Deadline for Proposals for SOT 2010 Annual Meeting Sessions: April 30, 2009

WHY SUBMIT A PROPOSAL?

1. To present new developments in toxicology.
2. To provide attendees an opportunity to learn about state-of-the-art technology and how it applies to toxicological research.
3. To provide attendees an opportunity to learn about the emerging fields and how they apply to toxicology.

SESSION TYPES

Continuing Education—Emphasis on quality presentations of generally accepted, state-of-the-art knowledge in toxicology

Note: CE Courses will be held on Sunday.

Symposia—"Cutting-edge" science; new areas, concepts, or data

Workshops—State-of-the-art knowledge in toxicology

Roundtables—Controversial subjects

Historical Highlights—Review of a historical body of science that has impacted toxicology

Informational Sessions—Scientific planning or membership development

Education-Career Development Sessions—Sessions that provide the tools and resources to toxicologists that will enhance their professional and scientific development

2010 Thematic Approach

The Scientific Program Committee will continue the thematic approach for the 2010 Annual Meeting. All proposal submissions will be reviewed for their relevance under the following themes—***Cell Signaling, Gene-Environment Interactions, Metabolic Disease, Mitochondrial Basis of Disease, Toxicity Testing in the 21st Century,*** and ***Translational Toxicology*** for the 2010 meeting. Please note that while we are actively soliciting proposals for the themes listed above, all proposal submissions will be reviewed under the current criteria for their timeliness and relevance to the field of toxicology.

Please refer to the SOT 2009 *Program*, Scientific Program Overview on the fold-out cover for a list of 2009 sessions highlighted under the thematic approach.

You can now submit your proposal on-line at www.toxicology.org

Preface

This issue of *The Toxicologist* is devoted to the abstracts of the presentations for the continuing education, symposia, workshop, roundtable, platform, and poster discussion sessions of the 48th Annual Meeting of the Society of Toxicology, held at the Baltimore Convention Center, March 15–19, 2009.

An alphabetical Author Index, cross referencing the corresponding abstract number(s), begins on page 469.

The issue also contains a Key Word Index (by subject or chemical) of all the presentations, beginning on page 487.

The abstracts are reproduced as accepted by the Scientific Program Committee of the Society of Toxicology and appear in numerical sequence.

Copies of *The Toxicologist* are available at $45 each plus $5 postage and handling (U.S. funds) from:

Society of Toxicology
1821 Michael Faraday Drive, Suite 300
Reston, VA 20190

CE 1 TOPICS IN ETHICS: CONFLICT OF INTEREST - REAL OR IMAGINED? PBDES AS A CASE STUDY.

S. Gilbert[1], P. Wexler[2], M. Goozner[3] and M. Brown[4]. [1]*INND, Seattle, WA,* [2]*National Library of Medicine, Bethesda, MD,* [3]*Center for Science in the Public Interest, Washington, DC and* [4]*Charles River Laboratories, East Thetford, VT.*

Throughout their professional lives, most toxicologists will confront an array of issues beyond the strictly scientific ones they have trained for. These may range across topics such as animals in research, human subject research, investigational and reporting bias, and conflict of interest concerns. The interdisciplinary nature of toxicology, its sometimes tangled regulatory framework, and implications for public safety and health, make policy considerations perhaps more relevant than they are for other sciences. Toxicologists, therefore, need to be braced for an array of ethical, legal, and social challenges, and to learn how to sensibly address allegations of conflict of interest or bias while practicing their science. This course will examine, through a case study related to polybrominated diphenyl ethers (PBDEs), the consequences of alleging conflict of interest or bias. In August, 2007 the EPA dismissed Deborah Rice from its PBDE review panel in compliance with a request from the American Chemistry Council, and expunged her comments from the official record. Dr. Rice had previously expressed her views about PBDE's dangers as part of work with the Maine government. The EPA's rationale was "the perception of a potential conflict of interest." This incident highlights the challenge of a scientist holding a scientifically credible opinion about an issue prior to review by an expert panel (on which he/she is serving) assigned to assess the same issue. Under what circumstance does a position become a conflict of interest or bias? The practical and ethical issues raised in staffing scientific review panels affects scientists and policy makers. Course time will be provided for a discussion of conflict of interest and an examination of related incidents. Students will be provided with a selected list of Web resources related to the ethical issues under discussion.

CE 2 FREE RADICALS FOR TOXICOLOGISTS - FROM THE BASICS TO INFLAMMATION AND DISEASE.

L. L. Mantell[1] and J. T. Zelikoff[2]. [1]*St John's University College of Pharmacy, Queens, NY and* [2]*New York University School of Medicine, Tuxedo, NY.*

The production of reactive oxygen species/reactive nitrogen species (ROS/RNS) has long been recognized to not only serve as a biomarker for oxidative stress, but also significantly contribute to the pathogeneses of various inflammatory tissue injuries and diseases. The emphasis of this course will be placed on an in-depth, state of the art review of the relationship among free radicals, immunologically-related inflammatory responses and environmental exposures and diseases. At the conclusion of this session, the participants will be able to describe the basic concepts of free radicals as they relate to immune-mediated events, better understand the production of reactive oxygen/nitrogen species (ROS/RNS) from both inflammatory responses and exposure to environmental toxicants, better understand the impact of ROS/RNS on normal physiological responses and pathological processes.

CE 3 CHARACTERIZING MODES OF ACTION AND THEIR RELEVANCE IN ASSESSING HUMAN HEALTH RISKS.

S. S. Olin[1] and S. M. Cohen[2]. [1]*ILSI Research Foundation, Washington, DC and* [2]*University of Nebraska Medical Center, Omaha, NE.*

Determining the mode(s) of action (MOA) of a toxicant is the goal of many toxicology studies, and these data are often used in risk assessment. A systematic approach to characterizing the mode(s) of action of toxicants is essential in the application of the framework for evaluating the relevance of an animal mode of action in assessing human risk. Frameworks for characterizing MOA data for carcinogens and analyzing its human relevance have been developed and cited in various national and international risk assessment guidelines. Recently, these concepts have been extended to non-cancer endpoints including reproductive, developmental, neurologic and other toxic effects. MOA evaluation is becoming a routine component of regulatory risk assessments thus an important consideration is always whether the MOA determined in animals can be assumed to be directly applicable for humans. The course will demonstrate the use of an MOA human relevance framework that asks first, is the weight of evidence sufficient to establish the MOA in animals? Application of modified Bradford Hill criteria to identify key events, including strength of evidence, leads to evaluation of the overall weight of evidence and discussion of possible alternative MOAs. Evaluation of the human relevance of the animal MOA includes assessing the weight of evidence both for qualitative and quantitative aspects. A brief history of and significance for risk assessment of MOA/human relevance analysis will lay the foundation providing the basic concepts involved in application of the framework. These applications will utilize selected case studies with both cancer and non-cancer endpoints. Case studies will examine issues such as multiple endpoints with shared or different MOAs, the extension of the framework to dose-response analysis, and the effect of life-stage on the analysis. Case studies used will show how the framework analysis is done to illustrate the importance of a systematic evaluation of the available data, and to provide the tools to begin applying the MOA/human relevance framework.

CE 4 EVALUATION OF TOXICITY TO MALE AND FEMALE REPRODUCTIVE SYSTEMS: BIOLOGY, STUDY DESIGN AND DATA INTERPRETATION.

K. Hew[1] and B. McIntyre[2]. [1]*Takeda Global Research & Development Center, Inc., Deerfield, IL and* [2]*Schering Plough Research Institute, Summit, NJ.*

The objectives this course are to provide the basic tools for toxicologists who desire a better understanding of how to assess toxicant-related effects on animal reproduction and the subsequent potential risk(s) to human reproduction. The anticipated audience includes toxicologists who work in regulated product development (e.g., pharmaceutical, chemical, and pesticide industries), as well as scientists who may be responsible for monitoring contracted reproductive toxicity studies so that they can understand the subject sufficiently to work with study directors (i.e., study design and interpretation of study results). Reproductive toxicity studies assess multiple interrelated endpoints in the male and female reproductive systems. In order to properly design, conduct, and interpret these studies, a broad knowledge of male and female reproductive organ development, anatomy, physiology, and endocrinology is required. Using this as a starting point, the overall designs of reproductive toxicity studies for regulatory submissions, and subsequent application of these data to assess potential risk in humans will be discussed. Additional presentations will provide an overview of the anatomy and physiology of the male and female reproductive systems, respectively, as well as endocrine regulation of these systems. This course will include an overview of the study designs to evaluate toxicity to male and female reproductive systems based on current regulatory guidelines. The course will conclude with case studies of reproductive toxicity data, subsequent interpretation, and how these results are being used to assess potential risks to human reproduction. In summary, upon completion of this course, the attendee will have an appreciation for the key information required for the design of reproductive toxicity studies and interpretation of reproductive toxicity data and will be able to provide guidance for risk assessment in reproductive toxicity evaluation.

CE 5 IMMUNOLOGY FOR TOXICOLOGISTS.

I. Kimber[1] and R. Pieters[2]. [1]*University of Manchester, Manchester, United Kingdom and* [2]*IRAS Utrecht University, Utrecht, Netherlands.*

The adaptive immune response that is found in mammals comprises a dedicated interacting system of tissues, cells and molecules that work in concert to provide specific immune responses and host resistance to pathogenic microorganisms and transformed cells. Specific immunity is supplemented by, and works in harmony with, the phylogenetically more ancient innate immune system. Immunotoxicology describes the study of adverse health effects that may result from the interaction of xenobiotics with one or more components of the immune system. Such health effects may take a variety of forms. These include frank immunotoxicity where there is a functional impairment of the immune system. The concern here is that compromised immune function may translate into an increased susceptibility to infectious and/or malignant disease. A second potential consequence of the interaction of chemicals or proteins with the immune system is allergy: defined as the adverse health effects that may arise from the stimulation of a specific immune response. Allergic disease may take one of several forms, those of greatest significance for toxicologists being skin sensitization and allergic contact dermatitis, allergic sensitization of the respiratory tract, food allergy, and idiosyncratic drug reactions. Finally, xenobiotics have also been implicated in the induction or exacerbation of autoimmune responses and autoimmune disease. This basic grade course will provide a firm grounding in fundamental and clinical aspects of immunology, and will describe the basic elements of immunotoxicity, allergy and autoimmunity in view of the interaction between innate and adaptive immunity. The objective is to deliver an accessible guide to the immune system and immunotoxicology for general toxicologists.

CE 6 PRINCIPLES AND APPLICATIONS OF TOXICOKINETICS.

M. J. Bartels[1] and C. Timchalk[2]. [1]*Dow Chemical, Midland, MI and* [2]*Batelle Pacific Northwest Laboratories, Richland, WA.*

Toxicokinetic (TK) data play an important role in chemical risk assessments. Chemical risk assessments are increasingly incorporating consideration of the mode of action (MOA) of the chemically-induced toxicity. Increasing reliance on MOA in

such evaluations in turn requires increasingly detailed information regarding the active chemical moiety (parent compound or metabolite) and relevant target tissue dose metrics. This course will begin by providing background on the need for and role of toxicokinetic data in risk assessments. This presentation will include a discussion of the interaction between evaluation of MOA and toxicokinetic data and the role of such data in both interspecies and high to low dose extrapolations in risk assessment. We will go on to describe basic principles of pharmacokinetics from both the classical and physiologically-based approaches. The presentation will provide the conceptual and mathematical basis for developing a better understanding of pharmacokinetics and how pharmacokinetic analyses are conducted. In addition, to this analyses we will address elements of the design of toxicokinetic studies. This presentation will include discussion of the interaction of key chemical characteristics with study design parameters and of the sampling and analysis considerations that shape study design. Finally, the presenters will provide examples of the integration of toxicokinetic data into current risk assessments, including the incorporation of human biomonitoring data in the evaluation of chemical exposures and risks.

CE 7 TRANSLATION OF SAFETY BIOMARKERS IN DRUG DISCOVERY AND DEVELOPMENT.

K. A. Criswell[1], N. Everds[2], D. Bounous[3], K. Criswell[1], J. Colangelo[1] and B. R. Michael[4]. [1]*Drug Safety, Pfizer Global Research & Development, Groton, CT,* [2]*Amgen Pharmaceutical, Seattle, WA,* [3]*Bristol-Myers Squibb, Princeton, NJ and* [4]*Michigan Technology & Research Institute, Ann Arbor, MI.*

There are several major areas that prove problematic in translating animal data/biomarkers to humans. This 5-speaker session will focus on translational issues identified in hematology, clinical chemistry, coagulation, protein assays and peptide assays. It will conclude with a risk assessment presentation that summaries the overall process in defining human relevance of safety and efficacy from preclinical data. Preclinical data gathered in laboratory animals is required by regulatory agencies to determine safety in humans prior to marketing of new drugs and applications. Species-specific differences in routine and more esoteric serum biomarkers may make the relevance of findings in animals difficult to interpret. Knowledge in this area is beneficial to the safe conduct of clinical trials and the inclusion of relevant biomarkers as effective safety and efficacy endpoints during new product development.
Research scientists, industry scientists, laboratory personnel, and pathologists interested in biomarker development, translation, execution and applications from preclinical through clinical trials may be interested. This symposium will focus on the difference between data obtained in preclinical and clinical circumstances. Therefore, it may be of interest to anyone in a preclinical research setting through those engaged in clinical trials.
After the session the participants will be able to 1) identify potential relevance or non-relevance of animal-based hematologic and clinical chemistry biomarkers to humans, 2) Assess the reliability of using coagulation biomarkers in preclinical species, 3) Identify methods of overcoming species-specific problems in protein and peptides biomarkers to allow translation, and 4) understand the overall process required to determine human relevance of animal data and the impact of biomarker utilization on speed and decision-making.

CE 8 CHARACTERIZING VARIABILITY AND UNCERTAINTY WITH PHYSIOLOGICALLY BASED PHARMACOKINETIC MODELS.

H. A. Barton[1], R. Setzer[1], G. Johanson[2] and C. Tan[3]. [1]*ORD National Center for Computational Toxicology, U.S. Environmental Protection Agency, Research Triangle Park, NC,* [2]*Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden and* [3]*Center for Human Health Assessment, The Hamner Institutes for Health Sciences, Research Triangle Park, NC.*

As pharmacokinetic (PK) models are increasingly applied in risk and safety assessments it is critical to improve the characterization of variability and uncertainty. Variability describes real differences among individuals arising from external exposure pathways, diet, health status, genetics, and other factors that contribute to differences in internal exposures or tissue dosimetry. Absent perfect knowledge, there are uncertainties arising from a range of sources including experimental error, that can impact confidence in model predictions. Physiologically based pharamacokinetic (PBPK) models provide a biologically motivated description of processes influencing the absorption, distribution, metabolism, and excretion of endogenous compounds or xenobiotics. PBPK models rely on a wide range of in vitro and in vivo data to estimate parameter values and demonstrate the predictive capabilities of the models. This course will describe characterization of variability and uncertainty using PBPK models from a number of perspectives. The range of PBPK model structures and their applications in risk and safety assessment will be presented. How to approach characterizing uncertainty in the presence of variability will be described. Data from humans can be analyzed using PBPK models to characterize PK variability. Finally, linking variations in external exposure pathways with PK variability provides methods to characterize human dosimetry for use in risk assessments or interpretation of biomonitoring data.

CE 9 CURRENT APPROACHES IN MIXTURE RISK ASSESSMENT.

M. Mumtaz[1], A. B. Lowit[2], C. J. Borgert[3] and K. Krishnan[4]. [1]*ATSDR, Atlanta, GA,* [2]*OPP, U.S. EPA, Washington, DC,* [3]*Applied Pharamcology and Toxicoogy Inc., Gainesville, FL and* [4]*Université de Montréal, Montreal, QC, Canada.*

Human exposure to combinations of chemicals and drugs is an everyday reality of life. There is tremendous interest in scientific and regulatory tools for evaluating the joint toxic action of chemicals and drugs in mixtures. This course will instruct participants in the methods and tools reflective of the current state of knowledge in the area of mixture risk assessment, as well as illustrative, real-life examples of their application to risk assessment. The first talk will introduce the various approaches to mixture risk assessment and illustrate the use of these methods to assess risks associated with human exposure to contaminants in selected hazardous waste sites. The second talk will describe the process of cumulative risk assessment of pesticides, highlighting the use of pharmacokinetic, pharmacodynamic and relative potency factors in the process. The third presentation will describe the development and application of relative potency factor approach to evaluate safety of mixtures of drugs. The final talk will discuss the current approaches and tools for assessing the role of interactions in mixture risk assessment, with particular emphasis on the use of physiologically-based pharmacokinetic (PBPK) models. Included in this course will be data evaluation strategies, data sets from real world examples, exercise results, and discussion of uncertainty pertaining to the application of various mixtures procedures. This course will be of interest to experimentalists, modelers, epidemiologists and risk assessors interested in the assessment of health risks associated with human exposure to chemical and/or drug mixtures.

CE 10 HOW SIMILAR IS SIMILAR AND HOW RELEVANT IS RELEVANT? CONSIDERATIONS IN THE DESIGN OF A PREDICTIVE DEVELOPMENT PROGRAM FOR BIOTHERAPEUTICS.

L. Burns-Naas[2], F. Geoly[3], J. Bussiere[4], J. Cavagnaro[5] and L. Andrews[1]. [1]*Pharmacology and Toxicology, genzyme, Framingham, MA,* [2]*Drug Safety Research and Development, Pfizer, San Diego, CA,* [3]*Pathology, Pfizer, Groton, CT,* [4]*Amgen, Thousand Oaks, CA and* [5]*Access BIO, Boyce, VA.*

Preclinical development programs that are designed to support the safe clinical use of biopharmaceuticals have considerations that are very different from programs designed to support the development of small molecule drugs. In particular, with more and more targeted therapeutics being developed a traditional development program is becoming more and more difficult. While the ICH S6 guidance continues to drive the program decisions more often than not a different approach is warranted due to species specificity and paucity of relevant animal models. To design a predictive non clinical program that will support not only first in human dosing but also eventual approval of the therapeutic is becoming more complex. Assuring safety in humans is the first and foremost task of a well designed program but assuring safety and application to specific patient populations is also essential to the targeted therapeutic products.
Topics to be addressed in this course will include general pathology and physiology issues between species that might contribute to species selection/interpretation, utility of tissue cross reactivity to determine relevant species, considerations into the development of a homologous protein (from bench to beast), development and characterization of animal models as relevant species (including KO animals and models of disease), and additionally what to do if nothing is "relevant". The course attendee will learn key concepts in the considerations for designing a predictive program for a biotherapeutic product.

CE 11 NEW FRONTIER IN METAL TOXICOLOGY: GENETIC SUSCEPTIBILITY, EARLY DIAGNOSIS, AND RELATED BIOLOGICAL INDICES.

C. D. Klaassen[2], M. P. Waalkes[3], D. A. Cory-Slechta[4], W. Zheng[1] and M. J. McCabe[4]. [1]*Purdue University, West Lafayette, IN,* [2]*University of Kansas, Kansas City, KS,* [3]*NCI at NIEHS, RTP, NC and* [4]*University of Rochester, Rochester, NY.*

Physical and chemical properties of many toxic metals are common in their tendency to donate electrons, their resistance to biotransformation and their similarity in physical sizes and electrical charges. Yet human responses to metal insults are not

uniform at all such that metal-caused diseases may manifest in a particular population and spare in others. With a better understanding of gene-environmental interaction, it becomes clear that the genetic predisposition may exist in exposed individuals who have an inherited sensitivity to metal-induced disorders. Thus, the individual susceptibility must be taken into account when developing biomarkers for exposure and/or risk assessment. In many clinical cases, the signs and symptoms of metal intoxication are subtle, undetectable and imperceptible. Because of these, clinically well defined metal diseases, such as manganese-caused parkinsonism or lead-induced learning deficit, are usually diagnosed too late for an effective therapeutic intervention. Thus, a reliable biomarker of a particular type of metal diseases, developed either based on injuries in biochemical and physiological functions or alterations in cellular signal pathways, bears a quintessential importance in metal toxicity research. This advanced course is intended to address the biological indices of metal toxicities from the angle of individual genetic susceptibility and populational adaptability for early diagnosis, by providing cutting-edge knowledge on the concepts, theories, clinical outcome, and research methodologies in this area. The Introduction will briefly review the unique physical, chemical and biological properties of metals which distinguish them from organic chemicals. The first lecture will discuss the recent advancement in understanding the genetic susceptibility that contributes to metal-induced toxicities. The second lecture will provide an overview on metal-related biomarkers that were established from animal and human studies and the application of these biomarkers in clinical diagnosis. The third lecture will use manganese as an example to address the methodological approaches to develop biomarkers and explore novel ideas to combine exposure indices with biological outcomes. The final lecture will illustrate an innovative way to explore metal toxicity by targeting at metal interaction with the cellular signal pathways. Speakers will survey these new frontiers in metal toxicological research by providing details specific to "hot" metals, such as lead, manganese, arsenic and mercury. Speakers will also discuss pertinent concerns and controversies, including mechanistic-based risk assessments, related to risks to humans exposed to these metals. The course will serve the purpose for those who desire an advanced introduction to mechanisms of metal toxicities, an advanced knowledge on metal-gene interaction and risk assessment, and an advanced technical approach in developing a useful biomarker for metal intoxication. The course will be of interest to others engaged in wider aspects of metal toxicology, neurotoxicology, carcinogenesis, risk assessment, and occupational health.

CE 12 STRESS AS A CONFOUNDING FACTOR IN TOXICOLOGY STUDIES.

K. Sprugel[1], D. Dorman[3], N. Everds[2], G. Foley[4], P. Snyder[5] and A. Jacobs[6]. *[1]Toxicology, Amgen, Seattle, WA, [2]Pathology, Amgen, Seattle, WA, [3]North Carolina State University, Raleigh, NC, [4]Schering Plough, Summit, NJ, [5]Veterinary Pathobiology, Purdue University, West Lafayette, IN and [6]ONDIO/CDER, Food & Drug Administration, Silver Spring, MD.*

Stress can confound the interpretation of toxicity studies. The biology of stress includes complex interrelationships between neurologic and endocrine pathways. Stressors can have effects on in-life, clinical pathology, endocrine, and immune system parameters. Effects on any of these systems may be observed during a toxicity study. The challenge in toxicology is to differentiate between primary test article-related changes and secondary changes related to stress. This differentiation is crucial to the assessment of stress in the regulatory environment. Major systems impacted by stress and the types of responses seen will be discussed. Biomarkers that are suggestive of a stress response will be discussed. Case studies will be presented to illustrate the challenges and best practices in characterization and interpretation of stress responses.

S 13 EAT WELL, BREATHE WELL: NUTRITIONAL DETERMINANTS OF SUSCEPTIBILITY TO AIRBORNE POLLUTANTS.

J. G. Wagner. *Michigan State University, East Lansing, MI.*

Susceptibility factors for adverse responses to air pollutant exposure include the host genome, exposure history, disease, age, and diet. In particular, the role of the underlying nutritional status has emerged as an important but understudied determinant of enhanced airway reactivity, inflammation, and immune responses that might be elicited or exacerbated by airborne toxicants. For example deficiencies in certain micronutrients are associated with enhanced inflammation to ozone, and dietary supplementation with antioxidants can protect from ozone-induced deficits in airway function. Both clinical and animal studies demonstrate that ozone-induced airway reactivity is related to increased body mass index. Similar relationships of nutritional factors and adverse airway responses exist for diesel exhaust, particulate matter, and cigarette smoke. Specific cellular and airway defenses include small molecular weight antioxidants (e.g., ascorbate, glutathione), and enzyme systems (e.g., catalase, SOD, Phase II enzymes) which are directly or transcriptionally affected by the diet. In addition, the type and amount of dietary lipids can predispose for either pro-or anti-inflammatory pathways. Based on our growing understanding of toxicological mechanisms that underlie the responses to many different types of inhaled pollutant exposure, it is now possible to test specific hypotheses for nutrient or lipid-based dietary interventions to protect from adverse airway inflammatory responses and their consequences in susceptible populations. To gain a clear understanding of these issues, it is important to address the current thinking and results from preclinical and clinical translational studies, approaches that merge basic toxicological principles and biochemical nutritional science, and actively study the comparison of nutrient deficiency, supplementation and energy imbalance on toxicological outcomes from air pollutant exposure.

S 14 FOOD FOR THE LUNG: HOW NUTRITION AFFECTS RESPIRATORY TOXICOLOGY.

I. Jaspers. *University of North Carolina, Chapel Hill, NC.*

Nutrition has been well recognized as an important factor influencing a number of biological processes including immune responses and ageing, as well as diseases, such as cancer. However, whether and how the nutritional status of an individual could modify responsiveness to inhaled toxicants is not well understood. In the context of the ongoing obesity epidemic as well as the continually growing market for nutritional supplements, the importance of potential interactions between nutrition and effects elicited by inhaled toxicants become apparent. This overview will discuss the significance of the relationship between nutrition and adverse health effects induced by inhaled toxicants.

S 15 CIGARETTE SMOKE AND ANTIOXIDANT THERAPIES IN COPD.

I. Rahman. *University of Rochester, Rochester, NY.* Sponsor: J. Wagner.

Oxidative stress from cigarette smoking induces inflammation and is an important etiological factor in the pathogenesis of chronic obstructive pulmonary disease (COPD). Antioxidant agents such as thiol molecules (glutathione and mucolytic drugs, such as N-acetyl-L-cysteine and N-acystelyn), dietary polyphenols (curcumin-diferuloylmethane, a principal component of turmeric; resveratrol-a flavanoid found in red wine; green tea-epigallocatechin-3- gallate; catechins/quercetin), can control nuclear factor-kappaB (NF-kappaB) activation, regulation of glutathione biosynthesis genes, chromatin remodeling, and hence airway inflammation. This presentation will discuss the role of oxidative stress in key signal transduction pathways and histone modifications involved in lung inflammation in response to cigarette smoke. Current results from studies using dietary polyphenols to modulate redox signaling and hence downregulation of pro-inflammatory mediators will also be emphasized

S 16 PROTECTION FROM OZONE AND ENDOTOXIN-INDUCED AIRWAY INFLAMMATION BY GAMMA-TOCOPHEROL.

J. G. Wagner. *Michigan State University, East Lansing, MI.*

Vitamin E (alpha-, beta-, gamma-, and delta- tocopherols and tocotrienols), is best known as a lipid-soluble antioxidant, but is also capable of modulating cellular functions important in immunity and inflammation. However alpha-tocopherol, the Vitamin E isoform for which an RDA has been established and is well-documented to limit lipid peroxidation pathways, has been ineffective against ozone-induced inflammation in both human and animals. We will present data demonstrating novel antinflammatory properties of gamma-tocopherol, a vitamin E isoform common in diets of corn, walnuts and sunflower seeds, to inhibit eicosanoid and cytokine production in airways and to limit nitrosative stress, inflammatory cell recruitment and airway hyperreactivity. Experimental results from allergic and non-allergic animals exposed to ozone or endotoxin will be presented.

S 17 DIETARY INTERVENTION WITH SULFORAPHANE, A PHASE II ENZYME INDUCER TO PROTECT FROM AIRWAY INFLAMMATION.

D. Diaz-Sanchez. *U.S. Environmental Protection Agency, Chapel Hill, NC.* Sponsor: J. Wagner.

Cellular oxidative stress is thought to be the principle mechanism by which oxidant pollutants such as ozone and particulates mediate their pro-inflammatory effects. Intervention studies with exogenous antioxidants have met with mixed results. An

alternative strategy is the induction of endogenous antioxidants such as Phase II enzymes that lead to the production and metabolism of glutathione, among others. This presentation will focus on results from in vitro, animal, and human studies using sulforaphane, a potent inducer of Phase II enzymes that occurs naturally in cruciferous vegetables. We have recently conducted a clinical trial using broccoli sprouts that contain high levels of sulforaphane, to induce mucosal Phase II enzyme expression in the upper airway of human subjects. Results from this and ongoing human studies that investigate the effectiveness of this nutritional intervention to prevent inflammatory effects of oxidative stress induced by pollutants will be presented.

S 18 OBESITY ENHANCES AIRWAY INFLAMMATION AND REACTIVITY TO OZONE.

S. Shore. *Harvard University, Boston, MA.* Sponsor: J. Wagner.

Emerging data indicates that changes in pulmonary function induced by ozone are increased in obese individuals. Data from our lab indicate that obese mice also have augmented responses to acute ozone exposure. Mice obese because of genetic deficiencies in leptin (ob/ob mice), the leptin receptor (db/db mice), carboxypeptidase E (Cpefat mice), as well as mice with diet induced obesity, each exhibit more robust ozone-induced increases in pulmonary resistance, airway responsiveness, and airway inflammation than lean mice. Data will be presented from these mouse models describing a role for adipokines including IL-6, TNFα, and adiponectin, in the relationship between obesity and responses to ozone

S 19 COMPLEMENTARY AND ALTERNATIVE MEDICINE (CAM)IN PROTECTING AGAINST INHALED TOXICANTS.

D. B. Peden. *University of North Carolina, Chapel Hill, NC.* Sponsor: J. Wagner.

Complementary and alternative medicine (CAM) therapies are an attractive approach to minimize airway responses to common environmental and occupational inducers of asthma and allergy exacerbation, such as ozone and endotoxin. Consequently, studies applying cutting-edge technologies to identify the underlying mechanisms and optimal use of anti-inflammatory CAM modalities are needed. We are currently translating in vitro and preclinical findings that used therapies predominately derived from food sources into clinical studies. Using established protocols, we are testing both the safety and efficacy of novel anti-inflammatory and antioxidant CAM therapies to modify pollutant-induced exacerbation of airway inflammation in human volunteers. Stratification of the study group by polymorphisms in key inflammatory or antioxidant genes (i.e., TLRs, GSTs) will enhance our understanding of both the toxicological and therapeutic outcomes. A broad overview of how nutritional CAM agents might be used in clinical studies to modify pollutant-induced exacerbation of asthma will be discussed.

S 20 MicroRNAs IN BIOLOGY AND TOXICOLOGY.

M. E. Hahn[1] and R. F. Novak[2]. *[1]Biology, Woods Hole Oceanographic Institution, Woods Hole, MA and [2]Wayne State University, Detroit, MI.*

Gene expression is highly regulated at many levels and altered gene expression is an important part of many toxicological mechanisms. Very recently, a fundamentally new mechanism of gene regulation, involving small RNAs known as microRNAs (miRNAs), has been discovered. MicroRNAs are single-stranded RNA molecules of ~22 nucleotides that function to regulate the synthesis of proteins by inhibiting the translation of mRNAs and promoting their degradation, or in some cases by stimulating their translation. MicroRNAs are abundant and evolutionarily conserved in eumetazoan animals. The human genome encodes hundreds of miRNAs, and a similar number of miRNAs occur in the genomes of other animals. Each miRNA can target hundreds of different messenger RNAs for degradation; up to 20% of the genes in a given genome may be regulated by miRNAs. The biological functions of miRNAs are not fully understood. However, recent studies have demonstrated important roles for miRNAs in the regulation of transcription factor expression and in pre-mRNA splicing. Studies in zebrafish and mammals have shown that miRNAs have important roles during embryonic development and that disruption of miRNA synthesis in embryos can have dramatic consequences. Altered miRNA expression is seen in a variety of cancers and in some cases is involved in the mechanism of tumorigenesis. Furthermore, miRNAs are involved in several human diseases and appear to regulate cellular responses to a variety of physiological and environmental stressors, including diabetes, high blood pressure, nutrient stress, hypoxia, and environmental chemicals. Thus, miRNAs have critical biological functions and there is an emerging understanding of the important role of miRNAs in toxicology, development, metabolic disease, and carcinogenesis. MicroRNAs have not yet been widely studied in a toxicological context; however, it seems likely that these small RNAs may have significant roles in regulating the genomic, proteomic and functional response of cells and tissues to chemicals. [Supported by a WHOI Independent Study Award and by Walter A. and Hope Noyes Smith.]

S 21 MicroRNA REGULATION OF SIGNALING PATHWAYS DURING DEVELOPMENT.

J. G. Patton. *Vanderbilt University, Nashville, TN.* Sponsor: M. Hahn.

Recent genomic analyses have suggested that higher eukaryotic genomes are pervasively transcribed but that most RNA transcripts are noncoding. MicroRNAs are a family of gene regulatory small noncoding RNAs that inhibit translation when paired with elements in the 3' UTR of target mRNAs. Target pairing is imperfect enabling microRNAs to target multiple genes and a key remaining question is to identify the exact targets and functions of specific microRNAs. We have been using zebrafish as a model system to study microRNA function during early vertebrate development. Using gain of function and loss of function experiments, we have discovered multiple levels of microRNA regulation controlling the Hedgehog and Wnt signaling cascades during muscle development and fin regeneration. Additionally, we have discovered a regulatory role for miR-200b in controlling trafficking of transmembrane proteins during osmotic stress.

S 22 MicroRNAs IN HUMAN CANCERS AND CARCINOGENESIS.

C. M. Croce. *College of Medicine, The Ohio State University, Columbus, OH.* Sponsor: M. Hahn.

Expression profiling has revealed that microRNAs are dysregulated in a variety of human cancers, and microRNA profiles have proved useful in classifying tumors. In addition, some microRNA alterations are characteristic of multiple tumor types, suggesting an important role of microRNAs as tumor suppressors or oncogenes. This presentation will review the role of microRNAs in human cancers, focusing on two case studies. One involves the down-regulation of miR-15a and miR-16-1 in chronic lymphocytic leukemia (CLL), the most common adult human leukemia. Deletion of these microRNA genes is thought to be involved in a substantial fraction of CLL cases. miR-15a and miR-16-1 act as tumor suppressors, targeting the BCL2 oncogene. In contrast, members of the miR-17/92 cluster are overexpressed in a variety of human tumors and stimulate cell proliferation. The important roles of microRNAs in cancer points to their potential as therapeutic targets.

S 23 ABERRANT microRNA EXPRESSION IN HUMAN BREAST ONCOGENESIS.

A. A. Dombkowski[1], R. Ranganathan[1], D. Cukovic[1], J. Zheng[1], S. Gajjala[1], R. F. Novak[1] and F. R. Miller[2]. *[1]Institute of Environmental Health Sciences, Wayne State University, Detroit, MI and [2]Karmanos Cancer Institute, Detroit, MI.*

Breast cancer is believed to develop in a multistep process, with premalignant lesions preceding invasive carcinoma. While recent work has implicated microRNAs in a variety of human diseases, including cancer, little is known about the role of microRNAs in preneoplastic events that precede malignant transformation. In this work we characterize miRNA expression associated with breast oncogenesis using a multistep cell line model comprised of MCF10A, AT, 3B, CA1h, and CA1a cell lines, and in associated mouse xenografts. This isogenic cell line series represents a progression from benign to premalignant cells to invasive carcinoma. Global miRNA microarrays were used to identify miRNAs that exhibit differential expression correlating with the progression of the disease. Principal components analysis (PCA) demonstrates that the cell lines are segregated along a trajectory of oncogenic potential based on the miRNA expression profiles. Among the microRNAs showing a marked increase of expression in the cell line progression are miRs 21, 200a, 200b, and 429. Several clusters of miRNAs were identified; each consisting of highly correlated expression profiles. Bioinformatics analysis of downstream targets using miR-AT, a computational tool developed in our laboratory, reveals gene ontologies and biological pathways associated with the target genes. Our results indicate that preneoplastic changes in miRNA expression may portend events observed in invasive carcinoma. These premalignant alterations offer potential opportunities for risk assessment biomarkers and targets for early intervention. This research was supported by the Wayne State University President's Research Enhancement Program, and microarray, bioinformatics, and cell culture work was facilitated by NIEHS P30 Center grant ES06639.

S 24 MicroRNA EXPRESSION IN HEPATIC AND NON-HEPATIC TISSUES OF DIOXIN-EXPOSED RODENTS.

A. B. Okey[1] and P. A. Harper[1, 2]. [1]*Pharmacology & Toxicology, University of Toronto, Toronto, ON, Canada and* [2]*Research Institute, The Hospital for Sick Children, Toronto, ON, Canada.* Sponsor: M. Hahn.

Dioxins such as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) are well-known to upregulate expression of hundreds of genes via the AH receptor (AHR). Gene expression-array studies in our laboratory and several other laboratories indicate that numerous genes also are downregulated by TCDD or by AHR status. Mechanisms of AHR-mediated upregulation (induction) by dioxin-like chemicals have been extensively studied but mechanisms of downregulation are obscure, as are the toxicologic consequences of downregulation. We hypothesized that downregulation of mRNA levels by TCDD was mediated by altered expression of microRNAs. Surprisingly, in livers of adult or fetal rodents TCDD has little effect on microRNA levels; thus microRNAs probably are not responsible for mRNA downregulation in liver nor are microRNAs likely to play a significant role in hepatic toxicity. In contrast to adult liver, TCDD causes significant changes in levels of several microRNAs in multiple non-hepatic tissues in fetal mice. MicroRNAs are particularly important in embryonic and fetal development. It is plausible that the potent teratogenic effects of TCDD may involve alteration of microRNA levels during critical developmental stages.

S 25 THE ROLE OF NUCLEAR RECEPTORS IN miRNA TRANSCRIPTION.

Y. M. Shah and F. J. Gonzalez. *National Cancer Institute, National Institutes of Health, Bethesda, MD.* Sponsor: M. Hahn.

miRNAs are a family of non-coding RNAs that inhibit mRNA transcription and/or translation via imperfect base pairing to their target genes. Over 600 miRNAs have been identified in mammals and provide a critical level of gene regulation important in all aspects of cellular physiology. However, relatively little attention has been focused to date on the transcriptional regulation of microRNAs within a cell. Profiling analyses have shown that the nuclear receptor (NR) superfamily of liganded transcription factors are major regulators of miRNA biogenesis. Several lines of evidence point to transcriptional regulation as the main step in the control of miRNA expression. NR regulation of miRNA transcription provides authentic cis binding sites and promoter regions of miRNA genes and may offer a unique opportunity to modulate miRNA expression for potential therapeutic intervention.

S 26 SUPERANTIGENS, CYTOKINE STORM, AND TOXIC REACTIONS.

G. Gerberick[1] and I. Kimber[2]. [1]*Procter & Gamble Co., Cincinnati, OH and* [2]*University of Manchester, Manchester, United Kingdom.*

The term superantigen (SAg) was coined by Marrack and Kapler in 1990 to describe a large family of exotoxins secreted primarily by Staphylococcus aureus and Streptococcos pyogenes that are associated with adverse health effects that can range from relatively mild and transient symptoms to catastrophic shock and death. These toxins have been implicated in a number of diseases including scarlet fever, staphylococcal food poisoning and cases of both streptococcal and staphylococcal toxic shock syndrome, as well as being suspected of playing roles in autoimmune diseases. A unique feature of SAgs is that, unlike conventional antigens, they do not require processing by antigen presenting cells (APC) and they can interact with a large proportion of T cells. SAgs have been well characterized and have very specific binding sites on the α or β chain of MHC class II molecules expressed on APC, and on the Vβ chain of the T cell receptor forming a tri-molecular complexes that bridge SAgs with T cells and APCs, thereby enhancing intracellular interactions. The polyclonal stimulation of T cells in juxtaposition with APC by SAgs leads to extensive cytokine production by both cell types including interleukin (IL)-2, interferon-γ and tumor necrosis factor-β by T cells, and IL-1β and tumor necrosis factor-β by APC. The collective action of these cytokines, known as cytokine storm, is the trigger for the clinical manifestations of superantigen immunotoxicity. Moreover, adverse health effects precipitated by cytokine storm are relevant also for considerations of drug safety. One illustrative example of the clinical picture of the TeGenero TGN1412 therapeutic monoclonal antibody was observed in the London UK 2006 trial. Finally, the structure of superantigens, the mechanisms through which they interact with the immune system, and the nature and clinical consequences of cytokine storm will be described and reviewed.

S 27 STRUCTURE AND FUNCTION OF SUPERANTIGENS.

I. Kimber. *University of Manchester, Manchester, United Kingdom.*

The first presentation will provide a background on what is known about the molecular structure and function of superantigens as immunotoxicant agents that are produced by bacteria and viruses. In recent years, much knowledge has been gained on how these fascinating molecules interact with biological systems to cause adverse health effects. Superantigen molecules are approximately 20 to 25 kD in molecular weight and are bifunctional in that they utilize at least two types of receptors expressed on immune cells. Specifically, each superantigen has a unique immune fingerprint based on its specificity for T-cell receptor Vβ2 elements and MHC Class II gene products.

S 28 CLINICAL MANIFESTATIONS OF SUPERANTIGEN DISEASES.

J. Parsonnet. *Dartmouth-Hitchcock Medical Center, Lebanon, NH.* Sponsor: F. Gerberick.

Superantigen mediated diseases range from common food poisoning to streptococcal toxic shock syndrome (flesh-eating bacterial disease). Superantigens are suspected in association with autoimmune diseases such as Kawasaki disease and Rheumatoid arthritis. Each of these diseases presents with a constellation of unique clinical signs and symptoms. Treatment of these diseases many involve antibiotics that reduce toxin production in combination with i.v. immunoglobulin (IVIG) therapy.

S 29 IMMUNE RESPONSES TO SUPERANTIGENS.

M. Kotb. *University of Cincinnati, Cincinnati, OH.* Sponsor: F. Gerberick.

Superantigens are unique in disease pathogenesis in that they form a trimolecular complex with the T-cell receptor and MHC Class II molecules on antigen presenting cells that lead to a cytokine storm. A unique feature of superantigens is that, unlike conventional antigens, they do not require processing by antigen-presenting cells and they can interact with a large number of T cells. Neutralizing antibodies are key to protecting the host from disease progression and newer research indicates that genetic susceptibility factors may be key in the intensity of the host response. For example, HLA alleles differ in their ability to present different SAgs and recent structural analyses has revealed that bound peptide may also play a role in modulating SAg binding to the MHC implying a linkage with susceptibility to SAg immunotoxicity. Specific human HLA haplotypes conferred strong protection from severe systemic disease caused by invasive streptococcal infection, whereas other haplotypes actually increased the risk of severe disease.

S 30 EXPERIMENTAL MODELS FOR EVALUATING BIOAVAILABILITY OF SUPERANTIGENS.

C. Squier. *University of Iowa, Iowa City, IA.* Sponsor: F. Gerberick.

Human diseases caused by superantigens begin with their interaction with epithelial cells such as those of the skin, oral, nasal or vaginal mucosa. In the study of superantigen-mediated diseases, it has become important to understand mechanistically the exposure to superantigens, especially through mucosal tissues. The histological classification of epithelial tissues can have effect on the permeability of superantigens and is based on features such as the number of cell layers, shape of cells and specialization of cells as well as presence and composition of the lipid-based permeability barrier. It is known also that other toxins or disruption of epithelial barrier can have a profound impact on the permeability and eventual systemic bioavailability of superantigens.

S 31 TOXICOLOGICAL CONSIDERATIONS FOR SUPERANTIGEN-MEDIATED DISEASES.

G. Gerberick. *Procter & Gamble Co., Cincinnati, OH.*

Superantigens can be considered as immunotoxicants that cause disease through their extreme activation of the immune system. However, the amount and dose metric for superantigen-mediated diseases is not understood well. In some instances, bacteremia is not a feature of the disease. For example, TSST-1 mediated menstrual toxic shock syndrome is believed not to involve any systemic infection of Staphylococcus aureus. Systemic penetration of the toxin through a mucosal barrier is a presumptive prerequisite for the development of the acute illness. It is reported that superantigens can stimulate T-cells in the picomole range.

S 32 ZINC, INFLAMMATION, AND DIABETES: INTRODUCTION.

L. Cai. *Medicine & Radiation Oncology, University of Louisville, Louisville, KY.*

Diabetes is a serious public issue due to its risk for chronic cardiovascular complications. However, mechanisms by which diabetes causes cardiovascular complications remain incompletely understood. Zinc (Zn) is one of the most abundant metals in the human body and therefore essential for the structure and activity of more than 300 enzymes and proteins. Zn deficiency was found to be associated with diabetes, but the direct role of Zn in diabetic etiology and its mechanisms are under-explored. Recent studies have shown that chronic inflammation is not only related to the onset of Type I and Type II diabetes, but also related to the development of diabetic complications. Zn deficiency may cause systemic inflammation that in turn becomes the initiate factor for the onset of diabetes and the development of diabetic complications. The current understanding of the roles of Zn homeostasis in the insulin signaling, systemic inflammation, diabetes and diabetic complications will be explored, as will the public awareness of proper intake of Zn-containing food in daily life. A brief overview highlighting the association of Zn with inflammation, diabetes and diabetic complications will begin this session. An important component of this exploration will cover how Zn sensitizes insulin function and the association of Zn with inflammation, insulin resistance and obesity. Researchers are aware that Metallothionein (MT) plays a critical role in Zn homeostasis, therefore, MT gene alterations and its association with Zn status, inflammation, diabetes and diabetic complications will be discussed. Finally, the evidence of Zn to protect ischemic and the diabetic heart will be presented.

S 33 PATHOPHYSIOLOGY OF CELLULAR ZINC AND REDOX BUFFERING MECHANISMS IN DIABETES.

W. Maret. *The University of Texas Medical Branch, Galveston, TX.* Sponsor: L. Cai.

Interference with the homeostatic control of cellular zinc metabolism can compromise many functions and cause cellular injury. Homeostatic control includes dozens of zinc regulatory proteins, tight binding of zinc to proteins, and a relatively limited zinc buffering capacity. Furthermore, the cellular zinc and redox buffering capacities overlap, because cellular thiols have dual functions in redox reactions and in zinc binding. When these thiols react with environmental toxins or reactive species generated under conditions of oxidative stress, zinc ions increase above their resting picomolar concentrations and elicit a cytoprotective (pro-antioxidant) response through MTF-1- and NRF2-mediated gene expression. If the buffering and adaptive capacities of cells are exhausted, potentially cytotoxic (pro-oxidant) zinc ion concentrations can occur. A factor in the pathophysiological threshold for zinc ion fluctuations is metallothionein, a redox-active zinc metalloprotein, in which thiol reactivity and zinc binding are linked. These fundamental principles are important for cellular signaling, because zinc ions are potent effectors of proteins. For example, zinc is involved in insulin storage and secretion in beta-cells and in the modulation of insulin signaling in target organs. The insulin-enhancing actions of zinc ions are due to zinc inhibition of protein tyrosine phosphatase 1B, the major phosphatase regulating the phosphorylation state of the insulin receptor. Reactive carbonyls formed during aberrant glucose metabolism, reactive species generated during inflammation, nutritional deficiencies, and environmental exposures to toxins all affect cellular physiology by interfering with zinc homeostatic mechanisms.

S 34 ZN REGULATION OF SYSTEMIC INFLAMMATION AND INSULIN RESISTANCE IN OBESITY.

J. Ye. *Molecular Biology, Pennington Biomedical Research Center, Louisiana State University, Baton Rouge, LA.* Sponsor: L. Cai.

Inflammation is elevated in obesity, and involved in the pathogenesis of many obesity-associated complications, such as type 2 diabetes and cardiovascular diseases. Inflammation increases the risk of type 2 diabetes through impairment of insulin action. It reduces body's response to insulin, and leads to so called "insulin resistance". The molecular mechanism is related to inhibition of signal transduction of the insulin receptor pathway. Through this mechanism, inflammation is able to convert transient physiological "insulin resistance" into permanent pathological "insulin resistance", which is the earliest event of type 2 diabetes. In the inflammatory response, the IKK/NF-kB pathway is activated, and required for expression of inflammatory cytokines. In obesity, this signaling pathway is activated by fatty acids and their derivatives (such as DAG or Ceramide). Activation of toll-like receptor 4 (TLR4) and protein kinase C (PKC) are the downstream events of the bioactive fatty acids. Additionally, a hypoxia response in the adipose tissue also plays an important role in the activation of NF-kB. In the adipose tissue, macrophage infiltration is a marker of chronic inflammation and serves to promote inflammatory response. Inhibition of NF-kB activity in macrophages is able to prevent inflammation, and protect mice from insulin resistance. Zn has dual activities in the regulation of NF-kB activity. It is required for DNA-binding of NF-kB, and also involved in activation of the negative feedback loop of the NF-kB pathway. At a high concentration, Zn may inhibit inflammation through the negative feedback mechanism. These possibilities suggest that administration of Zn in obese condition may reduce inflammation and provide beneficial effects in the prevention of inflammation, insulin resistance and type 2 diabetes.

S 35 METALLOTHIONEIN GENE POLYMORPHISMS AND ZINC HOMEOSTASIS IN THE SUSCEPTIBILITY OF DIABETES MELLITUS AND CARDIOVASCULAR COMPLICATIONS.

R. Giacconi[1], M. Malavolta[1], A. Bonfigli[2], R. Testa[2], F. Lattanzio[3] and E. Mocchegiani[1]. *[1]Immunology Center (Laboratory of Nutrigenomic and Immunosenescence), Research Department, INRCA, Ancona, Italy, [2]Diabetology Unit, INRCA, Ancona, Italy and [3]Scientific Direction, INRCA, Ancona, Italy.* Sponsor: L. Cai.

The contribution of zinc deficiency in diabetes pathogenesis has been reported in epidemiological studies. Zinc dyshomeostasis, favouring oxidative stress and inflammatory condition may play a role in diabetic cardiovascular complications (CVD). Metallothioneins (MT) are metal-binding proteins which regulates zinc homeostasis and counterbalance oxidative stress induced by the diabetic condition. Recently, several single nucleotide polymorphisms (SNPs) in MT genes have been involved in diabetes mellitus (DM2) predisposition. An association between –209 A/G MT2A polymorphism, hyperglycaemia, and the prevalence of ischaemic cardiomyopathy in old atherosclerotic patients with DM2 has been found. +647 Asp/Thr MT-1A polymorphism affects zinc homeostasis and is associated with longevity in Italian cohort. Thr/Thr genotype (named C+ genotype) is less frequent in centenarians and associated with lower intracellular zinc release (iZnR) induced by NO donors, increased MT levels and IL-6 plasma concentrations. We have found an association of +647 MT1A polymorphism with DM2. The study included 694 old Italian subjects: 242 healthy controls, 217 DM2 patients without CVD clinical evidence (DNC) and 235 diabetic patients with CVD diagnosis (DCVD). C+ carriers displayed higher glycemia and glycosylated hemoglobin than C- ones in DCVD group. A modulation of MT levels and iZnR in PBMCs were observed in DCVD cohort when related to +647 Asp/Thr MT1A polymorphism. In summary, we demonstrate an association of +647 Asp/Thr MT1A polymorphism with DM2 and its influence on glycemic control, iZnR and MT production, in presence of diabetic cardiovascular complications. These results enable us to further investigate the MT genetic background and zinc homeostasis in the prevention and treatment of DM2 and its complications.

S 36 PROTECTION OF METALLOTHIONEIN AND ZINC AGAINST DIABETIC COMPLICATIONS.

L. Cai. *Medicine, Pharmacology and Toxicology, University of Louisville, Louisville, KY.*

Cardiomyopathy and nephropathy are leading causes of mortality in diabetic patients. Although several mechanisms responsible for these complications have been proposed, oxidative stress has been widely considered as one of the major causes. Thus, several laboratories are trying to develop antioxidants used to prevent diabetic cardiomyopathy and nephropathy. Using animal models we and others have shown that metallothionein (MT) can provide a significant protection against diabetic cardiomyopathy and nephropathy. MTs are cysteine-rich metal-binding proteins with several suggested biological roles including antioxidant property. Both in vitro and in vivo studies have indicated that MT can act as an antioxidant in the heart and kidney to prevent any damage caused by a variety of oxidative stresses including diabetes. Since MT is ubiquitously expressed in mammalian tissues and is highly inducible by variety of reagents such as zinc, the potential clinical application for induction of MT as an antioxidant by zinc supplementation to prevent various diabetic complications including cardiomyopathy and nephropathy has been explored in diabetic animal models. Available clinical data also indicated beneficial effects of zinc supplementation against various diabetic pathogenesis. In addition, since zinc supplementation has been therapeutically used for several diseases in clinics, it is greatly potential for zinc to induce cardiac and renal MT synthesis for the prevention of cardiovascular diseases in diabetic patients.

S 37 SIGNALING MECHANISMS OF MYOCARDIAL PROTECTION BY ZINC.

I. Korichneva. *Medicine, UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ.* Sponsor: L. Cai.

The discovery of a novel regulatory role of zinc ions in redox signaling pathway, and identification and cloning of the molecular players in zinc homeostasis revealed that intracellular zinc signals and precise control of zinc movements are crucial for

proper cellular function. We were the first to demonstrate that oxidative stress triggers zinc release from the protein kinase C (PKC) regulatory domain executing the task of so-called "redox zinc switch", the reversible zinc release from the protein chelation sites upon oxidation of cysteines. Malfunction of this mechanism in ischemic hearts leads to zinc depletion of myocardial tissue that in turn may affect the integrity of important zinc-dependent proteins. Using Langendorff perfused rat and mouse hearts and fluorescent imaging combined with biochemical techniques we unveiled the protective action of intracellular supplementation of zinc ions to the hearts subjected to acute ischemia/reperfusion. We showed that the protection was linked to preservation of PKC isoforms delta and epsilon, which were tended to degrade rapidly to lower molecular weight fragments during oxidative stress. Surprisingly, the hearts of diabetic rats that had received streptozocin injection 5 weeks prior examination were protected from acute redox stress in Langendorff model reflecting probably the elements of preconditioning and elevated intracellular zinc. Zinc dyshomeostasis and serum zinc deficiency of diabetic animals prompted us to investigate zinc transporters in cardiomyocytes. We have found that the levels and the properties of the two transporters, members of solute-linked carrier (SLC30) gene family, ZnT1 and ZnT5 were changed in diabetic hearts. We further discovered that both transporters interact with PKC isoforms and changes in their expression affect translocation of both PKC delta and epsilon. The data suggest that zinc homeostasis and function of zinc transporters determine stress response and cardiac remodeling of diabetic myocardium and further propose investigation of protective role of zinc in oxidative stress and inflamation.

W 38 DOSE SELECTION AND DESIGN CONSIDERATIONS IN SAFETY STUDIES FOR BIOTHERAPEUTICS.

L. Andrews and T. MacLachlan. *Pharmacology and Toxicology, Genzyme, Framingham, MA.*

With many biotherapeutics being evaluated on a case-by-case basis there is often significant consideration that goes into selection of the highest doses to be used in a study, use of recovery groups, and the impact of immunogenicity on the outcome and interpretation of the study. Traditional approaches that rely upon a maximum tolerated dose for high dose selection may not be relevant or even feasible when considering biotherapeutic products. Establishing a range of toxicology endpoints in a study using a classical approach is often not feasibile or practical with biotherapeutic products due to challenges that might involve formulation, concentration, stability and volume issues. In addition, the use of recovery groups needs to be considered and the utility of the information gained from the use of additional animals added to a study. Aspects of full recovery evaluation and the impact of immunogenicity on the outcome and interpretation of the study design will be discussed. Challenges continue to exist in the appropriate study design for reproductive evaluation of biologics and the utiilty of such studies to the safety package. These considerations as well as challenges that may be encountered with reproductive study designs will be covered, in addition to addressing some of the challenges with respect to dose selection and study design considerations, including reproductive study designs for biotherapeutics. Emphasis will be placed on choosing a high dose for toxicology studies and how does that relate to clinical trial dosing strategies; the impact of immunogenicity on the dosing strategy and the potential to dose higher; the use and information to be gathered from recovery animals, and the selection of dose and dosing regimen for developmental and reproductive studies for biotherapeutics.

W 39 HOW HIGH IS HIGH ENOUGH WHEN SELECTING TOP DOSES FOR GENERAL TOXICOLOGY STUDIES?

C. Horvath. *Toxicology, Archemix Corp, Cambridge, MA.* Sponsor: L. Andrews.

In the practical art of applied nonclinical toxicology most of the recent debate on dose selection has focused on the method used for establishing the first-in-human dose (FIHD). Several methods have been proposed for this purpose, based on calculation of the no adverse effect (dose) level (NOAEL), pharmacologically active dose (PAD) or the minimum anticipated biologically effective (dose) level (MABEL). For many products, these methods will utilize pharmacology and/or toxicology information gathered from the low- or mid-dose groups, rather than the high-dose groups. Historically, high doses have been selected with the intention of demonstrating toxicity, often resulting in identification of the maximum tolerated dose (MTD) or dose-limiting toxicity (DLT). However, demonstration of toxicity or adverse effects, even if attributable to intended pharmacologic properties (supra-pharmacology), can be difficult for some products, especially biologics. For such products, there is a lack of consensus on the justification for selection of the highest dose in toxicology studies intended to support clinical dosing. Possible approaches might include a maximum feasible dose (MFD), multiple of human dose (MHD), multiple of human exposure (MHE), or other empirical selections (e.g., 100 mg/kg for monoclonal antibodies). Even if the highest dose is not identified as an MTD, it may provide significant safety margins over the lowest and highest planned human doses. However, even if the high dose exceeds the maximum pharmacologic effect dose (MPED), failure to establish an MTD may be seen by some regulatory reviewers as a reason to delay clinical development. This presentation will attempt to provide rationales for selecting the top dose for general toxicology studies.

W 40 RECOVERY GROUPS: A NECESSARY EVIL? PRECLINICAL DEVELOPMENT CONSIDERATIONS FOR DETERMINATION OF THE NEED FOR AND DURATION OF RECOVERY GROUPS.

J. Green. *Preclinical and Clinical Development Sciences, BiogenIdec, Cambridge, MA.*

The purpose of IND/CTX enabling toxicology studies is to identify and characterize potential target organs of toxicity that are related to the administration of the experimental drug under conditions that would simulate clinical use. In some cases the target organs of toxicity are found to be related to a targeted pharmacology and are referred to as primary or secondary 'hyperpharmacology' responses and in other cases the target organs may be related to off target effects. An important initial assessment of severity of the target organ change is whether or not this change is found to be reversibly upon cessation of treatment. In some cases the assessment of complete recovery of organ toxicity is relatively straight forward provided the study design has incorporated recovery groups and the duration of the recovery period is sufficiently long. In other cases, the assessment of recovery may be confounded by limitations of the study design and conclusions regarding the reversibility of a particular lesion may be less clear. In addition, for some biologics with very long residence times in vivo following the cessation of treatment (e.g., some mAbs) recovery times may be of very long duration in order to allow sufficient time for the completely clear the systemic circulation and allow for hyperpharmacologic effects to reverse. This lecture will comprehensively address considerations related to the incorporation of recovery groups into the design of toxicology studies intended to support the safe use of biotherapeutics in clinical development.

W 41 IMPACT OF IMMUNOGENICITY ON HIGH DOSE SELECTION FOR CHRONIC STUDIES – SHOULD YOU DOSE HIGHER? PROS AND CONS.

D. Weirda. *Biopharmaceutical Immunotoxicology, Eli Lilly & Co, Indianapolis, IN.*

The formation of neutralizing anti-drug antibodies in non-clinical studies with human biopharmceuticals may effectively reduce the pharmacodynamics of the drug as well as the duration of the toxicity studies. One strategy that has been recommended to mitigate against this risk is to dose through the formation of neutralizing antibodies by increasing either the frequency of dosing, or the administered dose level of drug, sufficiently to overcome any neutralizing or clearing effects of anti-drug antibody. A potential advantage of this strategy is that high doses of soluble antigens tend to induce immunological tolerization. On the other hand, a significant disadvantage is the possible loss of dose-response information required for estimating the safe clinical starting dose of the therapeutic. This presentation will provide an overview of factors and limitations that must be considered when deciding whether or not to implement a dosing through strategy.

W 42 HIGH DOSE SELECTION FOR DART STUDIES.

J. Couch. *Pharmacology/Toxicology, Genzyme, Framingham, MA.*

The guidelines for assessment of reproductive toxicity (ICH S5A & S5B) include recommendations for: selection of dose, dosing intervals, and duration of dosing of medicinal products. In the case of biologics, these recommendations may not always be appropriate as biologics have widely varied pharmacokinetic and pharmacodynamic parameters, clinical dosing regimens, and potential for immunogenicity. Selection of dose and dosing regimen for reproductive toxicology studies should therefore be considered on a case by case approach, including consideration of product-specific biology rather than based strictly on ICH S5A & S5B guidelines. Examples of preclinical development programs implementing case-based and clinically relevant approaches to the design of reproductive toxicology studies for biologics will be discussed.

W 43 WORKSHOP INTRODUCTION: SYSTEMS BIOLOGY & BIOLOGICAL MODELS.

S. Edwards[1] and C. Timchalk[2]. *[1]NHEERL, U.S. EPA, Research Triangle Park, NC and [2]Biological Sciences, PNNL, Richland, WA.*

As we consider the future of toxicity testing, the importance of applying biological models to this problem is clear. Modeling efforts exist along a continuum with respect to the level of organization (e.g. cell, tissue, organism) linked to the resolution

of the model. Generally, a tradeooff is made whereby higher levels of organization are models with lower resolution. Consideration will be given to modeling efforts across the full range of this spectrum. First, a model will be described for intracellular signaling including important information on how the choice of cell type for *in vitro* studies affect the signaling seen. Next, two systems approaches will be highlighted which model genome-wide molecular changes (i.e. 'omics) within and between tissues and the application to pharmaceutical target discovery and toxicity testing. Finally, biologically-based dose-response models for risk assessment and data requirements associated with these models will be covered followed by a progress report on the development of detailed tissue models and integration of such models with molecular and cellular changes. If incorporated into future toxicity testing, these approaches should greatly facilitate the definition and quantitative modeling of mode of action for important environmental stressors. The systems approaches also have the potential to greatly improve interspecies extrapolation. In addition, the models described will facilitate the use of *in vitro* data for risk assessment thereby increasing the number of chemicals that can be evaluated each year. In considering these different modeling approaches, we hope to gain a better understanding of the future opportunities and challenges we face as we strive for increasingly higher resolution models at greater levels of organization. [This abstract does not reflect EPA policy.]

W 44 QUANTITATIVE SYSTEMS ANALYSIS OF HEPATOCELLULAR RESPONSES TO INFLAMMATORY CYTOKINES AND PHARMACOLOGICAL AGENTS.

D. Lauffenburger. *Department of Biological Engineering, Massachusetts Institute of Technology, Cambridge, MA.* Sponsor: S. Edwards.

We are pursuing a systematic approach to quantitatively assess relationships between multiple combinations of inflammatory cytokines and pharmacological agents in inducing hepatotoxicity in a set of in vitro systems including primary rat hepatocytes, primary human hepatocytes, and a transformed hepatic cell line (HepG2). Our goal is to gain insights concerning how physiologically-relevant cytokines might facilitate development of lethal (apoptotic and necrotic cell death) and/or sub-lethal (loss of differentiated function) hepatotoxicities by idiosyncratic hepatotoxic drugs. In the work we report here, combinatorial data sets of cytokine- and drug-induced lethal hepatotoxicity phenotypes in each cellular system were used to identify multivariate relationships between underlying drug and cytokine treatment variables and to compare these relationships between cellular systems. Further studies combining cytokine treatment with non-idiosyncratic and idiosyncratic drugs showed that cytokine-drug hepatotoxicity synergies exist at physiologically relevant drug concentrations and are informative in distinguishing idiosyncratic hepatotoxic drugs from their non-hepatotoxic, non-idiosyncratic analogs. Because biological function is context sensitive and the structures, dynamics, and outputs of canonical signaling pathways vary from cell type to cell type and between normal and diseased cells, effective application of pathways maps to the study of disease and therapy requires context-specific information on specific cells and tissues in normal and abnormal states. Thus, we further analyzed key disparities between the human primary hepatocytes and HepG2 cell. The most striking differences were alterations in pathways involved in innate immune responses and NF-kB function, associated with substantive changes in consequent cytokine secretion. We believe that our combined quantitative experiment and computational modeling approach could find useful application therapeutics development as well as in environmental health applications.

W 45 INFORMATIC AND STATISTICAL INTEGRATION OF 'OMICS DATA TO MODEL CELLULAR RESPONSE TO STRESS.

K. Waters. *Pacific Northwest National Lab, Richland, WA.* Sponsor: R. Corley.

The advent of the genomic era has brought the promise of "systems science" methods to advance toxicological research and improve human and environmental health. However, development of interpretive and analytic computational tools has not kept pace with advances in the collection of data, both in terms of breadth (vast amounts of data) and depth (proteomics, metabolomics). The single greatest challenge for the implementation of the NRC vision for Toxicity Testing in the 21st Century is the abstraction of cell response network models from 'omics data which accurately reflect the circuitry needed for predictive mathematical modeling. The use of integrated genomic, transcriptomic, proteomic, and metabolomic data is essential to fully capture multiple levels of molecular hierarchy and modes of regulation necessary to reconstruct the global response of a cell to perturbation. For example, we have found that microarray data are sufficient to distinguish between antigenic- and particle-induced inflammation, where both the cell receptor interaction and toxicity mechanism are unique. However, integration of proteomic data allows discrimination between different classes of nanomaterials, such as amorphous silica, carbon nanotubes and crystalline silica, highlighting different pathways of cell activation. We also find that integrated data for RNA levels, protein abundance and phosphorylation status synergistically enhance network reconstruction beyond any single data type alone. Furthermore, identification of toxicity pathways and their distinction from adaptive/transient changes requires both temporal and dose-dependent measurements from in vivo and in vitro systems to account for inherent differences in exposure. Conserved response pathways between alveolar epithelial cells, macrophage cells and whole lung tissue provide cell-specific response measurements necessary for cell to tissue extrapolation. The linkage of computational and experimental approaches for cell response modeling will be illustrated. This work was funded by NIEHS through R01-ES016212 and U54-ES016015 and by the Environmental Biomarkers Initiative at PNNL.

W 46 GENE NETWORKS REFLECTING TISSUE-TISSUE INTERACTIONS HIGHLIGHT NOVEL CAUSAL PATTERNS OF ASSOCIATION WITH HUMAN DISEASE.

E. E. Schadt. *Genetics, Merck, Seattle, WA.* Sponsor: S. Edwards.

Network approaches to understanding complex system behaviors have largely ignored tissue-to-tissue communications that are critical to living systems manifesting complex behaviors like disease. To decipher the communication between tissues at the molecular level, we examine interactions among gene expression traits in blood, adipose, muscle, pancreas, liver, and brain tissues from human and experimental mouse cross populations using integrative genomics approaches previously applied to single tissues. Gene-gene relationships specific to interactions between two given tissues are observed to give rise to coherent subnetworks involved in important functions like circadian rhythm and energy balance that are independent of subnetworks detected from single tissue analyses, highlighting novel networks associated with disease that have previously escaped notice. Further, not only do the tissue-tissue networks highlight genes in one tissue that respond to changes in genes in a second tissue, but they elucidate entire subnetworks in one tissue that influence subnetworks in a second tissue. Our modeling approach provides direct support for cross-tissue processes influencing a diversity of disease traits related to obesity, diabetes, atheroscelrosis, and Alzheimer's, and suggests hypotheses on how biological processes observed in one tissue as driving a given disease (e.g., obesity) may influence processes observed in a different tissue as driving a related disease (e.g., diabetes). Many of the specific causal relationships we detect via the tissue-tissue networks would be difficult or impossible to detect via single-tissue analyses. Our analyses provide further support that complex traits like obesity, diabetes, and atheroscelrosis are emergent properties of complex interactions among molecular networks in different tissues that are modulated by complex genetic loci and environmental factors.

W 47 BIOLOGICALLY BASED DOSE-RESPONSE MODELING. THE POTENTIAL FOR ACCURATE DESCRIPTION OF THE LINKAGES IN THE APPLIED DOSE - TISSUE DOSE - HEALTH EFFECT CONTINUUM.

R. Conolly. *U.S. EPA, Research Triangle Park, NC.*

In the game of chess, computers have become stronger players than the strongest grandmasters. Computer simulations are now used to study events, such as the evolution of the universe shortly after the Big Bang, that cannot be studied in the laboratory. In biology, the "omics" technologies have stimulated development of computational tools that probe the biological structures that gave rise to the data. All of these developments are reflections of Moore's Law, which states that computing power doubles about every two years. It is difficult to see with any clarity where computational technologies will lead us in the coming years. What is not difficult to predict is that computation will be integral to scientific research in biology, toxicology, and human health risk assessment. Biology has until recently been a largely intuitive discipline but the future will require formulation of quantitative hypotheses amenable to evaluation in the laboratory and *in silico.* There is no point in arguing about whether or not this should happen. The only relevant questions are exactly how it will happen, and how best to manage and adapt to it. In this presentation these questions will be pursued in the context of dose-response analysis for toxic chemicals. Given knowledge of exposure, the shape of the dose response curve is the key to predicting heath risk, which in turn determines allowable levels of exposure and the associated economic costs of compliance. The public health and billions of dollars are at stake, so it is well worth doing a good job! Specific issues that will be addressed include (1) the state-of-the-art in dosimetry modeling, (2) strategies for computational modeling of complex intra- and intercellular signaling pathways to keep complexity at a manageable level and (3) use of computational modeling of data collected *in vitro* to provide estimates of risk *in vivo. This work has been reviewed by the EPA and approved for publication but does not necessarily reflect the views or policies of the Agency.*

W 48 VIRTUAL ORGAN MODELS FOR MULTI-SCALE INTEGRATION OF DOSE-RESPONSE RELATIONSHIPS.

R. A. Corley[1], K. R. Minard[1], R. E. Jacob[1], C. Timchalk[1], A. P. Kuprat[1], J. P. Carson[1], S. Kabilan[2], C. Frevert[2], M. Fanucchi[3] and D. R. Einstein[1]. *[1]Pacific Northwest National Laboratory, Richland, WA, [2]University of Washington, Seattle, WA and [3]University of Alabama, Birmingham, AL.*

Organs consist of a spatial organization of specialized cells that together carry out higher order functions. Spatial organization has largely been ignored in dose-response models due to computational and data limitations. New imaging and computational approaches are now enabling the development and functional validation of comprehensive virtual organs that capture 3D tissue architecture and cellular distributions. For example, multi-dimensional models of the respiratory and cardiovascular system and their associated imaging and computational technologies are improving our understanding of environment-disease interactions for human exposures to gases, vapors and particulates, as well as enhancing drug delivery or surgical interventions. Likewise, the 'omics' revolution significantly enhances the development of cellular response models as discussed by others in this symposium. To truly be effective for dose-response modeling, atlases must be constructed that map the spatial distribution of specialized cells with their functional attributes to the 3D organ models to provide an integrated dose-response framework. Similar approaches have recently been developed for the Allen Brain Atlas, a 3D interactive atlas of cell distribution and gene expression in the mouse brain. However, respiratory and cardiovascular atlases must extend beyond gene expression in normal tissue to integrate spatial and temporal changes in genes, proteins, and metabolic function in specialized cells. This presentation will focus on the current status of multi-scale virtual organ modeling using examples primarily from the respiratory system-but also from the heart, vasculature, brain and liver-to provide a perspective on where these models may impact human health research and risk assessment over the next 10 years. Funding from NIH (HL073598, ES011617, EB008192, HL077921 & HL084431), DOE, and Battelle IR&D.

W 49 STRATEGIES TO INTEGRATE SYSTEMS BIOLOGY INTO IN VITRO SCREENING IN EARLY NONCLINICAL SAFETY ASSESSMENT.

J. Davis[2] and D. Dambach[1]. *[1]Genentech, Inc., South San Francisco, CA and [2]Pfizer, Product Research & Development, Chesterfield, MO.*

The toxicity of pharmaceutical compounds can be due to their interactions with unanticipated molecules in the body (off-target) or the direct consequence of over-inhibiting or stimulating the intended molecular target in a desired or undesired location (target-based). Such complex processes of toxicity pose significant challenges to toxicologists who seek to either proactively minimize potential liabilities by devising screening strategies or to elucidate mechanistic understanding of an identified toxicity. The precept of systems biology (SB) is the ability to obtain, integrate and analyze complex data from multiple experimental sources using interdisciplinary tools with an overall goal of examining the gestalt of a biological process, e.g. disease or toxicity. A fundamental aspect of the application of a SB approach is the need to verify the physiological relevance of the data generated. Although most investigative toxicology studies that employ SB techniques are initiated as the result of a clinical or histological finding, SB approaches can be utilized and integrated to proactively evaluate potential target toxicity and to aid in the screening of molecules for favorable profiles during lead optimization. A common approach is to generate datasets *in vivo* using SB approaches and apply those learnings to develop in vitro models. The key to successfully implementing this approach is to anchor the data to traditional endpoints of interest, thus enabling a benchmarked relationship. The understanding of the relevance of SB data to the traditional endpoints coupled with data integration strategies aims at deriving more robust, mechanism-based risk assessments. Thus, it is important to implement strategies to obtain information early in the drug development process on potential safety risks, the challenges to evaluating predictivity, including *in vitro/in vivo* correlations, the need for increasing assay throughput, and general approaches to correlation/validation.

W 50 APPLICATION OF SYSTEMS BIOLOGY VISUALIZATION AND ANALYSIS TOOLS IN RISK ASSESSMENT.

H. Hamadeh. *Comparative Biology and Safety Sciences, Amgen, Inc., Thousand Oaks, CA.*

Data integration is the process of combining data residing at different sources and providing the user with a unified view of these data. Taking advantage of multiple data sets has proven to be advantageous when approaching toxicological problems. Integration of divergent data sets collected on molecules in earlier stages of preclinical development is technically and scientifically challenging. The choice of databases and analysis/visualization tools is key to a successful integration strategy that allows for successful interpretation and enhanced risk assessments. Specifically, a case study will highlight how integration of severity scores of microscopic observations, clinical pathology, and toxicokinetic data contributed to the identification of marker(s) for skeletal muscle lesions induced by a proprietary drug. In addition, this report will discuss how the question or challenge that is being addressed dictates the strategy of visualizing integrated data. Similar approaches should allow for correlation of biological parameters between different data types, which could lead to an improvement in biological interpretation.

W 51 DATA INTEGRATION STRATEGIES REVEAL POTENTIAL LIABILITIES IN EARLY LEAD OPTIMIZATION.

M. Cooper. *Discovery & Investigative Safety Group, Roche Palo Alto, Palo Alto, CA.*

Sound informatics support and ready access to safety data are critical components to effective lead optimization. Development of a safety knowledgebase capable of leveraging both internal and external data for use in lead optimization will be presented. The described safety knowledgebase enables scientists to combine information from in vitro and in vivo studies, pathway databases, and the public domain to elucidate mechanisms of toxicity. Understanding these mechanisms allows scientists to learn from past failures, develop appropriate screening strategies, perform enhanced risk assessment, and improve biomarker development. Technical challenges and use cases will also be discussed.

W 52 ORGAN SLICES PROVIDE MECHANISTIC INSIGHT INTO DRUG-INDUCED ORGAN INJURY AND FACILITATE COMPARISONS OF ANIMAL AND HUMAN TISSUE.

A. Vickers. *Drug Safety Evaluation, Allergan, Inc., Irvine, CA.*

Predicting the relevance of drug induced organ injury for humans, identified from animal studies, is being addressed with organotypic cultures via comparisons of animal and human tissue. The cellular pathways underlying the mechanisms of target organ injury are generally comprised of biochemical networks representing a myriad of cell-cell and cell-matrix interactions. The application of organotypic cultures combined with gene expression profiling plus biochemical measurements characterizes the molecular mechanisms of drug action on the activation of cell death and survival pathways including oxidative stress, inflammation, apoptosis, and repair, with the goal to identify key pathways that are causal to organ dysfunction and injury. These advancements along with the increased application of human tissue models to define clinical relevance of potential side-effects and use of biomarkers redefines the scope of translational research in toxicology. The increased utilization of such models earlier to support drug candidate selection will add value to the safety decision process. Several examples will be presented which elucidate the mechanisms of drug-induced organ injury, define species sensitivities and susceptibility to organ injury, and aid in characterizing human response. One example, drug induced mitochondrial injury demonstrates the interplay of cells in liver slices by the induction of oxidative stress, increased apoptosis and inflammation. A second example is a hemolysis model, comprised of whole blood co-cultured with a liver slice, to evaluate time- and concentration-dependent toxicity on red blood cells. This example reveals that an oxidative stress response occurs in red blood cells prior to hemolysis, and that compound metabolism contributes to the outcome. A third example reveals that drug retention in thyroid is associated with inhibition of thyroid peroxidase function and potentially thyroid hormone synthesis. In each of these examples rat and human response is compared.

W 53 SYSTEMS BIOLOGY APPROACHES TO OPTIMIZING A SCREENING BATTERY.

J. James Xu. *Automated Biotechnology, Merck & Co., North Wales, PA.*

Drug-induced liver injury (DILI) is the leading cause of drug safety attritions. By applying systems biology and integrating mining, modeling, manipulation and measurements, we have assessed a panel of in vitro assays with good predictivity to clinical DILI including a significant number of type II or idiosyncratic hepatotoxicity. Using drugs as test agents and measuring a panel of cellular phenotypes that are directly linked to key mechanisms of hepatotoxicity, we have developed an in vitro testing strategy that is predictive of many clinical outcomes of DILI. Mitochondrial damage, oxidative stress, and intracellular glutathione, all measured by high content cellular imaging in primary human hepatocyte cultures, are the three most important features contributing to the hepatotoxicity prediction. When

applied to over 300 drugs and chemicals including many that caused rare and idiosyncratic liver toxicity in humans, our testing strategy has a true-positive rate of 50-60% and an exceptionally low false positive rate of 0-5%. These in vitro predictions can augment the performance of the combined traditional preclinical animal tests by identifying idiosyncratic human hepatotoxicants such as nimesulide, telithromycin, nefazodone, troglitazone, tetracycline, sulindac, zileuton, labetalol, diclofenac, chlorzoxazone, dantrolene, and many others. Our findings provide insight to key DILI mechanisms, and suggest a new approach in hepatotoxicity testing of pharmaceuticals.

W 54 IN VITRO MICROARRAY ANALYSIS OF HEPATOCYTES FOR LEAD COMPOUND SELECTION.

C. E. Thomas, M. Renninger, A. Irizarry, D. Hall, A. Wilke and R. Jolly.
Investigative Toxicology and Pathology, Lilly Research Laboratories, Greenfield, IN.

Early identification of toxicologic concerns can improve drug candidate quality and reduce cycle times. This presentation will focus on the use of a contextual genomics database, DrugMatrix™, in early compound screening. In a rat primary rat hepatocyte model, sparse linear programming-derived gene signatures are leveraged to predict in vivo toxicities. Key to successful application of the technology is demonstration of its predictive power. We have tested in the hepatocyte model more than 100 proprietary compounds with known outcomes for hepatic pathology in short term rat safety assessment studies. The analysis demonstrated acceptable performance metrics for prediction of in vivo outcomes. In addition, a specific example will be presented which illustrates the use of in vitro gene signatures to dissociate phospholipidosis from target organ toxicity within a series of highly structurally related compounds. Overall, the data indicate that a robust contextual chemogenomics database can leverage in vitro gene signatures to direct project teams towards an SAR(s) that is most likely to yield a drug candidate with a favorable in vivo safety profile.

PL 55 AUTOMATED DOSE-RESPONSE ANALYSIS OF THE RELATIVE HEPATIC GENE EXPRESSION POTENCY OF TCDF IN C57BL/6 MICE.

L. D. Burgoon[1, 2, 5], Q. Ding[1, 2, 3], A. N'jai[1, 2, 3], E. Dere[1, 2, 3], J. Rowlands[4], R. A. Budinsky[4], K. E. Stebbins[4] and T. R. Zacharewski[1, 2, 3]. *[1]Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI, [2]National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI, [3]Center for Integrative Toxicology, Michigan State University, East Lansing, MI, [4]The Dow Chemical Company, Midland, MI and [5]Toxicogenomic Informatics and Solutions, LLC, Lansing, MI.*

Toxic equivalency factors (TEFs) are assigned to dioxins and dioxin-like chemicals based on relative potency (REP) values of all individual adaptive and toxic responses compared to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). We used Agilent 4x44k oligonucleotide microarrays to examine the hepatic gene expression potency of 2,3,7,8-tetrachlorodibenzofuran (TCDF), relative to TCDD. Immature ovariectomized C57BL/6 mice were gavaged with either 0.03, 0.1, 0.3, 1, 3, 10, 30, or 100 ug/kg TCDD, the WHO TEF adjusted doses (10 x TCDD dose) TCDF, or sesame oil vehicle, and sacrificed at 72hrs. 2,288 TCDD and 1,347 TCDF differentially expressed genes were identified. Automated dose response modeling (ToxResponse Modeler) identified 1,078 genes with 610 genes exhibiting a TCDD mediated sigmoidal dose-response (ED50s from 0.03 to 62.47 ug/kg), compared to 312 sigmoidal TCDF responsive genes (ED50s from 0.17 to 406.7). Of the 1,078 TCDD dose responsive genes, 705 were excluded due to the lack of a TCDF dose-response. Of these, REPs were calculated for the 83 genes that exhibited similar TCDD and TCDF induced sigmoidal dose-responses, slopes, and curve shapes. The median REP was 0.10, with a max REP of 0.56 and a minimum REP of 0.01. Further investigation is required to differentiate toxic and adaptive responses to develop agglomerative gene expression REPs that represent clusters of responses within common pathways or function. Although the median REP was 0.1, the significantly lower number of TCDF induced genes compared to TCDD suggests that the TEF of 0.1 is an over estimate of the potency of TCDF based on differential gene expression in C57BL/6 mice. This work sponsored by the Dow Chemical Company.

PL 56 METABOLOMICS: A NOVEL TOOL FOR UNDERSTANDING THE EARLY-STAGE MECHANISTIC UNDERPINNINGS OF DRUG ACTION AND SAFETY.

M. Milburn, R. Mohney, K. Boudonck, M. Mitchell, L. Guo and J. Ryals.
Metabolon, Inc., Durham, NC. Sponsor: P. Lapinskas.

Traditionally, drug action and safety has involved monitoring gross physiological changes to animals dosed with drug. With increasing numbers of drug candidates and potential targets, earlier information on potential drug safety issues is required before deciding which compounds to take into the clinic. Metabolomics, the global profiling of biochemicals, provides unparallel insight into the mechanistic action of drugs. Many of these biochemical changes are seen within hours of dosing, providing early-stage indication of drug safety issues. This presentation will demonstrate the utility of metabolomics in drug safety research through two case studies done in collaboration with leading pharmaceutical companies. Valproate (VPA) is a drug widely used to treat epilepsy, but it has serious adverse effects including hepatotoxicity, teratogenicity and antifolate activity. Rats were treated with VPA (500 mg/kg) or saline (vehicle) once daily for 1, 5 or 28 days. Urine and kidney tissue samples were collected from groups of 6 rats each (12 rats for vehicle group) at days 1, 5 and 28. Full data curation of kidney tissue samples yielded 547 metabolites, and urine yielded 657 metabolites. Analysis of the metabolic changes showed Valproate stimulated fatty acid omega-oxidation, likely to compensate for a defective beta-oxidation. Additionally,bile acids were identified as potential markers for VPA-induced liver toxicity. Fenofibrate (Fen) and Phenobarbital (Pb) are two known rodent carcinogens. To better understand their mechanism of toxicity, rats were dosed with fen (300 mg/kg/day), or Pb (50 mg/kg/day) or vehicle. Plasma and 24-hour urine samples from rats were collected at day 2 and day 14. A metabolomics analysis yielded 496 biochemicals in plasma and 974 compounds in urine. Potential cell proliferation biomarkers in plasma and urine were identified Their biochemical and physiological roles were related with liver and kidney malfunctions such as hyperplasia and cell proliferation.

PL 57 GENE EXPRESSION PROFILING IN PRIMARY MOUSE HEPATOCYTES TO SCREEN COMPOUNDS FOR CARCINOGENIC PROPERTIES.

J. V. Delft[1, 2], K. Mathijs[1, 2], J. Danyel[1, 2], K. Brauers[1] and J. Kleinjans[1, 2].
[1]Health Risk Analysis and Toxicology, Maastricht University, Maastricht, Netherlands and [2]Netherlands Toxicogenomcs Center, Maastricht University, Maastricht, Netherlands. Sponsor: H. van Loveren.

Sandwich-cultured mouse primary hepatocytes are an attractive model for toxicogenomics-based screening of chemicals to predict their toxicity. This is, because they are metabolically competent, the liver is frequently a target organ and mouse models gain in usage due to the development of transgenic models. Furthermore, mouse primary hepatocytes are favoured above rat hepatocytes, which are relatively unstable, as well as human hepatocytes, which are limited in availability. Therefore, we aim to develop in sandwich-cultured mouse primary hepatocytes transcriptomics-based prediction tools for the toxic properties of compounds, with the initial focus on specific classes of genotoxins and carcinogens. Compared to rat hepatocytes, the metabolic system of mouse hepatocytes showed to be more stable during several days, as shown by gene expression of phase I and II enzymes and activity of CYP450 enzymes. Time- and dose-dependent transcriptomics of benzo[a]pyrene exposed cells indicate that time has the biggest effect on the profiles, and that the modulation continuously increases over time (12-48h). Transcriptomics-based discrimination of genotoxic from non-genotoxic carcinogens was developed, showing that this was possible at various time points at 24h and 48h, but not at 12h, by Nearest Shrunken Centroids Analysis. Finally, the discrimination of true genotoxins from false-positive genotoxins was addressed at 24h and 48h. Correct classification was achieved for 9 out of the 10 compounds, at both time points. Currently, improvements are sought in the application of other supervised clustering algorithms and a mechanistic approach.

PL 58 MULTI-'OMICS CHARACTERIZATION OF THE ANTI-PARKINSON'S DRUG TOLCAPONE AND ITS POTENTIAL IN INDUCING IDIOSYNCRATIC LIVER TOXICITY - COMPARED TO ENTACAPONE.

B. Ganter[3], T. N. Plasterer[1], W. M. Hines[1], J. C. Fuscoe[2], R. D. Beger[2], J. J. Chen[2], W. Tong[2], S. A. Booth[1], P. L. Courchesne[1], J. M. Campbell[1], A. Graber[1], Y. Guo[1], T. Y. Li[1], M. D. Lynch[1], N. M. Morel[1], C. Zeng[1], F. A. Beland[2] and R. N. McBurney[1]. *[1]BG Medicine, Waltham, MA, [2]NCTR, FDA, Jefferson, AR and [3]Ingenuity Systems, Redwood City, CA.*

The Liver Toxicity Biomarker Study (LTBS) is a public/private consortium created to address the unmet need of predicting clinical idiosyncratic drug-induced liver injury (DILI) in the preclinical setting. The basic study design is to select multiple pairs of drugs with similar mechanisms of action where one contributed to cases of idiosyncratic liver injury in the clinical setting and the other has not — with both drugs being free of signs of liver toxicity in the preclinical environment. Drug pairs are evaluated in a 3-day and 28-day Sprague-Dawley rat model with multiple cross-omics modalities. The first paired compound analysis has been completed and the results will be presented — Tolcapone (DILI) versus Entacapone (clean).
The combined gene expression, proteomic, and metabolomic data analysis approach indicated induction of inflammation specific events triggered through LPS-BP and IL-1 induced cascades. These LBP/IL-1 mediated effects result in induction

of nuclear hormone receptors for both Tolcapone and Entacapone. The complex downstream effects induce select CYP450 genes indicative of Tolcapone being a preferential PXR/CAR activator (induction of Cyp3A4 [Tolcapone>>Entacopone] and OATP-2) distinct from Entacapone. In addition, Tolcapone down-regulated the expression of critical CYP450 genes, the products of which are required for metabolism and clearance of the compound. Thus, Tolcapone may exacerbate its own toxicity by inhibiting its clearance from the system, associated with a gene expression pattern indicative of a strong inflammatory response. These described mechanistic differences are consistent with idiosyncratic toxicity observed in the clinic for Tolcapone, but not for Entacapone. Interestingly, these overlapping and distinct drug characteristics were identified across all different omics' profiles.

PL 59 PROTEOME ANALYSIS OF LYMPH NODES IN A MOUSE MODEL OF CHEMICAL-INDUCED ASTHMA.

S. Haenen[1,2], E. Clynen[2], V. De Vooght[1], P. H. Hoet[1], L. Schoofs[2] and J. A. Vanoirbeek[1]. [1]*Occupational, Environmental & Insurance Medicine, K.U.Leuven, Leuven, Belgium and* [2]*Functional Genomics and Proteomics, K.U.Leuven, Leuven, Belgium.*

Asthma is one of the most prevalent chronic airway diseases, characterized by reversible airway obstruction, airway inflammation, and non-specific airway hyperreactivity. Up to 15% of all asthma cases in adults are due to chemical exposures at the workplace. The early identification of biomarkers of sensitization could help to move diagnosis to an earlier stage. Using a mouse model of chemical-induced asthma we explore the process of sensitization towards chemicals at the protein level. On days 1 and 8, mice are treated on both ears with 0.3% toluene-2,4-diisocyanate (TDI, 20µl), or the vehicle (2:3, acetone-olive oil). On day 15, mice are oropharyngeally challenged with 0.01% TDI or vehicle. On day 16, airway hyperreactivity to methacholine and BAL cell count are carried out. Two-dimensional differential gel electrophoresis (2D-DIGE) was used to analyze the differential expression of proteins in auricular lymph nodes of TDI-treated mice and vehicle-treated mice. Sensitized mice exhibit enhanced airway reactivity to methacholine (2.6 fold increase) compared to vehicle-treated mice, accompanied by a neutrophil inflammation (50%). Proteome analysis of the auricular lymph nodes illustrate differential expression of 52 proteins comparing TDI and vehicle-treated (control) mice ($p<0.01$). 36 proteins are found to be significantly upregulated in sensitized mice. 21 proteins could already be identified by peptide mass fingerprinting. Among the identified proteins structural proteins such as vimentin and immune related proteins, such as lymphocyte specific protein-1 involved in neutrophil activation, were found. This study demonstrates the use of 2D-DIGE in the search for (early) biomarkers of chemical-induced asthma. Further studies will have to point out whether (some of) these proteins could act as valuable biomarkers. Therefore, more samples (bronchoalveolar lavage fluid, serum,…) will be analysed.

PL 60 APPLICATION OF FTICR NON-TARGETED METABOLOMICS TO ASSESS THE PHARMACOLOGIC AND TOXICOLOGIC PROPERTIES OF PPAR ALPHA/DELTA DUAL AGONIST, GSK610742X.

S. Ritchie[2], W. Casey[1] and E. Brigham[2]. [1]*Safety Assessment, GlaxoSmithKline, Durham, NC and* [2]*Phenomenome Discoveries Inc, Saskatoon, SK, Canada.* Sponsor: P. Kwanyuen.

Being able to measure the metabolic and phenotypic effects of drugs is critical to understanding their pharmacologic and toxicologic modes of action. Recent advances in global metabolic profiling represent new opportunities to characterize the pharmacologic effects of drugs on a system-wide basis. Since no prior knowledge about the effect of a compound is required, the data can point to metabolic pathways directly affected by the treatment, which can then be used to build a hypothesis about the mechanism of toxicologic or pharmacologic activity. This poster highlights the sensitivity of a global metabolomic profiling technology based on accurate mass Fourier Transformation Ion Cyclotron Resonance (FTICR) mass spectrometry for identifying tissue-specific metabolic responses of animals treated with PPAR alpha/delta dual agonist GSK610742X. High doses of GSK610742X have been associated with skeletal myopathy in rodent models. The analysis of serum, adipose tissue, skeletal muscle, whole blood and liver revealed substantial changes in several different classes of lipids, including peroxisomally-derived vinyl-ether lipids, and early changes in bile acids. A dramatic increase in lipid peroxides, indicative of oxidative stress, was also observed. Although the liver and skeletal muscle were the sites anticipated to have the largest metabolic effects, changes in serum lipid composition was the most dramatically affected. It was also possible to track the metabolism of the drug in vivo without the need for isotope labelling. The structures of drug metabolites were identifiable due to the high accurate mass of the FTMS, making it possible to determine the relative tissue-specific deposition of the drug and its metabolites. In summary, the findings of this project provide new insight into tissue-specific aspects of PPAR physiology, as well data supporting a mechanistic understanding of PPAR-mediated skeletal myopathy.

PL 61 GENOMIC ANALYSIS OF SKELETAL MUSCLE INJURY INDUCED IN THE RAT BY CHRONIC EXPOSURE TO CHLOROQUINE.

K. Thompson, T. Miller, R. Honchel, B. Rosenzweig, P. Pine, J. Weaver, A. Knapton, J. Zhang and J. Hanig. *DAPR, CDER, FDA, Silver Spring, MD.*

Phospholipidosis (PL) is a common finding in preclinical studies of pharmaceuticals but is of uncertain toxicological significance, which can delay drug development and regulatory review. Studies were initiated to examine the relationship between PL and toxicity using drugs from different therapeutic classes at doses that induce PL in rats. Chloroquine (CHQ), which is associated with clinical myopathy during long term therapy, was administered in the feed at 5 dose levels (0.03 to 0.15%) for 4 weeks to male Sprague Dawley rats. The incidence of PL in tissues was assessed by Nile Red fluorescence above 630 nm. CHQ induced a dose and time-dependent induction of PL in spleen and skeletal muscle. In type I skeletal muscle, CHQ-induced PL was seen primarily in samples that also displayed mild to moderate levels of necrosis and inflammation. Type II skeletal muscle was less sensitive to CHQ. Functional analysis of Affymetrix microarray data for soleus muscle revealed significant upregulation of stress-induced genes and transcript levels for lysosomal and extracellular matrix proteins, while gene transcript levels for proteins involved in mitochondrial energy production were downregulated by CHQ treatment. Although CHQ reduced body weight gain when administered at levels above 0.03% in the feed, the observed changes in expression in soleus muscle were of limited comparability to a gene profile associated with skeletal muscle atrophy caused by weight loss. The transcriptional response in soleus muscle to CHQ treatment is consistent with reports that CHQ induces an increase in lytic vesicles in skeletal muscle, which is thought to promote its effect on phospholipid accumulation.

PL 62 MICROARRAY ANALYSIS OF CALCINEURIN INHIBITOR IMMUNOSUPPRESSANT-MEDIATED NEPHROTOXICITY IN THE RAT.

Y. Cui[1], J. Auman[2], Q. Huang[3], S. Jayadev[3] and R. S. Paules[1]. [1]*NIEHS, Durham, NC,* [2]*UNC Eshelman School of Pharmacy, Chapel Hill, NC and* [3]*Boehringer Ingelheim Pharmacology ., Inc., Ridgefield, CT.*

The use of calcineurin inhibitor (CI) immunosuppressants has revolutionized the clinical practice of organ transplantation. However, chronic nephrotoxicity limits their long-term utility. In order to understand the changes in gene expression that underlie the development of CI immunosuppressant-mediated nephrotoxicity, male SD rats were dosed daily with cyclosporine A (CsA) (2.5 and 25 mg/kg/day i.p.) or FK506 (0.6 and 6 mg/kg/day i.p.) for 1 to 28 days. Rats were also dosed with rapamycin (1 and 10 mg/kg/day i.p.), an immunosuppressant that does not elicit nephrotoxicity at therapeutic levels. Gene expression profiling was performed on RNA isolated from kidneys and blood 24 hours after 1, 7, 14 or 28 daily doses using the Affymetrix GeneChip Rat Genome 230 2.0 array. Our results indicate that repeated administration (14 and 28 days) of CsA (high dose) and FK506 affects similar biological processes in kidney. These processes are correlated with changes in kidney histopathology and kidney function. A gene expression signature quantitatively correlated with kidney damage was identified and consists of 10 genes, including Calb1, Egf and Slc12a3. Interestingly, the transcriptional change of this signature has an earlier onset than the kidney injury biomarkers Kim1 and Clusterin, and is CI-specific. The down-regulation of Slc12a3 (thiazide-sensitive sodium-chloride cotransporter) in distal convoluted tubules was also verified by immunohistochemistry staining. Since mutation of SLC12A3 can cause salt wasting disease in humans, the inhibition of this gene may play an important role in the CI immunosuppressant-mediated nephrotoxicity. Furthermore, a gene expression signature in blood was also identified, which can separate animals with tubule necrosis caused by CsA from the non-injured animals. This suggests that blood transcription profiling may be useful as an indicator of kidney injury.

PL 63 UTILIZING FUNCTIONAL GENOMICS IN YEAST TO DISCOVER NOVEL BIOMARKERS OF BENZENE TOXICITY IN HUMANS.

M. North, A. Loguinov, V. Tandon, B. Ko and C. D. Vulpe. *Nutritional Sciences and Toxicology, The University of California Berkeley, Berkeley, CA.*

The carcinogenic organic compound benzene is used extensively in industrial processes such as plastic production, and is also present in cigarette smoke and gasoline. In addition, there are thousands of benzene-contaminated sites in the

USA alone. With a large workforce exposed to the compound, and the ever-increasing identification of benzene exposure-associated diseases, there is a mounting effort to identify biomarkers for susceptibility. *Saccharomyces cerevisiae* is the best-characterized simple eukaryotic organism, and has hundreds of tools available for genetic study. This includes a complete set of non-essential gene deletions, genetically tagged so that individual strains can be identified in competitive growth experiments. Using this deletion set, parallel systematic analysis can be completed to identify mutant strains that are susceptible to toxicant treatments. We have used this technique to establish the cellular processes targeted by three of the most well studied benzene metabolites: hydroquinone, catechol, and 1,2,4-benzenetriol. Comparing the global deletome profiles of the metabolites revealed that deletion of certain genes renders sensitivity to all three compounds, for example the epimerase *RPE1*. This particular result indicates a requirement for NADH in metabolite detoxification; unsurprising since NADH is required for the function of oxidoreductases, which reduce the more toxic quinone forms of these metabolites (produced through autoxidation). Conversely, we also found that some mutations cause sensitivity to only one or two of the metabolites, for example *ira2*, a negative regulator of Ras. Several of the genes identified have direct human homologs with conserved biological function, and many more have functional orthologs, supporting the notion that the mechanisms of toxicity identified are relevant to human disease. This study highlights *S. cerevisiae* as a simple but valuable model for identifying biomarkers for genetic susceptibility to toxicant-related disease.

PL 64 EFFECT OF THE MARINE *VIBRIO VULNIFICUS* LIPOPOLYSACCHARIDE ON BRAIN MICROGLIA CYTOKINE AND CHEMOKINE RELEASE.

J. Frenkel[1], M. Aldulescu[1], M. L. Hall[1], J. L. Powell[3], K. B. Glaser[2] and A. M. Mayer[1]. *[1]Pharmacology, Midwestern University, Downers Grove, IL, [2]Abbott Laboratories, Abbott Park, IL and [3]University of Maryland School of Medicine, Baltimore, MD.*

Inflammation of the brain has been associated with the release of inflammatory mediators such as interleukin 1 α (IL-1α), interleukin 6 (IL-6), and macrophage inflammatory protein 2 α (MIP-2), as well as the anti-inflammatory mediator transforming growth factor β1 (TGF-β1) by microglia (BMG). *Vibrio vulnificus* (VvLPS) has been hypothesized to be involved in Vv (VvLPS) septicemia. We have recently reported that VvLPS stimulated rat neonatal BMG to release TNF-α, TXB2, O2-, and MMP-9 (Mayer et al. The Faseb Journal 21(5): A 404, 2007). The purpose of this investigation was to determine the effect of VvLPS on BMG priming and release of IL-1α, IL-6, TGF-β1, MIP-2, and lactate dehydrogenase (LDH). BMG were isolated from neonatal rats and then treated *in vitro* with VvLPS or *Escherichia coli* (EcLPS) for 17 hours. IL-1α, IL-6, TGF-β1, and MIP-2 were determined by immunoassay, and LDH by enzyme activity. Results were the following (n=2-3 experiments), LDH: release observed at >1 ng/mL VvLPS; IL-1α, IL-6, and MIP-2: concentration-dependent release detected at >1 ng/mL VvLPS; in contrast TGF-β1 release was measured at >1 μg/mL VvLPS. VvLPS appeared less potent than EcLPS. We conclude that VvLPS stimulated rat BMG cytokine and chemokine release in a concentration- and time-dependent manner. Further characterization of BMG response to VvLPS at both the functional and molecular level is ongoing in our laboratories. Supported by Midwestern University and the University of Maryland.

PL 65 RESVERATROL INHIBITS IL-2-INDUCED TOXICITY WHILE MAINTAINING EFFECTIVE TREATMENT OF MELANOMA BY DIFFERENTIALLY MODULATING THE SUPPRESSIVE FUNCTIONS OF MYELOID-DERIVED SUPPRESSOR CELLS.

H. Guan, P. S. Nagarkatti and M. Nagarkatti. *Pathology, Microbiology and Immunology, University of South Carolina School of Medicine, Columbia, SC.*

High-dose IL-2 therapy is an effective mode of treatment against melanomas. However, its use is limited by accompaniment of severe life-threatening toxicity including vascular leak syndrome (VLS). The precise mechanism/s of VLS is unclear and there is no specific therapy to block VLS and enhance IL-2-based immunotherapy. In this study, we report that administration of resveratrol into IL-2-treated melanoma tumor-bearing mice dramatically inhibited IL-2-induced VLS and enhanced IL-2 effectiveness. Resveratrol-treated mice showed decreased levels of metastasized tumor leading to increased survival when compared to the controls. Resveratrol administration prevented endothelial cell apoptosis and maintained endothelium integrity. Interestingly, resveratrol did not affect the emigration of lymphocytes across the endothelium and into tumor site. We noticed that production of TNF-alpha in the serum dramatically decreased with resveratrol treatment. Furthermore, we found that resveratrol could induce proliferation of myeloid-derived suppressor cells (MDSC). Amount of MDSC dramatically increased in the spleen, lung and liver in resveratrol-treated mice. Adoptive transfer of MDSC could prevent and block IL-2-induced VLS. We found the resveratrol-educated MDSC played a differential role on cytolytic killing of IL-2-activated killer T cells against endothelium and melanoma, which could be through the synchronized signaling from aryl hydrocarbon receptor and estrogen receptor. Our results demonstrate for the first time that resveratrol provides protection from IL-2-induced toxicity while maintaining IL-2 effectiveness by enhancing the suppressive function of myeloid-derived regulatory cells. PL 66 CERIUM OXIDE NANOPARTICLES INDUCE MAST CELL ACTIVATION, ALTER VASCULAR RELAXATION AND ARE ASSOCIATED WITH PRO-INFLAMMATORY CYTOKINE PRODUCTION.

J. M. Brown[1] and C. J. Wingard[2]. *[1]Department of Pharmacology & Toxicology, East Carolina University, Greenville, NC and [2]Department of Physiology, East Carolina University, Greenville, NC.*

Due to their unique physical and chemical characteristics, the use of nanoparticles has increased dramatically in recent years leading to a growing need for research examining the potential impact of nanoparticles on the environment and human health. Cerium oxide (CeO_2) represents an important nanomaterial with wide ranging applications; however, toxicity data for CeO_2 is limited. Mast cells have long been recognized for their prominent role in allergic inflammation, asthma, and cardiovascular disease. These cells reside within tissues including the respiratory tract where they can interface with environmental particles. The aim of this study was to examine the activation of mast cells and the vascular response following exposure to CeO_2. We examined the ability of CeO_2 to activate human and murine mast cells as measured by degranulation, cytokine production and quantitative PCR arrays. Additionally, we assessed vascular reactivity and cytokine profiles in a mouse model instilled with CeO_2. Mast cells were exposed *in vitro* to CeO_2 (0-300 μg/ml) for 6-48 hrs and both IgE and non-IgE mediated mast cell activation was examined. CeO_2 exposure resulted in minimal cytotoxicity as measured by LDH release and did not significantly affect mast cell degranulation. However, mast cell production of IL-8 and osteopontin was dose dependently increased following exposure to CeO_2. Mice exposed to CeO_2 exhibited reduced vascular relaxation to acetylcholine which was associated with an elevation in the cytokines IL-9 and IL-2. These findings demonstrate that CeO_2 can direct mast cell production of pro-inflammatory mediators which could potentially contribute to impaired vascular relaxation and adverse health effects in vivo. This work supported in part by a grant from Philip Morris USA/International to CJW.

PL 67 GENERATION OF REACTIVE OXYGEN SPECIES IN BEAS-2B AND INFLAMMATORY RESPONSES IN HMVEC-LB1 AND CO-CULTURES WITH WHITE BLOOD CELLS DURING *IN VITRO* EXPOSURE TO AMBIENT PARTICULATE MATTER.

S. Qu, E. N. Liberda, L. Chen and Q. Qu. *Environmental Medicine, New York University, New York, NY.*

Introduction: Particulate matter (PM) is a ubiquitous environmental pollutant that has been associated with increased risk of cardiopulmonary mortality and morbidity in urban communities. The present study measured the generation of reactive oxygen species (ROS), releases of IL-6 and IL-18, as well as levels of sICAM-1 and sVCAM-1 in epithelial and endothelial cells exposed to PM in vitro. Methods: ROS formation was assessed using 2',7'-dichlorodihydrofluorescein diacetate in BEAS-2B cells exposed to NIST fine PM (PM2.5), TiO2, SiO2, and carbon black. Commercially available ELISA kits were used to measure the concentrations of IL-6, IL-18, sICAM, and sVCAM in primary human vascular endothelial cells (HMVEC-LB1), human white blood cells (WBCs), and their co-cultures after exposure to NIST PM2.5 and size fractionated PM collected from Sterling Forest, Tuxedo, NY. Pretreatment of the cells with Deferoxamine or L-NAME was performed in order to examine if the oxidative stress and the eNOS pathway are involved in the PM induced cellular responses. Results and Conclusions: PM exposure induced significant dose-dependent increases of ROS formation in BEAS-2B cells, suggesting that ROS may be involved in PM associated toxicity. In addition, IL-6 was increased significantly in HMVEC-LB1 cells exposed to PM2.5 in both time- and dose-dependent manners. However, PM2.5 exposure for up to 24 hrs failed to induce any detectable production of IL-18, sICAM-1, and sVCAM-1 in HMVEC-LB1 cells. Furthermore, co-cultures with WBCs significantly enhanced PM2.5 induced IL-6 elevation in HMVEC-LB1 cells, suggesting that WBCs may play an important role in endothelial response to PM2.5. The present study suggests that HMVEC-LB1 cells can be successfully used as an in vitro model to examine the effects of PM exposure.

PL 68 HIGH PHYSIOLOGICAL LEVELS OF THE STRESS HORMONE, CORTICOSTERONE (CORT), EXACERBATE BRAIN INFLAMMATORY RESPONSES TO LIPOPOLYSACCHARIDE (LPS) AND TO THE NERVE AGENT, DFP: ROLE IN GULF WAR ILLNESS?

J. P. O'Callaghan[1], D. B. Miller[1] and S. M. Lasley[2]. [1]*CDC-NIOSH, Morgantown, WV and* [2]*Univesity of Illinois College of Medicine, Peoria, IL.*

Gulf War Illness (GWI) is a multi-symptom disorder with features characteristic of "sickness" behavior including, cognitive impairment, fatigue, depression, sleep disruption, GI and dermatological problems. Typically, sickness behavior is the normal manifestation of an inflammatory response to infection or injury and one that resolves with restoration of homeostasis. In GWI, the symptoms persist, findings suggestive of a heightened or chronic neuroimmune/neuroinflammatory reaction, the basis for which remains unknown. Undeniably, exposure of humans to infectious agents, or even acetylcholinesterase inhibitors presumed to be responsible for GWI, has occurred without the development of chronic sickness behavior and chronic peripheral/CNS inflammatory responses. Therefore, the question remains as to what combination of exposures and the environment of the 1991 Gulf War led to GWI. One answer may relate to a heightened physiological stress response associated with the short-term battlefield environment. Recent evidence suggests that the stressful environment under which troops operated may have altered the BBB and led to a stress/agent interaction unique to the first Gulf War. In support of this possibility, we found that one week of exposure to high physiological levels of CORT in the mouse results in an augmented neuroinflammatory response (induction of IL1-β, TNF-α and IL-6 mRNA) to challenge by the inflammogen, LPS; in contrast, acute exposure to CORT blocks the neuroinflammatory response to LPS. Moreover, we also found an enhanced expression of some proinflammatory cytokines in brain (TNF-α & IL-6) following exposure to the nerve agent, DFP. One week of prior exposure to CORT augmented these effects of DFP. Together, these observations are suggestive of a possible unrecognized link between the stressful environment of the Gulf War theater, agent exposures unique to this war, and a resulting adverse and persistent neuroinflammatory outcome.

PL 69 SOCS3 AND IGF-1 ARE POTENTIAL BIOMARKERS FOR DEOXYNIVALENOL-INDUCED GROWTH INHIBITION IN THE MOUSE.

C. J. Amuzie[1, 2], J. Shinozuka[3, 2] and J. J. Pestka[2, 1]. Deoxynivalenol (DON) is a trichothecene mycotoxin produced by *Fusarium* species, that is commonly detected in cereals worldwide. Upon oral exposure, DON is quickly absorbed and distributed (≤30 min) in rodents, with a consequent rapid systemic cytokine upregulation. Subchronic DON consumption impairs weight gain, thus eliciting public safety concerns. The mechanism(s) by which DON causes reduced weight gain and its linkages to cytokine upregulation are not well understood, creating uncertainty in public health assessment. Recently, several cytokine-inducible suppressors of cytokine signaling (CIS1, SOCS1,2,3,4,5,6 and 7) have been described. Among these, SOCS3 induction has been associated with reductions in weight gain and circulating insulin-like growth factor 1 (IGF-1), via a growth hormone (GH) pathway. We hypothesized that DON will induce SOCS3 and reduce IGF-1 in the mouse. RT-PCR revealed CIS1, SOCS1, SOCS2, and to a greater extent SOCS3 mRNA are rapidly (2h) and dose-dependently (0.1-12.5mg/kg bw) upregulated in muscle, spleen and liver of DON-exposed mice. Furthermore, SOCS3 protein was increased within 5 h after DON exposure. Consumption of DON (20ppm) for 8 wk reduced both circulating IGF1 (≈30%) and body weight (≈27%); and resulted in plasma DON concentration of ≈ 44 ng/ml. Taken together, DON-induced hepatic SOCS3 expression correlated with a reduction of circulating IGF-1. Since SOCS3 and IGF-1 are likely impacted by DON-induced cytokine upregulation, and the latter can modulate growth and weight gain, both endpoints have potential to serve as biomarkers of effect for this mycotoxin.

PL 70 HYPOXIA AND NEUTROPHIL ELASTASE INTERACT TO CAUSE HEPATOCELLULAR INJURY AND INCREASE OXIDATIVE STRESS AND PHOSPHORYLATION OF P38 MAPK.

E. Sparkenbaugh[1], K. Traore[2], K. Greenwood[1], P. Ganey[1] and R. Roth[1]. [1]*Pharmacology and Toxicology, Michigan State University, East Lansing, MI and* [2]*Department of Chemistry, Elizabeth City State University, Elizabeth City, NC.*

Inflammatory disease is characterized by the presence of hypoxia (HX) and activated neutrophils that secrete the serine protease, neutrophil elastase (EL). HX and EL are implicated in liver injury in inflammation-drug interaction models of idiosyncratic adverse drug reactions. We tested the hypothesis that HX and EL interact to cause hepatocellular injury in primary rat hepatocytes (HPCs) and human hepatoma, HepG2 cells. HPCs were exposed to 0-17 U/ml EL in oxygen replete (150 mmHg) or hypoxic (35 mmHg pO2) medium for 8h. Neither HX nor EL alone was cytotoxic, yet HX/EL treatment caused cell death. HepG2 cells were exposed to 0-60 U/ml EL in 150 mmHg or 15 mmHg pO2 for 24h. Only HX/EL cotreatment caused significant cell death. Additionally, EL treatment caused dose-dependent activation of caspase 3/7 that was not affected by HX coexposure. The injury caused by HX/EL was explored further in HepG2 cells. Intracellular reactive oxygen species production was significantly increased within 15 min exposure to HX/EL but required 180 min by HX alone. Phosphorylation of p38 (p-p38) was examined by immunocytochemistry. HX and EL each increased the number of p-p38 positive cells. No further increase was observed with cotreatment; however, there was selective nuclear translocation of p-p38 in HX/EL-cotreated cells. These results indicate that HX/EL treatment is cytotoxic to HPCs and HepG2 cells and selectively increases early oxidative stress and p-p38 nuclear translocation. (Supported by R01-ES004139 and T32-ES007255).

PL 71 ROLE OF NOS2 IN BLEOMYCIN-MEDIATED LUNG INJURY.

A. J. Gow[1], C. Guo[1], E. Atochina-Vasserman[2] and P. Scott[1]. [1]*Pharmacology & Toxicology, Rutgers University, Piscataway, NJ and* [2]*Pulmonary & Critical Care Medicine, University of Pennsylvania School of Medicine, Philadelphia, PA.* Sponsor: D. Laskin.

Recent evidence has shown that NOS2, the inducible isoform of nitric oxide synthase, is a critical mediator of acute pulmonary inflammation. Here, we examine the effect of NOS2 inhibition upon inflammation resulting from intratracheally administered bleomycin. Mice were sacrificed 8 days post administration of 8 U/kg of bleomycin sulfate (bleo) or saline (control), and lungs, bronchialveolar lavage (BAL), and cellular infiltrates were analyzed. One week prior to bleomycin administration, a mini-Alzet pump was placed subcutaneously containing either saline (control) or 1400W, a potent specific inhibitor of NOS2. In bleo mice there was a significant increase in nitrates within the BAL, indicating increased NOS2 activity. 1400W treatment abrogated this increase, showing that NOS2 is responsible for the increase in nitrates. Bleomycin administration induced pulmonary inflammation as shown by increased protein content and macrophage numbers within the BAL and the tissue inflammatory score. 1400W significantly reduced all of these indicators showing the importnace of NOS2 . As a measure of inflammatory signaling, we examined the ability of BAL from treated mice to induce chemotaxis in RAW cells. Bleo treated BAL produced a significant increase in chemotaxis over that from control. This increase was lost by treatment with 1400W. In addition, nitrosylated surfactant protein-D, another marker of inflammation, was increased in bleo treated BAL. This increase was inhibited by 1400W. We examined the level of chemokine expression by RT-PCR of BAL cells from bleo and control mice. GM-CSF was unaffected by bleo administration while IL-8 was induced, demonstrating the importance of neutrophil attraction in this model. Interestingly 1400W treatment significantly reduced IL-8 levels to below control. In contrast, TNF-α expression was increased in 1400W inhibited bleo treated mice. These observations indicate that NOS2 inhibition reduces lung injury in response to bleomycin and appears to accelerate repair.

PL 72 GENOMIC PROFILE OF RAT PLACENTA AFTER PHTHALATE EXPOSURE.

K. Johnson. *Nemours Biomedical Research, Alfred I. duPont Hospital for Children, Wilmington, DE.*

Assessing potential endocrine disrupting effects of human phthalate exposure requires development of appropriate biomarkers. With the long-term goal of developing surrogate tissue phthalate biomarkers, the aim of this research was to identify phthalate-induced genomic changes in rat placenta. Sprague-Dawley rats (n = 5) were fed control diet or diet containing 1750 ppm (165 mg/kg/day) dibutyl-phthalate (DBP) from gestational days (GD) 1 through 21. At GD21, placental gene expression was analyzed using Illumina RatRef-12 expression bead chips. In the target tissue (fetal testis), DBP exposure significantly increased formation of multinucleated germ cells. DBP did not significantly effect litter size, pup weight, or pup anogenital distance. 492 placental genes showed a z ratio of at least ±2. Similar to testis, DPB exposure decreased placental steroidogenic acute regulatory protein (Star) gene expression (-1.18 fold; -2.39 z ratio), and Ingenuity-based pathway analysis of the placental gene set revealed a significant change in functional pathways associated with lipid metabolism, including metabolism of eicosinoid and cholesterol transport. However, placental progesterone levels in DBP-treated animals were similar to control. Although preliminary, these data demonstrate that phthalate exposure alters gene expression within rat placenta and suggest similar functional pathways are affected in both the phthalate target tissue (testis) and a potential phthalate surrogate biomarker tissue (placenta). Future experiments will

phenotypically anchor phthalate-induced placental gene changes to fetal testis steroidogenic effects and identify/validate a placental surrogate biomarker gene set associated with phthalate endocrine disruption.

PL 73 TRADITIONAL CHINESE MEDICINE ON MALE GENITAL SYSTEM IN MICE EXPOSED TO DIESEL EXHAUST PARTICLES.

X. Hong[2], Q. Chen[2], Y. Song[2], J. Wang[2] and Q. Sun[1]. [1]*The Ohio State University, Columbus, OH and* [2]*Dongfang Hospital, Fuzhou, China.*

Background: Spermatic development and activity has been reported to be affected by air pollution exposure. However, the mechanisms remain unclear. We hypothesized that exposure to diesel exhaust particles (DEP) affected sperm count and motility, and Radix Astragali (RA), a traditional Chinese medicinal herb, had protective effects on sperms in mice. Methods: Male Institute for Cancer Research, Swiss-derived (ICR) mice at age of 5 weeks were randomized into DEP (360 μg), DEP + RA, or control groups (vehicle, n = 6) via intratracheal exposure twice a week for 4 weeks. RA (20mg/kg) was delivered intraperitoneally daily coupled with DEP exposure. Epididymis, sperm count, motility and weights were analyzed. The ability to induce acrosome reaction in sperm of mice was compared to their ability to fertilize in vitro oocytes from counterpart females (non-exposed). The levels of IL-1α and IL-1β in the testis were also examined by specific ELISA and real time PCR. Results: Epididymis weight and its ratio (epididymis weight/body weight) were significantly increased in the DEP group than in the control group. Sperm count, motility, and in vitro fertilization rate were significantly decreased in the DEP group compared with the control group. Testicular IL-1α and IL-1β levels were significantly higher in the exposed mice compared with the control mice. There were no significant changes about epididymis, sperm count and in vitro acrosome reaction in the RA treated mice compared with the control group. Testis weight and ratio (testis weight/body weight) showed no significant difference among the three groups.
Conclusion: Short-term exposure to diesel air pollution decreases sperm count and motility, and significantly reduced the capacity of the sperms to fertilize females. A traditional Chinese medicinal herb, Radix Astragali, has protective effects on sperm.

PL 74 HEDGEHOG SIGNALING REGULATES PROSTATE DEVELOPMENT: INTERPLAY OF PARACRINE AND AUTOCRINE MECHANISM.

M. Yu[1, 2] and W. Bushman[1, 2]. [1]*Molecular and Environmental Toxicology Center, Univ of Wisconsin-Madison, Madison, WI and* [2]*Department of Surgery, Division of Urology, University of Wisconsin-Madison, Madison, WI.*

Hedgehog (Hh) signaling plays an important role in prostate development and prostate cancer. The major goal of our research is to elucidate the molecular mechanisms by which Hh signaling regulates prostate growth. Here, we used both in vivo and in vitro methods to determine the paracrine and autocrine Hh effect on epithelium growth during prostate development. An immortalized mesenchymal cell line-UGSM-2 was transfected with activated form of Hh signaling intermediates Smo/Gli2 to simulate an activated ligand independent Hh paracrine pathway. UGS tissues isolated from both prenatal and postnatal stages were co-cultured with UGSM-2 cells in explant culture plates for one week. Immunostaining was performed for BrdU, and Pan-cytokeratin on the paraffin sections. The results showed that the paracrine Hh signals promote epithelial budding and proliferation at the stage of bud initiation, while inhibit epithelial proliferation on the initiated buds. By cre-lox mating strategy, we also achieved condtional activated and conditional null Hh signaling in mesenchyme layer. IHC staining on prostates from both prenatal and postnatal stage showed consistent results with in vitro explants co-culture experiment data. This suggests stage-specific Hh responsiveness during normal prostate development. For autocrine Hh signaling, we first detect its existence by X-gal staining using Ptc/LacZ and Gli1/LacZ mice. Then we also generated a mouse model that has activated or null autocrine Hh signaling by cre-lox mating system to observe its effect on progenitor cell proliferation. Our findings will introduce a novel paradigm into our efforts to understand normal growth regulation and offers important insights into the role of Hh signaling in prostate cancer.

PL 75 A MIXTURE OF IPRODIONE AND VINCLOZOLIN DELAYS THE ONSET OF PUBERTY IN THE MALE RAT IN A CUMULATIVE MANNER.

C. R. Blystone[1, 2, 3], C. S. Lambright[2], J. Furr[2], C. V. Rider[1, 2], V. S. Wilson[2] and L. E. Gray[2]. [1]*Reproductive Toxicology Division, U.S. EPA, Research Triangle Park, NC,* [2]*Environmental and Molecular Toxicology, NC State University, Raleigh, NC and* [3]*National Toxicology Program, NIEHS, Research Triangle Park, NC.*

Vinclozolin and iprodione are dicarboximide fungicides that display anti-androgenic effects in the male rat, which suggests co-exposure to these fungicides would lead to cumulative effects on androgen-sensitive endpoints. In order to test for cumulative effects by iprodione and vinclozolin, we examined the effects of a mixture of these fungicides on pubertal development in the male rat. The mixture combined a dose of iprodione that does not significantly affect androgen-dependent morphological endpoints, with vinclozolin (a 5x2 factorial design). Sprague-Dawley rats were dosed by gavage with effective vinclozolin doses (0, 10, 30, 60, and 100 mg/kg/d) with and without 50 mg iprodione/kg/d from postnatal day (PND) 23 to 55-57 (n = 8/group). Onset of puberty (progression of preputial separation (PPS)) was measured starting on PND 37. Organ weights, serum hormones, and ex vivo testis steroid hormone production under stimulated (+human chorionic gonadotropin (hCG)) and unstimulated (-hCG) conditions were measured at necropsy. Vinclozolin alone delayed pubertal progression, reduced androgen sensitive organ weights, and increased serum testosterone levels as previously reported. The addition of 50 mg/kg/d iprodione enhanced the vinclozolin-induced delay in PPS (PND 47.5 vs 49.1; 2-way ANOVA: iprodione main effect p = 0.0002) and reduction of several reproductive organ weights. Furthermore, the increase in serum testosterone by vinclozolin, due to its AR antagonism, was reduced by the addition of iprodione (a steroidogenic inhibitor) in vivo, but not ex vivo. These results demonstrate these fungicides interact when co-administered to delay pubertal development (i.e. PPS) in the male rat in a cumulative, antiandrogenic manner. *CRB and CVR were supported through the USEPA/NCSU Cooperative Training Agreement. This abstract does not necessarily reflect US EPA policy.*

PL 76 CYCLOPHOSPHAMIDE AND ITS ACTIVE METABOLITE PHOSPHORAMIDE MUSTARD CAUSE OVARIAN FOLLICLE LOSS AND DNA DAMAGE IN VIVO AND IN VITRO .

T. Truong, S. K. Petrillo and P. J. Devine. *INRS-Institut Armand-Frappier, Laval, QC, Canada.*

Cyclophosphamide (CPA) is an ovotoxic drug frequently used to treat multiple types of cancers. It is activated by cytochrome P450 enzymes to form phosphoramide mustard (PM) *in vivo*. PM is the active anticancer agent, but it also causes ovarian follicle destruction. We have shown that exposure of cultured rodent neonatal ovaries to PM *in vitro* cause concentration-dependent ovarian follicle loss and DNA damage at 24h. The goal of this study is to compare the effects of CPA *in vivo* with the *in vitro* effects of PM on mammalian oocytes. Single exposures to CPA or PM were carried out in vivo in adult mice and in a post-natal day 4 (PND4) ovarian culture system, respectively, to determine if oocytes suffer DNA double-strand breaks (DSBs). PND4 ovaries from CD-1 mice were exposed after 4 days of culture to PM (0.1-3μM). Following 8 days of culture, ovaries were fixed for follicle counts or for fluorescent immunohistochemistry using a phosphorylated histone H2AX (γ-H2AX), a marker of DNA DSBs. In culture, PM caused significant loss of primordial (3μM) and small primary follicles (≥0.1μM), relative to control. Under the same conditions, numbers of follicles with ≥5 γ-H2AX foci/oocyte were increased. CD1-mice injected with a single dose of CPA (75-250mg/kg) were sacrificed 1 or 8 days later. Compared to control, kidney and body weights did not change, whereas spleen weight decreased significantly at day 1 and increased at 8 days (250mg/kg), and liver weight significantly increased at 8 days after CPA exposures (250mg/kg). Primordial follicles were significantly decreased in CPA-exposed mice at both time points, while antral follicles were significantly decreased only at 24h (250mg/kg). γ-H2AX staining was observed in apoptotic granulosa cells of antral follicles and certain oocytes of small follicles, but individual foci were difficult to identify. Data indicate that DSBs can persist for at least 8 days in oocytes in cultured ovaries, and that such damage also occurs *in vivo*, suggesting a common mechanism both *in vivo* and *in vitro*.

PL 77 DIET-INDUCED OBESITY IN MALE MICE ASSOCIATED WITH REDUCED FERTILITY AND POTENTIATION OF ACRYLAMIDE-INDUCED GERM CELL TOXICITY.

U. Hoffler[1], R. Bai[1], G. Kissling[2], G. Travlos[3] and B. I. Ghanayem[1]. [1]*LP, NIEHS/NIH, RTP, NC,* [2]*BB, NIEHS/NIH, RTP, NC and* [3]*CMPB, NIEHS/NIH, RTP, NC.*

Over the past 20 years obesity trends have aggressively increased within the US with 60% of the states reporting prevalence of obesity ≥ 25%. Associated with elevated BMI, human risks for the development of chronic diseases: type 2 diabetes, infertility, cardiovascular diseases and cancer have also risen. Recently studies have suggested an association between obesity and male infertility. Current studies were designed to address the hypothesis that diet-induced obesity is associated with increased male infertility and obese male mice are more susceptible to reproductive toxicity of environmental chemicals such as acrylamide (AA). Genetically intact male C57Bl/6J mice were fed either a control or high fat diet (60% kcal fat) from 5 to 30 weeks of age. At age 30 weeks, mice fed high fat diet exhibited significantly

higher body weight and % body fat. Fertility of obese and control mice was compared by mating with untreated female mice. In late gestation females were sacrificed and uterine content examined. Significant decrease in the number of plugs and pregnancies were evident in females mated to obese vs. control males. Reduced hyperactivated sperm and lower counts were determined in obese vs. controls. To assess the reproductive effects of AA, 30 week obese or control mice were gavage treated with tap water or 25 mg AA/kg/day for 5 days and mated to untreated females. AA exposure exacerbated the decrease in number of plugs and pregnancies in females mated to obese and controls. The effect of AA was more striking in females mated to obese males, as the % of live fetuses decreased and resorptions (%) further increased. In conclusion, diet-induced obesity led to significant reduction in male fertility and exacerbated AA-induced germ cell mutagenicity. This model proved to be valuable in studying the impact of obesity on host susceptibility to environmental chemicals and may be used to study the link between obesity and chronic disorders in humans.

