestational day 1.5 to gestational day 8.5 using the Imtek small animal MicroCAT X-ray/CT scanner. A second set of Avy/a offspring was sham-irradiated in utero for 7 consecutive days. The results demonstrate that maternal exposure to this low dose of fractionated radiation shifts the coat color distribution of Avy/a offspring toward the brown pseudoagouti coat color phenotype (p=0.026). Additionally, preliminary DNA methylation analysis demonstrated increased methylation at several CpG sites upstream of the Avy cryptic promoter. These data indicate that the protective effect frequently observed following low dose radiation exposure may be mediated by epigenetic mechanisms that lead to increased DNA methylation at critical sites in the genome. To test this intriguing postulate, additional exposure groups will be added to this study.

PS 2000 EPIGENETIC MECHANISM FOR POTENTIATION ("PRIMING") OF PREGNANE X RECEPTOR-REGULATED GENE EXPRESSION BY DIMETHYL SULFOXIDE.

Y. Xie, S. Ke and Y. Tian. *VTPP, Texas A&M University, College Station, TX.*

Prior exposure to chemicals/agents may alter epigenome in such a way that subsequent exposure to the same or a different agent would produce different responses. This hypothesis obviously has important implications in xenobiotic/drug metabolism and detoxification, drug-drug interactions as well as therapeutic application of drug combinations. To test this hypothesis, we utilized the pregnane x receptor (PXR)-regulated luciferase reporter cell line (PXR-HepG2) to analyze the pretreatment (priming) effect of dimethyl sulfoxide (DMSO) on the rifampicin-induced PXR transcriptional activity. DMSO has extremely wide applications in medicine. It is a cryoprotectant for preserving organs, tissues and embryos. It has therapeutic applications for many inflammatory conditions, such as treatment for interstitial cystitis approved by FDA. We demonstrated that by pretreatment (priming) with 1.25-2.5% DMSO, PXR-regulated luciferase reporter gene induction was drastically elevated in PXR-HepG2. The DMSO priming effect on CYP3A4 induction was confirmed in human primary hepatocytes by RT-PCR. The priming effect persisted over 48 hours after removal of DMSO. DMSO treatment impacted epigenome by selectively changing the acetylation of histone H4 lysine 8. Pretreatment of methyltransferase inhibitor ADOX or histone deacetylase inhibitor TSA abolished the DMSO priming effect. However, treatment of ADOX after DMSO has not impact on DMSO priming effect. In contrary, treatment of TSA after DMSO priming enhanced the priming effect. Based on these observations and literatures (Science 293(5531):853-7; Genes Dev. 19(16):1885-93), we proposed a model of "Relay between histone methylation and acetylation on the transcription cycle" which posits transcription cycle begins with methylation of histone (e.g. H4R3) "a Ready State" which facilitates the histone acetylation, i.e. "Activation State". To turn off an active gene the acetylated histone needs to be deacetylated which leads to the "Inactive State" which then allows methylation of H4R3 ("Ready State"). (The research is supported in part by ES 09859).

PS 2001 EPIGENETIC REGULATION OF LINE- 1 RETROTRANSPOSON.

I. Teneng[1,2], J. L. Quertermous[3], D. E. Montoya-Durango[1,2] and K. S. Ramos[1,2,3]. *[1]Department of Biochemistry and Molecular Biology, University of Louisville School of Medicine, Louisville, KY, [2]Center for Genetics and Molecular Medicine, University of Louisville, Louisville, KY and [3]Department of Medicine, University of Louisville, Louisville, KY.*

Retrotransposons are mobile elements that self propagate within the genome via a copy and paste mechanism involving RNA intermediates and reverse transcriptase. LINE 1 (L1) is the most active and abundant mammalian retrotransposon. Although transcriptional regulatory control L1 is not completely understood, L1 promoter hypomethylation associated with increased expression has been described in several cancers including testicular tumors, urothelial bladder carcinoma, prostate carcinoma, hepatocellular carcinoma, chronic lymphocytic leukemia, and chronic myeloid leukemia. Previously we reported that environmental stressors like benzo(a)pyrene (BaP), dioxin and ultraviolet irradiation (UVB) activate L1 in several mammalian cell types. In this study we hypothesized that regulation of L1 by cell stressors involves modulation of epigenetic regulatory mechanisms. BaP treatment of HeLa cells decreased RNA and protein levels of critical DNA methyltransferases. Quantitative pyrosequencing analyses revealed a decrease in methylation at several CpG cytosines within the CpG island on the L1 promoter region. ChIP-qPCR analyses of HeLa cells following BaP treatment revealed changes in methylation and acetylation of critical histones associated to the L1 promoter. These data suggest that epigenetic mechanisms play an important role in stress regulation of L1.

This work was supported in part by NIH grant 5R01 ES004849 to K.S.R.

PS 2002 AN LC-MS/MS BASED METHOD TO QUANTIFY N^6-FORMYLATION OF LYSINE, A PATHOLOGICAL SECONDARY MODIFICATION OF HISTONE PROTEINS.

B. Edrissi[1], K. Taghizadeh[2] and P. Dedon[1, 2]. [1]*Biological Engineering, MIT, Cambridge, MA and* [2]*Center for Environmental Health Sciences, MIT, Cambridge, MA.*

DNA oxidation by endogenous and exogenous agents affects both base and sugar moieties of DNA, with the latter leading to formation of reactive electrophiles capable of forming adducts with neighboring nucleobases and proteins. We recently discovered an abundant endogenous modification of histones, N^6-formylation of lysine, that arises by transfer of the formyl moiety from a 3'-formylphosphate residue (a product of 5'-oxidation of deoxyribose in DNA). This adduct is a chemical analog of lysine N-acetylation that has important regulatory roles in gene expression. On the basis of this evidence, we aim to characterize N^6-formylation in terms of abundance and locality and investigate its possible role in interfering with acetylation signaling in cells. We now present an ultrasensitive and specific LC-MS/MS based method for quantifying N^6-formyl-lysine residues and report its application for measuring the adduct in different classes of histones and in response to various DNA oxidizing agents. N-formylation of lysine in histones may be an important epigenetic determinant of gene expression.

PS 2003 MOLECULAR MECHANISM OF BENZO[A]PYRENE-INDUCED GENETIC AND EPIGENETIC DAMAGES IN MAMMARY GLANDS.

Y. Lee, H. KIM, T. Kim, E. Lee and N. Patra. *College of Pharmacy, Pusan National University, PUSAN, Korea, South.*

Polycyclic aromatic hydrocarbons, such as benzo[a]pyrene (B[a]P), are known mammary carcinogens in rodents and may be involved in the ethological factor of human breast cancer. In this study, time and concentration-dependent gene expression profiling induced by B[a]P exposure were assessed to investigate the novel genes/pathways involved in the cellular response to B[a]P. To examine the precise mechanism for genetic alterations, we measured BPDE-I-protein adduct and oxidative DNA damage (8-OHdG) in the mammary glands. Taken together, expression levels of several genes involved in cell proliferation, cell cycle regulation and apoptotic cell death pathway were measured in mammary tissues. Moreover, it is not known whether B[a]P play any role in the methylation or demethylation of these genes. Using methylation specific RT-PCR methods, CpG island hypermethylation and histone H1 expression levels are also measured in mammary tissues. As expected, significant time- and concentration-dependent alteration in genetic biomarkers (BPDE-I-protein adduct and 8-OHdG) were observed in mammary tissues of ICR mice. B[a]P significantly inhibited the development of mammary glands following acute exposure of B[a]P with high dose. Expression changes of genes observed in this study were identified as xenobiotic metabolism, cell cycle regulation, apoptosis and chromatin remodeling. The recovery of gene expression identified in mammary glands is likely to be associated with levels of DNA damage because these genes expression occurred only after B[a]P exposure with the lower concentration. These results are relevant to biomarker screening approaches involving environmental exposures in which DNA adduct formation at specific tissues and compromise the correct identification of epigenetically responsive genes.

PS 2004 BIOLUMINESCENT BACTERIA AS BIOSENSORS FOR POLYCYCLIC AROMATIC HYDROCARBONS.

V. De La Rosa and W. Lee. *University of Texas at El Paso, El Paso, TX.*

Polycyclic aromatic hydrocarbons (PAH) are a group of carcinogenic persistent organic pollutants that are products of incomplete combustion reactions. Their toxicity is of concern to human health due to their bioaccumulation in the food chain and persistence in the environment. Current research is focused on developing highly sensitive analytical techniques to detect PAHs in the environment. It has been previously shown that bioluminescent bacteria serve as adequate biosensors for different contaminants. The goal of this project is to determine if bioluminescent bacteria can be used as an inexpensive, fast and highly sensitive biosensor for specific PAHs. In this study, a bioluminescent bacterium was exposed to four different PAHs at various concentrations to determine sensitivity and EC_{50}. Luminescence intensity was analyzed to measure sensitivity using a Luminoskan. Preliminary kinetic results show the decay of luminosity for most concentrations are likely to be 2nd order reactions and dosage response curves suggest a decrease in luminosity as PAH concentration increases. Future directions include reporting the EC_{50} for benzo[a]pyrene, phenanthrene, acetylanthracene and pyrene and a comparison of sensitivity among different bioluminescent strains. These results will be used to investigate the possible use of bioluminescent bacteria as biosensors for specific PAHs in the environment.

PS 2005 PERFLUORINATED CHEMICALS IN MUNICIPAL DRINKING WATER FROM CATALONIA, SPAIN: PUBLIC HEALTH IMPLICATIONS.

J. L. Domingo[1], I. Ericson[2], N. Ferre-Huguet[1], M. Nadal[1], B. van Bavel[2] and G. Lindström[2]. [1]*Toxicology, Rovira i Virgili University, Reus, Spain and* [2]*MTM Research Center, Örebro University, √ñrebro, Sweden.*

Perfluorinated chemicals (PFCs) are used in a wide variety of consumer products. Due to their persistence and bioaccumulative properties they are taken up by the general population from different sources. In this study, we analyzed (UPLC-MS/MS) the concentrations of 13 PFCs (PFBuS, PFHxS, PFOS, THPFOS, PFHxA, PFHpA, PFOA, PFNA, PFDA, PFUnDA, PFDoDA, PFTDA and PFOSA) in municipal drinking water samples collected from 40 different locations in Catalonia Spain. Detection limits ranged between 0.02 (PFHxS) and 0.85 ng/L (PFOA). PFHxS and PFOS were detected in 35 samples, with maximum concentrations of 5.30 and 58.1 ng/L, respectively, found in sample No. 14 collected near Barcelona City. PFBuS, PFHxA and PFOA were also frequently detected (31, 28 and 26 samples, respectively), with maximum levels of 69.4, 8.55 and 57.4 ng/L. However, PFDoDA and PFTDA could not be detected in any sample. The most contaminated samples were No. 6, 9 and 14 (Barcelona Province), with 11 compounds detected. In contrast, not any of the analyzed PFCs could be detected in samples No. 19 (Banyoles) and 22 (Lleida), while only one PFC was found in samples No. 5, 18, 30 and 37. Although currently there is no drinking water quality criteria established for PFCs in the European Union, recently the European Safety Authority established TDIs for PFOS and PFOA: 150 and 1,500 ng/kg/day, resepectively. Assuming a human water consumption of 2 L/day, the maximum daily intakes of PFOS and PFOA from municipal drinking water would be, for a subject of 60-kg b.wt., 1.94 and 1.91 ng/kg/day, values clearly lower than their TDIs. All PFOS and PFOA levels were also lower that the values of 1,000 ng PFOS/L (DWHA) and 500 ng PFOA/L (US EPA) potentially used for guidance purposes. Although PFOS and PFOA concentrations found in drinking water in Catalonia are not expected to pose health risks, safety limits for exposure to the remaining PFCs are clearly necessary.

PS 2006 PERFLUOROOCTANESULFONATE (PFOS) INCREASES DE NOVO TESTOSTERONE SYNTHESIS IN JUVENILE XENOPUS (SILURANA) TROPICALIS GONADS.

D. J. Fort[1], R. L. Rogers[1], P. D. Guiney[2] and J. A. Weeks[2]. [1]*Fort Environmental Laboratories, Stillwater, OK and* [2]*S.C. Johnson & Son, Racine, WI.*

The impact of the perfluorochemical, perfluorooctanesulfonate (PFOS), on gonadal steroidogenesis during sexual differentiation in Xenopus tropicalis was examined because of its ubiquity in the environment, bioaccumulative nature, and potential to disturb endocrine activity. In previous studies, exposure of Xenopus tropicalis to PFOS during development increased the proportion of phenotypic males, decreased mean plasma E2 levels, and increased mean plasma DHT levels compared to controls. Further, mean gonadal aromatase activity in X. tropicalis exposed to PFOS was decreased, but mean 5α-reductase and CYP17 activities were increased compared to control frogs. To further examine the apparent anti-estrogenic effects of PFOS, de novo testosterone synthesis in differentiating gonads was evaluated. Samples from the gonads were collected for testosterone synthesis measurement from juvenile control specimens and organisms exposed to PFOS (control, 0.05, 0.12, 0.29, 0.62, and 1.1 mg PFOS/L) from early embryo through metamorphosis. Increased testosterone synthesis was found in X. tropicalis exposed to 0.62 and 1.1 mg/L PFOS treatments compared to the control. Overall, the increase in testosterone synthesis was concentration-dependent. The increase in the proportion of phenotypic male frogs in our previous studies historically appears to be the result of reduced aromatase, increased 5α-reductase and CYP17 activities, and increased testosterone synthesis resulting from PFOS exposure. Overall, these results demonstrate the anti-estrogenic effects of PFOS in X. tropicalis.

PS 2007 CROSS-SPECIES GC-MS-BASED METABOLOMIC ANALYSIS OF HEPATIC LIPID COMPOSITION IN TCDD-TREATED C57BL/6 MICE AND SPRAGUE-DAWLEY RATS.

B. D. Mets[1, 2], L. D. Burgoon[1, 2], M. M. Angrish[1, 2], D. R. Boverhof[1, 2], A. Jones[1, 3] and T. R. Zacharewski[1, 2]. [1]*Biochemistry and Molecular Biology and Center for Integrative Toxicology, Michigan State University, East Lansing, MI,* [2]*National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI and* [3]*Chemistry, Michigan State University, East Lansing, MI.*

Mice and rats exhibit different genomic and phenotypic responses to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), including mouse-specific steatohepatitis. To investigate changes in lipid composition and gene expression, livers from immature,

ovariectomized C57BL/6 mice and Sprague Dawley rats were harvested 2, 4, 8, 12, 18, 24, 72 and 168 hrs following gavage with 30 μg/kg or 10 μg/kg TCDD, respectively. Fatty acid methyl esters derivatives from 24 and 72 hr treated liver lipid extracts were profiled by gas chromatography-mass spectrometry (GC-MS). Significant increases in unsaturated fatty acids (16:1n7, 18:1n9, 20:1n9, 18:2n6, 20:2n6, 18:3n3 at 24 and 72 hrs; 24:1n15 and 20:3n6 at 72 hrs) were detected in mice, while only 20 carbon fatty acids (20:1n9 at 24 and 72 hrs, 20:2n6 and 20:3n6 at 72 hrs) in rats. Quantitative real-time (QRT) PCR of lipid metabolism genes found Elovl6, Fads1, Fas, Vldlr were differentially regulated in the mouse, but not in the rat. Elovl5, a fatty acid elongase, exhibited a different expression profile in mouse compared to the rat. In addition, Scd1, a fatty acid desaturase was only induced in the rat. The late induction of these genes suggests a compensatory mechanism of gene regulation rather than direct AhR regulation, although putative dioxin response elements (DREs) were identified in the regulatory region as determined using computational searches and a position weight matrix derived from bona fide DREs. Collectively, these results suggest that species-specific changes in lipid metabolism and transport genes may be an important factor in the induction of steatohepatitis in mice. This work was supported by NIH/NIEHS grant R01ES013927.

PS 2008 CONCURRENT EXPOSURE OF PREGNANT MICE TO PFOS AND RESTRAINT STRESS: EFFECTS ON CORTICOSTERONE LEVELS IN THE OFFSPRING.

D. Ribes[1, 2], M. Torrente[1, 2], S. Fuentes[1, 2], M. Colomina[1, 2] and J. L. Domingo[1].
[1]Toxicology, Rovira i Virgili University, Reus, Spain and [2]CRAMC-Psychology, Rovira i Virgili University, Tarragona, Spain.

Stress can enhance the developmental toxicity of certain chemicals. Perfluorooctane sulfonate (PFOS), an organic persistent pollutant, is present in human tissues and wildlife samples on a global scale. Although prenatal PFOS exposure can cause developmental adverse effects, disruptive PFOS disorders on hormonal systems are still controversial. Nowadays, no studies concerning the effects of PFOS on stress response and plasma corticosterone levels have been reported. The aim of the present study was to assess the combined effects of maternal restraint stress and PFOS on HPA axis function in the offspring of mice. Twenty plug-positive females were divided in two groups. Animals received po 0 and 6 mg PFOS/kg/day on gestation days 12-18. One-half of the animals in each group were subjected to restraint stress (30 min/session, 3 sessions /day) during the same period. Five plug-positive females were also included as non-manipulated controls. At 3 months of age, the stress response was evaluated in the offspring by exposure to 30 min of restraint. Males and females were sacrificed to collect blood samples for the following purposes: to obtain levels of plasma corticosterone before stress exposure, immediately after 30 min of stress exposure, and recovery levels at 30 and 90 min after stress exposure. Corticosterone levels were lower in prenatally mice exposed to restraint. PFOS exposure diminished corticosterone concentrations in response to stress. However, this effect was only significant in females. The recovery pattern of corticosterone levels was mainly affected by prenatal stress. Interactive effects between PFOS and maternal stress were sex dependent. The current results suggest that prenatal PFOS exposure induced long lasting endocrine effects in female mice.

PS 2009 DEVELOPMENTAL TOXICITY OF PERFLUORONONANOIC ACID IN THE MOUSE.

C. Lau[1], K. P. Das[1], K. Tatum[2], D. Zehr[1], C. R. Wood[1] and M. B. Rosen[1].
[1]Reproductive Toxicology Division, NHEERL, ORD, U.S. Environmental Protection Agency, Research Triangle Park, NC and [2]Toxicology Curriculum, University of North Carolina, Chapel Hill, NC.

Perfluorononanoic acid (PFNA) is a persistent environmental contaminant. Although its levels in the environment are lower than those of perfluorooctane sulfonate (PFOS) or perfluorooctanoic acid (PFOA), its presence in humans appears to be on the rise. Previous studies have indicated developmental toxicity of PFOS and PFOA in the laboratory rodent models, the current study examines whether similar effects are extended to PFNA. PFNA was given to timed-pregnant CD-1 mice by oral gavage daily from GD 1-17 at 1, 3, and 5 mg/kg; controls received water. Like PFOS and PFOA, PFNA did not affect maternal weight gains, number of implantations, fetal viability or fetal weight. Maternal hepatomegaly and minor delays in anatomical development of the fetus were noted. Mouse pups were born alive and survival in the 1 and 3 mg/kg PFNA groups was not different from that in controls. In contrast, 80% of neonates exposed to 5 mg/kg PFNA died in the first 10 days of life. However, PFNA-induced neonatal death differed somewhat from that induced by PFOS or PFOA, in that pups exposed to PFNA survived a few days longer than those exposed to PFOS or PFOA, which typically died within the first 2-3 days of postnatal life. Surviving neonates exposed to PFNA exhibited dose-dependent deficits in growth and development (eye-opening, onset of puberty). In addition, increased liver weight seen in PFNA-exposed offspring persisted into adulthood and was likely related to the persistence of the chemical in the tissue. Evaluation of gene expression in fetal and neonatal livers revealed robust activation of peroxisome proliferator-activated receptor-alpha (PPARα) molecular signals by PFNA that resembled the response of PFOA. Our results indicate similar developmental toxicity between PFNA and PFOA, and suggest that these effects are common to perfluoroalkyl acids that persist in the body. This abstract does not necessarily reflect US EPA policy.

PS 2010 SERUM LEVELS OF DIOXIN AND DIOXIN-LIKE COMPOUNDS IN WOMEN LIVING IN A HIGHLY INDUSTRIALIZED AREA OF WEST VIRGINIA.

J. J. Diliberto[1], J. Becker[2], D. Jude[2], L. Sirinek[3], D. G. Patterson[4], W. Turner[4], R. Landy[5], T. Hughes[1], D. Staats[3] and L. S. Birnbaum[6]. *[1]NHEERL/ORD, U.S. EPA, RTP, NC, [2]Marshall University Medical Center, Huntington, WV, [3]WVDEP, Wheeling, WV, [4]CDC, Atlanta, GA, [5]ESC, U.S. EPA, Ft. Meade, MD and [6]NCEA/ORD, U.S. EPA, RTP, NC.*

Historical releases of dioxin and dioxin-like constituents with subsequent impacts to environmental media in the Kanawha River Valley (KV) of West Virginia have been well documented. This study evaluated the impact of potentially high background dioxin exposure to body burdens in women of reproductive age (ranging from 25 to 46) and living in or near KV. This cohort of women was derived from a larger study investigating the relationship between the women's dioxin levels and endometriosis. The study was conducted at Marshall University and all relevant procedures were performed under Marshall's IRB in accordance with 45 CFR 46.110(A)(8)(a). Serum was analyzed by high-resolution gas chromatography/isotope-dilution high-resolution mass spectrometry for dioxin and dioxin-like compounds. Results were reported on a whole-weight and lipid-adjusted basis and as international toxicity equivalents (WHO2005 TEQs). The major constituents of the total serum TEQ were 1,2,3,7,8-pentachlorodibenzo-p-dioxin (PCDD); 1,2,3,6,7,8-HxCDD; PCB126; 2,3,7,8-TCDD; 2,3,4,7,8-pentachlorodibenzofuran (PCDF); 1,2,3,4,7,8-HxCDF; and 1,2,3,4,6,7,8-HpCDD. The TEQ min/max and median/mean based on pg/g lipid were PCDD (0.22/9 & 3.5/3.22); HxCDD (5.2/45.8 & 22/21.5); PCB126 (3.8/67 & 12/14.5); TCDD (0.18/6.7 & 1/1.11); PCDF (0.25/10 & 3.4/3.65); HxCDF (1.3/9.3 & 3.2/3.54); and HpCDD (7/110 & 25/29), respectively. This study demonstrates that body burdens of these compounds in this age group of women are similar to levels recently reported in the general United States population and that living in an area of high levels of contamination is not necessarily reflected in the body burden for this class of chemicals. This abstract does not reflect USEPA policy.

PS 2011 GENE PROFILING IN WILD-TYPE AND PPARα-NULL MICE EXPOSED TO PERFLUOROOCTANE SULFONATE.

M. Rosen[1], J. Corton[2], J. Schmid[1], R. Zehr[1], K. Das[1], H. Ren[2], B. Abbott[1] and C. Lau[1]. *[1]Reproductive Toxicology, U.S. EPA, Research Triangle Park, NC and [2]Environmental Carcinogenesis, U.S. EPA, Research Triangle Park, NC.*

Perfluorooctane sulfonate (PFOS), a perfluoroalkyl acid (PFAA), is a persistent environmental contaminant found in the tissues of humans and wildlife. Health concerns have been raised over the last decade,in part, because of the long half-life of PFOS and other PFAAs in humans, although serum levels of PFOS have begun to decrease since its phase out in 2002 by its major manufacturer. PFOS is a weak activator of peroxisome proliferator-activated receptor-alpha (PPARα) and exhibits hepatocarcinogenic potential in rats. PFOS is also a developmental toxicant in rodents, where differences have been observed between its mode of action and that of perfluorooctanoic acid (PFOA), a related PFAA. Wild-type (WT) and PPARα-null (KO) mice were dosed by oral gavage with PFOS (3 or 10 mg/kg/day), or vehicle for 7 days. Animals were euthanized, livers weighed, and liver samples collected for preparation of total RNA. Gene profiling was conducted on 5 mice per group using Affymetrix 430_2 GeneChips. In WT mice, PFOS induced changes characteristic of PPARα activation including regulation of genes associated with fatty acid metabolism, peroxisome biosynthesis, and proteasome biogenesis. The expression of PPARα marker genes such as Cyp4a14, Ehhadh, and Pdk4 was up-regulated. In KO mice, PFOS altered the expression of a subset of genes related to lipid metabolism and, in contrast to data previously evaluated for PFOA, induced unique changes to genes associated with oxidative phosphorylation/electron transport and cholesterol biosynthesis. The constitutive androstane receptor (CAR) marker gene, Cyp2b10, was up-regulated across all treatment groups while Cyp7a1, a gene known to be regulated by liver X receptor (LXR) and retinoid X receptor (RXR), was up-regulated only in KO mice. These data suggest that PFOS may have the potential to activate nuclear receptors other than PPARα, such as CAR, LXR, or RXRα. This abstract does not necessarily reflect EPA policy.

PS 2012 PCB47: MORE THAN A CONSTITUTIVE ANDROSTANE RECEPTOR AGONIST.

B. Wang[1], K. Wang[3], I. K. Lai[1], L. W. Robertson[1, 2] and G. Ludewig[1, 2]. [1]*Human Toxicology, the University of Iowa, Iowa City, IA,* [2]*Occupational and Environmental Health, the University of Iowa, Iowa City, IA and* [3]*Biostatistics, the University of Iowa, Iowa City, IA.*

PCBs are persistent organic pollutants that were once widely applied industrially until their production was banned in the 1970s. PCB47 (2,2',4,4'-tetrachlorobiphenyl) is a substantial constituent of former commercial PCB mixtures and has recently been reported to be present in Chicago air. Because of its ortho-para-chlorination pattern, PCB47 is expected to exert toxicity through activation of the nuclear receptor CAR. However, few studies have been carried out to test this. The objective of this study was to compare the global gene expression in PCB47-treated rats with classical inducers-treated ones to explore the mechanisms of PCB47 toxicity. Sprague Dawley rats received short-term ip exposure to corn oil, phenobarbital (PB), 3-methylcholanthrene, β-naphthoflavone, dexamethasone, and PCB47. Liver RNA was extracted, pooled in each group and hybridized against a reference on Agilent 4 × 44 K whole rat genome oligo microarray. Principle component analysis and hierarchical clustering revealed that the gene expression of PCB47-treated male rats most closely resembled that of PB-treated males, while PCB47-treated females strongly differed from all other groups and the number of differentially expressed genes in PCB47-treated females was much higher than in PCB47-treated males and PB-treated males or females. Although both PCB47 and PB induced CYP2B genes, CYP2B1 and CYP2B2 were much more induced in females. Enzyme activity assays confirmed the induction, but with the opposite gender difference and much higher fold inductions. Functional classification reveled that only PCB47 up-regulated cell adhesion-related genes and down-regulated blood pressure and S1P signaling pathway related genes. In conclusion, this study suggests that PCB47 exerts its toxicity through both CAR-dependent and CAR-independent mechanisms and female rats show much stronger and differing effects on expression level than males. PS 2013 INDUCTION OF OXIDATIVE STRESS AND APOPTOSIS IN MOUSE CEREBELLAR GRANULE NEURONS BY VARIOUS PBDE CONGENERS.

S. C. Huang[1], G. Giordano[1] and L. G. Costa[1, 2]. [1]*Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA and* [2]*Department of Human Anatomy, Pharmacology and Forensic Science, University of Parma Medical School, Parma, Italy.*

Polybrominated diphenyl ether (PBDE) flame retardants have become widespread environmental contaminants. Exposure is believed to occur primarily through diet and dust. The ability of PBDEs to cause apoptotic cell death has been reported in various cell types including cerebellar granule cells, human astrocytoma cells, neuroblastoma cells and liver hematopoietic cells. Although the mechanisms involved in PBDE-induced apoptosis have not been fully understood, they are most likely related to oxidative stress and may involve the mitochondrial pathway. Aims of the present study were to compare the ability of commonly found PBDE congeners (the tetrabromodiphenyl ether 47, the pentabromodiphenyl ethers 99 and 100, the hexabromodiphenyl ether 153, and decabromodiphenyl ether 209) to induce oxidative stress-mediated apoptosis in mouse cerebellar granule cells. All congeners (except BDE-209) caused a concentration-dependent cell death (as assessed by MTT assay), which could be mostly ascribed to apoptosis (as assessed by Hoechst staining); they also increased formation of reactive oxygen species (as measured using dichlorofluorescein), and of lipid peroxidation (assessed measuring malondialdehyde levels). Comparison of tetra- and penta-brominated congeners indicated that BDE-100, which has the highest number of ortho bromines, was the most effective in causing apoptosis and oxidative stress, followed by BDE-47 and BDE-99 which appeared to have similar potency and efficacy. In contrast, BDE-209 was almost ineffective in inducing apoptosis and oxidative stress, probably due to its higher hydrophobicity which generally increases with the number of bromines. These findings suggest that PBDEs caused oxidative stress-mediated apoptotic cell death in mouse cerebellar granule neurons and that ortho-substituted congeners appear to be more toxic. (Supp. in part by P30ES07033).

PS 2014 ACTIVATION OF MITOCHONDRIAL TRANSCRIPTION IN THE LIVER OF PFOA TREATED RATS.

M. Walters, J. A. Bjork and K. B. Wallace. *Biochemistry and Molecular Biology, University of Minnesota Medical School, Duluth, MN.*

Perfluorooctanoic acid (PFOA) is a breakdown product of industrial surface-active compounds that has been identified in human and animal blood and tissues globally. In rodents, PFOA disrupts oxidative phosphorylation (OXPHOS) and activates the nuclear receptor peroxisome proliferator- activated receptor (PPAR) isoforms α and γ. PPARγ coactivator-1α (PGC-1α) is an upstream regulator of mitochondrial biogenesis and transcription of mitochondrial DNA (mtDNA). The goal of this study was to determine whether PFOA stimulates PGC-1α mediated mitochondrial biogenesis and transcription of mtDNA. Male Sprague-Dawley rats were administered PFOA at 30 mg/kg/day for 28 days and livers were harvested for mRNA and protein analysis. Gene transcription was quantified by real time PCR, and Western blot analysis was used to quantify protein. PFOA treatment caused a preferential stimulation of transcription of mitochondrial encoded genes. Associated with this was an increase in mtDNA copy number and stimulated transcription of the PGC-1α pathway, including PGC-1α and mitochondrial transcription factor A (Tfam). In contrast, protein expression for PGC-1α and Tfam were unchanged and Cox IV protein was reduced by PFOA treatment. We conclude that, in rats, PFOA treatment results in the transcriptional activation of the PGC-1α pathway, an increase in mtDNA replication, and preferential stimulation of transcription of mtDNA. These observations are consistent with a PPAR-mediated stimulation of mitochondrial biogenesis. (Supported by the 3M Co.)

PS 2015 HUMAN ORGANIC ANION TRANSPORTING POLYPEPTIDE 1B1- AND 1B3-MEDIATED UPTAKE OF A PREDOMINANT POLYBROMINATED DIPHENYL CONGENER, BDE 47.

E. Pacyniak, B. Hagenbuch and G. L. Guo. *Pharmacology, Toxicology & Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Polybrominated diphenyl ethers (PBDEs) are chemical additives serving as flame retardants found in a variety of manufactured goods. PBDEs are ubiquitously detected in the environment and are considered to be persistent and bioaccumulative. 2,2`,4,4`-tetrabromodiphenyl ether (BDE47, MW 485.8) is the predominant congener detected in human and wildlife samples. Although associated health risks to humans are currently not clear, numerous studies report neurological, reproductive and developmental toxicities as well as endocrine disruption upon BDE47 exposure in rodent models. Following exposure, BDE47 highly accumulates in the liver. We have shown that BDE47 activates the hepatic xenobiotic nuclear receptors PXR and CAR to induce Phase I and II metabolizing enzymes. Mechanisms by which PBDEs enter the liver have yet to be elucidated. Human organic anion transporting polypeptides (OATPs) are polyspecific organic anion transporters mediating uptake of numerous drugs and chemicals. Given that their substrates are in general amphipathic molecules with molecular weights of more than 350, the liver specific OATP1B1 and 1B3 are promising candidate transport systems for BDE47 uptake. Therefore, we tested the hypothesis that BDE47 is transported by OATP1B1 and 1B3. To test this hypothesis, we used Chinese Hamster Ovary (CHO) cell lines stably expressing OATP1B1 or 1B3 and determined uptake of radiolabeled BDE47. The results showed that BDE47 was transported by both, OATP1B1 and 1B3. Furthermore, we performed a detailed kinetic analysis and determined that OATP1B1 and 1B3 transported BDE47 with Km values of 251 and 389 nM respectively, and with Vmax values of 28.4 and 2.3 pmol/mg protein x min, respectively. The current study demonstrates that BDE47 is transported by OATP1B1 and 1B3. Based on the kinetic data we conclude that OATP1B1 has an approximately 20 fold higher capacity to mediate BDE47 uptake. Our results should help in better understanding the mechanism for the liver-specific accumulation of BDE47.

PS 2016 IN VITRO STUDY OF THE AIR DELIVERY OF PARTICLE-BOUND PBDES TO LUNG CELLS.

J. Kim[1], G. Luthe[1, 2], S. Flor[2], J. Klösener[2], T. M. Peters[2], L. W. Robertson[1, 2], P. S. Thorne[1, 2] and G. Ludewig[1, 2]. [1]*Interdisciplinary Graduate Program in Human Toxicology, The University of Iowa, Iowa City, IA and* [2]*Department of Occupational and Environmental Health, The University of Iowa, Iowa City, IA.*

Polybrominated diphenyl ether (PBDE) exposure is thought to occur primarily *via* inhalation of particles and dust-bound PBDEs. However, few studies have examined the effects of particle-bound PBDEs on human health. We hypothesized that human lung cells exposed *in vitro* to airborne PBDE-bound particles would produce intracellular reactive oxygen species (ROS) and undergo cytotoxicity. Our *in vitro* exposure model for particle-bound PBDEs consisted of silica particles coated with individual PBDE congeners (BDE 35, 47, and 99) and a dry powder sprayer connected to an exposure chamber holding Transwell® inserts. To validate and characterize the exposure system, the size, morphology, and spatial variability of particles were determined by scanning electron microscopy and image analysis. Cytotoxicity and intracellular ROS in human epithelial lung carcinoma cells (A549 and NCI-H358) were used to evaluate the biological effects of particle-bound PBDEs. The silica particles and particles coated with PBDEs were discrete spheres with no apparent particle aggregation. The particles were observed to be evenly de-

posited over the Transwell. We found a strong positive correlation between particle loading mass and particle number (R^2=0.97). Twenty four hours after airborne exposure to particles, no significant cytotoxicity was observed in any experiment. However, a statistically significant (p<0.05) increase in intracellular ROS was observed with 46 μg/cm^2 exposure to BDE 35 particles in both NCI-H358 and A549 cells and 29 μg/cm^2 exposure to BDE 35 and BDE 47 particles in A549 cells. These results demonstrate the reproducibility and sensitivity of this *in vitro* exposure system for application of particle-bound test compounds to cells and its potential for studying the toxic effects of inhaled particles. (Supported by NIH P42 ES013661 and P30 ES05605)

PS 2017 DOES DIETARY SELENIUM INFLUENCE THE EFFECTS OF PCB126 ON RAT PARAOXONASE 1?

H. Shen[1, 2], I. Lai[1, 2], L. W. Robertson[1, 2] and G. Ludewig[1, 2]. [1]*Interdisciplinary Graduate Program in Human Toxicology, Univesity of Iowa, Iowa City, IA and* [2]*Occupational & Environmental Health, University of Iowa, Iowa City, IA.*

Paraoxonase 1 (PON1), an antioxidant enzyme, is synthesized in the liver and secreted into the blood where it is associated with HDL and protects LDL against lipid peroxidation, a major risk factor in atherosclerosis. Our previous studies with rats showed that short term exposure to various PCB congeners significantly (up to 54%) reduced PON1 activities in serum/plasma and liver microsomes. This study was to analyze the effects of PCB126 on PON1 activity and whether selenium (Se), an antioxidant, can mitigate such effects. Male Sprague-Dawley rats, fed a Se-deficient (0.02ppm), adequate (0.2ppm), or supplemented (2ppm) diet for 3 weeks, were injected ip with PCB126 (a single injection of 0.2, 1, or 5 μmol/kg), and euthanized 2 weeks later. Serum and liver microsomal PON1 activities were measured spectrophotometrically using two substrates, paraoxon and phenylacetate. Dietary Se levels had no effect on serum PON1 activities, but seemed inversely related to liver microsomal PON1 activities. PCB126 significantly increased in a dose-dependent manner serum and liver microsomal PON1 activities within each Se-diet group, with the exception of a slight reduction of liver microsomal PON1 activity with high dose (5 μmol/kg) compared to the medium dose (1 μmol/kg) in Se-adequate and Se-supplemented rats. Thus our preliminary findings suggest a compensation for low levels of one antioxidant (Se) by an increase of another one (PON1) and that a single exposure to a very low dose of PCB126 may increase PON1 activity, possibly as a protective mechanism. Time and extended dose studies as well as lipid peroxidation determinations are needed to evaluate whether this protective effect of increased PON1 activity is maintained and sufficient to mitigate the oxidative damage caused by PCB126, thereby reducing the risk of cardiovascular and other diseases by this and possibly other ubiquitous contaminants. (Supported by NIEHS P42 ES013661 and DOD DAMD17-02-1-0241)

PS 2018 "POLYCHLORINATED BIPHENYLS (PCBs) AND POLYBROMINATED DIPHENYL ETHERS (PBDES) ARE INHIBITORS OF THE BREAST CANCER RESISTANCE PROTEIN (ABCG2) TRANSPORTER"

K. D. Christy[1], A. Manzella[1], M. Morris[2] and J. Olson[1]. [1]*Pharmacology and Toxicology, University at Buffalo, Buffalo, NY and* [2]*Pharmaceutical Sciences, University at Buffalo, Buffalo, NY.*

PCBs and PBDEs are structurally similar persistent contaminants that elicit a variety of biological and toxicological responses. ABCG2 is a novel 72 kDa protein that is expressed largely in the organs responsible for absorption and elimination of xenobiotics and plays a role in drug disposition and drug resistance (Koshiba 2008). MCF7/MX100 cells which specifically over express ABCG2 were used to assess the impact that in vitro exposure to PCBs and PBDEs have on the transporters ability to efflux a specific substrate of ABCG2, mitoxantrone. Flow cytometry was used to quantify the accumulation of mitoxantrone within the cells after exposure to a given PCB or PBDE, and compared that to the mitoxantrone level in control cells and cells exposed to 7, 8-benzoflavone, a specific inhibitor of ABCG2. Exposure to PCB 47 (2,2',4,4') at 0.1, 1.0, 5.0, 10, 25 and 50 μM produced a 1.4, 2.0, 4.7, 6.0, 7.1 and 7.5 – fold increase in the respective concentrations of mitoxantrone. Similarly, exposure to PBDE 47 (2,2',4,4') at 0.1, 1.0, 5.0, 10, and 25 μM produced a 1.2, 1.9, 2.7, 3.2, and 3.7-fold increase in the respective mitoxantrone levels. PCB 47 and PBDE 47 have IC50 values of 3.39 and 8.05 μM, respectively, suggesting that PCB 47 is a more potent and active inhibitor of ABCG2. In vitro exposure to other PCBs and PBDEs, inhibit to a variable extent the efflux transport of mitoxantrone and suggests that these compounds exhibit congener-specificity as inhibitors of ABCG2. The results of this study provide new insights into the effect that these compounds play on the inhibition of the ABCG2 drug transporter, which may in turn alter the disposition and excretion of xenobiotics. Future studies will also be assessing whether these compounds are also substrates for the ABCG2 transporter.

PS 2019 DIETARY EXPOSURE TO PBDES FROM A SUBSISTENCE DIET: FIRST NATIONS OF THE HUDSON BAY LOWLANDS, CANADA.

E. N. Liberda[1, 2], B. C. Wainman[3], I. Martin[1], A. LeBlanc[4] and L. J. Tsuji[1]. [1]*Environmental Resources, University of Waterloo, Waterloo, ON, Canada,* [2]*Environmental Medicine, New York University, New York, NY,* [3]*Obstetrics and Gynecology, McMaster University, Hamilton, ON, Canada and* [4]*Centre de Toxicologie de Quebec, Institut national de santé publique du Québec, Quebec City, QC, Canada.*

Introduction: Concerns regarding the persistence, bioaccumulation, long-range transport, and adverse health effects of polybrominated dipheyl ethers (PBDEs) have recently come to light. PBDEs may potentially be of concern to First Nations (indigenous) peoples of Canada who subsist on traditional foods, however there is a paucity of information on this topic. Methods: To investigate whether the traditional diet is a major source of PBDEs in sub-Arctic First Nations populations of the Hudson Bay Lowlands (James and Hudson Bay),Ontario, Canada, a variety of tissues from wild game and fish were analyzed for PBDE content (n=147) and dietary exposure assessed and compared to the US EPA RfDs. In addition, to examine the effect of isolation/industrialization on PBDE body burden, the blood plasma from three First Nations (Cree Nation of Oujé-Bougoumou, Quebec; Fort Albany First Nation, Ontario; and Weenusk First Nation [Peawanuck], Ontario, Canada) were collected (n=54) and analyzed using a log-linear contingency model. Results and Conclusions: The mean values of PBDEs in wild meats and fish adjusted for standard consumption values and body weight, did not exceed the US EPA RfD. However, maximum values for certain species did exceed RfD values and potentially pose a threat to small children or those who would consume several portions of meat a day. Log linear modeling of the human PBDE body burden showed that PBDE body burden increases as access to goods increases. Thus, household dust from material goods containing PBDEs is likely responsible for the human exposure; the traditional diet appears to be a minor source of PBDEs.

PS 2020 FISH INTAKE AND POPS CONCENTRATIONS IN HUMAN MILK IN COASTAL CITIES IN CHINA.

F. Kayama[2], J. Leng[1, 2], P. Wang[3], M. Nakamura[4], T. Nakata[4] and Y. Wang[1]. [1]*Department of Child, Adolescent and Women's Health, School of Public Health, Peking University, Beijing, China,* [2]*Environmental Medicine, Jichi Medical University, Shimotsuke, Tochigi, Japan,* [3]*Department of Social Medicine and Health Education, School of Public Health, Peking University, Beijing, China and* [4]*Chemical Research Section, Hiyoshi Corporation, Omihachiman, Shiga, Japan.* Sponsor: M. Denison.

In 2006-2007, we collected 60 and 48 donors of human milk in two coastal cities, Tianjin and Yantai, respectively, in China, in accordance with the WHO/UNEP global milk survey. We determined the concentrations of organochlorine pesticides by GC/MS/MS and doxins by XDS-CALUX bioassay in the individual milk specimen collected. Geometric mean concentrations ofβ-HCH:586.7 ng/g fat, total DDTs:855.9 ng/g fat and dl-PCBs:4.4 pg TEQ/g fat in the milk from Yantai were higher than those from Tianjin 254.4 ng/g fat, 654.7 ng/g fat, 1.9 pgTEQ/g fat, respectively. However, GM of HCB 41.1 ng/g fat and PCDD/Fs 13.1 pgTEQ/g fat from Tianjin were higher than those from Yantai: 15.7 ng/g fat, 9.9 pgTEQ /g fat. The low ratios of DDT/(DDE+DDD) in milk from both areas suggested that the past exposure contributed to the body burden of total DDTs. A body burden of dl-PCBs in the high sea fish intake group (more than 917.6 g/month) was higher than that in the low intake group either with or without adjustment of potential influencing factors. For β-HCH, a marginal P value (P=0.063) was observed between high and low sea fish consumption groups after adjusting potential influencing factors. Donors in high freshwater fish group (more than 181.9 g/month) showed higher PCDD/Fs and HCB levels compared to those in the low intake group either with or without adjustments. Further monitoring studies of POPs contamination in human milk as well as in foods are needed in China.

PS 2021 SCREENING-LEVEL ASSESSMENT OF RISK ASSOCIATED WITH EXPOSURE TO PBDES IN VEHICLES.

D. Staskal[1] and L. Birnbaum[2]. [1]*ToxStrategies, Austin, TX and* [2]*NCEA, U.S. EPA, RTP, NC.*

Polybrominated diphenyl ethers (PBDEs) have received increased attention because of their presence in human tissues and the environment in combination with reports of adverse effects. Human exposure pathways are thought to be via dust ingestion primarily, followed by dietary intake and inhalation, for adults. Most recently, it has been suggested that exposure to PBDEs may be occurring in vehicles because of the use of PBDEs in automotive components such as textile backings,

electronic insulation, polyurethane foams, and plastics. In this study, a screening-level risk assessment was conducted in an effort to provide preliminary estimates of theoretical risk associated with exposure to PBDEs in vehicles. Using standard approaches for calculating intake over a lifetime and for evaluating health risk, estimates of non-carcinogenic hazard and carcinogenic risk were assessed for a variety of scenarios involving adults and children exposed to PBDEs in car dust and air. Results indicated that non-carcinogenic hazard estimates for Σtri-hexa BDEs and BDE 209 (evaluated separately) in dust were below one for both adult and child exposure scenarios; however estimates approached one for children when calculations were based on high ingestion rates combined with high-end concentrations of PBDEs. Theoretical estimates of carcinogenic risk associated with exposure to BDE 209 in car dust were below acceptable risk levels ($<10^{-6}$) for all scenarios evaluated. Estimates of hazard and cancer risk associated with air were $<10^{-4}$ and $<10^{-11}$, respectively. Though these preliminary evaluations are not representative of risk for all humans nor are they representative of risk from all types of cars worldwide, they provide an indication of human health risk associated with PBDE exposure. Further characterization of levels in cars, investigation of toxicity, as well as specific exposure variables (*e.g.,* time in cars, absorption from dust and air), will decrease uncertainty in such quantitative assessments. *This abstract does not reflect EPA policy.*

PS 2022 RESULTS OF A NEW SURVEY SHOW INCREASING LEVELS OF PBDES IN U.S. FOOD.

A. J. Schecter[1], J. A. Colacino[1], K. Kurunthachalam[2], S. Yun[2], O. Päpke[3] and L. Birnbaum[4]. [1]*Environmental Sciences, University of Texas School of Public Health, Dallas, TX,* [2]*Wadsworth Laboratory, State University of New York, Albany, NY,* [3]*Eurofins, Hamburg, Germany and* [4]*U.S. EPA, Research Triangle Park, NC.*

We report for the first time PBDE levels in 30 matched food samples from Texas, California, and New York (90 total) collected in 2008. We note no significant geographical differences in total PBDE levels. Levels in meat, dairy, eggs, oils, and bread are higher than previously reported, while levels in fish collected in 2008 are lower than in fish collected in 2003. In 2003, PBDE levels in fish were highest, while in 2008, levels in meat were highest. Median total PBDE levels in foods of animal origin (chicken breast, sausage, beef baby food) from 2008 samples are 719 pg/g wet weight (ww). The minimum PBDE level in 2008 collected meat, 305 pg/g, exceeded the median PBDE levels in 2003 collected meat, 190 pg/g. The maximum PBDE level in 2008 collected meat, 3495 pg/g, exceeded the 2003 maximum, 1426 pg/g. PBDEs in dairy foods (butter, half and half, cheese, milk based infant formula) collected in 2008 exceeded those from 2003, with a median of 419 pg/g compared to a previous median PBDE level of 32.2 pg/g. The highest levels in dairy foods were observed in cheese and butter, with all six samples having PBDE levels above 1,000 pg/g. A 20 fold increase was noted in median PBDE levels in eggs; each of the samples collected in 2008 had PBDE levels over 1,300 pg/g (range 1350 – 1975 pg/g); previous median values were 85 pg/g. PBDEs in margarine also increased from 2003 levels, with a median value of 1485 pg/g compared to levels of 88 pg/g. Fruit and vegetable PBDE levels (median 11.2 pg/g, range 2.6 – 90 pg/g, n=14) were usually lower than meat, fish, and dairy, although highest levels in vegetables overlap with lowest found in food of animal origin. Further research is needed to determine why levels in this larger 2008 survey were unexpectedly higher than previously measured in US food. This abstract has been reviewed by EPA but represents the personal views of the authors and is not Agency policy.

PS 2023 EXPOSURE BASED WAIVING : THE APPLICATION OF THE TOXICOLOGICAL THRESHOLD OF CONCERN (TTC) TO INHALATION EXPOSURE FOR AEROSOL INGREDIENTS IN CONSUMER PRODUCTS.

P. Carthew. *Unilever, Bedford, United Kingdom.* Sponsor: P. Hepburn.

With the implementation of the 7th amendment to the Cosmetic's Directive in Europe, repeat dose toxicology testing of cosmetic ingredients will longer possible after 2013, and alternative approaches to evaluating the toxicological safety of ingredients for use in aerosols needs to be developed. Exposure-based waiving refers to exemption from conducting toxicology studies when the justification for the waiving is based on the fact that there is no relevant exposure of humans and the environment. Relevant exposure is interpreted as meaning that exposure remains within acceptable burden limits, and it can be assumed that the exposure is not associated with any hazard potential for human health and the environment. If a threshold of toxicologic concern (TTC) for inhalable ingredients could be established, below which it could be confidently assumed that there was no hazard potential, then aerosols could be designed to minimise the consumer exposure to ingredients to the point where inhalation testing would not be considered necessary. Considering the publicly available inhalation toxicology study data for chemicals allows us to compile a database of toxicology NOAECs (no observable adverse effect concentrations) and NOAELs (no observable adverse effect levels) for both local and systemic adverse effects respectively, and determine an appropriate benchmark dose (5th percentile) to use in determining a safe level of exposure to an aerosol ingredient. In reviewing inhalation studies for respiratory tract and systemic effects certain types of chemicals, such as genotoxic carcinogens were excluded, as they were not considered representative of the ingredients that are, or could be used, in aerosols for consumer use. Application of an appropriate safety factor to this benchmark value of the local and systemic NOAECs and NOAELs gives an exposure threshold of toxicologic concern (TTC) for local and systemic toxic effects, below which there is no toxicology safety concern.

PS 2024 EVALUATION OF *IN VITRO* MAMMALIAN GENOTOXICITY TESTS IN THE CURRENT CONTEXT.

R. K. Elespuru[1], R. Agarwal[2], A. Atrakchi[2], C. A. Bigger[2], R. H. Heflich[4], D. Jagannath[3], D. D. Levy[5], M. M. Moore[4], Y. Ouyang[2], T. W. Robison[2], R. Sotomayor[8], M. C. Cimino[6] and K. L. Dearfield[7]. [1]*CDRH, FDA, Silver Spring, MD,* [2]*CDER, FDA, Silver Spring, MD,* [3]*CVM, FDA, Rockville, MD,* [4]*NCTR, FDA, Jefferson, AR,* [5]*CFSAN, FDA, College Park, MD,* [6]*OPPT, U.S. EPA, Washington, DC,* [7]*OPHS, USDA, Washington, DC and* [8]*Genetic Tox Reg & Training Services, (Consultant), Gaithersburg, MD.*

With the advent of new technologies, e.g. genomics, and new regulations, e.g. European REACH, the field of regulatory genetic toxicology is in a state of flux. In the context of integrating new tests, we offer an analysis of current methods for evaluating mutagenic risk using the standard genotoxicity test battery. Some regulatory contexts consider genetic damage an important endpoint on its own, while others consider genotoxicity only in the context of carcinogenicity, and rely on correlations with rodent cancer bioassays. Since there is no ideal assessment for carcinogenicity, we suggest that a focus on mechanisms may be more appropriate. We address issues related to the in vitro mammalian cell genetic toxicity assays, including test results that are weak, associated only with toxicity or high concentrations, not accompanied by positive results in other tests, and/or not correlating well with rodent carcinogenicity tests. We summarize the results of international groups evaluating new tests and suggest options for integration of new technologies, including human monitoring. We conclude that improvements in data interpretation (e.g. FDA WoE document) and protocol updates provide justification for maintaining in vitro mammalian assays in the genotoxicity test battery. Disclaimer:The views and opinions expressed are solely those of the authors and are not official policy of the affiliated institutions.

PS 2025 DEVELOPMENT OF A STRUCTURE ACTIVITY RELATIONSHIP PROCESS TO CHARACTERIZE ACUTE TOXICITY FOR GHS CLASSIFICATION.

L. M. Milchak, P. H. Lieder, P. D. Heppner and R. S. Skoglund. *3M, St Paul, MN.*

A critical health hazard endpoint in the Globally Harmonized System of Classification and Labeling of Chemicals (GHS) is acute toxicity. The GHS classification scheme allows for extrapolation of data from other non-lethal toxicity tests, as well as the use of structure-activity relationships (SAR) to derive an Acute Toxicity Estimate (ATE). For mixtures lacking an ATE for any ingredient greater than 1%, the hazard communication (MSDS, label) under GHS must include a statement indicating the percentage of the mixture consisting of ingredient(s) of "unknown toxicity." An internal process was developed to derive ATEs consistent with GHS guidance. For the chemical of interest, the process begins with collection of pertinent physical and chemical properties with applicability to toxicity, as well as collection of other non-lethal toxicity endpoint data. This data is used in conjunction with commercially available and internally developed SAR software programs to provide estimates of predicted acute toxicity and the appropriate GHS acute toxicity category. A database was created to store the results of the estimation process, a description of the estimate rationale and the output from various software programs. The database also stores chemical structural information which allows for sub-structure searching and enhances consistency of estimates by allowing direct comparison of predicted values for similar compounds. Rule sets were developed to evaluate the likely reliability of the process based on chemical structure and properties, to facilitate consistency among estimates and to exclude estimates based on anticipated uncertainty. To date, the process has been applied to over 100 chemicals and/or toxicity endpoints. The availability of ATEs developed by this process increases the quality of the hazard determinations and classifications, eliminates the need for additional hazard communication statements concerning "unknown toxicity," and reduces the need for animal testing.

2026 SURVEY METHOD FOR CHEMICAL SUPPLY CHAINS UNDER REACH.

T. Anzai[1, 2] and P. Jenkinson[3]. *[1]Harlan Japan, Tokyo, Japan, [2]School of Medicines, Showa University, Tokyo, Japan and [3]SPL UK, Harlan SPL, Shardrow, United Kingdom.*

A new law concerning chemical control, "Registration, Evaluation, Authorization, and Restriction of Chemicals" (hereinafter called REACH), entered into effect in the European Union (EU) on June 1, 2007. REACH has a great impact on the activities of corporations, not only in EU industrialized nations, but also in Japan, U.S. and other non-EU industrialized nations because the law is a registration system vastly different from those adopted thus far by Japan, the USA, and Europe, in that the scope of advanced control by manufacturers and importers of chemical substances is expanded to existing chemical substances and chemical substances in articles that are already distributed around the world. A substance undergoes many processing operations by different manufacturers before it is imported in the EU in the form of an article or a product of any kind. As a result, one of the REACH management requirements, "A non-EU manufacturer of a chemical substance is required to notify an importer of an article that includes the substances produced by the manufacturer of its registration information," may frequently require a huge amount of work to fill in complex missing links. However, the problem is not limited to only the amount of work. If a specific company within a supply chain knows the complete picture of the network, it also knows the market and distribution channels of products for many of the other companies within the network to which it has no business connections. This can pose a problem not only from the viewpoint of corporate ethics, but also of antimonopoly laws. For these reasons, manufacturers around the world are searching for effective solutions, with no fruitful results. In this research, we provide an outline of REACH and problems on a supply chain survey, propose revolutionary solutions of these problems, and discuss their effectiveness and usage.

2027 POLICY, SCIENCE, AND COMMUNICATION: PROTECTING CHILDREN FROM THE HEALTH EFFECTS OF LEAD.

S. Gilbert[1] and H. Davies[2]. *[1]INND, Seattle, WA and [2]Washington State, Departmen of Ecology, Olympia, WA.*

Increasingly sophisticated toxicological research on the health effects of lead and other chemical agents as well as direct experience provides ample knowledge that should drive policy changes that support an environment in which children can reach and maintain their full potential. Despite seemingly overwhelming scientific evidence it can be very difficult to institute meaningful policy directives. The efforts to change official policy on childhood blood lead action level provides an excellent case study of the science vs policy conflict. In 1991, CDC established the policy that recommended action if a child's blood lead exceed 10 μg/dL. The national blood lead action level of 10 μg/dL is used as a standard by physicians and public health professionals to set state and local public health policy. Child health advocates in WA State worked to educate policy makers and public health professionals that there is no safe level of lead exposure and the blood lead action level should be lowered to 2 μg/dL based overwhelming data demonstrating the neurodevelopmental effects of low level lead exposure. These efforts had several positive out comes: 1) lead was placed on the WA persistent bioaccumulative toxics list; 2) WA enacted a law with strict regulations on lead in child products (now being preempted by a less strict federal law); 3) WA Department of Ecology developed a lead chemical action plan that documents use of lead and makes recommendations on restricting the use of lead; 4) WA Department of Health worked to revise the state policy on childhood blood lead testing; and 5) submitted resolutions at the WA Public Health Association supporting a blood lead action level of 2 μg/dL. The WA lead cap provides an overview of the human health and environmental concerns about lead and recommendations for reductions in the uses and releases of lead. These efforts have encountered resistance and failures to adopt a precautionary approach to childhood lead exposure. We will examine why this resistance occurs despite scientific evidence the children are harmed a blood levels above 2 μg/dL.

2028 BACKGROUND RATES OF LYMPHOMAS/LEUKEMIAS AND LEYDIG CELL TUMORS IN SPRAGUE-DAWLEY RATS.

L. A. Beyer, B. D. Beck and J. E. Goodman. *Gradient Corp., Cambridge, MA.*

The European Ramazzini Foundation (ERF) has conducted numerous bioassays with Sprague Dawley (SD) rats. When evaluating the results of animal bioassays, it is important to consider the overall background rates of disease in the animal model being used. However, in some ERF studies the background rates of certain cancers were higher than usual, making it difficult to evaluate the study results. Using published literature, we compared the rates of Leydig cell tumors and hematopoietic cancers in untreated SD rats in animal bioassays conducted by the ERF, to background rates reported by other laboratories. The endpoints were chosen due to their importance in evaluating MTBE carcinogenicity. For Leydig cell tumors, the mean ERF lab background rate was 5.8% *vs* 1.3% in the literature. In the total lymphomas/leukemias category, the percent of female rats in the ERF bioassays was, on average, more than triple the percentage identified in the other scientific literature (9.2% *vs* 2.6%). In contrast to other labs, the ERF lab reported background rates of lymphoimmunoblastic lymphoma in males and females, lymphoblastic lymphoma in females, and lymphoblastic leukemia in females. The rates of lymphocytic lymphomas and myeloid leukemia were similar for the ERF and other published literature. We recognize that changes in classification schemes over time and the limited data available make it difficult to evaluate the significance of findings for individual types of leukemia/lymphoma. Nonetheless, we conclude that the background rates for individual hematopoietic cancers in SD female rats as reported in the ERF studies are inconsistent with rates reported elsewhere and that overall, the ERF consistently reports higher percentages of female SD rats in the total leukemias/lymphomas category as compared to other published studies. If cancer rates in test animals are elevated, the rates in control animals should be considered when interpreting results, as elevations in cancer that are still within historical control rates could indicate a chance, rather than a significant, finding.

2029 TOXICITY CHARACTERISTICS OF CHEMICALS ON THE U.S. EPA DRAFT CONTAMINENT CANDIDATE LIST (CCL3).

J. Donohue, T. Moore and Q. Sinanaj. *Office of Water, U.S. EPA, Washington, DC.* Sponsor: E. Doyle.

The Safe Drinking Water Act Amendment of 1996 requires the United States Environmental Protection Agency (USEPA) to develop a Contaminant Candidate List (CCL) every 5 years to assist in priority-setting efforts. From each list, the Agency is required to make regulatory determinations for at least 5 contaminants 3 years after its publication. For CCL3, USEPA developed a process that considered a wide spectrum of potential drinking water contaminants. The process began with a Universe of about 6000 chemical contaminants. Using screening criteria for potency and occurrence plus expert judgment, the Universe was reduced to a preliminary CCL (PCCL). The draft CCL3 was selected using computerized classification tools and expert judgment to prioritize the PCCL based on potential toxicity (potency and severity) and occurrence (prevalence and magnitude). The draft CCL3 developed using this process was published in the Federal Register on February 21, 2008. EPA examined the toxicity data from the draft CCL3 to characterize its distribution and its sources. Based on the 10 point scale for potency, 82% of the selected chemicals had potency scores ≥5. Risk assessments conducted by the agency were the source of 63% of the toxicity data; other data sources included assessments by CalEPA, ATSDR, RAISHE and WHO (20%). The severity score was based on a 9 point scale with a score of 1 for no adverse effect to a score of 9 for death. More than 50% of chemicals had critical effects scored at six or higher. Approximately 33% were scored based on cancer as an outcome, 6% were scored based on reproductive and developmental effects, and scores for 13% were based on effects for other serious conditions or disorders assumed to be irreversible but not necessarily leading to death. [The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA.]

2030 BEST PRACTICE FOR INCURRED SAMPLES REPRODUCIBILITY BIOANALYSIS IN PRECLINICAL STUDIES.

M. J. Prosser, S. Grassi, M. Mameli, S. Barattè, M. Breda and M. Brughera. *Preclinical Development, Accelera - Nerviano Medical Sciences srl, Nerviano, Milano, Italy.*

During the 3rd AAPS/FDA (American Association of Pharmaceutical Scientists/Food and Drug Administration) Bioanalytical Workshop, it was suggested to test the reproducibility in the analysis of incurred samples for preclinical studies in addition to validation activities. FDA guidelines and published literature provide recommendations concerning the number and types of samples that should be reanalyzed and the way to evaluate these results. However follow-up activities and data reporting are still matter of discussion. Nevertheless, the application of these recommendations should improve the reliability of the bioanalytical results and ensure a better pharmacokinetic and safety assessment in preclinical settings. Usually, the validation of a bioanalytical method relies on data generated using spiked control biofluid samples. Actually incurred biological samples can vary in their composition when compared with the standards and quality control samples used to validate the method and analyze these samples. Laboratories where bioanalytical activities are performed have now to be aware of these new FDA recommendations and there is an increasing need to apply them in order to achieve compliance. Therefore, dedicated Standard Operating Procedures, focused on dealing, reporting, and using repeated results, need to be prepared referring to critical FDA recommendations as major guidelines. This Poster describes the results obtained from several set of incurred samples reanalysed to evaluate the reproducibility of bioanalytical methods supporting different GLP toxicokinetic studies.

PS 2031 ICCVAM/NICEATM/ECVAM/JACVAM SCIENTIFIC WORKSHOP ON ACUTE CHEMICAL SAFETY.

J. Strickland[1], M. Paris[1], D. Allen[1], R. Tice[2], H. Kojima[3], M. Wind[5], P. Prieto[4] and W. Stokes[2]. *[1]ILS, Inc./NICEATM, NIEHS, Research Triangle Park, NC, [2]NICEATM, NIEHS, Research Triangle Park, NC, [3]JaCVAM, Tokyo, Japan, [4]ECVAM, Ispra, Italy and [5]CPSC, Bethesda, MD.*

The evaluation and promotion of alternatives for acute systemic toxicity testing is one of ICCVAM's four highest priorities because (1) acute toxicity testing is the most commonly required product safety test worldwide and (2) it can cause significant pain and distress to test animals. We cosponsored a public workshop in February 2008 to review and consider standardized procedures to collect information pertinent to understand the mechanisms of lethality that should be included in future rat acute systemic toxicity studies to support further development of predictive mechanism-based in vitro test methods. This international workshop implemented one goal of the NICEATM–ICCVAM Five-Year Plan to identify approaches that would further reduce the potential pain and distress associated with acute toxicity testing by identifying more humane acute toxicity endpoints. The workshop reviewed public health significance and regulatory testing needs; human and animal assessments, biomarkers, and key pathways; humane endpoints; and the state of the science regarding in vitro methods that predict acute systemic toxicity. Breakout Groups identified knowledge gaps in understanding key toxicity pathways; recommended earlier humane endpoints for animal testing; suggested ways to obtain, from current in vivo testing models, mode of action and mechanistic information needed to develop and validate in vitro methods for assessing acute systemic toxicity; and explored avenues that would encourage industry to share information on in vitro and in vivo studies conducted in-house. This workshop recommended how mechanism-based in vitro test systems and earlier, more humane endpoints, could be developed to further reduce, refine, and eventually replace animal use for acute systemic toxicity testing while ensuring the protection of human and animal health. ILS supported by NIEHS contract N01-ES-35504. This presentation may not reflect the view of the US Consumer Product Safety Commission.