PL 78 THE ABILITY OF THE ARYL HYDROCARBON RECEPTOR TO REGULATE OVARIAN FOLLICLE GROWTH AND OVULATION MAY DEPEND ON SEXUAL MATURITY IN MICE.

I. Hernández-Ochoa, T. Leslie and J. A. Flaws. *Veterinary Biosciences, University of Illinois, Urbana, IL.*

The aryl hydrocarbon receptor (AHR) is a ligand-activated transcription factor known for mediating the toxicity of polychlorinated biphenyls and dioxins. However, the endogenous roles of the AHR are still under investigation. We previously have shown that young Ahr-deficient mice (AHRKO) have decreased numbers of antral follicles and corpora lutea (CL) compared to young wild-type mice (WT) on postnatal day (PD) 54. In addition, AHRKO cultured follicles have decreased follicle growth and estradiol (E2) production compared to WT cultured follicles on PD 32. These previous data suggest that the AHR may regulate follicle growth and ovulation in young mice. The current study evaluated the role of the AHR in follicle growth, steroidogenic capacity and ovulation in cycling adult mice. Ovaries were collected from WT and AHRKO adult mice (PD 90) and subjected to morphological evaluation of antral follicle and CL numbers. Growth of antral follicles (PD 90) was evaluated in culture by measuring follicle diameters for 168 h. Media samples from cultured follicles were collected at 72 h and 168 h, and subjected to measurements of androstenedione (ASD) and E2 levels. Interestingly, WT and AHRKO ovaries contained similar numbers of antral follicles (WT=167±20; AHRKO=160±25; p=0.56) and CL (WT=9±0.9; AHRKO=7.4±2.7; p=0.35). Further, isolated antral follicles from WT and AHRKO ovaries grew to similar sizes by 168 h of culture (WT=531±17.2 μm; AHRKO=530±18.4 μm; n=3 separate cultures; p=0.09). E2 levels produced by WT and AHRKO follicles were similar at 72 h and at 168 h. ASD levels produced by WT and AHRKO follicles were similar at 72 h, but AHRKO follicles produced 1.5-fold higher levels of ASD compared to WT follicles at 168 of culture (WT=1.9±0.2 ng/ml; AHRKO=2.9±0.2 ng/ml; p=0.04). Collectively, these data suggest that the reduced follicle numbers and ovulations present in young AHRKO mice are restored to normal levels in cycling adult AHRKO mice, possibly by compensation from increased levels of theca cell-derived hormones. Support: NIH HD047275.

PL 79 MOLECULAR PATHWAYS UNDERLYING CO-EXPOSURES TO DIFFERENT TESTICULAR TOXICANTS ACTING ON THE SAME OR DIFFERENT CELLULAR TARGETS.

S. N. Campion[1], M. Sandrof[1], Y. Sui[2], E. Houseman[2], Z. Wu[2] and K. Boekelheide[1]. *[1]Pathology and Laboratory Medicine, Brown University, Providence, RI and [2]Community Health, Brown University, Providence, RI.*

Paracrine-interacting cell types (Sertoli cells and germ cells) within the testis control the process of spermatogenesis. Exposure to testicular toxicants that target these different cell types ultimately results in germ cell apoptosis, disrupting spermatogenesis. Real-life exposures often involve mixtures of hazardous chemicals, therefore the current study was performed to investigate the effects of co-exposures to testicular toxicants. Adult male rats were exposed to 1% 2,5-hexanedione (HD), a Sertoli cell toxicant, in the drinking water for 18 days followed by acute co-exposure to a second testicular toxicant that targets either Sertoli cells (mono-2-ethylhexyl phthalate; MEHP or carbendazim; CBZ) or germ cells (x-irradiation; X-ray). Testis samples were collected 3 hrs later and total RNA was isolated and hybridized to Affymetrix Rat Genome 230 2.0 GeneChips. Ingenuity Pathways Analysis was performed to identify and compare biological pathways and functions significantly altered by each co-exposure. The predominant biological pathways altered following HD plus MEHP are drug metabolism, lipid metabolism, small molecule biochemistry and cellular assembly and organization, while cellular growth and proliferation, cellular movement, cellular development and cellular assembly and organization were the significantly altered pathways following HD plus CBZ exposure. HD plus X-ray co-exposure significantly changed genes involved in cellular movement, cell-to-cell signaling and interaction, small molecule biochemistry, and cellular growth and proliferation. The individual genes and biological pathways significantly changed by HD plus CBZ co-exposure and HD plus X-ray co-exposure are very similar. This suggests that similar molecular pathways are affected by co-exposures to testicular toxicants that target either the same or different cell types.

PL 80 *IN UTERO* TREATMENT WITH THE HERBICIDE LINURON PRODUCES MALE RAT REPRODUCTIVE MALFORMATIONS SIMILAR TO THE PHTHALATE ESTERS BUT THROUGH A DIFFERENT MECHANISM OF ACTION.

V. S. Wilson, C. Lambright, J. Furr, K. Howdeshell and L. E. Gray. *Reproductive Toxicology Division, U.S. EPA, ORD, NHEERL, RTP, NC.*

Although linuron has been reported to act as an androgen receptor (AR) antagonist, the suite of malformations observed in male rat offspring after in utero exposure differs from that of other AR antagonists and more closely resembles that produced by phthalate esters (PE) such as di-butyl phthalate and diethyl hexyl phthalate. However, only the PEs induce malformations of the gubernacular ligament. Many of the malformations in male rat offspring produced by PEs have been attributed to reduced fetal testosterone synthesis due to lowered steroidogenic gene expression and decreased insl3 gene expression from the fetal Leydig cell; insl3 being critical for proper gubernacular ligament development. The current study investigated the dose response effects of in utero linuron treatment on fetal testis gene expression and testosterone production. Pregnant Sprague Dawley rats were administered corn oil vehicle or 12.5, 25, 50 or 75 mg linuron /kg/day orally from gestation day (GD)13-18. Fetal testes were collected on GD18 for ex vivo testosterone (T) production and gene expression. Ex vivo T, but not progesterone production, was significantly decreased by 50 and 75 mg linuron/kg/day. Unlike the phthalate esters, linuron treatment did not affect insl3, cyp17α, cyp11α or StAR mRNA expression. In a second study, control GD18 fetal testes were incubated with increasing concentrations of linuron (1 to 300 μM) to evaluate if linuron inhibited T production in vitro. T production was significantly reduced at 30 μM and above whereas progesterone production was not reduced at any concentration indicating that linuron directly inhibited testosterone production in the absence of cytotoxicity. Taken together, these data demonstrate that even though the profile of malformations produced by linuron resembles, in part, that of phthalate esters, the mechanism of action of linuron clearly differs from the phthalate esters. Disclaimer: Does not necessarily reflect US EPA policy.

PS 81 ARYL HYDROCARBON RECEPTORS (AHR) OF SHARKS: STRUCTURAL AND FUNCTIONAL DIVERGENCE AMONG AHR PARALOGS.

R. R. Merson[1, 2], S. P. Hersey[1], T. W. Zalobowski[1], A. R. Albanese[1], D. G. Franks[2] and M. E. Hahn[2]. *[1]Biology, Rhode Island College, Providence, RI and [2]Biology, Woods Hole Oceanographic Institution, Woods Hole, MA.*

Toxic responses of vertebrates to 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) depend on binding and activation of the aryl hydrocarbon receptor (AHR) and subsequent gene dysregulation. The multiple roles and molecular targets of the AHR make it difficult to determine the precise mechanisms by which AHR agonists disrupt cell physiology. We investigated AHR protein function in spiny dogfish sharks (*Squalus acanthias*), which express several AHR genes, to determine whether the toxic response pathway and physiological roles of AHR are partitioned among the multiple AHR paralogs. We PCR-amplified and sequenced three AHR cDNAs, investigated their orthology with vertebrate AHRs, used *in vitro*-synthesized AHRs with [^{3}H]TCDD to determine ligand binding of each AHR, and performed transfection of shark AHR constructs into mammal cells followed by treatment with 3,3',4,4',5-pentachlorobiphenyl (PCB126) or 3-methylcholanthrene (3MC) to assess activation of a reporter gene regulated by dioxin response elements (DRE) and to identify subcellular localization by fluorescence microscopy. The three shark AHRs differ in their subcellular localization, ability to bind TCDD, and response to typical AHR agonists. AHR1 is cytoplasmic, does not bind TCDD, and is not activated by 3MC or PCB126. AHR2 is cytoplasmic, binds TCDD, upon treatment with PCB126 rapidly translocates to the nucleus, and can activate transcription in the presence of PCB126 or 3MC. AHR3 is constitutively nuclear, capable of binding TCDD, and can be activated by PCB126 or 3MC. This divergence in the ability of multiple AHRs to bind and respond to agonists, coupled with differences in AHR protein localization, support our hypothesis that multiple roles of AHR are partitioned among these distinct gene products. We are pursuing the use of shark AHRs to distinguish AHR-dependent, ligand-induced toxic responses from physiological roles involving other signaling pathways. Supported by RI-INBRE Grant P20RR016457 (NCRR), R01ES006272 (NIEHS).

PS 82 TRANSCRIPT DIVERSITY OF ARYL HYDROCARBON RECEPTOR 2 (AHR2) IN SHARKS.

T. W. Zalobowski and R. R. Merson. *Biology, Rhode Island College, Providence, RI.* Sponsor: M. Hahn.

Aryl hydrocarbon receptors (AHR) are intracellular proteins that bind environmental chemical contaminants, including 2,3,7,8-tetrachlorodibenzo-*p*-dioxin and related structures. Upon activation, conformational changes promote AHR nuclear translocation and subsequent transcriptional regulation of genes involved in cell physiology. *Squalus acanthias* (spiny dogfish shark) express more than 3 distinct *AHR* genes encoding well-conserved amino acid sequence in the bHLH and PAS domains and divergent sequence in the carboxyl-terminal half of the protein. Shark AHR2 is unique because it contains an octapeptide repeat motif (OPM) domain in the carboxyl-terminal region, which is not present in other vertebrate *AHR2* orthologues. To investigate the structure and function of the OPM domain, we used RT-PCR to amplify the entire OPM domain from multiple tissues of three sharks, and sequenced the OPM domain of genomic DNA and BAC clones containing *S. acanthias AHR2*. We identified at least 6 AHR2 isoforms from cDNA and additional sequence diversity in the genome. The number of octapeptide repeats in the OPM varies from 27 to 35 and three or more isoforms are expressed in individual sharks; however, there is no clear tissue-specific expression pattern. AHR2α is activated by ligand and supports expression of a dioxin response element-regulated luciferase reporter in transient transfection experiments. We are currently evaluating ligand activation and transcriptional activity of the other AHR2 isoforms. While it is unclear whether these AHR2 isoforms represent different genes, alternative splicing of a single *AHR2* gene, or another mechanism promoting genetic variability, our studies will clarify the role for AHRs in responses to environmental chemicals at cellular and genetic levels in cartilaginous fishes and provide additional information about the endogenous function of the AHR signaling pathway in vertebrates. Research supported by RI-INBRE Grant # P20 RR-016457 and ME-INBRE Grant # P20 RR-016463 from NCRR, NIH, and NIEHS Center for Membrane Toxicity Studies Grant # P30 ES003828-20 at the Mount Desert Island Biological Laboratory.

PS 83 TOXICITY OF TCDD IN NOVEL MOUSE LINES EXPRESSING RAT AH RECEPTOR VARIANTS.

R. Pohjanvirta[1, 2, 3]. [1]*Department of Food and Environment Hygiene, University of Helsinki, Helsinki, Finland,* [2]*Laboratory of Toxicology, National Public Health Institute, Kuopio, Finland and* [3]*Kuopio Research Unit, Finnish Food Safety Authority EVIRA, Kuopio, Finland.* Sponsor: M. Viluksela.

Han/Wistar (Kuopio) rats are exceptionally resistant to the acute toxicity of TCDD (LD50 >9,600 μg/kg). Their resistance has been shown to be mainly due to a splicing alteration in the AH receptor (AHR) resulting in the presence of two AHR proteins in these animals, a deletion (DEL) and an insertion (INS) variant (the predominant form), both of which are restructured at the transactivation domain in the C-terminal end of the AHR. Recently, novel mouse lines were generated on the C57BL/6 background which express globally rat wild-type (rWT), DEL variant or INS variant AHR (manuscript submitted). They proved to have no major phenotypic changes apart from increased testis size, and their AHRs were shown to be functional both physiologically and as mediators for TCDD. The lines exhibited clear sensitivity differences to acute toxicity of TCDD with rWT mice being highly sensitive, DEL mice moderately resistant and INS mice highly resistant. Here, the lines were further characterized by subjecting them to a time-course study (1, 3 and 6 days after 500 μg/kg; females) and to a dose-response study (125-1000 μg/kg; 4 days; males) with TCDD. In both studies, rWT mice displayed substantial body weight loss (14 or >20% by 6 or 4 days for females and males, respectively). In DEL mice, body weight decline was more moderate (4 and 10%). Strikingly, INS mice gained weight (6 and 1%) with the rate of change being significantly higher than in their controls on day-3. Despite the fact that INS mice express more AHR in thymus than rWT mice, thymus atrophied sooner and to a larger degree in rWT than in INS mice. The same was true of liver enlargement which reached significance already on day-1 in rWT mice but only on day-6 in INS mice. Histologically, liver was much more severely affected in rWT than in INS mice. These mouse lines thus represent a promising new tool for dioxin and AHR research.

PS 84 XENOBIOTICS-MEDIATED TRANSLOCATION OF ADENOVIRUS-DRIVEN CONSTITUTIVE ANDROSTANE RECEPTOR IN HUMAN PRIMARY HEPATOCYTES.

H. Li[1], T. Chen[1], J. Cottrell[2], L. Tompkins[1] and H. Wang[1]. [1]*Pharmaceutical Sciences, University of Maryland School of Pharmacy, Baltimore, MD and* [2]*Department of Pathology, University of Maryland School of Medicine, Baltimore, MD.*

The constitutive androstane receptor (CAR; NR1I3) is an important xenobiotic-sensing transcription factor that controls the expression of numerous hepatic genes involved in the detoxification of xenobiotics. In primary hepatocytes and intact liver, CAR resides in the cytoplasm under basal conditions and translocates to the nucleus upon exposure to inducers. However, human (h) CAR spontaneously accumulates in the nucleus of immortalized cell lines and exhibits constitutive activation in the absence of activators, which make the identification of CAR activators extremely challenging. Here, we have established an adenovirus-driven fluorescent protein-tagged hCAR expression system (Ad/EYFP-hCAR) in human primary hepatocytes (HPH). Our results demonstrated that Ad/EYFP-hCAR infected HPH with high efficiency, and the majority of the Ad/EYFP-hCAR (>90%) expressed in the cytoplasm of HPH without treatment, while translocated to the nucleus in response to chemical activators. Furthermore, 22 compounds including known hCAR activators, deactivators, typical activators of other nuclear receptors, as well as rodent CYP2B inducers lack of CAR activation information were evaluated in this system. In general, xenobiotics-mediated hCAR translocation in HPH significantly correlated with hCAR activation and target gene induction. Comparing with cell-based reporter assay in immortalized cells and nuclear translocation of hCAR in Car-/- mice, the established Ad/EYFP-hCAR translocation assay in HPH exhibits obvious advantages such as responding to both direct and indirect activators, and the potential for a high-throughput manner. Thus, nuclear translocation of Ad/EYFP-hCAR in HPH represents an efficient means for in vitro prediction of xenobiotics-mediated human CAR activation.

PS 85 CELL CYCLE WITHDRAWAL INCREASES LIGAND-MEDIATED CYP1A1 EXPRESSION IN HUMAN KERATINOCYTES.

G. L. Stevens[1], C. H. Sutter[1, 2] and T. R. Sutter[1, 2]. [1]*Biology, University of Memphis, Memphis, TN and* [2]*W. Harry Feinstone Center for Genomics, University of Memphis, Memphis, TN.*

Ligand-mediated induction of genes regulated by the aryl hydrocarbon receptor (AHR) reaches a maximum in confluent keratinocytes and is associated with the differentiation process. An early event in keratinocyte differentiation is cell-cycle withdrawal. Studies were carried out to determine if cell cycle withdrawal, independent of differentiation, triggered the increased level of AHR-regulated genes. Preconfluent normal human keratinocytes were pretreated with chemicals that induce cell cycle withdrawal at G0/G1, followed by treatment with 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and CYP1A1 mRNA analysis. mRNA levels of an early marker of differentiation, keratin 1, did not increase, indicating that cell cycle withdrawal occurred independent of differentiation. Pretreatment with TGFβ1, rapamycin or 8-Cl-adenosine increased TCDD-mediated CYP1A1 mRNA induction 2-, 3- and 20-fold, respectively, over the control samples (TCDD treatment only) demonstrating that cell cycle withdrawal increases AHR activation in human keratinocytes. Lower 8-Cl-adenosine concentrations that did not result in cell cycle withdrawal did not induce CYP1A1 mRNA, further supporting this association. Although cell cycle withdrawal increased TCDD-mediated induction of CYP1A1, the levels were still lower than TCDD-mediated induction in cells allowed to grow to confluence, indicating that additional density/differentiation-related signals are necessary for maximal AHR activation. As the chemicals used in this study have multiple effects (i.e. TGFβ is known to modulate AHR levels in some cell types), ongoing work includes measuring AHR levels and inducing cell cycle withdrawal through overexpression of cyclin-dependent kinase inhibitors.

PS 86 ROLE OF MU-OPIOID RECEPTOR IN ANTINOCICEPTION OF GABAPENTIN AND TRAMADOL.

X. Dai[1], C. D. Brunson[1], H. H. Loh[3], I. K. Ho[4, 2] and T. Ma[2]. [1]*Anesthesiology, University of Mississippi Medical Center, Jackson, MS,* [2]*Pharmacology and Toxicology, University of Mississippi Medical Center, Jackson, MS,* [3]*Pharmacology, University of Minnesota Medical School, Minneapolis, MN and* [4]*Mental Health and Substance Abuse Research, NHRI, Zhunan, Miaoli, Taiwan.*

Rational combination of antinociceptive agents with different mechanisms of action can improve efficacy and reduce toxicity. Tramadol is an atypical opioid agonist, which has been proposed to produce antinociception via both opioid and non-opioid pathways, and gabapentin is an antinociceptive adjuvant with unknown mechanism of action. Previously, we demonstrated that gabapentin enhances antinociceptive action of and reduces tolerance to tramadol. The mechanism responsible for the synergy of gabapentin and tramadol remains unclear. The μ-opioid receptor(μ-OR) plays a key role in the control of nociceptive pathways in the nervous system and is a major target for antinociceptive drugs. The present study is to determine whether the μ-OR is implicated in the antinociceptive synergy of gabapentin and tramadol. Experiments were conducted in adult male wild-type and μ-OR knockout mice. Gabapentin (75 mg/kg) and tramadol (60 mg/kg), alone or in combination, were administrated to mice by gavage and intraperitoneal injection, respectively. The tail-flick response of mouse was tested 60 min after drug administration. Antinociceptive responses in the tail-flick are expressed as the percentage of maximum possible effect (% MPE) at the time point at which the greatest antinociceptive responses were observed. The MPE values were 6% in wild-type

mice and 16% in μ-OR knockout mice after gabapentin administration (P<0.05). Following tramadol injection, the MPE values were 46% and 5% in wild-type and μ-OR knockout mice, respectively (P<0.05). The MPE values were 70% in wild-type mice and 13% in μ-OR knockout mice with administration of the two drugs in combination (P<0.05). The result indicated that μ-OR is a major target for tramadol but not for gabapentin. The μ-OR is also implicated in the antinociceptive synergy of gabapentin and tramadol.

PS 87 DEVELOPMENT AND APPLICATION OF A RECOMBINANT HUMAN HEPG2 CELL BIOASSAY FOR IDENTIFYING AHR LIGANDS.

A. Hayashi[1], W. Hu[2], M. R. Fielden[2] and M. S. Denison[1]. [1]*Environmental Toxicology, UC Davis, Davis, CA and* [2]*ICONIX Pharmaceuticals, Mountain View, CA.*

The aryl hydrocarbon receptor (AhR) is a ligand-dependent transcription factor that not only binds 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD, dioxin) and related halogenated aromatic hydrocarbons, but also many structurally unrelated chemicals, and it is responsible for many of the toxic and biological effects of these compounds. Stable transfection of an AhR-responsive luciferase reporter gene into mouse, rat and guinea pig cell lines allowed development of recombinant cell lines for use in the detection and characterization of novel AhR ligands (agonists and antagonists). However, a human CALUX cell bioassay would be useful for comparative studies and would provide us a more relevant assay to examine the activation of the human AhR by human therapeutic drugs. Accordingly, we have developed, characterized, and validated such a recombinant human hepatoma (HepG2) cell line (HG2L6.1c1). Luciferase induction in these cells occurred in a dose-, chemical- and time-dependent manner with an EC50 for TCDD of 1.29 nM. Optimal temperature and time for induction of luciferase activity in HG2L6.1c1 cells were found to be 33°C and 48 hours. This bioassay was used to screen 147 commercially available human therapeutic chemicals and other compounds, and the results compared to data using the mouse, rat, and guinea pig cell lines. The induction profiles of the pharmaceutical drugs revealed that although HG2L6.1c1 cells were somewhat less sensitive than that of other species, they could be used to identify several known and unknown human AhR agonists. Interestingly, some chemicals, such as the anthracyclins (epirubicin, daunorubicin), cadmium chloride and sodium arsenite, did not stimulate AhR DNA binding, but induced AhR-dependent gene expression. The availability of the human CALUX cell line provides an avenue in which to identify and characterize novel human AhR agonists. Supported by NIEHS grants ES04699 and ES012498.

PS 88 TRPA1 IS A MAJOR OXIDANT SENSOR IN AIRWAY SENSORY NEURONS.

S. E. Jordt[1], B. F. Bessac[1], M. Sivula[1], C. A. von Hehn[1], J. Escalera[1] and L. Cohn[2]. [1]*Pharmacology, Yale University School of Medicine, New Haven, CT and* [2]*Internal Medicine, Yale University School of Medicine, New Haven, CT.*

Sensory neurons in the airways are finely tuned to respond to reactive chemicals threatening airway function and integrity. Airway neurons are particularly sensitive to oxidants such as peroxides, ozone and oxygen radicals, formed in polluted air and during oxidative stress, and the oxidant gas chlorine that is frequently released in industrial and domestic accidents. Oxidant activation of airway neurons induces respiratory depression, cough, mucus secretion and pain. While normally protective, these responses can provoke severe complications in patients affected by inflammatory airway conditions such as rhinitis and asthma. Here, we show that both hypochlorite, the oxidizing mediator of chlorine, and hydrogen peroxide, a reactive oxygen species, activate Ca2+ influx and membrane currents in an oxidant-sensitive subpopulation of chemosensory neurons. These responses are absent in neurons from mice lacking TRPA1, an ion channel of the TRP gene family. TRPA1 channels are strongly activated by hypochlorite and hydrogen peroxide in primary neurons and heterologous cells. In tests of respiratory function, TRPA1-/- mice display profound deficiencies in hypochlorite- and hydrogen peroxide-induced respiratory depression. Thus, we identify TRPA1 as a major oxidant sensor in sensory neurons, initiating neuronal excitation and subsequent physiological responses in vitro and in vivo.

PS 89 THE ARYL HYDROCARBON RECEPTOR (AHR) SIGNALING PATHWAY INTERACTIONS INFLUENCES AHR-MEDIATED CHANGES IN MATRIX METALLOPROTEINASE GENE EXPRESSION.

T. Kung[2], K. A. Murphy[1] and L. A. White[1]. [1]*Biochemistry and Microbiology, Rutgers University, New Brunswick, NJ and* [2]*Joint Graduate Program in Toxicology, Rutgers University, New Brunwick, NJ.*

The aryl hydrocarbon receptor (AhR) is a basic helix-loop-helix transcription factor involved in regulation of gene expression. Originally identified as the receptor for environmental contaminants, such as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), it is now known to be activated by a variety of exogenous and endogenous compounds. Despite this, the endogenous function of this pathway remains unclear. We hypothesize that the AhR is a stress-activated pathway that functions to modulate normal cellular homeostasis involving the cellular decision to proliferate, undergo apoptosis, or migrate. Our laboratory has focused on this pathway's ability to alter cellular migration via regulation of matrix metalloproteinase (MMP) expression. MMPs are essential for tissue remodeling and cellular migration, and are inappropriately expressed in a variety of pathologies, such as rheumatoid arthritis and tumor metastasis. Our data show that AhR activation alters expression and activity of MMPs in human melanoma cells and in normal human keratinocytes, and that such changes in MMP expression are mediated through distinct mechanisms. We suggest that cell-type variations in the AhR-response are influenced by three factors: expression of AhR, expression of AhR repressor (AhRR), and cross-talk with other signaling pathways. In support of this, we have found a correlation between the AhR/AhRR ratio with melanoma aggressiveness and invasiveness. Our data also show that interactions between the AhR and Ras/Raf signaling pathway are critical for AhR-mediated induction of MMPs in melanoma cells. Both chemical inhibition of Ras/Raf and siRNA knockdown of Braf in human A2058 melanoma cells inhibits TCDD-induced expression of MMP-1. Conversely, inhibition of AhR also decreases ERK phosphorylation. Taken together, these data implicate cross-talk between the Ras/Raf and AhR signaling pathways to alter MMP-1 production in A2058 melanoma cells.

PS 90 BOTH AHR AND UNLIGANDED ERα ATTENUATE CYTOKINE-MEDIATED INDUCTION OF IL-8.

B. DiNatale and G. H. Perdew. *Department of Veterinary & Biomedical Science, The Pennsylvania State University, University Park, PA.*

Recent investigations have increasingly highlighted a role for the AhR in mediation of inflammatory responses. For example, we have recently shown that IL-1β signaling combines with activated AhR/ARNT heterodimer to synergistically induce IL-6 transcription in ER-positive ECC-1 endocervical cancer cells. Concurrently, it is well known that various nuclear receptors undergo crosstalk, with AhR and ERα being one example. Recently, we have found that crosstalk between unliganded ERα and AhR modulates IL-8 induction via a possible cytoplasmic interaction in ECC-1 cells. In the presence of the ER agonist estradiol, quantitative real time PCR shows that IL-1β induces a 300-fold increase of IL-8 mRNA over treatment with vehicle control. Removal of estradiol results in a 50% decrease in IL-8 transcription, while the presence or absence of the AhR agonist 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) has no effect on the IL-8 repression. Knockdown of either ERα or AhR through siRNA transfection rescues maximal IL-8 induction levels, even in the absence of estradiol. Interestingly, removal of either receptor also results in an approximate 6-fold increase of basal IL-8 transcription. siRNA knockdown of ARNT, which leads to a near complete ablation of TCDD-induced CYP1A1 induction, fails to prevent repression of IL-8 induction in the absence of estradiol; thus pointing to the involvement of AhR in a non-classical manner. Likewise, siRNA knockdown of ERβ also fails to prevent repression of IL-8. These results, combined with research having shown protein-protein interactions between ERα and NFκB, suggest the presence of a multi-protein complex in which the AhR and unliganded ERα interact with transcription factors in the cytoplasm to modulate inflammatory responses.

PS 91 ANALYSIS OF AHR PROTEIN STABILITY IN A YEAST EXPRESSION MODEL.

S. Wilson, K. Schmidt and R. S. Pollenz. *Biology, University of South Florida, Tampa, FL.*

The aryl hydrocarbon receptor (AHR) and the aryl hydrocarbon receptor nuclear translocator (ARNT) are well-characterized bHLH-PAS transcription factors involved in the response of organisms to certain environmental contaminants such as 2,3,6,8-tetrachlorodibenzo-p-dioxin (TCDD). Previous studies have demonstrated that the AHR is degraded following TCDD binding. To generate a model system useful to screen for proteins involved in TCDD-mediated AHR degradation, the cDNAs for mouse AHR and ARNT were stably integrated in the yeast genome. Initial studies of recombinant strains have shown that 1) both AHR and ARNT proteins can be detected by Western blotting, 2) treatment of the recombinant yeast strain with ligand induces a TCDD-responsive reporter gene and 3) the AHR protein is rapidly degraded in the yeast cells in a ligand-independent manner. Thus, the yeast has a functional AHR signaling system, but the rapid loss of the AHR in the absence of ligand has confounded the analysis TCDD-mediated degradation. To address whether the lack of AHR stability is due to improper folding of the AHR by the yeast chaperone proteins, the cDNA for mouse heat shock protein 90 was ligated into an expression vector immediately downstream of a constitutive promoter. The Hsp90 expression plasmid was then transformed into the recombinant strain and the stability of the AHR was directly evaluated by Western blotting and

immunoprecipitation. Another approach to assess protein turnover is to inhibit specific degradation pathways with chemical inhibitors. However, the yeast cell wall is impermeable to these compounds. To overcome this problem, the gene encoding the Erg6 cell wall protein was disrupted in the recombinant strain. This new strain was evaluated for AHR stability following treatment with various protease inhibitors in order to identify the pathway involved in the ligand-independent degradation of the AHR. Results suggest that folding of the AHR in yeast may comprise the ability to assess ligand-mediated degradation in this model system. Supported by NIEHS NIEHSES015481.

PS 92 THE ARYL HYDROCARBON RECEPTOR (AHR) IS NOT REQUIRED FOR ESTROGEN-DEPENDENT TUMOR FORMATION BY MCF-7 BREAST CANCER CELLS.

D. C. Spink[1], B. C. Spink[1] and J. A. Bennett[2]. *[1]Wadsworth Center, New York State Department of Health, Albany, NY and [2]Center for Immunology and Microbial Diseases, Albany Medical College, Albany, NY.*

The AhR was initially identified and characterized as a ligand-activated transcription factor mediating toxic effects of chlorinated dioxins and other halogenated and non-halogenated aromatic hydrocarbons. In recent publications, evidence supporting involvement of the AhR in cell-cycle regulation and tumorigenesis has been presented. To further define the roles of the AhR in cancer, we investigated the effects of AhR expression on cell proliferation, migration, invasion, and tumorigenesis of MCF-7 human breast cancer cells. In these studies, the properties of MCF-7 cells and two MCF-7-derived sublines, AhR100 cells, which express minimal AhR, and AhR2 cells, which overexpress AhR, were compared. Real-time PCR, Western immunoblots, experiments with CYP1A1- and CYP1B1-promoter-luciferase reporter constructs, and ethoxyresorufin O-deethylase assays showed the lack of AhR expression and AhR-regulated CYP1 expression in AhR100 cells, and the enhanced AhR expression and AhR-regulated CYP1 expression in AhR2 cells. In the presence of 1 nM estradiol, the proliferation rates of MCF-7, AhR100, and AhR2 cells were similar. However, AhR100 cells showed elevated rates of migration and invasion in chamber assays with 1 nM estradiol as the chemoattractant and enhanced colony formation in soft agar compared with those of MCF-7 and AhR2 cells. Futhermore, AhR 100 cells retained the ability to form tumors in severe combined immunodeficient mice when supplemented with estradiol, producing mean tumor volumes comparable to those from MCF-7 cells. In xenograft assays with AhR2 cells, decreased tumorigenesis, as evidenced by decreased tumor volumes in estrogen-supplemented mice compared with those from MCF-7, was observed. These studies indicate that invasion, migration, anchorage-independent growth, and estrogen-stimulated tumor formation of MCF-7 cells do not require the AhR, and tumor formation is inhibited by its overexpression. Supported by NIH grant CA081243.

PS 93 FUNCTIONAL ROLE OF VON-HIPPEL LINDAU TUMOR SUPPRESSOR GENE MUTATIONS IN ARNT-MEDIATED TRANSCRIPTIONAL REGULATION OF DRUG METABOLISM.

M. C. DeSimone[1], C. Powell[2], W. Rathmell[2, 1] and D. Threadgill[2, 1]. *[1]Curriculum in Toxicology, UNC Chapel Hill, Chapel Hill, NC and [2]Department of Genetics, UNC Chapel Hill, Chapel Hill, NC.*

The von-Hippel Lindau *(VHL)* tumor suppressor gene is commonly mutated in sporadic renal cell carcinoma, and while it plays a critical role in regulating the cellular response to hypoxia, little is known about the functional consequences of *VHL* mutations in the context of susceptibility to chemical insult. Mutations in *VHL* can disrupt its targeting of hypoxia-inducible factor 1 alpha (HIF1a) for degradation during normoxia. HIF1a and the arylhydrocarbon receptor (AhR) are both conditionally regulated basic helix-loop-helix transcription factors that share Per-Arnt-Sim homology domain for dimerization with the arylhydrocarbon nuclear translocator (ARNT). Consequently, we hypothesize that *VHL* status may determine susceptibility to chemical insult by altering xenobiotic induction, metabolism and ultimately detoxification. To investigate this we have generated *Vhl +/+, Vhl +/-, Vhl -/-* embryonic stem (ES) cells derived from C57BL/6J x BALB/c F1 blastocysts. In order to evaluate clinically relevant mutations in the *VHL* gene, we used site-directed mutagenesis of the human *VHL* gene to generate mammalian expression constructs, which were transfected into the *Vhl* null ES cells. To induce AhR mediated gene transcription, the transfected ES cells were treated with 13uM benzo(a)pyrene over a time course of 16hrs. *Cyp1a1* and *Cyp1b1* expression in *Vhl-/-* cells was induced 3- and 8-fold, respectively, while the same induction was not seen in cells expressing a human *VHL* gene. HIF1a regulated vascular endothelial growth factor (*Vegf*) expression was not induced in either cell line. Future studies will evaluate the transcriptional response to dioxin and hypoxia in the *VHL* mutant cell lines, as well as perform molecular analysis of the HIF1a:ARNT and Ahr:ARNT pathway interactions. This data suggests that VHL or VHL interacting partners may be disrupting AhR:ARNT transcriptional regulation of drug metabolizing genes and may be playing an important role in modulating chemical susceptibility.

PS 94 AMELIORATING EFFECT OF NOOTROPIC DRUG AMPAKINE CX-717 ON PRENATAL NICOTINE-INDUCED IMPAIRMENT IN SYNAPTIC AMPA RECEPTOR FUNCTION.

T. Kariharan, K. Parameshwaran, S. C. Brian, D. Murali and V. D. Suppiramaniam. *Pharmacal Sciences, Auburn University, Auburn, AL.*

Maternal smoking causes severe cognitive dysfunction in younger children. Prenatal Nicotine exposure impairs hippocampus dependent memory forms. Most of the excitatory neurotransmission in mammalian brain is mediated by glutamatergic AMPA receptors (AMPAR).We showed potent modulatory effect of nootropic drug Ampakine CX-717 on synaptosomal AMPAR activity. Therefore we hypothesized that AMPAR function and expression may be impaired in prenatal nicotine exposed rats and resulted impaired long-term potentiation and can be ameliorated by ampakine CX-717 treatment. Pregnant rats were treated with Nicotine from the day 3 of pregnancy until pups were born, via osmotic mini pumps implanted subcutaneously throughout gestation. Prenatal exposed animals showed spatial memory impairment in Y maze task, impaired basal synaptic transmission, significantly reduced LTP; reduced amplitude of AMPAR mediated whole cell synaptic currents and reduced activity of synaptosomal AMPAR single channel activity. Synaptoneurosomes isolated from prenatal nicotine treated Rat hippocampi and control Rat hippocampi and were reconstituted in lipid bilayers and the change of synaptic AMPAR activity by prenatal nicotine exposure and ameliorating effects of CX-717 on synaptic AMPARs were investigated. The AMPAR channel activity was elicited by addition of 290 nM AMPA; following which 4.0 μM of CX-717 was infused. The single channel activity elicited by 290 nM of AMPA was significantly decreased in prenatal Nicotine induced synaptosomal AMPA receptors compared to controls. open probability, dwell mean open time decreased in prenatal Nicotine exposed synaptosomes and were completely ameliorated by 4.0 μM of CX-717. It is concluded that by profoundly ameliorating synaptic AMPAR function, CX-717 can strengthen the synaptic communication required for learning and memory. Therefore, CX-717 may be a potential therapeutic option for cognitive impairment associated with prenatal nicotine exposure that impairs AMPAR function.

PS 95 INVOLVEMENT OF TRPV1 AND ER STRESS IN LUNG CELL DEATH *IN VITRO* AND ACUTE LUNG INJURY *IN VIVO.*

K. C. Thomas, G. S. Yost and C. A. Reilly. *Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

The capsaicin receptor, TRPV1, is activated by both exogenous (e.g., capsaicin) and endogenous (e.g., anandamide, H_2S, LTB_4) ligands. In human lung cells, plasma membrane and endoplasmic reticulum (ER) TRPV1 differentially regulate inflammatory cytokine gene expression and cell death after TRPV1 activation. Calcium efflux from the ER initiates the unfolded protein/ER stress response and cell death via EIF2αK3 activation and increased expression of pro-apoptotic DNA damage-inducible transcript 3 (DDIT3, CHOP or GADD153). Structural modifications to the 3-MeO-4-OH-benzylamide pharmacophore of capsaicinoids decreased TRPV1 activation and ER stress-induced cell death in lung cells. The endogenous TRPV1 agonist anandamide also induced ER stress and lung cell death in vitro. Endovanilloids including anandamide damage the lung during inflammation. Treatment of mice i.p. with LPS induced systemic inflammation and endovanilloid synthesis and caused lung injury in mice in a TRPV1- and ER stress-dependent manner. TRPV1 knockout mice and mice treated with TRPV1 antagonist LJO-328 were protected from lung injury and increased expression of GADD153 and IL-6 were not observed. Because TRPV1 contributes to lung injury during experimental endotoxemia, TRPV1 may be a novel target for prevention of lung injury during pathological systemic inflammation due to sepsis. This work was supported by NIH grant (HL069813).

PS 96 AHR-MEDIATED REGULATION OF STEAROYL-COA DESATURASE 1.

M. M. Angrish[1, 2, 3], L. D. Burgoon[2, 3], B. D. Mets[2, 3] and T. R. Zacharewski[1, 2, 3]. *[1]Genetics Program, Michigan State University, East Lansing, MI, [2]Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI and [3]Center for Integrative Toxicology & National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI.*

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is a potent, environmentally persistent contaminant that modulates gene expression through aryl-hydrocarbon receptor (AhR) mediated interactions with dioxin response elements (DREs) in the reg-

ulatory regions of genes. Recently, we identified species-specific gene expression changes associated with lipid metabolism that may be mediated through species-specific DREs in ovariectomized Sprague Dawley rats and C57BL/6 mice gavaged with 10 or 30 μg/kg TCDD, respectively. Rats experienced specific decreases in body weight gain while mice exhibited steatosis and steatohepatitis at 72 and 168 h, respectively. Gas chromatography/mass spectrometry (GC-MS) hepatic lipid profiling revealed a significant increase in monounsaturated fatty acids (MUFAs) in treated versus control mice. Of particular interest was the increase in oleate (C18:1 n-9; 1.5x at 24h & 2.0x at 72 h), the MUFA product of stearate (18:0). Stearoyl Co-A desaturase (Scd1) converts palmitate (16:0) and stearate (18:0) to the MUFAs palmitoleate (16:1 n-7) and oleate (18:1 n-9) respectively. Published Scd1 null mice studies implicate Scd1 in obesity, non-alcoholic fatty liver disease and the metabolic syndrome. QRTPCR confirmed species-specific induction of Scd1 in rat liver, but not in mouse liver. Non-conserved putative DREs in the regulatory region of the human, mouse and rat Scd1 gene were computationally identified using a position weight matrix. Reporter gene assays containing regions with these putative DREs indicated TCDD inducible alterations in reporter gene expression in the HepG2 hepatoma cell line. Band shift assays confirmed the formation of AhR/ARNT-DRE complexes with selected putative DREs. Collectively, these results suggest a role for Scd1 in the species-specific induction of steatosis and steatohepatitis by TCDD. Funded by NIH R01 ES013927 & SBRP P42ES04911.

PS 97 THE INVESTIGATION OF TISSUE-SPECIFIC MODULATION OF AHR-DEPENDENT GENE EXPRESSION.

T. Suzuki, S. Takamoto and K. Nohara. *National Institute for Environmental Studies, Tsukuba, Japan.*

The arylhydrocarbon receptor (AhR) is a ligand-activated transcription factor and mediates the toxicity of dioxins including 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Upon binding to TCDD, the AhR becomes activated and modulates target gene expression, such as CYP1A1. Although AhR-dependent gene expression varies greatly among tissues, the precise mechanism has not been clarified. AhR repressor (AhRR) and histone deacetylases (HDACs) are reported to play a significant role in suppressing the transcriptional activity of AhR. In this study, we investigated the mechanism of tissue-specific modulation of AhR-dependent gene expression by focusing on the functions of AhRR and HDACs. Female C57BL/6 mice were orally administered TCDD in a single dose of 2 μg/kg body weight, and their livers and spleens were examined. At 24 h after TCDD administration, the amount of TCDD in the liver was about 50-fold larger than in the spleen. On the other hand, the level of CYP1A1 induction was about 600-fold larger in the liver than in the spleen. Thus, the level of CYP1A1 induced by the same amount of TCDD was about 12-fold larger in the liver than in the spleen. Time-course study showed that CYP1A1 was markedly induced at 6 h in the liver and increased until 48 h. In the spleen, however, it was weakly induced at 6 h, peaked at 12 h, and decreased thereafter. In consistent with the weak induction of CYP1A1 in the spleen, AhRR was markedly induced at 6 h in the spleen and did not decrease until 48 h. The liver showed only a weak AhRR induction. Chromatin immunoprecipitation assay showed that HDAC3 was recruited to the CYP1A1 promoter in the liver upon TCDD exposure. However, the binding was decreased immediately after 12 h. These results indicate that AhRR is strongly induced in the spleen and attributes to the weak induction of CYP1A1 in the spleen compared to the liver.

PS 98 ACTIVATED ARYL HYDROCARBON RECEPTOR MODULATES THE GENOMIC BINDING PROFILE OF ESTROGEN RECEPTOR ALPHA.

S. Ahmed[1], E. Valen[2], A. Sandelin[2] and J. Matthews[1]. *[1]Department of Pharmacology & Toxicology, University of Toronto, Toronto, ON, Canada and [2]The Bioinformatics Centre, Department of Molecular Biology & Biotech Research and Innovation Centre, University of Copenhagen, Copenhagen, Denmark.*

In this study, chromatin immunoprecipitation followed by microarray technology (ChIP-chip) was used to compare the genomic binding profiles of the aryl hydrocarbon receptor (AHR) and estrogen receptor alpha (ERα). Chromatin was isolated from asynchronous T-47D human breast cancer cells treated with 10 nM 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) for 1h. Protein:chromatin complexes were isolated using specific antibodies against AHR and ERα. Immunoprecipitated DNA was linearly amplified and hybridized to Affymetrix® human promoter 1.0R tiling arrays that contain 25,500 promoter regions. Enriched regions were identified using CisGenome® and TileMap software set at a 1% false detection rate. Of the 905 ERα identified regions 214 overlapped (>50 % sequence identity) with the 1191 AHR identified regions following TCDD treatment. Conventional ChIPs confirmed the recruitment of AHR and ERα to 36 of the identified regions. Sequential ChIPs showed that both AHR and ERα are recruited at the same time to all of the identified regions we examined. The regions were mapped to the closet genes and qPCR was used to determine TCDD-dependent changes in mRNA levels. We identified mRNAs that were increased, decreased or unchanged following TCDD treatment. Computational analysis of the shared regions (bound by both AHR and ERα) revealed that there was an over-representation of AHREs and not ERE suggesting that AHR drives the recruitment of ERα. RNAi-mediated knockdown of AHR confirmed its requirement for the recruitment of ERα to the shared regions. However, knockdown of ERα did not affect the recruitment of AHR to the regions tested. Overall, AHR modulates the genomic binding patterns of ERα following the addition of the AHR selective agonist TCDD. Our findings confirm the strong functional overlap between ERα and AHR signaling pathways and that activation of AHR influences ERα activity.

PS 99 DIFFERENTIAL GENE REGULATION BY THE HUMAN AHR IN TRANSGENIC HUMANIZED MOUSE HEPATOCYTES.

C. A. Flaveny, I. A. Murray, B. DiNatale and G. H. Perdew. *Center for Molecular Toxicology and Carcinogenesis, Penn State University, University Park, PA.*

The human and mouse aryl hydrocarbon receptor (hAHR and mAHR) share limited (58%) transactivation domain (TAD) sequence identity and display distinct ligand affinity with the hAHR having 10-fold lower relative affinity for prototypical ligands such as 2,3,7,8 tetrachlorodibenzo-p-dioxin (TCDD). In addition the hAHR and mAHR also display functional differences. Previous studies have shown that the mAHR and hAHR can differentially recruit LXXLL co-activator-motif proteins and utilize different TAD subdomains in gene transactivation. We decided to investigate whether the hAHR and mAHR differentially regulate gene expression in response to TCDD. Hepatocytes were isolated from wild type C57BL6/J and hepatocyte-specific hAHR transgenic mice (B6.Cg-Ahrtm3.1Bra Tg (Alb-cre, Ttr-AHR)1Ghp) and treated with 10nM TCDD or vehicle for 6h. Microarray and quantitative-PCR analysis of TCDD-treated hepatocytes revealed that a number of classical AHR target genes such as Cyp1a1, Cyp1b1, Ahrr and Nqo1 are significantly induced by both receptors. Remarkably, of the 1752 genes induced in mAHR and 1186 genes induced in hAHR, only 266 genes (<10%) were significantly activated by both receptors in response to TCDD. Conversely of the 782 and 1103 genes significantly repressed in hAHR and mAHR hepatocytes respectively, only 463 (<25%) genes were significantly repressed by both receptors in response to TCDD treatment. Genes identified as differentially expressed are known to be involved in a number of biological pathways, including cell proliferation (e.g. Bcl2, Prkar2B, Cav2), and inflammatory response (e.g. Il-10, Mif). Limited overlap in the genes regulated by the mAHR and hAHR suggests that the hAHR may differentially modulate gene expression. Furthermore this discovery suggests that compared to the mAHR, the hAHR may play a contrasting role in TCDD toxicity and thus highlights the limitations of traditional TCDD toxicity studies in rodent models and how these studies relate to human risk. (Supported by grants from NIH ES04869 and Dow Chemical Company)

PS 100 TCDD DOWNREGULATES SOX9B mRNA EXPRESSION IN ZEBRAFISH JAW EXPLANTS.

K. M. Xiong[1], R. E. Peterson[2] and W. Heideman[1, 2]. *[1]Biomolecular Chemistry, University of Wisconsin at Madison, Madison, WI and [2]Pharmacy, University of Wisconsin at Madison, Madison, WI.*

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) causes craniofacial malformation in developing zebrafish embryos that includes dysmorphology of the upper and lower jaw. Overt TCDD toxicity that includes craniofacial malformation is mediated by AHR2 signaling in zebrafish embryos. Reduced sox9b expression is tantamount to TCDD-induced impairment of jaw development (Xiong KM et al 2008). Sox9b encodes a transcription factor essential for chondrogenesis. However, it is unclear how sox9b expression is regulated. We hypothesize that TCDD reduces sox9b mRNA expression by AHR2-mediated inhibition of a sox9b activator or induction of a sox9b repressor. To test this hypothesis we developed a larval zebrafish jaw explant model. The jaw was microdissected from 5 dpf larva and grown in organ culture media containing L-15, 10% FBS, penicillin and streptomycin. To determine if explanted jaws grow in culture, jaw explants were treated with BrdU 24 h post dissection and BrdU was detected by immunofluorescent microscopy. BrdU positive cells were identified in jaw explants confirming occurrence of cell proliferation in the explanted jaws. To determine if the jaw explants respond similarly to TCDD as jaws in intact larvae, 24 h post dissected jaw explants were exposed to 1 ng/μl TCDD or vehicle (0.1% DMSO) and qRT-PCR was done to measure cyp1a and sox9b mRNA abundance. Cyp1a mRNA expression in TCDD-treated explants was induced to a level comparable to jaws from larva treated in vivo with TCDD.

Importantly, reduced sox9b mRNA expression was identified in TCDD-treated jaw explants. The reduction of sox9b mRNA in jaw explants was similar to the magnitude of reduction in jaws from in vivo TCDD-treated larvae. Experiments using this jaw explant system to identify cis regulatory elements in the sox9b gene are described.

PS 101 MECHANISMS OF INTESTINAL BCRP INDUCTION BY 3MC: EVIDENCE FOR AHR SIGNALING PATHWAY.

L. M. Tompkins[1], H. Li[1], T. Nakanishi[2], D. Ross[2] and H. Wang[1]. *[1]University of Maryland, School of Pharmacy, Baltimore, MD and [2]University of Maryland, Greenebaum Cancer Center, Baltimore, MD.*

The gut and small intestine are the primary sites of absorption for nutrients and orally-administered drugs. Breast cancer resistance protein (BCRP; ABCG2), a novel efflux transporter, is responsible for the efflux of endobiotics and xenobiotics and determines the bioavailability of substrate drugs. Initially identified as the mediator of chemotherapeutic resistance in breast cancer tumors, BCRP expression has since been detected in normal tissues of the colon, small intestine, kidney, liver, and barrier structures such as the placenta and the blood-brain barrier. In the small intestine, several xenobiotic receptors including AhR have been postulated as regulators of xenobiotic-induced BCRP expression. However, the underlying molecular mechanisms of this induction are largely unexplored. In the human colorectal carcinoma cell line LS174T, quantitative real-time PCR data demonstrated regulation of BCRP expression by hCAR and AhR following treatment with phenobarbital (PB) and 3-methylcholanthrene (3MC), respectively. PB showed an 11-fold induction, but 3MC caused a 27-fold induction of BCRP expression. Additional AhR agonists demonstrated their ability to upregulate BCRP—the phytochemical, resveratrol with 3.8-fold induction and the proton pump inhibitor, omeprazole with 5.9-fold. Computer analysis of the BCRP promoter demonstrated the presence of several putative AhR response elements (AhRE) that may contribute to the observed induction in small intestine. Two promoter constructs, 1.2kb with 3 putative AhREs and 3.8kb with 5 putative AhREs, were treated with 3MC and were activated 2.5-fold and 5.9-fold, respectively. A greater response from the 3.8kb region having more AhREs suggests the involvement of more than one element for maximal AhR-mediated induction. Site-directed mutagenesis and EMSA studies are underway to confirm these findings. AhR agonists are found in natural products and commonly-used drugs presenting the potential for unexpected drug-drug interactions with BCRP substrate drugs.

PS 102 REPRESSION OF CARDIOMYOCYTE MARKERS BY AH RECEPTOR LIGANDS DURING DIFFERENTIATION OF MOUSE EMBRYONIC STEM CELLS.

Y. Wang, Y. Fan and A. Puga. *Environmental Health, University of Cincinnati College of Medicine, Cincinnati, OH.*

The vertebrate aryl hydrocarbon receptor is a ligand-activated transcription factor that regulates cellular responses to environmental polycyclic and halogenated compounds. We have mapped the network of AHR binding targets in the mouse genome through a multi-pronged approach involving ChIP-on-chip and global gene expression signatures, and have integrated this information into a prior functional knowledge base. Assembly of binding sequence motif analysis and extensive prior functional knowledge from Gene Ontology, interaction networks, KEGG pathways and literature molecular concepts reveals that the naïve AHR of unstimulated cells targets an extensive array of gene clusters involved in regulation of gene expression, differentiation and pattern specification, connecting multiple morphogenetic and developmental programs. Activation by ligand displaces the receptor from some of these targets towards sites in the promoters of xenobiotic metabolism genes. We have followed up these findings by using differentiating mouse embryonic stem cells to characterize the consequences of TCDD or benzo[a]pyrene exposure, for a period of up to 6 days from the pluripotent stage, on the expression of several dozen markers of pluripotency, morphogenesis, development and differentiation into specific cellular lineages. Using real-time RT PCR, we find that each ligand causes specific changes in expression of these genes, generally inducing a repression of differentiation. In the specific cardiomyocyte lineage, genes such as those coding for the alpha- and beta-myosin heavy chains or the transcription factor Nkx2.5, specifically upregulated during cardiomyocytes differentiation, are repressed by treatment with either TCDD or B[a]P. We also observe the repression of the cardiac troponin-T protein using immune flow cytometric detection. These data show that AhR possesses unsuspected regulatory functions that may become potential targets of environmental injury during development. (Supported by NIH R01ES6273, NIH R01ES10807, and NIH P30 ES06096).

PS 103 BENZO[*A*]PYRENE INCREASES REACTIVE OXYGEN SPECIES AND REGULATES THE METALLOTHIONEIN, CYTOCHROME P450 AND ALDO-KETO REDUCTASES MESSENGER RNA LEVELS IN HUMAN LUNG ADENOCARCINOMA A549 CELLS.

Y. Rodríguez-Yáñez[1], B. Cisneros[2], E. Brambila[3] and A. Albores[1]. *[1]Toxicology Section, CINVESTAV-IPN, Mexico City, D.F., Mexico, [2]Genetics Department, CINVESTAV-IPN, Mexico City, D.F., Mexico and [3]Biochemistry and Molecular Biology Department, Benemérita Universidad Autónoma de Puebla, Puebla, Pue, Mexico.*

The effects of benzo[*a*]pyrene (B*a*P), a polycyclic aromatic hydrocarbon and an environmental contaminant, on cytochrome P450 1A1 (*CYP1A1*), aldo-keto reductases 1C1 and 1C3 (*AKR1C1* and *AKR1C3*) and metallothionein 1A and 2A (*MT1A* and *MT2A*) mRNA levels, and ROS production; were analyzed in A549 cells. Cell cultures were treated with 1, 5, 10, 20, 30 and 50 μM B*a*P, for 1, 3, 6, 12 and 24 h, kept at 37°C and CO_2 5%. Cell viability was measured with propidium iodide assay. $^{\bullet}O_2^-$ and H_2O_2 intracellular production were evaluated with dihydroethidium (DHE) fluorescence and 2',7'-dichlorodihydrofluorescein diacetate (H_2DCFDA) assay, respectively. *CYP1A1*, *AKR1C1*, *AKR1C3*, *MT1A*, and *MT2A* mRNA levels were assessed by quantitative polymerase chain reaction (QPCR). Results shown that B*a*P does not affect cell viability at any treatment, and ROS production was increased in a concentration- and time- dependent manner. *CYP1A1*, *AKR1C1*, *AKR1C3*, *MT1A* and *MT2A* expression were up-regulated by B*a*P at different times and B*a*P concentrations. These results suggest that the pleiotropic effect of B*a*P on *CYP1A1*, *AKR1C1*, *AKR1C3*, *MT1A* and *MT2A* overexpression happen through different pathways. The extent by which *CYP1A1*, *AKR1C1*, *AKR1C3*, *MT1A* and *MT2A* are regulated by B*a*P itself, B*a*P metabolites and ROS requires further investigation. (Supported by grant CONACYT-SEMARNAT, FOSEMARNAT-2004-01-293, Mexico).

PS 104 MICRORNAS IN DEVELOPMENTAL TOXICOLOGY: EFFECTS OF TCDD ON MICRORNA EXPRESSION IN EMBRYOS.

M. J. Jenny and M. E. Hahn. *Biology, Woods Hole Oceanographic Institution, Woods Hole, MA.*

Many drugs and environmental chemicals are teratogenic, and fetal exposure is associated with human birth defects. However, mechanisms by which most developmental toxicants disrupt embryonic development are not well understood. MicroRNAs (miRNAs) are important regulators of a variety of cellular processes, including embryonic development and cellular differentiation. MiRNAs are single-stranded RNA molecules of ~22 nt that regulate protein expression by inhibiting mRNA translation and promoting mRNA sequestration or degradation. We hypothesized that exposure to xenobiotics can alter miRNA expression and contribute to the mechanisms by which environmental chemicals disrupt embryonic development. To test this hypothesis for one well-known teratogen, we exposed zebrafish embryos to DMSO (0.1%) or TCDD (5 nM) for 1 hr at 30 hours post fertilization (hpf). Three biological replicates of 200 pooled embryos were sampled at 36 and 60 hpf. TCDD caused strong induction of CYP1A at 36 hpf (62-fold) and 60 hpf (135-fold) as determined by qPCR. MiRNA profiling was performed using miRCURY LNA arrays (Exiqon). Samples were compared to a universal RNA reference made from equal amounts of all RNAs. Expression data were compared between sampling times and treatments. Eighty-two of the 223 miRNAs on the array were differentially expressed between 36 and 60 hpf (DMSO-treated embryos; fold-change: -4.01 to +5.41). Comparison of DMSO and TCDD-treated embryos showed 8 miRNAs with differential expression (1 induced; 7 repressed) at 36 hpf, and 14 miRNAs with differential expression (10 induced, 4 repressed) at 60 hpf. Changes were modest, but possibly of biological significance. For example, the down-regulation of miR-144 and miR-451 by TCDD at 60 hpf is intriguing because these miRNAs have been shown to be required for erythropoiesis and TCDD is known to inhibit definitive erythropoiesis in zebrafish embryos. Future directions include array profiling with a variety known teratogens and identification of miRNA target genes involved in developmental toxicity. [Support: Mellon Foundation and Smith Chair]

PS 105 3-METHYLCHOLANTHRENE INDUCED GENOME-WIDE BINDING PROFILES OF ARYL HYDROCARBON RECEPTOR AND ESTROGEN RECEPTOR ALPHA.

A. Pansoy, S. Ahmed, L. MacPherson and J. Matthews. *Pharmacology & Toxicology, University of Toronto, Toronto, ON, Canada.*

In this study, ChIP-chip was used to determine the 3-methylcholanthrene (3MC)-induced genomic footprints of aryl hydrocarbon receptor (AHR) and estrogen receptor α (ERα). T-47D human breast cancer cells were treated with 1 μM of 3MC

for 1 hour from which chromatin was isolated using specific antibodies against AHR and ERα. Isolated DNA was linearly amplified and hybridized to Affymetrix® human 1.0R promoter tiling arrays. Enriched regions were identified using CisGenome and TileMap v2 software. Of the 893 ERα-bound regions 225 overlapped (>50 % sequence identity) with the 734 AHR-bound regions (31%). Well described AHR and ERα target genes were among the identified regions. Recruitment of AHR and ERα to 35 of the identified regions was validated using conventional ChIP and changes in target gene expression were confirmed using qPCR. To determine if there were any temporal differences in the recruitment patterns, time course ChIP experiments were performed on cells treated with 1 μM of 3MC for 0 to 4.5 hours. Under these conditions 3MC and TCDD induced oscillatory binding of AHR, ERα, aryl hydrocarbon receptor nuclear translocator (ARNT), and nuclear receptor co-activator 3 (NCoA3) to CYP1A1 and CYP1B1 enhancer regions. Peak binding occurred at 0.5 to 1 hr and rebounded again after 4 hour. These transcription factors were also recruited in a temporal manner to estrogen responsive enhancer regions but displayed distinct temporal recruitment patterns. We compared the 3MC-AHR bound regions to ChIP-chip data obtained from TCDD-AHR bound regions and there was surprisingly little overlap between AHR-bound regions (30%), suggesting that AHR-ligands influence the chromatin binding profile of AHR. However, of the top 100 identified regions, 95% were identical between 3MC and TCDD. Overall, this study provides evidence for (1) overlapping chromatin binding patterns of AHR and ERα, (2) region-dependent oscillatory recruitment of AHR and ERα, (3) ligand-dependent chromatin binding profiles for AHR.

PS 106 LOW-DOSE REPRESSION OF ARYL HYDROCARBON RECEPTOR SIGNALING BY RESVERATROL IS MEDIATED BY ESTROGEN RECEPTORS IN HUMAN CANCER CELL LINES.

G. H. Perdew[1], B. D. Hollingshead[1], J. Morales[1], M. K. Takhar[2] and T. V. Beischlag[2]. *[1]Department of Veterinary and Biomedical Sciences, The Pennsylvania State University, State College, PA and [2]Faculty of Health Sciences, Simon Fraser University, Burnaby, BC, Canada.*

Resveratrol, a red wine phenolic, has been thought to have intrinsic cardio and chemoprotective effects. It is found in abundance in many foodstuffs such as grapes, berries and peanuts. At high doses (micromolar) it acts as a pharmacological antagonist of the aryl hydrocarbon receptor, a weak agonist for estrogen receptors and binds sirtuins. However, these levels are not attainable through regular diet and not likely to account for the protective effects attributed to resveratrol. We have observed that low, nanomolar doses of resveratrol are capable of significantly repressing dioxin inducible CYP1A1 transcription in human MCF-7 breast and Caco-2 colonic caner cell lines. These effects are dose-dependent and lead to a concomitant decrease in CYP1A1 protein and activity levels. While 100 nanomolar resveratrol repressed dioxin inducible CYP1A1 transcription by approximately 50%, it did not prevent nuclear translocation of the activated receptor or binding of the receptor to the regulatory regions of the CYP1A1 gene, nor did it displace 2-azido-3-[125I]iodo-7,8-dibromodibenzo-p-dioxin from the aryl hydrocarbon receptor. While low doses of resveratrol failed to activate estrogen receptor target gene transcription, repression of estrogen receptors' levels with siRNA's abrogated the repressive effect of resveratrol on dioxin inducible gene transcription. Therefore, this mechanism may account for some of the putative chemo-protective effects of dietary resveratrol. (Supported by grants from NIH ES04869 and the Natural Science and Engineering Research Council [NSERC] of Canada)

PS 107 DEVELOPING TOOLS FOR RISK ASSESSMENT IN PROTECTED SPECIES: RELATIVE POTENCIES INFERRED FROM COMPETITIVE BINDING OF HALOGENATED AROMATIC HYDROCARBONS TO ARYL HYDROCARBON RECEPTORS FROM BELUGA (DELPHINAPTERUS LEUCAS).

B. Jensen[1, 2] and M. Hahn[2]. *[1]College of Natural Sciences, Hawaii Pacific University, Kaneohe, HI and [2]Biology, Woods Hole Oceanographic Institution, Woods Hole, MA.*

Persistent organic pollutants such as halogenated aromatic hydrocarbons (HAHs) are biomagnified in food webs and accumulate to high concentrations in top predators, including odontocete cetaceans (toothed whales). The most toxic HAHs are the 2,3,7,8-substituted chlorinated dibenzo-p-dioxins and non-ortho-substituted polychlorinated biphenyls, which exert effects through the aryl hydrocarbon receptor (AHR). Understanding the impact of HAHs in wildlife is limited by the lack of taxon-specific information about the relative potencies of toxicologically important congeners. To assess whether Toxic Equivalency Factors (TEFs) determined in rodents are predictive of HAH relative potencies in a cetacean, we used beluga and mouse AHRs expressed in vitro from cloned cDNAs to measure the relative AHR-binding affinities of ten HAHs from five different structural classes. The rank order of mean IC50s for competitive binding to beluga AHR was: TCDD<TCDF<PCB-126< PCB-169< PCB-77< PCB-81<<< PCB-156~PCB-128< PCB-105< PCB-118. The rank order of mean IC50s for binding to the mouse AHR was TCDD<TCDF< PCB-126< PCB-169< PCB-81< PCB-77< PCB-156<< PCB-128~PCB-105~PCB-118. Calculated Ki values for binding of HAHs to beluga and mouse AHRs were highly correlated (r2= 0.9614). Comparison of Ki values indicated that the beluga AHR had a higher affinity than the mouse AHR for most of the HAHs tested, consistent with the ~2-fold higher [3H]TCDD-binding affinity determined previously. These results support the use of the WHO mammalian (rodent) TEFs for non- and mono-ortho PCB congeners in beluga and, by inference, other cetaceans. The overall higher HAH binding affinity of the beluga AHR as compared to a high-affinity AHR from a dioxin-responsive mouse strain indicates that beluga, and perhaps cetaceans in general, may be particularly sensitive to the toxic effects of AHR agonists.

PS 108 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN INCREASES OF MATRIX METALLOPROTEINASE-9 EXPRESSION THROUGH ACTIVATION OF ETS-1 IN HUMAN FIBROSARCOMA HT-1080 CELLS.

H. G. Kim, J. Choi and H. Jeong. *BK21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South.*

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD), a prototype of many halogenated aromatic hydrocarbons, is a ubiquitous, persistent environmental contaminant and the most powerful tumor promoter in rodent bioassays. In the present study, we investigated the effect of TCDD on the expression of matrix metalloproteinase-9 (MMP-9) in human fibrosarcoma HT-1080 cells. TCDD dose dependently increased MMP-9 mRNA and stimulated MMP-9 activity using reverse transcription-polymerase chain reaction and zymography assay, respectively. TCDD enhanced MMP-9 gene promoter activity; however, there was no response to TCDD in DNA constructs with an ETS-1 site mutation. Electrophoretic mobility shift assay revealed that TCDD induced the activation of the ETS-1 to a form capable of binding specifically to the ETS-1 sequence of the MMP-9 gene promoter. Furthermore, TCDD enhanced migration and invasion in human fibrosarcoma HT-1080 cells. Taken together, these results demonstrate that TCDD can stimulate the production of MMP-9 through activation of ETS-1 in human fibrosarcoma HT-1080 cells, which play an important cause of tumor-promotion.

PS 109 MODULATION OF GENE EXPRESSION NETWORKS BY 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) DURING VERTEBRATE DEVELOPMENT.

C. Mattingly[1], W. A. Toscano[2], N. E. Griffin[1] and A. J. Planchart[1]. *[1]MDIBL, Salisbury Cove, ME and [2]University of Minnesota, Minneapolis, MN.*

The Aryl hydrocarbon receptor (AhR) mediates toxicity of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). TCDD is the archetype of a family of related polychlorinated compounds found ubiquitously in the environment. Carcinogenic and endocrine activities of TCDD are well documented, however, little is understood about the developmental effects or molecular mechanisms of action of this compound. Among other effects, developmental exposure to TCDD results in craniofacial abnormalities and diseases similar to those associated with developmental exposure to retinoic acid and estrogen, respectively. Significant data suggest that there is cross-talk between receptors for TCDD, retinoids and estrogens. Using zebrafish (Danio rerio) as a vertebrate model, this project explores mechanisms underlying TCDD-mediated craniofacial abnormalities. Microarray technology was used to identifying significantly differentially expressed genes in zebrafish embryos exposed to control conditions or environmentally relevant levels of TCDD (1 nM). These results were evaluated in combination with curated data from the publicly available Comparative Toxicogenomics Database (CTD; http://ctd.mdibl.org) to identify gene networks targeted developmentally by TCDD. Effects of TCDD on specific members of a network were confirmed using quantitative RT-PCR. Results from this project may provide novel mechanisms for understanding specific developmental effects of TCDD.

PS 110 BODY-ONLY EXPOSURE SYSTEM FOR DETERMINING DERMAL ABSORPTION AND TOXICITY OF CHEMICAL VAPORS IN RATS.

A. J. O'Neill and L. Crouse. *Directorate of Toxicology, U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD.* Sponsor: G. Leach.

Assessment of the dermal absorption and toxicity of chemical vapors is necessary for improving the design criteria for personal protective equipment. The design of a practical in vivo test system was needed to evaluate percutaneous vapor exposure in

laboratory animals without inclusion of inhalation exposure. An in vivo system is beneficial because the metabolism/nervous/hormonal responses of the skin are intact. The body-only exposure system described herein is more simplistic and less labor intensive than previous work in this field. In the current system, rats are contained during the exposure in specialized restraint modules fitted into a chamber faceplate. The restrainers are oriented in the faceplate such that only the bodies of the rats (shaved) are located inside the exposure chamber and exposed to the vaporized test atmosphere. Pulmonary exposure by the rats to the test vapor is minimized by the orientation of the head of the rats outside the exposure chamber, a flexible barrier fitted around their necks, and maintenance of a slight negative pressure inside the chamber. The system was validated by exposing 6 rats, body-only, for 4 hours to an 8000 ppm vapor atmosphere of toluene. Blood samples were collected from each rat at 0, 1, 4, and 24 hour timepoints. The mean blood concentrations of toluene at the 1-, and 4-hour timepoints were 11 ± 5.1 and 9.9 ± 2.0 μg/ml, respectively, which are similar values to data contained in a previously published study utilizing a body-only exposure system. A nose-only inhalation exposure was also conducted with the same generation system and general study design as the whole-body exposure. The mean blood concentration of toluene for exposing 6 rats, nose-only, for 4 hours to a 7800 ppm vapor atmosphere of toluene at the 1- and 4-hour timepoints were 230 ± 11 and 200 ± 22 μg/ml, respectively. The current body-only exposure system appears to be an accurate and practical method for assessment of dermal absorption and toxicity of various chemical vapors in rats.

PS 111 A METHOD DEVELOPMENT STUDY TO ASSESS THE EFFECTIVENESS OF MEASURES TO PREVENT CROSS CONTAMINATION DURING TOPICAL APPLICATION OF A TEST ARTICLE TO THE GöTTINGEN MINIPIG.

O. I. Jumanca and W. Ruddock. *ITR Laboratories Canada Inc., Baie d'Urfe, QC, Canada.* Sponsor: B. Procter.

Although the rabbit is commonly used for the assessment of primary dermal irritation, pigs have generally been considered to be a better model for the more sophisticated study of dermal permeability and toxicity. Many studies have shown the close resemblance of human and minipig skin in terms of architectural structure/morphology, histology and physiological characteristics. As a model in toxicology, the minipig has been used extensively in dermal/topical application studies. One of the most significant issues for dermal studies is the extensive measures required to prevent cross-contamination of blood and tissue samples, taken to monitor local and systemic exposure to the test article. This is more difficult with the minipig simply because of it's size and temperament. ITR has completed a method development topical application study utilizing the Göttingen minipig. The study objective was to assess the effectiveness of control processes designed to preclude contamination of Control animals/samples with test substance. In the study, test animals were treated by non-occluded topical application of Lidocaine 2.5% cream (EMLA©) for 4 hours/day over 7 consecutive days. Control animals were similarly treated with Glycerin USP. Specific standard procedures were identified in the study protocol to highlight the areas of concern for the technical groups. This included those working with the animals, processing blood samples to plasma and the analytical department. Blood samples were collected at various time points during the treatment phase, processed and analyzed. Results from the analysis of blood samples collected during the study revealed that there were no measurable levels of drug in the Control animals at any time point. Treated animals, however, showed appropriate levels of drug at all time points. It can be concluded therefore, that the measures employed on the study were effective in preventing contamination of Control animals and samples with drug.

PS 112 DETERMINATION OF THE OPERATIONAL BARRIER PH OF PORCINE SKIN USING A DERMAL ABSORPTION MODEL.

J. E. Riviere and J. D. Brooks. *Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.*

The prediction of drug and chemical absorption across the skin is largely based on mathematical models that assume passive Fickian diffusion as the primary mechanism for transdermal delivery. This assumption implies that only non-charged neutral chemicals pass through the stratum corneum that comprises the epidermal penetration barrier. The purpose of the present analysis was to determine the effective pH of the skin barrier relative to dermal penetration by using a QSPeR model on an existing database of dermal permeability constants (log *kp*) consisting of 12 marker compounds in 24 diverse chemical mixture combinations obtained in porcine skin. Model fit was assessed as a function of penetrant's log D_{pH} at different pH. Log D_{pH} replaces the log octanol/water partition coefficient used in many QSPeR models which assumes a pH of 7.4. All analyses converged on a value for effective stratum corneum barrier pH of 6, a number within the range of measured stratum corneum pH. These results suggest that when such QSPeR equations are used to estimate dermal absorption, risk assessment models should employ this acidic pH as the operational value for barrier penetration. (Supported by NIOSH OH-07555)

PS 113 DERMAL UPTAKE OF INDUSTRIAL CHEMICALS - SHOULD EVAPORATION FROM SKIN BE INCLUDED IN THE BASIS FOR SKIN NOTATION?

G. Johanson, P. Mohlin and M. Rauma. *Work Environment Toxicology, Karolinska Institute, Stockholm, Sweden.*

Many skin penetrating chemicals are highly volatile and evaporation may significantly decrease the amount available for absorption following e.g. an accidental spill on the skin. The impact of evaporation in relation to dermal absorption was investigated for 83 substances, whereof 73 should have a skin notation according to the ECETOC criterion (Strategy for assigning a skin notation. ECETOC, Bruxelles, 31/1993). Evaporation rates were calculated from molar masses, vapor pressures, the universal gas constant, the temperature (set to 30°C=303K) and mass transfer coefficients in air. The latter depends mainly on molar volume, molecular weight and air speed over the exposed surface and was calculated with the Sparks method for an air speed of 0.6 m/s. Dermal absorption rates of neat chemical were calculated from published data on skin permeability coefficients. The time to complete elimination from the skin surface, either by evaporation or absorption, was calculated for an arbitrary initial thickness of 20 μm. The evaporation rate of the 73 chemicals varies from 10^2 (vinyl chloride) to 10^-5 (hydroquinone) on a relative scale (n-butyl acetate=1). Similarly, the time to total elimination (absorption+evaporation) varies from 0.2 seconds to 4 days and x of the 73 chemicals are eliminated in less than 1 hour. The absorbed fraction (absorbed/eliminated) varies from 0.997 (pentachlorophenol) to 10^-5 (tetrahydrofuran). For most substances (57 of 73), less than 50% is absorbed. In conclusion, the extent of evaporation varies widely between chemicals, ranging from practically negligible to the completely dominating source of elimination from the skin surface. Furthermore, the huge variability in time to elimination, ranging from seconds to days, suggests that the assumption of a uniform dermal exposure duration (1 hour in the ECETOC criterion) and infinite dose, often used in the decision basis for skin notation, may be misleading. The study was supported by the Swedish Council for Working Life and Social Research (FAS).

PS 114 POLYCYCLIC AROMATIC HYDROCARBONS IN BLACK TATTOO INKS AND SINGLET OXYGEN GENERATION.

K. Lehner, J. Regensburger, T. Maisch, R. Vasold, F. Santarelli, B. Koenig, E. Engel, M. Landthaler and W. Baeumler. *University of Regensburg, Regensburg, Germany.* Sponsor: P. Howard.

In recent years, the number of people with tattoos increased enormously. Black tattoo inks are based on Carbon Black, which is known to act as a significant strong sorptive phase for polycyclic aromatic hydrocarbons (PAHs). The US Environmetal Protection Agency US-EPA created a Priority Polluntant list for 16 PAHs, because many of PAHs are toxic or mutangenic. In addition, many PAHs are suspected to generate reactive oxygen species (ROS) under UV irradiation, such as singlet oxygen that affects DNA integrity. Since black tattoo inks are placed in the skin at high concentrations, the goal of our investigation was the determination of PAHs concentration in these tattoo inks. We developed an ultrasonic-assisted extraction method using a mixture of benzene/acetone, heat and centrifugation. We quantitatively extracted PAHs from 17 commercially available black tattoo inks using the Internal Standard method by HPLC Diode Array Technology and mass spectroscopy. The tattoo inks contained different amounts of PAHs according to the US-EPA list. The total amount of PAHs was up to 226 ug per mL tattoo suspension of black inks. In addition, we found a high amount of phenol with up to 430 ug per mL black tattoo ink. Then, we determined the quantum yield of singlet oxygen generation for each PAH using luminescence spectroscopy. The quantum yield of the different PAHs ranged from 0.46 to 0.82, which is higher than for photosensitizers used in photodynamic tumor therapy. Human keratinocytes were incubated with PAHs that have been extracted form 1mL Black Tattoo Ink. After irradiation with broadband UVA, MTT-assay showed significantly decreasing cell viability, which clearly depended on the UVA light dose and the respective black ink extract. In conclusion, black tattoo inks contain high amounts of PAHs and phenol. The PAHs generate singlet oxygen, which in turn affects cell viability. The work is supported by a grant of the 'Deutsche Forschungsgemeinschaft' (DFG, BA1741/3-2).

PS 115 EVALUATION OF THE SENSITIZING POTENTIAL OF DIPHOTERINE® IN ADULT VOLUNTEERS WITH NORMAL SKIN.

L. Mathieu[1], F. Burgher[1], A. H. Hall[2] and H. I. Maibach[3]. *[1]PREVOR, Valmondois, France, [2]TCMTS, Laramie, WY and [3]Dertmatology, UC San Francisco, San Francisco, CA.*

Diphoterine®, a decontamination solution for chemical splashes, contains an amphoteric compound. It is non-irritating, non-cytotoxic, non-mutagenic and non-toxic by dermal and oral routes in rodents. Its sensitizing capacity has been previously evaluated in the Guinea pig without any observed reaction. The objective was to assess the allergenic potential of Diphoterine® in humans when applied pure under an occlusive patch with dermatological control following the Marzulli-Maibach method. 164 normal volunteers were divided into 3 groups. A sample of 25 µL (on a paper filter disk) was applied on the homological (induction phase) and contralateral scapular area under an occlusive dressing. Another dressing without Diphoterine® was applied in the same conditions as a blank application. During the induction phase, the application of the product was renewed 3 times per week for 48H each time. There were 8 or 9 applications. The induction, latency and elicitation phases ended after 3 weeks, 2 weeks, and 1 week respectively. Neither the homolateral area during the Induction Phase nor the contralateral area during the revelation phase were wetted. 161 volunteers completed the study. Clinical examinations during the induction phase allowed continuing Diphoterine® and blank applications throughout this period and during the relevation phase. During the elicitation phase, no reaction was observed. An index of average irritation (I.I.M) was calculated at each examination. The I.M.M at day 22, for the 111 normal volunteers who had 9 successive Diphoterine® applications, was 0.09. Diphoterine® remains non-irritating during the first 5 applications, then becomes lightly irritating (I.M.M = 0.25) during the 3 following applications. Thus, among 111 normal volunteers, who received 9 successive dermal applications, Diphoterine® was not a skin irritant. To conclude, the risks of skin sensitization from dermal contact with Diphoterine are negligible. Thus Diphoterine® may be classified as hypoallergenic.

PS 116 CYTOKINES IN RAT SKIN AFTER A ONE-HOUR EXPOSURE OF JET PROPULSION FUEL-8.

T. J. Kannanayakal, C. M. Garrett and J. N. McDougal. *Pharmacology and Toxicology, Boonshoft School of Medicine, Wright State University, Dayton, OH.*

Jet Propulsion fuel-8 (JP-8) may cause inflammation upon skin contact. To develop therapeutic or prophylactic measures, we have to understand the trigger of inflammation induced by JP-8. One of the early events in inflammation is the expression of inflammatory cytokines. In this study, we have investigated the expression of inflammatory cytokines, interleukin (IL) -1 alpha, IL-1 beta, IL-6, macrophage inflammatory protein-2 (CXCL2) and tumor necrosis factor (TNF) alpha, at different times after a 1-h exposure of rat skin to JP-8. A patch containing five hundred microliters of JP-8 or an empty patch was placed on the fur-clipped back of male Fisher rats. At 0, 1, 2, 3, 4, and 8h post exposure, we humanely killed the rats using CO2 and excised the skin. We isolated protein, to quantify cytokines, by pulverizing and homogenizing the skin in extraction buffer with protease inhibitors. The cytokines were estimated using a sandwich ELISA utilizing capture and detection antibodies from R & D systems (Minneapolis, MN). IL-1 alpha decreased at 3h and CXCL2 increased at 1h post exposure. IL-1 beta, IL-6 and TNF alpha did not significantly change at any time point up to 8h. IL-1 alpha is thought to be preformed and stored in skin. The reduction in the level of IL-1 alpha may be due to its release in response to JP-8 exposure. Released cytokine binds to the receptor and may be internalized for degradation. CXCL2, a chemokine involved in the attraction of polymorphonuclear granulocytes, was detected in low amounts compared to the other cytokines. We expected to see a significant change in the signaling protein levels based on mRNA expression studies in our lab. In this study, we show that only two cytokines among the five studied have a change in protein levels. The decrease in IL-1 alpha and increase in CXCL2 levels may be some of the earliest protein events in the inflammatory cascade induced by JP-8. (Sponsored by Air Force Office of Scientific Research)

PS 117 UV EFFECTS AND CHEMICALS SKIN TOLERANCE ASSESSMENT USING THE *IN VITRO* RECONSTRUCTED HUMAN FULL THICKNESS SKIN MODEL REALSKIN.

M. Grandidier[1], D. Lelièvre[1], N. Li[1], E. Tinois-Tessonneaud[2] and J. Cotovio[1]. *[1]Life Sciences, L'OREAL Research, Aulnay sous Bois, France and [2]EPISKIN snc, Lyon, France.* Sponsor: E. Dufour.

In vitro Reconstructed human skin models are of growing interest for regulatory purposes in the framework of alternatives to animal testing, and for safety or efficacy studies.

The reconstructed human full thickness skin model RealSkin is an organotypic culture composed of a living dermal equivalent (human fibroblast-contracted collagen gel) and a well-stratified and fully differentiated epidermis (human keratinocytes). In the present study, we investigated dermis and epidermis compartments responses after exposure to different stress agents. Thus, tissues were subjected to UVs exposure as well as topical treatment with known potentially cytotoxic and non cytotoxic chemicals with available historical in vivo skin tolerance data.

For UV effects, skin tissues were exposed to increasing doses of UVA or UVSSR (UVA+B) from 0 to 55 J.cm-2. For skin tolerance studies, chemical were topically applied onto the skin. Following UV or product treatments, tissues were incubated overnight at 37°C, 5% CO2 with fresh maintenance medium. Cell viability assessment (MTT conversion test), pro-inflammatory mediator measurements and histological studies were performed. Our results showed that 1- UVA-induced damage predominantly affected the dermal compartment whereas UVA+B exposure simultaneously induced damages in both dermal and epidermal compartments, 2- The skin model with adapted protocols was able to discriminate between cytotoxic and non cytotoxic chemicals in relation with their irritant potency, 3- damages depth can be documented.

These preliminary results suggested that RealSkin is a promising tool for understanding in vitro skin tolerance effects of products and for studies involving UV effects. They may serve as a basis for further larger scale experiments.

PS 118 EFFECT OF METAL WORKING FORMULATIONS ON BIOCIDE ABSORPTION IN A PDMS MEMBRANE COATED FIBER.

R. E. Baynes and B. M. Barlow. *Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.*

Biocides and preservatives are commonly used in metal working industry applications as additives to extend the shelf life of commercially manufactured aqueous metal working fluid (MWF) formulations. While little is known of the dermal absorption and disposition of these and other MWF formulation components, 5 major classes of these biocides have been associated with occupational contact dermatitis (OCD) in metal machine workers exposed to these mixtures. A PDMS membrane coated fiber (MCF) was exposed to three industrial generic aqueous cutting fluid formulations; soluble oil (SO), semi-synthetic oil (SSYN), and synthetic oil (SYN), as well as surrogate formulations of PEG-200 (PEG) and mineral oil (MO) (to mimic synthetic and soluble oil formulations respectively) at three different concentrations (0.05%, 0.5%, and 5%) to determine the absorption of 37 solutes, including representatives from each of the 5 classes of biocides known to cause OCD. Log K_{mcf} values were used to quantify dermal absorption and to determine differences between the formulation and/or concentrations. Initial trends indicate that highest absorption occurs at the lowest concentration (absorption at 0.05%> 0.5%>5.0%) across formulations. This trend is best demonstrated in soluble oil (SO) formulation, and Log $K_{o/w}$ values best correlated with the 0.05% concentration (R^2 = 0.77). Changes in absorption of solutes with low log $K_{o/w}$ values were less likely to be influenced by changes in MWF concentrations, while changes in absorption were magnified at higher Log $K_{o/w}$ values. The biocide 4-tertiary amylphenol showed its most pronounced absorption difference between the 3 concentrations in the MO formulation, followed by SO, SYN, and then PEG; the later with little or no difference in absorption between the concentrations. These phenomena suggest that there is not only a chemical but also concentration dependent influence on absorption of individual solutes in the presence of more complex formulations or mixtures. This work was supported by NIOSH grant R01-01-03669.

PS 119 CUTANEOUS RADIATION INJURY: LIPOSOMAL GLUTATHIONE TREATMENT AND MONITORING BY OPTICAL REFLECTANCE SPECTROSCOPY.

K. D. Thrall[1], S. A. Bryan[1], T. G. Levitskaia[1], J. M. Peterson[1] and T. Guilford[2]. *[1]Pacific Northwest National Laboratory, Richland, WA and [2]Your Energy Systems, LLC, Palo Alto, CA.*

Exposure to ionizing radiation from radiological or nuclear weapons and terrorist devices will likely cause life threatening radiation cutaneous injuries. To date, mechanistic and health effects of cutaneous radiation injury have been investigated only to a limited extent, and no specific countermeasures are available for treatment. Radiation has been shown to deplete the function of glutathione reductase and a decrease in glutathione can occur systemically or locally in affected tissues. Thus it is hypothesized that the combined administration of topical and systemic glutathione will reduce the severity of cutaneous radiation injury and accelerate healing. A stable liposomal encapsulation of glutathione that can be orally and topically administered has recently become available and has been evaluated for efficacy in mitigating cutaneous radiation injuries using F344 rats exposed thigh only. Visually, glutathione reduced cutaneous injury and increased healing compared to

control (non-glutathione treated) animals. An optical spectroscopic method was developed and used to analyze the functional characteristics of the exposed leg tissue from day 1 to day 50 post-exposure. The system consists of a ultra-violet/visible/near-Infrared (UV-vis-NIR) spectrometer coupled fiber-optically with a reflectance/backscattering probe. A progressive time-change in the absorbance spectra of the irradiated skin was observed. A principal component analysis of the data was successful in monitoring progression of the skin injury with time, differentiating between levels of exposure, as well as differentiating between glutathione treated and non-treated animals. (Supported by LDRD Program at the Pacific Northwest National Laboratory, operated by Battelle for the U.S. DOE under Contract DE-AC05-76RLO 1830).

PS 120 RETINYL PALMITATE INCREASES THE MULTIPLICITY OF SKIN TUMORS IN CRL:SKH-1 (*HR*/*HR*) HAIRLESS MICE EXPOSED TO SIMULATED SOLAR LIGHT.

M. D. Boudreau[1], G. R. Olson[2], P. J. Webb[1], B. J. Miller[1], P. C. Howard[1], M. V. Pogribna[1], J. A. Nichols[1] and P. P. Fu[1]. [1]*Division of Biochemical Toxicology, National Center for Toxicological Research, FDA, Jefferson, AR and* [2]*Toxicologic Pathology Associates, NCTR, Jefferson, AR.*

Vitamin A (retinol) plays an essential role in various biological processes; however, vitamin A is sensitive to heat and light. In order to increase its stability, esters of vitamin A, such as retinyl palmitate (RP), are employed in formulations for cosmetic use. The long-term consequences of use of RP-containing cosmetic products and the effects of concomitant exposure to sunlight remain unknown. A 1-year study was conducted in mice to determine whether the topical application of creams containing RP would enhance the photocarcinogenicity of simulated solar light (SSL). Groups of 36 male and female SKH-1 mice were irradiated with SSL, emitted from filtered 6.5 kW xenon arc lamps at doses of 0, 6.85, or 13.7 mJ·CIE/cm^2, and received topical applications of control cream or creams containing 0.1% or 0.5% RP to the dorsal skin. The exposures and cream application treatments were conducted 5 days a week for a period of 40 weeks. A 12 week observation period followed the exposure period. Mice that received no cream treatment showed significant SSL exposure-dependent increases in the incidence and multiplicity of histopathology determined squamous cell neoplasms. The topical application of control cream significantly enhanced the incidence and multiplicity of squamous cell neoplasms when compared with no cream groups. In mice that received topical applications of RP-containing creams and SSL exposures, significant dose trend increases were observed in the multiplicity of squamous cell neoplasms when compared with control cream groups that received the same level of SSL exposure. The results of the 52-week photococarcinogenesis study demonstrate that the topical application of creams containing 0.1% or 0.5% increase squamous cell tumor multiplicity in SKH-1 mice exposed to SSL. Research supported by IAG 224-07-0007 between the FDA and the National Toxicology Program.

PS 121 PERCUTANEOUS ABSORPTION OF CHEMICAL VAPORS THROUGH EXCISED PIG SKIN. A BIOLOGICAL ENDPOINT MODEL FOR EVALUATING PROTECTIVE CLOTHING.

G. Leach[2], W. Reifenrath[1], G. Reddy[2] and W. McCain[2]. [1]*Stratacor, Inc., Richmond, CA and* [2]*Directorate of Toxicology, U.S. Army CHPPM, Aberdeen Proving Ground, MD.*

To define the kinetics of in vitro percutaneous absorption of solvent vapors, saturated concentrations of dioxane, isopropanol, methylethylketone, and toluene in static (still air at 30oC) and dynamic conditions (flowing air at 20oC) were exposed to freshly excised, split-thickness pig skin mounted in temperature controlled evaporation/penetration cells. Solvent concentrations in air (headspace over skin) were measured by gas chromatography (GC). Receptor fluid exiting the penetration cells was collected in 4 ml glass vials housed in brass jackets cooled to -20oC to prevent solvent loss, especially for toluene. Solvents were extracted from the receptor fluid with solid phase micro-extraction fibers (SPME) and quantified by GC. Static vapor phase permeability constants were determined over a 4 hour exposure period and mean values were 0.36 cm/h for toluene, 0.41 cm/h for isopropanol, 2.4 cm/h for dioxane and 3.6 cm/h for methylethylketone. Dynamic vapor phase permeability constants determined under analogous conditions were found to be approximately an order of magnitude lower and ranged from 0.045 to 0.083 cm/h for the four solvents. Higher Kp's for the static measurements may be due to a higher hydration state of the stratum corneum and may be more appropriate for solvent vapor trapped between protective clothing and the skin. Using the static vapor phase Kp values and acute reference exposure levels (California REL values, ug/m3), it is possible to calculate the necessary permeability values for protective clothing for a given air concentration of solvent. Such a biological endpoint model may be useful in striking a balance between protection and heat burden in the design of protective clothing.

PS 122 ESTIMATED DERMAL PENETRATION OF PERMETHRIN IN HUMANS BASED ON *IN VITRO* AND *IN VIVO* DATA.

J. Ross[1], J. Driver[1], W. Reifenrath[2] and N. Assaf[3]. [1]*Risk Sciences, LLC, Sacramento, CA,* [2]*Stratacor, Inc., Richmond, CA and* [3]*Valent BioSciences, Libertyville, IL.*

The objective of this study was to develop an estimate of the percent dermal absorption of permethrin in man. This was accomplished by assuming the ratio of the in vitro dermal absorption of permethrin of rat skin to the in vitro dermal absorption by human skin was the same as the ratio of in vivo dermal absorption of rats to in vivo dermal absorption by humans. Three different concentrations of 14C-permethrin, ranging from 2.25 µg/cm2 to 200 µg/cm2, were used in vitro with human and rat skin preparations, and in vivo on bare rat skin. Twenty-four hours after application of 14C-permethrin to the human skin preparations, the radiolabel recovered from dermis (bound skin residues) and receptor fluid was summed to determine percent dermal absorption. At doses of approximately 2.25, 20 and 200 µg/cm2 of permethrin, values of 1 +/- 1%, 3 +/- 4%, and 2 +/- 2%, respectively were obtained for percutaneous absorption (N = 9 /dose). The in vitro rat skin preparations incubated under the same conditions were found to absorb 20 +/- 9%, 18 +/- 5%, and 24 +/- 8%, respectively (N=6 / dose). In vivo rat dermal absorption, including carcass, feces, and urine following 24 hours of exposure at the same dosages were 22 +/- 8 %, 22 +/- 9 %, and 28 +/- 7%, at 24 hours respectively (N=6 /dose). Five days after the 24-hour exposure, the in vivo rat dermal absorption was 38 +/- 5 %, 38 +/- 17 %, and 30 +/- 13 %, respectively (N=6 /dose), Dose and test duration did not have a statistically significant effect on percutaneous absorption of permethrin in the rat in vivo. The ratio of dermal absorption by in vitro rat skin to absorption by in vitro human skin ranged from 7.3 to 20. This suggested in vivo human dermal absorption values for permethrin ranging from1.1 to 3.0% compared to the 24-hr in vivo rat values, or 1.9 to 5.2% compared to the 5-day in vivo rat values. These estimates of in vivo human dermal absorption of permethrin are consistent with previously reported values (1 to 5%) for in vivo human dermal absorption.

PS 123 DERMAL IRRITANCY OF ALIPHATIC HYDROCARBONS (C9-C14) USING THE *IN VITRO* EPIDERM FULL THICKNESS (EFT-300) SKIN MODEL.

R. Mallampati[1], R. R. Patlolla[1], R. J. Babu[2], M. Klausner[3], P. Hayden[3] and M. S. Sachdeva[1]. [1]*PHARMACEUTICS, FLORIDA A&M UNIVERSITY, Tallahassee, FL,* [2]*MatTek Corporation, 200 Homer Avenue, Ashland, MA and* [3]*Harrison school of pharmacy, Auburn university, Auburn, AL.*

Introduction: EpiDerm full thickness-300 (EFT-300) cultures contain normal human-derived epidermal keratinocytes (NHEK) and dermal fibroblasts (NHFB) in a highly differentiated skin-like tissue.The objective of the present work was to systematically evaluate the EFT-300 skin equivalent for studying the dermal irritancy of the aliphatic C9-C14 hydrocarbons, nonane, decane, undecane, dodecane, tridecane and tetradecane. Methods: The EFT-300 tissues were treated with 2.5ul of chemical and incubated at 37°C for 6,24 and 48hours. Tissue viability was assessed using the MTT assay at 24 and 48hours and morphological changes following treatment were evaluated using H&E histological cross-sections. ELISA assays were performed to measure the release of biomarkers including interleukin (IL)-1α, IL-6 and IL-8 into the culture medium. Results:Histological sections of EFT-300 at 24 hr did not show any structural changes to the viable tissue layers; however, the stratum corneum of tridecane treated tissues was slightly thickened. At the 48 hr time point, tridecane and tetradecane induced disruption of the stratum corneum. All hydrocarbons tested (C9-C14) induced the significant increase($p < 0.05$)in IL-1α, IL-6 and IL-8 release after 24 and 48 hours in the order tetradecane> tridecane>dodecane>undecane>decane>nonane. These results were comparable to earlier performed studies with hairless rats in vivo. Conclusions: EFT-300 skin cultures could discriminate the skin irritation potential of various aliphatic chemicals based on the release of biomarkers known to play a role in skin irritation. As the chain length increased (C9 to C14), increasing amounts of IL-1α, IL-6, and IL-8 were released into the medium. Our results suggest that the EFT-300 could be a good in vitro model to study the structural activity relationship of aliphatic hydrocarbons. Acknowledgements: Supported by international foundation for ethical research (IFER).

PS 124 SKIN PENETRATION OF PERMETHRIN AFTER TOPICAL APPLICATION TO EXCISED RAT AND HUMAN SKIN.

W. Reifenrath[1], J. Ross[2] and N. Assaf[3]. [1]*Stratacor, Inc., Richmond, CA,* [2]*Risk Sciences, LLC, Sacramento, CA and* [3]*Valent BioSciences, Libertyville, IL.*

The objective of this study was to determine the in vitro percutaneous absorption of permethrin to ultimately estimate of the potential for systemic absorption of permethrin following topical exposure in man. Carbon-14 labeled permethrin in

ethanol solution was applied to freshly excised human skin in an in vitro test system predictive of skin absorption in man. Twenty-four hours after application, the radiolabel recovered from dermis and receptor fluid was summed to determine percent absorption. At doses of approximately 2.25, 20 and 200 μg/cm2 of permethrin, values of 1 +/- 1%, 3 +/- 4%, and 2 +/- 2%, respectively were obtained for percutaneous absorption (N = 9 per dose). For reference purposes, excised human skin absorption of 14C-piperonyl butoxide (PBO) at 100 ug/cm2 was determined to be 7 +/- 5% (N=9). For additional reference purposes, excised rat skin absorptions of permethrin at 2.25, 20 and 200 μg/cm2 were found to be 20 +/- 9%, 18 +/- 5%, and 24 +/- 8%, respectively (N=6 per dose), approximately 10 times higher then human skin absorptions. Excised rat skin absorption of PBO was also higher (35 +/- 9%) than the value obtained for human skin by a factor of about 5. The human skin results for permethrin are consistent with a previously published value from our laboratory (2.7% for excised pig skin at 40 μg/cm2 permethrin) and show a relatively low and constant percent absorption over the dose range. The human skin results for PBO are lower than a previously reported value from our laboratory (13%), but higher than published values for human in vivo (1.5-3.7%), giving some confidence that the values for permethrin are not underestimating absorption for man.

PS 125 SKIN PENETRATION OF PERMETHRIN AFTER TOPICAL APPLICATION TO LIVE RATS.

T. Doherty[1], W. Reifenrath[1], J. Ross[2] and N. Assaf[3]. *[1]Stratacor, Inc., Richmond, CA, [2]Risk Sciences, LLC, Sacramento, CA and [3]Valent Biosciences, Libertyville, IL.*

The objective of this study was to determine the percutaneous absorption of radiolabeled permethrin in live rats to permit a calculation of the ratio of in vivo to in vitro values, determined in a separate study. Carbon-14 labeled permethrin in ethanol solution was applied to the clipped skin of live rats at doses of 2.25, 20 and 200 μg/cm2. As a reference compound, carbon-14 labeled piperonyl butoxide (PBO) was applied to live rat skin at a dose of 100 μg/cm2 . All applications were decontaminated at 24 hours post-application, and rats were terminated either at 24 hours (3 dose levels of permethrin, 6 rats per dose level, 18 rats total) or 5 days (3 dose levels of permethrin and a single dose level of PBO, 6 rats per dose level, 24 rats total). Twenty-four hours and five days after permethrin application, and five days after PBO application, the radiolabel recovered from carcass, urine and feces was summed to determine percent absorption. Recoveries across all compounds and doses were 85-90% and percutaneous absorption values were corrected for recoveries. For the 24 hour time point, at doses of 2.25, 20 and 200 μg/cm2 of permethrin, values of 22 +/- 8 %, 22 +/- 9 %, and 28 +/- 7%, respectively were obtained for percutaneous absorption (N = 6 per dose). For the 5 day time point, at doses of 2.25, 20 and 200 μg/cm2 of permethrin, values of 38 +/- 5 %, 38 +/- 17 %, and 30 +/- 13 %, respectively were obtained for percutaneous absorption (N = 6 per dose). For reference purposes, the five day percutaneous absorption of 14C-piperonyl butoxide (PBO) at 100 ug/cm2 was determined to be 42 +/- 3 % (N=6). Dose and test duration did not have a statistically significant effect on percutaneous absorption of permethrin in the rat in vivo.

PS 126 TRANS-EPITHELIAL ELECTRICAL RESISTANCE (TEER) MEASUREMENT ON *IN VITRO* CUTANEOUS AND OCULAR 3-D MODELS: A SENSITIVE PARAMETER NEEDING STANDARDIZED CONDITIONS.

T. Delanne, D. Lelièvre and J. Cotovio. *L'OREAL Research, Aulnaus Sous Bois, France.* Sponsor: E. Dufour.

The barrier function of epithelial tissues is well described with passive permeability assays using hydrophilic or hydrophobic markers. Two major routes are mainly involved in small molecules flux: trans-cellular route mainly dependent on chemicals lipophilicity and paracellular route linked to intercellular spaces and under tights junctions (TJs) control. Together with the proteo-lipidic complex of the cornified layers, TJs are important effectors of the barrier function of tissues. When TJs are not mature or damaged in 3-D tissues, hydrophilic compounds are able to diffuse from the upper layers to the basal one. Consequently, modifications of barrier function linked structures can influence trans-epithelial electrical resistance (TEER) state of the tissue. Purpose: Modifications and quality of the barrier function could be detected by using TEER measurements. In the present work, we studied tissue integrity modifications after chemical treatments. We evaluated commercially available in vitro 3-D engineered models: two reconstructed human epidermis models (EpiSkin large model, RHE small) and a human corneal epithelial model (RHCE) supplied by SkinEthic Laboratories. TEER measurements were conducted before and after surfactants treatment.
Material and Methods: TEER was measured during a time period in order to define acceptable and standardized steps where results could be regarded as stable prior to measurements. Results: Comparisons between two electrolyte media were done in order to optimize measurements. After topical treatment with SLS and Triton X-100, results showed a sharp TEER decrease since the lowest concentrations tested reaching low resistance values at the highest surfactant concentrations. Complementary cellular viability assays showed clear effects at highest doses. Conclusion: TEER method could be a useful parameter for quality control assessments and comparisons between 3-D models. In addition it could be used as a suitable easy to use tool, to describe barrier function, complementary to other studies.

PS 127 CYP450 CHARACTERIZATION OF THE RECONSTRUCTED HUMAN EPIDERMIS EPISKIN™ INVOLVED IN XENOBIOTIC METABOLISM.

J. Eilstein[1], P. Meunier[1], M. Manso[2], J. Pachot[2], V. Luu-The[3], F. Labrie[3], J. Meunier[1], J. Leclaire[1] and D. Duché[1]. *[1]Life Sciences Research-Safety Research Department, L'Oréal Advance Research, Aulnay-sous-Bois, France, [2]Oroxcell, Romainville, France and [3]Oncology and Molecular Endocrinology Research Center, Laval University Hospital Research Center (CRCHUL) and Laval University, Qu√©bec, QC, Canada.* Sponsor: E. Dufour.

The main role of human skin is its barrier function to environment and exogenous chemicals. However, it is not merely an inert organ but it is responsible for a wide range of metabolic activities and detoxification reactions. Previous studies have shown that the reconstructed human epidermis Episkin™, an in vitro skin model, expressed mRNAs of several isoforms of phase I metabolizing-enzymes, such as cytochromes P450 (CYP). However, the presence of mRNA material does not necessarily mean that it is translated into proteins or that the corresponding enzymes are active. A western blot methodology applied to Episkin™ microsomes, allowed us to determine CYP1A1, CYP1B1, CYP2C18, CYP2D6, CYP2E1, CYP2J2, CYP3A4, CYP3A5 and CYP3A7, which are the main CYP involved in the xenobiotic metabolism expressed in skin and in this particular model. In addition, in order to confirm the epidermal CYP functionality, the catalytic activities of CYP1A1/1B1, 2B6/2C18/2E1 and 3A isoforms were measured by using fluorogenic substrates. Results showed that CYP1A1, CYP1B1, CYP2D6, CYP2E1, CYP3A4, CYP3A5 and CYP3A7 enzymes were present in Episkin™. CYP1A1/1B1 and CYP3A isoforms were the main activities determined in the epidermis. CYP2B6/2C18/2E1 activities were also detected but at a too weak level to be quantified. No real correlation was observed between the CYP mRNA expression, translation into protein and activity levels. This demonstrates that catalytic activity studies are necessary steps to prove the real metabolic capabilities of any tissue. In conclusion, these findings confirm that Episkin™ is a metabolically active skin model for studying in vitro xenobiotic phase I metabolism and toxicity and selecting inducers or inhibitors for these enzymes.

PS 128 QUANTIFICATION OF PHASES 1 AND 2 METABOLIZING ENZYMES IN EPISKIN™ AND NORMAL HUMAN EPIDERMIS.

D. Duche[1], V. Luu-The[2], C. Ferraris[1], J. Leclaire[1] and F. Labrie[2]. *[1]Life Sciences - Safety Research Department, L'Oreal Advanced Research, Aulnay sous Bois, France and [2]Oncology and Molecular Endocrinology Research Center, Laval University Hospital Research Center (CRCHUL) and Laval University, Quebec, QC, Canada.* Sponsor: E. Dufour.

Episkin™ is a human skin model obtained from the in vitro differentiation of epidermal keratinocytes. To assess whether enzymes involved in detoxification of chemicals are expressed in Episkin™, we quantified, using the RT-PCR technique, their mRNA expression level in the model and biopsies of normal human epidermis and compared to each other. The data show that the expression profiles of phases 1 and 2 metabolizing enzymes in Episkin™ and epidermis are very similar, with low expression levels of CYP450s and very high expression levels of phase 2 enzymes. As example, glutathione-s-transferase P1 (GSTP1) is found at 5 to 13 millions copies/μg total RNA, catechol-O-methyl transferase (COMT) and steroid sulfotransferase (SULT2B1b) at 0.5 to 1 million and 0.6 to 2 millions copies/μg total RNA, respectively. N-acetyl transferase (NAT5) is expressed at a lower level (~50000 to 200000 copies/μg total RNA) and monoamine oxydase (MAO) at approximately 100000 copies/μg total RNA. In contrast with total skin where alcohol dehydrogenase (ADH1B) is expressed at very high levels, this enzyme is almost absent in Episkin™ and epidermis. Other phase 1 enzymes are also expressed at low levels. The highest expression levels are found for CYP1B1, CYP2E1 and CYP4B1 at approximately 100000 copies/μg total RNA. Similar to human skin, CYP450s (CYP2J2, 4F12, 4F8, 7B1, 26B and 39A1) metabolizing endogenous compounds are also present. The highly similar expression profiles of metabolizing enzymes between the reconstructed skin and a normal human epidermis, strongly suggest that Episkin™ is a good model for studying detoxification in human skin.

PS 129 AN INITIAL EVALUATION OF THE CELLSYSTEMS EST-1000 RECONSTRUCTED HUMAN SKIN MODEL FOR DISTINGUISHING R34 AND R35 CORROSIVES *IN VITRO* .

H. Bytheway[1, 2], D. Fuchs[3], H. Fuchs[3], R. Guest[1, 2], J. Hoffman[3], N. Warren[1, 2] and A. Whittingham[1, 2]. [1]*Harlan Laboratories, Indianapolis, IN,* [2]*SafePharm Laboratories, Derby, United Kingdom and* [3]*CellSystems Biotechnologie Vertrieb GmbH, St Katharinen, Germany.* Sponsor: S. Corney.

Skin corrosion refers to the production of irreversible damage to the skin following application of a test substance for up to 4 hours (Globally Harmonised System of Classification and Labelling of Chemicals (GHS)). Assessment of the potential of chemicals to induce skin corrosion is important in establishing procedures for their safe handling, packing and transportation. Validation studies have shown that tests employing reconstructed human skin models are able to reliably distinguish between known skin corrosives and non-corrosives. The reconstructed human epidermis model EST-1000 can be used in the assessment of skin corrosivity potential as indicated in the OECD Guideline for the testing of chemicals No 431. The purpose of this study was to assess whether the EST-1000 model can be used to correctly identify R 35 (UN packing group I) and R 34 (UN packing group II & III) chemicals by performing corrosivity testing in accordance with INVITTOX Protocol No 118. Two R 35 corrosive chemicals (1,2 diaminopropane and acrylic acid), two R 34 corrosive chemicals (2-tert.butylphenol and octanoic acid) and two non-corrosive chemicals (phenethyl bromide and 4-(methylthio)-benzaldehyde) were applied to EST-1000 tissues for periods of 3 minutes, 1 hour or 4 hours and tissue viability was determined by measurement of mitochondrial dehydrogenase activity using the MTT assay. The results of the study demonstrated that using the EST-1000 model in accordance with the INVITTOX protocol, it was possible to correctly identify the corrosive and non corrosive chemicals. Both R 35 corrosive chemicals were correctly identified and one of the R 34 corrosive chemicals was also correctly identified. The other R 34 chemical (2-tert.butylphenol) was overpredicted as a R 35 corrosive chemical. It is concluded that the EST-1000 model is a suitable candidate for distinguishing R 35 (UN packing group I) and R 34 (UN packing group II & III) chemicals.

PS 130 CHARACTERIZATION OF OXIDATIVE DEAMINASE ACTIVITY IN THE RECONSTRUCTED HUMAN EPIDERMIS EPISKIN™

E. Arbey, J. Eilstein, F. Canivet, J. Meunier, J. Leclaire and D. Duché. *Life Sciences Research-Safety Research Department, L'Oréal Advance Research, Aulnay-sous-Bois, France.* Sponsor: E. Dufour.

The skin is not just a passive physical barrier but is also a biological structure involved in a wide range of metabolic activities. The reconstructed human epidermis Episkin™ is a tool developed for studying, in vitro, skin toxicity of chemicals and their metabolism as alternative methods to animal experimentation. This implies that the model is metabolically active. Adenosine deaminase (ADA) and adenylate deaminase (AMPDA) are enzymes involved in the irreversible oxidative deamination of adenosine and adenosine derivatives to inosine and inosine derivatives, respectively. These enzymes, which are present in normal human epidermis, have a critical role in the adenosine homeostasis and may be in the proliferation and maturation of certain types of mammalian cells. In this work, we reported the characterization of oxidative deaminase activity in Episkin™ using adenosine derivatives as enzyme substrates (2',3'-O-isopropylidene adenosine…). Substrates disappearance and the corresponding inosine derivatives appearance were detected by UV-HPLC and demonstrate that ADA and /or AMPDA are present and efficient in Episkin™.

PS 131 IDENTIFICATION OF MOLECULAR THERAPEUTIC TARGETS IN PORCINE SKIN EXPOSED TO BROMINE USING TOXICOGENOMICS.

J. Rogers[1], J. Price[1], J. McDougal[2], M. Shaw[1], R. Kiser[1], F. Reid[1] and J. Graham[3]. [1]*Battelle, Columbus, OH,* [2]*Wright State University, Dayton, OH and* [3]*USAMRICD, APG, MD.*

Bromine is a toxic industrial chemical that is irritating and corrosive, resulting in significant skin damage. Little is known about therapeutic treatments of bromine burns to reduce burn severity and healing time. Treatment selection and development requires the understanding of the underlying molecular mechanisms. This study utilized toxicogenomic analysis to evaluate transcriptional changes and identify potential molecular therapeutic targets in porcine skin exposed to liquid bromine. Ventral abdominal sites on each of four weanling swine were exposed to 600 µL undiluted bromine for 45 sec or 8 min. At 24 hr and 7 days post-exposure, skin samples were excised, and total RNA was isolated, processed and hybridized to Affymetrix GeneChip® Porcine Genome Arrays (containing 20,201 genes). Analysis revealed 30% of the transcripts changed at 24 hours were the same regardless of whether the bromine treatment was 45 seconds or 8 minutes, and 62% of the transcripts changed at seven days were the same regardless of the exposure. Both the 45 sec and 8 min exposures shared about 13% to 14% of transcripts at 7 days. Ingenuity Pathways Analysis (IPA) revealed 6 of the top 10 biological functions were commonly shared, while 11 genes were common shared among 24 signaling pathways. In addition, the functions of dermatological diseases and conditions, inflammatory disease, and immune response were significantly changed in which IPA identified drugs in Phase II or Phase III clinical trials, or FDA-approved for use against specific gene targets. The genes encoding CASP3, CD40, IL-6, and VEGFA were commonly shared among these three functional categories. These results indicate that the transcriptional changes in bromine-burned skin are primarily affected temporally rather than exposure duration, and the transcriptional responses can be differentiated using transcriptomics analysis. This work was supported by the U.S. Army MRMC under Contract W81XWH-05-D-0001, Task Order 0010.

PS 132 INTRACUTANEOUS ADMINISTRATION AS A METHOD FOR EVALUATION OF PHOTOTOXICITY.

D. B. Learn, C. P. Sambuco, P. D. Forbes and A. M. Hoberman. *Charles River Laboratories, Horsham, PA.*

To elicit phototoxicity, the material of interest must be in the target tissue at the appropriate concentration and be exposed to the appropriate activating wavelengths of light. In certain cases, clinical phototoxicity can be difficult to replicate in animal models, presumably because of differences in exposure patterns, light sources, metabolism, administration or unidentified variables. Direct administration to the skin by intracutaneous administration ensures that the putative phototoxin is present in the target tissue (skin) during irradiation, bypassing tissue accumulation, metabolism or reasons that may not be known without extensive investigation. In this study, the PT of two known clinical phototoxins, doxycycline (DOX) and chlorpromazine (CTZ), were evaluated in albino hairless mice. The fluorescent source emitted principally ultraviolet A (UVA). A single UVA dose of 20 - 23 J/cm^2 was used for all exposures. When DOX at the maximum tolerated dose was administered for five consecutive days by intraperitoneal injection followed by single UVA exposure, no cutaneous phototoxicity was elicited. To assess direct administration of DOX or CPZ to the skin, each phototoxin was administered by the IC route and the mice irradiated as soon as possible after administration to ensure their presence in the skin during exposure. Under these conditions, skin reactions consistent with phototoxicity (erythema, edema) were elicited in the exposure site. The same dose (total of both sites approximated the maximum tolerated dose) administered to each mouse without exposure served as control for any non-specific skin reactions. These results demonstrate that the intracutaneous delivery route is useful in assessing potential phototoxicity of clinically relevant materials that cannot be easily evaluated by other dosing routes.

PS 133 THE USE OF HUMAN DATA WHEN CONDUCTING DERMAL SENSITIZATION QUANTITATIVE RISK ASSESSMENTS FOR FRAGRANCE INGREDIENTS; HOW WELL DOES THE LLNA PREDICT HUMAN NOELS?

A. Api, J. Lalko and V. T. Politano. *Research Institute for Fragrance Materials, Inc., Woodcliff Lake, NJ.*

Historical human data either from human repeated insult patch tests or human maximization tests are available for fragrance ingredients used in consumer products. When conducting a Quantitative Risk Assessment for the induction of dermal sensitization to a fragrance material, these data add an important aspect to the overall weight of evidence approach used to determine potency. A human sensitization test is not used to determine hazard; it is a test to confirm the lack of dermal sensitization at an exposure level previously identified as a NOEL in an animal model or derived as a likely NOEL from quantitative structure-activity relationships. The EC3 value calculated in the LLNA was demonstrated to closely correlate with the NOEL from human sensitization tests designed to confirm lack of induction. A detailed analysis of the dermal sensitization data for approximately 50 fragrance ingredients that have exhibited dermal sensitization has been conducted. The data show that for a majority of the materials reviewed, there is a very good correlation between the LLNA EC3 value and the NOEL in confirmatory human dermal sensitization tests. For a minority of materials the correlation is less predictive. When the correlation is not good, sometimes the data reveal that the LLNA EC3 value is much lower than the maximum tested NOEL in humans. For other materials the

data show that the EC3 value overestimates the NOEL in confirmatory human tests. These data illustrate the importance of conducting a confirmatory human sensitization test. The reason for this lack of correlation is not currently fully understood. It may be due to the amount of material that is absorbed and/or differences in the metabolic capabilities of mouse and human skin. As such dermal metabolism and penetration studies are needed to help further our understanding of dermal contact sensitization in addition to providing the needed perspective to help explain why some EC3 values do not correlate with human NOELs.

PS 134 HUMAN CADAVER SKIN: A VALID SURROGATE MODEL FOR THE DEVELOPMENT OF TOPICAL AND TRANSDERMAL DRUGS.

T. J. Franz, P. A. Lehman and S. A. Raney. *Cetero Research, Fargo, ND.*

Extensive use has been made of the human cadaver skin model in optimizing vehicles for topically applied products during the preclinical phase of the drug development process. However, its potential use in other phases of drug development has been limited as there is currently no formal regulatory acceptance of it as a valid surrogate model. Since validation of the model will require demonstration of good in-vitro/in-vivo correlation, an in-vitro comparison of five generic (test) glucocorticoid products with the corresponding innovator (reference) products was made in the model and the data compared to the in-vivo data which were the basis for FDA approval. Split-thickness human skin was divided into multiple sections, mounted in Franz Cells, and products applied at a dose of 6 μL/cm2. Absorption was measured by sampling the receptor solution periodically over a 48-hour period and assaying for drug content by LC-MS. Both rate of absorption and total absorption were calculated. Four of the five generic products were found to be equivalent to the corresponding innovator product in the cadaver skin model, in agreement with the clinical data which was determined by vasoconstrictor assay (VC). Test to reference ratios varied from 0.96-1.14 in-vitro and 0.92-1.11 in-vivo. However, one generic product was not equivalent to innovator (T/R = 0.63) and the reason for the discrepancy was found to be due to insensitivity of the VC assay, not to a failure of the model. New data continue to validate the human cadaver skin model as a powerful, sensitive, and relevant tool by which to accurately quantitate a chemical's rate of percutaneous absorption. The model has application within multiple areas of human pharmacology and toxicology, but especially the drug development process in which it can serve as a valid surrogate for evaluation of the systemic availability of topical drugs, particularly when safety questions arise due to formulation changes during Phases 2 or 3, or in lieu of human PK studies when line extensions are developed.

PS 135 STRATATEST™ TISSUE, A NOVEL IN VITRO ALTERNATIVE FOR CYTOTOXICITY TESTING.

C. Rasmussen, A. Comer, J. Pirnstill, S. Pirnstill, N. Simon, K. Gratz and L. Allen-Hoffmann. *Stratatech Corporation, Madison, WI.*

There is a substantial and growing need for accurate, reproducible *in vitro* test systems that are capable of replacing animal models in the evaluation and classification of chemical agents. The available human epidermal cell lines poorly duplicate the *in vivo* response of human skin to chemical agents. Tissue engineering strategies provide for models that more closely recapitulate the native environment. Stratatech Corporation has developed and standardized Stratatest™ tissue, a novel *in vitro* human skin model, for consumer product and drug discovery testing. This model is generated using NIKS® keratinocytes, a consistent source of non-tumorigenic, pathogen-free human keratinocyte progenitors. Stratatest™ tissue, which contains both epidermal and dermal components, is a fully-stratified, multi-layered tissue. Stratatest™ tissue exhibits the biological characteristics of human skin. Histological analysis revealed appropriate tissue architecture formation. Indirect immunofluorescent detection confirmed the expression pattern of proteins essential for the integrity, structure, and function of stratified squamous epithelial tissue. By measuring skin electrical impedance, we determined that Stratatest™ tissue possesses robust barrier function, a critically important parameter of skin function. The utility of this model for toxicity testing was evaluated by measuring the response of Stratatest™ tissues to the known irritant SDS. Tissues exposed to a range of concentrations were assayed for cytotoxic effects. Cell viability was determined by using MTT reduction and the extent of IL-1α secretion was detected by ELISA. Both cell viability and IL-1α secretion revealed a clear dose-dependent response. Evaluation of four independent Stratatest™ tissue batches indicated a high degree of reproducibility. These results not only demonstrate the similarity of Stratatest™ tissue to intact skin, both in structure and function, but support use of this reproducible and reliable model for toxicological screening applications.

PS 136 FROM TOPICAL ANTIDOTE AGAINST SKIN IRRITANTS TO A NOVEL COUNTER-IRRITATING AND ANTI-INFLAMMATORY PEPTIDE.

U. Wormser, A. Erlanger-Rosengarten, E. Proscura, E. Shapira and B. Brodsky. *Pharmacology, The Hebrew University, Jerusalem, Israel.*

The primary purpose of the present study was to investigate the mechanism of the counter-irritating activity of topical iodine against skin lesions induced by chemical and thermal stimuli. The hypothesis that iodine exerts its activity by inducing an endogenous anti-inflammatory factor was confirmed by exposing guinea pig skin to heat stimulus followed by topical iodine treatment and skin extraction. Injection of the extract into naïve guinea pigs reduced heat-induced irritation by 62%. The protective factor, identified as a new nonapeptide (histone H2A 36-44, H-Lys-Gly-Asn-Tyr-Ala-Glu-Arg-Ileu-Ala-OH), caused reduction of 40% in irritation score in heat-exposed guinea pigs. The murine analog (H-Lys-Gly-His-Tyr-Ala-Glu-Arg-Val-Gly-OH, termed IIIM1) reduced sulfur mustard (SM)-induced ear swelling at a dose-dependent bell shape manner reaching peak activity of 1mg/kg. Cultured keratinocytes transfected with the peptide were more resistant towards SM than the control cells. The peptide suppressed oxidative burst in activated neutrophils in a concentration-depended manner. In addition, the peptide reduced glucose oxidase-induced skin edema in mice at a dose-dependent bell shape manner. Apart from thermal and chemical-induced skin irritation this novel peptide might be of potential use in chronic dermal disorders such as psoriasis and pemphigus as well as non-dermal inflammatory diseases like multiple sclerosis, arthritis and colitis.
Keywords: skin burns, sulfur mustard, peptide, inflammation

PS 137 A STUDY OF PHOTOTOXICITY EVALUATION BY ORAL ADMINISTRATION TO BALB/C MICE.

S. Utsunomiya, Y. Takahashi, Y. Tanaka, K. Kumano, Y. Yamashita, T. Ichii, Y. Otsubo, T. Nakamura, H. Izumi, T. Sukamoto and R. Nagata. *Shin Nippon Biomedical Laboratories (SNBL), Ltd., Kagoshima, Japan.*

[Purpose] The phototoxicity of known phototoxic substances was evaluated in Balb/c mice by oral administration, in accordance with Wagai's method (1989) since there is a dearth of information about phototoxicity studies via oral administration. [Method] Nalidixic acid (NA) and 8-methoxypsoralen (8-MOP) were used as positive phototoxic substances. Male Balb/c mice (BALB/cAnNCrlCrlj, Charles River Japan Inc.), aged 6 weeks were used in the study. On the day before administration, the backs of the animals were shaved, and they were fasted from 4 hours before administration. The dosing preparations (400, 200, 100, and 50 mg/kg NA, and 40, 20, 10, and 5 mg/kg 8-MOP) were administered at 10 mL/kg. Thirty minutes after administration, the animals were irradiated with long-wave ultraviolet rays of approximately 20 J/cm^2 (approximately 2.8 mW/cm^2, approximately 120 minutes), using an Ultraviolet Irradiation Apparatus (Dermaray, M-DMR-50, Eisai Co., Ltd.). The thickness of both ears was measured with a dial thickness gauge (Peacock G-2, Ozaki Mfg. Co., Ltd.), and the ears and back skin were observed before administration and at 0.5, 24, and 48 hours after irradiation. Skin reaction (erythema and edema) at the ear and back skin were observed in accordance with the Draize method criteria. [Result] In the 100 mg/kg NA group and above, erythema scored as 1 to 3 was observed at irradiated sites in all animals from 0.5 hours after irradiation, and edema scored as 1 was observed at 24 or 48 hours after irradiation. In the 10 mg/kg 8-MOP group and above, erythema scored as 1 or 2 was observed at irradiated sites in all animals from 0.5 hours after irradiation, and edema scored as 1 or 2 was observed at 24 or 48 hours after irradiation. Ear thickness increased markedly at 400 and 200 mg/kg NA, and at 40, 20, and 10 mg/kg 8-MOP after irradiation. In this study, positive reactions were clearly observed, and ear thickness tended to reflect skin reaction.

PS 138 TOPICAL APPLICATION OF ANTI-INFLAMMATORY COMPOUNDS IN AN EX VIVO HUMAN SKIN INFLAMMATION MODEL.

D. C. Bunton, E. J. Moss and K. Macdonald. *Weipers Centre, Biopta, Glasgow, United Kingdom.* Sponsor: S. Kirk.

Atopic dermatitis (AD), a common chronic skin disease characterized by abnormal cytokine production and frequent skin infections, affects 10-20% of children and 2-3% of adults. AD has been reported to be associated with the activation of T cells that preferentially secrete Th2-like cytokines including IL-4, IL-5, IL-6, IL-10 and IL-13; this can be mimicked by exposure of the skin to lipopolysaccharide (LPS). This study aimed to demonstrate that the effectiveness of topically applied anti-inflammatory drugs used in the treatment of AD can be measured in explant human skin cultures stimulated with LPS. Full thickness skin biopsies (3mm diameter) from ethically donated tissue were inserted into 2mm holes cut into Transwell filters (pore size 0.40μm). The filter was placed in a well of a 24-well culture plate

with 1ml of culture medium (RPMI) containing 1% heat-inactivated human serum and 1% penicillin/streptomycin, with the epidermis facing upwards at the liquid-air interface and the dermis suspended in the culture medium. In order to stimulate inflammation, 10^{-5}M LPS was added directly to the culture medium, whereas dexamethasone cream LAW (Riemser, 0.05%) or triamcinolone acetonide cream (Ratiopharm, 0.1%) were applied topically to the epidermis. Culture plates were incubated at approx. 37°C, in an atmosphere of 5% CO_2 in air, for 24h.
LPS induced an increase in the concentrations of IL-6, IL-8 and IL-10 in the culture supernatant of 298%, 177% and 248% respectively. Topical application of dexamethasone and triamcinolone acetonide caused a reduction in the LPS stimulated release of IL-6 (32% and 82% respectively), IL-8 (114% and 121% respectively) and IL-10 (70% and 147% respectively) to almost control levels (100% reduction) detected in unstimulated skin biopsies. Triamcinolone acetonide was more effective at reducing the levels of inflammatory cytokines than dexamethasone. In summary, Biopta's full-thickness human skin culture system appears to be a suitable model for assessing the effectiveness of potential new topical treatments for AD, using IL-6, IL-8 and IL-10 as markers of inflammation.

PS 139 EFFECT OF BREVENAL ANTAGONISM IS CELL LINE DEPENDENT.

R. N. Murrell[1, 4], A. J. Bourdelais[2], D. G. Baden[2, 3] and J. E. Gibson[4, 1]. *[1]Environmental and Molecular Toxicology, NCSU, Raleigh, NC, [2]Center for Marine Science, UNCW, WIlmington, NC, [3]Chemistry, UNCW, WIlmington, NC and [4]Pharmacology and Toxicology, ECU, Greenville, NC.*

The dinoflagellate responsible for Florida red tides, Karenia brevis, produces at least a dozen toxins called brevetoxins and curiously also produces an antagonist, brevenal. Brevenal is a non-toxic short-chain trans-syn polyether molecule that competes with brevetoxin for its active site on voltage-gated sodium channels. Previous studies in our laboratory have indicated that 0.1 μg/ml and 1.0 μg/ml brevenal in combination with brevetoxin 2 at 10-4M to 10-7M is capable of preventing inhibition of CHO-K1 BH4 cell proliferation by brevetoxin. For the current study Jurkat E6-1 Cells were treated with brevetoxin 2 at 10-5.25M (IC50 established in a previous experiment) in combination with 0.1 μg/ml, 0.5 μg/ml, and 1.0 μg/ml brevenal and A549 bronchial epithelial cells were treated with Brevetoxin 2 at 10-12M to 10-5M in combination with 0.1 μg/ml, 0.5 μg/ml, and 1.0 μg/ml brevenal for 48 hours. Cell counts taken at 48 hours indicate that brevenal does not antagonize brevetoxin's effect on cell proliferation in the T cell lymphoma line Jurkat E6-1. However, A549 bronchial epithelial cells showed a significant increase in proliferation for all doses of brevenal tested. The antagonistic effects of brevenal are dependent on the type of cell tested and it is possible that this difference may be exploited when determining the pharmaceutical efficacy of brevenal. PS 140 DEVELOPMENT OF A SPECIFIC ASSAY FOR THE DETERMINATION OF AROMATASE ENZYME ACTIVITY.

H. Tinwell[1], J. Rascle[2] and R. Bars[1]. *[1]Research Toxicology, Bayercropscience, Sophia Antipolis, France and [2]Experimental Toxicology, Bayer CropScience, Sophia Antipolis, France.*

Concern over endocrine disruption is gaining momentum as reflected by the EPA's Endocrine Screening Program as well as the possible inclusion of cut-off criteria for compounds with endocrine disrupting properties in the revised 91/414 guidelines for pesticides. One of the tests requested by the EPA is an in vitro assessment of aromatase activity; however there are drawbacks to this approach as only inhibition of the enzyme can be detected and there is no metabolic component to the assay. To address these shortcomings, we have developed an assay which can detect both increases and decreases in aromatase enzyme activity and can be used to assess tissue samples following in vivo exposure. The aromatase reaction proceeds by co-incubating protein isolated from rat tissue (eg ovaries) with testosterone. The subsequent conversion of the testosterone to estradiol is assessed by determining estradiol production using a highly specific and sensitive radio immunoassay. Using this approach, we have shown linear increases in estradiol production as a function of protein concentration, testosterone concentration and incubation time. Using optimized test conditions, clear reductions in estradiol production, indicating an inhibition of the aromatase activity, have been obtained when incubating ovarian samples with the specific aromatase inhibitors Anastrozole & formestane. Under the same conditions of test, Aminoglutethimide inhibited aromatase activity to a lesser extent and Chrysin appeared to have no inhibitory ability. Marked increases in ovarian aromatase activity have been recorded when comparing ovary samples from non-pregnant rats with samples from rats in late pregnancy. Our aromatase enzyme data are supported by corresponding gene and protein expression data and are consistent with literature reports. In conclusion, we have developed a specific assay to detect both aromatase enzyme inhibition and activation. This assay can be applied to both in vitro and in vivo assessments as well as to tissues other than the ovaries.

PS 141 ESTROGEN RECEPTOR ALPHA OVEREXPRESSING MICE MAY BE A USEFUL TOOL FOR STUDYING THE EFFECTS OF ESTROGENIC COMPOUNDS ON THE REPRODUCTIVE SYSTEM.

J. Peretz, T. Paulose, R. K. Gupta and J. A. Flaws. *Veterinary Biosciences, University of Illinois UC, Urbana, IL.*

Estrogen is required during growth and development of the nervous, skeletal, immune, and reproductive systems. Estrogen receptor alpha (ESR1) acts as a physiological mediator of estrogenic action within these systems. To observe the effects of estrogenic compounds on the ESR1 pathway, we have generated and validated a transgenic mouse model that overexpresses ESR1 in several tissues, including the ovaries. Previous studies have shown that ovaries from ESR1 overexpressors (ESR1 OE) are morphologically normal. However, previous studies did not assess whether ovaries from ESR1 were functionally normal. Since estrogen is important for ovarian follicle growth and estradiol synthesis, this study tested the hypothesis that ovarian follicles from ESR1 OE grow faster and synthesize altered levels of estradiol compared to control mice. Antral follicles were isolated from ESR1 OE and control mice on postnatal day (PND) 30 and cultured in supplemented α–minimum essential media for 168 hours. Individual follicle diameters were measured every 24 hours. After culture, media was collected to perform competitive enzyme-linked immunosorbent assays for estradiol levels. The data indicate follicle growth was similar in ESR1 OE and controls (controls at 168h = 461.25 ± 30.65 μm ; ESR1 OE at 168h = 465.94 ± 30.39 μm ; n = 4). In addition, estradiol levels were similar in ESR1 OE and controls (controls at 168h = 2103.75 pg/mL ± 411.49 ; ESR1 OE at 168h = 1905.45 pg/mL ± 391.5; n = 4). Estradiol levels were also normalized to follicle size and no significant difference was found between ESR1 OE and controls. Collectively, these data indicate that ESR1 overexpression has no effect on mouse follicle growth or estradiol production in vitro. Therefore, ESR1 OE mice could prove to be an important tool for determining whether and how other estrogenic and xenobiotic compounds act through ESR1 and affect the reproductive system. Support: NIHR21ES12061, R01ES012893.

PS 142 ACTIVATION OF THE ARYL HYDROCARBON RECEPTOR (AHR) DURING PREGNANCY IMPAIRS MAMMARY EPITHELIAL CELL DIFFERENTIATION THROUGH DIRECT AND INDIRECT ACTIONS.

B. J. Lew, B. N. Winans and B. Lawrence. *Environmental Medicine, University of Rochester, Rochester, NY.*

Recently our laboratory made a novel discovery that exposure to the AhR agonist 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) during pregnancy causes severe defects in mammary differentiation, with decreased ductal branching, poor formation of alveolar structures, suppressed expression of milk proteins, and failure to nutritionally support offspring. The development of the mammary gland during pregnancy is a complex process, driven by numerous molecules produced systemically and locally. AhR activation by TCDD may impair mammary development through a direct effect on mammary epithelial cells (MECs), or by altering paracrine or systemic factors that drive pregnancy-associated differentiation. Using AhR-deficient (AhRKO) mice, we show that pregnant females have normal development of the mammary gland in the presence or absence of TCDD. Therefore, the effects of TCDD on mammary development are AhR mediated, and the presence of AhR is not crucial for the development of the mammary gland. To experimentally determine whether exposure to TCDD alters mammary gland development during pregnancy by a direct or indirect effect on MECs, we transplanted MECs from pre-pubertal AhRKO mice into wild-type (WT) mice and vice-versa. We analyzed glandular differentiation based on morphological development on the day of parturition. The glands were phenotyped for AhR protein expression to validate transplantation. When WT recipient animals were exposed to TCDD, MECs from AhRKO donors had a similar morphological impairment as observed in the WT host gland. When AhRKO recipient animals were exposed to TCDD, the MECs from WT donors did not develop as well as the AhRKO host gland. TCDD appears to impair mammary parenchymal tissue development in both a direct and indirect manner. This novel finding helps to explain the mechanisms by which AhR-mediated impairment of mammary development occurs during pregnancy.

PS 143 ARSENIC INHIBITION OF T47D CELL GROWTH IS ASSOCIATED WITH PROMOTER HYPOMETHYLATION OF RASSF1A AND CCND2 GENES.

Y. Zang and J. D. Yager. *Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Recent evidence has shown that arsenic acts as an environmental endocrine disrupter and has anti-proliferative effects in breast cancer cells. We previously reported that sodium arsenite (As) inhibited DNA synthesis stimulated by 100 pM estrogen (E2) in human breast cancer derived T47D cells, whose growth is E2-dependent. Under a longer treatment (6 days), As (0.1 – 5 μM) also inhibited E2 stimulated T47D cell growth. Tumor suppressor gene RAS association domain family 1A (RASSF1A) controls mitosis/centrosome at early cancer stages. Cyclin D2 (CCND2) is an important gene involved in cell cycle regulation. Both genes are silenced in most human breast cells due to promoter hypermethylation. Using methylation-specific PCR (MSP), we found that promoters of these two genes are heavily methylated in actively growing T47D cells, but not in non-tumorgenic human breast MCF 10F cells. Since arsenic has been reported to interfere with DNA methyltransferase and cell cycle regulation, we investigated if As changed the methylation status of these two tumor suppressor genes. Compared to cells treated with E2 (100 pM) alone, cells treated with E2 (100 pM) and As (0.1 μM) together exhibited lower methylation levels of the promoter regions of both RASSF1A and CCND2.

PS 144 AMPLIFICATION OF GLUCOCORTICOID-INDUCED CYTOTOXICITY OF NB2 LYMPHOMA CELLS BY RESVERATROL: EVIDENCE FOR A NOVEL MODE OF ACTION FOR POTENTIAL ENDOCRINE DISRUPTORS.

R. J. Witorsch. *Physiology and Biophysics, Virginia Commonwealth University, Richmond, VA.*

Nb2 rat lymphoma cells exhibit glucocorticoid receptor mediated apoptosis upon exposure to such compounds as dexamethasone, cortisol, or corticosterone. Accordingly, we have employed these cells as a "G-screen" assay system for the identification of xenobiotics with glucocorticoid or anti-glucocorticoid activity. Previous screening of 49 diverse chemicals implicated in endocrine disruption (e.g., heavy metals, organochlorines, flavonoids, phthalates, alkylphenols, diphenyl derivatives) exhibited no such activity over a 100,0000-fold concentration range (0.1 nM to 10 μM) (Witorsch et al., The Toxicologist Supplement to Toxicological Sciences: 90: 399, 2006). In this study we report that addition of resveratrol (10 μM), a plant-derived stilbene with little or no cytolytic activity, amplifies the dose-dependent cytolytic effect of either dexamethasone (1.56 to 25 nM) or corticosterone (6.25 to 100 nM) two to four-fold. The enhanced cytolysis produced by addition of resveratrol to dexamethasone (6.25 or 25 nM) or corticosterone (100 nM) is inhibited by the further addition of the glucocorticoid receptor antagonist, RU 486 (500 nM). Whereas amplification of dexamethasone-induced cytolysis is observed with 10 μM resveratrol, no such effect was observed with lower concentrations (1 nM to 1 μM) of the stilbene. Studies are currently underway to identify other xenobiotics that might modify glucocorticoid-induced apoptosis of Nb2 cells. Since endocrine disruption is usually associated with hormonal or anti-hormonal activity of xenobiotics, this serendipitous observation with resveratrol suggests an alternative and novel mode of action for potential endocrine disruptors, modulation of endogenous hormone interaction with the target cell. (Supported by a grant from the Thomas F. and Kate Miller Jeffress Trust).

PS 145 EVALUATION OF PITUITARY AND ADRENAL HORMONE RELEASE FOLLOWING EXPOSURE TO ATRAZINE AND ITS METABOLITE DEISOPROPYL-ATRAZINE (DIA), USING TISSUE PERIFUSION.

M. G. Hotchkiss, R. L. Cooper and S. C. Laws. *Reproductive Toxicology Division, NHEERL, ORD, U.S. EPA, RTP, NC.*

Atrazine (ATR) is one of the most widely used herbicides in the United States, with current total annual use of approximately 76 million pounds of active ingredient. Previous work in our laboratory has shown that ATR and its metabolite deisopropyl-atrazine (DIA) induce a dose-dependent increase in plasma ACTH, and serum corticosterone (CORT) and progesterone (P4), at 15 and 30 min after a single oral administration *in vivo*. Although the neuroendocrine mechanism for this increase in hypothalamic-pituitary-adrenal axis activation is currently unknown, ATR and DIA have been reported to directly alter steroidogenesis *in vitro*. To test whether ATR and DIA have a direct effect on the pituitary or adrenal glands, we examined hormone release from pituitary and adrenal tissue exposed to 50μM ATR or DIA, using a perifusion procedure. Tissues from adult male Wistar rats were exposed to two, twenty-minute challenges over a three hour period. A positive control challenge was included for pituitary (10nM CRF) and adrenal (1nM ACTH) tissues, as well as final challenge with KCl (60mM, pituitary), or ACTH (10nM, adrenal) to test for viability of the tissue at the completion of the perifusion. ATR and DIA had no apparent effect on release of ACTH or CORT. Interestingly, under these conditions, the parent compound (ATR) had no effect in either tissue, while treatment of adrenal tissue with its metabolite DIA produced a greater than two-fold increase from basal P4 release (3-7 pg/mg/min) during the 90 min following the onset of the first challenge. The DIA-induced increase in P4 release from the adrenal demonstrates a direct effect of the chemical on steroidogenesis in this tissue. These results suggest that increased adrenal hormone release observed in the male Wistar rat following *in vivo* exposure to these chlorotriazines is, in part, the result of a direct effect on the gland. *This abstract does not necessarily reflect EPA policy.*

PS 146 EFFECTS OF 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN ON INSULIN SECRETION STIMULATED BY GLUCOSE IN MICE.

K. Hisaka[1], Y. Wataru[1], N. Noriko[2], K. Naoto[3, 4], K. Takashi[3] and T. Chiharu[1, 2]. *[1]Laboratory of Environmental Health Sciences, Center for Disease Biology and Integrative Medicine, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [2]Research Center for Environmental Risk, National Institute for Environmental Studies, Tsukuba, Japan, [3]Department of Metabolic Diseases, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan and [4]Translational Systems Biology and Medicine Initiative, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan.*

Epidemiological and laboratory studies suggested that exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) affects glucose homeostasis and increased a risk of the onset of type-2 diabetes mellitus. In order to evaluate effects of TCDD on insulin secretion from Langerhans islets, we designed in vivo, ex vivo and in vitro experiments. In vivo Experiment: Male C57BL/6J and AhR-null mice were injected TCDD (10 μg/kg/ b.w.) i.p. fasted for 12 hours and administered glucose 24 hours post-administration. TCDD exposure significantly decreased plasma insulin concentration at 60 and 120 min after glucose challenge in C57BL/6J mice but not in AhR-null mice. In contrast, the plasma glucose concentration was not changed by TCDD exposure in the both strains. Ex vivo Experiment: We isolated Langerhans islets 24 h after TCDD administration, and determined glucose-stimulated insulin secretion from the islets. The insulin release was found to be significantly decreased by TCDD exposure at 60 min after glucose treatment. In vitro Experiment: Langerhans islets harvested from intact C57BL/6J mice were exposed to 0.1-100 nM TCDD for 24 h, followed by the determination of glucose-stimulated insulin secretion from the islets. Insulin secretion from the islets did not change by any doses of TCDD. In conclusion, insulin release in response to glucose stimulation was impaired by TCDD exposure and this effect was mediated by AhR signaling pathway. However, it is thought that TCDD did not directly affect the Langerhans islets. (This work was supported in part by Global COE Program 'Medical System Innovation on Multidisciplinary Integration' from MEXT, Japan.)

PS 147 DISRUPTION OF STEROIDOGENESIS BY DI-(2-ETHYLHEXYL) PHTHALATE AND ITS METABOLITES IN MA-10 CELLS.

C. D. Piché[1], R. Leask[1] and B. Robaire[2]. *[1]Chemical Engineering, McGill University, Montreal, QC, Canada and [2]Pharmacology and Therapeutics, McGill University, Montreal, QC, Canada.*

To improve the flexibility of plastics and aid in processing, small molecules called plasticizers are often added to the polymer blends. These molecules readily leach out of plastics and therefore have become ubiquitous in the environment. It has been estimated that humans are exposed to plasticizers on the order of 10 mg/day. This is a concern as correlations between testicular dysgenesis syndrome and exposure to plasticizers have been found. The cause of reproductive tract abnormalities is believed to be reduced testosterone production by Leydig cells. In this study we use the MA-10 mouse Leydig tumor cell line, which produces progesterone as a marker for testosterone, to test the effects of the common plasticizer di-2-ethylhexyl phthalate (DEHP) and four of its known metabolites; mono(2-ethylhexl) phthalate (MEHP), 2-ethylhexanol, 2-ethylhexanal and 2-ethylhexanoic acid. Cell viability (MTT assay, Sigma-Aldrich, Inc.) and progesterone production (ELISA, Fitzgerald Industries Int.) were evaluated after 24hrs of exposure to varying concentrations. The dose dependent effects of DEHP, MEHP and 2-ethylhexanal showed significantly reduced cell viability at high concentrations (≥ $1x10^{-4}$ M). The alcohol and acid had little effect on cell viability. DEHP, 2-ethylhexanal and 2-ethylhexanoic acid reduced progesterone production at concentrations as low as $1x10^{-5}$ M. 2-ethylhexanal showed the greatest suppression of progesterone (>60%), at concentrations that had little effect on cell viability. Understanding the response of Leydig cells to the degradation products of common plasticizers will ultimately allow the development of new plasticizers that avoid these bioactive metabolites.

PS 148 CYCLIC ETHANOL METABOLISM IN HYPOPHYSECTOMIZED RATS CONTINUOUSLY INFUSED ALCOHOL-CONTAINING DIETS.

T. M. Badger[1, 3], M. Ferguson[1] and M. J. Ronis[1, 2]. [1]*Arkansas Children's Nutrition Center, University of Arkansas Medical Sciences, Little Rock, AR,* [2]*Pharmacology & Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR and* [3]*Physiology & Biophysics, University of Arkansas for Medical Sciences, Little Rock, AR.*

Chronic ethanol (EtOH) intake induces hepatic alcohol dehydrogenase (ADH) expression via disruption of insulin signaling in liver (JBC 2006; 281:1126-34). Total enteral nutrition (TEN) is a method of slow and continuous (~23/day) feeding patients through an intragastric tube. Rats fed EtOH-containing diets by TEN continuously for 4 weeks do not attain a constant or steady-state of blood ethanol concentrations (BECs), but rather EtOH fluctuates between 0 and >400 mg/dl due to cyclic EtOH metabolism and excretion of EtOH. French et al. previously proposed that these EtOH pulses were due to altered thyroid function at high blood EtOH concentrations and consequent effects on basal metabolic rate (Am. J. Physiol. 2000; 279:G118-G125). We tested this hypothesis in hypophysectomized (HX) or sham-operated (SO) rats, because the absence of thyroid stimulating hormone (TSH) disrupts thyroid function and we could study EtOH pharmacokinetics in the TEN model in a low thyroid hormone state. We found that while body weight gains were lower ($P<0.05$) in HX rats, pulsatile BECs did not differ in HX and SO rats. We conclude that metabolism of EtOH in the TEN model is not influenced by thyroid function. Thus, in absence of data to the contrary, we have proposed that pulsatile BECs are produced by cyclic EtOH metabolism caused by time-dependent EtOH pharmacokinetics which initiates inhibition of hepatic insulin signaling that leads to reduced SREBP-1 and disinhibition of Class1 ADH transcription (JBC 2006; 281:1126-34) Supported in part by NIAAA008645.

PS 149 POTENTIAL ROLE OF THE ADRENAL AXIS ON THE REPRODUCTIVE EFFECTS OF ATRAZINE.

M. J. Fraites, A. Buckalew and R. Cooper. *ORD, NHEERL, Reproductive Toxicology, U.S. EPA, RTP, NC.*

We and others reported that atrazine (ATR) disrupts the regulation of the ovulatory luteinizing hormone (LH) surge and the hormonal control of other reproductive functions in the rat. In addition, administration of ATR or the intermediate metabolite deisopropylatrazine (DIA) stimulate adrenocorticotropin (ACTH), corticosterone (CORT), and progesterone (P4). In contrast, the diaminochlorotriazine (DACT) metabolite minimally affects the hypothalamic-pituitary-adrenal (HPA) axis. As adrenal activation may adversely affect LH secretion, these findings suggest that an atrazine-induced activation of the HPA axis may be an important part of the mode of action (MOA) through which the chlorotriazines alter reproductive function. Therefore, we hypothesized that only those metabolites that activate the HPA axis will affect LH release. Long-Evans rats with 4-day estrous cycles were restrained for 5 minutes or dosed by oral gavage at 0900h over one estrous cycle with 0.1% methyl cellulose vehicle, 75 mg/kg ATR, 10 or 60.2 mg/kg DIA, and 8.4 or 50.6 mg/kg DACT (14/10 light cycle, on 0500h). Dosing began on the day of vaginal estrus. On the next vaginal proestrus, groups of rats were decapitated at 1600, 1800, and 2000h. Serum LH, prolactin (PRL), and P4 were measured by radioimmunoassay. Restraint, ATR, and both doses of DIA decreased the amplitude of the proestrous LH surge. In contrast, only the highest dose of DACT affected the surge. PRL was unchanged by any treatment. Unlike ATR, both doses of DIA decreased P4. Higher plasma levels achieved by direct dosing with DIA may have contributed to this. These results confirm that treatments which activate the HPA axis also alter LH release. These data suggest that activation of this axis contributes to the ATR- and DIA-induced disruption of LH secretion. Other MOAs must also be explored due the ability of DACT to alter LH without significant adrenal activation. Additional studies are planned using specific inhibitors of the HPA axis response to determine the role of this axis in the reproductive toxicity of ATR. This abstract does not necessarily reflect EPA policy.

PS 150 TRANSCRIPTIONAL ACTIVATION OF ANDROGEN-REGULATED GENES BY ARYL HYDROCARBON RECEPTOR AGONIST IN ANDROGEN-RESPONSIVE CELL LINES.

Y. Gotoh[1], N. Sanada[2] and R. Kizu[1]. [1]*Faculty of Pharmaceutical Sciences, Doshisha Women's College of Liberal Arts, Kyotanabe, Kyoto, Japan and* [2]*Graduate School of Natural Sience and Technology, Kanazawa University, Kanazawa, Ishikawa, Japan.* Sponsor: T. Urushidani.

While aryl hydrocarbon receptor (AhR) agonists including dioxins and polycyclic aromatic hydrocarbons have attracted attention in term of endocrine disrupting effects, little is known about effects of AhR agonists on androgen receptor (AR) signal transduction pathways. AR is a ligand-activated transcription factor like AhR. Upon ligand binding, AR is translocated from cytosol to nuclear and thereby binds to androgen response element (ARE) to regulate gene transcription. In this study, we examined the effects of AhR agonists on transcriptional activation of prostate specific antigen (PSA) gene, a typical androgen-regulated gene, in LNCaP human prostate cancer cells expressing both AhR and AR. 3-Methylchlanthrene (3-MC), an AhR agonist, induced PSA mRNA expression and ARE-driven luciferase activities and the transactivation by 3-MC was attenuated by knocking-down of AhR or AR with the use of small interfering RNA. Moreover, 3-MC caused translocation of unliganded-AR from cytosol to nuclear. A co-immunoprecipitaion assay indicated that liganded-AhR formed a complex with unliganded-AR in 3-MC-treated cells. A chromatin immunoprecipitaion assay targeted to AREs in proximal promoter (-250 to -39 bp) and distal enhancer (-4170 to -3978 bp) regions of the PSA gene showed that AR bound to AREs on both proximal promoter and distal enhancer regions in 3-MC-treated cells. All these results suggest that liganded-AhR translocated unliganded-AR from cytosol to nuclear by forming a complex with unliganded-AR and that unliganded-AR subsequently bound to AREs in the transcriptional regulatory region of the androgen-regulated gene to transactivate gene expression.

PS 151 MICE LACKING MRP1 HAVE REDUCED TESTICULAR STEROID HORMONE LEVELS AND ALTERATIONS IN TESTOSTERONE SYNTHESIS.

J. Sivils[1], I. Gonzalez[1] and L. J. Bain[2]. [1]*Department of Biological Sciences, University of Texas El Paso, El Paso, TX and* [2]*Department of Biological Sciences, Clemson University, Pendleton, SC.*

The multidrug resistance-associated protein 1 (mrp1/abcc1) is a member of the ABCC efflux transporter family that eliminates a variety of endogenous and exogenous compounds from cells, including glucuronide, glutathione, and sulfate conjugates, protecting the organism from toxicity. Mrp1 is expressed at high levels in the testes, and can transport the steroid hormone conjugates 17β-estradiol glucuronide, dehydroepiandrosterone sulfate, and estrone 3-sulfate. The following work investigated whether mrp1 plays a role in protecting the testes and developing spermatozoa from aberrant hormone levels. Steroid hormone levels were determined in testis and serum of both wild-type mice and mice lacking the mrp1 gene (termed FVB/mrp1-/- mice). Testicular progesterone levels were not changed, but androstenedione, estradiol, and testosterone levels were significantly reduced by 4.5, 2.4-, and 1.7- fold, respectively, in the mice lacking mrp1. Serum testosterone was also reduced by 4.4-fold, but serum progesterone and androstenedione levels were unchanged. Investigating the mechanisms responsible for the reduction in steroid hormones showed no changes in the expression or activity of sulfotransferases or glucuronosyltransferases, enzymes that inactivate steroids, nor in the expression of other mrp transporters. However, there were changes in the activity of enzymes that synthesize testosterone from progesterone. Using progesterone as a substrate, testicular CYP17 activity was increased by 1.4- to 2.0-fold, while the percentage of androstenedione glucuronide formed was decreased by 2.6-fold in mice lacking mrp1. These results reveal that mice lacking mrp1 have reduced steroid levels in the testes. This reduction in steroid production may be a way to protect the testes and spermatozoa from excessive estrogen and maintain steroid homeostasis.

PS 152 USE OF TANDEM *IN VITRO* AND *EX VIVO* ASSAYS TO ASSESS CHEMICALS FOR THYROID HORMONE SYNTHESIS INHIBITION.

M. W. Hornung[1] and E. Burgess[2]. [1]*NHEERL, MED, U.S. Environmental Protection Agency, Duluth, MN and* [2]*Student Contractor Services, Duluth, MN.*

Disruption of thyroid hormone (TH) function may occur via multiple pathways including altered TH receptor binding, altered TH metabolism and elimination, and altered TH synthesis. To assess chemicals for their ability to affect TH synthesis, an in vitro enzyme inhibition assay and an ex vivo thyroid gland explant culture assay are being used. Thyroid peroxidase (TPO), the enzyme that catalyzes the iodination and coupling of tyrosines to produce TH, can be readily measured in vitro. This assay was used to determine the inhibitory potency of two model chemicals, methimazole and propylthiouracil (PTU), and a series of other chemicals of unknown thyroid disrupting activity. In the TPO inhibition assay, methimazole was the most potent of the two model inhibitors with an IC50 of 1.3 μM,whereas the IC50 for PTU was 11 μM. The other chemicals tested included a series of seven alkylphenols, two phthalates, three triazines, a thiazolone, triazole, thiazole, pyrazole, and imidazole, among others. None of the alkylphenols inhibited TPO when tested at concentrations up to 3.6 mM. Two chemicals that inhibited TPO activity in vitro were further tested in a *Xenopus laevis* thyroid gland explant culture assay in which inhibition of T4 release was the measured endpoint. Dimethyl-hydroxymethylpyrazole inhibited T4 release but only at concentrations that were overtly toxic to the thyroid gland as measured by the MTT cytotoxicity assay. 2-Mercaptobenzothiazole inhibited T4 release from thyroid glands at non-cytotoxic

concentrations and was more potent than methimazole for inhibition of T4 release. The action of this chemical on thyroid hormone function will be evaluated further in vivo in an *X. laevis*-based amphibian metamorphosis assay. This suite of assays provides a framework for determination of the potential for chemicals to affect thyroid hormone status. This abstract does not necessarily reflect EPA policy.

PS 153 ANTI-PROLIFERATIVE AND ANTI-STEROIDOGENIC EFFECTS OF POMEGRANATE COMPOUNDS IN HUMAN LNCAP PROSTATE AND H295R ADRENOCORTICAL CANCER CELLS.

J. Gasmi and T. Sanderson. *INRS-IAF, Montreal, QC, Canada.*

Prostate cancer is the second leading cause of cancer related deaths among men in many Western countries. It is a hormone-dependent cancer and its proliferation is stimulated by endogenous steroid hormones. Aromatase (CYP19) and 5α-reductase (SRD5A) are the key enzymes that synthesize these hormones. Aromatase converts androgens to estrogens and 5α-reductase converts testosterone to DHT. Natural compounds present in the pomegranate delay prostate cancer progression. They may act as inhibitors of steroidogenesis. Pomegranate compounds (punicic-, quinic-, gallic, trans vaccenic-, and cis-vaccenic acid, pelargonidin-, cyanidin-, malvidin- and delphinidin chloride, epicatechin gallate, epicatechin, kaempherol, and epigallocatechin) were tested in vitro in a hormone-dependent prostate cancer (LNCaP cells) and steroidogenesis (human adrenocortical H295R cells) model. Cells (between 1×10e5 and 2×10e5 cells/well) in 24-well culture plates were exposed to various concentrations of pomegranate compounds for 5 days with a fresh re-exposure after 48h. For cytotoxic effects, H295R were exposed once to pomegranate compounds for 24h. Cytotoxicity and antiproliferative effects were measured with MTT reduction assay. Catalytic activity of CYP19 was determined in H295R cells by tritiated water-release assay. Enzymatic activity of 5α-reductase was determined in LNCaP cells by LC-MS by measuring conversion of testosterone to DHT. Punicic acid had an antiproliferative effect in LNCaP cells reducing cell growth by 78, 89 and 89% at 10, 30 and 100μM respectively. Kaempherol reduced proliferation by 18, 30, 44 and 65% at 3, 10, 30 and 100μM respectively. Epigallocatechine reduced cell viability for 33 and 87% at 30 and 100μM respectively. Punicic acid was not cytotoxic in H295R cells, and at 30μM, decreased aromatase activity by 77% compared to control. CYP19 was not expressed in LNCaP cells. Preliminary results show that pomegranate compounds have an antiproliferative effects in LNCaP cells and punicic acid acts as an aromatase inhibitor in H295R cells.

PS 154 CRF ANTAGONIST EFFECTS ON THE EXPRESSION OF GHRELIN, ITS RECEPTOR (GHSR) AND A POSSIBLE IMPACT OF THE GROWTH HORMONE AXIS.

K. L. Sims[1], C. X. Zhang[2], O. P. Flint[2] and R. Denton[1]. *[1]Discovery Toxicology, Bristol-Myers Squibb Co., Wallingford, CT and [2]Discovery Toxicology, Bristol-Myers Squibb Co., Hopewell, NJ.*

Ghrelin stimulates growth hormone (GH) secretion in a variety of tissues including the mammary gland where the hormone serves to maintain a proliferative, rather than a differentiated phenotype. Following repeat dosing of a CRF antagonist for 2 weeks, mammary gland hyperplasia was observed accompanied by a significant increase in mammary expression of mRNA for both ghrelin (GHRL) and its cognate receptor, growth hormone secretagogue receptor (GHSR) in gland tissue. In proliferating (hyperplastic) mammary tissue from pseudo-pregnant castrated male rats, abundant expression of GHRL is observed, well above that observed in control animals. We evaluated whether CRF antagonists could alter proliferation of human breast adenocarcinoma cells (MCF-7), and whether GHRL and GHSR expression was changed. Increased proliferation of MCF-7 cells was observed following exposure to certain CRF antagonists. Using TaqMan™ real time PCR, we observed that GHSR was upregulated (1.7 × control) with 17 hours of treatment, while GHRL expression was unchanged. By 20 to 24 hours, GHSR was downregulated (-1.4 × control) while the GHRL mRNA was upregulated (1.5 × control). These data are consistent with our hypothesis that GHRL expression increases in the mammary gland during proliferation stimulated by either pseudopregnancy or specific CRF antagonist treatment. The data further suggests a mechanism whereby GHSR expression is upregulated until GHRL binds to the receptor, which quickly triggers GHSR downregulation to reduce the overall stimulatory GH effects.

PS 155 HYDROXYLATED PCBs INHIBIT AROMATASE ACTIVITY IN HUMAN PLACENTAL MICROSOMES.

E. Antunes Fernandes, S. Nijmeijer, M. van den Berg and M. van Duursen. *Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands.*

PCBs have been widely used in industrial and commercial applications and largely prohibited since the 1980's, PCBs are still abundant pollutants in humans and wildlife and can be biotransformed into two classes of metabolites, hydroxylated (OH) and methylsulfone (MeSO2) PCBs. Previous studies have shown that these metabolites act as endocrine disruptors by affecting steroidogenesis. In the present study, human placental microsomes were used to assess the effect of four common OH-PCBs on aromatase activity. Aromatase is a key enzyme in the steroidogenesis pathway, mediating conversion of androgens into estrogens. We tested four metabolites of the environmental common PCB 180. All four OH-PCBs showed similar inhibition of placental aromatase activity. More specifically, 4'OH-CB172, 3'OH-CB180, 3'OH-PCB182 and 5'OH-CB183 had an estimated IC50 of 10.2 μM, 13.3 μM, 41.6 μM and 31.5 μM, respectively. Moreover, the LOAEL of these OH-PCBs was similar and in the low μM range. The human placenta is largely responsible for exposure of the foetus to estrogens and androgens and has a high expression of aromatase. Moreover, this tissue is essential in the blood flow exchange between mother and foetus and therefore an important route of exposure of the unborn to PCBs and their metabolites. OH-PCBs are known to be more efficiently transferred to the foetus than the parent compounds. Measured levels of individual OH-PCBs in cord plasma have found to be 0.5 nM. Based on the results of our present study no effect on placental aromatase of these PCB metabolites should be expected. However, many more OH- and MeSO2-PCBs have been found in humans and wildlife and structure activity relationships (SAR) for aromatase inhibition are yet unknown. In view of this mixture exposure, the SAR for placental aromatase inhibition should be determined to identify possible risk. Further studies are now in progress in our laboratory to assess the specificity in relation to the position of the OH or MeSO2 groups.

PS 156 ANTIDIABETIC AND ANTIOXIDANT ACTIONS OF TAURINE AND STRUCTURALLY-RELATED SULFUR COMPOUNDS IN STREPTOZOTOCIN-INDUCED DIABETES IN RATS.

K. G. Pandya and C. A. Lau-Cam. *Pharmaceutical Sciences, St. John's University, College of Pharmacy, Jamaica, NY.* Sponsor: B. Billack.

This work has assessed the ability of taurine (TAU) and the structurally-related compounds aminomethanesulfonic acid (AMSA), homotaurine (HMTAU) and pantoyltaurine (PTAU) to attenuate hyperglycemia, hyperlipidemia and oxidative stress associated with diabetes in a small animal model. For this purpose, groups of 6 male Sprague-Dawley rats were divided into three groups: control group, diabetic group, and diabetic group treated with a sulfur compound. Diabetes was induced using a single, 60 mg/kg, intraperitoneal (i.p.) dose of streptozotocin (STZ). A sulfur compound was administered as two 1.2 mM/kg i.p. doses, 75 min and 45 min before STZ. Control animals received only physiological saline. At 24 hr post-STZ, blood samples were collected by decapitation into tubes containing disodium EDTA, and processed for their plasma fraction. Plasma glucose (GLU), cholesterol (CHOL), triglycerides (TG), malondialdehyde (MDA), reduced glutathione (GSH) and nitric oxide (NO) were measured using standard methods. Diabetes elevated GLU (>400%), CHOL (135%), TG (184%), MDA (75%) and NO (~5.6-fold) and decreased GSH (79%). Regardless of their carbon-chain length and the presence or lack of N-substitution, all the test compounds demonstrated a significant attenuating action on all plasma alterations examined here, with the magnitude of the effects varying within a narrow range of values, especially in terms of their effect on indices of oxidative stress. The present results suggest the need for a future study that will evaluate the effects of the present sulfur compounds when administered to diabetic animals on a chronic basis.

PS 157 DEVELOPMENT OF A HIGHLY SENSITIVE ANALYTICAL METHOD TO DETECT ESTROGEN METABOLITES IN BIOLOGICAL SAMPLES.

D. Scholten, P. Scherpenisse, A. A. Bergwerff, M. B. van Duursen and M. van den Berg. *Institute for Risk Assessment Sciences, Utrecht, Utrecht, Netherlands.*

Endocrine disruption and development of hormone-dependent cancers in humans may be associated with dietary exposure to low concentrations of estrone (E1), estradiol (E2) and their estrogenic and carcinogenic metabolites, e.g. 4-hydroxyestradiol (4OHE2). For experimental, epidemiological and dietary exposure studies, it is essential for these metabolites to be analyzed with detection limits in the picogram to nanogram range. So far, sensitive analytical techniques have been developed mostly for E1 and E2. Analysis of their hydroxylated metabolites is usually much less sensitive due to loss during the cleanup process, insufficient derivatisation and lesser sensitivity on GC-MS or LC-MS. We developed an analytical method using HPLC-MS/MS, able to determine low levels (<25pg/ml) of hydroxylated estrogen metabolites. The method includes desulfatation of conjugated estrogens in the biological matrix, solid phase extraction and derivatisation with either dansyl-chloride (DNS-Cl) or pyridine-3-sulfonyl chloride (PS-CL) to enhance ionization, detection and quantification by HPLC-MS/MS. The DNS-Cl method worked efficiently for E1 and E2, while the PS-Cl method enhanced detection for

2 and 4-hydroxylated metabolites of E1 and E2. Using human urine as initial biological matrix the following LODs were found: 10-30 pg/ml for E1, E2, 16αOHE1, 2OHE1, 2OHE2, 4OHE2, corresponding to an instrumental sensitivity of 1.6-3.1 pg on column for the DNS-Cl estrogens and a 1-1.7 pg on column sensitivity for the PS-Cl hydroxylated estrogens. Absolute recovery ranged from 50 to 76%. In view of the sensitivity of present method, estrogen metabolism can now be studied in a wide variety of biological matrices using small sample sizes, e.g. 1 ml. Applications can include serum, urine, culture medium from in vitro experiments and dairy products. Presently we focus on estrogen metabolism in in vitro systems and identification of estrogen metabolites in dairy products.

PS 158 IODIDE DEFICIENCY, THYROID HORMONES, AND NEURODEVELOPMENT.

M. E. Gilbert[1], J. Hedge[1], K. Grant[2, 1], D. Lyke[1], I. Gitata[2, 1], W. Anderson[1], J. Fisher[4], R. T. Zoeller[3] and K. M. Crofton[1]. *[1]Neurotoxicology, U.S. EPA, Research Triangle Pk, NC, [2]Zoology, NC State University, Raleigh, NC, [3]Zoology, U Massachusetts, Amherst, MA and [4]U Georgia, Anthens, GA.*

Iodide is an essential nutrient for thyroid hormone synthesis. Severe iodide insufficiency during early development is associated with cognitive deficits. Environmental contaminants can perturb the thyroid axis and this perturbation may be more acute under conditions of marginal iodine deficiency. The present study examined the relationship between graded levels of iodide deficiency in pregnant rats on hormonal status and behavioral indices of brain function in exposed offspring. This data is being generated to inform an exposure-dose-response model for developmental disruption of thyroid hormones. Female Long Evans rats (n=60, ~ 60 days of age) were placed on diets with varying degrees of iodine deficiency for 7 wks prior to breeding. Iodine was added to a casein-based diet (25 μg/kg background levels) resulting in the following experimental groups: total 25 μg/kg (severely deficient), 75, 175, 275 (normal control diet) and 1025 μg/kg (excess). Pups were sacrificed on postnatal day (PN) 4, 14 and 21 and blood, lung, liver, heart, thyroid glands, and brain were harvested. Dams were sacrificed at weaning for hormone analysis. Behavioral assessments were performed on male and female offspring (4-5 months of age) using a sensory gating paradigm based on auditory startle, spatial learning using a Morris water maze, and associative learning using a trace fear conditioning paradigm. Thyroxine was reduced (~45%) and TSH increased (2-3-fold) in dams and pups on PN21 in the 25 μg/kg iodine group. No changes in T3 were evident. Thyroid weights were significantly increased in pups on PN21 with nonsignificant increases also evident in dams. Preliminary analyses reveal no evidence of impairment in any of the behavioral tasks in either gender. These data demonstrate dose-dependent effects of iodine deficiency on thyroid hormones during development, however no impairments in behavioral indices of cognitive function were detected. (Does not necessarily reflect EPA policy)

PS 159 IODIDE DEFICIENCY: METABOLIC AND HORMONAL STUDIES FOR PBPK MODELING.

K. Crofton[1], J. Fisher[2], R. Zoeller[3], B. Blount[4], J. Hedge[1], W. Anderson[1] and M. Gilbert[1]. *[1]U.S. EPA, Research Triangle Park, NC, [2]Univ Georgia, Athens, GA, [3]Univ Massachusetts, Amhert, MA and [4]CDC, Atlanta, GA.*

Iodine is an essential nutrient and is critical for synthesis of thyroid hormones. Severe iodine deficiency is known to cause adverse health outcomes and remains a benchmark for understanding the effects of hypothyroidism. However, the implications of modest iodine deficiency on function of the thyroid axis remain unknown. The current study examined the relationship between graded levels of iodine deficiency in rats on thyroid hormones, thyroid iodine content, and urinary iodide excretion. Long Evans rats (n=25, female, 60 days of age) were placed on casein diets containing varying iodine concentrations for 8 weeks. Different iodine diets were created by adding 0, 50, 150, 250 and 1000 μg/kg to the base diet creating 5 iodine levels ranging from deficient (25 μg/kg) to normal (275 μg/kg) to excess iodine (1025 μg/kg). Food and water intake were monitored daily. Urine was captured in metabolism cages over a 6 h period on 2 consecutive days each week. At 8 weeks animals were sacrificed and blood and thyroid glands collected for thyroid hormones and iodine content, respectively. Neither food nor water intake varied as a function of treatment group over the course of the study. Animals in the lowest and the two highest iodine groups were of similar weights at the end of the study, while the intermediate treatment groups were ~6% lighter in weight. Serum total thyroxine (T4) was dose-dependently reduced with significant declines (~35 and 60%) at the two lowest iodine groups. No change in serum T3 was detected. At the end of the study, dose-dependent increases in thyroid weight (5.3, 6.6, 7.4, 8.1 and 11.5 μg) and declines in thyroidal (6.06, 5.58, 5.08, 3.02, 2.33 ng/gm) and urinary (606, 165, 84, 28.5, 20.1 ng/ml) iodide content were observed as a function of iodine in the diet. These data document a viable model of iodine deficiency to inform the development of physiologically based pharmacokinetic models. (Does not necessarily reflect CDC or EPA policy)

PS 160 REPRODUCTIVE TOXICITY AND PHARMACOKINETICS OF DI-N-BUTYL PHTHALATE (DBP) FOLLOWING DIETARY EXPOSURE OF PREGNANT RATS.

M. F. Struve[1, 2], K. W. Gaido[2], J. B. Hensley[2], K. P. Lehmann[2], S. M. Ross[2], M. A. Sochaski[2], G. A. Willson[3] and D. C. Dorman[1, 2]. *[1]College of Veterinary Medicine, North Carolina State University, Raleigh, NC, [2]The Hamner Institutes of Health Sciences, Research Triangle Park, NC and [3]EPL, Inc., Research Triangle Park, NC.*

Most rodent studies examining the developmental toxicity of DBP have relied on bolus gavage dosing. It has not been determined whether bolus dosing provides equivalent results to dietary dosing, which more accurately reflects human exposures. This study characterized the developmental toxicity of dietary DBP and compared these results to previous results obtained using gavage dosing. Pregnant CD rats were given 0, 100, or 500 mg DBP/kg/day in diet from gestational day (GD) 12 through 19. DBP exposure ended the morning of GD 19 and rats were killed 4 or 24 h thereafter. Similar to our previous bolus gavage studies, DBP dietary exposure resulted in significant dose-dependent reductions in testicular mRNA concentration of scavenger receptor class B, member 1; steroidogenic acute regulatory protein; cytochrome P450, family 11, subfamily a, polypeptide 1; and cytochrome P450 family 17, subfamily a, polypeptide 1. These effects were most pronounced 4 h after the end of exposure. Testicular testosterone was reduced 24 h post-exposure in both DBP dose groups and 4 h after termination of the 500 mg DBP/kg/day exposure. Maternal exposure to 500 mg DBP/kg/day induced a significant reduction in male offspring anogenital distance (AGD), and the presence of Leydig cell aggregates, increased cord diameters, and multinucleated gonocytes. Monobutyl phthalate, the developmentally toxic metabolite of DBP, and its glucuronide conjugate were found in maternal and fetal plasma, amniotic fluid, and maternal urine at levels previously reported following bolus gavage. Our results indicate that approximately equal doses from diet or gavage of DBP to pregnant rats result in qualitatively and quantitatively similar responses in male offspring. This study confirms that previous work using gavage is highly relevant for the risk assessment of DBP following human dietary exposure.

PS 161 APPLICATION OF AN INTELLIGENT TESTING STRATEGY TO THE U.S. EPA ENDOCRINE DISRUPTOR SCREENING PROGRAM.

K. M. Sullivan[1] and C. Willett[2]. *[1]Physicians Committee for Responsible Medicine, Washington, DC and [2]People for the Ethical Treatment of Animals, Norfolk, VA.*

The US EPA plans to initiate its Endocrine Disruptor Screening Program in early 2009. The EPA has designed its program in two tiers, consisting of in vivo and in vitro screens and tests; the results of Tier 1 screens would trigger further Tier 2 testing. However, the proposed screening battery has been criticized for the cost and time investments required, and its low specificity. We present the costs, in animal numbers and dollars, of the full Tier 1 battery as proposed by EPA, as well as a suggested revised intelligent testing strategy. This strategy would save animals and resources and result in more efficient screening and characterization of the endocrine-disrupting potential of chemicals. The revised preliminary tier includes physical and chemical data, existing toxicological data, and in vitro and (Q)SAR methods that are either validated or nearly validated. The results of this alternative Tier 1 can be used in a weight-of-evidence approach to 1) identify priority chemicals and 2) design an intelligent, chemical-specific strategy for further screening or testing. Such a strategy would greatly reduce the use of animal testing for both Tier 1 and 2, while maintaining a high level of sensitivity, for identification and classification of endocrine disrupting chemicals.

PS 162 SHORT-TERM EXPOSURE TO TRIFLURALIN DISRUPTS THYROID HORMONE HOMEOSTASIS IN RATS.

J. M. Hedge[1], K. B. Paul[2] and K. M. Crofton[1]. *[1]U.S. EPA, Research Triangle Park, NC and [2]UNC, Chapel Hill, NC.*

Trifluralin is a selective, preemergence 2,6-dinitroaniline herbicide used to control many annual grasses and broadleaf weeds. Human exposure is likely to occur via consumption of vegetables and fruit and possibly fish from trifluralin run off in water. It has previously been reported that trifluralin causes thyroid follicular cell tumors in rats from chronic feeding studies. Recently trifluralin was shown to reduce thyroxine (T4) by upregulating select hepatic UGT isozymes following a 2

week exposure. In order to generate baseline data for use in future mixtures studies we examined whether moderate to low doses of trifluralin would cause any perturbation of thyroid homeostasis in a short-term (4 day) exposure model. Female Long-Evans rats (26 days old, n=66) were dosed via oral gavage with trifluralin in corn oil vehicle (1ml/kg) at 0, 0.3, 1,3,10, 30, 50 or 300mg/kg/day for 4 consecutive days. Serum and livers were collected 24 hours after the last dose. Body weight gain was not affected by treatment. Liver to body weight ratio was significantly increased with 300mg/kg/day trifluralin (24%). T4 was significantly reduced by 25% only at the 300mg/kg/day dose. This work confirms that short-term exposure to trifluralin disrupts thyroid hormone homeostasis in rats. (This abstract does not necessarily reflect EPA policy)

PS 163 TRICLOSAN DISRUPTS THYROXINE: MECHANISMS AND LIFE-STAGE SUSCEPTIBILITY.

K. B. Paul[1], J. M. Hedge[2], M. J. DeVito[3] and K. M. Crofton[2]. [1]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC,* [2]*Neurotoxicology Division, NHEERL, ORD, U.S. EPA, RTP, NC and* [3]*Experimental Toxicology Division, NHEERL, ORD, U.S. EPA, RTP, NC.*

Triclosan (5-chloro-2-(2,4-dichlorophenoxy)phenol) decreases serum thyroxine (T4) in the weanling rat. Scientific uncertainties include: by what mode of action (MOA) does triclosan decrease T4, and does triclosan induce hypothyroxinemia in dams and neonates? To test the hypothesized MOA that triclosan decreases T4 via activation of the pregnane X and constitutive androstane receptors, and subsequent up-regulation of hepatic catabolism of hormones, weanling female Long-Evans rats received triclosan po (0-1000 mg/kg/day) for 4 days. Pentoxyresorufin-O-deethylase (PROD) and uridine diphosphate glucuronyltransferase (UGT) enzyme activities were measured in liver microsomes. qRT-PCR was used to measure mRNA expression of cytochrome P450s 1a1, 2b2, and 3a, UGTs 1a1, 1a6, and 2b5, sulfotransferases 1c1 and 1b1, and hepatic transporters OATP1a1 and 1a4, MRP2, and MDR1b. PROD activity increased ~800 percent and T4-glucuronidation increased 2-fold at 1000 mg/kg/day. CYP2b2, CYP3a, UGT1a1, and SULT1c1 mRNA expression levels were induced 2-fold, 4-fold, 2.2-fold, and 2.6-fold at 300 mg/kg/day, respectively. No changes were observed in mRNA levels for any transporters. These data support the hypothesized MOA for that triclosan-induced hypothyroxinemia. To determine if this MOA applies to dams and neonates, pregnant Long Evans rats received triclosan po (0-300 mg/kg/day) in corn oil from gestational day (GD) 6 to postnatal day (PND) 21. Serum and liver were obtained from pups on PND4, 14, and 21, and dams on PND22. Maternal weight-gain (GD19-PND13) decreased ~10% with 300 mg/kg/d treatment. Serum T4 was reduced in dams by ~30 percent at 300 mg/kg/day, with no T4 effects observed for PND4, PND14, or PND21 pups. This work suggests susceptibility differences between weanlings directly exposed and neonates exposed via dams. This abstract does not necessarily reflect the policy of the US EPA.

PS 164 COMPARATIVE DEVELOPMENTAL THYROID STUDIES WITH 6-PROPYL-2-THIOURACIL (PTU) USING TWO RAT STRAINS (WISTAR *VERSUS* SPRAGUE-DAWLEY) – RESULTS OF TREATMENT-RELATED EFFECTS IN THYROID HORMONES AND THYROID MORPHOLOGY.

S. Schneider[1], R. Buessen[1], W. Kaufmann[1], V. Strauss[1], B. van Ravenzwaay[1], C. Hastings[2] and F. Hess[2]. [1]*Experimental Toxicology & Ecology, BASF AG, Ludwigshafen, Germany and* [2]*BASF Corporation, Research Triangle Park, NC.*

Two comparative developmental thyroid studies with PTU [Study Design according to EPA Guidance Document (October 2005)] were conducted using different strains of rats (Wistar versus Sprague-Dawley) to determine relative sensitivity. Also, confirmation was needed to determine if Wistar controls had potential residual effects resembling "thyroid gland dysplasia" [term used for condition of follicular cell hypertrophy, decreased T4, & increased TSH in control Wistar rats as reported for RCC breeding colony in mid-1990's to 2000] ["Thyroid Gland Dysplasia in WistarHan Rats" Researcher–The RCC Magazine. No.21. April 2005]. Results are presented following treatment of time-mated female rats [Crl:WI(Han)] and [Crl:CD(SD)] with PTU at identical low and high oral gavage dose levels [namely, 0.1 and 2.5 mg/kg bw/day] daily on GD 6 through PND 10, as compared to respective sham-treated control groups. Results indicate that PTU-treated rats of both strains, demonstrate clear dose response relationships for Thyroid Hormones [decreased T4 (lesser effect for T3) and increased TSH for dams (GD 20) (PND 21) and fetuses (GD 20) and pups (PND 4 & 21)]. At these timepoints, correlative changes were observed for increased Relative Thyroid Weight in treated dams (GD 20) ((PND 21), and for Thyroid Morphology (increased incidence/severity of follicular cell hypertrophy / hyperplasia) in treated Dams / Fetuses / Pups, as compared to controls. Importantly, results indicate no apparent significant differences between the Wistar and S-D strains when tested in this study design. The results indicate both strains may be used to test for potential effects on thyroid hormone and light microscopy in fetuses/pups to ascertain NOAELs/LOAELs following exposure to dams during pregnancy and lactation. We confirm a lack of "dysplasia" in Wistar controls.

PS 165 EVALUATION OF SUBCHRONIC TOXICITY AND ESTROGENIC ACTIVITY OF BLACK COHOSH IN FEMALE WEANLING WISTAR HAN RATS EXPOSED BY GAVAGE.

M. D. Stout[1], S. A. Elmore[1], L. M. Fomby[2], P. M. Foster[1], D. R. Germolec[1], G. E. Kissling[1], D. E. Malarkey[1], G. S. Travlos[1], M. K. Vallant[1] and R. S. Chhabra[1]. [1]*NTP/NIEHS, Research Triangle Park, NC and* [2]*Battelle, Columbus, OH.*

Black cohosh is a popular herbal supplement taken by women for the treatment of menstrual cramps and menopausal symptoms. The recommended daily dose is 40 mg/day (~0.5–0.6 mg/kg/day). An often reported mechanism of action alludes to estrogen-mediated effects; however, results found in the literature are mixed. No significant estrogenic effects were observed in an uterotrophic assay conducted by the NTP. In order to address the lack of adequate toxicity data and to further examine the potential estrogenicity of black cohosh, the NTP conducted a 90-day study in 3 week-old female Wistar Han rats administered an ethanolic extract by gavage (in 0.5% aqueous methyl cellulose) of 0, 15, 125, 250, 500 or 1000 mg/kg. In addition to routine toxicity endpoints, reproductive organ weights, time to vaginal patency and analysis of estrous cyclicity were included. There was no apparent in-life toxicity following exposure. Increased platelet counts of up to 35% were observed at the two highest dosages. Increased liver weights were observed at 500 mg/kg (absolute) and 1,000 mg/kg (absolute and relative) and decreased albumin and total protein were observed at 1,000 mg/kg; however, these findings could not be correlated with histopathologic lesions. Vaginal patency was delayed by 3 days at 1,000 mg/kg, suggesting the possibility of anti-estrogenic activity, a finding in contrast to some previous reports; a decrease in pituitary gland weight may be related to this change. At 500 and 1,000 mg/kg, decreased thymus weights and cell death of thymic lymphocytes were observed. The cell death may have occurred primarily in a specific population of T-lymphocytes; however, further studies are needed to test this hypothesis. In conclusion, possible anti-androgenic activity was observed at the high dose, and the thymus appeared to be the only major target organ, following administration of up to 1000 mg/kg black cohosh to weanling female Wistar Han rats.

PS 166 IN UTERO EXPOSURE TO CHLOROQUINE REDUCES TESTOSTERONE AND STEROIDOGENIC GENE EXPRESSION IN FETAL RAT TESTES.

R. A. Clewell[1, 2] and M. E. Andersen[2]. [1]*University of North Carolina, Chapel Hill, NC and* [2]*The Hamner Institutes for Health Sciences, Research Triangle Park, NC.*

Chloroquine (CQ) is a commonly prescribed drug in the treatment and prevention of malaria, as well as several connective tissue disorders at doses in the range of 5 - 25 mg/kg/d. CQ is considered safe for use in pregnant women based on lack of evidence of increased miscarriage or overt birth defects in offspring of exposed mothers. Yet despite widespread use, few reproductive toxicity studies are available for this drug, particularly at human relevant doses. CQ disrupts steroid homeostasis in the adult rat. Since CQ is efficiently transferred to the fetus, the potential to interfere with steroidogenesis at a time when testosterone is critical for male sexual development exists. To investigate the effect on sexual development, pregnant Sprague-Dawley rats were given an oral gavage of water or CQ (10, 50, or 100 mg/kg/d) on gestation days (GD) 16-18. Maternal blood and male fetuses were collected on GD 19 and examined for early markers of endocrine disruption. Maternal serum estradiol levels were reduced at 10 mg/kg/d and increased at 100 mg/kg/d when compared to controls, while progesterone increased in a dose-dependent manner at doses ≧50 mg/kg/d, suggesting compensation by the maternal hypothalamus-pituitary-gonad axis. Anogenital distance was not affected by CQ on GD 19, but reduced coiling of the testicular artery at the high dose indicates delayed testes development. Fetal testes testosterone was decreased in all treatment groups in a dose-dependent manner. Microarray analysis of testes revealed significant down-regulation of several genes associated with fatty acid, cholesterol and steroid regulation at 100 mg/kg/d, including *Nppc*, *Srebp1* and *Tm7sf2*. Reproducible, but statistically insignificant, dose-related decreases were also seen in the expression of steroidogenic genes *Star*, *Cyp17a1*, *P450scc* and *3Hsdβ1* which

are modulated by other known anti-androgens. This study provides strong evidence that CQ is likely to disrupt testosterone-dependent development in the rat fetus at human relevant doses.

PS 167 KETAMINE-INDUCED NEURODEGENERATION IN THE NEWBORN RHESUS MONKEY.

X. Zou[1], T. A. Patterson[1], R. L. Divine[2], N. Sadovova[2], J. P. Hanig[3], M. G. Paule[1], W. Slikker[1] and C. Wang[1]. *[1]Division of Neurotoxicology, National Center for Toxicological Research, Jefferson, AR, [2]Toxicologic Pathology Associates, National Center for Toxicological Research, Jefferson, AR and [3]Division of Applied Pharmacology Research, Center for Drug Evaluation and Research, U.S. Food & Drug Administration, Silver Spring, MD.*

Ketamine is a widely-used pediatric anesthetic, but the types of toxic insult that lead to ketamine-induced neuronal death are not adequately understood. One of the main goals of this study was to determine whether there is a duration of ketamine-induced anesthesia below which no significant ketamine-induced neurodegeneration can be detected. Newborn rhesus monkeys (postnatal day 5 or 6) were administered ketamine intravenously for 3, 9 or 24 hours to maintain a steady anesthetic plane, followed by a 6-hour withdrawal period. The 24-hour duration was selected as a relatively long duration, while the 3-hour duration more closely approximates typical pediatric general anesthesia. Animals were subsequently perfused and brain tissue processed for analyses using silver and Fluoro-Jade C stains and caspase-3 immunostain. The results indicated that no significant neurotoxic effects occurred if the anesthesia duration was 3 hours. However, 9 and 24-hour ketamine infusions significantly increased the number of silver-impregnated grains and the number of caspase-3 and Fluoro-Jade C-positive neuronal profiles in layers II and III of the frontal cortex compared with controls. The extent of neurodegeneration seen with 24-hour exposure is indeed greater than that seen after a 9-hour exposure. Although a few caspase-3 and Fluoro-Jade C-positive neuronal profiles were observed in some additional brain areas including the hippocampus, thalamus, striatum and amygdala, no significant differences were detected between ketamine-treated and control monkeys in these areas. These data suggest that the newborn monkey is sensitive to anesthetic-induced neurodegeneration and that exposure of 9 hours or longer can induce neurodegeneration during this early stage of development. Supported by FDA/NCTR E-7189, CDER/FDA and NICHD.

PS 168 DIFFERENTIAL SPATIOTEMPORAL REGULATION OF BASIC HELIX-LOOP-HELIX (BHLH) AND HOMEODOMAIN (HD) TRANSCRIPTION FACTORS DURING GESTATIONAL LEAD EXPOSURE (GLE) SELECTIVELY INCREASES THE NUMBER OF LATE-BORN RETINAL NEURONS.

A. Giddabasappa, S. Mukherjee, W. Xiao, S. Chaney and D. A. Fox. *University of Houston, Houston, TX.*

GLE increases and prolongs the proliferation of retinal progenitor cells (RPCs) resulting in an increased number of late-born retinal neurons (rods and bipolar cells), but not Müller glial cells [SOT 2008]. Our present goals were to determine the spatiotemporal mRNA and protein expression profile of transcription factors (TFs)that produced this novel retinal phenotype. C57BL/6 female mice were exposed to water or 55 ppm lead throughout gestation (E) and until postnatal day 10 (PN10): period equivalent to human gestation. Affymetrix arrays and real-time PCR (RT-qPCR) determined retinal gene expression at E18.5 and PN2-10. Western blots and immunocytochemical confocal (IHC) studies used PN2-10 retinas. Peak [BPb] at PN0-10 was ~20 μg/dL. Microarray and RT-qPCR analysis revealed that Mash1 and Chx10 were upregulated in GLE retinas from PN6-10 and PN2-6, respectively. However, Hes1, NeuroD1, Otx2, Notch1, STAT3, CNTF, gp130, SOCs3 and Sp1 mRNA expression were not different from controls. Immunoblots revealed that GLE upregulated Mash1 expression from PN2-10; upregulated Hes1 expression from PN2-4 and downregulated its expression on PN6; upregulated Notch1-ICD/–ECD at PN4 and downregulated their expression at PN6; and did not change STAT3/pSTAT3 expression. In PN5 GLE retinas, IHC revealed that Mash1, Hes1 and Chx10 were upregulated in postmitotic and differentiating neurons. The GLE-induced upregulation of the Hes1 (bHLH TF)-Notch1 pathway is consistent with increased and prolonged RPC proliferation. The GLE-induced upregulation of Mash1 (proneural bHLH TF)and Chx10 (bipolar cell promoting HD TF) in post-mitotic RPCs in concert with the downregulation of Notch1-Hes1 and no change in STAT3/pSTAT3 is consistent with the selectively increased rods and bipolar cells. Thus, low-level GLE targeted specific bHLH and HD TFs during a critical stage of late retinal development, which produced a unique retinal phenotype. Supported by NIH Grants ES012482, EY07751 and EY07024.

PS 169 ASSESSMENT OF SYNAPSE FORMATION IN RAT PRIMARY NEURAL CELL CULTURE USING HIGH CONTENT MICROSCOPY.

J. A. Harrill, T. M. Freudenrich, B. Robinette and W. R. Mundy. *Cellular and Molecular Toxicology Branch, Neurotoxicology Division, U.S. EPA, RTP, NC.*

Cell-based assays can model neurodevelopmental processes including neurite growth and synaptogenesis, and may be useful for screening and evaluation of large numbers of chemicals for developmental neurotoxicity. This work describes the use of high content screening (HCS) to detect chemical effects on synaptogenesis *in vitro*. HCS was performed with a Cellomics ArrayScan VTi™, an automated epi-fluorescence microscope and image analysis system, using cells in a microtiter plate format. Cerebellar granule cells (CGCs) from PND7 LE rats were seeded at $1.33x10^5$ cells/cm^2 on laminin coated 96-well plates and grown for 2, 3, 5, 7, 9 or 14 days *in vitro* (DIV). Cells were then fixed and fluorescently labeled with antibodies against βIII-tubulin and syanpsin I to visualize neuronal cells bodies and qualitatively assess the development of pre-synaptic terminals. Synapsin staining was diffuse up to DIV3. Synapsin puncta appeared at DIV5 and were observed up to DIV14. DIV7 CGCs were then used to optimize a protocol for neurite and syanpsin I quantification using an ArrayScan VTi™. The number of synapsin puncta and total area of synapsin staining associated with neuronal cell bodies and neurites were used as endpoints to measure synaptogenesis. CGCs were then treated with 3 or 10 μM of the PKC inhibitor Bis1, the MEK inhibitor U0126, the Src kinase inhibitor SU6656 or vehicle control (0.1% DMSO) at 2 h post-seeding and evaluated on DIV7 with the ArrayScan protocol (n=4-6 wells/group). 3 μM SU6656 increased the density of synaptic puncta associated with neurites and cell bodies on DIV7. 3 μM Bis1 and 10 μM U0126 decreased the number and total area of synapsin puncta associated with cell bodies and neurites. 10 μM Bis1 produced large reductions in synapsin staining and decreases in total neurite length (16% of control), indicative of overt cellular toxicity. These data demonstrate this method can be used as a screening tool to detect chemical effects on synaptogenesis in primary cultures. *This abstract does not necessarily reflect USEPA policy.*

PS 170 LEAD EXPOSURE AND EXTERNALIZING BEHAVIOR IN KINDERGARTEN CHILDREN.

J. Liu[1], L. McCauley[1], J. Pinto-Martin[1], X. Shen[2], C. Yan[2] and H. Needleman[3]. *[1]University of Pennsylvania, Philadelphia, PA, [2]Shanghai Jiaotong University, Shanghai, China and [3]University of Pittsburgh, Pittsburgh, PA.*

Objectives: Studies on the effect of lead exposure on children's externalizing behavior (e.g. aggression, hyperactivity) are mixed. The purpose of this study was to provide further data on whether lead exposure is associated with increased externalizing behavior in kindergarten children, and assess whether the effect is independent of psychosocial factors in a non-clinical community sample of Chinese children. Method: Participants consisted of 650 5-6 years old kindergarten children in Jintan City, China. The Chinese version of the Child Behavior Checklist (CBCL) was used to measure behavioral outcomes. Blood lead level (BLL) was measured by a reference laboratory of the Centers for Disease Control and Prevention (CDC) in the Shanghai Lead Prevention Center. A self-administered parental questionnaire was used to collect information on potential confounds, including parental socioeconomic status, education, occupation, and marriage status. Results: Geometric mean BPb among subjects was 7.0 μg/dL (range, 2.3 -24.6 μg/dL). 544 (89.8%) children had BLL in the range of 0 to 9.9 μg/dL, while 62 (10.2%) of children had BLLs ≥ 10 μg/dL. Externalizing behavior was increased significantly in those with BLL greater than 10 μg/dL ($p<.05$). The group difference remained after controlling for potential demographic and psychosocial factors. Conclusions: This population-based study suggests that increased lead levels are associated with increased externalizing behavior and it has potential public health implications for prevention of lead exposure in children.

PS 171 CHANGE OF GENE EXPRESSION PROFILES IN ZEBRAFISH EMBRYOS AS AN ENDPOINT IN NEUROTOXICITY SCREENING.

C. Fan[1, 2], S. Padilla[1] and R. Ramabhadran[1]. *[1]U.S. EPA, Research Triangle Park, NC and [2]Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC.*

Chemicals that adversely affect the developing nervous system may have long-term consequences on human health. Little information exists on a large number of environmental chemicals to guide risk assessments for developmental neurotoxicity (DNT). As traditional DNT testing using rodents are costly, time consuming and labor intensive, alternative species such as zebrafish are being adapted for high-throughput toxicity screening. Hence, it is necessary to identify and characterize zebrafish biomarkers for assessing the DNT potential of chemicals. First, we described the developmental expression profile of 9 nervous system genes expressed in

untreated zebrafish embryos and larvae from 1 dpf to 6 days post-fertilization (dpf) determined using RT-qPCR. The data indicated that synapsin II and myelin basic protein (mbp) showed the largest increase in transcript levels. HuC, gap43, neurogenin 1 (ngn1), t1α tubulin, and gfap showed gene expression profile with an early increase followed by down-regulation. The transcripts of nestin and sonic hedgehog decreased during zebrafish development. We next investigated the changes in gene expression profile in zebrafish embryos exposed to two known developmental neurotoxicants (ethanol or valproate).from 0 to 5 dpf. Both toxicants affected gene expression at 3 and 6 dpf with some differences between the two chemicals. There were, however, some similarities with both valproate or ethanol exposure producing changes in mbp, nestin, and ngn1 expression when assessed at 3 dpf, and in mbp, gfap and ngn1 expression when assessed 24 hours after exposure had ceased (i.e., 6 dpf). Collectively, these data indicate that transcript levels of genes are responsive to developmental neurotoxicant exposure. It is possible to utilize the change of gene expression profiling as an endpoint to evaluate the developmental neurotoxicity. (This abstract does not necessarily reflect USEPA policy)

PS 172 EXPOSURE TO PYRETHROID INSECTICIDES ALTERS EXPRESSION OF GENES IMPORTANT FOR DOPAMINERGIC NEURONAL DEVELOPMENT.

A. DeMicco[1], K. R. Cooper[1], J. R. Richardson[2] and L. A. White[1]. *[1]Biochemistry and Microbiology, Rutgers University, New Brunswick, NJ and [2]Environmental and Occupational Health Sciences Institute, UMDNJ, Picataway, NJ.*

Pyrethroids are widely used residential and agricultural insecticides, and recent studies indicate that the developing embryo may be especially susceptible to pyrethroids exposure. Data from the Richardson laboratory show that developmental exposure of mice to deltamethrin (a type II pyrethroid) results in increased dopamine transporter (DAT) expression and increased expression of Nurr1 and Pitx3, transcription factors involved in dopaminergic system development. These mice also displayed increased locomotor activity. We have chosen to use the zebrafish to explore the hypothesis that developmental pyrethroid exposure alters dopaminergic neuronal development. To investigate the toxicity of pyrethroids in this model system, zebrafish embryos (3hpf) were exposed to pyrethroids and observed individually every 24h until 144 hpf. High doses of pyrethroids caused mortality (LC50 of 55μg/L for deltamethrin), pericardial edema, body axis curvature, and spasms. Lower doses caused hyperactivity, similar to the effects seen in mice. To evaluate changes in gene expression, quantitative RT-PCR was used to determine expression of DAT, Pitx3, Nurr1, and tyrosine hydroxylase (a marker of dopaminergic neurons). Deltamethrin (1μg/L) caused an increase in expression of DAT (3.4 fold), TH (3.2 fold) and the transcription factors Nurr1 (3.3 fold) and Pitx3 (3.6 fold) without causing overt toxicity. Furthermore, these changes persisted in 2 week old larvae that had been exposed to deltamethrin during early embryogenesis. These data validate the zebrafish as a model for studying pyrethroid neurotoxicity, and demonstrate that short-term exposure to deltamethrin during early development results in alteration of gene expression that persists for at least 2 weeks. Supported in part by NIEHS grants P30ES005022 and R01ES015991.

PS 173 NEUROTOXICITY OF TBT IN F1 RATS AS EVALUATED BY AN OPEN FIELD TEST AND PREPULSE INHIBITION TEST.

M. Tsunoda[1], H. Asakawa[2], K. Takaya[1], M. Hosokawa[1], C. Sugaya[1], Y. Inoue[1], Y. Kudo[1], T. Satoh[1], H. Katagiri[2], H. Akita[2], M. Saji[2], M. Wakasa[3], T. Negishi[3], T. Tashiro[3] and Y. Aizawa[1]. *[1]Preventive Medicine and Public Health, Kitasato University School of Medicine, Sagamihara, Kanagawa, Japan, [2]Kitasato University School of Allied Health Sciences, Sagamihara, Kanagawa, Japan and [3]Aoyama Gakuin University School of Science and Engineering, Sagamihara, Kanagawa, Japan.*

Neurotoxicity is one of the major effects of tributyltin (TBT). The effects on the next generation of F1 rats exposed to TBT via the placenta and their dams' milk may be stronger than those on adults. Pregnant Wister rats were exposed to TBT at 0 and 125 ppm in their food. Half of the female F1 rats in both groups were exposed to TBT at 125 ppm in their food from 9 to 15 weeks age. Female F1 rats were divided into: the control-control (CC), TBT-control (TC), control-TBT (CT), TBT-TBT (TT) groups (n = 10/group). After the administration, an open field test and prepulse inhibition (PPI) test were performed at 15 weeks of age. The mean body weight of the TC and TT groups was significantly lower than that of the CC group at 9 and 15 weeks of age. In the open field test, a marked decrease in the total locomotion distance was observed in the TT group, and the mean value was significantly lower than that of the CC group. For the locomotion distance between 15-20 min, the mean values in the CT, TC and TT groups were significantly lower than that in the CC group. The mean locomotor distance between 25-30 min in the TT group was significantly lower than that in the CC and TC groups. The mean values of instances of wall rearing in the TC, CT and TT groups were significantly lower than that in the CC group. The mean value of face washing in the TT group was significantly lower than that in the TC group. There were no significant differences in indexes of the PPI test. Exposure to TBT via the placenta and their dams' milk inhibited the development of F1 rats, which continued after weaning. Inhibition of the rats' activity induced by exposure to TBT via the placenta and their dams' milk and/or via food was suggested. The effects were most evident in the TT group.

PS 174 DEVELOPMENTAL NEUROTOXICITY OF ACRYLAMIDE IN WISTAR RATS.

M. V. Patel[1], S. M. Paneliya[1], M. M. Ghag[1] and P. B. Deshmukh[2]. *[1]Toxicology, Jai Research Foundation, Valavada-396108, Gujarat, India and [2]Toxicology and Pharmacology Services, Jai Research Foundation, Valavada-396108, Gujarat, India.*

There are innumerable hazardous contaminants in our environment. Some of these agents are known to be neurotoxic in animals and humans. Foetuses and neonates are known to be a high-risk groups. The present study was carried out in order to see the enhanced developmental neurotoxic effects in pregnant female rats using acrylamide. Pregnant Wistar rats (9-11 weeks old), weighing 190-205 gms) were dosed with acrylamide at 0,8, 12 and 16/18 mg /kg b. wt. form day 6 of gestation to day 21 of lactation. No maternal death or distinctive toxic signs were noted during gestation however, two dams from high dose group were found dead during lactation. The maternal body weight and feed consumption were significantly decreased in mid and high dose groups during gestation and lactation. The mean body weight and feed consumption of pups were significantly decreased at all the treatment groups. Survival index of the pups was decreased at high dose group on postnatal day 4, 21 and 28. During neurobehavioral observation of pups, circling behavioural (PND 11), abnormal gait (PND 21) and impaired mobility (PND 21) were observed in male and female pups from high dose group. The pups from the high dose groups were falls immediately during wire manoeuvre observation. The mean ambulatory activity on postnatal day 13 and 17 was decreased in the male and female pups from the mid and high dose groups. On PND 23 abnormal air righting reflex of the male and female pups were observed at mid and high dose groups and mean foot splay (mm) of male and female pups were significantly decreased at high dose group. It can be concluded that acrylamide did not showed selective developmental neurobehavioral toxicity. It was evident that the test substance was found to possess maternal toxicity but failed to reveal potential developmental toxicity.

PS 175 QUANTITATIVE ASSESSMENT OF [18F]-ANNEXIN V UPTAKE BY MICROPET IMAGING AS A BIOMARKER OF KETAMINE-INDUCED NEURONAL DEATH.

X. Zhang, G. D. Newport, T. A. Patterson, M. G. Paule, W. Slikker and C. Wang. *Neurotoxicology, NCTR/FDA, Jefferson, AR.*

Ketamine is a dissociative anesthetic that is primarily used for the induction and maintenance of general anesthesia. Recent reports indicate that ketamine anesthesia for 6-12 h triggers neuronal apoptosis in postnatal day (PND) 7 rats. In all apoptotic neurons, phosphatidylserine (PS) is rapidly redistributed from the inner to outer surface of the plasma membrane and can be selectively recognized and bound by annexin V. Because the high-resolution positron emission tomography scanner (microPET) provides in vivo molecular imaging at sufficient resolution to resolve neuronal activities in the rat brain, it has been proposed as a minimally invasive method for detecting apoptosis in the brain using the tracer [18F]-labeled annexin V. In this study, the effect of ketamine on the uptake and retention of [18F]-annexin V in the rat brain was investigated using microPET imaging. On PND 7, rat pups in the experimental group were exposed to 6 injections of ketamine (20 mg/kg at 2 h intervals) and control rat pups received 6 injections of saline. On PND 35, [18F]-annexin V (1 mci) was injected into the tail vein of treated and control rats and static microPET images were obtained over 2 h following the injection. Radiolabeled tracer accumulation in the region of interest (ROI) in the frontal cortex and hippocampus were converted into Standard Uptake Values (SUVs). After the injection, radiotracer was quickly distributed into the brains of both ketamine- and saline-treated rats. Compared with the control group, the uptake of [18F]-annexin V was significantly increased in the ROI of ketamine-treated rats. Additionally, the duration for wash-out of the tracer was prolonged in the ketamine-treated animals. This preliminary study demonstrates that microPET imaging is capable of distinguishing differences in retention of [18F]-annexin in different brain regions and suggests that this approach may provide a minimally invasive biomarker of neuronal apoptosis. Supported by NICHHD, NTP/NIEHS and FDA

PS 176 EARLY EXPOSURE TO OXYTOCIN ALTERS ZEBRA FINCH VOCAL DEVELOPMENT.

B. Riffle and K. Soderstrom. *Pharmacology and Toxicology, ECU, Greenville, NC.*

Autism spectrum disorder is associated with deficits in both social and language skills, and evidence suggests a role for oxytocin signaling in the etiology of autism. Peripheral administration of oxytocin (widely used during parturition)has been shown to distribute to the central nervous system, particularly in newborns (McEwen 2004). Oxytocin signaling has been established to be important in the modulation of social behaviors. The extent to which oxytocin signaling is involved in vocal development has not been established, possibly due to a lack of appropriate animal models. Since song birds learn a form of vocal communication, they represent a promising model for evaluating effects of oxytocin-related peptides on vocal development. As an avian species, zebra finches utilize mesotocin rather than oxytocin signaling (these nonapeptides differ by a single amino acid). To establish the suitability of zebra finches as an animal model to study developmental effects of oxytocin-related peptides, we have begun to characterize the receptor likely involved. Immunohistochemical experiments using an antibody raised from the mesotocin receptor specific previously cloned in our laboratory suggests that distinct mesotocin receptor expression occurs within the vocal motor brain regions and that mesotocin receptor expression varies as a function of age during vocal development. To determine if early exposure to oxytocin could alter normal vocal development, birds were treated with either oxytocin (300 mcg/kg, 1000 mcg/kg, or 3000 mcg/kg) or vehicle for five days (days 5-9). The birds were then raised by the same adult tutor. Songs were recorded at adulthood and ten song files were randomly selected for analysis. There was no statistical difference on note stereotypy by oxytocin treated animals due to dosage and thus the animals were pooled into one group. The songs produced by the oxytocin treated animals were less well-stereotyped than those of the vehicle treated animals ($p = 0.015$, two sample t-test). These preliminary results suggest that early post-natal oxytocin exposure may alter zebra finch vocal development.

PS 177 GESTATIONAL EXPOSURE TO TOLUENE DID NOT ALTER THE BEHAVIOR OR VISUAL FUNCTION OF OFFSPRING RATS.

W. K. Boyes, L. L. Degn, P. Evansky, T. E. Samsam, P. J. Bushnell, K. L. McDaniel, V. C. Moser, R. G. Ellis-Hutchings and J. M. Rogers. *NHEERL, EPA, Research Triangle Park, NC.*

Children of women who were exposed to organic solvents during pregnancy have shown altered physical development, behavior (Pearson et al, 1994; Arnold et al, 1994) and visual function (Till et al, 2001; 2003; 2005). We evaluated the offspring of pregnant Long-Evans rats who were exposed to toluene vapor at concentrations of 0, 10, 100 or 1000 ppm from days 8-19 of gestation. There were no effects of toluene on maternal body weight during pregnancy or preweaning growth of offspring at any concentration, but postweaning offspring weights were significantly lower through 18 weeks in the 1000 ppm group. One set of offspring was tested at 5 and 8 weeks of age using a functional observational battery (FOB) and motor activity (n=9-10/dose, 1 male/litter). There were no treatment effects on horizontally or vertically directed activity. Of all the FOB endpoints, only slight effects on reactivity and the click response were detected; while significant, these changes were neither dose-responsive nor convincing. The rats were then trained to perform a visual signal detection task to assess learning and sustained attention. No effects of toluene exposure were observed in a lever press task, visual discrimination task or the signal detection task. Beginning at approximately 75 days of age, electroretinograms (ERG), and pattern-elicited visual evoked potentials (VEP) were recorded from a second cohort of offspring (n=10/dose, 1 male offspring/litter). No statistically significant effects of toluene exposure were observed in any ERG or VEP parameter, or in contrast thresholds extrapolated from VEP contrast-amplitude functions. These experiments have not confirmed that gestational exposure to toluene alters the visual function or behavior of offspring.

This abstract does not reflect EPA policy.

PS 178 PROTECTION FROM KETAMINE-INDUCED DNA DAMAGE IN RAT FOREBRAIN CULTURE BY L-CARNITINE.

N. V. Sadovova[1], X. Zou[2], X. Zhang[2], J. P. Hanig[3], M. G. Paule[2], W. Slikker[2] and C. Wang[2]. *[1]Toxicologic Pathology Associates, Jefferson, AR, [2]Neurotoxicology, National Center for Toxicological Research/U.S. Food & Drug Administration, Jefferson, AR and [3]Center for Drug Evaluation and Research/U.S. Food & Drug Administration, Silver Spring, MD.*

Ketamine, a noncompetitive NMDA receptor antagonist, is used as a general pediatric anesthetic, and may cause neurodegeneration if administration occurs during critical periods of development. L-carnitine plays an integral role in reducing brain injury associated with mitochondrial neurodegenerative disorders. The purpose of this study was to investigate whether co-administration of L-carnitine could protect against or attenuate ketamine-induced cell death using newborn rat forebrain cultures. Neural cells collected from the newborn rat forebrain were incubated for 24 h with 1, 10 or 20 μM ketamine, normal culture medium (control), or ketamine (10 μM) plus 100, 500 or 1000 μM L-carnitine. A modification of guanine (8-oxoguanine) presumably induced by the reaction of endogenous and exogenous reactive oxygen species with nucleic acids was used as a biomarker for oxidative DNA damage. 8-oxo-dg ELISA and antibody to human 8-oxoguanine DNA glycosylase (hOGG1) which catalyzes the removal of the 8-oxoG through cleavage of the DNA phosphodiester bond, were used to explore the potential regulatory DNA repair system. The 8-oxo-dg ELISA and immunostaining data indicate that ketamine (10 or 20 μM) produced elevated levels of 8-oxoguanine, and a reduction in mitochondrial metabolism of MTT. Preliminary data also show increased DNA migration as indicated by an alkaline single cell gel electrophoresis (Comet assay). No significant effect was observed in the release of lactate dehydrogenase. Ketamine-induced DNA damage in forebrain culture was effectively blocked by L-carnitine (500 or 1000 μM), suggesting its potential protective effects via prevention of apoptosis and chromosome damage, and changing cellular transcriptional responses. Supported by NCTR/NTP IAG # 244-07-0007 (E-2155).

PS 179 VALPROATE-INDUCED ABNORMAL DEVELOPMENT NEUROTOXICITY IS AFFECTED BY MATERNAL CONDITIONS, INCLUDING SHIPPING STRESS.

M. Kuwagata[1, 2], T. Ogawa[2, 3], S. Shioda[2] and T. Nagata[1]. *[1]Laboratory of Pathology, Toxicology, Hatano Reseach Institute, Food and Drug Safety Center, Kanagawa, Japan, [2]Department of Anatomy I, Showa University School of Medicine, Tokyo, Japan and [3]Anti-aging Medicine Funded Research Labs, Showa University School of Medicine, Tokyo, Japan.*

Prenatal stress is known to affect the development of the brain, and to exaggerate the developmental toxicity of chemicals. Many studies on developmental neurotoxicity (DNT) use pregnant rodents mated at the supplier, which consequently suffer from the stress of shipping and environmental changes. We have demonstrated differences in developmental neurotoxicity induced by valproate (VPA) between pregnant rats mated at our own animal facility (in-house group) and rats purchased pregnant (supplier group). Rats were treated with VPA (800mg/kg) orally on gestation day (GD) 9 or 11 (VPAE9 or VPAE11), and the fetal brain was examined at E16 using immunohistochemistry for serotonin, tyrosine hydroxylase (TH), and TuJ1 (a neuronal marker). Cortical dysgenesis (abnormal cortical plate) was induced in both VPAE9 and VPAE11 groups. Abnormal traveling of the neural fasciculus at the isthmus, resulting in disturbance of the migration of TH-positive and serotonin neurons was observed in the hindbrain of only the VPAE11 group. Comparing the incidence of these abnormalities between the in-house and supplier groups, the incidence of the cortical dysgenesis was increased slightly, and that of the abnormal pons was clearly increased in the supplier group. Thus, observation of E16 brain clearly demonstrated that a difference in mating location (own animal facility or supplier) affects the reproducibility of VPA-induced DNT. (This research was supported by a grant for Long-range Research Initiative from the Japan Chemical Industry Association.)

PS 180 DISTRIBUTION OF C-FOS-LIKE IMMUNOREACTIVITIES IN THE NEONATAL RAT BRAIN SHORTLY AFTER MATERNAL DEPRIVATION IN THE BRDU-INDUCED HYPERACTIVITY MODEL.

T. Ogawa[1, 2], M. Kuwagata[2, 3], T. Nagata[3] and S. Shioda[2]. *[1]Anti-aging Medicien, Showa university, Tokyo, Japan, [2]Anatomy, Showa university, Tokyo, Japan and [3]Pathology, Hadano Research Institute, FDSC, Kanagawa, Japan.*

c-Fos has been used as a marker of neuronal activity, and immunohistochemistry of this protein is one of the most useful methods to investigate active brain areas in experimental animals. We applied c-Fos immunohistochemistry to develop a method to detect abnormal brain function during the neonatal period in a chemical-induced developmental disorder model. To investigate neonatal brain function, we induced maternal deprivation, which was enough to stimulate them and induced c-Fos immunoreactivities in the brain areas related to the olfactory system, and stress response. To produce a chemical-induced hyperactivity rat model, we treated pregnant rats with 50 mg/kg of 5-bromo-2-deoxyuridine (BrdU) from gestation day 9 to 15. Neonatal rats at 11 days of age were perfused with a fixative following one-hour maternal deprivation (neonatal rats were placed in a new empty cage for one hour). The number of c-Fos immunoreactive cells was counted in several brain areas and compared between the control and BrdU groups. The number of c-Fos immunoreactive cells in the BrdU group was decreased in the piriform cortex, the locus coeruleus and dorsal part of the septum, which plays an important role in neonatal learning and memory. We further analyzed Pearson product-moment cor-

relation coefficient between two brain areas for the number of c-Fos immunoreactive cells. In the control group, the number of c-Fos immunoreactive cells in the locus coeruleus correlated with brain areas such as the bed nucleus of the stria terminalis, piriform cortex, and the somatosensory cortex, however, these correlations disappeared in the BrdU group. Thus, c-Fos immunohistochemical observation provides a method to detect developmental neurotoxicity during the neonatal period.(Supported by a grant for Long-range Research Initiative from the Japan Chemical Industry Association)

PS 181 TIME COURSE OF CHOLINESTERASE INHIBITION FOLLOWING DEVELOPMENTAL CHLORPYRIFOS EXPOSURE USING DIFFERENT ADMINISTRATION PARADIGMS.

R. L. Carr and C. A. Nail. *Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.*

Chlorpyrifos (CPS) is widely used in agricultural settings and residue analysis has suggested that children in agricultural communities are at risk of exposure. This has resulted in a large amount of literature investigating the potential for CPS-induced developmental neurotoxic effects. Three of the most common routes of administration of CPS are orally in oil, subcutaneously in oil, and subcutaneously in DMSO. For comparison between these methods, rat pups were exposed daily from days 10-16 to CPS (5 mg/kg) either orally dissolved in corn oil (PO-Oil), subcutaneously dissolved in oil (SC-Oil), or subcutaneously dissolved in DMSO (SC-DMSO) at a rate of 1.0 ml/kg. A representative vehicle/route group was present for each treatment. A time course of acetylcholinesterase inhibition on the last day of exposure was conducted to determine the peak time of inhibition following each route. Samples were taken at 2, 4, 6, 8, 10,and 12 hours. In the forebrain, the time to peak inhibition was 4 hours following all routes and the level of inhibition was greatest in the SC-DMSO (~70%) followed by PO-Oil (~50%) and then SC-Oil (~42%). In the cerebellum, the time to peak inhibition was 6 hours following PO-Oil (~45%) and SC-Oil (~37%) but was 2 hours with SC-DMSO (~68%). Recovery in the forebrain was observed with all routes but in the cerebellum, recovery occurred in the oil routes but was not evident in the SC-DMSO route. These data suggest that using DMSO as a vehicle for CPS not only induces greater AChE inhibition but results in regional differences in the pattern of AChE inhibition and recovery.

PS 182 HIGH-THROUGHPUT BEHAVIORAL QUANTIFICATION OF DI(2-ETHYLHEXYL) PHTHALATE (DEHP) EXPOSED RATS.

T. J. Zarcone[1, 2], D. M. Carbonari[1], A. M. Katz[1], A. W. Duncan[1] and B. Weiss[1]. *[1]Environmental Medicine, University of Rochester Medical Center, Rochester, NY and [2]Pediatrics, University of Rochester Medical Center, Rochester, NY.*

Differences in performance between male and female rats are used to assess substances thought to affect sexual development of the brain. Most current methods for measuring sexually-differentiated behavior in rats have been limited to human observation requiring both subjective interpretation and limited quantification. Human observation is labor- intensive, restricting these techniques from being used as high-throughput screens for agents such as endocrine-active substances. This poster presents apparatus and methods for quantifying sexually- differentiated behavior as well as the effects of 125 or 250 mg/kg of di (2-ethylhexyl) phthalate (DEHP) given perinatally. Specifically, male and female pups were exposed, via the dam, from gestational day 14 to post natal day (PND) 3 and then measured for activity and play behavior. Ninety-six rats were processed in a between-group design with negative- (corn oil) and positive- (50 mg/kg vinclozolin (Vz)) control groups. Sex differences in activity did not appear until PND 54 in control and 125 mg/kg DEHP groups. The sex differences were not statistically significant for the 250 mg/kg DEHP and Vz groups. Quantitative assessment of play behavior showed negative-control male rats engaging in more rough-in-tumble play than females at all ages. DEHP and Vz did not impact male play behavior, but did increase female play behavior at all ages. This poster shows (1) that play behavior can be automated and computerized, producing quantified data which allows for high-throughput screening of chronic low dose exposures; and (2) that perinatal phthalate exposure can induce sexually-differentiated behavioral effects. (Preparation supported in part by NIEHS grants ES013247 and ES015509 and Center grant ES01247.)

PS 183 DEVELOPMENTAL EXPOSURE TO DELTAMETHRIN RESULTS IN REGIONAL ALTERATIONS IN SODIUM CHANNEL SUBUNIT AND BRAIN-DERIVED NEUROTROPHIC FACTOR mRNA EXPRESSION.

J. P. Magby and J. Richardson. *RWJMS, Piscataway, NJ.*

Developing animals are known to be more sensitive to the neurotoxic effects of the pyrethroid insecticide deltamethrin. Deltamethrin is thought to exert toxicity by delaying the closure of voltage gated sodium channels and leading to a persistent depolarization. In vitro studies have found that exposure to toxins that increase sodium flux into cultured neurons causes down-regulation of sodium channel subunits, which in turn affects the firing properties of the cells and synaptic activity. However, it is not clear if such an effect occurs in vivo. Here, we sought to determine whether developmental exposure to deltamethrin causes changes in sodium channel subunit expression. Pregnant mice were exposed throughout gestation and lactation to either 0 or 3 mg/kg deltamethrin every three days. The offspring were tested as adults for behavioral deficits and male offspring sacrificed at 10-11 months of age for determination of isoform-specific sodium channel (NaV) and BDNF mRNA expression by QPCR. Following developmental exposure to deltamethrin, NaV 1.3 expression was decreased by about 27% and NaV β3 by about 26% in the frontal cortex, with no significant effects on other α or β isoforms. In the striatum we observed an approximate 24% decrease in NaV 1.1, NaV 1.2, and NaV β1 along with 15 % reduction in NaV β3. Since reduction in sodium channel expression could potentially lead to alterations in synaptic activity, we determined the mRNA expression of brain-derived neurotrophic factor (BDNF), which is known to be regulated by neuronal activity. We saw a slight but non-significant reduction of BDNF mRNA in the frontal cortex. However, BDNF mRNA was reduced by about 66% in the striatum. Taken together, these data suggest that developmental deltamethrin exposure results in long-term alterations of isoform-specific sodium channel subunit expression which may result in region-specific alterations in neuronal activity and contribute to the behavioral deficits observed in mice developmentally exposed to deltamethrin.

Feron.

An extended (neuro)developmental study (OECD 415; EPA OPPTS 870 6300, 6800) was carried out in rats with the model developmental neurotoxicant methylmercury (MeHg; 0, 0,1, 0.4, 0.7, 1.0, 1.5, 2.0 mg/kg body weight; GD6-LD10). The study was designed to gather information on the relationship between conventional technologies and indicators for developmental (neuro)toxicity (mainly landmarks, behaviour and an extensive neuropathology survey, versus new (innovative) technologies, i.e. stereology, toxicogenomics, in vivo PET-imaging, ex vivo in vitro field potentials in hippocampal brain slices. In addition, a comparison was made between a classical NOAEL and a Bench mark approach. The innovative technologies were assessed on the control group and in the 0 and 1.5 mg MeHg/kg groups. The results showed that, whereas conventional endpoints showed hardly – if any- effects of prenatal exposure to MeHg, the new technologies (stereology, toxicogenomics, [18F]FDG micro PET and in vitro hippocampal synaptic excitability) all demonstrated that persistent deficits exist in the brain of the offspring during adulthood resulting from maternal exposure to MeHg. Moreover, the statistical power of the benchmark approach appeared stronger than that of the NOAEL approach since, unlike with the NOAEL approach, a dose response relationship was demonstrated for most parameters. Together, the results demonstrate that modern technologies and statistical approaches may have a higher throughput and are likely to show much stronger discriminative power when it comes to demonstrations of adverse effects of developmental (neuro)toxicants. The relevance of these findings will be discussed in the context of regulatory testing of developmental (neuro)toxicity.

PS 185 CA1 SYNAPTIC EXCITABILITY MEASURED *IN VITRO* IN HIPPOCAMPAL BRAIN SLICES IS CHANGED IN ADULT RAT OFFSPRING AFTER MATERNAL EXPOSURE TO MEHG.

D. M. De Groot[1], N. Cappaert[2], L. Van der Horst[1], M. Otto[1], W. Wadman[2] and H. Muijser[1]. *[1]TNO Quality of Life, Zeist, Netherlands and [2]Universiteit van Amsterdam, SILS-CNS, Amsterdam, Netherlands.* Sponsor: V. Feron.

In utero exposure to methylmercury (MeHg) induces developmental deficits in offspring, such as loss of memory function [1]. A key brain region involved in learning and memory is the hippocampus. It is known that acute in vitro exposure of hippocampal brain slices to MeHg may affect the amplitude of electrically induced field potentials [2]. We investigated ex vivo the excitability of the in vitro hippocampus of juvenile (33 days) or adult rats (68 days) born from mothers which

were exposed to MeHg during pregnancy and lactation (GD6-LD10; 1.5 mg MeHg /kg BW /day by gavage). Control mothers received the vehicle (corn oil). In hippocampal brain slices, the Schaffer collaterals were stimulated with bipolar, biphasic current pulses. Evoked field potentials were recorded in CA1 stratum radiatum and in stratum pyramidale. Short and long term plasticity were studied using paired pulse and repetitive stimuli, constructing input-output and interval curves. The results showed that 1) older rats had smaller amplitude field potentials in exposed as well as in control animals, 2) the release probability in MeHg exposed animals might be reduced in the first pulse at low intensity stimulation (10% of Imax) with small interpulse interval, and 3) unlike in the 28 day old MeHg offspring in which no changes were observed, in the 68 days MeHg group, increased population spike was observed at higher intensity (80% of Imax) and small interpulse intervals (<70 ms). These data suggest that there is more Ca2+ remaining in the presynaptic element of the 68 day MeHg group and point at life-lasting mechanistic changes in neural target tissues in the offspring after early maternal exposure as shown also by the toxicogenomics data [3].

PS 186 ASSESSMENT OF THE NEUROTOXICITY OF ACRYLAMIDE AND TRIMETHYLTIN CHLORIDE IN THE HARLAN HAN WISTAR RAT.

K. Weber[1, 2], N. Dhinsa[1, 2] and E. Wood[1, 2]. *[1]Harlan Laboratories, Indianapolis, IN and [2]RCC Ltd, Itingen, Switzerland.* Sponsor: S. Corney.

Acrylamide and Trimethyltin are known to induce peripheral and central nervous system damage. This study was designed to identify the neurotoxic properties of Acrylamide and Trimethyltin Chloride following repeated dose gavage administration for up to twenty-eight consecutive days in the Han Wistar rat. Open-field arena assessments, motor activity assessments and grip strength tests were performed weekly, together with bodyweights and dietary intake. Clinical observations and visual inspection of water bottles was also undertaken. At study termination, animals were subjected to in situ perfusion fixation. The brain was weighed and the brain, dorsal root ganglia, dorsal and ventral root fibres, eyes, optic nerve, sciatic nerve, tibial nerve, skeletal muscle and spinal cord for all perfused animals were processed and examined. Altered gait, lethargy, hunched posture, body tremors and respiratory pattern changes were detected following Acrylamide administration. Reduced transfer arousal and increases in urination and defecation were detected. Increased vocalisation was noted for females. Reduced forelimb grip strength and motor activity were detected, together with reduced bodyweight gains, dietary intake and food efficiencies. Changes in brain weights were detected and histopathological examination revealed effects in the spinal cord, ventral and root ganglia, and sciatic and tibial nerves. Altered gait, increased activity, pilo-erection, lethargy, body tremors, hunched posture and respiratory pattern changes were evident for animals treated with Trimethyltin Chloride. Lower transfer arousal and increased incidences of urination and defecation were also evident, together with increases in vocalisation. Increases in motor activity and reduced grip strength were noted. Histopathological examinations revealed changes in the spinal cord, dorsal root ganglia, dorsal and ventral roots and skeletal muscle. This study confirmed that the procedures employed are effective in identifying the neurotoxic effects of Acrylamide and Trimethyltin Chloride in the Harlan Han Wistar rat.

PS 187 DEVELOPMENTAL NEUROTOXICITY: PRACTICAL EXPERIENCE FROM THE CONDUCT OF A VALIDATION STUDY.

S. Corney[1, 2], C. Senn[1, 2], E. Sommer[1, 2], R. Gerspach[1, 2] and G. Krinke[1, 2]. *[1]Harlan Laboratories, Indianapolis, IN and [2]RCC Ltd, Itingen, Switzerland.*

A validation study was carried out to establish a "best practice" in our laboratory environment. Since a single positive control agent could not demonstrate the sensitivity and specificity of the battery of methods and functional tests, Methylazoxy methanol acetate (MAM) was selected, which de Groot et al. (2005) used in a model study for the morphologic approach of DNT testing. MAM was given to dams during days 13 to 15 of pregnancy at dose levels of 1.25, 5.0 and 7.5 mg/kg body weight/day. The pups were examined on day 11, 22 and 63 post partum. Brain weights were reduced at 7.5 mg/kg, independent from the fixation method. Prolonged fixation of the brains in formalin had an influence on brain weight. For instance, at 63 days, the fresh brain weight or the weight immediately after the perfusion fixation was 13 to 16% less than the weight after prolonged immersion. Therefore, the nature of brain fixation is critical for historical control data. For macroscopic morphometry the brains were photographed from the dorsal aspect with a millimeter scale, enabling the assessment of the length of forebrain and cerebellum. There was a dose-dependent reduction in the length of forebrain and a tendency for an increased length of cerebellum. At the microscopic level, the decrease in brain size was not observed, demonstrating the importance of accurate homology of brain sections and performance of linear morphometry for the detection of subtle differences. As some guidelines (US EPA) require examination of the peripheral nervous system in "plastic" sections, epoxy resin sections were produced, containing in continuity in a single section the dorsal and ventral nerve roots and the dorsal root ganglia. The peripheral sciatic nerve and its branches could be examined effectively in transverse epoxy resin sections, but for longitudinal sections paraffin embedding, presenting large nerve portions, was superior. Overall this study confirmed the feasibility of the methodology applied in our laboratory.

PS 188 BIOLOGICALLY-BASED MODELING TO ASSESS EARLY EMBRYONIC EXPOSURE TO XENOBIOTICS SUITED FOR NEUROBEHAVIORAL TERATOLOGY STUDIES.

M. R. Goldsmith, R. Tornero-Velez and C. C. Dary. *NERL/HEASD/EDRB, U.S. Environmental Protection Agency, Durham, NC.*

Quantitative means of assessing early embryonic exposure (EEE) to xenobiotics (XB) via maternal transfer early in the 1st trimester (GD15-50) remain relatively scant in the literature. This developmental stage is marked by unique physiology (i.e. cellular growth rates, nutrient mechanisms, vasculature, neuroendocrine modulation, metabolism and plasma/cell structures) not found in other life stages, suggesting a need to incorporate and translate these vital temporal details into a stage-specific biologically-based pharmacokinetic model (BBPK) for estimating embryonic dose-metrics early in organogenesis. We believe that neurobehavioral teratogens or NBT-exclusive "window of susceptibility" for XB coincide with EEE. To address both exposure and dosimetry at this life-stage we describe/develop an early gestational BBPK model that includes embryonic stage-relevant: (1) physiological growth functions for primordial organs, (2) diffusion-limited maternal transfer kinetics, (3) tissue-specific partition functions, and (4) α-fetoprotein binding QSAR. We use this model to probe exposure-dose scenarios of suspect etiological agents of adverse neurobehavioral phenotypes, such as pervasive developmental disorders (PDDs). Several NBTs, such as thalidomide, misoprostol, valproic acid, benzodiazepine and methyl mercury, have been implicated in PDD etiology. Coupled to maternal XB load derived from real or simulated exposure to these compounds, this model is used in identifying determinants of unique gestational dose-metrics (i.e., physicochemical/ADME properties and embryonic plasma binding) of NBTs. Similar models may be important tools in the exploration of other agents, environmental and therapeutic, in the XB-associated risk of PDD etiology in presumably genetically susceptible populations to identify research needs, both mechanistic and epidemiological, that will partially disentangle the complex underpinnings of neurobehavioral teratogenicity.

PS 189 EFFECTS OF PRENATAL HALOPERIDOL EXPOSURE ON THE DEVELOPING RAT.

R. L. Williams[1], R. R. Holson[2] and K. F. Soliman[3]. *[1]CDC/ATSDR, Atlanta, GA, [2]Psychology, New Mexico Tech, Albuquerque, NM and [3]College of Pharmacy and Pharmaceutical Sciences, Florida A&M University, Tallahassee, FL.*

Antipsychotics are drugs that were developed primarily to treat psychiatric illnesses including schizophrenia. Haloperidol is an antipsychotic which is frequently used during pregnancy either as an antiemetic, or antipsychotic. This experiment was designed to investigate the behavioral and neurochemical effects of prenatal haloperidol exposure on the developing rat offspring. Animals were kept in a control environment of 21 + 1 degrees C with lights on at 07:00 hr and off at 19:00 hr. Animals were injected with a sodium saline solution, or 5 mg/kg s.c. haloperidol from gestational day 6-20. After parturition, pups were culled to eight, consisting of 4 males and 4 females. At postnatal day (PD) 20 offspring were weaned and separated by sex. Offspring were tested for balance and motor activity using a negative geotaxis apparatus at PD 6, 7, 8, and 9. At PD 12, 15, 18, 21 and 24, groups of offspring were monitored with a developmental activity test. Other groups were tested for auditory startle at PD 21 and 61. On PD 15, groups of offspring were given a dose of sodium pentobarbital (25 mg/kg i.p.) and sleep time was measured. At PD 30, 60 and 120 offspring were tested for sleep time using a 25 mg/kg or 45 mg/kg dose of sodium pentobarbital. At PD 100, groups of offspring were tested for their learning ability in the complex maze for 5 consecutive daily 15 minute sessions. Water was available in the maze at arm 4 and 5 as a reward for learning the maze. At PD 30, groups of offspring were sacrificed and whole brains removed quickly, weighed and dissected into the caudate nucleus. The caudate nuclei were stored at -70 degrees C until neurochemical analysis. It was of interest to note that there were no statistically significant changes observed in the behavioral parameters, except that male offspring showed a decrease in auditory startle response. Also, the dopamine subtype D1 receptor density was not statistically significantly different from the D2 receptor sites in the caudate nucleus.

PS 190 MOLECULAR AND CELLULAR CHARACTERIZATION OF METHYMERCURY AND SELENIUM SYNAPTOTOXICITY IN THE DEVELOPING HIPPOCAMPUS OF RATS AND MICE.

J. Hradsky[2], U. Kreher[2], K. Braun[2] and R. Nass[1]. [1]*Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN and* [2]*Zoology/Developmental Neurobiology, Otto von Guericke University, Magdeburg, Germany.*

Methymercury (MeHg) exposure from occupational, environmental, and contaminated foods is a significant threat to public health. MeHg readily passes the brain barrier causing severe psychological and neurological problems. The developing nervous system is particularly vulnerable to the toxin, and although MeHg poisonings have been studied for decades, the molecular components and pathways involved in the cellular pathology are largely unknown. Several studies have demonstrated that selenium can be also neurotoxic, yet protect against the MeHg-induced pathology. The molecular mechanisms involved in the selenium induced neurotoxicity and protection are ill-defined. An aim of this study is to evaluate the neurotoxic effects of MeHg and selenium on developing neurons, and to identify cytoskeletal and synaptic proteins that may contribute to the neuropathology. Hippocampal primary cell cultures from rats and mice at 14 days were exposed to either MeHg or sodium selenide (NaSe) (0-50 uM), or in combination, for 24 hours and the number of dead cells determined using propidiumiodide as a marker for cell death. Immunocytochemical quantification of dendritic and synaptic proteins, including MAP2 and synaptophysin, was evaluated. A concentration-dependent increase in mortality was observed with single toxin exposures in either species, and results in dendritic fragmentation, loss of cellular integrity, and dramatic changes in a number of cytoskeletal and synaptic proteins. In contrast, co-exposure with the toxins resulted in maintenance of dendritic and synaptic integrity, that includes diffuse synaptic protein staining. Toxin-induced changes in the dendritic spines (size, volume, contact to presynaptic structures), as well as synaptic protein expression and localization are also described. This study is supported by XN3641A/0507

PS 191 LIFETIME STUDIES OF DEVELOPMENTALLY PB-EXPOSED MICE AND ALZHEIMER'S DISEASE BIOMARKERS IN THE BRAIN AND BLOOD: ALTERATIONS IN AMYLOID PRECURSOR PROTEIN, SPECIFICITY PROTEIN 1 (SP1) AND AMYLOID-BETA.

R. S. Dosunmu and N. H. Zawia. *Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.*

Alzheimer's disease (AD) is a progressive neurodegenerative disease that will affect 50 million Americans by 2020. Disease pathology is hallmarked by senile plaques composed of Amyloid-beta (Aβ) peptide aggregates and neurofibrillary tangles composed of hyperphosphorylated tau. Although AD is a disease of old age, it is not known when it begins or the underlying etiology. Thus, it is vital to pinpoint when in the lifespan the levels of Aβ peptide as well as its precursor Amyloid Precursor Protein (APP) depart from normal expression in the brain. Our lab has previously shown that the neurotoxicant, lead (Pb), causes a latent increase cortical brain APP expression by transcriptional up-regulation, thereby initiating an increase in Aβ. The objective of this study is to quantify APP and Sp1 (the regulator of APP expression) protein levels by Western blot analysis and Aβ by ELISA assay, in control and lead-exposed animals throughout the lifespan, in both the plasma and the brain. This will allow us to see if alterations in the brain are reflected in the blood and thus present these proteins as potential biomarkers to screen human populations.

PS 192 GENETIC VARIATION IN BEHAVIORAL AND BRAIN TRANSCRIPTIONAL EFFECTS OF MEHG EXPOSURE.

C. M. Foster[1], J. S. Spence[1], M. Beckmann[1], W. Curd[1], V. M. Phillip[1], S. Duvvuru[1], G. N. Barnes[2], M. Aschner[2] and E. J. Chesler[1]. [1]*Biosciences Division, Oak Ridge National Labs, Oak Ridge, TN and* [2]*Pediatrics, Vanderbilt University Medical Center, Nashville, TN.*

Methylmercury (MeHg) is a potent neurotoxin that affects the developing nervous system. It accumulates in the brain, most notably the cerebellum and hippocampus, causing irreversible damage. The neurotoxic effects and the mechanisms by which MeHg acts remain to be elucidated, especially in cases of long-term exposure. A study was conducted to evaluate genetic variation in MeHg effects on brain and behavior. Mice of both sexes from the BXD mouse progenitor lines (C57Bl/6 and DBA/2) and several BXD lines were exposed to MeHg perinatally. Pregnant mice were injected subcutaneously with 3mg MeHg/kg body weight or saline during gestation. Neonate offspring were injected during the first week of birth on postnatal days 3 and 5. Mice were assessed in open field, light-dark box and the Rota-rod apparatus at 4-5 weeks of age. Strain specific effects of MeHg on behavior were observed. Cerebella from separate mice, treated with the same MeHg exposure regimen, were dissected at 4-5 weeks of age and used for gene expression analysis using the Illumina Mouse Sentrix 6 array. Significant 2-way (treatment x strain) and 3-way (treatment x sex x strain) effects were detected. Analysis of significantly over-represented pathways and functional Gene Ontology categories reveals genetic variation in MeHg effects on neural development, Wnt signaling (Wnt, DVl and Axin), the MAP kinase pathway, and developmental GABAergic systems (GABA-C rho). The lipid metabolism category was also over represented, particularly due to steroid metabolizing genes. MeHg alters the expression of Glutathione-S-transferase, but these effects were not found to be strain specific in this subset of the BXD population. The implication for this project is that in addition to effects of MeHg on oxidative stress related genes; there are specific neurodevelopment effects that are the result of an interaction of a genetic predisposition and an environmental exposure.

PS 193 LOW-DOSE METHYLMERCURY (MEHG) EXPOSURE ACTIVATES CASPASE-3 IN POSTNATAL RAT HIPPOCAMPUS.

K. B. Sokolowski[1, 2], A. Falluel-Morel[2], X. Zhou[2] and E. DiCicco-Bloom[2, 1]. [1]*Joint Graduate Program in Toxicology, Rutgers, Highland Park, NJ and* [2]*Neuroscience and Cell Biology, Robert Wood Johnson Medical School, Piscataway, NJ.*

MeHg, an environmentally persistent toxicant, induces a spectrum of harmful effects on neurodevelopment. Our recent studies (Falluel-Morel et al. 2007) have shown that a single sc injection of 5μg/gbw MeHg in 7 day old (P7) rats acutely activates caspase-3, an apoptotic protease, leading to cell cycle arrest and cell death in hippocampus. Furthermore, reduced cell number and organ size were detected at P21 in addition to behavioral effects at P35. Caspase-3 activation, a marker for apoptosis, may involve either the extrinsic pathway that depends on caspase-8 or the intrinsic pathway (involving caspase-9), which we found to underlie hippocampal neurotoxicity (Sokolowski et al. 2008). Based on the pathway definition, we used low doses of MeHg in our model of hippocampus toxicity, to define the effects of environmentally relevant exposures. Of all the molecular markers we studied, including [3H]-thymidine incorporation, BrdU, total DNA content and absolute cell number, activated caspase-3 immunoassay was the most sensitive. Thus, capase-3, a significant endpoint protein, was detected using the most sensitive assay, immunohistochemistry, in the low-dose exposures. After 24hr treatment with MeHg (10, 0.6, 0.2, 0.1μg/g) or vehicle in the P7 rat, whole brains were prepared for frozen sectioning and caspase-3 staining. We found two-fold more activated caspase-3-positive cells in brains exposed to 0.2ug/g MeHg than in controls. The next higher dose, 0.6μg/g MeHg, elicited a five-fold increase in caspase-3-positive cells while the highest dose, 10μg/g MeHg, increased positive cells eight times greater than control. By using the most sensitive marker for apoptosis, caspase-3 staining, we now detect significant MeHg neurotoxicity at a 25-fold lower dose than previously defined. Future studies will characterize acute effects on hippocampal neurogenesis and later consequences on organ cell composition and cognitive functions. NIEHS: ES07148, ES05022, ES11256; USEPA R829391; FRM SPE2006

PS 194 GLIAL INFLAMMATORY RESPONSES AND AGE-DEPENDENT SUSCEPTIBILITY TO MANGANESE-INDUCED NEUROTOXICITY.

J. Moreno[1, 2], K. Streifel[2], K. Sullivan[2], M. Legare[1] and R. Tjalkens[1, 2]. [1]*ERHS, Colorado State University, Fort Collins, CO and* [2]*Cell and Molecular Biology Program, Colorado State University, Fort Collins, CO.*

Chronic exposure to manganese (Mn) produces a neurodegenerative condition of the basal ganglia characterized by gliosis and increased expression of inducible nitric oxide synthase (NOS2). Induction of NOS2 causes overproduction of nitric oxide (NO) and injury to surrounding neurons, resulting in neurochemical and motor deficits resembling those in parkinson's disease. Inflammatory activation of astrocytes is believed to be an early event in Mn neurotoxicity but glial responses to Mn in developing animals remains poorly understood. In this study we investigated the effect of juvenile exposure to Mn in mice on the activation of glia and production of NO, postulating that developmental Mn exposure would lead to selective sensitivity to gliosis and increased expression of NOS2 and NO production in adult mice exposed again later in life. Mice were exposed to saline, 10 or 30 mg/Kg Mn by daily gavage as juveniles, adults, and juveniles + adults. Immunohistochemical

analysis revealed increases in expression of IBA-1, a marker for microgliosis, proceeding elevated expression of GFAP, a marker for astrogliosis, in the striatum, globus pallidus, and substantia nigra pars reticulata of treated juvenile mice compared to controls. Co-immunofluorescence studies in Mn-treated adult mice pre-exposed as juveniles demonstrated increased expression of NOS2 in both astrocytes and microglia, as well as an increased neuronal staining in the striatal-pallidal pathway for 3-nitro-tyrosine (3-NTyr) protein adducts, a marker for NO/ONOO- formation. These data indicate that sub-acute exposure to Mn during development leads to inflammatory activation of microglia prior to astrogliosis, with subsequent expression of NOS2. Significantly, juvenile exposure to Mn resulted in greater levels of neuronal 3-NTyr protein adducts in mice re-exposed as adults than those that did not receive Mn as juveniles, suggesting that exposure to Mn early in life may predispose to neuronal injury upon subsequent challenge to the metal.

PS 195 MANGANESE IMPAIRS THE ABILITY OF ASTROCYTES TO PROMOTE NEURITE OUTGROWTH IN RAT HIPPOCAMPAL PRIMARY NEURONS.

L. G. Costa[1, 2], D. Pizzurro[1], K. Dao[1], M. Guizzetti[1] and G. Giordano[1].
[1]Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA and [2]Department of Human Anatomy, Pharmacology and Forensic Science, University of Parma Medical School, Parma, Italy.

Manganese (Mn) is an essential metal, necessary for the normal functioning of a variety of physiological processes. In humans, Mn neurotoxicity is characterized by a variety of psychiatric, cognitive and motor disturbances, the latter resembling parkinsonian symptoms. Among brain cells, astrocytes, which provide a major support for neurons, accumulate this metal at higher extent. Using a co-culturing system, we investigated the ability of Mn to alter the ability of astrocytes to promote neuronal outgrowth in primary hippocampal neurons. When astrocytes were pre-incubated with different concentrations of Mn (50, 100, 200, 500 μM) followed by treatment wash-out, before being co-cultured with neurons for 48 hours, their ability to promote neurite outgrowth was impaired in a concentration-dependent manner. Only the highest Mn concentration was toxic to astrocytes. At the concentration of 200 μM, Mn significantly decreased axon length (to 59.2±13.5% of control), neurite lenght (to 64.0±2.2% of control) and the number of neurites per cell (to 76.4±1.1% of control). These effects were prevented by pre-incubating astrocytes with the antioxidants melatonin (200 μM) and N-t-butyl-alpha-phenylnitrone (100 μM). Increasing astrocytic glutathione (GSH) levels with GSH ethylester (2.5 mM), or decreasing it with the GSH synthase inhibitor buthionine sulfoximine (25 μM) significantly decreased and increased, respectively, the ability of Mn to inhibit neurite outgrowth promoted by astrocytes . Mn also caused a decrease of fibronectin, an extracellular matrix protein, which plays a relevant role in neuronal differentiation promoted by astrocytes. These findings suggest that Mn impairs the ability of astrocytes to promote neuronal differentiation by a mechanism that may involve oxidative stress and impaired fibronectin expression. (Supp. in part by grant WB1XWH-05-1-0239 from the US DOD)

PS 196 PERINATAL LEAD EXPOSURE ALTERS POSTNATAL CHOLINERGIC AND AMINERGIC SYSTEM IN RAT BRAIN: REVERSAL EFFECT OF CALCIUM CO-ADMINISTRATION.

R. R. Gottipolu[1], D. B. Chinthirla[2] and C. S. Chellu[3]. *[1]Zoology, S.V.University, Tirupati, India, [2]Zoology, S.P.W. UG and PG College, Tirupati, India and [3]Natural Sciences and Mathematics, Savannah State University, Savannah, GA.*

Lead (Pb) is known to exert its neurotoxic effects by competing with calcium for calcium receptors coupled with second messenger functions. Our earlier physiological and pharmacological studies indicated the role of transmitter systems in Pb induced behavioral perturbations. In the present study, we have examined the alterations in synaptosomal acetylcholine (ACh), epinephrine, dopamine, acetylcholinesterase (AChE), and mitochondrial monoamine oxidase (MAO) by spectrophotometric assays in the cerebellum and hippocampus of perinatally Pb-exposed rats. Rats (Wistar) were gestationally exposed to 0.2% Pb (Pb acetate in drinking water of mother) from day 6 and the pups were exposed lactationally till weaning (postnatal day 21). The data obtained on different postnatal days (PNDs) 21, 28, 35 and 60 indicated that Pb significantly decreased synaptosomal AChE and mitochondrial MAO activities, and increased ACh, dopamine and epinephrine levels in both cerebellum and hippocampus. These alterations were greater at PND35. The changes in the cholinergic system (ACh and AChE) were more pronounced in hippocampus (ACh,37%; AChE,44%). The cerebellum exhibited similar changes in the aminergic system (MAO,41%; epinephrine,31%; dopamine,34%). The Pb-induced changes in cholinergic and aminergic systems correspond to the cognitive and behavioral involvement of these transmitters and brain regions. Calcium co-administration to Pb-exposed rats significantly reversed the Pb-induced alterations in these transmitters and enzymes. The reversal effect was greater at PND35. These data suggest protective effect of calcium in Pb-exposed animals. This study was supported by UGC grants No.F-33-364/2007, and UGC MRP-2503/2008.

PS 197 THE TRAJECTORY OF BRAIN MONOAMINES ACROSS TIME FOLLOWING MATERNAL LEAD (PB) EXPOSURE AND /OR PRENATAL STRESS IS ALTERED BY BEHAVIORAL HISTORY.

D. A. Cory-Slechta[1], M. B. Virgolini[2], A. Rossi-George[2] and M. Thiruchelvam[2].
[1]Environmental Medicine, University of Rochester Medical School, Rochester, NY and [2], EOHSI, Piscataway, NJ.

We previously found marked differences in the corticosterone response to stress challenges as a function of behavioral history (BH) in male and female offspring of rat dams treated with lead (Pb) +/- prenatal stress (PS). For example, delayed habituation and even sensitization of corticosterone levels were observed in females with no BH, as compared to habituation of stress-induced corticosterone increases in BH counterparts. This study examined whether BH also modified the neurochemical consequences of maternal Pb +/- PS. Offspring of dams exposed to 0, 50 or 150 ppm Pb drinking water from 2 mos prior to breeding through lactation +/- PS (prenatal restraint stress) either underwent behavioral testing on a fixed interval (FI) schedule of food reward, or were minimally handled and underwent no behavioral testing (NFI). Monoamines in midbrain, striatum and frontal cortex were compared in FI and NFI groups at the end of behavioral testing (6 mos of age), as well as to values derived from their mutual 2 mos old littermates. Comparisons of 6 mos FI vs. NFI values confirmed that BH differentially changed monoamines in all brain regions examined in both males and females. Changes in monoamine trajectories between 2 and 6 mos occurred even in FI and NFI control groups, confirming their normal dynamic nature. Pb +/- PS, however, interacted with BH, further modifying neurochemical changes across time, targeting striatal DA, frontal cortex and nucleus accumbens NE, and 5-HT in all regions in females, and striatal and nucleus accumbens DA in males. These findings underscore the significance of BH in defining the ultimate outcomes of Pb +/- PS and caution against generalizing neurochemical findings from non-behavioral to behavioral conditions. Understanding the impact of BH on monoamine systems may permit a better understanding of Pb +/- stress mechanisms, and guide the development of more precise behavioral therapeutic strategies to reverse such effects. ES012712

PS 198 ADVANTAGES OF MONKEY NEUROBEHAVIORAL ASSESSMENT USING THE FUNCTIONAL OBSERVATIONAL BATTERY (FOB) – COMPARATIVE STUDY WITH DOGS AND RATS.

Y. Deguchi, T. Yoshikawa, K. Yunomae, Y. Numata, R. Anraku, A. Tamai, T. Sukamoto, K. Fukuzaki and R. Nagata. *Drug Safety Research Laboratories, Shin Nippon Biomedical Laboratories (SNBL), Ltd, Kagoshima, Japan.*

[Background and Purpose] The FOB is widely used to identify potential neurotoxicity of various chemicals, mainly in rats; however, there have been few FOB studies in dogs and non-human primates. The purpose of this study was to compare neurobehavioral changes between rats, dogs and monkeys. [Methods] Six male cynomolgus monkeys, four male beagle dogs and six male SD rats were used. The FOB methods consisted of home-cage observation, handling-observation, open-field observation (except for monkeys) and manipulative measurements of activity/excitability, neuromuscular, sensorimotor and autonomic nervous functions. Neurobehavioral functions were determined by the FOB methods after dosing with chlorpromazine, haloperidol, diazepam or caffeine. [Results] Chlorpromazine induced signs of central nervous system (CNS) depression, including sedation, decreased sensory reactivity and hypothermia in all species, and a cataleptic state in monkeys and rats. Haloperidol induced similar signs of CNS depression, but did not induce sedation in rats or hypothermia in dogs or rats. Diazepam appeared to have an anxiolytic effect at a low dosage in monkeys and dogs, but did not induce excessive sedation. However, in rats, diazepam induced only sedation. Caffeine induced hyperactivity in monkeys and dogs, but produced a biphasic response of hyperactivity (low-dosage) and hypoactivity (high-dosage) in rats. The lowest doses effective in producing observable neurobehavioral changes were seen in monkeys, followed by dogs, and then rats, and the observed effects in monkeys most closely resembled the known clinical effects of these drugs in humans at clinical dosages.

[Conclusion] These results suggest that among these species, monkeys show the highest degree of sensitivity in neurotoxicity evaluations and are a more suitable species than dogs and rats for preclinical studies to predict adverse effects of new CNS compounds.

PS 199 MONITORING NEURITE MORPHOLOGY AND SYNAPSE FORMATION IN PRIMARY NEURONS FOR NEUROTOXICITY ASSESSMENTS AND DRUG SCREENING.

S. J. Hong and R. N. Ghosh. *Thermo Fisher Scientific, Rockford, IL.* Sponsor: A. Barchowsky.

Synapse formation during nervous system development and degeneration in the pathogenesis of human neurological diseases is a highly regulated process. Subtle changes in the environment of the complex neuronal network may cause either breakdown or creation of synaptic connections. Drug discovery screening for neurological diseases and compound neurotoxicity evaluation would benefit from robust, automated, quantitative in vitro assays that monitor neuronal function. We hypothesized that (1) toxic insults to the nervous system will cause neuronal synapses to deteriorate in the early phase of neurotoxicity, eventually leading to neurite degeneration and neuronal cell death if the damage is severe; and (2) an in vitro functional assay for synapse formation and neuronal morphology could be used to monitor and identify such neurotoxic events. We thus developed an automated, functional, high-content imaging assay to track and quantify the dynamic changes in neurite morphology and synapses. This assay identifies primary neuronal cells by a neuron-specific marker and detects synapses on the spines of neurites with pre- and post-synaptic markers. The multiplexed targets are simultaneously detected with four fluorescent colors, and the fluorescent images of the labeled neurons and synapses are acquired by an automated imaging instrument. The phenotypic features of neuronal morphology and the synapse are automatically identified and quantified by specialized image-analysis software. Such features are potential indicators for neuronal development, differentiation and neurotoxicity, and we could quantify changes in these features under different experimental conditions. By monitoring changes in these features, we could also quantitatively evaluate compounds involved in developmental neurotoxicity. In summary, this assay facilitates automation and streamlining of a laborious process in drug discovery screening and compound neurotoxicity assessments; it enables quantitative comparisons between compounds in neuronal morphology and function, particularly in neurite and synapse associated events.

PS 200 DIESEL EXHAUST EXPOSURE ALTERS MICROVASCULAR BLOOD FLOW AND WALL SHEAR RATE.

K. Sites, A. Goodwill, J. Frisbee and T. Nurkiewicz. *Center for Interdisciplinary Research in Cardiovascular Sciences, West Virginia University, Morgantown, WV.*

Pulmonary exposure to particulate matter (PM) is a known cause of systemic cardiovascular dysfunction; however, the mechanism(s) of damage are not fully understood. While this laboratory has characterized microvascular dysfunction after exposure to PM, the specific hemodynamic adjustments that follow PM exposure are unknown. The purpose of this study was to determine the effects of pulmonary exposure to diesel exhaust particles (DEP) on peripheral microvascular function and hemodynamics. Rats were intratracheally instilled with SRM 1650b (NIST, 100 μg/rat). The spinotrapezius muscle was prepared for intravital microscopy 24 hr after exposure. Arteriolar reactivity was assessed by iontophoretic application of endothelial-dependent (acetylcholine, ACh, 0.025 M) and endothelial-independent (sodium nitroprusside, SNP, 0.05 M) vasodilators. To assess the contribution of nitric oxide (NO) in this process, ACh applications were repeated in the presence of the NO synthase inhibitor, N^G-monomethyl-L-arginine (L-NMMA, 10^{-4} M). In all experiments, red cell velocity was measured to characterize the local hemodynamic consequences of DEP exposure. Plasma was sampled from each rat for multiplex analyses. Compared to controls, DEP exposure increased arteriolar flow (26 ± 5 vs 18 ± 3 nl/s) and decreased wall shear rate (3939 ± 415 vs 4840 ± 295 s^{-1}). Compared to controls, arteriolar responsiveness to ACh was enhanced by DEP exposure (80 ± 4 vs 93 ± 3 μm respectively). Furthermore, this response remained largely intact during L-NMMA superfusion in the DEP group (90 ± 10% vs 56 ± 13% in controls). DEP exposure did not affect arteriolar responsiveness to SNP. Several inflammatory mediators were altered in the plasma of DEP exposed rats. These results suggest that arteriolar volume flow and wall shear rate are adversely affected by DEP exposure. Such alterations in microvascular hemodynamics may be indicative of upstream PM-dependent effects and appear to be linked to circulating inflammatory mediators. Support: NIH RO1-ES015022 and HEI#4730 (TRN)

PS 201 TOXICOGENOMIC ANALYSIS OF CARDIOVASCULAR EFFECTS OF DIESEL EXHAUST IN APOE-/- MICE.