PS 2032 CONSIDERATIONS FOR CONDUCTING A CHEMICAL'S RISK ASSESSMENT UNDER REACH.

T. Petry, P. Bisht, S. Chakraborty and F. R. Tencalla. *ToxMinds BVBA, Brussels, Belgium.*

The European Union's REACH regulation for the management of risk to human health and the environment posed by chemical substances entered into force in June 2007. At its core, REACH will require producers and users of chemical substances to register these uses in a volume-triggered system. It demands the submission of chemical safety reports (CSR) containing information on the hazards, exposures and risks associated with the uses of chemical substances for review by the competent authorities and government-appointed expert committees. After a long process, the European Chemicals Agency (ECHA) published its detailed technical guidance documents supporting the REACH regulation in May 2008. These include concise guidance to support the process of risk assessment under REACH as well as in-depth guidance, which describe the required steps to risk characterization in technical detail. Due to the process established by the EU to reduce the need animal testing and foster the communication along the supply chain, hazard data will be available from a large number of sources and is expected to be of differing qualities. Conflicting information may potentially exist. The objective of the present investigation is to examine the EU's approach to conducting chemical risk assessment in this context and to detail the procedures registrants must follow to demonstrate the safety of their products. This paper will further illustrate on the basis of selected examples how special factors affecting information requirements, testing strategies and data waiving opportunities can be integrated into the risk assessment. This includes the use of grouping and read-across, as well as exposure-based and toxicokinetic arguments to waive the need for conducting animal toxicity studies. As the consideration of existing risk management measures is an integral part of the REACH safety concept, the paper will conclude by a short discussion of the iterative process of controlling risks within a chemical's life cycle under REACH.

PS 2033 DETERMINATION OF THE DERIVED NO EFFECT LEVEL FOR STYRENE: AN EXERCISE IN INTERPRETING REACH GUIDANCE.

M. L. Kreider[1] and E. Williams[2]. *[1]ChemRisk, Inc., Pittsburgh, PA and [2]ChemRisk, Inc., Houston, TX.*

Under the new European chemicals regulation, REACH, a new safety value, the Derived No Effect Level (DNEL) must be established for all chemicals manufactured, imported or used in the EU in quantities greater than 10 metric tonnes per year. A DNEL, expected to be used as part of the risk characterization and for hazard communication purposes, is to be calculated for all relevant exposure pathways, exposure populations, and for different endpoints of toxicity (e.g. acute irritation, repeated dose toxicity, reproduction, etc.). The EU has published guidance on how to derive the DNEL, but with the start of the registration looming, this guidance has yet to be put into practice and is in some places not prescriptive. Using the Agency for Toxic Substances and Disease Registry (ATSDR) dataset, we have determined DNELs for styrene, based on inhalational exposure. In doing so, we considered what effect key decisions would have on the calculated DNEL (where there was flexibility in the guidance or interpretation was necessary). Key decisions included the use of animal or human data, selection of dose descriptors, estimation of human equivalent concentrations (HECs) from animal studies, and selection of appropriate modifications and assessment factors. The resulting DNELs were then compared to existing risk criteria values or occupational exposure limits. For both general population and worker based exposures, the lowest DNELs were generated based on the neurological effects of styrene. DNELs based on general population exposures were generally more conservative than analogous risk criteria (ranging from approximately 0.05 to 2.5 ppm). The DNELs based on occupational exposure scenarios are dramatically lower than existing occupational standards (ranging from approximately 0.4 to 20 ppm). To our knowledge, this work represents the first rigorous application and interpretation of the EU guidance for determination of a DNEL and will prove useful as a model for determination of other DNELs under REACH.

PS 2034 ESTIMATION OF A TETRACHLOROETHYLENE INHALATION CANCER RISK FACTOR: COMPARISON OF MASSDEP AND U.S. EPA DOSIMETRIC DECISIONS UNDER UNCERTAINTY.

S. J. Baird, T. Zewdie, C. Smith and C. Rowan-West. *Office of Research and Standards, Massachusetts Department of Environmental Protection, Boston, MA.*

MassDEP derived a revised inhalation unit risk (IUR) for tetrachloroethylene (PCE) of $1x10^{-5}$ per ug/m^3 in 2007, finalized in September 2008. Following this derivation, USEPA released their draft Toxicological Review of PCE in June 2008 with IURs ranging from $2x10^{-6}$ to $2x10^{-5}$ per ug/m^3. Both groups selected mononuclear cell leukemia in rats as the most sensitive endpoint from the key inhalation bioassay studies, NTP 1986 and JISA 1993; concluded that mode of action was uncertain; used default linear low-dose extrapolation in calculation of the IUR; and considered multiple approaches for adjusting animal bioassay dosimetry to lower levels of human exposure. The dosimetric adjustments need to take into account potential differences in metabolism across species and dose-dependent differences in rates of metabolism in both animals and humans. Both groups selected total metabolized dose as the dose-metric because the active moity is not known and multiple metabolites could be responsible for the carcinogenic effects. However, MassDEP used Michaelis-Menton steady-state kinetic equations to estimate animal total metabolized dose, while USEPA used a pharmacokinetic (PBPK) model. To estimate human population metabolism at relevant human environmental exposure levels MassDEP and USEPA were informed by different PBPK models and estimates of expected extent of human metabolism. MassDEP used the analysis by Chui and Bois (2006) to estimate the fraction of PCE metabolized by humans while accounting for human population variability in low dose metabolism: they estimated an upper limit of human population metabolism of PCE of 61% at 1 ppb. USEPA presented a range of IURs based on results from three human PBPK models yielding central estimates of human low dose metabolism ranging from 3–33%, as calculated by MassDEP. While different decisions were made in the dosimetric extrapolation, MassDEP's IUR falls within the range of USEPA's values.

PS 2035 WEIGHT OF EVIDENCE PROCEDURES FOR SKIN NOTATION ASSIGNMENT IN OCCUPATIONAL HAZARD ASSESSMENT.

B. Gadagbui[1], G. Dotson[2], A. Maier[1] and G. Talaska[3]. *[1]Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH, [2]National Institute for Occupational Safety and Health (NIOSH), Centers for Disease Control and Prevention (CDC), Cincinnati, OH and [3]Department of Environmental Health, University of Cincinnati, Cincinnati, OH.*

Skin contact is a significant route of exposure in occupational settings. However, many occupational health risk assessments rely on qualitative "skin" notations to provide information on the potential for dermal exposures to contribute significantly to the systemic dose, and in particular, to inform the interpretation of quantitative risk assessments based on concurrent inhalation exposures. The underlying decision criterion for making such assignments is often not documented. Moreover, the traditional skin notation approach does not provide information on other effects of dermal exposure. We have reported previously on an enhanced notation strategy developed by the National Institute for Occupational Safety and Health

(NIOSH) that provides for the assignment of multiple skin notations that address systemic toxicity, direct skin effects, and dermal sensitization. The current work presents experience in applying the NIOSH strategy to over 70 chemicals. Weight of evidence decisions to address conflicting or limited data sets is highlighted. Examples of common situations include; 1) assigning a systemic effects notation where data or model predictions indicate absorption, but no or only limited dermal toxicity data are available, 2) differentiating among irritant severity levels when relying on qualitative studies that used different material dilutions and test systems, 3) developing notations for sensitization when limited human studies and standard animal assays provide conflicting results. The lessons learned in evaluating such problematic data sets provide the basis for refining weight of evidence evaluation procedures for hazard notations.

PS 2036 ICCVAM PERFORMANCE STANDARDS FOR THE MURINE LOCAL LYMPH NODE ASSAY (LLNA).

J. Matheson[1], M. Wind[1], A. Jacobs[2], D. Allen[3], T. Burns[3], E. Salicru[3], J. Strickland[3], R. Tice[4] and W. Stokes[4]. *[1]U.S. CPSC, Bethesda, MD, [2]U.S. FDA, Silver Spring, MD, [3]ILS, Inc./NICEATM, NIEHS, Research Triangle Park, NC and [4]NICEATM, NIEHS, Research Triangle Park, NC.*

ICCVAM develops performance standards to facilitate the efficient validation of modified versions of adequately validated alternative test methods. ICCVAM recently developed performance standards based on the ICCVAM-recommended LLNA protocol (ICCVAM 1999). The protocol was revised recently to reduce the minimum number of mice per dose group from five to four, and to provide guidance on reducing the number of positive control animals and determining the appropriate highest test dose. The performance standards include essential test method components, a minimum list of reference substances, and standards for accuracy and reliability. Essential test method components are the structural, functional, and procedural elements of a validated test method that must be included in a modified method in order for it to be evaluated using the established performance standards. Essential components of the LLNA include topical application of the test substance to the ears of mice, measurement of lymphocyte proliferation in the lymph nodes draining the area of test substance application, and use of the maximum soluble dose that does not result in systemic toxicity or excessive local irritation. The minimum list of reference substances for these LLNA performance standards includes 13 sensitizers and 5 non-sensitizers. The accuracy and reliability standards to be achieved by a modified LLNA are based on the performance of the traditional LLNA. These LLNA performance standards will facilitate rapid and efficient validation of modified LLNA protocols, such as those using non-radioactive markers of lymphocyte proliferation. New versions of the LLNA that provide improved performance or other advantages are expected to result in broader use of the LLNA, which will further reduce and refine animal use for allergic contact dermatitis assessments while ensuring human safety. ILS staff supported this abstract by NIEHS contract N01-ES-35504.

PS 2037 LLNA: CURRENT REGULATORY ISSUES.

D. A. Basketter[1], I. Kimber[2], R. Dearman[2], F. Gerberick[3] and C. Ryan[3]. *[1]DABMEB Consultancy Ltd, Sharnbrook, United Kingdom, [2]Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom and [3]Procter & Gamble, Cincinnati, OH.*

Legislation in the EU requires evaluation of the skin sensitization potential for more than 30,000 substances. For many of these the local lymph node assay (LLNA) is the required test, unless a scientific rationale can be provided for use of an alternative approach. Elements of the rationale may be that open application is unsuitable, or that the chemical is a member of a class for which there is evidence of common association with false positive or false negative results. Certain chemical classes, for example fatty alcohols, have been reported as potential false positives in the LLNA. It is important that the evidence for this is reviewed rigorously and documented, so that there is a general consensus about which substances truly represent false positives, rather than weak allergens for which hazard classification would rather be avoided. The OECD Test Guideline 429 for the LLNA provides for a minimum of 4 mice per dose group, or 5 of mice per group if statistics are required. Recent discussions at the Interagency Coordinating Committee for the Validation of Alternative Methods (ICCVAM) have suggested a change to LLNA requirements to mandate a minimum of 5 mice per group. This has prompted a retrospective analysis of published data from our own laboratories to determine whether use of 4 or of 5 mice has had any impact on performance of the LLNA . Of the datasets for 17 chemicals in the 4 animal assay (14 positive, 1 uncertain and 2 negative), 16 results were identical in the 5 animal assay. One marginally positive result in the 4 animal assay was negative in the 5 animal assay. Where potency determinations were made, the outcomes were essentially identical in both forms of the LLNA. It is concluded there is no scientific justification for removing the option of a 4 mice/group LLNA. This will help to keep to a minimum the number of animals used for skin sensitization testing under REACH.

PS 2038 NONCLINICAL RODENT STUDIES FOR A NOVEL PACLITAXEL-PEPTIDE CONJUGATE THAT TARGETS THE BRAIN.

B. Lawrence[1], R. Gabathuler[1], J. Castaigne[1], G. Goodfellow[2] and M. Demeule[1]. *[1]AngioChem Inc., Montreal, QC, Canada and [2]Toxicology, Development and Regulatory Services, Intrinsik Health Sciences Inc., Mississauga, ON, Canada.*
Sponsor: J. Daniels.

ANG1005 is a novel cytotoxic drug that combines a receptor-targeting peptide vector to 3 molecules of paclitaxel. The peptide vector can be applied to other molecular classes, including biologics, and is designed to enable transcytosis across the blood-brain barrier by targeting the low-density lipoprotein receptor-related protein. ANG1005 has been tested in Sprague-Dawley rats in safety pharmacology and toxicology studies. Following single intravenous (IV) doses of ANG1005 up to 300 mg/m^2, no behavioral/central nervous system effects were observed in male rats. In a single-dose IV toxicity study, ANG1005 was administered at 0 to 850 mg/m^2. Effects on white blood cells (and related parameters) and platelet counts were observed at dose levels ≥200 mg/m^2. Macroscopic findings and changes in organ weights were observed for the spleen at ≥400 mg/m^2 and for the testes at 850 mg/m^2. The maximum tolerated single IV dose was 400 mg/m^2. In a repeated-dose IV toxicity study, ANG1005 was administered at 0, 25, 50, or 100 mg/m^2 twice weekly for 4 weeks. ANG1005-related mortality was observed at 100 mg/m^2 after ~2 weeks (3/24 M, 2/24 F); and the dose lowered to 75 mg/m^2. Moderate dose-related decreases in testicular weights were observed in 50 or 100/75 mg/m^2 males, with partial recovery by Day 40. Corresponding macroscopic and microscopic changes were observed, with soft, small testes noted and minimal to moderate degeneration of the seminiferous tubules observed in 6/9 males at 100/75 mg/m^2 and in 1/10 males at 50 mg/m^2. These microscopic findings were not resolved during the recovery period *e.g.*, aspermia in the epidydmides; a known paclitaxel effect). The NOAEL in this study was 25 mg/m^2. Based on mortalities observed in this study [5/48 (10.4%) at 100/75 mg/m^2], the severely toxic dose in 10% of the animals (STD_{10}) was estimated to be 75 mg/m^2. The ANG1005 rodent studies supported in part the initiation of 2 Phase 1 clinical trials in brain cancer patients.

PS 2039 BEAGLE DOG TOXICITY STUDIES FOR A NOVEL PACLITAXEL-PEPTIDE CONJUGATE THAT TARGETS THE BRAIN.

B. Lawrence[1], R. Gabathuler[1], A. Regina[1], G. Goodfellow[2] and J. Castaigne[1]. *[1]AngioChem Inc., Montreal, QC, Canada and [2]Toxicology, Development and Regulatory Services, Intrinsik Health Sciences Inc., Mississauga, ON, Canada.*
Sponsor: J. Daniels.

ANG1005 is a novel cytotoxic drug that combines a receptor-targeting peptide vector to 3 molecules of paclitaxel. The peptide vector can be applied to other molecular classes, including biologics, and is designed to enable transcytosis across the blood-brain barrier by targeting the low-density lipoprotein receptor-related protein. The toxicity profile of ANG1005 in Beagle dogs has been investigated in a series of intravenous (IV) infusion toxicology studies. ANG1005 was administered at single IV dose levels of 0, 100, 200, or 400 mg/m^2 with both 400 mg/m^2 animals not surviving past Day 4. Reversible decreases observed for platelets, reticulocytes, and WBCs (all types) at 100 or 200 mg/m^2. The maximum tolerated IV dose was 200 mg/m^2. The mean half-life for all ANG1005-treated animals following a single dose was 2.76 ± 0.53 hr. In a repeated-dose IV toxicity study, ANG1005 was administered at 0, 15, 45, or 90 mg/m^2 twice weekly for 4 weeks. Modest hematological changes were observed in animals administered 90 mg/m^2 ANG1005, with the effects fully recovered by the end of the recovery period. Microscopic changes related to ANG1005 included unilateral and bilateral degeneration of the seminiferous tubules in the testes of males (a known effect of paclitaxel) in either the 45 mg/m^2 (1/4) or 90 mg/m^2 (1/6) treatment groups, with the effect reversible for the 90 mg/m^2 males. Plasma concentrations decreased mono-exponentially with an overall half-life of 2.68 ± 0.49 hr. The TK profiles of ANG1005 were similar at all dose levels, with no apparent gender differences. There were no treatment-related findings for the testes at the lowest dose (15 mg/m^2) and the NOAEL in this study was 15 mg/m^2. Based on the lack of severe findings in this study, the highest non-severe toxic dose (HNSTD) is 90 mg/m^2. The ANG1005 dog toxicity studies supported in part the initiation of 2 Phase 1 clinical trials in brain cancer patients.

PS 2040 AERODYNAMIC AND SAFETY PROFILES OF NEBULIZED ANTI-C5 MABS IN A GLP INHALATION TOXICOLOGY STUDY.

M. D. Reed[1], T. Peng[2], S. Allen[1], S. Liu-Chen[2], D. Miano[2], J. McDonald[1], L. Li[2] and Y. Wang[2]. *[1]Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM and [2]Alexion Pharmaceuticals, Cheshire, CT.*

Complement C5 plays a key role in the pathogenesis of asthma. A previous study demonstrated that a single nebulization delivery (10 min) of murine Anti-C5 was effective in ameliorating disease in rodents. To support the utility of aerosol delivery of anti-C5 mAb for intrapulmonary C5 inhibition in patients, a GLP toxicology study was performed with CD-1 mice to assess the safety of nebulized ALXN5100, a humanized anti-human C5 mAb and its surrogate, BB5.1, a mouse mAb specific to mouse C5 (Frei at al, 1987). Mice were exposed to low and high concentrations of BB5.1 (~0.12 mg/L: 30 and 120 min) for 4 and 14 days and ALXN5100 (~0.32 mg/L: 30 and 120 min) for 4 days. Vehicle control was also included. Particle sizes for both BB5.1 and ALXN5100 were ~1.5-2.2 micon MMAD (GSD ~2.2) after nebulization with a Pari LC plus jet-air nebulizer. Antibodies collected after nebulization showed intact mAb integrity and comparable activity as pre-nebulization controls. Average daily calculated inhaled/deposited (assumed 100%/ 10% pulmonary and tracheobronchial respectively) doses were ~3.4/.34 mg/kg (Low); ~13/1.3 mg/kg (High) for BB5.1 and ~9/.9 mg/kg (Low); ~37/3.7 mg/kg (High) for ALXN5100 after 4 and 14 days of exposure. Aerosol exposures to ALXN5100 were confirmed in serum and lung tissues of exposed mice. Exposures of BB5.1 caused no significant changes in serum C5 mediated hemolysis compared with preexposure values. Exposures to both test articles were well tolerated. No mortality, morbidity, adverse clinical signs or treatment-related effects in clinical pathology, body weight, organ weight, or BALF parameters were observed. Histopathology revealed minimal to mild nasal and tracheal epithelial degeneration consistent with inhalation exposures in rodents in both vehicle control and treated groups. No other treatment-related histopathology was observed. These results indicate that ALXN5100 has a safety profile consistent for nebulization delivery in clinical studies.

PS 2041 NON-CLINICAL SAFETY ASSESSMENT OF A BI-FUNCTIONAL ANTIBODY FUSION INHIBITOR TARGETING CD4 AND HIV.

M. Cooper, H. Stock, C. Ji, X. Liu, T. Zabka, F. Kirschenbaum, S. Spindeldreher, H. Kropshofer, K. Kolaja, S. Platz and J. Beck. *Discovery & Investigative Safety, Roche, Palo Alto, CA.*

Bi-functional fusion inhibitor (BFFI) is designed for treatment of HIV infection in treatment-experienced patients. BFFI is a fusion protein consisting of a humanized Immunoglobulin G1 (IgG1) isotype antibody that targets CD4 tagged with a fusion inhibitor peptide, T-651, which is derived from the HR2 region of HIV-1 gp41. The antibody carries the L234A and L235A double mutation, which attenuates Fc-mediated antibody dependent cell-mediated cytotoxicity (ADCC) and complement dependent cytotoxicity (CDC). The peptide is linked to the antibody via a glycine/serine linker sequence. To assess the non-clinical safety of BFFI, an in vitro immunosafety screening strategy was employed, followed by an in vivo two-week range-finding toxicology study in cynomolgus monkeys. In vitro immunosafety was assessed in peripheral blood mononuclear cell assays that examined T cell activation end points, including cell proliferation, CD25/CD69 expression, and cytokine secretion. Induction of effector function (CDC and ADCC) and cytokine release in a whole blood assay were also assessed. No perturbations in the in vitro assessments were observed. In addition, BFFI was well-tolerated up to 10.1 mg/kg in cynomolgus monkeys when administered via extended intravenous bolus every 3 days for 13 days. In vivo immunophenotyping was consistent with in vitro results, indicating no effect on T cell populations or markers of activation.

PS 2042 PRECLINICAL SAFETY EVALUATION OF AN ANTI-β7 INTEGRIN ANTIBODY TARGETING LYMPHOCYTE HOMING TO AND RETENTION IN THE GASTROINTESTINAL TRACT.

H. Wang, H. Hiraragi, M. Williams, E. Stefanich, K. Pham, D. Danilenko and T. Gelzleichter. *Genentech Inc, South San Francisco, CA.*

rhuMAb Beta7 is a humanized anti-β7 integrin monoclonal antibody that is being investigated as a potential therapeutic for inflammatory bowel disease. It binds α4β7 and αEβ7 integrins, which mediate lymphocyte homing to and retention in the intestinal mucosa. Studies in mice demonstrated that rhuMAb Beta7 selectively inhibits lymphocyte homing to mucosal tissues, such as the gastrointestinal (GI) tract, without affecting their trafficking to peripheral lymphoid tissues or the CNS. Repeat-dose toxicity studies were conducted in cynomolgus monkeys to evaluate the toxicity, toxicokinetics and pharmacodynamics (PD) of rhuMAb Beta7. It was well tolerated in cynomolgus monkeys following weekly intravenous (IV) or subcutaneous (SC) injection for 12 weeks at doses up to 50 mg/kg. Core safety pharmacology (cardiovascular, respiratory and neurological) endpoints were incorporated into the systemic toxicity study, and no drug-related effects were observed. Clinical signs including post-dose vomiting, hypoactivity and recumbency were observed in a subset of the animals given 5 mg/kg via IV injection. These clinical signs were manifest on the day of dosing following 3 or more doses, correlated with high-titer anti-drug antibodies, and were attributed to injection of a heterologous protein. Increases in peripheral blood gut homing memory T cells were observed, consistent with the anticipated PD effect of specific inhibition of lymphocyte homing to the GI tract. In contrast, no effect was observed on naïve or peripheral-homing memory cells. The PD effect was reversible following drug clearance. Other than minimal to slight perivascular infiltration of lymphocytes and macrophages in the SC injection sites that was attributed to injection of heterologous protein, no drug-related microscopic changes were noted. In conclusion, the NOAEL following weekly IV or SC injection of rhuMAb Beta7 for 12 weeks is 50 mg/kg, the highest dose tested.

PS 2043 NONCLINICAL SAFETY EVALUATION OF XOMA 052, A MONOCLONAL ANTIBODY TARGETING IL-1β, IN REPEAT DOSE TOXICITY STUDIES IN RATS AND CYNOMOLGUS MONKEYS.

K. E. Meyer[1], K. Der[1], J. Ma[1], Y. Espinoza[1], L. Cao[1], C. Gasper[1], R. Bauer[1], C. Bechtel[2], S. Tichenor[2] and C. Stewart[3]. *[1]Preclinical Safety Evaluation, XOMA (U.S.) LLC, Berkeley, CA, [2]Charles River Laboratories, Reno, NV and [3]MPI Research, Mattawan, MI.*

XOMA 052 is a potent Human Engineered™ monoclonal antibody that specifically binds to IL-1 beta (IL-1β) and blocks activation of the IL-1 receptor. IL-1β is a proinflammatory cytokine involved in the development of diabetes, rheumatoid arthritis, gout and other diseases. Binding to IL-1β is expected to prevent the cellular signaling events that produce inflammation. XOMA 052 is currently being developed for acute, chronic and orphan indications, including its evaluation in two Phase 1 clinical studies in Type 2 diabetes designed to assess safety, pharmacokinetics and measures of systemic inflammation. The rat and cynomolgus monkey were selected for safety evaluation due to similar binding affinity and in vitro functional activity with XOMA 052 and human, rat and monkey IL-1β. XOMA 052 was administered intravenously weekly for 4 weeks at doses up to 100 mg/kg in rats, and 4 and 13 weeks at doses up to 90 mg/kg in monkeys, each study with a recovery period of 2 months. The nonclinical safety evaluation included daily clinical observations, food consumption, body weights, hematology, clinical chemistry, coagulation parameters, urinalysis, ophthalmic examinations, electrocardiography (ECG), heart rate/blood pressure, T cell-dependent antibody response (TDAR), immunogenicity, as well as macroscopic and microscopic pathology. Pharmacokinetic analysis showed a half-life for XOMA 052 of 10-12 days in both species. The results showed no toxicologically significant findings, and the no-observed-adverse-effect level (NOAEL) was considered to be 100 mg/kg in rats and 90 mg/kg in monkeys. These studies supported the Phase 1 clinical evaluation of XOMA 052 in patients with Type 2 diabetes. Clinical studies in rheumatoid arthritis and acute gout will be initiated in 2008.

PS 2044 SAFETY ASSESSMENT OF A NON-DEPLETING ANTI-CD4 MONOCLONAL ANTIBODY (MAB) IN BABOONS.

K. P. Allamneni[1], J. C. Beyer[1], E. G. Stefanich[1], H. Scheerens[1], N. Makori[2] and C. Zuch de Zafra[1]. *[1]Genentech, Inc., South San Francisco, CA and [2]SNBL USA, Ltd., Everett, WA.*

MTRX1011A is a non-depleting, humanized mAb being evaluated in rheumatoid arthritis patients. It binds to CD4 resulting in receptor downmodulation and inhibits the function of residual surface CD4 molecules by blocking interaction with the major histocompatibility complex (MHC) II. The nonclinical safety assessment designed to support Phase I clinical trials of up to 8 weekly IV/SC doses consisted of a toxicology study evaluating toxicity, toxicokinetics, and safety pharmacology in baboons at 0, 5, 15, or 50 mg/kg/wk, hemolytic potential and blood compatibility testing, and tissue cross-reactivity analyses. The baboon was chosen as a relevant species due to the crossreactivity of MTRX1011A to human and baboon CD4+ T cells. MTRX1011A was well tolerated in baboons; no adverse effects were observed during the dosing phase or the 10-week recovery phase. There was no impact of MTRX1011A on a core battery of cardiovascular and neurological endpoints assessed as part of the toxicology study. MTRX1011A demonstrated nonlinear kinetics driven by saturable CD4-mediated elimination. Serum concentrations correlated with the downmodulation and saturation of CD4 on peripheral-blood T cells. MTRX1011A bound to CD4 on T cells and resulted in rapid internalization of the

antibody-CD4 receptor complex. These constituted expected pharmacologic responses. A subset of baboons developed anti-therapeutic antibodies but most maintained expected drug exposure and pharmacodynamic effects throughout the dosing phase. Additionally, MTRX1011A did not cause hemolysis of baboon or human erythrocytes and was compatible with baboon and human serum and plasma. In the tissue cross-reactivity study, biotin–MTRX1011A binding was observed in a pattern consistent with the expected distribution of CD4 expression in both human and baboon tissues. The IND-enabling toxicology program enabled entry of MTRX1011A into Phase I human clinical trials with an adequate safety margin.

PS 2045 THE ANTIDIABETIC METFORMIN IS TOXIC TO LIVER MITOCHONDRIA OF ZUCKER DIABETIC FATTY (ZDF) RATS: A CELLULAR METABOLOMIC STUDY WITH 13C-LACTATE AND CARBON 13 NMR.

G. Baverel, C. Pinteur, G. Martin and C. Gauthier. *Metabolomics and Metabolic Diseases, INSERM Unit # 820, Lyon Cedex 08, France.*

Metformin, one of the most widely used antidiabetic drugs, has been previously shown to decrease hyperglycemia in diabetic subjects and in diabetic animal models. This effect results in part from the inhibition of hepatic gluconeogenesis. Since lactate is the main gluconeogenic precursor, the objective of this study was to investigate in vitro the effect of metformin on hepatic lactate gluconeogenesis by using a cellular metabolomic approach. Precision-cut liver slices from adult male ZDF rats were incubated in oxygenated Krebs-Henseleit medium with variously 13C-labeled lactates (5 mM) or with 5 mM unlabeled lactate plus 25 mM 13C-bicarbonate. Substrate removal (lactate and glycogen) and product formation were measured by enzymatic and 13C-NMR methods. In slices from fasted lean ZDF rats, metformin dose-dependently inhibited 13C-glucose synthesis from [2-13C]-lactate (IC50 2.3 mM). The labeling patterns of the glucoses synthesized indicated that lactate gluconeogenesis involved not only the passage of carbons through pyruvate carboxylase and the reversible equilibration of oxaloacetate with fumarate but also pyruvate dehydrogenase and the entire tricarboxylic acid cycle. In slices from fed diabetic ZDF rats, 2 mM metformin did not change glycogen degradation but inhibited lactate consumption by 97%, glucose production from glycogen plus lactate by 18% and the synthesis of all the 13C-labeled glucose carbons from all 13C-labeled substrates by 70, 70, 71 and 63%, respectively. By contrast, metformin increased lactic acid production by 96% and ketogenesis by 78%. Metformin also caused a reduction of cellular ATP levels and of 13CO2 production from 13C-lactates but increased the beta-hydroxybutyrate/acetoacetate ratio which reflects the mitochondrial redox state. These results strongly suggest that a compound found to be toxic to liver mitochondria in vitro should not necessarily be withdrawn from drug development.

PS 2046 TOXICITY AND TOXICOKINETICS OF METFORMIN IN RATS.

M. Rhodes, D. Melich, H. Jordan, J. Nold, J. Chism and J. Polli. *GSK, Research Triangle Park, NC.*

Metformin is the first-line drug for the treatment of type 2 diabetes mellitus (T2DM) and is often prescribed in combination with other drugs in order to control a patient's blood glucose level and achieve HbA1c goal. New treatment options for T2DM will likely include fixed dose combinations with metformin, which, according to current FDA guidance, may require combination toxicology studies. Although metformin has been on the market for many years, there is little to no preclinical data to aid in design of these complex combination toxicology studies. Therefore, to understand toxicity of metformin alone, Crl:CD(SD) rats (12/sex/group) were administered metformin at 0, 200, 600, 900, or 1200 mg/kg/day by oral gavage for 13 weeks. Three animals/sex were added at each dose for toxicokinetic evaluation. Administration of ≥900 mg/kg/day resulted in moribundity/mortality and clinical signs of toxicity (hunched/thin appearance and frequent nonformed feces). Other adverse findings included increased minimal necrosis with inflammation of the parotid salivary gland for males given 1200 mg/kg/day, and body weight loss (≥20%) and clinical signs (associated with moribundity at the higher doses) in rats given ≥600 mg/kg/day. Metformin administration was associated with evidence of minimal metabolic acidosis (increased serum lactate and beta-hydroxybutyric acid, and decreased serum bicarbonate and urine pH) at doses ≥600 mg/kg/day. There were no marked (≥2-fold) sex differences in mean AUC0-24 or Cmax, nor were there marked differences in mean AUC0-24 or Cmax following repeated dosing compared to a single dose. The mean AUC0-24 tended to increase in approximate proportion with the increase in dose. The mean Cmax tended to increase less than proportionally with the increase in dose. The no observable adverse effect level (NOAEL) was 200 mg/kg/day (mean AUC0-24 = 41089 ng.h/mL; mean Cmax = 10272 ng/mL based on gender average end of study values). These effects should be taken into consideration when assessing potential synergistic toxicities of metformin fixed dose combinations.

PS 2047 PHARMACOLOGY AND TOXICOLOGY EVALUATION OF AN ANTISENSE INHIBITOR OF THE SODIUM-DEPENDANT GLUCOSE COTRANSPORTER 2 (SGLT2) IN MICE AND MONKEYS.

T. Zanardi[1], L. Shen[1], A. Siwkowski[1], E. Wancewicz[1], S. Bhanot[1], S. Han[2], E. Jeong[2], Y. Kim[2], S. Rime[2], M. Park[2] and S. P. Henry[1]. *[1]Isis Pharmaceuticals, Inc., Carlsbad, CA and [2]Korea Institute of Toxicology, Dajeon, Korea, South.*

ISIS 388626 is an antisense inhibitor of the sodium-dependent glucose cotransporter 2 (SGLT2). The low-affinity/high capacity SGLT2 plays a pivotal role in renal glucose reabsorption. Inhibition of SGLT2 in renal proximal tubular epithelium is intended to reduce hyperglycemia in diabetic subjects by increasing glucose excretion in the urine. Unlike most antisense oligonucleotides, which are 20-mers, ISIS 388626 is only 12 nucleotides long, with phosphorothioate linkages and two, 2'-MOE modifications at the termini. ISIS 388626 is homologous to SGLT2 mRNA in multiple species, including mouse, rat, monkey and human. Toxicity and pharmacologic activity of ISIS 388626 were evaluated after 13 weeks of treatment in both mice and monkeys at doses up to 30 mg/kg/week. Dose-dependent decreases in kidney SGLT2 mRNA were observed in both species, and were associated with the expected increases in urine glucose. Despite significant inhibition of SGLT2 mRNA in the kidney and the resultant glucosuria, no hypoglycemia was observed, and there were no histologic changes in the kidney due to SGLT2 inhibition. The remaining changes observed in these studies were typical of those observed for the chemical class, correlated with high concentrations of ISIS 388626, and were unrelated to inhibition of SGLT2. The kidney contained the highest concentration of ISIS 388626 in both mice and monkeys, and dose-dependent basophilic granule accumulation in tubular epithelial cells of the kidney, which is evidence of oligonucleotide accumulation in these cells, was the only histologic change identified. No changes in kidney function were observed as measured by evaluation of standard serum chemistry and urinalysis parameters. The dose-response relationships characterized in these studies, together with the well characterized toxicities and pharmacokinetics of this class of drugs support the clinical development of ISIS 388626.

PS 2048 28-DAY EXPLORATORY DRUG-DRUG INTERACTION STUDY OF CP-690, 550 AND CELLCEPT® IN CYNOMOLGUS MONKEYS.

D. J. Ball and E. Floyd. *Drug Safety R&D, Pfizer, Inc., Groton, CT.*

The Janus Kinase (JAK) inhibitor, CP-690,550 was administered by oral gavage to cynomolgus monkeys (2/sex/dose) at doses of 1 and 5 (0.5 and 2.5 BID) mg/kg, respectively. CellCept® (Mycophenolate mofetil;MMF) was administered orally by gavage to a third group of monkeys at a dose of 80 (40 BID) mg/kg. A fourth group of monkeys received CP-690,550 and MMF at doses of 5 and 80 (2.5 and 40 BID) mg/kg, respectively. The control group received 0.5% methylcellulose. All monkeys were treated for 28 consecutive days and BID doses were administered ~12 hours apart. Clinical signs and food intake were assessed daily, and body weights were recorded weekly. Physical examinations were performed and hematology, serum chemistry, immunophenotyping, and urinalysis parameters were monitored. Serum CP-690,550 and mycophenolic acid (MPA) concentrations were measured on Days 1, 8, and 28. At the conclusion of the dosing period, all monkeys were necropsied, examined for gross abnormalities, and selected tissues were collected for microscopic examination. Treatment-related changes were limited to decreases in the erythrocyte parameters of both sexes in the 5 mg/kg CP-690,550/80 mg/kg MMF group and females in the 1 and 5 mg/kg CP-690,550 groups. On Day 29, males and females in the CP-690,550/MMF group had RBC, HGB, and HCT values that were 0.81-0.90x the values for pretreatment Days 11/12. In addition, 1 female in the 1 and 5 mg/kg CP-690,550 group, respectively had similar changes in red blood cell parameters. There were no apparent differences in exposure for either CP-690,550 or MPA following co-administration of CP-690,550 and MMF. Systemic exposure, as measured by mean Cmax and mean AUC(0 to 12 hr) post the first dose, increased with increasing dose and there were no significant gender-related differences in systemic exposure of CP-690,550.

The oral administration of 5 mg/kg CP-690,550, either alone or in combination with 80 mg/kg MMF, to cynomolgus monkeys for 28 days was well tolerated and suggested slight additive pharmacological activity without any effect on toleration or pharmacokinetics.

PS 2049 IMMUNOTOXICITY TESTING IN RATS FOLLOWING 28-DAY ORAL EXPOSURE TO A NOVEL P38 MAP KINASE INHIBITOR.

S. Chanda[1], M. Lorenz[1], B. Wong[1], P. Weller[1], J. Mertens[2], E. Padgett[2], V. Peachee[3], K. White[3] and S. Platz[1]. [1]*Roche Palo Alto LLC, Palo Alto, CA,* [2]*WIL Research Laboratories LLC, Ashland, OH and* [3]*ImmunoTox, Richmond, VA.*

Pamapimod is a small molecule pyridone which selectively inhibits p38(α) MAP kinase. In efficacy models, 0.1-0.4 μM (0.04-0.16 μg/mL) of pamapimod resulted in 50% inhibition of IL-1β and TNFα production. Its immunotoxic effects were evaluated in an oral 28-day study in Wistar rats (10 rats/sex/group) with 50, 150 and 500 mg/kg/day of pamapimod ($AUC_{0\text{-}24}$ 98-585 μg.h/mL). No mortality was observed. Following pamapimod administration, clinical signs were mild (yellow material on body surface,salivation, ≥ 150 mg/kg/day) with lower body weights/food consumption at ≥ 50 mg/kg/day. At necropsy epididymal changes were noted in the 500 mg/kg/day group males. Higher white blood cell counts (lymphocytes and neutrophils) at the 150 and 500 mg/kg/day dose levels were noted but no alterations of the major organs in the immune system (including thymus and spleen weights). There were minor non-adverse differences in erythrocytic parameters (females ≥ 50 mg/kg/day and 500 mg/kg/day males). No effect of pamapimod was noted during the phenotypic analysis of splenic subpopulations (total B cells, T cells, CD4+ or CD8+ T subsets, natural killer cells, and macrophages). Cell-mediated immunity (anti-CD3-mediated proliferation) exhibited a slightly enhanced response ≥ 150 mg/kg/day. A dose-dependent decrease in the humoral immune response (T-cell dependent antibody-forming cell response) was observed. A lower innate immunity response (NK cell assay) was noted at the 500 mg/kg/day dose level. However, pamapimod changes were relatively minor compared to those of the positive control articles (cyclophosphamide and anti-asialo-GM1 treatment). In summary, dose-related effects of pamapimod on the various components of the immune system were consistent with the pharmacological action as a p38 MAP kinase inhibitor and the associated cytokine inhibitory mode of action and as such, represent enhanced pharmacological effects.

PS 2050 REPRODUCTIVE TOXICITY ASSESSMENT OF PAMAPIMOD, A NOVEL P38 MAP KINASE INHIBITOR.

M. Lorenz[1], R. D. Hood[2], N. Agnish[3], V. Sharper[4], P. Weller[1], B. Wong[1], K. Kolaja[1], S. Platz[1] and S. Chanda[1]. [1]*Roche Palo Alto, Palo Alto, CA,* [2]*R D Hood & Associates, Toxicology Consultants, Tuscaloosa, AL,* [3]*Consultant, West Milford, NJ and* [4]*Charles River Laboratories, Hosham, PA.*

Pamapimod is a small molecule pyridone which selectively inhibits p38(α) MAP kinase. In efficacy models, 0.1-0.4 μM (0.04-0.16 μg/mL) of pamapimod resulted in 50% inhibition of IL-1β and TNFα production. Its potential reproductive effects were assessed according to ICH recommendations. In a Segment I rat study (M: 30-1000 mg/kg/day for 28 days; F: 3-100 mg/kg/day for 15 days), when the males were given 1000 mg/kg/day ($AUC_{0\text{-}24h}$ 656 μg.h/mL), there was a slight decrease in the pregnancy rate (70.8%) compared to controls (88%). That dosage decreased sperm motility (~50%) and counts (25%). A low incidence of prolonged diestrus at dosages of 30 mg/kg/day or higher was observed, with no changes in mating or fertility. At 100 mg/kg/day, the numbers of corpora lutea and implantations were reduced but within historical control ranges. Increased postimplantation loss was also noted. In embryo/fetal development studies, decreased fetal body weight, delayed skeletal development, and increased fetal abnormalities in rats and rabbits were observed at dosages causing maternal toxicity, which also increased postimplantation loss in rabbits. These higher dosages in rats (≧ 30 mg/kg/day, $AUC_{0\text{-}24h}$ ≧ 21.9 μg.h/mL) delayed fetal ossification. In rabbits, 100 mg/kg/day dosages or higher ($AUC_{0\text{-}24h}$ ≧ 47.7 μg.h/mL) increased the incidences of fetal defects [missing forepaw digit(s)]and variations in ossification. In a perinatal/postnatal rat study, delays in skeletal development were largely reversed by Day 7 postpartum, with minor delays in ossification still evident only at the maternally toxic 100 mg/kg/day dosage ($AUC_{0\text{-}24h}$ 110 μg.h/mL). In summary, the highest dosages were associated with effects on reproductive parameters in rats and effects on fetal development in rats and rabbits, but the decreased ossification in rats was largely reversible.

PS 2051 ZIDOVUDINE (AZT) ALTERS HEMATOLOGIC PARAMETERS AND HEPATIC MITOCHONDRIAL FUNCTION IN B6C3F1 MICE.

V. G. Desai[1], T. Lee[2], C. L. Moland[1], W. S. Branham[1], S. M. Lewis[3], J. E. Leakey[3] and J. C. Fuscoe[1]. [1]*Division of Systems Toxicology, NCTR, Jefferson, AR,* [2]*Department of Information and Mathematics, Korea University, Jochiwon, Chungnam, Korea, South and* [3]*Office of Scientific Coordination, NCTR, Jefferson, AR.*

Sex-based differences in adverse effects of antiretroviral treatment have been observed in HIV-1 infected patients. The basis of the adverse effects is multi-factorial, with mitochondrial toxicity being recognized as a key element underlying most side effects of antiretroviral drugs. To get better insight into the mechanism of sex-related differences in drug toxicity, we measured hematologic parameters and hepatic expression profiles of 542 mitochondria-related genes in male and female B6C3F1 mice administered antiretroviral drug, zidovudine (AZT). Beginning at 8 weeks of age, animals were treated orally by gavage with 0, 400, 500, and 600 mg AZT/kg body weight/day for 12 weeks and were humanely sacrificed 24-hr following the last dose. In both male and female mice, red blood cell (RBC) count was lowered in conjunction with significantly higher levels of mean corpuscular volume (MCV) and mean corpuscular hemoglobin (MCH) at all AZT doses compared to controls. Sex-based differences were also noted in MCV and MCH levels at 400 mg/kg AZT, where female mice had higher levels compared to males. AZT also influenced expression levels of mitochondria-related genes, but only at the highest dose where several pro-apoptotic genes were up-regulated while genes involved in lipid metabolism were down-regulated. Sex-related difference in the transcriptional level of genes associated with oxidative phosphorylation was seen only in control mice. The results suggest that AZT-induced higher MCV and MCH levels may be in response to the lower RBC count that occurred even at the lowest AZT dose. Changes in mitochondria-related gene expression in the liver were evident only at the highest dose. Thus, hematotoxicity may be a primary event associated with AZT toxicity in B6C3F1 mice [support: OWH/FDA and in part by IAG (224-07-007) between NCTR/FDA and NIEHS/NTP].

PS 2052 NONCLINICAL SAFETY OF EITHER VCH-759 OR VCH-916, TWO NOVEL NON NUCLEOSIDE HCV NS5B POLYMERASE INHIBITORS, WITH OR WITHOUT RIBAVIRIN CO-TREATMENT IN A RAT 28-DAY TOXICITY STUDY.

C. Locas, I. Deschenes and J. Laterreur. *Preclinical Toxicology, Virochem pharam, Laval, QC, Canada.* Sponsor: G. Washer.

VCH-759 and VCH-916 are selective novel HCV NS5B polymerase inhibitors that have demonstrated potent antiviral activity in monotherapy Phase 1b clinical trial in HCV infected patients. Future therapies of Hepatitis C will involve antiviral agents in a combination with today's standard of care (PegInterferon and Ribavirin). A rat 28 day toxicity study, was performed to investigate the potential synergistic effects on toxicity profiles and mutual drug exposure of VCH-759 or VCH-916 either with or without Ribavirin co-treatment. Sprague-Dawley rats were treated by oral gavage with VCH 759 (200 mg/kg/day) or VCH 916 (100 mg/kg/day) twice daily with or without once daily Ribavirin (40 mg/kg/day) co treatment for 28 days. The doses were selected to achieve therapeutic systemic exposure and the standard toxicology parameters were monitored. There was no significant toxicity observed for the rats treated with VCH-759 or VCH-916 alone. The main observations in the Ribavirin alone group were effects on the haematological parameters (slight reduction on Red Blood Cell, Hemoglobin, Hematocrit) and elevated bone marrow myeloid to erythroid ratios with erythroid hyperplasia. These effects were similar to the reported toxicity of Ribavirin in rats namely an anemia associated with a bone marrow suppression. Coadministration of Ribavirin with either VCH-759 or VCH-916 resulted in minor, but reversible, reductions in weight gain or food intake. The hematology changes attributed solely to Ribavirin were neither mitigated nor exacerbated by coadministration of VCH-759 or VCH-916. Furthermore there was no significant interaction in drug exposure in the co-treated groups. In conclusion, the co-administrations of VCH 759 or VCH-916 with Ribavirin did not exacerbate the changes observed with Ribavirin alone and this favourable drug combination safety study in rats further support the clinical evaluation of VCH-759 or VCH-916 in combination with Ribavirin.

PS 2053 RODENT TOXICITY OF K777, A CANDIDATE THERAPEUTIC FOR TREATMENT OF CHAGAS DISEASE.

L. L. Rausch[1], J. Dobroff[1], R. Cerda[1], S. Nolan[1], D. Middaugh[1], S. Smith[1], J. McKerrow[2] and J. Mirsalis[1]. [1]*Toxicology and Pharmacokinetics, SRI International, Menlo Park, CA and* [2]*University of California San Francisco, San Francisco, CA.*

K777 is a candidate therapeutic for the treatment of Chagas Disease, a parasitic disease caused by the protozoan *Trypanosoma cruzi*. As part of the preclinical development of this drug, we have conducted single and repeat dose toxicity studies by oral gavage in male and female Sprague-Dawley rats. K777 was administered in a single dose at 50, 150 or 500 mpk, 7-daily doses at 50, 150, or 300 mpk, or 14-daily doses at 15, 50, or 150 mpk; 14-day recovery groups were included in both 7-and 14-day studies. All rats survived to scheduled sacrifice with minimal test article-related clinical observations. Rats administered a single dose of 500 mpk, had an 80% decrease in body weight gain during Days 1-3. In the 7-day study, rats administered 150 or 300 mpk exhibited shoveling behavior immediately post dose but not 1-2 hr post-dose. Male body weights at 300 mpk had a mean weight gain of <1% on Days

1-4 compared with an 11% gain in controls. Aspartate aminotransferase (AST) and alanine aminotransferase (ALT) values were significantly elevated in male and female rats on Day 8. At Day 8 interim necropsy, minimal hepatocellular necrosis was seen in the 300 mpk dose group for both male and female rats. In the 14-day study there was a 40 to 60% increase in AST and ALT values for males and females administered 150 mpk on Day 15. These results indicate that the liver is the primary target organ of K777 in rats. All hepatic changes resolved in the recovery groups of each study. In conclusion, oral administration of K777 in male and female rats resulted in hepatotoxicity at doses of 150 mpk and above, but the no observed adverse effect level (NOAEL) was approximately 50 mpk, and the hepatic effects are not expected to be dose limiting in clinical trials. Work supported by NIAID Contract N01-AI-60011.

PS 2054 MECHANISTIC INVESTIGATION OF N, N-DIETHYL-4-(PHENYL-PIPERIDIN-4-YLIDENEMETHYL)-BENZAMIDE -INDUCED INSULIN DEPLETION IN THE RAT AND RINM5F CELLS.

M. Otieno, N. Bavuso, J. Milano, L. Foster-Brown, K. Bui, Y. Li, D. Wescott, C. Louden, M. Dyroff and F. Pognan. *Safety Assessment, AstraZeneca Pharmaceuticals, Wilmington, DE.*

These studies describe the effect of N,N-diethyl-4-(phenyl-piperidin-4-ylidenemethyl)-benzamide (AR-M100390), a delta opioid agonist, on the pancreas and its mechanisms for pancreatic toxicity. Rats were treated with 5, 100, and 600 μmol/kg of AR-M100390 for 3 and/or 7 days; another group of rats treated with 600 μmol/kg of compound were allowed to recover for 14 days. AR-M100390 (600 μmol/kg) caused vacuolation in the β-cell of the rat pancreas that was associated with depletion of insulin and hyperglycemia after 7 days of dosing. The loss of insulin by AR-M100390 was due to specific inhibition of rat insulin2 mRNA transcription in vivo. Insulin depletion and hyperglycemia were reversible. The effects of AR-M100390 in rats was reproduced in the rat pancreatic β-cell line RINm5F, where it inhibited intracellular insulin content and secretion without affecting cell survival. Loss of insulin in vitro was also a result of specific inhibition of insulin2 mRNA transcription and was reversible. Pre-treatment of cells with the δ-opioid antagonist naltrindole or pertussis toxin did not reverse loss of insulin in AR-M100390-treated cells suggesting that the effects were not mediated by the δ-opioid receptor. AR-M100390 inhibited KCl-mediated calcium mobilization in RINm5F cells, suggesting that L-type calcium channels found in these cells and in pancreatic β-cells may partially play a role in the inhibition of insulin secretion by this compound. In summary, the in vitro and in vivo studies suggest that inhibition of insulin by AR-M100390 is due to a combination of inhibition of insulin synthesis and/or release

PS 2055 RATS TREATED WITH KNS-760704 SHOW A FAVORABLE SAFETY AND TOXICOLOGY PROFILE WITH HIGH BRAIN:PLASMA LEVELS THAT SUPPORT CLINICAL DEVELOPMENT IN ALS.

D. R. Demady[1], E. J. Popke[2], R. G. Lindahl[2], J. A. Dalton[2], S. W. Frantz[2], E. W. Ingersoll[1] and V. K. Gribkoff[1]. *[1]Preclinical Development, Knopp Neurosciences Inc., Pittsburgh, PA and [2]MPI Research Inc., Mattawan, MI.*

KNS-760704 is an orally administered small molecule currently in Phase 2 clinical trials for the treatment of amyotrophic lateral sclerosis (ALS). Safety and toxicity were evaluated across several studies in the Sprague Dawley rat, the primary rodent toxicology species. KNS-760704 was generally well-tolerated in IND-enabling and subsequent toxicology studies when dosed by oral gavage up to 2000 mg/kg as a single dose and with daily doses up to 500 mg/kg for 2 weeks and 300 mg/kg for 6 months, including a 3-month interim assessment. The most prominent effect was mortality in males and females at single doses greater than 500 mg/kg/day. Significant decreases in body weight gain in males were observed after 2 weeks of dosing at 500 mg/kg/day and 6 months of dosing at 300 mg/kg/day. The NOAEL after 6 months of dosing was 100 mg/kg/day in males and ≥ 300 mg/kg/day in females. In general, plasma levels of KNS-760704 followed first order kinetics and increased with dose with T½ ~4 hours and Tmax ~2 hours. Exposure (AUC 0-24) to KNS-760704 after 6 months of dosing at 300 mg/kg/day was 247,471 ng*hr/mL in males and 235,014 ng*hr/mL in females. In a separate study, oral bioavailability approximated 100% following single oral and IV doses. KNS-760704 was also evaluated in a CNS functional observational battery with no neurobehavioral effects seen after single doses up to 500 mg/kg. A pulmonary safety pharmacology study with single doses up to 500 mg/kg showed an increase in respiratory rate and minute volume and a decrease in tidal volume following single doses of 150 and 500 mg/kg with a NOAEL of 50 mg/kg. In a single-dose distribution study, brain:plasma levels of KNS-760704 ranged from 6:1 to 15:1 over 3 hours, which suggests that KNS-760704 may also concentrate in the human brain relative to plasma. These data demonstrate the preclinical safety of KNS-760704 and support its further clinical development.

PS 2056 PRECLINICAL SAFETY EVALUATION OF OT-551 HCL, AN OPHTHALMIC CLINICAL CANDIDATE FOR THE TREATMENT OF DRY AGE-RELATED MACULAR DEGENERATION.

R. W. Maher and G. Patil. *Othera Pharmaceuticals Inc., Exton, PA.*

A preclinical safety evaluation of OT-551 HCl was completed in support of an IND Submission for an ocular clinical evaluation in patients with early stages of dry age-related macular degeneration. An acute toxicity study in Sprague-Dawley rats was completed by infusion over 10 minutes with single i.v. OT-551 doses of 0, 10, 30, 100, or 200 mg/kg at 30 mL/kg. The no-observed-effect level (NOEL) was 10 mg/kg; the maximum tolerated dose (MTD) was 30 mg/kg with immediate post-dose decreased motor activity and labored breathing/respiration. Ocular toxicity studies with OT-551 were conducted in rabbits and dogs. Both species received 0, 1, 2, or 3% ophthalmic solutions of OT-551 (40 μl/dose) 3 times daily at 3-hour intervals for 28 days. In rabbits, no drug-related effects were found on daily observation, or with monitoring of body weight or food consumption, except for slight conjunctiva redness in some animals at all dose levels, including vehicle. Several animals treated with the mid and high doses showed mild conjunctival congestion, reflective of minor local irritation. No other ophthalmologic changes were noted. In dogs, slight conjunctival redness was noted in some animals at all dose levels and moderate redness in one high-dose animal. At necropsy, no clinically meaningful changes were observed following macroscopic or histopathology examinations. The no-observed-adverse-effect level (NOAEL) for OT-551 was 2% in dogs and 3% in rabbits. Plasma levels collected at 0.5 hr and later of OT-551 and TP-H (active metabolite) in all analyzed samples on Study Days 1 and 27 were below quantifiable limits of the LC/MS/MS assay (50 and 20 ng/mL, respectively). The in vitro genetic toxicology studies conducted with OT-551 determined that the compound was not mutagenic or genotoxic in the Bacterial Reverse Mutation Assay, Mammalian Chromosomal Aberration in CHO cells, or Mouse Micronucleus Assay. This series of preclinical safety studies supported an IND submission and the ongoing clinical safety and efficacy studies of OT-551.

PS 2057 HEMOSTATIC TEXTILE WOUND DRESSING STASILON™ EXHIBITS REDUCED SKIN ADHERENCE AND LOW TOXICITY.

C. J. Smith[1, 2], K. Rosiello[1, 3] and T. H. Fischer[1, 2]. *[1]Research & Development, Entegrion, Inc., Research Triangle Park, NC, [2]Pathology, UNC Chapel Hill School of Medicine, Chapel Hill, NC and [3]Kross Engineering, Worchester, MA.*

A hemostatic textile wound dressing (brand named Stasilon™) was developed using a proprietary weave of 65% (wt/wt) vitreous continuous filament e-glass and 35% (wt/wt) bamboo rayon fiber. The diameter of the continuous filament e-glass fibers is 7 microns + or - 10% and can not be reduced by any degree of rough handling. The underlying reason for the absolute inability to produce smaller diameter fibers with wear and/or damage is that the vitreous (like glass) nature of the parent fiber will not permit longitudinal fracture. Therefore, potentially carcinogenic fibers with diameters of 1.5-1 microns are not generated from use of the textile. Mechanical agitation of the parent 7 micron diameter e-glass fibers can shorten the original length of the wound dressing fibers, but can not reduce the original diameter. The chemical composition of the e-glass fibers is not intrinsically toxic, with tissue irritation for certain fiber size ranges being due to mechanical processes only. A battery of toxicology tests were conducted successfully, leading to 510(k) approval of the hemostatic textile for external application to breached skin for up to 30 days. The toxicology battery included evaluations of cytotoxicity in mammalian fibroblast cells; delayed contact sensitivity in guinea pigs; intracutaneous injections and dermal irritation in rabbits; systemic injections in albino mice; 31 day implantation into the paravertebral muscles of rabbits; hemolysis; Ames mutagenicity in strains TA97a, TA98, TA100, TA102 and TA1535 with and without S9 activation; and bacterial endotoxins and pyrogens. Stasilon™ wound dressing outperforms gauze in both stopping bleeding and not adhering to the wound site while exhibiting a highly favorable toxicological safety profile.

PS 2058 PRECLINICAL SAFETY ASSESSMENT OF INHALED XYLITOL: SUPPORTING STUDIES FOR CLINICAL TRIALS IN CYSTIC FIBROSIS.

L. Durairaj[2], S. Aimee[1], P. S. Thorne[2], J. Zabner[2], M. J. Welsh[2], J. McDonald[1] and M. D. Reed[1]. *[1]Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM and [2]Carver College of Medicine, University of Iowa, Iowa City, IA.*

Xylitol is a 5-carbon sugar that lowers airway surface liquid salt concentration potentially enhancing innate immunity and reducing airway infections. In order to support repeat dose clinical studies, a preclinical toxicology program was performed. Three groups of rats and dogs were exposed to nebulized xylitol (in water)

by nose-only or face mask inhalation for 14 days. Control (0.9% saline) and recovery groups (14 days) were included for each species. Mean daily aerosol exposures were ~3 and 3.5 mg/L for the rodent and dogs respectively. Particle sizes were in the inhalable range for both species (~2.5 micron MMAD, ~1.7 GSD). Mean calculated inhaled/ deposited (100%/tracheal-bronchial + pulmonary: ~ 10% rat, 20% dog) doses for each exposure group were ~55/ 5.6, 171/18.3, 354/37.9 and 27/5, 53/11, 105/21 mg/kg for rats and dogs respectively. Both species tolerated exposures well. There was no morbidity or mortality associated with treatment and no treatment-related findings in clinical observations, body weight, clinical pathology or organ weights in either species. No treatment related histopathology lesions were observed in dogs. Some rats among exposure groups sacrificed prior to the 24h post-exposure sacrifice had mottled lungs. These findings resolved after 24h. Consistent with rodent inhalation studies, histopathology revealed nonspecific remodeling and inflammatory responses of the upper airway. Findings were of similar incidence among treated and control groups. No other treatment-related histopatholgy was observed in rodents. These results suggest that inhaled xylitol has a safety profile consistent for use in human clinical populations.

PS 2059 14-DAY TOXICITY STUDY OF METASTIN 45-54 (NSC-D741805) IN FISCHER 344 RATS.

P. Terse[3], P. Tosca[1], J. Merrill[1], M. Ryan[1], B. Burback[1], J. D. Johnson[1], C. Briscoe[1], S. Seminara[2] and J. Tomaszewski[3]. *[1]Toxicology, Battelle, Columbus, OH, [2]Reproductive Endocrine Unit, Massachusetts General Hospital, Boston, MA and [3]Toxicology and Pharmacology Branch, National Cancer Institute, Bethesda, MD.*

Metastin 45-54 plays an important role in reproductive function through a G protein coupled receptor, GPR54. This decapeptide may be a potential candidate for clinical evaluation in patients with reproductive disorders. The objectives of this study were to determine target organ toxicity and its reversibility after administration of Metastin 45-54 (NSC-D741805) to Fischer 344 rats treated daily by the intravenous route of administration (tail vein) for 14 consecutive days followed by a 14-day recovery period. Thirteen male and ten female rats per group were administered vehicle (sterile normal saline) or Metastin 45-54. Dosages of 0, 30, 300, or 3000 μg/kg (0.18, 1.8, and 18 mg/m2) were administered at a dosing volume of 5 mL/kg. Administration of Metastin 45-54 did not elicit any clinical signs of toxicity, changes in body weight or food consumption compared to control. There were no drug-related hematology, serum chemistry, or coagulation effects. Increased Leuteinizing Hormone levels in treated rats indicated that exposure to Metastin 45-54 occurred during the study. FOB evaluations did not result in persistent or substantive neurotoxicological findings of any significance. There were no treatment-related findings in terminal body weight, organ weights, or gross findings at necropsy. There were no drug-related microscopic findings and, therefore, no target organs were identified. Based on these results, the no-observed-adverse-effect-level (NOAEL) was greater than 3000 μg/kg following 14-days of intravenous injection and 14-days of recovery. Furthermore, these data demonstrate a reasonable preclinical margin of safety of Metastin 45-54 following 14 day iv administrations in rodent species to support its clinical development. (This work was supported by NCI Contract No. N01-CM-42200 and by NICHD and NIDDK under NIH-RAID pilot program).

PS 2060 ELECTRORETINOGRAPHIC ASSESSMENT OF ROD AND CONE FUNCTION IN CYNOMOLGUS MONKEYS: EFFECTS OF DIGOXIN AND VORICONAZOLE.

J. Kinoshita, M. Ohba, T. Maejima, T. Ishizaka, T. Kimotsuki, M. Yasuda and S. Manabe. *Daiichi-sankyo Co. Ltd., Fukuroi, Shizuoka, Japan.*

In non-clinical studies, the evaluation of electroretinogram (ERG) according to a standardized procedure in humans is considered necessary in order to collect clinically relevant data. In the present study, we investigated whether the effects of 1) digoxin and 2) voriconazole, which have been reported to cause visual disturbances and reversible attenuation of ERGs in humans, can be detected by ERGs in cynomolgus monkeys. According to the procedure that was established based on the recommendation of the International Society for Clinical Electrophysiology of Vision (ISCEV), rod response (rod ERG), combined rod and cone response (standard combined ERG), cone responses (single-flash cone ERG and 30-Hz flicker ERGs) were evaluated. 1) After single dosing (0.1 mg/kg i.v., n=6) or repeated dosing (0.01 mg/kg/day i.m. for 1 month, n=5) of digoxin, increased implicit time in the combined response and increased implicit time and decreased amplitude in the cone responses were detected as suppressive effects. The above changes showed reversibility. No significant change was noted in the rod response after repeated dosing of digoxin. Thus, the effect of digoxin on ERGs was reversible and more prominent in the cone responses than in the rod response. 2) After single dosing (3, 6 mg/kg i.v. at 1-week intervals, n=6) of voriconazole, decreased amplitude and implicit time in the combined response and in the rod response and decreased amplitude in the cone responses were detected with a dose-dependent manner. The above changes showed reversibility. In addition, the effects of voriconazole on ERGs were more prominent in the rod response than in the cone responses. In conclusion, the effects of digoxin and voriconazole that have been reported in humans were detected by ERGs in cynomolgus monkeys. This method, by which drug-induced effects on the rod and cone function could be detected, is considered to be useful for the prediction of visual disturbances in humans.

PS 2061 THRESHOLDS IN PHOTOSAFETY ASSESSMENT: A MODEL CASE SUPPORTING TIERED TESTING AND RISK ASSESSMENT.

D. Bauer, H. Martus and W. Suter. *Preclinical Safety, Novartis Pharmacology AG, Basel, Switzerland.* Sponsor: P. Ulrich.

Photosensitization – sunlight-induced toxicity – is a common phenomenon mediated by many natural and synthetic compounds. There are well-established and routinely used test methods available to investigate phototoxicity (e.g. UV-vis light absorption spectrum, in vitro 3T3 NRU Phototoxicity Test, UV Local Lymph Node Assay). Despite the fact that the individual test systems usually provide well-defined results, translation of positive findings into a meaningful risk assessment still appears as a challenge. Some of the relevant determinants (e.g. reactivity of the excited state, sufficient distribution into light-exposed tissues) are not easily measurable and thus often not available for risk assessment. Therefore, empirical thresholds for specific endpoints (e.g. for molar extinction, photo irritation factor PIF or EC50 values under irradiation) are important in order to clearly indicate a remaining concern and to justify further testing. Based on accumulated in-house data (comprising Novartis development as well as reference compounds) we have analyzed different approaches in order to better quantify a) UV-vis absorption spectra (generation of critical absorption profiles in different solvents) and b) the endpoints of the in vitro 3T3 NRU Phototoxicity Test (EC50 value under irradiation, PIF value). The analysis of the UV-vis spectra database indicates that a standardized approach appears feasible allowing the definition of generally accepted critical absorption profiles (threshold spectra). The analysis of in vitro phototoxicity endpoints shows a clear correlation of PIF values with positive in vivo results (still without considering tissue concentrations). Although the current OECD Test Guideline 432 considers a PIF value of >5 as a positive result our dataset indicates that this threshold might be too conservative. It is evident that both approaches require much larger databases including well-defined datasets from different institutions in order to provide generally acceptable thresholds of toxicological concern.