C. G. Woods[1, 2], M. J. Campen[3], E. K. Rushton[1], L. A. Gephart[1], J. Pi[2] and G. D. Minsavage[4]. [1]*ExxonMobil Biomedical Sciences, Annandale, NJ,* [2]*The Hamner Institutes for Health Sciences, RTP, NC,* [3]*Lovelace Respiratory Research Institute, Albuquerque, NM and* [4]*CONCAWE, Brussels, Belgium.*

Particulate air pollution has been associated with increased cardiovascular mortality. The mechanisms underlying potential cardiovascular events are not well known, though oxidative stress may play a key role. In this study, the combustion emissions of two diesel fuel grades were evaluated, one containing 368 ppm sulfur (S500) and another containing 7 ppm (S15). ApoE -/- mice were exposed to filtered air, filtered diesel exhaust (S15) or unfiltered diesel exhaust (S15 or S500) with an average $PM_{2.5}$ concentration of 300 μg/m^3 for 6 hr/day for 1, 7 or 30 days. Microarray analysis in aorta showed that unfiltered S500 exhaust modulated more biological pathways than unfiltered S15 exhaust. At 1 day of exposure to S500 exhaust, genes involved in hypoxia signaling in the cardiovascular system were down-regulated, including endothelial cell nitric oxide synthase. By 7 days, S500 exhaust caused a decrease in apoptosis and inflammatory signaling mediated by NFκB and IL-8, along with PPAR signaling. Thirty day exposure reduced cardiac β-adrenergic signaling and expression of genes involved in free radical scavenging, though protein levels of antioxidant enzymes, Nqo1, Hmox1 were unaffected. Control and exposed animals exhibited only a moderate level of oil red o staining (indicative of lipid plaques) in aorta. Oxidative stress markers (TBARS, SOD activity) in lung and liver showed no significant changes. Interestingly, a decrease in total serum cholesterol resulted from 1 day exposure to S15 exhaust or 30 days of S500 exhaust. Our findings suggest that unfiltered diesel exhaust can affect gene networks related to endothelial dysfunction, oxidative stress, inflammation signaling and fatty acid metabolism. While these networks have been associated with the progression of atherosclerosis, the relevance of these gene expression changes are unclear, given the absence of marked pathological differences between control and exposed mice.

PS 202 DIESEL EXHAUST EXPOSURE AUGMENTS CONSTRICTOR SENSITIVITY TO ET-1 THAT IS ET_B RECEPTOR MEDIATED.

T. Cherng[1], M. J. Campen[2], B. R. Walker[1] and N. L. Kanagy[1]. [1]*Cell Biology and Physiology, University of New Mexico, Albuquerque, NM and* [2]*Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM.*

Epidemiological evidence shows that acute increases in air pollutants positively correlate with an increased incidence of acute and chronic cardiovascular disease. Previously we reported that acute exposure to diesel engine emissions (DE) enhances endothelin-1 (ET-1) induced vasoconstriction via a nitric oxide synthase (NOS)-dependent pathway. We hypothesized this augmentation might be caused by alterations in ET_B receptor (ET_BR) signaling. Intraseptal coronary arteries (inner diameter = 180 ± 11 μm) were obtained from rats exposed by inhalation for 5 hrs to DE (300 μg PM/m3) or air. Constrictor responses to ET-1 were recorded in pressurized coronary arteries using a videomicroscopy system. In endothelium-intact arteries, an ET_BR antagonist inhibited ET-1 constriction only in DE arteries, such that constriction in the presence of BQ-788 was not different between groups; similarly, we observed that constriction is not different between groups when the endothelium is inactivated. After specific blockade of the ET_AR, ET_BR-mediated constriction in DE arteries was almost abolished with endothelial removal (max: 17±5 vs. 6±4% denuded) but was increased in arteries from air rats (max: 2±2 vs. 18±5% denuded). This suggests that in DE arteries, the endothelial ET_BR mediates constriction, but in air arteries these receptors oppose constriction. In denuded arteries, the smooth muscle ET_BR mediates a modest constriction in air arteries that was diminished by DE exposure. Therefore, acute exposure to DE activates an ET_BR-mediated response that is quiescent in sham coronary arteries to augment ET-1 constriction. This ET_BR-mediated constriction is endothelium and NOS dependent, possibly caused by NOS-derived superoxide. Augmented coronary vasoreactivity to ET-1 following DE coupled with DE-induced production of the peptide may contribute to the increased incidence of coronary events during acute increases in air pollution levels.

PS 203 DIESEL EXHAUST PARTICULATE EXPOSURE AFFECTS ENDOTHELIN-1, ENOS, INOS EXPRESSION IN MOUSE LYMPH NODE ENDOTHELIAL CELLS.

C. Weldy, D. P. Cox, H. W. Wilkerson and T. J. Kavanagh. *Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.*

Increased exposure to traffic related air pollution has been associated with a greater incidence of cardiovascular related morbidity and mortality in humans. Diesel exhaust (DE) and diesel exhaust particulate (DEP) exposure has been demonstrated

to influence blood pressure (BP) and vascular reactivity. The mechanisms by which DEP affect vascular reactivity and BP are mostly unknown. In addition, it is not known if inhaled DEP target and remain in the lung or if these particles can pass through the lung epithelia into the systemic circulation. If DEP enter into the systemic circulation during in vivo exposure, endothelial cells lining the vasculature will come into direct contact with DEP. We investigated the effects of DEP on an immortalized mouse lymph node endothelial cell line (SVEC4-10). PM2.5 from a Cummins diesel engine operating under load were collected on a Teflon filter. SVEC4-10 cells were exposed to DEP in vitro. Cell viability, glutathione (GSH) depletion and mRNA expression levels for 6 genes (Edn1, ECE1, Ednra, Ednrb, eNOS, iNOS) were measured by qPCR with DEP concentrations up to 200ug/ml culture media. DEP induced no more than a 20% loss of cell viability (24hr exposure, 200 ug/ml). However, exposure to DEP for 3 hrs decreased Edn1 mRNA expression > 2 fold. Edn1 is the precursor gene of endothelin-1 (ET-1), a potent vasoconstrictor. Additionally there was a > 2-fold increase in eNOS mRNA and a substantial induction of iNOS. These responses were found in DEP exposures at concentrations as low as 10 ug/ml. Although these effects are not characteristic of endothelial responses expected in vivo (vasoconstriction), these results do suggest that DEP can influence the expression of vasoactive mediators. This work was supported by NIEHS grants 1P50ES015915, P30ES07033 and T32ES07032.

PS 204 EXPOSURE TO COMBINED VEHICULAR EMISSIONS ALTERS VASCULAR REACTIVITY IN APOE-/- MICE.

A. K. Madrid[1], J. G. Buntz[2], L. Chen[1], J. D. McDonald[2], J. L. Mauderly[2] and M. J. Campen[2]. *[1]Environmental Medicine, New York University, Tuxedo, NY and [2]Division of Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM.*

Traffic-related air pollution is consistently associated with cardiovascular morbidity and mortality. Recent human and animal studies suggest that exposure to vehicular exhaust (VE) in air pollution affects vascular function, specifically enhancing arterial vasoconstriction. The goal of this study was to examine the effects of short-term exposure to VE on vascular reactivity and on mediators of vascular tone. Two groups of ApoE-/- mice were exposed to 300ug PM/m3 of VE (a combination of diesel and gasoline engine emissions) by whole body inhalation for 6 h, then sacrificed either immediately or 18-h post-exposure. Control ApoE-/- mice were exposed similarly to filtered air (FA). The aorta was extracted from each animal and 3mm segments were mounted on a tension myograph system to measure contractile response. Data revealed no significant differences in the contractile response to phenylephrine (PE) in either exposure group. However, when comparing acute FA, VE exposed mice elicited an increase contractile response to the thromboxane mimetic, U46619, and a decrease in relaxation after administration of acytelcholine (ACh). These findings suggest that short-term exposure to VE is associated with acute endothelial response and vasoconstriction and is consistent with similar findings from coronary and mesenteric vessels. Identification of the target pathways controlling vascular tone that are susceptible to emissions requires further study.

PS 205 COMPARING THE TOXICITY OF FRESH AND AGED BIODIESEL AND DIESEL EXHAUST USING SEPARATE PARTICLE AND GASEOUS EXPOSURE SYSTEMS.

K. de Bruijne[1], K. G. Sexton[1], S. Ebersviller[1], Y. Lin[1], I. Jaspers[1, 2] and H. E. Jeffries[1]. *[1]Envr Sciences & Eng, University of North Carolina, Chapel Hill, NC and [2]CEMALB, Chapel Hill, NC.*

Biodiesel (BD) is rapidly becoming a popular alternative fuel for petroleum based diesel (PD). However, little is currently known about its toxicological effects. Our previous PD exhaust (PDE) studies have shown that atmospheric aging of the mixture modifies its chemical composition, ultimately affecting its toxicological potential. The goal of this current project is to determine the relative toxicities of fresh and photochemically aged exhaust of 100% BD in an urban-like atmosphere. The second goal is to repeat the experiments using PDE instead of BD for a direct comparison. Each exhaust sample was injected into a 120 m3 outdoor smog chamber and aged utilizing natural sunlight and humidity. All emissions were injected directly from a 1991 F350 Ford pickup truck into the chamber for equal time of exhaust emissions. Two separate exposure systems, Electrostatic Aerosol in Vitro Exposure System (EAVES) and Gas In Vitro Exposure System (GIVES) were used simultaneously to expose human respiratory epithelial cells across an air-liquid interface to particulate and gas-phase components, respectively. We have compared the toxicity of unreacted "fresh" emissions and photochemically-aged emissions. Following exposures, cells were analyzed for lactate dehydrogenase (LDH) and inflammatory cytokine production (IL-8) using RT-PCR. Fresh and aged emissions from both fuels increased IL-8 and LDH levels as compared to the clean air control. However, each BD exposure indicated a lesser toxic response than its corresponding PDE exposure. In addition, our results suggest that aging significantly enhances the toxicological responses of fresh BD and PDE emissions in the particle phase, and decreases in the gas phase (when particles are present). This suggests that the gaseous components are partitioning onto the particles during the aging process. Taken together, these results further support the importance of fuel type and atmospheric aging when examining the toxicity of vehicle emissions.

PS 206 EFFECTS OF CONCENTRATED AMBIENT PARTICLES ON HEART RATE VARIABILITY IN SPONTANEOUSLY HYPERTENSIVE RATS IN DETROIT, MICHIGAN.

A. S. Kamal[1], J. G. Wagner[2], B. Mukherjee[1], M. Morishita[1], J. R. Harkema[2], G. J. Keeler[1] and A. C. Rohr[3]. *[1]University of Michigan, Ann Arbor, MI, [2]Michigan State University, East Lansing, MI and [3]Electric Power Research Institute, Palo Alto, CA.*

Recent studies report a reduction in heart rate variability (HRV) in rodents in relation to concentrated ambient particles (CAPs); however, the mechanism by which these particles alter HRV is not well understood. The goal of this study was to determine if specific particle constituents were related to changes in HRV. AirCARE 1, a mobile laboratory with an EPA/Harvard fine particle (PM2.5) concentrator was situated near the Ambassador Bridge in Detroit, MI, a non-attainment area for PM2.5. Spontaneously hypertensive rats instrumented for ECG telemetry were exposed to CAPs 8 h/day for 13 consecutive days in August 2005 and February 2006, and heart rate (HR), and indices of HRV (SDNN and rMSSD), were calculated for 30-min intervals during exposures. A Semi-continuous Elemental Automated Sampler collected trace metal samples every 30 minutes. In addition, CO, NOx, SO2, O3 and elemental carbon were monitored continuously. Mean exposure concentrations were 518 μg/m3 and 350 in August and February, respectively. Using mixed modeling analysis, SDNN in CAPs-exposed rats was determined to be significantly different from filtered-air control rats in both seasons. Episodic decreases in SDNN in CAPs-exposed rats were observed, with the most notable depression associated with a spike in chromium, barium and samarium 90 minutes prior to a significant reduction in SDNN. 30-min interval concentrations of anthropogenic trace metals, elemental carbon and gases did show a significant reduction in SDNN with the CAPs-exposed rats. Several significant increases in SDNN were also observed but were not well associated with a specific CAPs species or with a pollution episode. These results demonstrate that CAPs-induced changes in cardiac function may be related to specific components of PM2.5 from various emission sources in Detroit.

PS 207 DIESEL EXHAUST PARTICLES INCREASE PERMEABILITY, INDUCE REACTIVE OXYGEN SPECIES AND ARE CYTOTOXIC TO *IN VITRO* CAPILLARY ENDOTHELIAL TUBES.

M. Chao[1], J. Koslosky[2], I. P. Po[1], D. R. Gerecke[1], K. K. Svoboda[3], R. Laumbach[4] and M. K. Gordon[1]. *[1]Pharmacology and Toxicology, Rutgers University, Piscataway, NJ, [2]Molecular and Cell Biology, Bristol-Myers-Squibb, New Brunswick, NJ, [3]Biomedical Sciences, Baylor College of Dentistry, Dallas, TX and [4]Environmental and Occupational Medicine, UMDNJ, Robert Wood Johnson Medical School, Piscataway, NJ.*

Epidemiological studies demonstrate that acute exposures to diesel exhaust particles (DEP) correlates with an increase in reported myocardial infarctions (MI) within 48 hr. Other studies find that inhaled DEP gain access to the bloodstream. How DEP penetrate into the capillary lumen to induce an MI is unknown. We have been examining how DEP might enter capillaries, and what the downstream consequences are, by using human umbilical vein endothelial cells (HUVECs) assembled into in vitro capillary tubes. We have shown that increasing concentrations of DEP (1-100 μg/ml), sonicated to sizes ≤ 2.5 μm (PM2.5), increase tube cell death, as determined by LDH and TUNEL assays. DEP can be found in the lumen of tubes, and endothelial cell-cell adherens junctional components become redistributed in response to DEP. This would result in making the tubes leaky. Even low DEP doses (5-10 μg/ml) show local vascular endothelial (VE) cadherin relocalization away from the plasma membrane after a 24 hr exposure, as assessed by confocal microscopy. Westerns of culture medium demonstrated increased secretion of VEGF-A with increasing doses of DEP, which would also favor vascular permeability. In response to DEP endothelial capillary tubes produce reactive oxygen species (ROS), as determined by a Promega ROS detection kit. Western blotting indicates that heme oxygenase (HO-1) and thioredoxin reductase are upregulated in a dose dependent manner. In summary, our in vitro capillary endothelial tube data suggest

that DEP make capillaries leaky by disrupting endothelial adherens junctions and inducing secretion of VEGF-A. The production of potentially damaging ROS is also induced by DEP. Supported by NIEHS P30ES005022.

PS 208 ACTIVATION OF GSK-3β PLAYS A CRITICAL ROLE IN DIABETES-RELATED CHANGES IN CARDIAC ENERGY METABOLISM, LIPID ACCUMULATION, INFLAMMATION, AND REMODELING: METALLOTHIONEIN PREVENTION *VIA* AKT2 PRESERVATION.

Y. Wang. *Medicine, University of Louisville, Louisville, KY.*

Glycogen synthase kinase-3β (GSK-3β) was found to play a pivotal role in a few cardiac disorders. We have shown that cardiac-specific metallothionein (MT)-overexpressing transgenic (MT-TG) mice were highly resistant to diabetic cardiomyopathy. Therefore, we investigated whether MT's cardiac protection against diabetes is mediated by inactivation of GSK-3β. Diabetes was induced by streptozotocin with single dose injection in both MT-TG and wild-type (WT) mice. Cardiac changes including energy utilization, lipid accumulation, inflammatory response and fibrotic remodeling have been examined at 2 weeks, 2 and 5 months after diabetes with Western blotting, RT-PCR, and immunohistochemical assays. Results showed that GSK-3β was significantly activated in the hearts of WT diabetic mice, but not MT-TG diabetic mice. Correspondingly, cardiac glycogen synthase (GS) phosphorylation, hexokinase (HK) II and PPARα expression, which mediate glucose and lipid metabolism, were also significantly changed along with cardiac lipid accumulation, inflammation (TNF-α, PAI-1 and ICAM-1), and fibrosis only in the WT diabetic mice. To further confirm the pivotal role of GSK-3β in the above pathogenic changes, pharmacological inhibition of GSK-3β activity in the WT diabetic mice was found to completely prevent these effects. To define how MT inactivates GSK-3β, Akt2 levels were found to be significantly reduced in the hearts of WT diabetic mice, but not MT-TG diabetic mice. Knockdown of Akt2 expression by siRNA resulted in a significant activation of GSK-3β, along with inactivation of GS, decrease of HK II and increase of PPARα expression. These results suggest that activation of GSK-3β plays a critical role in changing cardiac energy utilization, increasing cardiac lipid accumulation, inflammation, and remodeling. Inactivation of GSK-3β by MT is mediated by preventing diabetes-attenuated Akt2 expression and plays a critical role in its cardiac protection against diabetes (Supported, in part, by research grants from ADA, JDRF.).

PS 209 ARYL HYDROCARBON RECEPTOR HETEROZYGOUS MICE EXHIBIT ENHANCED SENSITIVITY TO VASOCONSTRICTORS.

M. K. Walker[1], N. Zhang[1], L. Agbor[1] and W. Wang[2]. *[1]Pharmacy, University of New Mexico, Albuquerque, NM and [2]Chemistry, University of New Mexico, Albuquerque, NM.*

Aryl hydrocarbon receptor (AHR) null mice are hypertensive at modest altitude and hypotensive at sea level. We tested the hypothesis that blood pressure would be normal in AHR heterozygous mice at modest altitude, but these mice would exhibit altered vascular responses to vasoconstrictors. We measured mean arterial blood pressure (MAP) in C57Bl/6 AHR wildtype (WT) and heterozygous (Het) mice by in dwelling catheters using radiotelemetry and then treated the mice with inhibitors of angiotensin II formation (captopril), endothelin-1 signaling (PD155080), or both. In addition, we assessed vasoconstrictor responses to phenylephrine (PE) ± endothelial nitric oxide synthase (eNOS) inhibitor, LNNA, in isolated aortic rings. AHR Het mice were normotensive, compared to WT mice (MAP: 105±1.3 mm Hg, WT; 106±2.1 mm Hg, Het; n=8/genotype). While captopril significantly reduced MAP in both genotypes, the decrease in AHR Het mice was significantly greater (Δ BP: -10.6±1.3 mm Hg, WT; -15.4±1.1 mm Hg, Het; n=8/genoptype; $p<0.05$). In contrast, PD155080 did not decrease MAP in WT mice, but did decrease it in AHR Het mice (Δ BP: -1.8±0.9 mm Hg, WT; -5.7±1.2 mm Hg, Het; n=8/genoptype; $p<0.05$). The two drugs together were additive in reducing MAP in both genotypes. In addition, aorta from AHR Het mice constricted to a significantly greater degree to PE than from WT mice (% KCL constriction: 29±6, WT; 40±5, Het). Since PE constriction is offset by eNOS production of the vasodilator, nitric oxide (NO), blocking eNOS activity reveals the degree of NO production. PE-induced constriction was not significantly different between AHR WT and Het mice following preincubation with LNNA(% KCl constriction: 114±8, WT; 129±14, Het). Taken together these data suggest that AHR Het mice exhibit an enhanced response to vasoconstrictors, including angiotensin II, endothelin-1, and PE, and this enhancement may be mediated, in part, by a reduction in NO production. Supported by HL078914.

PS 210 DOXORUBICIN INDUCED PLATELET CYTOTOXICITY AND APOPTOSIS, POTENTIAL CONTRIBUTING FACTOR TO DOXORUBICIN ASSOCIATED THROMBOCYTOPENIA.

E. Kim, K. Lim, J. Noh, K. Kim and J. Chung. *College of Pharmacy, Seoul National University, Seoul, Korea, South.*

Doxorubicin (DOX) is a widely used anti-cancer drug for solid tumors and hematological malignancy, yet its active use is impeded by serious adverse effects including thrombocytopenia. While bone marrow toxicity of DOX has been suggested to be the sole mechanism underlying the reduced platelet counts, direct effects of DOX on platelets have never been examined. Here we investigated the toxicity of DOX on platelets and its underlying mechanism in an effort to elucidate the contribution of platelet cytotoxicity in DOX-induced thrombocytopenia. In freshly isolated human platelets, DOX induced platelet cytotoxicity in a time and concentration dependent manner. DOX-mediated ROS generation, reduced glutathione and subsequent protein thiol depletion were shown to mediate the DOX-induced platelet cytotoxicity. Conspicuously, DOX-treated platelets displayed apoptotic features like caspase-3 activation, reduced mitochondrial transmembrane potential and phosphatidylserine exposure as shown by flow cytometric analysis. More importantly, DOX-mediated platelet cytotoxicity was significantly enhanced by shear stress, important complicating factor in cancer patients and these results could be further confirmed in vivo animal model where intravenous infusion of DOX damaged platelet integrities significantly. In summary, we demonstrated that DOX can directly induce platelet cytotoxicity through ROS generation, GSH decrease and protein thiol depletion. Protein thiol depletion was the key step linking DOX-mediated ROS generation with platelet cytotoxicity and apoptosis. With this study, we believe that important evidence was given into the role of DOX-induced platelet cytotoxicity in the development of thrombocytopenia in DOX treated patients.

PS 211 ARSENIC REQUIRES SPHINGOSINE-1-PHOSPHATE TYPE 1 RECEPTORS TO STIMULATE VASCULAR REMODELING.

L. R. Klei[1], A. C. Straub[1], D. B. Stolz[2] and A. Barchowsky[1]. *[1]Environmental and Occupational Health, Universtity of Pittsburgh, Pittsburgh, PA and [2]Cell Biology and Physiology, University of Pittsburgh, Pittsburgh, PA.*

Environmental arsenic exposure from drinking water is a major public health concern associated with increased risk and incidence of cardiovascular diseases and cancers. Even with low environmental exposures, arsenic affects a number of vascular beds causing liver diseases (sinusoidal capillarization and portal hypertension), ischemic heart disease, peripheral vascular disease (arteriosclerosis obliterans), and tumor angiogenesis. We previously established that activating Rac1-GTPase and NADPH oxidases is essential for arsenic-stimulated pathogenic vascular cell signaling. However, the mechanism for initiating this arsenic signaling is unknown. Here we show that arsenic stimulated the sphingosine-1-phosphate type 1 receptor ($S1P_1$) to initiate Rac1-mediated signaling for angiogenic gene expression and tube formation in human microvascular endothelial cells (HMVEC). In addition, we demonstrated that S1P1 is highly expressed on liver sinusoidal endothelial cells (LSEC) and is required for arsenic-stimulated LSEC defenestration. Arsenic-stimulated signaling in HMVEC and LSEC was inhibited by Pertussis toxin or a selective inhibitor of Rac1. Arsenic- and S1P-stimulated LSEC defenestration and HMVEC tube formation were blocked by VPC 23019, a $S1P_1$ antagonist. $S1P_1$ knockdown with siRNA inhibited arsenic-stimulated HMVEC angiogenic gene induction and tube formation. In contrast, $S1P_1$ knockdown did not affect arsenic induction of HMOX1 or IL8. Since excess or inappropriate signaling through $S1P_1$ contributes to oxidant-mediated vascular disease and increased tumor angiogenesis, these findings may provide mechanistic insight into an initial step in the vascular pathogenesis of arsenic. *Supported by NIEHS R01ES013781.*

PS 212 MITOCHONDRIAL REACTIVE OXYGEN SPECIES CAUSE ZIDOVUDINE-INDUCED CARDIAC MITOCHONDRIAL TOXICITY *IN VIVO*.

W. Lewis, J. Kohler, I. Cucoranu, E. Fields, S. He, A. Hoying, R. Russ, A. Abuin, D. Tran, D. Johnson and S. Hosseini. *Pathology, Emory School of Medicine, Atlanta, GA.*

Transgenic mice (TG) were used to explore mechanisms of mitochondrial oxidative stress from zidovudine (AZT) used to treat HIV/AIDS. TGs either depleted or over-expressed mitochondrial superoxide dismutase (SOD2-OX and SOD2+/- KOs, respectively) or expressed mitochondrially-targeted catalase (mCAT). TGs and wild type (WT) littermates were treated (oral AZT; 0.22 mg/day; 35d). As a biological read out, cardiac mitochondrial oxidative events and dysfunction were defined in "2 by 2" protocols. Left ventricle (LV)mass and LV end diastolic dimension

were determined echocardiographically. Mitochondrial H2O2, aconitase activity, histology and ultrastructure were analyzed. AZT-treated WTs exhibited oxidative stress and cardiac dysfunction. Mitochondrial H2O2 increased and aconitase was inactivated in SOD2+/- KOs, and cardiac dysfunction worsened with AZT. Conversely, native cardiac function was preserved in SOD2-OX hearts and in mCAT hearts. In SOD2-OX and mCAT TGs, mitochondrial H2O2, aconitase, LV mass and cavity volume resembled that of vehicle-treated WTs. Both SOD2-OX and mCAT prevent or attenuate oxidative stress and AZT-induced cardiac dysfunction. AZT worsens SOD2+/- KO cardiac dysfunction and increases mitochondrial H2O2. Since dysfunctional changes are attenuated by decreasing H2O2 and worsened by increasing H2O2, oxidative stress from H2O2 is crucial pathogenetically in AZT-induced mitochondrial toxicity.

PS 213 THE PHARMACOKINETIC/PHARMACODYNAMIC RELATIONSHIP: IS THE KINETIC PROFILE AFFECTED BY CARDIOVASCULAR EFFECTS?

B. M. Roche[1], S. Hong[2], T. Vinci[1], S. Graves[2], C. Hassler[1] and J. D. Johnson[2]. *[1]Safety Pharmacology, Battelle, Columbus, OH and [2]Chemistry Technical Center, Battelle, Columbus, OH.* Sponsor: M. Hejtmancik.

To achieve toxic effects in a toxicology study or obtain cardiovascular changes in a safety pharmacology study, selection of doses that will also allow for determining a maximum safe starting dose in man is critical. The selected high doses for non-clinical studies often results in nonlinear kinetics. Current thinking is that the profiles characteristic of non-linear kinetics (e.g., plateau before decay) are indicative of saturation. An alternative theory is the physiologic response, particularly the cardiovascular (CV) response, may result in a kinetic profile similar to those attributed to nonlinear kinetics. We investigated the effects of decreasing BP and HR on the kinetics of diltiazem (D) in a rat hemodynamic model and cisapride (C) in a guinea pig CV model. These studies were conducted remotely using the Empis/Culex to dose/collect blood samples while measuring HR and BP simultaneously using telemetry. A blood collection catheter was placed in the carotid artery (femoral vein in rats) and a dosing catheter in the jugular vein. Rats were iv dosed with 3 doses of D (2.5, 5, and 10 mg/kg) with washout between doses. Guinea pigs were given a single iv dose of C (3 mg/kg). D at 10 mg/kg decreased HR and BP significantly in all animals. Nonlinear (atypical) PK profiles were found in these animals and associated with the significant decreases in HR and BP. C decreased HR in 4 guinea pigs however, transient decreases in BP were recorded in only 2 guinea pigs. PK profiles for those 2 guinea pigs resulted in atypical profiles during early time points when changes in the CV endpoints were maximal. However, the animal that demonstrated less CV effects showed typical decay in C concentrations over time. There was a strong association between atypical PK profiles and duration/extent of decreases in HR and BP after dosing with D and C. The simultaneous collection of cardiovascular and kinetic information demonstrated that alterations in BP and HR may also explain the changes in the kinetic profile.

PS 214 DEVELOPMENT OF METHODS TO IMAGE CALCIUM TRANSIENTS IN HUMAN CARDIOMYOCYTES.

D. L. Misner, J. Q. Ly, A. Orogo, H. Uppal, D. Button, S. Platz and K. Kolaja. *Nonclinical Safety, Roche Palo Alto, Palo Alto, CA.*

The early identification of potential cardiovascular effects, as well as detection of drug-induced arrhythmias including torsades de pointes is critical to the evaluation of potential new chemical entities. Determination of effects on additional channels may provide further insight into mechanistic understanding of a compound's action on cardiac function. Once established for a compound and/or compound class, such an assay may provide a relatively fast and easy way to de-risk cardiovascular liability. The ability to test compounds on human cardiac function, and specifically effects on calcium channels/handling, has been limited by the availability of human cardiomyocytes. Human cardiomyocytes are now available commercially in sufficient number to study effects of compounds on cardiac channel function and calcium signaling, in the most relevant species. We sought to establish conditions to study cardiac function and calcium handling in primary human cardiomyocytes by imaging intracellular calcium using calcium sensitive fluorescent dyes and then to determine the sensitivity of the assay to known cardiotoxicants that affect the calcium signaling pathway. We first established conditions to image calcium levels in cardiomyocytes using Fura-2AM dye and then evoked reproducible responses using high potassium extracellular solution. Our results indicated that the calcium influx induced by high potassium was blocked in a concentration-dependent manner by calcium channel antagonists nifedipine and verapamil, indicating that activation of voltage-gated calcium channels mediated the signal, at least in part. Finally, we tested doxorubicin, a well-known cardiotoxicant, and effects on calcium signaling. Doxorubicin also inhibited calcium responses concentration-dependently. These preliminary results suggest that human cardiomyocytes may be useful tool to evaluate compounds effects on calcium signaling, either directly or through downstream effects on cell health/viability. Additional compounds will be evaluated to establish broad utility of the assay.

PS 215 DOBUTAMINE CARDIAC "STRESS" TEST IN THE RAT: STRAIN COMPARISON AND POTENTIAL UTILITY IN CARDIOVASCULAR TOXICITY STUDIES.

J. Callaway[1], M. S. Hazari[2], N. Haykal-Coates[2], D. W. Winsett[2], D. L. Costa[2] and A. K. Farraj[2]. *[1]School of Medicine, University of North Carolina, Chapel Hill, NC and [2]Experimental Toxicology Division, Environmental Protection Agency, Research Triangle Park, NC.*

Electrocardiogram (ECG) exercise testing is used in patients with risk of heart disease. The test stresses the patient while monitoring them for ECG abnormalities, possibly indicating underlying cardiovascular (CV) disease. Dobutamine, a β1-adrenergic agonist that increases heart rate (HR) and contractility, can be administered intravenously (i.v.) and used in place of exercise. We examined the utility of a dobutamine stress test in rats to assess differences in strains and use as a measure of cardiac toxicity. Wistar-Kyoto (WKY), spontaneously hypertensive (SH) and spontaneously hypertensive heart failure (SHHF) rats were surgically implanted with radiotelemeters and a chronic i.v. catheter in the left jugular vein. After recovery, conscious rats were monitored with ECG and placed in a whole-body plethysmograph (WBP) to monitor ventilatory parameters. The i.v. catheter was exteriorized from the WBP and attached to an infusion pump, delivering increasing doses of dobutamine (10, 20, 40 and 80 ug/kg/min) to the conscious animal. WKY rats experienced a dose-dependent increase in HR [average maximum of 511 bpm at highest dose] and cardiac arrhythmias (7 total on average), both of which were potentiated in SHHF rats (532 bpm and 23 arrhythmias). There were no significant differences between WKY and SH results or in any ventilatory parameters. A group of animals from each strain was also tested under urethane anesthesia (1.5g/kg ip). Each strain had reduced HR response to increasing doses of dobutamine and minimal arrhythmia. In conclusion, the dobutamine stress test shows that SHHF rats are prone to elevated HR and arrhythmic events when compared to the healthier strains. As a methodology, this test can be a valuable tool to assess the impacts of air toxicants on the CV system of animals with pre-existing disease. (This abstract does not reflect EPA policy.)

PS 216 INCIDENCE AND SPECIFICITY OF DRUG-INDUCED TRAFFICKING INHIBITION OF CARDIAC ION CHANNELS.

B. A. Wible, Y. A. Kuryshev, P. J. Hawryluk and A. M. Brown. *ChanTest Corporation, Cleveland, OH.*

The hERG potassium channel is the most common target for drug-induced QT prolongation resulting in torsades de pointes (TdP). HERG or IKr current can be compromised in two ways: via drug-induced direct block of the channel and/or drug-induced trafficking inhibition resulting in fewer channels at the cell surface. To determine the incidence of trafficking inhibition, the Prestwick Chemical Library (1120 structurally diverse compounds) was screened in HERG-Lite®, the only high-throughput assay able to predict hERG trafficking inhibitors and blockers. A total of 12.4% (138/1120) of the compounds in the library showed significant trafficking inhibition in HERG-Lite®. Of these, 49 were pure trafficking inhibitors as no block was detected in automated patch clamp (APC; PatchXpress®, MDS-AT). The remaining 89 were dual risk compounds in that they showed both trafficking inhibition in HERG-Lite and direct block in APC. Of the 285 compounds identified by APC as hERG blockers, 31% were also trafficking inhibitors. The specificity of drug-induced trafficking inhibition was assessed by monitoring the cell surface expression of six other cardiac ion channels: Nav1.5, KvLQT1-minK, Kir2.1, Kir2.2, Kv1.5, and Kv4.3 in an assay modeled after HERG-Lite®. The well-known hERG trafficking inhibitors—geldanamycin, arsenic trioxide, pentamidine, and cardiac glycosides—all showed distinct patterns of effects on the other cardiac ion channels, including increases in surface expression in some cases, suggesting considerable specificity in drug-induced trafficking inhibition.

PS 217 CELLULAR OXIDATIVE STRESS ALTERS ENOS FUNCTION BUT NOT EXPRESSION IN EA.HY926 CELLS.

L. D'Angelo and D. Morel. *Pharmacology and Toxicology, University of the Sciences, Philadelphia, PA.*

Vascular endothelium is both a target for angiotoxins, many of whom serve to increase cellular oxidative stress, and a source of protection against vascular damage. A key player in the maintenance of endothelial function and vascular homeostasis is

nitric oxide (NO) production mediated by endothelial nitric oxide synthase (eNOS). To examine the interaction between oxidative stress and endothelial function, the NO production capacity by human EA.hy926 cells, a cell model for vascular endothelium was studied. Nitric oxide (NO)-specific difluorofluorescein dyes, DAF-FM and DAF-FM-DA (® Calbiobiochem) were used to measure extracellular and intracellular NO production and total and active (phosphorylated) eNOS expression measured by western blotting under basal and oxidative stress induced conditions. Oxidative stress was verified by increased dichlorofluorescein fluorescence. EA.hy926 cells exhibited comparable total eNOS and somewhat greater phosphorylated eNOS expression (normalized to β-actin) relative to human umbilical vein endothelial cells; basal cell-mediated NO production, however, was negligible. Induction of cellular oxidative stress by glutathione depletion and/or hydrogen peroxide, increased intracellular NO, but not extracellular NO, approximately 2-fold. This induction of cellular oxidative stress had no effect on total or phosphorylated eNOS expression, or the ratio of phosphorylated to total eNOS. In contrast, pretreatment with vitamin C or with 5-50mM menadione increased cellular oxidative stress but reduced intracellular NO production; vitamin C pretreatment produced no change in total eNOS, phosphorylated eNOS or the ratio of phosphorylated to total eNOS. These data suggest that while EA.hy926 cells contain adequate total and active eNOS expression, demonstrable NO production in quiescent cultures requires induction of cellular oxidative stress. This oxidative stress-induced NO production may be specific for certain reactive oxygen species such as hydrogen peroxide, and is not mediated by changes in total or active eNOS expression.

PS 218 HYPOXIA-INDUCIBLE FACTOR 1α IS CRITICALLY INVOLVED IN METALLOTHIONEIN PROTECTION AGAINST DIABETIC CARDIOMYOPATHY.

W. Xue, L. Cai, Y. Kang and W. Feng. *University of Louisville, Louisville, KY.*

Background: Previous studies have shown that metallothionein (MT) is effective in the prevention of diabetic cardiomyopathy, and hypoxia-inducible factor 1α (HIF-1α) is known to be a master transcription factor regulating a variety of key genes involving in angiogenesis and glycolysis in the heart. Given that the expression of a variety of agiogenic factors, such as vascular endothelial growth factor (VEGF) and glycolysis enzymes, such as hexokinase II (HK-II), are regulated by transcription factor HIF-1, it is interesting to investigate the role of MT in the regulation of HIF-1 activation. Objective: The purpose of this study was to examine whether or not MT affects HIF-1α activity in the heart of diabetic mice and in the cardiac cells cultured in a media that mimics diabetic conditions leading to the regulation of angiogenic factors and glycolytic enzymes. Methods: Diabetes was induced by streptozotocin (150 mg/kg) in a cardiac-specific MT or HIF-1α over-expressing transgenic mouse models. The primary mouse neonatal cardiomyocytes and embryonic rat cardiac fibroblast H9c2 cells were cultured. mRNA and protein levels of VEGF, HK-II and activity of HIF-1 were analyzed by RT-PCR, Western blotting and HIF-1 dependent luciferase activity assays. Results: Diabetes decreased cardiac VEGF and HK-II protein level in mice; both cardiac-specific MT and HIF-1α over-expression could relieve this suppression. Further analysis showed that MT over-expression increased HIF-1α protein level in diabetic heart. Stably over-expressing MT in H9c2 cells increased HIF-1α mRNA level, indicating the transcriptional modulation of HIF-1α by MT. The addition of MT into the cultures of H9c2 cells transfected with HIF-1-specific reporter gene relieved high glucose suppression of hypoxia-induced luciferase activity. Conclusion: MT rescues HIF-1α transcriptional activity leading to normalization of VEGF and HK-II in cardiomyocytes under diabetic conditions.

PS 219 ENHANCED CONSTITUTIVE ENDOTHELIUM-DEPENDENT VASODILATION IN ARYL HYDROCARBON RECEPTOR NULL MICE.

N. Zhang, M. T. Walsh and M. K. Walker. *Pharmacy, University of New Mexico, Albuquerque, NM.*

Aryl hydrocarbon receptor (AHR) mice were reported hypertensive at modest high altitude and hypotensive at sea level. After being acclimated to altitude for generations, the AHR null mice start losing their high blood pressure phenotype. Since the constitutive nitric oxide (NO) production in vascular endothelium plays a crucial role in maintaining normal blood pressure, we tested the hypothesis that AHR null mice has enhanced constitutive endothelium-dependent vasodilation mediated by elevated endothelial nitric oxide synthase (eNOS) expression. We assessed vascular responses to vasoconstrictor phenylephrine (PE) ± endothelial nitric oxide synthase inhibitor, N-nitro-L-arginine (LNNA) in aortic rings isolated from C57Bl/6 wildtype and AHR null mice. We also measured aortic eNOS protein expression by western blot and 24 hr nitrate/nitrite (NOx) excretion by Griess assay in mouse urine. In addition, we measured eNOS mRNA expression in cultured human aortic endothelial cells treated with AHR siRNA. Compared to PE treatment, AHR null mice aortic rings showed a greater change in response to PE treatment after preincubation with LNNA (Δ% of maximal KCl constriction: 85±6, WT; 123±5, AHR null; $p<0.05$), which revealed an enhanced constitutive NO production in AHR null mice. In addition, aortic eNOS protein expression in AHR null mice was significantly increased by 3-fold compared to wildtype mice. The 24 hr urine NOx excretion was also significantly increased (267±66 pmol, WT; 966±237 pmol, AHR null; $p<0.05$). In human aortic endothelial cells culture, eNOS mRNA was increased 2-fold with AHR siRNA treatment ($p<0.05$). These data suggest that AHR null mice exhibit an enhanced constitutive endothelium-dependent vasodilation mediated by elevated eNOS expression. In order to estimate the role of this vasodilatory effect on blood pressure regulation, we will assess the blood pressure of wildtype and AHR null mice with LNNA treatment. Supported by HL078914.

PS 220 MOLECULAR RESPONSE TO IMPLANTATION OF BARE METAL OR PACLITAXEL-ELUTING STENTS IN EXPLANTED INTACT HUMAN ARTERIES.

S. Amisten[1,3], A. Albrekt[2], B. Ganter[3] and D. Erlinge[1]. *[1]Cardiology, Lund University, Lund, Sweden, [2]SCIBLU Microarray Resource Center, Lund University, Lund, Sweden and [3]Ingenuity Systems, Redwood City, CA.*

Drug-eluting cardiovascular stents were developed to address the problem of arterial restenosis associated with bare metal stents. Recently, some concerns have emerged regarding the safety of drug-eluting stents, particularly delayed arterial healing and increased risk of stent thrombosis in carriers of drug-eluting stents. To identify the molecular response to stent implantation, gene expression profiling was performed on human thoracic arteries fitted with bare metal or paclitaxel-eluting stents using a unique in vitro stent model and the expression profiles were analyzed using IPA pathways analysis tools. Implantation of paclitaxel-eluting stents affected pathways associated with the regulation of platelet activation, suggesting a net prothrombotic effect (down-regulation of prostaglandin I2-synthase, up-regulation of substance P and matrix metallopeptidase 1) and reduced migration and proliferation of endothelial cells (down-regulation of vascular endothelial growth factor A, hepatocyte growth factor and placental growth factor). This study demonstrates for the first time the identification of molecular targets likely to be associated with the delayed healing and increased risk of stent thrombosis observed in carriers of paclitaxel-eluting stents. Implantation of bare metal stents also resulted in an unexpected up-regulation of genes encoding for enzymes of the cholesterol biosynthesis pathway. This might be important considering that oxidized cholesterol is an important component in the development of atherosclerotic lesions. Interestingly, HMG-CoA reductase, the rate-limiting enzyme for cholesterol synthesis targeted by statin drugs, was significantly up-regulated by bare metal stents. We propose that our model may be used as a complement to animal models and cell culture in evaluating the effects of novel drug-eluting stent candidates in human arteries in order to further the understanding of the molecular responses to drug-eluting stent implantation.

PS 221 PREDICTION OF DRUG-INDUCED TORSADES DE POINTES IN CYNOMOLGUS MONKEY PAPILLARY MUSCLE MODEL.

J. Matsuo, K. Yunomae, A. Suzuki, M. Ban, Y. Arimura, M. Haruyama, Y. Deguchi, T. Nakamura, T. Sukamoto, K. Fukuzaki and R. Nagata. *Shin Nippon Biomedical Laboratories(SNBL), Ltd., Kagoshima, Japan.*

Delayed repolarization is caused by many drugs (cardiac and non-cardiac) and is linked to torsades de pointes (TdP). The purpose of this study was to evaluate the suitability of cynomolgus monkey versus guinea pig papillary muscle models to predict the potential for TdP. [Methods] Action potential was recorded in male cynomolgus monkey and guinea pig papillary muscle by the microelectrode technique. The effects of 3 drugs with torsadogenic potential, namely E-4031 (0.1, 0.3 and 1 μmol/L), *dl*-sotalol (3, 30 and 300 μmol/L), and erythromycin (30, 100 and 300 μmol/L), were evaluated. The effects of moxifloxacin (3, 10 and 30 μmol/L), a recommended positive control for QT interval prolongation in thorough QT/QT_c clinical trials, were also assessed. [Results] At a stimulation rate of 1.0 Hz, all drugs induced prolongation of action potential duration at 90% repolarization (APD_{90}) in a concentration-dependent manner in both cynomolgus monkey and guinea pig papillary muscle. At 0.2 Hz, clear reverse use-dependent effects of drugs on APD_{90} and triangulation (difference in action potential duration between 90% and 30% repolarization; APD_{30-90}) were observed in cynomolgus monkey papillary muscle compared with that of guinea pig. At 0.2 Hz, E-4031, *dl*-sotalol, and erythromycin (but not moxifloxacin) induced early afterdepolarization (EAD) and triggered activity (TA) in cynomolgus monkey papillary muscle. No drug induced either EAD or TA in guinea pig papillary muscles. [Conclusion] These results indicate that the *in vitro* cynomolgus monkey papillary muscle model can detect the potential for TdP, and that is more sensitive than the guinea pig model.

PS 222 ELECTROPHYSIOLOGICAL PROFILING OF CARDIAC PROGENITORS FROM ADULT HUMAN MYOCARDIUM.

L. Polonchuk[1], J. Ly[2], J. Jin[2], M. Sweeney[2], H. Uppal[2], K. Kolaja[2], A. Breidenbach[1] and D. Misner[2]. *[1]Non-Clinical Safety, F.Hoffmann - La Roche Ltd, Basel, Switzerland and [2]Non-Clinical Safety, Roche Palo Alto LLC, Palo Alto, CA.*

Background: Development of in vitro toxicity assays based on the human stem cell-derived cardiomyocytes would provide an opportunity to assess the specific cardiac safety end-points early in the drug development process. Objective: Electrophysiological properties of cardiac progenitors from adult human myocardium were investigated with special focus on establishment of cell-based high throughput cardiac toxicity screens. Methods: Characterization of ionic currents in clonal cardiac progenitors (CPs) derived from adult human heart was performed using automated patch clamp system PatchXpress 7000A. The cells were maintained in M-199 medium containing 10% FBS and subcultured every 48 hours on collagen/laminin extracellular matrix. Results: Outward potassium current mainly consisting of slow and rapid delayed rectifier (IKr, IKs) and Ca2+-activated clotrimazole-sensitive (IKCa) components were recorded. Inward cardiac sodium current suppressed by flecainide was present in all cells after 4 weeks in culture. Nifedipine-sensitive L-type Ca2+ current (ICa,L) was detected in ~10% of CPs. The inward rectifier potassium current (IK1) and a pacemaker current (If) could also be recorded. These results demonstrate the presence of functional cardiac currents in cardiac progenitors derived from adult human myocardium. For the first time assay protocols and procedures were established to measure the main cardiac currents in CPs and characterize their electrophysiological properties in a high throughput electrophysiology platform. Conclusion: Cardiac progenitors from adult human myocardium appear to be a promising model for the early in vitro cardiac safety assessment. Further validation of the model with tool compounds toward regulatory acceptance should evaluate predictivity of the model for clinical effects.

PS 223 NEAR INFRARED (NIR) IMAGING OF LYMPHATIC FUNCTION IN CONTROL SUBJECTS AND IN PERSONS WITH LYMPHEDEMA.

M. V. Marshall, J. Rasmussen, I. Tan, K. E. Adams, C. E. Fife, L. Smith, E. A. Maus and E. M. Sevick-Muraca. *Institute of Molecular Medicine, University of TX Health Sci. Ctr. Houston, Houston, TX.*

Although the lymphatics are thought to play a crucial role in cancer metastases, diabetes, asthma, and obesity, there is little understanding of lymph function even in health. Acquired lymphedema can be caused by the filarial parasite or by trauma due to radiation therapy, infiltrating cancer, surgery, or infection, and congenital lymphedema involves structural changes in the architecture of lymphatic transport. A method to image lymphatic function was developed using indocyanine green (ICG) as a contrast agent and detection of its fluorescence following excitation by NIR light. After obtaining IRB approval and informed consent, 24 normal volunteers and 20 persons with stage I or II unilateral lymphedema of one limb were enrolled in a clinical study to evaluate lymphatic function. Intradermal injections of ICG (0.025 mg/injection) were made in arms or legs of all subjects, with up to 0.4 mg injected; imaging began after all injections were made. Dynamic imaging in arms of control subjects revealed a mean velocity of 0.62cm/sec, 0.82 cm/sec in asymptomatic arms, and 0.69 cm/sec in symptomatic arms. Velocity was similar between right and left legs and approximately 50% greater than arm velocity. Reversal of lymph flow was sometimes observed in the affected and unaffected limbs of persons with lymphedema. In conclusion, we observed four distinct structural patterns of lymphatic disorders in persons with lymphedema: absence of lymph flow or distinct lymph channels, lymphatic hyperplasia, lymphatic tortuosity, and reversal of lymph flow. Structural changes are likely responsible for functional effects. This procedure demonstrates the utility of using optical imaging with NIR light and a fluorescent dye to characterize lymphatic function. Similar results have been seen in animal models. We intend to expand these results by identification of genetic differences in genes associated with lymphatic structure or transport. Supported in part by ACS grant RSG-06-213-01-LR and NIH grant RO1 CA112679.

PS 224 GERANYLGERANYLACETONE (GGA) PROTECTS THE HEART FROM DOXORUBICIN CARDIAC TOXICITY WHILE REDUCING TUMOR VOLUME OF BREAST CANCER.

P. Sysa, Y. Xu, D. Bedja, S. Pin, V. Ramen, E. Gabrielson, A. Tsao, A. Moens, D. Kass, J. Coulter and K. L. Gabrielson. *Johns Hopkins University, Baltimore, MD.*

Background: Doxorubicin is widely used for the treatment of both solid tumors and hematological malignancies; however, its use is limited by cardiotoxic adverse effects. Geranylgeranylacetone (GGA), an anti-ulcer agent, used in Japan since 1984, with no known adverse effects, has been shown to inhibit ovarian cancer progression in vivo in mice. In oxidative stress animal models, GGA also reduces cell death. We hypothesized that GGA would prevent doxorubicin cardiac toxicity, limited cardiac cell death and oxidative stress, yet improve doxorubicin's chemotherapeutic effect. Nude mice implanted with human breast cancer cells (MDA-231) were studied after single or combination chronic treatments. Results: GGA reduced doxorubicin toxicity by significantly maintaining heart fractional shortening after chemotherapy and significantly decreasing the TUNEL positive cells in the heart. This was accompanied by a reduction in cardiac superoxide formation, partially mediated through the source nitric oxide synthase. In xenografts implanted nude mice, GGA+DOX treatment also significantly reduced tumor mass versus DOX treatment alone. Metastases were reduced in the combined GGA-DOX treatment as observed by histopathology and by fluorescence optical imaging of tomato red in tumor cells. In vitro, GGA inhibited lysophosphatidic Acid (LPA)-induced matrigel invasion by MDA-231 cells suggesting rho pathway inhibition. Conclusion: GGA is a prospective drug for use as a part of anti-cancer treatment scheme.

PS 225 COMPARISON OF ECG TELEMETRY DATA IN FREELY-MOVING DOGS, USING NON-INVASIVE AND INVASIVE METHODS.

J. Briffaux, E. Chalencon, C. Bory, P. Lege, S. Baudet and S. Milano. *MDS Pharmacology Services, St Germain sur l'Arbresle, France.*

Electrocardiography (ECG) investigations are routinely performed during preclinical toxicology studies in non-rodent species. The pertinence and reliability of these data may be compromised, however, by the need to restrain the animal during the recording of surface ECG traces and by their limited duration (a few minutes). Telemetry may be employed to improve both the quality and duration of ECG investigations, but the surgical methods used to implant the sensors are often incompatible with the objectives of a regulatory toxicology study. Surface ECG recording and data transmission through Bluetooth technology may be used to address these difficulties, allowing long-term ECG signal acquisition from freely-moving and socialised animals. Our objective was to compare surface ECG data recorded with a Jacket External Telemetry device (JET, DSI, USA) with those obtained using gold-standard invasive telemetry. Six dogs were surgically equipped with a telemetry implant (TLM11M2-D70-PCT, DSI) to collect the lead II-ECG; these data were analyzed by Notocord-HEM. The same dogs were also equipped with the JET setup with cutaneous patch electrodes connected to record a 6-lead (I, II, III, aVR, aVL, aVF) ECG; these data were analyzed by Ponemah-P3 Plus. ECG data were collected simultaneously from both devices for 24 hours before and after oral administration of 30 mg/kg of sparfloxacin. The duration of the RR, PR and QT intervals and of the QRS complex were measured with each device at specific time-points. There was an excellent correlation of the data generated by the two devices ($r > 0.95$) both before and after sparfloxacin treatment. It was concluded, therefore, that non-invasive surface ECG recording may be reliably achieved in the free-moving dog during the course of a regulatory toxicology study using the JET device. This technology may prove to be a powerful tool for the detection of ECG-modifying properties of new drugs in regulatory toxicology studies (e.g. QT prolongation).

PS 226 METALLOTHIONEIN PROTECTS CARDIAC CELLS AGAINST ANGIOTENSIN II-INDUCED APOPTOSIS THROUGH SUPPRESSION OF P53 EXPRESSION AND ACTIVATION *IN VITRO* AND *IN VIVO*.

Q. Liu, G. Zhou, Y. Tan and L. Cai. *GI, University of Louisville, Louisville, KY.* Sponsor: L. Cai.

Our previous study has shown the antioxidant protein metallothionein (MT) significantly prevented Ang II-induced NADPH oxidase activation, nitrosative stress, and apoptosis in the heart, which led to a significant prevention of cardiac remodeling and dysfunction. Since we found that tumor suppressor protein p53 played an important role in Ang II-induced cardiac apoptotic cell death, the present study was to define whether MT protection against Ang II-induced cardiac cell death was mediated by suppression of p53 expression and activation. Cardiac H9C2 cells were pretreated with and without 25-50 μM zinc (Zn) to induce MT synthesis and then exposed to 100 nM Ang II for 7 hr or 24 hr. Exposure of cells to Ang II for 7 hr and 24 hr induced a significant increase apoptotic cell death which detected by DNA fragment ELISA assay, and caspase-3 and caspase-8 cleavage, along with significantly increased total and phosphorylated p53 expressions. Pretreatment with Zn induced MT synthesis, detected by Western blotting assay, and also significantly inhibited Ang II-induced total and phosphorylated p53 expression and apoptotic cell death. To eliminate the inhibitory effect of Zn directly on Ang II-induced p53 expression and apoptosis, pre-exposure of cardiac cells to low dose of cadmium that significantly induced MT synthesis also showed a protection against Ang II-induced p53 expression and apoptosis, suggesting the protective role of MT, instead

of Zn, against Ang II effect on p53 and cell death. To validate the in vitro finding into an in vivo model, Ang II was infused into transgenic mice with cardiac-specific overexpression of MT (MT-TG) and their wild-type (WT) mice. Ang II induced significant up-regulation of total and phosphorylated p53 expression along with induction of apoptotic cell death in the hearts of WT mice, but not in those of MT-TG mice. These results suggest that MT protect the heart against Ang II-induced apoptotic cell death via suppression of p53 expression and activation (Supported in part by ADA and AHA grants).

PS 227 EGCG, A MAJOR GREEN TEA POLYPHENOL, PROTECTS ENDOTHELIAL CELLS AGAINST PCB-INDUCED CELL DAMAGE *VIA* INCREASED NRF2 SIGNALING.

S. Han, Z. Majkova, Y. Zheng, Y. Choi, S. Eum, M. Toborek and B. Hennig. *University of Kentucky, Lexington, KY.*

Polychlorinated biphenyls (PCBs) are widespread and persistent environmental contaminants that have been shown to induce oxidative stress and inflammation in endothelial cells. Epigallocatechin gallate (EGCG) is believed to improve health and protect against vascular diseases such as atherosclerosis. Recently, EGCG has been demonstrated to induce NF-E2-related factor (Nrf2), a transcription factor that regulates expression of many antioxidant and phase II detoxifying enzymes. Thus, we hypothesized that EGCG may enhance the defensive mechanism of vascular endothelial cells against exposure to environmental contaminants such as PCB126 via upregulation of Nrf2. To test this hypothesis, we studied inflammatory parameters, including adhesion molecules. Primary vascular endothelial cells were pretreated with EGCG, followed by exposure to PCB126. Both EGCG and PCB126 significantly increased Nrf2 protein expression in a dose-dependent manner. In contrast, Nrf2-regulated phase II detoxifying enzymes, such as NAD(P)H:quinone oxidoreductase1 (NQO1), were significantly increased by EGCG treatment but not after exposure to PCB126. Both PCB126 and EGCG activated extracellular signal-regulated protein kinase1/2 (ERK1/2), and the pharmacologic inhibition of this kinase reduced Nrf2 protein expression. Caveolin-1 silencing abolished both the PCB- and EGCG-stimulated Nrf2 and NQO1 protein expression. In addition, treatment with EGCG decreased the level of platelet/endothelial cell adhesion molecule-1 in the cells independent of PCB126 exposure. These findings suggest that EGCG induces Nrf2 expression mainly via an ERK1/2 signaling pathway, with subsequent upregulation of its target protein NQO1. Furthermore, functional caveolae appear to be necessary for Nrf2-mediated regulation of EGCG-associated cell protection. This may explain in part the protective properties of EGCG against PCB-induced cellular toxicity. (Supported by grants from NIEHS, NIH (P42ES07380), and the UK AES)

PS 228 INTRANASAL BENZO[A]PYRENE ALTERS DIEL RHYTHM OF BLOOD PRESSURE IN RATS.

N. J. Gentner and L. P. Weber. *University of Saskatchewan, Saskatoon, SK, Canada.*

Polycyclic aromatic hydrocarbons (PAHs), including benzo[a]pyrene (BaP), are environmental contaminants formed during organic material combustion (e.g. burning fossil fuels and cigarette smoke). BaP toxicity may be mediated by activation of the aryl hydrocarbon receptor and/or formation of reactive metabolites, both of which lead to increased oxidative stress. Since air pollution and cigarette smoking are known to increase cardiovascular disease in humans, it is hypothesized that increased oxidative stress from BaP exposure will increase blood pressure in rats. Rats implanted with femoral radiotelemetry blood pressure catheters were exposed daily to BaP (0.01 mg/kg, intranasal) or vehicle (tricaprylin) for 7 days. Since vascular oxidative stress can reduce nitric oxide, causing endothelial dysfunction and increased peripheral resistance, plasma nitrate/nitrite levels were also measured. The slope of the rise in blood pressure (dP/dt) with each pulse was extracted from the pressure waveforms as a measure of vascular stiffness. BaP exposure significantly increased diastolic and systolic pressure ($p<0.0005$ and $p=0.015$ for BaP factor in 3-way ANOVA, respectively) compared to control. BaP exposure also significantly decreased pulse pressure and increased heart rate. Paradoxically, no significant difference in dP/dt was detected between treatment groups, while plasma nitrate/nitrite levels in the BaP-exposed rats increased to approximately 125% of the control group. Systolic, but particularly diastolic pressure failed to decrease in BaP-exposed rats primarily during the afternoon (period of inactivity/sleep for rats). This failure of blood pressure to dip during sleep is associated with increased risk of serious cardiovascular events in humans. The elevated diastolic pressure observed in this study is not consistent with the elevated nitric oxide production. Furthermore, increased nitric oxide levels should have caused a decrease in dP/dt. Therefore, factors other than endothelial function appear to be altered to produce the elevated peripheral resistance observed in this study, particularly during sleep, in BaP-exposed rats.

PS 229 CHANGES OF DYNAMIC BEAT-TO-BEAT QT-TQ INTERVAL RELATIONSHIP IN CONSCIOUS DOG MODEL OF SHORT AND LONG QT SYNDROMES.

A. Kijtawornrat[1,2], Y. Panyasing[1,2], C. Del Rio[1], T. Mongkolmaneepol[1], L. Snedden[1], J. Schmidt[1] and R. L. Hamlin[2,1]. *[1]QTest Labs, LLC, Columbus, OH and [2]The Ohio State University, Columbus, OH.* Sponsor: M. Hejtmancik.

Repolarization restitution refers to the relationship of QT duration to the preceding TQ duration, and has been hypothesized to predict the arrhythmia due to reentry. Changes of ventricular repolarization time can affect restitution and possibly lead to unstable reentry and arrhythmia. This study was designed to evaluate restitution parameters [the 5th percentile of TQ interval (TQmin), QT/TQ ratio, the percentage of beats with QT/TQ ratio >1] in the conscious, sling-trained canine model of short QT syndrome in comparison with the long QT syndrome. The RR, QT, and TQ intervals were examined in sling–trained, conscious dogs infused with escalating concentrations of pinacidil, nicorandil, sotalol, and quinidine. The QT shortening drugs (pinacidil and nicorandil) significantly decreased QT, QTc(B,F,V), and TQmin intervals in a dose-dependent manner. The QT/TQ ratio and the percentage of beat with a QT/TQ ratio > 1 were increased significantly ($p<0.01$) after giving pinacidil and nicorandil. In contrast, QT lengthening drugs (sotalol and quinidine) significantly prolonged QT, and QTc(B,F,V) intervals in a dose-dependent manner. The percentage of beats with a QT/TQ ratio > 1 was significantly reduced ($p<0.05$) and the lower TQ interval boundary (TQmin) was significantly increased ($p<0.05$) after infusion of QT lengthening compounds. In conclusion, ECG restitution changes can be use as biomarkers to predict arrhythmia vulnerability in a conscious sling-trained dog model of short and long QT syndromes.

PS 230 A DISSECTING AORTIC ANEURYSM MODEL INDUCED BY N-(2-AMINOETHYL) ETHANOLAMINE IN RAT.

Y. Xu, Y. Yang, J. Ruiz and P. Boor. *Pathology, Universtiy of Texas Medical Branch, Galveston, TX.*

Dissecting aortic aneurysm (DAA) is a tear in the wall of the aorta that causes blood to flow between the layers of the media of the aorta and forces the layers apart. Aortic dissection is a medical emergency and can quickly lead to death, even with optimal treatment. Our aim is to study the toxicity of the industrial chemical N-(2-aminoethyl) ethanolamine (AEEA) in the development of DAA. In an in vivo study, pregnant Sprague-Dawley rat dams were treated with AEEA by intraperitoneal (IP) injection on gestation days 14-21, a period of rapid aortic development. Seven groups were treated (1 mg/kg to 100 mg/kg AEEA). The control group received normal saline. The aortas from newborn pups were harvested and examined for dissecting aneurysm. Pregnant rats died with the two highest doses of AEEA (75 mg/kg, 100 mg/kg) after 5-6 IP injections. No lesions were found in pups (0/12) at 1 mg/kg and in pups in the control group (0/23). The DAAs were detected in other groups: 8/27 pups at 10 mg/kg, 14/29 pups at 25 mg/kg, and 6/9 pups at 50 mg/kg. In a preliminary in vitro study, the primary cultured vascular smooth muscle cells (SMC) of aortas from fetuses of Sprague-Dawley rats were exposed to AEEA. The cytotoxicity of AEEA was determined over a 24-hour incubation period with a range of concentrations from 5 to 200 mM AEEA, using the standard MTT measure of cellular viability. An approximately 50-60% decrease in viability was noted at 25 mM AEEA or above. Our data indicate that AEEA given IP results in the development of DAA.

PS 231 A NINETY-DAY SUBCHRONIC INHALATION TOXICITY STUDY OF GOLD NANOPARTICLES IN SPRAGUE-DAWLEY RATS.

I. Yu[1], J. Sung[1], J. Ji[2], J. Park[4], J. Yoon[3], K. Jeon[3], B. Choi[1], M. Song[1], J. Lee[1], K. Song[1], J. Han[5], Y. Chung[5], J. Jeong[6], B. Han[6] and H. Chang[7]. *[1]Biosafety Evaluation Headquarter, KEMTI, Incheon, Korea, South, [2]Samsung Electronics, Suwon, Korea, South, [3]HCT, Co., Icheon, Korea, South, [4]Preventive Medicine, Chung-Ang University, Seoul, Korea, South, [5]OSHRI, KOSHA, Daejeon, Korea, South, [6]NITR, Korea Food and Drug Administration, Seoul, Korea, South and [7]Pathology, Kosin Universtiy, Busan, Korea, South.*

Gold nanoparticles (NPs) have been used extensively for therapeutic purpose or food supplement. Especially inhalation toxicity of gold NPs could be urgent information to ensure workers and consumers'health. Gold NPs (4-5 nm) were generated and distribution of NPs measured. Rats were divided into 4 groups with 10 rats in each group: control group, low (2.36×10^4 particle/cc, 1.90×10^6 nm^2/cc), middle (2.36×10^5 particle/cc, 1.68×10^7 nm^2/cc) and high-dose group (1.85×10^6 particle/cc, 3.64×10^8 nm^2/cc). The animals were exposed to gold NPs 6 h/day, 5 day/week, for 90-day duration. Mortality and clinical observations were conducted daily and body weight and food consumption were recorded weekly. Lung

function tests were performed weekly. At the end of the study, all rats were subjected to full necropsy and absolute and relative organ weights were recorded. Blood samples were collected for hematology and clinical chemistry. Male rats did not show significant changes in body weight during the 90-day experiment, but female rats in the low-dose group showed significant body weight changes when compared with the control group from day 42 of exposure. There were no significant changes in food consumption, lung function test or hematology values in male or female rats during the study. There were no specific symptoms observed in opthalmological examination or urinalysis for male or female rats. There were no dose-dependant changes in blood biochemical values or absolute and relative organ weights for male and female rats. Hitopathological pathological exmaination showed some inflammatory changes in the high dose group. Therefore, the current results indicate inhalation exposure of gold NPs at the concentrations described in this report have no significant influence on health.

PS 232 COMPARISON OF THE PULMONARY TOXICITY OF MICRO AND NANO SIZED GOLD PARTICLES IN RATS.

I. Gosens, D. L. Leseman, J. J. Boere, Y. Wallbrink, L. de la Fonteyne, F. R. Cassee and W. H. de Jong. *National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands.*

Introduction: Due to physical characteristics such as size and surface to volume ratios, the interaction of nanoparticles versus micro sized particles of the same material with biological systems might be markedly different. Pure gold was chosen as a model particle to study effects on systemic and lung inflammatory markers. In addition, gold particles, especially in the nano size range are produced for medical application, but not much is known about potential toxic effects. A recent biodistribution study has demonstrated a more widespread distribution for 10 nm sized particles compared to 250 nm after i.v injection in rats. The present study was focused on the toxicity of gold particles. Methods: A single dose of 50 μg of spherical gold particles in aqueous suspension of 10 nm and 250 nm (SPI supplies), diluted 10% by adding phosphate buffered saline were administered to male WU Wistar-derived rats by intratracheal instillation. A single dose of 50 μg and 250 μg DQ12 quartz was used as a positive control. Dynamic light scattering (NanoSight) was used to determine the particle size distribution in the suspensions prior to application. Broncho alveolar lavage fluid and blood was collected to assess the effect on cell differentials, oxidative stress and inflammation after 19 and 72 hrs. Results: The 10 nm gold particles formed aggregates and had a mean particle size distribution of 175 nm, while 250 nm gold particles had a size distribution of 220 nm. A significant increase in monocytes and IL-6 levels is observed in the lung 72 hrs after 250 nm gold application, but this was not evident for 10 nm gold particles. After 19 hrs, an oxidative stress response is seen in the lung using 250 nm, but not with 10 nm particles. No sign of systemic inflammation by gold particles is seen. Conclusion: A difference was found for the 10 nm gold particles compared to 250 nm after intratracheal instillation. The 250 nm particles elicit a mild inflammatory response in the lung, whereas the 10 nm particles did not.

PS 233 EVALUATION OF THE EFFECT OF PARTICLE SIZE ON THE TOXICITY AND TOXICOKINETICS OF FULLERENE C60 IN RATS AND MICE FOLLOWING NOSE-ONLY INHALATION EXPOSURE.

N. J. Walker[1], G. L. Baker[2], J. A. Dill[2], D. R. Germolec[1], K. L. White[3] and J. H. Roycroft[1]. *[1]National Toxicology Program, National Institute of Environmental Health Sciences, RTP, NC, [2]Battelle Toxicology Northwest, Richland, WA and [3]Virginia Commonwealth University, Richmond, VA.*

Fullerene C60 is a 1nm diameter molecule that can aggregate into larger crystals up to several mm in size. C60 was selected for study to evaluate the hypothesis that decrease in particle size leads to an increase in potency of toxicity of nanoscale materials. In this study we evaluated the effect of inhalation exposure to two different sized particles of C60. Wistar-Han rats and B6C3F1 mice were exposed by nose–only inhalation to two sizes of C60 (0.05 μm or 1μm) 3 hours per day 5 days per week for 90 days. Exposure concentrations were 0, 0.5, 2.5 mg/m3 for 0.05 μm C60, and 0, 5, 15 and 30 mg/m3 for the 1μm C60. A complete necropsy and histopathological evaluation were conducted on all animals. Tissue distribution of C60 as well as lung clearance was also determined. In addition effects of exposure on organ weights, clinical chemistry, hematology, micronucleus formation, and effects on the reproductive tissues and immune system/function were also evaluated. There were no biologically significant exposure-related changes in these parameters in rats or mice exposed to either 0.05 μm or 1μm C60. Pathological effects were generally restricted to increased lung pigmentation (attributable to lung deposition of C60) and histiocyte infiltration (compensatory response to clear C60 from the lung). In both rats and mice, there was a shift in inflammatory cell populations in lung lavage fluid. These findings indicate that inhalation exposure to C60 particles caused negligible toxicity and that a decrease in particle size to the nanoscale did not exacerbate toxicity. These data are consistent with the observed lack of toxicity of C60 after both shorter-term exposures and in studies using intratracheal instillation.

PS 234 DISTRIBUTION OF $[^{14}C]C_{60}$ IN PREGNANT AND LACTATING RATS.

R. Snyder, T. Fennell, G. Taylor, A. H. Lewin, J. Burgess and S. Sumner. *RTI International, RTP, NC.*

The potential for workplace and environmental exposure to carbon nanoparticles such as Buckminsterfullerene (C_{60}) has generated a need to understand basic properties of C_{60} in biological systems. This study was conducted to determine the distribution of $[^{14}C]C_{60}$ in the pregnant rat and fetus, and in the lactating rat and offspring. Four dams were dosed via tail vein injection on gestational day (gd) 15 with 0.28 mg/kg body weight $[^{14}C]C_{60}$ (~ 3 μCi per rat) prepared in 5% polyvinylpyrrolidone in saline (PVP), and four dams were dosed with PVP alone. Urine (0-24hr) and tissues (24 hr) were collected from the dams. Eight lactating rats were dosed on postnatal day (pnd) 8 with 0.36 mg/kg $[^{14}C]C_{60}$ prepared in PVP, and sacrificed at 24 hr or 48 hr after exposure. In the pregnant dams, radioactivity was distributed to the placenta (approximately 2% of the dose), to the fetus (1.0%), and to the female reproductive tract (3.0%). Radioactivity was distributed to the milk (< 1%) and mammary tissue (<1%) in the lactating rats, and to the GI tract (<1%) and liver of the pup (< 1%). For the pregnant dam, radioactivity was distributed to the urine (<2%), feces (2%), blood (0.9% per mL) and plasma (1.7% per mL), brain (< 1%), lung (<1%), heart (<1%), liver (~43%), spleen (4%). In comparison to the pregnant dam, lactating rats had a similar radioactivity distribution to the blood and plasma at 24 hr after exposure (with a 50% decrease by 48 hr), a higher distribution to the lung, and a decreased distribution to the liver. Metabolomics analysis of urine indicated that dams exposed to C_{60} had a decrease in metabolites derived from the Krebs cycle and an increase in metabolites derived from the urea cycle or glycolysis; with alterations in the levels of some sulfur-containing amino acids and purine/pyrimidine metabolites. This study indicated that C_{60} can cross the placenta and can be transmitted from mother to offspring via milk. This research was funded by RTI International.

PS 235 ASSESSMENT OF THE DISTRIBUTION OF INTRAVENOUSLY-INJECTED SILVER NANOPARTICLES IN PREGNANT MICE AND DEVELOPING EMBRYOS.

C. A. Austin[1, 6], T. H. Umbreit[2], K. M. Brown[1], D. S. Barber[4], B. J. Dair[2], S. Francke-Carroll[3], A. Feswick[4], M. A. Saint-Louis[5] and P. L. Goering[2]. *[1]Biological Sciences Department George Washington University, Washington, DC, [2]CDRH, U.S. Food & Drug Administration, Silver Spring, MD, [3]CFSAN, U.S. Food & Drug Administration, College Park, MD, [4]Center for Environmental and Human Toxicology, University of Florida, Gainesville, FL, [5]Biology Department Villanova University, Philadelphia, PA and [6]Syracuse Research Corporation, Arlington, VA.*

The translocation of nanoparticles across the placenta and accumulation in developing embryos *in vivo* has not been widely studied. The objective of this study was to evaluate the distribution of silver (Ag) nanoparticles in pregnant mice and translocation to developing embryos. Ag nanoparticles (fabricated in-house, 7-9 nm in diameter as measured by dynamic light scattering) in citrate buffer were injected i.v. into pregnant CD-1 mice on gestation days (GD) 7, 8, and 9 (total: ~9 μg Ag/mouse). Controls received citrate buffer only. Mice were euthanized on GD10 and brain, heart, kidneys, liver, lungs, lymph nodes, ovaries, spleen, and thymus were collected from each dam. From each litter, the myometrium and endometrium of the uterus, chorio-allantoic placentas, visceral yolk sacs, and embryos were collected. Tissue Ag levels were quantitated using inductively coupled plasma mass spectrometry (ICP-MS). In treated dams, Ag (in ng Ag/mg tissue) was detected at statistically significant ($p<0.001$) concentrations (compared with controls) in the liver (2.94), spleen (1.33), lungs (0.676), and visceral yolk sacs (1.95). Average accumulation in the liver was 64% of total detected Ag; average accumulation in the spleen, lungs, and visceral yolk sacs was 4, 2, and 1.6% of total detected Ag, respectively. Thus, Ag nanoparticles injected into pregnant mice distributed to maternal liver, spleen, and lungs, with the highest accumulation in liver. Ag nanoparticles distributed to the visceral yolk sacs, but did not accumulate in uterine tissue, chorio-allantoic placentas, or developing embryos to statistically significant levels.

PS 236 ASSESSMENT OF THE TOXICITY OF MULTI-SIZED SILVER AND GOLD NANOPARTICLES IN ZEBRAFISH EMBRYOS.

O. Bar-Ilan, R. M. Albrecht, V. E. Fako and D. Y. Furgeson. *Division of Pharmaceutical Sciences, School of Pharmacy, University of Wisconsin-Madison, Madison, WI.*

Nanoscale engineering represents a current dynamic area of interdisciplinary research incorporating nanoparticles into a diverse product matrix. Due to the disparate physicochemical properties and functions correlated with nanoparticles,

there is an acute need for assessing nanotoxicity. Nanoparticle size, surface functionalization, and chemical composition are but three critical nanotoxic metrics. Zebrafish (*Danio rerio*) embryo exposures with non-functionalized, colloidal silver (cAg) and gold nanoparticles (cAu) in an array of sizes (3, 10, 50, and 100 nm) produced a range of toxic effects. Using a semi-quantitative scoring system, cAg3, 10, 50, and 100 elicited nearly 100% embryonic mortality 120 h post-fertilization (hpf); cAu3, 10, 50, and 100 exposures resulted in less than 3% mortality 120 hpf. While cAu induced minimal sublethal toxic effects, cAg exposures generated various embryonic and morphological malformations including stunted growth, opaque and non-depleted yolks, circulatory malformations, and jaw defects amongst others at 120 hpf. Both cAg and cAu were taken up by the embryos and results from vector control experiments suggest cAg sublethal toxicity and mortality were a result of the nanoparticles themselves or Ag^+ ions formed either during *in vivo* nanoparticle destabilization or as a residual synthetic contaminant. Although cAg toxicity was size-dependent at specific concentrations and time points, the most striking result is that parallel sizes of cAg and cAu induced significantly divergent toxic profiles, with the former being toxic and the latter inert at all sizes tested. Thus, we propose that nanoparticle chemistry is as, if not more, important than specific nanosizes at inducing toxicity *in vivo*. Ultimately, nanotoxicity assessments using the zebrafish embryo model should identify nanomaterial physicochemical characteristics that yield minimal or no toxicity for improved rational designs of nanomaterials.

PS 237 EXAMINATION OF POTENTIAL DERMAL IRRITATION FOR DIFFERENT SIZES OF METAL NANOPARTICLES.

D. R. Mattie, R. J. Godfrey, T. A. Bausman, M. J. Wagner, L. N. Talton, P. Gunasekar, K. Prabhakaran, N. M. Schaeublin and S. M. Hussain. *711 HPW/RHPB, Air Force Research Labs, Wright Patterson, OH.*

Nanoparticles can have properties different than larger sizes of the same material. Knowledge about potential health effects is limited. Exposure of skin to nanoparticles is possibly and could result in dermal irritation. In an effort to test nanoparticles in vivo while minimizing the number of rabbits used, nine nanoparticles were placed on the backs of 4 rabbits to determine if they cause skin irritation. The study followed the Environmental Protection Agency Health Effects Test Guidelines, Office of Prevention, Pesticides and Toxic Substances 870.2500, Acute Dermal Irritation, as the basic procedure. We determined the ideal number of sites when placing Hilltop Chambers on the skin is 8 sites per rabbit. Three other sites are used as a control with no chamber at all. Four rabbits were used to expose 9 nanoparticles, three times for each nanoparticle. A randomized rotation was employed to blind those reading the sites. Each of the 4 rabbits had at least one negative control site with a Hilltop Chamber only and seven sites with nanoparticles (six for one rabbit with two negative controls). Each nanoparticle site on each rabbit was a different nanoparticle so that each nanoparticle was still placed on 3 different rabbits. Nanoparticles used were suspended in 0.5 ml of saline: Aluminum (50, 80 nm); Silver with proprietary organic coating (10 and 80 nm); Silver without coating (10, 25, 80 nm); Tungsten (60 nm); and Aluminum Oxide (30 nm). After the 72 hour observation, skin was collected for histopathology. The results demonstrated that none of the nanoparticles tested produced skin irritation.

PS 238 LACK OF DERMAL PENETRATION FOLLOWING TOPICAL APPLICATION OF COATED AND UNCOATED NANO- AND MICRON-SIZED TITANIUM DIOXIDE TO INTACT AND DERMABRADED SKIN IN MICE.

N. V. Gopee[1], C. Cozart[1], P. Siitonen[1], C. S. Smith[2], N. J. Walker[2] and P. C. Howard[1]. *[1]National Center for Toxicological Research, Jefferson, AR and [2]National Institute for Environmental Health Sciences, RTP, NC.*

Dermal transport and possible toxicity of nanoscale metal oxides used in cosmetic and personal care products are relatively unexplored and is the focus of this study. We previously reported that ~10% and 6% of intradermally injected PEG-coated quantum dots (QDs) bioaccumulate in the liver and lymph nodes. The topical application of QDs to dermabraded skin resulted in accumulation of ~1% and ~0.1 % of the applied dose in the liver and lymph nodes, respectively. We also demonstrated that following intradermal injection, the biodistribution of three different types of TiO_2, uncoated nano, coated nano and micron, depended upon the size and coating properties. In that study an increase in titanium (Ti) in liver accounted for ~10% of injected dose of all three TiO_2, in lymph nodes the Ti accounted for ~1% of injected dose seen with coated nano and micron TiO_2, and Ti accumulated in kidneys exclusively with micron TiO_2 (~16% of dose). In the present study, emulsions containing 5% of either nanoscale (25 nm primary particle size) uncoated anatase TiO_2, micronscale anatase TiO_2 and nanoscale (14 x 79 nm rods) polystearate/alumina-coated TiO_2 were topically applied to intact dorsal or inguinal and axillary regions or to dermabraded skin of hairless mice. Lymph nodes, liver, spleen, kidneys and blood were collected at 6 and 24 hours post application and Ti levels were quantified by ICP-MS. No significant elevations in Ti levels were observed in all the organs analyzed for the three different TiO_2 formulations when applied to intact and dermabraded skin. The results suggest that both intact and compromised skin of hairless mice may be an effective barrier in preventing dermal penetration and subsequent organ bioaccumulation of topically applied nano-and micron-sized TiO_2 of different surface coatings.

These studies were supported by an IAG between the National Toxicology Program and FDA (IAG# 244-07-0007).

PS 239 PULMONARY RESPONSES TO DIESEL FUEL CATALYST CERIUM OXIDE NANOPARTICLES.

J. Y. Ma[1], H. Zhao[1], M. Barger[1], M. Rao[1], T. Meighan[1], V. Castranova[1] and J. Ma[2]. *[1]HELD, NIOSH, Morgantown, WV and [2]School of Pharmacy, West Virginia University, Morgantown, WV.*

Cerium oxide has been used as a fuel-borne catalyst to lower the mass of diesel exhaust particles (DEP), but is emitted as nanoparticles in the diesel exhaust. While the health effects of DEP have been investigated for decades, the potential pulmonary toxicity of cerium oxide nanoparticles has not been characterized. The objectives of this study were to investigate the effects of cerium oxide on the pulmonary immune/inflammatory responses. Rats (Sprague Dawley) were exposed to cerium oxide (0.5 to 20 mg/kg) by intratracheal instillation. Alveolar macrophages (AM) were isolated via bronchoalveolar lavage (BAL) the next day. Cerium oxide exposure was found to induce significant neutrophil infiltration and elevate lactate dehydrogenase activity and albumin content in the BAL fluid, suggesting that these particles induced inflammation, cytotoxicity and epithelial damage. The results also show a direct interaction of cerium oxide with AM, resulting in elevated AM phagocytic activity as monitored using confocal microscopy, increased reactive oxygen species production in response to zymosan challenge as indicated by enhanced chemiluminscence generation, and increased production of the pro-inflammatory cytokines IL-12 and TNF-α. However, cerium oxide significantly reduced nitric oxide production by AM in response to ex vivo LPS challenge, demonstrating that these particles may modify AM host defense capability. Analysis of mRNA levels of several genes using real time RT-PCR indicate that cerium oxide significantly increased suppressor of cytokine signaling and osteopontin (OPN) in BAL cells, while OPN was also increased in the lung tissue. When OPN was analyzed at 28 days post exposure, there was a further increase of mRNA in lung tissue. These results show that cerium oxide-mediated lung toxicity includes pulmonary inflammation and lung injury, and a persistent induction of OPN in lung tissue, which has been associated with lung fibrosis.

PS 240 BIODISTRIBUTION OF QUANTUM DOTS AFTER PULMONARY EXPOSURE IN RATS.

J. R. Roberts, D. Schwegler-Berry, R. Chapman, J. M. Antonini, J. Scabilloni, V. Castranova and R. R. Mercer. *HELD/PPRB, NIOSH, Morgantown, WV.*

The potential use of quantum dots (QD) as a medical diagnostic tool, as well as in other biomedical applications, has led to concern regarding their toxicity, potential systemic distribution, and biopersistence. In addition, little is known about workplace exposure to QD, such as research, manufacturing, or medical settings. We have shown that pulmonary exposure to functionalized QD caused a dose-dependent increase in lung injury and inflammation which persisted up to 28 days. The goal of the present study was to assess the biodistribution of QD in rats after pulmonary exposure. QD were composed of a cadmium-selenium (CdSe) core (~5nm) with a zinc sulfide (ZnS) shell functionalized with carboxyl (COOH-QD) or amine (NH_2-QD) terminal groups Male Sprague-Dawley rats were intratracheally-instilled (IT) with saline, COOH-QD, or NH_2-QD (12.5 μg/rat). On days 0, 1, 3, 7, 14, and 28 post-IT, the left lung, lung-associated lymph nodes (LALN), heart, kidneys, spleen, liver, brain, and blood were collected for metal analysis of Cd content by neutron activation. Right lungs from rats in each group were either subjected to bronchoalveolar lavage (BAL) to retrieve BAL fluid and cells for analysis of damage, or were preserved and sectioned for histopathology, confocal imaging, and autometallographic silver enhancement of Cd. No Cd was detected in the liver, spleen, heart, brain, or blood at any time point. At days 7 and 14, when lung injury and inflammation were at their greatest, approximately 3-5 % of the total Cd instilled was detected in the LALN of rats treated with COOH-QD, and approximately 10-20% was located in the kidney in these rats. By day 14, Cd was also found to be present in the kidneys of rats treated with NH_2-QD. Both forms of QD caused significant lung injury and inflammation, with particles present in alveolar macrophages, on epithelial surfaces, and in the interstitium, which persisted in the lungs up to 28 days post-exposure. QD are not readily cleared from the lungs after IT and translocation to other organs appears to be related to damage to the air-blood barrier.

PS 241 INVESTIGATION OF NANOPARTICLES-INDUCED TOXICITY USING CAENORHABDITIS ELEGANS FUNCTIONAL GENOMICS.

J. Choi and J. Roh. *Environmental Engineering, University of Seoul, Seoul, Korea, South.* Sponsor: D. Ryu.

In the present study, toxicity of nanoparticles (i.e. silver nanoparticle, fullerene, carbon nanotube) was investigated in Caenorhabditis elegans using functional genomic tools. Whole genome microarrays were used to screen for global changes in C. elegans transcription profiles following nanoparticle exposure and with subsequent quantitative analysis conducted on selected genes. The integration of gene expression with organism and population level endpoints was investigated using C. elegans functional genomics tool, to test the physiological relevance of nanoparticle-induced gene expression. Silver nanoparticle exerted considerable toxicity in C. elegans, observed most clearly as a dramatic decrease in reproduction potential after silver nanoparticle exposure. Significant decreases in reproduction parameter concomitantly occurred in silver nanoparticle exposed C.elegans. Overall results of functional genomic using mutant analysis suggested that the sod-3 and daf-12 genes may be related to silver nanoparticle -induced reproductive failure in C. elegans and that oxidative stress may be an important mechanism in nanoparticle -induced toxicity. This study also suggested that the interpretation of microarray and subsequent quantitative gene expression data was greatly strengthened by linking them with organism and population level experiments and functional genomics using mutant strains appears to be an ideal tool for biomarker discovery in toxicological research as it can reveal the physiological meaning or function of observed altered gene expressions. Acknowledgment: This work was accomplished through the supports of the Ministry of Environment as "The Eco-technopia 21 project"

PS 242 INVESTIGATION OF THE ROLE OF AIRWAY INFLAMMATION BY NANOPARTICLES IN RESPIRATORY ALLERGY INDUCED BY TMA.

H. Muijser[1], Y. Staal[1], J. van Triel[1], J. Arts[2] and F. Kuper[1]. *[1]Quality of Life, TNO, Zeist, Netherlands and [2]AkzoNobel T&E, Arnhem, Netherlands.* Sponsor: B. Blaauboer.

Nanoparticles are increasingly used in a wide range of applications, and may have a higher toxic potential than similar particles of larger sizes. Nanoparticles can induce inflammatory reactions in the lung and may thus interfere with existing allergic inflammation. Our study aimed to assess whether inhalation exposure to nanoparticles aggravated a respiratory allergic response in Brown Norway (BN) rats. The rats were topically sensitized to trimellitic anhydride (TMA) and were challenged by inhalation to TMA 14 days later. Next, animals were exposed by inhalation to carbon nanoparticles (about 30nm), aggregated carbon nanoparticles, fine carbon nanoparticles (about 300nm), multi-walled carbon nanotubes (MWCNT) or clean air 5 hours/day, 2 days/week during 3 weeks, and thereafter challenged with TMA again. The allergic rats exhibited an altered breathing pattern (apnoeas), and a slightly increased breathing frequency during challenge, allergic laryngitis and increased granulomatous inflammation in the lungs. Exposure to nanoparticle aggregates and fine particles induced accumulation of black particles in the larynx, lungs and mediastinal lymph nodes. Exposure to nanotubules induced black granula, tubules and tubular aggregates in the lungs only. Exposure to carbon nanoparticles or carbon particles did not aggravate the TMA-induced allergy. Therefore, it was concluded that nanoparticles or nanoparticle aggregates did not alter the allergic response against TMA in BN rats, despite the presence of distinct particle accumulation in case of the nanoparticle aggregates.

PS 243 PBPK MODELING OF MICRO AND NANO SIZED FLUORESCENT POLYSTYRENE SPHERES.

X. Chang[1], K. Sarlo[2], N. J. Walker[1], K. Blackburn[2], E. Clark[2], J. Chaney[2], J. Grothaus[2] and C. J. Portier[1]. *[1]NIEHS, Reseach Triangle Park, NC and [2]Miami Valley Laboratories, Procter & Gamble, Cincinnati, OH.*

To understand the kinetics of nanoparticles in comparison to that of chemically-identical larger particles, we developed a physiologically-based pharmacokinetic (PBPK) model for micro and nano sized fluorescent polystyrene spheres using distribution data in rats. Four differently sized spheres (1000, 100, 40, 20nm) were dosed to rats as a single intravenous (IV) injection or pharyngeal aspiration into the airways, and the subsequent tissue distribution was assessed. Using these data, a full tissue compartment model was constructed consisting of blood, lymphatic system and twelve tissue blocks, each described using diffusion-limited kinetics. The model was initially fit to the IV data on 1000nm spheres and applied to predict kinetics of the 3 nanosized spheres with same exposure route. The model successfully simulated the kinetics of 1000nm spheres. It also predicted tissue kinetics well from micro to nano in several major organs such as liver, lung, and heart. The model prediction suggested that compared to microspheres, the 40 and 20 nm spheres had a reduced distribution to the spleen and bone marrow and an increased distribution to the brain. However, it is unclear whether the slight increase in distribution to the brain for the small particles is real because the particle concentration in brain samples was near or below the limit of detection (<0.04% of total spheres). By re-optimizing certain parameters, we also fit the model to IV data on each of the 3 nanosized spheres respectively. The resulting model fit well for 100nm spheres, but was inadequate for 40 and 20nm spheres, for which further modifications of model structure may be needed. A comparison of model parameters optimized specifically for each sized particle indicated that the smaller particles tend to stay longer in blood circulation. Regardless of particle size, the estimated partition coefficients are always high for spleen and liver, but low for brain, suggesting a common kinetic mechanism of these particles in major organs.

PS 244 ALTERED GENE EXPRESSION PROFILES IN MURINE BRAINS FOLLOWING EXPOSURE TO INHALED NICKEL NANOPARTICLES.

P. Gillespie, G. Kang, T. Gordon and L. Chen. *New York University School of Medicine, Tuxedo, NY.*

The respiratory tract is the primary target for inhaled nanoparticles (NPs). However, there is evidence that once deposition occurs, these particles can escape clearance mechanisms and target secondary organs like the brain. The aim of this study was to examine the transcriptional response of three regions (olfactory bulb, midbrain, and cerebellum) in the mouse brain following exposures to inhaled nickel nanoparticles (Ni NPs). Utilizing a whole-body exposure system, C57 male mice inhaled either 100 μg/m3 of spark generated Ni NPs or filtered air for 5h/d, 5d/w, for up to 5m. The three regions were collected 1w, 3m, and 5m, post exposure (24h) for gene expression analyses (n=4/group). Since studies suggest that NPs damage tissue through oxidative stress and inflammatory mediated pathways, PCR profiling systems for both pathways were used to evaluate the change in expression of 168 genes in each region as compared to controls. A change of 3-fold or higher was considered important. After 1w of exposure, the expression of approximately 50 oxidative stress and inflammation related genes were altered in all regions. Following 3 and 5m of exposure, more changes in gene expression were observed in the olfactory bulb (85 and 72, respectively) followed by the cerebellum (35 and 45, respectively) and the midbrain (21 and 28, respectively). To confirm these results, individual real time RT-PCR was performed on selected genes: Mcp-1, Tnfα, Il-1b, Ho-1, and Gpx-1. Brain deposition of inhaled Ni NPs was determined for all regions, using graphite furnace atomic absorption spectroscopy. A significant difference was only observed for the olfactory bulb (n=8, $P<0.05$). These results suggest that all three regions are affected by exposures of inhaled Ni NPs via oxidative stress- inflammatory mediated pathways; but, the olfactory bulb may be a more sensitive target to adverse effects. Additional studies are needed to link the changes in gene expression to mechanisms of toxicity.

PS 245 POTENTIAL CARDIOVASCULAR EFFECTS OF FULLERENE C60 INHALATION EXPOSURE.

P. P. Simeonova[1], A. Erdely[1], A. Liston[1], M. I. Luster[1], J. Roycroft[2], D. Germolec[2] and N. J. Walker[2]. *[1]NIOSH, CDC, Morgantown, WV and [2]NIEHS, Research Triangle Park, NC.*

Fullerenes are forms of carbon nanomaterials used in a wide variety of commercial applications and have the potential for significant human exposure. Based on ambient ultrafine particle research, it is predicted that small particles may have systemic toxicity related to cardiovascular outcomes. This study evaluates the cardiovascular effects of subchronic inhalation exposure of B6C3F1 mice to C60 particles (diameter 1 and 0.05 μm). The initial screening for cardiovascular toxicity was conducted applying a custom-designed TaqMan array for genes known to play an important role in the mechanisms of atherosclerosis such as inflammation, oxidative stress, and coagulation. We observed changes on expression of several genes related to stress response, including c-fos, and heat shock protein (hsps) 25, 70, and 90 in the aortas of the exposed mice independent of the size of the particles. These findings were confirmed by a real-time RT-PCR. Hsps are incremental in triggering many autoimmune/chronic inflammatory diseases. In this regard, it has been suggested a multifaceted role for hsps in atherosclerosis. For example, it has been reported that the expression of hsps is upregulated very early at lesion-prone sites in the aortas of young apoE-/- mice. Thus, fullerene exposure of wild type mice, not prone to develop atherosclerosis, resulted in a cardiovascular stress response which may provide a predisposition to atherogenesis. **Disclaimer:** The findings and conclusions in this abstract are those of the authors and do not necessarily represent the views of the National Institute for Occupational Safety and Health.

PS 246 GOLD NANOPARTICLE (AUNP) SURFACE CHARGE INFLUENCES TOXICITY.

L. Truong[1, 2], S. Harper[1, 2], J. Miller[2, 3], J. Hutchison[2, 3] and R. Tanguay[1, 2]. *[1]Environmental & Molecular Toxicology, Oregon State University, Corvallis, OR, [2]The Oregon Nanoscience and Microtechnologies Institute and the Safer Nanomaterials and Nanomanufacturing Initiative, Pacific Northwest, OR and [3]3Department of Chemistry, University of Oregon, Eugene, OR.*

Nanoparticles can vary in size, chemical composition, surface chemistry and surface area. Small changes in these features impart different properties to a nanoparticle, including how they interact with and potentially influence biology. Early life stages are often sensitive to chemical insult, which make embryonic zebrafish as an ideal platform to investigate the biological activity and toxic potential of gold nanoparticles (AuNP). In initial studies, developmental responses to waterborne exposure to AuNPs were determined using a wide range of concentrations (0.016 to 250 µg/mL (ppm)). Cationic, N,N,N trimethylammoniumethanethiol (TMAT), and anionic, 2-mercaptoethanesulfonate (MES), AuNPs produced with a 1.5nm core size induced developmental toxicity in embryonic zebrafish. TMAT was more overtly developmentally toxic, while MES induced more sublethal effects at this developmental stage. The most susceptible early developmental stage to nanomaterial exposure was determined to be 24 hours post fertilization (hpf) and 48 hpf for TMAT and MES, respectively. Narrowing the window of exposure allowed for genomic evaluations to be conducted in order to determine gene expression responses to each AuNP exposure. Nimblegen zebrafish arrays with 37,157 genes were used with RNA isolated from embryonic zebrafish exposed to the lowest observable adverse effect (LOAEL) for TMAT (50ppm) and MES (10 ppm) at 24 and 48 hpf. The combination of these studies illustrates the value of the embryonic zebrafish model to determine structure activity relationship, and that the surface charge of AuNP influences biological responses. Supported by NIEHS P3000210, EPA RD-833320, T32 ES07060, and Air Force Research Laboratory under agreement # FA8650-05-1-5041.

PS 247 PULMONARY BIOASSAY STUDIES WITH SEPIOLITE NANOCLAY SAMPLES IN RATS.

D. B. Warheit, C. M. Sayes, M. Golt and K. L. Reed. *DuPont Haskell Lab, Newark, DE.*

Sepiolite is a magnesium silicate nanoclay mineral. A pulmonary bioassay toxicity study was conducted in male rats with sepiolite, PBS, quartz particles and ultrafine titanium dioxide particles. Following intratracheal instillation exposures at doses of 1 and 5 mg/kg, the groups were evaluated by bronchoalveolar lavage (BAL) at 24 hours, 1 week, 5 weeks, and 3 months postexposure. Results showed that quartz particles produced sustained, lung inflammation. Exposures to uf TiO2 particles, sepiolite or PBS produced transient lung inflammation. However, unlike the other particle-types, sepiolite clay exposures produced macrophage-agglomerates or giant cells, recovered in BAL fluids at 1 wk, 5 wk and 3 month postexposure time periods. The biological significance of these findings is unknown. Following the bronchoalveolar lavage procedure, the lungs of randomly selected rats were then infused with formaldehyde fixative. Lung tissues from PBS control, high-dose Min-U-Sil quartz, negative control ultrafine TiO2, low and high dose sepiolite-exposed rats at 3 months postexposure were then processed for lung tissue histopathological analyses. Sagittal lung sections were prepared for histology and evaluated by light microscopy. Histopathology results revealed that quartz particles produced foamy alveolar macrophage accumulation and patchy evidence of alveolar tissue thickening, indicating incipient phases of lung fibrosis. Exposures to the ultrafine TiO2 particles resulted in accumulation of phagocytic alveolar macrophages but no tissue thickening. Exposures to sepiolite particles produced evidence of multinucleated giant cells in airspaces and patchy evidence of minimal septal tissue thickening, suggesting the development of lung fibrosis. The severity and frequency of tissue thickening with sepiolite particle exposures appeared to be dose related. Follow-up, dedicated lung tissue histopathology studies currently are in progress to determine the reproducibility of this effect and the role of giant cells (if any) in producing minimal lung fibrosis following pulmonary sepiolite exposures.

PS 248 INFLUENCE OF PHYSICOCHEMICAL PROPERTIES OF NANO-SILICA PARTICLES ON *IN VIVO* TOXICITY.

T. Yoshikawa[1, 2], H. Nabeshi[1, 2], Y. Nakazato[1, 2], K. Matsuyama[1, 2], A. Arimori[1, 2], M. Isobe[1, 2], T. Imazawa[2], Y. Abe[2], H. Kamada[2, 3], N. Itoh[1, 2], S. Tsunoda[2, 3] and Y. Tsutsumi[1, 2, 3]. *[1]Graduate School of Pharmaceutical Sciences, Osaka University, Suita, Osaka, Japan, [2]National Institute of Biomedical Innovation, Ibaraki, Osaka, Japan and [3]The Center for Advanced Medical Engineering and Informatics, Osaka University, Suita, Osaka, Japan.* Sponsor: T. Yoshikawa.

Nanometer-size amorphous silica particles (nano-silica), which are used as functional additives in cosmetics and foods, have quickly become essential nanomaterials in our lives. With few exceptions however, there are insufficient data available on risk assessment of nano-silica. We therefore analyzed the influence of the physicochemical properties of nano-silica on acute toxicity. We have previously shown that injection of smaller nano-silica particles into mice induced acute toxicity as particle size decreased. In the present study, we used fluorescent-labeled nano-silicas whose surface was either unmodified or modified with -NH2 and -COOH (70-nm diameter, designated SP-plain, SP-NH2, and SP-COOH, respectively), to evaluate the influence of nano-silica surface properties on in vivo toxicity and distribution. Methods) Acute toxicity tests were performed according to the following procedures. BALB/c mice were injected with 2 mg of SP-plain, SP-NH2, or SP-COOH. Survival of SP-injected mice was monitored, and histopathology tests were performed twenty-four hours after SP-injection. For image analysis, hairless mice (Hos: HR-1) were injected intravenously with nano-silicas. At indicated time points, optical imaging was performed using a Xenogen IVIS 200 imaging system. Results and Discussions) A single intravenous injection of SP-plain induced acute lethal toxicity in mice. In contrast, injection of SP-NH2 and SP-COOH into mice caused little toxicity. In vivo optical imaging of the mice revealed that SP-plain had spread throughout the liver, whereas SP-NH2 and SP-COOH accumulated around the gallbladder. These results suggest that surface properties of nano-silicas were a critical factor for its liver accumulation and expression of toxicity.

PS 249 SYSTEMICALLY-INTRODUCED NANOSCALE CERIA BIODISTRIBUTION AND TOXICITY.

R. A. Yokel[1, 2], R. L. Florence[3], J. Unrine[4], M. T. Tseng[5], U. M. Graham[1], R. Sultana[1], D. A. Butterfield[6, 7], P. Wu[8] and E. A. Grulke[8]. *[1]Pharmaceutical Sciences, University of Kentucky, Lexington, KY, [2]Toxicology, U KY, LEX, KY, [3]Plant and Soil Sciences, U KY, LEX, KY, [4]Anatomical Sciences & Neurobiology, U of Louisville, Louisville, KY, [5]Center for Applied Energy Research, U KY, LEX, KY, [6]Chemistry, U KY, LEX, KY, [7]Center of Membrane Sciences, U KY, LEX, KY and [8]Chemical & Materials Engineering, U KY, LEX, KY.*

Objective: Characterize biodistribution and toxicity of nanoscale ceria that had entered blood. Rationale: Ceria was chosen as a model insoluble, stable, metal oxide tracer with extensive engineered nanomaterial (ENM) applications. Materials: A 5% crystalline aqueous ceria dispersion, mean size ~ 30 nm (PSD); primary size ~ 3 to 5 nm (HR-TEM); surface area ~13 m2/g. Procedures: The effect of saline and 10% sucrose on ceria agglomeration was assessed. Ceria was given to un-anesthetized rats i.v. (0, 50, 250 or 750 mg/kg) terminated 1 or 20 hr later to assess its biodistribution, by ICP-AES/ICP-MS cerium analysis, and potential to produce neurotoxicity, assessed by 4-hydroxy-2-nonenal (HNE), 3-nitrotyrosine (3-NT), and protein carbonyls in frontal cortex (FC), hippocampus (HC) and cerebellum (CB). Five min prior to termination anesthetized rats were given i.v. Evans blue (EB)-albumin and Na fluorescein (Na2F) as blood-brain barrier integrity markers. Results: Saline and 10% sucrose caused ceria agglomeration in vitro. Fresh blood incubated with ceria for 1 hr showed primary and agglomerated ceria by HR-TEM/STEM. Ceria $t_{1/2}$ in the rat was << 1 hr. Brain EB and Na2F increased. Tissue [Ce] was ceria dose-dependent (spleen > liver > brain > blood serum) and accounted for ~ 50% of the dose. 4-HNE increased in the HC; 3-NT changed little in FC, HC or CB; and protein carbonyls decreased in the CB. Conclusions: Ceria was cleared by peripheral tissues. Much less entered the brain. The results provide a foundation to study the impact of physico-chemical properties of ENMs on peripheral organ distribution, brain entry and resultant toxicity. Supported by the Office of the VP for Research, U KY and US EPA STAR Grant RD-833772.

PS 250 FATE OF ULTRAFINE (UFTIO2) OR FINE TITANIUM DIOXIDE (FTIO2) FOLLOWING INTRATRACHEAL INSTILLATION IN RATS.

T. M. Sager[1] and V. Castranova[2]. *[1]School of Public Health, Harvard University, Siler City, NC and [2]HELD, PPRB, NIOSH, Morgantown, WV.*

Nanotechnology is expanding due to the unique properties of nanoparticles. Studies report that pulmonary exposure to nano-sized particles may produce greater pulmonary effects than their larger fine–sized particle counterparts. However, differences in fate and clearance of inhaled nano-sized and fine-sized particles are unclear. This study explores differences in lung burden as well as translocation to the interstitium and the bronchial-associated lymphatic tissue (BALT) between rats exposed to UFTiO2 vs. FTiO2. Rats were exposed to an equal surface area dose of UFTiO2 or FTiO2 (0.52 mg/rat or 10.7 mg/rat, respectively). Metal analysis indicates that the amount of UFTiO2 remaining in the lung decreased by 51% from 7 to 42 days post-exposure, while the lung burden of FTiO2 decreased by only 12% . The amount of TiO2 present in the tracheo-bronchial (TBL) and thymic lymph nodes (TLN) was also assessed. Lymph node burden for UFTiO2 from 7 to 42 days post-exposure increased by 246%, while a 134% increase was observed for FTiO2. Although relative migration of UFTiO2 to the lymph nodes exceeded that for FTiO2, this difference could not account fully for the much lower lung clearance of

FTiO2 relative to UFTiO2, suggesting particle overload in rats exposed to FTiO2. Lung burden of TiO2 was measured in both lavaged and unlavaged lungs at 7 and 42 days post-exposure. The amount of TiO2 present in the lavagable fraction represents particles phagocytosed by lavagable alveolar macrophages or present as free particles in the airspaces. The non-lavagable UFTiO2 or FTiO2 fraction in the lung increased from 7 to 42 days post-exposure. With UFTiO2, the majority of the particles were non-lavagable, suggesting migration to the interstitium. In contrast, the majority of FTiO2 was found in lavagable alveolar macrophages. In summary, the results indicate that UFTiO2 migrates more rapidly to the interstitium than FTiO2 which is phagocytosed more avidly by alveolar macrophages.

PS 251 TOXICITIES OF NANOPARTICLES IN AN ENVIRONMENTALLY RELEVANT FISH MODEL.

J. Blatt Nichols[1], I. Wirgin[1], R. Chambers[2] and T. Gordon[1]. *[1]Environmental Medicine, NYU School of Medicine, Tuxedo, NY and [2]Howard Marine Sciences Laboratory, Northeast Fisheries Science Center, National Oceanic and Atmospheric Administration Fisheries Service, Highlands, NJ.*

Toxicities of aqueous suspensions of nanoparticles were tested in early life stages of an environmentally relevant fish species, *Microgadus tomcod* (Atlantic tomcod). Embryos were exposed to graded concentrations of nanoparticles which included: fullerenes, functionalized single-walled carbon nanotubes (SWNT) and metal oxides of silver, copper, iron, nickel and Zn (Ag, Cu, Fe, Ni and Zn). Also tested were manufactured nanoparticles consisting of a fullerene shell with erbium or yttrium metal catalysts derived from various stages in their production process including soot, sludge and the finished material. Particles were dispersed in 5 ppt artificial sea water or DMSO and sonicated for one hour. Exposure began at 14 days post fertilization and continued until death or hatching. Survivorship and hatching success were evaluated. Fullerene exposure resulted in 100% mortality at 500 μg/l while SWNTs did not induce significant changes in mortality or hatching. Mortality increased with graded doses of Cu, Fe and Zn while no changes in mortality or hatching were detected with Ag or Ni at concentrations up to 10 μg/ml. The finished manufactured nanoparticles caused dose responsive toxicities that were 100% lethal at 50 μg/ml. Soot and sludge particles with both erbium and yttrium resulted in dose dependent increases in mortality but erbium-containing particles were more toxic and caused 100% mortality at 10 and 50 μg/ml for soot and sludge, respectively. These results indicate that nanoparticles containing some metals (Cu, Fe, Zn) are toxic to fish embryos. Particles containing erbium and yttrium were more harmful than those containing only carbon. Fullerenes induced mortality in these embryos but SWNTs did not. Future studies will determine if these effects are modified by exposures in natural water samples of different salinities, are conserved in a second fish species, *Fundulus heteroclitus*, as well as attempt to elucidate mechanisms of toxicity.

PS 252 GOLD AND SILVER NANOMATERIALS REDUCE THE INFLAMMATORY RESPONSE TO INJURY.

K. S. Saili[1, 2], S. L. Harper[1, 2], K. P. Vercruysse[3] and R. L. Tanguay[1, 2]. *[1]Department of Environmental & Molecular Toxicology, Environmental Health Sciences Center, Oregon State University, Corvallis, OR, [2]Oregon Nanoscience & Microtechnologies Institute, Corvallis, OR and [3]Department of Chemistry, Tennessee State University, Nashville, TN.*

The role of inflammation in rheumatoid arthritis (RA) is well known. Inflammation has also been implicated in the pathogenesis of other chronic diseases including cancer. The widespread role of inflammation in disease underscores an urgency to identify new and improved anti-inflammatory treatments. Chrysotherapy, injection of gold (Au) salts, has been used for decades as a standard RA treatment despite an unclear mode of action. We tested the hypothesis that nanomaterials formed upon injection of Au ions are the primary agents responsible for reducing inflammation in patients undergoing chrysotherapy. The anti-inflammatory potential of Au and silver (Ag) nanomaterials produced in organic media was measured using a larval zebrafish inflammation model. An inflammatory response can be induced in zebrafish by amputating the caudal fin. We tracked inflammatory cells by exposing transgenic zebrafish with fluorescent neutrophils to nanomaterials in solution with neutral red, a macrophage stain. We pre-exposed 3 days post fertilization (dpf) larvae to Au or Ag nanomaterials for 18 hours, then amputated their caudal fins at 4 dpf followed by immediate immersion in NOAEC nanomaterial solutions. The total area of neutrophils at the site of injury 8 hours post amputation was measured. Nine of 14 nanomaterials reduced total neutrophil area at the amputation site. Of these, 4 Ag and 1 Au nanomaterial caused a greater than 40% reduction in neutrophils. We are currently quantifying macrophage responses and investigating potential mechanisms by which neutrophils are reduced. Elucidation of the in vivo mode of action of Au and Ag nanomaterials is anticipated to contribute to the development of novel anti-inflammatory therapies. Supported by NIEHS P3000210, EPA RD-833320, T32 ES07060, Air Force Research Laboratory under agreement #FA8650-05-1-5041, and the W.M. Keck Foundation.

PS 253 EVALUATION OF SIZE-DEPENDENT BIOLOGICAL BEHAVIOR OF NANO-SILICAS.

H. Nabeshi[1, 2], T. Yoshikawa[1, 2], K. Matsuyama[1, 2], Y. Nakazato[1, 2], A. Arimori[1, 2], M. Isobe[1, 2], T. Imazawa[2], Y. Abe[2], H. Kamada[2, 3], N. Itoh[1], S. Tsunoda[2, 3] and Y. Tsutsumi[1, 2, 3]. *[1]Graduate school of Pharmaceutical Sciences, Osaka university, Suita, Osaka, Japan, [2]National Institute of Biomedical Innovation, Ibaraki, Osaka, Japan and [3]The Center for Advanced Medical Engineering and Informatics, Osaka University, Suita, Osaka, Japan.* Sponsor: H. Nabeshi.

(Objective) Nanomaterials have recently been successfully employed in various industrial applications in medicine and cosmetics. Because nanometer-size amorphous silica particles have already been used as functional additives in cosmetics and foods, there is an urgent need for their risk assessment. We have here performed comparative toxicity studies of various sizes of silica particles (SP; SP70: 70 nm, SP100: 100 nm, SP300: 300 nm, SP1000: 1000 nm). (Method) We performed acute toxicity studies using intravenous injections of single doses (100 mg/kg) of SPs of various sizes, to evaluate their harmful effects in BALB/C mice. Six h after SP injection, serum was collected and subjected to analysis for markers of toxicity. Cytotoxicity of SP-treated HaCaT cells uated by [3H]-thymidine incorporation over 24 h. Furthermore, intracellular localization of SPs was analyzed by TEM. To analyze genotoxicity, we performed the alkaline comet assay and the Ames test. (Results and Disuccustion) Acute toxicity testing showed evidence of marked liver toxicity only in SP70- and SP100-injected mice; furthermore, SP70-injected mice died within 12 h after injection. In vitro, SP exhibited dose- and size-dependent cytotoxicity against HaCaT. TEM analysis revealed the entrance of SP70 into the nucleus. Therefore, evidence for genotoxicity of SP was investigated. When HaCaT were treated with 30 μg/ml SP for 3 h, DNA fragmentation was observed in all SP-treated groups. In the Ames test, SP treatment resulted in more than double the spontaneous mutation rate. In particular, SP70 exerted the strongest mutagenic effect. These results indicate that acute toxicity, cytotoxicity and genotoxicity tend to increase as particle size decreases.

PS 254 CLEARANCE OF THE VASCULAR INFUSED CERIUM OXIDE BY RETICULOENDOTHELIAL CELLS IN RAT.

M. T. Tseng[1], X. Lu[1], R. Florence[8], R. Sultana[5], P. Wu[7], D. A. Butterfield[5, 6], E. A. Grulke[7], U. Graham[4], J. Unrine[3] and R. A. Yokel[8, 2]. *[1]Anatomical Sciences & Neurobiology, U Louisville, Louisville, KY, [2]Toxicology, U KY, Lexington, KY, [3]Plant and Soil Sciences, U KY, Lexington, KY, [4]Center for Applied Energy Research, U KY, Lexington, KY, [5]Chemistry, U KY, Lexington, KY, [6]Center of Membrane Sciences, U KY, Lexington, KY, [7]Chemical & Materials Engineering, U KY, Lexington, KY and [8]Pharmaceutical Sciences, U KY, Lexington, KY.*

Objective: Biodistribution and biotransformation of the internalized nanoparticles (NP) is regulated by the strategically placed reticuloendothelial cells. The objective of this study is to determine the threshold level and time course of phagocytic cells responses in liver, lung, spleen and kidney after iv infusion of cerium oxide NP. Methods: Commercial cerium oxide from Sigma (primary particle size ≈30 nm) suspended in water was infused (50, 250, 750 mg/kg) in adult male Fischer 344 rat. They were terminated at 1 or 20 hr later. Tissue ceria level was determined by ICP-AES/ICP-MS and ROS related markers were assayed. Organs rich in RES as well as hippocampus and cerebellum were collected for histological and ultrastructural analysis. The latter included the use of HRTEM, STEM, and EDX for elemental detection of ceria. Results: A dose and time dependent retention of ceria was observed in peripheral organs, but, not in the brain. HRTEM reveal occasional ceria NP in capillaries and the associated astrocytes in the brain. By contrast, agglomerated ceria NP was abundant in the phagocytic cells of the RES. Cytotoxicity was occasionally observed in cells engulfed large NP aggregates, however, general cytoarchitecture was maintained. Conclusion: Vascular infusion of cerium oxide NP appeared to be relatively non-toxic in rat. RES cells provide the initial retention of ceria NP in a dose and time dependent fashion. However, the long-term consequences of the detained NP remain to be determined. Supported in part by the Office of the Vice President for Research, University of Kentucky and US EPA STAR Grant RD-833772.

PS 255 THE EFFECTS OF SUB-CHRONIC EXPOSURE TO INHALED NICKEL NANOPARTICLES ON THE CARDIOVASCULAR SYSTEM.

G. Kang, P. Gillespie, A. Gunnison, T. Gordon and L. Chen. *Environmental Medicine, New York University School of Medicine, Tuxedo, NY.*

As applications of nanotechnology continue to expand rapidly, there is an urgent need to evaluate the potential health effects of engineered nanoparticles (NPs) in occupational and environmental settings. Since there is a well-established association between inhaled ambient ultrafine particles and increased risk of cardiopul-

monary disease, it has been suggested that inhaled NPs may also induce similar effects on the cardiovascular system. This study was designed to determine if long-term exposure to inhaled nickel (Ni) NPs induced adverse effects on the cardiovascular system, resulting in exacerbation of atherosclerosis in a sensitive mouse model. Male ApoE knockout mice were exposed either to filtered air or Ni NPs at 100 μg/m3, 10% of the current occupational guideline, for 5h/d, 5d/wk for either 1 week or 5 months. Various indicators of oxidative stress and inflammation were measured in the lung and cardiovascular tissue, and plaque formation on the aorta was determined after 5m of exposure. The analyses of bronchoalveolar lavage fluid (BALF) revealed significant oxidative stress and pulmonary inflammation at both time points. This data was consistent with up-regulations of heme-oxygenase-1 (Ho-1), interleukin-6 (Il-6) and monocyte chemotactic protein-1 (Mcp-1) genes in the lung tissues. Those three genes were also up-regulated in the heart tissue after 5-m of exposure, suggesting systemic effects induced by inhaled Ni NPs. Furthermore, Mcp-1 was over-expressed in the aorta tissue, along with Cd68 and vascular cell adhesion molecule-1 (Vcam-1), after the 5-m exposure. This phenomenon coincides with increased plaque formation in the aortic arch, providing a molecular basis for the exacerbated atherosclerosis. These results suggest that inhaled Ni NPs, at occupationally relevant concentrations, can induce significant chronic effects on the cardiovascular system, including exacerbation of atherosclerosis. Further studies are needed to investigate potential mechanisms in which inhaled NPs could affect the cardiovascular system.

PS 256 SILVER NANOPARTICLE AND FULLERENE STUDIES WITH ADULT AND EMBRYONIC OYSTERS, CRASSOSTREA VIRGINICA.

A. Ringwood[1], M. McCarthy[1], D. Carroll[2], J. Berry[2] and N. Levi-Polyachenko[3]. *[1]Biology, UNC-Charlotte, Charlotte, NC, [2]Wake Forest University, Center for Nanotechnology and Molecular Materials, Winston-Salem, NC and [3]Wake Forest University Health Sciences, Winston-Salem, NC.*

The fate and effects of nanoparticles on aquatic organisms are important environmental concerns that must be addressed as the production and uses of nanoparticles continue to increase. The purpose of these ongoing studies is to characterize the toxicity of various nanoparticle preparations (silver nanoparticles and fullerenes) on oysters, Crassostrea virginica, a common estuarine species. As filter-feeders, oysters a very valuable model species for characterizing nanoparticle bioavailability and interactions with basic cellular processes. Laboratory exposure studies were conducted with adult and embryonic oysters as well as with isolated hepatopancreatic cells. The potential for hepatotoxicity was evaluated using a lysosomal destabilization assay, and lipid peroxidation assays were used to assess oxidative damage. For the embryo assays, newly-fertilized oyster embryos were exposed to the nanoparticles and then the percent normal development after 48 hours was assessed. We used these studies to address important issues, such as relative sensitivity of embryos compared to adults, tissue distribution, and cellular accumulation and effects. Generally, embryos tend to be slightly more sensitive than adults, and isolated hepatopancreas cells were similar in toxicity to the whole oyster studies. Fluorescent confocal microscopy and atomic absorption spectrometry were used to verify the accumulation of the nanoparticles inside hepatopancreas cells and embryos. Significant accumulation of fullerenes inside lysosomes was observed supporting the model that endosomal pathways are a likely mechanism of accumulation. For the Ag nanoparticles, significant relationships were observed between tissue Ag levels and toxicity. These kinds of basic studies are essential for addressing the potential impacts of nanoengineered particles on fundamental cellular processes as well as aquatic organisms.

PS 257 INTEGRATION OF GENOMIC AND PROTEOMIC BIOSIGNATURES IMPROVES THE DISCRIMINATION OF RESPONSE TO NANOPARTICLES IN A MOUSE MODEL.

B. Webb-Robertson[1], K. Waters[1], S. Varnum[1], J. Teeguarden[1], J. Jacobs[1], R. Zangar[1], E. Kisin[2], A. Murray[2], A. Shvedova[2] and J. Pounds[1]. *[1]Pacific Northwest National Laboratory, Richland, WA and [2]National Institute of Occupational Health and Safety, Morgantown, WV.*

Health risks associated with contact and consumption of nanomaterials is largely unknown and a topic of considerable interest to both manufacturers and consumers. We compared the pulmonary response to repeated exposure to single-walled carbon nanotubes, crocidolite asbestos, and ultrafine carbon black in a mouse model. Biological signatures of exposure were derived using both genome and proteome profiles though high-content analytical platforms, including microarray, global mass spectrometry-based proteomics, and multiplexed protein ELISA microarray. The goal of this study was to derive biomarkers of response from these data streams and to evaluate the screening potential of integrated biosignatures for hazard assessment. We developed a biosignature integration approach that fuses the multiple data sources at a molecular level. Probability models were derived for individual datasets by using partial least squares discriminant analysis and transformed into likelihood values associated with the probability that a particular sample was exposed to one of the defined particles or the control group. The screening potential of each biosignature was then assessed using the probability model to give insight into particle classes that biomarkers may be derived from each data source. Finally, Bayesian statistics were applied to the likelihood probability models to fuse all data streams into a single model. We find that the probability models associated with individual data types can only successfully separate less than 90% of the samples with cross-validation. However, the integrated probability model can nearly perfectly classify all samples. Using this approach, we identified a panel of biosignatures for each particle class with statistical power to predict response to particulates.
Supported by Environmental Biomarkers Initiative and ES016015

PS 258 POLYETHYLENE GLYCOL (PEG) NANOGEL AGGREGATE DRUG DELIVERY SYSTEM FOR TARGETED SYSTEMIC DELIVERY.

M. V. Deshmukh[1], H. Kutscher[1], D. Laskin[2], S. Stein[1] and P. Sinko[1]. *[1]Department of Pharmaceutics, Rutgers University, Piscataway, NJ and [2]Department of Toxicology, Rutgers University, Piscataway, NJ.*

The aim of this work is to develop a novel aggregated nanogel particulate (ANP) drug delivery system that targets the lung, liver or spleen using stable aggregates of a PEG nanogel. PEG nanogel particles were successfully formed by irreversibly cross-linking 8 Arm-PEG thiol polymer and a cross-linker (HBVS) in PB (pH 7.4). The effect of stirring time, cross-linker concentration, surfactant and sonication on particle size was systematically investigated. Additional experiments to grow the nanogels to micron-sized ANP were performed. Stability studies of ANPs were done at 37oC in rat plasma, PBS (pH 7.4) and PB (pH 7.4). Dynamic light scattering (DLS) and transmission electron microscope (TEM) were used for analyzing the size of ANPs. Among the parameters, sonication and the presence of surfactant (Tween 80, 0.1%v/v) were found to be critical for forming hydrogel nanoparticles. DLS and TEM results showed that after stirring the reaction mixture for a long time, the nanogel particles form aggregates due to hydrophobic interactions. Both small (20 nm) and large (≥1 μm) particles were observed in the reaction mixture. Stability studies indicated ANPs were stable in rat plasma, PBS and PB. Male Sprague-Dawley rats were intravenously administered with either HiLyte Fluor™ 750 dye alone (DYE) or ANPs covalently labeled with HiLyte750 (DYE-ANPs). Biodistribution of ANPs was determined using a Xenogen IVIS 100 Imaging System. DYE was quickly eliminated from the body, whereas DYE-ANPs accumulated in the lung within 30 minutes and the majority of the DYE-ANPs remained in the lung for 24 hours. In conclusion, these results show that it is feasible to produce nanosized PEG hydrogel particles and that these nanoparticulates can form stable micron-sized aggregates. The micron-sized ANPs are retained in the body for more than 24 hours and are predominately found in the lung.
Support: NIH/NIAMSD CounterACT Program (Award: U54AR055073)

PS 259 TISSUE-SPECIFIC ANTIOXIDANT RESPONSES OF OYSTERS, CRASSOSTREA VIRGINICA, TO SILVER NANOPARTICLE EXPOSURES.

M. McCarthy[1], D. Carroll[2], J. Berry[2] and A. Ringwood[1]. *[1]Biology, UNC-Charlotte, Charlotte, NC and [2]Wake Forest University, Center for Nanotechnology and Molecular Materials, Winston-Salem, NC.*

As nanoparticle technologies continue to grow, there is an increased potential of introduction of nanoparticles to aquatic environments. It is therefore important to characterize the potential risks to ecological receptors. Oxidative damage and impacts on antioxidant responses may impact the physiology and fitness of organisms directly, and may also increase their susceptibility to other stressors. Silver (Ag) nanoparticles are used extensively in clothing and other applications as an anti-microbial compound. The purpose of this ongoing work is to characterize the antioxidant-related responses of oysters (Crassostrea virginica) to Ag nanoparticle exposures. For these studies, gill and hepatopancreas tissues were removed from oysters following exposures to a range of Ag nanoparticle concentrations to evaluate tissue-specific antioxidant responses (e.g. glutathione and catalase concentrations). Gill and hepatopancreas tissues were also assessed for expression of metallothionein genes (MT I and II) using QT-PCR. Metallothioneins may play a dual role in ameliorating the adverse effects of metal nanoparticles by scavenging excess metal ions, and by functioning as an antioxidant by removing oxyradicals. Lipid peroxidation assays were also conducted to assess for evidence of tissue damage associated with oxyradial production. While the results indicated little direct tissue damage following short term exposures to Ag nanoparticles, tissue-specific alterations of antioxidant responses were observed.

PS 260 NICKEL (NI) NANOPARTICLE (NP) INHALATION INDUCE SERUM NEUROANTIBODIES IN C57 MICE: TIME RESPONSE TO 5 MONTH EXPOSURE.

H. A. El-Fawal[1], P. Gillespie[2], G. Kang[2] and L. Chen[2]. *[1]Albany College of Pharmacy and Health Sciences, Albany, NY and [2]NYU School of Medicine, Tuxedo, NY.*

Potential adverse health effects of nanotechnologies are of concern. Unlike other particles, NPs may gain access to the CNS causing toxic insult. Detection of antibodies to nervous system (NS) proteins in response to Ni-NPs following a 6 wk exposure was reported in mice. In the present study, 3 month old male C57 mice were exposed to 100 μg/m^3 of spark generated Ni NPs (GFG-100 Palas, Germany) or filtered air in a whole-body exposure system for 5h/d, 5d/wk for 1, 6, 15, 17, 20 and 23 wks. In addition, mice subjected to hypoxia (n=3) were a positive control. Particle size was measured by a differential mobility analyzer-condensation nucleus counter system and exposure concentrations determined gravimetrically. Facial vein bleeding was used for serum isolation. Antibodies, IgG, against neural proteins [neurofilaments (NF), glial fibrillary acidic protein (GFAP) and myelin basic protein (MBP)]were detected in sera using ELISA. Levels of IgG against neural proteins in controls (n=4-6/time point) were only marginally above the blocking-buffer blank. In Ni-NP exposed mice titers of IgG against NF proteins showed significant increases as early a 1 wk of exposure and were comparable to levels detected in hypoxic mice. IgG against GFAP were significantly elevated at 15 wks and for MBP at 15 and 17 wks. For anti-MBP these were comparable to hypoxic mice. Beginning at 17 wks, IgG against NF and MBP began to decline reaching control levels at 23 wks. This may reflect saturation of circulating IgG in the presence of elevated antigen. Declines in GFAP titers may reflect the occurrence of astrogliosis, rather than gliotoxicity after wk 15 and warrants investigation. The detection of neuroantibodies confirms earlier findings and suggests that Ni-NP exposure induces neurotoxicity. Ni is known to induce oxidative stress and mitochondrial dysfunction in other tissues. These mechanisms are also involved in neurodegeneration. In contrast to Ni salts, where neurotoxicity has not been reported, NPs may pose a risk to the NS.

PS 261 EXPOSURE ASSESSMENT AND HEALTH STATUS OF THE WORKERS HANDLING TITANIUM DIOXIDE.

G. Ichihara[1], W. Li[2], T. Kobayashi[3], X. Ding[2], Y. Fujitani[4], Y. Liu[2], U. Sai[1], N. Hata[1], Q. Wang[2] and S. Ichihara[5, 1]. *[1]Occupational and Environmental Health, Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Shanghai Institute of Planned Parenthood Research, Shanghai, China, [3]Tokyo Institute of Technology, Yokohama, Japan, [4]National Institute for Environmental Studies, Tsukuba, Japan and [5]Human Functional Genomics, Mie University Life Science Research Center, Tsu, Japan.*

Titanium dioxide is widely used as pigment, sunscreen or photocatalyst. The present study investigated possible respiratory and cardiovascular effects of titanium dioxide on workers handling them. Ambient exposure level in a factory handling titanium dioxide was assessed using condensation particle counter (CPC). Personal samplers were also used to weigh different sized titanium oxide particles. The workers were interviewed with questionnaire and examined by physicians. Chest X-ray, spirometer, echocardiogram and echocardiography were also conducted. The number of particle evaluated by CPC was 4.5 to 5 x 10^4 per cm^3, which was comparable to the number of particles evaluated by CPC in the office. The size-differentiating personal samplers showed that the weight density of the particles larger than 1 micrometer in the packing area was about 500 times greater than in the office. Granular shadows in the lung was found in one worker and aortic valve stenosis was found in another worker, but their association with exposure to titanium dioxide was not obvious. No lung fibrosis was detected by the chest X-ray. No abnormality in respiratory function was found by the spirometer testing. The particle number evaluated by CPC did not correspond with macroscopic dustiness which is thought to be associated with aggregated particles, as shown by size-differentiating impact separators. The present study did not show any respiratory or cardiovascular abnormality associated with titanium dioxide exposure for one to seven years.

PS 262 INFLAMMATORY EFFECTS OF AEROSOL EXPOSURE OF DIFFERENT TITANIUM DIOXIDE TYPES.

K. Savolainen, L. Pylkkänen, E. Rossi, J. Koivisto, M. Vippola, H. Wolff, S. Matikainen and H. Alenius. *Finnish Institute of Occupational Health, Helsinki, Finland.*

Titanium dioxide is widely used in the field of nanotechnology. The present study investigated inflammatory changes in the lungs induced by airway exposure to different TiO2 nanoparticles using mouse and cell models. BALB/c mice were exposed (for 2 hours, for 1 week, or for 1 month) by inhalation to the several different forms of TiO2. The commercial TiO2 materials studied were; coarse rutile, nano-sized rutile, nano-sized anatase and silicon coated nano-sized rutile. In addition, inhalation exposure was carried out with nano-sized TiO2 generated in a gas-to-particle conversion machine. Aerosol properties were characterized for size distribution, number concentration, mass concentration, surface area, and for shape and composition of agglomerates. Titanium concentration of the lung tissue was analyzed by Inductively Coupled Plasma Mass Spectrometry (ICP-MS). Inflammatory cell infiltration was characterized from bronchoalveolar lavage (BAL) fluid. Expression of cytokines and chemokines in the BAL cells and lung tissue was assessed by real-time PCR. In addition, effects of in vitro exposure of human macrophages to different TiO2 nanoparticles were assessed by ELISA. Exposure to TiO2 nanoparticles coated with amorphous silica elicited clear-cut pulmonary neutrophilia but no airway inflammation was observed after exposure to any other TiO2 materials tested. TiO2 particles accumulated exclusively to alveolar macrophages. Pulmonary neutrophilia was accompanied by the increased expression of TNF-alpha and CXCL1 (neutrophil attracting chemokine) in the lung tissue. In line with this, in vitro exposure of human macrophages to silica coated TiO2 elicited significant induction of TNF-alpha and neutrophil attracting chemokines, CXCL1 and CXCL8. Present results emphasize that it is vitally important to take into account that alterations of nanoparticles, e.g. by surface coating, may drastically change their toxicological potential.

PS 263 MANGANESE-30 AND ALUMINUM-80 NANOPARTICLES ALTER EXPRESSION OF OXIDATIVE STRESS-RELATED GENES IN MOUSE BRAIN.

M. Rahman[1], J. Wang[2], T. A. Patterson[1], G. D. Newport[1], J. J. Schlager[3], S. M. Hussain[3] and S. F. Ali[1]. *[1]Division of Neurotoxicology, NCTR, Jefferson, AR, [2]DDDP/OND/CDER/FDA, Silver Spring, MD and [3]AFRL/Wright-Patterson AFB, Dayton, OH.*

Nanoparticles (NPs) are small scale engineered materials (< 100 nm) with unique physical and chemical properties, however, their potential to produce toxicity has not been fully evaluated. Recently, we have reported that manganese, silver and copper nanoparticles induce expression changes in dopaminergic system-related genes in PC-12 cells. We have also shown that these NPs are capable of producing free radicals and oxidative stress. In this study we evaluated the effects of manganese-30 (Mn-30) and alumunium-80 (Al-80) nanoparticles in mice. Adult-male mice were injected (ip) with a 500 mg/kg single dose of Mn-30 or Al-80 and sacrificed 24 hours after the injection. Brains were quickly removed and dissected into caudate nucleus, frontal cortex and hippocampus, and real time RT-PCR analysis was performed using Mouse Oxidative Stress and Antioxidant Defense Arrays. In caudate, Al-80 up-regulated the expression of Aass, Als2, Apc, Aqr, Cat, Duox1, Ercc6 and Txnip; whereas Mn-30 up-regulated only the expression of Txnip. In frontal cortex, the expression of Nqo1 and Txnip was up-regulated and the expression of Txnrd3 was down-regulated after Mn-30 treatment. Al-80 down-regulated the expression of Gpx1, Prdx6-rs1, Ctsb, Cyba, Gpx2, Sod2, Noxo1, Zmynd17 and Nox1, and up-regulated the expression of Fmo2 in frontal cortex. In hippocampus, Mn-30 induced expression changes of 12 genes, in which Aass, Ncf2, Nxn, Txnip, Ucp3 and Gusb were up-regulated; and Atr, Gab1, Slc38a1, Slc41a3, Tmod1 and Gapdh were down-regulated. These data suggest that Mn-30 and Al-80 nanoparticles may produce dopaminergic neurotoxicity by generating free radicals and altering the expression of genes associated with oxidative stress and apoptosis.

PS 264 THE NAPHTHOL SELECTIVE ESTROGEN RECEPTOR MODULATOR (SERM), LY2066948 IS PRIMARILY OXIDIZED TO AN O-QUINONE ANALOGOUS TO THE NAPHTHOL EQUINE ESTROGEN, EQUILENIN.

T. B. Gherezghiher, J. Sohn, R. P. Chandrasena, Z. Qin, G. J. Thatcher and J. L. Bolton. *Medicinal Chemistry and Pharmacognosy, University of Illinois at Chicago, Chicago, IL.*

LY2066948 is a novel selective estrogen receptor modulator (SERM) which is in development by Eli Lilly for the potential treatment of uterine fibroids and myomas. LY2066948, in simile with the equine estrogen equilenin, contains a naphthol group expected to undergo oxidative metabolism to a naphthalene-3,4-diol. The 3,4-diol metabolite of equilenin, 4OH-EN, is a carcinogen that autoxidizes to a genotoxic and redox-cycling o-quinone. LY2066948 was synthesized and assayed for antiestrogenic activity and was confirmed to be a more potent antiestrogen than 4-hydroxytamoxifen, as measured by induction of alkaline phosphatase activity in Ishikawa endometrial cancer cells and ERE-luciferase expression in MCF-7 breast cancer cells. The naphthalene-3,4-diol metabolite of LY2066948 was indeed identified as an oxidative product in the model reaction with tyrosinase (phenol monooxygenase); interestingly, in the presence of ascorbate to prevent autoxidation, the 3,4-diol was formed quantitatively. Incubation of LY2066948 with tyrosi-

nase in the presence of GSH gave the expected GSH conjugates formed from trapping of the o-quinone, which were characterized by LC-MS-MS. In incubations with dexamethasone-induced rat liver microsomes, GSH conjugates were also observed, although in lesser amounts. In accordance, incubation with CYP450 3A4 supersomes gave only a very minor amount of naphthalene-3,4-diol metabolite. In simile with equilenin, LY2066948 is oxidized to a naphthalene-3,4-diol metabolite, that readily autoxidizes to an o-quinone that is a potentially cytotoxic electrophile, and redox-cycling genotoxin. Further studies are warranted to study this metabolite and validate its formation in vivo.

PS 265 AN APPROACH BASED ON LC/ESI-MS TO DETECT DIOL METABOLITES AS BIOMARKERS OF EXPOSURE TO STYRENE AND 1, 3-BUTADIENE.

S. Shen[1, 2, 3], F. Zhang[2], S. Zeng[1] and J. Zheng[2, 3]. [1]*Department of Pharmaceutical Analysis and Drug Metabolism, College of Pharmaceutical Sciences, Zhejiang University, Hangzhou, Zhejiang, China,* [2]*Center of Developmental Threapeutics, Children's Hospital Research Institute, Seattle, WA and* [3]*Department of Pediatrics, University of Washington, Seattle, WA.*

Styrene and 1,3-butadiene are important intermediates extensively used in the plastics industry. They are mainly metabolized through cytochromes P450-mediated oxidation to the corresponding epoxides, which are subsequently converted to diols by epoxide hydrolase or through spontaneous hydration. The resulting styrene glycol and 3-butene-1,2-diol have been suggested as biomarkers of exposure to styrene and 1,3-butadiene, respectively. Unfortunately, poor ionization of the diols within electrospray mass spectrometers becomes the obstacle to the detection of the two diols by LC/ESI-MS. We developed an LC/ESI-MS approach to analyze styrene glycol and 3-butene-1,2-diol by means of derivatization with 2-bromopyridine-5-boronic acid (BPBA), which not only dramatically increases the sensitivity of diol detection but also facilitates the identification of the diols. The analytical approach developed is simple, quick, and convincing without need of complicated chemical derivatization. In order to evaluate the feasibility of BPBA as a derivatizing reagent of diols, we investigated the impact of diol configuration on the affinity of a selection of diols to BPBA using the established LC/ESI-MS approach. We found that cis-diols showed higher affinity to BPBA than trans-diols and that the reactivity of vicinal diols to BPBA decreased with the increase in their molecular rigidity. In conclusion, BPBA may be used as a general derivatizing reagent for the detection of vicinal diols by LC/MS.

PS 266 QUINONE METHIDE: REACTIVE METABOLITE OF DAURICINE.

J. Zheng[1, 2], Y. Wang[3], D. Zhong[3], Q. Li[3] and X. Chen[3]. [1]*Department of Pediatrics, University of Washington, Seattle, WA,* [2]*Center for Developmental Therapeutics, Seattle Children's Hospital Research Institute, Seattle, WA and* [3]*Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, China.*

Dauricine (DRC), a bisbenzylisoquinoline alkaloid, has received great attention due to its wide range of pharmacological activities. Recently, we found DRC produced selective lung injury *in vivo*. In addition, the pulmonary toxicity was reversed by pretreatment with ketocanozole, a CYP3A inhibitor. This indicates that DRC-induced toxicity requires cytochrome-P450-mediated metabolic activation. With the structure of *para*-methylene phenol in DRC, we speculated that the alkaloid may be metabolized to a quinone methide intermediate. To clarify our speculation, we incubated DRC with mouse liver microsome in the presence of glutathione (GSH) as a trapping agent. A total of ten GSH conjugates were detected by LC-MS/MS using neutral loss, full scanning, and MS/MS scanning technique. One GSH conjugate with $[M+1]^+$ 930 m/z was found to be the major one among the ten GSH conjugates detected. We chemically synthesized the GSH conjugate which is designated as 10-glutathionyl DRC confirmed by LC-MS/MS and NMR. The formation of the GSH conjugates was found to require NADPH, and the absence of NADPH in these microsome incubations failed to produce any GSH conjugates after exposure to DRC. To identify those cytochromes P450 responsible for the bioactivation of DRC, we incubated DRC with a selection of individual recombinant human cytochrome P450 enzymes. Among the P450 enzymes tested, CYP3A4 is the only one found to catalyze the formation of the quinone methide metabolites. In addition, we incubated human liver microsome with DRC mixed with individual cytochrome P450 inhibitors. As expected, CYP3A4 inhibitor ketoconazole dramatically suppressed the formation of the quinone methide metabolites. We have fully identified a quinone methide metabolite derived from DRC. This facilitates the understanding of the biochemical mechanism of pulmonary toxicity by DRC.

PS 267 DIFFERENTIAL LOCALIZATION OF FLAVIN-CONTAINING MONOOXYGENASE ISOFORMS 1, 3, AND 4 IN RAT LIVER AND KIDNEY.

R. M. Novick[1], A. M. Mitzey[2], M. S. Brownfield[2] and A. A. Elfarra[1, 2]. [1]*Molecular and Environmental Toxicology, University of Wisconsin - Madison, Madison, WI and* [2]*Comparative Biosciences, University of Wisconsin - Madison, Madison, WI.*

Flavin-containing monooxygenases (FMOs) play a significant role in metabolism of drugs and endogenous or foreign compounds. In this study, the regional distribution of FMO isoforms 1, 3, and 4 were investigated in rat liver and kidney using immunohistochemistry (IHC). Rabbit polyclonal antibodies to rat FMO1 and FMO4, developed using antipeptide technology, and anti-human FMO3 antibody were used; specificities of the antibodies were verified using western blotting, immunoprecipitation, and IHC. The results show distinct localization patterns of FMO1, 3, and 4 in rat liver and kidney. In liver, the highest immunoreactivity for FMO1 and FMO3 was detected in the perivenous region and decreased in intensity toward the periportal region. In contrast, FMO4 immunoreactivity was detected with the opposite lobular distribution. In the kidney, the highest immunoreactivity for FMO1, 3, and 4 was detected in the distal tubules. FMO1 and FMO4 immunoreactivity was also detected in the proximal tubules with strong staining in the brush borders, whereas little FMO3 immunoreactivity was detected in the proximal tubules. Immunoreactivity for FMO3 and FMO4 was detected in the collecting tubules in the renal medulla and the glomerulus but little FMO1 immunoreactivity was detected in these regions. This data provides a compelling visual demonstration of the isoform-specific localization patterns of FMO 1, 3 and 4 in the rat liver and kidney. In addition to rat tissues, the FMO4 antibody reacted with mouse and human tissues, providing the first evidence for expression of FMO4 at the protein level in these tissues.

PS 268 *IN VITRO* CHARACTERIZATION OF HEPATIC EUGENOL AND METHYLEUGENOL BIOACTIVATION *VERSUS* DETOXIFICATION PATHWAYS.

C. Meredith, E. Massey and E. Minet. *Group R&D, British American Tobacco, Southampton, United Kingdom.*

Eugenol (CAS no. 97-53-0) is found in cosmetics, essential oils and herbal products and has been added to cigarettes as a constituent of cloves. The US NTP program reported "no evidence" of eugenol-induced carcinogenicity in rats, but "equivocal" evidence for tumor induction in female mice. Using *in vitro* tests for genotoxicity, eugenol has been demonstrated to be positive on occasions. In contrast, a variety of studies in animal models indicate that the structurally-related compound, methyleugenol (CAS no. 93-15-2), is consistently carcinogenic. To further understand the underlying mechanism of allylbenzene activation and detoxification, we have compared the oxidative and conjugative metabolism of eugenol and methyleugenol *in vitro*. Pooled human liver microsomes and S9 fractions were incubated with C^{14}-eugenol and C^{14}-methyleugenol (20 μM final, 1.5 μCi C^{14} per compound) in the presence of phase I and phase II enzyme co-factors. Soluble metabolites were quantified by radio-HPLC and identifed by co-elution with standards. Protein-bound metabolites were quantified following extraction of the insoluble fraction. CYP450-dependent formation of 1-hydroxy genotoxic precursors accounted for 19% and 5% of total eugenol and 30% and 37% of total methyleugenol in microsomes and S9 fractions respectively. Upon addition of glucuronide, eugenol was almost entirely conjugated and only traces of 1-hydroxy eugenol were observed (1% in the presence of S9). Glucuronidase treatment of these samples further confirmed that 1-hydroxy eugenol is a trace metabolite. In contrast, methyleugenol is not glucuronidated and formation of the 1-hydroxy metabolite remained at 37% of the initial dose. Our data indicate that methyleugenol metabolism leads to the accumulation of the 1-hydroxy genotoxic precursor, while eugenol metabolism to the 1-hydroxy compound is prevented by direct glucuronidation. The result supports the existing evidence for the genotoxicity of methyleugenol and the absence of genotoxicity for eugenol.

PS 269 COVALENT BINDING AND GLUTATHIONE DEPLETION: COMPARISON OF NON-CYTOTOXIC DIETHYL MALEATE WITH THE CLARA CELL TOXICANT, NAPHTHALENE.

D. M. Krawiec, D. Morin and A. Buckpitt. *VMB, UC Davis, Davis, CA.*

Naphthalene (NA) is a polycyclic aromatic hydrocarbon (PAH) known to elicit a cytotoxic response in nonciliated bronchiolar epithelial (Clara) cells of the murine lung. Doses of 150 mg/kg i.p. or 2 ppm via inhalation will result in the depletion of glutathione (GSH) and the covalent binding of NA reactive metabolites to macromolecular protein targets but the precise mechanisms by which NA injures

Clara cells remain unclear. Diethyl maleate (DEM) is a non-cytotoxic compound known to deplete GSH in a dose-dependent manner. A dose of 1000 mg/kg i.p. depletes GSH in the airway epithelium from a starting concentration of 24.4 nmoles/mg protein to 3.32 ± 1.92 (N=4) within 15 minutes, and GSH levels remain significantly depressed (p-value < 0.05) for at least 2 hours after dosing. The extent of depletion seen following this dose is similar to the extent of depletion seen from a 250 mg/kg i.p. dose of NA. The similarities in GSH depletion caused by DEM and NA combined with the fact that NA is toxic but DEM is not, suggested that comparative studies might reveal additional fundamental insights into the mechanism of NA toxicity. The studies reported here were designed to be comparative—using an ex vivo system to isolate the lung—with NA or DEM instilled via the trachea to interact with Clara cells. Doses of DEM and NA showing similar GSH depletion (100μM and 250μM, respectively) in this ex vivo lung preparation show similar levels of covalent binding: 0.44 ± 0.08 nmoles/mg protein (n=6) for DEM and 0.64 ± 0.13 (n=6) for NA, despite the disparity in toxicity. Additional work comparing the epithelial protein targets should reveal whether these are key differences in the non-toxic DEM and the cytotoxic naphthalene. Supported by NIEHS 04311 and 04699.

PS 270 COMPARISON OF METABOLISM OF INHALED GLUCOCORTICOIDS BY CYTOCHROME P450 3A ENZYMES AND IDENTIFICATION OF POTENTIALLY TOXIC METABOLITES.

C. R. Orton[1, 2], T. Murai[3], R. M. Ward[2] and G. S. Yost[1]. *[1]Pharmacology and Toxicology, University of Utah, Salt Lake City, UT, [2]Pediatric Pharmacology Program, University of Utah, Salt Lake City, UT and [3]Drug Metabolism and Pharmacokinetics Research Laboratories, Daiichi-Sankyo Co., LTD., Tokyo, Japan.*

Asthma is a chronic inflammatory disease of the airways estimated to affect 20.5 million Americans (6.2 million children under 18 years). Inhaled glucocorticoids are the bastion of asthma treatment while it is estimated approximately 30% of all asthmatics have some degree of steroid resistance. Glucocorticoids are metabolized by members of the cytochrome P450 (P450) 3A family of enzymes primarily in the liver and lung. The major goal of this research is to determine how metabolism of glucocorticoids by P450 3A enzymes could have an effect on their efficacy in asthmatic patients. We compared the metabolism of five therapeutically relevant glucocorticoids using in vitro incubations of each with either P450 3A4, 3A5, or 3A7. Predicted P450 metabolites were identified for each drug using selected ion monitoring (SIM) HPLC-MS/MS. All previously reported metabolites, as well as several unreported were identified. These included potentially reactive intermediates that include alkane dehydrogenation products and epoxides that could be toxicologically significant. These intermediates were verified with glutathione (GSH) trapping. Additionally, comparing metabolism of the five drugs across the different isoforms showed significant differences between the rates at which metabolites are formed by each P450 3A isoform. These differences in metabolism could become important factors in determining the most effective glucocorticoid asthma treatment.

PS 271 COMPARISON OF BIOCHEMICAL ANALYSIS TO GENE EXPRESSION AND LASER SCANNING CYTOMETRY FOR THE ASSESSMENT OF RAT HEPATIC CYTOCHROME P450 (CYP) ENZYME INDUCTION.

L. M. Fasulo, S. J. Schomaker, A. M. Ryan, J. M. Kreeger, C. Okerberg, A. C. Shen, A. B. Jakowski, J. M. Wolfgang, P. J. Small, C. A. Tabor, B. Lu and M. P. Lawton. *Drug Safety Research & Development, Pfizer Inc., Groton, CT.*

The purpose of this study was to compare 2 *ex vivo* methods, gene expression (GE) and laser scanning cytometry (LSC), against traditional biochemical (BC) methods to evaluate hepatic CYP induction in male rats exposed to xenobiotics. Sprague-Dawley rats were dosed with either 5-pregnen-3β-ol-20-one-16α-carbonitrile (PCN, 50mg/kg, 5 days), isoniazid (ISO, 100mg/kg, 4 days), β-naphthoflavone (β-NF, 100mg/kg, 4 days), phenobarbital (PB, 100mg/kg, 5 days), dexamethasone (DEX, 50mg/kg, 5 days), or 1-aminobenzotriazole (AMB, 100mg/kg, 2 days). All compounds are known CYP inducers except for AMB which is an inhibitor of cytochrome P450. Corresponding control groups received equivalent volumes of the appropriate vehicle. Upon completion of the dosing phase, animals were sacrificed, livers were removed and sectioned, and either processed for histological examination and LSC or frozen for BC and GE analysis. The isozymes evaluated in all three procedures were CYP1A1, 2B, and 3A. CYP1A2 was evaluated by GE and BC only. Since CYP2E protein is regulated by post-translational modification, it was evaluated by LSC and BC only. GE data matched 100% of the isozymes detected by BC for β-NF (1A1, 1A2, 3A, 2B) but only 50% for PB (3A, 2B), PCN (1A1, 3A), ISO (1A1, 2B) and DEX (3A, 2B). LSC data matched 100% of the isozymes detected by BC for ISO (1A1, 3A, 2E, 2B), 75% for PCN (1A1, 3A, 2B) and β-NF (1A1, 3A, 2B), 50% for PB (3A, 2B) and only 25% for DEX (3A). Both GE and LSC data showed 100% false positive results for the inhibitor, AMB. These data suggest that measuring functional protein via traditional biochemical methods, provides a more complete and detailed assessment of rat hepatic CYP induction than measuring either mRNA levels via GE or protein levels via LSC methods. While gene expression and laser scanning cytometry have utility for CYP assessment in vivo, biochemical methods remain the gold standard.

PS 272 MECHANISM-BASED INACTIVATION OF CYTOCHROME P450 3A4 BY RETRONECINE-TYPE PYRROLIZIDINE ALKALOIDS.

J. Dai[1, 2] and J. Zheng. *[1]Center for Developmental Therapeutics, Seattle Children's Hospital Research Institute, Seattle, WA and [2]Department of Pediatrics, University of Washington, Seattle, WA.*

Retrorsine and monocrotaline are two representative retronecine-type pyrrolizidine alkaloids known to be hepatic and pulmonary toxins, respectively. It has been documented that their toxicities are attributed to metabolic activation by cytochromes P450 to form dehydrogenerated reactive intermediates which, in turn, produce toxicities possibly by covalent binding to macromolecules. The objective of this study is to determine whether retrorsine and monocrotaline irreversibly inactivate P450s as mechanism-based inactivators. We examined the inhibitory effects of retrorsine and monocrotaline on human P450s 1A2, 2A6, 2B6, 2C9, 2C19, 2D6, 2E1, and 3A4. Retrorsine showed time-dependent inhibition on P450 3A4 in the presence of NADPH, but no such inhibition was observed on the other P450 isoenzymes tested. Unlike retrorsine, monocrotaline failed to inhibit P450 3A4. Further studies showed that the activity loss of P450 3A4 by retrorsine metabolism was in a concentration-dependent way, which was not recovered after equilibrium dialysis. The presence of dextromethorphan, a P450 3A4 substrate, protected the enzyme from the inactivation by retrorsine. Exogenous nucleophile glutathione (GSH) and reactive oxygen species scavengers catalase and superoxide dismutase could not protect P450 3A4 from the inactivation. Both retrorsine and monocrotaline were found to be metabolized to the corresponding electrophilic intermediates trapped by GSH. In conclusion, retrorsine is a mechanism-based inactivator of P450 3A4, but monocrotaline failed to show such inhibition, even it is metabolically activated.

PS 273 IDENTIFICATION OF HUMAN CYTOCHROME P450 ENZYMES INVOLVED IN THE METABOLISM OF IN-1130, A NOVEL ALK5 INHIBITOR.

Y. W. Kim, D. Kim, Y. J. Chung, I. Y. Cho and Y. Y. Sheen. *Pharmacy, Ewha Womans University, Seoul, seoul, Korea, South.* Sponsor: J. Chung.

We have investigated the pharmacokinetics and metabolism of 3-((5-(6-methylpyridin-2-yl)-4-(quinoxalin-6-yl)-1H-imidazol-2-yl)methyl)benzamide (IN-1130); a novel ALK5 inhibitor, which suppresses renal and hepatic fibrosis, and also exerts anti-metastatic effects on breast cancer-bearing MMTV-cNeu mice model. We have identified the cytochrome P450s (CYPs) responsible for metabolism of IN-1130 in liver microsomes of rat, mouse, dog, monkey and human, and in human CYP supersomesTM, using specific CYP inhibitors. The order of disappearence of IN-1130 in various liver microsomal systems studied was as follows: monkey, mouse, rat, human, and dog. Five distinct metabolites (M1-M5) were identified in all the above microsomes and their production was substantially inhibited by CYP inhibitors such as SKF-525A and ketoconazole. Among nine human CYP supersomesTM examined, CYP3A4, CYP2C8, CYP2D6*1, and CYP2C19 were involved in the metabolism of IN-1130, and the production of metabolites were significantly inhibited by specific CYP inhibitors. IN-1130 disappeared fastest in CYP2C8 supersomes. CYP3A4 produced four metabolites of IN-1130 (M1-M4), whereas supersomes expressing human FMO cDNAs, such as FMO1, FMO3, and FMO5, produced no metabolites. Hence, we conclude that metabolism of IN-1130 is mediated by CYP3A4, CYP2C8, CYP2D6*1, and CYP2C19.

PS 274 COMPARISON OF SEMIEMPIRICAL AM1, PM3, AND SAM1, AND A DENSITY FUNCTIONAL THEORY METHOD TO PREDICT ACTIVATION ENERGIES OF CYTOCHROME P450-MEDIATED HYDROXYLATION OF ALIPHATIC SUBSTRATES.

A. N. Mayeno[1], J. L. Robinson[1, 2], R. Yang[1] and B. Reisfeld[1, 2]. *[1]Environmental & Radiological Health Sciences, Colorado State University, Fort Collins, CO and [2]Chemical & Biological Engineering, Colorado State University, Fort Collins, CO.*

Predicting the biotransformation of xenobiotics can be useful in estimating the toxicity and efficacy of drugs and other chemicals. Here, we present results extending the rapid methodology of Korzekwa *et al.* (*J. Am. Chem. Soc.*, 112, 7042-7046, 1990) in estimating the activation energy of hydrogen-abstraction by cytochrome

P450 (CYP) enzymes, where the *p*-nitrosophenoxy radical is used as a simple surrogate for the CYP active oxygen species. The activation enthalpy is estimated with a linear regression model using the reaction enthalpy and ionization energy (of the substrate radical) as predictor variables, calculated by semiempirical (SE) quantum chemical methods. While Korzekwa *et al.* used the SE method AM1, we apply PM3 and SAM1, and compare the results of the three methods. For 20 diverse substrates, the AM1-, PM3-, and SAM1-derived regression models showed R^2 values of 0.93, 0.93, and 0.96, respectively. The range of estimated activation enthalpies was similar for AM1 and PM3, but shifted toward lower values for SAM1, with substrates of different chemical classes sometimes ordered differently by the different methods. AM1, PM3, and SAM1 reaction enthalpies were substantially different from those determined by density functional theory (DFT), suggesting inaccuracies in the SE-calculated heats of formation. AM1, PM3, and SAM1 transition structures were compared and differences in geometry were found for certain substrates. Because AM1, PM3, and SAM1 calculations can differ from those of DFT for radical reactions, predictive models developed using semiempirically-derived predictors may be subject to further improvement. (This study was supported, in part, by NIEHS grant K25 ES012909.)

PS 275 FUNCTIONAL CHARACTERIZATION OF CYTOCHROME P450 3A37 FROM TURKEY LIVER WITH AFLATOXIN B1 OXIDIZING ACTIVITY.

S. Rawal and R. A. Coulombe. *Toxicology Graduate Program, Utah State University, Logan, UT.*

In humans, hepatic cytochromes P450 (CYP) 1A2 and 3A4 bioactivate aflatoxin B1 (AFB1) to exo-AFB1-8,9-epoxide (AFBO) which is a requisite step in the toxic and carcinogenic action of this mycotoxin. We previously demonstrated that the extreme sensitivity of turkeys to AFB1 is associated with efficient hepatic epoxidation by CYP3A4 and CYP1A2 homologues. Heterologously expressed turkey CYP1A5 metabolizes AFB1 to AFBO and the detoxified metabolite aflatoxin M1 (AFM1) as human CYP1A2. Turkey CYP3A37 cloned from liver RNA was 76% identical to human CYP3A4, and the E. coli expressed protein CYP3A37 possessed metabolic similarities to human CYP3A4. Like CYP3A4, CYP3A37 efficiently metabolized AFB1 to exo-AFBO and the detoxified metabolite aflatoxin Q1 (AFQ1). Formation of exo-AFBO was inhibited by the specific CYP3A4 inhibitor 17α-ethynylestradiol (IC50 = 40.18 μM), while prototype inhibitors to other mammalian isoforms (1A2, 2D, 2E and 3A1) either slightly inhibited this activity, or not at all. Like its human homologue, CYP3A37 also had nifedipine oxidase activity. Polyclonal anti-CYP3A37 antibody directed against specific active-site peptides inhibited both AFBO formation and nifedpine oxidase activity. The comparative kinetic constants for exo-AFBO formation of expressed CYP3A37 and CYP1A5 (Km and Vmax: 16.79 ± 5.1 μM and 1.17 ± 0.082 nmol min-1 nmol-1 P450; 65 ± 12μM and 0.61 ± 0.037 nmol min-1 nmol-1 P450, respectively), lead us to believe that CYP3A37 may predominate over CYP1A5 in AFB1 bioactivation in turkey liver. Supported by National Research Initiative Grants no. 2002-35204-12294 and 2006-04819 from the USDA.

PS 276 PHOSPHORYLATION OF SERINE-10 IN HISTONE H3 IS A CRITICAL MARK ESSENTIAL FOR INDUCTION OF THE CYP1A1 GENE BY THE ACTIVATED AH RECEPTOR.

C. Ma, M. Schnekenburger, Y. Xia and A. Puga. *Environmental Health, Kettering lab, Cincinnati, OH.*

Metabolic bioactivation of polycyclic and halogenated aromatic hydrocarbons, such as benzo[a]pyrene and 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), is catalyzed by a cytochrome P450 monooxygenase encoded by the substrate-inducible Cyp1a1 gene. Cyp1a1 induction requires trans-activation by the heterodimeric transcriptional complex formed by the liganded Ah receptor (AHR) and its partner, ARNT. Previously, we have shown that Ah receptor ligands also activate signal transduction pathways, although the molecular mechanisms by which these pathways may contribute to AHR activation and the ensuing toxicity have yet to be defined. TCDD induces in Hepa-1 mouse hepatoma cells the immediate activation of extracellular signal-regulated kinases (ERKs) and Jun N-terminal kinases (JNKs), two members of the mitogen-activated protein kinase (MAPKs) family involved in modulation of transcription factor activity and regulation of gene expression. Here we find that Cyp1a1 induction by the AHR/ARNT is associated with modification of specific chromatin marks, including hyperacetylation of histone H3K14 and H4K16, trimethylation of histone H3K4, and phosphorylation of H3S10. Chromatin immunoprecipitation studies show that the phosphorylation of Ser-10 in histone H3 is linked to the recruitment of AHR to the Cyp1a1 promoter. Specific pharmacological inhibitors of the ERK (extracellular signal regulated kinase) and the JNK (Jun N-terminal kinase), but not as much of the p38 MAP kinase, block the AHR-dependent phosphorylation of this serine residue and the transcriptional induction of the Cyp1a1 gene. These results show that by modification of histone marks, MAP kinases play a central role in the regulation of Cyp1a1 expression that does not involve phosphorylation events directed to the AHR itself, underscoring the requirement for a concerted series of chromatin remodeling events to complete the initial steps of gene trans-activation by the Ah receptor(Supported by NIH R01ES6273, NIH R01ES10807, and NIH P30 ES06096).

PS 277 CYP1A, 1B, AND 1C GENE EXPRESSION AND EROD ACTIVITY IN RAINBOW TROUT GILL FILAMENTS - INDUCTION IN LABORATORY AND IN FIELD.

M. Jönsson, J. Olsson and I. Brandt. *Environmental Toxicology, Uppsala University, Uppsala, Sweden.* Sponsor: M. Hahn.

The fish gill is highly exposed to waterborne chemicals and is potentially useful in environmental monitoring. EROD activity is a biomarker for exposure to AhR agonists. The EROD reaction is catalyzed by CYP1A and other CYP1 enzymes. In fish four CYP1 subfamilies are present - CYP1A, 1B, 1C, and 1D, and rainbow trout (Onchorhyncus mykiss) have two known CYP1 genes, CYP1A1 and 1A3. The aims of this study were to identify other CYP1 subfamily genes in rainbow trout, to establish methods for quantitative expression analysis (qPCR) of these genes and to study CYP1 gene induction along with EROD induction in gill filaments. Three CYP1B- and 1C-like gene products were cloned from rainbow trout. QPCR primers were designed and tested for these sequences (putatively CYP1B1, 1C1, and 1C2), the CYP1As, β-actin and EF1α. Finally CYP1 expression was quantified in gill filaments of rainbow trout exposed (24 h) to waterborne 3,3',4,4',5-polychlorinated biphenyl (PCB126; 10 nM) or acetone (20 ppm; carrier), or kept in cages (2 days) at 3 sites in the Uppsala region (immediately downstream from the Uppsala STP outlet, at a marina, and in a reference lake). The cloned nucleotide sequences showed a close similarity to CYP1B1, 1C1 and 1C2 in other fish. All CYP1 genes studied (including the cloned ones) were induced by PCB126. Generally CYP1A1, 1A3, and 1C1 showed a higher level of expression in the caged fish than in unexposed fish, whereas CYP1B1 and 1C2 were not induced in field. Fish caged at the STP showed a higher level of CYP1A1 and 1A3 than fish from the reference lake. EROD induction was observed in PCB126-exposed fish as well as in all caged fish. Conclusions: The predicted protein sequences of the cloned genes indicate that they belong to the CYP1B and 1C subfamilies. The fact that they were induced by PCB126 suggests AhR regulation. The generally low levels in unexposed fish may imply that rainbow trout CYP1s have a low constitutive expression. This study was founded by the MistraPharma Program, The Swedish Research Council Formas, and Carl Trygger's Foundation.

PS 278 ALTERATION OF THE PHARMACOKINETICS OF RUTAECARPINE AND ITS METABOLITE BY PHENOBARBITAL IN RATS.

J. Choi, J. Kim, Y. Seo, S. Shin, M. Kang, Y. Jahng and T. Jeong. *Pharmacy, Yeungnam University, Gyeongsan, Gyeongbuk, Korea, South.*

To investigate the possible interaction between rutaecarpine and phenobarbital in rats, phenobarbital in saline at 80 mg/kg was given ip to male SD rats for 3 consecutive days. Saline was given to control animals. One day after phenobarbital pretreatment, rutaecarpine at 16 mg/kg was administered through penile vein. Blood was collected and analyzed by using HPLC. The pharmacokinetic parameters were determined with the non-compartmental model. Pre-treatment with phenobarbital significantly altered the pharmacokinetic profiles of rutaecarpine and its metabolite, 10-hydroxyrutaecarpine. The AUC of rutaecarpine was reduced to approximately 50% of control and the plasma half-life of rutaecarpine was significantly shortened when compared with control. In addition, the Cmax of 10-hydroxyrutaecarpine was increased approximately 160% of control. The AUC and the plasma half-life of 10-hydroxyrutaecarpine were decreased to 76.9% of control and to 82.7 min from 175.9 min, respectively. The results suggested that phenobarbital might accelerate the metabolism of rutaecarpine, thereby changing the pharmacokinetic parameters of rutaecarpine in male SD rats. (Supported by a grant from the Korea Research Foundation)

PS 279 CYP 450 DEPENDENT BIOACTIVATION OF XENOBIOTICS INTO TOXIC METABOLITES: AN *IN VITRO* APPROACH.

P. Grossi, L. Vignati, A. Moscone, D. Pezzetta and M. Brughera. *Preclinical Development, Accelera - Nerviano Medical Sciences srl, Nerviano, Milano, Italy.*

Many of the adverse drug reactions observed in the clinic can be caused by the activation of drugs into reactive intermediates or metabolites by cytochrome P450 (CYP). In the last few years, several in vitro tools have being developed to facilitate metabolism-mediated toxicity studies. In order to reduce late attrition due to P450 metabolism-dependent toxicity and to improve safety of drug candidates, we developed two in vitro cell-based assays by combining an activating system (human CYPs) with target cells (HepG2 cells): in the first method we incubated microsomes containing cDNA-expressed CYPs together with HepG2 cells; in the second

approach HepG2 cells were transiently transfected with CYP3A4 or CYP2E1. Both assay systems were used to study CYPs substrates known for their potential to form metabolites that exhibit higher toxicity than the parent compounds. Results demonstrated that both assay systems are capable to metabolize the test compounds leading to increased toxicity, compared to their respective control systems. The co-incubation with CYPs inhibitor confirmed that the formation of reactive metabolites was CYPs dependent. These in vitro tools to screen for metabolic activation, or de-activation are considered useful, rapid and relatively inexpensive for the prediction of CYPs metabolism-mediated toxicity.

PS 280 *IN VITRO* AND *IN VIVO* METABOLISM OF ARQ 501 (β-LAPACHONE) IN HUMANS.

R. E. Savage, X. Miao, P. Song, T. Hall, Y. Wang, C. Zhong, R. Yang, H. Wu, J. Lapierre, D. Kizer, M. A. Ashwell, T. C. Chan and R. Goldstein. *Preclinical Development, ArQule, Inc., Woburn, MA.*

ARQ 501 is a fully synthetic version of the natural product β-lapachone and has shown promising anticancer activity in clinical trials. The studies presented here were designed to characterize phase I and phase II metabolism of ARQ 501 in humans. LC/MS/MS analysis was employed to profile metabolites in vitro from human blood, microsome, and hepatocyte samples as well as in vivo from plasma samples obtained from treated patients. Where feasible, metabolites were confirmed with synthetic standards. Human metabolite profiles obtained from patient plasma revealed that hepatic phase II metabolism was the dominant pathway with both sulfation and glucuronidation products being present. However, in vitro metabolism of ARQ 501 by human hepatocytes occurred solely via glucuronidation. Additionally, a novel in vivo glucosylsulfate metabolite of ARQ 501 which was not present in vitro was identified. Studies exploring extrahepatic metabolism as a potential cause for these differences are ongoing. Results from in vitro experiments of ARQ 501 in human blood demonstrated evidence for metabolism of ARQ 501 by red blood cells (RBC).

PS 281 CHARACTERIZATION OF A NOVEL CYTOCHROME P450, CYP2S1 USING A PROTEIN EXPRESSED FROM A SYNTHETIC GENE.

P. H. Bui[1, 2] and O. Hankinson[1, 2]. [1]*Pathology of Laboratory Medicine, University of California, Los Angeles, Los Angeles, CA and* [2]*Molecular Toxicology IDP, University of California, Los Angeles, Los Angeles, CA.*

CYP 2S1 was recently identified in the human and mouse and shown to be inducible by dioxin, polycyclic aromatic hydrocarbons (PAHs), and hypoxia. Induction by dioxin and PAHs is mediated by the Aryl Hydrocarbon Receptor (AHR). In the human, CYP2S1 is highly expressed in epithelial cells of tissues that are exposed to the environment, such as the skin, and the respiratory and intestinal tracts. However, the biological function of CYP2S1 has yet been determined. We are investigating its possible role in xenobiotic and carcinogen metabolism using an in vitro approach. Obtaining a large quantity of active enzyme for in vitro substrate screening has been challenging. We encountered difficulties in obtaining heterologous expression of CYP2S1 in mammalian cells and bacteria. For example, the bacterially expressed material contained large amounts of inactive CYP2S1 (more than 70% of CYP2S1 was present as P420, an inactive form of P450) that compromised activity and substrate characterization. Recently, a synthetic gene approach has been introduced to improve heterologous gene expression. Using this strategy we successfully overexpressed CYP2S1 in an E. coli. Synthetic CYP2S1 gene expression was 4- to 5- fold higher than that of the native gene and it yielded more than 90% active CYP2S1 (accessed by the presence of P450). In addition, synthetic gene expression has enabled us to purify the CYP2S1 with high yield, (12 nmoles per milligram), which is sufficient for crystallization for structural studies. Furthermore, using the purified synthetic CYP2S1 protein, we have demonstrated its ability to metabolize a wide variety of substrates, including several carcinogenic PAHs. However, the biological role of CYP2S1 in metabolizing these substrates will need to be confirmed in vivo.

PS 282 MICE LACKING THE GENE FOR CYTOCHROME P450 (CYP)1A2 DISPLAY INCREASED LEVELS OF F2-ISOPROSTANES, OXIDATIVE DNA ADDUCTS, AND AUGMENTED SUSCEPTIBILITY TO HYPEROXIC LUNG INJURY.

B. Moorthy[1], L. Wang[1], X. I. Couroucli[1], G. Zhou[2] and W. Jiang[1]. [1]*Pediatrics, Baylor College of Medicine, Houston, TX and* [2]*Insitute of Biotechnology, Texas A&M University System, Houston, TX.*

Supplemental oxygen therapy is frequently administered to infants having pulmonary insufficiency. However, hyperoxia contributes to bronchopulmonary dysplasia (BPD) in infants. In this study, we tested the hypothesis that mice lacking the gene for CYP1A2 would display increased susceptibility to hyperoxic injury in vivo, a phenomenon that would be accompanied by augmented levels of F2-isoprostanes and oxidative DNA adducts in livers and lungs of these animals. Twelve week-old male wild type (WT) (C57BL/6J) mice or mice lacking the gene for CYP1A2 were exposed to hyperoxia (greater than 95% O2) or room air for 24-72 h. The CYP1A2 (-/-) mice were more susceptible to lung damage than similarly exposed WT animals. Seventy-two hours of hyperoxia caused significant (1.5-2 fold) increases in F2-isoprostanes in liver and lung of WT animals, compared to room air controls, as determined by GC/MS. In the CYP1A2 (-/-) mice exposed to hyperoxia, the F2-isoprostane levels in lung and liver were enhanced 5-fold compared to room air controls. Oxidative DNA adducts, as determined by 32P-postlabeling, were augmented in the lungs of WT and CYP1A2 (-/-) mice exposed to 72 h of hyperoxia, compared to room air controls, with CYP1A2 (-/-) mice showing a greater degree of enhancement. The major DNA adducts were derived from cyclopurine dinucleotides (e.g., AcA, GcA) or from F2-isoprostanes. Our results indicate that hepatic CYP1A2 enzyme plays a protective role in hyperoxic lung injury. The positive correlation between lipid peroxidation product levels (e.g., F2-isoprostanes), oxidative DNA adducts, and extent of lung injury suggests that both lipid peroxidation and oxidative DNA damage contribute to lung injury, and that CYP1A2 enzyme protects against injury by detoxifying lipid hydroperoxides. Further studies could lead to the development of novel strategies for the prevention/treatment of BPD in infants. (Supported by HL087174.)

PS 283 ETHANOL METABOLISM AND RELATED CYTOTOXICITY IN AR42J CELLS.

K. K. Bhopale, G. Ansari and B. S. Kaphalia. *Pathology, The University of Texas Medical Branch, Galveston, TX.*

Alcoholic chronic pancreatitis (ACP) is one of the major public health problems that causes significant morbidity and mortality. Due to the lack of a suitable model, the underlying mechanism of ACP is poorly understood. Using alcohol dehydrogenase (ADH)-deficient rat pancreatic tumor (AR42J) cells and human hepatocellular carcinoma (HepG2 cells), we have reported earlier that cytotoxicity of ethanol is associated with the formation of nonoxidative metabolites of ethanol, fatty acid ethyl esters (FAEEs). To determine the role of ethanol metabolism in ethanol-induced acinar cell injury, we incubated ethanol (800 mg%) with AR42J cells pretreated with inhibitor of all the ADH isozymes or class I and II ADH [1,10 phenonthroline or 4-methylpyrazole (4-MP), respectively], cytochrome P450 2E1 (sodium azide) or catalase (1,2-dichloroethylene), and evaluated the formation of total FAEEs and resultant cytoxicity after incubation at 37C for 6 hr. Significant increases in the formation of FAEEs were observed in the cells incubated with 1,10-phenonthroline (~2-fold) and 4-MP (~1.4-fold) vs. control. A significant cell death by ethanol was observed in the cells pre-incubated with 1,10-phenonthroline vs. 4-MP. Inhibition of ADH isozymes by 1,10-phenonthroline probably impairs ADH-catalyzed ethanol oxidation and facilitates the formation of FAEEs as an alternative mechanism for ethanol disposition. Our results suggest that impaired ADH (as reported in chronic alcohol abuse) could be a key factor for the ethanol metabolism via nonoxidative pathway(s) and resultant cytotoxicity. Further studies to determine the underlying mechanism(s) of ethanol-induced pancreatic acinar cell injury are in progress.

PS 284 DIFFERENTIAL EXPRESSION OF FIVE CYP1 MRNAS IN RESPONSE TO PCB126 IN FUNDULUS HETEROCLITUS.

J. Zanette[1, 2], M. J. Jenny[2], B. R. Woodin[2], J. V. Goldstone[2], L. A. Watka[3, 2], A. C. Bainy[1] and J. J. Stegeman[2]. [1]*Biochemistry, Universidade Federal de Santa Catarina, Florianopolis, SC, Brazil,* [2]*Biology, Woods Hole Oceanographic Institution, Woods Hole, MA and* [3]*University of Massachusetts Dartmouth, North Dartmouth, MA.*

The identification and characterization of new cytochrome P450 (CYP)genes, particularly in family 1, provides insight into the evolution of detoxification/bioactivation mechanisms of organic contaminants (e.g., PCBs and PAHs). Degenerate primers were designed to amplify new CYP1s (1B1, 1C2 and 1D1) from Fundulus heteroclitus, a frequently used model organism in environmental studies. Full-length sequences were obtained by RACE PCR and assignment to specific CYP1 subfamilies was confirmed by phylogenetic analysis. F. heteroclitus were injected with PCB126 (31 nmol/g fish) or DMSO (control). Expression levels of CYP1A, 1B1, 1C1, 1C2 and 1D1 were analyzed by real-time RT-PCR in eight organs (liver, gill, testis, gut, brain, eye, kidney, heart). CYP1A was the most abundant transcript in liver and gut, and CYP1D1 was most abundant in heart, kidney, eye, brain, gill and testis. The higher levels of CYP1D1 in most of the organs suggest there may be

physiological roles for this gene in fish. Higher levels of CYP1B1 mRNA were observed in heart, eye and brain, and the highest levels of the CYP1Cs were observed in testis. PCB126 induced expression of CYP1A and 1B1 in all organs, while 1C1 was induced in all organs except testis. Although the CYP1Cs had similar transcript profiles in the different organs of control fish, CYP1C2 was less responsive to PCB126 compared to CYP1C1. Interestingly, CYP1D1 was not induced by PCB126 in any of the organs. The most significant changes in Cyp1 expression in response to PCB126 was CYP1C1 (~1000-fold) in liver, followed by induction of CYP1A (~500-fold) in testis. CYP1B1 in liver and gut, CYP1A1 in brain and CYP1C1 in gill were also strongly induced (~100-fold). The differential response of CYP1s in response to PCB126 could improve sensitivity in the use of CYP1s as biomarkers of aquatic contamination employing F. heteroclitus.(NIH 5P42ES007381 and 1R01ES015912)

PS 285 CELL CYCLE PROGRESS AND APOPTOSIS ARE INTERRELATED IN CELLS TREATED WITH TOXIC CHEMICALS.

R. N. Ghosh and S. J. Hong. *Thermo Fisher Scientific, Rockford, IL.* Sponsor: A. Barchowsky.

Normal cells progress through the cell cycle free of anomalous events affecting cell growth and proliferation. In contrast, when cells suffer a toxic insult or stress, the cell cycle is often stalled while the stressed cell recovers from the damage. However, if the damage is too severe to rescue the stressed cells, cell death can occur. Because cell proliferation and apoptosis processes are closely linked, we propose that the simultaneous monitoring of these events in cells will provide insight on specific mechanisms involving cell cycle arrest and cell death progression. We developed a quantitative cell-based imaging assay that simultaneously monitors multiple indicators of both cell cycle (cell number, BrdU incorporation, DNA content) and cell death (cell loss, nuclear morphology, p53 induction, and caspase 3 activation). To test our hypothesis, we quantitatively measured these different cell cycle and apoptosis features in a range of cancer cells treated with Actinomycin D. We found that Actinomycin D causes cell cycle arrest as an early event and then induces apoptosis through caspase 3 activation. Because the multiplexed assay enables identification of drugs that either induce cell cycle arrest or induce cell death, we also tested our hypothesis on other compounds that may result in either outcome. We found that okadaic acid, arsenite, camptothecin and etoposide inhibit cell cycle and activate cell death mechanism through p53 and caspase 3. In conclusion, we simultaneously quantified cell cycle and apoptosis features under different conditions and drug treatments and found that the cell cycle arrest and apoptosis progress occurs as interrelated events in response to various cytotoxic insults.

PS 286 CHARACTERIZATION OF THE CYTOTOXIC PATHWAYS ACTIVATED BY AMIODARONE AND ITS MAJOR METABOLITE DESETHYLAMIODARONE.

J. E. Black, J. F. Brien, W. J. Racz and T. E. Massey. *Pharmacology & Toxicology, Queen's University, Kingston, ON, Canada.*

Amiodarone (AM) is a potent antidysrhythmic agent associated with several adverse effects, one of which is potentially life-threatening pulmonary fibrosis. The mechanisms involved in amiodarone-induced pulmonary toxicity (AIPT) have yet to be fully elucidated. Desethylamiodarone (DEA) is a primary metabolite of AM and may contribute to the pathogenesis of AIPT. The objective of this study was to characterize the cytotoxic pathways activated by AM and DEA using the HPL1A human peripheral lung epithelial cell line as a model of target cells in AIPT. Determination of apoptotic cell death was achieved by annexin-V-FITC staining with flow cytometric analysis and detection of activated caspase-3 was measured by immunoblotting. Necrotic cell death was determined by propidium iodide staining, followed by flow cytometric analysis. Treatment with 20 μM AM for 24 h increased the percentage of necrotic cells from 10.8% (control) to 81.4%, but decreased the percentage of apoptotic cells from 9.1% (control) to 1.9% ($p<0.05$). In contrast, treatment with 3.5 μM DEA for 24 h increased the percentage of cells exhibiting necrosis from 10.8% (control) to 20.5%, and increased the percentage of apoptotic cells from 9.1% (control) to 21.5% ($p<0.05$). Treatment with DEA, but not AM, increased intracellular levels of activated caspase-3. In addition, DEA induced cell death at an earlier timepoint and at lower concentrations than AM, confirming that DEA is a more potent cytotoxicant than AM. Hence, despite a difference of only one ethyl group in chemical structure, AM activates primarily necrotic pathways, whereas DEA activates both necrotic and apoptotic pathways. In view of these results, therapeutic treatments targeting AIPT will have to address cell death pathways initiated by both AM and DEA. (Funded by CIHR Grant No. MOP-13257).

PS 287 PROFILING ENVIRONMENTAL CHEMICALS IN APOPTOSIS PATHWAY USING A HIGH-THROUGHPUT FORMAT.

M. Cho[1], R. Huang[1], K. Leister[1], K. L. Witt[2], C. S. Smith[2], J. Inglese[1], R. R. Tice[2], C. P. Austin[1] and M. Xia[1]. *[1]NIH Chemical Genomics Center, Bethesda, MD and [2]National Toxicology Program (NTP), National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

Caspases, a family of cysteine proteases, play a critical role in apoptosis, a form of programmed cell death involved in embryonic development, homeostasis, and the pathology of many diseases. There are two characterized apoptotic pathways, extrinsic and intrinsic; the target of a toxic insult determines the pathway activated. Caspase 9 is an initiator of the intrinsic pathway, while caspase 8 is an initiator of the extrinsic pathway. Both these caspases activate downstream caspases 3 and 7, which then cleave other protein substrates within the cell, resulting in apoptosis. To evaluate the potential for environmental chemicals to activate apoptosis, we screened an NTP library of 1408 compounds in assays measuring the activity of caspases 3/7, 8, and 9. The assays were optimized and validated in Jurkat cells in a 1536-well plate format using quantitative high-throughput screening (qHTS)(1). Screening results confirmed the activity of several compounds known to induce caspase 8 or 9. For example, staurosporine stimulated caspase 9, while Trail and human Fas ligand activated caspase 8, all in a concentration-dependent manner. We also identified several other compounds that stimulate these caspases. Some compounds activated caspase 3/7 through the caspase 8 pathway, others through caspase 9, and others through both caspases 8 and 9. The data generated from this screening provide important information for further understanding the ability of environmental chemicals to stimulate the apoptosis pathway. Inglese et al. 2006. Proc Natl Acad Sci USA 103:11473.

PS 288 FASL AND TRAIL GENE-DEFICIENT MICE SHOW ALTERED SPERMATOGENESIS AND DIFFERENTIAL SENSITIVITY TO MEHP-INDUCED GERM CELL APOPTOSIS.

Y. Lin[1], P. Yao[2] and J. H. Richburg[1,3]. *[1]College of Pharmacy, University of Texas at Austin, Austin, TX, [2]Cell and Molecular Biology, The University of Texas at Austin, Austin, TX and [3]Center for Molecular and Cellular Toxicology, The University of Texas at Austin, Austin, TX.*

FasL and TRAIL are ligands of the TNF protein superfamily and are expressed in the testis by Sertoli cells and implicated in the control of germ cell apoptosis. However, neither the physiological function, nor the functional involvement of these ligands in toxicant-induced germ cell apoptosis is clearly established. Here we report the testicular phenotype of FasL and TRAIL gene-deficient mice (FasL-/-, TRAIL-/-, respectively). Evaluation of young peri-pubertal (28-day-old) FasL-/- and TRAIL-/- mice show increased germ cell apoptotic rates (20.58% and 21.54%) as compared to the C57BL/6J wild-type strain (5.16%). The testis of FasL-/- mice show a higher level of TRAIL protein expression by western blot analysis, while TRAIL-/- mice show an increase in FasL expression, suggesting that these proteins may compensate for each other. Histological analysis of testis cross sections reveals abnormal germ cell development in young FasL-/- mice. The testis of young TRAIL-/- mice show an overt meiotic arrest of spermatocytes. In adult, 44-day-old FasL-/- and TRAIL-/- mice, a decrease in mature spermatid formation occurs (reduced to 51% and 39%). Surprisingly, exposure of young FasL-/- mice to the Sertoli cell toxicant mono-(2-ethylhexyl) phthalate (MEHP) caused a decrease in the basal germ cell apoptotic rate, whereas a slight increase was observed in TRAIL-/- mice. Interestingly, the expression of c-FLIP, a protein modulator of death receptor activation, was rapidly and strongly induced after MEHP exposure in young FasL-/- mice, while its expression was only gradually increased in the testis of TRAIL-/- mice. Taken together, these data point to disparate functional roles for FasL and TRAIL in spermatogenesis and in triggering germ cell apoptosis after MEHP injury. It is hypothesized that c-FLIP serves as the mechanism that distinguishes the biological pathways influenced by FasL and TRAIL.

PS 289 A MAVERICK ROLE FOR HAIRLESS ON THE REGULATION OF APOPTOSIS.

C. O'Driscoll[1], D. L. Gorsche[2] and J. P. Bressler[1,2]. *[1]Division of Toxicological Sciences, Department of Environmental Health Sciences, Bloomberg School of Public Health, Baltimore, MD and [2]Hugo Moser Research Institute at Kennedy Krieger, Baltimore, MD.*

Although hairless (hr) is widely expressed throughout the body its effects have only been well characterized in the skin and hair follicle. It has been observed that hr KO mice exhibit accelerated brain aging, but the mechanism behind this increased vulnerability has not been elucidated. This study explores the role of hr both in vitro in

P19 cells and in vivo in the brains of wildtype (hr+/hr+), heterozygous (hr+/hr-) and KO mice (hr-/hr-). Exposure of the P19s to cadmium, mercury and apoptosis inducers (staurosporine and thapsigargin) increased the expression of hr. Transfection of the P19s with a plasmid which over expresses hr significantly increased the proportion of cells which survive these chemical insults. Cytochrome C was also retained within the mitochondria and the expression of BCL2 was increased when compared to control transfected cells. In situ hybridization revealed widespread endogenous expression of hr in the brains of 7 day old wildtype mice. The highest levels were in the cerebellum and hippocampus but lower levels were also detected in the cortex and optic nerve. Subcutaneous injections of ethanol (5 mg/kg) were administered to 7 day old mice to induce apoptotic neurodegeneration. Postmortem examination of the brain tissue revealed increased apoptosis in both the heterozygous and KO mice compared to the wildtype mice, this increased apoptosis was confirmed by western blotting, caspase activity assay and immunocytochemistry. These findings indicate that hr plays a greater regulatory role in cell cycle and apoptosis than was previously recognized.

PS 290 BCL-XL ATTENUATES BAX-INDUCED INHIBITION IN MITOCHONDRIAL RESPIRATION AND CALCIUM RELEASE OF PRIMARY CULTURE ASTROCYTES.

D. J. Dorta[1, 2], A. V. Teles[2], R. P. Ureshino[2], G. S. Lopes[2], Y. Hsu[3] and S. S. Smaili[2]. *[1]Chemistry, Faculty of Philosophy, Sciences and Letters of Ribeirão Preto - University of São Paulo, Ribeir√£o Preto, SP, Brazil, [2]Pharmacology, Federal University of São Paulo, S√£o Paulo, S√£o Paulo, Brazil and [3]Biochemistry and Molecular Biology, Medical University of South Carolina - USC, Charleston, SC.*

Apoptosis is a natural cell elimination process involved in a number of physiological and pathological events. This process can be regulated by members of the Bcl-2 family. Bax, a pro-apoptotic member of this family, accelerates cell death, while the pro-survival member, Bcl-xL, can antagonize the pro-apoptotic function of Bax to promote cell survival. In the present study, we have evaluated the effect of Bcl-xL on Bax-induced alterations in mitochondrial respiration and calcium release. We found that in primary cultured astrocytes, recombinant Bcl-xL is able to antagonize Bax-induced decrease in mitochondrial respiration when stimuled with an ATP regenerative system. We also confirm its ability to inhibit Bax-induced calcium release previous shown by our group. The present result argue in favor of an interaction between the two proteins and indicate that this interaction may contribute to the anti-apoptotic property of Bcl-xL.

PS 291 EFFECTS OF THE COFFEE DITERPENE KAHWEOL ON THE INDUCTION OF APOPTOSIS IN HUMAN LUNG ADENOCARCINOMA A549 CELLS.

H. Kim and H. Jeong. *BK21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South.*

The coffee-specific diterpenes kahweol have been reported to be protective against various type of cancer. Animal data support such a chemopreventive effect of coffee. However, the precise underlying protective mechanisms are poorly understood. In this study, we investigated the effects of kahweol on cell cycle progression and induction of apoptosis in human lung adenocarcinoma A549 cells. Our results show that treatment with kahweol results in a significant inhibition of cell proliferation in a dose-dependent manner and causes apoptotic death in human lung adenocarcinoma A549 cells. We found that kahweol inhibits considerably the expression of Bcl-2 whilst increasing that of Bax; it also stimulates the cleavage of caspase-3 and PARP (poly ADP-ribose polymerase). In addition, kahweol-induced apoptosis was confirmed by TUNEL assay. Furthermore, kahweol inhibited dose-dependent signal transducer and activator of transcription 3 (STAT3) phosphoryation. These findings suggest that kahweol induced apoptosis via down-regulation of STAT3 signaling pathway.

PS 292 BDO2 INDUCED APOPTOSIS IN PROSTATE CANCER CELLS IS MEDIATED BY THE ANDROGEN RECEPTOR.

S. Koppula[1], M. Tan[3], W. Gray[1, 2] and A. Hurst[1, 2]. *[1]Environmental Toxicology, Southern University, Baton Rouge, LA, [2]Chemistry, Southern University A & M, Baton Rouge, LA and [3]Biology, Southern University A & M, Baton Rouge, LA.*

Both animal and human population studies suggest a correlation between reproductive carcinogenicity and 1,3 Butadiene (BD) exposure. However, the direct effects of BD on reproductive tissue in cell culture models have not been fully investigated. The current study examines the effect of Butadiene-diepoxide BDO2, the metabolite of BD on prostate cell culture. The aim of the study was to investigate the mechanism of BDO2-induced cytotoxicity and assertain the involvement of the androgen receptor (AR) in this process. Our objective was achieved by determining the cytotoxicity of BDO2 in AR+ LNCaP and AR- DU-145 prostate cancer cells using tryphan blue dye exclusion and cell viability MTT assay. We determined whether the AR was playing a role in mediating cytotoxicity by transfecting DU-145 cells with pCMV-hAR expression plasmid. PSA secretion and its RNA expression,the pre-apoptotic (Bax) and anti-apoptotic (Bcl2) protein levels were examined in the absence and prescence of functional AR. We observed a dose-dependent modulation in Bcl2/Bax ratio in AR+ LNCaP and AR- DU-145 cells. Tryphan blue exculsion experiment showed a slight increase in cell death in both LNCaP and DU-145 cells treated with BDO2. The MTT assay indicated that BDO2 induced 20-30% cell death at concentration greater than 100nM in both cell lines. On the other hand, PSA mRNA expression levels in DU-145 cells transfected with AR showed a 2-fold increase in prescence of BDO2 as compared to LNCaP cells. However, PSA secretion was not restored in DU-145 cells transfected with AR. The results of our study suggest that cell death induced by BDO2 in prostate is mediated by the AR, which is resposible for cellular and molecular processes associated with cell death by apoptosis in prostate cell models.

PS 293 HEAT SHOCK-INDUCED CELL DEATH.

I. M. Mahajan and S. B. Bratton. *Division of Pharmacology and Toxicology, The University of Texas at Austin, Austin, TX.*

Heat shock therapy is currently undergoing clinical trials, alone or in combination with other therapies for the treatment of various cancers, including gastric and metastatic colon cancers. Unfortunately, though intense heat shock induces apoptosis, the underlying mechanisms remain controversial and unclear. We have recently shown that heat shock does not require any of the known initiator caspases or their activating complexes in order to induce apoptosis (Milleron and Bratton, J. Biol. Chem. 281, 16991-17000). Herein, we demonstrate that heat shock-induced cell death does require mitochondrial outer membrane permeabilization (MOMP), as cells deficient in the BH3-only proteins, Bid and Bim, or the proapoptotic Bcl-2 family members, Bax and Bak, were resistant to cell death. Remarkably, heat shock also activated c-Jun N-terminal kinases (JNKs) and induced MOMP through a novel tumor necrosis factor (TNF) receptor-associated factor 2 (TRAF2)-dependent, but TNF receptor 1 (TNFR1)-independent mechanism. Thus, we speculate that JNKs may sensitize cancer cells to heat shock-induced MOMP by activating Bid and Bim. Studies are currently underway to further delineate the upstream pathways responsible for JNK activation following heat shock (The American Cancer Society, RSG-05-029-01-CCG; NIH, CA129521).

PS 294 MECHANISMS OF LEAD-INDUCED APOPTOSIS IN HUMAN LEUKEMIA (HL-60) CELLS.

C. G. Yedjou[1] and P. B. Tchounwou[2]. *[1]Biology, Jackson State University, Jackson, MS and [2]Biology, Jackson State University, Jackson, MS.*

Lead is a multi-targeted toxicant that affects many organ systems including; the gastrointestinal tract, hematopoietic system, cardiovascular system, central and peripheral nervous systems, immune system, and reproductive system. There are many published studies that have documented the adverse effects of lead in children and the adult population. Previous in vitro studies in our laboratory have shown that lead nitrate induces cytotoxicity to HL-60 cells in a dose-dependent manner. However, the molecular mechanisms of toxicity and carcinogeneis are still largely unknown. In this research, we hypothesized that oxidative stress plays a key role in lead nitrate-induced toxicity and cell death in human Leukemia (HL-60) cells. To test this hypothesis, we performed lipid hydroperoxide assay for assessing the levels of the degradation products of polyunsatured fatty acid (PUFA) hydroperoxide in lead nitrate-treated HL-60 cells and the flow cytometric analysis of phosphatidylserine externalization to detect the percentage of death cell. Data generated from lipid hydroperoxide assay resulted in a significant increase ($p < 0.05$) in the production of hydroperoxides (degradation products of lipid peroxidation) with increasing doses of lead nitrate in treated cells. Upon 24 h of exposure, the hydroperoxide concentrations in the sample [μM] (mean ±SE, n = 3) compared to untreated control were 6.7 ± 2, 7.1 ± 1, 14.7 ± 2, 15.7 ± 6, 16.2 ± 4, and 15.2 ± 1 in 0, 10, 20, 30, 40, and 50 μg/mL of lead nitrate, respectively. The results of flow cytometric assessment (Annexin V) also showed a strong dose-response relationship between lead nitrate exposure and early stage apoptosis in HL-60 cells. In summary, these studies show that lead nitrate represents an apoptosis-inducing agent in human Leukemia (HL-60) cells and its apoptotic mechanism is mediated through oxidative stress and phosphatidylserine externalization.

PS 295 METALLIC NICKEL PARTICLES INDUCE CELL APOPTOSIS THROUGH A CASPASE-8/AIF-MEDIATED CYTOCHROME C-INDEPENDENT PATHWAY.

J. Zhao, L. Bowman, X. Zhang, X. Shi, V. Castranova and M. Ding. *PPRB, NIOSH CDC, Morgantown, WV.*

Numerous studies have described the pathogenic and carcinogenic effects of nickel compounds, but little has been published on the biologic effects of metallic nickel. The present study investigates metallic nickel particle-induced apoptosis and the signal pathways involved in this process in JB6 cells. Using MTT the assay, we found that metallic nickel nanoparticles (80 nm) exhibited higher cytotoxicity than fine particles (3 μM). Both metallic nickel nano- and fine particles induced JB6 cell apoptosis in a dose-dependent manner. Western-blot analysis showed an upregulation of proapoptotic factors, including Fas, FADD, caspase-8, DR3 and BID, following exposure to metallic nickel particles. Metallic nickel particles showed only a very slight activation of caspase-3, -6 and -9. IP western blot analysis demonstrated the formation of the Fas-related death-inducing signaling complex (DISC) during the apoptotic process. Furthermore, during this process, lamin A, β-actin and PARP were cleaved. Moreover, we found that apoptosis-inducing factor (AIF) was upregulated and released from mitochondria into cytoplasm in nickel- treated cells. However, no cytochrome c release from mitochondria into the cytoplasm was found in nickel-treated cells. In addition, activation of anti-apoptotic factors, including phospho-Akt and Bcl-2, was detected. In conclusion, we report for the first time that metallic nickel nanoparticles caused higher cytotoxicity and apoptotic induction than fine particles in JB6 cells. Apoptotic cell death induced by metallic nickel particles in JB6 cells is through a caspase-8/AIF-mediated cytochrome c-independent pathway. Activation of Bcl-2 and Akt may play an importment role in preventing cytochrome c release from mitochondria into the cytoplasm and may also be important in the carcinogenicity of metallic nickel particles. The data obtained from this study will be of benefit for elucidating the pathogenic and carcinogenic potential of metallic nickel particles.

PS 296 P53-DEPENDENT AND P53-INDEPENDENT APOPTOSIS IN CHROMIUM CARCINOGENESIS.

A. O. Chiu[1], N. H. Chiu[1], R. Hill[2], P. W. Lee[2] and J. D. Robertson[3]. *[1]NCEADC & ODW, U.S. EPA, Washington, DC, [2]Microbiology & Immunology, Dalhousie University, Halifax, NS, Canada and [3]Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS.* Sponsor: D. Singh.

In multicellular organism, cells with genomic damages have arrests-of-cell-cycles (senescence) and apoptosis and become cancerous. This carcinogenic experiment has been demonstrated in animals. Using hexavalent chromium as an example, we show in vitro how the metal can affect at the p53-dependent, p53-independent-apoptosis and senescence. Cr (VI) is converted to Cr (V) and Cr (IV) intracellularly. Both of these can cause changes in the genome such as DNA double-strand-breaks. We have demonstrated in vivo with Drosophila wing-spot screening that Cr (IV) induces both somatic recombination and somatic mutation without apoptosis while Cr (V) induces apoptosis and the somatic mutation event. Cancer occurs with increased Cr-induced genetic plasticity not accompanied by cell death or oncogenic-senescence. With Raji and a colon cancer cell-line we show how chromium can affect p53-dependent and p53-independent-apoptosis. Apoptosis can occur via a direct activation of caspase-2 at the time of exposure from the disruption of the phosphodiester bond. It can also occur with additional changes of p53/ HAUSP/BAX and SMAC. Cr also caused oncogenic-senescence through p21/Arf/Rb subsequent to the exposure. The multistage/multipathway of cancer progression at the organismic level as first defined by Leslie Foulds is now demonstrated experimentally at the subcellular level with chromium exposure. This is consistent to virus-induced (e.g., Maloney murine-leukemia-virus) cancer with shortened latency from losses of the functions of p53/p21/H2AX (independently, or in combination) in targeted knockout mice. This multistage/ multipathway carcinogenic mechanism now can be related to the genetic modifications of p53, p21, or H2Ax at the cellular level both in subcellular level and mathematically. Disclaimer: The opinions and conclusions in this abstract are only those of the authors and do not reflect the institutions they represent.

PS 297 MT ATTENUATES CARDIAC CELL DEATH *VIA* SUPPRESSION OF ER STRESS IS ONE OF THE MECHANISMS AGAINST DIABETIC CARDIOMYOPATHY.

J. Xu, Q. Liu, Y. Tan, G. Wang and L. Cai. *Department of Medicine, University of Louisville, Louisville, KY.*

Our previous studies showed that cardiac MT overexpressing mice(MT-TG) are highly resistant to diabetic cardiomyopathy. Since apoptosis plays a critical role in the development of diabetic cardiomyopathy, and ER stress is one of the intrinsic apoptosis pathways, the present study was to test whether ER stress exists in the diabetic hearts, and whether MT prevents diabetic cardiomyopathy by blocking ER stress-induced cell death. Diabetes was induced by streptozotocin (one dose of 150 mg/kg)in both MT-TG and wild-type(WT) mice. Cardiac cell death was detected by in situ TUNEL staining and Western blotting of the activated form of caspase-3. Representative makers of ER stress were detected by Western blotting assay. We found that cardiac apoptosis in the WT, but not MT-TG, diabetic mice was significantly increased 2 weeks, and slightly increased 2 and 5 months after diabetes onset. In parallel with apoptotic cell death, Western blotting revealed that the hallmarks of ER stress, including GRP78 and GRP94, ATF6, and phosporylated eIF2α all significantly increased in the hearts of WT, but not MT-TG, diabetic mice 2 weeks, and slightly increased 2 months after the onset of diabetes. To further define the direct link of ER stress to apoptotic cell death and also confirm the direct cardiac protection of MT against ER stress-induced apoptotic effect, ER stress animal model was generated by was induced by direct administration of ER stress inducer(tunicamycin at 1 mg/kg and 1.5 mg/kg). Treatment with tunicamycin for 12 hr significantly increased cardiac cell death, detected by TUNEL staining and Western blotting of activated caspase-3, in the hearts of WT mice, but not MT-TG mice. These results suggest that ER stress exists in the diabetic heart and is involved in the induction of cardiac cell death. MT prevented both diabetes- and ER stress-induced cardiac cell death, implying that MT protection of diabetic ER stress-induced cardiac cell death is at least one of the mechanisms against diabetic cardiomyopathy (Supported,in parts, by ADA grants).

PS 298 ANGIOTENSIN II-INDUCED CARDIAC APOPTOSIS IS MEDIATED BY P53-DEPENDENT AND -INDEPENDENT PATHWAYS.

G. Zhou[1, 2], X. Li[2] and L. Cai[1, 2]. *[1]Medicine and Radiation Oncology, University of Louisville, Louisville, KY and [2]Chinese-American Research Institute for Diabetic Complications, Wenzhou Medical College, Wenzhou, China.*

Our previous studies showed that angiotensin II (Ang II)-induced cell death plays a critical role in the development of diabetic cardiomyopathy. Tumor suppressor gene p53 was implicated in the pathogenesis of Ang II-induced cardiac cell death. However, the direct causative role of p53 in Ang II-induced cardiac apoptosis and its signaling pathways remain unclear. Therefore, cardiac H9C2 cells were exposed to Ang II at 100 nM for 7 hr and 24 hr, which significantly induced cardiac apoptotic cell death, along with significant increases in the total and phosphorylated p53 expressions. Interestingly, Ang II induced a time-dependent translocation of p53 from cytosol to mitochondria and nucleus. Furthermore, both mitochondrial permeability, detected by fluorescent staining and flow cytometry, and mitochondrial cytochrome c release, detected by Western blotting, significantly increased at 7 hr. P53 expression and activation were inhibited by pretreatment with p53 inhibitor pifithrin-a (PFT-a). However, pretreatment of the cells with PFT-a only inhibited apoptosis at 24 hr, but not at 7 hr after Ang II treatment. Pretreatment of cells with PFT-a also inhibited Ang II-induced caspase-8 activation.In vivo, FVB mice were given subcutaneously injection of Ang II at the dose of 1 mg/kg body weight with and without PFT-a at 2.2 mg/kg body weight twice at 30 min before and 1 hour after Ang II treatment. Expressions of both total and phosphorylated p53 were increased in Ang II-treated mice, but not in Ang II/PFT-a-treated mice. Ang II-induced capase-3 activation in the hearts was prevented in Ang II/PFT-a-treated WT mice only at 24 hr, not at 7 hr after Ang II administration. These results suggest that Ang II-induced cardiac apoptosis is mediated by both p53-dependent and -independent pathways. The activation of mitochondrial cytochrome c release mediated apoptotic signaling pathway plays a critical role in Ang II-induced p53-dependent pathway (Supported, in parts, by ADA and AHA grants).

PS 299 INHIBITION OF APOPTOSIS IN PRIMARY RAT HEPATOCYTES BY 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN.

M. Chopra[1], G. Meiss[2] and D. Schrenk[1]. *[1]Food Chemistry and Toxicology, University of Kaiserslautern, Kaiserslautern, Germany and [2]Institute of Biochemistry, Justus-Liebig-University, Giessen, Germany.*

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is a highly toxic pollutant ubiquitously present in the environment. Most of the toxic effects of TCDD are believed to be mediated by high-affinity binding to the aryl hydrocarbon receptor (AhR) and subsequent effects on gene transcription. TCDD was classified as a class 1 human carcinogen. It causes cancer in multiple tissues in different animal species. In initiation-promotion studies TCDD was shown to be a potent liver tumor-promotor. Among other hypotheses it has been suggested that TCDD acts as a tumor-promotor by preventing initiated cells from undergoing apoptosis. In rat hepatocytes in primary culture TCDD (1 nM) inhibits UV-C light induced apoptosis.

This effect is seen with internucleosomal DNA-fragmentation as well as with chromatin condensation and fragmentation and appears to be mediated by the AhR. Apoptosis induced by UV-C light in these cells is caspase-dependent and is accompanied by alterations in apoptosis-related gene expression such as up-regulation of pro-apoptotic bcl-2 family genes like bak and bax, and a marked down-regulation of the expression of the anti-apoptotic bcl-2. TCDD treatment of irradiated hepatocytes does not alter these changes. Up-stream apoptotic events, namely caspase-activation and cleavage of poly (ADP-ribose) polymerase (PARP) and inhibitor of caspase-activated DNase (ICAD) are not inhibited by TCDD treatment; neither does TCDD affect CAD and ICAD gene expression. Furthermore, we performed an in vitro CAD activity assay. TCDD did neither act on CAD-catalyzed internucleosomal cleavage of DNA in TCDD-treated cells nor did it affect the degradation of isolated DNA. Since TCDD does act only on down-stream nuclear events of apoptosis we believe nucleases to be putative targets of this pollutant. We hypothesize that TCDD inhibits late-stage apoptotic events maintaining chromosomal integrity probably in order to sustain metabolic capacity and hepatic elimination of substrates despite of an initiation of apoptosis.

PS 300 SATRATOXIN G –INDUCED APOPTOSIS IN MOUSE OLFACTORY SENSORY NEURONS IS NOT MEDIATED BY DOUBLE-STRANDED RNA-ACTIVATED PROTEIN KINASE R (PKR).

J. Shinozuka[1, 2], Z. Islam[1], C. C. Hegg[1], J. Harkema[1], J. Kim[1] and J. J. Pestka[1]. *[1]Michigan State University, East Lansing, MI and [2]Mitsubishi Tanabe Pharmacology Corporation, Saitama, Japan.*

Satratoxin G (SG) is a macrocyclic trichothecene mycotoxin produced by Stachybotrys chartarum. Acute intranasal exposure of mice to SG specifically induces apoptosis in olfactory sensory neurons (OSNs) of the nose. We have previously reported mRNA expression of double-stranded RNA–activated protein kinase (PKR), is increased in SG-treated mouse ethmoid turbinates and the neural crest-derived rat pheochromocytoma cell line, PC-12. PKR inhibition blocked SG-induced apoptotic gene expression and apoptosis in PC-12 cells suggesting a role for this widely expressed serine/theonine kinase. We tested the hypothesis that PKR mediates SG-induced OSN apoptosis in vivo and in vitro. To test the in vivo role of PKR, wild-type (WT) and homozygous PKR knockout (KO) C57Bl6 mice were intranasally exposed to SG (250 μg/kg bw) and then ethmoid turbinates examined 24 h later for expression of apoptosis-related genes (Fas, FasL, p53, BAX, PKR, caspase-3 and caspase-activated DNAase) and histopathological effects. SG induced robust apoptotic gene expression in WT mice and these responses were not suppressed in PKR-KO mice. OSN cell death and TUNEL positivity were also similarly observed in SG-treated WT and PKR-KO mice. In addition, when C57Bl6 mice were pretreated with vehicle or the PKR inhibitor C16 (75 μg/mouse/d for 5 d), marked apoptotic gene expression was observed in both vehicle- and inhibitor-treated animals. We also examined the role of PKR in SG-induced cell death in the OP6 cell line, derived from the E10 mouse olfactory placode and differentiated to OSN-like cells. SG (25 ng/ml) was found to induce cytotoxicity in OP6 cells as revealed by a cell death detection ELISA at 6 h and by the MTT assay at 24 h. However, pretreatment with the PKR inhibitors C16 and 2-AP failed to block SG-induced cytotoxicity. Taken together, these data suggest that, unlike PC-12 cells, SG-induced apoptosis in OSNs was not PKR-dependent.

PS 301 THE CYTOLETHAL EFFECTS OF JS-K, AN ANTI-TUMOR NITRIC OXIDE RELEASING PRODRUG, IN HUMAN PHARYNGEAL CARCINOMA FADU CELLS.

J. Liu[1], X. Wang[2], W. Qu[1], R. Dong[1], L. K. Keefer[3], J. E. Saavedra[4] and M. P. Waalkes[1]. *[1]ICS, LCC, NCI at NIEHS, Research Triangle Park, NC, [2]LP, NIEHS, Research Triangle Park, NC, [3]CS, LCC, NCI at Frederick, Frederick, MD and [4]SAIC, NCI at Frederick, Frederick, MD.*

Pharyngeal cancer is very common in certain regions of East Asia and Africa, and effective chemotherapy is presently unavailable. JS-K is a nitric oxide (NO) releasing prodrug, which has been shown to be effective against several cancer cells and cancer xenografts. This study was conducted to further examine the effect of JS-K on the human FaDu pharyngeal carcinoma cell line. Cells were treated with JS-K or JS-K plus other anticancer agents for 48 hours. Cell viability was then determined by the MTS assay. JS-K-induced alterations in gene expression were determined at the transcriptional level by real time RT-PCR, and at the protein level by confocal imaging. JS-K was cytolethal to FaDu cells in a concentration-dependent manner, with an LC_{50} of approximately 10 μM. JS-K at 3 μM additively enhanced the cytolethal effects of other anticancer agents including cisplatin (10 μM), fluorouracil (100 μM), or arsenic (10 μM) towards FaDu cells. Gene expression analysis suggests that JS-K was able to suppress the expression of efflux transporters *ABCC1* and *ABCC2* transcripts and decreased the immunostaining for ABCC2 protein. JS-K also increased the expression of *TNFR* and enhanced immunostaining of caspase-3, suggesting the activation of TNF-α-mediated cell death pathways in FaDu cells. JS-K appeared to impact the expression of genes involved in metastasis, including a decreased expression of vascular endothelial growth factor (*VEGF*) and increased expression of tissue inhibitor of metalloproteinase-1 (*TIMP1*). Taken together, these data indicate JS-K is effective in killing FaDu cells when used alone and in combination with other anticancer drugs. The combined effects appear to be due, at least in part, to reduced expression of efflux transporters and activation of TNF-α mediated cell death pathways.

PS 302 CARDIOLIPIN OXIDATION, HYDROLYSIS AND ACCUMULATION OF MONOLYSOCARDIOLIPINS AND OXIDIZED FREE FATTY ACIDS DURING APOPTOSIS: ROLE OF CYTOCHROME C.

V. A. Tyurin[1, 3], M. Y. Jung[1, 3], Y. Y. Tyurina[1, 3], T. Prieto[2], Q. Zhao[1, 3], A. A. Kapralov[1, 3], N. A. Belikova[1, 3], I. Nantes[2] and V. E. Kagan[1, 3]. *[1]Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA, [2]Centro Interdisciplinar de Investigação Bioquímica-CIIB, Universidade de Mogi das Cruzes-UMC, Mogi das Cruzes-SPF, Brazil and [3]Center for Free Radical and Antioxidant Health, University of Pittsburgh, Pittsburgh, PA.*

Oxidized phospholipids are important signaling participants of the mitochondrial stage of apoptosis. Accumulation of oxygenated molecular species of cardiolipin, CL and its hydrolysis products – monolyso-CL and free fatty acids – has been detected during early apoptosis in different cell lines. Apoptosis-associated selective oxidation of CL is due to the formation of complex between CL and cyt c with a peroxidase activity triggered by oxidized equivalents generated by disrupted electron transport of mitochondria. Using ESI-MSn analysis we demonstrated that hydroperoxy-, hydroxy- and hydroperoxy-/hydroxy- derivatives were the most dominant oxidation products of CL. Now, we discovered that cyt c itself is able to hydrolyze oxidized CL with the formation of two major products – non-oxidized monolyso-CL and oxidized free fatty acids; the identity and structure of the products were confirmed by 2D-HPTLC followed by fluorescence HPLC and LC-ESI-MS analysis. Non-enzymatic oxidation of CL by Fe/H2O2, Fe/Ascorbate or by a lipid-soluble azo-initiator, AMVN, did not result in accumulation of CL hydrolysis products. CL hydrolysis products were not detected after incubation of non-oxidizable TOCL with cyt c/H2O2. Further, incubation of isolated mouse mitochondria with an organic hydroperoxide, tBOOH, also caused accumulation of monolyso-CL and oxidized free fatty acids. Finally, apoptosis induced by actinomycin D in cyt c+/+ (but not in cyt c-/-) mouse embryonic cells resulted in CL oxidation and accumulation of CL hydrolysis products. Thus, cyt c displays a CL-specific phospholipase A activity directed towards hydrolysis of oxidatively modified polyunsaturated acyls in sn-2 position. Support: U19A1068021, HL70755, PA Dept of Health SAP 4100027294.

PS 303 MULTIPLEXED ASSAY PANEL OF CYTOTOXICITY IN HK-2 CELLS FOR DETECTION OF RENAL PROXIMAL TUBULE INJURY POTENTIAL OF COMPOUNDS.

Y. Wu[1], D. Connors[2], L. Barber[2], S. Jayachandra[2], U. Hanumegowda[1] and S. Adams[1]. *[1]Discovery Toxicology, Bristol Myers Squibb, Wallingford, CT and [2]Lead Discovery, Bristol Myers Squibb, Wallingford, CT.*

Proximal tubules of the kidneys are common targets of nephrotoxic compounds. Screens to predict nephrotoxic potential of compounds with insights to mechanisms of toxicity facilitate lead optimization, guide structure-activity relationships, minimize risks of clinical nephrotoxicity and therefore are valuable in the process of drug discovery. In vitro cytotoxicity assays routinely measure mitochondrial function; although a good marker of effect, it seldom provides insight into mechanism. We developed an in vitro assay multiplexed to measure several endpoints of cytotoxicity using HK-2 cells in 96-well format. Assays for lactate dehydrogenase leakage as a marker of necrosis, cellular caspase 3/7 activation as a marker of apoptosis, resazurin dye reduction as a marker of mitochondrial function and Hoechst 33342 staining for double-strand DNA were multiplexed to maximize the ability to detect cell injury. Assays were performed after 5- or 24 hour incubations to further enhance the sensitivity of detection of toxicity. Individual assays were optimized for cell density, assay linearity and assay performance under multiplexed conditions. Inducers of apoptosis (staurosporine) and necrosis (perhexiline) were used to validate the mechanistic aspects of cell death (apoptosis, necrosis). Nephrotoxic com-

pounds (5-fluorouracil, gentamicin, cisplatin, acetaminophen, p-aminophenol, potassium dichromate, ibuprofen, doxorubicin, cyclosporine A, citrinin, puromycin) with known direct or indirect association to injury to proximal tubules were used to determine the potential of this method to detect proximal tubule toxicity. Overall, this cost-effective multiplexed platform is more sensitive than a single endpoint assay, provides mechanistic cues of toxicity and is amenable for higher throughput screening. Limitations of the assay in predicting in vivo toxicity, such as those seen in nonspecific cytotoxicity and the importance of in vivo disposition are also highlighted.

PS 304 MULTI-PARAMETER CYTOMETRY TO DETECT DRUG-INDUCED MITOCHONDRIAL TOXICITY.

N. Li, H. Hamadeh, J. Lawrence, C. Qualls and P. Narayanan. *Investigative Toxicology, Amgen, Seattle, WA.*

Mitochondrial dysfunction has been increasingly implicated as a mechanism for drug-induced toxicity. Screening for mitochondrial dysfunction prior to lead optimization is being conducted by several pharmaceutical companies in lieu of cytotoxicity assays. In this study, we selected 30 drugs/compounds that were known to induce various organ-toxicities related to mitochondrial dysfunction in both humans and animals. Compounds were categorized into four major groups: mitochondrial respiratory chain inhibitors, oxidative stress inducers, mitochondrial polymerase inhibitors, and various kinase inhibitors. In addition, 10 drugs/compounds that did not induce mitochondrial toxicity were chosen as negative controls. A high-throughput multiparameter flow cytometry-based platform using human promyelocytic leukemia cell line (HL-60 cells) was set up to monitor mitochondrial membrane potential (MMP) change (using potentiometric dye JC-1), intracellular reduced glutathione (GSH) level (using monobromobimane), and cell viability (using calcein-AM) simultaneously. Results obtained (IC50 values for each parameter per compound) demonstrated that disruption of MMP is the earliest indicator for the onset of mitochondrial damage. Over 60% of compounds screened triggered MMP change within 6 hours, progressing to 90% at 24 hours accompanied by depletion of intracellular GSH and decreased viability at 24 hours. Our results also demonstrated that a comparison of drug-induced changes in glucose as opposed to galactose/glutamine-enriched medium and vice versa is essential to separate mitochondrial dysfunction from frank cytotoxicity. In conclusion, a comprehensive analysis of MMP/GSH/viability could increase the probability of predicting mitochondrial toxicity in a cell-based screening system. Cytometry-based screening-assays with human cell lines have excellent correlations (~ 90%) with in vivo human toxicity.

PS 305 NADPH CYTOCHROME P450 REDUCTASE MEDIATES REDOX CYCLING BY 2- AND 4-HYDROXYESTRADIOL CATECHOL METABOLITES.

K. C. Fussell[1], M. A. Gallo[1, 2] and J. D. Laskin[1, 2]. *[1]Pharmacology and Toxicology, Rutgers University, Piscataway, NJ and [2]Environmental & Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

Estrogen exposure is a major risk factor for the development of breast-cancer. Estrogens are known to modulate cellular proliferation by binding to nuclear receptors, a process that alters transcription of estrogen-responsive genes. Previous studies demonstrated that the exogenous estrogen equilenin, a component of hormone replacement therapy, and diethylstilbestrol are converted to catechol metabolites; subsequent oxidation reactions generate redox-active ortho-quinones. One-electron reduction of the quinones by NADPH-dependent oxidoreductases to semiquinones and their subsequent reaction with molecular oxygen generates reactive oxygen intermediates (ROI). In the present studies we compared redox cycling of two endogenous catechol estrogens, 2- and 4-hydroxyestradiol, with estradiol and 2-methoxyestradiol. Using Supersomes that overexpress human cytochrome P450 reductase we found that the estrogens (1-300 μM) readily generated ROI as measured by the formation of hydrogen peroxide and hydroxyl radicals. Redox cycling was found to be NADPH- and cytochrome P450 reductase-dependent and inhibited by diphenyleneiodonium, confirming that the reaction was mediated by cytochrome-P450 reductase flavoenzyme. The Km's of the catechol estrogens were both approximately 1 μM, indicating similar binding efficiency with the enzyme. However, the Vmax's varied from 0.5-5 nmoles min-1 mg-1 protein in the rank order 4-hydroxyestradiol > 2-hydroxyestradiol >> estradiol and 2-methoxyestradiol. The finding that the Km's were similar yet the Vmax's different, suggests that 4-hydroxyestradiol is a more efficient generator of ROI than 2-hydroxyestradiol. Taken together, these data indicate that NADPH-cytochrome P450 reductase mediates redox cycling by catechol estrogens, implying that NADPH-cytochrome P450 reductase has a role in endogenous estradiol redox cycling and potentially, in the etiology of breast cancer. Supported in part by NIH grants ES05022, AR055073, CA100994 and CA093798.

PS 306 EXAMINATION OF GENETIC DAMAGE IN GLUTATHIONE (GSH)-DEPLETED CELL CULTURES USING THE MICRONUCLEUS TEST, SINGLE CELL GEL ELECTROPHORESIS ASSAY (COMET), AND 8-HYDROXY-DEOXYGUANOSINE (8-OH-DG) LEVELS IN NUCLEAR DNA.

D. Geter, F. Zhang, M. Schisler, A. Wood, L. Kan, Y. Jeong, M. Bartels and B. Gollapudi. *The Dow Chemical Company, Midland, MI.*

David Geter, Fagen Zhang, Melissa Schisler, Amanda Wood, Lynn Kan, Yo-Chan Jeong, Michael Bartels, Gollapudi, Bhaskar. Toxicology and Environmental Research & Consulting, The Dow Chemical Company, Midland, Michigan, 48674. Depletion of GSH in cells exposed to certain xenobiotics has been implicated in oxidative stress leading to damage of cellular macromolecules such as proteins, lipids, and DNA. Diethyl maleate (DEM), is known to conjugate with GSH and rapidly lower cellular GSH levels. The objective of these studies was to investigate the influence of DEM-induced GSH depletion on various genotoxicity end points in mouse lymphoma L5178Y (TK+/-) cell cultures. Cells were exposed to DEM for four hours at concentrations of 0, 6.7, 13.5, 26.9, 53.8, 107.6, and 215.3 ug/ml. Genotoxicity was evaluated by examining the induction of 1) micronuclei (20 h post-treatment), 2) DNA strand breaks (immediately following treatment), 3) 8-OH-dG levels in nuclear DNA (immediately following treatment), and correlating these end points to cellular GSH levels. A significant increase in micronuclei was observed at exposure concentrations starting at 53.8 ug/ml. However, induction of DNA strand breaks as measured by the alkaline comet assay was only evident at concentrations of 107.6 ug/ml and higher. Quantifiable levels of 8-OH-dG (≥ 2 adducts per 1 x 10^8 NT) were not detectable at any exposure concentration under the experimental conditions despite the fact that GSH levels were significantly reduced at all test concentrations in a dose-dependant manner. Taken together, these results demonstrate an association between DEM-induced genotoxicity and GSH depletion in cell cultures. Although the mode of action for the observed genotoxicity is not discernible from these studies, it is postulated that oxidative stress resulting from GSH depletion is partly responsible for the effect.

PS 307 IDENTIFICATION OF AN FAD-INDEPENDENT REDOX CYCLING ACTIVITY FOR 9, 10-PHENANTHRENEQUINONE IN MOUSE LUNG EPITHELIAL CELLS.

S. Yang[1], J. P. Gray[2], V. Mishin[3], Y. Wang[1], D. E. Heck[4], D. L. Laskin[3] and J. D. Laskin[1]. *[1]Environmental & Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, [2]Science, U.S. Coast Guard Academy, New London, CT, [3]Pharmacology & Toxicology, Rutgers University, Piscataway, NJ and [4]Environmental Health, New York Medical College, Valhalla, NY.*

9,10-Phenanthraquinone (PQ) is a component of airborne particulate matter and can cause protein oxidation and cytotoxicity via a one or two-electron reduction. One electron reduction of PQ results in a semiquinone radical; oxidation of the radical leads to the formation of reactive oxygen species including superoxide anion, hydrogen peroxide and hydroxyl radicals. In the lung, this can cause alveolar inflammation, epithelial cell damage and pulmonary fibrosis. Using mouse MLE-15 lung epithelial cells, we discovered a strong NADPH-dependent redox cycling activity in cytosolic cellular fractions. Purification and sequencing identified this material as sepiapterin reductase (SPR), an enzyme catalyzing the final step in the biosynthetic pathway of tetrahydrobiopterin. Human SPR was cloned and its enzymatic activities characterized. In addition to reducing sepiapterin, the enzyme readily mediated PQ redox cycling as measured by hydrogen peroxide formation in the Amplex Red assay. Dicoumarol was found to be a noncompetitive inhibitor (IC50 = 200 nM) of sepiapterin reduction without inhibiting redox cycling. Similar selective inhibition of SPR was found with N-acetylserotonin (2.5 μM), indomethacin (8.1 μM), ethacrynic acid (22.9 μM), and rutin (24.0 μM) while PQ was a noncompetitive inhibitor of SPR activity. Sepiapterin reduction and redox cycling activity were not inhibited by diphenyleneiodonium, a finding consistent with the fact that SPR does not contain flavin cofactors. Taken together, our data identify a novel enzyme in lung epithelial cells that mediates chemical redox cycling. Redox cycling via SPR may be an important mechanism by which contaminants in airborne particulate matter redox cycle and initiate toxicity. Supported by CA100994, CA132624, CA093798, ES004738, ES005022, GM034310 and AR055073.

PS 308 SELECTIVE CHEMICAL REDOX CYCLING BY NADPH-CYTOCHROME P450 REDUCTASE AND SEPIAPTERIN REDUCTASE.

Y. Wang[1], S. Yang[1], V. Mishin[2], J. P. Gray[3], D. E. Heck[4], D. L. Laskin[2] and J. D. Laskin[1]. *[1]UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, [2]Rutgers University, Piscataway, NJ, [3]U.S. Coast Guard Academy, New London, CT and [4]New York Medical College, Valhalla, NY.*

Redox cycling is a process by which redox active chemicals undergo a one electron enzymatic reduction to free radical intermediates. Under aerobic conditions, oxidation of the radical back to the parent compounds generate superoxide anion, hydrogen peroxide and, in the presence of redox active metals, highly toxic hydroxyl radicals. In the present studies, we compared chemical redox cycling by NADPH-cytochrome P450 reductase (EC 1.6.2.4, CPR), a microsomal NADPH-dependent oxidoreductase, and sepiapterin reductase (EC 1.1.1.153, SPR), a nonflavin-containing cytoplasmic oxidoreductase important in the biosynthesis of tetrahydrobiopterin. Using Amplex Red to quantify hydrogen peroxide production during redox cycling, 9,10-phenanthrenequinone was found to be the most potent redox cycler for CPR, followed by menadione, nitrofurantoin, paraquat, mitomycin c and diquat. The Vmax ranged from 4.4 to 10.4 μmol hydrogen peroxide/mg protein/min, while the Km varied from 1.2 μM to 434 μM. In contrast, SPR only catalyzed redox cycling of 9,10-phenanthrenequinone and menadione (Vmax = 2.0 μmol hydrogen peroxide/mg protein/min vs. 5.0 nmol hydrogen peroxide/mg protein/min, respectively), with little or no activity for nitrofurantoin, mitomycin c, paraquat and diquat. Redox cycling of 9,10-phenanthrenequinone mediated by CPR was inhibited by diphenyleneiodonium, a flavoprotein inhibitor, while no inhibition was found in SPR catalyzed redox cycling of this compound. These findings are consistent with the fact that only CPR is a flavoenzyme. Taken together, our results demonstrate distinct substrate specificities for the one electron reduction of redox active chemicals by CPR and SPR. Depending on enzyme tissue distribution for SPR and CPR, this may be an important mechanism mediating selective toxicity of redox active chemicals. Supported by CA100994, CA132624, CA093798, ES004738, ES005022, GM034310 and AR055073.

PS 309 CHARACTERIZATION OF HYDROXYL RADICAL FORMATION DURING AUTOOXIDATION OF GLUTATHIONE.

L. Louis[1], V. Mishin[1], J. P. Gray[2], D. E. Heck[3] and J. D. Laskin[4]. *[1]Pharmacology & Toxicology, Rutgers University, Piscataway, NJ, [2]Science, U.S. Coast Guard Academy, New London, CT, [3]Environmental Health, New York Medical College, Valhalla, NY and [4]Environmental & Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

Glutathione (GSH) is an important intracellular antioxidant. However, it can also undergo non-enzymatic autooxidation and form reactive oxygen intermediates (ROI) including superoxide anion, hydrogen peroxide and hydroxyl radicals. These processes can generate a variety of GSH degradation products including GSH- and Cys-Gly sulfenic acid, which may be cytotoxic to cells. In the present studies we characterized the formation of hydroxyl radicals during non-enzymatic autooxidation of GSH. Hydroxyl radicals were detected by quantifying formation of 2-OH terephthalate in reaction mixes using HPLC with fluorescence detection. We found that autooxidation of GSH was time- and concentration-dependent in the range of 0.1-1.2 mM. Hydroxyl radical formation was dependent on $FeCl_2$, but not $FeCl_3$, and blocked by dimethylsulfoxide (DMSO), a well established hydroxyl radical scavenger. We also found that the generation of hydroxyl radicals generated during iron supported Haber-Weiss reactions ($FeCl_2$/$FeCl_3$ complexed with EDTA) were significantly suppressed by GSH at physiological concentrations. Under these conditions, reduced GSH can be considered an antioxidant with signficant hydroxyl radical scavenging activity. Taken together, our data demonstrate that GSH autooxidation in the presense of transition metals can be a source of highly toxic hydroxyl radicals. Moreover, the dual pro- and antioxidant effects of reduced GSH may have significant physiological importance. Supported by CA100994, CA132624, CA093798, ES004738, ES005022, GM034310 and AR055073.

PS 310 A ROLE FOR OXIDATIVE STRESS IN SULFUR MUSTARD ANALOG CEES-INDUCED LUNG CELL INJURY AND ANTIOXIDANT RESCUE.

B. J. Day[1, 3, 4], N. Gould[1, 4] and C. W. White[2]. *[1]Medicine, National Jewish Health, Denver, CO, [2]Pediatrics, National Jewish Health, Denver, CO, [3]Medicine, University of Colorado Health Sciences, Aurora, CO and [4]Pharmaceutical Sciences, University of Colorado Health Sciences, Aurora, CO.*

Sulfur mustards have been used as warfare agents since WWI and still pose a significant threat against civilian and military personnel alike. Sulfur mustard exposure can cause significant blistering of the skin as well as respiratory injury and fibrosis. Currently, no antidote exists for SM exposure but recent studies, using the SM analog 2-chloroethyl ethyl sulfide (CEES), have focus on the ability of antioxidants to prevent toxicity. Though antioxidants can prevent CEES-induced toxicity, it is largely unknown why these compounds are effective against these types of alkylating agents. Using human bronchial epithelial (16HBE) cells and primary small airway epithelial (SAE) cells we show that CEES causes a significant increase in mitochondrial ROS peaking 12h after exposure. We have also identified a catalytic antioxidant metalloporphyrin that can rescue airway cells from CEES-induced toxicity when added 1h after CEES exposure. In addition, the catalytic antioxidant can prevent increases in ROS, DNA oxidation, and decreases in intracellular GSH. These findings suggest a role for oxidative stress in CEES toxicity and provide a rationale to investigate antioxidants as rescue agents.

PS 311 METABOLISM OF 4-HYDROXYNONENAL IN POST-MITOCHONDRIAL FRACTIONS OF MOUSE LUNG AND LIVER.

R. Zheng[1], V. Mishin[1], A. Groves[1], C. R. Gardner[1], D. E. Heck[2], D. L. Laskin[1] and J. D. Laskin[3]. *[1]Pharmacology & Toxicology, Rutgers University, Piscataway, NJ, [2]Environmental Health, New York Medical College, Valhalla, NY and [3]Environmental & Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

4-Hydroxynonenal (4-HNE), an end product of lipid peroxidation, is generated in cells in response to oxidative stress. This highly reactive aldehyde readily forms adducts with proteins, lipids and DNA which can be detected in many tissues including the lung and liver in response to chemical toxicants. In the present studies we characterized 4-HNE metabolism in S9 post-mitochondrial fractions from liver and lung; metabolites were analyzed using HPLC with UV detection. The rate of metabolism was determined by the disappearance of 4-HNE (100 μM) over time in S9 reaction mixes. In both liver and lung, 4-HNE was readily metabolized over time. Both NADH and NADPH enhanced metabolism; in liver S9 fractions the rate of metabolism was 74.8 nmol/min/mg protein with 1 mM NADH and 29.9 nmol/min/mg protein with 1 mM NADPH. Metabolism was significantly reduced in lung S9 fractions (12.5 nmol/min/mg protein in the presence of NADH). A time-dependent increase in the production of three metabolites was detected in liver, but not lung S9 fractions. In both liver and lung samples, 4-HNE-protein adducts were detected using western blotting in conjunction with 4-HNE-adduct antibodies. In both tissues, over 20 distinct proteins were modified by 4-HNE. At least four modified proteins with molecular weights ranging from 30-150 kDa were unique to liver S9 fractions suggesting that the action of 4-HNE is distinct in the two tissues. Taken together, our data demonstrates that both liver and lung can metabolize 4-HNE. Differences in metabolism of 4-HNE in the two tissues suggest distinct mechanisms of cytotoxicity. Supported by CA100994, CA132624, CA093798, ES004738, ES005022, GM034310 and AR055073.

PS 312 CYTOCHROME P4501A1 INDUCED BY 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN MEDIATES THE PRODUCTION OF REACTIVE OXYGEN SPECIES IN ENDOTHELIAL CELLS.

P. G. Kopf and M. K. Walker. *Pharmacy, University of New Mexico, Albuquerque, NM.*

We have shown that subchronic 2,3,7,8,-tetrachlorodibenzo-p-dioxin (TCDD) exposure of adult mice results in hypertension, cardiac hypertrophy, and reduced nitric oxide (NO)-mediated vasodilation. Moreover, increased superoxide production was observed in cardiovascular organs of TCDD exposed mice and this increase contributed to the reduced NO-mediated vasodilation. Further, others have shown that cytochrome P4501A1 (CYP1A1) contributes to TCDD-induced toxicity. Based on these results, we tested the hypothesis that TCDD exposure increases reactive oxygen species (ROS) production in endothelial cells by the induction of CYP1A1. A dose-response to 24 hour TCDD exposure (10 pM-10 nM) was performed in confluent primary human aortic endothelial cells (HAECs). ROS production was measured using the oxidant-sensitive fluorescent probes dihydroethidium (DHE) and 2',7'-dichlorofluorescin diacetate (DCFH-DA), measures of superoxide, and hydrogen peroxide and hydroxyl radical, respectively. These same measures were performed with HAECs transfected with siRNA targeting the aryl hydrocarbon receptor (AhR), CYP1A1, and CYP1B1 to determine the role of each in ROS production in TCDD-exposed HAECs. TCDD exposure resulted in a dose-dependent increase in CYP1A1 and CYP1B1 mRNA expression and enzymatic activity. Moreover, a 1 nM TCDD exposure resulted in a maximal increase in DHE (Cont = 1.0±0.3; TCDD = 5.1±1.0; p = 0.002) and DCFH-DA (Cont = 1.0±0.2; TCDD = 4.1±0.5; p = 0.002) fluorescence. siRNA targeting of AhR and CYP1A1 decreased TCDD-induced DHE (siAhR: Cont = 1.0±0.1; TCDD = 1.3±0.2; p=0.093) (siCYP1A1: Cont = 1.0±0.1; TCDD = 1.1±0.1; p = 0.454) and

DCFH-DA (siAhR: Cont = 1.0±0.2; TCDD = 1.3±0.3; p = 0.370) (siCYP1A1: Cont = 1.0±0.1; TCDD = 1.3±0.2; p = 0.114) fluorescence, while siRNA targeting of CYP1B1 did not. These data suggest that TCDD exposure of HAECs results in increased ROS production, AhR mediates this increase, and CYP1A1 may be a source of this ROS. Supported by HL078914.

PS 313 DETECTION OF CIGARETTE SMOKE-INDUCED REACTIVE OXYGEN SPECIES (ROS) USING A CM-H2DCFDA FLUORSCENCE INDICATOR.

T. Carr[1], T. Tai[1], S. Faux[2] and M. Gaca[1]. *[1]Group R&D, British American Tobacco, Southampton, United Kingdom and [2]Toxicology group, Advanced Technologies (Cambridge) Ltd, Cambridge, United Kingdom.* Sponsor: C. Meredith.

Reactive oxygen species (ROS), thought to be generated by cigarette smoke, may potentiate the total physiological oxidative stress load and may be a factor in development of various smoking related diseases. To establish the role of ROS generation induced by cigarette smoke total particulate matter (TPM), we investigated the fluorescence probe, 5-(and-6)-chloromethyl-2',7'dichlorodihydrofluorescein diacetate (CM-H2DCFDA), a fluorphore which reacts with ROS, in in vitro cultures of lung epithelial cells. Monolayers of human lung epithelial cells (NCI-H292) were initially primed with CM-H2DCFDA for 1 hour at 37°C followed by treatment with oxidative stress positive controls; potassium bromate, tert-butyl hydroperoxide or hydrogen peroxide. The levels of oxidative stress caused by incubation with the positive controls, potassium bromate (0.1-28mM), tert-butyl hydroperoxide (0.1-2000μM) or hydrogen peroxide (0.78-200μM), for 1 hour at 37°C were compared to incubation with TPM (1.56- 200μg/ml). Relative fluorescence was measured using a microplate fluorescence spectrophotometer at excitation and emission wavelengths of 485nm and 530nm respectively. The concentrations of agents that induced formations of ROS at levels significantly higher than the media control were; potassium bromate - 14mM, tert-butyl hydroperoxide - 7.8μM, with saturation at 15.6μM, hydrogen peroxide - 0.78μM, with saturation at 1.56mM. TPM treatment induced ROS at a concentration of 6.25μg/ml, which increased in a dose dependent manner, with saturation at 50μg/ml. The increase in ROS production, compared to control, was 42% for potassium bromate (14mM), 26% for Tert-butyl hydroperoxide (7.8μM), 27% for hydrogen peroxide (0.78μM) and 25% for TPM (6.25μg/ml). This study demonstrates CM-H2DCFDA fluorescence indicator is a simple and reproducible method to determine intracellular ROS generation. In conclusion, we suggest this may be a useful in vitro model to investigate ROS generation and oxidative stress in response to cigarette smoke.

PS 314 AN IMAGING APPROACH TO THE STUDY OF HYDROGEN PEROXIDE GENERATION BY MITOCHONDRIAL DYSFUNCTION IN LIVING CELLS.

W. Cheng[1], H. Tong[2], E. Miller[3], C. Chang[3], R. Zucker[4], T. Hofer[5] and J. Samet[2]. *[1]Department Environmental Science and Engineering, University of North Carolina, Chapel Hill, NC, [2]Human Studies Division, NHEERL, U.S. EPA, Chapel Hill, NC, [3]Department of Chemistry, University of California, Berkeley, CA, [4]Reproductive Toxicology Division, NHEERL, U.S. EPA, Research Triangle Park, NC and [5]German Research Center for Environmental Health, Gauting, Germany.* Sponsor: M. Madden.

Zinc is an essential micronutrient with numerous catalytic and structural cellular functions. Zinc is also a common environmental metallic contaminant that has been implicated in a variety of oxidant-dependent toxicological responses. In order to characterize the role of ROS in Zn2+-induced toxicity, we have used an imaging approach that employs the H2O2-specific fluorophore PG-1 and the mitochondrial potential sensor JC-1 in living cells. Treatment of A431 skin carcinoma cells with Zn2+ pre-loaded with PG-1 resulted a significant increase in H2O2 production that could not be inhibited by the addition of extracellular catalase. Moreover, oxidoreductase, GTPase or receptor or cytosolic kinase inhibitors failed to block Zn2+-induced H2O2 generation. In contrast, the a mitochondrial inhibitor CCCP blunted H2O2 production in Zn2+-treated A431 cells. Mitochondria was further implicated as the source of Zn2+-induced H2O2 formation by the observation that exposure to Zn2+ caused a loss of mitochondrial membrane potential over a time course that preceded the increase in PG-1 fluorescence detected in A431 cells. Lastly, we demonstrate that Zn2+ exposure resulted in rapid swelling of mitochondria isolated from mouse hearts. Taken together, these findings show a disregulation of mitochondrial integrity that leads to H2O2 formation in A431 cells exposed to Zn2+. Similar findings were also observed in primary cultures of human airway epithelial cells. These demonstrate the utility of an imaging approach to the study of the role of oxidant stress in toxicological responses. This abstract of a proposed presentation does not necessarily reflect EPA policy.

PS 315 GENOME-WIDE IDENTIFICATION OF OZONE TOXICITY MODULATING PROTEIN IN BUDDING YEAST.

M. Papaccioli[1], J. Rooney[2], T. Begley[2] and T. Gordon[1]. *[1]Nelson Institute of Environmental Medicine, New York University, Tuxedo, NY and [2]Gen*NY*sis Center for Excellence in Cancer Genomics, University at Albany, Rensselaer, NY.*

S.cerevisiae was used to test the hypothesis that there will be phenotypic differences in growth and survival amongst yeast deletion strains when exposed to ozone. Approximately 5,500 strains of yeast, each containing a single gene deletion, were spotted on agar plates and exposed for 5 hours to two different concentrations of ozone; 5ppm and 2.5ppm. Directly after the exposure, the plates were incubated at 300C for 48 hours and digitally scanned at 24 and 48 hours post exposure. The growth of each deletion was assayed based on the density of each exposed spot and compared to wild type spots. At 24 hours post exposure, some strains displayed clear growth inhibition and at 48 hours post exposure, some strains showed lack of survival indicating toxicity. Upon analysis, the sensitive strains had gene deletions involved in various pathways and sensitivity was used to identify ozone toxicity modulating proteins. Two particular gene products, Yap1 and Skn7 were classified as modulating the toxicity of ozone, and these proteins are transcription factors or activators involved in oxidative stress. Another gene product of interest, Pdr17, is a protein involved with lipid synthesis. Also, gene products involved with membrane transport and membrane permeability were identified as being important for modulating the toxicity of ozone. A plausible explanation for the identification of these gene products is that ozone interacts with lipids on the membrane via lipid peroxidation and promotes oxidative stress. In total, we identified over 300 ozone toxicity modulating proteins. Validation assays are being performed with serial dilutions of yeast exposed to varying concentrations of ozone, and mutant complementation experiments will be preformed on a targeted set. Importantly, this is the first high throughput screen to identify proteins that modulate the toxicity of ozone and our results will be projected into human cell systems using homology based approaches.

PS 316 STATUS OF GLUTATHIONE IN MOUSE EMBRYONIC STEM CELLS AFTER OXIDANT EXPOSURE.

F. Skufca, L. Godsman, S. Worley, E. Lively, C. Gardiner and G. DeKrey. *School of Biological Sciences, University of Northern Colorado, Greeley, CO.*

Embryonic stem (ES) cells are pluripotent, self-renewing cells derived from blastocyst stage embryos. ES cells are being used as an alternative model for developmental toxicology, they are important for cloning, and they may be used in the future for human therapies. Experiments were conducted to elucidate the status of glutathione present in the oxidized (GSSG) and reduced (GSH) forms in mouse ES (mES) cells after treatment with tertiary-butyl hydroperoxide (tBH) to cause oxidative stress. Glutathione was measured at picomolar levels by fluorimetric HPLC after derivatization of extracted mES cells with dansyl chloride. GSH content decreased significantly from 1.92 ± 0.22 (mean ± SEM) fmol per cell to 1.10 ± 0.16 fmol per cell ($p < 0.02$) following 15 minutes exposure to 1.06 mM tBH in culture medium. GSSG increased significantly from 0.25 ± 0.04 fmol per cell to 0.91 ± 0.13 fmol per cell ($p < 0.0001$) following the same exposure and time. By 60 minutes, both GSH and GSSG had returned to control levels. The loss of GSH was accounted for by increases in GSSG. By contrast, mES cells exposed to 10.6 mM tBH for 15 minutes were unable to recover GSH levels after 60 minutes. Previous studies in this laboratory have shown that mouse blastocyst stage preimplantation embryos were unable to recover from 15 minutes exposure to tBH at 0.026 mM. These data suggest that mES cells are less sensitive to reactive oxygen species than are preimplantation embryos.

PS 317 5-CARBOXAMIDO-5-FORMAMIDO-2-IMINOHYDANTOIN (2-IH), A NEW OXIDATION PRODUCT IN DNA.

L. M. Ball[1], W. Ye[1], R. Sangaiah[1], D. Degen[1], A. Gold[1], K. Jayaraj[1], K. M. Koshlap[2], G. Boysen[1], J. Williams[4], K. B. Tomer[4], V. Moceanu[3], N. Dicheva[3], C. E. Parker[3] and R. G. Schaaper[4]. *[1]Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]School of Pharmacy, The University of North Carolina at ChapelHill, Chapel Hill, NC, [3]Michael J. Hooker Proteomics Center, The University of North Carolina at ChapelHill, Chapel Hill, NC and [4]NIEHS, Research Triangle Park, NC.*

Oxidation of DNA bases by reactive oxygen species results in adverse outcomes including cancer, ageing and other degenerative processes. The products of single-electron oxidants (such as 8-oxoguanine) have been extensively characterized, however the outcome of two-electron oxidation is less well documented. We show here that oxidation of short strands of DNA by peracids and other model two-electron

oxidants converts guanine bases into 5-carboxamido-5-formamido-2-iminohydantoin (2-Ih). The product has been characterized by mass spectrometry (ESI-MS, ESI-MS/MS and MALDI-MS) and ^{1H} and ^{13C} nuclear magnetic resonance spectroscopy both in the intact oligonucleotide sequence and as the deoxynucleoside obtained by enzyme digestion of the DNA. Labeling studies with base and deoxynucleoside showed that the reaction proceeds by initial epoxidation of the C4–C5 bond of Gua followed by a 1,2-shift of C6 of Gua to give a dehydrodeoxyiminodihydantoin and subsequent hydrolytic opening of the imidazolone ring to give 2-Ih. One of two added oxygen atoms is derived from the oxidant, the other from water; molecular oxygen is not directly required. This lesion is stable through DNA digestion and chromatographic purification, suggesting that it will be detectable if formed in vivo, for instance by peracids formed from lipid peroxidation. No 8-oxoguanine derivative was seen in these oxidations. The 2-Ih lesion thus appears to be a pathway-specific lesion and holds promise as a potential biomarker.

PS 318 HEMOGLOBIN/HAPTOGLOBIN AGGREGATES PRODUCED BY PEROXIDASE ACTIVITY ARE TAKEN-UP AND INJURE MACROPHAGES.

A. Kapralov[1, 2], W. Feng[1, 2], I. I. Vlasova[1, 2], A. Maeda[1, 2], J. A. Carcillo[3], H. Bayir[1, 3] and V. E. Kagan[1, 2]. *[1]Center for Free Radical and Antioxidant Health, University of Pittsburgh, Pittsburgh, PA, [2]Departments of EOH, University of Pittsburgh, Pittsburgh, PA and [3]Departments of Critical Care Medicine, University of Pittsburgh, Pittsburgh, PA.*

As a hemoprotein, Hb can, in the presence of oxidizing equivalents such as H2O2, act as a peroxidase with very high oxidizing potential. In red blood cells, this dangerous activity is strictly regulated by reducing environment and lack of oxidizing equivalents. The ferric form of Hb is short-lived and the hemoprotein is effectively converted into ferro-Hb by metHb reductase. For stroma-free Hb this regulation is lost and a potential for Hb to become a peroxidase is very high. This potential may be markedly increased by inflammatory cells generating oxygen radicals, superoxide. The latter can be converted into H2O2 – a fuel for Hb capable of feeding its peroxidase activity. It has been proposed that extra-cellular Hb is controlled by its binding with haptoglobins (Hpt) (types 1-1 or 2-2) resulting in apparent weakening of the peroxidase activity. We demonstrate that: 1) Hb peroxidase activity is not significantly decreased by binding with Hpt; 2) Hb/Hpt peroxidase complexes undergo self-inflicted cross-linking provided H2O2 is available; 3) inflammatory cells generate superoxide->H2O2 at levels sufficient to maintain the peroxidase activity of Hb/Hpt complexes; 4) Hb/Hpt aggregates are taken-up by macrophages at rates comparable or exceeding those for non-covalently-cross linked complexes; 5) the engulfed Hb/Hpt aggregates stimulate oxidative stress and injury to macrophages; 6) plasma of patients with severe sepsis contains Hb/Hpt aggregates. We speculate that there is a real possibility that severe pro-inflammatory conditions (eg, sepsis) with relatively high concentrations of circulating H2O2 may be associated with peroxidase-mediated covalent cross-linking of Hb/Hpt complexes, their up-take by professional phagocytes and impairments of immune functions of macrophages. Supported by NIH HL70755,HD057587-01A2,DAMD 17-01-2-637,AHA-0535365N,NS061817-01

PS 319 COMPARISON OF THE ACUTE OXIDATIVE DAMAGE OF TRANSITION METALS ON TWO CELL LINES.

V. C. Bukowski, R. S. Chapman and S. S. Leonard. *PPRB, NIOSH, Morgantown, WV.*

Previous research has shown chromium (Cr), cadmium (Cd) and nickel (Ni) to be carcinogenic. Cr is used in pigment production, electroplating, and stainless steel welding. Cd is used in steel electroplating, plastic pigmentation, and battery production. Ni is used in steel and alloy production, electroplating, and jewelry. Cr, Cd, and Ni all produce acute and chronic effects in various organs in the body. These effects are determined by the route of exposure and chemical composition of the metal. Our research goal was to assess the acute oxidative damage of three metal compounds; sodium dichromate ($Na_2Cr_2O_7$), cadmium chloride ($CdCl_2$) and nickel chloride ($NiCl_2$) on RAW 264.7 mouse monocyte macrophage cells and HepG2/C3A human hepatocellular carcinoma cells. Electron spin resonance was used to analyze free radicals produced by $Na_2Cr_2O_7$, $CdCl_2$, and $NiCl_2$ under various conditions. A Fenton-like system was used with hydrogen peroxide (H_2O_2) as well as exposure to RAW 264.7 cells and HepG2/C3A cells. The results showed that in a Fenton-like system only $Na_2Cr_2O_7$ was able to produce measurable free radicals. This was also true when the RAW 264.7 cells were treated with the metal compounds. However, HepG2/C3A cells produced free radicals after $Na_2Cr_2O_7$ and $CdCl_2$ exposures. In addition, H_2O_2 and oxygen consumption were measured in the two cell lines after being treated with the metals. There was no significant increase in oxygen consumption for either cell line. A significant increase in H_2O_2 for both cells lines was observed when treated with $Na_2Cr_2O_7$. There was little to no increase in H_2O_2 when the cells were treated with the other metals ($CdCl_2$ and $NiCl_2$). A comet assay was used to determine the DNA damage. The results showed significant DNA damage in the cells for all three metals. These results imply that $Na_2Cr_2O_7$, $CdCl_2$ and $NiCl_2$ produce cellular oxidative damage through the use of three different mechanisms.

PS 320 INVOLVEMENT OF OXIDATIVE AND NITROSATIVE STRESS IN SYSTEMIC LUPUS ERYTHEMATOSUS.

G. Wang, S. S. Pierangeli, E. Papalardo de Martinez, G. Ansari and M. Khan. *Pathology, UTMB, Galveston, TX.*

Environmental factors, including chemical exposure, are known to contribute to the development of systemic lupus erythematosus (SLE) and other autoimmune diseases (ADs). Previous studies in our laboratory using an autoimmune-prone MRL+/+ mice exposed to trichloroethene suggested an association between oxidative/nitrosative stress and autoimmune response. However, relevance and involvement of oxidative/nitrosative stress in disease prognosis and pathogenesis in humans are not understood. To investigate the status of oxidative/nitrosative stress in ADs, sera from 72 SLE patients with various SLE scores (SLE disease activity index; SLEDAI) and 40 age-and gender-matched healthy controls were evaluated for oxidative/nitrosative stress markers. Serum analysis showed significantly higher levels of both anti-malondialdehyde (MDA)- and anti-4-hydroxynonenal (HNE)-protein adduct antibodies in SLE patients. Interestingly, our data showed not only increased number of subjects positive for anti-MDA- or anti-HNE-protein adduct antibodies, but also greater increases in both these antibodies in SLE patients with greater SLEDAI (>6), which were significantly higher than the group with lower SLEDAI (6). Data also showed a good correlation between anti-MDA or anti-HNE antibodies and SLEDAI (r = 0.734 and 0.647, for anti-MDA and anti-HNE antibodies, respectively). Serum Cu/Zn superoxide dismutase levels were reduced in SLE patients, suggesting a compromised antioxidant balance. Furthermore, sera from SLE patients had higher levels of both iNOS and nitrotyrosine, suggesting increased nitrosative stress. These findings support an association between oxidative/nitrosative stress and SLE, and suggest that oxidative/nitrosative stress markers may be useful in evaluating the prognosis of SLE as well as in elucidating the mechanisms of disease pathogenesis, especially in relation to exposure to environmental agents that are known to cause oxidative stress.

PS 321 THE ROLES OF OXIDATIVE STRESS AND PHAGOCYTIC ACTIVATION IN THE SUBACUTE TOXICITY OF THE WATER CHLORINATION BY PRODUCTS, DI- AND TRI-CHLOROACETATE.

E. Hassoun, J. Cearfoss and J. Spildener. *Pharmacology, The University of Toledo, Toledo, OH.*

Dichloroacetate (DCA) and tricholoroacetate (TCA) are byproducts produced during the process of water chlorination and were found to be hepatotoxic and hepatocarcinogenic in rodents. The roles of oxidative stress and phagocytic activation in the toxicity of the compounds have been studied in B6C3F1 male mice. Groups of mice were administered daily doses of 7.7, 77, 154, and 410 mg/kg of each of DCA and TCA, by gavage, for 4 weeks. Mice were sacrificed at the end of the treatment period and hepatic tissues were collected and studied for the production of superoxide anion (SA) and lipid peroxidation (LP). Peritoneal lavage cells were also collected and studied for SA production, myeloperoxidase (MPO) activity and tumor necrosis factor alpha (TNF-alpha) production. While DCA treatment resulted in dose-dependent increases in SA production in the hepatic tissues, TCA treatment was associated with significant SA suppression in those tissues, as compared with the controls. Also DCA resulted in Dose-dependent increases in hepatic LP, however, TCA treatment was associated with significant increases in hepatic LP, only with doses above 77 mg/kg/day. Treatment with DCA and TCA also resulted in significant modulations in MPO activity, SA production and TNF alpha levels in the peritoneal lavage cells. These results indicate the involvement of oxidative stress and phagocytic activation in the long term toxicity of the compounds. (Supported by NIH/NIEHS # 1R15ES013706-01A1).

PS 322 THE CHEMICAL SECURITY ANALYSIS CENTER: KNOWLEDGE MANAGEMENT AND CHEMICAL THREAT AWARENESS.