PS 2062 AN *IN-VITRO* MOTILITY ASSAY AS A PREDICTIVE MODEL OF GASTROINTESTINAL ADVERSE DRUG REACTIONS.

J. Valentin[1], C. Keating[2], S. Gibbons[2], V. Martinez[1] and D. Grundy[2]. *[1]Safety Assessment - Safety Pharmacology, AstraZeneca R&D, Macclesfield, United Kingdom and [2]Department of Biomedical Sciences, University of Sheffield, Sheffield, United Kingdom.* Sponsor: J. Valentin.

Gastrointestinal adverse drug reactions (GADRs), such as constipation and diarrhoea, are among the most frequently reported events in all phases of clinical drug development and a significant cause of compound attrition during pre-clinical development. Consequently, pharmaceutical discovery requires robust, simple and predictive models capable of detecting and quantifying potential GADRs during the early phases of drug development. Here we report upon the validation of an *in-vitro* assay, developed to detect and quantify changes in intestinal motility as a surrogate marker for the presence of constipation/diarrhoea-type events in humans. In vitro recordings of intraluminal pressure were used to monitor the presence of colonic peristaltic motor complexes (CPMC) in segments of mouse colon mounted horizontally in an organ bath and perfused with Krebs solution (37°C). CPMC frequency, amplitude and total activity generated were assessed. Twelve compounds, with or without identified motility-related GADRs were assayed, in a blind manner, for their effects on CPMCs. For all compounds, cumulative concentration-response curves were constructed at concentrations covering the maximal free therapeutic plasma concentration in humans. The model detected stimulatory and inhibitory responses, likely correlating to the occurrence of diarrhoea or constipation, respectively. Dose-related effects could be identified and for several compounds, a potential mechanism of action (neurogenic vs myogenic) could be inferred. The model identified 7 true positives and 3 true negatives, whilst only 1 false positive and 1 false negative were detected. This resulted in a model sensitivity of 88%, specificity of 75% and a predictability of 83% (considered "good" by the European Centre for the Validation of Alternative Methods criteria). These results support the potential value of this model as a screening method in safety pharmacology assessment of compounds in development.

PS 2063 ASSESSMENT OF HERG PARAMETERS IN LQT PREDICTIONS.

C. E. Laurent, J. Cayer, E. Beauchemin, G. Laprise and D. Salvail.
IPSTherapeutique, Sherbrooke, QC, Canada.

In vitro assessment of drug effects on the protein encoded by the human ether-a-go-go gene (hERG) is frequently used to screen for predicting proarrhythmic side effect of new chemical entities in early development. Although a good correlation exists, between prolongations in QTc (LQT) (measured in vivo or in vitro) and those of ventricular action potential duration (APD), the correlation between hERG current inhibition and QTc prolongation is not always accurate. It is common practice to work with hERG peak amplitude; however, changes in current amplitude may not provide enough information on how compounds affect the ventricular repolarisation process to fully account for their potential arrhythmogenicity. In this study, using hERG-expressing cells, current kinetics and total amount of charge transferred (AUC) along with current amplitude were analysed to evaluate their relevance as LQT predictors. Methods: The whole-cell patch–clamp technique was used to evaluate the effect of two drugs known to be torsadogenic in humans (droperidol and cisapride) and one proprietary compound A on the hERG channel current expressed in HEK293 cell line. The effects of these same molecules on the ECG and APD were evaluated using the isolated heart perfusion system (Langendorff) and the hight-impedance microelectrode technique. Results: Compound A (hERG ampl IC50 = 1.1 μM, hERG AUC IC50= 0.7μM), prolonged QTc by 10% at IC50. Droperidol (hERG ampl IC50 = 4.80 μM, hERG AUC IC50= 4.3 μM) prolonged QTc by 14% at IC50. Cisapride (hERG ampl IC50=0.07μM, hERG AUC IC50=0.04μM), prolonged QTc by 10% at IC50. Conclusion: hERG current data successfully predicted the changes in QTc induced by Compound A, but failed to predict the changes in QTc for Droperidol and Cisapride which were -5.7% and 3.5% respectively. Changes in APD90 and APD30 were not more predictive than hERG results, whether it be amplitude or amount of charge transferred. More research is necessary to determine if the use of additional hERG current parameters could enhance the predictive power of the hERG inhibition assay.

PS 2064 REPEATED TRAINING FOR PRIMATE CHAIR RESTRAIN DOES NOT AFFECT CARDIOVASCULAR SAFETY PARAMETERS IN CYNOMOLGUS MONKEYS.

M. Niehoff, B. Schmelting and U. Zuehlke. *Covance Laboratories GmbH, Muenster, Germany.* Sponsor: G. Weinbauer.

It is generally accepted that training of nonhuman primates can significantly impact study conduct and outcome depending on the parameters studied. However, controlled studies using trained animals and quantitative endpoints in the field of primate toxicology are rare. The present work evaluated the effects of repeated training for simulated infusion in a primate chair using cardiovascular endpoints in telemeterized monkeys. Four conscious male animals (M. fascicularis, 4-6 yrs, 5-8 kg), fitted with telemetry implant providing recordings of heart rate, and respiratory rate, blood pressure and body temperature, were used. Animals were studied during periods of free movements (ca. 60 min), handling/restrain (ca. 30 min), chair restrain infusion (ca. 60 min) and again during free movement (ca. 60 min). Data logging rate was 60 seconds yielding 210 individual data sets for each parameter and animal. This sequence was repeated four times with a 3-4 day interval between each repetition. During the first session, systolic and diastolic blood pressure as well as heart and respiratory rate increased, on average, by 39%, 38%, 79% and 35%, respectively, during handling/restrain compared to free movement. During the infusion period, parameters remained elevated to the same extent whereas within 30 min of return to free movement condition, all parameters returned to baseline ranges (119 mmHg, 87 mmHg, 148 bpm and 31 bpm). Surprisingly, the magnitude of increase in cardiac parameters and respiratory rate remained similar on all subsequent three sessions without any evidence of acquaintenance to the experimental conditions. Body temperatures remained basically unaffected despite handling on all four occasions. In conclusion, training of male cynomolgus monkeys for repeated primate chair restrain – at least for four sessions - was not accompanied by measurable adaptations using cardiac parameters as endpoint. These observations strengthen the need for control animals in any cardiovascular safety studies and general toxicity studies.

PS 2065 NESTIN STAINING AS A MARKER OF NEUROMUSCULAR JUNCTION (MNJ) INTEGRITY IN ROUTINE TOXICOLOGY STUDIES.

F. Reno[1], E. Drevon-Gaillot[2], M. Perron[2] and R. Burnett[2]. *[1]Toxicology Consultant, Merritt Island, FL and [2]MDS Pharmacology Services, St Germain sur l'Arbresle, France.*

Introduction: In toxicology studies where muscle is a potential target organ, it is important to monitor changes in NMJs. In complement to functional evaluation through electrophysiology, NMJ changes can be assessed in teased muscle preparations and in frozen sections demonstrating acetyl cholinesterase activity. These methods are difficult to apply to large numbers of samples in routine GLP studies hence immunohistochemical visualization of NMJ intermediate filaments, such as nestin, was investigated. Methods: In a pilot study, 4μ paraffin sections of gluteus muscle obtained from control rat were reacted with an antibody against nestin using the streptavadin biotin method. The optimal dilution was 10 μg/mL. In a further study, groups of 4 rats were given a single I.M. injection of 2 or 6 U of Botulinum toxin prior to sampling 7, 30, 60 or 90 days later. Results: In control muscles, nestin staining was localized to the NMJ on each muscle fiber, appearing as a fine fusiform area closely bound to the longitudinal fiber, with a crescent-shaped transverse section. In affected muscle, three patterns were seen: 1) fusiform or crescent-shaped localized staining 2) diffuse staining 3) circular staining around the fiber. The circular staining was considered to be an intermediate form in the degenerative or regenerative phases. In rats injected with Botulinum toxin at 6 U/rat, the affected fibers showed a diffuse nestin staining after 30 days, with 2 rats showing both diffuse and circular staining and 2 rats with a normal crescent-shaped staining by Day 90. Those given 2 U/rat had diffuse and circular staining on Day 30, but had returned to normal by Day 90. Conclusion: Nestin can be used on paraffin sections as an indicator of the structural integrity of NMJs in routine toxicology studies.

PS 2066 ARE PHOSPHOLIPOGENIC COMPOUNDS ASSOCIATED WITH MORE TOXICITIES THAN NON-PHOSPHOLIPOGENIC COMPOUNDS?

L. R. Barone[1], S. Boyer[2], J. Damewood[3], J. Fikes[1], S. Matis[4], G. Gipson[4] and P. Ciaccio[1]. *[1]Safety Assessment, AstraZeneca, Wilmington, DE, [2]Safety Assessment, AstraZeneca, Molndal, Sweden, [3]Chemistry, AstraZeneca, Wilmington, DE and [4]Discovery Informatics, AstraZeneca, Wilmington, DE.*

A clear causal link between toxicity and phospholipidosis (PLD) has not been established, although drug accumulation and higher rates of associated toxicities are often cited in the literature. In view of this, an internal *in vivo* toxicology report database was searched using common PLD indicator terms to identify phospholipogenic compounds and explore their relationship with non-PLD histologic findings. This experiment was designed to ask whether phospholipogenics are associated with a higher frequency of histologic changes and not whether the phospholipodotic process itself is a cause. Positive compounds were confirmed by well validated *in silico* and *in vitro* models, by electron microscopy and/or a pathologist's interpretation. For comparison, a non-phospholipogenic compound data set was generated using the absence of PLD indicator terms. Negatives were confirmed *in silico* and/or *in vitro*. The data sets comprised 46 phospholipogenic and 55 non-phospholipogenic compounds. PLD and non-PLD histologic findings were tracked for nine organs: Adrenal Gland, Bone Marrow, Kidney, Liver, Lymph Node, Lung, Reproductive Organs, Spleen and Thymus. Data were controlled for study duration, and in most instances, maximum tolerated doses had been employed. Main study species were rat, mouse and dog. Phospholipogenic compounds had more non-PLD histologic changes in all organs than the non-phospholipogenics. The liver exhibited the highest percentage of findings in both compound sets with a statistically significant and markedly higher frequency of necrosis in livers with phospholipogenics compared to the non-phospholipogenics. Also, a statistically significant, higher frequency of lymphocytolysis occurred in thymus, lymph nodes and spleen with phospholipogenics. In conclusion, this unbiased analysis suggests that phospholipogenic compounds appear to be 'dirtier' in their toxicologic profiles than non-phospholipogenic compounds.

PS 2067 CYTOTOXICITY STUDIES OF IONIC LIQUIDS FOR POTENTIAL ANTICANCER DRUG THERAPY.

V. Kumar[1], R. E. Parchment[2], J. Lee[3], P. E. Noker[4], R. N. Misra[3], V. L. Narayanan[3], J. E. Tomaszewski[3] and S. V. Malhotra[1]. *[1]Laboratory of Synthetic Chemistry, SAIC-Frederick Inc./ NCI Frederick, Frederick, MD, [2]Laboratory of Human Toxicology and Pharmacology, SAIC-Frederick, Inc./ NCI Frederick, Frederick, MD, [3]Developmental Therapeutics Program, National Cancer Institute, Bethesda, MD and [4]Southern Research Institute, Birmingham, MD.*

The designer' aspect of ionic liqs. (ILs) renders the possibilities for prepn. of compds. with tunable' physiochem. properties and toxicity. As a result ILs are appealing materials for drug development and therapeutics. An understanding of their toxicity (cell & animal) and physiochem. properties (e.g. hydrophilicity and lipophilicity) is necessary in selection and design' of ILs in relation to specific therapeutic application. Here we implemented this approach through toxicity studies using CD-1 mice on a wide range of ILs (including imidazolium, pyridinium, ammonium, phosphonium, pyrrolidinium, piperidinium, isouraniouum based salts with different combinations of anions) and testing their ability to solubilize water insol. anti-cancer drug agents. The mice were administered the ILs up to their highest strength or

largest dose vol. that are considered good practice via iv, i.p. and po routes. Each mouse was then obsd. for toxic signs for up to 14 days after dosing. The automated data collection system (Provantis) was used to collect and file the screening results effectively. The biol./therapeutic effects evaluated by in vitro cultured NCI 60 cell lines showed tumor cell death by representative ionic liqs. in a dose-dependent manner. Our studies for the first time illustrate the possibilities in tailoring of clin. useful ionic liqs., based on their integrated in vitro and in vivo screening, for drug formulations and anticancer potential. Collaborative efforts across various disciplines are essential to fully explore the potential of ILs as therapeutic agents and for their broader applications in biomedical field.
Acknowledgment: Funded by NCI Contract N01-CO-12400 and NO1cM-52203.

PS 2068 THE EXTRACTABLES AND LEACHABLES SAFETY INFORMATION EXCHANGE (ELSIE):DEVELOPING AN EXTRACTABLES/LEACHABLES DATABASE.

D. J. Ball[1], S. L. Beck[2] and A. J. Shaw[3]. *[1]Drug Safety R&D, Pfizer, Inc., Groton, CT, [2]Safety Assessment, GlaxoSmithKline Ltd., Ware, United Kingdom and [3]Analytical R&D, Pfizer, Inc., Groton, CT.*

Assessing the safety of extractables and leachables (E&L) is an essential element of the research and development process for a great variety of pharmaceuticals, biologics and medical devices. Detailed assessments of these compounds must be included in applications submitted to health regulatory authorities. Although safety data on E&L is publicly available in peer-reviewed scientific journals and government reports and databases, these data have never been incorporated into a single comprehensive and readily accessible database, nor has there been any industry-wide effort to compile, organize, appraise and summarize this data. Currently, industry and regulators have no central source of safety data on which to base decisions regarding the need for additional safety studies. Therefore, there is a risk that such studies may be conducted unnecessarily. Additionally the same or similar container closure materials are used in many different pharmaceuticals, biologics, and medical devices. There is no repository of extractables information about these materials that could provide a basis for screening and selecting materials for use in product development and expedite further product-specific extraction studies.
The Extractables and Leachables Safety Information Exchange is developing a comprehensive database that will provide a jointly-developed and credible source of (i) safety information on E&L and (ii) extraction profiles and study protocols for a range of materials. Such a database will advance principles of quality by design by enhancing the prospects for identifying potential safety issues at the initial stages of the development process, when container-closure materials are being screened and selected; support member companies' regulatory filings; reduce duplication of effort and minimize testing; decrease the risk of substantial, unanticipated delays and associated costs; and serve as a forum for exchanging experience and perspectives among industry and government experts.

PS 2069 LACTOSE POWDER PHARMACEUTICAL ACTIVE BLENDS; BEHAVIOR IN RODENT AND NON-RODENT INHALATION EXPOSURE SYSTEMS AND EFFECT OF INCREASING ANIMAL NUMBERS.

C. J. Hardy[1], S. A. Moore[1], D. W. Coombs[1] and J. M. Domanski[2]. *[1]Inhalation, Huntingdon Life Sciences, Huntingdon, United Kingdom and [2]Inhalation, Huntingdon Life Sciences, East Millstone, NJ.*

Generation of aerosol from non-micronised lactose powder formulations results in a significant change in the proportions of pharmaceutical drug and vehicle compared with those in the original bulk material The ability to predict this 'fold-change' is a tool for predicting future operating conditions and test substance usage. 'Fold-change' data were collated from multiple snout/head rodent/rabbit and face-mask non-rodent inhalation exposure systems used at HLS. The fold change was lower and less variable with increasing drug blend strength; 5.6 down to 1.6 for rodent system using 0.4% and 40% blends respectively, and 8.5 down to 1.8 for non-rodent system using 0.4% to 40% blends respectively. Test drug specificity was evident for both types of system. A rodent system and 20% blend, resulted in a fold change difference from 1.8 at 0.6µg/L to 2.1 at 251µg/L for Compound 1, compared with no difference in fold value of 1.4 at 5.0µg/L and 177µg/L for Compound 2. Inclusion of an additive reduced the propensity for increasing the drug:total particulate fold-change in both systems; 5.5 down to 3 at 1% active and 10 down to 3.5% at 1% drug and 1.3 at 40%. Animal numbers influenced the system exposure performance. Twenty-six rats in a 1 week study compared with 132 in a 2 year study reduced aerosol concentration from 22% to 30%; similarly 42 and 156 mice reduced concentration from 6% to 36%, and 6 and 22 rabbits reduced concentration from 13% to 20%. We are therefore able to predict with accuracy the drug requirements for a given study design, factoring in the effects of increasing animal numbers. This is of particular importance when active drug is expensive and non-clinical programme time lines are critical, as well as achieving the required dose on day 1 of a study, vital in providing toxicokinetic data indicating achieved dose.

PS 2070 ROLE OF ACADEMIA IN A GLOBALLY COMPETITIVE DRUG DEVELOPMENT MARKET.

D. P. Waller[1], P. J. Baneux[2] and T. Welsh[2]. *[1]University of Illinois at Chicago, Chicago, IL and [2]Northwestern University, Chicago, IL.* Sponsor: J. Herman.

Biotechnology companies are increasingly seeking sites within the US and foreign countries to outsource studies supporting drug development. This is driven by high costs for the up to date infrastructure needed to meet government regulations and testing requirements. New directions in drug development related to gene therapy and nanomedicine have created specific needs to move products forward. This support may include accredited vivarium capacity, specialized facilities and state of the art instrumentation. These are expensive and difficult to operate efficiently. Limited use in a company based research program makes it difficult to justify such expenses. Sophisticated systems with high acquisition costs are often found in academic institutions to support their large leading edge research endeavors. Academic institutions leverage several users within their institutions to justify and operate such support systems. Frequently, these support systems are underutilized and require subsidies to operate within the academic environment. Such academic resources can be identified by drug development entities creating an opportunity for the academic community to leverage their assets. However, regulatory compliance rigor, administrative hurdles, timeliness and intellectual property issues associated with private industry working within an academic environment often prevent their use. Contract research organizations can provide an effective pathway to the utilization of such assets, leveraging government research funds spent to provide high tech resources and thereby increasing or keeping research within US institutions. Appropriate oversight and monitoring can establish confidence in a timely and regulatory compliant research project. Preexisting relationships with an academic institution can provide a clear path to the utilization of the academic assets with minimal delay. The leveraging of these expensive assets benefit both the academic institution and the drug industry to provide effective solutions to difficult problems with minimized costs.

PS 2071 TEN HELAS3 CELLS CAN BE TUMORIGENIC IN SUPER IMMUNODEFICIENT NOG MICE.

Y. Ohnishi[1], K. Machida[2], H. Suemizu[1], K. Kawai[3], R. Sawada[4], T. Ishikawa[4] and T. Tsuchiya[4]. *[1]Biomedical Research Department, Central Institute for Experimental Animals, Kawasaki, Japan, [2]Testing Services Department, Central Institute for Experimental Animals, Kawasaki, Japan, [3]Pathology Research Department, Central Institute for Experimental Animals, Kawasaki, Japan and [4]Division of Medical Devices, National Institute of Health Sciences, Tokyo, Japan.* Sponsor: M. Kurata.

The test for tumorigenicity (TT) is an essential checkpoint for safety assessment of cellular materials used in cell therapy. To select suitable mice as a xenogenic host for TT, susceptibilities of NOG mice (NOD/Shi-*scid IL2Rγ*^{null} mice) to xenotransplanted HeLaS3 tumor cells were examined in comparison with those of NOD/Shi-*scid* and of nude mice. When ten thousand HeLaS3 cells were subcutaneously inoculated into the flank of female mice, incidence of tumor takes at day 22 was 5/5 (100%) in NOG, 1/5 (20%) in NOD/Shi-*scid*, and 0/5 (0%) in BALB/cA-*nu* mice. The incidence at a cell dose of one hundred was 0/5 (0%) in NOD/Shi-*scid* and 3/5 (60%) in NOG mice. Similar results were obtained by using male mice. NOG mice showed tumor formation even at inoculation with ten HeLaS3 cells (total of 5 from ten mice tested). We confirmed that the tumors formed were originated from inoculated HeLaS3 cells by histochemistry including staining with anti-HLA antibodies. Higher susceptibility of NOG mice to xenotransplanted tumor cells was recognized in experiments with another cell line, LM-2-JCK. These data suggest that NOG mice should be the most suitable host mice for TT.

PS 2072 PRECLINICAL TOXICOLOGY OF 2, 2, 5, 7, 8-PENTAMETHYL-6-CHROMANOL, A NOVEL CHEMOPREVENTIVE AGENT, IN RATS AND DOGS.

K. K. Kabirov[1], I. M. Kapetanovic[2], M. Lindeblad[1], D. M. Tessier[1] and A. V. Lyubimov[1]. *[1]University of Illinois at Chicago, Chicago, IL and [2]National Cancer Institute, Bethesda, MD.*

The toxicity of 2,2,5,7,8-pentamethyl-6-chromanol (PMCol; 0, 100, 500 and 2000 mg/kg/day) was studied in CD rats following 28 days of daily oral gavage administration. Toxicity of PMCol at 500 and 2000 mg/kg/day was manifested by de-

creased body weight gains and food consumption, elevated levels of bilirubin, protein, alanine aminotransferase (ALT), cholesterol, blood urea nitrogen and blood urea nitrogen/creatinine ratio, and decreased concentrations of inorganic phosphorus. Treatment-related anemia, increases in leukocyte, lymphocyte, monocyte, and platelet counts and in fibrinogen levels, decreases in prothrombin time, and increases in serum thyroxine and thyroid-stimulating hormone levels were also seen. Plasma drug levels were increased with increasing dose of PMCol. Relative liver, spleen and kidney weights were increased. Treatment-related histopathology findings in kidney and stomach were seen. Neurotoxicity of PMCol was revealed by FOB as an increase in supported rears. The no-observed adverse effect level (NOAEL) for PMCol in male rats was 100 mg/kg/day. In female rats, the NOAEL was not established due to meaningful increase in cholesterol levels seen in the 100 mg/kg/day dose group. The toxicity of PMCol was also assessed in male dogs following 4 week oral treatment by capsule administration at doses of 0, 50, 200 and 800 mg/kg/day. Toxicity was observed at 200 and 800 mg/kg/day. There were clinical signs of toxicity, decreases in body weights, body weight gain and food consumption, decreased levels of protein and calcium, increased levels of alkaline phosphatase and ALT, increased platelet counts, decreased triiodothyronine and thyroxin levels. A microvesicular vacuolation of hepatocytes and atrophy of the thymus were observed. The NOAEL in male dogs was 50 mg/kg/day. PMCol did not show any mutagenic activity in the standard genotoxicity battery testing (bacterial mutagenesis, in vitro chromosomal aberration, and in vivo mouse micronucleus).

PS 2073 ROLE OF HUMAN CYP450 ENZYMES IN MDMA METABOLISM AND CYTOTOXICITY.

I. Antolino Lobo[1], S. M. Nijmeijer[1], M. van den Berg[1], J. Meulenbelt[2, 1] and M. B. van Duursen[1]. [1]*Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands and* [2]*National Poisons Information Centre, National Institute for Public Health and the Environment, Bilthoven, Netherlands.*

There is ongoing discussion if toxicity of 3,4-methylenedioxymethamphetamine (MDMA) is caused by parent compound or metabolites. If metabolites play a role in MDMA toxicity, the role of specific P450 enzymes is still unclear. MDMA is metabolized via two routes: 1) O-demethylenation leading to 3,4-dihidroxymethamphetamine and 3,4-dihidroxyamphetamine metabolites 2) N-dealkylation followed by oxidation to benzoic acid derivates. P450s are responsible of MDMA oxidation and at least CYP2D6 is playing a role in this process, but involvement of other P450s can not be excluded. Knowledge about involvement of specific P450s is relevant because of large differences in human susceptibility exist. By using immortalized human liver epithelial cells (THLE) transfected with P450s (T5-CMV1A2, T5-CMV3A4, T5-CMV2D6) we studied cytotoxicity of MDMA metabolites. Cytotoxicity measurements (MTT) indicate a dose dependent reduction starting at 250 mM MDMA in THLE cells with human CYP1A2. Using furafylline as specific CYP1A2 inhibitor we observed an additional 10-20% increase in cytotoxicity at concentrations of 25-100 mM. This indicates that metabolism via CYP1A2 of MDMA has a detoxifying effect, rather than causing bioactivation. MDMA concentrations itself (0.25-1 mM) also inhibited CYP1A2 activity. If this was caused by cytotoxicity or substrate inhibition is yet unknown. Similar experiments with CYP3A4 indicate a significant role of the parent compound in cytotoxicity at similar concentrations. Further studies with CYP3A4 inhibitors have to show the specific role of MDMA metabolism and this P450 enzyme. Additional experiments with CYP2D6 are ongoing. These results indicate that the THLE cells expressing high constitutive P450 activities are a good model to study bioactivation and detoxification mechanisms. Further experiments are ongoing in our laboratory to elucidate the role of human relevant P450s in MDMA toxicity.

PS 2074 PROTECTION OF RED BLOOD CELL ACETYLCHOLINESTERASE BY ORAL HUPERZINE A AGAINST EX VIVO SOMAN EXPOSURE: NEXT GENERATION PROPHYLAXIS AND SEQUESTERING OF ACHE OVER BCHE.

J. Haigh[1], P. Mattern[1], P. Aisen[2], G. Garcia[1], B. Doctor[1] and R. Gordon[1]. [1]*Department of REgulated Activities, Walter Reed Army Institute of Research, Silver Spring, MD and* [2]*Neurology, Georgetown University Med Center, Washington, DC.*
Sponsor: S. Baskins.

In a Phase I clinical trial to determine the tolerability and safety of the specific acetylcholinesterase (AChE) inhibitor huperzine A, twelve healthy elderly individuals received an escalating dose regimen of huperzine A (100, 200, 300, and 400 μg doses, twice daily for a week at each dose), with three individuals receiving a placebo. Red blood cell AChE and plasma BChE were measured in unprocessed whole blood samples following each dose, and then for up to 48 h following the final and highest (400 μg) dose to monitor the profile of inhibition and recovery of AChE. Significant inhibition of AChE was observed, ranging from 30 – 40% after 100 μg to >50% at 400 μg, peaking 1.5 h after the last dose. Gradual recovery of AChE activity then occurs, and 48 h after the last dose, red blood cell AChE had recovered to 95% of control (pre-dose) values. Huperzine A levels in plasma peaked 1.5 h after the final 400 μg dose. Plasma BChE was unaffected by huperzine A treatment (as expected). Aliquots of huperzine A-containing and placebo blood samples were exposed ex vivo to the irreversible nerve agent soman (GD) for 10 min, followed by removal of unbound huperzine A and soman from the blood by passing through a small C18 reverse phase spin column. Eluted blood was diluted in buffer, and aliquots assayed at various time intervals to determine the time taken to achieve full return in free AChE activity, and the proportion that is protected from soman exposure. Huperzine A-inhibited AChE activity was restored almost to the level that was initially inhibited by the drug. The increased doses of huperzine A were well tolerated by these patients, with a higher proportion of red blood cell AChE sequestered (protected) than has been previously demonstrated for pyridostigmine bromide (PB), indicating the potential improved prophylaxis against OP poisoning.

PS 2075 EFFECTS OF A REDUCED DARK-CYCLE ON THE GROWTH, FOOD INTAKE AND GENERAL CONDITION OF CD-1 MICE DURING A CHRONIC STUDY.

D. Farrell and G. Washer. *LAB Research Inc., Laval, QC, Canada.*

Light-dark cycles in typical non-clinical studies are standardized to 12-hours light (07:00-19:00) and 12-hours dark (19:00-07:00). In such studies it is not uncommon to occasionally interrupt the light-dark cycle for protocol-mandated activities such as toxicokinetic sampling. However, such interruptions are typically very infrequent within the context of a normal study. In some instances, such as to mimic a clinical dosing regimen, or to maximize systemic exposure via multiple daily dosing, it can become necessary to interrupt the normal light-dark cycle on a routine basis. As part of carcinogenicity study in CD-1 mice, vehicle control (sterile water) animals were dosed twice daily by oral gavage, at 12 hour intervals. Due to the size of the cohort, this necessitated that the dark cycle be abbreviated by approximately 2 hours each day, resulting in a cycle of 14-hours light (07:00-21:00) and 10-hours dark (21:00-07:00). As a nocturnal species, mice consume the majority of their food during the night. Therefore in order to ascertain whether, and to what extent the reduced dark period impacted food intake, growth and general condition as compared to mice on a standard cycle, these data from a control group of 110 male and 110 female CD-1 mice were compared to background data from age-matched CD-1 control mice which were subject to a standard light cycle. Single-housed mice were given ad libitum access to a standard laboratory diet (Teklad Certified Global Rodent Diet 2018C) and food intake and body weight were individually measured weekly for the first 13 weeks and monthly thereafter. All mice were routinely evaluated for clinical condition and ophthalmological exams and white cell differential counts were assessed at 12 months and beyond. Evaluation of food intake, body weight progression, clinical condition, differential white cell counts and ophthalmological examination results following 12 months on the reduced dark cycle revealed generally minor differences from mice exposed to a standard 12-hour cycle.

PS 2076 THE EFFECT OF DITHIOCARBAMATES ON THE INDUCTION OF MITOCHONDRIAL-DEPENDENT APOPTOSIS AND THE EXPRESSION OF MITOCHONDRIAL HEAT SHOCK PROTEINS IN RAT HIPPOCAMPAL ASTROCYTES.

A. Solanki and L. D. Trombetta. *Pharmaceutical Sciences, St. Johns University, New York, NY.*

Copper dimethyldithiocarbamate (CDDC) is a copper based fungicidal alternative suggested as a replacement for the wood preservative chromated copper arsenate (CCA). Dithiocarbamate exposure induces oxidative stress, lipid peroxidation and has been shown to induce apoptosis. Mitochondria play a central role in the regulation of apoptosis. An important event in mitochondrial-dependent apoptosis is the release of cytochrome C into the cytosol. The purpose of this investigation was to study the relationship between mitochondrial related apoptosis and the expression of mitochondrial HSPs in astrocytes in dithiocarbamate exposures. Rat hippocampal astrocytes exposed to 35 μg/mL of DDC or 2 μg/mL of CDDC for 1 hour were shown to release significant increases of cytochrome C at 12 hours post treatment. Cytosolic HSPs have been implicated in cell survival and are induced during times of stress but little is known about the induction of mitochondrial HSP expression and toxic insult. The present investigation has shown a statistically significant induction of two mitochondrial HSPs, HSP60 and mtHSP70, during exposure to dithiocarbamates in concert with the induction of mitochondrial dependent apoptosis through cytochrome C release by ELISA and Western Blot, respectively. Apoptosis was also confirmed histologically by the TUNEL assay. Thus, the induction of apoptosis through a mitochondrial dependent pathway via cytochrome C release and the concomitant increase in expression of mitochondrial HSP's was shown in dithiocarbamate toxicity in astrocytes.

PS 2077 EVALUATION OF CORTICOSTERONE AND METABOLITES IN A CHRONIC MILD STRESS RAT MODEL.

K. Navetta, T. Swanson, R. Chapin and J. Colangelo. *Drug Safety Research and Development, Pfizer, Groton, CT.*

Corticosterone is a steroid hormone secreted by the adrenal gland and is involved in the regulation of fuel metabolism, immune reactions, and stress responses. When clinical signs of stress and changes to immune organs are observed during drug development studies, differentiating between direct immunotoxicity and changes mediated by stress can be difficult. Recent research suggests that when corticosterone levels are elevated by either administration of exogenous corticosterone or by exposure to environmental stressors, changes in tissues known to be affected by stress resulted. The measurement of corticosterone during drug development studies may allow researchers to predict if changes in immune organs are the indirect result of stress or a direct drug related effect on the immune system. Previously, assessment of corticosterone levels required multiple blood samples collected over a period of time. Serial blood sampling is unfeasible in small animals, and the use of urinary corticosterone is becoming the preferred method for corticosterone assessment. A correlation between blood and urinary corticosterone has been observed and studies are ongoing to assess the use of urinary corticosterone as a pre-clinical biomarker of stress in rats (J. Immunotoxicol, 4:25-38, 2006). To aid in biomarker development, an assay to measure corticosterone and two metabolites in female rat urine has been developed. The assay utilizes HPLC coupled with mass spectrometric detection. The linear range is 0.05 to 2.0 μg/ml and assay precision is within 22%. The assay was used to measure corticosterone and two metabolites in the urine of rats exposed to chronic mild stress with and without treatment with Imiprimine. Higher levels of corticosterone and 6-α hydroxycorticosterone were observed in the urine of rats exposed to chronic mild stress without Imiprimine treatment when compared to the vehicle control rats. Corticosterone sulphate levels were below the LLOQ for most of study samples but future plans include concentrating or extracting the urine to enhance the measurement of the sulphate metabolite.

PS 2078 THE DETECTION OF NK CELLS FOLLOWING THE ADMINISTRATION OF BIOENGINEERED MONOCLONAL ANTIBODIES TO NON-HUMAN PRIMATES.

S. Fraser, N. Hiatt and P. Lappin. *Charles River Laboratories, Reno, NV.* Sponsor: S. Chuang.

CD56 is the most commonly used antigen for immunophenotypic analysis of Natural Killer (NK) cells in humans; however this antigen is not consistently present on non-human primate (NHP) NK cells, a key animal model used in preclinical safety assessment and immunotoxicology studies of biopharmaceuticals in development. The antigen most often used to identify NK cells in the NHP is CD16 (FcγRIIIA, the low affinity Fc receptor). Recently the efficacy of many new antibody biopharamaceuticals has been enhanced through engineering of the Fc fragment to increase antibody dependent cell-mediated cytotoxicity (ADCC). However, the administration of an antibody biopharmaceutical with an engineered Fc fragment often interferes with immunophenotypic detection of the CD16 antigen in NHPs, making it appear as though either CD16 expression or the total NK population has been reduced. To characterize the apparent alterations in NK cells associated with CD16 labeling, CD159a (NKG2A which does not bind Fc fragments) was evaluated as a second NK cell marker in NHPs. CD159a was observed to bind approximately 80% of the cells that label positive with CD16 in cynomolgus monkeys. Because of the potential for bioengineered monoclonal antibodies to alter the ability to detect NK cells by immunophenotyping, both CD16 and CD159a were evaluated in several NHP preclinical studies. In one study, cynomolgus monkeys were administered an antibody biopharmaceutical with an engineered Fc fragment once weekly for 5 weeks. Through the dosing phase of the study there was a reduction in CD16 labeling of NK cells; with a corresponding albeit much smaller reduction in CD159a+ NK cells, consistent with a true antibody-associated decrease in cell numbers, but to a much smaller magnitude than suggested by the anti-CD16 data. In this and additional evaluations with antibody biopharmaceuticals, the ability to evaluate alterations in NHP NK cells has been enhanced by the utilization of CD159a in conjunction with CD16 to monitor the anti-CD16/FcγRIIIA (CD16) receptor dynamics.

PS 2079 AMIODARONE INDUCES PRO-FIBROTIC AGENTS IN RAT PLEURAL MESOTHELIAL CELLS.

U. Doshi and J. M. Cerreta. *PHS, St. John's University College of Pharmacy and Allied Health Professions, Queens, NY.* Sponsor: L. Trombetta.

Clinical studies have demonstrated an association between amiodarone therapy and a variety of pulmonary complications ranging from sub-acute necrotizing pneumonitis to pulmonary fibrosis. Fibrosis is characterized by increased expression of extracellular matrix proteins and such expression may involve pro-fibrotic agents such as Angiotensin II (Ang II), Transforming Growth Factor β1 (TGF β1) and Connective Tissue Growth Factor (CTGF). This study investigated the effect of amiodarone on the levels of the pro-fibrotic proteins TGF β1, CTGF and Ang II and the extracellular matrix protein elastin in rat pleural mesothelial cells (RPMCs). RPMCs were maintained in Ham's F-12 medium at 37°C in a humidified atmosphere of 5% CO2 / balanced air. Confluent cultures of RPMCs were treated with 5μg/ml of amiodarone for 24hrs, followed by protein extraction and western blot analyses for CTGF and TGF β1. To investigate the effect of amiodarone on elastin, confluent cultures were treated with 5μg/ml of amiodarone for 24hrs, after which the original medium was replaced with medium containing 100μg/ml of β-aminopropionitrile to prevent elastin cross-linking. Effects of amiodarone on Ang II levels were studied by treating RPMCs with 5μg/ml of amiodarone for 24hrs. After 5 days of additional culture, levels of soluble elastin and Ang II present in the medium were analyzed using Enzyme Linked Immunosorbent Assays. Amiodarone treated cultures had increased levels of TGF β1 (132%±5.8; $P<0.05$) and CTGF (202.2%±9.7; $P<0.05$) in comparison to controls. Perturbation of RPMCs by amiodarone increased the accumulation of soluble elastin (197.8%±17.2; $P<0.001$) and Ang II when compared to controls. Such findings suggest that amiodarone induces the expression of pro-fibrotic proteins that in turn increase levels of extracellular matrix proteins creating a fibrotic-like response in RPMCs.

PS 2080 EFFECT OF PARTICLE SIZE ON THE REGIONAL DEPOSITION OF TECHNITIUM-99M LABELED PARTICLES IN RODENTS.

P. Kuehl[1], T. Anderson[2], T. Holmes[1], B. Gershman[2], D. Irwin[2], E. Thompson[2], J. Norenberg[2] and J. McDonald[1]. *[1]LRRI, Albuquerque, NM and [2]University of New Mexico Center for Isotopes in Medicine, Albuquerque, NM.*

There is extensive information detailing the deposition patterns of various particles in the human respiratory tracts and several manuscripts detailing deposition in preclinical species. However, the majority of the data in rodents was generated prior to significant advancements in rodent imaging capabilities. In order to address this need and determine the effect particle size has on the deposition patterns in rodent species these experiments were conducted. Rats and mice were exposed, via nose only inhalation, to particles ranging from 0.5 to 5 microns mass median aerodynamic diameter (MMAD). The aerosols were composed of technetium-99m radiolabeled sulfur colloid particles. Aerosols were generated with a series of compressed air jet nebulizers to achieve each desired particle size (0.5, 1.0, 3.0 and 5.0 micron). Aerosol samples were collected to characterize the activity aerosol concentration and the particle size distribution. Impactor analysis detailed that mass and activity median aerodynamic diameters (AMAD) correlated with each other. For example for the target particle size of 0.5 micron the MMAD was 0.62 micron and the AMAD was 0.57 micron. These data indicate that the aerosols of Tech-99m and the sulfur colloid particles were homogeneous. This trend of MMAD and AMAD agreement was consistent from 0.5 to 5 microns. In order to determine deposition animals were sacrificed immediately following inhalation exposures and were imaged using a small-animal SPECT-CT camera. Data analysis indicated that 11 μCi of material in lungs of the mouse and 60 μCi in the lungs of the rat after exposure to the 0.5 micron aerosol. Increasing particle size resulted in an increase in deposition in the nasal region and resulted in an increase in stomach uptake.

PS 2081 ADHESION MOLECULE EXPRESSION AND CYTOTOXICITY IN DIACETYL EXPOSED RAT LUNGS.

D. W. Gardiner[1, 2], W. Goldsmith[2], J. B. Morris[3], L. A. Battelli[2], S. Friend[2], V. Castranova[2] and A. Hubbs[2]. *[1]CSU, Fort Collins, CO, [2]NIOSH, Morgantown, WV and [3]UConn, Storrs, CT.*

Diacetyl (2,3-butanedione), a volatile component of butter and butter flavoring, gives food the flavor and aroma of butter, and has been associated with fixed airways obstruction in the microwave-popcorn and flavoring industries. Inhaled diacetyl vapors cause epithelial necrosis in the rat and mouse upper respiratory tract. Many cytotoxic agents cause both apoptotic and necrotic cell death but the role of apoptosis in diacetyl-induced cell death is unknown. Dicarbonyl/xylulose reductase (DCXR) metabolizes diacetyl to acetoin and appears to play a role in mucosal absorption of diacetyl. In human skin, DCXR localizes to the cytoplasm near the adhesion molecules, e-cadherin and β-catenin. Therefore, we hypothesized that diacetyl causes apoptosis and changes in epithelial adhesion molecules. Lungs were collected from Sprague Dawley rats one day after a 6 h exposure to inhaled air (n=6) or 317 ppm diacetyl vapor (n=6). Apoptosis was assessed by the TUNEL assay and immunofluorescence for activated caspase-3. DCXR, e-cadherin, and β-catenin were visualized by immunofluorescence and confocal microscopy. Diacetyl

increased the number of TUNEL and activated caspase 3 positive cells in mainstem bronchus epithelium. However, most cells in necrotic foci did not exhibit these apoptotic markers. DCXR staining was most intense in terminal bronchiolar cells morphologically consistent with Clara cells. In some necrotic foci in the mainstem bronchus epithelium, the normal thin linear staining of β-catenin at intercellular junctions was replaced by more focal globular expression. Detaching necrotic cells also often lost β-catenin and e-cadherin expression. Such alterations may play a role in, or possibly result from, necrosis, apoptosis, and/or epithelial detachment. These findings indicate that both apoptosis and necrosis contribute to diacetyl-induced epithelial injury and suggest that diacetyl may alter intercellular adhesion complexes of respiratory epithelium.

PS 2082 REPEATED EXPOSURE OF HUMAN BRONCHIAL EPITHELIAL CELLS TO OZONE SUPPRESSES THEIR RESPONSE TO STAPHYLOCOCCUS AUREUS.

S. J. Snow[1], S. Randell[1, 3] and I. Jaspers[1, 2]. [1]*Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC,* [2]*Center for Environmental Medicine, Asthma, and Lung Biology, and Department of Pediatrics, University of North Carolina at Chapel Hill, Chapel Hill, NC and* [3]*Cystic Fibrosis/Pulmonary Research and Treatment Center, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Ozone (O3) is a common air pollutant that causes a variety of adverse health effects including altered host vulnerability to pathogens. Pulmonary clearance of Staphylococcus aureus is decreased after O3 exposure, but the mechanisms that underlie altered host susceptibility are poorly understood. Our goals were to determine whether UNCN3T cells, a human bronchial epithelial cell line grown at air-liquid interface, secrete pro-inflammatory cytokines in response to repeated exposure to environmentally relevant levels of O3, and if repeated O3 exposures alter responsiveness of these cells to a S. aureus filtrate challenge. We determined that this cell line did not release cytokines following exposure to O3. We found that repeated exposures to a low dose (0.2 ppm) and high dose (0.8 ppm) of O3 followed by a S. aureus filtrate challenge attenuated the release of MIP-3α, Gro-α, IL-6, ENA-78, and G-CSF, as compared to air control cells. Furthermore, O3 pre-exposure significantly decreased phosphorylation of p65 20 minutes and 60 minutes after administration of the bacteria filtrate and significantly decreased phosphorylation of ERK1/2 20 minutes after the S. aureus filtrate challenge. These results indicate that repeated exposures to low level O3 attenuates airway epithelial pro-inflammatory responses to S. aureus filtrate This response could increase host susceptibility to this prevalent pathogen.

PS 2083 OZONE-INDUCED EXACERBATION OF ACUTE LIVER INJURY IN MICE.

D. Ibrahim Aibo[1, 2], J. Stokes[1], N. Birmingham[1], J. Maddox[1, 3], R. Roth[1, 3], J. R. Harkema[1, 2] and P. Ganey[1, 3]. [1]*, Center for Integrative Toxicology, Michigan State University, East Lansing, MI,* [2]*Pathobiology, Michigan State University, East Lansing, MI and* [3]*Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

Ozone (O3), an oxidant air pollutant in photochemical smog, principally targets epithelial cells lining the respiratory tract. However, changes in global gene expression have also been reported in livers of O3-exposed mice. Overdose with acetaminophen (APAP) is the most common cause of drug-induced liver injury in developed countries. In the present study, we examined the effects of a single, ambient O3 exposure on livers of mice treated with a hepatotoxic dose of APAP. C57BL/6J male mice were fasted overnight and then given APAP (300 mg/kg ip) or saline vehicle (0 mg/kg APAP). Two hours later, mice were exposed to 0 or 0.5 ppm O3 for 6 hours. They were sacrificed 1 or 24 hours after O3 exposure. Animals killed at the 24-hour timepoint were given bromodeoxyuridine (BrdU) two hours before sacrifice to identify hepatocytes undergoing reparative DNA synthesis. Liver tissue samples were processed for light microscopic examination and morphometric analyses. Blood samples were analyzed for plasma alanine aminotransferase activity (ALT). Saline-treated mice exposed to either air or ozone had no liver injury. All APAP-treated mice developed marked hepatic centrilobular necrosis that increased in severity with time after APAP exposure. O3 exposure increased the severity of APAP-induced liver injury as indicated by a 60% and 33% increase in necrotic hepatic tissue and plasma ALT, respectively. APAP also induced a 10-fold increase in BrdU-labeled hepatocytes that was 80% attenuated by O3. Gene expression analysis at 1 hour after O3 revealed that APAP and O3 coexposure resulted in greater expression of p21 and Socs3 mRNA and less IL-6 mRNA expression compared to APAP alone. These results suggest that acute exposure to oxidant air pollution exacerbates drug-induced liver injury and delays hepatic repair.

PS 2084 INHALED GLUCOCORTICOID CAUSES RAPID VASOCONSTRICTION IN THE ISOLATED AND PERFUSED RAT LUNG.

P. Ewing[1], C. Sjöberg[2], P. Andersson[1], S. Edsbäcker[1], V. Ryrfeldt[3] and P. Gerde[4, 3]. [1]*AstraZeneca, Lund, Sweden,* [2]*Flexura KB, Stockholm, Sweden,* [3]*Karolinska Institutet, Stockholm, Sweden and* [4]*Inhalation Sciences AB, Stockholm, Sweden.*

Rationale: Recently it was shown in the clinic that inhaled corticosteroids cause rapid bronchial vasoconstriction. The aim of the present study was to investigate whether vasoconstrictive effects on pulmonary circulation could be detected after short inhalation of a glucocorticoid in a preclinical model: the isolated and perfused rat lung (IPL). Methods: Using the recently developed DustGun Technology, we exposed the IPL by inhalation to a dry powder aerosol of budesonide (BUD). The pulmonary perfusate flow rate was assessed during 100 min post dose. A reduction in perfusion flow was interpreted as vasoconstriction. Main Results: The onset of vasoconstriction was significant within 10-40 min after inhalation exposures to 10 and 50 μg BUD compared to vehicle (lactose) (p=0.012 and 0.049, respectively). Throughout the whole perfusion period (100 min), 2 μg BUD had no effect while 10 μg had more pronounced effect than 50 μg BUD. Co-administration of a selective α1-adrenoceptor antagonist (prazosin 50 nM added to the perfusate) with 10 μg BUD reduced vasoconstriction by approximately 50% during 100 min of perfusion (p=0.003).
Conclusions: The results suggest that corticosteroid-induced airway vasoconstriction is at least partly driven by an α1-adrenoceptor mediated mechanism. The rapid onset of vasoconstriction after inhalation of budesonide suggests that this is a nongenomic effect. This ex-vivo study supports clinical observations of vasoconstriction after inhalation of corticosteroids. This model could serve as a complement to clinical models to uncover effects and mechanisms of pulmonary/bronchial circulatory changes.

PS 2085 IMMUNE RESPONSES IN NEONATAL AND ADULT RATS EXPOSED TO SOOT.

L. S. Van Winkle, D. S. Anderson, P. Edwards, J. Chan, J. Mathison and V. Mitchell. *VM:APC/Center for Health and Env., UC Davis, Davis, CA.*

Exposure to particulate air pollution (PM) has been correlated with increased morbidity and mortality in adults and with increased asthma in children. PM contains combustion products including organic compounds bound to particulates and in the gas phase. We exposed neonatal (7d old) and adult male Sprague Dawley rats to inhaled soot generated by diffusion flame for 6 hrs. Control rats were exposed to filtered air. This soot was low in organic carbon; simulating the particulate fraction of PM. Airway epithelial cell injury was assessed 2 hrs post exposure using differential permeability to fluorescent dyes, high resolution histopathology and by measuring LDH release into bronchoalveolar lavage fluid (BALF). BALF and peripheral blood differentials as well as cytokine profiles in serum and BALF were measured at 6, 24 and 48 hours post PM. We found that exposure to soot stimulated an increase in circulating neutrophils in adult rats and an increase in lavage neutrophils in neonates. LDH release was significantly increased in the BALF of neonates only at the 2 hr timepoint but cellular injury was not apparent at either age. Cytokines measured by a multiplex assay in both BALF and the peripheral blood were altered by exposure to PM compared to age matched filtered air controls. There were temporal differences by age. BALF IL-1Beta significantly increased at 2 hrs following PM in adult rats. TNF-a ($P<0.0092$) and IL-6 ($P<0.0211$) cytokine levels in serum were decreased in neonates 48 hrs post PM. We conclude that low PAH soot does not cause frank cytotoxicity in airways of neonatal or adult rats but that exposure to soot causes changes in neutrophil abundance and changes in key cytokines in both the lavage and peripheral blood. There are temporal and spatial differences in neonatal responses compared to adult responses. Funded by EPA RD83241401 and NIH ES/HL06700. Although funded in part by the USEPA this research has not been subject to USEPA required peer and policy review and therefore does not reflect the views of the Agency and no official endorsement should be inferred.

PS 2086 SYSTEMIC DISPOSITION OF INHALED NITRIC OXIDE, A SIGNIFICANT COMPONENT OF VEHICULAR EMISSIONS.

T. L. Knuckles[1], A. K. Lund[1], M. Madden[2], S. N. Lucas[1] and M. J. Campen[1]. [1]*Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM and* [2]*Human Studies Division, U.S. EPA, Chapel Hill, NC.*

Nitric oxide (NO) is a common component of fresh diesel and gasoline engine emissions that rapidly transforms both in the atmosphere and once inhaled. Because of this rapid transformation, extremely limited information is available in terms of potential human exposures and health effects. Healthy young rats were exposed to whole diesel emissions (DE) adjusted to 300 $\mu g/m^3$ of particulate matter, filtered air (FA), or 10 ppm NO as a positive control. Animals exposed to DE and

FA groups were also pre-injected (ip) with either saline or 200 μM n-acetyl-cysteine (NAC), a known thiol-containing scavenger of NO. Following 1 or 2 h of exposure, plasma NOx, a measure of total nitrites and nitrates, were determined. Predictably, pure NO exposures lead to a doubling of plasma NOx from 4 μM in the FA group to 10 μM in the DE group. Whole DE, which contained ~3.5 ppm NO, for 1 h also lead to a doubling of plasma NOx; contrary to expectations, the presence of NAC increased the levels of plasma NOx in the DE exposure group. After 2 h of exposure, the effect of NAC was lost, potentially because the $T_{1/2}$ of NAC is ~45 min in the circulation. In a separate series of experiments, human subjects were exposed to DE or FA on separate occasions for two hours and plasma was taken immediately following exposure and 20 h post-exposure. Plasma NOx was increased immediately following exposure compared to FA and this increase was resolved 24 h post-exposure. The role of NO-generated biochemical species on cardiovascular disease is at present unknown, but given the lack of change in carboxyhemoglobin in both rat and human studies, plasma NOx appears to be a useful biomarker of acute exposure to complex emissions. Based on the findings with NAC, we predict that individual nutritional and physiological status may prove essential to determining the biochemical transformation of NO systemically, and thereby influence toxic outcomes. (This abstract does not necessarily reflect EPA policy).

PS 2087 HYPOXIA INDUCIBLE FACTOR 1 ALPHA (HIF1α) MEDIATES OZONE-INDUCED LUNG INJURY IN MICE.

Y. Saini[1, 2, 3], D. I. Aibo[2, 4], K. Y. Kim[2], J. R. Harkema[2, 4, 5] and J. J. LaPres[1, 2, 3]. *[1]Genetics, Michigan State University, East Lansing, MI, [2]Center for Integrative Toxicology, Michigan State University, East Lansing, MI, [3]Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI, [4]Department of Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI and [5]The National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI.*

Ozone, a potent oxidant gas in photochemical smog, poses a threat to the respiratory tract. Its increased ambient levels have been linked to lung injury, inflammation and airway hyper-responsiveness. In children, ozone is known to worsen the asthmatic symptoms even at concentrations below the U.S. Environmental Protection Agency standard. Hypoxia Inducible Factor 1 alpha (HIF1α) is an oxygen-regulated transcription factor that is critical to the development of the lung. The role of HIF1α in ozone-induced lung injury has not been determined. To characterize HIF1α's role in this process, an inducible, lung-specific HIF1α knockout mouse model was generated. In this study, wild type (WT) and HIF1α lung-deficient female mice were exposed for five nights (8 hours per night) to filtered air alone (0 ppm ozone) or 0.5 ppm ozone. Interestingly, we observed that HIF1α deficient mice were more resistant to ozone-induced toxicity when compared to WT controls. Bronchoalveolar lavage fluid analysis revealed increased numbers of neutrophils and total inflammatory cells following ozone exposure in WT mice as compared to HIF1α deficient mice. Finally, inflammatory cytokine profiling in the lung revealed perturbations in the ozone-induced response of cytokines such as KC, IL-4, and eotaxin. Moreover, a significant increase in IL-6 was only observed in the HIF1α deficient mice following 5 days of ozone exposure. These results suggest that HIF1α mediates the ozone-induced pulmonary inflammation in response to airway injury following inhaled toxicant challenge.

PS 2088 ROLE OF MITOGEN ACTIVATED KINASE-1 (MAK1) IN HYPOXIA-INDUCED OXIDATIVE STRESS IN MACROPHAGES.

A. Jankowski Connor[1], Y. Liu[1], J. D. Laskin[2] and D. L. Laskin[1]. *[1]Rutgers University, Piscataway, NJ and [2]UMDNJ-Robert Wood Johnson Med Sch, Piscataway, NJ.*

Hypoxic insult to the lung initiates a cascade of events that ultimately results in tissue damage. These include the production of reactive oxygen species and oxidative stress, inflammation and the release of proinflammatory cytokines and eicosanoids, and alterations in mitochondrial function and apoptosis. In the present studies we analyzed the effects of hypoxia on the responses of macrophages, which are highly sensitive to oxidative stress. For these studies RAW 264.7 macrophages were exposed to hypoxia for 3-24 hr. This was accomplished by culturing the cells in DMEM/1% FBS at 37°C in a modular incubator chamber adjusted to 0-5% O2 and 5% CO2 balanced with nitrogen. Exposure of macrophages to hypoxia resulted in a time-dependent induction of mRNA expression for the oxidant enzyme NADPH oxidase (NOX2), intercellular adhesion molecule (ICAM)-1, vascular endothelial growth factor (VEGF), inducible nitric oxide synthase (iNOS), cyclooxygenase-2 (COX-2), and the adenosine A2A receptor (A2AR), a marker of cell injury. These effects were most pronounced after 16 h exposure to hypoxia. In contrast, hypoxia had no effect on superoxide dismutase or tumor necrosis factor-alpha expression. To investigate potential mechanisms regulating hypoxia-induced alterations in gene expression, cells were transfected with MAPK1 siRNA for 6 h using HiPerFect transfection reagent, 48 h prior to hypoxia. This siRNA transfection suppressed MAPK1 expression by about 70%. Knockdown of MAPK1 in macrophages resulted in significant decreases in hypoxia induced expression of iNOS, COX-2, VEGF and A2AR. These data demonstrate that macrophages are highly responsive to hypoxia and that MAK1 is involved in their activity. This may be important in the pathophysiology of lung injury associated with oxidative stress. Supported by AR055073, ES004738, ES005022 and APERG.

PS 2089 NQO1 MODULATES LUNG RESPONSES TO OZONE IN ADULT AND NEONATAL MICE.

E. N. Potts[1], N. Mason[2], R. L. Auten[2] and W. Foster[1]. *[1]Pulmonary Division, Duke University Medical Center, Durham, NC and [2]Neonatology, Pediatrics, Duke Univeristy Medical Center, Durham, NC.*

Rationale: Mice exposed to ozone during postnatal development fail to gain weight normally and also develop airway hyperresponsiveness (AHR, asthma phenotype). NAD(P)H quinone oxidoreductase (NQO1) has been identified in epidemiologic studies as a host factor for susceptibility to ozone. We have reported that humans homozygotic for a single nucleotide polymorphism (SNP) on NQO1 (known to produce a non-functional/NQO1variant enzyme) are protected from acute ozone-induced airflow obstruction, and that adult NQO1 null (-/-) mice have less lung inflammation and reduced AHR after ozone versus WT mice. We hypothesized that during early postnatal life the absence of NQO1 may also prevent the adverse effects of ozone impaired weight gain and ozone-induced AHR. Methods: C57Bl/6 (WT) and NQO1-/- pups were exposed beginning at birth to repetitive exposure to FA or 1.0 ppm ozone (3 h/day, 3d/wk x 4 wk). At day 28, pulmonary mechanics were measured by forced oscillometry in response to increasing doses of MCh aerosol. Results: for equivalent litter sizes, both WT and NQO1-/- pups had decreased weight gain compared with unexposed pups, with more severe effects in NQO1-/- pups (12% reduction for WT, vs. 22% reduction in the NQO1 -/-). Compared to FA, both WT and NQO1-/- mice exhibited ozone-induced AHR; despite the greater wgt loss, ozone-exposed NQO1-/- pups were consistently less sensitive to aerosol MCh challenge at each dose escalation as compared to airway responsiveness of ozone-exposed WT pups.
Conclusions: Ozone-impaired postnatal wgt gain was dissociated from ozone-induced AHR to MCh challenge: absence of NQO1 in neonatal mice reduces (or delays) ozone-induced lung injury and induction of AHR. Supported by:EPA-RD83329301 and NIH ES11961 & ES16347.

PS 2090 INHALATIONAL EXPOSURE TO VEHICULAR EMISSIONS INCREASES VASCULAR OXIDATIVE STRESS *VIA* THE LECTIN-LIKE-OX-LDL SCAVENGER RECEPTOR (LOX-1).

A. K. Lund, J. Lucero, M. A. Nadine, L. Selita', M. J. Harman and M. J. Campen. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

Epidemiological studies report a positive correlation between traffic-related air pollution and increased rates of cardiovascular morbidity and mortality; however, the underlying cellular mechanisms have not yet been elucidated. We have previously reported that vascular oxidative stress levels are significantly elevated in apolipoprotein KO (ApoE-/-) mice exposed to vehicular emissions, which appears to mediate increases in endothelin-1 and matrix metalloproteinases, expression of which are associated with progression of atherosclerosis. Since ROS production promotes formation of oxidized LDL (oxLDL), we investigated whether the effects of oxLDL on the vasculature are mediated via the lectin-like-ox-LDL receptor (LOX-1), the major receptor for oxLDL in endothelial cells. To test this hypothesis, 10 wk old male ApoE-/- mice on a high fat diet received either mouse IgG (control, 16 μg protein/ml, 0.1 ml/mouse, i.p.) or the neutralizing antibodies to LOX-1 (anti-mouse LOX-1/SR-E1 antibody: 16 μg protein/ml, 0.1 ml/mouse, i.p) every other day. Mice were randomly assigned to inhalational exposure of either filtered-air (FA: n=12 anti-LOX-1, n=12 IgG) or a mixed exposure of 250μg PM/m3 diesel exhaust + 50μg PM/m3 gasoline engine exhaust (n=12 anti-LOX-1, n=12 IgG) for 6 hr/day for 7 days. Upon sacrifice, aortas were split and snap frozen. TBARS analysis of the aorta show significant elevations in oxidative stress from mice exposed to vehicular exhaust (25.7 ± 1.6 nmol/ml/mg), compared to FA (9.6 ±1.4 nmol/ml/mg). Furthermore, anti-LOX-1 treatment ameliorated the increase in vascular lipid peroxidation in vehicular exhaust-exposed animals (6.7 ± 1.1 nmol/ml/mg). No significant difference was noted in between IgG and anti-LOX-1 treatment in FA-exposed mice. Such findings indicate that effects of ROS (and

subsequent oxLDL) generated from vehicular exhaust exposure in the vasculature are likely mediated through the LOX-1 receptor. Funded by NIH K99ES016586 (AKL) and NIH 1R01ES014639 (MJC).

PS 2091 CYTOTOXICITY AND NECROTIC CELL DEATH IN HUMAN BRONCHOALVEOLAR A549 CELLS FOLLOWING EXPOSURE TO FINE PARTICULATE MATTER (PM2.5) COLLECTED IN SOUTHEASTERN LOUISIANA.

B. Bourgeois, V. Rangan and D. Owens. *Environmental Toxicology, Southern University, Baton Rouge, LA.* Sponsor: R. Uppu, Ph.D..

Material suspended in the air in the form of minute solid particles or liquid droplets, especially when considered an atmospheric pollutant constitutes particulate matter (PM). Fine particles less than 2.5μM in diameter are designated PM2.5. The smaller the particle, the easier it is deposited into lung alveoli. Inhalation of PM2.5 often prompts a toxic response that is manifested by the release of cytokines. Based on this concept, the cytotoxicity of PM2.5 on A549 human bronchoalveolar carcinoma cells was studied, utilizing a Promega Cell Titer 96 Aqueous assay. Cell viability curves were generated in triplicate for three different batches of PM 2.5 suspensions. Batch 1 was utilized at concentrations of 600μg/mL, 300μg/mL, 200μg/mL, 100μg/mL, and 50μg/mL; batch 2 was utilized at concentrations of 250μg/mL, 200μg/mL, 100μg/mL, 50μg/mL, and 10μg/mL; batch 3 was utilized at concentrations of 181.8μg/mL, 145.44μg/mL, 109.05μg/mL, 72.7μg/mL, 36.3μg/mL, and 18.15μg/mL. Batch 1 showed an IC50 of 238μg/ml; batch 2 showed an IC50 of 59μg/ml; and batch III showed an IC50 of 130μg/ml. The variation in IC50 is likely due to the fact that batches were collected at different locations. The presence of transition metals in PM2.5 particulates is believed to be the major cause of toxicity. As a result, cytotoxicity was also measured in the presence of deferoxamine mesylate, a well known transition metal chelating agent, at deferoxamine concentrations of 0.75mM, 0.50mM, and 0.0375mM. Tests showed a remarkable reduction in PM2.5 cytotoxicity. The reduction in cytotoxicity suggests that deferoxamine mesylate provides protection to A549 cells, and, that transition metals are indeed involved in mediating PM2.5 toxicity. Utilizing the highest PM2.5 concentration (600μg/mL), mechanisms of cell death were investigated utilizing fluorescence microscopy. At this concentration, the three PM 2.5 batches showed a 70 + 20 %, 62 + 25%, 60 + 19% cellular necrosis (Acridine Orange/Etidium Bromide).

PS 2092 CHOLESTEROL SECOALDEHYDE ACTIVATES PHOSPHOLIPASE A2 AND CAUSES BARRIER DYSFUNCTION IN VASCULAR ENDOTHELIAL CELLS: IMPLICATIONS IN VASCULAR DISEASES.

N. L. Parinandi[1], M. Ahmad[1], A. C. Raghavamenon[2], S. Sliman[1], S. Butler[1], S. I. Sherwani[1] and R. M. Uppu[2]. *[1]Davis Heart & Lung Research Institute, The Ohio State University College of Medicine, Columbus, OH and [2]Environmental Toxicology and the Health Research Center, Southern University and A&M College, Baton Rouge, LA.*

Oxidative modification of cholesterol by ozone leads to the formation of several products, including a major product, 3β-hydroxy-5-oxo-5,6-secocholestan-6-al (cholesterol secoaldehyde or ChSeco). ChSeco has been shown in lung lavage of the ozone-exposed animals, arterial plaque, and in the brain of Alzheimer's patients. *In vitro* , ChSeco has been shown to initiate the foam cell formation, promote misfolding of proteins, and is cytotoxic to several mammalian cells. As the vascular endothelium is in constant contact with the circulating oxysterols, here, we investigated the mechanism(s) of ChSeco-induced cytotoxicity, alterations in morphology, activation of PLA2, and barrier dysfunction in cultured bovine pulmonary artery ECs (BPAECs) and pulmonary microvascular ECs (BLMVECs). Cells were treated with different concentrations of ChSeco (10 to 100 μM) for 1 and 2 h, following which the cytotoxicity (LDH release and cell morphology), release of [^{3}H] arachidonic acid (as an index of PLA_2 activation), and barrier function (electrical resistance in EC monolayers grown on gold electrodes) were determined. It was observed that ChSeco induced cytotoxicity, alterations in cell morphology, release of [^{3}H]-arachidonic acid, and decline in the electrical resistance in the EC monolayers with increase in dose of ChSeco and time of treatment of cells with ChSeco, as compared to that in the control untreated cells. Using specific inhibitors ($AACOCF_3$, methyl arachidonate fluorophosphates, and PX-18), our study also revealed that ChSeco specifically activated both the Ca^{2+}-dependent and Ca^{2+}-independent PLA_2. The results of the current study provides mechanistic insights into the oxysterol-mediated vascular dysfunctions observed during the onset and subsequent progression of the cardiovascular and cerebrovascular diseases.

PS 2093 FIBROBLAST/ENDOTHELIAL CELL CO-CULTURES TO ASSESS THE EFFECTS OF CHEMICAL AND MICROBIAL TOXINS ON ANGIOGENIC RESPONSES.

J. P. Fabisiak, C. Mathias, K. A. Brant and R. Stalter. *Environmental & Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

We previously showed that co-exposure of human lung fibroblasts (HLF) to Ni (a component of atmospheric PM) and MALP-2 (a microbial toxin) amplifies release of angiogenic factors, like IL-8 and VEGF. Here we evaluate if HLF-derived factors can modulate endothelial cell (EC) angiogenic responses in a co-culture system. HLF were seeded on glass coverslips. After 24 hr culture human lung microvascular EC were added and cultured in media optimized for the monolayer culture of EC. At various times, cells were stained for the EC-specific marker, PECAM. In the presence of exogenous VEGF, bFGF, EGF, and IGF, EC in co-culture with HLF readily formed capillary-like tubular structures. EC organized into elongated linear chains with extensive cell-cell contacts between days 3–5. Tube formation continued with marked branching (day 7) until a plexus of interconnected tubules formed (day 14). Amongst the exogenous growth factors, VEGF alone was necessary and sufficient for tube formation. We next collected conditioned media (CM) from HLF alone treated for 48 hrs with Ni(200 μM), MALP-2(600 pg/ml), or Ni/MALP-2 together. HLF/EC co-cultures were then exposed to CM diluted 50%, 25% and 10% in basal medium for 11 days. At 50% dilution, CM from HLF treated with Ni, MALP-2, or Ni/MALP-2 increased total tubular length by 145%, 269%, and 418%, respectively, compared to CM from untreated cells. Branching was enhanced 14-fold by MALP-2 CM and 18-fold by Ni/MALP-2 CM. The effects were attenuated but still observable for MALP-2 and Ni/MALP-2 CM at the 25% dilution. None of the CM showed stimulation at the 10% dilution. Thus, MALP-2, alone or combined with Ni, can stimulate EC angiogenic responses, presumably via the release of stromal-derived factors. HLF/EC co-cultures provide a robust and quantifiable way to probe microbial and chemical toxins for potential to modulate angiogenesis, which could influence neoplastic, fibrotic, and cardiovascular effects. Supported by NIH grant R01 ES11986.

PS 2094 CAN ALTERED MYOCARDIAL CA2+ HANDLING BE USED AS A BIOMARKER FOR ASSESSING CARDIOMYOPATHY AND ARRHYTHMOGENESIS OF DRUG CANDIDATES?

J. Qian and L. Guo. *Safety Pharmacology NCS, Hoffmann-La Roche Inc., Nutley, NJ.*

Since cardiotoxicity is the leading cause of drug attrition, it has become imperative to evaluate new in vitro biomarkers that can be used to identify compounds with cardiac liability early in drug development to reduce late-stage failures and post-approval withdrawals. Emerging evidence suggests that the mismanagement of myocardial Ca2+ may be a common endpoint of cardiotoxicity. To test the usefulness of altered Ca2+ handling as a predictor of cardiotoxicity, cytosolic Ca2+ was imaged with Fura-2 fluorescence dye in cultured guinea pig ventricular cardiomyocytes exhibiting rhythmic spontaneous beatings (SBs), and the acute effects of 15 reference compounds (n ≥ 5 cardiomyocytes/compound, 5-10 min exposure for each concentration) were investigated. These compounds possessed diverse cardiac liabilities through different modes of action and each exhibited a unique profile of cytosolic Ca2+ perturbation. Compounds with cardiomyopathy as the primary cardiac liability (doxorubicin and epirubicin) predominately decreased the cytosolic Ca2+ transients and the sarcoplasmic reticulum (SR) Ca2+ content as measured by a fast, brief application of caffeine (10 mM). Compounds associated primarily with hERG inhibition-related arrhythmogenesis (cisapride, terfenadine, dofetilide, E-4031 and amiodarone) mainly reduced the SB rate and the basal level [Ca2+]i. Sunitinib and imatinib had a profound effect combining features from the above mentioned types of cardiotoxicants. Compounds that caused TdP via an action other than direct hERG inhibition (aconitine, pentamidine and ouabain) induced alterations in the SB rate, basal level [Ca2+]i, cytosolic Ca2+ transient amplitude and SR Ca2+ content based on their known pharmacological effects. Finally, amoxicillin and aspirin produced no physiologically relevant effects on any of the parameters at concentrations up to 100 μM. Results of this pilot study provide evidence, as a "proof of concept", that altered Ca2+ handling can be used as a valuable biomarker in early cardiac drug safety assessment.

PS 2095 METHOD VALIDATION AND BACKGROUND DATA FOR AN *IN VITRO* HERG ASSAY.

H. Penton, T. Yamamoto and M. Vézina. *Toxicology, Charles River, Senneville, QC, Canada.*

The potential for compounds to invoke cardiotoxicity is still in the forefront of the pharmaceutical industry as one of the major causes of drug withdrawal from the market. With the recent adoption of the ICH S7B guideline, the requirement for in

vitro hERG evaluation of all pharmaceutical compounds targeted for human use is fundamental. The Human ether-a-go-go (hERG) related gene potassium channel (IKr) plays a major role in the repolarizing phase of cardiomyocyte action potential. It is the blockade of this channel and the consequent possibility of QT prolongation and increased susceptibility of torsade de pointes that is of primary concern. It has been suggested that there is a potential difference in endogenous voltage-activated potassium currents between the Chinese Hamster Ovary (CHO) and Human Embryonic Kidney (HEK) cell lines expressing the hERG channel, therefore, both were tested. Using whole cell patch clamp technique, reference compounds were tested for hERG inhibition while cells were being held at constant physiological temperature for testing. Data were captured using the 21 CFR Part 11 compliant PatchMaster Pro (HEKA). Electrophysiological characteristics of hERG behaviour were studied in three steps: stimulus-response relationship, voltage range and gating kinetics. The hERG tail current was pharmacologically verified using both negative controls (0.3% DMSO, Aspirin – 100 μM) and a positive control (Cisapride – 1 to 100 nM). Results obtained were comparable to published data. The conditions for testing the whole cell patch clamp in vitro hERG assay were considered valid and acceptable in our facility for use in determining effects on cardiovascular potassium channels.

PS 2096 ENDOTHELIAL CELL-SPECIFIC ARYL HYDROCARBON RECEPTOR NULL MICE DISPLAY LOW SYSTEMIC BLOOD PRESSURE AT MODEST ALTITUDE.

L. Agbor, M. T. Walsh and M. K. Walker. *Pharmacy, University of New Mexico, Albuquerque, NM.*

Aryl hydrocarbon receptor (AHR) null mice are hypertensive at modest altitude, but hypotensive at sea level. We tested the hypothesis that endothelial cell-specific deletion of AHR would result in a similar blood pressure phenotype as ubiquitous deletion. Mice harboring AHR with exon 2 flanked by loxP sites (AHRfx/fx) were crossed to mice expressing cre-recombinase driven by the Tek endothelial cell-specific promoter to produce Cre+/AHRfx/fx (ecAHR KO) as conditional knockouts and Cre-/AHRfx/fx (ecAHR WT) as littermate controls. To confirm AHR excision, ecAHR KO and WT mice were treated with 450 ng/kg 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and cardiac cytochrome P4501A1 (CYP1A1) mRNA measured. Mean arterial blood pressure (MAP) was measured in ecAHR KO and WT male mice using tail cuff plesthymography, which was confirmed by indwelling catheters and radiotelemetry. In addition, MAP was measured after treating ecAHR KO and WT male mice with the endothelial nitric oxide synthase inhibitor, LNNA, (250 mg/l in drinking water). Finally, to assess nitric oxide (NO) production we measured urinary excretion of total nitrites/nitrates (NOx). We found that TCDD significantly induced CYP1A1 mRNA in cardiac endothelial cells in ecAHR WT mice, but failed to induce it in ecAHR KO mice. MAP of ecAHR KO mice was significantly lower as measured by tail cuff and confirmed by radiotelemetry (MAP: ecAHR null: 105±1 mm Hg; ecAHR WT; 120±2 mm Hg), but no significant difference was detected in urine NOx. Interestingly, however, while LNNA increased MAP in ecAHR null mice, the response was even greater in ecAHR WT mice (ΔMAP: ecAHR null, +8-12 mm Hg; ecAHR WT, +18-20 mm Hg). These data suggest that hypertension at modest altitude observed in mice with complete deletion of AHR is not a result of loss of AHR from endothelial cells. Further, our data suggest that loss of AHR solely in endothelial cells may reduce NO-dependent control of blood pressure, although this cannot account for the apparent hypotensive phenotype. Supported by HL07843.

PS 2097 BENZO(A)PYRENE AND α-NAPHTHOFLAVONE INDUCED CARDIAC TOXICITY IN *FUNDULUS EMBRYOS.*

W. Dong, C. Thornton and K. Willett. *pharmacology, The University of Mississippi, University, MS.*

Both halogenated and polycyclic aromatic hydrocarbons (HAH and PAH) exposures are known to cause cardiac toxicity in fish embryos. This study is designed to further understand the mechanisms involved following exposure to a mixture of benzo(a)pyrene (BaP) and α-naphthoflavone (ANF) using *Fundulus heteroclitus* embryos. We found the critical window of susceptibility for cardiac toxicity development, including pericardial edema and tube heart, followed a 4.5 to 72 hours post fertilization (hpf) exposure. CYP1A and CYP1C1 mRNA were significantly induced by BaP + ANF, compared to DMSO, (1500- and 120-fold, respectively) at 48 hpf but at 72 hpf this induction was decreased to 500- and 50-fold. Reactive oxygen species (ROS) formation in the heart was visualized using confocal microscopy after embryos were incubated for 1 hr with dihydroethidium (50 μM). By 96 hpf, embryos exposed to BaP + ANF showed 2.1-fold higher cardiac ROS formation than controls. *Fundulus* embryos exposed to BaP + ANF + Vitamin E (VE 250 μM), for 14 dpf showed lower cardiac toxicity compared to BaP + ANF treated embryos. We also found induced apoptosis in the heart by BaP + ANF at 10, 12 and 14 dpf, but VE inhibited BaP + ANF induced apoptosis at 14 dpf. On going work includes studying apoptosis and myocyte proliferation at earlier time points corresponding to the heart formation (~72 hpf). These results indicate that BaP + ANF induce ROS and apoptosis in association with cardiac toxicity. This research is supported by NIEHS funding (R01ES012710) and NCRR; NSF Microscopy Core (0619774).

PS 2098 THE IMPORTANCE OF ASSESSING THE PHARMACOLOGICAL EFFECTS OF NOVEL CHEMICAL ENTITIES ON LEFT VENTRICULAR PRESSURE AND CONTRACTILITY.

K. Norton and M. Vézina. *Toxicology, Charles River, Senneville, QC, Canada.*

The ICH S7A guideline requires effects of test substances on the cardiovascular system be assessed with respect to BP, HR and ECG intervals. The guidelines then states that where adverse effects may be suspected additional supplemental safety pharmacology studies, including ventricular contractility should be conducted as deemed appropriate. However the definition of an adverse effect is ill defined and as such traditional approach to assessing effects is primarily limited to the core battery requirements. Failure to conduct supplementary studies is also in part due to limitations of study designs, where LVP and contractility assessment were limited to acute studies due to limitations of surgical and monitoring techniques. However with advances in telemetry it is now feasible to develop chronic models for assessing LVP and contractility in conjunction with BP, HR and ECG. The objective of this study was develop a model for continuous evaluation of LVP and contractility and highlight potential adverse effects not detected by traditional assessments. Dogs were surgically implanted with Data Sciences International (DSI) telemetry transmitter. LVP, contractility, ECG and BP were assessed over a 4 week baseline period and again for up to 24 hours following administration of Atenol and Pemobendan. Atenol, caused a rapid decrease in HR, ~30%, which was also followed by a rapid and sustained decreased in maximum left ventricular contractility of a similar magnitude. No effects were noted on blood pressures. Pemobendan caused a rapid increase in maximum left ventricular contractility (+dP/dt mmHg/sec). Contractility increased by ~100% and remained elevated for up to 4 hours. Over the same period no significant changes in heart rate or systemic blood pressure were noted. In conclusion this model demonstrates that assessment of heart rate and blood pressure alone, may result in missing potential adverse pharmacological effects and that it is essential to assess contractility as part of full cardiovascular safety assessment program.

PS 2099 TRANSPLACENTAL EXPOSURE TO ARSENIC INDUCES HEPATIC CHANGES IN APOE-/- MICE.

N. N. Ngalame, J. I. Arteel, G. E. Arteel and J. States. *Pharmacology/Toxicology, University of Louisville, Louisville, KY.*

Exposure to arsenic via drinking water is a serious health concern in the US, and also a worldwide problem. Epidemiological studies have shown that chronic consumption of arsenic contaminated drinking water is linked to higher rates of cardiovascular disease. It has recently been shown that transplacental exposure to 85 mg/L sodium arsenite (NaAsO2; 49 ppm As) in drinking water accelerates atherosclerosis in ApoE-/-mice without a high lipid diet. However, the mechanism by which arsenic induces atherosclerosis is not elucidated. We hypothesized that transplacental exposure to arsenic induces hepatic changes in the ApoE-/- mice which predisposes them to accelerated atherogenesis. To test this hypothesis, the livers of 10 week old mice transplacentally exposed to arsenic (49 ppm) were collected for protein expression, global DNA methylation, and histology studies. Transplacental exposure to arsenic increased the expression of Hsp70, total Hsp70 (Hsp 70 + Hsc 70), and Srebp1 as determined by Western blot analysis of liver homogenates. Global DNA methylation was assessed by methyl acceptance assay. There was a significantly higher incorporation of methyl groups (hypomethylation) per microgram of DNA in control mice compared to arsenic exposed mice (hypermethylation). Liver sections fixed in formalin were processed for Hematoxylin/Eosin (H/E) staining to look for necroinflammation and liver morphology, but there was no difference in the liver histology between arsenic exposed and control mice. However, analysis of plasma samples for indices of liver damage showed that arsenic exposure significantly increased plasma levels of alanine aminotransferases (ALT) and aspartate aminostransferases (AST) suggesting liver injury. Taken together; these results suggest that transplacental exposure to arsenic induces hepatic changes, which might be associated with inflammatory responses that are the driving force behind the accelerated atherogenesis. Supported in part by USPHS grants ES015812 and ES014443 and U of L Competitive Enhancement Grant.

PS 2100 DIOXIN INHIBITS HEART REGENERATION IN ADULT ZEBRAFISH.

V. Mehta[1], R. E. Peterson[2] and W. Heideman[2]. [1]*Molecular and Environmental Toxicology Center, University of Wisconsin-Madison, Madison, WI and* [2]*School of Pharmacy, University of Wisconsin, Madison, Madison, WI.*

Humans do not have the capacity to regenerate damaged heart tissue and instead form a scar that is non-contractile resulting in reduced cardiac function. It therefore becomes necessary to use other vertebrate models to understand the molecular mechanisms underlying the tissue regeneration process. One such model is the zebrafish, as it can replace damaged tissues and organs such as the heart, fins, spinal cord and the retina without forming scar tissue. We have found that the environmental contaminant 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) inhibits regeneration of the zebrafish ventricle after surgical wounding. Adult male zebrafish were exposed to 70 ng/g TCDD or vehicle i.p. and 24 h later were anaesthetized and 20% of the ventricle was surgically resected. The hearts were analyzed at 4,7,14 and 21 days post amputation and assessed for signs of recovery. TCDD exposed fish displayed a continued presence of a blood clot at the site of injury that was not replaced by new muscle compared to the vehicle control group. TCDD exposed fish also exhibited reduced cell proliferation as seen via BrdU incorporation compared to vehicle control using confocal microscopy. Amputated TCDD exposed fish displayed signs of pericarditis while this was not observed in the control group. TCDD also markedly altered expression of the epicardial cell layer transcript, raldh2, as demonstrated via in-situ hybridization in TCDD exposed hearts compared to vehicle control. Interestingly, TCDD was found to have no effect on unamputated hearts as observed via gross morphology. This indicates that TCDD has no effect on the maintenance of a normal adult heart, but interferes with a process that is critical in the healing of wounded myocardium. Elucidating the molecular mechanisms by which this occurs are currently being investigated. This work is supported by NIH Grant ES012716 and UW Sea Grant.

PS 2101 CHEMOTHERAPEUTIC AGENT DOXORUBICIN INDUCES CARDIAC FAILURE IN MALES BUT NOT FEMALES EXPOSED AS NEONATES.

M. Lorenzo[1], S. Pin[1], D. Bedja[1], P. Sysa[1], M. Askok[1], Y. Xu[2], Y. Zhang[2], K. Becker[2] and K. L. Gabrielson[1]. [1]*Johns Hopkins University, Baltimore, MD and* [2]*National Institute on Aging, Baltimore, MD.*

Pre-pubertal girls exposed to doxorubicin for cancer therapy are more likely to develop cardiomyopathy later in life. Additionally, estrogen is cardioprotective against doxorubicin toxicity in adult rodents. To model this problem we randomly treated two litters of Sprague Dawley rat pups (n=3/group). Males or females pups were administered either saline or 1mg/kg doxorubicin every other week intraperitoneally in a volume of 25-50 μL in one, two or three doses starting at day 14. Rats were evaluated monthly by trans-thoracic echocardiography to follow left ventricular systolic function. At 4-5 months of age, doxorubicin treated males showed a significant decline in left ventricular systolic function (FS%, fractional shortening) with a FS% mean ± SD of (51%± 9) compared to (69%± 2) in female doxorubicin treated rats (ANOVA p< .001). FS% was (70%± 2) for female controls and (70%± 2) for male controls. When FS% declined to 40%, (around month 5)male rats were euthanized. The FS% in female rats at 12 months was 65±3 demonstrating protection from doxorubicin cardiotoxicity. To understand the mechanism of protection, a second group of eight litters were treated similarly and euthanized 2 months after the last doxorubicin injection before a decline in heart function was observed by echocardiography. RNA was isolated from hearts of doxorubicin and saline treated males and females and screened by Illumina microarray (n=3/group). The doxorubicin treated females have a preservation of pathways involved in ribosome biogenesis and translation, heart morphogenesis and steroid receptors compared to the doxorubicin treated males. Pathways important in apoptosis were not activated in the doxorubicin treated females compared to males. Conclusion: Susceptibility in males to doxorubicin cardiac toxicity may be partly due to a reduction of cardiac protein translation and an activation of apoptosis.

PS 2102 PULMONARY COMPLICATIONS RESULTING FROM GENETIC CARDIOVASCULAR DISEASE IN TWO RAT MODELS.

J. Shannahan[1], A. Ledbetter[2], M. Schladweiler[2], A. Ghio[3] and U. Kodavanti[2]. [1]*Cirriculum in Toxicology, UNC-Chapel Hill, Chapel Hill, NC,* [2]*ETD, NHEERL, U.S. EPA, Research Triangle Park, NC and* [3]*HSD, NHEERL, U.S. EPA, Chapel Hill, NC.*

Underlying cardiovascular disease (CVD) has been considered a risk factor for exacerbation of air pollution health effects. Therefore, rodent models of CVD are increasingly used to examine mechanisms of variation in susceptibility. Pulmonary complications and altered iron homeostasis secondary to CVD may influence outcomes of air pollution exposure. In this study we characterized baseline pulmonary endpoints of iron homeostasis, oxidative stress, and inflammation in rat models of CVD. Healthy normotensive Wistar Kyoto (WKY), spontaneously hypertensive (SH), and the spontaneously hypertensive heart failure (SHHF) rats were evaluated at 11-14 wk old. Blood pressure and heart rate measurements taken by tail cuff were increased in SH and SHHF rats relative to WKY rats (SHR>SHHF>WKY). Breathing parameters measured using whole body plethysmography demonstrated increases in breathing frequency and tidal volume resulting in increased minute volume in SHHF and SH relative to WKY rats (SHR>SHHF>WKY). High blood pressure was correlated with increased minute volume. BALF protein and neutrophils were increased in SHHF and SH relative to WKY rats (SHHF>>SH>WKY). Real-time RT-PCR indicated differences in markers of inflammation and oxidative stress in lungs among strains. Pulmonary MIP-2, IL-1α, and HO-1 expressions were greater in SHHF and SHR relative to WKY. Affymetrix gene array data demonstrated alterations of several genes related to heme metabolism in lungs of SHHF but not SH rats when compared to WKY. BALF non-heme iron was also increased in SHHF relative to WKY and was associated with increases in transferrin and ferritin. This study demonstrates that SHHF have greater pulmonary complications of oxidative stress, inflammation and altered iron homeostasis than WKY or SH rats which may play a role in their increased susceptibility to air pollution. Funded by EPA/UNC CR833237 (This abstract does not reflect US EPA policy)

PS 2103 EXOGENOUS NITRIC OXIDE GAS MIMICS DIESEL EMISSIONS-INDUCED IMPAIRMENTS OF VASCULAR ENDOTHELIAL NITRIC OXIDE SYNTHASE FUNCTION.

J. Buntz[1], T. Cherng[2], S. N. Lucas[1], T. L. Knuckles[1], J. Seagrave[1], N. L. Kanagy[2] and M. J. Campen[1]. [1]*Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM and* [2]*Vascular Physiology, University of New Mexico School of Medicine, Albuquerque, NM.*

Detrimental effects of vehicular emissions on the vascular system have been increasingly recognized as an important potential contributor to the overall cardiovascular disease risk. Our data show that diesel engine emissions (DE) can induce alterations in blood pressure and electrocardiographic indices that may represent inadequate coronary perfusion. Previously, we have shown that coronary arteries exhibited enhanced constriction to the peptide endothelin-1 (ET-1) after DE exposures. In this study, we have looked at the effects of DE and one of the principal gaseous components thereof, nitric oxide, on the level and function of a crucial vascular regulatory enzyme, endothelial nitric oxide synthase (eNOS). Healthy, male Sprague-Dawley rats were exposed whole body to DE (350 μg PM/m^3) or nitric oxide (10 ppm) for a single 5 hour period. Aortic eNOS protein was significantly elevated (~3-fold) following DE and NO exposures compared to that found in filtered air-exposed control rats. Further investigation revealed that while total NOS activity, measured by a citrulline formation assay, was elevated in the aortas of exposed rats, the activity to protein concentration ratio of NOS was reduced, suggesting dysfunction of this protein with a compensatory synthesis of new protein. Furthermore, coronary artery constriction to ET-1 was enhanced following NO exposure in a manner similar to that seen in DE experiments. Thus, it appears that exogenous nitric oxide has the capacity to disrupt normal eNOS function, leading to compensatory molecular responses in endothelial cells. These studies 1) characterize a potentially crucial pathway underlying air pollution-induced endothelial dysfunction and 2) identify monoxide gases as potential environmental drivers of this effect. This project was funded by NIH R01ES014639 and EPA STAR Award RD-83186001.

PS 2104 DIFFERENTIAL OXIDATIVE PROPERTIES OF DIESEL EXHAUST PARTICLES.

N. Manzo[1], J. Richards[2], R. Slade[2], L. Martin[1] and J. Dye[2]. [1]*Mol. Biomed. Sci., NCSU, Raleigh, NC and* [2]*ORD, NHEERL, U.S. EPA, RTP, NC.* Sponsor: G. Hatch.

Diesel exhaust particles (DEP) accounts for a significant percentage of particulate matter (PM) released into the atmosphere and are associated with adverse pulmonary effects. Due to their extremely small size and high surface area, DEP can adsorb toxic substances, thus potentially influencing its effects. DEP compositions vary and are often characterized by their ratio of elemental to organic carbon (EC/OC). We hypothesized that lung epithelial cells exposed to DEP rich in adsorbed OC compounds would result in greater antioxidant responses, enhanced inflammatory chemokine release, or possibly cell injury. Three samples of varying EC/OC ratios were evaluated: OC deficient ultrafine carbon black (CB), OC poor NIST diesel standard reference material 2975 (SRM 2975), and OC rich diesel automobile (DEP_A) particles. LA-4 epithelial cells were exposed (25μg/cm^2) for 24hrs. Antioxidant responses of GSH vs. GSSG and heme oxygenase-1 (HO-1)

were determined using HPLC and realtime RT-PCR, respectively. Inflammatory chemokine release and expression of RANTES and MIP-2 were evaluated by ELISA and realtime RT-PCR. Cell injury was inferred by the release of LDH. Exposure to DEP_A resulted in significant increases in GSH, GSSG and HO-1 expression, but only minor increases in cell injury. Particle exposures had no effect on MIP-2 gene expression or release. While RANTES expression and release was not altered by CB, SRM 2975 reduced its release (most likely due to particle adsorption) without alterations in its expression, and DEP_A not only reduced its release (again due to adsorption) but also decreased its gene expression. In conclusion, DEP can selectively bind mediators, thus interfering with their quantification which must be considered when interpreting their release. In addition, it appeared that epithelial exposure to simple elemental carbon particles was largely innocuous, while particles with increasing OC content (and related adsorbed material) were seemingly associated with cellular antioxidant responses. Funded by the EPA CT826512010 (Abstract does not represent USEPA policy).

PS 2105 METABOLIC ACTIVATION AND PULMONARY TOXICITY OF DAURICINE IN CD-1 MICE.

H. Jin[1], J. Dai[1], F. Zhang[1], S. Shen[1], Y. Wang[2], D. Zhong[2], X. Chen[2] and J. Zheng[1,3]. Dauricine (DRC), a bisbenzylisoquinoline alkaloid, is the major bioactive component isolated from the root of *Dauricum D.C.*, which has been commonly used in traditional Chinese medicine as a remedy for the treatment of throat swelling, amygdalitis and chronic bronchitis. The objective of the studies was to evaluate toxicity of DRC. DRC was found to produce selective pulmonary toxicity in mice. Animals were treated i.p. with DRC, dose-dependent increases in LDH activities were observed in lung lavage fluids recovered from DRC-treated mice (150 mg/kg) to levels that were as much as 3.5 times controls. Ethdium-based staining studies showed that remarkable cells lost membrane integrity in the lungs obtained from the animals treated with DRC at the dose of 150 mg/kg. We examined the histopathalogic changes by H&E stain, and significant alveolar edema along with the swelling of alveolar epithelia and some hemorrhage was observed in the mice given the same dosage of DRC. We also evaluated the cytotoxicity of DRC in three human lung cell lines. DRC (40 μM) caused up to 60% cell death in all three cell lines and is much more cytotoxic than 4-ipomeanol and monocrotaline, known pulmonary toxins. In animal studies, we found that ketoconazole, an inhibitor of CYP3A, showed protective effect on the pulmonary injury induced by DRC. This indicates the pulmonary toxicity of DRC requires P450-mediated activation. We successfully identified a quinone methide metabolite of DRC after exposure to mouse lung microsomes. In addition, the presence of ketocanozole in the microsomal incubation inhibited the formation of the quinone methide metabolite. In conclusion, bisbenzylisoquinoline alkaloid DRC produced selective pulmonary injury. The pulmonary toxicity appears to depend on the metabolic activation of DRC mediated by CYP3A. The electrophilic quinone methide metabolite is speculated to be responsible for the pulmonary toxicity induced by DRC.

PS 2106 INFLAMMATORY EFFECTS OF THE SULFUR MUSTARD 2-CHLOROETHYL ETHYL SULFIDE IN MOUSE LUNG.

V. Sunil[1], F. Kahn[1], K. Patel[1], R. Malaviya[1], N. Bremmer[1], J. D. Laskin[2] and D. L. Laskin[1]. [1]*Rutgers University, Piscataway, NJ and* [2]*UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

Sulfur mustard gas is a potent vesicant known to damage lung tissue. Toxicity is due to alkylation of critical proteins that maintain the integrity of the lung, resulting in inflammation and oxidative stress. To elucidate inflammatory mechanisms mediating sulfur mustard gas induced respiratory damage, we used 2-chloroethyl ethyl sulfide (CEES), a lung toxicant and model sulfur mustard analog. Male mice (B6129F, 8-10 weeks) were instilled intratracheally with CEES (3 or 6 mg/kg) or control. Animals were sacrificed 3, 7 and 14 d later and bronchoalveolar lavage (BAL) fluid and lung tissue collected. Treatment of mice with CEES resulted in a time-dependent increase in cell number and total protein in bronchoalveolar lavage (BAL) fluid indicating injury to the lower lung. Increases in NOx levels were also detected in BAL fluid from CEES treated mice 7 and 14 d post exposure. This was associated with increased inducible nitric oxide synthase gene expression which was most prominent at the 6 mg/kg dose of CEES and was evident at all post exposure days. CEES instillation also resulted in increased gene expression of TNFR1 (p55 receptor for TNFα), amphiregulin (ligand for epidermal growth factor receptor) and Nrf2 (a redox-sensitive transcription factor), but reduced expression of cyclooxygenase-2 (enzyme that mediates the production of prostanoids) and MIP-2 (macrophage chemotactic factor). The effects of CEES on inflammatory mediator gene expression were most pronounced 3 day after exposure. Taken together, these data suggest that CEES modulates redox status in the lung and the production of inflammatory mediators. These changes may be important in the cytotoxic pulmonary response to sulfur mustard. Supported by NIH grants AR055073, ES004738, and ES005022.

PS 2107 EXTRAPULMONARY EFFECTS OF INHALED OZONE IN A RODENT MODEL.

L. B. Joseph[1], C. Michael[1], A. Groves[1], A. J. Gow[1], J. D. Laskin[2] and D. L. Laskin[1]. [1]*Rutgers University, Piscataway, NJ and* [2]*UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

Ozone is a respiratory irritant known to cause lung damage. This is associated with macrophage accumulation and the release of cytotoxic and proinflammatory mediators, which have been implicated in toxicity. Evidence suggests that the pathogenic response to inhaled ozone is exacerbated in the patients with chronic inflammatory conditions such as COPD. Inflammatory mediators generated in the lung are known to cause extrapulmonary effects, targeting sensitive organs such as the liver. We speculated that exposure to ozone in the presence of chronic lung inflammation modifies the hepatic response to this oxidant. To test this possibility, we compared the effects of inhaled ozone on wild type mice and transgenic mice lacking surfactant protein-D (SPD), which exhibit hallmarks of COPD. Although no major structural differences were noted in histologic sections of livers of WT and SPD-/- mice, trichrome staining indicated greater fibrosis in sinusoidal endothelium and in areas surrounding the portal triad in the SPD-/- mice. Constitutive expression of cyclooxygenase-2 (COX-2), a key enzyme in inflammatory eicosanoid production, was also greater in liver macrophages from SPD-/- mice relative to WT mice, whereas hepatic expression of high mobility group box 1 (HMGB1), a marker of oxidative stress, was similar in the two mouse strains. Inhalation of ozone (0.8 ppm, 3 hr) was associated with a time-dependent increase in the number of macrophages in lungs of wild type mice, which was most pronounced 72 hr post exposure. In contrast, in SPD-/- mice, lung macrophage numbers decreased 48-72 hr after ozone, reducing pulmonary inflammation. In WT mice ozone inhalation caused an increase in liver HMGB1 and COX-2 expression while in SPD-/- mice, decreased expression of HMGB1 was observed with no effects on COX-2. These data suggest that chronic pulmonary inflammation leads to oxidative stress in the liver, which can be mitigated by exposure to inhaled irritants that exacerbate pulmonary inflammation (NIH ES004738, ES005022, CA132624, AR055073, HL074115).

PS 2108 COMPARISONS OF DIFFERENT LUNG MORPHOMETRY METHODS OF MEAN LINEAR INTERCEPT AND MEAN CHORD LENGTH IN QUANTIFYING MILD MOUSE EMPHYSEMA.

K. M. Gideon[1], D. Kobayashi[2] and K. M. Lee[1]. [1]*Toxicology Northwest, Battelle, Richland, WA and* [2]*Division of Pulmonary & Critical Care Medicine, Washington University St. Louis School of Medicine, St. Louis, MO.*

ABSTRACT BODY: Mouse emphysema models following chronic cigarette smoke exposures are widely used in efficacy testing of COPD drug candidates and potentially reduced exposure cigarette products. There are however currently no consensus in the morphometric evaluation procedures that are critical in quantifying phenotypic changes (i.e., airspace enlargement). Procedural information is scanty in literature and appears to vary as does methods and reporting of data. The objectives of the project were to define and compare two of most widely used morphometry procedures, the mean linear intercept (Lm) and the mean chord length (MCL) in detecting subtle emphysema changes in mouse lung following chronic smoke exposures. Potential variables and factors that may affect the outcomes were also identified and discussed with the intention of recommending standardization of each procedure. Female AKR mice (~12 wks at start) were exposed to mainstream smoke from 2R4F reference cigarettes (filter removed), 2-4 cig/day, 6 d/wk for 24 wks. Up to 10 mice/group were subjected to Wk 24 necropsy and histopathologic examination. Microscope slides of lung tissues were analyzed by image analysis (Image Pro Plus® Version 6.2.1, Media Cybernetics, Bethesda, MD)to determine Lm and MCL. The morphometry results were method dependent as well as sample acquisition dependent. The outcomes ranged from statistically insignificant to mild degree of emphysema (significant increases in Lm and MCL: ~10-13%). Key variables include: 1) filed selection and the exclusion criteria – random or selective (e.g., fields containing large airways and vessels excluded), 2) the use of parallel horizontal lines only for MCL or both the parallel horizontal and vertical lines, 3) a Quality Control review or verification by histopathologist, and 4) automation and consistency in method application among groups. (Funded by Battelle Biology and Health Science Initiative)

2109 BLEOMYCIN-INDUCED PULMONARY FIBROSIS: COMPARATIVE TOXICOLOGY AND PATHOLOGY FROM IT *VS.* INHALATION.

M. Doyle-Eisele, J. McDonald and A. Gigliotti. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

Intratracheal (IT) bleomycin (BS), one of the most commonly used animal models for pulmonary fibrosis (PF), causes patchy fibrosis in the lung. While these models do not elucidate the human condition, they are representative of many of the clinical and subclinical PF characteristics. This model allows 7-10 days for the pneumonia-like symptoms to resolve and then retains the animals through 14-28 days for the onset of PF. In this study, we compared the dose dependency and time-course of toxic response and cellular mediators (collagen, αSMA, CTGF, TIMP1, TGFB1, and fibronectin) associated with the manifestation of PF via IT and inhalation in F344 rats. The novel delivery of BS in rats should enhance the inflammation and other results (including time-course) associated with PF. Animals were examined for in-life clinical signs, gross and microscopic pathology, and changes in cellular mediators. Rats received 3-6 mg/kg, IT or 0.12 mg/kg, inhalation. 3 mg/kg IT induced minor cytokine and microscopic changes through 21 days. As a follow-on study the dose was increased to 6 mg/kg, however the onset of pneumonia and PF caused mortality by day 11. 3.5 mg/kg was evaluated through 28 days and caused reversible respiratory distress, increases in collagen, αSMA, CTGF, TIMP1, TGFβ1, lung inflammation, and significant changes in pathology that included dimpling, hardening, and remodeling of the lung tissue and the formation of fibrotic patches throughout the lung. In contrast, inhaled BS caused an increase in αSMA only with slight inflammation and changes in pathology. The decreased response is likely due to the dose dependency of the model. A limitation during the initial development of the inhaled model was the solubility of BS in saline. Follow-on studies examined the use of water which increases the maximum feasible dose in the inhalation system. Higher inhaled doses generate increased toxicity and fibrosis. In conclusion, we've shown the administration method combined with the dose play an important role in the onset of PF symptoms and resulted pathology in murine models.

2110 PROLONGED AIRWAY HYPERRESPONSIVENESS AFTER SUB-CHRONIC INHALATION EXPOSURE TO BREVETOXINS.

W. M. Abraham[1], J. Zaias[2], A. J. Bourdelais[3] and D. G. Baden[3]. [1]*Research, Mount Sinai Medical Center, Miami Beach, FL,* [2]*Pathology, U Miami, Miami, FL and* [3]*Center for Marine Sciences, UNC, Wilmington, NC.*

Brevetoxins (PbTxs) are potent polyether neurotoxic compounds produced by the dinoflagellate *Karenia brevis*. Surf and wind can aerosolize these PbTxs resulting in inhalation exposure at or near beaches that can produce both immediate and chronic asthma-like symptoms in humans, especially those with pre-existing airway diseases. To understand the more chronic effects of inhaled PbTxs, we challenged 4 "asthmatic" sheep with 20 breaths of a 300 pg/ml solution containing equal amounts of PbTx-2 and PbTx-3, on 4 consecutive days. This combination of PbTxs represents the most prevalent PbTxs aerosolized during a red-tide event, and the dosing approximates exposure during light exercise. We measured airway responsiveness to inhaled carbachol, and performed bronchoalveolar lavage (BAL) before and serially after the last PbTx challenge. Compared to pre-challenge, the sheep developed airway hyperresponsiveness (a hall-mark of asthma) that was as severe on the 7th day after challenge as was seen 2h after the last exposure ($P<0.05$). After 14 days airway responsiveness was normal. To determine if an irritant remained in the airways that contributed to this prolonged airway hyperresponsiveness, we assessed the BAL fluid for bronchoconstrictor activity by aerosolizing cell free supernatants back into 5 PbTx-naive sheep and measuring airway resistance. BAL fluid obtained on the last exposure day and 1 day later, caused a mean 60% increase in airway resistance ($P<0.05$). A measurable constrictor effect in BAL fluid obtained 7 days after challenge, but not at 14 days, was seen. The BAL fluid-constrictor activity was partially blocked by pre-treating the sheep with the PbTx antagonist, β-naphthoyl-PbTx. We conclude that low level PbTx exposures can induce airway hypresponsiveness that lasts for 1 week. The airway responsiveness may be triggered in part by residual PbTx in combination with soluble mediators that are present in the airways during this period. Supported by NIH-P01 ES 10594.

2111 NONINVASIVE AND INVASIVE PULMONARY FUNCTION IN MICE WITH OBSTRUCTIVE AND RESTRICTIVE RESPIRATORY DISEASES.

J. A. Vanoirbeek[1], M. Rinaldi[2], V. De Vooght[1], S. Haenen[1], B. Nemery[1], W. Janssens[2] and P. H. Hoet[1]. [1]*Lung Toxicology Research Unit, K.U.Leuven, Leuven, Belgium and* [2]*Pulmonary Medicine Research Unit, K.U.Leuven, Leuven, Belgium.*

Pulmonary function analysis has become an important tool in the evaluation of different murine respiratory disease models. It is still unclear however, which test is optimal for a particular disease as the most commonly used pulmonary function variables of humans are not routinely applied in mice. With this study we wanted to delineate the potential and restrictions of several existing pulmonary function techniques and validate some common variables between humans and mice. We therefore evaluated one noninvasive (whole body plethysmography) and two invasive pulmonary function setups (forced maneuvers system from Buxco and forced oscillation technique-FlexiVent from Scireq) in different mouse models. Two models of asthma (occupational and allergic), a model of pulmonary emphysema and a model of pulmonary fibrosis were compared with healthy controls. We found that noninvasive tests were not useful for our purpose. However, invasive forced expiratory flow-volume curves adequately measured hyper-responsiveness to methacholine, airflow limitation and airway obstruction, which best correlated with the invasive measurement of respiratory resistance. Both invasive techniques were efficacious for the quantification of restriction or hyperinflation via changes in total lung capacity or vital capacity, and compliance of the respiratory system was proved to be useful and specific in this setting. Forced oscillation variables may have less clinical value but were shown to be additional for the further description of the underlying lung disease. We conclude that invasive pulmonary functions are very useful in the description of respiratory disease models and may bring murine models more close to human pathology.

2112 CALIFORNIA 2008 WILDFIRES: MOUSE LUNG RESPONSE TO PM EXPOSURE.

T. C. Wegesser[1], K. E. Pinkerton[2] and J. A. Last[1]. [1]*Pulmonary/Critical Care Medicine, University of California, Davis, Davis, CA and* [2]*Department of Pediatrics, University of California, Davis, Davis, CA.*

Central and Northern California experienced thousands of forest and brush fires during the last week of June in 2008 giving rise to several weeks of severe fire-related particulate air pollution throughout the region. PM10 (coarse) and PM2.5 (fine) concentrations greatly in excess of the air quality standards and among the highest values reported at these stations since data have been collected. Toxicity of coarse and fine PM obtained during the time of peak concentrations of smoke in the air were determined using a mouse bioassay and compared with PM samples collected under normal conditions from the region during the month of June in 2007. We determined total and differential cell content and total protein content of lung lavage fluid, and performed histological evaluation of inflammatory cell influx. Inflammatory and toxic responses of the mice were readily observed with intratracheal instilled total doses of 10-100ug of coarse PM or 25-100ug of fine PM per mouse. Concentrations of PM were not only higher during the wildfire episodes, but the PM was much more toxic to the lung on an equal weight basis than was PM collected from normal ambient air in the region. Our data suggest that inflammatory and toxic effects observed from both coarse and fine PM collected during wildfires from California contain chemical components that are toxic to the lung and especially to alveolar macrophages. Thus, the common assumption for regulatory purposes that all particles of a given size class in ambient air are equally toxic is not valid.

2113 THE AMOUNT OF BODY FAT IS RELATED TO EXPOSURE OF PERSISTENT ORGANIC POLLUTANTS IN SWEDISH MEN FROM THE GENERAL POPULATION.

M. P. Lind[1], K. Michaelsson[2], A. Wolk[1], L. Lind[3] and A. Glynn[4]. [1]*Institute of Environmental Medicine, Karolinska institutet, Stockholm, Sweden,* [2]*Department of Surgical Sciences, Uppsala University Hospital, Uppsala, Sweden,* [3]*Department of Medicine, Uppsala University Hospital, Uppsala, Sweden and* [4]*Toxicology Division, Swedish National Food Administration, Uppsala, Sweden.*

Obesity and associated metabolic syndrome diseases are growing problems in the industrialized world. Increased caloric intake and decreased physical activity are believed to be the causes of this dramatic rise. However, recent findings highlight the possible involvement of environmental "obesogens" or endocrine-disrupting chemicals such as persistent organic pollutants (POPs) that can disrupt homeostatic controls over adipogenesis and energy balance. The present study hypothesized that the level of POP contaminants within a human was related to the amount of body fat. In a sample of men (n= 108, mean age 62 years, range 41-76), circulating levels of two markers of POP exposure, the anti-androgenic compound1,1-dichloro-2,2-bis(p-chlorophenyl)-ethylene (p,p-DDE) and the di-ortho chlorine substituted PCB congener PCB153, were analyzed together with total body fat evaluated by dual-energy X-ray absorptiometry (DXA). Univariate results indicate that both p,p-DDE and PCB153 were related to the amount of body fat ($r= 0.27$, $p= 0.004$ for p,p-DDE and $r= 0.34$, $p= 0.0001$ for PCB153). In multiple regression analysis adjusting for age, height and weight, both p,p-DDE ($p= 0.005$) and PCB153 ($p= 0.03$) were still significantly related to the amount of body fat. Conclusion: In a population sample of Swedish men, two markers of POP exposure, p,p-DDE and the PCB congener PCB153, were related to the amount of body fat also after the

adjustment of height and weight. This finding suggest that exposure of POPs could be of importance for development of obesity in humans, but further analyses of the associations are needed before conclusions about causality can be made. Most importantly, the associations has to be confirmed also in women.

PS 2114 DIESEL-EXHAUST PARTICULATE (DEP AND NANOPARTICLE (NP) EXPOSURES: CAN DEP TELL U.S. ABOUT POTENTIAL HEALTH RISKS OF NP?

T. W. Hesterberg[1], C. A. Lapin[2], C. M. Long[3] and P. A. Valberg[3]. *[1]Navistar, Inc., Warrenville, IL, [2]Lapin & Associates, Glendale, CA and [3]Gradient Corporation, Cambridge, MA.*

Potential health risks of engineered NPs are increasingly studied in vitro and in laboratory animal experiments, but there is a lack of data on humans exposed to NP. However, there is an abundance of human data for another source of NP exposure, notably for NP found in DEP. In laboratory settings, human-volunteer exposure studies report DEP number concentrations (i.e., $>10^6$ particles/cm^3) that exceed the highest measured values reported to date in manufacturing and handling of engineered NPs. Recent human DEP exposure studies, using sensitive physiological instrumentation and well-characterized exposure concentrations and durations, suggest that elevated DEP exposures (from older diesel-engine technologies, and at levels 1 to 2 orders of magnitude higher than environmental or occupational concentrations) may trigger short-term changes in, for example, lung and systemic inflammation, thrombogenesis, and brain activity. In these reports, considerable uncertainty remains as to (1) which DE constituents underlie the observed responses (i.e., NPs, DEP mass, DE gases), (2) the relevance of these findings to newer diesel-engine technologies, and (3) the implications of the observed changes for the development of disease. However, if we consider the elevated DE exposures that have existed in some occupational settings (and thus, high NP concentrations), and if we assume that DE NPs are the most biologically active component of DEP, accumulated worker health data do not appear to support the idea that NPs in DE lead to enhanced toxicity compared to other inhaled particles. In summary, the elevated levels of NPs in DEP, combined with available human data on DEP health effects, do not support the idea that high levels of NP exposure per se (at least in the DEP context) must be highly toxic by virtue of the NP content alone.

PS 2115 INTERSPECIES EXTRAPOLATION OF TOXICITY DATA IN ECOLOGICAL RISK ASSESSMENT: ISSUES AND SOLUTIONS.

A. Pfingst and M. Stelljes. *SLR International Corp, Bothell, WA.*

Extrapolation of toxicity data across species is a primary source of uncertainty in ecological risk assessment. In the 1990s, USEPA and other agencies recommended use of allometric equations for such extrapolations. Since metabolic rate is directly proportional to body weight, these equations could be used to modify results of toxicity tests in laboratory animals for wildlife species merely through comparison of body weights. The approach most generally used the ratio of the target to test species body weights raised to the 0.75, resulting in higher toxicity reference values (TRVs) for larger species than for smaller species. For example, using this approach, lead TRVs for herbivorous mammals in the arctic can range from 4.2 mg/kg-day for the lemming to 1,043 mg/kg-day for the caribou. Similarly, for carnivorous mammals the TRVs range from 2.5 mg/kg-day for the weasel to 68 mg/kg-day for the arctic fox. Without using such an equation, the lead TRV for all mammals is assumed to be equal to 7.63 mg/kg-day, the value developed for the test species (rat). USEPA no longer recommends use of allometric equations for interspecies extrapolation of toxicity data, citing field data that do not support their use. However, the current practice of assuming equivalent toxicity ignores the differences in body sizes and metabolic rates across species. From a regulatory standpoint, the chosen approach is a key component in differentiating between sites that require additional work and those that do not. For metabolically activated compounds, allometric equations should provide more accurate predictions of potential toxicity than the assumption of equivalent toxicity. For chemicals that do not require metabolic activation, another metric should be used that does not assume equivalent toxicity. Therefore, the current USEPA approach is not recommended as it ignores all physiological, anatomical, and toxicological knowledge of different species. New guidance, supported by both field data and toxicological literature, should be developed to reduce uncertainty in interspecies toxicity data extrapolation.

PS 2116 A MECHANISTIC STUDY ON THE AMIDARONE-INDUCED PULMONARY TOXICITY IN RATS.

B. Al-shammary, M. Khalifa and S. Albakheet. *Pharmacology, King Saud University, Riyadh, Saudi Arabia.* Sponsor: N. Zawia.

Amiodarone (AM) is gaining support as a first-line antidysrhythmic drug despite its potentially fatal pulmonary toxicity. The goal of this study was to investigate some possible mechanisms associated with AM-induced pulmonary toxicity (AIPT) in rats. To achieve this goal, Sprague-Dawley rats were given AM in a dose level of 80mg/kg/day/i.p for one, two, three and four weeks. Rats were weighed at day 7, 14, 21 and 28 following AM injection. Bronchoalveolar lavage (BAL) was obtained from each group and used for determination of total leukocytic count. Lung samples obtained from each group were weighed. Homogenization was done freshly and the homogenate was used for determination of biochemical parameters such as ATP content, lipid peroxides, (GSH, catalase, SOD, GPx, and GR activities), NO and hydroxyproline levels. Histopathology of lung fragments was also investigated. Results revealed that administration of AM for one week show a significant decrease in body weight together with an increase in both lung weight and lung/body weight coefficient. GSH depletion was observed. Considerable increases in lung hydroxyproline level with some histopathological alterations were apparent. Treatment for two weeks produces significant increase in BAL fluid, total leukocytic count and elevation of both GR activity and NO level in lung homogenate. Loss of cellular ATP and inhibition of most antioxidative protective enzymatic system appeared. Alteration in SOD activity was appeared following daily treatment for three weeks. In rats treated with AM for four weeks, more severe toxicity was apparent together with significant reduction in GR activity. Histopathological diagnosis was mostly granulamatous inflammation and interstitial pneumonitis in rats treated for three and four weeks respectively. No fibrosis was detected in either one of the aforementioned groups. Lastly, it is evident that AIPT might occur in rats in a sequence of edema, inflammatory reactions and sever imbalance between ROS production and antioxidant defenses ending ultimately in sever lung toxicity.

PS 2117 INCREASE OF DOPAMINE LEVELS AFTER FIPRONIL TREATMENT.

A. Anadon, M. A. Martinez, R. Pita, M. Martinez, V. Caballero, I. Ares, E. Ramos and M. R. Martinez-Larrañaga. *Department of Toxicology and Pharmacology, Faculty of Veterinary Medicine, Universidad Complutense, Madrid, Spain.*

Fipronil, a phenylpyrazole insecticide is a potent blocker of GABA receptors, which are believed to be its primary target site. Because of its high insecticidal activity against many insects and other arthropod pests, fipronil has found many uses in agriculture, veterinary medicine and urban pest control. In relation to the oral LD50 values of fipronil in insects and rats, the sensitivity of insects to fipronil is 700- to 1300-fold higher than that in rats. Limited information is available on the in vivo CNS effects of fipronil. Because of a variety of putative biochemical and physiological target sites may contribute to fipronil toxicity, the objective of the present study was to investigate neurochemical effects following the administration of fipronil (5, 10 and 15 mg/kg/day, orally for 5 days) in male Wistar rats (n =6/group). Animals were sacrificed 24 hours following fipronil administration and their brains were rapidly removed. The hypothalamus, midbrain and striatum were dissected and analyzed for content of dopamine (DA) and its metabolites dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) using a HPLC method with electrochemical detection. Fipronil causes a dose-dependent increase of DA levels. Fipronil, at the highest dose, increased DA levels in hypothalamus (66%, $P<0.001$), midbrain (51%, $P<0.001$) and striatum (40%, $P<0.001$). In contrast, fipronil, at the highest dose, decreased DOPAC levels in hypothalamus (39%, $P<0.001$), midbrain (48%, $P<0.001$) and striatum (19%, $P<0.001$) respect to corn oil controls. Similarly, Fipronil decreased the turnover [(DOPAC+HVA)/DA] in hypothalamus (20%, $P<0.01$), midbrain (64%, $P<0.001$) and striatum (35%, $P<0.001$) respect to corn oil controls. These results demonstrate that fipronil toxicity may be mediated by dopamine receptors. This work has been supported by projects No. CCG07-UCM/AGR-2618 & Consolider-Ingenio 2010 No. CSD2007-063 (MEC), Spain.

PS 2118 MULTIMODAL BIOSENSOR FOR ANALYSIS OF BLOOD ESTERASES.

G. F. Makhaeva[1], I. N. Kurochkin[2], A. V. Eremenko[2], M. V. Porus[2], G. V. Dubacheva[2], L. V. Sigolaeva[2], I. I. Kurochkin[2], N. P. Boltneva[1], E. V. Rudakova[1] and R. J. Richardson[3]. *[1]Institute of Physiologically Active Compounds RAS, Chernogolovka, Russia, [2]Chemistry Department, Moscow State University, Moscow, Russia and [3]Environmental Health Sciences/Toxicology, University of Michigan, Ann Arbor, MI.*

The aim of this work was to develop a multimodal biosensor for simultaneous analysis of blood esterases including acetylcholinesterase (AChE), butyrylcholinesterase (BChE) and carboxylesterase (CaE). The task can be solved when sensors and sensor arrays are used that are formed by layer-by-layer (LBL) technology. The sensor array application enables the measurement of multiparameter analytical responses that can be analyzed using modern mathematical approaches, thus providing simultaneous quantitative assay of mixtures of esterases. Based on LBL technology, a bielectrode measuring system was created for the simultaneous analysis of choline and phenol. The measuring process of the bielectrode system was optimized for the analysis of individual activities of AChE, BChE and CaE, as well as

analytical responses of binary (AChE/BChE) and ternary (AChE/BChE/CaE) mixtures using esters of choline and phenol as the esterase substrates. Procedures for input data preparation (analytical responses of the test mixtures) along with different algorithms for calculation of the component concentrations in a mixture were developed. The algorithms for the calculation of the concentrations of separate components in the mixture (concentrations of AChE/BChE/CaE) were developed based on methods of formal kinetics and neural networks. The mean error of the calculation of the component concentrations in the mixture was about 8% for binary mixtures and 15-20% for ternary mixtures of esterases. Preliminary experiments were performed on the quantitative determination of the content of AChE/BChE/CaE in samples of plasma and whole blood of rats and humans. The results were validated using standard biochemical methods for the respective esterase assays. Supported by ISTC project # 3130.

PS 2119 KINETIC DIFFERENCES IN THE INTERACTIONS OF CHLORPYRIFOS OXON WITH BUTYRYLCHOLINESTERASE AND ACETYLCHOLINESTERASE.

J. Shenouda[1], P. Green[1] and L. Sultatos[2]. *[1]Pharmacology and Physiology, UMDNJ - Graduate School of Biomedical Sciences, Newark, NJ and [2]Pharmacology and Physiology, UMDNJ - New Jersey Medical School, Newark, NJ.*

The organophosphorus insecticides are commonly utilized throughout the world, and account for about half of all insecticide use in the United States. The acute toxicity observed following exposure to toxic levels of these chemicals is the accumulation of excess acetylcholine resulting from inhibition of acetylcholinesterase (EC 3.1.1.7) and probably butyrylcholinesterase (EC 3.1.1.8). Previous studies from this laboratory have shown that the interactions of some organosphates with acetylcholinesterase are far more complex than originally thought, with the inhibitory rate constant k_i changing as a function of inhibitor concentration (concentration-dependent inhibition kinetics). In the present study, chlorpryifos oxon (*O,O*-diethyl *O*-(3,5,6-trichloro-2-pyridyl) phosphate) displayed concentration-dependent inhibition kinetics towards human recombinant acetylcholinesterase. For example, 2 nM chlorpyrifos oxon yielded a k_i of 9.32 $nM^{-1}h^{-1}$, whereas 10 nM inhibitor gave a k_i of 1.36 $nM^{-1}h^{-1}$. In sharp contrast, no evidence of concentration-dependent inhibition kinetics was observed with the inhibition of butyrylcholinesterase with chlorpyrifos oxon. With a range of chlorpyrifos oxon concentrations from 0.3-10 nM, estimates of the k_i ranged from 30 $nM^{-1}h^{-1}$ – 70 $nM^{-1}h^{-1}$, with no pattern of concentration-dependent inhibition. Stopped-flow studies determined the K_d for chlorpyrifos oxon binding to butyrylcholinesterase to be 2.52 nM. These data suggest that active site gorge differences between these two enzymes have important mechanistic implications for concentration-dependent inhibition kinetics. (Supported by Grant ES012648 from NIEHS).

PS 2120 DOSE-RESPONSE EVALUATION OF C57BL/6 MICE FOR MOTOR ABNORMALITIES AND PARKINSON-PATTERNED NEUROPATHOLOGY AFTER PARAQUAT AND MANEB EXPOSURE.

L. J. McIntosh[1], J. P. O'Callaghan[2], S. A. Benkovic[2], D. B. Miller[2], R. Patten[3], M. J. Collier[4], R. C. Switzer[5], S. Warren[1] and A. A. Li[1]. *[1]Exponent, Inc., Menlo Park, CA, [2]Molecular Neurotoxicology Laboratory, Centers for Disease Control, Morgantown, WV, [3]Huntingdon Life Sciences, Reproductive Studies Group, Eye, Suffolk, United Kingdom, [4]Huntingdon Life Sciences, Behavioural Group, Eye, Suffolk, United Kingdom and [5]NeuroSciences Associates, Knoxville, TN.*

The combination of paraquat and maneb (PQ/MB) has been proposed to be a risk factor for Parkinson's Disease. C57Bl/6 mice were dosed daily from PND 5-19 (0.3/1.0 mg/kg PQ/MB) and/or twice weekly from week 28-31 of age (10/30 mg/kg PQ/MB), the levels reported in the literature to cause loss of substantia nigra cells. This high dose was reduced to 5/15 mg/kg PQ/MB following lethality in naïve males after the fourth of seven injections as adults. Additionally, two other doses were derived from human PQ exposure models and were administered as a middle dose (0.06/0.18 mg/kg PQ/MB juvenile, 0.6/1.8 mg/kg PQ/MB adult) and a low dose (0.0007/0.002 mg/kg PQ/MB juvenile and adult) to represent exposure levels more relevant to humans. Animals dosed as juveniles only, as adults only, or both, were tested for motor activity and arena behavior at 32 weeks, and then perfusion fixed for evaluation of neuropathology at 33 weeks. One additional group dosed as juveniles and adults was tested again at 62 weeks and sacrificed at 70 weeks of age. At 32 weeks of age, there were no effects of treatment on behavioral endpoints. At 62 weeks of age, treated animals were similar to controls in the arena and activity cage, except in high dose females where ambulatory and rearing activity was increased. Staining with anti-GFAP and deOlmos' amino cupric silver method did not detect any degenerative response related to treatment across the entire brain at either 33 or 70 weeks of age in either gender. Stereological analysis and quantification of dopaminergic neurons in the substantia nigra is ongoing.

PS 2121 PRENATAL EXPOSURE TO PERMETHRIN CAUSES VASCULAR MALFORMATIONS IN THE FETAL BRAIN AND DECREASES MOTILITY OF ADULT MICE.

S. Imanishi, H. Akanuma, M. Okura, H. Shiraishi, H. Fujimaki and H. Sone. *National Institute for Environmental Studies, Tsukuba, Japan.*

Recently, permethrin, a pyrethroid insecticide, was shown to cause abnormalities in the central nervous system (CNS). Previously, we demonstrated that permethrin decreased both endothelial differentiation from mouse embryonic stem cells and angiogenesis of human brain microvascular endothelial cells in vitro. Abnormalities in the CNS may result from defects in formation of the brain vasculature. In the present study, we investigated the effect of prenatal exposure to permethrin on brain vascular formation in the mouse fetus and on the behavior of mice after maturation. Mice at embryonic day (ED) 10 were administered permethrin at the dose of 0, 2, 10, 50 or 75 mg/kg dissolved in corn oil. Fetal brains were obtained at ED17. The length of the anterior-posterior axis was shorter in the groups treated with permethrin at the dose of 10, 50 or 75 mg/kg than those treated with corn oil alone. Vascular malformation were observed in all of the permethrin treated groups, and included shortened lengths of vessels, an increased number of small branches and, in some cases, insufficient fusion of the anterior communicating arteries. For the behavioral test, mice at ED10 were administrated permethrin at the dose of 0, 2, or 50 mg/kg dissolved in corn oil. Motility was examined at 8 weeks and 12 weeks using the Modified-SHIRPA test. At 8 weeks, although no change was observed in spontaneous behavior, motility of male mice in an open field was significantly decreased in both permethrin treated groups. At 12 weeks, no change was detected in female mice, while a significant decrease of spontaneous behavior and open field motility was detected in male mice. However, no significant change was detected in brain weight, body weight or brain morphology. Our results suggest that morphologic abnormalities in the fetal brain caused by prenatal exposure to permethrin recover in the postnatal period, but functional abnormalities in the male brain worsen.

PS 2122 DELAYED EFFECTS OF ACUTE EXPOSURE TO CHLORPYRIFOS IN AN ANIMAL MODEL (TG2576) OF ALZHEIMER`S DISEASE.

J. G. Salazar[1, 4], D. Ribes[1, 2], F. Sanchez-Santed[3], J. L. Domingo[1] and M. Colomina[1, 2]. *[1]Toxicology, Rovira i Virgili University, Reus, Spain, [2]CRAMC-Psychology, Rovira i Virgili University, Tarragona, Spain, [3]Neurosciences & Health Sciences, University of Almeria, Almeria, Spain and [4]Toxicology & Pharmacology, University of Los Andes, Merida, Venezuela.*

In mammals, exposure to organophosphates (OP) has been related to long lasting cognitive effects. Although the OP insecticide chlorpyrifos (CPF) is widely used in agricultural activities and household, it acts as a cholinesterase (ChE) inhibitor. In the present study, we evaluated the delayed effects produced by administration of a single s.c. dose of CPF (0.50 mg/kg) to male adult transgenic mice carrying the Swedish mutation for the familiar Alzheimer disease (Tg2576) and their corresponding wild-type mice. Body weight changes were recorded during the experiment. ChE activity was measured in brain 72 hr after CPF treatment in order to determine the inhibition percent achieved. A functional observation battery (FOB) was applied at 72 hr and at 8 weeks after CPF exposure. Effects on spatial learning and memory were evaluated 17 weeks after treatment in a Morris water maze test. Motor coordination and balance were tested using a rotarod 19 weeks after CPF administration. A 52.7% ChE inhibition, and a decrease in body weight 72 hr after treatment were observed. No differences between Tg2576 and wild-type were noted in spatial task acquisition. However, CPF-treated transgenic mice showed an improvement in the retention task. On the other hand, motor learning and coordination were impaired in treated transgenic mice. The current results suggest that a moderately low CPF exposure improves long term memory in Tg2576 mice in the classic version of the water maze task, but it impairs motor function.

PS 2123 COMPARATIVE SENSITIVITY OF EEG AND THE PHOTIC AFTERDISCHARGE (PHAD) TO BRAIN CHOLINESTERASE (CHE) INHIBITION BY CARBARYL.