J. Moser[1, 2], W. P. Ashman[1, 2], P. S. Grasso[1] and G. R. Famini[1]. *[1]Chemical Security Analysis Center, Department of Homeland Security, Aberdeen Proving Ground, MD and [2]Battelle Memorial Institute, Columbus, OH.*

The Chemical Security Analysis Center (CSAC) was established within the Department of Homeland Security to develop and implement a capability for providing chemical threat awareness and assessment as applied to issues related to homeland security and to serve as the central repository of chemical threat characterization data. In support of this mandate, the CSAC develops knowledge man-

agement capabilities related to chemical threats that include toxic industrial chemicals, chemical warfare agents, pesticides, pharmaceuticals, and other threats as they are identified. The objective of the CSAC knowledge management project is to provide verifiable chemical threat information with a capability for an efficient chemical data search, review, analysis and output. This effort involves identification and collection of chemical data sources, incorporation of the data into computer electron format as needed, evaluation and ranking of the data contained in the sources, and the development of a computer assisted workbench graphical user interface for searching, reviewing, analyzing and outputting data. Interagency collaboration is required to identify data sets, information sources, and subject matter experts. The CSAC utilizes this extensive data repository to develop comprehensive science and technology based assessments of specific chemical hazards and threats, to compile scientific information related to single topics in a series of source books, and to provide expert analytical support through a centralized 24/7 reachback capability to respond to chemical threat-related inquiries from federal agencies.

PS 323 STEERING UNDERGRADUATE ENVIRONMENTAL SCIENCE RESEARCH IN NORTH DAKOTA.

D. A. Sens. *Pathology, University of North Dakota, Grand Forks, ND.*

The University system of North Dakota has made a concerted effort to introduce research into the undergraduate curriculum. A major part of this effort has been to provide undergraduate research in the area of environmental science and human health. The Short Term Educational Experiences for Research (STEER) program of the National Institutes of Health Sciences has provided this opportunity to undergraduate at the University of North Dakota (UND), one of the State's two research intensive universities. The STEER program was further enhanced at UND by an administrative commitment for 10 to 15 additional undergraduate summer research opportunities. Undergraduate research was stimulated at the State's four year primarily undergraduate universities (PUI) through support from the INBRE program sponsored by the National Center for Research Resources of the NIH. At least one laboratory at each PUI is active in environmental based research and overall 8 of 11 laboratories have an environmental component to their undergraduate-based research. Currently, over 50 undergraduates are actively engaged in undergraduate research during the academic year or summer months. Current efforts are centered on adding undergraduate research to the Community-based Tribal Colleges within the borders of North Dakota.

PS 324 TOXICOLOGY IN THE TEXTBOOKS USED IN THE LOWER LEVELS OF FINNISH COMPREHENSIVE SCHOOLS.

R. O. Juvonen and M. A. Rimpiläinen. *Pharmacology and Toxicology, University of Kuopio, Kuopio, Finland.* Sponsor: M. Viluksela.

Toxicology is a multidisciplinary science that examines the adverse effects of chemicals in biological systems. Its major task is to protect human beings against these adverse effects. In that respect, it is important that basic aspects of toxicology are taught at home and during the first school years. The aim of this study was to find out how many and what kind of items of toxicology are found in the textbooks used at lower levels of Finnish comprehensive schools. For that purpose 25 toxicology related items, pictures and texts were analyzed in 18 textbooks devoted to environmental and natural sciences in the topics of biology, geography, physics, chemistry and health education. The total number of toxicological related subjects was found to be 1422. Their number increased from 32/book in the first grade to 167/book in the sixth grade. Chemicals were the largest group of toxicology related subjects (46 %), followed by poisonous organisms (27 %), intoxicants (17 %), environmental pollutants and hazardous waste(8 %) and warning labels of chemicals (4 %). Pictures and textual subjects were found in equal amounts in the textbooks used in first and second grade but the amount of the text increased to being more than 80 % by the sixth grade. It is concluded that toxicology related subjects have been incorporated in all of the textbooks used by the lower level of Finnish comprehensive schools. However, the amount of toxicology related material should be enlarged and expanded to include different groups of chemicals, pharmaceuticals, intoxicants and hazardous environmental agents.

PS 325 JOHN SNOW, THE FATHER OF EPIDEMIOLOGY, WAS A TOXICOLOGIST: THE NEED FOR SYSTEMS APPROACHES TO CHEMICAL CAUSATION.

B. D. Goldstein. *Univ Pittsburgh Graduate School of Public Health, Pittsburgh, PA.*

Ideally, toxicology and epidemiology are cooperative disciplines in evaluating the cause of human disease by chemical and physical agents. Unfortunately, toxicological sciences, including insights into disease mechanisms, are being assigned a lesser role in establishing causation by various regulatory bodies and by state and federal courts. The diminishing role for toxicology in part comes from advocates of the Precautionary Principle (PP) who insist that only an epidemiological association need be the basis for regulatory action. As many PP advocates contend that John Snow, known as the father of epidemiology for his work on cholera, epitomizes the PP, it is pertinent to evaluate the scientific background and methodology used by Snow. In fact, Snow was a superb toxicologist. His pulmonary studies in laboratory animals led to innovative approaches to the then new field of anesthesiology, including studies relating chloroform levels in air and inhalation rate to chloroform blood concentrations and anesthetic effect. He developed devices to improve inhalation and was one of the first to consider structure-activity relationships in CNS toxicity. His understanding of the respiratory system led him to discount the prevailing view that cholera was caused by inhalation. He also reasoned from the absence of blood abnormalities in early cholera patients that this gastrointestinal disease could not have been transmitted from lung to GI tract through the blood. His groundbreaking study of a specific London cholera epidemic was not a chance observation but rather was the result of a fully conceived hypothesis which the epidemic allowed him to test. Rather than being consistent with a call to act without basic scientific understanding, Snow's approach to the challenge of cholera causation epitomizes the importance of toxicological science working collaboratively with epidemiology and exposure assessment to understand and effectively prevent human disease caused by external agents.

R 326 DEVILS LIE IN THE DETAILS: PRACTICES AND PROBLEMS IN NEUROPATHOLOGY - SIGNIFICANCE FOR NEUROTOXICOLOGY.

B. Jortner[1], M. T. Butt[2] and R. H. Garman[3]. [1]*Laboratory for Neurotoxicity Studies, Virginia Tech, Blacksburg, VA,* [2]*Tox Path Specialists, LLC, Walkersville, MD and* [3]*Consultants in Veterinary Pathology, Inc., Murrysville, PA.*

The pathologic examination of the nervous system is an important component of experimental and regulatory neurotoxicology and in studies of neurodegenerative disease. Given the significance of the scientific and public health assessments, the ease with which histologic artifacts can be introduced into the process, and the possibility that the latter may be interpreted as representing toxicant-induced changes it is imporant to highlight these issues. Recent publications so interpreting such artifacts underscore the need for a review of this subject within the toxicology community. Mark Butt will provide an overview of the proper practice of neuropathology as it relates to study design, tissue fixation and specimen preparation. Robert Garman will describe the artifacts found in histologic preparations of the central nervous system, including their genesis, morphology and potential interpretative problems while Bernard Joynter will review similar aspects of artifacts of the peripheral nervous system. This session will be of interest to pathologists, toxicologists, and neuroscientists involved in neurotoxicologic investigations.

R 327 THE USE OF ENGINEERED NANOMATERIALS IN FOOD AND FOOD-RELATED PRODUCTS: IS THIS A CONCERN FOR HUMAN AND ENVIRONMENTAL SAFETY?

B. Magnuson. *Cantox Health Sciences International, Mississauga, ON, Canada.*

The advent of nanotechnology has brought with it questions related to human and environmental safety. The application of nanotechnology to food packaging and as food or color additives has generated questions on the safety of nanomaterials in biological systems. Thus, it is important that we consider concerns expressed in the literature, press, and general toxicology community for unforeseen human and environmental health effects that may potentially be associated with the use of engineered nanomaterials in food and food-related products. In order to understand these potential concerns we need to consider both general and specific questions. Does the current regulatory framework adapt well to engineered nanomaterials in food as it is designed to do for other new materials manufactured for use in foods? Are there knowledge gaps and/or research needs for regulators that when filled may better prepare us to assess human health and environmental risks of food-related engineered nanomaterials? Can toxicology data generated on nanomaterials via dermal or pulmonary exposure be of use in informing us in the assessment of risks from oral exposure to nanomaterials in food packaging or food additives? Does nanoencapsulation of a dietary or nutritional supplement as a means to alter bioavailability also increase its potential for toxicity? In exploring these issues, we will also take the opportunity to identify planned and ongoing research efforts in the area of food-related nanomaterials safety to facilitate discussion.

HH 328 A QUARTER OF A CENTURY (1984-2009) SINCE THE BHOPAL DISASTER: LESSONS LEARNED.

B. Mahadevan[1] and M. Soni[2]. [1]*Mechanistic and Predictive Toxicology, Schering-Plough Research Institute, Summit, NJ and* [2]*Soni & Associates Inc., Vero Beach, FL.*

Bhopal was the site of one of the worst industrial disasters in history. During the night of December 2, 1984, nearly 30 metric tons of methyl isocyanate from the Union Carbide India Limited (UCIL), pesticide factory in Bhopal, India, leaked

into the surrounding environment. On that fateful night over 2,000 individuals died immediately and more than 200,000 were directly affected. What followed this incident was the devastating impact of the chemical on the eyes, lungs and gastro-intestinal systems. Gynecological and obstetric complications soon became apparent, as did neurological disorders, immunological changes, emotional and mental stress. Twenty-five years later, the impact of the gas leak is evidenced by continuing medical and environmental issues. Besides safety challenges, the sheer scope of the Bhopal incident made it an extremely complex problem of public communication. The post-Bhopal era also witnessed a worldwide regulation on chemicals and toxicity and a demand by communities to the right to information. The story of the Bhopal gas disaster demonstrates the complexity of the interaction of science, public reaction and government in forming the regulatory policy. The historic, scientific and global impact of the disaster wlll be explored to enable us to develop better public and environmental health and safety policies, to provide the current status of health effects from the disaster, and a review of the lessons learned from the disaster.

IS 329 PEER REVIEW OF TOXICOLOGY, EXPOSURE, AND RISK DATA: ENSURING THE BEST SCIENCE.

P. Wexler[1], N. Carmichael[2], S. Chou[3], M. Dourson[4], T. Junghans[5], M. S. Wolfe[6], R. Menzer[7], P. Preuss[8] and M. van Raaij[9]. *[1]Toxicology and Environmental Health Information Program, National Library of Medicine, Bethesda, MD, [2]European Centre of Ecotoxicology and Toxicology of Chemicals, Brussels, Belgium, [3]Agency for Toxic Substances and Disease Registry, Atlanta, GA, [4]Toxicology Excellence for Risk Assessment, Cincinatti, OH, [5]Technical Resources International, Bethesda, MD, [6]Office of Liason, Policy, and Review, National Toxicology Program, Research Triangle Park, NC, [7]Retired, Gulf Breeze, FL, [8]NCEA, ORD, U.S. Environmental Protection Agency, Washington, DC and [9]Center for Substances and Integrated Risk Assessment, National Institute of Public Health and the Environment (RIVM), Bilthoven, Netherlands.*

Toxicology data bases are increasingly important tools in the regulatory and risk assessment process. While most toxicologists are well-versed in the intricacies of peer review in relation to journal publications and grants, there is considerably less understanding of how this process works in the evaluation of chemical toxicities and risk values as reflected in certain databases and monographic series. Therefore it is important to present examples of the scientific peer review process within the context of online databases and publications focusing on the toxicity and risk assessment of chemicals. Issues such as panel selection, impartiality and conflicts of interest, funding, transparency in the conduct of meetings, procedure for reaching consensus, opposing views, and public involvement will be discussed for a number of high profile tools widely consulted in the toxicology community. Our panel of experts will reference many of these databases used including the National Library of Medicine's Hazardous Substances Data Bank, Toxicology Excellence for Risk Assessment International Toxicity Estimates for Risk, the International Agency for Research in Cancer's IARC Monographs and the European Centre of Ecotoxicology and Toxicology of Chemicals. Evaluating chemical toxicity when confronted with either a paucity of data or a bewildering array of sometimes conflicting data can be a particular challenge. High quality peer-reviewed databases can play a critical role in supporting the Globally Harmonized System (GHS) of Classification and Labeling of Chemicals and be relevant to ethical concerns such as the reduction of animal testing, by offering consolidated and vetted information. With an increasing insistence that the regulatory framework be supported by the best science, this session will delve into ways of reaching consensus and credible decisions on chemical toxicity and human health. It should appeal to a broad cross-section of toxicologists.

PS 330 NEUROTOXIC EFFECTS OF TIN COMPOUNDS:FROM ION CHANNEL TO BEHAVIOUR.

K. Krüger[1], H. Straub[1], N. Binding[2] and U. Musshoff[1]. *[1]Institute of Physiology I, M[o]nster, Germany and [2]Institute of Occupational Medicine, M[o]nster, Germany.*
Sponsor: K. Golka.

The central nervous system is a target of some organotin compounds as neurotoxic symptoms, neurobehavioral alterations, impaired learning and performance can be the result of organotin exposure. The aim of the present study was to contribute to the understanding of the mechanisms involved in these neurotoxic symptoms. Therefore, we investigated the effects of monomethyltin trichloride (MMT), dimethyltin dichloride (DMT) and trimethyltin chloride (TMT) on (1) neuronal ion channels expressed from rat brain in Xenopus oocytes, (2) the excitatory Schaffer collateral-CA1 synapse in hippocampal slices of young and adult rats, (3) the one-trial shock motivated passive avoidance response (PAR) of young rats in a step-through apparatus at postnatal days 32-36 injected previously with the compounds once at postnatal day 7 or repetitively every second day from P7 - P30. (1) In concentrations of 100 µmol/l all three substances significantly reduced NMDA-mediated ion currents by 29%-35%, whereas AMPA-mediated currents were slightly inhibited by 20% only by TMT. (2) The three organotin compounds reduced the amplitudes of the evoked synaptic potentials and the LTP in correlation to the number of methyl groups attached; TMT, the most potent blocker, inhibited the induction of LTP completely at a concentration of 10 µmol/l. (3) However, neither single nor chronic injections of any of the tested concentrations of MMT, DMT (0.75, 6, 15 µmol/l) or TMT (0.75, 3, 6 µmol/l) produced a significant impairment of retention in the PAR. The results show that the organotin compounds, especially DMT and TMT, disturb the function of glutamatergic receptors and, consequently, affect the hippocampal Schaffer collateral-CA1-synapse in a receptor specific manner. Although the organotin compounds clearly affect excitatory synaptic processes, the learning behaviour was not affected in the tested animals in the concentrations used.

PS 331 NEURONAL Ca CHANNEL SUBTYPES DIFFERENTIALLY MODIFY SENSITIVITY TO METHYLMERCURY-INDUCED CELL DEATH.

K. E. Krcmarik, B. Pace-Graczyk, R. K. Hajela and W. D. Atchison. *Department PHM/Toxicology Michigan State University, East Lansing, MI.*

Voltage gated Ca channels (VGCC) are a sensitive target of methylmercury (MeHg). MeHg blocks current carried through VGCC, but VGCC also contribute to the MeHg-induced elevation of intracellular [Ca^{2+}], suggesting that MeHg facilitates VGCC Ca^{2+} influx. This conundrum has been difficult to explain. The objective of this study was to determine if expression of a single phenotype of VGCC in a non-neuronal cell would increase its susceptibility to cytotoxicity induced by MeHg, and to what extent is the subtype of VGCC important? HEK293 cells were transiently transfected with cDNAs for human P/Q- (α1A), N- (α1B), or L-type (α1C) VGCC subunits. Following expression of the recombinant protein, cells were exposed in culture to MeHg (1,2 or 5µM) for 1 or 3 hrs. Cytotoxicity was determined 24 hrs later using a commercial "live/dead" assay. MeHg caused a concentration-dependent increase in cytotoxicity following expression of any of the three VGCC α1 subunits. Further, cytotoxicity following 3- hrs exposure was greater than that following 1-hr. However, the three VGCC subtypes differentially affected the relative sensitivity of the cells to MeHg. Cells containing α1A were most sensitive and exhibited 15 - 30% cell death after 1, or 3 hrs exposure to 5 µM MeHg, respectively. In contrast, α1C -containing cells were relatively insensitive, showing between 5-13% cytotoxicity after 1 and 3 hrs exposure respectively. α1B-containing cells were intermediate in their sensitivity. The ability of a VGCC antagonist to protect cells against MeHg-induced cytotoxicity was tested using 1µM nimodipine. MeHg induced cytotoxicity was significantly reduced after 3-hrs exposure to 1µM MeHg. Nimodipine did not reduce cytotoxicity following only 1-hr exposure to MeHg. In conclusion, VGCC clearly contribute to the cytotoxicity produced by MeHg even in a nonneuronal cell, however there is differential sensitivity depending upon the VGCC subtype. Furthermore L-type VGCC are less sensitive in this regard. Supported by NIEHS grant R01ES03299 and an ASPET SURF Fellowship to B.P-G.

PS 332 REGULATION OF ATP7A IN COPPER HOMEOSTASIS AS AFFECTED BY IRON STATUS IN THE BLOOD-CEREBROSPINAL FLUID BARRIER.

A. Monnot, M. Behl, Y. Zhang and W. Zheng. *Purdue University, West Lafayette, IN.*

Copper (Cu) is an essential trace element vital for brain function; excess or deficiency of Cu can result in neurological malfunction. Cu ions are transported across cellular membranes by ATP7A, a membrane ATPase translocating Cu with concurring ATP hydrolysis. The homeostasis of Cu in the cerebrospinal fluid (CSF) is believed to be regulated by the blood-CSF barrier (BCB) in the choroid plexus (CP). While it is known that ATP7A regulates Cu transport in the gastrointestinal track, the mechanisms underlying Cu transport in the BCB and the impact of Fe on these processes were largely unknown. This study was designed to test the hypothesis that (1) ATP7A plays an important role in transporting Cu ions through the BCB and (2) Fe status may alter the expression and/or localization of ATP7A in this tissue. The 64Cu efflux study was conducted in an immortalized choroidal epithelial Z310 cells. Incubation of the cells with p-chloromercuribenzoate (p-CMB), a potent inhibitor of ATP7A, significantly increased the cellular level of 64Cu ($p<0.05$) in comparison to controls, suggesting ATP7A expels Cu to the extracellular medium. Z310 cells were further treated with (i) various concentrations of Cu, (ii) 10 uM deferoxamine to induce Fe deficiency (Fe-D), and (iii) 20 uM hemin to overload Fe (Fe-O). Cu treatment did not affect either mRNA or protein levels of ATP7A; however, Fe-D, but not Fe-O, significantly increased the expression of ATP7A mRNA. Intracellular trafficking of ATP7A in the CP was investigated with confocal immunofluorescence. The freshly isolated CP tissues were treated with 10

uM Fe in an artificial CSF. Interestingly, the ATP7A proteins in the control tissue were primarily located toward the apical membrane facing the CSF; Fe treatment caused the relocation of ATP7A from the apical membrane to the cytoplasm. Taken together, these data suggest that ATP7A in the BCB plays an important role in Cu transport between the blood and CSF and that Fe status significantly alters the function of ATP7A and thereby affects Cu transport at the BCB. (Supported by NIH/NIEHS ES08146).

PS 333 DIVALENT CATION-MEDIATED CELL DEATH INDUCED BY METHYLMERCURY IN A MOTOR NEURON CELL LINE (NSC34).

M. Fain[3, 1], A. Negroni[2, 1], R. K. Hajela[1] and W. D. Atchison[1, 3]. *[1]Department PHM/Toxicology Michigan State University East Lansing, MI, [2]RISE, Univ Puerto Rico-Cayey, Cayey, PR and [3]College of Vet Med, Michigan State University East Lansing, MI.*

In Amyotrophic Lateral Sclerosis-ALS, and especially its prevalent form, Sporadic-ALS (SALS), interaction between genetic factors and environmental exposures has strongly been implied, but never tested directly. Metals including lead and mercurials such as methylmercury (MeHg) have been regularly suggested to contribute to ALS, but again, this has not been tested directly. Glutamate-mediated excitotoxicity contributes to motor neuron degeneration in ALS. This may be due to impaired astrocytic glutamate uptake, or enhanced Ca^{2+} and Zn^{2+} influx through Ca^{2+}-permeable kainate/AMPA receptors. We tested the sensitivity of a motor neuron cell line (NSC34) to increases in divalent cations (Me^{2+}) and Ca^{2+}-mediated cytotoxicity induced by acute exposure to MeHg. Changes in intracellular [Me^{2+}] were monitored using Ca-sensitive fluorophore fura-2, and were compared to those occurring in a well-described neuronal cell model, the NGF-differentiated PC12 cell. Bath exposure to 5μM MeHg caused two patterns of response in NSC34 cells: both a single phase, and a biphasic increase in fura-2 fluorescence. In comparison to a non-motor neuron (PC12 cells), the response to MeHg in NSC34 cells was more variable, and occurred at higher concentrations. TPEN (20μM), a divalent cation chelator, decreased the MeHg-induced response suggesting that a Me^{2+} such as Zn may also increase. Cytotoxicity was determined in NSC34 cells 24 hrs after exposure to MeHg for 1 hr using a "live/dead" assay. MeHg (0.1-10μM) caused a concentration-dependent increase in cytotoxicity. The Ca^{2+}_i chelator BAPTA significantly reduced the % of cells which died in response to MeHg at 5 and 10μM. Thus in a motor neuron cell line, acute exposure to MeHg causes an increase in both $[Ca^{2+}]_i$ and an endogenous Me^{2+}. Chelation of the $[Ca^{2+}]_i$ reduced the incidence of MeHg-induced cytotoxicity in this cell line. Supported by NIEHS grant R01ES03299, 5T35RR017491-07, 5R25GM059429-10 to the UPR-Cayey and the MSU McNair-SROP Program.

PS 334 BRAIN GLUCOSE UTILIZATION FOLLOWING CHRONIC MANGANESE EXPOSURE IN MALE SPRAGUE-DAWLEY RATS.

T. Smith[2], N. Tantawy[3], T. Peterson[3] and V. A. Fitsanakis[1]. *[1]Biology, King College, Bristol, TN, [2]Physics, King College, Birstol, TN and [3]VUIIS, Vanderbilt University, Nashville, TN.*

Manganese (Mn) is toxic at high concentrations, and prolonged exposure may result in manganism, a neurological disorder similar to Parkinson's disease. Data suggest Mn accumulates in mitochondria, which may result in toxicity. Unfortunately, few studies have characterized neuronal changes resulting from low-level, chronic exposure. Using non-invasive μPET (micro positron emission tomography), we quantified brain glucose uptake, an indirect measure of cellular respiration, in male Sprague-Dawley rats.

Rats were injected (iv) with isotonic saline (CN) or MnCl2 (3 mg/kg/week; TX), and routinely imaged using fluorodeoxyglucose (FDG), a radioactive μPET tracer. Each rat also underwent μCT (micro computer tomography) to aid in identification of brain nuclei in μPET images. Raw data was reconstructed using ordered subsets expectation maximization 2D (OSEM2D), and dose-corrected for each scan. μPET and μCT images were registered the Ruben Rat Brain atlas for analysis of various regions of interest (ROI; striatum, cortex, thalamus, cerebellum, hippocampus and whole brain). ROI were evaluated for standard uptake value (SUV) of FDG.

By week 2, treated rats (n = 7) had decreased body mass ($p < 0.001$) compared to controls (n = 6). Both striatum ($p = 0.0074$) and hippocampus ($p = 0.0072$) were also smaller (by mass) in TX compared to CN. Whole brains from TX animals scanned during weeks 4-7 demonstrated a small trend towards increased FDG uptake (11%; $p = 0.58$), which increased to 17% ($p = 0.40$) by weeks 8-11. ROI values normalized to whole brain values, to identify areas responsible for this trend, showed increased striatal FDG uptake in weeks 4-7 (4.6%; $p = 0.14$) that was statistically significant by weeks 8-11 (11.5%, $p = 0.00015$).

These data are consistent with other work suggesting preferential striatal Mn accumulation, with some distribution throughout the entire brain. More importantly, our data suggest that low-level chronic Mn exposure may lead to increased cellular metabolism, perhaps through mitochondrial uncoupling.

PS 335 EFFECT OF PERINATAL AND CONTINUOUS LEAD EXPOSURE ON HISTONE MODIFICATIONS IN THE HIPPOCAMPUS OF YOUNG ADULT RATS.

Y. Zhou, J. L. McGlothan, T. Verina and T. R. Guilarte. *EHS, Johns Hopkins University, Baltimore, MD.*

Lead (Pb2+) is a ubiquitous neurotoxicant that affects the intellectual capacity of children. Recent evidence suggests that epigenetics play an important role in cognitive function. Modifications in the N-terminal tail of histones change the structure of chromatin and regulate gene transcription. In this study, we investigated whether different Pb2+ exposure paradigms altered histone modification in the hippocampus of young adult rats. Adult female rats were fed a 0 or 1500 ppm lead acetate diet prior to and during gestation and lactation and pups were removed from the Pb2+ exposure at postnatal day 21 (PN21) or PN50. Rats were euthanized at PN50, the hippocampus dissected and histones extracted to assess histone modifications. We measured acetylation of H3 (lys9 and lys14), acetylation of H4 (lys5), and monomethylation of H3 (lys4) by western blot. Phosphorylation of H3 (ser10) was not detectable by western blot, therefore, it was measured by immunohistochemistry. Blood Pb2+ levels at PN21 were 29.4 ± 3.9 ug/dL (n=12). For animals that were removed from the exposure at weaning, blood Pb2+ levels at PN50 were 1.2 ± 0.1 ug/dL (n=12) while animals with continuous exposure had 13.7 ± 0.6 ug/dL at PN50 (n=13). Control rats had blood Pb2+ levels of 0.6 ± 0.1 ug/dL (n=40). Western blots of hippocampal histone extracts showed no significant effect of Pb2+ in any of the histone modifications tested. However, counting of cells that stained for phosphorylation of histone H3 (ser10) in the dentate gyrus of PN50 rats exposed to Pb2+ perinatally was different (p=0.056) from controls. No significant effect was measured with rats continuously exposed to Pb2+. These preliminary findings suggest a selective effect of perinatal Pb2+ exposure on H3 Ser10-phosphorylation in the dentate gyrus. This histone modification is associated with initiation of transcription of the immediate early gene c-fos and depends on NMDA receptor signaling (Chandramohan et al., J. Neurochem. 101: 815, 2007). [Supported by ES06189 to TRG]

PS 336 MANGANESE STABILIZES CELLULAR PRION PROTEINS AND ALTER THE RATE OF PROTEINASE-K DEPENDENT LIMITED PROTEOLYSIS.

A. Kanthasamy[1], C. Choi[1], V. Anantharam[1], E. Nicholson[2], J. A. Richt[2] and A. Kanthasamy[1]. *[1]Department of Biomedical Science, Iowa Center for Advanced Neurotoxicology, Iowa State University, Ames, IA and [2]National Animal Disease Center, Ames, IA.*

Prion diseases are fatal neurodegenerative diseases in both animals and humans. The key event in the pathogenesis of prion diseases is the conversion of normal cellular prion proteins (PrP^c) to the proteinase K (PK) resistant, abnormal form (PrP^{sc}); however, the cellular mechanisms underlying the conversion remain enigmatic. Binding of divalent cations such as copper to the octapeptide repeat regions of PrP has been shown to be important for the stability of the protein. Nevertheless, the roles of other divalent cations in the normal processing of cellular PrP^c are not well understood. In the present study, we examined the effect of manganese (Mn) on PrPc expression and degradation in neuronal cells expressing mouse prion proteins with a genetically altered novel epitope (mAb 3F4). Exposure of Mn (100μM) over the course of 24 hr increased PrP levels in both cytosolic and membrane-rich fractions in a time-dependent manner. Interestingly, Mn treatment neither increased PrP mRNA transcripts as measured by qRT-PCR nor altered the mRNA stability as determined in actinomycin D treated cells, indicating that the effect of Mn may be at the level of post-translation and/or degradation levels of PrP. In order to determine whether the accumulation of PrP is due to impairment of the proteasomal degradation pathway by Mn, proteasomal activity and ubiquitination were measured. The results showed no significant alteration of the proteasomal degradation pathway. Notably, pulse-chase analysis showed that the PrP^c turnover rate is significantly decreased with manganese treatment. Furthermore, limited digestion with PK also revealed that manganese treatment decreased the digestion rate of the PrP. These data together clearly suggest that the divalent metal manganese can alter the normal processing of PrP, resulting in the accumulation of PrP with altered susceptibility to PK (supported by DoD/MHRP grant W81XWH-05-10239 and NIH grant ES10586).

PS 337 ACUTE EXPOSURE TO LEAD (PB) RESULTS IN AN INCREASED ACCUMULATION OF β-AMYLOID IN THE CHOROID PLEXUS.

M. Behl, Y. S. Zhang and W. Zheng. *Health Sciences, Purdue University, West Lafayette, IN.*

β-Amyloid (Aβ) proteins are known to participate in the etiology of Alzheimer's disease (AD) and are cleared by the choroid plexus (CP), a barrier between the blood and cerebrospinal fluid that plays a critical role in transport of materials between these two body fluids. Cumulative evidence from human and animal studies shows that Pb accumulates in the CP in an age-dependent fashion. The aim of this study was to investigate whether and how Pb exposure disrupted Aβ transport in the CP. Rats received a single ip injection of 50 mg/kg Pb acetate or Na acetate and 24 h later, were anesthetized and infused with FAM labeled Aβ (200 pmol) for 15 mins in the lateral ventricle. The CP was then examined by confocal microscopy for live Aβ uptake. Data showed a visible increase in intracellular Aβ in the Pb-exposed group compared to controls. In vitro studies were conducted by pre-incubating choroidal epithelial Z310 cells with 10 μM Pb for 24 h, followed by 1-h incubation with Aβ (2 μM). ELISA analysis demonstrated a 25% increase ($p<0.05$) in intracellular Aβ in the Pb treated cells. To explore a mechanism for this finding, we assessed whether the expression and function of LRP1, an Aβ efflux transporter, was altered by Pb exposure. Confocal microscopy revealed that LRP1 was re-distributed from the cytosol in control animals towards the apical surface of the CP in Pb exposed ones (50 mg/kg ip, 24 h). Quantitative Real time RT-PCR and Western blot analyses revealed a significant decrease in LRP1 mRNA and protein levels ($p<0.05$) following Pb exposure in rats. When Z310 cells were exposed to Pb(10 μM, 24 h), a similar reduction of LRP1 mRNA and proteins ($p<0.05$) was also observed. These results suggest that Pb accumulation in the CP leads to increased levels of intracellular Aβ; this effect seems to be associated, at least in part, with the altered clearance of Aβ via its efflux transporter LRP1. Our finding supports the possibility that Pb exposure eventually exacerbates AD by potentially interfering with Aβ clearance at the CP. (Support in part by ES08146 and ES013118)

PS 338 LEAD EXPOSURE DECREASES COPPER CLEARANCE FROM THE CEREBROSPINAL FLUID (CSF) BY THE BLOOD-CSF BARRIER.

Y. Zhang, M. Behl, Q. Fan and W. Zheng. *Purdue University, West lafayette, IN.*

Copper (Cu) is essential to a variety of normal body metabolic processes; yet elevated Cu levels can cause systemic or neurological diseases. Our previous study indicates that exposure to lead (Pb) results in a great accumulation of Pb in the choroid plexus (CP), a tissue where the blood-CSF barrier (BCB)is located. The current study was designed to test the hypothesis that acute Pb exposure disrupted Cu transport at the BCB resulting in an increased Cu levels in the CSF. Rats received an injection of 50 mg Pb/kg daily for 5 days. At the end of exposure, rats were subjected to an in situ ventriculo-cisternal perfusion of [64Cu] in artificial CSF along with a space marker [14C]sucrose. At steady state, [64Cu] in the CSF outflow in Pb-treated animals (58.2±4%) was significantly increased by 13% as compared to controls (51.6±2%) ($p<0.05$); Pb treatment, however, did not affect the outflow of [14C]sucrose, suggesting a decreased Cu clearance by the CP in Pb exposed rats. Choroidal epithelial Z310 cells were used to further verify this effect. Cells were incubated with a combination of 2 μM Cu and 0.5 μCi/mL [64Cu] for 1 h followed by treatment with 10 μM Pb for 24h. A 65% increase in intracellular Cu levels was observed in Pb-treated cells. To study the mechanism, Z310 cells were grown on Transwell membranes simulating an in vitro BCB model. [64Cu] along with [14C]sucrose was added to the donor chamber and the radioactivity was determined in the acceptor chamber. Pb treatment did not affect the Cu transport from the basolateral (blood) side to apical (CSF) side. Interestingly, a decreased transport of Cu from the apical to the basolateral side with an elevated intracellular Cu accumulation was observed in Pb-exposed cells ($p<0.05$). The same treatment did not affect [14C]sucrose transport, suggesting that Pb treatment did not cause non-specific leakage across the barrier. Taken together, it appears likely that Pb exposure decreases Cu clearance from the CSF by altering Cu transport across the BCB. (Support by ES08146)

PS 339 NEUROTOXIC EFFECTS OF ARSENIC COMPOUNDS: FROM ION CHANNELS TO BEHAVIOUR.

H. Straub[1], K. Krüger[1], N. Binding[2] and U. Musshoff[1]. *[1]Institute of Physiology I, Münster, Germany and [2]Institute of Occupational Medicine, Münster, Germany.*
Sponsor: K. Golka.

Arsenic compounds have been shown to disturb cognitive functions in relation to learning and memory in animals and humans.

The aim of the present study was to contribute to the understanding of the toxicological mechanisms underlying these findings. Therefore, we investigated the effects of arsenite (iA-III) and its metabolites monomethylarsonic acid (MMA-V), dimethylarsinic acid (DMA-V), monomethylarsonous acid (MMA-III) and dimethylarsinous acid (DMA-III) on (1) glutamate receptors from rat brains expressed in Xenopus oocytes, (2) the CA1 synapse in hippocampal slices of young and adult rats, and (3) the one-trial shock motivated passive avoidance response (PAR) of young rats in a step-through apparatus at postnatal days 32-36 injected previously with the compounds once at postnatal day 7 or chronically every second day from P7 - P30.

(1) While MMA-V and MMA-III (10 μmol/l) enhanced NMDA-mediated ion currents, DMA-V and DMA-III reduced them and iA-III had no effects. AMPA-induced ion currents were reduced by MMA-III and DMA-V, while MMA-V and iA-III had no effects.

(2) The induction of LTP was reduced by iA-III in adult and young rats. Compared to the absent effects of MMA-V and DMA-V on the synaptic transmission, the trivalent compounds MMA-III and DMA-III strongly reduced the amplitudes of evoked excitatory postsynaptic potentials and of high frequency stimulated LTP at a concentration of 10 μmol/l.

(3) Surprisingly, the passive avoidance learning of young rats was not affected by a single injection of 6 μmol/kg of any of the substances tested and not even by a single injection of 28 μmol/kg MMA-III or DMA-III. Chronic injections of 28 μmol/l iA-III or DMA-III also showed no effect, whereas chronic injections of 14 μmol/l MMA-III significantly impaired the PAR.

The results show that some organic arsenic compounds, especially the trivalent metabolites, disturb the function of glutamatergic receptors and synaptic transmission, but in the concentrations used only MMA-III has significant effects on learning behavior.

PS 340 EFFECTS OF CALCIUM DISODIUM EDTA ON MANGANESE TOXICITY IN MITOCHONDRIA AND NERVOUS SYSTEM OF *CRASSOSTREA VIRGINICA.*

S. Crawford, E. Lagares, C. Saddler, D. Samuel, E. Catapane and M. A. Carroll. *Biology, Medgar Evers College, Brooklyn, NY.*

Excessive levels of Manganese (Mn) produces Manganism, which is similar to Parkinsons. Mn may impair dopamine production, disrupt dopamine receptors or increase mitochondrial oxidative stress. p-Aminosalicylic acid (PAS) alleviates symptoms of Manganism, but its mechanism of action is unknown. *Crassostrea virginica*, has a Mn-sensitive dopaminergic system innervating the gill. We showed PAS, an anti-inflammatory drug with chelator activities, prevented loss of dopamine in Mn treated *C. virginica* and PAS protected against adverse affect of Mn on mitochondrial O_2 consumption. The actions of PAS is thought due to its chelating actions. We compared the efficacy of PAS with another metal chelator, calcium disodium EDTA (EDTA). Animals were exposed to Mn with and without EDTA for 3 days. Biogenic amines were measured by HPLC with fluorescence detection. Cerebral ganglia, visceral ganglia and gill were dissected, weighed, homogenized, centrifuged, filtered and injected into a HPLC system with a Phenomenex Gemini 5μ C18 column and a Jasco FP 2020 Spectrofluorometer with a50 mM acetate buffer mobile phase. EDTA treatments protected against effects of Mn. In other experiments gill mitochondria were treated with EDTA or another chelator, diaminocyclohexanetetraacetic acid (DACH)in the presence of Mn using a YSI Micro-Biological O_2 Monitor with micro-batch chambers. Mn caused dose dependent decreases in mitochondrial respiration. Pretreating mitochondria with EDTA blocked the toxic effects. Adding EDTA to Mn treated mitochondria reversed the toxic effects. DACH was not effective in blocking or reversing actions of Mn and had its own inhibitory effects on mitochondrial respiration. The study shows the chelator EDTA was an effective blocker against the toxic effects of Mn. It also provides evidence that ameliorating effects of PAS on Manganism is related to its chelating actions. These findings provide insights into actions of Mn and PAS in treatments of Manganism.

PS 341 EFFECTS OF P-AMINOSALICYIC ACID ON THE NEUROTOXICITY OF MANGANESE ON THE DOPAMINERGIC INNERVATION OF GILL OF THE BIVALVE MOLLUSC, *CRASSOSTREA VIRGINICA.*

M. Nelson, T. Huggins, R. Licorish, M. A. Carroll and E. J. Catapane. *Biology, Medgar Evers College, Brooklyn, NY.*

Lateral cilia of gill of *Crassostrea virginica* are controlled by a dopaminergic-serotonergic innervation. Dopamine is an excitatory neurotransmitter within ganglia, but an inhibitory transmitter at gill, causing cilio-inhibition. High levels of manganese (Mn) are neurotoxic to people, causing Manganism, a Parkinsons-like disease. Clinical interventions for Manganism have not been very successful. Recently, p-

aminosalicylic acid (PAS) was reported an effective treatment of severe Manganism in humans. PAS is an anti-inflammatory drug with chelating properties. Its mechanism of action is unknown. Previously, we showed short-term treatments of *C. virginica* with Mn disrupts the dopaminergic innervation of gill. Here we examined acute effects of PAS, EDTA and acetylsalicylic acid (ASA) on effects of Mn on gill innervation, and if effects of a 3 day treatment with Mn could be decreased by cotreating with PAS. Beating of lateral cilia were measured by stroboscopic microscopy of gill preparations with the ipsilateral visceral ganglia (VG) attached. For the acute experiments the cerebrovisceral connective innervating the VG was stimulated using suction electrodes, before and after additions of PAS, EDTA and ASA to gill. For 3 day experiments animals were treated by removing their right shells and placing them in containers of aerated artificial sea water containing Mn, PAS, or PAS plus Mn and tested by superfusion of VG with dopamine. Applying PAS and EDTA to gill blocked the neurotoxic effects of Mn, while ASA did not. Short term treatments with Mn produced a dose dependant impairment of the dopaminergic, cilio-inhibitory system which was decreased by cotreating animals with PAS. The study shows PAS protects the animal against neurotoxic effects of Mn and the mechanism of action of PAS in alleviating Manganism may be more related to its chelating abilities than its anti-inflammatory actions.

PS 342 PERIPHERAL AND CENTRAL INFLAMMATORY RESPONSE TO LPS CHALLENGE IS POTENTIATED BY EXPOSURE TO MANGANESE IN THE ABSENCE OF ENHANCED BRAIN AND LIVER ACCUMULATION.

N. M. Filipov[1, 3], R. B. Pringle[1] and L. Bennett[2]. *[1]CEHS, Basic Sciences, Mississippi State University, Mississippi State, MS, [2]Pathobiology and Population Medicine, Mississippi State University, Mississippi State, MS and [3]Physiology anad Pharmacology, University of Georgia, Athens, GA.*

Excessive manganese (Mn) exposure can cause manganism, a neurological disorder that resembles Parkinson's Disease (PD). Several studies suggest that Mn affects glial cells resulting in excessive inflammation and that peripheral immune activation and ensuing inflammation may play a role in neurodegenerative diseases. In an earlier study, our objective was to determine the potential interaction between Mn and a prototypical inflammogen, lipopolysaccharide (LPS) in vivo. We observed that C57BL/6 mice exposed to Mn (3.5 mg/kg; i.p.) for 12 days (d) and then challenged with LPS (1.5 mg/kg; i.p.) on d 12 had greater inflammatory response in both the brain and the periphery relative to mice exposed to Mn or LPS alone. Importantly, these mice also had the greatest locomotor deficits. In the present study, the experimental paradigm was repeated with a subset of mice being challenged with LPS 3 days after the last Mn dose (d 15). In addition, level of inflammation and Mn accumulation was evaluated in the globus pallidus (GP), a known target for Mn. Our results indicate that (i) Mn accumulation in the GP and several other brain areas is not affected by LPS, (ii) mice exposed to Mn have heightened central and peripheral inflammatory responses even when the LPS challenge is 3 d after the last Mn dose, and (iii) locomotor deficits following LPS are augmented by the prior Mn exposure. Thus, so long as peripheral inflammation occurs at times of increased Mn body burden, it may potentiate the neurotoxic effects of this metal. (Supported by NIEHS ES11654)

PS 343 MUSCARINIC M3-MEDIATE INTRACELLULAR CALCIUM CHANGES IS PH SENSITIVE AND DEPENDANT.

H. Wang[1], A. Martin[2], Y. Huang[1] and R. S. Aronstam[1]. *[1]Biological Sciences, Missouri University of Science and Technology, Rolla, MO and [2]cDNA Resource Center, Missouri University of Science and Technology, Rolla, MO.*

The level of intracellular calcium is critical in many cell functions, apoptosis, and metal-induced neurotoxicity. Muscarinic M3 receptor is known to play a role in regulating intracellular calcium. Enhanced intracellular calcium through this process is primarily via ER-calcium release (early phase) and via transmembrane (TM) calcium flux (later phase). Cellular pH status constitutes an important cellular microenvironment modulating cell functions. We believe that cellular pH may serve as an important factor which can modulate M3-calcium flux and therefore cell function or toxicity. Chinese hamster ovary (CHO) cells with transfected-M3 receptor are cultured at various pHs (pH 8.3, 7.4, 6.8, 5.3). These cells were then challenges by a low (6*10-7 M) or high (10-5M) levels of Carbamylcholine chloride (CCh), a specific ligand to muscarinic M3 receptor. At pH 8.3, most of the CHO cells died. Under lower CCH challenge at pH 6.8, the initial peak of intracellular calcium (ER-calcium release) dropped 17% and a 62% reduction in later TM flux-induced intracellular calcium (plateau level) when compared to those levels at pH 7.4. The intracellular calcium was almost totally suppressed at pH 5.3. Thus, low pH seemed to suppress intracellular calcium, affecting TM calcium flux more than ER calcium release. Under challenge by higher level of CCh, high initial ER calcium releases (1000-1300 nM) were observed at all pH conditions (7.4, 6.8, 5.3). However, at very low pH (5.3), this intracellular calcium concentration failed to maintain and dropped off rapidly. Thus, strong M3 stimulation can overcome the suppression effect by lower pH (6.8) for ER-calcium release. However, reversal on the suppression of intracellular calcium via TM calcium flux by strong M3 receptor stimulation at very low pH (5.3) is less effective. Thus modulations on muscarinic M3 receptor and cellular pH may alter the level of intracellular calcium.(Suppotted by the MST cDNA Resource Center. www.cdna.org)

PS 344 CHRONIC MANGANESE EXPOSURE INDUCES MICROGLIAL DYSTROPHIC CHANGES, INOS EXPRESSION AND IRON ACCUMULATION IN THE NON-HUMAN PRIMATE SUBSTANTIA NIGRA.

T. Verina[1], J. S. Schneider[2] and T. R. Guilarte[1]. *[1]EHS, Johns Hopkins University, Baltimore, MD and [2]Pathology, Anatomy and Cell Biology, Thomas Jefferson University, Philadelphia, PA.*

Manganese (Mn) exposure at high doses produces cognitive, psychiatric and motor dysfunctions with symptoms reminiscent of Parkinson's disease. Several basal ganglia nuclei, including the substantia nigra pars reticulata (SNr), have been implicated in the pathogenesis of manganism. Increasing evidence suggests that microglial activation is involved in development of neurodegenerative disorders. Thus, we investigated whether Mn-induced neurotoxicity is associated with microglial changes in the SNr and pars compacta (SNc). We examined microglia in the midbrain of Cynomolgus macaques exposed to different weekly doses of Mn (3.3–5.0, 5.0-6.7, 8.3-10 mg Mn/kg; ip). In controls, we observed sparse LN3-positive cells with fine ramified processes characteristic of resting microglia. On the other hand, in Mn-treated animals, microglial cells were increased in number and frequently fused into rod-like cell aggregates. Reactive microglial cells exhibited dystrophic changes including beading, bulbous spheroids and hypertrophic cytoplasm. Microglia activation was more prominent in the SNr than in the SNc. We also observed microglia engulfing pyknotic bodies potentially representing either phagocytized cellular remnants and/or apoptotic cells. In the SNr of animals that received the highest weekly doses of Mn, we observed that dystrophic cellular compartments of activated microglial cells were usually co-labeled with increased iNOS expression and ferric iron. Therefore, it appears that in the SNr of Mn-exposed animals, microglia become activated, increase iNOS levels and presumably nitric oxide production potentially leading to iron release from ferritin. These events can produce neurotoxic effects as well result in microglial injury reducing their capacity to support normal neuronal functions. Similar microglial dystrophic changes have been described in the aging brain and in human neurodegenerative diseases. [Supported by ES010975 to TRG]

PS 345 VANADIUM CAN SYNERGISTICALLY INCREASE MANGANESE-INDUCED NEUROTOXICITY IN DOPAMINERGIC NEURONAL CELLS *VIA* A CASPASE MEDIATED PATHWAY.

H. Afeseh Ngwa, A. Kanthasamy, V. Anantharam and A. G. Kanthasamy. *Iowa State University, Ames, IA.*

Chronic exposure to manganese (Mn) is known to cause Parkinson's disease (PD) like symptoms. Consequently, there is a growing concern that chronic exposure to welding fumes may be associated with increased incidences of PD. Welding fumes contain many different metals, including Mn and vanadium which is typically present as vanadium pentoxide (V2O5). Unfortunately, the possible neurotoxic effects of V2O5 are not well characterized. In this study, we examined the effect of V2O5 on a dopaminergic cell culture model (N27 cells) and characterized the oxidative signaling events. Our results revealed that exposure to 3-300μM V2O5 for up to 12 hr resulted in a time- and dose-dependent increase in cell death with the EC50 value determined to be 37μM. Exposure to 40μM V2O5 resulted in a significant increase in reactive oxygen species generation, followed by cytochrome c release from the mitochondria, and activation of mitochondrial-dependent proapoptotic events such as sequential activation of initiator caspase-9, and executioner caspase-3. We also found that V2O5 exposure induced proteolytic cleavage of native protein kinase Cδ (PKCδ) to yield catalytically active and regulatory fragments with increased PKCδ kinase activity. Pretreatment with caspase inhibitors blocked V2O5-induced proteolytic cleavage of PKCδ, demonstrating the role of caspase-3 in kinase proteolysis. Pharmacological attenuation of caspase-3 and PKCδ activity prior to V2O5 treatment significantly suppressed increases in DNA fragmentation. The use of siRNA-mediated knockout of PKCδ effectively blocked V2O5-induced apoptosis, further confirming the role of PKCδ in the neurotoxicity of V2O5. We also found that non-toxic doses of Mn potentiated V2O5-induced neurotoxicity. Together, our results demonstrate V2O5 alone and synergistically with Mn exert

neurotoxic effects in a dopaminergic cell model of PD via caspase-3 dependent proteolytic activation of PKCδ, suggesting a possible role of vanadium neurotoxicity in environmentally linked PD (supported by NIH grant ES10586).

PS 346 METHYLMERCURY-INDUCED DEATH IN *C. ELEGANS* AND ITS' ISOLATED EMBRYONIC NEURONS.

J. Tew[1], A. Rivera[2, 1], R. K. Hajela[1] and W. D. Atchison[1]. *[1]Department PHM/Toxicology Michigan State University East Lansing, MI and [2]RISE, Univ Puerto Rico-Cayey, Cayey, PR.*

The nematode *Caenorhabditis elegans (C. elegans)* is a valuable model organism that has been used extensively in neurobiology to study neuronal development, and cell death. *C. elegans* may provide new insights in studying early developmental and chronic effects, or cell-specific effects of neurotoxicants. Effects of methylmercury (MeHg) on lethality and growth in *C. elegans* were examined. MeHg (5-300 μM) was applied to the liquid culture medium, and exposure was continuous for 6-48 hrs. Cultures were synchronized so that toxicity could be examined in the larval (L1-L2) stages. In some experiments, aged worms (L4) were also examined. There was both a concentration- and time-dependent increase in whole organism toxicity with MeHg. After 6 hrs, an approximate LC_{50} in the L1-L2 worms was 220 μM; this was reduced to ~ 100 μM after 12, 24, and 48 hr (approximately 1 generation time) exposures. Significant differences in body length, an effective measure of growth, were seen after 6-hr of exposure to MeHg > 100 μM, and at 48 hrs with exposure to MeHg > 5 μM. No difference was seen in lethality between L1-2 and L3-4 populations. Viability on whole worm populations, even when age-synchronized, depends on factors other than direct neurotoxicity. Thus, we then assayed viability using acutely dissociated embryonic neurons in culture. The *C. elegans* Nw1229 line constitutively expresses GFP tagged to the DPY20 gene in all neurons. After 2-4 days, when the GFP expression is robust, cells received 1hr MeHg treatment in the culture medium. Following replating, GFP-tagged cells were assayed for viability using ethidium homodimer. Sensitivity to MeHg-induced cell death was markedly increased in the GFP-labeled neurons, with a significant increase in mortality seen at 1.2 μM. Thus isolation of pan-GFP-expressing neuronal cells permits examination of MeHg-induced neurotoxicity in *C. elegans* at concentrations approximately equal to those of mammalian neurons. Supported by NIH grant R01ES03299, a grant from MSU OVPRGS, the RISE Program at UPR-C and MSU McNair-SROP.

PS 347 ESTROGEN ANTAGONIZES THE PRO-INFLAMMATORY EFFECTS OF MANGANESE ON EXPRESSION OF NITRIC OXIDE SYNTHASE 2 (NOS2) IN ASTROCYTES.

S. McGrath, J. Moreno and R. Tjalkens. *ERHS, Colorado State University, Fort Collins, CO.*

Degenerative movement disorders affecting the basal ganglia, including Parkinson's and Huntington's diseases, are debilitating diseases that affect more men than women. It is well documented that animal models show the same sex-dependent neurodegeneration and most evidence indicates that estradiol (E2) is the key neuronal protectant influencing gender susceptibility. However, the mechanism by which E2 is protective is poorly understood. Manganism, a degenerative movement disorder caused by excessive accumulation of manganese (Mn) in basal ganglia, presents with clinical features similar to Parkinson's disease, but the relative gender susceptibility to Mn is not well understood. Additionally, epidemiological evidence suggests that children exposed to moderately high levels of Mn in drinking water suffer from cognitive deficits (Woolf, Wright et al. 2002) but the gender-specific risk is similarly unknown. Because astrogliosis and expression of inducible nitric oxide synthase (NOS2) is a known neuropathological feature of Mn neurotoxicity, we postulated that E2 might antagonize Mn-dependent induction of NOS2 in astrocytes at the level of gene transcription. Astrocytes exposed to 30 uM MnCl2 and the inflammatory cytokines TNFα (10 pg/ml) + IFNγ (1 ng/ml) had a significant increase of NOS2 mRNA and protein expression compared to control. Upon 24hr pre-incubation with 10 uM 17-beta-estradiol, Mn- and cytokine-induced NOS2 mRNA and protein expression was significantly decreased. Additionally, live-cell fluorescence imaging indicated that E2 effectively prevented activation of NF-κB in Mn- and cytokine-treated transgenic astrocytes expressing an NF-κB-GFP reporter construct. Previous studies from our laboratory indicated that NF-κB is a critical transcription factor mediating expression of NOS2 in response to Mn in astrocytes. The capacity of E2 to block inflammatory activation of astrocytes and to decrease expression of NOS2 suggests a potential mechanism for neuroprotection that may also influence gender susceptibility.

PS 348 DIFFERENTIAL GENDER AND STRAIN SUSCEPTIBILITY TO THE MOTOR EFFECTS INDUCED BY CHRONIC LOW-LEVELS OF ARSENIC EXPOSURE IN C57BL/6J AND CD-1 MICE.

J. H. Limón-Pacheco[1], U. Bardullas[1], M. Giordano[1], L. Carrizales[2], S. Mendoza-Trejo[1] and V. M. Rodríguez[1]. *[1]Neurobiología Conductual y cognitiva, Instituto de Neurobiología, UNAM, Quer√©taro, Mexico and [2]Facultad de Medicina, Universidad Autónoma de San Luis Potosí, San Luis Potos√≠, Mexico.*

Although other authors have discussed the differential susceptibility to tumor formation among different mouse strains after As exposure, there is no information related to differential behavioral and gender susceptibility. Thus, it is important to study the differential effects of As exposure according to gender and mouse strain in order to define a better animal model to evaluate the neurotoxic effects of chronic low-level arsenic exposure. In the present study male and female C57Bl/6J and CD-1 mice were exposed to environmentally relevant doses of 0.05, 0.5, 5.0 or 50 mg As/l of drinking water during four months. Spontaneous locomotor activity was assessed every month. C57Bl/6J male mice exposed to 0.5 mg As presented hyperactivity, while the group exposed to 50.0 mg As showed hypoactivity after four months of exposure. In contrast, C57Bl/6J female mice exposed to 0.05, 0.5 and 5.0 mg As presented hyperactivity after one, two, three and four months of As exposure. CD-1 male mice exposed to 5 and 50 mg As presented hyperactivity after two, three, and four months of As exposure; while the group exposed to 0.05 mg As/l showed hyperactivity after four months of exposure. No differences in spontaneous locomotor activity were observed in female CD-1 mice at any time point. These results show important differences in spontaneous locomotor activity associated to gender and mouse strains. Female C57Bl/6J mice are more susceptible than male mice; while male CD-1 mice are more susceptible to chronic low-level exposure to As than female mice. This work was supported by grants CONACYT 60662, PAPIIT 214608-19, CONACYT 46-161-M, U. P. Bardullas (228586) and J.H. Limón-Pacheco (43533) received a fellowship from CONACYT.

PS 349 MAGNETIC RESONANCE IMAGING (MRI) AND ^{1}H-MAGNETIC RESONANCE SPECTROSCOPY (MRS) IN THE MANGANESE-EXPOSED NON-HUMAN PRIMATE BRAIN.

J. L. McGlothan[1], P. B. Barker[2], J. S. Schneider[3], T. Syversen[4] and T. R. Guilarte[1]. *[1]Department Env Hlth Sci, Johns Hopkins University School of Public Health, Baltimore, MD, [2]Department Radiology, Johns Hopkins Hospital, Baltimore, MD, [3]Department Pathol, Anatomy & Cell Biol, Thomas Jefferson University Philadelphia, PA and [4]Department Neurosci, Norwegian Univ Sciences & Tech, Trondheim, Norway.*

This study is part of a multidisciplinary effort investigating the behavioral, *in vivo* neuroimaging and neuropathological effects of chronic Mn exposure in non-human primates. It comprises one of the largest cohorts studied using MRI and MRS. Male research naïve Cynomulgus macaques received baseline MRI and MRS studies prior to Mn administration and at two different time points during the administration of weekly doses of Mn. For the MRI studies, a Pallidal Index Equivalent [PIE; (signal from a brain region/frontal white matter signal)] was measured in several brain regions including the cerebellar white matter, globus pallidus, caudate, putamen, thalamus and substantia nigra. The pituitary gland and muscle surrounding the skull were also measured. A comparison of the PIE indicated increases in the globus pallidus, substantia nigra and putamen as well as the pituitary gland relative to baseline indicative of increased Mn accumulation. Unexpectedly, a significant decrease in PIE was measured in the thalamus as a result of Mn exposure. However, if a PIE is calculated using muscle, rather than frontal white matter as the denominator, all brain regions demonstrate increased PIE during Mn exposure relative to baseline. This observation confirms our previous findings (Guilarte et al., Tox Sci 94: 351, 2006) that the commonly used Pallidal Index, where the frontal white matter signal is used as the reference region (denominator), is not an accurate measure of regional brain Mn accumulation. Preliminary analysis of the MRS data in post-frontal white matter suggests a transient increase in the choline/creatine ratio (Cho/Cr). Elevated Cho/Cr ratio is indicative of inflammation or demyelination. The latter suggests white matter involvement in Mn neurotoxicity. [Supported by ES010975 to TRG]

PS 350 RESPONSE OF NEURAL STEM CELLS TO TRIMETHYLTIN INJURY IN THE MURINE HIPPOCAMPUS.

B. Weig, H. E. Lowndes and K. R. Reuhl. *Pharmacology and Toxicology, Rutgers University, Piscataway, NJ.*

Stem cells in the developing mammalian brain migrate from the ventricular zone to form secondary sites of neurogenesis that persist in the adult: the subventricular zone (SVZ), and the hippocampal subgranular zone (SGZ). SVZ cells occupy the

anterolateral wall of the lateral ventricles and continuously produce neuroblasts that migrate to the olfactory bulb to create new olfactory neurons. SGZ stem cells migrate into the granule cell layer to form new granule cells in the hippocampus dentate gyrus. The response of SVZ and SGZ stem cells to hippocampal injury was studied in two-month old male C3H mice treated with the selective limbic system neurotoxicant trimethyltin (TMT). The fluorescent carbocyanine dye spDiI was injected unilaterally into the lateral ventricle of mice to label migrating SVZ cells. Bromodeoxyuridine (BrdU; 80 mg/kg; ip.) was administered to only label proliferating cells prior to injury. The mice were then dosed with TMT (2.7 mg/kg; ip) and brain sections taken 7 or 28 days later. Very few spDiI+ cells were found in the hippocampus of uninjured animals, though there tended to be an increased number of cells at 28 days (p=0.0523). TMT injury had no effect on the number of BrdU+ or spDiI+ cells in the hippocampus at 7 days. However, 28 days after TMT injury there was nearly a 4-fold greater number of spDiI+ cells in the hippocampus. The spDiI+ cells were localized throughout the dentate gyrus, including the subgranular zone. TMT injury also appeared to prevent the loss BrdU+ cells in the hippocampus that occurred in uninjured animals 28 days after labeling. Very few spDiI+ cells (<15%) had co-labeled with BrdU. Phenotypic markers for astrocytes (GFAP) or neurons (NeuN) rarely co-localized with spDiI+ cells indicating a limited potential for terminal differentiation, suggesting the majority (>85%) may remain in an undifferentiated state. This study suggests that SVZ cells are stimulated to migrate into the TMT-injured hippocampus dentate gyrus and that injury may promote the survival of new cells. PS 351 MOLECULAR AND GENETIC ANALYSIS IN A NOVEL MODEL OF METHYLMERCURY NEUROTOXICITY.

N. VanDuyn[1], R. Settivari[1], L. Chen[3], A. Braun[2] and R. Nass[1]. *[1]Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN, [2]Zoology/Developmental Neurobiology, Otto von Guericke University, Magdeburg, Germany and [3]Genetics, Cell Biology, and Development, University of Minnesota, Minneapolis, MN.*

Methylmercury (MeHg) exposure from occupational, environmental and food sources is a significant threat to public health. The toxin easily passes the blood brain barrier and can cause severe psychological and neurological problems. Although MeHg poisonings have been studied for decades, the molecular determinants involved in the cellular pathology are largely unknown. We have developed a novel model of methymercury toxicity in the genetically tractable nematode C. elegans. We show that MeHg exposure confers animal death at low concentrations, and that the sensitivity is partially dependent on growth medium. Consistent with vertebrate studies, growth in the presence of selenium dramatically rescues the MeHg-induced death, and this effect is dependent on a live bacteria food source. Developmental defects are also observed as older larvae exposed to non-lethal doses of MeHg show a significantly decrease in brood size. Exposure of younger larvae to similar concentrations of MeHg results in over a 2-fold delay in development. Whole genome microarray and real-time PCR results show a very strong induction of specific heat shock proteins and glutathione transferases following exposure to MeHg. In particular, gst-38 is significantly upregulated at both the mRNA and protein levels following MeHg exposure, and this upregulation can be surpressed by coexposure with selenium. Gene expression studies also indicate a significant induction of genes involved in electron transport, cell growth and protein folding. Overall these studies suggest that C. elegans is a powerful model system to explore the molecular basis of MeHg toxicity. We will also describe our current work in mammalian neuron cultures that builds on our in vivo studies, as well as our preliminary results from a novel genome-wide screen to identify mediators and suppressors of the MeHg neurotoxicity.

PS 352 EVALUATION OF TELLURIUM TOXICITY IN RAT HIPPOCAMPAL ASTROCYTES.

S. Roy and D. Hardej. *Pharmaceutical Sciences, St. John's University, Jamaica, NY.*

Tellurium (Te), a trace element, is present in the earth's crust, seawater, soil and also in body fluids such as blood and urine. Plants can also accumulate Te from the soil. This element is widely used in the electronics industry, photography, in the vulcanization of rubber and in pesticides. Occupational and environmental exposure is common, and yet little is reported about cytotoxic effects of tellurium compounds. Several studies have reported that both organic and inorganic tellurium compounds exhibit toxicity in rats by causing peripheral neuropathy resulting from demyelination. This effect is attributed to inhibition of squalene epoxidase, an enzyme necessary for cholesterol biosynthesis. Teratogenic and hematologic disorders have also been reported. Limited studies have addressed its potential adverse effects to the central nervous system. The purpose of this study was to evaluate toxic effects of diphenyl ditelluride and tellurium tetrachloride in rat hippocampal astrocytes. Cells were grown to 90% confluency and treated for 24 hrs. with the following concentrations of each compound: 250, 125, 62.5,31.25, 15.625,7.8125, 3.90, 1.95, 0.98, 0.49, 0.24 μM. Cell viability was measured by MTT Assay. Significant decreases in cell viability were seen at all concentrations tested for both compounds. Viability studies were confirmed with light and scanning electron microscopy. Cellular distortion involving loss of processes and plasmalemmal alterations including cytoplasmic blebbing were observed in concentrations of 125, 62.5, 31.25, 15.625 μM. In order to investigate whether cell injury was accompanied by lipid peroxidation, a thiobarbituric acid reactive substance (TBARS) assay was performed using concentrations of 125, 62.5, 31.25, 15.625 μM for both compounds. Lipid peroxidation was not observed in astrocytes treated with either of the compounds and cellular injury does not appear to involve peroxidative processes.

PS 353 REDUCED ATMOSPHERIC MANGANESE IN MONTREAL FOLLOWING REMOVAL OF METHYLCYCLOPENTADIENYL MANGANESE TRICARBONYL (MMT).

J. Zayed[1], A. Joly[1], J. Lambert[2], C. Gagnon[3], K. Szyncel[1], G. Kennedy[4] and D. Mergler[5]. *[1]Department of environmental and occupational health, University of Montreal, Montreal, QC, Canada, [2]Department of Social and Preventive Medicine, University of Montreal, Montreal, QC, Canada, [3]Montreal Urban Community, Montreal, QC, Canada, [4]Department of Engineering Physics, Polytecnic School, Montreal, QC, Canada and [5]CINBIOSE, University of Quebec in Montreal, Montreal, QC, Canada.*

Methylcyclopentadienyl Manganese Tricarbonyl (MMT) was used as an antiknock agent and as an octane booster in Canadian unleaded gasoline. Its combustion leads to Mn emissions. Considering that MMT is no longer used in the Canadian gasoline since 2003, the objective of this research was to examine the variations in atmospheric Mn in Montreal (Canada) from 2001 to 2007, covering the period prior to and following MMT use. Three sampling stations were selected because their proximity to roads with widely differing and well-known traffic. Filters from 2001 to 2007 were obtained. The first sample of each month was selected and Mn analysis was performed by neutron activation analysis. TSP (total suspended particulates) was calculated by weighing the filters before and after dust collection. Results show a significant decrease of Mn over time at each station, while TSP decreased significantly in two stations, with one showing a trend. Comparing atmospheric Mn during and after the period of use of MMT 2001 – 2003 vs 2005 – 2007 showed a significant decrease at all stations. For TSP, only one station showed borderline significant difference between these two periods. The difference between the two periods shows 41% and 17% of decrease for Mn and TSP, respectively. These data suggest that the combustion of MMT led to an increase of airborne Mn of approximately 24%. These results should help in decision-making processes leading to the acceptance or rejection of the use of MMT in gasoline in other countries.

PS 354 EFFECTS OF CHELATING AGENTS ON MANGANESE AND CADMIUM ACCUMULATIONS IN GILL OF *CRASSOSTREA VIRGINICA.*

S. Murray, M. Yates, Y. Perdomo, M. A. Carroll and E. J. Catapane. *Biology, Medgar Evers College, Brooklyn, NY.*

Manganese (Mn) is needed for normal physiological functions, but high amounts are toxic and cause Manganism, which is similar to Parkinsons disease. Both conditions disrupt dopamine neurons. Cadmium (Cd) has no known biological functions. In humans it adversely affects kidney, liver and lung by inducing apoptotosis or carcinogenesis. Routes of exposure include cigarette smoke and ingestion of Cd contaminated food. Cd pollution is widespread in aquatic environments and marine animals accumulate cadmium in their tissues. p-Aminosalicylic acid (PAS) is being used to alleviate symptoms of Manganism in humans. PAS is an anti-inflammatory drug with chelating ability. The ability of PAS to ameliorate symptoms of Manganism is postulated to be due to its chelating actions. We showed PAS was effective in reducing Mn accumulations, but not Cd accumulations in oyster gill. Sodium EDTA (EDTAna) was moderately effective in reducing Cd accumulations. In clinical setting, calcium EDTA (EDTAca) is the preferred form for metal chelation therapy. This study sought to compare the efficacy of various chelating agents on Mn and Cd accumulations. We incubated gills of *Crassostrea virginica* for 10 hours with Mn or Cd, followed by 3 day treatments with the metal chelators, diaminocyclohexanetetraacetic acid (DACH), EDTAna or EDTAca. Mn and Cd levels were measured using electrothermal vaporization with deuterium lamp background correction in an Atomic Absorption spectrophotometer with a THGA graphite furnace. All 3 chelating agents reduced Mn accumulations. DACH was most effective, followed by EDTAca and EDTAna. Low concentrations of EDTAna did not reduce Cd accumulations; however, higher concentrations of EDTAna were moderately effective. The EDTAca was significantly more effective

in reducing Cd accumulations, especially at low concentrations. The study shows the chelating agents are effective in reducing Mn and Cd accumulations and supports the hypothesis the mechanism of action of PAS in treatment of Manganism is related to its chelating abilities.

PS 355 NEUROTOXIC EFFECTS OF ARSENITE IN ASTROGLIAL AND NEURONAL MODELS: MECHANISMS INVOLVED IN DIFFERENTIAL SUSCEPTIBILITY.

Y. Castro-Coronel[1, 2], J. Robledo[1], L. Ramírez-Martínez[1], A. Ortega[1], L. Del Razo[2] and E. López-Bayghen[1]. *[1]Department .Genética y Biol. Mol., Cinvestav-IPN, Mexico DF, Mexico and [2]Sección Externa de Toxicología, Cinvestav-IPN, Mexico DF, Mexico.*

Chronic exposure to inorganic arsenic produces toxic damage in CNS, disrupting neurological functions. Glutamate (Glu), being the main excitatory neurotransmitter is critically involved in these events. Glu levels are tightly regulated through Na+-dependent Glu transporters in order to avoid its well-characterized excitotoxic effects. In order to gain insight into the molecular mechanisms of arsenite toxicity, we analyzed the effects of arsenite exposure in Glu transport. To this end, arsenite was applied in epidemiologically relevant doses (< 5 μ M) to confluent neuronal and glial cultured cells, and Glu transport was evaluated through a [^{3}H]-D-aspartate uptake assay. The human neuroblastoma SH-SY5Y and the rat glioma C6 cell lines as well as a Bergmann glia primary culture were used. Arsenite exposure reduced the uptake activity in glial cultures whereas in the neuronal cell line an increase in uptake was found. It has been reported that oxidative stress can severely affect Glu transporters; therefore we evaluated lipid peroxidation in glial cells; however no correlation was found since arsenite did not induce lipoperoxidation in these cells, although we did observe an increase in glutation levels. Proliferation and activation of p53 were also evaluated under arsenite exposure. An increase in p53 protein levels and its DNA binding activity was found both in neuronal and glial cells in a dose-dependent manner. Interestingly, arsenite exposure significantly decreased the proliferation rates in C6 and SH-SY5Y cells. These results strongly suggest that Glu accumulation and p53-dependent transcriptional regulation participate in the molecular mechanisms of arsenite neurotoxicity. Supported by CONACyT 50414

PS 356 RELATIONSHIP BETWEEN BLOOD MANGANESE-IRON RATIO AND EARLY ONSET NEUROBEHAVIORAL ALTERATIONS.

D. M. Cowan[1, 2], W. Zheng[2], Y. Xou[3], X. Shi[4], J. Chen[4], F. S. Rosenthal[2] and Q. Fan[3]. *[1]ChemRisk, Boulder, CO, [2]School of Health Sciences, Purdue University, West Lafayette, IN, [3]Department of Occupational Medicine, Zunyi Medical College, Zunyi, Guizhou, China and [4]Guizhou Institute of Occupational Safety and Health, Zunyi, Guizhou, China.*

A biomarker for early onset neurobehavioral alterations in manganism remains unknown. The purpose of this study was to use a neurobehavioral test battery to identify subtle changes in Mn-induced motor and memory dysfunction and to relate the quantifiable neurological dysfunction to an established Mn exposure index such as blood Mn-Fe ratio (MIR). A total of 323 subjects were recruited to control (n=106), low (122), and high (95) exposure groups. The test battery consisted of standard procedures including the nine-hole and groove-type steadiness tester, Benton test, and Purdue pegboard. No health problems or clinically diagnosed neurological dysfunctions were observed except for increased blood pressure in Mn-exposed smelters. Benton test did not reveal any abnormal memory deficits among Mn-exposed smelters, nor did the groove and nine-hole tests detect any abnormality in dynamic and static steadiness in tested subjects. Purdue pegboard test showed a remarkable age-related decline in fine movement coordination among all study participants regardless of the Mn exposure condition. Mn exposure significantly exacerbated this age-related decline. Statistical modeling revealed that the plasma and erythrocyte MIR (pMIR and eMIR, respectively) were associated with Purdue pegboard scores. Among all subjects whose MIR were above the cut-off value (COV), pMIR was significantly correlated with pegboard scores (r=-0.261, p=0.002), whereas for those whose age were above 40 years the eMIR, but not pMIR, was associated with the declined pegboard performance (r=-0.219, p=0.069). When both factors were taken into account (age >40 and MIR > the COV), only pMIR was inversely associated with pegboard scores. Combining their usefulness in Mn exposure assessment, we recommend that the blood Mn-Fe ratio may serve as a reasonable biomarker not only for judgment of Mn exposure but also for health risk assessment.

PS 357 DECREASED DMT1, TF AND HEPCIDIN GENE EXPRESSIONS IN LEUCOCYTE OF MANGANESE EXPOSED WORKERS.

Q. Fan[1], Y. Zou[1], J. Liu[1], C. Yu[1], J. Chen[2], X. Shi[2], Y. Zhang[3] and W. Zheng[3]. *[1]Department of Preventive Medicine, Zunyi Medical college, Zunyi City, China, [2]Guizhou Institute of Occupational Safety and Health, Zunyi City, China and [3]Health Sciences, Purdue University, West Lafayette, IN.*

Manganese (Mn) is widely used in several industries including the manufacture of steel. Increased uptake of Mn leads to manganism, mainly resulting in progressive neurological disorders, similar to Parkinson's disease. Previous literature suggests that there are a set of common genes involved in the absorption, transportation and metabolism of Mn and iron (Fe) and Mn exposure alters Fe metabolism. This study was designed to test the hypothesis that workers exposed to Mn had an altered expression of genes involved in Fe metabolism in the leucocyte. A Mn exposed group (n=62), working in a Mn-Fe alloy factory was compared to non-Mn-exposed (control) workers (n=39) from a pig iron plant in Zunyi City, China. The working environment of both groups were similar except for a difference in airborne Mn concentrations. The geometric mean of Mn concentrations in the air of the Mn-exposed and control workers was 0.003 mg/m3 and 0.18 mg/m3, respectively. A real-time RT PCR was used to determine mRNA levels of divalent metal transporter 1(DMT1), transferrin (TF), transferrin receptor (TfR) and hepcidin in the leucocyte. Mn concentrations in the plasma and in the erythrocytes were analyzed by AAS. Results revealed a significant decrease in the expression of DMT1, TF and hepcidin genes in Mn-exposed workers by 77.9%, 80.7% and 90.1%, respectively, as compared to controls. There was no significant difference observed in TfR levels. By adjusting for age, sex and cumulative exposure, the expressions of DMT1, TF and hepcidin genes were inversely correlated with the Mn concentrations in the erythrocytes; their Spearman r are -0.22, -0.18, - 0.24, respectively (all p values were <0.01). In summary, Mn exposure decreases the expressions of DMT1, TF and hepcidin in the leucocytes. Further studies are warranted to elucidate the mechanism of Mn action.(DOD W81XWH-05-1-0239, NIH/NIEHS ES-08164,and China NSF 30760209).

PS 358 MANGANESE MODIFICATION OF GLUTAMINE TRANSPORT IN PRIMARY ASTROCYTES.

M. Sidoryk[1], E. Lee[2], H. Jiang[1], J. Albrecht[3] and M. Aschner[1]. *[1]Department of Pediatrics, Vanderbilt University, Nashville, TN, [2]Department of Neurology, Meharry Medical College, Nashville, TN and [3]3. Department of Neurotoxicology, Medical Research Centre, Polish Academy of Sciences, Warsaw, Poland.*

Glutamine (Gln) plays an important role in the CNS as an energy metabolite and as a precursor of neurotransmitters: excitatory glutamate (Glu) and inhibitory γ-aminobutyric acid (GABA). Previous studies have shown that astrocytic Gln transport is impaired following manganese (Mn) exposure. The present studies were performed to investigate the hypothesis that Gln transporter expression dysregulation by Mn plays a role in neurotoxicity. mRNA expression and protein level of Gln transporters belonging to the systems: N (SNAT3, SNAT5), ASC (ASCT2), A (SNAT2) and L (LAT2) was studied in rat neonatal primary astrocyte cultures exposed to Mn. Significant ($p<0.01$) inhibition of SNAT3 mRNA expression was observed after incubation of cells with 1000 μM Mn for 4h and with 500, 1000 μM Mn for 8h and 24h. Expression of the mRNA coding for SNAT2 and LAT2 was inhibited at 100, 500 and 1000 μM Mn after 8h and 24h treatment. Mn exposure didn't affect expression of mRNA coding for SNAT5 and ASCT2 transporters. 500 μM and 1000 μM Mn caused decreased SNAT3 protein level after 1h and 4h and degradation after 8h and 24h of treatment. Incubation of astrocytes with Mn resulted also in decreased protein level of SNAT2 (after 4h, 8h and 24h treatment with 1000 μM Mn and after 8h and 24h treatment with 500 μM Mn) as well as LAT2 (after 8h and 24h exposure for 500 μM and 1000 μM Mn). Treatment of the cells with Mn didn't change neither SNAT5 nor ASCT2 protein levels. Taken together, these studies demonstrate that Mn causes disability of astrocytic Gln transport by decrease in Gln transporters genes expression. These alternations can diminish the availability of precursor for synthesis of Glu and GABA in neurons, leading to decrease in these neurotransmitters neuronal pools, a phenomenon known to be associated with Mn toxicity. This work was supported by Public Health Service of National Institute of Health Grant ES007331.

PS 359 METHYLMERCURY-INDUCED OXIDATIVE STRESS IN CULTURED ASTROCYTES LEADS TO NRF2 ACTIVATION AND NUCLEAR TRANSLOCATION.

H. Jiang[1], Z. Yin[1], E. Lee[1], J. Rocha[2], J. Cai[3] and M. Aschner[1]. *[1]Pediatrics Toxicology, vanderbilt university, Nashville, TN, [2]Biochemistry, University of Santa Maria, Santa Maria, Brazil and [3]Ophthalmology, Vanderbilt University, Nashville, TN.*

Methylmercury (MeHg) is a significant environmental contaminant that will continue to pose great risk to human health. A number of studies suggest that oxidative stress mediates MeHg-induced neuronal damage. NF-E2-related factor 2 (Nrf2)

was identified as a major regulator of cytoprotective genes in oxidative damage. Under normal conditions, Nrf2 in the cytoplasm is bound to Keap1. In the presence of oxidative stress, the Keap1-Nrf2 complex dissociates and Nrf2 translocates into the nucleus. Upon activation, Nrf2 upregulates the expression of genes associated with antioxidant responses. In our study, we investigated the protective effects of Nrf2 in response to MeHg exposure in astrocytes. Primary astrocytes were prepared from cerebral cortices of one-day-old Sprague–Dawley rats. MeHg toxicity in astrocytes was assessed by lactate dehydrogenase (LDH) leakage into the culture medium. Cytotoxicity was determined by measuring the conversion of a tetrazolium salt (3-(4, 5-Dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide, MTT) to a formazan product. Apoptosis was assessed by measuring caspase-3 activities. Cells were treated with MeHg at 1 or 10μM for 1, 8, or 16h, then whole-cell, or nuclear and cytoplasmic Nrf2 expression levels were assessed by western blot analysis; nuclear translocation of Nrf2 was examined by immunocytochemistry staining with laser confocal microscopy. Our results showed that MeHg led to a significant increase LDH release, MTT reduction and activation of caspase-3 ($p<0.05$ by ANOVA). These effects were significantly attenuated by the antioxidants ebselen or trolox ($p<0.05$). MeHg treatment (8 and 16 hrs) significantly ($p<0.01$) amplified Nrf2 levels by 3-5 fold and Nrf2 translocated to the nucleus. These results indicate that MeHg exerts its neurotoxicity through oxidative stress and activation of the Nrf2-ARE pathway in astrocytes is likely associated with protection against oxidative damage caused by MeHg.

PS 360 ANTIOXIDANTS INFLUENCE METHYLMERCURY-INDUCED OXIDATIVE REACTION IN PRIMARY CULTURED ASTROCYTES.

Z. Yin, D. Milatovic, H. Jiang, E. Lee and M. Aschner. *Vanderbilt Medical Center, Nashville, TN.*

Methylmercury (MeHg) is a well-documented neurotoxin in animals and humans. It is well established that MeHg preferentially accumulates in astrocytes, affecting their ability to induce and/or exacerbate neuronal dysfunction. The present study was designed to test that MeHg activates stress related proteins and that its effects can be attenuated by antioxidants. Astrocyte oxidative damage and inflammatory reaction were detected by measuring protein expression using antibodies to DJ-1, Caspase-3, TRPM2 and PPAR. DJ-1 is as an antioxidant protein or a redox sensor in oxidative stress. TRPM2 is a membrane protein that can be activated by oxidative stress and confers susceptibility to cell death. PPARs are nuclear hormone receptors that can be triggered by various compounds including prostaglandins in response to inflammatory reaction. Western blotting analysis and immunofluorescent assays were employed. The potentiometric dye tetramethylrhodamine ethyl ester (TMRE) was used to probe mitochondrial membrane potential ($\Delta\psi m$). Results showed a significant ($p<0.05$) reduction of DJ-1 expression and caspase-3 activation in cultured astrocytes exposure to MeHg at 10 μM. Pre-treatment of ebselen or trolox partially reversed the MeHg effects, maintaining DJ-1 expression and caspase-3 activation at levels indistinguishable from controls. A significant ($p<0.05$) increase in TRPM2 immunofluorescence was also observed upon exposure to MeHg, consistent with activation of oxidative reaction. The presence of PGJ2, an anti-inflammatory reagent, significantly ($P<0.05$) reduced the activation of TRPM2. MeHg significantly ($p<0.05$) increased PPARγ expression, suggesting increased inflammatory response. The administration of PGJ2 maintained the expression of PPARγ indistinguishable from controls. TMRE imaging demonstrated that MeHg resulted in collapse of $\Delta\psi m$ ($p<0.05$ vs. control), ebselen or trolox partially reversed this effect of MeHg. These results indicate that induction of oxidative damage, inflammatory reaction and associated mitochondrial dysfunction represent important mechanisms of MeHg neurotoxicity.

PS 361 *CAENORHABDITIS ELEGANS* AS A MODEL TO STUDY MECHANISMS OF METHYLMERCURY TOXICITY.

K. J. Helmcke[1, 2], D. Miller[3] and M. Aschner[1, 2]. [1]*Pharmacology, Vanderbilt University, Nashville, TN,* [2]*Center In Molecular Toxicology, Vanderbilt University, Nashville, TN and* [3]*Department of Cell and Developmental Biology, Vanderbilt University, Nashville, TN.*

Methylmercury (MeHg) is a toxicant having detrimental effects on the mammalian nervous system, but the mechanisms of toxicity are unknown. Humans are exposed to MeHg in seafood and the toxicant is able to traverse the blood-brain and placental barriers, making it harmful to the nervous system, particularly that of the developing fetus. *Caenorhabditis elegans* is an organism amenable to use in toxicological research. Therefore, *C. elegans* was used as a model to discern pathways involved in MeHg developmental neurotoxicity. Previous results indicated that although MeHg was lethal to *C. elegans*, surviving animals show no defects in locomotion, birthrate or neuronal morphology. However, MeHg accumulated in treated animals in a dose and time-dependent manner (after 15 hour treatment L4 worms treated at 0.1 and 0.4 mM MeHg had 20- and 150-fold increases in MeHg content, respectively) and induced a dose-dependent delay in development and pharyngeal pumping rate (after 15 hour exposure of L4 worms, at 0.1 and 0.4 mM MeHg, pumping rate was reduced 27% and 70%, respectively) indicating an effect of MeHg on the pharyngeal nervous system. GFP reporters will be used to determine if MeHg affects the differentiation or morphology of neurons that control pharyngeal pumping. Following initial MeHg insult, worms were less sensitive to subsequent MeHg exposure, shifting the lethality dose-response curves of MeHg rightward with increasing initial MeHg exposure. These results indicate that exposure to non-lethal concentrations of MeHg induces factors in *C. elegans* that protect it from additional insults and candidates are being studied to assess involvement in this process.

PS 362 ASSESSMENT OF MANGANESE EXPOSURE BY 3D HIGH-RESOLUTION T1-WEIGHTED MRI.

U. Dydak[1, 2], Y. Jiang[3], L. Long[3], J. Chen[4], W. Li[3], J. Murdoch[5], D. Meier[6], M. Aschner[7] and W. Zheng[1]. [1]*School of Health Sciences, Purdue University, West Lafayette, IN,* [2]*University of Indiana School of Medicine, Indianapolis, IN,* [3]*Guangxi Medical University, Nanning, China,* [4]*Guizhou Institute of Occup. Safety and Health, Zunyi, China,* [5]*Philips Healthcare, Cleveland, OH,* [6]*University and ETH Zurich, Zurich, Switzerland and* [7]*Vanderbilt University, Nashville, TN.*

Exposure to excessive manganese (Mn) leads to psychological and motor disorders, indicating a permanent damage to certain brain structures. Yet, there has been no reliable means for early, pre-symptomatic diagnosis and assessment of Mn intoxication. The aim of this study was to use magnetic resonance imaging (MRI) as a non-invasive method to distinguish Mn-exposed subjects from the control subjects. A group of 10 smelting workers as well as a group of 10 control subjects with no history of Mn exposure were recruited from a Mn-Fe alloy manufacturer in Zunyi, China. All study subjects were subjected to physiological examination, blood testing, and MRI examination. High-resolution 3D T1-weighted isotropic images ($1x1x1.25\ mm^3$) were acquired in addition to conventional axial T1-weighted 5mm thick slices and analyzed by visual inspection and region of interest (ROI) analysis. The pallidal index (PI) was calculated based on (1) the signal ratio between a ROI within the globus pallidus (GP) and white matter in the frontal cortex (PIwm) and (2) the signal ratio between the same ROI in the GP and a ROI in the neck muscle (PImu). Results showed that 3D T1weighted MRI was much more sensitive than the axial T1-weighted method in identifying Mn deposit in brain. PImu and PIwm, based on the 3D T1w-MRI, showed 90% and 70% success in predictibility, respectively, in identifying the Mn exposed smelters out of the 20 subjects scanned. Thus, it appeared that PImu was more accurate than PIwm in distinguishing Mn exposed smelters from the control workers. In addition, 3D imaging allowed us to trace the regions of Mn accumulation in high detail to the most interior parts of the GP. Further analysis of changes in brain metabolites as seen by MRS is in progress. (Supported by DoD USAMRMC W81XWH-05-1-0239)

PS 363 PRENATAL EXPOSURE TO BENZO(A)PYRENE IMPAIRS LATER-LIFE CORTICAL NEURONAL FUNCTION.

M. M. McCallister[1], M. Maguire[1], A. Ramesh[2], Q. Aimin[1], S. Liu[1], H. Khoshbouei[1], M. Aschner[3], F. F. Ebner[4] and D. B. Hood[1]. Prenatal exposure to environmental contaminants, such as Benzo(a)pyrene [B(a)P] has been shown to impair brain development. We hypothesize that glutamate receptor subunit expression is vital for cortical evoked responses and that prenatal B(a)P exposure modulates the temporal developmental expression of glutamatergic receptor subunits in the somatosensory cortex. To characterize prenatal B(a)P exposure on the development of cortical function, pregnant Long Evans rats were exposed to 300μg/kg BW B(a)P by oral gavage on gestational days 14 to 17. At this dose, B(a)P had no effect the number of pups born per litter, the pre-weaning growth curves and initial and final brain to body weight ratios. Control and B(a)P-exposed offspring were profiled for B(a)P metabolites in plasma and whole brain during the pre-weaning period. A time-dependent decrease in total metabolite concentration was observed in B(a)P-exposed offspring. On PND100-120, cerebrocortical mRNA expression was determined for the glutamatergic NMDA receptor subunit NR2B and neural activity was recorded from neurons in primary somatic sensory cortex. Semiquantitative PCR revealed a significant reduction in NR2B mRNA expression in B(a)P-exposed offspring relative to controls. Recordings from

B(a)P-exposed offspring revealed that N-methyl-D-aspartate (NMDA) receptor-dependent evoked neuronal activity in barrel cortex was also significantly reduced as compared to controls. Analysis showed that the greatest deficit in cortical neuronal responses occurred in the shorter latency epochs post-stimulus. This suggests that in utero exposure to B(a)P results in reduced expression of the NR2B receptor subunit which results in later life deficits in cortical neuronal activity in the offspring. Supported in part by U54NS041071, S11ES014156, T32MH065782, and RRO3032.

PS 364 MEHG-INDUCED OXIDATIVE STRESS IN MICROGLIAL CELLS AND ITS ROLE IN NEUROTOXICITY.

M. Ni and M. Aschner. *Pharmacology, Vanderbilt University, Nashville, TN.*

MeHg poisoning in Minamata Bay and recent studies in human cohorts have provided ample evidence for the neurodevelopmental effects of MeHg and its wide range of neurological symptoms. Microglial cells, accounting for 12% of the brain cells are "professional phagocytes" and their activation contributes to neuronal damage. Given their prominent role in the maintenance of CNS homeostasis, we initiated a project to investigate effects of MeHg on microglial cell function, testing the hypothesis that these cells modulate MeHg's effects. Primary microglial cells were prepared from cerebral cortices of 1- day Sprague-Dawley rats. Cytotoxicity was determined by measuring conversion of tetrazolium salt (MTT) to formazan product and quantification of the leaked LDH into the culture medium. Nrf-2, p-AKT and p- ERK were quantified by WB using infra- red dye conjugated secondary antibodies. Immunostaining was carried out with a Nikon eclipse microscope. Both the MTT and LDH assays confirmed the toxicity of MeHg to microglial cells. MeHg caused microglial death in a concentration-dependent manner and increased COX2 expression after 6- hour treatment, suggesting the existence of MeHg- induced inflammation. This was further confirmed by observing a concentration-dependent decrease in microglia glutathione (GSH) levels after MeHg treatment, indicating the accumulation of free radicals. Nrf-2, a nuclear transcription factor, binds with KEAP1 in the cytoplasm in the absence of oxidative stress. In response to the oxidative stress, Nrf-2 is released from KEAP1 and undergoes nuclear translocation. Immunostaining studies suggest Nrf-2 nuclear translocation after 24h MeHg treatment at both 1uM and 5uM MeHg exposure. It has been documented that AKT and ERK are phosphorylated as a result of oxidative stress. Consistent with these observations, MeHg significantly increased phospho-AKT after 30 min treatment. Our results suggest that oxidative stress promotes the nuclear translocation of Nrf-2 and selectively activates downstream AKT pathways, and implies the involvement of microglia in MeHg-induced neurotoxicity. Supported by NIEHS 10563

PS 365 OXIDATIVE DAMAGE AND NEURODEGENERATION IN MANGANESE-INDUCED NEUROTOXICITY.

D. Milatovic[1], Y. Yu[1], R. C. Gupta[2], S. Zaja-Milatovic[3] and M. Aschner[1]. *[1]Pediatrics, Vanderbilt University, Nashville, TN, [2]Breathitt Veterinary Center, Murray State University, Hipkinsville, KY and [3]Cancer Biology, Vanderbilt University, Nashville, TN.*

Exposure to excessive manganese (Mn) levels in certain occupational or dietary conditions results in neurotoxicity to the extrapyramidal system and the development of Parkinson's disease (PD)-like movement disorders, called manganism. Although the mechanisms by which Mn induces neuronal damage are not well defined, its neurotoxicity appears to be regulated by a number of factors, including mitochondrial dysfunction and oxidative injury. To investigate the mechanisms underlying this neurotoxicity, we studied the effects of Mn on reactive oxygen species (ROS) formation, neuroinflammation, changes in high-energy phosphates (HEP) and associated neuronal dysfunctions in mouse brain and neonatal rat primary neurons. Biomarkers of oxidative damage, F2-isoprostanes (F2-IsoPs) and pro-inflammatory prostaglandins E2 (PGE2) were significantly ($p<0.0.5$) increased (145% and125%, respectively) in brain of C57Bl6 female mice exposed to Mn (100 mg/kg, sc) for 24 hours. At the same time, quantitative morphometric analysis of striatal medium spiny neurons (MSNs) revealed significant decreases ($p<0.05$) in spine number and spine density to 50% and 59% of controls, respectively. Additionally, cultured neonatal rat primary neurons exposed to 500 μM MnCl2 for 2 hours showed significant ($p<0.05$) increase (139%) in F2-IsoPs and decrease (67%) in HEP (ATP), as determined by GC-MS and HPLC, respectively. These results are consistent with oxidative stress, neuroinflammation, mitochondrial dysfunction and consequent neurodegeneration as major mechanisms in Mn-induced neurotoxicity (Supported by DoD W81XWH-05-1-0239).

PS 366 ESTROGEN ATTENUATES MANGANESE-INDUCED GLUTAMATE TRANSPORTER IMPAIRMENT IN RAT BRAIN ASTROGLIAL CULTURES.

E. Y. Lee[1], H. Jiang[2], Z. Yin[2], M. Sidoryk[2] and M. Aschner[2]. *[1]Neurology, Meharry Medical College, Nashville, TN and [2]Pediatrics, Vanderbilt Medical center, Nashville, TN.*

Chronic exposure to manganese (Mn) can cause manganism, a neurodegenerative disorder similar to Parkinsonism. Mn inhibits glutamate uptake and decreases glutamate transporter expression in astrocytes. Many neurological disorders including Alzheimer's disease (AD) and Parkinson's disease (PD) are associated with impairment of astroglial glutamate transporters, indicating that these transporters play a central role in mediating neurodegeneration. 17β-Estradiol (E2) has been shown to be neuroprotective in AD and PD and some selective estrogen receptor modulators (SERMs), including tamoxifen (TX), possess neuroprotective properties. The regulation of astroglial glutamate transporters is postulated as one of the underlying mechanisms for E2 and/or SERMs neuroprotection. We have hypothesized that E2 and/or TX attenuate Mn-induced glutamate transporter impairment in rat primary astroglial cultures. Cell viability, glutamate uptake, western blot, RT-PCR, and immunocytochemistry were used to test our hypothesis. The results have shown that astrocyte preincubation with E2 or TX protected against Mn-induced cytotoxicity. E2/TX increased glutamate transporter function and reversed Mn-induced glutamate uptake inhibition, mainly via upregulation of glutamate/aspartate transporter (GLAST). E2 and TX increased the levels of GLAST protein/mRNA and attenuated Mn-induced inhibition of GLAST protein expression, as well as mRNA levels. In addition, E2/TX increased the expression of transforming growth factor β1 (TGF-β1), a potential modulator of the stimulatory effects of E2/TX on glutamate transporter functions via MAPK/ERK and PI3K/Akt signaling pathways. Taken together, these findings suggest that E2/TX enhance astroglial glutamate transporter expression and function, at least in part, via an increase in TGF-β1 expression. Supported by R01 ES10563.

PS 367 SUPPRESSION OF DFP-INDUCED OXIDATIVE INJURY AND DENDRITIC DAMAGE BY MEMANTINE.

S. Zaja-Milatovic[1], R. C. Gupta[2], M. Aschner[3] and D. Milatovic[3]. *[1]Cancer Biology, Vanderbilt University, Nashville, TN, [2]Breathitt Veterinary Center, Murray State University, Hopkinsville, KY and [3]Pediatrics, Vanderbilt University, Nashville, TN.*

Increasing evidence suggests that in addition to excessive cholinergic stimulation, organophosphates, such as DFP (diisopropylphosphorofluoridate) induce activation of glutamatergic neurons, and generation of reactive oxygen (ROS) and nitrogen (RNS) species, leading to neuronal degeneration. We studied multiple affectors of DFP exposure, critical to causing cerebral oxidative damage and whether NMDA receptor antagonist memantine provides neuroprotection by preventing DFP-induced biochemical and morphometric changes in rat brain. Rats treated with DFP (1.25 mg/kg, s.c.) developed onset of toxicity signs within 10-15 min, which progressed to maximal severity of seizures and fasciculation within 60 min. At this time point, biomarkers of cerebral ROS generation, F2-isoprostanes (F2-IsoPs) and F4-neuroprostanes (F4-NeuroPs) were significantly increased ($p<0.01$) to 142% and 225% of control, respectively. Severe seizures also induced significant ($p<0.001$) depletion in high energy phosphates followed by three fold elevation of citrulline (a marker of RNS) in rat cerebrum. Quantitative morphometric analysis of pyramidal neurons of the hippocampal CA1 region 1 h following DFP exposure revealed significant decreases ($p<0.01$) in dendritic lengths and spine density to 30% and 58% of control, respectively. When rats were pretreated 30 min before DFP exposure with an NMDA receptor antagonist memantine (18 mg/kg, s.c.), in combination with atropine sulfate (16 mg/kg, s.c.) a significant attenuation in DFP-induced increases in F2-IsoPs, F4-NeuroPs, citrulline and depletion of HEP ware noted. Furthermore, attenuation of biomarkers of oxidative damage following memantine pretreatment was accompanied by rescue from dendritic degeneration of pyramidal neurons in the CA1 hippocampal area. These findings support a prominent role of memantine in promoting neuronal survival following anticholinesterase-induced seizures (Supported by NINDS NS057223).

PS 368 SURFACE DENTAL ENAMEL LEAD LEVELS AND ANTISOCIAL BEHAVIOR IN BRAZILIAN ADOLESCENTS.

K. P. Olympio[1], P. V. Oliveira[2], J. Naozuka[2], M. A. Cardoso[3], W. R. Günther[1] and E. H. Bechara[4]. *[1]Saúde Ambiental, Faculdade de Saúde Pública (FSP), Universidade de São Paulo (USP), S√£o Paulo, Brazil, [2]Química Analítica, Instituto de Química (IQ), USP, S√£o Paulo, Brazil, [3]Epidemiologia, FSP, USP, S√£o Paulo, Brazil and [4]Bioquímica, IQ, USP, S√£o Paulo, Brazil.* Sponsor: S. Barros.

Lead is long known as a ubiquitous, insidious and devastating neurotoxicant. Lead poisoning is reportedly linked to a high risk for learning disabilities, aggressiveness and criminal offenses. We now study a connection between lead exposure and anti-

social/delinquent behavior in Brazilian adolescents living under adverse socioeconomic conditions. Thus, a transversal study was designed with 173 youths aged 14-18 and their parents (n=93), residing in low-income neighborhoods of Bauru, SP, with high criminality indices. To evaluate the delinquent/antisocial behavior, the Self-Reported Delinquency (SRD) and Child Behavior Checklist (CBCL) questionnaires were responded by the youths and their parents, respectively. The body lead burdens were evaluated in acid-etch microbiopsies drawn from the enamel surface of right upper incisors. The dental enamel lead levels (DELL) were quantified by graphite furnace atomic absorption spectrometry and, in order to evaluate the biopsy depth, the phosphorus content was measured using inductively coupled plasma optical emission spectrometry. Logistic regression was used for modeling the association between DELL and each syndrome scale and the DSM-oriented scales defined by CBCL and SRD scores. Covariates included familial and social variables. The odd ratios adjusted for covariates, considering a lead level ≥75 percentile as a high exposed-lead group and <75 percentile as low exposed-lead group, indicated that high DELL is associated with increased risk of exceeding the clinical score for somatic complaints, social problems, rule-breaking behavior and externalizing problems (CI 95%). Here, high DELL was not found to be associated with elevated SRD scores. In conclusion, it seems that exposure to high lead levels can indeed trigger antisocial behavior, which claims for public policies to prevent lead poisoning. Support: CAPES, FAPESP.

PS 369 DETECTION OF MITOCHONDRIAL TOXICITY IN HEPG2 CELLS USING SOLUBLE OXYGEN AND PH SENSORS.

M. Banker[1], J. Hynes[2] and Y. Will[1]. [1]*Exploratory Safety Differentiation, Pfizer Global Research & Development, Groton, CT and* [2]*Luxcel, Cork, Ireland.*

Mitochodnrial Toxicity has been implicated as a major contributor to drug-induced toxicity (Wallace KB.Mitochondrial off targets of drug therapy.Trends Pharmacol Sci. 2008). We have developed a screen to measure oxygen consumption using soluble sensors in 96 well format, using isolated rat liver mitochondria (Will Y, Hynes J, Ogurtsov VI, Papkovsky DB.Analysis of mitochondrial function using phosphorescent oxygen-sensitive probes.Nat Protoc. 2006). In addition to general cytotoxicity screening via ATP depletion, this assay has become part of our routine screening paradigm. Performing these measurements s in whole cells would be advantages, as isolated organelles could potentially overpredict and might not be suitable for in vitro /in vivo correlations. However, in cells oxygen consumption measurements alone would not delineate between true mitochodnrial toxicity and general cytotoxicity unless combined with subsequent measurements of pH changes, indicative of glycolytic compensation. True mitochodnrial toxicity would results in a decrease in oxygen consumption with subsequent increase in acidification due to compensation by glycolysis. In contrast, cytotoxicity resulting from other than mitochondrial insult, would lead to a decrease in oxygen consumption without subsequent acidification. Here we show that classical mitochodnrial toxicants such as rotenone, antimycin, oligomycin and FCCP follow the predicted paradigm. Drugs, previously described by us to have mitochodnrial liabilities, such as nefazodone, flutamide, phenformin, usnic acid and sorafenib also follow the pattern of oxygen depletion and pH increase. In contrast, drugs that where mitochondrial liabilities are not thought to be the primary reason for observed toxicity, such as tamoxifen, ketoconazole, troglitazone, showed decreases in oxygen consumption without pH changes. Both parameters could be monitored in real time and long before ATP depletion could be observed, which makes this screen a much more sensitive readout with additional mechanistic insights.

PS 370 METAL TOXICITY IN *DANIO RERIO.*

D. Jackson[1], J. Lewis[1], C. Baer[2] and M. Permenter[2]. [1]*U.S. Army Center for Environmental Health Research, Fort Detrick, MD and* [2]*SAIC, Inc., Fort Detrick, MD.*

The zebrafish, *Danio rerio*, is an attractive model for toxicogenomic studies because of its low maintenance costs and sequenced genome. To develop rapid screening methods for leading genomic indicators of toxicant exposure and effect, we exposed 25 male zebrafish for 24 h to $NiCl_2$, $CdCl_2$ and $Na_2Cr_2O_7$ at the 96 h LC_{20}, LC_{40}, and LC_{60} concentrations for each metal. Five fish from each group were used for histopathology. For all conditions, four pools of liver RNA from five fish each were used for gene expression studies on custom microarrays. We observed no marked histological changes in fish exposed to Ni. Fish exposed to Cd showed gill hyperplasia and lamellar fusion of minimal severity. The Cr exposed fish displayed gill hyperplasia, lamellar fusion, and hemorrhage in the gills. These Cr exposed fish also experienced atrophy of the intestinal mucosal folds and pharyngeal epithelium. We found no evidence of liver pathology at the histological level in any case. However, we did observe alterations in gene expression in the livers of exposed fish; the Cr exposure affected the largest number of genes, followed by Cd and Ni. Many of the changes in gene expression correlate well with known effects of the metals. Thus, transcriptional analysis of the zebrafish liver appears to be a feasible approach for studying toxicological effects and identifying potential biomarkers of exposure for a wide variety of chemicals. Opinions, interpretations, conclusions, and recommendations are those of the authors and are not necessarily endorsed by the U.S. Army. Research was conducted in compliance with the Animal Welfare Act, and other Federal statues and regulations relating to animals and experiments involving animals and adheres to principles stated in the Guide for the Care and Use of Laboratory Animals (NRC 1996) in facilities that are fully accredited by the Association for the Assessment and Accreditation of Laboratory Animal Care, International. The research described herein was sponsored by the U.S. Army Medical Research and Materiel Command, Military Operational Medicine Research Program.

PS 371 CULTURE, CHARACTERIZATION, AND IN VITRO TOXICITY OF ARSENIC IN MOUSE PRIMARY UROEPITHELIAL CELLS.

P. C. Wilga[1], J. M. McKim[1], J. W. Yager[2], H. Clewell[3], R. Thomas[3] and E. A. Crecelius[4]. [1]*CeeTox Inc., Kalamazoo, MI,* [2]*University of New Mexico, Albuquerque, NM,* [3]*Hamner Institute, Research Triangle Park, NC and* [4]*Battelle Marine Sciences Lab, Sequim, WA.*

The purpose of this study was to develop a novel *in vitro* mouse uroepithelial cell culture to improve cancer risk assessment for arsenic, including use of genomic data for understanding the mode of action and cellular exposures for potential quantitative assessment and innovative dose-response assessment. Female mice 56-60 days old (C57BL/6J) were used to acquire primary bladder epithelial cells. The bladder was surgically excised and rinsed with defined keratinocyte-SFM medium (37°C). Epithelial cells were isolated by making a longitudinal incision to expose the interior cells and then gently scraping the interior to release the cells. Bladder cells from 50 mice were pooled. Cells were centrifuged and washed with keratinocyte-SFM to remove debris. Total cell yield was approximately 0.5×10^6 cells per bladder and viability was >80%. Prior to seeding, RT-PCR in the cell pellet confirmed a high expression of Keratin-10, a marker of epithelial cells. Cells were seeded at approximately 0.4×10^6 per well into collagen-coated, 24-well plate inserts. After acclimation of cells through growth and maintenance phases, cells were treated for 24 hr with 0, 0.1, and 0.5 μM arsenite, plus combination arsenite (As) and dimethylarsinic acid (DMA) exposures at (1.6 μM As + 0.7 μM DMA), (3 μM As + 3 μM DMA), and (5 μM As + 10 μM DMA). Cell viability analysis showed a concentration-dependant decrease in ATP relative to controls from approximately 80% at (1.6 μM As + 0.7 μM DMA) to less than 40% at (5 μM As + 10 μM DMA). This cell model may be useful in assessing arsenic toxicity and improving risk assessment models.

PS 372 BIOACTIVATION OF NEVIRAPINE BY P450 AND SULFOTRANSFERASES.

M. Novalen and J. Uetrecht. *Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada.*

Background: NVP causes a skin rash in female Brown Norway (BN) rats with very similar characteristics as in humans, allowing it to be used as a model for mechanistic studies. We have shown that oxidation of the NVP methyl group (12-hydroxylation) is required for induction of the rash. Previously, we demonstrated that the inhibition of P450 decreases other oxidative metabolites but not 12-OH-NVP. 12-OH-NVP can be further oxidized to a carboxylic acid and inhibition of P450 markedly decreases the formation of the carboxylic acid. Inhibition of alcohol dehydrogenase did not decrease formation of the carboxylic acid. We propose that P450 mediates both the formation and further oxidation of 12-OH-NVP. Male BN rats are less susceptible to developing skin rash and their blood levels of NVP and 12-OH NVP are lower while concentration of the carboxylic acid is higher. We propose that the 12-OH-NVP is sulfated in the skin by sulfotransferases. The subsequent loss of the sulfate could yield a reactive quinone methide that binds to proteins in the skin and lead to a rash. The goal of this work was to study the metabolism of 12-OH-NVP, an obligate intermediate in rash induction. **Methods and Results:** 12-OH-NVP was incubated with rat liver microsomes (RLM). Oxidation of 12-OH-NVP to 4-COOH-NVP was observed but no aldehyde intermediate was observed. There are other examples in which an alcohol is oxidized to a carboxylic acid without escape of the intermediate aldehyde. RLM isolated from male BN rats produced more carboxylic acid than RLM from female rats which is consistent with the in vivo results. The levels of 12-OH-NVP sulfate were measured in plasma of female BN rats treated with NVP at escalating doses to 150 mg/kg/day and determined to be 1 - 7 μg/ml. **Conclusions:** 12-OH-NVP is oxidized by P450. The circulating levels of 12-OH-NVP sulfate are significant and are the most likely link between the 12-OH-NVP oxidation and the skin rash but further studies to determine the effect of manipulation of sulfation on rash incidence are required. This work was supported by grants from CIHR.

PS 373 AN IN VITRO MODEL FOR ASSESSING THE EFFECTIVENESS OF ANTIOXIDANTS IN COSMETICS.

C. A. Lazaro[1], P. R. Vavilikolanu[1], D. D. Robinson[2], B. D. Jeffy[2], P. C. Wilga[2], S. A. Thompson[2], K. L. Rutherford-Root[2] and J. M. McKim[2]. *[1]Alberto-Culver USA Inc., Melrose Park, IL and [2]CeeTox Inc., Kalamazoo, MI.*

Oxidative stress in skin has been linked to the development of wrinkles, the aging process and other more serious effects. *In vitro* cell-based systems that can rapidly and efficiently evaluate whether a new chemical or formulation has antioxidant properties are important in the development of new products for the cosmetic industry. The aim of this study was to induce oxidative stress in normal human epidermal keratinocyte (NHEK) cells and then demonstrate protection in the presence of Trolox (Vitamin E) and test products. Oxidative stress was induced with two model compounds: menadione, which requires metabolism to reactive quinone intermediates, and cumene hydroperoxide, which does not require metabolism in order to produce oxidative stress. Formation of reactive oxygen species was monitored with 5-(and-6)-chloromethyl-2'-7'-dichlorodihydrofluorescein diacetate (CM-H_2DCFDA) and glutathione (GSH) status. Cell viability was measured with propidium iodide. NHEK cells were seeded into 96-well culture plates (10,000 cells/100 μL) and cultured with human keratinocyte growth medium and 10% BSA. Exposures to menadione (20 μM) and cumene hydroperoxide (100 μM) were for 3, 6, or 24 hr. Menadione increased DCFDA signal by approximately 2- to 3-fold after 6 hr and reduced GSH to levels less than 50% of controls after 6 and 24 hr. These effects were greatly reduced in the presence of Trolox (50 μM). Cumene hydroperoxide (20 and 100 μM) also produced significant oxidative stress, increasing DCFDA signal by 8- to 10-fold relative to controls and reducing GSH levels after a 6 hr exposure. These oxidative stress effects were also significantly reduced in the presence of Trolox. When the NHEK model was used to evaluate the antioxidant properties of new products, it was possible to demonstrate clear antioxidant properties.

PS 374 DOMINANT NEGATIVE ZEBRAFISH AHR2 PROTECTS AGAINST TCDD TOXICITY.

K. A. Lanham[1], R. E. Peterson[2] and W. Heideman[2]. *[1]Biomolecular Chemistry, UW Madison, Madison, WI and [2]School of Pharmacy, UW Madison, Madison, WI.*

Zebrafish embryos exposed to 2,3,7,8 tetrachlorodibenzo-*p*-dioxin (TCDD) develop cardiac and vascular defects, including pericardial and yolk sac edema, heart looping defects and reduced peripheral blood flow. These effects are mediated by the zebrafish aryl hydrocarbon receptor 2 (AHR2). Although gene knockdown by morpholino technology is useful, and has provided considerable insight into the role of AHR2 in vivo, its efficacy is limited to the first few days of development. This work describes the construction and characterization of a dominant negative form of AHR2 (dnAHR2), and the establishment of transgenic zebrafish lines that express dnAHR2 in a ubiquitous manner. The expression of the dnAHR2 protein was verified by Western Blot analysis of protein lysates isolated from F1 offspring. In addition, dnAHR2 expressing fish show reduced induction of AHR2 target genes and are protected against the endpoints of dioxin toxicity. A constitutively active form of AHR2 (caAHR2) has also been constructed, and transgenic lines expressing caAHR2 under the control of an ecdysone inducible promoter are being established. The use of these modified AHR2s, driven by tissue specific promoters, will provide greater insight into tissue specific mechanisms of dioxin toxicity. (Supported by: NIEHS, NIH Grant T32 ES007015 and NIH RO1 ES012716)

PS 375 ALDO-KETO REDUCTASE GENES IN ZEBRAFISH.

S. Karchner, J. Goldstone and J. J. Stegeman. *Biology, Woods Hole Oceanographic Institution, Woods Hole, MA.* Sponsor: M. Hahn.

Ortho-quinones of PAH such as BaP-7,8-dione (BPQ) can participate in redox cycling leading to radical formation. BPQ is formed by the sequential action of CYP1A to form the 7,8-epoxide, epoxide hydrolase to form BP-7,8-dihydrodiol, and dihydrodiol dehydrogenases (aldo-keto reductases or AKRs), to form the *o*-quinone. Several mammalian AKRs catalyze the NADP-dependent oxidation of PAH trans-dihydrodiols to the *o*-quinones, via the catechol, including human AKR1A1 and AKR1C (AKR1C1-AKR1C4) proteins. To address questions of oxidative damage to DNA induced by AH receptor agonists during development, we have examined *AKR1* family genes in zebrafish. Full-length coding sequences for five zebrafish genes identified from the zebrafish genome were cloned and sequenced. The amino-acid sequences inferred for the full-length coding regions of the zebrafish sequences were up to 76% identical to mammalian AKR1s. Bayesian analysis gave molecular phylogenies with two sequences clustering with human and mouse AKR1As, and two sequences that clustered with the AKR1Bs. Exon-intron boundaries in the *AKR1A*-like genes were identical to each other and like those in known *AKR1A*s. Likewise the three *AKR1B*-like genes had exon-intron boundaries that were similar to each other and like the exon-intron boundaries in mammalian *AKR1B*s. However, one of these zebrafish genes had lower percent identity to the mammalian *AKR1B*s, suggesting it may represent a separate subfamily. The zebrafish *AKR1A*-like genes exhibited shared synteny with human *AKR1A1*. However, the zebrafish *AKR1B*-like genes have complicated syntenic relationships with the human *AKR1C*s. The five genes exhibit very different patterns of expression during zebrafish development, and one of the *AKR1B* genes was expressed at high levels only during early development. These zebrafish AKR1s have also been heterologously expressed in *E. coli*, demonstrating the formation of functional proteins. (NIH 1R01ES015912)

PS 376 DECISION STRATEGY FOR DETECTION OF OCULAR IRRITANTS: ALTERNATIVE TESTS FOR HAZARD PROFILING OF PHARMACEUTICAL PROCESSES.

M. J. Olson[1], F. J. Guerriero[2] and C. W. Seaman[3]. *[1]CEHS, GlaxoSmithKline, Research Triangle Park, NC, [2]CEHS, GSK, Philadelphia, PA and [3]CEHS, GSK, Ware, United Kingdom.*

Evaluation of potential for acute chemical irritation of the eye is a core part of hazard profiling for chemicals in occupational settings. Developing hazard test programmes for ocular effects requires attention to a variety of unique challenges. These include scientific and ethical concerns for existing test methods, changes in worldwide regulation of hazard classification/labeling, and development of a strategy for a wide range of novel chemical entities. This presentation focuses on experience with alternative methods in a specific strategy applied to substances from GSK processes. In keeping with existing guidance, initial assessment reviews elements such as physical-chemical properties and SAR outcomes. A second tier incorporates results from existing studies as well as use of inference from dermal irritation studies. If information is insufficient, a suite of in vitro/ex vivo studies are applied: an in vitro irritation screen (reconstituted human epidermal cultures, SkinEthic), human corneal epithelial cultures (HCE assay, SkinEthic) and the Rabbit Enucleated Eye Test (REET). Hazard assessment for most substances relies on combination of two or more of these tests. Provision is made for a limited in vivo study to resolve questions over equivocal results (OECD 405). Outcomes from the GSK strategy are used for classification, labeling and hazard communication and are consistent with integrated testing strategies defined within EU REACH Regulations. This unique approach identifies severe eye irritants amongst materials early in the product development process, but also selects for chemicals unlikely to possess significant irritant potential. For example, testing of a number of chemicals in the OECD 405 in vivo test for regulatory filings provided no evidence of hazard, as suggested by outcomes from the HCE and REET. Since early 2006 the GSK in-house worker safety program applied to 46 total substances from a variety of pharmaceutical processes has not resulted in need for in vivo eye irritation tests.

PS 377 MULTI-PHASE ANALYSIS OF UPTAKE AND TOXICITY IN ZEBRAFISH: RELATIONSHIP TO COMPOUND PHYSICAL-CHEMICAL PROPERTIES.

C. Doshna[1], J. Benbow[1], M. DePasquale[1], C. Okerberg[1], S. Turnquist[1], D. Stedman[1], B. Chapin[1], L. Sivaraman[1], G. Waldron[1], K. Navetta[1], J. Brady[1], M. Banker[1], A. Casimiro-Garcia[1], A. Hill[2], M. Jones[2], J. Ball[2] and M. Aleo[1]. *[1]Global R & D, Pfizer, Groton, CT and [2]Summit plc, Oxfordshire, United Kingdom.*

Transparency of larvae, amenability to high throughput screening and relative ease and cost of husbandry are some of the many appealing qualities of using Zebrafish (Zf) as a model for toxicity assessment. Unlike mammalian models however, routes of drug administration for Zf are typically limited to exposure in their supportive media which may lead to variable uptake. The ability to better predict drug exposure and toxicity endpoints in Zf based on physical-chemical characteristics would be highly beneficial. Tuebingen Zf were exposed to more than 70 compounds or vehicle in Danieau's solution in a 24-well dish at 72 hours post fertilization (hpf). At 120 hpf, Zf were assessed for lethality, lowest observed effect concentration (LOEC), LC100, gross morphology and compound uptake. Compound uptake (average ng/Zf) was quantified at multiple concentrations by mass spectrometry. Determined endpoints were compared to physical-chemical properties (total polar surface area, calculated partition coefficients (cLogD, cLogP), basic pKa and molecular weight). Lipophilicity (cLogP) seemed to correlate better than cLogD with both ng/Zf and LC100. At 100 μM, compounds with a cLogP value between 1 and 3 had a mean uptake value of 82 ± 88 ng/Zf vs. 0.4 ± 0.1 or 63 ± 40 ng/Zf for compounds with cLogP values that spanned between 0-1 or 3-5, respectively. There was also a correlation between LOEC and basic pKa such that the stronger the basic group of the compound, the higher the LOEC. Therefore any one physical-chemical property alone may not be adequate to predict compound uptake into Zf. A general trend between compound cytotoxicity (using a transformed human liver

epithelial (THLE) cell viability assay (LC50 at 72 hr)) and Zf toxicity (LOEC or LC100) was visually apparent; although there was not a one-to-one correlation based on concentration in the medium. These results illustrate the challenges of predicting compound uptake into Zf.

PS 378 COLIPA PROGRAM ON OPTIMIZATION OF EXISTING *IN VITRO* EYE IRRITATION ASSAYS FOR ENTRY INTO FORMAL VALIDATION: TECHNOLOGY TRANSFER AND INTRA/INTER LABORATORY EVALUATION OF AN EPIOCULAR ASSAY FOR CHEMICALS.

J. W. Harbell[1], B. Le Varlet[2], M. Marrec-Fairley[3], Y. Kaluzhny[4] and P. McNamee[5]. *[1]Mary Kay Inc, Addison, TX, [2]Consultant, Ingénierie, Mont/©lier, France, [3]COLIPA, Brussels, Belgium, [4]MatTek Corp., Ashland, MA and [5]Procter & Gamble Co., Egham, United Kingdom.*

The European Union will ban *in vivo* eye irritation tests on ingredients for cosmetic products after March 2009. COLIPA, (European Cosmetics Association) is actively working to bring *in vitro* eye irritation tests to formal validation with ECVAM. This poster details the Colipa program on technology transfer and reproducibility of MatTek's EpiOcular™ assay as one of the two human reconstructed tissue assays. This EpiOcular protocol differs from previous time-to-toxicity protocols in that it uses a single exposure period for each chemical and a prediction model based on a cut-off in relative survival (≤ 60% = irritant (I) (R36 and R41); >60% = non-classified (NC)). Test substance exposure time is 30 minutes with a 2-hour post-exposure incubation for liquids and 90 minutes with an 18-hour post-exposure incubation for solids. After the post-exposure, tissue viability is determined by tetrazolium dye reduction (MTT). Combinations of 20 coded chemicals were tested in 7 laboratories. A standardized protocol and laboratory documentation were used by all laboratories. MatTek provided initial training and then each laboratory operated independently during the technology transfer study. Twenty liquids (11 NC/9 I) by ECVAM plus 5 solids (3 NC/2 I) were selected so that both exposure regimens could be assessed. Concurrent positive (methyl acetate) and negative (water) controls were tested in each trial. Chemical decoding occurred only after study completion. In all, 298 independent trials were performed and demonstrated 99.7% agreement in prediction (NC/I) across the laboratories. Coefficients of variation for the % survival of tissues across laboratories was generally modest (<16%) except where tissue survival values were low. Using these data, a formal submission was sent to ECVAM in support the protocol's entry into a formal validation study.

PS 379 PROTECTIVE EFFECTS OF EXOGENOUS ANTIOXIDANTS ON LIPID PEROXIDATION AND ANTIOXIDANT ENZYMES IN MYCOTOXINS-INDUCED TOXICITY.

M. J. Ruiz[1], G. Font[1], A. J. Garcia[1], M. Fernandez[1] and A. Anadon[2]. *[1]Department of Toxicology, Faculty of Pharmacy, Universitat de Valencia, Valencia, Spain and [2]Department of Toxicology and Pharmacology, Faculty of Veterinary Medicine, Universidad Complutense, Madrid, Spain.*

Mycotoxins are secondary metabolites of various moulds. During mycotoxins exposure in mammal's cells there is a generation of reactive oxygen species (ROS) and mycotoxins can produce oxidative stress in exposed cells. Cells have different antioxidant mechanisms, the primary defense is offered by enzymatic and nonenzymatic antioxidants, which have been shown to scavenge free radicals and ROS. Antioxidants belonging to the second line of defense include glutathione (GSH), vitamin C and vitamin E. Mammal cells were individually exposed at different concentrations of mycotoxins (ranged from 1 to 50 μM). A second experiment was conducted to investigate the capacity of antioxidants (GSH, vitamin C and vitamin E) to protect mammal cells of mycotoxins. After different time periods (ranged from 2 to 48-h), GSH content, the activities of antioxidant scavenger enzymes and generation of intracellular ROS by the sensitive fluorogenic probe 2, 7-dichlorodihydrofluorescein diacetate (H2-DCFDA) were determined. Increases in lipid peroxides were observed in cells which grow up in media deficient of antioxidants and which were exposed to mycotoxins. Decrease in lipid peroxidation was observed in those assays which exposed mycotoxins together antioxidants. Significant decrease in GSH content and alteration of antioxidant enzymes were recorded in mammal cells exposed mycotoxins in deficient antioxidants media. The results obtained from use of different antioxidants and ROS scavengers suggested a role of mycotoxins in oxidative stress. The use of antioxidants provides protection against toxicity caused by mycotoxins in the mammal cells assayed. These results indicate ROS are formed from mycotoxins and its oxidant effects can be abrogated by glutathione and other exogenous antioxidants. This work was supported by the Science and Education Spanish Ministry (AGL2007-61493).

PS 380 GATA2: A POTENTIAL CANDIDATE GENE OF BLUE COHOSH TOXICITY IN JAPANESE MEDAKA.

M. Wu[1, 2, 3], A. K. Dasmahapatra[1, 2, 3], Z. Ali[1] and I. A. Khan[1, 3]. *[1]National Center for Natural Product Research, University of Mississippi, University, MS, [2]Department of Pharmacology, University of Mississippi, University, MS and [3]Environmental Toxicology Research Program, University of Mississippi, University, MS.*

Blue cohosh (Caulophyllum thalictroides) (BC) is a perennial herb used by the Native American Indian women to induce labor and to treat other uterine complications. The safety and effectiveness of this herbal product has not yet been evaluated by the Food and drug administration of America (FDA), however, several reports indicated that BC by some unknown mechanisms is able to induce teratogenic effects in cardiovascular system in new born babies. For experimental verification of the teratogenic effects of BC we have used Japanese medaka (Oryzias latipes) embryo-larval development as our experimental model. Fertilized medaka embryos were exposed to methanolic extract of BC root (0-10 μg/ml) from 3-5 day post fertilization (dpf) and were used for biochemical and morphological analysis on 6 and 10 dpf, respectively. It was observed that BC was able to induce cardiovascular abnormality in a dose-dependent manner; however, total cellular protein, RNA, and DNA contents of the embryos remained unaltered. Several transcription factor mRNAs such as emx2, en2, otx2, shh, wnt1, zic5 and iro3 which were expressed in the brain of medaka embryos during development were also remained unaltered after BC treatment. Craniofacial and tail cartilage development as observed on 10 dpf was found to be normal in BC-treated embryos. However, by applying subtractive Hybridization technique we observed that the transcription factor GATA2 was over expressed in BC-treated embryos. We therefore conclude that the teratogenic effect of BC in cardiovascular development of medaka was probably mediated through GATA2 signaling pathway (supported by COBRA P20RR021929).

PS 381 A CELL VIABILITY ASSAY FOR ESTIMATING *IN VIVO* TOLERATION IN RODENTS.

M. D. Aleo[1], J. Aubrecht[1], M. J. Banker[2], J. W. Benbow[3] and D. Nettleton[2]. *[1]Drug Safety R&D, Pfizer Global R&D, Groton, CT, [2]Exploratory Safety Differentiation, Pfizer Global R&D, Groton, CT and [3]CVMED Chemistry, Pfizer Global R&D, Groton, CT.*

The application of safety screening paradigms is expected to revolutionize the drug discovery process. However, with the exception of mechanistic assays for genetic toxicology and safety pharmacology screening, screening strategies to assess general safety are inadequate. In this regard, the value of in vitro cell viability assays for assessing in vivo chemical safety has long been debated with differing outcomes. A retrospective analysis of results from rat in vivo toleration studies (4-14 days, varying doses) conducted with diverse chemical matter that spans a broad array of therapeutic targets (protease inhibition, cGMP modulation, 3 GPCRs, and 3 kinase programs) shows that cell viability (using the SV-40 transformed human liver epithelial cell line), is generally predictive of overall safety outcomes using an equally weighted scoring system (0-4 component, 0-12 overall score). Scoring based on systemic toleration (mortality, body weight, food consumption, adverse clinical signs), clinical chemistry/hematology parameters (deviations from normal ranges) and organ pathology (necrosis or incidence and severity of histologic change). As an overall probability, compounds with LC50 values <10 μM were generally less tolerated (33%<4, 23% 4-8, 44%>8) than compounds with LC50 values 50-300 μM (67%<4, 21% 4-8, 13%>8, $p < 0.004$ by Fisher's Exact Test). Refinements predicting overall toleration for individual compounds could be made when exposure was taken into consideration. Safety margins (LC50/AUCaverage) of <1 lead to higher adverse outcomes in rodent studies (0%<4, 29% 4-8, 71%>8) compared to safety margins >10 (61%<4, 27% 4-8, 12%>8). This work shows that overall toleration of new chemical matter in a short-term in vivo rat study can be predicted based on knowledge of its LC50 value and anticipated exposure values, reinforcing the age-old axiom that the dose makes the poison.

PS 382 DEVELOPING PREDICTIVE TOXICITY SIGNATURES USING *IN VITRO* DATA FROM THE EPA TOXCAST PROGRAM.