D. F. Lyke[1], J. Mwanza[2], J. E. Graff[1] and D. W. Herr[1]. *[1]Neurotoxicology, U.S. EPA, RTP, NC and [2]NRC, Washington, DC.*

We have reported that inhibition of brain ChE by treatment with carbaryl decreased the duration of the flash-evoked PhAD (Mwanza *et al.*, 2008) and may increase Theta activity in the EEG (Graff *et al.*, 2007). We examined if changes in the non-stimulus evoked EEG were more sensitive to brain ChE inhibition than the PhAD. Long Evans rats were implanted with epidural screw electrodes. After recovery, restrained animals were tested for 2 days using similar conditions (no flash stimulus) as PhAD studies for acclimation. On day 3, the rats' pupils were dilated,

and 10 min later they were dosed (po) with 0, 1, 10, 30, or 50 mg/kg carbaryl (corn oil vehicle). EEG recording (30 segments of 2s) occurred 5, 15, and 30 min later. The EEG was transformed using a FFT and the spectra averaged. Immediately after testing rats were sacrificed, the brains removed, flash frozen, and stored at -80°C until determination of brain ChE activity by radiometric assay. Because the electrophysiological and ChE data were dependant measures, orthogonal linear regression was used to examine the relationship between %control physiological endpoints and %control brain ChE activity. Measurement error variances were estimated from independent studies for the physiological variables and brain ChE activity. Changes in Theta EEG activity of about 30% were significant, but the PhAD duration required about 50% change for significance. Considering animals with >10% brain ChE inhibition, regression indicated EEG changes associated with 46-52%, and decreased PhAD with about 38%, control brain ChE activity. The similarity was due to the asymptotic levels of brain ChE inhibition produced over this dosage range of carbaryl. Orthogonal regression improved the fit to the data, especially for the PhAD. The results indicate that the non-stimulus driven EEG and the flash-evoked PhAD have approximately similar sensitivities to inhibition of brain ChE. [2]*Supported by a NRC Fellowship. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.*

PS 2124 NEONATAL PARATHION EFFECTS ON COGNITIVE FUNCTION IN AGING RATS.

O. A. Timofeeva[1], L. Yang[1], F. J. Seidler[2], T. A. Slotkin[2, 1] and E. D. Levin[1, 2]. *[1]Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC and [2]Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

Developmental exposure of rats to the organophosphate (OP) pesticides chlorpyrifos, diazinon and parathion has been found in our studies and others to cause persistent neurobehavioral effects in juvenile and young adults. The current study was conducted to determine the persisting effects of early postnatal exposure on cognitive function in older adult and aged rats. On postnatal days 1-4, we administered parathion to male and female Sprague-Dawley rat pups at doses near the threshold for overt signs of systemic toxicity and spanning the threshold for barely-detectable cholinesterase inhibition (0, 0.1 or 0.2 mg/kg/day). The rats began training on the 16-arm radial maze starting when they were one year of age. The controls showed the normal sex difference in this spatial learning and memory task with the males having significantly fewer working memory errors than females. This normal sex effect was not evident in either of the parathion-exposed groups. The males in the 0.1 mg/kg/day parathion exposure group were significantly worse than the control males. The parathion exposed females show slight though nonsignificant reductions in errors. This study demonstrates the selective long-term behavioral alterations caused by exposure to the OP parathion at a low dose briefly during postnatal development, which does not produce clinical signs of toxicity. As we have seen previously with chlorpyrifos exposure during the same postnatal period, normal sex differences in cognitive function were eliminated by parathion. Males are particularly at risk for long-term parathion-induced cognitive impairments. This effect was seen more than a year after the brief period of low-level postnatal exposure. (Supported by NIH ES10356)

PS 2125 CRITICAL WINDOWS OF EXPOSURE FOR DEVELOPMENTAL CHLORPYRIFOS EFFECTS ON BEHAVIORAL FUNCTION IN ZEBRAFISH.

D. Sledge[1], J. Yen[2], T. Morton[1], L. Dishaw[1], K. Shuler[1], S. Donerly[2], E. Linney[2] and E. D. Levin[1]. *[1]Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC and [2]Department of Molecular Genetics and Microbiology, Duke University Medical Center, Durham, NC.*

Developmental exposure of rats to the pesticide chlorpyrifos (CPF) has been found to cause persistent neurobehavioral impairment. In a parallel series of studies with zebrafish, we are also finding persisting behavioral dysfunction after developmental CPF exposure. We have developed a battery of measures of zebrafish behavior, which are reliable and sensitive to toxicant-induced induced damage. This study determined the critical window of developmental CPF exposure for causing persisting neurobehavioral effects. Tests of learning (3-chamber tank spatial discrimination), stress response (novel tank diving test) and sensorimotor response (tap startle response and habituation) were conducted with adult zebrafish after early developmental CPF exposure. The CPF exposure level was 100 ng/ml with durations of 0-1, 0-2, 0-3, 0-4 and 0-5 days after fertilization. In the 3-chamber learning test, the 0-5 day CPF exposure group had significantly lower learning rate. Both the 0-4 and 0-5 groups were significantly hyperactive in the learning test. In the novel tank diving task the zebrafish exposed to CPF 0-5 days had a significantly reduced amount of time in the bottom of the tank. This group also was significantly hyperactive. In the tap startle response test the 0-5 day group had significantly less habituation to startle than controls. This study demonstrates the selective long-term behavioral alterations caused by exposure to CPF in zebrafish. We are in the process of evaluating the effects of starting the exposure at a later time to attempt to define the precise developmental window necessary for causing the behavioral effects. The characterization of critical windows for neurobehavioral toxicology in zebrafish will greatly facilitate the determination of the molecular mechanisms critical for long-term neurobehavioral impairment after developmental toxicant exposure. (Supported by NIH ES10356)

PS 2126 RELATIVE POTENCIES OF TYPE I AND TYPE II PYRETHROIDS FOR INHIBITION OF SPONTANEOUS FIRING IN NEURONAL NETWORKS.

S. Losa[2], A. M. Johnstone[1] and T. J. Shafer[1]. *[1]Neurotoxicology Division U.S. EPA, RTP, NC and [2]NC State University, Raleigh, NC.*

Pyrethroids insecticides commonly used in pest control disrupt the normal function of voltage-sensitive sodium channels. We have previously demonstrated that permethrin (a Type I pyrethroid) and deltamethrin (a Type II pyrethroid) inhibit sodium channel-dependent spontaneous network activity of rat cortical neurons in vitro; both compounds had similar effects. The current study further compared effects of Type I and II pyrethroids by characterizing the concentration-response of inhibition of spontaneous activity by β-cyfluthrin, cypermethrin and λ-cyhalothrin (Type II), as well as bifenthrin, teflutrin, *S*-bioallethrin and resmethrin (Type I), and fenpropathrin (mixed type). Primary cultures of rat cortical neurons from postnatal day 1-2 pups were grown on multiple electrode arrays. After 10-30 days in vitro, spontaneous network activity consisting of individual spikes and bursts developed and stabilized. Concentration-dependent effects of pyrethroids (1nM to 50μM) on spontaneous network activity were determined in the presence of 10μM biccuculine and 20μM SCH50911 (to inhibit gabaergic input). All 11 compounds caused a concentration-dependent decrease in mean network spike rates. λ-Cyhalothrin was the most potent compound, with an IC_{50} of 25 nM, while *S*-bioallethrin, fenpropathrin and resmethrin were the least potent, with IC_{50} values of ~1.5 μM. Using deltamethrin as the index chemical, relative potencies ranged from 0.12 to 7.0. In general, Type II compounds were more potent than the Type I compounds or fenpropathrin. A mixture of 5 compounds (permethin, cypermethrin cyfluthrin deltamethrin and esfenvalerate) similarly decreased spontaneous spike rate in a manner that was not effect additive. These data demonstrate that demonstrate that Type I and Type II pyrethroids inhibit network activity in a similar manner. Whether pyrethroid effects are dose-additive is currently being examined.(This is an abstract of a proposed presentation and does not necessarily reflect Agency policy)

PS 2127 TYPE I AND TYPE II PYRETHROID ALTERATIONS IN SPONTANEOUS BURSTING PARAMETERS IN RAT CORTICAL NETWORKS MEASURED USING MULTIELECTRODE ARRAY RECORDINGS.

A. M. Johnstone[1], S. Losa[2] and T. J. Shafer[1]. *[1]Neurotoxicology Division U.S. Environmental Protection Agency, Research Triangle Park, NC and [2]NC State University, Raleigh, NC.*

Pyrethroids are widely used in agricultural, industrial and residential settings to control insect pests. Pyrethroids prolong sodium channel inactivation, although their complete mode of action is not fully understood. We previously reported that permethrin (a Type I pyrethroid) and deltamethrin (a Type II pyrethroid) disrupt bursting characteristics of rat hippocampal neurons in vitro by increasing the interspike interval (ISI) and decreasing the burst duration (BD). Here, we utilize cortical neurons grown on multielectrode arrays to analyze effects of 5 pyrethroid compounds [permethrin (P), cypermethrin (Cy), β-cyfluthrin (βC), deltamethrin (D) and esfenvalerate (Esf)] on spontaneous network burst characteristics. Effects of approximate IC_{50} concentrations for decreases in spontaneous spike rate of each compound on bursts per minute (BPM), % of spikes occurring within a burst (%SB), BD and ISI were determined. In addition, effects of a mixture of these compounds (52.2% P, 28.8% Cy, 12.9% BC, 3.4% D and 2.7% Esf; 2.68 μg/mL total pyrethroid) on burst parameters were also examined. Individually, Cy (100 nM) significantly decreased BPM by 52.3% (p=0.03), and Esf (1000 nM) significantly decreased %SB by 45.6% (p=0.05) and increased ISI by 17.7% (p=0.01) compared to control (defined as bursting activity in the presence of the GABAergic blockers bicuculline, 10uM and SCH50911, 20uM). Individually, D (100 nM), P (1000 nM) and βC (500 nM) did not significantly alter any burst parameter. In the mixture, both %SB and BD were significantly reduced by 49.6% (p=0.01) and 61.6% (p=0.01), respectfully. These data demonstrate that individual pyrethroids alter burst characteristics of cortical neuronal networks individually as well as in mixtures. Whether these effects are dose-additive or effect additive is currently being examined. (This is an abstract of a proposed presentation and does not necessarily reflect Agency Policy).

PS 2128 INFLUENCE OF PYRETHROID INSECTICIDES ON SODIUM AND CALCIUM INFLUX IN NEOCORTICAL NEURONS.

Z. Cao[1], T. J. Shafer[2] and T. F. Murray[1]. *[1]Department of Pharmacology, Creighton University School of Medicine, Omaha, NE and [2]Neurotoxicology Division, U.S. Environmental Protection Agency, Research Triangle Park, NC.*

Pyrethroid insecticides bind to voltage-gated sodium channels and modify their gating kinetics, thereby disrupting neuronal function. Using murine neocortical neurons in primary culture, we have compared the ability of 11 structurally diverse pyrethroid insecticides to evoke Na^+ and Ca^{2+} influx. Pyrethroid insecticides including telfluthrin, deltamethrin, λ-cyhalothrin, β-cyfluthrin, esfenvalerate, S-bioallethrin, fenpropathrin, cyperthrin and biofenthrin produced concentration-dependent elevations of intracellular Na^+ and Ca^{2+}. Two pyrethroids, resmethrin and permethrin, did not produce Na^+ or Ca^{2+} influx. The EC_{50} values for active pyrethroids on Na^+ influx ranged from 1.44 μM (deltamethrin) to 5.86 μM (fenpropathrin). The corresponding potencies on Ca^{2+} influx varied from 1.93 μM (ensfenvarate) to 11.9 μM (tefluthrin). Tefluthrin was the most efficacious pyrethroid insectide as demonstrated by an increment of $[Na^+]_i$ greater than 20 mM. Biofenthrin was a low efficacy pyrethroid producing an increase of $[Na^+]_i$ less than 3 mM. The rank order of efficacy of pyrethroids in the Na^+ influx assay was telfluthrin> deltamethrin> λ-cyhalothrin> β-cyfluthrin> esfenvalerate> S-bioallethrin> fenpropathrin> cyperthrin> biofenthrin. Similarly, pyrethroids also displayed distinct efficacies in the Ca^{2+} influx assay. The rank order of efficacy on Ca^{2+} influx was deltamethrin> telfluthrin> λ-cyhalothrin> β-cyfluthrin> esfenvalerate> fenpropathrin> cyperthrin > biofenthrin> S-bioallethrin. These data suggest that the most salient differences between pyrethroids on Na^+ and Ca^{2+} influx were in their respective efficacies rather than potencies. Assessment of the influence of pyrethroid mixtures on Na^+ influx revealed predictable additive effects. These data indicate that monitoring of pyrethroid effects on neuronal $[Na^+]_i$ using the fluorescent dye SBFI is a useful assay for comparison of pyrethroid efficacies. (This abstract does not necessarily reflect Agency Policy)

PS 2129 STRUCTURE ACTIVITY RELATIONSHIP OF PYRETHROIDS ON THE HUMAN T-TYPE VOLTAGE-SENSITIVE CALCIUM CHANNEL.

N. R. Catlin[2], E. Mutanguha[1] and S. B. Symington[1]. *[1]Biology and Biomedical Science, Salve Regina University, Newport, RI and [2]Pathology and Laboratory Medicine, Brown University, Providence, RI.* Sponsor: K. Boekelheide.

Pyrethroids are widely used insecticides in both agricultural and vector control programs. Given the widespread use of these compounds for the control of insect vectors of devastating human and animal diseases (particularly in urban environments) and additional exposure via dietary uptake, human consumption is likely. The aim of this study was to determine the effects of various pyrethroids on the current characteristics of the human T-type voltage-sensitive calcium channel (Cav3.2). Cav3.2 cDNA was transcribed into cRNA using the mMessage mMachine in vitro transcription kit and injected into defollicated Xenopus oocytes. Cav3.2 currents were electrophysiologically characterized using the two-electrode voltage clamp technique with Ba2+ as a charge carrier. The toxic enantiomer of cypermethrin (1R) inhibited peak current at the highest concentration examined (10-7M) by approximately 20%, while the non-toxic enantiomer of cypermethrin (1S) had no effect on Cav3.2 peak current compared to DMSO control. Dose response curves were generated for bioallethrin, cypermethrin, deltamethrin, fenpropathrin, and permethrin. Bioallethrin, cypermethrin, and deltamethrin decreased peak current in a concentration-dependent manner while fenpropathrin and permethrin had no effect on the peak current compared to DMSO control. Furthermore, deltamethrin was the most efficacious of the pyrethroids examined which resulted in a 40% reduction of Cav3.2 peak current at a saturating concentration (10-7M). These results indicate that pyrethroids are potent and stereospecific inhibitors of human Cav3.2.

PS 2130 ULTRASTRUCTURAL STUDY OF CHROMATOLYTIC AND VACUOLAR CHANGES IN SENSORY NEURONS IN ORGANOPHOSPHATE-INDUCED DELAYED NEUROTOXICITY (OPIDN).

M. Burgess, S. K. Hancock, J. Hinckley, T. Rogers-Cotrone, K. Lowe, M. F. Ehrich and B. S. Jortner. *Laboratory for Neurotoxicity Studies, Virginia Tech, Blacksburg, VA.*

OPIDN results in distal axonopathy progressing to myelinated nerve fiber degeneration. In this study we use a previously described model of OPIDN in rats (Jortner et al., Tox. Pathol. 33:378, 2005), to assess the ultrastructural effects of this process on the cell bodies of somatosensory neurons of dorsal root ganglia, a population of cells giving rise to affected fibers. Young adult male Long-Evans rats were administered two organophosphates over a 63-day period, with sacrifice on days 28, 63 and 90. The test compounds were tri-ortho-tolyl phosphate (TOTP) given by gavage at 300 mg/kg on alternate days during the 14-28 and 49-63 day periods (14 total doses) and/or chlorpyrifos in two 60 mg/kg subcutaneous exposures (on days 7 and 42). There was TOTP-related OPIDN, including the presence of inhibition of brain neurotoxic esterase and bilateral distal axonopathy progressing to myelinated fiber degeneration. The lesions were most marked on day 90, following the full course of treatment and a subsequent four-week period without exposure to organophosphates. Previous light microscopic study of the dorsal root ganglia (DRG) revealed chromatolysis, and vacuolation of neurons at the 90-day interval (Jortner et al. Toxicologist 47:468, 2008). When examined by electron microscopy, the perikaryal vacuoles were present in occasional rats exposed to TOTP with or without chlorpyrifos, and consisted of one or more large membrane-bound vacuoles containing a sparsely granular material lacking organelles. Chromatolysis was defined by peripheral displacement of both the nucleus and Nissl substance, and was noted in all TOTP-exposed rats. Both of these effects have previously been associated with axonal degeneration or aging (Groves and Scaravilli in Dyck et al. Peripheral Neuropathy, 4th ed.). Their presence in OPIDN is likely associated with the toxicant-induced axonal injury. Supported by USAMRMC DAMD17-99-1-9489.

PS 2131 COMBINATIONS OF NEUROTOXICANTS (MALATHION AND LEAD ACETATE) DISRUPT THE BLOOD BRAIN BARRIER (BBB) BY REDUCING TIGHT JUNCTION PROTEINS.

P. Balbuena, W. Li and M. Ehrich. *Virginia Maryland Regional College of Veterinary Medicine, Blacksburg, VA.*

Neurotoxicity by organophosphorus (OP) compounds and lead remains a problem for both humans and animals because combined exposures in environmental settings occur. We previously noted that OP compounds such as malathion and chlorpyrifos could disrupt BBB integrity using in-vitro models (Neurotoxicol 26, 277; SOT 2007 abstract 707), and that a combination of malathion and lead enhanced such disruption (SOT 2008 abstract 2277). This study examined the neurotoxicants alone and in combination for ability to disturb BBB integrity by decreasing tight junction proteins. Rat brain endothelial (RBE4) cells were cultured in petri dishes and induced to form tight junctions with astrocyte-conditioned media. Cells were then exposed to malathion 10uM, malaoxon 1uM, or lead acetate 1uM and 10uM alone and in combination with an OP compound for a 24 hr period. OP compounds were applied first, lead was added 10 hr later, and cultures incubated for an additional 14 hr. Then, western blots were performed to determine total protein expression. Positive controls for tight junction proteins occludin, claudin 1, and zona occludens 1 (ZO1) were included. The results were analyzed utilizing the Odyssey infrared imaging system. Occludin was reduced by up to 75% and 80% by 1uM and 10uM lead acetate respectively, about 60% by malathion 10uM, and about 80% by malaoxon 1uM. Combinations of neurotoxicants decreased occludin 70% to 90%. ZO1 was decreased by lead acetate about 40% and by OP compounds about 30%; together they decreased ZO1 about 60%. Claudin 1 was reduced about 30% by neurotoxicant mixtures and by lead alone about 40%, but not by OP compounds. Results suggest a relationship between induction of damage to BBB integrity and a decrease of proteins that form the tight junction in rat brain endothelial cells. In RBE4 cells, therefore, at least one of the mechanisms that OP compounds and lead utilize to disrupt BBB integrity is by decreasing occludin, claudin 1, and ZO1 tight junction proteins in the barrier.

PS 2132 STRUCTURE-DEPENDENT EFFECTS OF DIELDRIN ANALOGS ON DOPAMINE CATABOLISM.

E. M. Allen, J. Yunden and J. A. Doorn. *Medicinal and Natural Products Chemistry, University of Iowa, Iowa City, IA.*

Dieldrin, a banned organochlorine pesticide, is considered one of the twelve most persistent, bioaccumulative, and toxic chemicals by the US EPA and is ranked seventeenth on the 2005 CERCLA Priority List of Hazardous Substances. A number of epidemiological studies have shown a correlation between Parkinson's disease (PD) and pesticide exposure, particularly dieldrin. PD is a progressive disease that leads to the degeneration of dopaminergic neurons in the substantia nigra pars compacta. Increased concentrations of dieldrin have been found in the brains of PD patients. This compound has also been shown to adversely affect a number of cellular processes yielding toxic intermediates and oxidative stress, effects that may increase the propensity to develop PD. These processes include disruption of dopamine (DA) catabolism and trafficking, potentially leading to an increase in the

endogenous neurotoxin 3,4-dihydroxyphenylacetaldehyde (DOPAL). The goal of this study is to determine which structural features of dieldrin are responsible for its ability to disrupt PD-relevant cellular processes. In order to achieve this aim, various analogs of dieldrin were used, including endrin, aldrin, and isodrine. Endrin is an isomer of dieldrin, aldrin lacks the epoxide found in dieldrin, and isodrine is an isomer of aldrin. The relative effects of these compounds on DA catabolism were analyzed using nerve growth factor-differentiated PC6-3 cells. The extracellular concentrations of DA and its metabolites were monitored over a 4-hour time-course and quantified by HPLC. It was found that dieldrin and endrin showed a time-dependent increase in extracellular 3,4-dihydroxyphenylacetic acid (DOPAC) whereas isodrine and aldrin showed a decrease in DOPAC formation, compared to controls. When analyzing DOPAL formation, aldrin and dieldrin showed time-dependent increases, as compared to controls, and endrin and isodrine showed no effect. These results indicate there is a structure-specific effect on DA catabolism by dieldrin and its analogs.

PS 2133 DELTAMETHRIN EXPOSURE CAUSES CASPASE-3 MEDIATED APOPTOSIS IN SK-N-AS NEUROBLASTOMA CELLS.

M. M. Hossain and J. Richardson. *RWJMS, Piscataway, NJ.*

Deltamethrin is a commonly used type II pyrethroid pesticide that has been demonstrated to affect dopaminergic neurons both in vitro and in vivo. Recently, we have demonstrated that exposure of SK-N-MC neuroblastoma cells stably expressing the dopamine transporter undergo apoptosis following exposure to deltamethrin (Elwan et al., 2006). However, the pathway by which deltamethrin induces apoptosis is not well understood. In the present study, we utilized a dopaminergic-like neuroblastoma cell line (SK-N-AS) to determine the molecular pathway responsible for deltamethrin-induced apoptosis. Exposure of SK-N-AS cells to deltamethrin (100 nM-50 μM) resulted in time and dose dependent cell death as measured by lactate dehydrogenase (LDH) leakage. After 48 hr of exposure, cell death (35-45%) was only observed at concentrations >10 μM. However, significant apoptosis (21-121% increase), as measured by DNA fragmentation was observed at lower concentrations (100 nM-5 μM). Co-treatment with the specific caspase-3 inhibitor Z-DEVD-FMK (50 μM) completely blocked deltamethrin-induced DNA fragmentation. These results suggest that caspase-3 may be the key mediator of deltamethrin-induced apoptic cell death in SK-N-AS neuroblastoma cells. Supported in part by NIEHS grant R01ES015991.

PS 2134 SAFETY OF PRALIDOXIME ADMINISTERED IN A RAT MODEL OF METHOMYL TOXICITY.

F. J. Baud[1], P. Houzé[1, 2] and A. David[1]. *[1]University Paris 7, Paris, France and [2]Toxicological Laboratory, Faculty of Pharmacy, Paris, France.*

Objective: The treatment of organophosphate (OP)insecticide poisonings includes the administration of antidotes including atropine and pralidoxime. A recent clinical trial showed large doses of pralidoxime significantly reduced morbi-mortality in acute human OP poisonings. However, OPs and carbamates induce the same signs and symptoms while pralidoxime is efficient in OP and potentially harmful in carbamate poisoning. This study was designed to assess whether a therapeutic dose of pralidoxime would result in further respiratory toxicity in rats poisoned with methomyl. Methods: male Sprague-Dawley rats were poisoned using a 2.3 mg.Kg-1 dose of methomyl (M) (50% of the ip MLD measured in our laboratory). Poisoned rats were treated with pralidoxime (base: 50 mg.Kg-1) administered IM at the time of maximal respiratory effects, 5 min post injection of M. Ventilation was assessed using whole body plethysmography in awaken animals and central temperature using infra-red telemetry. Results are expressed as mean +/- SEM. Statistical analysis used parametric tests with $p< 0.05$. Results: M induced a significant decrease in core temperature,a decrease in respiratory rate resulting from an increase in expiratory time. M increased the tidal volume. Respiratory toxicity occurred 5 min after injection and lasted 20 min. In comparison with the M group, the administration of pralidoxime did not induce any significant differences regarding the core temperature (35.3 + 0.6 vs 35.0 + 0.2°C), the respiratory rate (85 + 2 vs 80 + 4 b/min), the expiratory time (0.55 + 0.05 vs 0.56 + 0.04 s), and the tidal volume (3560 + 440 vs 3340 + 850 μl). Discussion: in a previous study we showed a 50 mg/kg of pralidoxime (base) administered IM completely but transiently reversed paraoxon-induced respiratory toxicity. The use of pralidoxime for patients with carbamate toxicity is controversial as pralidoxime may increase the toxicity of monomethylcarbamate. In the present study, the administration of a single therapeutic dose of pralidoxime did not further increase methomyl-induced respiratory toxicity.

PS 2135 LONG TERM EFFECTS OF SARIN EXPOSURE ON COGNITION.

T. V. Damodaran[3, 1], M. B. Abou-Donia[1] and W. H. Meck[2]. *[1]Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC, [2]Psychological and Brain Sciences, Duke University Medical Center, Durham, NC and [3]Medicine, Duke University Medical Center, Durrham, NC.*

Organophosphorus (OP) chemical warfare agents like sarin inhibit cholinesterases by phosphorylation at the active site serine. We have shown earlier by a series of biochemical, cellular, molecular and global gene expression approaches that sarin exposure at lethal (1 X LD 50) and sub-lethal dose (0.5 X LD 50) affects central nervous system for a very long time after the initial acute exposure. In this study, we investigated the effect of a single acute exposure of (1 X LD 50) sarin on the cognition, six months post-exposure in Sprague-Dawley rats. Firstly, Water Maze method was employed which consisted of training to swim to a platform location that was held constant throughout training to assess the reference memory. Rats received 3 trials a day for 9 days (4 acquisition / 1 probe test, 2 New location tests / 1 re-acquisition / 1 probe test). Behavior was tracked by a video camera and analyzed by video track software. Data obtained strongly suggest significant impairment of the reference memory. Secondly, prepulse inhibition test of the acoustic startle response was used to assess sensori motor reactivity which showed small difference between sarin treated and control mice. Thirdly, 12-Arm Radial Maze test was used to assess errors in reference and working memory. The data indicated that sarin treated mice showed significantly different pattern for both a) choices to criterion and b) latency to complete a choice. Sarin treated mice made more wrong choices and acted more quickly, suggesting significant impairment in cognitive function. Thus this study adds further proof to our hypothesis that initial events mediated by disrupted cholinergic and non-cholinergic pathways decide the long term pathological outcome at several levels.

PS 2136 EXPOSURE OF C. ELEGANS TO THE GLYPHOSATE-CONTAINING PESTICIDE ROUNDUP LEADS TO DOPAMINERGIC NEURONAL DEGENERATION AND MITOCHONDRIAL INHIBITION.

A. N. Justice, R. E. Barnett, A. L. Valente and V. A. Fitsanakis. *Biology, King College, Bristol, TN.*

The incidence of Parkinson's disease (PD), a neurodegenerative disorder affecting dopaminergic (DA) neurons, has been positively correlated with areas that have high rates of pesticide usage. Additionally, data suggest neurodegeneration may result from increased ROS production and mitochondrial dysfunction. In the present studies, three strains of the nematode C elegans, N2 (wild type), NW1229 (neurons labeled with green fluorescent protein [GFP]) and BZ555 (GFP-labeled DA neurons), were exposed to the glyphosate-containing pesticide, RoundUp (RU), to examine potential mechanisms of toxicity. Acute treatments, in which worms were incubated with RU for 30 min, were conducted in synchronous L2 worms. For N2, the LC50 ≈ 7.28% (95% CI: 5.56 – 9.52; r2 = 0.6886). NW1229 nematodes were also treated with varying glyphosate concentrations (0, 1, 5, 10 and 15%). Compared to control NW1229, ≈ 75.9.2% worms treated with 5% glyphosate died ($p < 0.01$). Photomicrographs indicate this dose corresponded to nerve ring and dorsal nerve cord neurodegeneration. In order to ascertain whether DA neurons were specifically sensitive, BZ555 were exposed to varying concentrations of glyphosate (0, 1, 5, 10 and 15%). Similar to data from NW1229, at 5%, ≈ 56.2% of the worms were dead compared to controls ($p < 0.01$). Photomicrographs indicate loss of neuronal projections from the CEP neurons into the nose region. Mitochondrial dysfunction was determined by incubating worms with tetramethylrhodamine ethyl ester (TMRE), a fluorescent dye which is only taken up by mitochondria with an active membrane potential ($\Delta\psi$).N2 and NW1229 worms were exposed, post-treatment (RU), to 50 μM TMRE for 30 min. Analysis of fluorescence indicates a negative correlation between TMRE uptake and increasing RU concentration. This is particularly pronounced in the nerve ring. Taken together, these data suggest that RU is capable of inducing neurodegeneration in C. elegans, and that mitochondrial dysfunction is a likely mechanism of action.

PS 2137 TREATMENT OF CAENORHABDITIS ELEGANS WITH ROUNDUP AND MANZATE SUGGESTS LETHALITY MEDIATED BY MITOCHONDRIAL INHIBITION.

R. Negga, R. E. Barnett, D. A. Rudd, N. S. Davis, H. E. Hatfield, J. Stuart and V. A. Fitsanakis. *Biology, King College, Bristol, TN.*

Previous studies demonstrated a positive correlation between high levels of pesticide usage and Parkinson's Disease (PD). PD is also known to involve mitochondrial inhibition. In order to better characterize the potential relationship between two common pesticides and neurodegeneration, we chronically and acutely exposed

wild type (N22) Caenorhabditis elegans to varying concentrations of RoundUp (RU: glyphosate) or Manzate (MZ: manganese/zinc ethylene-bis-dithiocarbamate) for 24 hours or 30 min, respectively. To further model environmental exposure, a additional population of worms was exposed first to RU for 30 min, followed by a 24-hour incubation with MZ. The LC50 was determined by counting the number of live worms remaining 24 hours post-exposure. The LC50 for acute RU was ~ 7.5% (95% CI: 5.6-9.5%; r2 = 0.6886), chronic RU, ~ 5.7% (95% CI: 5.1-6.3%; r2 = 0.9433) and for chronic MZ, ~0.80% (95% CI: 0.66-0.86%; r2 = 0.9719). Quite surprisingly, acute treatment with MZ, even at the highest concentration (30%) only resulted in ~50% lethality (r2 = 0.6184). For the combination treatment (RU + MZ), the LC50 was ~12.5% (95% CI: 12.3-13.3%; r2 = 0.6670). Additional experiments were completed using tetramethylrhodamine ethyl ester (TMRE), a fluorescent dye selectively taken up by mitochondria with intact membrane potentials ($\Delta\psi$). Following acute exposure to 10% RU, the LC40, worms were incubated with 50 μM TMRE for 30 min. Data analysis suggests a decreased uptake of TMRE, particularly in the worm's nerve ring. Interestingly, the LC50 values for the individual treatments were well within concentrations available for purchase at most major retail stores, and were similar to the recommended usage for each agrochemical (2% for RU and 0.658% MZ).Taken together, these data demonstrate that acute or chronic exposure to these common pesticides results in significant lethality at concentrations near the recommended application, and the mechanism of action may involve mitochondrial inhibition.

PS 2138 EVALUATION OF PRO-2-PRALIDOXIME (PRO-2-PAM) FOR BRAIN PROTECTION AGAINST ORGANOPHOSPHATE AGENT EXPOSURE IN GUINEA PIGS.

J. Demar[1, 2], R. Ratcliffe[1], M. Medynets[1, 2] and R. Gordon[1]. [1]*Regulated Laboratories, Walter Reed ARmy Institute of REsearch, Silver Spring, MD and* [2]*GCD, The Geneva Foundation, Lakewood, WA.* Sponsor: S. Baskins.

Organophosphorus (OP) chemical warfare agents can severely inhibit brain acetylcholine esterase (AChE) activity, leading to rampant seizures (status epilepticus) and neuronal cell death. Treatments for OP poisoning include the oxime 2-pralidoxime (2-PAM), which directly reactivates AChE. 2-PAM, however, is charged and thus cannot effectively cross the blood-brain barrier to restore brain AChE activity. We are evaluating the ability of pro-2-PAM, a non-polar derivative of 2-PAM, to enter the brain and prevent seizures in an animal model of OP agent exposure. Young adult male guinea pigs were surgically implanted with radiotelemetry probes to record brain electrical activity (electroencephalogram; EEG). One week post-surgery, animals were injected with pyridostigmine bromide (0.026 mg/kg, i.p.), followed 20 min later by the OP diisopropylfluorophosphate (DFP; 8 mg/kg, s.c.) and then 1 min later by atropine (2 mg/kg, i.m.) and 2-PAM or pro-2-PAM (i.m.) at 1 - 3 human auto-injector dose equivalents. Post-injections, changes in EEG activity were continuously monitored by radiotelemetry. Animals were euthanized at 1.5 or 24 h post-DFP injection and brain collected for AChE activity assay. Brains taken at 24 h were also formaldehyde preserved for histopathology. We found by EEG that the DFP reliably produced status epilepticus in these animals; and, at all doses tested, 2-PAM was ineffective at alleviating their seizures. In contrast, pro-2-PAM suppressed seizure formation up to 24 h, at > 1.5 auto-injectors. Consistent with this, pro-2-PAM also displayed higher brain AChE activity at 1.5 h after DFP exposure. Histopathology analysis (for 24 h) using hematoxylin & eosin and fluoro-jade stains showed pro-2-PAM but not 2-PAM prevented death of neurons in certain brain regions. In conclusion, our results show pro-2-PAM enters the brain and protects against OP induced seizures plus neuronal cell death via restoration of brain AChE activity.

PS 2139 EVALUATE THE ROLE OF DIQUAT IN NIGRAL NEURODEGENERATIVE DISORDER.

S. S. Karuppagounder, U. Subramaniam, V. Suppiramaniam and M. Dhanasekaran. *Pharmacal Sciences, Auburn University, Auburn, AL.*

Objective: To evaluate the neurotoxic (in vitro and in vivo) effects of diquat.
Background: Chronic exposure to pesticides and/or herbicides can directly induce neurotoxic effects or results in accumulation of various toxic metabolic by-products which has the ability to cause symptoms of Parkinson's disease (PD). Environmental neurotoxins such as paraquat and MPTP have been implicated the etiopathology and progression of Parkinson's disease. Interestingly, diquat chemically resembles the dopaminergic neurotoxin-MPTP and paraquat. Diquat (1,1'-ethylene-2,2'-dipyridylium) is currently being widely used as a herbicide in USA and other parts of the world. However, the behavioral and biochemical effects (in vitro and in vivo) of diquat have not been well established.
Design/Method: For the in vitro study, effect of diquat on cell viability (SH-SY5Y cells human neuroblastoma) was evaluated. We also studied the in vitro effect of diquat on complex-I activity and Reactive Oxygen Species (ROS) generation. For the in vivo study, C57/BL6 mice were divided into two groups and intraperitoneally administered with vehicle or toxins twice a week for six weeks. Behavioral parameters such as, akinesia, catalepsy, swim test, tremor, straub tail and rotorod were observed after the last treatment. Striatum was dissected and analyzed for the monoaminergic neurotransmitters employing HPLC-ECD. Statistical data analysis was performed using Sigma stat.2.03 software.
Results: Diquat dose-dependently inhibited the cell viability of SH-SY5Y cells. Diquat increased the generation of ROS significantly. In the mice, diquat significantly reduced the locomotor activity but had no effect on the monoaminergic neurotransmitter in the striatum.
Conclusions: Diquat inhibited the neuronal cell growth, increased the generation of reactive oxygen species and also induced behavioral changes. Thus, diquat may significantly increase the risk for nigral neurodegeneration.
Acknowledgement: This study was supported by Department of Pharmacal Sciences, Auburn University, Auburn, AL.

PS 2140 DEVELOPMENT OF AN *IN VITRO* ASSAY FOR THE CONVERSION OF PRO-2-PAM TO 2-PAM.

F. Khan[1, 2], A. Campbell[1], S. Thangavelu[1, 2] and R. Gordon[1]. [1]*Department Regulated Laboratories, Walter Reed ARmy Institute of Research, Silver Spring, MD and* [2]*GCD, The Geneva Foundation, Lakewood, WA.* Sponsor: S. Baskins.

The inhibition of acetylcholinesterase (AChE) by organophosphate compounds (OP) results by phosphorylation of an active site serine residue that leads to accumulation of neurotransmitter acetylcholine in synapses of the central and peripheral nervous systems and over-stimulation of post-synaptic cholinergic receptors. Thus, a cholinergic crisis and death can result from AChE inhibition. Compounds comprised an oxime moiety (RCH=NOH) are able to reactivate OP-inhibited AChE by dephosphorylating the enzyme's active site. The present oxime of choice in the United States is pralidoxime chloride (2-PAM). 2-PAM does not reactivate central nervous system (CNS) AChE because it's positively charged chemical structure precludes blood brain barrier (BBB) penetration. Therefore, CNS AChE remains inhibited. In Our DFP rat seizure/SE model it was observed that Pro-2-PAM rather than 2-PAM protects DFP-induced neurotoxicity and status epileptics. Bodor's group has suggested that Pro-2-PAM after crossing the blood brain barrier becomes converted to 2-PAM by NAD/P redox system in the brain. In the present study we are looking for NADPH oxidase activity which can convert Pro-2-PAM to 2-PAM in guinea pig brain homogenate. NADPH oxidase activity was measured by photo-luminescence assay using lucigenin substrate. We have also developed a high pressure liquid chromatography (HPLC) assay. In this assay conversion of pro-2-PAM to 2-PAM can be quantified. Inhibition of conversion from Pro-2 PAM to 2-PAM was up to 30% by Diphenylene¬iodonium (DPI) in rat brain homogenate. A series of inhibitors of oxidation-reduction system tested against our assay system, did not show any inhibition of the conversion of Pro-2-PAM to 2-PAM. Currently, we are analyzing various enzyme co-factors of oxidation-reduction enzyme system with and without guinea pig brain homogenate which may be involved in the conversion of Pro-2-PAM to 2-PAM as our preliminary results indicate.

PS 2141 CHOLINESTERASE INHIBITION IN CHLORPYRIFOS WORKERS IN RELATION TO URINARY 3, 5, 6-TRICHLORO-2-PYRIDINOL.

L. L. Aylward[1], D. H. Garabrant[2], S. Berent[2], Q. Chen[2], C. Timchalk[4], C. J. Burns[3], S. M. Hays[1] and J. W. Albers[2]. [1]*Summit Toxicology, LLP, Falls Church, VA,* [2]*University of Michigan, Ann Arbor, MI,* [3]*The Dow Chemical Company, Midland, MI and* [4]*Battelle Pacific Northwest Division, Richland, WA.*

We evaluated the quantitative relation between measured red blood cell acetylcholinesterase (RBC AChE) and plasma butyrylcholinesterase (BuChE) activities with exposure to chlorpyrifos (CPF) as assessed by measurement of urinary 3,5,6-trichloro-2-pyridinol (TCPy) in a study group of workers occupationally exposed in the manufacture of chlorpyrifos and a referent group of chemical manufacturing workers. Measures of plasma BuChE and RBC AChE activity and urinary TCPy concentration collected over a year-long study in CPF-exposed workers (n=53) and referents (n=60) were analyzed using linear mixed models to characterize exposure-response relationships. Median and 95th percentile urinary TCPy concentrations in CPF workers were 10-fold and >30-fold higher, respectively, than in the referents. RBC AChE activity was unrelated to exposure, up to the maximum of 1,000 μg TCPy/g creatinine (Cr), while plasma BuChE activity was negatively related to urinary TCPy concentrations above 110 μg TCPy/g Cr. No-effect levels for inhibition of plasma BuChE and RBC AChE corresponded to absorbed doses of CPF of approximately 5 and >50 μg/kg-d, respectively. PON1 phenotype was not significantly related to cholinesterase (ChE) inhibition at the observed exposure levels.

These findings are consistent with previous no-effect level determinations for ChE inhibition in humans and suggest that general population CPF exposure levels are substantially below the identified no-effect levels. The dose-response relationships observed in this study are consistent with predictions from the previously published PBPK/PD model for CPF, supporting its use in other risk assessment efforts. 17% of unexposed referents experienced one or more plasma BuChE measures more than 20% below baseline over a year of repeated, periodic measurements, suggesting that ongoing monitoring programs may have a substantial rate of false positive results.

PS 2142 2, 5-HEXANEDIONE ADDUCTION IMPAIRS NEUROFILAMENT SUBUNIT INTERACTION WITH CYTOSKELETAL POLYMER.

L. Zhang[1], R. M. LoPachin[1], A. Sean[1] and A. P. DeCaprio[2]. [1]*Anesthesiology, Albert Einstein College of Medicine, Bronx, NY and* [2]*Environmental Health Sciences, University of Massachusetts, Amherst, MA.*

2,5-Hexanedione (HD) forms dimethylpyrrole adducts with neurofilament (NF) subunits, which we hypothesize, impair the interaction of these proteins with the axon cytoskeletal polymer. Because subunits remain attached to the fast transport vector kinesin, distal axon atrophy develops due to accelerated anterograde egress and localized depletion of NF proteins. Accordingly, we have characterized the structure and protein content of the axonal cytoskeleton from moderately affected rats intoxicated at different daily HD dose-rates; i.e., 175 and 400 mg/kg. Computer-based quantitative morphometric analyses of cytoskeleton in CNS (rubrospinal tract) and PNS (tibial nerve) axons did not reveal consistent spatial (e.g., interneurofilament distances) differences among NF and microtubule (MT) components. However, regardless of dose-rate, the corresponding NF content per axon was significantly decreased (38%-65%), whereas no MT changes were detected. This confirms that selective NF loss mediated axon atrophy. Consistent with HD pyrrole adduction of lysine residues, separation of spinal cord proteins by 2D-Difference Gel Electrophoresis and subsequent MS identification showed reduced detection of NF subunits and other proteins (e.g., alpha-internexin). Immunoblot analysis of a taxol/AMPPNP preparation of spinal cord cytoskeleton showed that HD did not alter the distribution of proteins (e.g., alpha-tubulin, KIF1A, MAP2C, tau, NF-H) at either dose-rate. However, NF subunits and KIF5 exhibited comparable higher molecular weight complexes that were more prevalent in samples from HD-intoxicated animals. This correspondence among aggregates might reflect HD adducted NF subunit proteins that could not insert into the cytoskeletal polymer and, therefore, remain associated with the motor vector. These data support the hypothesis that pyrrole adduct formation causes NF loss and axon atrophy by disrupting polymer turnover. Sponsored by ESO7912-10.

PS 2143 THE EFFECT OF 2, 5-HEXANDIONE ON THE PERMEABILITY OF BLOOD-NERVE BARRIER.

Q. Liu and Y. Zheng. *The Key Lab, National Institute of Occupational Health and Poison Control, Chinese CDC, Beijing, China.* Sponsor: Y. Zheng.

To study the effect of 2,5-hexandione, a metabolite of n-hexane, on the permeability of blood-nerve barrier, male adult Wistar rats were administered by gavage with 400 mg.kg-1.d-1 2,5-hexandione for 4 weeks as treatment group, and 0.09% sodium chloride with the same dosage as control group. Evens Blue, a fluorescent dye was injected through left femoral vein to the treatment and control rats, after recycling, fixation, embedding and slicing, the distribution of Evens Blue was observed under fluorescence microscopy. Integral absorbance was assessed by Image-Pro Plus. The difference between the 2,5-hexandione treated and the control groups was compared. In the transversal sections of sciatic-tibial nerves in the 2,5-hexanedione treated group, the integral absorbance of fluorescence in the proximal section was stronger than those of the intermediate and the distal section ($p<0.01$), and the integral absorbance of fluorescence in the intermediate section was stronger than that of the distal section ($p<0.01$). In the control group, the weak fluorescence was widely distribution, and the integral absorbance in the distal section was stronger than that of the proximal section ($p<0.05$). In the treated rats, the integral absorbance of fluorescence in the proximal, intermediate and distal sections was stronger than those of the controls ($p<0.01$). For the vertical sections of sciatic-tibial nerves in rats the 2,5-hexanedione treated rats, fluorescence was observed in both the proximal and distal sections. The weak fluorescence in the distal section of the sciatic-tibial nerves of the control was observed, and almost no fluorescence was showed in the proximal section. The fluorescence of the proximal and distal sections of the treated rats was stronger than the controls. The permeability of blood-nerve barrier could be increased by 2,5-hexanedione.

PS 2144 PROTEIN POST-TRANSLATIONAL MODIFICATIONS MEDIATE THE PATHOGENESIS OF γ-DIKETONE AXONOPATHY.

D. Tshala-Katumbay[1, 3], P. Desjardins[2], M. Sabri[1, 3], R. Butterworth[2] and P. Spencer[1, 3]. [1]*Neurology, Oregon Health & Science University, Portland, OR,* [2]*Neuroscience Research Unit, Université de Montréal, Montr√©al, QC, Canada and* [3]*CROET, Oregon Health & Science University, Portland, OR.*

We exploit the protein reactive and axonopathic properties of γ-diketone-like 1,2-diacetylbenzene (1,2-DAB) or 2,5-hexanedione (2,5-HD) to elucidate protein modifications associated with nerve fiber (axon) degeneration. We used two-differential in-gel electrophoresis (2D-DIGE), matrix assisted laser desorption ionization time-of-flight tandem mass spectrometry (MALDI-TOF/MS-MS) and western blot to analyze and compare the lumbosacral proteome of male Sprague Dawley rats treated with 20 mg/kg/day 1,2-DAB, or equipotent doses of 2,5-HD i.e. 500 mg/kg/day, or equimolar doses of their respective non-protein-reactive and non-axonopathic isomers 1,3-DAB or 2,3-HD (negative controls), or equivalent volume of vehicle, 5 days a week for up to 3 weeks. Common protein targets of 1,2-DAB and 2,5-HD included neurofilament triplet protein L, gelsolin, protein disulfide isomerase (PDI), glutathione S-transferase, NADH dehydrogenase 1α, pyruvate kinase, and fatty acid synthase. In general, the expression of proteins involved in maintaining the physical integrity of axons and regulating protein-folding mechanisms was reduced whereas that of proteins supporting the energy metabolism was increased. Intriguingly, the expression of cytosolic PDI was reduced while that of membrane-bound PDI was increased and S-nitrosylated proteins were detected. Markers of oxidative stress (e.g. HO-1) including nitric oxide synthases (NOS isoforms) retained normal mRNA/protein expression. The similarity of the neuroproteomic patterns of 2,5-HD and 1,2-DAB axonopathy suggests common biomarkers and/or mechanisms of neurotoxicity associated with their parent solvents n-hexane and 1,2-diethylbenzene, respectively. It is possible that changes in PDI expression and/or activity mediate the pathogenesis of γ-diketone axonopathy via protein misfolding and/or S-nitrosylation. Supported by NIH grants P42ES10338, U19ES11384, K01NS052183 and the Oregon Worker Benefit Fund.

PS 2145 ESTROUS CYCLE AND ESTRADIOL SUPPLEMENTATION MODIFY PARAQUAT TOXICOKINETICS IN MOUSE STRIATUM.

B. K. Barlow, J. Kochar, B. Winnik, B. Buckley and M. Thiruchelvam. *Environmental & Occupational Health Sciences Institute, Piscataway, NJ.*

Paraquat (PQ), a widely used herbicide, has reproduced Parkinson's disease (PD) features in animal models. As observed with most reports considering PD and gender, the toxicity of PQ to the nigrostriatal system is strongly modified by gender. Estrogen is a potent regulator of brain dopamine systems and has widely been regarded as a neuroprotective agent. PQ has a long half-life in mouse brain, but the kinetic mechanisms in brain are unknown and may be impacted by female gonadal steroids. The current study was undertaken to determine if differential PQ kinetic profiles existed between genders and between stages of the estrous cycle in C57Bl/6J mice. To understand the role of physiological levels of hormones on PQ toxicokinetics, normal-cycling females were injected with a single dose of 10 mg/kg PQ (in saline, i.p.) on the morning of proestrus, estrus, or metestrus (males were similarly treated) and striatal PQ levels were determined 1, 2, or 5 days post-exposure; subsequently, a similar study was undertaken to extend the time-course (including proestrus and estrus females and males) for PQ determinations at 1, 5, or 15 days post-exposure. Additionally, to understand the role of estradiol status at and following exposure, ovariectomized females were injected with oil or 3 μg estradiol (in oil, s.c.) 2 hours before PQ injection; some females also received 3 μg estradiol daily until 15-days post-PQ. The results from these experiments show effects of treatment group, stage at exposure, and/or interactions with time. At later times (e.g. 5 or 15 days), females exposed on proestrus had lower PQ levels than those exposed on estrus, and females who received daily estradiol had lower levels than oil-treated females, suggesting that gonadal-steroid status at exposure and after exposure play a role in the toxicokinetic profile of PQ. This knowledge may be important in addressing the role of gender in toxicant models of PD, as well as provide insight into the toxicodynamic effects of PQ in brain.

PS 2146 OXIDATIVE STRESS AND ANTIOXIDANT MECHANISMS IN THE PARAQUAT-MANEB MOUSE MODEL– A GENDER COMPARISON.

A. A. Baker, B. K. Barlow and M. Thiruchelvam. *Environmental and Occupational Health Sciences Institute, Joint Institute of the University of Medicine and Dentistry of New Jersey-Robert Wood Johnson Medical School and Rutgers, The State University of New Jersey, Piscataway, NJ.*

Parkinson's disease is a neurodegenerative disorder, characterized by loss of the nigrostriatal dopaminergic system. Oxidative stress has been implicated as the mechanism responsible for the neuronal demise. Similarly, in the paraquat (PQ) and

maneb (MB) mouse model, a significant increase in oxidative stress has been observed and overexpression of superoxide dismutase (SOD) and glutathione peroxidase (Gpx) protect against this. The increases in oxidative stress are greater in males than females, with the females being spared from dopaminergic cell death. Thus, this study sought to determine whether there were differences in oxidative stress response and antioxidant defense mechanisms between the genders. Male and female C57BL6 mice were treated 2X a week for 6 weeks with saline or 7 mg/kg PQ + 30 mg/kg MB and were sacrificed 2 or 7 days after the last treatment. Changes in oxidative stress and enzyme activity were determined in the striatum, frontal cortex and olfactory bulb. A significant increase in lipid peroxidation in the striatum was observed 7 days after the last exposure in both males and females, with a larger increase seen in the males. A significant increase in SOD activity was observed in the striatum of females but not males, suggesting a possible neuroprotective response in the females. No significant changes in oxidative stress or enzyme activity were observed in the olfactory bulb or frontal cortex in either gender. This indicates that the effects of paraquat and maneb are relatively selective to the nigrostriatal system, as previously demonstrated. Further analysis of other antioxidant enzymes including GPx and glutaredoxin, changes in enzyme protein levels as well as changes in the ventral midbrain are underway. The results from these studies will further our understanding of the oxidative stress response in the PQ-MB mouse model and determine the gender-related differences.

PS 2147 MOUSE CEREBELLAR ASTROCYTES PROTECT CEREBELLAR GRANULE NEURONS AGAINST TOXICITY OF THE POLYBROMINATED DIPHENYL ETHER (PBDE) MIXTURE DE-71.

G. Giordano[1], T. J. Kavanagh[1] and L. G. Costa[1, 2]. [1]*Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA and* [2]*Department of Human Anatomy, Pharmacology and Forensic Science, University of Parma Medical School, Parma, Italy.*

A large body of evidence indicates that polybrominated diphenyl ether (PBDE) flame retardants have become widespread environmental pollutants. Body burden is particularly high in infants and toddlers, due to exposure through maternal milk and house dust. Animal studies suggest that PBDEs may exert developmental neurotoxicity, via mechanisms that are still elusive. PBDEs have been reported to cause oxidative stress and apoptotic cell death in neurons in vitro, when tested in monocultures. Here we report the results of experiments in which mouse cerebellar granule neurons (CGNs) are co-cultured with cerebellar astrocytes. Astrocytes were found to protect neurons against the toxicity of the PBDE mixture DE-71. Astrocytes from *Gclm (-/-)* mice, which lack the modifier subunit of glutamate cysteine ligase and, as a consequence, have very low GSH levels, were much less effective at protecting CGNs from DE-71 toxicity. In vivo, where both neurons and astrocytes would be either *Gclm (+/+)* or *Gclm (-/-),* the toxicity of DE-71 to CGNs is predicted to vary 16.8-fold, depending on genotype. Hence, in addition to being intrinsically more susceptible to DE-71 toxicity because of their low GSH content, CGNs in *Gclm (-/-)* mice would also suffer from the lack of a full protective effect provided by astrocytes. Since several polymorphisms, including some in the Gclm gene, cause very low levels of GSH, it may be speculated that such individuals might display a higher susceptibility to the neurotoxic effects of PBDEs.(Supp. in part by P30ES07033).

PS 2148 CYTOTOXICITY OF DINITROBENZENE ISOMERS ON C6 GLIOMA CELLS.

B. Rivera and R. T. Miller. *Biological Sciences, University of Texas at El Paso, El Paso, TX.*

Dinitrobenzene (DNB) refers to a mixture of three isomers: 1,2-, 1,3- and 1,4-DNB. These DNBs are used as common intermediates in the dye and plastics industries. 1,2- and 1,4-DNB cause methemeglobinemia, in contrast, 1,3-DNB is a purported neurotoxicant in rats. To our knowledge, no studies have been conducted to determine if the cytotoxic effects of 1,2- and 1,4-DNB parallel those of 1,3-DNB in neuronal or glial cell-culture models. The purpose of this in vitro study was to compare the relative ability of different cytotoxicity assays to detect early changes in cell viability. C6 Glioma cells were exposed to 10 – 250 μM of each DNB for up to 6 hours. Cytotoxicity was then determined using MTT reduction for mitochondrial integrity, neutral red (NR) uptake for lysosomal integrity, and LDH release a marker for cell death. C6 Glioma cells exhibited a concentration- and time-dependent decrease in NR uptake following a four hour exposure to 1,2- and 1,4-DNB with effects most evident between 50-250 μM; however NR uptake was the most apparent with 1,3-DNB exposure. In contrast to results obtained with NR, no reduction of MTT by C6 glioma cells was observed at any time or concentration used in these studies. Statistically significant increases in media LDH vs. total LDH after four hour exposure were observed only for 1,2-DNB and 1,3-DNB at 250 μM. Being the more efficient redox-cycler, 1,4-DNB caused LDH leakage beginning at 100 μM, thus revealing its greater potency in this model. The redox-cycler for potency in the LDH assay was 1,4->1,2->1,3-DNB. These results also indicate that differences do exist in the abilities of the 3 cytotoxicity assays to detect early changes in cell viability. However, each assay remains crucial in the overall study of cell viability because each assay is based on different cellular parameters and can give insight into cellular localization as well as mechanism of toxicity of toxicants. This project was supported in-part by 5G12-RR008124 from NCRR to the BBRC at UTEP and by NIEHS/NIH grant ES011982 to RTM. The views stated in this abstract are not necessarily the view of NIH/NIEHS.

PS 2149 AGING AND LIFE-STAGE SUSCEPTIBILITY: TOLUENE EFFECTS ON PROTEIN CARBONYL CONTENT IN FRONTAL CORTEX AND CEREBELLUM OF BROWN NORWAY RATS.

P. R. Kodavanti[1], J. E. Royland[1], J. H. Richards[2], J. Besas[1] and R. C. MacPhail[1]. [1]*Neurotoxicology Division, U.S. EPA, RTP, NC and* [2]*Experimental Toxicology Division, U.S. EPA, RTP, NC.*

The influence of aging on susceptibility to environmental contaminants is poorly understood, largely due to a lack of data on exposures in older adults and adequate animal models. We examined the acute effects of the volatile organic compound, toluene, in a study investigating multiple toxicological endpoints. The objective of this study was to test whether oxidative stress plays a role in the adverse effects caused by toluene exposure, and if so, if effects were age-dependent. We selected protein carbonyl as an indicator of oxidative stress because carbonyl content of cells is a useful indicator of oxidative protein damage and has been linked to the adverse effects associated with chemical exposures. Brown Norway rats (4, 12, and 24 months) were dosed orally with toluene (0, 0.65 or 1 g/kg) in corn oil. Four hours later, brains were removed and placed on ice. Frontal cortex and cerebellum were dissected, quick frozen on dry ice, and stored at 80oC until analysis. Protein carbonyls were assayed using commercial kits. One-way ANOVA indicated that hydrogen peroxide, a positive control increased protein carbonyls in cortical tissue in vitro in a concentration-dependent manner. Two-way ANOVA indicated a significant effect of age and toluene on protein carbonyls in both frontal cortex and cerebellum. In control rats, there was an age-dependent increase in the protein carbonyls indicating increased oxidative stress in 24 month old rats compared to 4 or 12 month old rats. Although toluene increased protein carbonyls in both brain regions and in all age groups, step-down analyses indicated toluene effects were statistically significant only in 12 month old rats. These results indicate that frontal cortex and cerebellum of 12 month old rats are more susceptible to oxidative damage caused by toluene when compared to 4 month and 24 month old rats. (This abstract does not necessarily reflect USEPA policy).

PS 2150 POSTNATAL EXPOSURE TO METHYLMERCURY ENHANCES DEVELOPMENT OF PARALYTIC PHENOTYPE IN SOD1-G93A FEMALE MICE.

F. Johnson and W. Atchison. *Pharmacology and Toxicology, Michigan State University, East lansing, MI.*

The effect of methylmercury (MeHg) on time course of development of a paralytic amyotrophic lateral sclerosis (ALS) phenotype (ALS like) was investigated using the transgenic mouse model SOD1G93A (G93A). We postulated that MeHg exposure would hasten the onset of ALS phenotype and increase further changes in intracellular Ca2+ ([Ca2+]i seen in brainstem motor neurons in this mouse model. Female mice expressing the mutated form of human superoxide dismutase 1 gene (G93A) or wildtype control (wt) were exposed chronically to 0, 1 or 3 ppm MeHg in drinking water from PND29. Motor function was tested using a variable speed rotarod. Hypoglossal motor neurons (NXII) in brainstem slices were loaded with a Ca2+ -selective fluorophore and imaged using laser scanning confocal microscopy.

At 3 ppm MeHg, 50% of ALS mice exhibited rotarod test failure (a clinical sign ALS) at ~98 days compared to 112 days for untreated G93A mice. When compared to wt mice, [Ca2+]i from untreated G93A mice was significantly ($p<0.05$) increased by KCl depolarization. In contrast, [Ca2+]i. from MeHg-treated G93A slices was highly variable when depolarized by high [K+]o. [Ca2+]i was significantly ($p<0.05$) decreased by kainic acid in slices from untreated G93A mice when compared to untreated wt females. However, [Ca2+]i from MeHg-treated mice was potentiated by kainic acid, in contrast, AMPA reduced [Ca2+]i. Additionally, there

was no significant differences in [Ca2+]I when NAS [a GluR2 subunit lacking blocker] or CNQX (a blocker at AMPA and kainate receptors) was added. These data suggest that chronic exposure of G93A female mice to MeHg, hastens the onset of hind limb paralysis and changes the sensitivity and responsiveness of glutamate receptors. Supported by NIH grant 5T32 ES007255-19, R21ES014357 and R01ES03299.

PS 2151 CRUCIFEROUS NUTRACEUTICAL 3*H*-1, 2-DITHIOLE-3-THIONE PROTECTS HUMAN PRIMARY ASTROCYTES AGAINST NEUROCYTOTOXICITY ELICITED BY MPP+, 6-OHDA, ACROLEIN AND HNE.

Z. Jia, H. Zhu, H. P. Misra and Y. Li. *Edward VIA Virginia College of Osteopathic Medicine, Blacksburg, VA.*

Astrocytes possess important roles in maintaining normal brain function and providing trophic support to the neurons. They are also chief target by a range of toxic insults of prooxidants including 1-methyl-4-phenylpyridinium (MPP+), 6-hydroxydopamine (6-OHDA), acrolein and 4-hydroxy-2-nonenal (HNE). Recently, we have observed that the cellular antioxidants and phase 2 enzymes can be upregulated by 3 *H*-1,2-dithiole-3-thione (D3T), a cruciferous nutraceutical against many prooxidants in human neuroblastoma cell lines. However, the regulation of the above cellular factors by D3T in astrocytes has not been investigated. In this study, we showed that incubation of human primary astrocytes with micromolar concentrations (5-100 microM) of D3T for 24 h resulted in significant increases in the levels of reduced glutathione (GSH), glutathione reductase (GR) and phase 2 enzyme NAD(P)H:quinone oxidoreductase 1 (NQO1). D3T treatment also caused time-dependent increases in mRNA expression of gamma-glutamylcysteine ligase catalytic subunit, GR and NQO1 in these cells. Incubation of the astrocytes with MPP+, 6-OHDA, acrolein and HNE led to concentration-dependent decreases in cell viability as detected by 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium reduction assay. Pretreatment of human primary astrocytes with D3T was found to afford remarkable protection against the neurocytotoxicity elicited by the above neurotoxicants. Taken together, this study demonstrates for the first time that cruciferous nutraceutical D3T potently induces cellular GSH system and phase 2 enzyme NQO1 in primary human astrocytes and D3T-upregulated cellular defenses are accompanied by a markedly increased resistance to the above neurotoxicants. The results of this study may have important implications for development of novel neuroprotective strategies.

PS 2152 ACUTE METHAMPHETAMINE (METH)-INITIATED OXIDATIVE STRESS AND NEUROTOXICITY ARE NOT MODULATED BY NUCLEAR FACTOR-E2-RELATED FACTOR 2 (NRF2).

A. Ramkissoon[1] and P. G. Wells[1, 2]. *[1]Department of Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada and [2]Department of Pharmacology and Toxicology, University of Toronto, Toronto, ON, Canada.*

Reactive oxygen species (ROS) can oxidatively damage cellular macromolecules, and/or activate redox-sensitive transcription factors such as Nrf2, leading to the transcription of genes that modulate toxicity. Whether METH-initiated oxidative stress can activate Nrf2 that modulates neurotoxicity is uncertain. We used Nrf2 wild-type and knockout mice to determine if Nrf2 plays a role in METH-initiated oxidative DNA damage, quantified by 8-oxo-2'-deoxyguanosine formation. Mice were administered 4 doses of METH (10 mg/kg i.p.) or saline, with a 2-hr interval between each dose. After 3 hr, METH treatment enhanced DNA oxidation 2-fold in the striatum of Nrf2 wild-type and Nrf2 knockout mice, and up to 15-20% in the cortex and midbrain, compared to saline controls ($p<0.05$). However, there was no difference between Nrf2 wild-type and Nrf2 knockout mice in either basal or METH-enhanced DNA oxidation at this dose and time. To further investigate the role of Nrf2 in METH-initiated neurotoxicity, mice were treated as described above, sacrificed 3 days after the last dose and analyzed for tyrosine hydroxylase (TH) and glial fibrillary acidic protein (GFAP) in the striatum. METH treatment decreased TH staining in the striatum of Nrf2 wild-type and Nrf2 knockout mice by an average of 50% compared to saline controls ($p<0.05$), indicating degeneration of dopaminergic nerve terminals. Similarly, METH increased striatal GFAP by 2.2-fold compared to saline controls ($p<0.001$), indicating neurodegenerative glial activation. However, there was no effect of Nrf2 genotype on either TH or GFAP in METH-treated mice. Therefore, while Nrf2 can mitigate the degenerative affects of some ROS-enhancing neurotoxins administered chronically, it does not play a measurable role in oxidative stress and neurotoxicity caused by acute METH administration. [Support: CIHR, CIHR/Rx&D HRF].

PS 2153 NEUROTOXICITY STUDIES OF ORTHO, META AND PARA-N-1-PHENYL SUBSTITUTED SPIROHYDANTOIN ANTICONVULSANT COMPOUNDS.

R. A. Stephani, P. Gutta, H. J. Patel and I. Lengyel. *Department of Pharmaceutical Sciences, Saint John's University, Jamaica, NY.*

Previously we reported the neurotoxocity of an initial series of N,N'-disubstituted-spiro-hydantoins that were prepared by reaction of the corresponding N,N'-disubstituted ureas with ninhydrin, followed by treatment with aqueous sodium periodate. The spirohydantoins exhibited anticonvulsant activities in both the maximal electro-shock (MES) and pentylenetetrazole (PTZ) tests. Rotarod assay and righting reflex assays were done to determine the neurotoxicity of these compounds. The neurotoxicity of the spirohydantoins with different alkyl substituents in the para position of the N1-aryl ring did not show much difference until the chain length exceeds three carbons. Beyond that they showed a greater toxicity e.g.: butyl analog. In order to determine if the position of various groups at ortho, meta or para of the aryl group has any effect on neurotoxicity, a new series of compounds were prepared and tested. All the synthesized compounds passed the righting reflex assay. Compounds with the same group at the ortho or meta positions did not show much difference in their neurotoxicity in rotarod assay when compared to the para position of the aryl ring. This demonstrates that neurotoxicity of this class of compounds is dependent on the size of the substituent rather than its position on the aryl ring.

PS 2154 THE HUNTINGTON'S DISEASE MUTATION LEADS TO AN ALTERATION IN MANGANESE TRANSPORT OR STORAGE.

B. B. Williams[1, 2], B. K. Vadodaria[1, 2], J. G. Anderson[3], G. F. GF Kwakye[1, 2], D. D. Li[1, 2], H. L. Tanner[1, 2], K. M. Erikson[3] and A. B. Bowman[1, 2]. *[1]Neurology, Vanderbilt University, Nashville, TN, [2]Kennedy Center for Research on Human Development, Vanderbilt University, Nashville, TN and [3]Nutrition, The University of North Carolina Greensboro, Greensboro, NC.*

Huntington Disease (HD) is a neurodegenerative disorder caused by an expansion of a CAG repeat in the first coding exon of the Huntingtin gene. However, the mechanism by which the mutant HD protein causes pathology is unknown. Remarkably, many of the proposed mechanisms of HD are similar to those identified for neurotoxic metals and other toxins (e.g. mitochondrial dysfunction and oxidative stress). Therefore, we hypothesized that metals which impact pathophysiological mechanisms common HD will exhibit a gene-environment interaction. Using a cellular model of HD, we have found that expression of the mutant huntingtin protein induces a resistance to manganese (Mn) toxicity but not metals such as zinc, copper, or cobalt. In addition, the cells expressing the HD mutation have increased sensitivity to other toxins. Additionally, primary cultures from the YAC128 mouse model of HD recapitulate this Mn gene-environment interaction. To understand the cellular basis of this interaction we investigated the transport and storage of Mn. We find that net accumulation of Mn is significantly decreased in cells expressing mutant HD under both basal and Mn exposure conditions. Interestingly, the deficiency in basal Mn levels correlates with a substantial decrease in the levels of the Mn-dependent enzyme superoxide dismutase 2 (SOD2), which plays a key role in limiting mitochondria oxidative stress. To explore the differences in Mn transport, we examined iron transport under basal and high iron exposure in mutant and wild-type cells. These data indicate that functional differences in the transferrin receptor pathway only partially contribute to the Mn-HD gene-environment interaction, implicating an additional unidentified Mn transport pathway. Thus, glutamine expanded HD causes a defect in Mn transport or storage, and leads to a loss of Mn-dependent enzymes such as SOD2.

PS 2155 CUPRIZONE INDUCED-DEMYELINATION ALTERS THE EXPRESSION OF GENES INVOLVED IN ARACHIDONIC ACID METABOLISM IN THE MOUSE BRAIN.

C. D. Toscano, S. Palumbo and F. Bosetti. *NIH, Bethesda, MD.*

Chronic cuprizone exposure produces progressive demyelination in mice which reverses upon its removal from the diet. Although the mechanism of demyelination is unknown, activation of glia is integral to the process. Since metabolism of arachidonic acid (AA) is involved in glial activation, we hypothesized that cuprizone exposure would alter expression of AA cascade genes. Mice were exposed to cuprizone for 6 weeks after which they were returned to a normal diet. Histochemistry with the myelin stains Black Gold and Fluoromyelin demonstrated that frank demyeli-

nation and influx of glial cells into the corpus callosum begins at week 3 and peaks at week 5. However, a decrease in myelin and oligodendrocyte markers, myelin basic protein (MBP) and 2, 3-cyclic nucleotide 3-phosphodiesterase (CNPase), was evident at week one. Increased expression of CD11b and glial acidic fibrillary protein (GFAP), evidence of activated microglia and astrocytes, was also observed at week one. Coincident with these early changes, is an increase in cyclooxygenase (COX)-2 and lipoxygenase (LOX)-15 expression, suggesting that these arachidonic acid metabolism genes are either involved in or respond to the earliest sign of demyelination. Expression of LOX-5 was not significantly changed during the early stages of demyelination but it peaked during week 5, when glial markers and frank demyelination also reached their peak of expression, suggesting that LOX-5 expression is a consequence of the massive influx of inflammatory cells into the area of demyelination. While expression of LOX-12 was not consistently increased during demyelination, increased LOX-12 expression was observed during the remyelination, suggesting a role for this isoform in the recovery process. Our study is the first to demonstrate that multiple enzymes involved in arachidonic acid metabolism are altered in the cuprizone model of demyelination and remyelination. These data may help to develop new therapeutic targets to treat demyelinating diseases, such as multiple sclerosis.

PS 2156 CORTICOSTERONE ATTENUATES HIPPOCAMPAL NEUROTOXICITY AND REACTIVE GLIOSIS THROUGH REGULATION OF THE BLOOD-BRAIN BARRIER IN C57BL/6J MICE TREATED WITH KAINIC ACID.

S. A. Benkovic, J. P. O'Callaghan and D. B. Miller. *TMBB, CDC-NIOSH, Morgantown, WV.*

High levels of stress or stress hormones have been reported to exacerbate human disorders of several physiological systems. As a model of stress, male mice were implanted with 0, 10, 35 or 100 mg/21d release corticosterone (CORT) pellets (0, 19, 67, and 190 mg/kg/d). After 7d, mice were injected with saline or 25 mg/kg kainic acid (KA), were scored for seizures (Racine scale), and were allowed to recover for 12 or 24h (histology), 7d (ELISA for GFAP), or 1, 3, 6, or 12h (western blot for IgG). Tissue was prepared for histological analysis of neurodegeneration by the cupric-silver stain; astrogliosis by ELISA and immunohistochemistry for GFAP; and microglial activation by Iba-1, CD11c, isolectin, and reactive silver staining. Treatment of mice with CORT caused no neuronal death, and attenuated damage caused by KA. GFAP levels were elevated seven-fold in KA-treated mice. Increasing doses of CORT caused greater decreases in basal GFAP, and CORT pre-treatment attenuated KA-induced protein elevation. GFAP staining revealed hypertrophic astrocytes with thick processes following KA treatment. Astrocytic hypertrophy was attenuated by CORT pre-treatment. Iba-1 and silver staining revealed a population of resting microglia in all brain regions. Basal Iba-1 staining was attenuated by high doses of CORT. Lectin and CD11c stained microglia were observed in regions that displayed KA-induced neurodegeneration and were rarely observed in control or CORT-treated animals. KA treatment caused a breach of the blood-brain barrier (BBB) and resulted in hippocampal levels of IgG that were increased by one hour. IgG levels were maximal at six hours post-treatment, and returned to baseline by 12 hours. CORT pre-treatment attenuated KA-induced BBB opening and IgG influx. Our data indicate CORT does not cause neuronal damage, and attenuates excitotoxic neurodegeneration and glial activation that has BBB disruption as a component of the pathological mechanism.

PS 2157 CYANIDE-MEDIATED INCREASE IN CA^{2+} AND NITRIC OXIDE IS ASSOCIATED WITH CYTOCHROME OXIDASE INHIBITION.

H. B. Leavesley, S. Mukhopadhyay, L. Zhang, L. Li, X. Zhang, J. L. Borowitz and G. E. Isom. *Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN.*

Cyanide is a potent neurotoxicant that inhibits mitochondrial (mt) respiration at the level of cytochrome c oxidase (CcOX). Acute cyanide exposure causes dopaminergic cell death in the *substantia nigra*, which may lead to a delayed-onset Parkinson-like syndrome. Our studies have shown that nitric oxide (NO), produced by nitric oxide synthase (NOS), plays a role in cyanide inhibition of CcOX and the subsequent death of dopaminergic cells. Cyanide (5 μM) increased generation of mt NO (NO_{mt}) in mesencephalic cell culture. The rise in NO_{mt} could originate from cytosolic NOS or mt (mtNOS). In this study, we examined the mechanism by which cyanide increases NO_{mt} in N27 rat dopaminergic cells. Since Ca^{2+}-bound calmodulin (Ca^{2+}-CAM) is an activator of NOS and cyanide increases cytosolic free Ca^{2+} (Ca^{2+}_{cyt}), we compared cyanide-induced changes in Ca^{2+}_{mt} to NO_{mt}. Cyanide-mediated changes in Ca^{2+}_{cyt} and Ca^{2+}_{mt} were monitored in whole cells using the fluorescent probe Fluo-4 AM. It was noted that changes in Ca^{2+}_{mt} did not correlate with changes in NO_{mt}. Within the 1-10 μM KCN range, Ca^{2+}_{mt} peaked at 8 μM KCN. In contrast, NO_{mt} increased at 3 μM KCN, as determined by DAF-FM fluorescence. To further examine the mechanism of NO_{mt} elevation, ruthenium red was employed to block Ca^{2+}_{mt} uptake. Ruthenium red treatment enhanced NO_{mt} by 50%, suggesting that elevated Ca^{2+}_{mt} did not increase NO_{mt}. Examination of Ca^{2+}_{cyt} showed a direct correlation between cyanide-mediated changes in NO_{mt} and Ca^{2+}_{cyt}. Thus, it appears that cyanide increases NO_{mt} primarily through activation of cytosolic NOS, not mtNOS. It is concluded that the cyanide-induced rise in Ca^{2+}_{cyt} stimulates to the cytosolic production of NO, which then enters mt to interact with CcOX, thereby enhancing cyanide inhibition of oxidative phosphoryation. (Supported in part by NIH Grant ES04140.)

PS 2158 INDUCIBLE EXPRESSION OF BNIP3 IN CLONAL MESENCEPHALIC CELLS LEADS TO NECROPTOTIC DEATH.

S. Mukhopadhyay, L. Li, L. Zhang, H. B. Leavesley, J. L. Borowitz and G. E. Isom. *Purdue University, West Lafayette, IN.*

BCL2/adenovirus E1B 19 kDa interacting protein 3(BNIP3) is a member of the BH3-only subfamily of pro-apoptotic Bcl-2 proteins and is associated with hypoxia-mediated cell death. To study involvement of BNIP3 in KCN-mediated cell death, a tetracycline (tet) inducible stable cell line was constructed. The cell line was prepared by stable transfection of the TetR plasmid in immortalized dopaminergic neuronal cells (N27), to obtain N27-TetR clones. The clones were stably transfected with expression plasmids containing BNIP3 gene downstream of cytomegalovirus promoter carrying tetO sequences. In the cells BNIP3 expression increased in a dose-dependent and time-dependent manner following tet treatment. Both Propidium Iodide (PI) and trypan blue staining showed that minimal necrotic death occurred within 24 hrs of Tet-on (0.5μg/ml). However cell viability decreased within 24hrs of tet (0.5μg/ml) treatment as detected by the MTT assay. Upon Hoescht 33258 staining, apoptotic death was observed based on nuclear morphological changes. Nuclear fragmentation, typical of apoptosis, was not observed but chromatin condensation was arrested at stage I in which nuclei exhibit a wrinkled pattern of peripheral chromatin condensation. DNA laddering was detected. At higher concentrations of tet(>0.5μg/ml) the DNA fragmentation was reduced and cell death shifted to necrosis as indicated by a smear on 1.5% agarose gel. Prolonged tet treatment for >48 hrs or treatment with cyanide (400μM) shifted the mode of cell death to necrosis as confirmed by trypan blue and PI staining. Cell viability decreased following KCN treatment (400μM) as measured by trypan blue cell counting. Neither the apoptosis nor necrotic death was associated with caspase 3 activity. It was concluded that following tet induced expression of BNIP3, a continuum of caspase-independent cell death from apoptosis to necroptosis to necrosis could be produced depending on the dose and duration of exposure to tetracycline and cyanide. (Supported by NIH grant ES04140)

PS 2159 EARLY LETHAL EPILEPSY IN MICE WITH COMBINED GLUTAMATE-CYSTEINE LIGASE MODIFIER SUBUNIT AND L-GULONOLACTONE OXIDASE DEFICIENCY.

Y. Chen[1], E. Johansson[1], C. P. Curran[1], X. Liu[2], K. D. Holland-Bouley[2], S. C. Danzer[2], H. G. Shertzer[1], D. W. Nebert[1] and T. P. Dalton[1]. *[1]Department of Environmental Health, University of Cincinnati, Cincinnati, OH and [2]Department of Neurology, Cincinnati Children's Hospital, Cincinnati, OH.*

Reduced glutathione (**GSH**) and ascorbic acid (**AA**) are two major antioxidants in maintaining redox homeostasis and protecting against oxidative damage to the central nervous system (**CNS**). GSH and AA can interact as a redox couple, such that depletion of either one of them can be compensated for by the continued presence or compensatory rise of the other. In addition, both antioxidants have been suggested to act as neuromodulators in the glutaminergic system. We have generated the *Gclm(-/-)* knockout mouse line by disrupting the gene encoding the modifier subunit of the rate-limiting enzyme in GSH biosynthesis. *Gclm(-/-)* mice exhibit 15-40% of normal tissue GSH levels with a compensatory increase in ascorbate and reveal no overt phenotype. The *Gulo(-/-)* mouse, having ablation of the *L*-gulono-γ-lactone oxidase gene, cannot synthesize AA and, like humans, depends on dietary ascorbate for survival. In the current study, we generated *Gclm(-/-)Gulo(-/-)* double-knockout mice to test the hypothesis that deficiency in both GSH and AA will render these mice highly susceptible to endogenous oxidative damage. Unexpectedly, we observed that the concomitant loss of both *Gclm* and *Gulo* genes in mice causes growth retardation and lethal spontaneous epilepsy between the 2nd and the 3rd

postnatal week. Histologically, these mice showed neuronal loss and glial proliferation in the cerebral cortex and hippocampus. The mortality in double-knockout mice was prevented by AA supplementation in the drinking water. Remarkably, when AA was stopped for 2 weeks, these rescued double-knockout mice developed epilepsy and similar pathological changes in brain; these mice died within 3 weeks of AA withdrawal. Thus, this lethal epileptic phenotype, associated with combined GSH and AA deficiency, implies that a significant and underestimated role of GSH-AA interaction occurs in the CNS under physiological conditions.

PS 2160 OXIDATIVE STRESS PRODUCTS 4-HYDROXY-2-NONENAL AND MALONDIALDEHYDE ARE INHIBITORS OF CELLULAR ALDEHYDE DEHYDROGENASES AND REDUCTASES INVOLVED IN DOPAMINE CATABOLISM.

Y. Jinsmaa, V. R. Florang and J. A. Doorn. *University of Iowa, Iowa City, IA.*

Previous work demonstrated a role for oxidative stress in pathogenesis of Parkinson Desease (PD), and it has been proposed that a toxin endogenous to dopamine (DA) neurons yields selective neurodegeneration. In this study, it is hypothesized that oxidative stress products inhibit metabolism of a toxic and reactive intermediate of DA catabolism. Inhibition of cellular aldehyde dehydrogenase (ALDH) and aldehyde reductase (AR) by oxidative stress products 4-hydroxy-2-nonenal (4-HNE) and malondialdehyde (MDA) was studied in PC6-3 cells. The highly toxic product of DA catabolism, 3,4-dihydroxyphenylaldehyde (DOPAL) is generated from DA by mitochondrial monoamine oxidase and oxidized to 3,4-dihydroxyphenylacetic acid (DOPAC) or reduced 3,4-dihydroxyphenylethanol (DOPET) by ALDH and cytoplasmic AR, respectively. In this study, differentiated PC6-3 cells ($6x10^4$) were treated with various concentration of 4-HNE or MDA (0, 2, 10, 25, 50 and 100μM) in the presence of dopamine for 1 hr at 37°C and DA metabolites were analyzed using HPLC. Results showed concentration-dependent increase of DOPAL and decrease of DOPAC in both groups suggesting inhibition of ALDH activity by the lipid aldehydes. However DOPET was elevated only in 4-HNE group but not for MDA, suggesting MDA might also be inhibitor of AR. To study the effect of MDA on AR, the cytosolic fraction (1mg/ml) containing AR from undifferentiated PC6-3 cells was incubated with DOPAL (10μM) and NADPH (1mM) for 1hr at 37°C in the presence of MDA (0, 2, 10 and 25μM) or 4-HNE (25μM). The result showed concentration-dependent inhibition of enzyme activity in MDA-treated cells and effect was significant even at the lowest concentration of aldehyde tested (2μM) with 35% inhibition of AR but not by 4-HNE (25μM). In summary, these data demonstrated the dramatic effect of lipid peroxidation products, 4-HNE and MDA on DA catabolism as both aldehydes can generate abberant level of endogenous toxin DOPAL, which may contribute to development of PD.

PS 2161 UNCOUPLING PROTEIN 2 ENHANCEMENT OF CYANIDE NEUROTOXICITY: INVOLVEMENT OF MITOCHONDRIAL NITRIC OXIDE SYNTHASE.

L. Li, X. Zhang, L. Zhang, S. Mukhopadhyay, H. B. Leavesley, J. L. Borowitz and G. E. Isom. *Medicinal Chemistry & Molecular Pharmacology, Purdue University, West Lafayette, IN.*

Expression of uncoupling protein-2 (UCP-2) in brain is upregulated in a number of pathological conditions, including hypoxia, chemical-induced seizures and brain injury. In these conditions mitochondrial nitric oxide synthase (mtNOS) has been reported to be up-regulated. We have shown previously that UCP-2 up-regulation enhances cyanide-induced toxicity of dopaminergic cells. To elucidate the underlying mechanisms, a tetracycline (tet)-inducible cell line was constructed in which UCP-2 can be overexpressed. After addition of tet, the protein level of UCP-2 was time and dose-dependently increased. This was accompanied by up-regulation of mtNOS as detected by Western blotting in isolated mitochondria. The mtNOS activity was determined by monitoring nitric oxide (NO) production and mitochondrial respiration. It is well known that NO can directly inhibit the respiratory chain (cytochrome c oxidase), resulting in decreased ATP generation and reduced membrane potential ($\Delta\Psi$m). UCP-2 overexpression (tet-on) was accompanied by a marked increase of NO, which in turn reduced state 3 respiration. Activation of mtNOS was mediated by [Ca2+]m overload, since ruthenium red (RuRed), a specific inhibitor of the mitochondrial Ca2+ uniporter, blocked NO generation following induction of UCP-2. It was observed that UCP-2 overexpressed cells were more sensitive to cyanide than non-induced cells, as reflected by mitochondrial dysfunction (deceased $\Delta\Psi$m, ATP and mitochondrial swelling). RuRed and NOS inhibitors (7-nitroindazole and L-NMMA) inhibited cyanide-induced cell death by blocking mtNOS activity and decreasing NO generation. It was concluded that mtNOS activation with NO generation plays an important role in mediating the enhanced sensitivity to cyanide in cells in which UCP-2 is overexpressed. (This study was supported by NIH grant ES04140).

PS 2162 REACTIVE OXYGEN SPECIES PRODUCED BY MITOCHONDRIAL RESPIRATORY INHIBITORS POTENTIATES EXCITOTOXICITY-INDUCED CELL DEATH IN ORGANOTYPIC HIPPOCAMPAL SLICE CULTURES.

R. A. Schuh[1, 2] and P. Fishman[1, 2]. *[1]Research, VA Maryland Health Care System, Baltimore, MD and [2]Neurology, University of Maryland School of Medicine, Baltimore, MD.*

Two intensively investigated hypotheses of human neurodegenerative disease involve the role of mitochondrial dysfunction and the toxic actions of the excitatory neurotransmitter glutamate. We demonstrated increased cell death in organotypic rat hippocampal slices exposed for 24h to very low concentrations of NMDA plus rotenone, a broad-spectrum insecticide that inhibits complex I of the mitochondrial electron transport chain, (ETC). The increased cell death was synergistic at low NMDA concentrations and additive at higher concentrations and appeared to be neuron-specific. Additionally, similar results were obtained in the same culture system when mitochondrial toxins inhibiting ETC complexes II – IV were used concomitantly with NMDA. Inhibition of respiratory complexes within the ETC gives rise to oxidative stress and bioenergetic failure. Thus, in this study, we investigated the potential ameliorative effects of EUK 134, a salen-manganese complex that scavenges reactive oxygen species. Organotypic rat hippocampal slice cultures were exposed to rotenone (100 nM) concomitantly with NMDA (1 or 10 μM) in the presence of EUK 134 (20 μM) for 24h then assessed for cell death as determined by propidium iodide fluorescence. Separate experiments utilized antimycin A (100 nM, a complex III inhibitor) to investigate whether the response was complex I- or rotenone-specific. EUK 134 ameliorated cell death in slices exposed to ETC inhibitors plus NMDA. Complete protection was not observed suggesting that, although oxidative stress may contribute to cell death potentiation in this culture system, bioenergetic failure may also play a role. This further suggests that a combinatorial therapeutic approach may be required to ameliorate the potentiated cell death.

PS 2163 NEUROTOXIC IMPLICATION OF GLIAL INFLAMMATORY RESPONSE BY HISTONE DEACETYLASE INHIBITORS.

B. Viviani, M. Boraso, I. Lotterio, S. Rubisse, E. Corsini, A. De Francesco, S. Bellosta, C. L. Galli and M. Marinovich. *Department of Pharmacological Sciences, University of Milan, Milan, MI, Italy.*

Histone deacetylase inhibitors (HDACi) have currently entered clinical trials for hyperproliferative disorders due to their pro-apoptotic and anti-inflammatory effect, but still very little is known about their activity towards non-tumorous cells. In the present study we evaluated whether the HDACi, Trichostatin A (TSA), induces cytotoxicity and regulates the inflammatory response in a neural model of inflammation in vitro. To this purpose, primary glial cells were exposed to lipopolysaccharide (LPS) 10 ng/ml, with or without TSA. Cytokines release was measured by ELISA and/or by an appropriate biological assay. TSA did not affect glial viability at any of the concentrations used (0.01-200 nM), but it dose-dependently enhanced LPS-induced release of both Interleukin-1 β (IL-1β) and Tumor necrosis factor-α (TNF-α) from glial cells, and significantly reduced the production of the anti-inflammatory cytokine interleukin-10 (IL-10). This unexpected effect occurred only in glial cells and was maximal at 10 nM, whereas TSA significantly reduced the release of pro-inflammatory cytokines from LPS-stimulated primary macrophages.
The enhancement of TNF-α release from glia was maximal when LPS and TSA (0.1-100 nM) were applied simultaneously, but it was less pronounced if glia was pre-treated for 1h with TSA and TNF-α was measured by biological assay. Biological assays differ from ELISA, since they detect only the cytokines that have been processed to be biologically active. These results suggest that TSA enhances LPS-induced release of proinflammatory cytokines but also interferes with the proteolytic cleavage of pro-TNF-α to its mature form. The pro-inflammatory setting triggered by TSA is specific for glial cells, suggesting that histone acetylation may participate in sustaining the inflammatory response associated with a variety of neurodegenerative/neurotoxic conditions.

PS 2164 DIFFERENTIAL RESPONSE OF BRAIN AND LIVER FREE FATTY ACIDS FOLLOWING ADMINISTRATION OF A SYNTHETIC ANALOG OF CERULENIN, C-75 IN CD-1 MICE.

Z. K. Binienda[1], I. A. Ross[2], B. Gough[1], T. Riccio[1], S. F. Ali[1] and C. S. Kim[2]. *[1]Neurotoxicology, FDA/NCTR, Jefferson, AR and [2]DOT/OARSA, FDA/CFSAN, Laurel, MD.*

A potential drug for the treatment of obesity, C-75, has a stimulatory effect and as C-75-CoA derivative, an inhibitory effect on carnitine palmitoyltransferase 1(CPT 1), the main regulatory enzyme in fatty acids oxidation. In rodents, C-75 has been shown to reduce body weight by inducing anorexia. The mechanisms involved in C-75 metabolic actions altering feeding behavior are unclear. Here, we examined the response of brain and liver free fatty acids (FFAs) in adult CD-1 mice injected i.p. either with saline (control) or C-75 at 20 mg/kg. Mice were sacrificed 1, 2, 4 and 24 hrs following the injection to harvest whole brain and liver. Long chain FFAs were extracted with chloroform and methanol (4, 8 v/w) from tissue homogenates and the extracts were shaken, followed by centrifugation. The supernatants were reconstituted with Hepes, chloroform and methanol (3.2, 4, 8 v/w). The chloroform was then evaporated under a stream of nitrogen. The residue was reconstituted with ether- hexane (50:50, v/v) and eluted by column chromatography on acid-washed Florisil. FFAs were derivatized with BF3/methanol and fatty acid methyl esters quantitated by gas chromatography. While concentrations of saturated FFAs in the liver and brain did not show changes following the C-75 injection, unsaturated brain FFAs were progressively increasing. The level of C-14.1 (myristoleic acid) near doubled from control level 0.63 ± 0.1 μg/mg protein to 1.06 ± 0.1 μg/mg protein, respectively, 24 hrs following treatment. Preliminary data suggest a regulatory role of brain unsaturated fatty acids in C-75-induced anorexia.

PS 2165 CONTINUOUS INTRAVENOUS INFUSION IN THE MOUSE: A SUITABLE ALTERNATIVE SAFETY ASSESSMENT MODEL TO AVOID HISTAMINERGIC REACTION IN THE RAT?

H. van Wijk and C. Springall. *Covance Laboratories Ltd, Harrogate, United Kingdom.*

It is known that certain peptides, proteins and macromolecules elicit a histaminergic response in vitro and in vivo. Numerous studies have documented the influence of infusion rate on the severity and probability of histamine release from mast cells in animal species and in humans. The need for improvements in the development of vascular infusion systems for rodents will continue to increase as the use of mouse models increases and more parentally-delivered protein and peptide therapeutics enter development. The rat is probably the most commonly used animal for pre-clinical continuous infusion. However, the rat is a particularly sensitive species with regard to histaminergic reactions. Additionally, repeat intravenous (iv) bolus administration of drugs which elicit histaminergic-type reactions pose a particular problem in rodents, as infiltration of an irritant solution around the tail vein (perivascular) can potentially lead to necrosis and make further injections difficult or impossible. A mouse continuous vascular infusion study was conducted, using a test article that was histaminergic in the rat. Pharmacokinetic and other data are presented from this study. The mouse model proved a viable alternative technique for avoiding histaminergic reaction in the rat.

PS 2166 HAEMATOLOGY AND SERUM CHEMISTRY PARAMETERS IN CYNOMOLGUS MONKEYS (MACACA FASCICULARIS): COMPARISON BETWEEN PURPOSE-BRED AND CAPTURED ANIMALS.

P. Colombo, U. Bonfanti, D. Lamparelli and C. Bernardi. *Preclinical Development, Accelera - Nerviano Medical Sciences srl, Nerviano, Milano, Italy.* Sponsor: M. Brughera.

Although the large majority of non-human primates used nowadays for biomedical research are purpose-bred, there might still be a few "nicks" for which older and captured animals are required. Blood samples from purpose-bred and captured cynomolgus monkeys (Macaca fascicularis) originated from the same geographic area and kept under the same environmental and feeding conditions were collected, and standard hematologic and serum biochemistry parameters examined and compared. Statistically significant differences were observed in some parameters, particularly in eosinophils, total protein, globulins, alanine amino transferase, and creatinine. Mean values for these parameters were always higher in captured animals than in purpose-bred monkeys. In addition eosinophils, large unstained cells, creatinine, alanine amino-transferase, total proteins and globulins also showed significant differences between gender. Relevant differences present in both sexes, but without a statistical significance, were observed in basophils and monocytes. Fibrinogen, aspartate amino-transferase, alkaline phosphatase, g-glutamyl transferase, lactate dehydrogenase, a-hydroxybutyrate dehydrogenase, iron, potassium and phosphorus generally showed statistical significance differences only in one sex. From the analysis of these data it was concluded that significant differences in basal values might be observed in clinical pathology results in animals with different breeding background, and this should be carefully considered in pharmacotoxicological studies. Particularly, experimental data have to be compared from those obtained in the same animals before any pharmacological treatment, or with those filed in historical database and obtained from animals characterized by the same breeding background. After years of experience in performing preclinical studies in monkeys, Accelera has build a robust database for the control of experimental data.

PS 2167 TRANSGENIC RASH2 MOUSE: A MODEL FOR DERMAL CARCINOGENESIS.

M. Paranjpe[1], M. L. Wenk[1], D. Brecha[1] and G. B. Smith[2]. *[1]BioReliance Corporation, Rockville, MD and [2]Vertex Pharmaceuticals, Inc., Cambridge, MA.*

Transgenic TgAC mice have been used in 26 week dermal carcinogenicity studies, as an acceptable alternative to the traditional two-year mouse carcinogenicity assay, as they are sensitive to dermal carcinogens and promoters. Due to limitations and hypersensitivity associated with the TgAC mouse model for dermal carcinogenicity, an effort was made to characterize the rasH2 as an alternative model for dermal carcinogenesis. One group of mice (vehicle control group) was treated with 0.1 ml of acetone and three groups of mice were treated with either 2.5, 5 or 10 microgram of TPA (positive control) in 0.1 ml acetone. Each mouse was treated 3 times per week with either acetone or a different dose of TPA for 26 weeks. The vehicle control treated rasH2 mice did not develop any tumors at the site of application whereas the TPA treated rasH2 mice showed a significantly increased incidence of neoplasia both grossly and microscopically. The percentage of rasH2 animals with at least 1 nodule at the site of application varied between 84% to 92% in males and 76% to 100% in females. Additionally, the tumor burden (number of tumors per animal) increased in a dose responsive manner in both sexes of mice. The tumor burden in males increased from 1.48 to 3.0 and in females from 1.24 to 2.76 along the dose range. The results of our experiments demonstrate that the rasH2 mouse is a potentially suitable alternative model for dermal carcinogenicity as these mice developed tumors consistently at the site of application with positive control material TPA and there was no development of tumors in the vehicle control animals. These results indicate the necessity for additional validation studies with recognized dermal carcinogens to further characterize this model and creation of an historical tumor database demonstrating the response to various classes of carcinogens, non-carcinogens and vehicles.

PS 2168 CONTROL DATA IN DEVELOPMENTAL TOXICITY STUDIES IN THE WISTAR HANNOVER RCCHANTM: WIST RAT.

K. Weber[1, 2], R. Gerspach[1, 2], S. Whitlow[1, 2] and M. Josten[1, 2]. *[1]Harlan Laboratories, Indianapolis, IN and [2]RCC Ltd, Itingen, Switzerland.* Sponsor: S. Corney.

In developmental toxicity studies, which focus on adverse effects on the embryo or the fetus evaluations of reproduction data and of external, visceral or skeletal malformations or variations are important in the assessment of the teratogenic potential of the test item. Little is published on the historical range of such data. The present analysis was made on the vehicle-treated (highly purified water, watery suspensions of carboxy methyl cellulose, or corn oil) control groups of 34 developmental toxicity studies performed at RCC Ltd Switzerland during 2002 to 2006. The historical control data show the Wistar Hannover RccHanTM: WIST Rat to be highly fertile, in terms of achieved pregnancies. Sex ratios of live fetuses are similarly and, due to low pre- and post-implantation losses the resulting litter sizes are suitable for reproduction data evaluation in developmental toxicity studies as well as in reproduction studies in general. Regarding the external examinations, no generalized occurrence of a special external abnormality was established. In addition, there was no shift in the general pattern of abnormalities or variations over the years of observation as well as in the mean fetal weights. Visceral examinations revealed only very few structural abnormalities or structural variations which moreover occur at low incidences. Variations at higher incidences showed an equal distribution over the time period. The skeletal and cartilage examination again, revealed only a few abnormalities or variations. The pattern of ossification in the control fetuses was rather homogeneous and allows the accurate estimation of delayed or accelerated ossification in test item-treated fetuses. There was no indication of a shift in the pattern of findings in any parameter examined during the observed time period in the Wistar Hannover RccHanTM: WIST Rat.

PS 2169 CONTINUOUS BLOOD PRESSURE MEASUREMENT IN CONSCIOUS, UNRESTRAINED CYNOMOLGUS MONKEYS *VIA* AN IMPLANTED PA-C10 (MOUSE) TRANSMITTER.

A. Mitchell, A. C. Jenkins and R. D. Sarazan. *Safety Pharmacology, Covance Laboratories Inc., Madison, WI.*

Accurate determination of arterial blood pressure (BP) in conscious, unrestrained monkeys currently entails use of invasive telemetry techniques. In this study, the functionality and tolerability of a less invasive method was evaluated. A mouse BP transmitter (DSI, model PA-C10) was surgically implanted into a femoral artery of a male and a female cynomolgus monkey. BP and ECG data were collected continuously by jacketed external telemetry (JET) for at least 24 hours bi-weekly for 15 weeks. Evaluated were surgical implantation site, clinical pathology (CP) data, quality of BP signals, data dropout, systolic, diastolic, mean arterial pressure, and pulse rate. After completion of the collection period, animals were euthanized and the femoral arteries and portions of the quadriceps muscles were evaluated macroscopically and microscopically. The incision sites in the inguinal area healed uneventfully. CP results obtained on Days 48 and 93 indicated no health abnormalities. BP signals were of excellent quality during light/dark cycles and did not interfere with ECG signals. For BP data, 1-minute averages were calculated and were excluded from further analysis when signal dropout was evident within the respective minute. Average data dropout due to unfavorable positioning of the animal was 32%. No device-related macroscopic findings were noted. Expected microscopic findings consistent with the presence of an indwelling catheter, such as thickening of the intima and disruption of the internal elastic lamina in the femoral artery were found in both animals. No macroscopic or microscopic findings were noted in the muscle samples. In conclusion, implantation of a mouse PA-C10 BP transmitter using a minimally invasive technique produced reliable BP data for at least 24 hour intervals with insignificant data dropout in conscious, unrestrained non-human primates with no adverse histological findings. This novel technique could be a viable option for high quality ECG and BP measurements in toxicology studies up to 15 weeks in length.

PS 2170 AMIODARONE EXPOSURE DURING MODEST INFLAMMATION INDUCES IDIOSYNCRASY-LIKE LIVER INJURY IN RATS.

J. Lu[1, 3], R. A. Roth[2, 3] and P. E. Ganey[2, 3]. [1]*Department of Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI,* [2]*Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI and* [3]*Center for Integrative Toxicology, Michigan State University, East Lansing, MI.*

Idiosyncratic adverse drug reactions (IADRs) depend on sensitivity factors within the host. Amiodarone (AMD), a class III antiarrhythmic agent effective in treating atrial fibrillation, is known to cause idiosyncratic, hepatotoxic reactions in human patients. One hypothesis for the etiology of IADRs is that a concurrent inflammatory stress results in decreased threshold for drug toxicity, causing liver injury at an otherwise "safe" dose. To test this hypothesis, lipopolysaccharide (LPS), a cell wall component of Gram negative bacteria, was administrated to animals to induce low-level inflammation. Male rats were treated intravenously with nonhepatotoxic doses of LPS or its vehicle, and AMD or its vehicle. Liver injury, as marked by increases in serum alanine aminotransferase (ALT) activity and by midzonal hepatocellular necrosis in H&E stained liver sections, was observed only in groups of animals treated with both LPS and AMD. Dose-dependent mortality was observed in the LPS/AMD group with AMD doses greater than 60 mg/kg. The time of AMD administration relative to LPS was critical to the development of liver injury: AMD injected 2h after LPS resulted in a significant increase in ALT activity, whereas AMD injected 2 to 4h before or 4h after LPS failed to cause this response. These results demonstrate that AMD treatment during modest inflammation can induce severe hepatotoxicity in rats, a response resembling IADRs in human patients. (Supported by NIH GMO75865.)

PS 2171 ROLE OF CANNABINOID RECEPTORS 1 AND 2 *IN OVA* -INDUCED ALLERGIC AIRWAY RESPONSES IN C57BL/6 MICE.

P. W. Karmaus[1, 2], J. E. Oberdick[2], B. L. Kaplan[2], N. P. Birmingham[2], J. R. Harkema[3] and N. E. Kaminski[2, 4]. [1]*Cell and Molecular Biology, Michigan State University, East Lansing, MI,* [2]*Center for Integrative Toxicology, MSU, East Lansing, MI,* [3]*Pathobiology and Diagnostic Investigations, MSU, East Lansing, MI and* [4]*Pharmacology and Toxicology, MSU, East Lansing, MI.*

In previous studies, mice deficient in cannabinoid receptors ($CB1^{-/-}CB2^{-/-}$) experienced exacerbated immune reactions in models of in vivo contact dermatitis as well as in response to influenza challenge. Thus we hypothesized that $CB1^{-/-}CB2^{-/-}$ (KO) mice are more prone to develop an ovalbumin (OVA)-induced airway hypersensitivity reaction compared to WT mice. The purpose of this study was to assess whether KO mice are predisposed to develop allergic airway disease using a model of OVA-induced airway hypersensitivity. Female C57Bl/6 wild-type (WT) and KO mice on C57Bl/6 background were intranasally sensitized with 30µl of 1% OVA in saline or saline alone (SAL) for 4 consecutive days. On days 14 and 21 after sensitization, mice were challenged with OVA or SAL. Mice were sacrificed 6 or 96 h after the last challenge. Blood and bronchoaveolar lavage fluid (BALF) were collected for IgE antibody and cellular analyses. Left lungs were fixed in 10% neutral buffered formalin and processed for microscopy. In response to OVA-instillation, an influx of neutrophils with a lesser number of eosinophils was observed 6 h post challenge in the BALF. An influx of eosinophils was further increased at 96 h, whereas neutrophil counts were decreased. Morphometric analysis of the interstitium revealed an increase of eosinophils in OVA-treated groups at 6 and 96 h, in both genotypes. Significant intraepithelial mucus production was detected at 96 h in OVA-treated mice. Also, elevated OVA-specific IgE was observed with no differences between OVA-instilled WT and KO mice, with the exception of lower plasma IgE levels in KO compared to WT mice. These findings suggest that the absence of CB1 and CB2 does not alter the response to OVA in a model of allergic airway disease. (Supported by: MSU Respiratory Research Initiative, NIH: DA07908, NIH: T35RR017491).

PS 2172 A TECHNIQUE FOR SUBRETINAL ADMINISTRATION IN RABBITS.

M. Vézina and M. Bussières. *Toxicology, Charles River, Senneville, QC, Canada.*

Subretinal administration of therapeutic agents can be advantageous to localize exposure close to a discrete region within the retina, or when a local depot delivery is required for slow release in the eye. The subretinal injection procedure was optimized for dose volume/placement and minimal injury to the retina: 15 New Zealand White rabbits underwent subretinal injections with/without partial vitrectomy. Animals were anesthetized with ketamine/xylazine and the eye exposed by a lateral canthotomy and pseudo-proptosis. A topical anesthetic and mydriatic were applied and the eye was hydrated throughout the procedure. Under a surgical ophthalmic microscope, a 25G fiberoptic light source was inserted for visualization of the retina. A 41G needle, microextension tube and 1cc syringe were used to administer the subretinal injection via a 20G sclerotomy. In some animals, prior to subretinal injection, a partial vitrectomy was performed with the integrity of the globe maintained by a BSS+ infusion. The injections were administered in one or two phases. A bleb was created by either a direct 50 to 150 µL injection of methylene blue (MB) solution (for visualization) to different regions of the retina, or a small saline bleb was created to cause the initial lift of the retina, followed by inflation of the bleb with MB solution. The most successful blebs were located in the vicinity of the optic disc or myelinated nerve fibers. Bleb creation was more difficult as distance from the optic disc increased. The vitrectomy did not provide any advantage for larger volumes of administration as blebs up to 150 µL were successfully created without it. Using saline to first lift the retina, provided some advantage against reflux that could occur during direct injections, however, on several occasions this method proved to be worse with the low viscosity solution used. The injected liquid resorbed within 1-2 days. Retinal histopathology through the bleb did not reveal any changes except at the discreet point of needle entry. Overall, the best technique was the direct injection without vitrectomy, near the optic disc.

PS 2173 CLINICAL PATHOLOGY REFERENCE INTERVALS IN CYNOMOLGUS MACAQUES (MACACA FASCICULARIS): ERYTHROCYTE INDICES DIFFER BETWEEN INDONESIAN, INDOCHINESE AND MAURITIUS POPULATIONS.

L. Ramaiah, T. Ramani, P. Reese, C. S. Auletta and S. J. Gosselin. *Safety Assessment, Huntingdon Life Sciences, East Millstone, NJ.*

The cynomolgus macaque accounts for the majority of nonhuman primate importations for biomedical, pharmacology and toxicology research. The species can be classified into three genetically diverging populations according to geographical region of origin: 1) Indochina (mainland), 2) Insular Asia (Phillipines, Malaysia, and Indonesia), and 3) Mauritius. Phenotypic heterogeneity between populations has been documented and must be taken into consideration when designing and interpreting toxicology studies. Population differences have been noted for erythrocyte counts (RBC) and mean erythrocyte size (mean corpuscular volume, MCV), among others. However, biochemistry, hematology and hemostasis reference intervals for each subspecies have not been defined. The purpose of this study was to assess biological variation and establish reference intervals for hemotologic, hemostasis, and clinical chemistry parameters in cynomolgus monkeys imported from China, Vietnam, Cambodia, Indonesia, and Mauritius. Reference intervals and

summary statistics (ANOVA/Tukey) were determined for each population using data from prepubertal and young adult control animals of both sexes. Complete blood count and serum chemistry differences were demonstrated between these three populations and between sexes. Indochinese macaques had significantly higher MCV's and MCHC's and lower RBC counts when compared to Indonesian and Mauritian macaques. There was an inverse relationship between MCV and RBC with consistent erythrocyte mass across populations. Variability between animals was greatest in Indonesian macaques. We discuss the potential causes and consequences of variability in MCV, and advocate classification of study animals according to the three genetically defined populations to minimize outcome variability. Finally, we discuss heterogeneity between animals and populations in the context of current importation practices and industry needs.

PS 2174 TUMOR GROWTH OF NEGATIVE AND POSITIVE CONTROL CELL LINES FOR TUMORIGENICITY STUDIES IN IMMUNOCOMPROMISED MICE.

D. L. Newcomb[2], S. M. Jackman[1], M. V. Schriver[1], L. E. Black[2] and A. M. Hoberman[1]. *[1]Charles River Laboratories, Horsham, PA and [2]Charles River Laboratories, Reno, NV.*

Tumorigenicity studies for cell lines used to produce biologic therapeutics are required by regulators to assess risks of cell therapies intended for human use. U.S. guidelines require the use of reference cell lines as positive controls to increase confidence in the validity of the results. Therefore, we investigated the tumorigenicity and tolerability of reference cell lines following administration to two strains of immunocompromised mice [NOD/NCrCrl-Prkdc^{SCID} (NOD/SCID) and Crl:NU-foxn1 (nude)]. Mice were given a single subcutaneous dose of positive control cell lines HT-1080 cells (1 x 10^3, 1 x 10^5 or 1 x 10^7 cells) or PC-3 cells (2.5 x 10^6 and 5 x 10^6 cells), or the negative control cell line MRC-5 (1 x 10^7 cells). Viability, clinical observations, body weights, palpable mass observations, necropsy evaluations and histopathology were performed; surviving mice were sacrificed on study day 61. The MRC-5 cells were not tumorigenic in either mouse strain, confirming the utility of this cell line as a negative control. No tumors were seen at the lowest dose of HT 1080 cells. At higher doses, HT-1080 cells caused mortality, tumors and additional signs of toxicity in NOD/SCID mice and mortality and tumors in nude mice. Neither dose of the PC-3 cells caused mortality or macroscopic changes in either mouse strain. However, both doses caused signs of toxicity in the NOD/SCID mice and tumors in both mouse strains. Both cell lines produced larger tumors at the primary site in NOD/SCID mice, as compared with nude mice at the same cell doses. The low dose of PC-3 cells induced only a single tumor in one nude mouse, but produced tumors in all NOD/SCID mice. The high doses of both HT-1080 and PC-3 cells consistently produced tumors in both mouse strains. In conclusion, MRC-5 cells can be used as a negative control and both HT-1080 and PC-3 cells can be used as positive controls in either mouse strain with careful consideration to study design, mouse strain and dose.

PS 2175 THE INFLUENCE OF A HIGH SALT DIET ON A RAT MODEL OF ISOPROTERENOL-INDUCED HEART FAILURE.

A. P. Carll[1], N. Haykal-Coates[2], D. W. Winsett[2], M. S. Hazari[2], A. Nyska[3], J. H. Richards[2], D. L. Costa[4] and A. K. Farraj[2]. *[1]SPH, UNC, Chapel Hill, NC, [2]NHEERL, ETD, U.S. EPA, RTP, NC, [3]Sackler School of Medicine, Tel-Aviv University, Timrat, Israel and [4]ORD, U.S. EPA, RTP, NC.*

Rat models of heart failure (HF) show varied pathology and time to disease outcome, dependent on induction method. We found that subchronic (4 weeks) isoproterenol (ISO) infusion exacerbated cardiomyopathy in Spontaneously Hypertensive Heart Failure (SHHF) rats. Others have shown that dietary salt loading induces HF in spontaneously hypertensive (SH) rats without acute injury. We hypothesized that ISO and salt combined would induce injury and more overt HF in SHHF rats than either treatment alone. Rats (male, 90d) were infused for 4 weeks with ISO (2.5mg/kg/d s.c.) or saline via osmotic pump. Starting 2 weeks into the infusion regimen, rats were fed high-salt diets (4, 6, or 8% NaCl) for 6 weeks. We previously reported that relative to the control diet, the 8% salt diet increased heart mass, heart failure markers (plasma B-type natriuretic peptide, IL-6), lung lymphocytes, and indicators of lung injury and edema (bronchoalveolar albumin and protein), while it increased urine pro-atrial natriuretic peptide relative to ISO treatment. In the present study we examined the cardiac effects of ISO and salt diet on histopathology and markers of acute injury. ISO caused 29% lethality while high-salt diet had no effect on mortality. ISO-treated rats that died prematurely had elevated serum levels of heart fatty acid-binding protein (H-FABP) and cardiac troponin I (cTnI). At 4 weeks post-infusion, there was no effect of ISO and/or salt diet on cTnI or H-FABP. Preliminary histopathologic analysis indicates that high salt diet may have exacerbated cardiomyopathy in normal SHHF rats, but the effects of salt on ISO-treated SHHFs was unclear. Further examination of physiologic and histologic effects may conclusively determine if a high salt diet exacerbates ISO-induced heart failure in the SHHF rat. (Abstract does not reflect EPA policy; Supported by UNC/EPA CR83323601.)

PS 2176 MOUSE MODEL FOR TREATING METASTATIC HUMAN OVARIAN CANCER WITH HYPERTHERMIC INTRAPERITONEAL CHEMOTHERAPY.

V. A. States[2], J. H. Masters[2], C. S. Muenyi[1], J. States[1, 2] and C. Helm[2, 1]. *[1]Pharmacology & Toxicology, University of Louisville, Louisville, KY and [2]Brown Cancer Center, University of Louisville, Louisville, KY.*

Ovarian cancer is 4th leading cause of cancer death in women in the U.S. Diagnosis is usually at late stage when the cancer has metastasized within the peritoneal cavity. Frontline therapy consists of cytoreductive surgery followed by chemotherapy with platinum-based drug and a taxane. The newest modality of chemotherapy includes intraperitoneal lavage with hyperthermic cisplatin solution. Platinum resistance limits the effectiveness of chemotherapy and results in recurrence of platinum resistant tumors in over half the patients. This platinum resistant disease eventually kills the patients. Hence, there is an urgent need for efficacious therapy and an in vivo model to test new therapeutic regimens. We have developed a mouse xenograft model for metastatic, platinum resistant human ovarian cancer. Methods for intraperitoneal injection of the cancer cells were refined to promote formation of multiple (>10) small tumors less than 5 mm in diameter. Mice were scanned by microCT to determine the size and location of the tumors which was confirmed upon autopsy. Tumor bearing mice were treated with a combination of cisplatin, arsenic, and hyperthermia for 60 min by continuous flow intraperitoneal chemotherapy. The tumors were collected immediately after and 24 h after treatment. Platinum accumulation and retention in the tumors was determined by ICP-MS. Preliminary data suggest that platinum is readily accumulated and retained in the tumors exposed to cisplatin either alone or in combination with arsenic and/or hyperthermia. Expression of P53 and several p53 regulated proteins involved in DNA damage response was determined by western blot of tumor extracts. These results suggest that the model will be useful for evaluating intraperitoneal delivery of new combination chemotherapies and for determining modulation of tumor responses related to cisplatin resistance. Supported in part by USPHS grants ES011314 and ES014443 and a grant from University of Lousiville School of Medicine.

PS 2177 A RAT MODEL OF IDIOSYNCRATIC HEPATOTOXICITY: CONVERTING CARBAMAZEPINE TO A HEPATOTOXICANT.

A. Leone, E. Taylor, J. Proctor, M. Kao, J. Troisi, A. Fermier, L. Varacallo, P. Taggart, J. McCarty, S. P. Sawant, A. Collins, A. Nie, J. Hastings, P. G. Lord, M. F. Kelley and M. McMillian. *Johnson & Johnson, Raritan, NJ.*

The liver is the most common serious target organ for drug-related idiosyncratic toxicities, which are currently difficult to predict and are the leading cause for black-boxed and withdrawn drugs. Oxidative stress/ reactive metabolite (OS/RM) - sensitive gene expression, together with covalent binding and glutathione conjugates, can be used to screen for OS/RM, which may be toxic in susceptible patients. Many of OS/RM compounds, such as carbamazepine, are safe at high doses preclinically (LD>4000 mg/kg). A hypothesis for idiosyncratic hepatotoxicity is that immune cell activations, as occur in ongoing inflammation/ infection, sensitize some patients to relatively safe drugs. Roth et al at Michigan State have used a low dose lipopolysaccharide (LPS) pretreatment to convert safe drugs to hepatotoxicants in rodents. Many classical hepatotoxicants and NSAIDs produce Kupffer cell activation due to endotoxin absorption from the gut, which potentiates direct hepatotoxic effects of OS/RM compounds. Intravenous low dose LPS converted carbamazepine into a hepatotoxicant, but only in some rats. The sensitive rats showed gene responses suggesting that LPS blocks induction of many protective OS/RM-sensitive genes, as well as repressing several metabolism and transporter genes. In the hope of getting a more reproducible conversion of carbamazepine into a hepatotoxicant, dextran sulfate sodium (DSS) was used to increase endogenous endotoxin absorption from the colon. However, no conversion of carbamazepine was observed after DSS (24 hours or four days, 5% in drinking water), and instead there was a potentiation of the protective OS/RM gene responses, suggesting desensitization of Kupffer cells in this model, as reported previously. Further study is required to improve and understand conversion of non-toxic OS/RMs, such as carbamazepine, into idiosyncratic hepatotoxicants.

PS 2178 2-ACETYLAMINOFLUORENE EFFECTS ON CELL PROLIFERATION AND DNA ADDUCT FORMATION IN LIVERS OF LEAN AND DIET-INDUCED OBESE MICE.

M. J. Iatropoulos[1], J. Duan[1], A. M. Jeffrey[1], M. W. Leach[2], A. N. Hayes[2], N. Stedman[2] and G. M. Williams[1]. *[1]Department of Pathology, New York Medical College, Valhalla, NY and [2]Exploratory Drug Safety, Wyeth Research, Andover, MA.*

Non-alcoholic fatty liver is a risk factor for hepatocellular carcinoma. To explore possible mechanisms for this susceptibility, the effects of the activation-dependent DNA-reactive hepatocarcinogen, 2-acetylaminofluorene (AAF) were studied in lean (conventional) C57BL/6 (LEAN) and diet-induced obese DIO C57BL/6 (DIO) male mice, 6 months old at study initiation. AAF was administered by gavage at 2.24 (LD) or 22.4 (HD) mg/kg (3 x week: Mon, Wed and Fri) for 31 days. Control male LEAN and DIO mice received 12450B (10% Kcal from fat) and 12492 (60% from fat) diets (Research Diets Inc.), respectively. The rate of hepatocellular proliferation (replicating fraction or RF) was assessed by scoring of the immunohistochemical proliferating cell nuclear antigen (PCNA). DNA adduct formation was measured by nucleotide ^{32}P-postlabeling (NPL). The mean RF of the DIO control group (3.55 ± 0.65) was higher ($p<0.05$) compared to LEAN controls (2.72 ± 0.84), and the mean RF in both DIO ($p<0.05$) and LEAN ($p=0.06$) groups administered AAF was lower compared to respective controls, possibly reflecting the block to DNA synthesis produced by adduct formation. In the LEAN groups, the RF reduction was dose proportional (RF 2.21 in LD and 2.07 in HD), but not in the DIO AAF groups (RF 2.25 in LD and 2.48 in HD). AAF adducts were increased similarly and in a dose proportional manner in both LEAN and DIO AAF groups, reaching 59 (adducts in 10^9 nucleotides) in LD and 218 in HD LEAN, and 44 in LD and 189 in HD DIO mice. We interpret these findings to suggest that a factor in predisposing fatty livers to cancer development is increased cell proliferation, but that enhanced activation of a carcinogen may not be involved.

PS 2179 GENDER-DEPENDANT REACTIVE OXYGEN SPECIES-MEDIATED NEURODEGENERATION IN UNTREATED AGED ACATALASEMIC MICE.

A. Shapiro[1], J. Perstin[1] and P. G. Wells[1, 2]. *[1]Department of Pharmaceutical Science, University of Toronto, Toronto, ON, Canada and [2]Department of Pharmacology and Toxicology, University of Toronto, Toronto, ON, Canada.*

Oxidative stress occurs when the formation of reactive oxygen species (ROS) exceeds the detoxifying capacity of antioxidative enzymes like catalase, which metabolizes hydrogen peroxide. Neurodegenerative deficits may result from endogenous or xenobiotic-enhanced formation of ROS, which oxidatively damage cellular macromolecules and/or alter signal transduction. Reduced antioxidative activity, due either to a genetic deficiency and/or a progressive loss of antioxidative activity with age, may accordingly contribute to neurodegeneration associated with normal aging and various degenerative diseases. We have previously shown in utero that acatalasemic embryos are more susceptible to the pathogenic effects of endogenous ROS. Herein, we use aging catalase-deficient (C3Ga.Cg-Catb/J) acatalasemic mice and wild-type catalase-normal controls, aged 18 to 24 months, to determine what if any role catalase plays in protecting the brain from ROS-mediated, age-dependent motor coordination deficits quantified using a rotarod test. Aged female acatalasemic mice showed a substantial 64% loss in motor coordination compared to catalase-normal controls as demonstrated by decreased latency to fall (40 vs. 110 sec respectively, $p<0.001$). In contrast, aged male acatalasemic mice were not different from the male catalase-normal controls. This gender specificity is consistent with results from mice oxidatively stressed in utero with methamphetamine. These results provide the first evidence that catalase plays an important neuroprotective role with aging, and suggests that catalase deficiencies may constitute a risk factor for neurodegenerative outcomes.

PS 2180 COMPARATIVE INTRAOCULAR PRESSURE MEASUREMENTS IN MULTIPLE SPECIES USING 2 HANDHELD TONOMETERS.

M. Bussières and M. Vézina. *Toxicology, Charles River, Senneville, QC, Canada.*

Elevations or reductions in intraocular pressure (IOP) can play a significant role in ocular toxicity observed during ocular or systemic non-clinical toxicology studies. This effect has been well documented in glaucoma patients where control of IOP does not always prevent continued retinal degeneration. The data presented compares IOP measurements from 2 commonly used handheld devices, the TonoPen XL and the Tonovet in conscious male (M) and female (F), normotensive rabbits (n=20), dogs (n=20) and monkeys (n=18). The TonoPen is an aplanation device that requires local anesthetic and is actuated by movement of the operator's hand. The Tonovet, a rebound tonometer, is self actuating and does not require any local anesthetic. IOP was measured first with the Tonovet followed by the TonoPen at least twice for each eye. Data were obtained from dilated eyes (all species) and undilated eyes (rabbit only) and at 2 calibration settings (d or p) for the Tonovet (monkeys and rabbits). For dilated dog eyes, the IOP was similar between the TonoPen and Tonovet at approximately 16.5/17.5 mmHg for M/F, respectively, however the variability in the Tonovet data was slightly higher. For dilated monkey eyes, the results were again similar at approximately 15/19 mmHg for M/F, respectively with the Tonovet at the "d" setting. At the "p" setting M/F were 8.3/8.8 mmHg, respectively. Dilated rabbits were approximately 16/19 mm Hg for M/F with the TonoPen and 15/19 mmHg with the Tonovet at the "d" setting, with less variability using the Tonovet. At the "p" setting M/F averaged 8.3/8.8 mmHg, respectively. Undilated rabbit eyes were less variable: 16/16.5 mmHg for M/F on the TonoPen, 14/13.5 mmHg for M/F on the Tonovet on "d" and 8.9/8.1 mmHg on the Tonovet on "p", with much less variability using the Tonovet. In conclusion, based on the variability and ease of use, the TonoPen appears to have some advantage for use in dogs over the Tonovet, the Tonovet a greater advantage over the TonoPen for rabbits and the Tonovet a slight advantage over the TonoPen for monkeys at the "p" setting.

PS 2181 TOXICITY OF ORALLY ADMINISTERED POLYETHLENE GLYCOL (PEG-400) VEHICLE FORMULATIONS IN TRANSGENIC MICE.

S. A. Shah, P. I. Atkins, C. Brown, I. C. Agagbor, M. G. Paranjpe and E. A. Zahalka. *Mammalian Toxicology, BioReliance, Rockville, MD.*

The gavage route of administration of pharmaceuticals is commonly used in preclinical studies to mimic the intended clinical route and/or to increase the systemic exposure of the compound. Many pharmaceutical agents intended for oral administration require PEG-400 for solubilizing the drug but this may become problematic if the Vehicle itself demonstrates toxicity. The toxicity of PEG-400 via the oral route is variably documented in the scientific literature. Characterizing these toxic effects will facilitate efficient interpretation of the toxicity data of formulations containing PEG-400. This study investigated the toxicity of PEG-400 Vehicles administered by gavage (10 mL/kg) daily for either 28 consecutive days in C57BL/6 and CByB6F1 wild-type mice (10 mice/sex/formulation) or for 26 weeks in p53+/- and Tg.rasH2 transgenic mice (25 mice/sex/formulation) that were used in short-term carcinogenicity studies. The Vehicle formulations contained between 10-100% PEG-400. Animals were observed during the course of the study for clinical signs, moribundity, mortality, body weights, food consumption, and organ weights/histopathology. Daily administration of up to 100% PEG-400 for 28 days showed no significant toxicity in C57BL/6 or CByB6F1 mice. However, daily dosing of 26% and 100% PEG-400 Vehicles over 26 weeks led to 8-17% mortality in p53+/-, C57BL/6 and Tg.rasH2 mice. As compared to the sham control, in these animals there were significant decreases in body weights and food consumption. There were no treatment-related effects on organ weights. Microscopic abnormalities in the nasal cavity, esophagus, kidneys, spleen and trachea were considered due to PEG-400. In conclusion, oral administration of 26-100% PEG-400 formulations showed no adverse toxic effects when administered to mice daily for 28 days, however, it caused significant toxicity when administered for longer period in 26 week carcinogenicity studies using transgenic mice. There were no PEG-400 treatment-related neoplastic lesions noted in these studies.

PS 2182 ADOPTIVE TRANSFER OF B- LYMPHOCYTES IN A MOUSE MODEL OF CHEMICAL-INDUCED ASTHMA.

V. De Vooght, S. Haenen, B. Nemery, P. Hoet and J. Vanoirbeek. *Lung Toxicology Research Unit, K.U.Leuven, Leuven, Belgium.*

To investigate the underlying mechanisms of an established model of chemical-induced asthma, we transferred B- lymphocytes from sensitized mice to naïve mice. BALB/c mice where dermally sensitized with 0.3% TDI (20 μl/ear), on day 1 and 8. On day 15, mice were sacrificed and the auricular lymph nodes isolated. B-lymphocytes (CD19+) where separated from the whole cell suspension and 175,000 cells where injected in the tail vein of naïve mice. Three days later, these mice received a single oropharyngeal challenge with 0.01% TDI (20 μl) or vehicle (acetone/olive oil) (controls). Airway reactivity to methacholine (resistance assessed by forced oscillation method, FlexiVent) and total and differential cell counts in the broncho-alveolar lavage (BAL) fluid were measured 24 hours after challenge. Mice that received B-lymphocytes from TDI-sensitized mice showed a 3-fold increase in methacholine reactivity and an 8-fold increase in BAL neutrophils after challenge with TDI, compared to those challenged with vehicle. Transfer of the whole cell suspension without CD19+ lymphocytes (325,000 cells) resulted in a less pronounced airway reactivity to methacholine (1.5-fold) and a lower influx of neutrophils (1.3-fold) in the lungs. We were able to passively sensitize naïve mice with B-lymphocytes from TDI-sensitized mice. Following passive sensitization and an airway challenge, these mice showed an "asthmatic" response. These data suggest an important role for B-lymphocytes beside the already known important role of T-helper lymphocytes in chemical-induced asthma. In future experiments the role of other cell types will be determined.

2183 FEASIBILITY AND VARIABILITY OF TESTICULAR VOLUME MONITORING IN THE MARMOSET MONKEY (CALLITRIX JACCHUS).

S. H. Korte, G. F. Weinbauer and M. Luetjens. *Covance Laboratories GmbH, Muenster, Germany.*

Marmosets represent a New World primate species that is being used in preclinical safety evaluations including assessment of toxicity to male fertility. Although the endocrine regulation of testicular function is different between Old World and New World monkeys, the histoarchitecture of the germinal epithelium is comparable to human testis including the arrangement of spermatogenic stages (2). Longitudinal testicular volume determination provides a convenient parameter for monitoring testicular toxicity. The present work evaluates the feasibility of testicular volume (TV) measurements in the marmoset model in the context of toxicity studies. TV was determined in sedated animals using calipers and the formula for a regular ellipsoid. Data for both testes were collected from 60 mature and naive animals, weighing 240-410 gram, on 2 or 3 occasions in weekly intervals. Average combined TV for all animals was 0.62 mL ± 0.13 mL (SD) without a statistically significant difference between left and right testis (P = 0.48). The intra-individual coefficient of variation of 2-3 determinations was 22 ± 0.05 % (range 14 – 35 %). In comparison, variability of this parameter in over 100 cynomolgus monkeys for 3 repeated caliper determinations was 15% (3). Comparison of baseline and terminal TV determinations in 13-week and 26-week toxicity studies did not yield significant differences. Testis volume and weight for 56 animals at necropsy was highly correlated (P < 0.0001, Pearson R = 0.68) but was markedly different regarding absolute values: 1.15 ± 0.18 gram vs 0.58 ± 0.13 mL. This data indicate a high precision but low accuracy of testicular volume determination with an approximate 50% underestimation of actual testicular weight by caliper-based testicular volume. Testicular weight correlation with body weight was weak (R-squared = 0.15). In conclusion, caliper-based determination of TV in the marmoset is feasible and can be applied in acute and chronic toxicity studies and male fertility studies. 1. Luetjens et al. Biol Rev 80: 475 (2005); 2. Weinbauer GF et al. Toxicol Sci 84: 194 (2005).