R. Judson, D. Dix, K. Houck, M. Martin and R. Kavlock. *NCCT, U.S. EPA, Research Triangle Park, NC.*

A major focus in toxicology research is the development of in vitro methods to predict in vivo chemical toxicity. Numerous studies have evaluated the use of targeted biochemical, cell-based and genomic assay approaches. Each of these techniques is potentially helpful, but provides only a partial view of the complex biology that leads to tissue, organ or whole organism toxic effects. Here we present the first results from the ToxCast program that combines multiple types of assays into "toxicity signatures" that are optimally predictive of particular in vivo toxicity endpoints.

A toxicity signature is in essence a function that takes as input the results of a set of assays run on a chemical, and produces a prediction of the toxicity of that chemical for a specific in vivo endpoint. We used the EPA ToxCast program Phase I data, which includes about 600 in vitro assays run on a total of 320 chemicals, the majority of which are pesticide active compounds. The corresponding in vivo toxicity data is taken from the Toxicology Reference database (ToxRefDB), which is tabulated data from guideline animal studies for chronic, cancer, developmental and reproductive toxicity endpoints. We present a variety of machine learning approaches to mine this complex data set for toxicity signatures with both high sensitivity and specificity. These include linear discriminant analysis, support vector machines and neural networks. In addition to these automated approaches, we also present more hypothesis-driven, mechanism-based signatures including ones probing nuclear receptor-mediated liver toxicities. An important observation from these first analyses is that one often needs to include assays of multiple types, probing multiple mechanisms or pathways, to adequately predict in vivo toxicity across a wide range of chemicals. Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.

PS 383 ALTERNATIVE PORCINE CORNEAL OCULAR REVERSIBILITY ASSAY CORRELATES WITH DRAIZE REVERSIBILITY DATA.

M. Piehl, R. C. Soda, M. R. Carathers, A. L. Donovan and D. R. Cerven. *MB Research Laboratories, Spinnerstown, PA.*

No established alternative ocular irritation assay can measure corneal tissue damage and reversibility. With the support of a Colgate-Palmolive Grant for Alternative Research, we have developed an alternative assay: Porcine Corneal Opacity Reversibility Assay (PorCORA). PorCORA measures corneal damage and recovery for extended time periods using porcine corneas excised from byproduct abattoir eyes. Test articles are dosed directly onto the corneal surface, and tissue damage and recovery are assessed by sodium fluorescein (NaFL) retention in the same corneas over time (21 days). We have confirmed NaFL retention results and corneal recovery in the PorCORA system via several approaches. Both fluorescence and reflective confocal microscopy confirm damage indicated by fluorescein retention in the cultured corneas. In addition, we have shown histological evidence that also correlates well with NaFL staining in the PorCORA assay. Overall, PorCORA is predictive and representative of corneal tissue damage and recovery. Here we report the results of a 32-reference chemical validation including chemicals from the following classes: acetates, acids, alcohols, alkalis, esters, hydrocarbons, inorganics, ketones, surfactants, and several solid compounds. PorCORA generates a mean (4 corneas per experimental condition) "days to clear" endpoint when corneas no longer retain NaFL stain (1-21 days). When compared to mean days to clear (corneal effects) from the ECETOC Eye Irritation Data Bank (historical Draize data), the correlation coefficient is r = 0.84, and r = 0.82 for the MMAS (ECETOC). To determine if the PorCORA system can distinguish between reversible and irreversible corneal damage, we considered corneas that retained NaFL at 21 days to be irreversible. PorCORA reversibility results (reversible vs. irreversible) correlated very well with ECETOC data, yielding 91% accuracy, 92% sensitivity, 89% specificity, 86% positive predictivity, and 94% negative predictivity for the 32 compounds tested.

PS 384 PORFOCAL, FOR YOUR EYES ONLY!

M. R. Carathers, M. Piehl, R. C. Soda and D. R. Cerven. *MB Research Laboratories, Spinnerstown, PA.*

MB Research Laboratories has developed a procedure for the culturing of excised porcine corneas for a period of up to 21 days. Using these corneas, we have developed a method, PorFocal, to evaluate the effects of multiple doses of low-level irritants. Corneas are excised from enucleated porcine eyes from the abattoir, and can be cultured in a living state for up to 21 days. In order to detect and quantify low-level damage to corneal tissue, this assay was created to assess ocular irritation by measuring cell viability using a dead stain, Ethidium homodimer (EtH), and fluorescence confocal microscopy. For the PorFocal assay, eight cultured corneas (4 per test material) were treated with either Phosphate Buffered Saline (PBS) or 0.01% Benzalkonium chloride (BAK) for a total of 10 doses (2x/day on days 1, 2, and 6; 1x/day on days 0, 3, 7, and 8) at 50 µl/treatment. On day 8, these corneas were incubated for 30 minutes with 2 µM EtH dead cell stain and imaged using confocal microscopy. The EtH stained dead cell nuclei were imaged in 6 random 450 µm x 450 µm x 56 µm-deep tissue fields via confocal z-stacks composed of eight 8 µm-thick optical slices. A maximum projection of image z-stacks was created so that no nucleus was counted twice. All dead nuclei (cells) were counted for each tissue field, the counts were summed, and statistical analysis was performed using ANOVA. PBS-treated corneas (n=4) exhibited 1659 dead cells and 0.01% BAK-treated corneas (n=4) exhibited 3591, a 216% increase in cell death, which was statistically significant ($p<0.001$). These data indicate that low-level damage can be detected by using confocal microscopy. Future directions for this project include increasing the amount of replicates to decrease variance. Also, the complimentary component of the staining kit is a live cell stain. This stain could be further developed and a ratio of live to dead cells in each group could yield higher-sensitivity corneal irritation measurements.

PS 385 *IN VITRO* MODELS FOR PREDICTION OF CHEMICAL METABOLISM AND TOXICITY.

C. Murray, S. Ding, D. Lee, A. Vardy, C. Elcombe and C. Wolf. *CXR Biosciences, Dundee, United Kingdom.*

The use of cell lines for drug and chemical toxicity screening, although very attractive, has serious limitations because of the limited expression of cytochrome P450 isozymes. In addition, cell line toxicity assays give little easily measurable information about the toxic mechanism. In order to circumvent these issues we have generated a range of cell lines which have been engineered to report on different pathways of toxic insult. These include oxidative stress, DNA damage, NFκB signalling, apoptosis, heat shock response, etc. In addition, we have developed a number of adenoviral vectors which allow the expression of single or multiple human P450s in any cell line of interest. P450 expression was achieved using a novel approach using the foot-and-mouth disease virus peptide 2A sequence which allows the expression of multiple proteins of a single promoter system. Using this approach we have expressed CYP3A4, CYP2D6, CYP2A6 and CYP1A1 at levels at least equivalent to those normally found in human liver. In order to exemplify the utility of this model in chemical screening, we have taken a cell line where the antioxidant responsive element (ARE), activated by Nrf2, is used to drive a luciferase reporter. We have then exposed these cells to either 7-ethoxycoumarin or butylated hydroxyanisole and have demonstrated that ARE activity is only induced in cells which express cytochrome P450 enzymes CYP1A1 and CYP2A6. These data demonstrate the power of this experimental approach to give a more accurate assessment of toxicity associated with exposure to chemical agents.
Acknowledgements are made to Millipore Inc. and NC3Rs in the funding of this work.

PS 386 PREDICTIVE CYTOTOXICITY MEASUREMENTS BY MONITORING HEAT SHOCK PROTEINS, P38 AND THE CELL PROLIFERATION IN HIGH-CONTENT SCREENING CELL-BASED ASSAYS.

M. Anhalt, S. J. Hong and R. N. Ghosh. *Thermo Scientific, Rockford, IL.* Sponsor: A. Barchowsky.

Heat shock proteins (HSPs) play crucial roles in maintaining cellular homeostasis and promoting cell survival by refolding or degrading damaged proteins in response to various cell stresses. There are five major HSP families including small HSPs, Hsp60 or chaperonins, Hsp70, Hsp90 and Hsp110. HSPs are involved in many cellular functions such as signaling, protein synthesis, folding and degradation, protein translocation and cell death. We hypothesized that multiplexed monitoring of HSPs in cells can be used for in vitro predictive cytotoxicity assessments. To test our hypothesis, we monitored multiple HSPs in cells to evaluate the cellular stress affected by toxic chemicals. We developed four quantitative cell-based imaging high-content screening (HCS) assays towards the following combinations of HSPs in cells: (1) Hsp27 and phosphorylated-Hsp27, (2) Hsp60 and Hsp90beta, (3) Hsp70 and Hsp90alpha, (4) FKBP52 (Hsp59). Cells were treated with different cytotoxic chemicals and then fluorescently labeled, imaged and quantitatively analyzed using a high-content analysis platform. We used cell number, nuclear size, p38 MAPK activation and BrdU incorporation as known reference markers for cellular stress. Dose and time course responses of HSPs against different stressors show that many heat shock proteins are induced by different stressors at different times. Interestingly, these heat shock proteins respond at a lower dose in cells than in animal as measured by rodent LD50 values, substantiating HSP proteins as potential in vitro predictive toxicity indicators. In summary, monitoring key heat shock proteins in cells enables quantitative detection of cellular stress mediated by cytotoxic agents in high content screening assays.

PS 387 EFFECTS OF *IN VITRO* METABOLISM ON THE ENDOCRINE ACTIVITY OF SUBSTANCES IN THE YEAST-BASED REPORTER GENE ASSAY.

C. Woitkowiak, S. Boehn, T. Bernshausen, E. Fabian, H. Kamp, H. Huener, A. Verlohner, B. van Ravenzwaay and R. Landsiedel. *Experimental Toxicology and Ecology, BASF SE, Ludwigshafen, Germany.* Sponsor: A. Van Cott.

Test substances can be screened for potential endocrine activities using in vitro assays, e.g. yeast-based reporter gene assays (YAS for androgenic and YES for estrogenic activities). The xenobiotic metabolic capacity of yeast cells, however, is not

well investigated. Using model compounds, we evaluated whether the addition of metabolically active rat liver in vitro systems increases the predictive value of the yeast assay. Testosterone (T) was almost completely metabolized by microsomes under the chosen incubation conditions. DME-DES (the non-estrogenic dimethylether of the estrogenic diethylstilbestrol) and DES-DP (DES-propionate) were also extensively metabolized.
Incubates of T with active microsomes (AI) as well as heat-deactivated microsomes (HDC) were transferred into the YAS assay, and corresponding incubates of DES derivatives (DME-DES and DES-DP) were tested in the YES assay. In the YAS assay, T and its HDC showed the well-established androgenic activity. The AI of T had a lower androgenic activity, demonstrating that the deactivation of the androgenic activity of T can be detected with this in vitro system. DME-DES and its HDC showed no estrogenic activity in the YES assay, whereas its AI showed an estrogenic response, demonstrating that the activation of the estrogenic activity of DME-DES can be detected with this in vitro system. Surprisingly, for DES-DP, the HDC as well as the AI showed direct estrogenic activity. Investigations of the metabolic capacity of the yeast cells itself revealed that their esterases are able to saponify DES-DP forming estrogenic DES. Thus, we demonstrated a successful integration of metabolic capacity in the YES/YAS in vitro assay, allowing for a more accurate assessment of the endocrine potential of test substances including their potential metabolic activation or deactivation.

PS 388 EVALUATION OF THE SKIN SENSITIZATION POTENTIAL OF HAIR-DYE, PARA-PHENYLENEDIAMINE BY NONRADIOACTIVE MURINE LOCAL LYMPH NODE ASSAY USING BROMODEOXYURIDINE WITH FLOW CYTOMETRY AND IMMUNOHISTOCHEMISTRY.

K. Jung, I. Bae and K. Lim. , *AMOREPACIFIC.Co. R&D Center, Gyeonggi-do, Korea, South.* Sponsor: J. Chung.

Although para-phenylenediamine (PPD) has been widely used as hair-dye precursor throughout the world, a skin sensitization potential was suspected. In the current study, we investigated the skin sensitization potential of PPD using non-radioactive murine local lymph node assay (LLNA) with 5-bromo-2'-deoxyuridine(BrdU) using flow cytometry(LLNA:BrdU-FC) and immunohistochemistry(LLNA:BrdU-IHC) technique. Female Balb/c mice were applied topically with the increasing concentration of PPD, positive control DNCB or negative control, SLS on the dorsal of both ears for three consecutive days. To assess proliferating cells in lymph node, BrdU was injected (ip.) to mice at 12hr and 24hr before sacrifice. After sacrifice, auricular lymph nodes were isolated and undergone lymphocyte preparation and tissue processing for immunohistochemistry. Proliferative response in draining lymph nodes was assessed by evaluating BrdU incorporation into cells using flow cytometry and immunohistochemistry. The weight of ear and lymph node in the mice treated with PPD, DNCB and SLS were also tested for the evaluation of irritation potential. As a result, PPD treatment significantly increased the stimulation index by LLNA:BrdU-FC and LLNA:BrdU-IHC in a dose-dependent manner and stimulation index of 3% PPD was more than three. Contact dermatitis reactions, consisting of increased ear weight and lymph node and the presence of inflammatory infiltrates, were also observed by 3% PPD. These data were comparable to the previously reported EC3 value of PPD tested in LLNA assay using radioisotope. With this result, we could suggest that the new non-radioisotopic LLNA with flow cyotometry and immunohistochemistry method can be a valid model for the evaluation of the skin sensitization potential.

PS 389 MECHANO-TOX *IN VITRO* MECHANISTIC TOXICITY SCREENING FOR DRUG DISCOVERY.

R. Annand, M. Jacewicz, J. Gilbert, T. Nakano and K. Tsaioun. *Apredica, Watertown, MA.* Sponsor: A. Brown.

In a drug discovery setting, traditional in vitro screening, such as cytotoxicity assessment, is inadequate to identify all compounds that show toxicity in man. One of the reasons for this high false-negative rate is the failure of cells in culture to express all of the potential mechanisms for toxicity. We have put together a package (MECHANO-Tox) of mechanism-based in vitro models to address the toxicity of potential drugs on a mechanistic level. Phospholipidosis (PLD), the excessive accumulation of phospholipids in organelles within the cells, is a clinically relevant toxicological mechanism. More than 50 drugs, mainly cationic amphiphiles, are known to cause PLD. The PLD-Screen Phospholipidosis Assay, a cell-based in vitro screen, uses fluorescence to detect phospholipid accumulation. Tamoxifen causes lipid accumulation in treated patients. In the PLD-Screen, tamoxifen causes a 4-fold increase in cellular phospholipids at sub-lethal concentrations. Idiosyncratic toxicity is a major problem for drug screening. Proposed mechanisms for idiosyncratic toxicity include mitochondrial toxicity and the generation of reactive metabolites. The MITOXI-Screen Mitochondrial Toxicity assay facilitates the identification of mitochondrial toxicants. In this screen, cells are grown in conditions that render them sensitive (MITO-S) or resistant (MITO-R) to mitochondrial toxin. Treatment with Antimycin A causes complete growth inhibition of MITO-S cells at concentrations where no effect is observed on MITO-R culture. The REACTI-Tox Reactive Metabolite screen detects the generation of reactive metabolites in vitro. Test compounds are subjected to metabolic activation in the presence of an electrophile. Adduct formation is monitored by LC/MS/MS. Ticrynafen is known to form reactive intermediates that bind to Cyp2C9 in vivo. The REACTI-Tox Assay readily detects adducts from the reactive metabolite in vitro. Application of the MECHANO-Tox package will allow the earlier prediction of toxicity for classes of compound whose toxicity is difficult to identify through traditional studies.

PS 390 ASSESSMENT OF DRUG INDUCED CARDIOTOXICITY IN TRANSPARENT ZEBRAFISH.

L. J. D'Amico[1], W. L. Seng[1], P. McGrath[1], Y. Yang[2] and W. Suter[2]. [1]*Phylonix Pharmaceuticals, Inc., Cambridge, MA and* [2]*Novartis Pharmaceuticals, East Hanover, NJ.*

Cardiotoxicity is the leading cause of drug withdrawal and a major reason for clinical trial delays or failure. We and others have shown that pharmacologic response to well characterized cardiotoxins in zebrafish larvae is strikingly similar to response in humans (Parng 2002; Langheinrich et al. 2003; Milan et al. 2003; Parng et al. 2003; Sedmera et al. 2003; Zhang et al. 2003; Parng et al. 2004b; Parng 2005; Milan et al. 2006, McGrath et al. 2008). Although zebrafish have only one atrium and one ventricle and beats per minute are faster than human (~150 vs ~70), drugs that elicit cardiomyopathy, arrhythmia, negative inotropic effects, or QT prolongation in humans also cause bradycardia and slow circulation in zebrafish; drugs that rarely induce cardiotoxicity in normal clinical use did not cause significant cardiotoxicity in zebrafish. In a recent study, we assessed effects of short term exposure to 10 cardiotoxic drugs: astemizole, amiodarone, clozapine, clomipramine, erythromycin, haloperidol, lidocaine, quinidine, terfenadine, verapamil. Heart rate, rhythmicity, circulation and morphological endoints were assessed visually. For heart rate and rhythmicity, 48 hour post fertilization zebrafish were exposed to compounds for 4 hours, and dose responses were generated. For morphological endpoints, zebrafish were exposed to compounds for 24 hours. Results for these 10 positive reference compounds were in good agreement with previously published results in zebrafish and there was 100% correlation with results in humans. The ability to assess morphology in the transparent animal without performing expensive and time consuming surgery and histology is a significant advantage. This convenient model can be used to profile compound safety and toxicity in a physiologically intact animal prior to assessment in mammals.

PS 391 *IN VITRO* MODEL TO PREDICT THE ORAL BIOAVAILABILITY OF AROMATIC AMINE HAIR DYES.

H. Rothe and C. Goebel. *P&G Service GmbH, Darmstadt, Germany.* Sponsor: F. Gerberick.

Application via the oral route is a key requirement for the safety assessment of hair dyes. For a relevant estimation of the systemic exposure, consideration of a potential barrier for the uptake form the intestine is relevant. In pharmacology, CaCo-2 cell lines are widely used to predict the absorption rate of candidate drug compounds across the intestinal epithelial cell barrier in vitro. (Sambury et al., 2005).
As an in vitro measure for the oral bioavailability we analyzed the apparent permeability coefficient (Papp) of the apical-to-basal-route for 13 hair dye molecules of the phenylenediamine-, aminophenol- and antrachinon-type). The permeability characteristics (Papp of 50 μM after 60 min) of each individual molecule across the intestinal barrier was categorized by comparison to the reference substances Propranolol for high permeability (90 % absorption in humans) and ranitidine for low permeability (50 % absorption in humans). The obtained permeability category was compared to the percentage of bioavailability following oral dosage of the radiolabelled compound in a rat ADME study. For 12 out of 13 hair dyes, a high permeability was determined and for one molecule (antrachinon-type) a low permeability was found. For all hair dyes tested, the results obtained in CaCo-2 cells correlated well with the in vivo findings.
We conclude that CaCo-2 cells represent a promising in vitro model to predict the bioavailability after oral dosing and will contribute to further reduce animal testing.

PS 392 TESTING OF THE EPIOCULAR™ TISSUE MODEL FOLLOWING EXTENDED SHIPPING TIMES.

M. Klausner[1], P. J. Hayden[1], M. Genno[2] and J. Kubilus[1]. [1]*MatTek Corporation, Ashland, MA and* [2]*Kurabo Industries, Osaka, Japan.*

The EpiOcular tissue model has been commercially available since 1996 and is used extensively by companies to evaluate the ocular irritancy of new formulations and products. Functional quality control (QC) tests involve determination of the exposure time that reduces tissue viability to 50% (ET-50) following exposure to Triton

X-100 (0.3%). These QC tests show a high level of intra-lot reproducibility and long term inter-lot stability of the tissue model. Coefficients of variation (CV) in the standardized QC assay average < 7% and the yearly average ET-50 has ranged from 22.0 – 27.3 minutes over the period 1996-2007. Recently, a new ocular irritancy protocol has been developed which extends the domain of applicability to a broad variety of organic chemicals. The assay protocol was tested extensively in a European Cosmetic, Toiletry and Perfumery Association (Colipa) sponsored prevalidation study and will enter formal validation early in 2009. The current study investigated QC testing results following the extended times required for shipment of the tissue from the US to Japan.
Over a 12-month period, 22 independent lots of EpiOcular tissue were shipped to Kurabo Industries (Osaka, Japan), an EpiOcular distributor. Standardized QC testing was performed 4-6 days later by Kurabo with the following results: ET-50 = 23.2 +/- 4.1 min (n = 22 tissue lots). All tissue lots tested within the QC acceptance range of 12.2 min < ET-50 < 37.5 min and compared favorably with the 1996 average ET = 24.9 +/- 6.3 minutes (upon which QC acceptance criteria are based). These results demonstrate successful shipment of EpiOcular and establish the feasibility of transfer of the in vitro ocular irritation assay to Japan and other venues requiring elongated shipping times.

PS 393 MODELING INDIVIDUAL VARIABILITY FROM *IN VITRO* DATA.

R. M. Gardner[1], J. F. Nyland[2] and E. K. Silbergeld[1]. [1]*Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD and* [2]*Department of Pathology, Microbiology, and Immunology, University of South Carolina School of Medicine, Columbia, SC.*

A major challenge in toxicology is identifying and quantifying the range and variability of human response. We have developed an in vitro model system combined with a multi-level approach to biostatistical modeling to investigate variability in human response. Twenty donors gave a blood sample six separate times over a period of at least six months. Peripheral blood mononuclear cells (PBMCs) were isolated and cultured for 48 hours in the presence of low levels (up to 200nM) inorganic mercury (Hg) and the immune stimulant lipopolysaccharide (LPS). Cells treated with LPS alone were used as a control in order to estimate baseline responsiveness. We measured cytokine production in the supernatants of the cell cultures to gauge immune response. A simple linear regression of Hg treatment versus cytokine production indicated that there is a significant and consistent dose-response increase in the production of TNFα with Hg treatment. We saw a considerable amount of variation in the baseline response to LPS (a 50-fold range, 61.5 pg/ml TNFα to 3463.4 pg/ml TNFα) and also in the subsequent response to Hg, both within and between people. Therefore, we chose to use a multi-level modeling approach with log-transformed data that allows for the quantification of both inter-individual and intra-individual variation using Markov chain Monte Carlo (MCMC) methods for analysis. "Individual-level" characteristics, such as sex and race, along with "visit-level" characteristics, such as monthly fish consumption and medication use, were tested in this model for their effects on cytokine production in response to Hg treatment. These methods allowed us to define the range of response to Hg among individuals. We have observed that while there is a considerable range in a person's initial cytokine response to LPS, the slope of the dose-response curve to increasing Hg concentrations is highly consistent across all individuals tested.

PS 394 THE USE OF THE SKINETHIC HUMAN CORNEAL EPITHELIAL (HCE) MODEL TO PREDICT OCULAR IRRITANCY APPLIED TO A LARGE SET OF 435 INDUSTRIAL CHEMICALS: APPLICABILITY DOMAINS DEFINITION.

J. Cotovio[1], M. Grandidier[1], C. Amsellem[2], J. Ovigne[1], D. Lelièvre[1], C. Capallère[3], J. Meunier[1] and J. Leclaire[1]. [1]*Life Sciences, L'OREAL Research, Aulnay Sous Bois, France,* [2]*EPISKIN SNC, Lyon, France and* [3]*SkinEthic Laboratories, Nice, France.* Sponsor: E. Dufour.

The 7th amendment of the EU Cosmetic Directive will lead to the ban of animal testing for cosmetic ingredients in March 2009. Thus alternative methods are urgently required in order to evaluate eye damage potential of chemicals. The HCE model from SkinEthic laboratories is a standardized epithelium reconstructed with immortalized human corneal epithelial cells. We have used the HCE model to evaluate in vitro eye irritation potential of chemicals. Because intrinsic cytotoxicity potential of chemicals is decisive factor affecting cornea after contact, we have used cell viability (MTT test) assessment as the main endpoint to classify chemicals. Adapted protocol assays were based on specific contact times and a specific post-treatment incubation period. The "long" 1hour + 16 hours HCE assay established on a set of 102 chemicals, was applied to an extended set of 435 industrial "real life" chemicals (EU classification: 367 Non classified, 49 R41 and 19 R36). The Prediction Model (PM) based on a 50 % viability cut-off allowed the drawing up of 2 chemicals classes (irritants and non irritants). Inter and intra-batch reproducibility was assessed by using a specific controls (Triton X100), positive control (ethanol) and negative control (Phosphate buffer). The overall performances were good (90% sensitivity, 81% specificity and 83% concordance) and well balanced. The published "short" treatment HCE assay (10 min.) was part the full protocol and applicability domain definition was an important preliminary requirement. Results showed the validity of intrinsic reactivity potency, as the main sorting criteria enabling the choice of the most adapted HCE exposure-time allowing the maintenance of balanced performances. The HCE protocol, focused on reactivity-based oriented assays strategy, proved to be an efficient in vitro tool for the in vitro assessment of ocular irritancy potential of chemicals.

PS 395 EPIGENETIC CYTOTOXICITY OF METALS ON MOUSE EMBRYONIC STEM CELLS.

D. I. Gazarian and F. A. Barile. *Pharmaceutical Sciences, St. John's University, Queens, NY.*

An ever-increasing comprehension of gene function leads to a realization that DNA sequences of targeted genes, albeit a very important hereditary indicator, are very much susceptible to a variety of modifications, triggered by exogenous elements. Such DNA alterations, along with modifications to associated proteins, interfere with gene expression by inducing errors in DNA packaging into chromatin and subsequently in replication and transcription. This study examines epigenetic cytotoxicity of eight metals (As, Mn, Li, Hg, Cd, Ni, Pb, Cu) on pluripotent mouse embryonic stem (mES) cells (ES-D3, ATCC), derived from the cell mass of mouse blastocysts. During the first stage, the cells were seeded on collagen type-I coated 96 well plates, allowed to incubate for 24 hours, following one hour of exposure to corresponding metals. Cytotoxic effects were monitored using cell viability (MTT) assay. The data show the cells responded to the presence of metals by increasing proliferation, as compared to control, and directly proportional to increasing doses of the metals. In order to investigate a true epigenetic effect, a quantitative polymerase chain reaction (PCR) technique was performed. mES cells were seeded on 6 well plates, as above. At the end of the exposure period, cells were collected, pelleted and mRNA was extracted using Dynabeads® mRNA Direct™ Kit. The three template genes, Rad18, Top3a, and Ogg1 were chosen for their known role in DNA damage repair and genome stability. The PCR data reveals a decrease in expression levels of the three genes. Such a decrease in expression of DNA repair genes correlates with mutational events, thus suggesting that alteration of DNA repair mechanisms in the presence of acute metal exposure contribute to a variety of epigenetic events. (Supported in part by grants from Alternatives Research and Development Foundation, 35332-985; International Foundation for Ethical Research, 35262-985).

PS 396 A YEAST-BASED MODEL SYSTEM TO EVALUATE TOXICITY TO HUMAN STEROID HORMONE RECEPTOR SIGNALING.

X. Tan, M. Wilson and C. Miller. *Department of Environmental Health Sciences, Tulane Cancer Center, Center for Bioenvironmental Research, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA.*

Hsp90 protein complexes regulate key signaling pathways. Steroid hormone receptors (SHRs) are among the best characterized substrates for Hsp90 regulation and they serve as therapeutic targets in hormone-dependent cancers. Drugs that interact with Hsp90 have been developed as cancer therapeutic agents. However, drugs targeted to a SHR or Hsp90 chaperone-substrate complex may have toxic effects on other receptors or substrate proteins. We developed a model yeast system engineered to express human androgen, estrogen α, estrogen β, glucocorticoid, mineralocorticoid, or progesterone hormone receptors along with relevant reporter genes to explore this problem. Radicicol, an Hsp90 inhibitor, preferentially inhibited signaling by SHRs. We observed SHR signaling inhibition in yeast cells treated with radicicol concentrations (3nM-3μM) that were not generally toxic. Low doses of radicicol (<1 μM) did not decrease cell growth, but inhibited signaling by all six SHRs in a dose-dependent manner. IC50 values for signaling inhibition by radicicol were similar for all six SHRs (0.4 to 1.2 μM). Targeting one SHR in a cancer with this type of Hsp90 inhibitor may have off-target effects on other SHRs. This model system may be useful for assessing the toxicity of pharmaceutical agents and xenobiotic agents (e.g. endocrine disruptors) that exert effects on steroid hormone signaling pathways. Supported by NIH 3R33CA101622-03.

PS 397 A HIGH CONTENT SCREENING (HCS) APPROACH FOR IDENTIFYING ANTIBACTERIALS THAT IMPAIR MITOCHONDRIAL PROTEIN SYNTHESIS IN CELLS.

S. Nadanaciva, C. Zurenko, P. A. Billis, D. Gebhard and Y. Will. *Pfizer Inc, Groton, CT.*

Over 50% of antibacterials are protein synthesis inhibitors that target the bacterial ribosome as their primary mode of action. One of the challenges associated with the development of these compounds is mitochondrial toxicity since there is a structural similarity between bacterial ribosomes and the host's mitochondrial ribosomes. Impairment of protein synthesis within mitochondria leads to depletion of mitochondrial DNA-encoded proteins. Hence, identifying drugs that impair protein synthesis in the off-target, the mitochondrion, is important in the drug discovery process. We describe here a high content screening (HCS) approach for identifying drugs that impair mtDNA-encoded protein synthesis in cells. HepG2 cells seeded in 96-well format were grown in a selection of drugs in a dose-response manner over a period of 5 days. The effect of each drug on mtDNA-encoded protein synthesis was assessed using an antibody against cytochrome c oxidase together with a fluorophore-conjugated secondary antibody. Cytochrome c oxidase is a mitochondrial protein which has 3 subunits encoded by mtDNA and made by mitochondrial ribosomes. The effect of the drug on overall cytotoxicity was assessed with the nuclear stain, DAPI. Our results show that the assay is a high throughput method of identifying drugs such as many antibacterials which impair mtDNA-encoded protein synthesis.

PS 398 INTER-LABORATORY VALIDATION STUDY OF *IN VITRO* EYE IRRITATION TEST; SHORT TIME EXPOSURE (STE) TEST.

H. Sakaguchi[1], N. Ota[2], T. Omori[3], H. Kuwahara[4], T. Sozu[5], Y. Takagi[6], Y. Takahashi[1], H. Tanigawa[7], M. Nakanishi[7], T. Nakamura[8], T. Morimoto[9], S. Wakuri[10], Y. Okamoto[7], M. Sakaguchi[2], T. Hayashi[4], T. Hanji[6] and S. Watanabe[8]. *[1]Kao Corp., Tochigi, Japan, [2]Pola Chemical Industries, Kanagawa, Japan, [3]Kyoto University, Kyoto, Japan, [4]Kanebo cosmetics INC, Kanagawa, Japan, [5]Osaka University, Osaka, Japan, [6]Pias Corp., Osaka, Japan, [7]KOSÉ Corp., Tokyo, Japan, [8]LION Corp., Kanagawa, Japan, [9]Sumitomo Chemical Co., Ltd., Osaka, Japan and [10]FDSC., Kanagawa, Japan.* Sponsor: J. Avalos.

Short Time Exposure (STE) test is an easy in vitro eye irritation test that assesses cytotoxicity in SIRC (rabbit corneal cell line) cells following a one 5 minute dose treatment. To assess reliability (including transferability and inter-lab reproducibility) and relevance of STE test, a validation study with 5 laboratories was conducted. The standard protocol of the STE test for this study was prepared and fixed before study began. At first, three standard substances (sodium lauryl sulfate, SLS; calcium thioglycollate, CT; and Tween 80, TW80) were evaluated to confirm reliability of the STE test. Three experiments of each substance were evaluated using 5%, 0.5% and 0.05% test material and saline as vehicle. The mean cell viability (CV) was then calculated. Both the CV and rank classification based on the prediction STE model were compared with their background data from the STE test developer. The CV of SLS and TW80 was less than 7% and more than 90%, respectively, for all three doses in all laboratories. For CT, 5%, 0.5% and 0.05% solutions showed less than 20% CV, about 70% CV, and more than 85% CV, respectively, in all laboratories. These CV values were similar with the developer's background data. The rank classification of SLS, CT, and TW80 were 3, 2, and 1, respectively, in all 5 laboratories. Also, these ranks were the same as developer background data. From these data, a good reliability of the STE test was obtained. To be completed by the end of 2008, we are further evaluating this assay's reliability and relevance by testing in 5 labs for additionally 25 substances. This validation study is supported by JSAAE (Japanese Society for Alternative to Animal Experiments).

PS 399 *IN VITRO* SKIN IRRITATION ASSESSMENT OF DYES AND COLORING CHEMICALS USING THE ECVAM VALIDATED EPISKIN ASSAY.

F. Amaral, E. Lambert, C. Chesneau, L. Martin, D. Lelièvre, M. Grandidier and J. Cotovio. *L'OREAL, Aulnay sous bois, France.* Sponsor: E. Dufour.

The in vitro reconstructed human epidermis EpiSkin has been scientifically validated in 2007 as a full replacement model for the Draize rabbit acute skin irritation test. The test is based on tissue viability assessment by using the MTT test and allows the discrimination between irritants (R38) and not classified (NC) chemicals. The MTT assay is a standard colorimetric method: Yellow MTT is reduced to purple formazan by epidermis living cells. Therefore, due to the reading method, any chemical able to color the tissue or induce indirect and non specific coloration absorbing closely to formazan can result in a possible viability overestimation. The purpose of this study was to assess the use of the validated EpiSkin protocol for the in vitro prediction of colored chemicals irritancy potential (e.g. hair dyes). Colored chemicals as dyes can be retained in the epidermis or difficult to wash-off and induce a possible residual staining. Consequently, after formazan extraction, non specific remaining color may modify final readings. In order to eliminate colorimetric interference, we introduced specific controls fitting to the validated protocol course. Control tissues followed the same treatment steps than treated ones, MTT step excepted. Stratum corneum were removed from all tissues before color extraction. These controls enabled the quantification of non specific optical density (NSOD) and the definition of acceptable limits. Therefore calculations take into account only the true OD related to mitochondrial activity of living cells. Histological analysis was conducted in order to document strong coloring chemicals results. R38 and NC dyes have been evaluated by using this strategy.
We showed that the EpiSkin assay is a suitable and reliable method for in vitro skin irritation prediction of chemicals likely to color tissues. The applicability domain of the Episkin skin irritation assay can therefore be extended to these chemical families.

PS 400 QUANTITATIVE STRUCTURE–ACTIVITY RELATIONSHIP (QSAR) MODELS AS SUITABLE ALTERNATIVES FOR EXPERIMENTS WITH FISH.

E. Zvinavashe[1, 2], H. Berg vanden[1], A. Soffers[1], J. Vervoort[3], A. Freidig[4], A. Murk[1] and I. Rietjens[1]. *[1]Toxicology, Wageningen University, Wageningen, Netherlands, [2]IRAS-Toxicology, Utrecht University, Utrecht, Netherlands, [3]Biochemistry, Wageningen University, Wageningen, Netherlands and [4]Kinetics and Metabolism, TNO Quality of Life, Zeist, Netherlands.* Sponsor: B. Blaauboer.

Quantitative structure–activity relationship (QSAR) models are expected to play a crucial role in reducing the number of animals used for toxicity testing due to the adoption of the new European Union (EU) chemical control system called Registration, Evaluation, and Authorization of Chemicals (REACH). In the present study, the potential of using *in vitro* toxicity data to predict the acute *in vivo* toxicity of chlorinated alkanes to fish was investigated. Chlorinated alkanes are widely used in the production of adhesives and lubricants, have large production volumes, and therefore have a large potential for environmental pollution. A fast, cost-effective method that minimizes animal use is therefore required to assess their toxicity. Acute cytotoxicity of a series of chlorinated alkanes to Chinese hamster ovary cells was observed at concentrations similar to those that have been shown previously to be toxic to fish. Strong correlations exist between the acute *in vitro* toxicity of the chlorinated alkanes and (i) hydrophobicity [modeled by the calculated log K_{ow} (octanol–water partition coefficient); r^2 = 0.88, r^2_{int} = 0.85 and r^2_{ext} = 0.74] and (ii) *in vivo* acute toxicity to fish (r^2= 0.76). A QSAR model has been developed to predict *in vivo* acute toxicity to fish based on the in vitro data and even on *in silico* log K_{ow} data only. The developed QSAR model is applicable to chlorinated alkanes with up to 10 carbon atoms, up to eight chlorine atoms, and log K_{ow} values lying within the range from 1.71 to 5.70. Out of the 100 196 compounds on the EU market, the QSAR model covers 77 of them. These findings demonstrate that *in vitro* experiments and even *in silico* calculations can replace animal experiments in the prediction of the acute toxicity of existing and new chlorinated alkanes that have similar chemical structures as the ones tested in the present study.

PS 401 A 3D SKIN MODEL FOR COSMETIC, CHEMICAL AND MEDICAL DEVICE PHOTOTOXICITY TESTING.

L. F. Pratt, D. R. Cerven and G. L. DeGeorge. *MB Research Laboratories, Spinnerstown, PA.*

We have enhanced our validated in vitro phototoxicity test using human skin models by exploring inflammatory mediator and gene expression endpoints. The Enhanced Phototoxicity Assay in Reconstituted Skin (EPARS) is based upon a 3D skin model that closely parallels human skin morphology. Major advantages of this test system are that test substances can be applied topically, avoiding the problems of (1) difficulty in solubilizing test materials, and (2) indirect application of test materials to cell monolayers via culture media. In addition, the tissues are composed of differentiated layers of primary human keratinocytes, a more relevant model than mouse tumor fibroblasts. Phototoxic effects are determined by measuring the viability of UV irradiated vs. non-irradiated exposed tissues. In order to increase the sensitivity and specificity of the test, we have measured the release of cytokines into the culture media via ELISA. The release of the inflammatory factor PGE2 was shown to be an early predictor of the toxic effects demonstrated in the viability assay. When compared to human phototoxicity test results and the 3T3 NRU PT validation test material set, EPARS had 100% accuracy, sensitivity and

specificity. Microarray analysis of gene expression showed that chlorpromazine treatment with UVA irradiation caused changes in gene expression over time that were not observed without UVA irradiation. These genes include those for keratins, collagens and fibronectins. EPARS is an accurate and sensitive test for detecting phototoxic substances at doses representative of those that cause actual human skin reactions. Thus, EPARS is a highly predictive phototoxicity assay, with endpoints of inflammatory mediator and gene expression that allow for investigation into the mechanisms of photosensitivity in a wide variety of consumer products.

PS 402 AN IMPROVED *IN VITRO* MODEL FOR SAFETY SCREENING OF DRUGS IN DEVELOPMENT: ACCURATE EVALUATION OF DRUG-MEDIATED CYP INHIBITION USING H-CLASS MICROSOMES.

J. Fleischer[1, 2], T. Moeller[2, 1], J. Lee[2, 1], D. Dryden[2, 1] and T. Christopher[1, 2]. *[1]Development Services, Celsis IN VITRO Inc, Baltimore, MD and [2]Products, Celsis IN VITRO Inc, Baltimore, MD.*

Human liver microsomes are a well-characterized in vitro model for identifying cytochrome P450 (CYP) inhibition during drug development. Use of hepatic microsomes from human donors reduces concerns about species differences and also may reduce the use of animals during preclinical development. However, the utility of this model is limited by variations in enzyme activity among different microsomal preparations, variations among the isozymes within a single preparation, and also by overall low CYP isoform enzyme activity. In drug safety studies, low microsomal CYP enzyme activity can preclude accurate quantitation of CYP inhibition. Selective pooling of well-characterized microsomes can overcome these limitations. Using a proprietary algorithm, we created H-class microsomes that provide consistently higher activity across the panel of clinically relevant CYP isoforms, particularly those isoforms that are lower in activity. IC50 values of known inhibitors of CYP1A2, CYP2A6, CYP2B6, CYP2C8, CYP2C9, CYP2C19, CYP2D6, CYP2E1, and CYP3A4 were determined using isoform-selective substrates. The rate of CYP substrate metabolite formation was measured using HPLC-UV or LC/MS assays. Under these conditions, the average dynamic range of CYP enzyme activity increased by 90% in H-class microsomes relative to microsomes with lower activity, avoiding the occurrence of below quantifiable limit (BQL) data and allowing for accurate calculation of IC50 values. H-class microsomes represent an important emerging tool for accurate CYP inhibition characterization during drug development.

PS 403 A TRANSGENIC MODEL FOR ARSENIC METHYLATION AND ITS BIOLOGICAL EFFECTS IN *DROSOPHILA.*

J. G. Muñiz Ortiz and I. Cartwright. *Molecular Genetics, University of Cincinnati College of Medicine, Cincinnati, OH.*

When inorganic arsenic is ingested by humans there is metabolic conversion to methylated arsenical species, readily detectable in urine. Contrary to an earlier belief that methylated species represented metabolic detoxification products, it is now accepted that certain methylated arsenicals are more toxic than their inorganic progenitors, particularly where cells are exposed chronically to low levels. The genotoxicity of such methylated species, howsoever caused, seems to be much greater than that of inorganic arsenic, and is likely to be relevant to the carcinogenic potential exhibited by long term arsenic exposure. We wished to explore this potential in a highly genetically manipulable background in order to shed light on the critical mechanisms and pathways involved in arsenic-mediated carcinogenesis. Others had shown that *Drosophila* exposed directly to methylated arsenicals exhibit a clearly analogous genotoxic response, but fail to do so when fed inorganic arsenite owing to apparent absence of the relevant methylation pathway. We circumvented this by introducing the human gene for the enzyme arsenic(III) methyltransferase (AS3MT), under easily manipulated regulatory control, into *Drosophila*. We have confirmed that transgenic flies can be induced to express an antigenically cross-reactive form of the human enzyme, and that its expression appears to affect neither the normal developmental cycle nor fertility of the transgenic lines. Nor is there any obvious differential toxic effect (e.g., enhanced mortality) when arsenite is fed to transgenic lines either uninduced or induced for expression of AS3MT. Nonetheless, when larval extracts from such lines were analyzed for arsenic speciation via HPLC/ICP-MS we found that both mono and dimethylated arsenic species were present in large amounts, but only when AS3MT was induced. Thus the model can now be used to explore the nature and extent of genotoxic outcomes in many informative genetic backgrounds, as well as the effects of different polymorphic variants of AS3MT found in exposed human populations.

PS 404 ENVIRONMENTAL MUTAGENESIS AND CYTOCHROME P450 ACTIVITIES IN THE NEMATODE CAENORHABDITIS ELEGANS.

M. C. Leung[1], M. McKeever[1], A. Berkowitz[1], W. A. Boyd[2], A. Bunger[3], J. H. Freedman[2], R. L. Walsky[3], H. M. Stapleton[1] and J. N. Meyer[1]. *[1]Nicholas School of the Environment, Duke University, Durham, NC, [2]Laboratory of Molecular Toxicology, National Institute of Environmental Health Sciences, RTP, NC and [3]Pfizer Global Research and Development, Groton, CT.*

The nematode Caenorhabditis elegans is emerging as an important alternative model in toxicology. It offers unique advantages over conventional models, including ease of maintenance, short life cycle, genetic manipulability, well-developed bioinformatics, and high-throughput capability. A major concern about using the C. elegans model in toxicology, however, is a lack of understanding about its xenobiotic metabolism capabilities. There is also limited information on how C. elegans responds to known human mutagens. The current study addresses these questions using two different approaches: (1) testing toxicity and DNA damage induced by known environmental mutagens that require metabolic activation, in strains of C. elegans carrying mutations in DNA repair genes; and (2) characterizing the catalytic activities of C. elegans microsomes using standard CYP substrates. Aflatoxin B1 (AFB1) exposure was found to significantly inhibit ($P < 0.05$) the growth and reproduction of C. elegans, and have a greater effect on repair-deficient than repair-proficient strains. Benzo[a]pyrene (BaP) was no more toxic to repair-deficient than repair-proficient animals, however. These results suggest that C. elegans metabolizes AFB1, but not BaP, to DNA-reactive forms. Furthermore, C. elegans microsomes were found to have a lower cytochrome C reductase activity than rainbow trout microsome (6.8 vs 29.6 nmol/min mg, respectively) and show no 7-ethoxyresorufin-O-deethylase (EROD) activity at a detection limit of 2 pmol/min mg. Further experiments are being carried out to identify any DNA damage caused by AFB1 and BaP exposure as well as the presence of any higher eukaryote CYP-like activities in C. elegans.

PS 405 INFLAMMATORY CYTOKINE RESPONSE IN EPIDERM FT: A TISSUE MODEL FOR CUTANEOUS SM EXPOSURE.

O. E. Clark, E. W. Nealley, A. L. Miller, K. W. Leiter and W. J. Smith. *Research Division, USAMRICD, Aberdeen Proving Ground, MD.*

Sulfur mustard (2, 2'-dichlorodiethyl sulfide, SM) is a cytotoxic alkylating agent with mutagenic and vesicating properties. Our research focus is the mechanism of toxicity of SM for the purpose of developing medical countermeasures to this chemical threat. A major feature of SM tissue injury is inflammation. We have used Epiderm Full Thickness 200 (EFT-200, MatTek Corp. Ashland, MA 01721) tissue construct with both dermal and epidermal components as a model to measure cytokine release after SM exposure. EFT-200 secreted increased levels of IL-8 and GM-CSF inflammatory cytokines in the growth media when measured at 24 hrs (Miller A., et. al., SOT 2007). MatTek Corporation has recently modified the EFT-200 to eliminate keratinocytes migrating to the bottom portion of the dermal construct. We tested this new construct, Epiderm Full Thickness 400 (EFT-400, MatTek Corp), along with the EFT-200, to evaluate the new construct as an improved model for human tissue inflammatory response to SM. Release of IFN-γ, Il-1β, IL-2, IL-4, IL-5, IL-10 or TNF-α was not increased following 100μM and 300μM SM exposure in either model over 24 hrs. EFT-200 had a variable response with high background levels of IL-8 and IL-6. EFT-400 had dose response increase of IL-8 and GM-CSF following SM exposure starting at 2 hrs and continuing through 24 hrs. This early dose response of EFT-400 is a valuable addition to this model for testing release of inflammatory cytokines following exposure to SM. This will enable the model to be used in elucidating early inflammatory changes following chemical exposure. The new EFT-400 model from MatTek exhibits an improved dose response over 24 hrs, and low background makes it a valuable and improved in vitro model for cutaneous exposure of chemical toxicants.

PS 406 USE OF THE RECONSTRUCTED EPIVAGINAL™ TISSUE MODEL TO SCREEN IRRITATION POTENTIAL OF FEMININE HYGIENE PRODUCTS.

C. Cannon, S. Ayehunie, P. J. Hayden, K. LaRosa and M. Klausner. *MatTek Corporation, Ashland, MA.*

The vaginal mucosa is commonly exposed to chemicals and therapeutic agents that may result in irritation/inflammation which can make women susceptible to infections such as HIV-1 and HSV-2. Hence, chemical/formulation or therapeutic agent induced vaginal irritation should be a concern for toxicologists. Traditionally, testing of such materials has been performed using the rabbit vaginal irritation (RVI) assay. In the current study, we investigated whether the organotypic, highly differ-

entiated EpiVaginal tissue could be used as an non-animal alternative. The EpiVaginal tissue was exposed to a single application of six chemicals at three concentrations and the effects on tissue viability (MTT assay), barrier disruption (measured by trans-epithelial electrical resistance {TEER} and sodium fluorescein {NaFl} leakage), and inflammatory cytokine release (Interleukin {IL}-1α, IL-1β, IL-6, and IL-8) were examined. When compared to untreated controls, two irritating test articles, benzalkonium chloride and nonoxynol 9, reduced tissue viability to <40% and TEER to <60% and increased NaFl leakage by 11-24% and IL-1α and IL-1β release by >100%. Four other non-irritating materials had minimal effects on these parameters. Assay reproducibility was confirmed by testing the chemicals using three different production lots and by using tissues derived from cells of three different donors; coefficients of variation were <12%. In conclusion, decreases in MTT and TEER, and increases in NaFl and IL-1α and IL-1β release appear to be useful endpoints for preclinical toxicity screening of chemicals, formulations, and medical devices and should be investigated further as an in vitro alternative for the current RVI assay.

PS 407 METABOLISM OF 7-ETHOXYCOUMARIN BY ISOLATED PERFUSED RAINBOW TROUT LIVERS.

J. W. Nichols, G. J. Lien, A. D. Hoffman and P. N. Fitzsimmons. *U.S. EPA/ORD/NHEERL/Mid-Continent Ecology Division, Duluth, MN.*

Isolated trout livers were perfused using methods designed to preserve tissue viability and function. Liver performance was evaluated by measuring O_2 consumption, vascular resistance, K^+ leakage, glucose flux, lactate flux, alanine aminotransferase leakage, and metabolic clearance of 7-ethoxycoumarin ($CL_{H,7\text{-}EC}$). Livers perfused with solutions containing 1.0, 2.5, or 10.0 g/L bovine serum albumin exhibited relatively stable physiological performance for up to 10 h. $CL_{H,7\text{-}EC}$ decreased rapidly during the first 1-2 h, probably due in part to non-steady-state conditions. $CL_{H,7\text{-}EC}$ declined slowly thereafter, decreasing by 30 to 40% between 2 and 10 h. A linear equation was subsequently developed to correct measured levels of clearance for decreasing metabolic activity over time. To illustrate the value of this preparation, experiments were conducted to examine the effects of protein binding on hepatic clearance of 7-EC. Clearance rates corrected for declining metabolic activity ($CL_{H,7\text{-}EC,CORR}$) changed in nearly direct proportion to changes in the free concentration of 7-EC efferent to the liver, as predicted by theoretical models of liver function. Additional studies were performed to characterize the concentration-dependence of 7-EC metabolism. Metabolic activity increased linearly with the total concentration of 7-EC afferent to the liver resulting in constant levels of $CL_{H,7\text{-}EC,CORR}$. $CL_{H,7\text{-}EC,CORR}$ values for four livers averaged 12.0 ± 5.0 mL/h/g-liver (mean ± SD, n= 60 individual determinations) and were in good agreement with an estimate of hepatic clearance obtained by extrapolating published *in vitro* data from isolated trout hepatocytes. The extended viability of isolated trout livers achieved in this study creates new opportunities for research on hepatic function in fish. This abstract does not necessarily reflect U.S. EPA policy.

PS 408 AN EVALUATION OF THE VENOUS EQUILIBRIUM MODEL FOR HEPATIC CLEARANCE USING ISOLATED PERFUSED RAINBOW TROUT LIVERS.

A. D. Hoffman[1], T. L. ter Laak[2], P. N. Fitzsimmons[1] and J. W. Nichols[1]. *[1]U.S. EPA/ORD/NHEERL/Mid-Continent Ecology Division, Duluth, MN and [2]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands.*

The venous equilibrium model is widely used to describe hepatic clearance (CL_h) of chemicals metabolized by the liver. If chemical delivery to the tissue does not limit CL_h, this model predicts that CL_h will approximately equal the product of intrinsic metabolic clearance and a term (f_u) that describes the free chemical concentration in plasma (or in the case of isolated perfused livers, the perfusion buffer). Despite its general acceptance, experimental efforts to validate the model have provided contradictory results, particularly for compounds that are highly bound or are substrates for specific transport proteins. These efforts have been further complicated by the challenge of measuring f_u accurately. In this study we evaluated the venous equilibrium model by perfusing isolated trout livers with four polyaromatic hydrocarbons (PAHs): naphthalene, fluoranthrene, phenanthrene, and anthracene (log K_{ow} 3.7 to 4.8). The effect of f_u on CL_h was studied by manipulating the concentration of bovine serum albumin in the perfusion buffer using an experimental design wherein each liver acted as its own control. Free chemical concentrations afferent and efferent to the liver were measured using solid phase microextraction (SPME) fibers. Additional SPME fibers were implanted into the tissue itself. Fluoranthene, phenanthrene, and anthracene were extensively metabolized resulting in extraction fractions (E) ranging from 25 to 75%. Naphthalene was less well metabolized (E < 25%). Preliminary findings provide support for the venous equilibrium model; for each of the three highly metabolized PAHs, an increase in f_u resulted in a roughly proportional increase in CL_h. Free chemical concentrations within the tissue were also found to be close to those in buffer samples efferent to the liver. Ongoing work is designed to characterize the quantitative relationship between f_u and CL_H. This abstract does not necessarily reflect U.S. EPA policy.

PS 409 HEPATOPROTECTIVE MECHANISMS OF ARALIA CONTINENTALIS AGAINST OXIDATIVE STRESS-INDUCED CELL DEATH IN HEPATOCYTES.

Y. Chung[1], Y. Hwang[2], J. Choi[2] and H. Jeong[2]. *[1]Division of Food Science, International University of Korea, Jinju, Jinju, Korea, South and [2]BK21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South.*

In the present work, we investigated the protective effects of the ethanol extract of Aralia continentalis roots (AC) on tert-butyl hydroperoxide (t-BHP)-induced hepatotoxicity in a cultured Hepa1c1c7 cell line and in mouse liver. Pretreatment with AC prior to the administration of t-BHP significantly prevented the increase in serum levels of hepatic enzyme markers (ALT, AST) and lipid peroxidation and reduced oxidative stress, as measured by glutathione content, in the liver. Histopathological evaluation of the livers also revealed that AC reduced the incidence of liver lesions. The in vitro study showed that AC significantly reduced t-BHP-induced oxidative injury in Hepa1c1c7 cells, as determined by cell cytotoxicity, intracellular glutathione content, lipid peroxidation, reactive oxygen species (ROS) levels, and caspase-3 activation. Also, AC up-regulated phase II genes including heme oxygenase-1 (HO-1), NAD(P)H:quinone reductase, and glutathione S-transferase. Moreover, AC in¬duced Nrf2 nuclear translocation and ERK1/2 and p38 activation, pathways that are involved in inducing Nrf2 nuclear translocation. Taken together, these results suggest that the protective effects of AC against t-BHP-induced hepatotoxicity may, at least in part, be due to its ability to scavenge ROS and to regulate the antioxidant enzyme HO-1 via the ERK1/2 and p38/Nrf2 signaling pathways.

PS 410 REDUCTIVE METABOLISM OF *N*-(1-(3, 4-METHYLENEDIOXYPHENYL) PROPAN-2-YL)-*N*-METHYLHYDROXYLAMINE IN HUMAN HEPATOCYTES.

A. Miyajima-Tabata[1], M. Sunouchi[1], K. Nakazawa[1], R. Kikura-Hanajiri[2] and Y. Goda[2]. *[1]Division of Pharmacology, National Institute of Health Sciences, Tokyo, Japan and [2]Division of Pharmacognosy and Phytochemistry, National Institute of Health Sciences, Tokyo, Japan.* Sponsor: M. Ema.

3,4-Methylenedioxymethamphetamine (MDMA) is a designer drug with a central nerve stimulation and hallucinogenic action, and controlled all over the world. Metabolism of MDMA has been studied well and Cytochrome (CYP) 2D6 and CYP1A2 catalyze *O*- or *N*-demethylation in human liver. *N*-(1-(3,4-methylenedioxyphenyl)propan-2-yl)-*N*-methylhydroxylamine (*N*-OH MDMA) has been recently distributed as a drug of abuse as well as MDMA and has become a serious problem in Japan. We found that MDMA and 3,4-methylenedioxyamphetamine (MDA) were detected in urine samples when *N*-OH MDMA was administrated to rat. In this study, we investigated whether *N*-OH MDMA was metabolized into MDMA and MDA in human hepatocytes. Cryoserved suspensional human hepatocytes were incubated with *N*-OH MDMA in Williams' E medium for 0, 1, 2, 4 hours in a 5%CO_2 incubator at 37°C. Concentration of *N*-OH MDMA, *N*-hydroxy-1-(3,4-methylenedioxyphenyl)-2-aminopropane (*N*-OH MDA), MDMA, MDA, and methamphetamine-d4 (internal standard) were measured using UPLC-MS. *N*-OH MDMA was stable during 4-hour incubation in the medium without the cells and MDMA or MDA was not generated. When *N*-OH MDMA was incubated with hepatocytes, MDMA and MDA were increased time dependently. *N*-OH MDMA was metabolized into MDMA and MDA approximately by 10% and 3%, respectively after 2-hour incubation. We also studied the metabolism of *N*-OH MDA in human hepatocytes. MDA was generated from *N*-OH MDA with hepatocytes, similarly. These results suggest that *N*-OH MDMA is reduced into MDMA and MDA in human liver and these metabolites show neuropsychiatric impairment.

PS 411 DISPOSITION OF QUANTUM DOTS IN HEPG2 CELLS.

W. E. Smith[1], J. H. Tracy[1], C. C. White[1], T. K. Bammler[1], X. Hu[2], X. Gao[2], T. J. Kavanagh[1] and D. L. Eaton[1]. *[1]Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA and [2]Department of Bioengineering, University of Washington, Seattle, WA.*

Quantum dots (QDs) are nanometer-sized crystals that offer advantages over organic dyes and fluorescent proteins, such as high levels of brightness and photostability. QDs are generally constructed of a core metal composite surrounded with

various coatings specific to the intended use. The core composition of QDs commonly consists of Cd and Se, and less commonly, Hg, Te, In and As. While metals utilized for this core composition can be toxic, the wide variety of QD preparations makes it difficult to predict cellular response *in vivo* or *in vitro*. In order to gain a better understanding of their disposition within the liver, human hepatocellular carcinoma (HepG2) cells were exposed to poly(maleic anhydride-alt-1-tetradecene), tri-n-octylphosphine oxide (PMAT-TOPO) co-polymer CdSe-based QDs at varying concentrations (5-100 nM). QD uptake into HepG2 cells was evaluated at 3, 6 and 24 hours using both confocal and traditional fluorescent microscopy. HepG2 cells sequestered QDs from culture media in a time- and dose-dependent manner. QD uptake was pronounced by 3 hours of exposure. Cell viability (as measured by LDH release) was not altered. Our preliminary results suggest that this particular class of stable QDs has no adverse effects on HepG2 cells under the conditions tested. Currently, we are conducting similar experiments with human primary hepatocytes. Primary cells reflect pharmacokinetic aspects of liver more closely than HepG2 cells, including absorption, distribution, metabolism, and excretion of xenobiotics. In contrast to HepG2 cells, the availability of primary cells is limited. Therefore, we are using HepG2 cells to optimize experimental parameters which we will then test with primary hepatocytes. This approach optimizes the use of primary cells and also assesses the suitability of HepG2 cells as an *in vitro* model for nanoparticle toxicity studies as compared to primary hepatocytes. This work was supported by NIEHS Grants R01ES016189

PS 412 MITOCHONDRIAL TOXICITY OF USNIC ACID: MECHANISM OF ACTION CONTRIBUTES TO ITS IDIOSYNCRATIC HEPATOTOXICITY.

Q. Shi[1], L. Guo[1], E. Blann[1], J. Leakey[1], D. M. Svancara[2], E. J. Natoli[2], S. Nadanaciva[2], P. Billis[2], M. J. Banker[2], J. A. Dykens[2] and Y. Will[2]. *[1]NCTR, Jefferson, AR and [2]Pfizer, Inc., Groton, CT.*

The lichen metabolite usnic acid has been promoted as a dietary supplement for weight loss, although serious cases of hepatotoxicity have been associated with its use. Evidence is rapidly accumulating that mitochondrial impairment contributes to the etiology of drug-induced hepatotoxicity. Accordingly, we examined effects of usnic acid (UA) on mitochondrial function using isolated organelles, transformed HepG2 cells, and primary rat and human hepatocytes. In freshly isolated rat hepatocytes, usnic acid rapidly depleted ATP and was cytotoxic in a dose and time dependent manner. In isolated rat liver mitochondria, usnic acid profoundly uncoupled respiration and exacerbated Ca2+-induced permeability transition. At higher concentrations it inhibited immunocaptured mitochondrial Complex-V (ATPase). In intact HepG2 cells, UA increased oxygen consumption at low concentrations, and repressed it at higher exposures. Concurrent acceleration of media acidification reflects increased glycolytic flux to compensate for loss of mitochondrial function. Finally, in primary human hepatocytes, UA decreased mitochondrial membrane potential, depleted reduced glutathione, resulting in cell injury. The observed mitochondrial uncoupling would consume calories and dissipate the energy as heat, which would facilitate weight loss. However, such mitochondrial impairment yields cytotoxic oxidative and bioenergetic stress that induce irreversible mitochondrial failure, and hence the hepatotoxicity associated with usnic acid.

PS 413 EFFECT OF ROTENONE AND CYCLOSPORINE A ON HUMAN AND RAT LIVER SLICES.

R. T. Dunn[1], C. Afshari[2], R. Hernandez[2], Y. Chen[2], M. Higgins[2], J. Lawrence[2], C. Qualls[2] and H. Hamadeh[2]. *[1]Toxicology, Amgen Inc, Thousand Oaks, CA and [2]Investigative Toxicology, Amgen Inc, Thousand Oaks, CA.*

Liver slices have emerged as a model of toxicity that bridge between simpler in vitro cell culture models and fully integrated in vivo models of toxicity. The present study was undertaken to examine the toxicity of rotenone (ROTE), a mitochondrial poison, and cyclosporine A (CSA), an inhibitor of the bile salt export pump (BSEP). Liver slices from both rat and human donors were cultured for 6, 24 and 48 hours in the presence of either DMSO (0.1%), rotenone or CSA at 0.1, 0.3, 1.0, 3.0, 10, 30, and 50 (CSA) or 100 μM (ROTE). Biochemical endpoints including ATP, LDH, K+ were measured at each time point. In addition, mRNA was extracted from slices of each group and transcript profiles obtained using either rat or human microarrays (Affymetrix). Finally selected slices were analyzed histologically to determine the extent of toxicity and to correlate findings with the biochemical and genomic data. Rotenone exhibited toxicity in liver slices as early as 6h with ATP being the most sensitive endpoint. ATP was diminished by >50% at 6h by 10 μM ROTE. Liver slices were resistant to CSA up to 50 μM with little biochemical evidence of toxicity. For both compounds, the gene expression results could be categorized into early transient changes, early persistent changes, and late changes. In addition, molecular evidence could be delineated consistent with the proposed toxicologic activity of each compound. The comparison of rat and human data proposes congruence as well as differences in how liver slices from different species respond to these compounds.

PS 414 OPTIMIZING CULTURE CONDITION FOR IMPROVED PREDICTION OF HEPATOTOXICITY OF HIGH PROTEIN BINDING COMPOUNDS.

N. Matsumoto, E. Todo, Y. Takenobu and S. Kim. *Ono Pharmaceutical Co., Ltd., Mishima-gun, Osaka, Japan.*

In vitro toxicity tests are generally performed under conditions with relatively low protein concentrations. Theoretically, non-protein bound fraction of drugs are pharmacologically and toxicologically active in vivo. Therefore, the concentrations having effects in such test systems can not be directly compared with in vivo plasma concentrations of high protein binding drugs. We investigated the value of in vitro predictive hepatotoxicity tests performed in the presence of human serum albumin and human alpha-1 acidic glycoprotein. Cytotoxicity test against human hepatocytes, mitochondrial membrane potential in hepatocellular carcinoma HepG2 cells, and steatosis assay (fat accumulation) in immortalized human hepatocyte FaN-4 cells were performed using reference hepatotoxic and non-hepatotoxic drugs. Therapeutic index, the ratio of the toxic concentration to the peak plasma concentration at effective dose, was employed to assess the value of these tests. As a result, hepatotoxic drugs tended to have narrow therapeutic indexes as compared with non-hepatotoxic drugs in all three tests. Toxic effects of drugs with high protein binding (>90%) were generally impaired by adding plasma proteins to the cell culture systems. However, the degree of impairment of toxic effects was not correlated well with plasma protein binding ratio of these drugs. That is, some drugs showed marked decrease in toxic effect but the others showed only marginal decrease nevertheless comparable high protein binding levels. Consequently, it is more valuable to actually perform the in vitro toxicity tests with physiological protein concentrations than to speculate from the plasma protein binding ratio of the drug and the results of in vitro toxicity tests performed with low protein concentrations.

PS 415 XENOBIOTIC METABOLIZING ENZYME (XME) EXPRESSION IN AGING HUMANS.

J. S. Lee, W. O. Ward, H. Ren, B. Vallanat, M. DeVito and J. C. Corton. *NHEERL, U.S. EPA, Durham, NC.*

In the presence of foreign compounds, metabolic homeostasis of the organism is maintained by the liver's ability to detoxify and eliminate these xenobiotics. This is accomplished, in part, by the expression of XMEs, which metabolize xenobiotics and determine whether exposure will result in toxicity. Our previous microarray studies demonstrate that age alters the expression of XMEs in rats and mice. To determine if aged humans also exhibit changes in XME expression, we examined gene expression profiles using Affymetrix Human U133 Plus 2.0 arrays in liver samples from young (21-45 years) and old (69+ years) men and women. Five to seven livers per age group were profiled. Differentially expressed genes (DEG) were determined using a one-way ANOVA ($p<0.05$) followed by a Benjamini-Hochberg FDR multiple testing correction (<0.05) using Rosetta Resolver®. Principal component analysis showed a clear age-dependent separation in expression profiles between young and old hepatic transcripts in males and females. We identified 370 genes that were altered between young and old men and 1163 genes that were altered between young and old women. Top canonical pathways were identified using Ingenuity® Pathway Analysis. Protein ubiquitination pathway is affected in both older men and women. We found that age caused minimal numbers of changes in the gene expression of XMEs (8 in males and 33 in females between young and old, respectively). Most of these changes were in the expression of Phase III genes (transporters). The expression of solute carriers increased with age in men, and the majority decreased with age in women. In addition, we identified 93 or 49 gene expression differences between men and women in the young or old groups, respectively, some of which were XMEs. These studies indicate that the livers from aging humans exhibit a number of changes in XMEs that may lead to differences in the metabolism of xenobiotics. (This abstract does not necessarily reflect US EPA policy).

PS 416 THE FETAL/NEONATAL MOUSE LIVER EXHIBITS TRANSCRIPTIONAL FEATURES OF THE ADULT PANCREAS.

J. S. Lee, W. O. Ward, H. Ren, B. Vallanat, R. Grindstaff, M. George, D. Delker and J. C. Corton. *NHEERL, U.S. EPA, Durham, NC.*

Metabolic homeostasis of the organism is maintained by the liver's ability to detoxify and eliminate xenobiotics through the expression of xenobiotic metabolism enxymes (XME). The fetus and neonate have been hypothesized to exhibit in-

creased sensitivity to xenobiotic toxicity. This project was designed to examine differentially expressed genes (DEG) in early life stages in the livers from male C57BL/6 and C3H/HeJ mice. Gene expression profiles were generated using Affymetrix Mouse 430 2.0 arrays for early life stages (gestation day (GD) 19, postnatal day (PD) 7, PD32) and compared to young adults (PD67). Principal component analysis (PCA) showed a clear age-dependent separation in expression profiles between GD19, PD7 and PD67 hepatic transcripts. Differentially expressed genes (DEG) were determined using a one-way ANOVA ($p<0.05$) by Rosetta Resolver®, a Benjamini-Hochberg FDR multiple testing correction (<0.05), and a fold-change cutoff of 1.5. Gene expression changes were the most abundant at the early time points in male C57BL/6 (10,068 and 5,989 DEG for GD19 and PD7 respectively). We found 139, 93, and 12 XMEs significantly altered in the GD19, PD7, and PD32 when compared to PD67, respectively. qRT-PCR confirmed altered expression for selected genes. Because the fetal liver is a site of hematopoiesis, we hypothesized that some of the differences in gene expression between GD19 and PD67 were due to the presence of hematopoietic progenitor cells. We compared the liver profiles with a mouse tissue microarray dataset which included adult tissues involved in hematopoiesis. Suprisingly, PCA and hierarchical clustering showed embryonic liver clustering with embryonic and adult pancreas and separate from adult liver and hematopoietic tissues. These results indicate that there are extensive gene expression differences between early (fetal, neonatal) and adult liver and that the fetal/neonatal liver exhibits transcriptional similarities with the pancreas. (This abstract does not necessarily reflect US EPA policy).

PS 417 GSH MODULATION, A STRESSED LIVER MODEL TO EVALUATE DRUG-INDUCED HUMAN LIVER INJURY.

A. E. Vickers[1], R. L. Fisher[2], J. R. Sinclair[1] and S. Morris[1]. [1]*Drug Safety Evaluation, Allergan Inc, Irvine, CA and* [2]*Vitron Inc., Tucson, AZ.*

GSH levels are modulated in human liver slices to provide insight into whether drug induced hepatotoxicity is enhanced by a poor liver GSH status. Liver slice GSH levels were modulated in several ways: 1) depletion of GSH with BSO (L-buthionine-S-sulfoximine) which inhibits the synthesis of GSH, 2) reduction of GSH by DEM (diethyl maleate) which is a thiol conjugating agent, 3) reduction of GSH by APAP (acetaminophen) at a concentration associated with hepatotoxicity in humans, 4) and enhancing GSH levels by supplementation of the cultures with GSH to determine if there is a protective effect in the presence of abundant GSH. Methimazole (MMI) is associated with hepatotoxicity and is used as a reference compound in this model. After 72 hr, MMI treatment in the absence of GSH modulation caused significant increases in liver slice GSH levels with 50-250 μM MMI, which was preceded by an up-regulation of GSH synthesis genes, glutamate cysteine ligase (GCLc) and glutathione-S-transferase (mGST1a). Significant decreases in liver slice GSH levels and ATP levels occurred with MMI concentrations ≥ 500 μM. Depletion of GSH levels by BSO, DEM or APAP were not further reduced by 500 μM MMI. An increase in liver slice AST and ALT leakage was enhanced by co-administration of MMI with acetaminophen or BSO; while intracellular K+ levels remained stable. In the presence of GSH supplementation, MMI treatment yielded ALT leakage values equivalent to control slices, suggestive of a protective effect by excess GSH. MMI likely induces oxidative stress at high concentrations, which is likely exaggerated when liver GSH levels are decreased by the co-administration of some drugs or health status.

PS 418 COMPARISON OF THE EFFECT OF GSH DEPLETION IN MULTIPLE SPECIES AND THE EFFECT ON REACTIVE METABOLITE CYTOTOXICITY.

D. D. Baker[1], O. Laskin[2], L. Latriano[2], R. Amin[2] and P. Lapinskas[1]. [1]*Experimental Toxicology, Celgene, Inc., San Diego, CA and* [2]*Early Drug Development, Celgene, Summit, NJ.*

Previously in our laboratories, a reactive metabolite cytotoxicity assay (RMCA) was developed using fresh rat hepatocytes (RH) based on the working hypothesis that if cytotoxic reactive metabolites (CRM) are formed from a parent toxicant, depletion of reduced glutathione (GSH) would lead to increased cytotoxicity. CRM play a key role in drug-induced hepatotoxicity, especially for idiosyncratic hepatotoxicity. In order to expand current knowledge of species differences and the impact on drug development; the RMCA was employed in hepatocytes (heps) from multiple species: mouse (MH), dog (DH), monkey (MKH), and Human (HH). Heps were treated with buthionine sulfoximine (BSO, an inhibitor of γ-glutamylcysteine synthetase), which reduces/inhibits GSH synthesis. Basal GSH levels among species varied dramatically with RH having the lowest levels and MH having the highest levels and DH and HH intermediary. Dose-dependent decreases in cellular GSH in response to BSO were observed across all species of heps. BSO treatments were optimized to deplete GSH to less than or equal to 20% of controls where no apparent cytotoxicity (based on cellular ATP content as determined using a luminescence assay) was observed. The exception was MH which could not be optimized due to cytotoxicity closely following BSO depletion. Heps were treated with prototypical hepatotoxicants (HTX including cyclophosphamide, acetaminophen and a competitor kinase inhibitor) that are known to form CRM upon hepatic metabolism. These HTX were consistently more cytotoxic in the BSO-treated than the untreated cells with RH being the most sensitive to this effect; most likely due to their low basal GSH levels. In contrast, heps with high basal levels of GSH were not as sensitive to this effect. However, there was still a clear response to the HTX in all species except MH. The RMCA is proposed to be deployed as a screening assay in discovery with RH and a development assay with DH, HH, MKH in later stage drug development.

PS 419 DEVELOPMENT OF IN VITRO TOXICOGENETIC MODELS FOR HEPATOTOXICITY.

S. Martinez[1], B. Bradford[1], R. Kaiser[2], V. Soldatow[2], K. Amaral[2], S. Ferguson[2], C. Black[2], E. LeCluyse[2] and I. Rusyn[1]. [1]*Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC and* [2]*CellzDirect/Invitrogen Corporation, Durham, NC.*

Numerous studies support the fact that a genetically diverse mouse population may be useful as an animal model to understand and predict toxicity in humans. We hypothesized that cultures of hepatocytes obtained from a large panel of inbred mouse strains can produce data indicative of inter-individual differences in *in vivo* responses to hepato-toxicants. In order to test this hypothesis and establish whether high-throughput *in vitro* studies using cultured hepatocytes from genetically distinct mouse strains are feasible, we aimed to standardize cell isolation and culture conditions and determine whether near-physiological maintenance of the cells isolated from different mouse inbred strains can be achieved. Hepatocytes were isolated from 15 strains of mice (A/J, B6C3F1, BALB/cJ, C3H/HeJ, C57BL/6J, CAST/EiJ, DBA/2J, FVB/NJ, BALB/cByJ, AKR/J, MRL/MpJ, NOD/LtJ, NZW/LacJ, PWD/PhJ and WSB/EiJ) and cultured for up to 7 days in traditional 2D culture. The cells have been assessed for viability and functionality on a daily basis by measuring production of lactate, pyruvate, and urea, as well as leakage of lactate dehydrogenase as a measure of membrane integrity. We also employed calcein and ethidium fluorescence staining to assess cell viability at 1, 3, 5 and 7 days of culture. Our data shows that high yield (48 to 87 million hepatocytes/mouse) and viability (86 to 98%) can be achieved across a panel of strains. Furthermore, we conclude that cell function of hepatocytes isolated from different strains and cultured under standardized conditions is comparable and cells remain viable and metabolically active as indexed by lactate, pyruvate and urea production. These experiments open new opportunities for high-throughput and low-cost *in vitro* assays that may be used for studies of toxicity in a genetically diverse population. (Supported, in part, by grants from NIEHS R01-ES015241 and US EPA RD-833825)

PS 420 PRECISION-ORGAN SLICE TECHNOLOGY TO EVALUATE LIVER TOXICITY OF PERFLUORINATED COMPOUNDS (PFCS).

W. T. Haines[1], S. J. Borghoff[1], D. E. Malarkey[2], T. J. Painter[1], G. S. Travlos[2], K. Thayer[2] and R. L. Melnick[2]. [1]*Integrated Laboratory Systems, RTP, NC and* [2]*NIEHS, RTP, NC.*

PFCs are a class of widespread environmental contaminants that are resistant to hydrolysis and persist in the environment. Once absorbed they are poorly eliminated from the body and have been shown to be hepatotoxic and cause developmental, reproductive, immunological and endocrine effects in rodents and non-human primates. To evaluate chain length and functional group dependent effects of PFCs directly without the influence from absorption or elimination, an in vitro liver slice model system was proposed. The objective of this study was to assess the use of liver slices to evaluate and compare the toxicity from exposure to a single PFC (initially assessed using perfluorooctanoate, PFOA) vs. mixtures of PFCs. Precision-cut rat liver slices were prepared with a Brendel/Vitron tissue slicer and incubated in media for up to 48 hours in a high oxygen environment. Liver slices were exposed to 0.1% DMSO (vehicle) or PFOA (400 μM; serum concentration in rats associated with toxicity) for 6, 12, 24 and 48 hours. Viability of liver slices was assessed by measuring ATP and marker enzyme activities to assess cytotoxicity (AST, ALT, LDH, SDH) and evaluated H&E stained slices histopathologically. In general, ATP levels were lower in slices exposed to PFOA compared to vehicle exposed slices at ≥ 12 hours of exposure. After 12 hours, all marker enzyme activity measured in PFOA exposed liver slices were at or below 50% of values measured in vehicle exposed slices and approached 0% by 48 hours. These results correlated with changes observed histopathologically in which ~30% of the cells in slices exposed to PFOA for 12 hours appeared viable. Slices exposed to the vehicle were found to be ~ 30% viable at 48 hours, while no viable cells were observed at either 24 or 48 hours in

slices exposed to PFOA. This study demonstrated that the liver slice model system will be useful to evaluate chain length and functional group on dose-dependent effects of PFCs. Supported by NIEHS Contract No. N01-ES-35513.

PS 421 CROSS-FUNCTIONAL DRUG CLASS COMPARISON OF THE TRANSCRIPTOMES OF IDIOSYNCRATIC HEPATOTOXICANTS IN PRIMARY HUMAN HEPATOCYTES: ASSOCIATION WITH KNOWN DEATH MEDIATORS.

M. J. Liguori, A. C. Ditewig, Y. Yang, J. F. Waring and E. A. Blomme. *Investigative Toxicology, Abbott Laboratories, Abbott Park, IL.*

Idiosyncratic drug reactions (IDRs) continue to confound development of new drug candidates, and these unanticipated toxicities pose a substantial risk to the public health and to the pharmaceutical industry in general. These adverse reactions are not predictable using standard pre-clinical strategies and therefore are unrecognized until the very late stages of clinical evaluation. This type of toxicity is not limited to any one class of drugs, but been manifested in a wide spectrum of pharmacologic classes including quinolone antibiotics, thiazolidinediones (TZDs), and in neurological therapies. Uncovering common hepatotoxic mechanisms that link distinct classes of compounds would add great value to the fundamental understanding of late-stage adverse reactions. To compare potential similarities in mechanisms of hepatotoxicity, primary human hepatocytes were exposed to 3 well-known drugs associated with hepatic IDRs, including trovafloxacin (quinolone class), troglitazone (TZD class), and nefazodone (anti-depressant) for 24h. Levofloxacin and rosiglitazone, devoid of hepatic IDRs, were also evaluated as negative controls. Subsequently, these cell systems were analyzed for transcriptomic changes using Affymetrix human genome microarrays. Each of the three test items invoked a dose-dependent increase in the total number of gene expression changes. With potential toxicological implications, the IDR-invoking compounds modulated over 300 transcripts in common and apart from the negative comparators. Further interrogation of the roles of these gene products revealed an association with known death mediators, such as TGF-β, GADD45β, PARP, Mitofusin-1, and IRF-1. In addition, critical genes controlling cell cycle were consistently dysregulated by the IDR associated agents, including CCNL1, BCL3, MDM2, and IGF2. Thus, evaluation of overlapping transcriptomic changes, in the context of cross pharmaceutical class IDRs, may provide insights into common mechanisms of toxicity.

PS 422 MULTIPARAMETRIC HEPATOTOXICITY SCREENING IN HEPG2 CELLS WITH COMPARISON IN PRIMARY HEPATOCYTES.

K. F. Marcoe, Y. Ovechkina, R. Keyser, P. T. Nguyen and C. O'Day. *Cell Biology, MDS Pharmacology Services, Bothell, WA.* Sponsor: J. Briffaux.

Drug-induced hepatotoxicity remains a major cause for failures during drug development. Hepatic apoptosis induction, phospholipidosis and neutral lipid accumulation detection late in the drug development pipeline has contributed to these setbacks. Earlier identification of potential liabilities can result in recommendations to minimize these risks during lead optimization as well as understand their relevance in provoking clinical hepatotoxicity. Development of in vitro multiplexed high content screening platforms have enabled more comprehensive predictive early toxicity assessments previously only attainable in more complex in vivo models. In this study we used multiplexed high content screening with automated fluorescence microscopy and image analysis in a 384-well microtiter plate format to identify and quantify apoptosis induction, phospholipidosis and neutral lipid accumulation potential of sixteen compounds in HepG2 cells and compared findings obtained using this approach with primary hepatocytes. Selected compounds included acetaminophen, amitriplyline, astemizole, cervastatin, chlorpromazine, isoproterenol, troglitazone, rosiglitazone, valproic acid, propranolol, aminodarone, cyclosporine A, methotrexate, staurosporine, tomoxifen and terfenadine. High concordance was found with the reported toxicity profiles for the tested compounds. Comparative responses in primary hepatocytes were attained using a novel data analysis approach. Our high-throughput in vitro multiplexed hepatotoxicity screen offers comprehensive predictive information allowing pre-selection of drug scaffold designs with long-term toxicity considerations and can provide evaluations in normal primary hepatocytes.

PS 423 ASSAY VALIDATION OF HEPATOTOXICITY IN qHTS USING HUMAN PLATEABLE CRYOPRESERVED HEPATOCYTES.

T. Moeller[1], S. J. Shukla[2] and M. Xia[2]. *[1]Celsis IN VITRO Technologies, Halethorpe, MD and [2]NIH Chemical Genomics Center, Bethesda, MD.*

The liver is the key organ for the biotransformation of endogenous and exogenous compounds to aid in their clearance from the body. In many cases, the metabolism of these compounds is critical to protect the body from toxic levels, but in some cases, the metabolites of parental compounds may incur hepatotoxicity. Taking the metabolism of compounds into account is essential not only to drug development, drug safety and environmental health issues, but also to evaluate the risks associated with injury to the liver. The ability to screen compounds to assess hepatoxicity is crucial, but has been traditionally limited to in vivo testing for accurate evaluation, which is not desirable for ethical and efficiency reasons. In vitro testing, which reduces animal use, has become a viable option with the advent of specific markers and sensitive reagents. The development of quantitative high throughput screening (qHTS) allows one to test an enormous number of potential toxins in relevant cellular systems, like primary human hepatocytes. For proof of concept, we have developed methods to utilize plateable cryopreserved human hepatocytes (PCHH) in a 1536-well format in order to screen known toxic compounds. PCHH were plated at two different cell concentrations in collagen-coated 1536-well plates. Test compounds, dosed over a four-log range, were added four hours after plating and incubated for an additional 40 hours. Intracellular ATP content was measured to determine IC50 for 12 compounds, including doxorubicin, tamoxifen, staurosporine, and phenylmercuric acetate. The signal-to-background ratio assay window is above 100-fold, which indicates that the 1536-well plate format is robust and can be utilized for assessing hepatotoxicity using primary human hepatocytes in a qHTS platform. The wide range of toxins identified from the qHTS approach illustrates the utility of this platform. Additionally, qHTS can be employed to further explore the susceptibility of hepatocytes to various mechanisms of toxicity using appropriate cellular death markers.

PS 424 MULTIPLEX CYTOTOXICITY ASSAY FOR PRIMARY HEPATOCYTES.

Y. Wu, U. Hanumegowda and S. Adams. *Discovery Toxicology, Bristol Myers Squibb, Wallingford, CT.*

A multiplex cytotoxicity assay for primary human (freshly isolated and cryopreserved) and rat hepatocytes (freshly isolated) in 96-well format was developed to help identify modes of toxicity. Broadly, cytotoxicity can be classified as apoptosis or necrosis. Cell necrosis is generally viewed as cell swelling and leakage of cellular components due to loss of membrane integrity, while apoptosis is viewed as cell shrinkage with activation of catalytic enzymes (ex., caspases). Understanding the mode of toxicity could be valuable in guiding structure-activity relationships during drug discovery. The multiplex cytotoxicity assay detects apoptosis and necrosis in a single assay, using lactate dehydrogenase (LDH) leakage, caspase 3/7 activation, and mitochondrial function (resazurin dye reduction) as endpoints. The performance of individual assays (ex., ranges of assay linearity and cell seeding densities) was examined and optimized under multiplexed conditions using compounds with known modes of toxicity. Staurosporine, an apoptosis inducer, activated caspase 3/7 without causing LDH leakage and perhexiline, a necrotic toxicant, caused LDH leakage without caspase activation. Ibuprofen, potassium dichromate and quinine caused changes in both caspase activity and LDH leakage, and all compounds decreased cell viability as measured by mitochondrial function (dye reduction). The concentration-response curves, however, were different for each endpoint for every compound, suggesting a limitation of a single-endpoint assay to detect cytotoxicity adequately. Within LDH endpoint there was difference between fresh and cryopreserved hepatocytes further highlighting the limitations of single-endpoint assay. With three cytotoxicity endpoints from a single treatment, the multiplex assay offers the unique advantages of 1) better detection of cytotoxicity that could be missed using a single endpoint, 2) insight into the mode of toxicity such as apoptosis or necrosis, 3) cost and time-effective operation, and 4) better data quality by using same treatment conditions.

PS 425 PROTECTION BY THE PROLYL HYDROXYLASE INHIBITOR, EDHB, AGAINST CELL KILLING AFTER CHEMICAL HYPOXIA IN CULTURED RAT HEPATOCYTES.

G. Lovelace[1], J. R. Patnaik[1], J. R. Nixon[1], H. Jaeschke[2], Z. Zhong[1], G. L. Wright[1] and J. J. Lemasters[1]. *[1]Center for Cell Death, Injury & Regeneration; Department of Pharmaceutical & Biomedical Sciences, Medical University of South Carolina, Charleston, SC and [2]Department of Pharmacology, Toxicology & Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

BACKGROUND: KCN and iodoacetic acid (IAA) simulate the ATP depletion and reductive stress of anoxia by inhibiting respiration and glycolysis, respectively. Our AIM was to study the effects of ethyl 3,4-dihydroxybenzoate (EDHB), a prolyl hyroxylase inhibitor and HIF-1α stabilizing agent, on killing of cultured rat hepatocytes during such chemical hypoxia. METHODS: Rat hepatocytes cultured overnight in 24-well plates were exposed to 2.5 mM KCN plus 200 μM IAA in the presence of 0-1000 μM EDHB, and cell viability was monitored by propidium iodide fluorometry. RESULTS: In the absence of KCN+IAA, EDHB up to 200 μM

had no effect on viability, but higher concentrations caused toxicity. In the presence of KCN+IAA, EDHB decreased cell killing from ~80% to ~25% after 2 h. Cycloheximide (50 μg/mL), an inhibitor of protein synthesis, actinomycin D (5 μg/ml), an inhibitor of mRNA synthesis, and CCCP (5 μM), a protonophoric uncoupler, did not abrogate cytoprotection. However, EDHB failed to decrease killing of mouse hepatocytes exposed to 10 mM acetaminophen. CONCLUSION: EDHB strongly protects against lethal cellular injury after chemical hypoxia, but such protection is not mediated by new gene expression. The results suggest that proline hydroxylation may promote cell killing after ATP depletion by mechanisms that are independent of HIF-1α-dependent transcription.

PS 426 8-BR-CAMP INDUCES MULTIDRUG RESISTANCE-ASSOCIATED PROTEIN EXPRESSION IN HUH7 CELLS AND PRIMARY HUMAN HEPATOCYTES.

S. Kulkarni and A. L. Slitt. *Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.*

3'-5'-cyclic adenosine monophosphate (cAMP) is an important second messenger that activates protein kinase A (PKA) which controls the transcription of multiple genes in liver that maintain glucose homeostasis, metabolism, and transport. The cAMP/ PKA pathway has been shown to contribute to the regulation and maintenance of metabolic homeostasis during stress and nutritional changes. Two studies have illustrated that the expression of the uptake transporter Oatp2 is upregulated by glucose deprivation and stimulation of the cAMP/PKA pathway. The purpose of this study was to determine whether treatment with a known activator of the cAMP/PKA pathway, 8-Bromoadenosine-3', 5'-Cyclic Adenosine Monophosphate [8-Br-cAMP], upregulates human MRP mRNA expression in a human hepatocarcinoma cell line (Huh7) and primary human hepatocytes. Huh7 cells and primary hepatocytes were treated with 0.1-2.0mM 8-Br-cAMP for 24 hours. Total RNA or cell lysate was isolated and MRP expression was analyzed by the Branched DNA Signal Amplification Assay. In Huh7 cells 8-Br-cAMP treatment induced MRP2, 3 and 4 expression by 5, 3 and 10 fold respectively in a dose-dependent manner. 8-Br-cAMP treatment also induced MRP expression in primary human hepatocytes. Because MRPs are coordinately induced with genes regulated through NRF2 and the antioxidant response element (ARE), we examined expression of GCLC and NQO1, two prototypical genes regulated primarily by Nrf2 after 8-Br-cAMP treatment. 8-Br-cAMP induced GCLC and NQO1 mRNA expression by 8 and 5 fold in Huh7 cells and 2 and 4 fold in human hepatocytes respectively. Moreover, 8-Br-cAMP treatment resulted in a dose-dependant activation of the antioxidant response element in Huh7 cells transiently transfected with an ARE-luciferase reporter construct. The above findings strongly suggest that cAMP/PKA is an upstream signaling pathway involved in activation of NRF2 and upregulation of MRP2-4 efflux transporters. (Supported by NIH grants P20RR016457, KES013782A, RES016042A)

PS 427 PROFILING OF MULTIPLE TRANSCRIPTION FACTORS ACTIVITY IN MOUSE LIVER.

S. Romanov[2], D. M. Gatti[1], M. Tsuchiya[1], M. Zeng[2], A. Medvedev[2] and I. Rusyn[1]. *[1]Environmental Sciences & Engineering, University of North Carolina, Chapel Hill, NC and [2]Attagene, Inc., Research Triangle Park, NC.*

Assessing the impact of xenobiotics on gene regulatory pathways that control liver function is of major importance for the science of toxicology. Many metabolic and signal transduction pathways affected by the chemicals operate through a repertoire of transcription factors (TF) that orchestrate changes in gene expression. However, none of the currently available methods is suited for evaluation of more than one TF at a time in vivo. Here, we describe a novel approach enabling functional profiling of multiple toxicologically relevant TFs in liver of experimental animals. To permit the approach, we used "hydrodynamic" tail-vein injection to deliver a library of 45 reporter plasmids carrying response elements for a panel of transcription factors into the liver of mice (C57BL/6J, male, 6-8 weeks of age). We show that reporter transcripts produced by the library can be simultaneously and reproducibly detected, and quantified in liver samples extracted from the animals several weeks following the transfection, thus enabling the in vivo profiling of activity of multiple TFs. Our data further demonstrates the utility of this approach for organ-specific evaluation of xenobiotics across multiple signal transduction endpoints in vivo. These experiments open new opportunities for mechanistic studies of toxicant-perturbed transcription regulatory networks in vivo and will provide invaluable data for interpretation of the relationships between gene expression changes and toxicity. (Supported, in part, by grants from NIEHS R01-ES015241 and US EPA RD-833825)

PS 428 REACTIVE OXYGEN SPECIES-RELATED MECHANISMS PARTICIPATE IN THE SENSITIVITY OF M-CSF-PRIMED RAT KUPFFER CELLS TO LPS CHALLENGE.

Z. Wang, J. E. Klaunig and L. M. Kamendulis. *Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Kupffer cells (KCs), tissue macrophages in the liver, represent about 20% of the hepatic nonparenchymal cells. Reactive oxygen species (ROS) modulate the activity of many signal transduction pathways. Little is known about the mechanisms by which macrophage colony-stimulating factor (M-CSF) priming modulates the sensitivity of KCs to lipopolysaccharide (LPS). Here, we hypothesized that NADPH oxidase-dependent ROS contributes to LPS-induced activation of MAPK family members and NF-kB in M-CSF primed rat primary KCs in vitro. A novel system was established to isolate and culture high pure KCs from rats involving enzymatic liver perfusion, elutriation centrifugation, and cell sorting with ED2 (KC marker). M-CSF (10ng/ml) in culture medium promoted relative increased number of KCs which survived for over 4 weeks in vitro. M-CSF priming also enhanced a mature phenotype and morphology, and the ability to phagocytize FITC-latex beads. Although not detectable in KCs without LPS treatment, TNFa and IL-6 markedly increased after exposure to LPS, with peak levels (>100-fold) seen at day 7 by ELISA. In addition, M-CSF priming significantly enhanced LPS-induced ROS production (2-fold), and CD14 expression (2.5-fold). Further, M-CSF priming markedly enhanced LPS-stimulated activation of MAPK extracellular receptor activated kinase 1/2 (ERK1/2), p38 and c-jun–N-terminal kinase (JNK), as well as activation of NF-kB with decreased cytoplasmic I-kBa expression, a critical step in NF-kB activation. Pretreatment with diphenyleneiodonium, an inhibitor of NADPH oxidase, reduced LPS-induced increases in ERK1/2, JNK and NF-kB, and decreased I-kB. Taken together, sensitization of M-CSF primed KCs appears to be mediated through enhanced signaling through TLR4/CD14, which increases NADPH oxidase-derived ROS and subsequent MAPK and NF-kB in KC. Therefore, blocking ROS-dependent signaling may be a promising strategy to prevent untoward liver effects elicited by LPS-mediated KC sensitization. (Supported in part by NIH CA100908)

PS 429 MALE-PREDOMINANT EXPRESSION OF HEPATIC TRANSPORTER OATP1A1 EXPLAINS THE GENDER DIFFERENCE IN PLASMA LEVELS OF UNCONJUGATED BILE ACIDS IN MICE.

Y. Zhang and C. D. Klaassen. *Pharmacology, Toxicology & Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

After developing a LC-MS/MS method for quantification of bile acids in plasma, liver, and bile, we noted that the plasma concentrations of unconjugated bile acids (alpha-muricholic acid, beta-muricholic acid, cholic acid, and deoxycholic acid) were lower in male than in female mice. To identify the underlying mechanism for this gender difference in circulating unconjugated bile acids, mRNA levels of hepatic genes involved in bile acid biosynthesis, conjugation, and transport were quantified in adult male and female mice. No gender difference was observed in the mRNA expression of the rate-limiting bile acid synthetic enzyme Cyp7a1, bile acid conjugation enzymes (Fatp5 and mBaat), or the canalicular bile salt export pump (Bsep). However, male mice exhibited slightly lower expression of sodium taurocholate co-transporting polypeptide (Ntcp), but much higher expression of organic anion transporting polypeptide 1a1 (Oatp1a1). To determine whether male-predominantly expressed Oatp1a1 accounts for the lower plasma levels of unconjugated bile acids in male mice, plasma concentrations of unconjugated bile acids were quantified in wild-type and Oatp1a1-null mice. Oatp1a1-null mice had higher circulating levels of unconjugated bile acids than wild-type mice, and no gender difference in plasma unconjugated bile acids was observed. To further determine the role of Oatp1a1 in transporting unconjugated bile acids, wild-type and Oatp1a1-null male mice were subjected to a diet supplemented with 0.3% deoxycholic acid (DCA). After treatment, plasma DCA concentration in Oatp1a1-null male mice was about 40-fold higher than in wild-type male mice. In conclusion, this study demonstrates that male mice have lower plasma concentrations of unconjugated bile acids than female mice, and this is due to higher expression of Oatp1a1, which transports unconjugated bile acids from plasma into liver. (Supported by NIH ES09716, ES07079, ES013714, ES09649, and RR021940.)

PS 430 ALCOHOL CIRRHOSIS UPREGULATES MULTIDRUG RESISTANCE-ASSOCIATED PROTEIN TRANSPORTER EXPRESSION IN HUMAN LIVER.

V. R. More, Q. Cheng and A. L. Slitt. *Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.*

Transporters are an integral component for liver detoxication of drugs and environmental chemicals. Previous studies in rodents have demonstrated that drug- and disease-induced liver injury alters transporter expression. However, limited data

exist regarding regulation of transporter expression with various types of liver injury in humans. Alcohol-induced liver disease represents a major type of liver injury that is present in the American population with approximately 13,000 deaths per year because of alcohol-induced liver cirrhosis. Because there is a sizable population that presents with liver cirrhosis, it is important to know whether cirrhosis alters transporter expression for two main reasons. First, it is important to understand pharmacokinetics due to alterations in transporter expression. Second, it is important to understand how the liver adapts to different types of injury and the molecular mechanism by which adaptation occurs. Therefore, we examined the expression of major drug transporters in livers from normal non-cirrhotic and cirrhotic humans. Total RNA was isolated and mRNA expression was quantified using the Branched DNA Signal Amplification Assay. Cirrhosis significantly increased the mRNA expression of Multidrug Resistance-Associated Protein (MRP) 2 and 4, and tended to increase Organic Anion Transporting Polypeptide 1B1 (OATP1B1). Cirrhosis increased MRP2-5 protein expression in liver. Because MRP2-4 are coordinately increased with genes regulated by the NRF2-KEAP1 pathway, we hypothesized that NRF2 is activated during cirrhosis. Cirrhosis increased NRF2 levels in liver nuclear fractions and increased the mRNA and protein expression of NAD(P)H:Quinone Oxidoreductase 1 (NQO1), a gene well characterized to be upregulated through this pathway. In summary, in human liver, MRP2-5 are appreciably increased during cirrhosis, which is associated with activation of NRF2-KEAP1 pathway. (Supported by The Rhode Island Foundation, NIH grant #KES013782A, P20RR016457)

PS 431 AROMATIC HYDROXYLATION IS A MAJOR NOVEL PATHWAY IN THE METABOLISM OF THE MYCOTOXIN ZEARALENONE.

E. Pfeiffer[1], A. Hildebrand[1], G. Damm[1], A. Rapp[1], B. Cramer[2], H. Humpf[2] and M. Metzler[1]. [1]*Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany and* [2]*University of Muenster, Muenster, Germany.*

We have recently reported that zearalenone (ZEN) undergoes extensive oxidative metabolism with rat liver microsomes, resulting in the formation of eight monohydroxylated metabolites; however, the exact chemical structures of these novel oxidative ZEN metabolites were not disclosed (Pfeiffer et al., Mol Nutr Food Res 2007, 51, 867-871). It was the aim of the present study to reveal the oxidative metabolism of ZEN in human liver microsomes (HLM). We report here that HLM convert ZEN to four major metabolites through monohydroxylation at the aromatic ring, and two minor metabolites monohydroxylated at the aliphatic moiety. The aromatic hydroxylation of ZEN is supported by the following findings: (i) loss of one deuterium in each of the four major, but not of the minor, metabolites when ZEN specifically labeled with deuterium at both aromatic positions was incubated with HLM, (ii) the four major metabolites were substrates of the enzyme catechol-O-methyltransferase, and (iii) two of the four major metabolites were identical in LC-MS and GC-MS analysis with reference compounds synthesized from ZEN through nitration to two isomeric mononitro-ZENs, followed by reduction to the respective amines and subsequent oxidation to quinone imines, hydrolysis to quinones, and reduction to catechols. The structures of the synthetic compounds were established by 1H and 13C NMR spectroscopy. The other two aromatic hydroxylation products were identified as the respective zearalenols. Evidence for the aromatic hydroxylation of ZEN under in vivo-like conditions was obtained when ZEN was incubated with precision-cut rat liver slices: analysis by LC-MS revealed the presence of two glucuronides and one methyl ether of one of the aromatic hydroxy-ZENs. In conclusion, this study has clearly shown that ZEN is prone to aromatic hydroxylation. Further investigations are now warranted to demonstrate this novel pathway in ZEN metabolism in vivo and to assess its toxicological relevance. Supported by "Food and Health" of KIT.

PS 432 METABOLISM COMPARATIVE CYTOTOXICITY ASSAY (MCCA) AND CYTOTOXIC METABOLIC PATHWAY IDENTIFICATION ASSAY (CMPIA) WITH CRYOPRESERVED HUMAN HEPATOCYTES FOR THE EVALUATION OF METABOLISM-BASED CYTOTOXICITY *IN VITRO* : PROOF-OF-CONCEPT STUDY WITH AFLATOXIN B1.

A. P. LI. *IN VITRO ADMET Laboratories, Advanced Pharmaceutical Sciences, Columbia, MD.*

The Metabolism Comparative Cytotoxicity Assay (MCCA) and the Cytotoxic Metabolic Pathway Identification Assay (CMPIA) have been developed to allow a systematic investigation of the role of P450 metabolism in xenobiotic toxicity. The MCCA was designed for the initial identification of the role of metabolism in cytotoxicity by comparing the cytotoxic potential of a toxicant in metabolically competent (cryopreserved human hepatocytes) and metabolically incompetent (CHO) cells, in the presence and absence of an irreversible, nonspecific P450 inhibitor, 1-aminobenzotriazole (ABT). The CMPIA was designed to identify specific P450 isoforms involved in metabolic activation via cytotoxicity evaluation in the presence and absence of isoform-selective P450 inhibitors. Results of a proof-of-concept study with the MCCA and CMPIA with a known hepatotoxicant, aflatoxin B1 (AFB1), are reported. In the MCCA, AFB1 was found to have significantly higher cytotoxicity in human hepatocytes than CHO cells, therefore confirming its requirement for biotransformation to be toxic. ABT was found to effectively attenuate AFB1 cytotoxicity, confirming that P450 metabolism was involved in its metabolic activation. ABT had no effects of AFB1 cytotoxicity in CHO cells. In the CMPIA, AFB1 cytotoxicity was found to be attenuated by ketoconazole and diethyldithiocarbamate, but not by furafylline, quinidine, and sulfaphenazole. The results suggest that the isoforms inhibited by ketoconazole (mainly CYP3A4) and diethyldithiocarbamate (mainly CYP2A6, and CYP2E1), but not the isoforms inhibited by furafylline (mainly CYP1A2), sulfaphenazole (mainly CYP2C9) and quinidine (mainly CYP2D6) are involved in the metabolic activation of AFB1. This proof-of-concept study suggests that MCCA and CMPIA with cryopreserved human hepatocytes are potentially useful for the evaluation of the relationship between human xenobiotic metabolism and toxicity.

PS 433 MITOCHONDRIA AS A SITE OF METABOLISM OF DICHLOROACETATE.

W. Li[1], M. O. James[1], P. Reid[1] and P. W. Stacpoole[2, 3]. [1]*Medicinal Chemistry, University of Florida, Gainesville, FL,* [2]*Medicine, University of Florida, Gainesville, FL and* [3]*Biochemistry and Molecular Biology, University of Florida, Gainesville, FL.*

Dichloroacetate (DCA) is a common contaminant of municipal drinking water and is also a therapeutic agent for the treatment of several metabolic and vascular disorders. By inhibiting mitochondrial pyruvate dehydrogenase kinase, DCA stimulates the activity of the pyruvate dehydrogenase complex, and thus reduces the production of lactate and other pyruvate precursors. Pharmacokinetic studies in humans and rodents showed that DCA treatment results in a prolongation of its elimination half-life, probably through inhibition of glutathione transferase zeta 1 (GSTz1, also known as maleylacetoacetate isomerase), the only enzyme so far known to catalyze the conversion of DCA to glyoxylate. Like other GSTs, GSTz1 is present in the cytosol, and in vitro studies of DCA biotransformation to date have investigated the properties of the cytosolic enzyme. Since DCA is known to be taken up into and concentrated in mitochondria, its principal site of action, it is of interest to explore the role, if any, of mitochondria in the biotransformation of DCA. Initially, suspensions of washed mitochondria from human or rat liver were incubated with ^{14}C-DCA in the presence or absence of ATP, Coenzyme A, glutathione, or mixtures of these cofactors. Over a 30 min incubation period, significant biotransformation was observed only when glutathione was present. The products were identified as glyoxylate, glycine, CO_2 and oxalate. Hepatic mitochondria from rats treated with DCA for 8 weeks at 500 mg/kg did not convert ^{14}C-DCA to metabolites. Expression of GSTz protein was detected in human and rat liver mitochondria by Western Blotting against a rabbit antibody to human GSTz1. Studies of sub-mitochondrial fractions showed that GSTz was present in the soluble, but not the membrane compartments of mitochondria. We conclude that hepatic mitochondria are able to metabolize DCA as evidenced by the presence of GSTz and the in vitro activity results. Supported in part by the US Public Health Service, ES 07355 and ES 014617.

PS 434 *IN VITRO* METABOLIC STABILITY OF CHEMICALS IN RAINBOW TROUT (ONCORHYNCHUS MYKISS) COMPARED TO HUMAN CRYOHEPATOCYTES.

K. M. Johanning, J. E. Hill, R. L. Johnson, L. Dungan, K. Asrican and J. Hill. *CellzDirect/Invitrogen Corp, Austin, TX.* Sponsor: P. Guiney.

Assessment of bioaccumulation of chemicals that may be found in the environment is becoming increasingly important. REACH legislation is in effect in European countries with the aim of improving protection of human health and the environment. Other environmental and government organizations in the world, including the US, are joining this effort. Bioconcentration factor (BCF) assessment has been based on in vivo modeling. In vivo testing requires large numbers of test organisms and is time and cost intensive. Incorporation of in vitro metabolism data into a BCF assessment and an extrapolation method has been developed (Cowan-Ellsberry et al., 2007). Phase I and Phase II drug metabolizing enzymes mediate the biotransformation of xenobiotics in mammalian and some aquatic species (e.g. fish). Additional enzyme systems (e.g. carboxyl esterases) are also believed to play a role in the metabolic turnover of certain xenobiotics by some fish species. The present study was designed to utilize cryohepatocytes from rainbow trout, and assess metabolic stability of three chemicals (nonylphenol, methoxychlor and ethinylestradiol). The metabolism of these chemicals was compared to their metab-

olism in human cryohepatocytes. One year old rainbow trout (male and female) were euthanized, livers flushed through the hepatic vein. Hepatocytes were isolated by collagenase perfusion and cryopreserved in liquid nitrogen. Human livers were perfused and hepatocytes isolated and cryopreserved. Test chemical incubations were performed at pH 7.8 and 12 °C (trout) and pH 7.4 and 37oC (human) to reflect physiological conditions of each species. Disappearance of parent chemical was measured by LC-MS/MS or GC-MS. Differences were observed in the metabolism of each chemical and between species. These results demonstrate the possible use of rainbow trout cryopreserved hepatocytes as an in vitro model system to predict bioaccumulation of environmental chemicals.

PS 435 COBALT CHLORIDE, A LEAKAGE PRODUCT OF COBALT NANOPARTICLES, IS TOXIC TO RAT LIVER MITOCHONDRIA: A CARBON 13 NMR STUDY.

G. Baverel, M. Bernier, C. Pinteur, R. Nazaret, G. Martin and C. Gauthier.
Metabolomics and Metabolic Diseases, INSERM Unit # 820, Lyon Cedex 08, France.

It is known that cobalt chloride (CoCl2) may be released from cobalt nanoparticles but its cellular toxicity remains poorly characterized. The objective of the present study was to test if CoCl2 interfers with the metabolism of the liver. Given the importance of lactate as a physiological substrate of the liver, we have conducted a study in vitro to characterize the effect of CoCl2 on hepatic lactate metabolism. For this, precision-cut liver slices from 48h-fasted Wistar rats were incubated in oxygenated Krebs-Henseleit buffer containing either unlabeled lactate or variously 13C-labeled lactates or lactate + 13C-bicarbonate in the absence and the presence of CoCl2. At the end of the incubation period, substrate removal and product formation were measured by enzymatic and carbon 13 NMR methods. CoCl2 inhibited gluconeogenesis from 5 mM lactate in a dose-dependent manner with a IC50 of 0.7 mM. The labeling patterns of the glucoses synthesized from [1-13C]-, [2-13C]- and [3-13C]-lactate as well as from lactate plus 13C-bicarbonate indicated that lactate gluconeogenesis involved mainly the passage of carbons through pyruvate carboxylase and the reversible equilibration of oxaloacetate with fumarate and, to a small extent, pyruvate dehydrogenase and the entire tricarboxylic acid cycle. Addition of 0.7 mM CoCl2 led to a large reduction (> 50%) of lactate removal, glucose synthesis and alanine synthesis. CoCl2 also induced a large inhibition of ureagenesis and ketogenesis (from endogenous substrates) and greatly elevated ammonium accumulation. The cellular ATP levels and the beta-hydroxybutyrate/acetoacetate ratio, a marker of the mitochondrial redox state, were reduced by CoCl2. It is concluded that, in rat liver cells, CoCl2 is toxic to the mitochondria leading to a fall of cellular ATP levels that results in a strong inhibition of lactate removal and lactate gluconeogenesis as well as of ureagenesis and ketogenesis.

PS 436 BILIARY EPITHELIAL CELL CULTURE PREDICTS TOXICITY BY 1-ARYLOXYPROPAN-2-OL IN THE RAT.

V. Bhaskaran, L. Watson, L. Lehman-Mckeeman, B. Gemzik and M. Otieno.
Discovery Toxicology, Bristol-Myers Squibb, Lawrenceville, NJ.

Exposure of cells lining the biliary tract to high concentrations of drugs or metabolites due to biliary clearance renders the cells susceptible to cytotoxic cell damage. Although the incidence of drug-induced biliary toxicity is low, the often progressive nature of toxicity and uncertain translation across species warrants minimizing as a potential liability during drug discovery. The aim of these studies was: (1) develop and characterize a primary culture of rat biliary epithelial cells (BEC), (2) evaluate its utility to predict biliary toxicity detected in rats treated with an aryl ether of propane-1,2-diol, and (3) interrogate the system with other known biliary toxicants. A rat BEC cell line that expresses cholangiocyte markers gamma-glutamyl transpeptidase and cytokeratin 7 was established. UGT1A1, 1A2, 1A6, and GSTYC2 mRNAs were detected in the cells at 16, 33, 43, and 77% of levels in liver, respectively. CYP1A2 and CYP3A1 mRNAs were barely detected (<1% of liver levels). The cells retained expression of several transporters in culture, specifically, Abca1, Asbt, Mrp2, Mrp3, Mdr1a and Abcg1, that were expressed at 8, 16, 29, 53, 57, and 97% of levels found in ileum, respectively. The cells were used to test whether hyperplasia and degeneration of small bile ducts caused by 1-aryloxypropan-2-ol in the rat was due to direct cellular injury. The parent molecule and its hydroxyacid metabolite, 3-aryloxy-2-hydroxypropanoic acid, were not toxic, but the diol metabolite 3-aryloxypropane-1,2-diol decreased cell viabilty by 65% (IC50 ~10μM) implicating this metabolite as the potential proximal biliary toxicant. Interestingly, the hydroxyacid metabolite selectively increased biliary cell proliferation in vitro suggesting a differential role of the metabolites in the hyperplasia and biliary cell loss detected with the parent molecule in rats. This system was also sensitive to treatment with the biliary toxicants chlorpromazine, terbinafine, ticlopidine, and propafenone.

PS 437 MEASUREMENT OF LIVER ALANINE AMINOTRANSFERASE ISOENZYME (ALT1 & ALT2) ACTIVITY BY D-CYCLOSERINE INHIBITION.

R. Goldstein[1], D. Nettelton[1], F. Rajamohan[1], R. Yang[2], D. Gong[2] and W. Reagan[1]. *[1]DSRD-Biomarkers, Pfizer, Groton, CT and [2]School of Medicine, University of MD, Baltimore, MD.*

ALT activity is routinely used as an indicator of hepatocellular damage, but ALT is also an important enzyme involved in gluconeogenesis and amino acid metabolism. The cloning and expression of human and rat ALT1 and ALT2 proteins has allowed the development of immunoassay methods to measure ALT isoenzymes (ALTiso) mass and there is some indication that isoenzyme analyses may differentiate between hepatocellular injury versus metabolic adaptation. As an alternative approach, we used recombinant ALT1 and ALT2 proteins to develop an assay to measure ALTiso activity based on their differential inhibition by D-Cycloserine. At optimal D-Cycloserine concentrations, there is a 35% to 40% difference in inhibition between the recombinant ALTiso's activities. Human and rat recombinant ALT1 and ALT2 enzymes are similarly differentially inhibited. A preliminary reference range (n=30) of ALT1 and ALT2 activities in fasted normal rat liver homogenates is 134 to 381 and 26 to 118 μU/mg of protein, respectively. Intra-assay (n=3; 6 replicates) and inter-assay precision (n=3, 4 replicates over span of 3days) for ALT1 is 5.9% and 3.5% and for ALT2 is 8.7% and 10.2%, respectively. ALT2 activity in working dilutions of the liver homogenate prepared in the 125mM Tris buffer, pH-9 with 150mM NaCl, 25% glycerol and Roche Complete EDTA-free Protease Inhibitor were stable for 3 days at 4°C. The stock liver homogenate was stable for 30 days @-80°C and for 3 freeze-thaw cycles, but lost approximately 25% of the ALT2 activity when stored for 3 days at 4°C. The measurement of ALTiso activity by D-Cycloserine inhibition provides an alternate quantitative method. The method should be adaptable to laboratory automation and potentially applicable for use with both human and rat samples. Current efforts are to utilize this assay for characterization of changes in liver ALT activity in animals treated with xenobiotics and to optimize a serum ALT isoenzyme activity assay using this method.

PS 438 IN SITU BIOMONITORING USING CAGED JUVENILE CHINOOK SALMON (*ONCORHYNCHUS TSHAWYTSCHA*) AT A RIVER SUPERFUND SITE IN THE PACIFIC NORTHWEST.

M. A. Kelley[1], A. Gillespie[1], B. Duncan[2], T. McDonald[1], G. D. Zhou[1], S. Wang[1], L. Y. He[1] and K. C. Donnelly[1]. *[1]Texas A&M University, College Station, TX and [2]U.S. EPA Region 10, Seattle, WA.*

Contaminated sediments represent a potential threat to human and ecological health. Due to the complexity of these materials, there is a great deal of uncertainty associated with risk characterization of sediments. A series of *in situ* studies were conducted at a Superfund site in the Pacific Northwest. River sediment at the site is contaminated with polycyclic aromatic hydrocarbons (PAHs) and polychlorinated biphenyls (PCBs). Current studies are aimed at measuring biomarkers in caged juvenile Chinook salmon (*Oncorhynchus tshawytscha*). Based on existing data, four stations were selected for water and sediment sampling. Salmon fingerlings were also caged and exposed at each sampling station for 7-8 days. Following sacrifice, fish tissues were analyzed for body burden of PAHs and PCBs. Mean levels of contaminants present in sediment samples collected each July from 2004 through 2007 ranged from 1394 to 3037 ng/dry g for total PAHs and from 16 to 1904 ng/dry g for total PCBs. Mean total PAHs in surface water collected ranged from 231 to 1595 ng/L. PCBs were only detected in water during only one sampling event. Analysis of fish tissue detected total PAH levels as high as 251 ng/g wet weight, while PCB levels were below detection. DNA adduct analysis was performed by ^{32}P-postlabeling of salmon gill tissue, which was collected during the 2004, 2006, and 2007 sampling events. DNA adduct levels were significantly higher in the exposed salmon versus controls at selected stations in 2004 and 2006, however no significant difference was present during the 2007 sampling event when exposure levels were lower than other years. Results confirm that tissue concentrations provide a sensitive measure of contaminants in the water column. However, DNA adduct analysis is useful as a marker of genetic damage when high exposure levels of contaminants are present. This research was supported by NIEHS Superfund Basic Research Program Grant No. P42ES0947.

PS 439 DETECTION AND QUANTIFICATION OF BAP AND BBF FROM SEDIMENTS AND TILAPIAS OF THE CUCHARILLAS MARSHLAND, PUERTO RICO.

P. Nieves[2, 1], W. L. Lopez[1] and B. Zayas[1]. *[1]School of Environmental Affairs, Metropolitan University, San Juan, PR and [2]School of Science and Technology, Metropolitan University, San Juan, PR.* Sponsor: D. Herrenos.

PAH is a family of planar compounds that are bioaccumulated and biomagnified through the food chain. These compounds including Benzo (a) pyrene (BaP) and Benzo (b) fluoranthene (BbF) can be bioactivated yielding highly carcinogenic

metabolites which has the potential to intercalate into DNA. The first aim of this study is the monitoring of BaP and BbF from soils of the Cucharillas marshland and tissues of Orocrhombis mossambicus (tilapias) that inhabit within the marsh. The Cucharillas marshland is surrounded by multiple industries and a thermoelectric plant that are potential sources of environmental contaminants including PAHs and PCBs. The fact that it continues to be used for recreational activities presents a potential source of exposure of carcinogens to surrounding communities. Soils (sludge) and tilapias were obtained from potential contaminated areas in the marshland. The optimized and applied methodology for extraction and isolation of PAHs included: Ultra sonic and microwave extraction techniques for soils and fish respectively, followed by column filtration (silica, alumina and sodium sulfate). For optimization of the method control sludges and tilapias were spiked with BaP, BbF and the internal standard (decafluorobiphenyl). Analysis of the samples and identification of the monitored PAHs were performed by HPLC analysis. Preliminary results indicate the presence of PAHs on tilapias and soil samples at the parts per million (ppm) levels. Furthermore, evidence of bioaccumulation was suggested since the concentration level detected on tilapias were higher than in soil samples. Mass characterization of these carcinogens is being performed by Electrospray ionization masspectrometric techniques. Similar concentrations of BaP and BbF found on sediments or fish will be used to evaluate their potential cytotoxic effects on human normal cells. This study presents evidence of the presence of environmental carcinogens on the Cucharillas marshland.

PS 440 TRANSLATING *IN VITRO* ESTROGENIC ASSAY RESULTS TO ECOLOGICAL RISK ASSESSMENT.

C. Mori[1], S. Thakali[1], A. Tarrant[2], M. Sharma[1], H. Yekel[3] and T. Verslycke[1]. *[1]Gradient Corporation, Cambridge, MA, [2]Woods Hole Oceanographic Institution, Woods Hole, MA and [3]Wyeth Pharmaceuticals, Malvern, PA.*

In vitro assay results are increasingly used to evaluate endocrine activity of a wide range of environmental pollutants. However, translating in vitro assay results into the existing risk assessment framework is challenging since regulatory guidance on this issue is currently lacking. The United States Environmental Protection Agency (US EPA)'s Endocrine Disruptor Screening Program (EDSP) plans to screen and test potential endocrine disrupting chemicals, starting in 2009, and will rely largely on the results of in vitro assays in its initial screening stage (Tier I). It is yet to be determined how these screening results will be translated into 'risk', communicated to the public, and potentially used for regulation. We developed an in vitro fish estrogen receptor (ER) competitive binding assay to quantitatively assess estrogenicity of several known active pharmaceutical ingredients (APIs, e.g., progesterone, gestodene, and medrogestone). We subcloned zebrafish ERα into a tagged expression vector and incubated this receptor with one of the APIs along with a positive control. The relative potency obtained from the in vitro assay was used to derive a predicted no (adverse) effect concentration (PNEC) for each API, based on their relative binding affinities to ERα and the literature-reported PNEC for ethinylestradiol (EE2). These results were used to provide risk-based guidance with existing risk assessment procedures. We propose that, along with the results from 'traditional' toxicity testing, this approach can be used to evaluate the ecological risk of estrogenic chemicals. These methods also provide an approach as to how future screening results of US EPA's proposed EDSP could be interpreted.

PS 441 THE CYTOCHROME P450 (CYP) GENE SUPERFAMILY IN *DAPHNIA PULEX*.

W. S. Baldwin[1, 2], P. B. Marko[2] and D. R. Nelson[3]. *[1]Environmental Toxicology Program, Clemson University, Pendleton, SC, [2]Biological Sciences, Clemson University, Clemson, SC and [3]Molecular Sciences, University of Tennessee-Memphis, Memphis, TN.*

Cytochrome P450s (CYPs) are essential eukaryotic enzymes for making endogenous structural, signaling, and defensive molecules. A subset of CYPs has evolved as critical components of the detoxification systems of vertebrates and invertebrates. Data mining and manual curation of the *Daphnia pulex* genome identified 75 functional CYP genes, and three CYP pseudogenes. These CYPs belong to 4 clans, 13 families, and 19 subfamilies. The CYP 2, 3, 4, and mitochondrial clans are the same four clans found in other sequenced protostome genomes. Phylogenetic comparison of *D. pulex* CYPs to insects, vertebrates and sea anemone (Nematostella vectensis) CYPs using MrBayes show that the CYP2 clan, and to a lesser degree, the CYP4 clan has expanded in *D. pulex*, whereas the CYP3 clan has expanded in insects. However, the expansion of the *D. pulex* CYP2 clan is not as great as the expansion observed in deuterostomes and the nematode C. elegans. Mapping of CYP tandem repeat regions demonstrated the unusual expansion of the CYP370 family of the CYP2 clan. The CYP370s are similar to the CYP15s and CYP303s in insects that have always been solo genes but in Daphnia they make up about 20% of all the CYP genes. Lastly, our phylogenetic comparisons provide new insights into the potential origins of otherwise mysterious CYPs such as CYP46 and CYP19 (aromatase). Overall, the cladoceran, *D. pulex* has a wide range of CYPs with the same clans as insects and nematodes, but with distinct changes in the structure of each clan.

PS 442 TEMPORAL EXPRESSION OF FOUR ESTROGEN-RESPONSIVE PLASMA PROTEINS IN ADULT SHEEPSHEAD MINNOW EXPOSED TO STRONG AND WEAK ESTROGEN AGONISTS.

M. J. Hemmer, K. A. Salinas and P. S. Harris. *Gulf Ecology Division, U.S. EPA, Gulf Breeze, FL.* Sponsor: M. Barron.

Protein profiling via high throughput mass spectrometry can be used for detection of biomarkers that can be applied diagnostically to screen chemicals for endocrine modifying activity. In previous studies using sheepshead minnows (*Cyprinodon variegatus*, SHM), mass spectral analysis detected four peptides (2950.5, 2972.5, 3003.4, 3025.5 m/z) in the plasma of estrogen-treated male fish and untreated gravid females compared to unexposed males. In this study, accumulation and clearance of the four protein biomarkers was determined in adult male SHM during and after cessation of exposure to either the native ligand 17β-estradiol (E2) or the weak estrogen agonist, bisphenol-A (BPA). Fish were continuously exposed to either 0.3 μg E2/L, 0.5 μg BPA/L or a triethylene glycol solvent control for 7 days using a flow-through dosing system followed by placement in untreated seawater for the remainder of the 20 day experiment. Fish were sampled on days 1, 3, 5, and 7 of exposure followed by sampling at discrete intervals for up to 13 days post-exposure. At each interval, plasma from 5 fish was analyzed for presence of the four peptide biomarkers by MALDI-TOF-MS. Exposure to E2 and BPA caused significant increases in the four protein biomarkers during the exposure period. Average levels of expression ranged from 30 fold (2972 m/z) to approximately 80 fold over control values for the 2950 m/z protein biomarker. After cessation of chemical exposure, mean biomarker expression levels of the E2 treated fish remained relatively constant for 3 days followed by gradual plasma clearance reaching solvent control values by day 20. In contrast, BPA treated fish demonstrated significantly elevated expression ($p=0.05$) of the four biomarker proteins through day 20 with the 2950 and 3025 m/z markers remaining 56 and 29 fold higher, respectively, than solvent control values. Results of this study indicate time dependent clearance of the estrogen-responsive proteins from the plasma which may be detectible for several weeks after initial exposure to an estrogenic compound.

PS 443 EVALUATION OF THE EFFICIENCY OF THE TREATMENT BY PHOTOELECTROCATALYSIS AND CONVENTIONAL CHLORINATION IN THE REMOVAL OF THE AZO DYES FROM AQUEOUS SAMPLES USING THE SALMONELLA MUTAGENICITY ASSAY.

E. R. Ferraz[1], M. M. Osugi[2], M. V. Zanoni[2], A. R. Araújo[2], K. Rajeshwar[3] and D. P. Oliveira[1]. *[1]Departamento de Análises Clínicas, Toxicológicas e Bromatológicas, Universidade de São Paulo, Ribeir√£o Preto, S√£o Paulo, Brazil, [2]Universidade Paulista Júlio de Mesquita Filho - UNESP, Araraquara, S√£o Paulo, Brazil and [3]University of Texas at Arlington, Arlington, TX.*

Introduction: The literature shows that the conventional treatment by activated sludge employed by the dyeing industry has not effectively removed the azo dyes from effluents as well as the mutagenicity. Objectives: To compare the use of the photoelectrocatalysis with conventional chlorination as an alternative method for the treatment of aqueous samples that contain mutagenic azo dyes, using CI Disperse Red 1 (CAS n. 2872-52-8), CI Disperse Orange 1 (CAS n. 2581-69-3) and CI Disperse Red 13 (CAS n. 3180-81-2). Methods: Initially, we evaluated the mutagenicity of the original dyes with the strains TA98, TA100, YG1041 and YG1042. In order to preliminarily evaluate the efficiency of the degradation product, we used the strain TA98. Salmonella mutagenicity assay was performed using the pre-incubation protocol, in the presence and absence of S9. The photoelectrocatalytic oxidation experiments were performed in a photoelectrochemical reactor equipped with water refrigeration using an ultra-thermostatic bath and Ti/TiO2 thin film electrodes. Conventional chlorination was performed with chlorine gas. Results: The original studied dyes tested positive for the strains TA98 and YG1041, and for both, we observed a decrease of the effect in the presence of S9. Apparently photoelectrocatalysis completely removed the mutagenicity of the dyes and seems to be more efficient than chlorination for the treatment of mutagenic dyes and this result was published in Electrochimica Acta (in press). Conclusion: Probably pho-

toelectrocatalysis is a promising method in the degradation of dyes. It is believed that this method mineralize the dyes to CO2 and H2O, removing completely their mutagenicity.

PS 444 MOLECULAR CLONING OF AKR1A GENE AND ITS COMPARATIVE EXPRESSION WITH CYP1A IN RESPONSE TO BENZO(*A*)PYRENE TREATMENT IN TILAPIA (*OREOCHROMIS NILOTICUS*).

C. Osorio-Yánez[1], M. Pérez-Núñez[2], J. L. García-Tavera[2], O. Zapata-Pérez[2] and A. Albores[1]. [1]*Toxicology Section, CINVESTAV-IPN, Mexico City, D.F, Mexico and* [2]*Marine Sciences Department, CINVESTAV-IPN, M√©rida, Yucat√°n, Mexico.*

Benzo(*a*)pyrene (B*a*P) is a polycyclic aromatic hydrocarbon widely distributed in aquatic ecosystems. This compound requires bioactivation by cytochrome P450 1A (CYP1A) and aldo-keto reductase 1A (AKR1A) enzymes to carry out its toxic effects such as DNA damage, reactive oxygen species generation, among others. B*a*P is also able to regulate the expression of CYP1A and AKR1A genes through different pathways. AKR1A gene expression has not been studied in Tilapia (*Oreochromis niloticus*), a tropical fish of great ecological and economical importance. The aim of this study was to compare the B*a*P inductive effects on AKR1A and CYP1A gene expression in Tilapia's liver by measuring their mRNA levels. We performed a time-response curve using 20 mg/kg B*a*P given intraperitoneally and livers were collected at 3, 6, 12, 18, 24, 72 and 120 h after treatment. Hepatic cDNA was obtained from tilapias and analyzed by Quantitative Real-Time PCR assay. Previously, AKR1A cDNA was cloned, sequenced and compared with those AKR1A cDNA reported sequences in the GeneBank DNA database. AKR1A from Tilapia has a 324 pb open reading frame encoding a 108 amino acid protein with a theoretical molecular weight of 12 kDa. The AKR1A amino acid sequence is closely related to zebrafish (80% identity). In liver, CYP1A mRNA expression was constitutively higher than of AKR1A mRNA. On the other hand, B*a*P exposure remarkably induced both genes but CYP1A gen expression is evidently higher than that of AKR1A. In addition, mRNA CYP1A expression peaked at 6 h whereas AKR1A did so at 24 h. Thus, AKR1A is present in tilapia's liver and is B*a*P inducible; the time peak shown by CYP1A and AKR1A suggests that the induction mechanism by which these genes are modulated might be somewhat different. Efforts should be done to investigate the pathways differences for the induction of AKR1A and CYP1A mRNAs.