2184 EFFECTS OF ORAL ALUMINUM EXPOSURE IN NEUROGENESIS AND BEHAVIOR IN A MOUSE MODEL OF ALZHEIMER DISEASE.

M. Colomina[1, 2], D. Ribes[1, 2], P. Vicens[1, 2] and J. L. Domingo[1]. *[1]Toxicology, Rovira i Virgili University, Reus, Spain and [2]CRAMC-Psychology, Rovira i Virgili University, Tarragona, Spain.*

Although the neurotoxic effects of oral aluminum (Al) in humans and animals are well know, the relationship between Al and Alzheimer disease (AD) is still a controversial issue. In a previous study, we administered for 4 months low Al doses to wild and transgenic (Tg 2576) mice carrying the Swedish mutation for familiar AD. An impairment in learning and memory in a complex water maze task was only observed in wild mice. It suggested Al impair cognition in non vulnerable subjects, but not an acceleration of AD at early stages. In the present study, we tested a higher Al dose for a more prolonged period of time (6 months). Tg 2576 and their respective wild type mice, were exposed through the diet to 0 and 11g/kg of Al lactate from 6 to 12 months of age. At 11 months of age, learning and memory were evaluated in the water maze task. After behavioral testing, mice were treated with bromodeoxiuridine (BrdU) to study cell proliferation survival and differentiation in the dentate gyrus of the hippocampus. At sacrifice, brain cortex and hippocampus samples were obtained to measure β-amyloid 1-40 and 1-42 levels. Results showed a deleterious cognitive Al effect in both acquisition and retention in Tg mice. No significant differences were observed in the neurogenesis study. However, in general terms proliferation in the hippocampus was diminished in Tg mice, while the number of surviving cells was decreased in Al-exposed Tg mice. Moreover, β-amyloid levels were higher in Tg mice, increasing Al exposure β-amyloid concentrations in the cortex of these animals. In conclusion, exposure of Tg mice to Al lactate during 6 months impaired cell survival in hippocampus, increased β-amyloid 1-40 levels, and impaired acquisition and retention of the water maze task. It indicates that exposure to high Al doses for a prolonged period of time can accelerate cognitive impairment in vulnerable subjects.

2185 THE USE OF THE TG.RASH2 MOUSE IN CARCINOGENICITY STUDIES.

J. Younan and L. Kolodzieyski. *ITR Laboratories Canada Inc., Baie d'Urfe, QC, Canada.* Sponsor: B. Procter.

The objective of the study was to evaluate the response of the Tg.rasH2 mouse test system to two known carcinogens and to demonstrate its utility as a quicker and more cost-effective alternative to the conventional two-year mouse bioassay. Fifteen (15) male and 15 female Tg.rasH2 mice were assigned to each of 3 dose groups. Animals of Group 1 received purified water by oral gavage once daily for 26 consecutive weeks. Animals of Group 2 received a total of 3 intraperitoneal injections of Urethane (1000 mg/kg each) at 2-day intervals, while animals of Group 3 received a single intraperitoneal injection of MNU (MNU= N-methyl-N-nitrosourea) at 75 mg/kg. Parameters monitored during the study included mortality, clinical observations, including examinations for the presence of palpable masses, body weights and food consumption. Upon completion of the 26-week treatment/holding period, all surviving animals were euthanized and subjected to a necropsy examination. Subsequently, tissues collected from all animals were examined histopathologically. A total of 2 Control, 28 Urethane-treated and 23 MNU-treated animals died or were preterminally euthanized due to poor clinical condition during the study. Bronchiolo-alveolar carcinoma of the lungs and hemangiosarcoma of the spleen were considered to be the cause of mortality/morbidity of the 2 Control females. Bronchiolo-alveolar adenoma and/or carcinoma and hemangiosarcoma were considered to be the cause of mortality/morbidity in the majority (26/28) of the Urethane-treated animals, while malignant lymphoma of the hemolymphoreticular tissue was considered to be the cause of mortality/morbidity in the in the majority (17/23) of the MNU-treated animals. In conclusion, the intraperitoneal administration of 2 known carcinogens (Urethane and MNU) to Tg.rasH2 produced a clearly higher incidence of benign/malignant tumors resulting in significantly higher mortality rates among the animals treated with the carcinogens in comparison to Controls.

2186 HUMAN CONSTITUTIVE ANDROSTANE RECEPTOR(CAR)SUPPORTS THE HYPERTROPHIC BUT NOT THE HYPERPLASTIC RESPONSE TO THE MURINE NON-GENOTOXIC CARCINOGEN PHENOBARBITAL (PB) *IN VIVO* .

C. R. Elcombe[1], J. Ross[1], N. Scheer[2], A. Rode[2] and C. Wolf[1]. *[1]CXR Biosciences, Dundee, United Kingdom and [2]TaconicArtemis GmbH, Cologne, Germany.*

PB is a non-genotoxic carcinogen that in mice induces hepatomegaly (characterised by hypertrophy and hyperplasia)and, following long-term treatment, hepatocellular tumours, possibly due to its ability to increase cell proliferation. The relevance of these tumours to human health is controversial due to the lack of a clear molecular mechanism and suitable human-like models. PB has been shown to activate the murine and human constitutive androstane receptors (CAR) and pregnane X receptors (PXR. CAR knockout mice can not activate the Cyp2b10 gene in response to PB, nor do the hypertrophic and hyperplastic responses elicited by PB occur. PB (80mg/kg ip.,4 days) was administered to double "humanised" CAR and PXR (huPXR/huCAR) mice and wild type C57BL/6J mice to investigate whether hyperplastic responses to chemicals observed in rodents are relevant to man. Mice which were devoid of both receptors (PXRKO/CARKO) were used as controls. Mice were implanted with osmotic pumps containing BrdU to allow determination of replicative DNA synthesis Relative liver weights were increased (to about 120% of controls) by PB in the wild type (WT) mice and "humanised" mice but not in the PXRKO/CARKO animals. P450 induction was observed in WT and huPXR/huCAR mice but not in the PXRKO/CARKO mice, as determined by catalytic activity measurements and immunoblotting. The nuclear incorporation of BrdU was determined as a measure of cell proliferation. PB increased the hepatocellular labelling index (S-phase) by approximately 5-fold in the WT mice. However, no change in S-phase was detected in either the huPXR/huCAR or PXRKO/CARKO mice following PB treatment. These data suggest that the human receptors are able to support the chemically-induced hypertrophic response but not the hyperplastic response. These data, obtained using novel human response models, suggest that it is unlikely that exposure to PB poses an hepatocarcinogenic hazard to humans.

2187 SEROTONIN TRANSPORTER DENSITY AND 5-HT1A FUNCTIONING IN BTBR MICE — A MODEL OF AUTISM.

G. G. Gould, T. F. Burke, J. G. Hensler and L. C. Daws. *Department . Physiology and Pharmacology, University TX Hlth. Sci. Center at San Antonio, San Antonio, TX.*

Autism spectrum disorders (ASD) are developmental psychiatric disorders affecting roughly 1 in 150 children. ASDs are complex disorders, likely arising from multiple genetic and environmental factors. However, a common finding from ASD studies in humans is dysfunction of central serotonin systems. Until recently, an animal model for ASD has been unavailable and this has hindered progress in identifying underlying neural mechanisms. Now, the BTBR T+ tf/J (BTBR) inbred mouse has emerged as a promising model for translational ASD studies because it parallels all three behavioral traits used as clinical diagnostic criteria (McFarlane et al., Genes

Brain Behav. 2008;7:152-63). To assess how the tone of the serotonergic (5-HT) system may differ in BTBR mice, we examined the density of serotonin transporters (SERT), and functioning of G-protein coupled 5-HT1A receptors by autoradiography. The SERT terminates serotonergic neurotransmission by high affinity uptake of 5-HT; while 5-HT1A receptors are major modulators of 5-HT neurotransmission. Fresh frozen brains of four-month old male BTBR and C5710/J mice were sectioned on a cryostat and incubated in 1nM [3H] cyanoimipramine to determine SERT density. Sections were also used to determine 5-HT1A receptor binding capacity for G-proteins by measuring [35S]GTPγS binding stimulated by the agonist 8-OH-DPAT. We found that SERT density is significantly reduced by 20-30% throughout the hippocampus (N=8, $p<0.05$). Also, 8-OH-DPAT stimulated [35S]GTPγS binding is 28% higher in the hippocampus of BTBR mice than in C5710/J mice, and this difference is significant (N= 8, $p = 0.03$). Thus, both the main regulator and a primary modulator of serotonin neurotransmission differ between BTBR and C5710/J control mice, indicating potential dysfunctions of the BTBR 5-HT system. Thus the BTBR model may be used to study the serotonergic dysfunction in ASD including the neurochemical underpinnings of the disease, and the potential for genetics to interact with environmental factors to determine ASD symptom severity.

PS 2188 KANAMYCIN INDUCES CHANGES IN AUDITORY BRAINSTEM RESPONSE (ABR) IN CYNOMOLGUS MONKEYS.

H. Kuse, Y. Tsuda, K. Sugimoto and K. Horiguchi. *Kannami Laboratory, Bozo Research Center Inc., Kannami City, Japan.* Sponsor: Y. Asano.

There are only a few reports of auditory brainstem response (ABR) in monkeys. Therefore, using female cynomolgus monkeys (5-7 years old), we first tried to collect physiological data on ABR (Exp. 1), and then, we examined time-course changes in ABR following a single intravenous or intramuscular administration of kanamycin (KM) (Exp. 2).In Exp. 1, ABR was recorded under ketamine and xylazine mixed-anesthesia in 17 animals. Acoustic stimulation was given through a headphone attached to the ears using clicks. The stimulation frequency was 10 Hz, and the average of electrical signals was 1000 sweeps. The stimulus intensity was between 20 and 90 dB sound pressure level (SPL). At the stimulus intensity of 20 dB SPL, all the animals examined showed flat ABR waves; however, at 30 dB SPL, 3 waves were identified with a 5 millisecond latency from stimulus. In Exp. 2, 3 of the animals which were used in Exp. 1 were administered a single intravenous dose of 100, 200 or 300mg/kg of KM. ABR was recorded before KM-treatment and at 1, 2, 4 and 6 hours after KM-treatment. The animals treated with 300mg/kg KM died at the end of dosing. There were no changes in ABR in the animal treated with 200mg/kg KM. On the other hand, in the animal treated with 100 mg/kg KM, the amplitude of each ABR component declined only in the left-ear side at 2 hours after dosing. In addition, the ABR threshold of the left ear rose up to 30 dB after 2 hours after dosing, but it returned to normal 2 hours later. In this animal, 500mg/kg KM was administered intramuscularly once again 1 week later. Similar changes in ABR were observed only in the left-ear side from 6 to 7 hours after dosing. In addition, the ABR threshold of the left ear rose up to 20 dB, but returned to normal 8 hours later. Since it is generally said that drug-induced auditory disturbances develop bilaterally, the KM-induced unilateral auditory disturbance as detected in the present study is interesting.Judging from the results of this study, ABR is considered to be a useful method to examine abnormalities in auditory function in monkeys.

PS 2189 HAZARD IDENTIFICATION OF POTENT DERMAL SENSITIZERS.

J. C. Gould. *Pharmacology Qual. Env. Health & Safety, Bristol-Myers Squibb, New Brunswick, NJ.*

Dermal sensitization is of particular concern in the workplace for the substances that are potent sensitizers. The Local Lymph Node Assay (LLNA) is a useful tool to identify dermal sensitization hazards and to determine the relative potency, which aids in selection of effective safe handling guidance. 29 LLNA studies conducted according to the OECD 429 method on pharmaceutical or chemical process compounds were identified as potent dermal sensitizers, EC3 < 1%. The EC3 is the concentration at which the stimulation index for the experimental group was 3-fold greater than that for the vehicle control group. Certain parameters were examined to determine if there was any predictability to identify potent dermal sensitizers. These included structural alerts, molecular weight (MW) as well as the usefulness of the log-linear extrapolation approach for estimating the potency. A computer structure activity analysis was conducted using Derek for Windows ® version 10.0.2. (2006) identified 14 as negative and 15 as positive for structural alerts, the most common being "hydrazine or precursor." This indicates that many of the structural moieties responsible for causing a sensitization reaction are not known. The examination of the MW showed that all 29 molecules had MW less than 550d. For 21 of the compounds, a follow up study was needed to calculate the EC3. The datasets from primary and follow up experiments were used to compare the intercalated vs. extrapolated EC3 according to the equation published by Gerberick et.al. (2006). Direct comparison of the two EC3 values identified 8/21 with an extrapolated EC3 in the correct order of magnitude, 8 incorrectly (5 were too high and 3 were too low) and 5 could not be calculated based on the experimental data. A discussion on the dose response and use of the extrapolation equation is presented. This abstract emphasizes the use of a tiered approach and the importance of the LLNA to correctly identify potent dermal sensitizers. Determining an accurate potency is an important hazard identification step, supporting the development of worker protection from sensitization hazards.

PS 2190 EFFECTS OF CONCENTRATED AMBIENT ULTRAFINE PARTICLE-CONTAINING AEROSOLS IN MICE WITH NEURONAL DYSFUNCTION.

A. Elder, N. Corson, R. Gelein, P. Mercer, J. Panza, M. Blair, K. Tieu and G. Oberdörster. *Environmental Medicine, University of Rochester, Rochester, NY.*

Recent studies suggest that the central nervous system (CNS) is a site for accumulation of ultrafine particles (UFP, <100 nm) following respiratory tract exposure, with accompanying increases in inflammatory and oxidative stress markers, and that exposure may accelerate neuropathology. We hypothesized that inhaled UFP-containing aerosols can accelerate neuropathological changes and neuronal dysfunction in mice that are prone to neuronal protein aggregation. We exposed transgenic (Tg) R6/2 mice (model of Huntington's disease) and their non-transgenic (Ntg) littermates to concentrated ambient UFP-containing aerosols (HUCAPS; 76.2 nm ± 8.5, 2.06 x $10^5/cm^3$ ± 1.82) or filtered air for 4 hours/day for 6 weeks, starting at 1 week of age. Neurobehavioral function was measured at weekly intervals for the last 4 weeks of the exposure period. No alterations were observed in cellular or biochemical parameters in lavage fluid that would indicate an exposure- or genotype-related lung inflammation. As expected, locomotor function decreased over time in Tg as compared to Ntg mice. In comparison to air-exposed Tg mice, the HUCAPS-exposed Tg mice had slightly earlier locomotor functional decrements. A separate group of mice was exposed for 4 weeks to silver (Ag) UFP (22.4 nm ± 1.3; 5.78 x $10^5/cm^3$ ± 0.57) to evaluate the CNS accumulation of model UFP in Tg and Ntg R6/2 mice. Ag accumulated in all brain regions examined in the mice (olfactory bulb, striatum, cerebellum, cortex); however, Tg mice consistently accumulated more Ag as compared to Ntg mice. These results indicate that ambient UFP accelerate pathology in a model that is prone to protein aggregation and neuronal dysfunction, possibly due to altered UFP translocation kinetics. This research was funded by NIEHS Center grant P30 ESO1247 and RO1 CA134218.

PS 2191 DEVELOPMENT OF A MOUSE MODEL FOR SULFUR MUSTARD-INDUCED OCULAR INJURY.

A. L. Ruff[1], A. J. Jarecke[2], K. A. Whitten[1], D. J. Hilber[2], S. Dodson[1] and J. F. Dillman[1]. *[1]Cell and Molecular Biology, USAMRICD, Aberdeen Proving Ground, MD and [2]U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD.*

Ocular exposure to sulfur mustard (SM) can cause a severe acute injury that is characterized by inflammation and corneal erosions. After an initial recovery phase, a delayed injury phase ensues which is characterized by corneal opacity, neovascularization, and erosion that severely compromise eye function. Little is known regarding the molecular events that lead to SM-induced ocular pathology. Knowledge of these mechanisms is necessary for the rational development of therapeutics. Though the clinical and histopathological aspects of ocular SM injury have been studied in rabbits, this animal model is not well suited for mechanistic molecular studies because the reagents necessary for molecular studies in rabbits are limited. In contrast, the mouse has been widely used for mechanistic molecular studies of ocular injury. Many of the cellular and molecular events implicated in the pathogenesis of human eye disease/injury have correlated well to mouse models, and reagents are also widely available for the mouse. For these reasons we are developing a mouse model of SM-induced ocular injury. The right eyes of mice were exposed to neat SM vapor using a vapor cup. A dose response and time course study was conducted in which the time of exposure and the amount of SM liquid in the vapor cup reservoir of were varied. Ocular injuries were then evaluated over 28 days. Increasing the dose led to significant corneal and ocular involvement as well as marked ocular inflammation. Fluorescein staining revealed acute widespread destruction of the corneal epithelium. Re-epithelialization occurred 5-7 days after exposure, but was followed by dose-dependent persistent epithelial defects, neovascularization, and chronic corneal edema. These injuries led to corneal clouding and eventual scarring. The development of this model will further our understanding of the molecular mechanisms of SM-induced ocular pathology and accelerate the development of therapeutics for this injury.

PS 2192 USE OF LABELED SINGLE WALLED CARBON NANOTUBES TO STUDY TRANSLOCATION FROM THE LUNGS.

R. R. Mercer, J. F. Scabilloni, L. Wang, L. A. Battelli and V. Castranova. *PPRB, NIOSH, Morgantown, WV.*

Colloidal gold nanoparticles (10nm) were used to label single walled carbon nanotubes (SWCNT) in studies aimed at determining how SWCNT clear from the lungs. Gold labeled SWCNT were delivered to the lungs by pharyngeal aspiration to C57BL/6 mice. Neutron activation analysis (NAA) of lung, blood and other organs was carried out at various time points after aspiration to determine if the gold labeled SWCNT translocated out of the lungs. Five mice per group were studied at 1 hour, 1 day, 3, 7 and 28 days after exposure to a single dose (40ug) of gold labeled SWCNT. A phosphate buffered saline (PBS) aspiration group served as the negative control. At sacrifice, the lungs, GI tract, heart, brain, liver, kidneys, right cranial mediastinal lymph node and a blood sample were taken for analysis of gold content by NAA. Lungs from additional mice were fixed and sectioned for study of the gross distribution of gold labeled SWCNT in the lungs. Gold content of the PBS aspiration group was negligible. For labeled SWCNT, blood gold content was below detectable levels for all time points. Lymph node gold content was not significantly different from the PBS group at any time point. Only lung and GI tract had significant labeled SWCNT at any time point. Lung gold content was 0.181±.008, 0.13±0.006, 0.089±.014, 0.096±.006 and 0.049±.007 ug (mean±SE) at 1 hr, 1 day, 3, 7 and 28 days, respectively. Initially there was a rapid decline of burden from the lungs due to mucociliary clearance which was correlated with GI tract content. Lung burden decreased by 49% between 7 and 28 days. Histological examination demonstrated significant gold labeled SWCNT still present in the airways at 7 and 28 days. While it is uncertain as to the mechanism of the slower phase clearance of lung burden between 7 and 28 days it does not appear to be due to transport to major organs.

PS 2193 PERSISTENT PULMONARY INFLAMMATION, AIRWAY MUCOUS METAPLASIA AND MIGRATION OF MULTI-WALLED CARBON NANOTUBES FROM THE LUNG AFTER SUBCHRONIC EXPOSURE.

A. Hubbs[1], R. R. Mercer[1], J. E. Coad[2], L. A. Battelli[1], P. A. Willard[1], K. Sriram[1], M. Wolfarth[1], V. Castranova[1] and D. Porter[1]. *[1]NIOSH, Morgantown, WV and [2]WVU, Morgantown, WV.*

Multi-walled carbon nanotubes (MWCNTs) are manufactured carbon compounds with many commercial applications. The fiber-like dimensions of MWCNTs, their durability, and ability to cause peritoneal inflammation are reminiscent of asbestos, but their toxicity is incompletely investigated. To address the hypothesis that MWCNTs cause persistent morphologic changes and migrate beyond the lung, C57BL/6J mice were exposed by pharyngeal aspiration to 20 or 80 μg MWCNTs (mean dimensions of 4.2 μm x 49 nm) or vehicle. Lung and tracheobronchial lymph node were collected for histopathology 7 and 56 days after exposure. MWCNTs principally accumulated in macrophages and caused granulomatous inflammation. Inflammation extended to the pleura in 7/8 and 4/8 MWCNT-exposed mice at 7 and 56 days, respectively. Both short and long MWCNTs projected beyond the cytoplasmic margins of some macrophages, indicating incomplete phagocytosis or cytoplasmic penetration after phagocytosis. Airway epithelial changes included hypertrophy, cellular atypia and mucous metaplasia. Sirius Red staining demonstrated fibrosis of granulomas and alveolar septa by 7 days post-exposure. Activated caspase-3 and TUNEL assays of the 80 μg exposure group at 7 days post-exposure demonstrated increased apoptosis in alveolar macrophages. MWCNTs accumulated in the draining tracheobronchial lymph nodes and were principally intracellular. At 56 days post-exposure, subpleural lymphatics were focally dilated in one mouse and peribronchiolar lymphatics were dilated in all 4 mice in the 80 μg exposure. Subpleural lymphatics were also dilated in one mouse at 7 days post-exposure. In 4 mice, including both mice with subpleural lympangiectasia, MWCNTs appeared to penetrate the pleura. These findings demonstrate that MWCNTs cause persistent pulmonary inflammation, can be translocated within the lung by alveolar macrophages, can migrate from the lung to the regional lymph node and can penetrate the cytoplasm of macrophages.

PS 2194 CARBON NANOTUBES TESTED IN 5- AND 90-DAY INHALATION STUDIES IN RATS.

R. Landsiedel[1], L. Ma-Hock[1], B. van Ravenzwaay[1], V. Strauss[1], S. Burkhardt[1], A. O. Gamer[1], K. Wiench[1] and F. Luizi[2]. *[1]Product Safety, BASF SE, Ludwigshafen, Germany and [2]Nanocyl S.A., Sambreville, Belgium.*

Carbon nanotubes (CNT) are nanomaterials with outstanding characteristics. Using CNT in various applications can free inhalable CNT. First concerns occurred when epithelioid granulomas and interstitial inflammation in the mouse lung were reported after intratracheal instillation of single-wall CNTs. Similar findings were also reported for multi-wall CNT after i.p. injection and instillation in rats. As these represent non-physiologic exposures, we performed specially designed 5- and 90-day-inhalation studies. Aerosols of multi-wall CNT were generated by a brush generator and well characterized. In the 5-day study, concentrations of 2.5, 10 and 30 mg/m3 were tested. Multifocal granulomatous inflammation accompanied by diffuse histiocytosis, hyperplasia/-trophy of the bronchial epithelium and granulocytic infiltration was noted in the lungs. Moreover, multi-focal degeneration of the olfactory epithelium was observed in the nasal cavity at the high concentration. A strong increase of biochemical and cytological parameters in the broncho-alveolar lavage fluid was consistent with the histological findings. Some effects at the low concentration were reversible, whereas others, such as PMN count, did not fully recover within 21 days. In the 90 day study, concentrations of 0.1, 0.5 and 2.5 mg/m3 caused effects comparable to those described above. At the low concentration granulomatous inflammation of minimal grade without neutrophilic infiltration and lipoproteinosis was observed in a few animals; more pronounced effects were seen at the higher concentrations. The mediastinal lymph nodes of all animals contained macrophages with black matter, forming small granulomas within the lymph nodes.
This is (one of) the first subchronic inhalation study with multi-wall CNT. Using actual aerosols we could give accurate concentration-effect data and define a LOAEC of 0.1 mg/m3. This can be the basis for further risk assessments of multi-wall CNT production, handling and use.

PS 2195 PULMONARY TOXICITY OF INHALED MULTI-WALLED CARBON NANOTUBES.

D. W. Porter[1, 2], M. G. Wolfarth[1], B. T. Chen[1], W. McKinney[1], A. F. Hubbs[1], L. Battelli[1], M. Andrew[3], D. G. Frazier[1] and V. Castranova[1, 2]. *[1]PPRB, NIOSH, Morgantown, WV, [2]Physiology and Pharmacology, West Virginia University, Morgantown, WV and [3]BEB, NIOSH, Morgantown, WV.*

The large scale manufacture of multi-walled carbon nanotubes (MWCNT) suggests occupational exposures may occur. In order to investigate the pulmonary toxicity of MWCNT, male C57BL6/J mice (6 weeks old) were exposed to aerosolized MWCNT (10 mg/m^3, 5 hours per day; mass mode aerodynamic diameter 1.3 μm, count mode aerodynamic diameter 0.4 μm) for 2, 4, and 8 days. All mice were sacrificed at one day post-exposure. In bronchoalveolar lavage (BAL) studies, polymorphonuclear leukocytes (PMNs) were assessed to index pulmonary inflammation, BAL fluid lactate dehydrogenase (LDH) activity was measured as a marker of cytotoxicity, and BAL fluid albumin was determined as a marker of the lung air-blood barrier integrity. Air-exposed controls had 0.2 ± 0.1 (x 10^3) PMNs/mouse. MWCNT exposure increased PMNs levels to 153.7 ± 26.6 and 125.2 ± 26.2 (x 10^3) PMNs/mouse after 2 and 4 days exposure, respectively. After 8 days exposure, PMNs increased further to 1,151.7 ± 124.2 (x 10^3) PMNs/mouse. In air-exposed controls, BAL fluid LDH activity was 58 ± 3 (units/l), and MWCNT exposure induced significant increases to 131 ± 6, 159 ± 9, and 252 ± 10 (units/l) after 2, 4 and 8 days exposure, respectively. Air-exposed control BAL fluid albumin was 0.13 ± 0.01 (mg/ml), and MWCNT exposure induced significant increases to 0.19 ± 0.01, 0.28 ± 0.02, and 0.37 ± 0.02 (mg/ml) after 2, 4 and 8 days exposure, respectively. Histopathological evaluation of lungs after 4 and 8 days of exposure confirmed pulmonary inflammation. After 8 days of MWCNT exposure, some mice had histopathological evidence of fibrosis at sites of MWCNT deposition. In summary, these data indicate that exposure to aerosolized MWCNTs results in dose-dependent increases in pulmonary inflammation and damage, suggesting that aerosolized MWCNT may pose an occupational health hazard. However, additional dose-response and time course studies are necessary to fully evaluate the potential health risks posed by exposure to aerosolized MWCNT.

PS 2196 PULMONARY TOXICITY OF MULTI-WALLED CARBON NANOTUBES.

M. G. Wolfarth[1], D. W. Porter[1, 3], A. F. Hubbs[1], S. Leonard[1], L. Battelli[1], M. Andrew[2] and V. Castranova[1, 3]. *[1]PPRB, NIOSH, Morgantown, WV, [2]BEB, NIOSH, Morgantown, WV and [3]Physiology and Pharmacology, West Virginia University, Morgantown, WV.*

Occupational exposures may occur due to the large scale manufacture of multi-walled carbon nanotubes (MWCNT). Because the toxicity of carbon nanotubes can be influenced by the presence of metal contaminants, bulk MWCNT were examined for their metal content. These analyses determined MWCNT had 0.78% metal contamination, with Fe (0.32%) being a major constitutent. Acellular electron spin resonance studies determined that MWCNT do not generate ROS, despite the presence of trace iron in the MWCNT. In order to investigate the pulmonary toxicity of MWCNT, male C57BL6/J mice (6 weeks old) were exposed by pharyngeal aspiration to MWCNT (0-40 μg/mouse) and mice were sacrificed at 1,

7, 28 and 56 days post-exposure. In bronchoalveolar lavage (BAL) studies, polymorphonuclear leukocytes (PMNs) were assessed to index pulmonary inflammation, BAL fluid lactate dehydrogenase (LDH) activity was measured as a marker of cytotoxicity, and BAL fluid albumin was determined as a marker of the lung air-blood barrier integrity. MWCNT exposure induced dose- and time-dependent changes, with maximum changes occurring at 7 days post-exposure for all three BAL markers. At 7 days post-exposure, mice exposed to 40 μg/mouse MWCNT had increased BAL PMNs (724-fold), BAL fluid LDH activity (2.6-fold) and BAL fluid albumin (2.4-fold) versus vehicle-exposed controls. At 56 days post-exposure, mice exposed to 40 μg/mouse MWCNT still had increased BAL PMNs (22.3-fold), BAL fluid LDH activity (1.9-fold) and BAL fluid albumin (1.6-fold) versus vehicle-exposed controls. Thus, relative to 7 days post-exposure, these BAL markers had decreased, but were still significantly elevated above vehicle-exposed controls at 56 days post-exposure. At 28 and 56 days post-exposure, histopathology confirmed persistent interstitial inflammation and indicated fibrosis. In summary, these data indicate that exposure to MWCNT results in dose- and time-dependent changes in pulmonary inflammation and damage, suggesting that MWCNT may pose an occupational health hazard.

PS 2197 NEUROINFLAMMATION AND BLOOD-BRAIN BARRIER CHANGES FOLLOWING EXPOSURE TO ENGINEERED NANOMATERIALS.

K. Sriram, D. W. Porter, A. M. Jefferson, G. X. Lin, M. G. Wolfarth, B. T. Chen, W. McKinney, D. G. Frazer and V. Castranova. *Centers for Disease Control & Prevention (CDC)-NIOSH, Morgantown, WV.*

The unique physico-chemical properties of engineered nanomaterials influence their ability to aerosolize, and thus inhalation exposure is of major occupational concern. Inhaled nanoparticles can potentially translocate to the brain via olfactory sensory neurons or through systemic circulation and cause irreversible damage to the nervous system. To determine if engineered nanomaterials pose a neurological risk, we evaluated the effects of multi-walled carbon nanotubes (MWCNT) in a murine model. Male C57BL/6J mice were exposed to MWCNT either by pharyngeal aspiration (single dose of 10-80μg/mouse; 1, 7, 28, or 56d post-exposure) or whole-body inhalation (10mg/m^3 x 5h/d x 2, 4, 8 or 12d; 1d post-exposure). MWCNT exposure elicited neuroinflammation, altered blood-brain barrier (BBB) integrity and induced cellular stress in discrete brain areas. Specifically, MWCNT induced (2 to 16-fold) the mRNA expression of several proinflammatory chemokines (Ccl2, Ccl3, Ccl4, Cxcl2), cytokines (Il-1β, Il-6, Tnfα), selectins (Sele, Selp) and markers of cellular stress (Hspb2, Mt1, Mt2). Exposure to MWCNT also decreased the expression of BBB-related markers (Edn2, Vegfa), suggestive of alterations in BBB integrity. In the hippocampus, MWCNT altered the expression of certain Alzheimer's–related genes (Aplp2, Apba2, Apba3, Bace1, Bace2, Ctsc, Ctsd), which interact with or are involved in the processing of amyloid-precursor protein. The neurotoxic responses were comparable between the two routes of exposure and some of the effects persisted until 56d post-exposure. Taken together, our findings suggest that exposure to an engineered nanomaterial like MWCNT, can elicit neuroinflammation, disrupt BBB integrity and cause cellular/molecular changes that could potentially culminate in neurodegeneration.

PS 2198 NANOPARTICLE DISPERSION METHOD USING NATURAL LUNG SURFACTANT.

L. Wang[1, 2], V. Castranova[1, 2], R. R. Mercer[1, 2], N. Wu[2], T. Li[3], S. Li[3], J. Hall[1], M. Li[2] and Y. Rojanasakul[2]. *[1]National Institute for Occupational Safety and Health (NIOSH), Morgantown, WV, [2]West Virginia University, Morgantown, WV and [3]National Institute of Occupational Health and Poison Control, CDC, Beijing, China.*

Nanomaterials, as a class of small-scale (<100 nm) substances with unique mechanical, optical and electrical properties, are increasingly being used in a wide range of industries. Their unique properties present new challenges to understanding the toxicity of these materials to humans and the environment. Lung is the major target organ for airborne nanoparticles. *In vitro* and *in vivo* exposure studies often rely on the use of suspended nanoparticle preparations. However, nanoparticles suspended in culture medium or physiologic saline solution tend to form micrometer-sized aggregates. Increasing evidence indicates that the degree of dispersion of nanoparticles has a strong influence on their biological activities. In this study, we test a new method of nanoparticle dispersion using natural lung surfactant, Survanta®, as a dispersing agent. Dose dependence studies of Survanta® were performed on single-walled carbon nanotube (SWCNT) dispersion. Our results show that Survanta® at a concentration of 150 μg/ml, which is comparable to that found in normal rodent lungs, was optimal in dispersing SWCNT (0.1 mg/ml), producing well dispersed preparations as analyzed by microscopic and light scattering methods. This dose of Survanta® was found to be non-toxic and non-inflammatory *in vivo* and *in vitro* when used alone, and did not mask the bioactivity of SWCNT. We also found that the dispersed form of SWCNT was more effective in inducing cytotoxicity and lung fibrosis than the non-dispersed form, indicating the importance of nanoparticle dispersion on biological activities. Since Survanta® is commercially available and its one step nanoparticle dispersion is simple and rapid, this method provides major advantages over existing methods of nanoparticle dispersion. Furthermore, our stability studies showed that Survanta®-dispersed nanoparticles remain well dispersed for months and upon dilution with aqueous medium.

PS 2199 BIODEGRADATION OF SINGLE WALLED CARBON NANOTUBES THROUGH PEROXIDASE CATALYSIS.

N. V. Konduru[1], I. I. Vlasova[1], B. L. Allen[2], E. R. Kisin[3], A. R. Murray[3], A. A. Kapralov[1], A. Star[2], A. A. Shvedova[3] and V. E. Kagan[1]. *[1]Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA, [2]Department of Chemistry, University of Pittsburgh, Pittsburgh, PA and [3]Pathology/Physiology Research Branch, Health Effects Laboratory Division (HELD), NIOSH, Morgantown, WV.*

Management of exposure to bioengineered single walled carbon nanotubes (SWCNT) is becoming a major environmental and health challenge. Because of unique characteristics, SWCNT have found increased applications in various fields of science and technology. With increased risk of human and environmental exposure, strategies to degrade SWCNT are also garnering interest. Here, we show - for the first time - that two peroxidases, namely myeloperoxidase and horseradish peroxidase are effective in catalyzing the biodegradation of SWCNT. A systematic characterization of resulting products of degradation was performed using transmission electron microscopy (TEM), dynamic light scattering (DLS), gel electrophoresis, mass spectrometry, UV-Vis-NIR spectroscopy and thermogravimetric analysis (TGA). We also demonstrate that unlike naïve non-biodegraded nanoparticles, the peroxidase degraded particles did not elicit pulmonary inflammatory response in mice as evidenced by the release of pro-inflammatory cytokines and the content of neutrophils (PMN) in bronchoalveolar lavage. These results mark a novel approach to employ peroxidase catalysis for directed biodegradation of carbon nanotubes in biofluids/tissues as well as in environmental settings. Supported by NIOSH OH008282, NORA 927000Y, National Heart,Lung and Blood Institute Grant HL-70755, The Swedish Research Council, the Swedish Council for Working Life and Social Research, The Human Frontier Science Program (HFSP)and the 7th Framework Program of the European Commission.

PS 2200 PULMONARY AND SYSTEMIC INHALATION TOXICITY OF MULTI-WALLED AND SINGLE WALLED CARBON NANOTUBES.

J. D. McDonald[1], L. Mitchell[1, 2], S. Burchiel[2] and A. Gigliotti[1]. *[1]Lovelace Respiratory Research Institute, Albuquerque, NM and [2]University of New Mexico, Albuquerque, NM.*

Inhalation of multiwalled carbon nanotubes (MWCNTs) and single walled carbon nanotubes (SWCNT) at particle concentrations up to 1 mg/m3 did not result in significant lung inflammation or tissue damage, but caused systemic immune function alterations. C57BL/6 adult (10-12 week) male mice were exposed by whole-body inhalation to control air or 0.3 or 1 mg/m3 respirable aggregates of MWCNTs or SWCNTs for 14 days, with either immediate sacrifice or sacrifice of a recovery group 30 days after the end of exposure. Histopathology of lungs from exposed animals showed alveolar macrophages containing significant amounts of black particles; however, there was minimal to no inflammation or tissue damage observed. Bronchial alveolar lavage fluid also demonstrated particle-laden macrophages; however, white blood cell counts were not increased compared to controls. Both types of carbon nanotubes caused systemic immunosuppression after 14 days and after recovery. Immunosuppression was characterized by reduced T-cell-dependent antibody response to sheep erythrocytes as well as T-cell proliferative ability in presence of mitogen, Concanavalin A (Con A).

PS 2201 SINGLE-WALLED CARBON NANOTUBES: SKIN EXPOSURES.

A. R. Murray[1, 2], E. Kisin[1], S. S. Leonard[1], S. H. Young[1], C. Kommineni[1], V. E. Kagan[3], V. Castranova[1, 2] and A. A. Shvedova[1, 2]. *[1]PPRB, NIOSH, Morgantown, WV, [2]Department of Physiology/Pharmacology, WVU, Morgantown, WV and [3]Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Nanotechnology is a newly developing field resulting in the development of unique materials with a variety of applications from electronics to engineered tissue. SWCNT are of the most interest because of their unique mechanical and electrical

properties which result from their fibrous shape and small size. The most common technique for manufacturing SWCNT relies on the use of iron as a transition metal catalyst and can result in the presence of up to 30% metal catalyst in raw SWCNT. The low density of SWCNT may lead to inhalation as well as deposition on exposed skin, which provide routes of exposure that are important to consider when evaluating toxicity. We hypothesized that SWCNT are toxic to the skin, and this toxicity is dependent on the ability of SWCNT to interact with the skin and initiate oxidative stress, and the induction of transcription factors leading to inflammation. To test this hypothesis, the effects of SWCNT were assessed both *in vitro* and *in vivo*. Engineered skin exposed to SWCNT showed increased epidermal thickness and accumulation and activation of dermal fibroblasts, which resulted in increased collagen as well as release of pro-inflammatory cytokines. Exposure of JB6 cells to unpurified SWCNT resulted in the production hydroxyl radicals as detected by ESR and caused a significant dose-dependent activation of AP-1 and NFκB, while partially-purified SWCNT activated only NFκB. Topical exposure of SKH-1 mice (5 days, 40, 80, 160 μg/mouse/day) to SWCNT caused oxidative stress, depletion of GSH, oxidation of protein thiols and carbonyls, elevated MPO activity, and an increase of dermal cell numbers resulting in skin thickening. Altogether, these data indicated that topical exposure to unpurified SWCNT induced free radical generation, oxidative stress, and inflammation, leading to dermal toxicity. PS 2202 PULMONARY EFFECTS OF SINGLE-WALLED CARBON NANOTUBES: INHALATION VS ASPIRATION.

E. Kisin[1], A. R. Murray[1], A. F. Hubbs[1], R. R. Mercer[1], P. Keohavong[3], N. Sussman[3], B. T. Chen[1], G. Deye[2], V. Castranova[1], P. A. Baron[2], V. E. Kagan[3] and A. A. Shvedova[1]. *[1]PPRB, NIOSH, Morgantown, WV, [2]DART, NIOSH, Cincinnati, OH and [3]Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Health effects and occupational risk of exposures associated with manufacturing and application of nanoparticles are critical points for the safe and sustainable development of nanotechnology. The toxic effects of nanoscale materials have not been fully characterized and the limited *in vivo* studies indicate the urgent necessity for further toxicological assessments of nanomaterials. Some argue that pharyngeal aspiration – a single exposure to a bolus of SWCNT - is an artificial exposure where the single large dose contributes to the pulmonary response. Moreover, aspiration studies reported thus far have been relatively high dose exposures, which may not be relevant to chronic lower dose seen in occupational settings. Inhalation of SWCNT more closely mimics occupational and environmental venues than the above mentioned administrations providing more dispersed SWCNT structures while bolus effects are avoided. By applying a new technique to aerosolize SWCNT, we obtained stable and uniform SWCNT dispersions with a concentration of 5 mg/m^3 and a count mode aerodynamic diameter of 240 nm for the inhalation experiments. In the current study, we utilized non-purified SWCNT containing up to 17.7% of iron for both inhalation (5 mg/m^3, 5 hrs/day for 4 days) and aspiration (varying doses of 5-20 μg/mouse) exposures. Pathological events in both exposure routes were realized through qualitatively similar synergized interactions of early inflammatory response and oxidative stress culminating in the development of multifocal granulomatous pneumonia and interstitial fibrosis. Quantitatively, SWCNT inhalation was more effective than aspiration in causing inflammatory response, oxidative stress, collagen deposition and fibrosis as well as mutations of K-*ras* gene locus in the lung of C57BL/6 mice. Acknowledgements: supported by NIOSH OH008282, NIH HL70755, NORA 927000Y, and EC-FP-7-NANOMMUNE-214281.

PS 2203 SINGLE-WALLED CARBON NANOTUBES INDUCE PULMONARY AND VASCULAR RESPONSE FOLLOWING INTRATRACHEAL INSTILLATION.

M. C. Schladweiler[1], J. H. Shannahan[2], R. F. Thomas[1], R. Saxena[1], M. Gilmour[1] and U. P. Kodavanti[1]. *[1]NHEERL/ETD/PTB, U.S. EPA, Durham, NC and [2]Curriculum in Toxicology, UNC-Chapel Hill, Chapel Hill, NC.*

Carbon-based nanotubes have been shown to induce varying degrees of pulmonary response in rodents influenced by the dose, the extent of agglomeration, and the functional properties. We hypothesized that low concentrations of non-modified or acid-functionalized (AF) single walled carbon nanotubes (SWCNT) will cause distinct pulmonary and aortic effects on markers of inflammation, coagulation, vasoconstriction following pulmonary exposure. Male Wistar Kyoto rats (12 week old) were intratracheally instilled with pre-characterized freshly sonicated suspensions of SWCNT or AF-SWCNT at 0, 100 or 500 μg/kg in saline. Pulmonary injury and inflammatory effects were small as determined by bronchoalveolar lavage fluid (BALF) analysis and were concentration-dependent. Small increases in BALF protein were noted with high dose of both types of tubes while albumin increased only with AF-SWCNT. Surprisingly, small but significant increases in BALF γ-glutamyl transferase activity (marker of cell membrane damage) were noted only with high concentrations of SWCNT but not AF-SWCNT. LDH activity was increased 4-d at high concentration of both types of SWCNT. Both types of nanotubes moderately increased BALF neutrophils at high concentration while no increase in macrophages occurred (1-d>4-d). Real-time PCR for mRNA markers of oxidative stress, inflammation, vasoconstriction, thrombosis and cell filamentous components in rats exposed to AF-SWCNT revealed pulmonary induction of HO-1, MIP-2, endothelin-1, PAI-1 and β-catenin at both time points (1-d>4-d). However, mRNA expression for any of the biomarkers was not altered in the aorta at either time points. Pulmonary instillation of SWCNT produces acute pulmonary inflammatory, vasoconstrictive and prothrombotic effects in rats, whereas these effects are not evident within 4 days in the aorta. (Does not reflect US EPA policy). Supported in part by EPA SEE Program and EPA/UNC CR833237).

PS 2204 PULMONARY EFFECTS FROM ACUTE EXPOSURE TO AEROSOLIZED SINGLE-WALLED CARBON NANOTUBES.

A. K. Madl, K. Durinick, A. Lam, T. Guo, S. V. Teague, Y. Qu and K. E. Pinkerton. *University of California, Davis, Davis, CA.*

Although nanotechnology is still an emerging field and the enthusiasm for the potential societal benefits of engineered nanomaterials continues, concerns are being raised about whether our knowledge of possible health risks is keeping pace with products going to market. Single-walled carbon nanotubes (SWCNTs) have gained notable attention for application in a number of industries because of their unique electronic, optical, mechanical, chemical, or even biological properties. Due to the potential for human exposure, toxicological studies are needed to understand the potential health hazards of these nanomaterials. To better understand the biological responses associated with acute SWCNT exposure, Sprague Dawley rats were exposed to either aerosolized SWCNTs (300 or 1000 μg/m3, raw [FeSWCNT or purified cSWCNT) or fresh air via nose-only inhalation for 6 hours for 1 day. Cytotoxicity markers (total protein, lactate dehydrogenase [LDH], and gamma-glutamyl transferase [GGT]) in bronchoalveolar lavage and mucin and collagen staining in lung tissue were used as a means to assess immediate and persistent (0, 1, 3, 7 and 28 d post-exposure [PE]) effects of acute exposure to SWCNTs. Results showed that markers for cytotoxicity (LDH, GGT) were acutely increased up to 7 d PE, whereas mucin staining in proximal airways initially increased and then decreased at 7 and 28 d PE, and collagen staining in the alveoli increased at 7 d PE. Effects in all cases were transient, influenced by dose and particle composition (e.g., iron content), and generally were resolved by 7-28 d PE. While these data suggest that exposure to aerosolized SWCNTs may induce cytotoxic and structural responses in the lungs, further research is needed to evaluate whether these changes are suggestive of precursor events to pathological changes or lung remodeling that might develop under more severe or prolonged exposure conditions and may have implications for human health risk for persons potentially exposed to airborne SWCNTs.

PS 2205 INHALED MULTI-WALLED CARBON NANOTUBES STIMULATE A PLEURAL INFLAMMATORY RESPONSE IN THE LUNGS OF MICE.

J. C. Bonner[1], J. P. Ryman-Rasmussen[1, 4], M. F. Cesta[1, 4, 5], A. R. Brody[2], J. K. Shipley-Phillips[3], J. Everitt[6], E. W. Tewksbury[4], O. R. Moss[4], B. A. Wong[4], D. E. Dodd[4] and M. E. Andersen[4]. *[1]Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC, [2]Molecular and Biomedical Sciences, North Carolina State University, Raleigh, NC, [3]Population Health and Pathobiology, North Carolina State University, Raleigh, NC, [4]The Hamner Institutes for Health Sciences, Research Triangle Park, NC, [5]Experimental Pathology, NIEHS, Research Triangle Park, NC and [6]GlaxoSmithKline, Research Triangle Park, NC.*

Carbon nanotubes have recently been reported to have asbestos-like properties since they stimulate the formation of pleural granulomas when injected into the abdominal cavity of mice. This has raised legitimate concerns over the safety of nanotubes because mesothelial granulomas that form on the pleural surface have the potential to develop into mesothelioma, a type of cancer associated with the inhalation of asbestos fibers. Here we report that male C57BL6 mice that inhaled an aerosol of multi-walled carbon nanotubes (6-hr exposure at 100 mg/m3) developed inflammatory foci on the pleural surface of the lung, even though very little inflammation or fibrosis was observed within the lung parenchyma. These foci were primarily monocytic and persisted at 14 days post-exposure. We observed nanotubes dispersed throughout the lung at 1 day post-exposure with some embedded within the pleural wall. Most of the carbon nanotubes (>90%) were contained within macrophages throughout the 14 day study period. Inhalation is the most relevant route of occupational exposure to carbon nanotubes, and our findings are the first to demonstrate that inhaled carbon nanotubes cause pleural inflammation. We emphasize that further work is urgently needed to assess whether longer term, lower concentration nanotube exposures cause similar pleural responses as seen with this

single high exposure concentration and to assess whether these pleural lesions are likely to progress to neoplasia. (Funded by The Hamner Institutes for Health Sciences and North Carolina State University College of Agricultural and Life Sciences).

PS 2206 COMPARATIVE PROTEOMICS, GENOMICS AND PULMONARY TOXICITY OF INSTILLED SINGLE WALLED CARBON NANOTUBES, CROCIDOLITE ASBESTOS AND ULTRAFINE CARBON BLACK IN MICE.

J. Teeguarden[1], K. Waters[1], B. Webb-Robertson[1], S. Varnum[1], J. Jacobs[1], R. Zangar[1], E. Kisin[2], A. Murray[2], A. Shvedova[2] and J. Pounds[1]. [1]*Pacific Northwest National Laboratory, Richland, WA and* [2]*National Institute of Occupational Health and Safety, Morgantown, WV.*

CNT have emerged as a nanomaterial of considerable concern to the occupational and environmental health and safety communities. Early, consistent reports from high-dose, short-term screening studies in rodents suggest a sequence of biological events and pulmonary pathology similar to that caused by asbestos and synthetic vitreous fibers (SVF). Whether CNT strictly adhere to the asbestos paradigm of pulmonary toxicity is a question of critical importance. The pulmonary response of mice exposed repeatedly (4 doses, 28 days, pharyngeal aspiration) to single-walled CNT (SWCNT), crocidolite asbestos (AS) and ultrafine carbon black (CB) was assessed by global proteomics and genomics of lung tissue and ELISA protein microarray of bronchial lavage fluid. Three cytokines, IL-6 and IL-12 and Mip-1g were considerably higher in SWCNT and AS treated animals compared to CB. The T cell chemotactic protein MDC was present in high levels in SWCNT and AS groups, but not detectable in control or CB treated groups. Two sentences on similarities and differences via proteomics. Microarray analysis of lung tissue revealed over 3000 genes significantly changed by SWCNT exposure, compared to only 469 with AS and 71 with CB. Strikingly, the significant genes lists for CB and AS were complete subsets of the SWCNT data set, with both the number of genes and magnitude of gene changes being the highest in the SWCNT treatment group.

PS 2207 PERMEABILITY OF THE BLOOD-CSF BARRIER IN THE CHOROID PLEXUS AS AFFECTED BY SINGLE-WALLED CARBON NANOTUBES, *IN VITRO* .

S. Peterson and W. Zheng. *Health Sciences, Purdue University, West Lafayette, IN.*

Nanotechnology is an emerging field and has made great advances in production and product integration. Nanoparticle use in medical imaging, diagnosis and drug delivery vectors has created novel exposure routes, raising concerns about biological fate and susceptible organs. The blood and the brain are separated by two distinct barrier systems: the blood-brain barrier (BBB) and the blood-cerebrospinal fluid barrier (BCB). The BCB is formed by the choroid plexus, a tissue with high blood flow and large surface area. The BCB plays a key role in maintaining the homeostasis of internal milieu and protecting the brain against toxic insults in the blood. Improper function of the BCB has been linked to a variety of neurodegenerative diseases. The hypothesis tested was that exposure to single-walled carbon nanotubes (SWCNT) may damage the structure and function of the BCB. A BCB model utilizing an immortalized Z310 choroidal epithelial cell line was used to assess the effect of SWCNT exposure. Cell viability and ROS generation were determined with the colorimetric MTS and fluorometric DCF assays, respectively. A confluent cell monolayer grown on a permeable membrane in the Transwell inserts was used to estimate the para-cellular diffusion of C-14 labeled sucrose, a parameter reflecting the leakage of the barrier. Following 24-hr incubation with SWCNT, the cell viability decreased 6% ($p<0.05$) and 17% ($p<0.01$) at the dose of 10 and 50 μg/mL, respectively. More drastic alterations were observed with 72 hr treatments where 10 and 50 μg/mL caused a 16% ($p<0.05$) and 27% ($p<0.01$) loss in cell viability. A concentration of SWCNT as low as 1 μg/mL created a significant increase in ROS generation after a 24-hr exposure. The diffusion rate of sucrose across the cell monolayer after treatment with 10 μg/mL SWCNT for 48 hrs approached, but did not reach a statistical significance ($p=0.0585$). Taken together, our data suggest that SWCNT exposure produces a negative effect on BCB function. Additional studies are warranted to better characterize nanoparticle toxicity on brain barrier systems.

PS 2208 ENHANCED OCCUPATIONAL EXPOSURE TO NANOMATERIALS WHEN MIXED IN ENVIRONMENTALLY-RELEVANT MATRICES.

D. R. Johnson[1], A. J. Kennedy[1], J. A. Steevens[1] and M. M. Methner[2]. [1]*Environmental Laboratory, U.S. Army Engineer Research & Development Center, Vicksburg, MS and* [2]*Nanotechnology Research Center, National Institute of Occupational Safety and Health, Cincinnati, OH.*

The goal of this research was to assess the release of engineered nanomaterials into the laboratory when handling and preparing nanomaterials for mixing into environmentally-relevant matrices. Air-borne fullerene (C60), underivatized multi-walled carbon nanotubes (Raw MWCNT), hydroxylated MWCNT (MWCNT-OH), and carbon black (CB) were measured as the nanomaterials were weighed and transferred to beakers filled with water, as well as when sonicated in de-ionized water and reconstituted freshwater with natural organic matter (100 ppm). Air-borne nanomaterials were measured for 20 minutes using a handheld condensation particle counter, confirmed by transmission electron microscopy, and expressed as total particles per cubic centimeter of sampled air within six specific size ranges from 300-10,000 nm. After adjustment for background particle number concentrations, it was evident that increases in air-borne particle concentrations occurred for each nanomaterial except CB during weighing. Air-borne particle concentrations were inversely correlated with particle size. Sonicating nanomaterial-spiked water resulted in increased air-borne nanomaterials. The increase in air-borne nanomaterials after sonication was most evident with MWCNT-OH, the more hydrophilic form of MWCNT, in water with natural organic matter and CB, a natural functionalized carbon-based NM. In conclusion, engineered nanomaterials, especially when functionalized or in water containing natural organic matter, can become air-borne when mixed in solution by sonication, putting workers at increased risk of occupational exposure of air-borne nanomaterials.

PS 2209 IN VITRO BIOCOMPATIBILITY OF SILVER NANOPARTICLES ANCHORED ON MULTI-WALLED CARBON NANOTUBES.

A. B. Castle[1], E. E. Gracia-Espino[2], C. Nieto-Delgado[2], H. Terrones[2], M. Terrones[2] and S. M. Hussain[1]. [1]*711 HPW; RHPB, Air Force Research Labs, Wright Patterson, OH and* [2]*Advanced Materials Department and Laboratory for Nanoscience and Nanotechnology Research, IPICYT, San Luis Potos√≠, Mexico.*

Silver nanoparticles (Ag NPs) have a variety of applications due to their high extinction coefficient and surface plasmon resonance emission. By manipulating the surface and the core-shell structure of Ag NPs, different functionalities can be engineered to explore the molecular behaviors in living cells. This study investigates if Ag NPs anchored to different types of multi-walled carbon nanotubes (MWCNTs) show biocompatibility. Ag NPs were anchored via a novel chemical route involving silver nitrate, nanotubes and a reducing agent. Scanning electron microscopy (SEM), X-ray powder diffraction, and transmission electron microscopy (TEM) were performed to characterize the nanomaterials. The human keratinocyte cell line (HaCaT) was exposed to the nanomaterials at various concentrations and time points and biocompatibility was evaluated using mitochondrial function and morphology. MWCNTs correspond to pure MWCNTs, COx-MWCNTs to carbonyl doped and CNx-MWCNT to N-doped. The chemical reactivity of the Ag NPs on the nanotubes was MWCNTs< COx-MWCNTs< CNx-MWCNT. The average Ag NP size on the nanotubes was MWCNTs 6.64nm +/- 2.25nm; CNx-MWCNTs, 13.24nm +/- 3.94nm, and COx-MWCNT/Ag were 11.75nm +/- 4.65nm. The X-ray diffraction patterns show peaks corresponding to graphite and silver. Cytoviva enhanced light microscopy imaging revealed nuclear binding for all of the materials. After 48 hour exposure, there was disruption of the actin filaments and continued nuclear localization and binding. The MTS assay did not show a reduction in mitochondrial function, indicating potential for biocompatibility. The lack of toxicity combined with NPs binding to the nucleus indicates potential for a novel method of delivering Ag or other nanoparticles to the nucleus. Further studies are in progress to demonstrate biocompatibility and to deliver modified Ag NPs in a non-invasive way to other specific regions within cells.

PS 2210 IL-1β REGULATES THE EXPRESSION OF MIP-1α AND MIP-1β INDUCED BY CARBON NANOTUBES IN A MULTIPLE CELLULAR CO-CULTURE SYSTEM.

E. Alfaro-Moreno[1, 2], B. Vanaudenaerde[2], B. Nemery[2] and P. Hoet[2]. [1]*Investigacion Basica, Instituto Nacional de Cancerologia, Mexico, D.F., Mexico and* [2]*Lung Toxicology Unit, K.U. Leuven, Leuven, Belgium.*

In vitro models are very useful to understand the cellular mechanisms related to particulate matter (PM) toxicity. The use of single cell cultures, or even co-cultures of two different cells may overlook the important interactions with other cell types and the communication with distant cells, such as the possible cross talk between the lung epithelium and the vascular endothelium. In the present study, we evaluated the proinflammatory effect of single wall carbon nanotubes (SWCNT) on co-cultures of multiple human cells that have been used successfully to evaluate urban PM. METHODS. Single cultures (pneumocytes, A549; macrophages, THP-1; mast cells, HMC-1), Bicultures (A549+THP-1; A549+HMC-1; THP-1+HMC-1) and Tricultures (A549+THP-1+HMC-1) were exposed to 0, 1, 3, 10 or 30 μg/cm2 of SWCNT. Inserts containing endothelial cells (EAHY926) were introduced to some Tricultures after 12 h of exposure. TNFα, IL-1β, IL-6, IL-8, MIP-1α, MIP-1β and G-CSF concentrations were quantified in all the cultures after 24 h of ex-

posure. Antibodies against TNFα, IL-1β and IL-6 were added together with the SWCNT to evaluate its role in the expression of MIP-1α and MIP-1β in Tricultures+EAHY926. The results were expressed as fold changes compared to unexposed cultures. RESULTS. Single cultures: IL-1β was induced in THP-1 cultures (3 fold) while IL-8 was induced in HMC-1 cultures (3 fold). Bicultures: Increases of TNFα (4 fold), IL-1β (2.5 fold) and IL-6 (2.5 fold) were observed in A549+THP-1 Bicultures. Tricultures: No changes in any of the evaluated cytokines were observed when Tricultures were exposed, but increases in MIP-1α (1.5 fold) and MIP-1β (2 fold) were found when EAHY926 cells were introduced in the system. Anti IL-1β enhanced the expressions of MIP-1α (13 fold) and MIP-1β (20 fold). CONCLUSIONS. IL-1β seems to play an important role in regulating the expression of MIP-1α and MIP-1β when pneumocytes+macrophages+mast cells exposed to SCWNT are in communication with endothelial cells.

PS 2211 FUNCTIONALIZATION-DEPENDENT CYTOTOXICITY OF SINGLE- AND MULTI-WALLED CARBON NANOTUBES.

L. Manzo[1,2], E. Roda[1], D. Sarigiannis[3], G. Cimino-Reale[3], P. Mustarelli[1], A. Profumo[1] and T. Coccini[1,2]. *[1]University of Pavia, Pavia, Italy, [2]Department of Toxicology, Maugeri Foundation Hospital, Pavia, Italy and [3]Joint Research Centre, European Commission, Ispra, Italy.*

Recently developed functionalization schemes have extended the application spectrum of carbon nanotubes (CNTs) enhabling the implementation of new functions that cannot otherwise be acquired by pristine nanotubes. Functionalization has been shown to impact on the biological response to CNTs suggesting that toxicological profile may also be modified. In this study, the cytotoxicity of single-walled CNTs (SW), multi-walled CNTs (MW) and functionalized MW (MW-COOH, MW-NH2) was investigated in human astrocytoma D384 and lung carcinoma A549 cell cultures using MTT assay and calcein/propidium iodide (PI) staining. The test nanomaterials were characterized by thermal analysis (TGA), infrared spectroscopy, and atomic force microscopy to assess the degree of purity and functionalization. The cells were exposed to the CNTs (0.1-100μg/ml) for 24, 48, 72h in medium containing 10%FCS. Quartz (SiO2) and carbon black were also similarly tested. In both cell types, MTT data revealed strong cytotoxicity (50% loss of cell viability) of SW after 24h-exposure already at 0.1μg/ml, without further changes at higher concentrations or longer incubation times. At all time-points MTT metabolism was decreased by about 50% by all the other compounds at 10μg/ml and with no exacerbation at the higher dose. Parallel assays using calcein/PI staining did not confirm MTT cytotoxicity data neither in D384 nor in A549 cells. Cell viability was not affected by any CNT type at any concentration or time of exposure, whereas extensive cell killing was observed in the preparation exposed to the positive control SiO2. The results indicate that CNTs can interact with certain types of dye markers that are commonly used in cell culture experiments. This may lead to artefactual data. A study design using multiple tests is recommended in investigations examining CNT toxicity in vitro (Grants from the Italian Ministries of Health, Education and Research).

PS 2212 THE IMPORTANCE OF CELL TYPE FOR *IN VITRO* TESTING OF CARBON NANOFIBERS USING CELL COLONY FORMATION AS ENDPOINT.

T. Syversen, K. Gellein, S. Hoel and L. Evje. *Department of Neuroscience, Norwegian University of Science and Technology, Trondheim, Norway.*

Carbon nano materials are difficult to test by standard in vitro cytotoxicity tests as they may interfere with colorimetric assays. A range of carbon nano tubes as well as carbon particles have been tested using several cell types (RBE4, A549 and NHK3025) for their ability to inhibit cell colony formation and development. Carbon fibers were added to cell cultures prior to, simultaneously or soon after seeding cells at low concentration. Fiber samples were added as suspended by thorough mixing or repeated sonication at low energy. After appropriate exposure the cultures are stained with Giemsa and analyzed. A number of indicators can easily be recorded, e.g. number and size of colonies, number of cells in a colony as well as other morphological characteristics. The test will differentiate between particles like single wall carbon nanotubes (SWCNT), carbon black and even different batches of chemically equivalent carbon particles. Samples were tested in the concentration range of 0.5 to 20 mg per litre. Plating efficiency was reduced by 30-90% in a dose-response manner and differed considerably between the cell types tested. We found that RBE4 cells were the most sensitive cells in this assay and effects could be observed at concentrations as low as 1 mg per litre and the test could differentiate between different production batches of carbon fibers.

PS 2213 A COMPARATIVE STUDY OF EFFECTS OF SINGLE-WALL CARBON NANOTUBES AND CROCIDOLITE ASBESTOS IN HUMAN BEAS-2B CELLS.

M. Pacurari, V. Castranova, S. Friend, V. Robinson and V. Vallyathan. *CDC/NIOSH/HELD, Morgantown, WV.*

Single-wall carbon nanotubes (SWCNT) are of great interest to many aspects of industry including, but not limited to, electronics and pharmaceutics. As SWCNT-manufactured goods are being introduced into market, concerns regarding their potential for producing environmental and human health risks have been raised. In the present study, we investigated SWCNT effects on the human broncho-epithelial cells (BEAS-2B. Exposure of BEAS-2B cells to SWCNT resulted in dose-dependent loss of cell viability and oxidative stress by means of dose-dependent increase in OH radical production and superoxide dismutase activity (SOD). Furthermore, SWCNT induced time- and dose-dependent apoptosis and phosphorylation of histone γ-H2A.X, a variant of histone H2A that is activated following DNA damage. Whether SWCNT have the potential to induce apoptosis, BEAS-2B cells were exposed for different time points to SWCNT (50 μg/cm2), and analyzed for PARP activation, as a molecular marker of apoptosis. The level of cleaved PARP increased after 18h of exposure. This level decreased when cells were allowed to recover for 6h in normal growth media. We also examined the ability of SWCNT to induce the transactivation of activator protein-1 (AP-1) and nuclear factor-kappaB (NF-κB), transcription factors that are important members of signal transduction pathways. SWCNT induced greater activation of AP-1 and NF-κB at lower doses as compared to higher doses. These effects were diminished by PD98059, an inhibitor of MAP kinase. Crocidolite asbestos was used as a positive control along with SWCNT, and the effects of crocidolite were far greater as compared to SWCNT. Considering the role of airway epithelium as a barrier and its role in pulmonary functioning, the results of the present study suggest that interaction of SWCNT with airway cells may cause adverse biological responses that may initiate respiratory diseases.
Key words: Apoptosis, asbestos, carbon nano-particles, cell toxicity, oxidative stress,

PS 2214 AEROSOLIZATION DELIVERY SYSTEM OF AIRBORNE NANOPARTICLES FOR NOSE-ONLY INHALATION STUDIES.

S. Teague, A. K. Madl, T. Guo, Y. Qu and K. E. Pinkerton. *University of California, Davis, Davis, CA.*

Understanding human health risks associated with engineered nanomaterials is particularly challenging because of the wide range of plausible exposure scenarios. While workers, consumers, or the general public may potentially be exposed to nanoparticles through a number of pathways (e.g., dermal, ingestion, ocular), inhalation, at least from an occupational standpoint, is likely to be one of the most significant routes of exposure. For hazard assessment of inhaled nanoparticles, it is critical to have a means to deliver respirable airborne nanoparticles for experimental animal studies. An aerosolization system was developed to administer nanomaterials from a dry bulk media into respirable airborne particles for delivery into a nose-only inhalation system. Utilization of a cannula-based feed system, diamond grinding wheel, cyclone-type conditioning chamber, and Krypton-85 source (charge neutralization) allows for efficient delivery of otherwise difficult to produce respirable-size particles. Different nanomaterials (e.g., single-walled carbon nanotubes, ultrafine carbon black) were tested with the aerosolization system and aerosolized particles were characterized by size, mass, and number distribution using a gravimetric filter analysis, inertial cascade impactor, and scanning mobility particle sizer with a condensation particle counter, as well as by particle morphology using transmission electron microscopy. Aerosolized particles represented a wide range of size and morphological characteristics with particles spanning the fine (0.1-2.5 μm) and ultrafine (<0.1 μm) size range mostly in an agglomerated state. An advantage that this system offers over other aerosol-generating systems is that it utilizes relatively small amounts of dry material (<0.3 g) to generate respirable particle concentrations up to 1 mg/m3 continuously over a 6-hr period. Relating exposure characteristics of airborne particles in experimental studies to those in human exposure settings will be important for establishing exposure/dose-response relationships and standards to protect human health.

PS 2215 COMPARISON OF CARBON NANOTUBE-INDUCED CYTOTOXICITY IN A549 AND NORMAL HUMAN BRONCHIAL EPITHELIAL (NHBE) CELLS.

V. Walker, T. Hulderman and P. P. Simeonova. *Health Effects Laboratory Division, NIOSH/CDC, Morgantown, WV.*

The most attractive features of nanomaterials including their small size, large surface area, and reactivity might also be the main factors for their toxicity. Pulmonary bronchial epithelial cells are a potential target for toxicity during respiratory exposure. The tumor cell line A549, a pulmonary human type-II like epithelial cells, is

widely used for evaluation of particle toxicity. We hypothesized that A549 cells are more resistant to toxicity compared to the normal epithelial cells. To test this hypothesis we examined the dose-dependent cytotoxicity effects of single-walled (SWCNT) and multi-walled (MWCNT) carbon nanotubes on NHBE and A549 cells using lactate dehydrogenase (LDH) release and the cell proliferation/viability WST-1 assays. We found that NHBE exhibited marked cytotoxicity, similar to that observed with hydrogen peroxide treatment (positive control), consistently by 24 hours post-exposure to high concentrations [50-150μg/106 cells (1.5-4.5μg/ml)] of CNT. In comparison, exposure of A549 cells to similar concentration of CNT resulted in only a milder response. Overall, the results presented here indicate that SWCNT or MWCNT induce cytotoxicity in human lung epithelial cells in a time and dose-dependent manner. Furthermore, we demonstrate a large variation between the particle-induced cytotoxic responses in A549 cells and normal primary epithelial cells.

PS 2216 CELLULAR AND MOLECULAR MECHANISMS OF BROMATE-INDUCED TOXICITY IN RAT AND HUMAN KIDNEY CELLS.

X. Zhang[1], R. J. Bull[2], J. A. Cotruvo[3], J. Fisher[4] and B. S. Cummings[1].

The cellular and molecular mechanisms of bromate-induced toxicity in normal rat kidney (NRK) and human embryonic kidney cell lines (HEK293) after acute exposures were investigated. Bromate (added as $KBrO_3$ at 0-0.8 mg/ml) exposure decreased MTT staining after 48 hr in both cell lines. Bromate also increased phosphatidylserine externalization in tandem with decreases in membrane integrity after 48 hr as assessed by annexin V and PI staining. Cell cycle analysis demonstrated that bromate induced G2/M arrests in both cell lines. These data suggest that the mechanism of cell death induced by bromate is necrosis. Immunoblot analysis demonstrated that G2/M arrest correlated to induction of p53, p21 and phospho-cdc2 in HEK293 cells. Further, bromate treatment induced both time- and concentration-dependent increases in the activity of the mitogen activated proteins kinases (MAPK) p38 and ERK1/2. The activity of p38 and ERK1/2 increased after just 15 min of bromate exposure, prior to any increase in cell death or cell cycle arrest. Inhibition of p38 and ERK1/2 using SB202190 and PD98059, respectively increased bromate-induced decreases in MTT staining. Interestingly, treatment of cells with SB202190, but not PD98059, partially reversed bromate-induced G2/M arrest in HEK293 cells. Further, bromate exposure increased the expression of thioredoxin 1 in HEK293 cells after just 15 min. These data demonstrated the novel finding that bromate induced activation of MAPK and thioredoxin, which correlates to cell cycle arrest and cell death. This work was supported by Awwa RF 4042, IOA, MWD, NWRI, Calleagas Water, Long Beach Water, SNWA, LADWP, Veolia, Environment Abu Dhabi and the Georgia Cancer Coalition.

PS 2217 THE NOVEL TUMOR PROMOTER PALYTOXIN ACTIVATES EXTRACELLULAR SIGNAL REGULATED KINASE 5 THOUGH A NA+, K+-ATPASE-DEPENDENT PATHWAY.

E. Wattenberg and A. T. Charlson. *Division of Environmental Health Sciences, University of Minnesota, Minneapolis, MN.*

Palytoxin is classified as a non-12-O-tetradecanoylphorbol-13-acetate (TPA)-type skin tumor because it does not bind to or activate protein kinase C. The novel characteristics of palytoxin led us to investigate how it affects cellular signal transduction pathways. We previously showed that palytoxin stimulates the activation of three major members of the mitogen activated protein kinase (MAPK) family, c-Jun N-terminal kinase (JNK), p38, and extracellular signal regulated kinase (ERK) 1/2. Here we report palytoxin also activates ERK5, another MAPK family member, in mouse keratinocytes derived from initiated mouse skin (308 cells) and HeLa cells. By contrast, TPA does not activate ERK5 in these cell lines. The putative cell surface receptor for palytoxin is the Na+, K+-ATPase. Accordingly, ouabain blocked the ability of palytoxin to activate ERK5. We did not detect the activation of ERK5 by ouabain alone, however, indicating a divergence in the signaling pathways activated by these two ligands for the Na+, K+-ATPase. The activation of ERK5 by palytoxin was not mimicked by cycloheximide, okadaic acid, or sodium orthovandate. These results indicate that the stimulation of ERK5 by palytoxin is not simply due to its ability to inhibit protein synthesis or to inhibit tyrosine or serine/threonine phosphatases. Thus palytoxin appears to activate ERK5 through a mechanism that differs significantly from the mechanisms by which it activates JNK, p38, and ERK1/2. The observation that ERK5 is involved in the regulation of cell proliferation and survival suggests that ERK5 may be an important target of palytoxin action.

PS 2218 INHIBITION OF CALCIUM-INDEPENDENT PHOSPHOLIPASE A_2 ACTIVATES MAP KINASE SIGNALING PATHWAYS DURING CYTOTOXICITY IN PROSTATE CANCER CELLS.

B. Sun, X. Zhang and B. Cummings. *Pharmaceutical and Biomedical Sciences, UGA, Athens, GA.*

The p53-dependent and -independent signaling pathways activated during cytotoxicity induced by Ca^{2+}-independent phospholipase A_2 ($iPLA_2$) inhibitors in prostate cancer cells were investigated. $iPLA_2$ inhibition using siRNA, or the selective inhibitor bromoenol lactone (BEL), decreased growth in LNCaP (p53 positive) and PC-3 (p53 negative) human prostate cancer cells. Decreased cell growth correlated to time- and concentration-dependent activation of the mitogen activated protein kinases p38 and ERK1/2. p38 was activated in both cell lines, while ERK1/2 was transiently activated in only PC-3 cells. Inhibition of p38 using SB202190 inhibited the ability of BEL to activate p53 and p21 in LNCaP cells, and reversed BEL-induced G2/M arrest in PC-3 cells. In contrast, inhibition of ERK1/2 using PD98059 only slightly altered p53 activation in LNCaP cells. Interestingly, $iPLA_2$ inhibition significantly increased the activity of epidermal growth factor receptors (EGFR) in PC-3 cells, but not LNCaP cells. Treatment of PC-3 cells with the EGFR inhibitor AG1478 prevented BEL-induced ERK1/2 activation. Similar results were seen using the matrix metalloproteinases inhibitor GM6001. Neither of these inhibitors altered BEL-induced p38 activation. Inhibition of ERK1/2 prior to treatment with BEL decreased PC-3 cell growth in comparison to cells exposed to BEL alone. Similar results were seen in LNCaP cells when p38 was inhibited. In contrast, inhibition of p38 in PC-3 cells protected against BEL-induced cytostasis. These data demonstrate the novel findings that $iPLA_2$ inhibition differentially activates p38 and ERK1/2 in prostate cancer cells, and further suggest that these signaling kinases have differential roles in prostate cancer cell growth.

PS 2219 THE TUMOR SUPPRESSOR GENE TSC-2 MODULATES TRANSLATION INITIATION OF CYCLIN D1 THROUGH ERK CROSSTALK WITH 4EBP1.

J. D. Cohen[1], J. M. Gard[2], R. B. Nagle[2], T. J. Monks[1] and S. S. Lau[1].
[1]Pharmacology and Toxicology, University of Arizona, Tucson, AZ and [2]AZCC, U of A, Tucson, AZ.

The mTOR and MAPK signaling cascades have been implicated in a number of human cancers. The tumor suppressor gene tuberous sclerosis-2 (Tsc-2) functions as a negative regulator of mTOR. Critical proteins in both pathways are activated following treatment of Eker rats ($Tsc\text{-}2^{EK/+}$) with 2,3,5-tris-(glutathion-S-yl) hydroquinone (TGHQ), which also results in loss of the wild-type allele of Tsc-2 in renal preneoplastic lesions and tumors. Western blot analysis of kidney tumors formed following 8-months of TGHQ treatment of $Tsc\text{-}2^{EK/+}$ rats revealed increases in B-Raf, C-Raf, p-ERK, cyclin D1, 4EBP1, and p-4EBP1-Thr70, -Ser65, and -Thr37/46 expression. Concomitant with increases in expression of these proteins in TGHQ-induced tumors, similar changes are observed following TGHQ transformation of primary renal epithelial cells derived from $Tsc\text{-}2^{EK/+}$ rats (QTRRE cells). QTRRE cells are null for tuberin due to loss of heterozygosity at the Tsc-2 allele and exhibit high ERK, B-Raf and C-Raf kinase activity, and increased expression of cyclin D1, 4EBP1, and all p-4EBP1s. Following siRNA knockdown of C-Raf, Western blot analysis revealed a significant decrease in C-Raf, cyclin D1, and all p-4EBP1 forms noted above. In contrast, siRNA knockdown of B-Raf resulted in a nominal change in these proteins. Furthermore, treatment of the QTRRE cells with the Raf kinase inhibitor Sorafenib (therapeutic anti-cancer agent) and the MEK1/2 kinase inhibitor PD 98059, both produced a significant decrease in the protein expression of cyclin D1 and all p-4EBP1s. Western analyses revealed three distinct species of 4EBP1, with the lowest molecular weight band lacking phosphorylations on Thr65 and Thr70. Moreover, treatment with both inhibitors causes an increase in the relative abundance of all three bands. The data indicate that Raf-MEK-ERK participates in crosstalk with 4EBP1, which represents a novel pathway interaction leading to increased protein synthesis, cell growth, and kidney tumor formation. (GM39338, ES007091, ES06694)

PS 2220 OVERLAPPING SIGNAL SEQUENCES AND PHOSPHORYLATION CONTROL NUCLEAR LOCALIZATION AND ENDOPLASMIC RETICULUM RETENTION OF GLUCOSE REGULATORY PROTEIN GRP58.

E. Unni, A. K. Adikesavan and A. K. Jaiswal. *Pharmacology and Exp. Therapeutics, Univ of Maryland School of Medicine, Baltimore, MD.* Sponsor: B. Moorthy.

Glucose regulatory protein (GRP58), has two thioredoxin-like domains and is known to function as thiol-dependent oxidoreductase. GRP58 is present in cytosol, nucleus and endoplasmic reticulum (ER). GRP58, retained in ER, specifically in-

teracts with glycoproteins such as calnexin and calreticulin, and act as a molecular chaperone during glycoprotein biosynthesis and folding. We investigated the signals that control localization of GRP58 in the cytosol, nucleus and ER for specific functions. Procite search revealed that GRP58 contains putative nuclear localization (494KPKKKKK500) and ER retention (502QEDL505) signals. Deletion/mutation of nuclear localization signal (NLS) abrogated nuclear import of GRP58. NLS attached to EGFP localized EGFP in the nucleus. However, deletion/mutation of putative ER retention signal alone did not alter ER retention of GRP58. Interestingly, a combined deletion/mutation of NLS and ER retention signals blocked the GRP58 retention in the ER. These results concluded that overlapping NLS and ER retention signal sequences regulate nuclear localization and ER retention of GRP58. Further studies demonstrated that thioredoxin domains do not play a role in subcellular localization of GRP58. We also investigated a role of phosphorylation in subcellular distribution of GRP58. GRP58 immunoprecipitated from cytosolic, nuclear and ER compartments all were phosphorylated at serine residues. However, GRP58 from cytosol and nucleus but not from ER were also phosphorylated at tyrosine residues. Reverse IP experiments showed similar results. Netphos and Prosite search have shown presence of putative PKC and tyrosine kinase sites. These sites have been mutated in GRP58 to determine the role of specific site(s) of phosphorylation in subcellular distribution of GRP58. The mutants will also be used in identifying whether GRP58 play a role in translocating other proteins such as STAT3 to the nucleus which are found associated with GRP58 in cell membrane, ER and nucleus.

PS 2221 KEY ROLES OF ANNEXINS AND PHOSPHOLIPASES IN TOXICANT INDUCED REGULATION OF CELL SIGNALING RELEVANT TO CANCER.

B. L. Upham[1], P. Babica[1], J. Park[1], I. Sovadinova[1], L. Blaha[1], D. A. Whitten[2], C. G. Wilkerson[2] and J. E. Trosko[1]. *[1]Pediatrics and Human Development, Michigan State University, East Lansing, MI and [2]RTSF - Proteomic Core, Michigan State University, East Lansing, MI.*

Lower molecular weight polycyclic aromatic hydrocarbons (PAHs) with specific structural features are potent in vitro inhibitors of gap junctional intercellular communication (GJIC) and activators of mitogen-activated protein kinases (MAPKs), two cellular events linked with tumor promotion and other pathologies. We found that inhibition of GJIC and activation of MAPK are induced in a rat liver epithelial cell line (WB-F344) within several minutes by a model representative of lower molecular weight PAHs, 1-methylanthracene (1-MeA), and these effects are preceded with the activation of phosphatidylcholine-specific phospholipase C (PC-PLC) and the release of arachidonic acid also suggesting an activation of phospholipase A2 (PLA2). We used advanced proteomics techniques (SILAC – Stable Isotopes Labeling with Amino Acids in Cell Culture, ZOOM® isoelectric fractionation, 1-DE, 2-DE and mass spectroscopic identification) to further identify early upstream biochemical signaling events. Among the proteins specifically affected within a 5 min exposure time to 1-MeA, annexins A1, A3 and A5 showed significant responses characterized by their disappearance from plasma membrane and reciprocal increases in the fraction of soluble proteins. Western blotting and immunostaining experiments on annexin A3 indicated a translocation from the plasma membrane within 30 s of exposure followed by reintegration back into the plasma membrane after 60 min. Interestingly, removal of annexin A3 from plasma membrane was effectively prevented by pre-treatment of the cells with PC-PLC inhibitor, D609. We hypothesize that annexins closely interact with phospholipases in the plasma membrane until removed from the membrane in response to 1-MeA, and the subsequent phospholipase-induced events then regulate GJIC and MAPK. Support: NIEHS grant #R01 ES013268-01A2 to Upham.

PS 2222 DIFFERENTIAL REGULATION OF MITOGEN-ACTIVATED PROTEIN KINASES BY ACETAMINOPHEN AND ITS REGIOISOMER 3'-HYDROXYACETANILIDE IN TAMH CELLS.

B. Stamper[1], F. Farin[2], T. K. Bammler[2], R. P. Beyer[2], N. Fausto[3] and S. D. Nelson[1]. *[1]Medicinal Chemistry, University of Washington, Seattle, WA, [2]Environmental Health, University of Washington, Seattle, WA and [3]Pathology, University of Washington, Seattle, WA.*

Acetaminophen (4'-Hydroxyacetanilide, APAP), a widely used analgesic and antipyretic that is considered to be relatively safe at recommended doses, is the leading cause of drug-induced liver failure in the United States. 3'-Hydroxyacetanilide (AMAP), a regioisomer of APAP, is useful as a comparative tool for studying APAP-induced toxicity since it is non-toxic relative to APAP both in vivo in mice and rats, and in vitro in TGF-alpha transgenic mouse hepatocytes (TAMH line). Our data suggests that differential modulation of mitogen-activated protein kinase (MAPK) cascades by these isomers plays a major role in differentiating their toxicological outcomes. More specifically, APAP treatment leads to c-Jun N-terminal kinase (JNK) activation, a MAPK related to cellular stress, whereas AMAP treatment leads to activation of extracellular-signal-regulated protein kinase (ERK), a MAPK related to cell proliferation and survival. MAPK cascade expression and activation were measured using microarray and Bioplex technologies, respectively. Our microarray data suggests APAP treatment up-regulates gene expression at multiple levels of the JNK cascade including a JNK-specific scaffold protein. Expression data was confirmed by Bioplex, which measures MAPK phosporylation ratios. APAP treatment led to a significant activation of JNK compared to AMAP. In contrast, microarray analysis on the AMAP treated dataset shows an up-regulation of ERK gene activity. Furthermore, Bioplex data showed AMAP treatment led to significant ERK phosphorylation compared to APAP. Cell viability assays confirmed that activation of JNK by APAP was related to higher cell death, whereas activation of ERK by AMAP may be cytoprotective.

PS 2223 HEMATOPOEITIC CELL KINASE (HCK) ACTIVATES P38 *VIA* APOPTOSIS SIGNALING KINASE 1(ASK1) AND MAPK KINASE KINASE 6 (MKK6) DURING THE DEOXYNIVALENOL-INDUCED RIBOTOXIC STRESS RESPONSE.

H. Bae[1, 2], L. L. Vines[1, 2], J. J. Pestka[1, 2, 3] and S. Li[4]. *[1]Food Science and Human Nutrition, Michigan state university, East Lansing, MI, [2]Center for Integrative Toxicology, Michigan state university, East Lansing, MI, [3]Microbiology and Molecular Genetics, Michigan state university, East Lansing, MI and [4]Medicine, University of Massachusetts Medical School, Worcester, MA.*

Although the trichothecene mycotoxin deoxynivalenol (DON) is believed to act via a ribotoxic stress response, the signaling mechanisms remain incompletely characterized. The goal of this study was to: (1)verify the role of hematopoietic cell kinase(Hck) in p38 activation and proinflammatory gene expression in vivo and (2) identify downstream kinases involved in DON-mediated Hck activation to p38 in vitro. Peritoneal macrophages elicited from wild-type (WT) and homozyogous Hck knockout (KO) mice were compared relative to their capacity to respond to DON. Incubation of WT macrophages with DON (500 ng/ml) induced robust p38 activation and proinflammatory gene expression, however, these responses were markedly reduced in Hck-KO mice. A similar trend toward reduced proinflammatory gene expression was also observed in spleen and Peyer's patch samples obtained from orally gavaged (5 mg/kg body weight DON) Hck-KO mice as compared to DON-treated WT mice. When DON-induced Hck signaling pathways leading to p38 activation were investigated in RAW 264.7 macrophages, the Hck inhibitor PP2, was found to inhibit activation of ASK1 and MKK3/6 which are kinases known to be upstream of p38. Immunoprecipitation revealed that phosphorylated MKK3/6 was shown to interact with the Hck within 5 min after DON treatement. Activated Hck was transiently detectable by Western blotting in ribosomal fractions within 5 min, and concurrent p38 interaction observed. MKK6 but not MKK3 was likewise found to transiently interact with the ribosome. These data suggest that rapid sequential activation of Hck-ASK1-MKK6-p38 via the ribosome is a critical signaling pathway for mediating DON-induced ribotoxic stress response in murine macrophages.

PS 2224 NON-COPLANAR PCBs INDUCE APOPTOSIS RELATED GENES AND INHIBIT CELL PROLIFERATION IN NORMAL LIVER EPITHELIAL CELLS BUT PROMOTE FOCI FORMATION IN INITIATED LIVER EPITHELIAL CELLS.

B. V. Madhukar and G. Chen. *Pediatrics/Human Development, Michigan State University, East Lansing, MI.*

Polychlorinated biphenyl (PCB) mixtures are widespread environmental contaminants. The coplanar isomers of these mixtures are ligands for the Ah receptor; the non-coplanar (NC)isomers that are the major components of PCB mixtures are poor ligands for the AhR. Both types of PCB isomers were shown to promote carcinogenesis through non-mutagenic pathways. The mechanisms by which the NC-PCBs promote neoplastic growth are not clear. Since mitogenic signaling pathways play a central role in cell growth and proliferation we examined the activation of ERK signaling pathway in a rat liver epithelial cell line WB by 2,2',4,4'-tetrachlorobiphenyl (TCB) as a prototype of NC-PCBs. At micromolar concentrations TCB caused activation of ERK. The activation of ERK did not cause proliferation of the liver cells. Instead in cells treated with 20.0 μM TCB cell proliferation was inhibited and apoptotic changed ensued. Flow Cytometric analysis revealed that there was no increase in cells undergoing transition from G1 to S phase of cell cycle. In contrast, treatment with transforming growth factor-α (10.0 ng/ml) that also activated ERK there was significant increase in the number of cells undergoing G1 to S phase transition. Microarray analysis of gene expression profiles of TCB treated cells showed elevated expression of apoptosis related genes such as Bax in these cells. In contrast, when the cells were initiated with the carcinogen N-methyl-N-nitrosoguanidine for a short period and subsequently treated with TCB there was significant increase in the number of transformed foci formed in the culture suggesting that TCB exerted tumor promoting effect in the initiated cells. Taken together

our results suggest that activation of ERK does not necessarily exert proliferative effect in normal cells but following initiation with a carcinogenic agent NC-PCBs exert non-genotoxic effects to promote the growth of initiated cells (supported by grants from Philip Morris External Research Program and NIH ES-04911).

PS 2225 CYTOTOXICITY, CELL DEATH AND ACTIVATION OF MAP KINASES PATHWAYS IN PRIMARY HEPATOCYTES IN RESPONSE TO AFLATOXIN B1 AND OCHRATOXIN A, TAKEN INDIVIDUALLY OR COMBINED.

W. Hassen[1], G. De Sousa[2], H. Bacha[1] and R. Rahamani[2]. *[1]Toxicology, Faculté de Médecine Dentaire, Monastir, Tunisia and [2]Toxicology, INRA Sophia-Antipolis, Sophia-Antipolis, France.*

Aflatoxin B1 (AFB1) and Ochratoxin A (OTA) are two common contaminant mycotoxins which can occur jointly in a wide range of food commodities. Both mycotoxins have several toxic effects but share a significant carcinogenic potential. Considering the concomitant production of AFB1 and OTA, it is very likely that humans are always exposed to the mixture rather than to individual compounds. The aim of the present study was to investigate the effect of AFB1 and OTA taken individually or combined on cytotoxicty, cell death (apoptosis/necrosis) and on mitogen-activated protein kinases (MAPK) cascades including ERKs, SAP/JNK and p38 which are major MAP kinases pathways. The study was conducted using primary rat hepatocytes, recognized as the most appropriate in vitro system which takes into account xenobiotic metabolism and biotransformation. Our results clearly showed that both AFB1 and OTA induced hepatocytes cell death with IC50 about 0.1µM and 1µM, respectively. In addition, examination of the kind of cell death showed that both mycotoxins induced, in a dose dependant manner, apoptosis and necrosis. Furthermore, AFB1 and OTA significantly increased phosphorylated Raf, MEK 1/2, ERK 1/2 and c-jun in rat hepatocytes but had a slight effect on p38 MAPK activation. A selective phosphorylation of ERK proteins and of their substrate ELK1/2 and p90RSK was observed. Altogether, our study showed that AFB1 and OTA combination effects are clearly synergistic. The present studies provided evidence of a direct association between cell survival, cell death and cancer development. The understanding of the role of this signalling cascade could be relevant to explain the molecular basis of liver/renal diseases and tumorogenesis induced by naturally occurring mycotoxins.

PS 2226 O, P'-DDT INDUCES CYCLOOXYGENASE-2 GENE EXPRESSION IN MURINE MACROPHAGES: ROLE OF AP-1 AND CRE PROMOTER ELEMENTS AND PI3-KINASE/AKT/MAPK SIGNALING PATHWAYS.

J. Kim, E. Han, Y. Hwang and H. Jeong. *BK21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South.*

Dichlorodiphenyltrichloroethane (DDT) has been used as an insecticide to prevent the devastation of malaria in tropical zones. However, many reports suggest that DDT may act as an endocrine disruptor and may have possible carcinogenic effects. Cyclooxygenase-2 (COX-2) acts as a link between inflammation and carcinogenesis through its involvement in tumor promotion. In the present study, we examined the effect of o,p'-DDT on COX-2 gene expression and analyzed the molecular mechanism of its activity in murine RAW 264.7 macrophages. Exposure to o,p'-DDT markedly enhanced the production of prostaglandin E2 (PGE2), a major COX-2 metabolite, in murine macrophages. Furthermore, o,p'-DDT dose dependently increased the levels of COX-2 protein and mRNA. Transfection with human COX-2 promoter construct, electrophoretic mobility shift assays and DNA-affinity protein-binding assay experiments revealed that o,p'-DDT activated the activator protein 1 (AP-1) and cyclic AMP response element (CRE) sites, but not the NF-kB site. Phosphatidylinositol 3 (PI3)-kinase, its downstream signaling molecule, Akt, and mitogen-activated protein kinases (MAPK) were also significantly activated by the o,p'-DDT-induced AP-1 and CRE activation. These results demonstrate that o,p'-DDT induced COX-2 expression via AP-1 and CRE activation through the PI3-K/Akt/ERK, JNK, and p38 MAP kinase pathways. These findings provide further insight into the signal transduction pathways involved in the carcinogenic effects of o,p'-DDT.

PS 2227 CIGARETTE SMOKE REGULATES HDAC2 *VIA* SERINE PHOSPHORYLATION IN MACROPHAGES AND LUNG EPITHELIAL CELLS: IMPLICATIONS IN STEROID RESISTANCE.

D. Adenuga[1], T. H. March[2], J. Seagrave[2] and I. Rahman[1]. *[1]Environmental Medicine, University of Rochester Medical Center, Rochester, NY and [2]Lovelace Respiratory Research Institute, Albuquerque, NM.* Sponsor: N. Ballatori.

Rationale: Loss of HDAC2 is implicated in an impaired response to glucocorticoids in patients with chronic obstructive pulmonary disease (COPD). We recently found that HDAC2 is a target of cigarette smoke (CS)-induced serine phosphorylation however the mechanism is unknown. We hypothesize that CS-mediated phosphorylation of HDAC2 occurs on specific serine sites through a CK2-mediated mechanism and regulates enzyme activity. **Methods:** Monocyte/macrophage (MM6), bronchial epithelial (H292) and primary airway epithelial (SAEC) cells were exposed to cigarette smoke extract (CSE). Mice were exposed to subchronic CS. Serine phosphorylation of HDAC2 from lung tissue and cell extracts was determined. To inhibit CSE-induced phosphorylation, H292 cells were pretreated with 4,5,6,7 tetrabromobenzotriazole (TBB), a specific CK2α inhibitor. **Results**: HDAC2 was phosphorylated on serine residues in MM6, H292 and SAEC cells in response to CSE and in lung tissue HDAC2 from mice exposed to CS. Inhibition of phosphorylation, observed with the CK2α inhibitor (TBB), and co-immunoprecipitation of pCK2α/CK2α with HDAC2 indicated a prominent role for the CK2 holoenzyme in CSE-induced HDAC2 phosphorylation. Phosphorylation of an HDAC2 88-amino acid c-terminal deletion mutant indicated that S^{422}, S^{424}, S^{467} and S^{471} were not required for HDAC2 phosphorylation. Increased phosphorylation of HDAC2 was associated with transient formation of deacetylase co-repressor complex with HDAC1 in response to CSE. HDAC2 phosphorylation had no effect on nucleo-cytoplasmic shuttling either with CSE or by increasing intracellular phosphorylation with a PP2A phosphatase inhibitor, okadaic acid. **Conclusion:** CK2-mediated serine phosphorylation of HDAC2 is a key regulator of HDAC2 enzyme activity in response to inflammation and lung injury. Thus, inhibition of CK2α on HDAC2 may reverse steroid resistance in response to environmental stimuli.

S 2228 HEAT SHOCK PROTEINS AND THE TOXICOLOGICAL RESPONSE.

K. Gabrielson[1], Y. Kang[3], A. De Maio[2] and L. Hendershot[4]. *[1]Molecular and Comparative Pathobiology, Johns Hopkins University, Baltimore, MD, [2]Department of Surgery, University of California, San Diego, CA, [3]Department of Medicine, University of Louisville, Louisville, KY and [4]Genetics Tumor Cell Biology, St. Jude Hospital, Memphis, TN.*

Heat shock proteins (HSPs) are protein chaperones that facilitate protein folding and function. HSPs are induced by heat stress, oxidative stress and multiple classes of toxins. In order to fully understand HSP, it is important to review the latest research on HSP biology in inflammation, metal toxicity, cardiac physiology, neurodegeneration, and endoplasmic reticulum stress. During inflammation, HSP70 is important in antigen presentation. HSP70 interacts with lipids and proteins and binds to its own message to change the mRNA stability to modulate inflammatory response. During metal toxicity, signal transduction pathways induced by metals are tightly linked to protective heat shock protein pathways. HSP gene expression can be induced pharmacologically by novel agents currently being tested to induce protection against toxicities. For cancer therapy, HSP90 inhibitors are currently being tested in clinical trials. In cancer cells, inhibition of HSP90 is attractive since HSP90 chaperones multiple proteins including erbB2 and Akt, telomerase, endothelial nitric oxide synthase, channels, hormone receptors like glucocorticoid receptor, and transcription factors like HIF1α and AhR. It is not yet known whether HSP90 inhibitors will induce sufficient cancer cell death without inducing toxic side effects. Conversely, HSP90 inhibitors are proposed to reduce neurodegeneration, yet inhibition of HSP90 function in cardiomyocytes or endothelial cells in vitro is detrimental to cellular function. Finally, the unfolded protein response (UPR) is a common stress response in various toxicities (from insecticides to metals). This exquisite pathway links endoplasmic reticulum and nucleus to influence cellular fate. The latest findings of the role of HSPs in the response to toxicities, inflammation and cellular degeneration will be presented.

S 2229 HEAT SHOCK PROTEIN IMMUNOMODULATORY RESPONSE.

A. De Maio[1], K. L. Gabrielson[3], Y. Kang[2] and L. Hendershot[4]. *[1]Surgery, University of California, San Diego, CA, [2]Medicine, University of Louisville, Louisville, KY, [3]Molecular and Comparative Pathobiology, Johns Hopkins University, Baltimore, MD and [4]Genetics/Tumor Cell Biology, St Judes Childrens Hospital, Memphis, TN.*

Heat shock proteins (hsps) are intracellular chaperones that are involved in the folding and assembly of newly synthesized proteins. In conditions of stress, hsps play a key role in the refolding of denatured proteins, in the recovery from the stress, and in protection from subsequent insults. Recently, hsps have also been found in the extracellular medium after an array of insults. Extracellular hsps act as "danger" signals and are capable of activating the immune system. The mechanism involved in hsps release is controversial since this protein does not present a consensual secretory signal. Hsp70, which is the major inducible form of hsps, has been observed in the plasma membrane of stressed as well as transformed cells, exposing the C-terminal of the molecule to the extracellular environment. Moreover, Hsp70 can integrate into artificial lipid bilayer openings of ion conductance pathways. The lipid

specificity of Hsp70 is almost exclusive for phosphatidyl serine (PS). However, the interaction of Hsp70 with membranes could be enhanced by the presence of cholesterol and sphingolipids, which are components of detergent resistant membranes (DRM) of lipid rafts. In fact, Hsp70 has been detected in DRM fractions isolated from cells. Surface Hsp70 is released into the extracellular environment still associated with membranes, which have been named export cellular vesicles (ECV). The Hsp70 present in the membrane of ECV shares the same characteristics of this protein in the plasma membrane. ECV containing Hsp70 displayed a robust capacity for activating macrophages. We proposed that ECV are part of a natural mechanism for the communication between epithelial and immune cells, which has been coined "the health surveillance system." Consequently, the release of ECV containing Hsp70 could alter the immune system when an injury occurs and activate the body's machinery to combat further propagation of the insult.

S 2230 HEAT SHOCK PROTEIN 90 EXPRESSION AND FUNCTION IN NEURODENERATION AND CARDIAC DEGENERATION: CLINICAL IMPLICATIONS OF HSP90 INHIBITORS.

K. L. Gabrielson[3], A. De Maio[1], Y. Kang[2] and L. Hendershot[4]. *[1]Surgery, University of CA, San Diego, CA, [2]Medicine, University of Louisville, Louisville, KY, [3]Molecular and Comparative Pathobiology, Johns Hopkins University, Baltimore, MD and [4]Genetics / Tumor Cell Biology, St. Jude's Children's Hospital, Memphis, TN.*

HSP90 is a chaperone protein for hundred of proteins including erbB2 and Akt, telomerase, endothelial nitric oxide synthase, various channels, hormone receptors such as glucocorticoid receptor, and transcription factors such as HIF1α and AhR. Up-regulation of HSP90 in the heart is observed in diabetes, doxorubicin-induced cardiac toxicity and cyclosporine A-induced cardiac toxicity. It is currently not known if an up-regulation of HSP90 in the heart is protective or whether this up-regulation predisposes the heart to dysfunction. In the brain, HSP90 may play a role in neurodegeneration. As such, HSP90 inhibition may be beneficial and inhibitors are proposed to treat neurodenerative diseases. HSP90 inhibitors are also currently being tested in clinical trials for cancer therapy. In this setting, HSP90 inhibitors induce the degradation of the client proteins of HSP90 with reduction of cancer cell volume. This presentation will review some of the latest findings relevant to the clinical use of HSP90 inhibitors, potential side-effects or potential benefits. A novel transgenic mouse with cardiac specific HSP90 over-expression will also be discussed.

S 2231 UNFOLDED PROTEIN RESPONSE- ROLE OF ENDOPLASMIC RETICULUM AND NUCLEAR SIGNALING PATHWAYS IN TOXICITIES.

L. Hendershot[4], K. L. Gabrielson[3], A. De Maio[1] and Y. Kang[2]. *[1]Surgery, University of California, San Deigo, CA, [2]Medicine, University of Louisville, Louisville, KY, [3]Molecular and Comparative Pathobiology, Johns Hopkins University, Baltimore, MD and [4]Genetics / Tumor Cell Biology, St. Jude's Childrens Hospital, Memphis, TN.*

The endoplasmic reticulum (ER) is the major site of synthesis of secretory and membrane proteins. In order to properly prepare these nascent proteins for an extracellular fate, the ER lumen possesses a unique environment that is specialized for high fidelity protein folding and assembly. It contains high concentrations of molecular chaperones, folding enzymes, and ATP, which aid proper maturation of proteins. However, it also possesses an oxidizing environment, which favors intra- and inter-molecular disulfide bond formation, and mM concentrations of Ca2+ that pose unusual complications for folding. Only proteins that fulfill quality control standards are allowed to exit ER and travel further along the secretory pathway toward their final destinations. If the extracellular environment is altered through changes in normal physiology or the presence of toxic compounds, unfolded proteins will accumulate in the ER. This upsets the normal ER homeostasis and induces a signaling pathway called the unfolded protein response (UPR), which serves to alleviate the stress. In cases of prolonged or extreme stress, apoptotic pathways are activated to eliminate the affected cells in order to protect the organism. The initial phase of the UPR is cytoprotective. First, ER chaperones and folding enzymes are upregulated to cope with large numbers of unfolded proteins. Second, protein translation is transiently attenuated to diminish the load of unfolded proteins. And third, the degradative capacity of the cell is enhanced to dispose of unfolded proteins. However, if ER stress is not resolved, the UPR switches gears and guides the cell toward death in order to protect the organism. The balance between cytoprotective and cytodestructive components of the UPR is not well understood and appears to vary greatly by tissue type. In many cases, the cytodestructive part of the UPR is responsible for the pathologies associated with various diseases and toxicities. The components of the UPR that sense ER stress and initiate the response as well as the downstream effectors will be discussed along with the role of the UPR in disease.

S 2232 CROSS TALK OF HEAT SHOCK AND HEAVY METAL REGULATORY PATHWAYS.

Y. Kang[2], K. L. Gabrielson[3], A. De Maio[1] and L. Hendershot[4]. *[1]Surgery, University of California, San Diego, CA, [2]Medicine, University of Louisville, Louisville, KY, [3]Molecular and Comparative Pathobiology, Johns Hopkins University, Baltimore, MD and [4]Genetics/Tumor Cell Biology, St. Judes Children's Hospital, Memphis, TN.*

Toxic metal exposure activates several adaptive signaling pathways as well as the expression of heat shock proteins (HSPs) in mammalian system. The cross talk between the adaptive signaling pathways and HSPs constitutes a complementary protective mechanism against metal toxic insult. This cross talk involves regulation by HSPs of adaptive signaling pathways and HSP inhibition of detrimental pathways such as apoptosis. On the other hand, heat shock causes activation of signaling pathways leading to HSPs production, which requires the participation of metals such as zinc in the process. In particular, the final common pathway involved in the expression of HSPs is controlled by heat shock factors (HSFs), the function of which is zinc-dependent. Pharmaceutical agents can stimulate HSPs production, which prepares mammalian cells for protection against subsequent toxic metal exposure. Therefore, the co-existence and cross talk between the metal-induced signaling pathways and the HSPs production make mammalian system well prepared for toxicological exposure, however, disturbance of the cross talk results in diseases.

W 2233 BIOMARKERS FOR ASSESSING THE SYSTEMIC INFLAMMATORY RESPONSE SYNDROME IN TOXICOLOGY STUDIES.

C. Louden. *Pathology, Johnson & Johnson, Alderley Park, United Kingdom.*

Systemic inflammatory response syndrome (SIRS) is a state of whole body inflammation that can result in multiple organ dysfunction (MOD), circulatory collapse and even death. SIRS is considered as a self-defense mechanism to non-specific insults that arise from chemical, necrotic (as a result of tissue damage), ischemic, or infectious stimuli that induce organ pathology. SIRS and MOD are complex processes that involve hemodynamic, humoral and cellular responses, complement activation and cytokine cascade. SIRS and MOD develops in stages that are mediated in part through acute phase proteins, cytokine dysregulation and hemodynamic events. In toxicology studies, safety evaluation of xenobiotics, pharmacologically active immune stimulants and immunosuppressants can induce SIRS and MOD in rats, dogs and non-human primates and therefore measurement of circulating mediators as biomarkers of SIRS and MOD will enable clinicians to avoid a potentially severe catastrophic event. Furthermore chemically-induced pathology resulting from events such as ischemia, extensive tissue damage and necrosis, activation and release of stress hormones all can induce SIRS and MOD as a secondary toxic response. Whole body SIRS is considered an adverse finding in pre-clinical toxicology studies. Therefore, knowledge and use of the appropriate inflammatory biomarkers that reflects this pathological process is quite useful both preclinically and clinically. Additionally, pre-clinical and clinical monitoring of biomarkers that are early predictors or reporters of SIRS are valuable to the toxicologist in hazard identification and risk assessment of novel therapeutics with the potential to cause a pro-inflammatory response. To adequately explore these issues, we will highlight the progress and challenges of SIRS.

W 2234 CURRENT CONCEPTS AND AN OVERVIEW OF THE PATHO-PHYSIOLOGY OF CYTOKINE STORM, SIRS AND MOD.

S. D. Burdett[1] and C. Louden[2]. *[1]Wright State University, Dayton, OH and [2]Pathology, Johnson & Johnson, Raritan, NJ.*

Systemic inflammatory response syndrome SIRS)can be caused by ischemia,inflammation,trauma,infection,or combined insults. Multi-organ dysfunction syndrome (MODS)is a state of physiological derangement in organ dysfunction caused by hypoperfusion,or hypotension. Independent of etiology SIRS, has the same pathophysiologic properties and many consider the syndrome a self-defense mechanism. Inflammatory cascade is complex and involves humoral and cellular responses, complement, and cytokines. TNF-a, IL-1, IL-6, and IL-8 are the primary cytokines in the cascade. SIRS is best summarized as a 3-stage process; but, a multi-hit theory causing progression to MODS has been proposed. In this theory, the event that initiates the SIRS cascade primes the pump and with each additional event, an altered or exaggerated response causes progression to occur. To counteract the acute inflammatory response, the body is equipped to reverse this process via counter inflammatory response syndrome (CARS). IL-4 and IL-10 are cytokines responsible for decreasing the production of TNF-a, IL-1, IL-6, and IL-8. The acute phase response also produces antagonists to TNF-a and IL-1 receptors. These antagonists

either bind the cytokine or block the receptors. The balance of SIRS and CARS determines prognosis after an insult. Evidence suggests, because of CARS, many of the new medications meant to inhibit proinflammatory mediators may lead to deleterious immunosuppression. Studies have been designed to help differentiate causes of SIRS by evaluating acute-phase reactants. C-reactive protein, procalcitonin (PCT), interleukin-6 and other acute phase reactants were evaluated. PCT was a consistent useful biomarker in differentiating SIRS from sepsis. Unfortunately, PCT and newer acute-phase reactants are not available commercially and the impact on clinical care is not maximized. However, PCT and many newer acute phase reactants may provide insight into the inflammatory response to either underlying diseases or reactions to experimental medications.

W 2235 DIAGNOSIS OF SYSTEMIC INFLAMMATORY RESPONSE IN PRECLINICAL DRUG DEVELOPMENT.

W. Shao[1] and C. Louden[2]. [1]*Safety Assessment, Merck & Co., West Point, PA and* [2]*Toxicologic Pathology, Johnson & Johnson, Raritan, NJ.*

Preclinical drug development can be complicated by the challenge of precisely diagnosing systemic inflammatory response or differentiating between toxicity and exaggerated immunopharmacology. The systemic inflammatory response is an innate systemic inflammatory reaction in response to diverse tissue injury or infection. During the response, the concentrations of some serum proteins called acute phase proteins (APPs) elevate or decrease significantly. The analysis of these acute phase proteins as inflammatory biomarkers has shown great diagnostic values of detecting and monitoring diseases and is thus increasingly used in human and veterinary medicine. However, the application of APPs in preclinical drug development is still underdeveloped. In this presentation, we will discuss our advances in optimizing the diagnosis of systemic inflammatory response in preclinical safety assessment by using these acute phase proteins.

W 2236 IN VITRO APPROACHES TO INVESTIGATING CYTOKINE RELEASE FOLLOWING POTENTIAL AGONIST IMMUNOSTIMULATION.

C. J. Betts[1], M. Jacobsen[1] and C. Louden[2]. [1]*AstraZeneca Safety Assessment, Macclesfield, United Kingdom and* [2]*Pathology, Johnson & Johnson, Raritan, NJ.*

To develop safer and more effective drugs for diseases, development of agonists/antagonists of the immune system has highlighted potential dangers. In a Phase 1 study, with TGN1412, six volunteers suffered life-threatening adverse effects secondary to uncontrolled inflammatory cytokine release. Because of the many biologics and small molecules that target receptors on lymphocytes and antigen presenting cells in pre-clinical and clinical development, there is a need for accurate prediction of potential cytokine dysregulation, as seen with TGN1412. Adverse reactions to TGN1412 occurred despite appropriate in vivo preclinical testing, raising the question whether pertinent in vivo data was overlooked, the correct end points assessed or that in vivo studies lacked the sensitivity or specificity that could have predicted the clinical response. There is a growing need for in vitro approaches to address cytokine dysregulation. In vitro, the testing of human peripheral blood cells by free, cross-linked or plate bound biologics is one option that could provide answers to the problem of species-specificity. Similarly, stimulation of blood-derived Dendritic Cells or other innate immune system components may provide information on the action of agonists on bacterial or viral antigen pattern recognition receptors. However, design of such in vitro studies needs to be carefully considered to ensure that conditions closely match those in vivo. Alternatively, 'cell chips' are designed to give not only an indication that a perturbation of the immune system occurs in response to a compound, but also elucidate the potential immunological mechanism involved. The induction of cytokine promoter-regulated EGFP expression in different functional cell lines is available for the mouse and may be extended to humans to predict potential adverse effects in vivo. Data generated using these emerging in vitro methods may provide useful important with pre-clinical to clinical translation thus improving risk assessment and risk management.

W 2237 MONOCLONAL ANTIBODY INDUCED CYTOKINE RELEASE SYNDROME: PRECLINICAL SCREENING.

P. J. Bugelski[2] and C. Louden[1]. [1]*Pathology, Johnson & Johnson, Alderley Park, United Kingdom and* [2]*Centocor R&D, Radnor, PA.*

Monoclonal antibodies (mAb) are widely used in anti-inflammatory and tumor therapy. They are highly efficient in certain diseases, but can cause a variety of adverse effects. Toxicity may result from the expected pharmacological effects of the antibody and from interaction with antigen expressed on tissues other than the intended target. This can result in mild infusion reactions or cytokine release syndrome (CRS). A number of mAb are associated with CRS. These include: alemtuzumab; LO-CD2a/BTI-322; rituximab; CP-870,893; ibritumomab and TGN1412. In this talk, the cytokines involved, the mechanisms mediating cytokine release and the role of Fc receptors in CRS associated with mAbs will be reviewed briefly. The poor predictive value of studies in animals, the promise of in vitro screens with human cells and approaches to supporting first in human studies will be the major focus of the presentation.

W 2238 OPPORTUNITIES AND CHALLENGES FOR SAFETY EVALUATION OF SMALL AND LARGE MOLECULE HIGH RISK TARGETS.

H. Parmar[1] and C. Louden[2]. [1]*AstraZeneca Pharmaceuticals, Loughborough, Leicestershire, United Kingdom and* [2]*Pathology, Johnson & Johnson, Raritan, NJ.*

The human genome readout identified a number of potential drug targets. Target knowledge are rudimentary and speculative. Scientific research is needed to understand biology, efficacy and safety of these targets. In-vitro and in-vivo models not always predict and this is exacerbated when quantitative and qualitative species differences exist. For example, the same receptor may produce opposing responses in two species. This may be due to different homology, polymorphisms and ligand activity on the same receptors. Evaluation of CD-28 (TGN1412T) in non-human primate at doses 500-fold greater than the first human dose did not elevate cytokines TNF, IFN alpha, IL-6 etc. However,massive increase (>2000-fold)in these cytokines caused serious adverse effects after a single dose in volunteers. These findings can impact development of monoclonal antibodies, vaccines etc., The biology of these targets need to be understood,special techniques need to be employed to assess the spectrum of effects anticipated upon human administration.
Apart from the traditional toxicology studies, new methodologies need to be developed to model effects in humans that take into account in vitro and in vivo effects in different species. Restricted early Phase 0 clinical studies using micro dosing, microdialysis and other ex-vivo techniques using human tissue samples for exploratory analyses can give a better framework of understanding about how such targets will behave in humans upon first administration. Other PK/PD modeling approaches need to be developed to select first dose in man that takes in account receptor occupancy, MTD, PD effect size, target organ tissue effects and down stream up or down regulation of certain mechanisms. Some of these approaches will be described in this presentation. A holistic model will be described that can be applied to such complex targets in a systemic manner so as to obtain the best quality information before selecting the first doses in man.

W 2239 WORKSHOP INTRODUCTION.

J. DeWitt. *Pharmacology and Toxicology, East Carolina University, Greenville, NC.*

Perfluoroalkyl acids (PFAAs) used to manufacture myriad consumer products and are present in the environment, humans and wildlife. PFAAs undergo degradation to a limited number of extremely stable products, including PFOA and PFOS; both are reported to alter immune function. Human immunologic and body burden data from a highly exposed population will provide context for the discussions of rodent data that follow. The animal data will address propose modes of action for PFOA and PFOS, and body burdens associated with altered immune function. This workshop will appeal to a broad range of meeting attendees, including immunotoxicologists, risk assessors, and molecular, and regulatory toxicologists. The immunomodulation of PFOA and PFOS reported in rodent models has increased the level of regulatory concern regarding these chemicals. The doses of PFOA or PFOS administered in rodent studies result in serum concentrations that are 100-200 fold greater or slightly below, respectively, the amounts reported in serum of occupationally exposed humans. The corresponding suppression in antibody responses of the dosed rodents suggests that PFOA or PFOS may be immunomodulatory in highly-exposed humans.

W 2240 IMMUNE STATUS IN A COMMUNITY EXPOSED TO PFOA: FINDINGS FROM THE C8 SCIENCE PANEL STUDY.

T. Fletcher[1], G. Leonardi[1], B. Genser[2] and M. Luster[3]. [1]*PEHRU, London School of Hygiene and Tropical Medicine, London, United Kingdom,* [2]*BGSTATS, Graz, Austria and* [3]*Luster Assoc., Morgantown, WV.*

New findings are presented on the relationship between PFOA and immune biomarkers in a very large cross sectional survey carried out during 2005-6 in a population of 69,000 children and adults in the mid-Ohio Valley exposed via drinking water to PFOA from a nearby industrial source. This population has significant

higher exposure than national backround: serum analyses of several PFAAs found a range of concentrations up to 22000 μg/l of PFOA in serum, with a median of 28.2 (interquartile range 13.4-70.6 μg/L). PFOS was closer to normal values (median 20.2, interquartile range 13.9-29.0 μg/L). The dependence of a number of immune and inflammation biomarkers (including total IgA, IgM, IgG, IgE. ANA and CRP), on PFOA and PFOS is investigated by multivariate regression models with adjustment for potential confounders including age, smoking and BMI.

W 2241 PFOA-INDUCED IMMUNOMODULATION IN MICE: AN OVERVIEW.

J. DeWitt[1] and R. Luebke[2]. [1]*Pharmacology and Toxicology, East Carolina University, Greenville, NC and* [2]*ORD/NHEERL/ETD/ITB, U.S. EPA, RTP, NC.*

PFOA suppresses T-dependent antibody responses (TDAR) in C57BL/6 mice, at a benchmark dose of 3 mg/kg/d. This presentation will discuss possible modes of PFOA action for TDAR suppression, including corticosterone production and peroxisome proliferator activated receptor alpha (PPARα) activation. The data indicate that suppression of TDAR is not the product of generalized toxicity as evaluated by corticosterone production or clinical blood chemistries and not exclusively dependent on the presence of PPARα.

W 2242 ADJUVANCY AND IMMUNOSUPPRESSION: MECHANISMS OF IMMUNOMODULATION FOLLOWING DERMAL EXPOSURE TO PFOA IN MICE.

S. Anderson, L. Butterworth, L. G. Jackson, F. Frasch, J. Franko and B. J. Meade. *NIOSH, Morgantown, WV.*

The majority of investigations into the immunotoxic effects of perfluoroalkyl acids have focused on immunosuppression following the oral route of exposure. The potential for dermal exposure exists not only in the manufacturing of products and reformulations but also in use of end products such as fire-retardants. Recent studies have demonstrated that as compared to oral dosing, dermal exposure results in qualitatively similar immunosuppressive effects and additionally, that while not allergenic itself, dermal exposure to PFOA simultaneously with exposure to a respiratory allergen augments the IgE response to that allergen. This presentation will discuss the modulation of immune related genes following PFOA exposure, helping to explain the reciprocal relationship between the mechanisms governing immune suppression and augmentation of IgE-mediated hypersensitivity and demonstrating the kinetics of absorption and penetration of PFOA through human and mouse skin. Genetic diversity in these immune responses was also demonstrated between Th1 and Th2 strains of mice.

W 2243 SUPPRESSION OF IMMUNE FUNCTION IN MICE AFTER DEVELOPMENTAL EXPOSURE TO PFOS.

M. Peden-Adams. *Department of Pediatrics and Marine Biomedicine and Environmental Science Center, Medical University of South Carolina, Charleston, SC.*

Maternal PFOS exposure caused no significant dose-responsive changes in maternal or pup body weights, cell phenotype, or macrophage function in B6C3F1 pups. Suppression of NK cell function and IgM production were documented but were not evident until 8 weeks of age, at lower doses in male than female pups; NOAEL and LOAEL values were 0.1 and 1.0 mg/kg/d (males only) following maternal PFOS exposure, respectively. This study establishes that the developing immune system is sensitive to PFOS and results in functional deficits in innate and humoral immunity detectable at adulthood.

W 2244 EVALUATION OF THE IMMUNE SYSTEM IN RATS AND MICE ADMINISTERED AMMONIUM PERFLUOROOCTANOATE (APFO).

S. E. Loveless. *DuPont Haskell Global Centers for Health and Environmental Sciences, Newark, DE.*

Relatively few studies have examined effects on the immune system after exposure to APFO or PFOA. In earlier studies in rats or monkeys exposed to APFO from one month to two years, nothing remarkable was observed in microscopic examinations of spleen, thymus and mesenteric lymph nodes at any dose, including doses that resulted in significant increases in liver weights. More recently, repeated high doses of APFO for about two weeks have been reported to affect immune system function in mice. To examine dose response characteristics in both rats and mice, animals were dosed by oral gavage with 0.3 to 30 mg/kg/day of linear ammonium perfluorooctanoate (APFO) for 29 days following USEPA 870.7800 immunotoxicity guidelines. Anti-sheep red blood cell (SRBC) IgM levels, clinical signs, body and liver weights, spleen and thymus weights and cell number, selected histopathology, and serum corticosterone concentrations were evaluated. In rats, APFO had no effect on production of anti-SRBC antibodies. Ten and 30 mg/kg/day resulted in systemic toxicity based on body weight effects and increases in serum corticosterone levels to 135 and 196% of control, respectively. In mice dosed with 10 and 30 mg/kg/day, marked systemic toxicity and stress was observed, as evidenced by a loss in body weight of 3.8 and 6.6g, respectively, a tripling of liver weight), ~230% increase in serum corticosterone, and increases in absolute numbers of PMNs and monocytes and a decrease in absolute lymphocyte numbers. Immune-related findings at 10 and 30 mg/kg/day that likely represent secondary responses to the systemic toxicity and stress observed include: decreased IgM antibody production, decreased spleen and thymus weights and cell numbers; microscopic depletion/atrophy of lymphoid tissue starting at 10 mg/kg/day in the thymus and 30 mg/kg/day in the spleen. In summary, no immune-related changes occurred in rats, even at doses causing systemic toxicity. In mice, immune-related changes occurred only at doses causing significant systemic toxicity and stress.

W 2245 SESSION OVERVIEW.

D. R. Petersen. *toxicology, University of Colorado, Denver, CO.*

Acrolein, acrylamide, 4-hydroxy-2-nonenal (HNE) and other α,β-unsaturated carbonyl compounds are members of a large class of chemicals known as the type-2 alkenes. These chemicals are characterized by a conjugated structure that is formed when an electron-withdrawing group is linked to an alkene. α,β-unsaturated carbonyl derivatives are used extensively in various industries and these chemicals are recognized as significant environmental pollutants and dietary contaminants. Consequently, human exposure to the conjugated alkenes is pervasive and has been associated with toxicity of most major organ systems. There is also substantial evidence that endogenous production of acrolein and HNE is an important component of diseases that involve cellular oxidative stress and lipid peroxidation; e.g., Alzheimer's disease and atherosclerosis. Clearly, type-2 alkene exposure has diverse pathogenic implications therefore the potential role of these chemicals in human disease processes and environmentally acquired toxicities will be discussed. The conjugated α,β-unsaturated carbonyl structure of the type-2 alkenes is a soft electrophile that forms adducts with soft biological nucleophiles; i.e., cysteine sulfhydryl groups. In addition, amine groups on lysine and histidine residues are potential targets for adduct formation with these bifunctional chemicals. Accordingly, focus on the emerging recognition that type-2 alkenes produce toxicity through a common molecular mechanism involving the formation of adducts on functionally critical proteins will be a focal point of discussion. We will also consider how relative electrophilic reactivity and the route of intoxication determine the toxicological outcome of type-2 alkene exposure (e.g., hepatotoxicity, neurotoxicity). The leading researchers in the toxicity of α,β-unsaturated carbonyl compounds will provide unique information at the interface of chemistry and toxicology. Such information could offer insight into how the chemical environment impacts human health and might identify efficacious remediation strategies.

W 2246 α, β-UNSATURATED CARBONYL TOXICITY: SOFT-SOFT INTERACTIONS DESCRIBED BY QUANTUM MECHANICAL PARAMETERS.

T. Gavin. *Chemistry, Iona College, New Rochelle, NY.* Sponsor: R. LoPachin.

Conjugated α,β-unsaturated carbonyl compounds such as acrylamide (ACR), acrolein and 4-hydroxy-2-nonenal (HNE) are classified as type-2 alkenes. Chemicals in this class have broad industrial applications and are well recognized as human toxicants. Type-2 alkene exposure is pervasive and occurs through occupation, dietary contamination, industrial pollution, automobile exhaust and cigarette smoking. The pi electrons of a conjugated structure such as an α,β-unsaturated carbonyl are highly polarizable (mobile) and, therefore, the type-2 alkenes are considered to be soft electrophiles. As such, these chemicals preferentially form Michael-type adducts with soft biological nucleophiles, primarily sulfur groups on cysteine residues. The shape and energy of the respective frontier molecular orbitals govern these types of "soft-soft" interactions. Consequently, the propensity of a soft electrophile to form an adduct with a soft nucleophile can be defined by quantum mechanical (QM) parameters such as softness (σ), hardness (η) and chemical potential (μ). This talk will focus on the protein adduct chemistry of the type-2 alkenes. Comparisons of calculated QM parameters with corresponding adduct kinetics (second order rate constants) and measures of in vitro toxicity (IC50's) have indicated that the toxicity of the type-2 alkenes is a function of relative electrophilic softness. Evidence will also be presented that the preferred soft nucleophilic target of these electrophiles is the sulfhydryl thiolate-state of specific cysteine residues

within protein catalytic triads. As discussed in subsequent presentations, this unified adduct-based mechanism for type-2 alkenes has significant implications for the pathogenesis of human diseases and environmentally acquired toxicities.

W 2247 ATHEROGENIC EFFECTS OF ENALS.

S. Srivastava and D. J. Conklin. *Cardiovascular Medicine, University of Louisville, Louisville, KY.*

Enals are alpha,beta-unsaturated aldehydes that are ubiquitous pollutants in air, water and food and are generated endogenously by lipid peroxidation and during the metabolism of xenobiotics. Acrolein (C-3 alkene) and crotonaldehyde (C-4 alkene) are major constituents of automobile exhaust and cigarette smoke. Moreover, acrolein is generated endogenously by oxidation of lipids, myeloperoxidase activity, and from allylamine and cyclophosphamide metabolism. Hexenal (C-6 alkene) is abundant in fruits and is used as a flavouring agent. Additionally, 4-hydroxynonenal (HNE; C-9 alkene) is the most abundant aldehyde generated during the oxidation of lipids. These enals exert a variety of atherogenic effects including endothelial activation, smooth muscle cell proliferation, foam cell formation and enhanced cytokine production. Moreover, acrolein and HNE modify several proteins in vascular cells in vitro. MALDI-TOF analysis and confocal imaging show that most of these adducts are localized in the endoplasmic reticulum (ER). In addition, enals also cause the induction of ER-chaperone proteins and activate both the alarm and adaptive phases of the unfolded protein response (UPR). Chemical chaperones of protein-folding inhibit enal-induced UPR, inflammatory signaling and endothelial activation, and genetic ablation of the alarm phase gene, activating transcription factor 3 (ATF3), enhances inflammatory signaling. Moreover, enals (e.g., acrolein) exposure in vivo causes dyslipidemia in C57BL/6 mice and exacerbates atherosclerotic lesion formation in apoE-null mice. This presentation will discuss the molecular mechanisms by which enal-induced ER-stress affects cardiovascular cell signaling and UPR, and how regulation of enal metabolism modulates ER-stress and atherogenesis.

W 2248 OVERVIEW OF PROTEIN TARGETS MODIFIED BY THE α, β-UNSATURATED ALDEHYDE 4-HYDROXYNONENAL: INSIGHTS INTO MOLECULAR MECHANISMS PREDISPOSING PROTEINS TO MODIFICATION.

D. R. Petersen. *Toxicology, University of Colorado, Denver, CO.*

A number of chronic diseases are associated with significant inflammation resulting in oxidative stress, which is a documented stimulus for the peroxidation of cellular lipids. Among the end products of lipid peroxidation is the type-2 alkene, 4-hydroxynonenal (4-HNE) proposed to be involved in both survival and the cytotoxic responses of cells to oxidative stress. Whereas many of the cellular mechanisms involved in the 4-HNE responses are presumed to involve protein modification, identification of the specific nucleophilic amino acid targets of this type-2 alkene is under intense investigation. To date, the primary amino acid residue identified is the soft nucleophile, cysteine. This presentation will provide an overview of these studies with special emphasis on cellular factors, the structural properties of target proteins as well as the cellular consequences associated with protein modifications by type-2 alkenes.

W 2249 TYPE-2 ALKENES PRODUCE NERVE TERMINAL DAMAGE: RELEVANCE TO NEUROTOXICITY AND NEURODEGENERATIVE DISEASES.

R. M. LoPachin. *Anesthesiology, Albert Einstein College of Medicine, Bonx, NY.*

Synaptic dysfunction appears to be an early pathogenic event in Alzheimer's disease, amyotrophic lateral sclerosis and Parkinson's disease. Although the molecular mechanism of this synaptotoxicity is not known, evidence suggests that these diseases are characterized by a common pathophysiological cascade involving oxidative stress, lipid peroxidation and the subsequent liberation of α,β-unsaturated aldehydes such as acrolein and 4-hydroxy-2-nonenal (HNE). A diverse body of in vivo and in vitro data have shown that these soft electrophilic chemicals can cause nerve terminal damage by forming Michael-type adducts with nucleophilic sulfhydryl groups on presynaptic proteins. Therefore, the endogenous generation of acrolein and HNE in oxidatively stressed neurons of certain brain regions might be mechanistically related to the synaptotoxicity associated with neurodegenerative conditions. In addition, acrolein and HNE are members of a large class of structurally related chemicals known as the type-2 alkenes. Chemicals in this class (e.g., acrylamide, methylvinyl ketone, methyl acrylate) are pervasive environmental pollutants and new research has shown that these α,β-unsaturated carbonyl derivatives are also toxic to nerve terminals. In this talk, we provide evidence that the regional synaptotoxicity, which develops during the early stages of many neurodegenerative diseases, is mediated by endogenous generation of acrolein and HNE. Based on a presumed common nerve terminal site of action, we propose that the onset and progression of this neuropathogenic process is accelerated by environmental exposure to other type-2 alkenes and/or electrophilic chemicals.

W 2250 USING CARBONYL SCAVENGERS TO PROBE THE TOXICOLOGICAL SIGNIFICANCE OF ACROLEIN-MEDIATED PROTEIN ADDUCTION IN LUNG CELLS.

P. C. Burcham. *Pharmacology, University of Western Australia, Nedlands, WA, Australia.*

Acrolein and related carbonyl compounds are important toxic by-products of organic matter (e.g., plastics, wood and tobacco) combustion. Due to its strong electrophilic character and the readiness with which it attacks cell proteins, acrolein is a key mediator of the life-threatening damage to lung epithelium that accompanies smoke inhalation injury in fire victims. Since therapeutic options during the management of smoke inhalation injury are limited, our laboratory has explored the use of nucleophilic drugs to block the contribution of carbonyl compounds to smoke toxicity. Testing a range of putative protectants during in vitro experiments using lung-derived cell lines, we have demonstrated that diverse carbonyl scavengers effectively block toxicity elicited by smoke released during polyethylene combustion. However, intriguing differences emerge between individual carbonyl scavengers when the molecular mechanisms underlying their cytoprotective actions are studied. Whereas some scavengers protect key cellular agents such as intermediate filaments against adduction and cross-linking and attenuate transcriptional responses to acrolein, others have little effect on these end-points. In this presentation, we propose that careful attention to the chemistry underlying protein adduction during acrolein toxicity, together with the use of appropriate nucleophilic reagents will provide helpful new insights into the toxicological events that mediate acutely smoke-poisoned lung.