PS 445 THE CYTOCHROME P450 EFFECT ON THE CLEAVAGE OF THE CHROMOPHORE GROUP OF THE MUTAGENIC DYES DISPERSE RED 1, DISPERSE ORANGE 1 AND DISPERSE RED 13 AND THE RELATION BETWEEN THE GUANOSINE REACTION AND AZO BOND FOR THEIR MUTAGENICITY.

F. M. Chequer[1], M. V. Zanoni[2] and D. P. Oliveira[1]. [1]*Departamento de Análises Clínicas, Toxicológicas e Bromatológicas, Universidade de São Paulo, Ribeir√£o Preto, S√£o Paulo, Brazil and* [2]*Universidade Paulista Júlio de Mesquita Filho – UNESP, Araraquara, S√£o Paulo, Brazil.*

Many azo dyes widely used for coloring proposes in different kind of industries are toxic/mutagenic, as well as their breakdown products. The objectives of this work were: (1) To evaluate of the mutagenicity of Disperse Red 1 (CAS: 2872-52-8), Disperse Orange 1 (CAS: 2581-69-3) and Disperse Red 13 (CAS: 3180-81-2) using the micronucleus assay (MN); (2) To investigate if the cytochrome P450 is able to break the azo bond;(3) To determine if the mutagenic activity could be related to the link of chromophore group with the guanosine. The cytokinesis-block micronucleus assay was used to evaluate the mutagenicity of the dyes in human lymphocytes and HepG2 cells. The action of Cyt P450 on the azo bond was monitored by the decrease of the spectral absorbance of each dye after incubation with S9 for 45 minutes at 37oC. The guanosine was added to different concentrations of each dye and the reaction was also monitored by spectrophotometer. The three dyes showed dose dependent increase in the frequency of MN, for both lymphocytes and HepG2. The incubation of the dyes with S9 clearly reduced the color, indicating the cleavage of azo bond. The reaction of guanosine with the dyes lightly reduced the spectral absorbance of the azo bond, suggesting that the bind of this nucleotide with cromophore group is weak. We concluded that the dyes Disperse Red 13, Disperse Red 1 and Disperse Orange 1 are mutagenic. The chemical studies showed that the azo bond was cleaved after oxidation by S9, and similar results should be reproduced in in vivo situations. Therefore, further studies are necessary in order to elucidate the chemical structure of compounds formed after the cleavage of azo bond by Cytochrome P450 isoforms. The mutagenic effect of the dyes does not seem to be related with the bind of guanosine with the chromophore group.

PS 446 INVESTIGATION OF MITOCHONDRIAL TOXICITY OF MICROCYSTIN-LR.

G. Jasionek[1] and D. Papkovsky[1, 2]. [1]*Biochemistry Department, University College Cork, Cork, Ireland and* [2]*Luxcel Biosciences Ltd, Cork, Ireland.* Sponsor: Y. Will.

Numerous lethal animal poisonings and a number of cases of human illnesses have attracted the attention of researchers to microcystins, hepatotoxins produced by many species of cyanobacteria. Because of their potential adverse effects, microcystins have become an important issue in water quality. A simple, high throughput method for the assessment of MCLR toxicity has been developed, which is based on the measurement of alterations in biological oxygen consumption using a phosphorescent oxygen-sensitive probe and fluorescent plate reader detection. We analyzed the effects of MC-LR on primary hepatocytes, HepG2 cells, mitochondria isolated from rat liver and Zebra fish embryos. MC-LR inhibited the respiration of primary hepatocytes with EC50 = 2.74 ± 0.65 nM, while HepG2 cells showed no sensitivity to MC-LR. Facilitated delivery of MC-LR into HepG2 cells by means of transfection reagents resulted in a marked changes in respiration. HepG2 showed enhancement in O2 consumption measurable at 0.1–30 nM MC-LR. An uncoupling effect of MC-LR on mitochondrial state 2 and state 3 respiration was observed when using glutamate/malate as a substrate, MCLR activates O2 consumption by ETC Complex I of rat liver mitochondria. For Zebra fish embryos, 48h after hatching, treated with MCLR for 3, 6 and 24h, oxygen consumption was seen to reduce significantly after 24h incubation. The results demonstrate that MC-LR is a potent mitochondrial toxin and ETC uncoupler, while O2 consumption assay can be used for high sensitivity detection of MC-LR using primary hepatocytes, common cell lines and facilitated delivery, or animal models such as Zebra fish.

PS 447 THE INTERACTION OF THE FOOD DYE SUDAN III AND ITS REDUCED METABOLITES WITH GUANOSINE AND SCREENING OF THE MUTAGENIC ACTIVITY EVALUATION WITH SALMONELLA TEST.

T. B. Zanoni[1], M. V. Zanoni[2] and D. P. Oliveira[1]. [1]*Departamento de Análises Clínicas Toxicológicas e Bromatológicas, USP-Universidade de São Paulo, Araraquara, S√£o Paulo, Brazil and* [2]*Instituto de Química, Universidade Paulista Júlio de Mesquita Filho, Araraquara, S√£o Paulo, Brazil.*

A lot of dyes are used as food additives and the azo dyes are the most used. Although Sudan dyes are nonauthorized they have been illegally used to enhance or to maintain the appearance of food products. According to the literature Sudan I is mutagenic for different systems, but few information was found about the toxicity of Sudan III that has chemical structure similar to Sudan I. In this work, we investigated the ability of Sudan III as well as it is reduced metabolites with guanosine, a DNA nucleotide. Guanosine (at 1,4x10-4 mol.L-1) was added to Sudan III (5,5x10-5 mol.L-1) and the reactions were monitored using a diode array spectrophotometer. Using a spectroeletrochemical method Sudan III at 5,x10-5 mol.L-1 was reduced for 40 minutes (25oC) at an oxidative potencial - 1,5 V, on the absence of oxygen. The mutagenicity of Sudan III was preliminary evaluated with Salmonella/microsome assay, using pre-incubation protocol and TA98 and TA100 strains, in the presence and absence of S9, using the maximal dose of 1mg/plate. The Sudan III reacts with guanosine, generating a stable product with spectral absorbance different from the original dye. After the reduction step, we observed that the Sudan III red color changed to purple indicating that the azo bond was modified and this radical also interacts to guanosine. At the tested conditions, Sudan III tested negative for the mutagenic activity. Our results clearly demonstrated that Sudam III as well as the reduced product interact with DNA, but probably this effect was not due to point mutation.

PS 448 IN VITRO FISH METABOLISM PREDICTS ELIMINATION OF SUSPECT BIOACCUMULATIVE CHEMICALS.

P. D. Guiney[1], J. A. Weeks[1], K. M. Johanning[2], J. E. Hill[2] and R. L. Johnson[2]. [1]*SC Johnson & Son, Inc., Racine, WI and* [2]*CellzDirect/ INVITROGEN Corporation, Austin, TX.*

Implementation of the European REACh legislation requires significant additional testing, including bioaccumulation assessments in fish. Traditional bioconcentration factor (BCF) testing is costly and animal intensive. There is a need to develop alternative methods which reduce the number of test animals or avoid their use by application of *in vitro* test systems. Xenobiotic biotransformation is a critical process in fish and of great interest due to the increased need for better bioaccumulation estimates but, it is not well understood. The susceptibility of a chemical to metabolize can have important significance for *in vivo* bioaccumulation estimates. The primary objective for this study was to conduct an *in vitro* metabolic stability/profiling of fragrance chemicals in fish (rainbow trout) using liver S9 fractions.

A GC-MS method was developed for four suspect bioaccumulative chemicals (including several isomers): Sanjinol, Coniferan, Precyclemone B, and Vernaldehyde with log Kow values of 4.3, 4.9, 5.2, and 5.9 respectively. The GC-MS method allowed for parent quantification, characterization of fragments from profiling experiments and separation of potential metabolites. Samples were incubated at five time points (extending to 60 or 120 minutes) at two different concentrations of S9 protein (0.2 and 1 mg/ml) and three chemical concentrations. Incubations included enzymatic cofactors NADPH, UDPGA and PAPS. Zero-time incubations, heat-treated S9, no cofactors, solvent alone, and no S9 served as controls to distinguish between enzymatic metabolism and nonspecific chemical degradation. All four chemicals were rapidly metabolized (range 28% to >98%) by trout S9 fractions after one hour. This turnover was due to enzymatic action as confirmed by the control test groups. These results support the previously unknown metabolism of these modeled persistent chemicals which decreases their estimated BCF values. This type of data will be central for the future modeling of aquatic bioaccumulation.

PS 449 THE EFFECT OF 2, 4-DINITROPHENOL ON ZEBRAFISH SWIM PERFORMANCE.

J. S. Marit[1] and L. P. Weber[1, 2]. *[1]Veterinary Biomedical Sciences, Univerisity of Saskatchewan, Saskatoon, SK, Canada and [2]Toxicology Centre, University of Saskatchewan, Saskatoon, SK, Canada.*

Examination of fish swim performance is a potentially environmentally relevant, non-lethal endpoint for examining fish survivability. Zebrafish (*Danio rerio*) served as the model to investigate the acute affect on swim performance of a toxicant that acts as an oxidative uncoupler. Fish (n=10 per group) were aqueously exposed in a static medium to 0, 6, and 12 mg/L 2,4-dinitrophenol for 24 hours. Critical swimming speed (U_{crit}, a measure of swimming speed and endurance) was determined using a Loligo Systems mini swim tunnel in clean water. Fish were recorded at various intervals of U_{crit} with a high speed camera. The acquired images were used for swim motion analysis. Following U_{crit} analysis, fish were euthanized and their whole body triglyceride levels were determined as a marker of energy stores. No fish died during the control exposure, while mortalities in the 6 and 12 mg/L exposure groups were 20 and 30 percent, respectively. U_{crit} was significantly decreased ($p<0.05$ in Tukey's test after 1-way ANOVA) in fish exposed to 12 mg/L, but not 6 mg/L dinitrophenol. However, the oxidative uncoupler did not have a significant effect on swim motion (e.g. maximum amplitude of tail bend, angle of tail bend and length compression during swim stroke) at a sub-maximal speed nor on triglyceride levels. In conclusion, this study shows that acute exposure to a mitochondrial electron transport chain uncoupler can affect swim endurance (U_{crit}) without altering the manner in which they swim. Since swim performance is linked to both predator evasion and food acquisition, the decreased swim performance may result in a decrease in fish survivability.

PS 450 DNA SEQUENCE CHARACTERIZATION OF GOWANUS CANAL SOIL BACTERIA WITH POTENTIAL USE IN BIOREMEDIATION.

J. Levia and C. Bolnet. *Medgar Evers College, Brooklyn, NY.*

Bioremediation is a process that uses either naturally occurring or deliberately introduced microorganisms to break down environmental pollutants to return the natural environment altered by contaminants to its original condition. Our group is interested in soil bacteria from a particularly polluted area of Brooklyn New York: the Gowanus Canal (GC). The GC was a hub for Brooklyn's maritime and commercial shipping activity. The industrial sector around the canal grew substantially over time to include stones and coal yards, manufactured gas plants, tanneries, factories for paint, chemical plants, and sulfur producers, all of which emitted substantial water and airborne pollutants. With six million annual tons of cargo produced and trafficked through the waterway, the GC, in the beginning of the 20th century, ranked among the nation's busiest and most polluted canal. In this study we aimed to isolate and characterize naturally-occurring GC soil bacteria with bioremediation potential. Soil samples from GC were diluted, plated on starch agar plates and then incubated at 37 0C for 1-3 days. DNA was extracted from pure cultures exhibiting starch breakdown. The PCR amplification of the 16S rRNA gene was performed using fD1and rP1 primers. The PCR products were sequenced using Big-Dye terminator version 3.1 ready reaction cycle sequencing kit and an Applied Biosystems genetic analyzer AB13730. The sequenced fragments were compared to GenBank bacterial sequences using Basic Local Alignments Search Tool (BLAST). Our search results revealed 1) an isolate exhibiting 100 % nucleotide similarity to Bacillus pumilus, a bacterium well known for alkaline protease production in environmental decontamination of Dioxin. 2) an isolate having 99% nucleotide similarity to Alcaligenes faecalis, a bacterium that can detoxify arsenic to arsenate 3) an isolate exhibiting 100% nucleotide similarity to Rhodococcus equi, a bacterium involved in hydrocarbon biodegradation. In conclusion, we have isolated and characterized three types of soil bacteria from the GC that appear to be involved in naturally occurring bioremediation.

PS 451 EVALUATION OF THE POTENTIAL FOR INTERACTIONS AMONG THE BACILLUS THURINGIENSIS CRY PROTEINS PRODUCED BY MON 89034 × TC1507 × MON 88017 × DAS-59122.

S. L. Levine. *Regulatory, Monsanto company, Saint Louis, MO.*

Monsanto and Dow AgroSciences have developed the combined trait corn product MON 89034 × TC1507 × MON 88017 × DAS-59122-7 that resists insect feeding damage by producing Bacillus thuringiensis (Bt) proteins. The insecticidal proteins produced include the Cry3Bb1, Cry34Ab1, Cry35Ab1, Cry1A.105, Cry2Ab2, and Cry1F proteins. The Cry3Bb1, Cry34Ab1 and Cry35Ab1 proteins control rootworm feeding. The Cry1A.105, Cry2Ab2 and Cry1F proteins control leaf damage caused by lepidopteran pests of corn. In support of the environmental assessment, studies were performed to assess the potential for interaction among these Bt proteins. Demonstrating a lack of interaction allows studies completed for the individual products to be used to inform the safety of the combined trait product. The potential for interaction among the rootworm-active proteins, the lepidopteran-active proteins, and between the rootworm-active and the lepidopteran-active proteins was evaluated with a whole plant bioefficacy assay and bioassays with corn leaf tissue. To assess the potential for interaction among the rootworm-active Bt proteins and between the rootworm and lepidopteran-active proteins, bioefficacy assays were performed to evaluate root feeding damage after infestation with western corn rootworm. Treatments included a control, the single event products and the combined trait product. The combined activity of the rootworm-active proteins was consistent with dose additivity, and there was no interaction between the rootworm and lepidopteran-active traits. To assess potential interaction among the lepidopteran-active proteins, and between the lepidopteran- and rootworm active proteins, insect bioassays were performed with lyophilized leaf incorporated into an artificial diet and fed to larval European corn borer. The combined activity of the lepidopteran-active proteins was consistent with dose additivity and there was no interaction between the lepidopteran and rootworm-active traits. Taken together, the results of these studies demonstrate a lack of interaction among these Bt proteins.

PS 452 AN INTEGRATED BIOMARKER APPROACH FOR ASSESSING HEALTH IMPACTS ON KILLIFISH (*FUNDULUS HETEROCLITUS*) INHABITING THE HEAVILY CONTAMINATED NY/NJ HARBOR ESTUARY.

S. M. Bugel[1], L. A. White[2] and K. R. Cooper[2]. *[1]Department of Environmental Sciences, Rutgers University, New Brunswick, NJ and [2]Department of Biochemistry & Microbiology, Rutgers University, New Brunswick, NJ.*

This study used a multi-tiered approach to evaluate fish population health by examining a suite of biomarkers in killifish inhabiting Newark Bay (n=25) and a reference population in Tuckerton, NJ (n=25). Biomarkers investigated included classical evaluations (histopathology, morphometrics, gonad maturation), hepatic mRNA expression (CYP1A, metallothionein, vitellogenin I), ovarian aromatase mRNA expression, hepatic protein levels (CYP1A and vitellogenin) and chemical analyses (PAHs in bile). Newark Bay fish had significantly higher levels of bile PAHs compared to reference fish. Newark Bay females had significantly higher concentrations of naphthalene, pyrene and benzo[a]pyrene (2.5, 5.8 and 3.5 fold higher, respectively, $p\leq0.05$). Newark Bay males had significantly higher concentrations of pyrene (7.2 fold higher, $p\leq0.05$), and higher concentrations of naphthalene (4.2 fold higher, $p=0.06$) and benzo[a]pyrene (9.3 fold higher, $p=0.07$). Newark Bay fish also had significantly higher expression of CYP1A mRNA for both males and females (4.8 fold and 2.4 fold higher, respectively, $p\leq0.05$). Reproductive biomarkers support endocrine disruption in the Newark Bay female population. There was a significant increase in the percent of pre-vitellogenic follicles and a significantly decreased percent of follicles at the mid-vitellogenic and mature stages in Newark Bay females ($p\leq0.05$). Expression of vitellogenin mRNA was significantly decreased in Newark Bay females (6 fold lower, $p\leq0.05$) while aromatase (CYP19A) was significantly increased (210 fold higher, $p\leq0.05$). Efforts to strip spawn Newark Bay females failed to produce viable eggs when at the same time Tuckerton females produced large numbers of viable eggs. We conclude that the reproductive health of killifish in the NY-NJ Harbor Estuary is impaired, possibly due to disruption of steroid signaling leading to decreased vitellogenin production. *Funding: NJDEP-SR03-038 & NJAES 01201*

PS 453 OXIDATIVE BALANCE IN OYSTER (CRASSOSTREA SPP) OF ESTUARY BOCA DE CAMICHIN, NAYARIT.

J. B. Velázquez-Fernández, L. Ortega-Cervantes, Y. Y. Bernal-Hernández, L. Robledo-Marenco, E. Rojas and M. Medina-Díaz. *Laboratorio de Contaminación y Toxicología Ambiental, Universidad Autónoma de Nayarit, Tepic, Nayarit/Tepic, Mexico.* Sponsor: B. Quintanilla.

Among marine species in Mexico, the capture of the oyster is the seventh economically important. The Nayarit state ranks fifth in the production of oyster nationally. Since in last years has decreased oyster production, it is important to identify bio-

chemical biomarkers to infer about the health status of these organisms by exposure to pollutants. Within the biochemical biomarkers are those for oxidative stress. The thiobarbituric acid reactive species (TBARS) and total levels of glutathione (total GSH) show information about the oxidative damage and the antioxidant defense (no enzymatic) of organism, respectively. The aim of this study was to obtain information about the REDOX balance in Crassostrea spp. Oysters were sampled at three points in the estuary Boca Camichín, Nayarit (n=25). The extraction of the organism was carried out in less than two hours after its collection, and immediately antioxidant was added. The determination of TBARS was done by the method of Jain (1989). Total GSH levels were determined using a commercial kit. Differences were found between the control group and the group collected from Boca Camichin regarding to TBARS and total GSH levels. These results suggest that the organisms are importantly exposed to prooxidant agents.

PS 454 BIOLOGICALLY-BASED MODELING OF MODULATION OF MAP KINASE SIGNALING PATHWAY BY LF IN TOXIGENIC PHASE OF ANTHRAX INFECTION.

P. J. Robinson[1], E. J. Fleming[1], J. M. Gearhart[1], C. Hack[1], G. A. Andrews[2] and B. W. Gutting[2]. *[1]RHPB, Air Force Research Laboratory, Dayton, OH and [2]Naval Surface Warfare Center, Dahlgren, VA.*

Anthrax (Bacillus anthracis) owes its virulence to the production of the multicomponent anthrax toxin which mediates the toxigenic (terminal) stage of infection. One toxin component, lethal factor (LF), cleaves most isoforms of mitogen-activated protein kinase kinases (MAPKKs) close to their N-terminus. This interferes with a major signaling pathway linking the activation of membrane receptors, such as TLR4, to the transcription of several genes, including those encoding pro-inflammatory cytokines, as well as the p38 MAPK dependent expression of pro-survival genes. We have developed an initial model for this phase involving interaction of LF with host cells (macrophages). Cleaving MAPKK by LF leads to a decline (to zero) in the signaling output that has a characteristic half-time that can be correlated with the net potency of the toxin, as exemplified by reductions in macrophage viability in vitro in a number of studies. LF gains access to the host cell cytosol after it is secreted by germinating spores (early infection) or after it is endocytosed during toxemia (later, systemic infection). In either case, translocation of LF from the endosome to the cytosol is mediated by pores formed by another secreted toxin component, protective antigen (PA). A kinetic model has been developed that simulates the accumulation of LF in the macrophage cytosol over time. Our model is applied to published in vitro/in vivo dose-response and time-course datasets showing the differential susceptibility of various macrophages to LF/PA and/or bacterial exposures, often together with MAPKK cleavage data. This model, in combination with a proliferation model that simulates LF dosimetry and a description of the cellular response to signal reduction (alterations in gene expression leading to changes in cytokine production, apoptosis etc.), provides a model framework that predicts the time-course of the physiological effects of anthrax lethal toxin in biologically varied individuals.

PS 455 DEVELOPMENT OF A QUANTITATIVE MODEL INCORPORATING KEY EVENTS IN A HEPATOXIC MODE OF ACTION TO PREDICT TUMOR INCIDENCE.

N. S. Luke[1], M. J. DeVito[1], R. B. Conolly[2] and H. A. El-Masri[1]. *[1]U.S. EPA /ORD/NHEERL/ETD/PKB, Research Triangle Park, NC and [2]U.S. EPA /ORD/NCCT, Research Triangle Park, NC.*

Biologically-Based Dose Response (BBDR) modeling of environmental pollutants can be utilized to inform the mode of action (MOA) by which compounds elicit adverse health effects. Chemicals that produce tumors are typically described as either genotoxic or non-genotoxic. One commonly proposed MOA for non-genotoxic carcinogens is characterized by the key events of cytotoxicity and regenerative proliferation. The increased division rate associated with such proliferation causes an increase in the probability of mutations, which can result in tumor formation. In this presentation, three carcinogens which are thought to induce tumors in mice through a cytotoxic mode of action (chloroform, carbon tetrachloride, and dimethyl formamide) are quantitatively compared using a generalized BBDR quantitative model for tumor incidences. For each compound, a physiologically based pharmacokinetic (PBPK) model is developed and linked to a pharmacodynamic model of cytolethality and cellular proliferation. The rate of proliferation is then linked to a clonal growth model which predicts tumor incidences. Comparisons of the BBDR simulations and parameterizations suggested that the only significant variation among the models for the three chemicals arise in a few parameters expected to be chemical specific (such as metabolism and cellular injury rate constants). The BBDR model was used to quantitatively indentify limits of cellular injury and proliferation that would result in a significant increase in tumor incidence. Results of the generalized BBDR model simulations provide evidence to inform the use of cytoxicity and cellular proliferation as key events within this MOA for these chemicals. This BBDR model or subsequent versions in this iterative process may prove useful in testing if cytotoxicity and cellular proliferation can be considered a cancer MOA for chemicals that produce liver tumors when their chemical specific parameters are available. (This abstract does not reflect USEPA policy.)

PS 456 CHROMOSOMAL TRANSLOCATION IN THYROID CARCINOGENESIS.

A. O. Chiu[1], N. H. Chiu[2] and D. Singh[1]. *[1]ORDNCEA, EPA, Washington, DC and [2]NCEA ODW, U.S. EPA, Washington, DC.*

Cancer development involves an escape from apoptosis and oncogenic-senescence after the carcinogen exposure. These can occur simultaneously in a multicellular organism and reflects in Weibull's time-to-tumor model. Different anti-oncogenic (of p53, p27, Arf) effects are multiplicative to bring about cancer development in our calculations. In contrast, radiation induced adenocarcinoma of thyroid resulted from genetic damages and specific fusion of anti-oncogenes in proximity. These anti-oncogenes control cell-division (Ret) and differentiation (Pax8). By reviewing genetics literature of thyroid multinodular follicular carcinomas, we propose the following thyroid carcinogenic mechanism: Exposure to ionization radiation leads to DNA double-strand-breaks in those "chromosomal-territories" of actively transcribing endocrine gland such as the thyroid. Most likely this is accompanied by chromosomal translocation to neighboring loci of a different chromosome. These include the recombination of antic-oncogenes in proximity controlling cell division (Ret) and cell differentiation (Pax8) of a progenitor thyroid cell. This loss-of-heterozygosity leads to apoptosis/senescence escape. Unlike many cancer cells, the resulted cancerous cells somehow retain the differentiated thyroid functions due to the proximity of anti-oncogenes controlling cell division and differentiation. In addition, gene conversion occurs in neighboring cells instead of translocation. Thus it can lead to the appearance of multinodular follicular carcinoma in the thyroid with differences in the DNA sequence as identified in a single individual. The chances of different mutation at the same loci via mistakes in the DNA replication can also occur but in a magnitude six-order-of-magnitude lower.
Disclaimer: The opinions and conclusions in this abstract are only those of the authors and do not reflect the institutions they represent.

PS 457 ENVIRONMENTAL EXPOSURES TO THYROID DISRUPTING CHEMICALS: KEY CONSIDERATIONS FOR DEVELOPING A BBDR-HPT AXIS MODEL FOR THE PREGNANT MOTHER AND FETUS.

B. O. Fatuyi[1], M. Mumtaz[2] and J. W. Fisher[1]. *[1]Environmental Health Science, University of Georgia, Athens, GA and [2]Computational Toxicology Laboratory, Division Toxicology and Environmental Medicine, Agency for Toxic Substances and Disease Registry (ATSDR), Atlanta, GA.*

Many chemicals found in the environment are known to act on the HPT (Hypothalamic-Pituitary-Thyroid) axis by differing modes of action; but the public health implications remain controversial and elusive to scientific inquiry. BBDR models provide a tool for better understanding complex exposure-response relationships. Yet no computational tools are currently available to assist in interpreting the potential developmental health effects of thyroid active chemicals. To describe normal condition and chemical disrupted status of the HPT axis the following 'pregnancy factors' need to be quantitatively described relative to the influence of one factor on another: 1) The influence of the placenta on metabolism of thyroid hormones and the maternal transfer of thyroid hormones from the placenta to the fetus, 2) the influence of estrogen hormone on the fetal serum levels of TGB binding protein and its control of free and bound serum thyroid hormones, 3) the complex relationship between hCG hormone (synthesized in embryo and placenta), TSH, and synthesis of fetal thyroid hormones, 4) urinary clearance of iodide, and 5) growth of the fetus and 6) maternal and fetal contributions to the functioning of the fetal HPT axis during maturation. The present research reports on key biological factors required for the creation of a BBDR HPT axis model in developing fetus and pregnant mother and builds upon a recently published rodent BBDR HPT axis model (McLanahan et al., 2008). Dynamic changes in circulating thyroid hormones and TSH levels occur in the maturing euthyroid fetus. The ultimate goal of this research is to develop a Biologically Based Dose Response (BBDR) model for the HPT axis in the pregnant mother and fetus for use in public health assessments of exposures to thyroid active chemicals. This work is supported by ATSDR Cooperative Agreement 1U01US000078.

PS 458 A MORPHOMETRY MODEL OF THE RABBIT LUNG FOR PARTICLE DEPOSITION MODELING.

E. Hack and J. M. Gearhart. *Wright-Patterson AFB, Wright-Patterson AFB, OH.*

A rabbit lung model was developed based on information available in the published literature. The airways of the lung were described with a symmetric geometry, similar to what has been used for typical path deposition models. Although the rabbit lung is known to be more asymmetric or monopodial than this idealized model, it is expected that, on average, regional deposition (e.g., tracheobronchial or pulmonary) will be adequately characterized by this model. The lung airways are grouped by branching generation, which is the number of bifurcations down from the trachea to the airway. The airways are described by the average number, length, diameter, branching angle, and gravity angle for the airways in each branching generation. The geometry of the tracheobronchial (TB) region (generations 1-14) was defined by integrating the data primarily from Kliment (1974), Ramchandani et al. (2001), and Schlesinger and McFadden (1981), and Rodriguez et al. (1987) data were used to define the pulmonary (PUL) region. The morphometry data were used in a typical path deposition model based on the work of Yeh and Schum (1980), and Wojciak (1988). Deposition via diffusion, sedimentation, and inertial impaction was modeled for TB and PUL deposition. An empirical function of the diameter and air flow rate was fit to Raabe (1975) data and used for extrathoracic (ET) deposition. The model predictions were in good agreement with the data. Monte Carlo analysis of deposition with variability distributions for breathing frequency, tidal volume, and breath pause time shows significant variation in deposition, though there is less variability for 1 μm particles. Predictions of deposition in the human lung are significantly higher than that of rabbit lungs.

PS 459 AN INTEGRATED QSAR-PBPK MODEL FOR SIMULATING INHALATION AND DERMAL KINETICS OF VOLATILE ORGANIC CHEMICALS (VOCS) IN HUMANS.

E. Kamgang and K. Krishnan. *SEST, University of Montreal, Montreal, QC, Canada.*

Quantitative-structure activity relationship (QSAR) approach is potentially useful for estimating chemical-specific input parameters for developing physiologically-based pharmacokinetic (PBPK) models. QSARs for partition coefficients, metabolic parameters and absorption rates can facilitate the rapid development of PBPK models for simulating the pharmacokinetics and internal dose of chemicals. The objective of this study was to develop an integrated QSPR-PBPK model for simulating the pharmacokinetics of VOCs in humans exposed by inhalation and/or dermal routes. For this purpose, available experimental data on human blood:air (Pb:a), fat:air (Pf:a), octanol:air (Po:a) and water:air (Pw:a) for 35 hydrocarbons (alkanes, alkylenes, aromatic hydrocarbons...) were analyzed. The resulting QSARs, along with tissue composition data, permitted the calculation of the muscle:air, liver:air, stratum corneum:air and Pf:a for VOCs that could be described using the following fragments: CH3, CH2, CH, C, C=C, H, benzene ring and H in benzene ring structure. The predicted partition coefficients were within a factor of 0.77 – 1.15 of the experimental values. The skin permeability coefficients (Kp) were also calculated on the basis of log Pow and moelcular weight, whereas the CLint for humans were obtained by fractional body weight scaling of QSAR-derived CLint in rats. The QSAR algorithms were then incorporated along with the equations constituting PBPK model, within Microsoft EXCEL spreadsheet. The integrated QSAR-PBPK model adequately simulated the pharmacokinetics of m-xylene in humans on the basis of molecular structure both for inhalation (33 ppm, 7 h) and dermal (1 mmol/L air, 20 min) exposures. The integrated QSPR-PBPK modeling approach developed in this study would be potentially useful as a tool for predicting in vivo kinetics and bioaccumulation of chemicals in humans under data-poor situations.

PS 460 PBBK/BD MODEL OF FRANCISELLA TULARENSIS IN RHESUS MONKEYS.

M. Lumpkin, G. Diamond, S. Massulik and P. Coleman. *Syracuse Research Corp, N. Syracuse, NY.*

Although physiological modeling of chemicals in animals and humans is now being employed as a regulatory tool for risk assessment, the same technology for microbial agents is in very early stages of development. The need for biokinetic/dynamic models for microbial agents is great, particularly for biothreat agents of concern for intentional releases. We are developing a physiologically based biokinetic/biodynamic (PBBK/BD) model for inhalation infection of Francisella tularensis, the agent causing tularemia, in Rhesus monkeys. The model was adapted from a prototype model for deposition and clearance of Bacillus anthracis spores and includes pulmonary deposition of particles, bacteria-phagocyte interactions, and transport of intra- and extracellular bacteria through the lung and thoracic lymph nodes. The model was optimized for predicting kinetics of disease progression for the highly virulent SCHU-S4 strain of F. tularensis. The literature for F. tularensis is equivocal regarding the requirement for bacterial uptake into phagocytes to precede growth in non-human primates. Therefore, we used the model to explore the effects of alternative growth scenarios on simulated kinetics of infection. By allowing for growth of bacteria following escape from phagocytes, the model is able to replicate observed kinetics of bacterial growth in lung and thoracic lymph nodes of Rhesus monkeys. This work illustrates the utility of modeling and simulation for testing mechanistic hypotheses about microbial pathogenesis that could be validated experimentally.

PS 461 A PHYSIOLOGICALLY BASED BIOKINETIC AND BIODYNAMIC (PBBK-BD) MODEL OF SYSTEMIC *BACILLUS ANTHRACIS* TOXINS.

E. J. Fleming[1], C. Hack[1], P. J. Robinson[1], S. R. Channel[2], T. L. Nichols[3], B. W. Gutting[4] and J. M. Gearhart[1]. *[1]711HPW/RHPB, HJF, Wright-Patterson AFB, OH, [2]SAIC, Linton, IN, [3]NHSRC, U.S. EPA, Cincinnati, OH and [4]NSWC, Dahlgren, VA.*

A multispecies physiologically based biokinetic and biodynamic (PBBK-BD) model of inhalation anthrax is being developed. The goal is to quantitatively describe the mechanisms of *Bacillus anthracis* (BA) spore lung deposition and clearance, BA spore germination and growth, subsequent release of anthrax toxins, and role of toxin systemic kinetics and dynamic response in experimental outcomes in order to perform cross-species extrapolation of disease response. A key element for simulating the whole animal anthrax disease response is to mechanistically and quantitatively describe the biokinetics of protective antigen (PA) as it is released from vegetative BA, circulates via the blood stream to organs then attaches to cell membranes via PA receptors, capillary morphogenesis protein (CMG2) or tumor endothelial marker (TEM8). The systemic model has been developed and initially parameterized according to PA receptor density and kinetic data. Relative density values for PA receptors were derived from published studies in which mRNA expression levels of CMG2 and TEM8 were measured in tissues of mice, while binding affinities of PA to its receptors were derived from published binding stoichiometry studies. The model predicted the half life of PA in blood, which was validated by published data on serum PA in mice following IV dosing with PA, and serum PA in rats following IV injection of lethal toxin (PA + lethal factor). This systemic model also makes good predictions of circulating PA levels in the serum of New Zealand White rabbits with inhalation anthrax. Further, we can predict organ-specific pathology with the inclusion of PA receptor density in our model. Together with our previously developed BA inhalation and proliferation models, the systemic model enables the simulation of circulating toxin levels in animals with inhalation anthrax and the associated organ pathology. This work was funded in part by the Defense Threat Reduction Agency as project BA06TAS022.

PS 462 USE OF A PBPK MODEL TO DETERMINE THE POTENTIAL EFFECTS OF ALBUMIN AND PON1 ESTERASE ACTIVITIES ON CHLORPYRIFOS PHARMACODYNAMICS.

T. S. Poet[1], M. J. Bartels[2] and C. Timchalk[1]. *[1]Battelle, Pacific Northwest Division, Richland, WA and [2]The Dow Chemical Company, Midland, MI.*

Paraoxonase (PON1) is found in the liver and blood where it hydrolyses the active oxon metabolites of a number of organophosphorus (OP) insecticides, including chlorpyrifos. Human developmental differences and polymorphisms in PON1 activities have led to concerns about OP exposures in potentially sensitive populations. role of albumin esterase in the hydrolysis of chlorpyrifos-oxon has been demonstrated in vitro. Albumin esterase does not show the same developmental differences or polymorphisms that have been seen for PON1, as blood levels of this protein are fairly constant through life stages and across species. A validated PBPK/PD model for chlorpyrifos was used to determine the potential role of PON1 esterase activity differences and albumin esterase activities on chlorpyrifos-oxon detoxification. Humans are potentially exposed to chlorpyrifos as residues on food, so oral exposures of 3 doses/day were simulated. Brain esterase shows ~10% inhibition in a healthy adult with blood oxon of ~0.3 nmol/L, equivalent to a daily exposure of ~ 1.6 mg chlorpyrifos/kg/day. Young children are reported to have ~1/3 the PON1 activity of adults. In an individual with 1/3 PON1 activity, a modeled 10% brain esterase inhibition would occur at ~0.35 mg chlorpyrifos/kg/day. In a theoretical situation where only albumin esterases are present in the complete absence of PON1 activity, the PBPK model predicts 10 % brain esterase inhibition at

~ 0.15 mg/kg/day. Likewise, oxon concentrations and blood cholinesterase inhibition are decreased by albumin esterase activity. These simulations suggest that at environmentally relevant chlorpyrifos exposure levels, 1/3 the levels of PON1 will still metabolize chlorpyrifos-oxon to a sufficient extent to protect against brain inhibition and serum albumin esterase must be considered as a potential mechanism of elimination of chlorpyrifos-oxon.

PS 463 IMPROVING RISK ASSESSMENT FROM DIETARY EXPOSURES BY MODELING VARIATION AND UNCERTAINTY IN EXPOSURE AND Dose-Response USING LINKED EXPOSURE AND PBPK/PD MODELS.

P. M. Hinderliter[1], P. S. Price[2], K. D. Schnelle[3], C. Timchalk[1] and T. S. Poet[1]. *[1]Battelle, Pacific Northwest Division, Richland, WA, [2]The Dow Chemical Company, Midland, MI and [3]Dow AgroSciences LLC, Indianapolis, IN.*

Dietary risk assessment is most often conducted based on the ratio of exposure to a No-Observed Adverse Effect Level in animals and requires the use of "safety" or "uncertainty" factors to address interspecies extrapolation and human variation. Uncertainty in these assessments can be reduced by coupling physiologically based pharmacokinetic and pharmacodynamic (PBPK/PD) models in humans with models of variation in human physiology and longitudinal models of dietary exposures. Linked models allow the inclusion of objective data on uncertainty and variation in diet, physiology, and metabolism, resulting in direct predictions of the potential for effects. A case study is presented for chlorpyrifos, a model compound exhibiting low-dose "first pass" metabolism by gut, liver, and blood. Publicly available dietary residue data and publicly available dietary software models (CARES and LifeLine) are used to estimate longitudinal exposures (five consecutive daily doses) for adults and children. Interindividual variation in physiology is directly simulated using P3M, a model of interindividual variation in physiology. PBPK/PD, physiology, and dietary exposure models are linked using the "person-oriented approach" developed for the US EPA. The combined model directly predicts the interindividual variation in exposure, intestinal and hepatic bioactivation and detoxification, circulating blood levels, and pharmacodynamic endpoints. Uncertainties in exposure, physiology, and metabolism are modeled using 2D Monte Carlo simulation. Safety/uncertainty factors are not required in this analysis since animal data are not used and variability in humans is modeled directly. The techniques developed in this case study demonstrate the feasibility of linking multiple models that link data on food residues to predictions of risk of adverse effects and is an example of source-to-effect modeling.

PS 464 DEVELOPMENT AND VALIDATION OF AN OPEN SOURCE COMPUTATIONAL FRAMEWORK FOR FORWARD AND REVERSE DOSIMETRY OF ORGANOPHOSPHORUS INSECTICIDE MIXTURES.

J. H. Ivy[1, 2], B. Reisfeld[1, 2, 3], M. Lyons[1, 2, 3], T. Renner[1], A. N. Mayeno[1, 3] and R. Yang[1, 3]. *[1]Quantitative & Computational Toxicology Group, Colorado State University, CO, [2]Chemical & Biological Engineering, Colorado State University, Fort Collins, CO and [3]Environmental & Radiological Health Sciences, Colorado State University, Fort Collins, CO.*

Although various biomarkers have been used to assess exposure to and poisoning from organophosphorus (OP) insecticides, the complexity of OP absorption distribution, metabolism, and elimination warrants integration of computer-assisted modeling tools with the biomarker data for more accurate quantitation and assessment of target tissue dosimetry. Here we describe the development and current capabilities of a novel computational framework for dosimetry of OP insecticide mixtures. This open source software package has features for both forward dosimetry, in which a calibrated model is used to predict biomarker data from known exposures, and reverse dosimetry, in which a calibrated model is used to reconstruct absorbed dose and exposure from collected biomarker data. To this end, the framework contains tools for Monte Carlo and Bayesian analyses, statistical post-processing and visualization of results, and a graphical user interface. As a first step toward a general OP mixture dosimetry model, we have implemented a physiologically-based pharmacokinetic (PBPK) model for a mixture of chlorpyrifos [*O,O*-diethyl *O*-(3,5,6-trichloro-2-pyridyl)phosphorothioate] (CP) and diazinon [*O,O*-diethyl *O*-(2-isopropyl-6-methyl-4-pyrimidinyl)-phosphorothioate] (DZ). Using this model within the framework, we found good agreement between the output of simulations and published results for CP and DZ exposure biomarkers in rodents. We also found good agreement between reconstructed and experimental dosing scenarios using *in vivo* biomarker data for rodents as input. Future developments of the framework will include additional validation from targeted *in vivo* studies, validation using human exposure data, and dose reconstruction using biomarker levels from human epidemiological databases. This project is supported by EPA STAR Grant #R833451.

PS 465 USING QSAR TO PREDICT PBPK/PD MODEL PARAMETERS FOR ORGANOPHOSPHORUS CHEMICALS.

C. D. Ruark, C. Hack, P. J. Robinson and J. M. Gearhart. *HJF, Wright-Patterson AFB, OH.*

In vitro rates of phosphorylation, dealkylation, and regeneration by acetylcholinesterase, butyrylcholinesterase, carboxylesterase, and other esterases are important pharmacodynamic parameters, while metabolic activation and clearance are important pharmacokinetic parameters of organophosphate (OP) compounds and their metabolites. These parameters are key for accurate characterization of physiologically-based pharmacokinetic/pharmacodynamic predictions in animals and humans but are not currently available for many OP compounds. This data gap can be filled through the methodology of quantitative structure-activity relationship (QSAR), and the results can be applied to assess the health effects and variability in human populations with OP exposure. The relationships presented here between structure and cholinesterase activity of OP compounds were modeled using Ampac 8.0 and Codessa 2.51 (Semichem, Inc.). In order to describe the structure of these OP compounds, regression techniques were applied to over 500 analyzed topological, geometric, constitutional, thermodynamic, electrostatic, and quantum mechanical descriptors to obtain statistically verified equations for the QSAR models. The results of an AChE bimolecular rate constant regression, with a total of 679 structures, show that an R^2 of 0.71 can be achieved with 40 descriptors. The best one-parameter correlation was found to be the average nucleophilic reactive index for a carbon atom with an R^2=0.12. The AChE dataset was found to be normally distributed, with rate constants ranging from $\log_{10}(-1.638)$ to $\log_{10}(10.450)$ $M^{-1}min^{-1}$ with a mean value of $\log_{10}(4.406)$. Finally, the assessment of the applicability domain was described through the leave-one-out principle yielding a Q^2 = 0.67. With the development of a QSAR toolbox complementing PBPK/PD modeling of OP chemical warfare agents, better assessment of these chemical threats can be made to assist in medical response management and planning in the future.
This project received support from the Defense Threat Reduction Agency - Joint Science and Technology Office, Basic and Supporting Sciences Division.

PS 466 ACCOUNTING FOR STEREO-ISOMERS AND IONIZATION IN A PBPK/PD MODEL OF VX EXPOSURE.

T. R. Covington[1], E. M. Jakubowski[2], J. M. McGuire[2], R. A. Evans[2], S. W. Hulet[2] and J. M. Gearhart[1]. *[1]HJF, 711th HPW/RHPB, Wright-Patterson AFB, OH and [2]U.S. Army ECBC, Aberdeen Proving Ground, MD.*

Historically, chemical warfare nerve agent (CWNA) exposure threats were thought of as primarily lethal exposure level effects restricted to the combat theater, yet civilian population exposures are now of concern as well as evidenced by terrorist attacks with sarin in Japan in 1994 and 1995. In order to better describe the complex kinetics and dynamic effects of VX, an existing physiologically-based pharmacokinetic/pharmacodynamic (PBPK/PD) model for VX (based on previously developed PBPK/PD models for diisopropylfluorophosphate and sarin (GB)) was extended to account for stereoisomers and the ionization of VX. This extended model simulates exposure via intravenous, subcutaneous, or dermal exposure in the guinea pig or Gottingen minipig. It consists of 3 sub-models: one for each of the stereoisomers of VX and one for cholinesterase (AChE, BChE, and CE) inhibition by VX. The model also accounts for differences in diffusion, urinary clearance, binding to red blood cells (RBCs) and plasma, and cholinesterase inhibition, regeneration, and aging due to ionization of VX by calculating instantaneous concentrations of ionized and non-ionized chemical using the Henderson-Hasselbalch equation and tissue-specific pOH values. Simulated endpoints included fluoride ion regenerated VX G-analog in RBCs and plasma, plasma and tissue VX concentrations, and inhibition of cholinesterases (Jakubowski et al., 2001). Species differences in response, due to differing pharmacokinetic profiles of VX, were addressed. The blood concentration and urinary excretion of VX were used as a confirmation of the low in vivo metabolism of VX relative to other CWNAs, like GB and soman. This extended model, validated with multiple data types in different species, provided the basis for predicting data from human IV and oral exposure presented in a peer-reviewed publication (Sidell and Groff, 1974). (This project received support from the Defense Threat Reduction Agency - Joint Science and Technology Office, Basic and Supporting Sciences Division.)

PS 467 ASSESSING THE INFLUENCE OF DIETARY MANGANESE VARIABILITY AND INHALED EXPOSURE BY PHARMACOKINETIC MODELING.

A. Nong[1], M. D. Taylor[2], D. C. Dorman[1,3], M. E. Andersen[1] and H. J. Clewell[1]. [1]*The Hamner Institutes for Health Sciences, Research Triangle Park, NC,* [2]*Afton Chemical Corporation, Richmond, VA and* [3]*College of Veterinary Medicine, North Carolina State University, Raleigh, NC.*

Manganese (Mn) is an essential dietary element for various important biological functions. Symptoms of central nervous system toxicity are known to occur at high inhalation concentration of exposures. Although abundant in food and drinking water, health risk concerns are generally aimed at the potential exposures in some populations to Mn airborne particles from industrial ore and alloy production, commercial use, and car emissions. The objective of the present study is to assess the daily dietary contribution of Mn on the tissue accumulation of Mn from inhalation exposure. With a recently developed physiologically-based pharmacokinetic (PBPK) model for adult rodents and nonhuman primates, variability of steady-state blood and brain Mn levels in a simulated adult human population was determined using Monte Carlo techniques. Population model simulations of steady-state tissue concentrations were generated with population dietary Mn intake distribution data in North America (mean: 2.43 mg/day [0.07 – 6.2 mg/day], standard deviations: 1.8 mg/day). A 4-fold difference in blood and brain Mn concentrations was determined between the 5th and 95th percentile values based on dietary only input. Brain and blood Mn concentrations increased by 2 times at highest dietary input and an inhaled exposure of 0.05 μg Mn/m3 (the current U.S. EPA RfC). 2-fold difference 5th and 95th percentile blood and brain Mn concentrations from an inhaled input at 0.5 mg Mn/m3 suggests the important contribution of a variable population diet. Since Mn tissue levels are regulated to prevent toxicity over a definite range of exposures, determining the changes above basal tissue Mn levels from inhaled Mn is crucial for a dosimetry-based risk assessment. Evaluating the variability of dietary Mn intake enables the identification of a possible point-of-departure tissue Mn reference concentration for the health risk assessment of Mn.

PS 468 UNDERSTANDING MN KINETICS IN RATS DURING GESTATION AND LACTATION USING PBPK MODELING.

M. Yoon[1], A. Nong[1], H. J. Clewell[1], M. D. Taylor[2], D. C. Dorman[1,3] and M. E. Andersen[1]. [1]*The Hamner Institutes for Health Sciences, Research Triangle Park, NC,* [2]*Afton Chemical, Richmond, VA and* [3]*North Carolina State University, Raleigh, NC.*

A PBPK model describing Mn kinetics in rats during the perinatal period was developed to improve our understanding of inhalation exposure conditions that could lead to increased central nervous system Mn concentrations in developing rats or humans. The model includes changes in physiology of the rat during gestation and lactation and describes Mn behaviors in the body with saturable tissue binding, homeostatic control of uptake and excretion, and tissue-specific increases in Mn from inhalation. A series of model modifications were made for the pregnant, lactating dam, fetus, and pups compared to adults, including: efficient, but saturable, maternofetal transfer of Mn, tissue binding capacities in the developing fetus and pup, increased dietary Mn absorption in the lactating dam to maintain maternal homeostasis in the face of Mn loss through milk, more efficient gastrointestinal tract absorption, and low basal, but inducible, biliary excretion in pups. The ability of the pup to enhance biliary excretion when challenged with excess Mn was also required for simulating inhalation exposure during the early postnatal period. In general, these changes were concordant with the biology of essential metals during development. The resulting model simulations match a variety of published studies on maternal Mn homeostasis during gestation and lactation, milk Mn levels, placental levels, late gestation fetal tissue levels, and changing patterns of neonatal tissue Mn levels for both normal dietary intake and with Mn inhalation. The successful description of Mn concentrations across these lifestages suggests that the present model can help to understand the relationship of Mn tissue concentrations in target organs across different developmental stages and their potential risks. This PBPK model will be useful in assessing whether infants and children should be regarded as susceptible populations for Mn inhalation.

PS 469 DEVELOPMENT OF A PBPK MODEL FOR HEXAVALENT CHROMIUM IN RATS AND MICE TO ESTIMATE EXPOSURE TO ORAL MUCOSA AND SMALL INTESTINE EPITHELIUM.

J. L. Campbell, Y. Tan and H. J. Clewell. *Center for Human Health Assessment, The Hamner Institutes for Health Sciences, Research Triangle Park, NC.*

In a recent NTP bioassay, hexavalent chromium (CrVI), administered as sodium dichromate in drinking water, induced tumors in the intestine of mice and the oral mucosa of rats. The mode of action for CrVI carcinogenicity is thought to be associated with its reduction to trivalent chromium (CrIII) in the epithelial tissues of the portal of entry. The purpose of this study was to extend the PBPK model of oral CrVI exposure in rats developed by O'Flaherty et al. (2001), in order to simulate the exposure of the target tissues in both rats and mice. The O'Flaherty rat model was extrapolated to the mouse using known physiological parameter values and allometric scaling of chromium kinetic parameters. An oral mucosa compartment was added to the rat model and compartments for the stomach, small intestine and large intestine were added to the mouse description. The model was then used to assess the uptake and tissue distribution of total chromium in the NTP kinetic studies (i.e., exposure in drinking water for 21 days followed by sacrifice 48 h after removing the dosing solution from the animals). An apparent non-linear, dose-dependent uptake of chromium from drinking water in these studies could be adequately described using Michaelis-Menten kinetics. The model was also able to reproduce data from other studies of chromium kinetics in rats and mice from the literature. After incorporating magnetic resonance imaging data on the rate of reduction of CrVI to CrIII in the intestinal lumen and tissues, the model will be used to predict target tissue exposure to CrVI and CrIII under the exposure conditions of the NTP bioassays, as well as at lower concentrations, in support of the design of an experimental study to evaluate the potential for a dose-dependent transition in the mode of action for CrVI carcinogenicity.

PS 470 HARMONIZATION OF CYCLIC SILOXANES PBPK MODEL STRUCTURES.

Y. Tan[1], Y. Yang[1], M. E. Andersen[1], H. Clewell[1] and K. P. Plotzke[2]. [1]*The Hamner, Research Triangle Park, NC and* [2]*Dow Corning Corporation, Midland, MI.*

Cyclic siloxanes,D4 and D5, are low molecular weight siloxanes which are mainly used as intermediates in the production of silicone polymers. D4 and D5 can also be found in various consumer products. The general population may be exposed to low levels of these siloxanes through dermal, inhalation and oral routes while workplace exposures mainly occur by inhalation. There are currently six published PBPK models describing aspects of the pharmacokinetics of D4 and D5 for various exposure routes in rat and human. Each model addressed the unique kinetic properties of D4 and D5 (highly lipophilic yet with low blood:air partition coefficient)and provided a reasonable description of the available time-tissue data. However, these models also had specific characteristics, differing among the suite of models, that accommodated the kinetic differences among the different exposure routes and the differing breadth of specific data sets. In this work, we have developed an internally consistent, multi-dose route, multi-compound PBPK model to describe the variety of datasets across species, routes, and compounds. Our approach was to use inhalation and dermal exposure data to develop a 'base' model that was then used to evaluate results from oral administration. The time-course behavior of D4 in plasma after oral gavage is very different from the inhalation and dermal kinetics. The base model underestimated the exhalation rate and plasma concentration in the postexposure period after oral exposure. To account for this route-specific kinetics, a process whereby the orally administered compound(s) are assumed to enter the systemic circulation as a micro-emulsion that distributes to the various lipid pools and the liver, and becomes further distributed to the body via effluent venous blood was incorporated into the base model. Although this approach improved model fits to the oral uptake data, it is unclear whether the differences between the base model and oral uptake model are intrinsic to oral administration or an artifact of high bolus doses in lipophilic vehicles.

PS 471 ADDRESSING PUBLIC EXPOSURES TO PRIORITY SOLVENTS USING HUMAN PBPK MODELS.

M. A. Ray[1], S. E. Ritger[1], M. Mumtaz[2], P. Ruiz[2], C. Welsh[3], D. A. Fowler[4], D. Keys[1] and J. Fisher[1]. [1]*College of Public Health, University of Georgia, Athens, GA,* [2]*Computational Toxicology Laboratory, Division Toxicology and Environmental Medicine, Agency for Toxic Substances and Disease Registry (ATSDR), Atlanta, GA,* [3]*Division of Regional Operations, Agency for Toxic Substances and Disease Registry (ATSDR), Atlanta, GA and* [4]*Division of Health Assessment and Consultation, Agency for Toxic Substances and Disease Registry (ATSDR), Atlanta, GA.*

Determining public health outcomes from exposure to environmental chemicals is a challenging and controversial research area. ATSDR is mandated by Congress to identify significant human exposure levels, develop methods to determine such exposures, and design strategies to mitigate them. Translational research is underway to develop human physiologically based pharmacokinetic (PBPK) models for priority environmental contaminants. This research focuses on development of a generic PBPK model structure for simulation of three routes of exposure (oral ingestion, dermal absorption, inhalation) to eight priority VOCs (acetone, perchloroethylene, chloroform, trichloroethylene, benzene, carbon tetrachloride, methylene chloride,

and vinyl chloride). Coded using Berkeley Madonna simulation software, the model consists of blood, rapidly and slowly perfused tissue, fat, liver, kidney, and skin compartments. Previously published human PBPK models were slightly modified to conform to our model structure, while chemical specific parameters for each VOC were retained. To evaluate model fidelity, predictions of our generic model were compared with published model predictions as well as published kinetic data sets. Good agreement was generally obtained for all VOCs. PBPK models allow evaluation of multiple exposure pathways and describe the impact of physiological state (e.g. enzyme induction, exercise), disease state (e.g. obesity, asthma, diabetes), reproductive state, life stage and life style on dosimetry and public health. This work is supported by a contract with Eastern Research Group (Contract no. 0133.19.011/1 for the CHCL3 model) and Cooperative Agreement 1U01US000078 (for additional VOCs).

PS 472 DEVELOPMENT OF A RAT PBPK MODEL FOR A PROMINENT N-ALKANE, TETRADECANE, FOUND IN AVIATION FUELS JP-8 AND S-8.

S. A. Martin, R. T. Tremblay and J. W. Fisher. *Environmental Health Science Department, University of Georgia, Athens, GA.*

The US Air Force is transitioning from petroleum-based Jet Propellant-8 (JP-8) to a 50:50-blend of JP-8 and synthetic jet fuel (S-8) derived from a Fischer-Tropsch synthetic process using natural gas or coal. The goal of this project is to develop a PBPK hydrocarbon mixture model. In the present study we report on the development of a PBPK model for inhaled aerosolized tetradecane (C14). Rats were exposed nose-only to 4 hr 89 mg/m3 of aerosolized C14 with 84% representing aerosol droplets size 4μm MMAD. C14 was also monitored in fuel studies in which male F344 rats were exposed via nose-only inhalation to aerosolized fuel concentrations of 900, 1060, 200 mg/m3 for JP-8, S-8, 50:50 blend. In these exposures C14 was present at 5.4 mg/m3 (JP-8), 11.7 mg/m3 (S-8), and 1.0 mg/m3 (Blend) representing approximately 1% of each fuel droplet. Exposures to a "designer mixture" of eight prominent fuel hydrocarbons were also conducted with C14 present at 62 and 137 mg/m3, comprising 14% of each droplet. Droplet size range for these studies was 1-3μm. The C14 PBPK model compartments consisted of the liver, fat, brain, richly and slowly perfused tissues. The model was configured for gas exchange of the vapor phase of C14 and for deposition and systemic uptake of aerosol droplets in the upper respiratory tract and deep lung. Fractional deposition of droplets was predicted using the Multiple-Path Particulate Dosimetry (MPPD2) model. Interesting features of this C14 PBPK model include rapid uptake and slow elimination from fat, excretion into feces, bidirectional diffusion behavior vs flow-limited, and rapid uptake of aerosol droplets. For C14-only exposure, the model adequately simulates tissue kinetic behavior compared to in vivo time course data points. In the presence of fuel, simulations also tracked well with tissue loading and clearance in the rat, responding to MPPD2 model predicted regional deposition. This is the largest n-alkane known to be used in a PBPK model. (AFOSR Grant #: FA9550-07-1-0132)

PS 473 DEVELOPMENT OF A MULTIROUTE HUMAN PBPK MODEL FOR BROMODICHLOROMETHANE (BDCM).

E. Kenyon[1], T. Leavens[2] and R. Pegram[1]. *[1]ORD/NHEERL/ETD/PKB, U.S. EPA, Research Triangle Park, NC and [2]College of Veterinary Medicine, NCSU, Raleigh, NC.*

BDCM is an animal carcinogen and developmental toxicant. Due to its presence as a disinfection byproduct in finished drinking water, BDCM may pose a risk for exposure via ingestion, inhalation or dermal exposure. Utilizing a unique data set in which human subjects were exposed to BDCM by both the dermal and oral routes (Leavens et al., 2007), we have developed a refined human multi-route PBPK model. Compartments in the model are skin, liver, gut, fat, brain, kidney, and slowly and rapidly perfused tissue groups; tissue transport is blood-flow limited and metabolism occurs in the liver by a single pathway. Chemical-specific parameters for tissue solubility and metabolism as well as initial organ volumes and blood flow rates were obtained from the literature; subject-specific values were available for height, weight and fat volume. The preliminary model adequately predicted individual blood time course data following dermal exposure, whereas the same model poorly predicted blood time course data following oral exposure. Sensitivity analysis (SA) allowed identification of parameters that were uniquely sensitive for dermal compared to oral exposure and identification of parameters most appropriate to estimate from the available human data. Based on SA, parameters governing oral absorption and metabolism were critical for the oral route, whereas for the dermal route skin permeability was the single most influential parameter. Model-based analysis suggests the need for a second pathway for metabolic clearance (a mechanism not included in other PBPK models for BDCM). Preliminary in vitro studies support this conclusion. These results point to the critical role for model-based analysis in both the design and interpretation of data from human studies. (This abstract does not necessarily reflect Agency policy).

PS 474 CONTRIBUTION OF TOXICOKINETIC MODELING FOR THE STUDY OF THE IMPACT OF PHYSICAL EXERTION ON THE ASSESSMENT OF OCCUPATIONAL EXPOSURE TO ACETONE (ACE).

A. Bérubé[1], G. Charest-Tardif[1], I. Sari-Minodier[2] and R. Tardif[1]. *[1]GRIS, Santé environnementale et santé au travail, Université de Montréal, Montr√©al, QC, Canada and [2]Laboratoire de biogénotoxicologie et mutagenèse environnementale, Aix-Marseille Université, Marseille, France.*

This study aims at assessing the impact of workload on urinary levels of ACE and its potential influence in the previous determination of the corresponding biological exposure indices (BEI). A physiologically based pharmacokinetic (PBPK) model was developed and validated in order to simulate weekly occupational exposure (8h/day, 5 days) to ACE at the threshold limit value (TLV) according to the American Conference of Governmental Industrial Hygienists (500 ppm). Simulations were then conducted under workload levels corresponding to rest (12.5 W), 25 W and 50 W and the impact on the urinary level of ACE at the end of the last shift was studied. Other values of ACE excretion such as blood level and expired air concentration for different workloads were also examined. The predicted values were compared to the results of both experimental and field studies which supported the adoption of the current BEI (50 mg/L) for ACE. For an exposure to TLV, the end-of-shift values for workloads of 25 W and 50 W showed 1.6-fold and 3.5-fold increases compared to the value at rest (27,9 mg/L), respectively. These results show that not taking into account the workload level leads to an underestimation of the actual exposure for workers whose physical activity is as great as 50 W. Also, there was a slight accumulation of ACE among the week (5-days), with a prior-to-shift value of 6.9 mg/L at 50 W on the last day, which is about 4.5 higher than the given endogenous level (1.5 mg/L). The PBPK model described well the magnitude of the significant impact of workload on ACE BEI and internal exposure. The predicted values revealed that workers with heavy tasks may be at greater risk. Overall, these results showed that workload should be taken into account when interpreting biomonitoring exposure indicators for ACE for an optimal protection of workers. (Supported by Afsset, France and IRSST, Canada)

PS 475 PBPK MODELING AS A TOOL FOR PREDICTING THE WOMEN LIFETIME EXPOSURE OF PBDE: FROM INFANTS TO ELDERLY.

C. Emond and M. Pelekis. *Environmental and occupational health, University of Montreal, Montreal, QC, Canada.*

Polybrominated diphenyl ethers (PBDE) are brominated flame retardants. Because PBDEs migrate to humans, and because children, infants and fetuses are thought to be more sensitive particularly for non-cancer effects there is a need to understand the tissue distribution. The objective of this project was to use a PBPK model to characterize the influence of age-specific physiological parameters on the body burden during lifetime exposure to PBDEs, including gestational status. A PBPK model has been developed to describe the ADME for BDE-47 in women during their lifetime including lactational and transfer from mother to fetus. This model contained 6 compartments: brain, liver, fat, rest of the body, placenta, and fetus and are connected through systemic circulation. Model parameters were obtained from the literature. Schecter et al (2007) reported that blood concentration in women range from 1.92 and 175.2 ng BDE47/g lipid corresponding to 48% of total BPDEs. Simulations were performed to predict the exposure that will result in equivalent tissue concentrations for a woman who is 25 years old. The major factor influencing the tissue concentration is the elimination such as extraction coefficient (E). For example, considering a low blood concentration measure of 1.93 ng/g lipid in blood at 25 year old woman this women need to be exposed to 0.00122 ug of BDE-47/kg of body weight /day for a (E= 0.000) or at 94 ug of BDE-47/kg of body weight/day for a (E= 0.005). Similarly, for the higher concentration of 75.2 ng of BDE-47/g lipid in blood at 25 year old this women will be exposed to 0.11 ug of BDE-47/kg of body weight /day for a (E= 0.000) or 85.5 ug of BDE-47/kg of body weight/ day for (E= 0.005). Development of lifetime PBPK model provides a powerful tool for risk assessment. During lifetime, women go through different critical stages thus, understanding the relationship between these critical stages and dose metric parameters are important determinants in understanding the latency of disease, the clinical signs of which may appear many years after the exposure.

PS 476 PHYSIOLOGICAL MODEL BASED EVALUATION OF DIFFERENTIAL GASTROINTESTINAL ABSORPTION PATTERNS OF TCDD IN RAT AND HUMANS: IMPLICATIONS IN HUMAN HEALTH RISK ASSESSMENT.

M. Pelekis and C. Emond. *University of Montreal, Montreal, QC, Canada.*

Human health risk assessments for 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) involve extrapolation of data from animals to humans and/or data directly measured in humans. Physiologically based pharmacokinetic model (PBPK) is a tool that has been used in TCDD human health risk assessment. Exposure of TCDD in animals and humans results from oral absorption. In almost all PBPK modeling activities published to date, absorption of TCDD is described as a first order process. The goal of this study was to: (1) improve the physiologically based absorption modeling using GastroPlus®, (2) investigate the difference of the amount of TCDD absorbed in rats and humans and (3) to assess its implications in risk assessment. GastroPlus® simulates the absorption and pharmacokinetics of orally dosed compounds and is based on the ACAT model. Each Gastrointestinal tract (GIT) compartment is described with data including volumes, transit times, lengths, and radii. Absorption is modeled via a system of linear and non-linear rate equations that consider 6 compound states, 18 compartments and 3 states of excreted material. The results show that an oral administration of 1mg per day in the fasted and fed rats resulted in approximately 50% difference in the amount absorbed with higher absorption observed in the fasted rat. Similarly, an oral administration of 1mg per day in the fasted and fed human adults resulted in approximately 250 % of difference in the amount absorbed with higher absorption observed in the fasted humans. In addition, the absorption of TCDD in both rats and humans occurred predominantly in the duodenum and jejunum. The total amount absorbed in fasted rats and humans is approximately the same as are the respective amounts absorbed in the respective GIT compartments. However, the total amount absorbed in fed rats is approximately 3X times higher than the amount absorbed in fed humans and the same ratio applies to the respective GI compartments. The implications of the differential absorption in the human health risk assessment estimates are analyzed.

PS 477 USE OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODEL TO PREDICT TISSUE DISPOSITION IN PIGS FED MELAMINE.

J. L. Buur[1], R. E. Baynes[2] and J. E. Riviere[1]. [1]*College of Veterinary Medicine, Western University of Health Sciences, Pomona, CA and* [2]*Center for Chemical Toxicology and Pharmacokinetics, NCSU, Raleigh, NC.*

The recent detection of melamine in milk products and the previous detection of melamine in the feed of swine and poultry raised important food safety concerns. Specifically, there is concern about human exposure from contaminated swine, poultry, or dairy products. The purpose of this study was to develop a PBPK model for melamine in swine that could be used to predict a safe withholding period. Initial PBPK models were focused on melamine disposition in rats following oral bolus exposure. This resulted in a 4 tissue compartment PBPK model that compared favorably (R^2 = 0.59 - 0.76) with limited published tissue data. Allometric strategies were then used to model melamine disposition in pigs following IV bolus exposure that resulted in better predictions (R^2 = 0.89) for plasma data. The PBPK model was further refined and used to predict a meat withdrawal time of 21 hours for a 5.12 mg/kg single oral bolus. Although there is no available in vivo data to validate these estimates, these studies were consistent with FDA reported levels and further supported our hypothesis that food animals exposed to melamine-contaminated feed should be withheld from slaughter for at least 1-2 days. These recommendations are point estimates and do not reflect possible population variability that could result in withholding times 2-3 times longer or more than our current estimates. Further studies are needed to improve the validation of our model assumptions. However, even with limited data, this approach can predict internal dose metrics in swine and be used to estimate human exposure to melamine in the food supply.

PS 478 PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODELING OF BROMODICHLOROMETHANE IN HUMAN.

E. Demchuk and H. Hansen. *Computational Toxicology Laboratory, Agency for Toxic Substances and Disease Registry, Atlanta, GA.* Sponsor: B. Fowler.

Bromodichloromethane (BDCM) is a major brominated trihalomethane found in public water supplies after chlorine disinfection. The sources of water contamination with bromine include the Superfund National Priority List (NPL) sites. The ATSDR Sequoia/HazDat database suggests that approximately 15% of NPL sites are bromine contaminated. The common routes of exposure to BDCM include: inhalation of near-saturated air during showering and bathing, concomitant long-term contamination of air circulation systems in living areas, transdermal uptake (especially associated with swimming pools and bath tubs), and oral ingestion with drinking water. Despite wide-spread exposures, the health effects of BDCM in humans are not fully understood, and safe exposure levels for routes other than oral have not been established. The present report describes a new physiologically-based pharmacokinetic (PBPK) model specifically developed and parameterized to assess BDCM exposures in humans. The flow-limited PBPK model includes lung, skin, liver, kidney, fat, slowly and rapidly perfused-tissue compartments linked by the systemic circulation. The model was validated using actual human exposure data. Additional realism to the model was conveyed by appropriate consideration of differences in human physiology introduced by changing exercise load. It was found that the transdermal route may contribute significantly under the whole-body exposure conditions. The transdermal route may become dominant in well-evacuated environments. It was found that contribution of transdermal exposures for competitive swimmers could be up to 3-4 times greater than from inhalation exposures.

PS 479 AGE- AND GENDER-STRUCTURED DISTRIBUTIONS FOR PHYSIOLOGICAL PARAMETERS: ASSESSMENT OF HUMAN VARIABILITY IN THE EXPOSURE-INTERNAL-DOSE RELATIONSHIP FOR DICHLOROMETHANE (DCM).

P. M. Schlosser[1], A. Bale[2] and G. S. Cooper[2]. [1]*NCEA, U.S. EPA, RTP, NC and* [2]*NCEA, U.S. EPA, Washington, DC.*

The U.S. EPA is revising its IRIS assessment for DCM, a high production volume chemical that has been used in paint strippers, in manufacturing drugs, film coatings, electronics, and polyurethane foam, and in other processes. DCM exposure causes a variety of effects in multiple organs of rats and mice. David et al. (Regul Toxicol Pharmacol, 2006, 45:55-65) developed a PBPK model to describe DCM dosimetry among humans. Markov-Chain Monte Carlo analysis was used to estimate distributions for metabolic parameters but then a full-population distribution for the polymorphism in glutathione S-transferase was used. The body weight (BW) distribution ranged 7-133 kg, which includes individuals from several months old to obese adults. But when we set physiological parameters for a 1- or 70-year-old person based on Clewell et al. (Toxicol Sci, 2004, 79:381-93), the predicted internal doses fell well outside the distribution otherwise predicted. Thus, the physiological parameter distributions used by David et al. do not appear to fully characterize human variability. We then developed distribution functions for key physiological parameters, including BW, in the U.S. population based on census data and other published analyses. Age and/or gender could either be specified or randomly chosen from a full population distribution (gender ratio depends on age). Then age- (and gender-)specific distributions were defined for BW, alveolar ventilation, cardiac output, and fat and liver fractions of BW. Using these revised distributions, for example, increased the ratio of the 99th percentile:mean liver-specific GST-mediated metabolism for the general population from 3.5 to 5.6. The mean value for this metric increased from 3.6 to 6.4x10^{-6} mg/L liver/day. If model predictions are to replace default methods (and uncertainty factors), the model should fully describe the population variability. The analysis, results, and opinions presented are those of the authors and do not necessarily represent EPA policy or decisions.

PS 480 EVALUATING PBPK MODELING TECHNIQUES USING CALIBRATION DESCRIPTORS.

J. L. Matthews[1], M. V. Smith[1] and G. E. Kissling[2]. [1]*SRA International, Inc., Durham, NC and* [2]*NIEHS, Research Triangle Park, NC.* Sponsor: S. Atwood.

PBPK models have demonstrated their usefulness in both the human and rodent contexts and are increasingly used in risk assessment. One of their applications is the prediction of quantities not directly observed, such as tissue concentrations over time and the area under such concentration curves (AUC). Published models rarely have confidence intervals for estimated parameters or model predictions. The utility of these confidence intervals depends on their reliability, but that may be affected by model selection. To investigate these issues, we focus on the transport of compound into tissue: the biologically-relevant diffusion-limited compartments or simplified flow-limited compartments. We constructed a generic eleven compartment PBPK model with diffusion-limited liver and adipose compartments and used a protocol typical for the National Toxicology Program toxicokinetic studies to generate test data. One thousand test data sets were created for each of several compounds with varying diffusion characteristics. A series of three models were evaluated for the compounds, including diffusion-limited transport for both liver and adipose, for liver but not adipose, and flow-limited transport for both liver and adipose. Utilizing simplex-based optimization routines, the simulated data sets are

used to estimate parameter sets associated with all three PBPK models. Model selection statistics are computed and evaluated. Confidence regions for both parameter estimates and the AUC for tissue compartments are found and their coverage evaluated. The results suggest that including biologically-relevant diffusion-limited compartments in PBPK models, even for compounds which are essentially flow-limited, may yield more reliable confidence intervals for model predictions despite requiring the estimation of additional parameters.

PS 481 MITOCHONDRIAL FUNCTION AND OXIDATIVE STRESS IN DIABETIC NEPHROPATHY IN STREPTOZOTOCIN-TREATED RATS.

L. H. Lash and Q. Zhong. *Pharmacology, Wayne State University Sch. Med., Detroit, MI.*

Male S-D rats were given streptozotocin (STZ; 60 mg/kg, ip) to induce diabetes. We investigated cellular and mitochondrial glutathione (mtGSH) status and energetics in renal cortical mitochondria and primary cultures of proximal tubular (PT) cells from STZ-treated rats at 30 and 90 days post-STZ (with age-matched control rats). Diabetic nephropathy (DN) typically develops at 45-60 days post-STZ. We tested the hypothesis that diabetes, and ultimately DN, are characterized by enhanced oxidative stress that leads to mitochondrial dysfunction and that, while there may be an initial up-regulation of mtGSH transport, these carriers are down-regulated as rats progress to a state of DN. Histopathological changes were observed even at 30 days and were more extensive at 90 days. Primary cultures of PT cells from 30-day STZ rats exhibited greater morphological injury than those from control rats after exposure to thiol oxidants (tert-butyl hydroperoxide, methyl vinyl ketone) or a mitochondrial toxicant (antimycin A). Although mitochondrial State 3 respiration with succinate as substrate was significantly higher in renal mitochondria from STZ rats (respiratory control ratio = 4.74 in STZ vs. 3.41 in control), PT cells from control rats exhibited higher mitochondrial membrane potential (JC-1 fluorescence) than PT cells from STZ rats. Levels of reactive oxygen species (2,7-dichlorofluorescein fluorescence) were significantly higher in PT cells from STZ rats as well, consistent with an enhanced oxidative stress. Although rates of mitochondrial GSH transport were only modestly different between control and STZ rats, mRNA expression of the two mitochondrial GSH carriers (the dicarboxylate carrier [Slc25a10] and the 2-oxoglutarate carrier [Slc25a11]) was significantly higher in STZ rat kidney at 30 days, consistent with an initial up-regulation of mitochondrial GSH transport. These results demonstrate that diabetes causes renal oxidative stress and mitochondrial dysfunction and that there are early and modest compensatory changes in mitochondrial GSH transport.

PS 482 MULTIDRUG RESISTANCE PROTEIN 2 MEDIATES TRANSPORT OF N-ACETYL-S-(1, 2-DICHLOROVINYL)-L-CYSTEINE.

N. Abuladze[1], K. Tsirulnikov[1], M. Koag[1], K. Faull[1], G. Bondar[1], W. Dekant[2], I. Kurtz[1] and A. Pushkin[1]. *[1]UCLA, Los Angeles, CA and [2]University of Würzburg, Würzburg, Germany.*

N-acetyl-S-(1,2-dichlorovinyl)-L-cysteine (Ac-DCVC) is a metabolite of a common industrial contaminant and potent nephrotoxicant trichloroethylene (TCE). Ac-DCVC may be deacetylated in the renal proximal tubule by aminoacylase 3 (AA3), and the product of this reaction, DCVC, may be transformed into toxic/mutagenic products. Both Ac-DCVC and DCVC are found in the urine of mammals exposed to TCE but the nature of the apical transporter(s) mediating transport of Ac-DCVC is unknown. In the present study we explored the hypothesis that the multidrug resistance protein 2 (Mrp2) is involved in the excretion of Ac-DCVC in renal proximal tubules. Using immunohistochemistry and immunoelectron microscopy, we localized Mrp2 to the apical membrane of mouse S1 nephron segment where it co-localized with AA3. Mouse Mrp2 was then expressed in the mouse proximal tubule mPCT cell line. Microsomal membranes were isolated from these cells and used to make inside-out vesicles. The ability of Mrp2 to transport Ac-DCVC into the vesicles was first evaluated in an assay, which measured the effect of Ac-DCVC on the ATP-dependent transport of glutathione. Ac-DCVC significantly inhibited the transport rate of glutathione whereas DCVC had no effect. The inhibiting effect of Ac-DCVC was higher than the typical substrate of Mrp2, estradiol 17-β-D-glucuronide. Several other mercapturic acids, good substrates of AA3, also significantly inhibited the ATP-mediated transport of glutathione by Mrp2. The transport of Ac-DCVC by Mrp2 was confirmed using LC-MS whereas no transport of DCVC was detected. The results suggested that Mrp2 is involved in the renal excretion of Ac-DCVC. Given the much lower toxicity of Ac-DCVC to S1 than S2 and S3 proximal tubules, it could be suggested that the apical localization of AA3 may protect from the Ac-DCVC mediated toxicity in S1 tubule via prevention of cytoplasmic deacetylation of Ac-DCVC. In addition, Mrp2 and AA3 may form a transport metabolon mediating the coordinated transport and deacetylation of Ac-DCVC. (NIH ES12935)

PS 483 IMPAIRED RENAL FUNCTION AND GLUCOSE METABOLISM IN CALCINEURIN A ALPHA KNOCKOUT MICE.

R. N. Reddy[1, 2] and J. L. Gooch[1, 2]. *[1]Nephrology, Emory University, Atlanta, GA and [2]Atlanta VA Medical Center, Atlanta, GA.*

Calcineurin, a serine/threonine protein phosphatase was originally discovered as a target of the immunosuppressant drug cyclosporine and since then calcineurin inhibitors have been successfully employed to prevent rejection of transplanted organs in humans. However, long term use of cyclosporine results in adverse drug reactions including nephrotoxicity and post-transplantation diabetes mellitus. Availability of catalytic subunit isoform specific calcineurin knockout mice has led to important advances in our understanding of cyclosporine-induced toxicity. Previously, immunological defects in calcineurin A beta knockout mice have been reported. Due to the early lethality of the calcineurin A alpha knockout mice, evaluation of role of calcineurin A alpha had been difficult. Recently, we rescued these mice from early lethality and mice were evaluated for important organ function tests. Calcineurin A alpha knockout mice show significant increases in the blood urea nitrogen (BUN) and decreases in glomerular filtration rate (GFR) with inflammatory and fibrotic changes upon histopatholgical examination of the kidneys which are similar to those observed in transplant patients with cyclosporine-induced nephrotoxicity. These findings are also supported by increased production of TGFbeta and fibronectin by alpha knockout cells. These mice also showed elevated blood glucose levels with decreased tolerance to intra-peritoneal glucose administration which could be similar to cyclosporine-induced post-transplantation diabetes mellitus, however further evaluation is required. Taken together these results show that the pathophysiology of calcineurin A alpha knockout mice is similar to calcineurin inhibitor toxicity and that these mice could be a useful model in studying the mechanisms of calcineurin inhibitor toxicity.

PS 484 2-BROMOETHANAMINE (BEA) INDUCES PAPILLARY NECROSIS BY IMPAIRING THE FUNCTION OF TONEBP UNDER HYPERTONIC STRESS IN KIDNEY CELLS.

M. A. Lanaspa, A. Andres-Hernando, C. J. Rivard, A. E. Crunk, N. Li and T. Berl. *Renal Medicine, University of Colorado Health Sciences Center, Denver, CO.* Sponsor: C. Franklin.

Renal papillary necrosis (RPN) may occur as a consequence of long-term abuse of analgesics including nonsteroidal antiinflamatory drugs (NSAIDs). While this is probably mediated by direct toxicity of the drug, the molecular mechanisms whereby NSAIDs induce papillary necrosis are not well-understood. A major limitation to the study of RPN pathogenesis is the required chronic exposure before clinical detection of injury. In the present study, 2-bromoethanamine (BEA), a well-known papillotoxic drug, was employed to simulate rapid NSAID toxicity using inner medullary collecting duct (IMCD3) cells. While exposure to 10 μM BEA had no effect on cellular viability under isotonic conditions, when cells were subjected to a sublethal hypertonic stress (550 mOsm/kgH2O) a 50% lost in cell viability was determined in the first 24 hours and nearly complete cell death was determined after 48 hours. This data suggest that BEA exerts cytotoxicity only under hypertonic conditions. Since TonEBP (Tonicity Enhacer Binding Protein) is a transcription factor that is critical to cell survival in hypertonic conditions, we undertook experiments to examine the effect of BEA on TonEBP expression. Exposure of cells to 10 μM BEA resulted in a substantial reduction in TonEBP protein expression after 24 hours. Furthermore, hypertonicity induced expression of TonEBP target genes including aldose reductase, betaine/GABA transporter and Hsp70 was markedly blunted in BEA treated cells. In addition, in BEA treated IMCD3 cells, TonEBP was not translocated to the nucleus under acute hypertonic stress for proper transcription of target genes. Finally, we found a substantial decrease in TonEBP expression in medullary kidney tissues from mice injected with a single IP dose of BEA (150 mg/kg). Our data therefore supports the notion that TonEBP is a potential target for BEA and possibly other nephrotoxins leading to the process of papillary necrosis.

PS 485 POTENTIAL TOXICITY OF GLUCOSAMINE MEDIATED THROUGH TRANSFORMING GROWTH FACTOR β (TGFβ).

A. A. Ali[1], S. M. Lewis[1], H. L. Badgley[1], W. T. Allabin[1], V. H. Frankos[2] and J. E. Leakey[1]. *[1]Office of Scientific Coordination, NCTR, Jefferson, AR and [2]Division of Dietary Supplement, FDA-CFSAN, College Park, MD.*

POTENTIAL TOXICITY OF GLUCOSAMINE MEDIATED THROUGH TRANSFORMING GROWTH FACTOR β (TGFβ). A.A. Ali, S.M. Lewis, H. L. Badgley, W.T. Allaben, V. H. Frankos* and J.E.A. Leakey. Office of Scientific Coordination, National Center for Toxicological Research. Jefferson, AR 72079. *FDA-CFSAN, 5100 Paint Branch Parkway, College Park, MD 2074

Osteoarthritis, a degenerative joint disease, is the most common form of arthritis affecting at least 20 million Americans, a number that is expected to double over the next two decades. While it is estimated that up to 5 million Americans have consumed the dietary supplement (H J Kennedy: Clin. Ther 27:1847-1858, 2005), glucosamine as a treatment for joint pain or as a prophylactic for healthy joints, its efficacy, safety and mode of action remain controversial. In this study, five concentrations of glucosamine (15, 30, 120, 300 and 600 mg/Kg/day, oral gavage), separate and in combination with chondroitin sulfate, were given to lean Zucker rats for 6 weeks. While such treatment did not significantly alter serum insulin and leptin levels, urinary glucosamine concentrations, detected by HPLC, were increased by oral glucosamine treatment. Glucosamine (300 or 600 mg/kg/day) increased TGFβ mRNA content in liver and kidney tissues. Two-fold up regulation of TGFβ mRNA was detected by real time PCR in liver of the rats sacrificed at 1 and 4 hours after the last treatment. A two-fold increase in TGFβ mRNA expression in kidney from rats sacrificed at 4 hours after the last glucosamine (600 mg/Kg/day) treatment was also detected. TGFβ is known to stimulate extracellular matrix formation in responsive cell types. While increased extracellular matrix can be beneficial to damaged cartilage in arthritic joints, it can produce pathogenic sclerotic conditions in kidney (S. Chen: Seminars in Nephrology, 23:532-543, 2003). Research was supported in part by IAG 224-93-001 between the NCTR/FDA and NIEHS/NTP.

PS 486 IN THE RAT, GAMMA-HYDROXYBUTYRATE IS DETOXIFIED NOT ONLY BY HEPATOCYTES BUT ALSO BY RENAL PROXIMAL TUBULES: A CARBON 13 NMR STUDY.

M. El Hage, G. Baverel and G. Martin. *Metabolomics and Metabolic Diseases, INSERM Unit # 820, Lyon Cedex 08, France.*

Gamma-hydroxybutyrate (GHB) is both a physiological brain metabolite and a drug of abuse (date rape drug). We have conducted a study to evaluate the capacity of the kidneys to eliminate such a compound that, when ingested in gram amounts, remains at high concentrations in the blood for hours and exerts toxic effects. For this, renal proximal tubules isolated from fed and 48h-fasted Wistar rats were incubated at 37°C with 1 and 5 mM of unlabelled GHB or with [U-13C]GHB in Krebs-Henseleit medium with an atmosphere of 5%CO2/95%O2. Precision-cut liver slices prepared from fed and 48h-fasted rats were also incubated under the same experimental conditions. At the end of incubation, substrate removal and product formation were measured by 13C NMR spectroscopy using a high field NMR spectrometer (500 MHz). At both 1 and 5 mM concentration, unlabelled and labelled GHB was shown to be metabolized not only by liver cells, which are considered to be the main cells responsible for GHB disposal in vivo, but also at significant rates by proximal tubular cells. The nutritional state did not influence GHB utilization either in liver or in renal cells. The NMR spectra obtained did not reveal any labelled product of GHB metabolism in renal proximal tubules whereas some glucose became labelled after incubation of liver slices; although GHB was not a good gluconeogenic precursor, this reveals that GHB carbons were incorporated into the oxaloacetate pool. The latter data indicate that, in both liver and renal proximal cells, most of the GHB metabolized was converted into CO2, presumably by the beta-oxidation pathway. In tubules from 48h-fasted rats, 5 mM GHB only slightly inhibited the removal of lactate (1 and 5 mM) and glucose synthesis. This study establishes that, beside the liver, the kidneys may significantly contribute to the removal and metabolism of GHB in vivo without dramatically altering the renal metabolism of lactate, a major substrate of the kidneys.

PS 487 *IN VITRO* NEPHROTOXICITY INDUCED BY AMINOCHLOROPHENOLS.

D. Palmer[2], A. Sweeney[1], A. Kraynie[1], C. Schuetz[1], D. K. Anestis[1] and G. O. Rankin[1]. *[1]Pharmacology, Physiology & Toxicology, Marshall University, Huntington, WV and [2]West Virginia State University, Institute, WV.*

Chloroanilines are widely used as chemical intermediates in the preparation of dyes, agricultural chemicals and pharmaceuticals. In mammals, chloroanilines and their phenolic metabolites are known nephrotoxicants. The purpose of this study was to examine the structure-nephrotoxicity-relationships among select aminochlorophenols using a rat renal in vitro model and to explore the role of reactive aminochlorophenol-derived chemical species in 4-amino-2-chlorophenol (4A2CP)-induced cytotoxicity. Isolated rat renal cortical cells (IRCC) were obtained from male Fischer 344 rats and incubated in Krebs-Henseleit buffer (pH = 7.37) at 37 degrees C under a 95% oxygen/5% carbon dioxide atmosphere with shaking. 4-Aminophenol (4AP), 4A2CP, 4-amino-3-chlorophenol (4A3CP), 4-amino-2,6-dichlorophenol (4A2,6DCP), or 2-amino-4,5-dichlorophenol (2A4,5DCP) (0.5 mM or 1.0 mM final bath concentration) or vehicle was added to 3 ml of IRCC suspension (~4 million cells/ml) and incubation continued for 60 minutes. In some experiments using 4A2CP, cells were pretreated with glutathione (1.0 mM), N-acetyl-L-cysteine (NAC, 2.0 mM), ascorbate (1.0 mM), piperonyl butoxide (PIBX 1.0 mM) or indomethacin (1.0 mM). Cytotoxicity was measured by quantitating the release of lactate dehydrogenase (LDH). At 0.5 mM, 4A2,6DCP and 4A2CP showed marked cytotoxicity, while 4AP and 2A4,5DCP were cytotoxic at 1.0 mM. These results demonstrate that the number and position of chloro groups determine the degree of toxicity. Also, the position of the hydroxyl and amino groups influences the cytotoxicity. Glutathione, NAC, ascorbate and PIBX markedly attenuated 4A2CP cytotoxicity, while indomethacin did not inhibit cytotoxicity. These results suggest that reactive cytotoxic chemical species are produced from 4A2CP in IRCC, but cyclo-oxygenase does not bioactivate 4A2CP to a toxic species. (Supported by NIH Grant 5P20RR016477 to the West Virginia IDeA Network for Biomedical Research Excellence)

PS 488 POTENTIAL ROLE OF OXIDATIVE STRESS IN RESVERATROL PROTECTION OF CISPLATIN *IN VITRO* RENAL TOXICITY.

M. Valentovic and J. G. Ball. *Pharmacology, Physiology and Toxicology, Marshall University School of Medicine, Huntington, WV.*

Nephrotoxicity is a major adverse effect associated with cisplatin, a cancer chemotherapeutic agent. The development of interventions to delay or prevent the cisplatin associated renal toxicity would be of direct clinical relevance. Resveratrol (RES) is a naturally occurring phytochemical reported to possess some anticancer and antioxidant properties. This study tested the hypothesis that RES reduces the oxidative stress associated with cisplatin. Male Fischer 344 rats (200-250 g) were anesthetized with isoflurane and the kidneys were isolated, decapsulated and rinsed in 3 ml ice cold Krebs buffer. Renal cortical slices were prepared and 50-100 mg of tissue was pre-incubated with ethanol (VEH) or 30 ug/ml resveratrol (RES, final concentration) for 30 min at 37oC under an oxygen atmosphere. The tissue were then incubated for 120 min in 3 ml oxygenated Krebs containing 0, 75, or 150 ug/mL cisplatin in an oxygen atmosphere and constant shaking at 37oC. Loss of membrane integrity was evaluated as leakage of lactate dehydrogenase (LDH) following the 120 min incubation. Total renal glutathione, glutathione peroxidase activity, lipid peroxidation and protein carbonyls were measured as markers of oxidative stress. Lipid peroxidation was increased ($p<0.05$) by 75 and 150 ug/ml cisplatin relative to VEH values. A 30 min pre-incubation with RES prevented cisplatin-mediated increase in lipid peroxidation and protein carbonyls. RES pre-incubation and cisplatin did not alter glutathione peroxidase activity. RES also had no effect on cisplatin-mediated decline in total renal glutathione levels. These findings support the hypothesis that RES pre-incubation diminishes cisplatin in vitro renal toxicity and oxidative stress. (Supported by NIH Grant COBRE 5P20RR020180).

PS 489 ANALYSIS OF RENAL BIOMARKERS IN RAT URINE SAMPLES FROZEN FOR 44 MONTHS FROM A STUDY ON PUROMYCIN AMINONUCLEOSIDE (PAN).

M. Perron[1], R. Burnett[1], A. Reiniche[1], J. Briffaux[1], D. Eisinger[2] and J. Mapes[2]. *[1]MDS Pharmacology Services, St Germain sur l'Arbresle, France and [2]Rule Based Medicine (RBM), Austin, TX.*

Introduction- Following the FDA/EMEA suggestions on new renal biomarkers based on the C-Path Predictive Safety Testing Consortium (PSTC) submission, we quantified the proposed renal biomarkers in samples of urine collected from control and PAN-treated rats. The samples had been retained frozen (-20°C) for 44 months. Methods- Wistar and Sprague Dawley (SD) rats (3 males/group) received a single IV injection on day 0 of either saline or PAN at 100 mg/kg. A third group was given 75 mg/kg IV on days 0, 1 and 2. Urine was collected pre-treatment; serum and urine were collected on days 3 and 10 prior to autopsy and analyzed for standard parameters. Kidneys were processed and stained with either hematoxylin and eosin or Desmin and examined histologically. RBM's multiplex quantitative immunoassays developed for the PSTC work were used for quantifying the levels of β2 microglobulin, calbindin, clusterin, cystatin-C, kidney injury marker 1 (KIM-1) and 8 other markers. Results- Histologically, SD rats showed a similar slight mesangial thickening in the renal glomeruli with both treatment regimes. Wistar rats, however, showed a slightly greater change, particularly in the rats given a single dose – as clearly demonstrated with Desmin staining. Creatinin, total protein and N-acetyl-D-glucosaminidase recorded on Day 10, generally correlated with the histopathology. The frozen samples analyzed by RBM proved usable and several markers showed marked rises on Day 10 in all treated groups, with KIM-1, Clusterin and β2-Microglobulin being the most sensitive. Individual variation masked any such effects on Day 3. Conclusions- A panel of multiple biomarker assays were sensitive detectors of Puromycin-induced renal damage in urine stored for 44 months at -20°C. An elevation of several markers was evident on Day 10 (KIM-1, Clusterin, β2-Microglobulin and Neutrophil gelatinase-associated lipocalin in particular).

PS 490 SUBCHRONIC TOXICITY OF BETA-PICOLINE IN FISHER 344 RATS AND B6C3F1 MICE.

M. E. Wyde[1], S. Elmore[1], B. Sparrow[2] and M. Hejtmancik[2]. *[1]NTP, NIEHS, Research Triangle Park, NC and [2]Battelle, Columbus, OH.*

Beta-Picoline is a high production volume industrial chemical that is used as a chemical intermediate in the production of dyes, resins, insecticides, waterproofing agents, niacin and niacinamide. It is present at measurable levels in the drinking water of cities across the United States, leading to the potential for long-term exposure to the general population through water sources. The goal of the current study was to evaluate the subchronic toxicity of beta-picoline and provide data for the appropriate selection of doses for a 2-year bioassay with beta-picoline. Beta-picoline was administered to Fisher 344 rats and B6C3F1 mice in drinking water for 13 weeks at levels of 0, 78, 156, 312, 625, and 1250 mg/L. In mice, toxicity was not observed at any of the doses tested. A transient decline in water consumption in both sexes of the 1250 mg/L group was observed within the first few weeks of the study was overcome as the study progressed, suggesting an initial aversion to the palatability of this concentration of beta-picoline. In rats, there were no treatment-related effects on survival, clinical observations, organ weights, or gross lesions. There were significant decreases in terminal body weights and mean water consumption of both sexes of the 625 and 1250 mg/L groups. Hyaline droplets were observed in the kidneys of male rats exposed to 1250 mg/L and a few males exposed to 625 mg/L. Corresponding increases in renal α2u-globulin concentrations were observed in the 625 and 1250 mg/L male groups, but were also observed in the 312 mg/L males. There was also an increase in the severity of nephropathy in males in the 625 and 1250 mg/L groups and an increase in the incidence in the 625 and 1250 mg/L females compared to controls. The kidney was a target organ for beta-picoline toxicity in rats. The observed lesions in this study are consistent with α2u-globulin-associated nephropathy in male rats.

PS 491 N-CADHERIN EXPRESSION DICTATES ACUTE INJURY IN RESPONSE TO MERCURIC CHLORIDE AND SIMULATED ISCHEMIA.

A. R. Parrish[1] and R. C. Burghardt[2]. *[1]Systems Biology, College of Medicine, Texas A&M Health Science Center, College Station, TX and [2]Veterinary Integrated Biosciences, College of Veterinary Medicine, Texas A&M University, College Station, TX.*

Acute kidney injury often occurs on a background of chronic kidney disease. We have established an aging model of CKD in our laboratory that recapitulates the increased sensitivity to acute kidney injury seen in the elderly. However, the mechanisms underlying the increased susceptibility of the aging kidney to injury remain poorly defined. As previous studies from our laboratory have demonstrated that the N-cadherin/α-catenin complex is a target of acute nephrotoxic and ischemic injury in the kidney, we examined expression of N-cadherin in the aging kidney. Aging is associated with specific loss of N-cadherin and α-catenin expression. To test the hypothesis that the loss of N-cadherin/α-catenin expression increases the susceptibility of the aging kidney to injury, confluent cultures of L and LN cells, a cadherin/catenin-deficient cell line and L cells stably expressing N-cadherin and α-catenin, respectively, were challenged with mercuric chloride (10 μM) or a simulated ischemic insult (mineral oil overlay) for 2-6 hr in serum-free media. Cell viability was assessed using the neutral red viability assay. Interestingly, a significant loss of viability was seen at all timpeoints in L, but not LN, cells (20% of control in L cells; 100% of control in LN cells at 6 hr). A similar result was seen when the cells were challenged with a simulated ischemia; at 6 hr LN cell viability was 60% of control while L cell viability was 20% of control. The data suggests that the loss of the N-cadherin and α-catenin could account for the increased susceptibility of the aging kidney to injury as the lack of the N-cadherin/α-catenin complex is associated with increased injury.

PS 492 PHARMACOLOGICALLY-INDUCED MITOCHONDRIAL BIOGENESIS AIDS IN RECOVERY OF FUNCTION OF OXIDANT-INJURED RENAL CELLS.

J. A. Funk and R. G. Schnellmann. *Pharmaceutical and Biomediacal Sciences, Medical University of South Carolina, Charleston, SC.*

Decreased mitochondrial function is associated with diseases affecting metabolic homeostasis and acute organ injuries, such as acute kidney injury (AKI). A primary consequence of impaired mitochondria in the pathophysiology of AKI is depletion of ATP, which can limit the ability of injured cells to recover and restore organ function. Thus, there is a need for pharmacological agents that promote mitochondrial biogenesis and restore cellular functions. The compound SRT1720 is a potent activator of the NAD+-dependent protein deacetylase SIRT1, an enzyme known to activate PGC-1α, the master regulator of mitochondrial biogenesis. We hypothesized that SRT1720 will induce mitochondrial biogenesis in renal proximal tubular cells (RPTC) and restore mitochondrial functions following an acute injury. RPTC treated with increasing concentrations of SRT1720 or diluent were examined for changes in mitochondrial proteins, oxygen consumption, and ATP. RPTC were then exposed to the model oxidant tert-butyl hydroperoxide (TBHP, 400μM), and injured cells were examined for changes in morphology and density, and ATP levels. In a recombinant SIRT1 activity assay, SRT1720 enhanced SIRT1 activity 2-fold at 0.1μM and 8-fold at 30μM compared to controls. RPTC treated with 1 to 10μM SRT1720 exhibited concentration-dependent increases in nuclear-encoded ATP synthase β and mitochondrial-encoded ND6 proteins by 24 hrs. At 3μM SRT1720, basal and FCCP-uncoupled respiration and ATP levels increased approximately 50% over controls. TBHP induced RPTC death and loss at 24hrs. The remaining sublethally injured cells exhibited morphological changes and 50% decreases in ATP levels. In contrast, sublethally injured RPTC treated with SRT1720 exhibited control levels of ATP. Data from these studies indicate that SRT1720 enhances SIRT1 activity, induces mitochondrial biogenesis, and increases mitochondrial function within 24hrs in RPTC. Furthermore, SRT1720 restored ATP levels in oxidant-injured cells, suggesting that it may be useful in the treatment of AKI.

PS 493 EFFECT OF URINARY CONSTITUENTS ON THE DIFFERENTIAL SENSITIVITY TO ETHYLENE GLYCOL-INDUCED RENAL TOXICITY IN WISTAR AND F344 RATS.

Y. Li and K. McMartin. *Pharmacology, Toxicology & Neuroscience, LSU Health Sciences Center, Shreveport, LA.*

Ethylene glycol (EG) is nephrotoxic because its metabolite—oxalic acid, which precipitates with calcium to form calcium oxalate monohydrate (COM), accumulates in the kidney and produces necrotic damage. The EG metabolic pathway in humans and rats is considered to be similar. Previous studies have shown that rat cells are more sensitive than human cells to oxalate damage, although Wistar and F344 cells react the same. Wistar rats accumulate more oxalate in the kidney and are more sensitive to kidney toxicity than the F344 rat, but the mechanism for the strain difference is not known. We hypothesized that the supersaturation of calcium oxalate (CaOx SS) in the urine of Wistar rats is higher than that of F344 rats, thereby allowing for greater COM crystal deposition in the Wistar rat. Age-matched male Wistar and F344 rats were treated with 0.75% EG in drinking water for 8 wk. 24-h urine was collected at 0, 2, 4, 6 and 8 wk for analysis of key electrolytes that were used to calculate the ion-activity product as an index of the CaOx SS. Our data supported the different sensitivity to renal toxicity from EG between the two rat strains (Wistar > F344). CaOx SS did not differ between the two rat strains before EG treatment. After treatment, plasma oxalate level and urine oxalate excretion were markedly greater in Wistar rats than in F344 rats, while urine calcium was slightly decreased in Wistars. These results led to a higher CaOx SS in urine of EG treated Wistar rats, which could explain the enhanced accumulation of oxalate in the kidney. The mechanism for the greater urinary oxalate excretion in the Wistar may relate to differences in renal oxalate transporters. Supported by the American Chemistry Council.

PS 494 METABOLITES OF DIETHYLENE GLYCOL (DEG) ARE RESPONSIBLE FOR THE RENAL TOXICITY ASSOCIATED WITH ACUTE DEG POISONING.

L. M. Besenhofer, M. C. Cain, B. Latimer and K. McMartin. *Pharmacology, Toxicology & Neuroscience, LSU Health Sciences Center, Shreveport, LA.*

Diethylene glycol (DEG) is a chemical intermediate, industrial solvent and antifreeze agent. Ingestion of DEG, primarily through mistaken use of adulterated pharmaceuticals, has been linked with a large number of cases of acute kidney failure. DEG targets the kidneys, liver and central nervous system, but the mechanisms of toxicity and whether DEG or its metabolites are responsible for the toxicity remain unknown. The purpose of this study was to correlate the kinetics of DEG and its metabolites with the development of toxicity to determine the responsible toxic agent. Adult male Wistar rats were placed in one of four treatment groups including: water, low dose DEG (2 g/kg), high dose DEG (10 g/kg), or high dose DEG + 4-methylpyrazole (4-MP, an inhibitor of the presumed DEG metabolic pathway). Compared to controls, rats treated with high dose DEG had significantly decreased blood bicarbonate levels, urine pH and blood pH, with increased blood urea nitrogen (BUN), serum creatinine and serum AST. These parameters indicated that metabolic acidosis began within 4 h of DEG treatment, while kidney and liver toxicity began at about 24 h post DEG treatment. Metabolic acidosis occurred to a small extent in the low dose DEG group, but the animals recovered by 24 h. No signs of any toxicity were observed in the DEG + 4-MP treated group throughout the time course. DEG was completely eliminated from the plasma by 24 h, except in rats experiencing the most severe toxic syndromes. Ethidium homodimer renal perfusion revealed that the DEG-induced proximal tubular necrosis was blocked by treatment with 4-MP. These results demonstrate for the first time that a metabolite(s) of DEG, rather than DEG itself, is responsible for its toxicity, and that 4-MP

may be a useful antidote in treating DEG poisoning by blocking its metabolism. This project is supported by research agreement with American Chemistry Council.

PS 495 IN ISOLATED RABBIT RENAL PROXIMAL TUBULES, THE BETA-LACTAM ANTIBIOTIC CEPHALORIDINE DOES NOT INHIBIT THE MITOCHONDRIAL UPTAKE OF SUCCINATE, A BIOMARKER OF ITS NEPHROTOXICITY: A CELLULAR METABOLOMIC STUDY WITH CARBON 13 NMR.

G. Baverel, S. Cadi-Soussi and G. Martin. *Metabolomics and Metabolic Diseases, INSERM Unit # 820, Lyon Cedex 08, France.*

The beta-lactam antibiotic cephaloridine, which has been withdrawn from the market, is used as a model compound in nephrotoxicity studies. In isolated rabbit renal mitochondria, it has been shown that cephaloridine (i) inhibits succinate uptake and (ii) reduces respiration. In the present study, we have re-examined this problem using isolated rabbit renal proximal tubules. For this, tubules were incubated for 4 hours in oxygenated Krebs-Henseleit buffer containing either 1,4-13C-succinate, or 2,3-13C-succinate or succinate + 13C-bicarbonate without or with cephaloridine. At the end of incubation, substrate removal and product formation were measured by enzymatic and carbon 13 NMR methods. Enzymatic fluxes were calculated by combining these results with an original mathematical model of renal succinate metabolism. Succinate was converted at high rates into fumarate, malate, glucose and CO2, and to a lesser extent, into, pyruvate, alanine, lactate and alpha-ketoglutarate. Cephaloridine induced an increase in the accumulation of fumarate, malate and a decrease in the production of glucose and CO2; it also reduced the cellular level of ATP. Surprisingly, it did not change the removal of succinate. Fluxes through malate dehydrogenase, glucose 6-phosphatase and citrate synthase were also diminished by cephaloridine. In conclusion, the absence of inhibition of mitochondrial uptake of succinate in intact rabbit renal proximal tubules strongly suggests that results obtained with isolated mitochondria do not necessarily apply to mitochondria in intact cells and, therefore, should be interpreted with great caution. These results also suggest that mitochondrial functions should be studied in intact cells.

PS 496 IMPACT OF ASSAY SELECTION AND STUDY DESIGN ON CYTOTOXICITY OF MEDICAL DEVICES.

D. M. Lehmann, D. O'Mara, M. E. Richardson and K. W. Ward. *Nonclinical Safety, Bausch & Lomb, Rochester, NY.*

Biocompatibility testing of medical devices usually requires an assessment of cytotoxicity. Assay selection and protocol design often depend on a specific testing standard rather than on the specific form and function of the medical device. The chemical and/or physical characteristics of some medical devices may predispose them to false positive results in certain cytotoxicity assays. A direct comparison of cytotoxicity assay responses for non-structural medical devices such as multipurpose solutions (MPS) for contact lens care is not currently available in the literature. In this series of experiments, we used the direct contact, agar diffusion, and elution assays to assess the cytotoxicity of several commercially available MPS. Determination of cytotoxicity was based on visual evidence of morphological change in L929 cells using standard United States Pharmacopeia methods. All commercial MPS passed the agar diffusion assay regardless of whether the solution was applied via MPS-soaked filter disk or in conjunction with two commercial contact lenses. A modified elution assay was developed to evaluate the potential cytotoxicity of different concentrations of MPS in the absence of a contact lens. In this assay, both the duration of contact and strength of the MPS impacted the findings. When tested at 50% strength for 48 hours, Optifree Replenish MPS was non-cytotoxic, but Optifree Express and Aquify showed signs of cytotoxicity. When tested at 25% strength for 48 hours, all MPS evaluated were non-cytotoxic. Our findings demonstrate that cytotoxicity test conditions for medical devices can dramatically influence outcomes, even for products available commercially and with a history of safe consumer use. Taking these findings into account, we propose that cytotoxicity testing requirements should be flexible to allow for several assays to be used to control for false positive results. Furthermore, individual assay protocols must be tailored to the physical and chemical characteristics as well as the intended use of the medical device.

PS 497 REVISIONS TO FDA REDBOOK 2000 GUIDELINES FOR THE SAFETY ASSESSMENT OF FOOD INGREDIENTS.

J. K. Park, C. Whiteside, S. Thurmond, I. S. Chen, A. Khan, T. Walker, S. Park, A. J. Zajac and D. G. Hattan. *CFSAN/OFAS, FDA, College Park, MD.*

The FDA has recently revised the toxicological guidance for the safety assessment of food ingredients, also known as Redbook 2000. The term "food ingredients" includes food additives, color additives used in food, food contact substances (formerly indirect food additives), and substances that are classified as generally recognized as safe (GRAS). A food ingredient is considered safe if there is a reasonable certainty of no harm from its intended use. The safety determination is contingent upon comparison of exposure (or dietary intake) information with the results of toxicological studies. The revised Redbook chapters are available on FDA's website and incorporate information from recent scientific research and technological advances on toxicity testing and take into account comments received from the scientific community on Redbook 2000. We also have added internet links to relevant information available on other FDA sites and tried to make the guidance consistent with recommendations from other agencies on toxicological testing. Some of the revisions include: (1) providing updated guidance regarding the conduct of carcinogenicity studies, for instance, recommending fewer sampling time points and less handling of test animals to minimize unnecessary stress on the animals, and in utero exposure phase for addition to carcinogenicity studies, (2) updating information on the use of computerized systems for data standards and data generation, (3) providing detailed guidance regarding the conduct of recommended genetic toxicity tests, and (4) inclusion of updated guidance for short-term, subchronic, and chronic toxicity studies as well as reproduction studies, developmental toxicity studies, neurotoxicity testing studies and epidemiology studies. These revisions also include discussions that establish the basis for the new recommendations made in Redbook 2000 by the FDA.

PS 498 USE OF CONSEXPO IN CONSUMER PRODUCT RISK ASSESSMENTS FOR CALIFORNIA PROPOSITION 65 COMPLIANCE.

N. Pechacek, L. Milchak, R. Roy and R. Skoglund. *3M, St. Paul, MN.*

California Proposition 65 (Prop 65) requires a clear and reasonable warning for products that contain a chemical, or chemicals, known to the state of California to cause cancer or reproductive toxicity (i.e., "listed" chemicals). Warning is not required if the exposure to a listed chemical poses no significant risk. ConsExpo 4.1 is a consumer exposure model developed by the National Institute for Public Health and the Environment (RIVM) in the Netherlands. The model uses mathematical algorithms to estimate exposure via inhalation, ingestion, and dermal contact. Input parameters can be obtained from various sources including Prop 65 regulation and guidance, scientific literature, product-specific use surveys, experimentally-derived values, or professional judgment. ConsExpo can perform exposure assessments at different levels of detail, from initial screening-level assessments utilizing conservative assumptions to detailed assessments requiring significantly more information. The model can be used to evaluate the need for Prop 65 warnings for a variety of consumer products. The model may be valuable for providing exposure estimates, particularly in cases where initial screening-level assessments have been performed and indicate the need for more sophisticated modeling. Limitations of the model include the lack of readily-available values for certain input parameters and the inability to customize the model for certain exposure scenarios and model outputs. Validation efforts are suggested to ensure greater confidence in the predicted exposure estimates.

PS 499 EVALUATION OF PROPYLENE GLYCOL MONOCAPRYLATE IN THE LOCAL LYMPH NODE ASSAY.

R. Roy, P. H. Lieder and L. M. Milchak. *Medical Department, 3M, St. Paul, MN.*

Propylene glycol monocaprylate (PGMC; octanoic acid, monoester with 1,2-propanediol; CAS# 68332-79-6 and 31565-12-5) finds many applications in personal care, industrial, and pharmaceutical products (e.g. as a solubilizer and penetration enhancer in topical formulations). PGMC may be used on food and feed crops both before harvest to protect against mites and after harvest to prevent microbial damage during storage. PGMC and its breakdown products are approved for food use by FDA. A full acute (limit-dose) toxicity test battery has previously been generated in support of EPA registration of PGMC as a biochemical pesticide. Based on oral LD50, dermal LD50 and inhalation LC50, PGMC was classified as "non-toxic"; PGMC was a "non-irritant" in both dermal and eye irritation studies. However, based on the results of the Guinea Pig Maximization Test, PGMC (65% purity) was considered to have the potential to cause skin sensitization. Recently, as part of a new product development program, better characterized and higher purity (98.9%) PGMC was tested in the LLNA to determine its dermal sensitizing potential. Based on a preliminary dermal irritation toxicity screen, PGMC concentrations of 10%, 25% and 50% were chosen for the LLNA. Ear swelling measurements and individual animal observations indicated that none of the PGMC treatments resulted in dermal irritation. The stimulation index (SI) of the positive control, 25% alpha-hexylcinnamaldehyde was 7.4. The mean SI values for the 10%, 25% and 50% PGMC treatment groups were 2.2, 2.8, and 2.6, respectively. Because the mean SI for each of the three treatment groups was less than 3, PGMC

was not considered to be a dermal sensitzer at any of these concentrations. The results of the LLNA provide further support for the safe use of high purity PGMC in personal care and other products.

PS 500 VALPROATE REDUCES NEURITE OUTGROWTH BUT REVERSIBLE IN HUMAN SY5Y NEUROBLASTOMA CELLS.

Y. Qian, Y. Zheng and E. Tiffany-Castiglioni. *Texas A&M University, College Station, TX.*

Valproate (VPA) is a commonly prescribed mood stabilizer. However, emerging evidence indicates that VPA administration frequently causes the reversible syndrome of parkinsonism and cognitive decline (P/CD) in patients. The mechanism of this phenomenon is unknown. In this study, we used human SY5Y neuroblastoma cells as a neuronal model to investigate the effects of VPA on neurite outgrowth and neurofilament expression. Data showed that the treatment with VPA (0-1.0 mM) for 3 days significantly reduced cell proliferation at 1.0 mM and neurite outgrowth length at both 0.5 and 1.0 mM in human SY5Y neuroblastoma cells, but not in human CCF astrocytoma cells. A prolonged treatment with 0.5 mM VPA in neuroblastoma cells revealed a reduced neurite outgrowth starting at day 3 through day 6. In comparison, the same treatment significantly induced a reduced cell proliferation starting at day 4 through day 6. In parallel to these alterations, both mRNA and protein levels of neurofilament 160 (NF160) were significantly reduced, starting at day 2 and day 3, respectively, by the treatment. Interestingly, the reduced neurite outgrowth by VPA could be completely reversed by the concomitant administration with nerve growth factor (NGF, 10 ng/ml) for 16 hrs or by the removal of VPA from the medium after 2 days. NF160 protein levels also rebounded to control levels by VPA removal, but not by NGF treatment. These data suggest that VPA-modulated NF160 expression was probably involved in the prohibition and the reversal of neurite outgrowth, consistent with VPA-induced reversible syndrome of P/CD in patients.

PS 501 28-DAY ORAL (GAVAGE) TOXICITY STUDY WITH ETHYLMETHANESULFONATE (EMS) IN THE RAT.

T. Pfister[1], L. Müller[1], E. Gocke[1], P. Larson[2], T. Lavé[1] and A. Eichinger-Chapelon[3]. *[1]Nonclinical Drug Safety, F. Hoffmann-La Roche, Basel, Switzerland, [2]Virology and Transplantation, F. Hoffmann-La Roche, Nutley, NJ and [3]RCC, Itingen, Switzerland.*

The purpose of this study was to assess the general toxicity of EMS in a subacute toxicity study in Wistar rats. EMS was administered daily by oral gavage at doses of 0, 20, 60 and 180/120 mg/kg/day for 28 days. Satellite animals were used for recovery and exposure assessment. The incidence and severity of findings were generally dose-dependent occurring at doses of 60 mg/kg/day or above. Decreases in food consumption and body weight were the dose-limiting effects. The starting top dose of 180 mg/kg/day had to be ceased after 5 days due to severe body weight loss. After a 9-day treatment pause animals were re-dosed at 120 mg/kg/day. Organ toxicity was characterized by decreased red and white blood cell counts, hematocrit, and haemoglobin, fatty atrophy of bone marrow, and involution of the thymolymphatic system. Effects on sexual organs were lower organ size for testes, epididymides, seminal vesicles, prostate, and uterus. The main histopathological findings in testes were tubular atrophy and single germ cell necrosis, and in epididymides reduced spermatozoa. Other target organs were the pancreas (acinar cell vacuolation), thyroid gland (follicular cell hypertrophy), and salivary gland (secretory depletion of convoluted ducts). Reversibility was observed for the effects on food consumption and body weight and for findings which are most likely secondary to changed physiological conditions (e.g. thyroid gland and pancreas findings, thymus involution). Findings typically attributable to the genotoxic effect of EMS persisted at least in the high dose group (e.g. hematopoiesis, lymph node and testis findings). The systemic exposure to EMS was monitored by hemoglobin ethylvaline adduct measurement. The low dose of 20 mg/kg/day was the No-Observed-Adverse-Effect Level (NOAEL).

PS 502 A REPRODUCTION/DEVELOPMENTAL TOXICITY SCREENING ASSAY IN RATS WITH HIGH PURITY MONOOCTYLTIN TRIS(2-ETHYLHEXYLMERCAPTOACETATE)(MOTE).

I. Waalkens-Berendsen[1], W. Gaoua-Chapelle[2], S. Reiss Murphy[3] and C. Farr[3]. *[1]TNO Quality of Life, Zeist, Netherlands, [2]Arkema, Colombes Cedex, France and [3]Arkema Inc., Philadelphia, PA.*

Monooctyltin compounds have been previously tested in reproductive studies using mixtures of monooctyltin and dioctyltin compounds. These studies were performed using a mixture with high content (85%) monoctyltin trichloride (MOTC) and dioctyltin chloride (DOTC) (11%). The NOAEL for maternal toxicity was set at approx. 0.6 mg/kg bw/day because of decreased thymus weight and lymphoid depletion. The NOAEL for fertility and developmental effects was approx. 6 mg/kg bw/day as a consequence of increased post-implantation losses and decreased pup viability. A mixture with high content of DOTC (>94%) and low MOTC (2.2%) was also evaluated in a comparable study showing the same immunotoxicity and fertility effects. We therefore investigated whether the toxicity observed in both fertility studies was the consequence of monooctyltin or dioctyltin content. We evaluated MOTE (CAS No. 27107-89-7) with high purity (>97%) containing less than 0.5% dioctyltin bis 2-ethylhexylmercaptoacetate (DOTE), in a reproduction/ developmental toxicity screening assay in rats. Groups of 12 rats/sex received MOTE at 0, 200, 500 and 1250 mg/kg diet throughout the pre-mating period, during the mating and post-mating periods until final sacrifice (28 days) for the males, and through pre-mating (2 weeks) and mating periods, during pregnancy and lactation, until day 4 post-partum inclusive, for the females. Microscopic examination was performed on the testes, epididymides, seminal vesicles, prostate, ovaries, uterus and thymus. There were no toxic effects on parental males and females. No effects were recorded on fertility or on pre- and post-natal development. In this study, the NOAEL for parental toxicity, fertility and developmental toxicity is approx. 72 and 96 mg MOTE/kg bw/day for male and female animals, respectively. This indicates that immunotoxicity and effects on fertility observed in previous fertility studies are likely to be the consequence of the dioctyltin concentration.

PS 503 SUBCHRONIC TOXICITY OF CITRONELLYL NITRILE IN RATS.

C. Letizia, V. T. Politano and A. Api. *RIFM, Woodcliff Lake, NJ.*

The subchronic toxicity of citronellyl nitrile (CAS No. 51566-62-2), a widely used fragrance ingredient, was evaluated in a 90-day oral toxicity study in rats. Male and female rats (10/sex/dose) were gavaged once daily with citronellyl nitrile in corn oil at dose levels of 0, 10, 30, 100 or 300 mg/kg/day. Control animals received the vehicle alone. Observations included morbidity and mortality assessments, body weights, food consumption, estrous cycle and ophthalmology. Hematology, blood chemistry and urinalysis were evaluated at weeks 7 and 13. A complete necropsy was conducted on all animals. There were no unscheduled deaths and there were no clinically observable signs of toxicity. There were no adverse effects on bodyweights, food consumption, or hematology and there were no treatment related ocular effects and no treatment-related effects on female estrous cycles. A statistically significant increase in total protein was observed in high-dose females and a statistically significant increase in albumin levels was observed in high-dose-males. No macroscopic abnormalities were detected at necropsy. A statistically significant increase in absolute and relative liver weights was noted in both sexes in the high-dose group and in males in the 100 mg/kg/day dose group. Marginal centrilobular hepatocyte enlargement was observed in both sexes in the high-dose group and in 2 males and 1 female in the 100 mg/kg/day dose group but was considered to be adaptive in nature. A higher incidence of lower grades of severity of adipose infiltration of the marrow was noted in high-dose females but was not statistically significant and was considered to be a marginal effect as there were no corresponding hematological changes. Based on these findings, the No Observed Effect Level (NOEL) was concluded to be 30 mg/kg. The No-Observed Adverse Effect Level (NOAEL) was concluded to be 300 mg/kg/day as the liver changes identified histopathologically were considered to be adaptive in nature and the bone marrow changes observed in high-dose females were marginal and were not accompanied by any hematological changes.

PS 504 FRAMEWORK FOR THE SAFETY ASSESSMENT OF MATERIALS USED IN AUTO INTERIORS.

P. J. Beattie[2], J. P. Rinkevich[1] and T. G. Osimitz[1]. *[1]Science Strategies, LLC, Charlottesville, VA and [2]General Motors Corporation, Warren, MI.*

Next to homes and offices, we spend the most time in automobiles: individuals spend approximately 97 min/day inside a vehicle (Tsang and Klepeis, 1996; Klepeis et al. 2001). Time spent inside a vehicle range from 12 min at the 5th percentile to 570 min at the 99th percentile. The Suppliers Partnership for the Environment (SP), an innovative collaboration between automobile manufacturers, their suppliers, and the U.S. Environmental Protection Agency (EPA) has formed a Chemical Issues Work Group to provide a forum for discussing emerging chemical issues within the automotive supply chain. The purpose of the Workgroup is to share best practices and to develop a common approach to material risk assessment for automotive products. We have developed a Material Assessment Strategy (MAS) for evaluating potential chemical exposures to passengers in automotive compartments. The key elements include criteria for hazard assessment. Hazards examined include carcinogenicity, mutagenicity, developmental toxicity, reproductive toxicity, sensory irritation, dermal sensitization, pulmonary sensitization, endocrine disruption and aquatic toxicity. Chemicals with identified hazards undergo tiered exposure assessment and subsequent risk characterization. Tier I exposure assessment

consists of conservative ("worst case") assumptions regarding airborne chemical levels and the availability of residues on exposed interior surfaces. Tier II employs mathematical models to estimate the dynamics of air and surface levels in a car under various conditions. Tier III uses actual analytical determinations of airborne and interior surface levels (both total and transferable) to estimate occupant exposure. The exposure estimates are used to conduct a risk characterization for the appropriate endpoints. We demonstrate the application of this framework from hazard identification through risk assessment with example chemicals.

PS 505 APPLYING THE THRESHOLD OF TOXICOLOGICAL CONCERN TO LOW LEVEL INGREDIENTS IN AIR FRESHENERS.

T. Petry[1], C. Namali[2], P. H. Lloyd[2], U. Vedula[3] and F. J. Joachim[3]. *[1]ToxMinds BVBA, Brussels, Belgium, [2]SC Johnson Ltd, Frimley, Surrey, United Kingdom and [3]SC Johnson & Son Inc., Racine, WI.*

Humans are exposed to numerous chemicals through sources such as foods, medicines and consumer products. Consumer safety is of paramount importance, yet detailed toxicological data may be lacking for chemicals present in consumer products at low levels. This represents a challenge in assuring consumer safety at a time when there is strong public and regulatory pressure to reduce animal testing and to increasingly rely on information from alternative methodologies. However, validated alternatives to repeated dose toxicity tests in animals are unlikely to be available in the near future. This may be overcome by the applying the Threshold of Toxicological Concern (TTC), an increasingly accepted tool used in the absence of chemical-specific toxicity data. The concept relies on information from the general toxicity database to establish exposure thresholds for groups of chemicals, below which there would be no appreciable risk to human health. Using the TTC framework, this investigation examined whether consumer exposure to low level ingredients present in air fresheners was of negligible risk. Air fresheners may contain natural oils, solubilizers, and/or gelling components amongst other ingredients. Groups of chemicals for which the TTC approach is not considered suitable (e.g., heavy metals, high potency carcinogens) are not used as ingredients in air fresheners. It was assumed that the low level ingredients released from the said product belonged to structural Class III, the most conservative of the Cramer Classes, and consumer exposure was modeled using RIVM's ConsExpo model on the basis of measured product emission rates. An additional uncertainty factor was applied to account for extrapolation from the oral to the inhalation route. It was concluded that consumer exposure to ingredients present at concentrations below 0.1% in air freshener formulations was well below the limit set for Class III compounds and consequently did not present a safety concern for systemic endpoints.

PS 506 TRICLOSAN IN PERSONAL CARE PRODUCTS: DETERMINISTIC AND TOXICOKINETIC-BASED HUMAN HEALTH RISK ASSESSMENTS.

L. T. Navarro and J. Plautz. *Home & Personal Care, Ciba Inc., Basel, Switzerland.*

Triclosan (Irgasan®;5-Chloro-2-(2,4-dichlorophenoxy) phenol) has a long history of safe use as an antimicrobial in home and personal care products and has been extensively studied to ensure it is acceptable and safe for its intended uses. The majority of the human health-related test results for triclosan (TCS) are confidential to Ciba, thus speculation and unsubstantiated statements appear regularly indicating triclosan should be avoided, removed from consumer products, or raise concerns for severe adverse health effects. With this poster, we present an overview of our key hazard data for TCS, exposure estimates for consumer-used products containing TCS (up to 0.3%), and a risk characterization calculation and assessment for human health. Data are available on metabolism and pharmacokinetics for TCS including ADME studies in hamsters, mice, rats, and humans. These data indicate humans exposed to TCS are best represented by hamsters as a laboratory model, in which we established a NOAEL = 75 mg/kg/d from a lifetime study wherein liver and kidney changes defined the effects. TCS is readily absorbed, fully metabolised, and eliminated (no bioaccumulation) from the body of humans and all other mammalian species used. Total exposure to TCS from personal care products give a range of systemic estimated doses (SEDs) depending on the types of products included. Several risk calculations will be presented, but as an example: including exposure to the full range of products containing TCS gives a human SED of about 0.245 mg tcs/kg/day. The Margin of Safety (MoS) is about 300, which is derived against the hamster lifetime NOAEL: [75 mg/kg/d √ 0.245 = 306]. With 100 considered as minimally acceptable using animal data, we find triclosan is safe for the intended uses. Other exposure based estimates give higher MoS and also show TCS exceeds acceptance criteria for safe use in personal care products.

PS 507 THE COLIPA STRATEGY FOR DEVELOPING AND PREVALIDATING *IN VITRO* ALTERNATIVES FOR SKIN SENSITIZATION TESTING.

P. Aeby[1], T. Ashikaga[2], S. Bessou-Touya[3], W. Diembeck[4], F. G. Gerberick[5], M. Marrec-Fairley[1], G. Maxwell[6], J. Ovigne[7], H. Sakaguchi[8], K. Schroeder[9] and M. Tailhardat[10]. *[1]COLIPA, Brussels, Belgium, [2]Shiseido Research Centre, Yokohama-Shi, Japan, [3]Pierre Fabre, Castres, France, [4]Beiersdorf, Hamburg, Germany, [5]Procter & Gamble Company, Cincinnati, OH, [6]Unilever, Sharnbrook, United Kingdom, [7]L'Oréal, Aulnay sous Bois, France, [8]Kao Corporation, Tochigi, Japan, [9]Phenion GmbH & Co. KG (Henkel), Düsseldorf, Germany and [10]LVMH Recherche, Saint Jean de Braye, France.*

Allergic contact dermatitis is a delayed-type hypersensitivity reaction induced by small reactive chemicals (haptens). Currently, the sensitizing potential of chemicals is usually identified on the basis of animal studies, such as the local lymph node assay (LLNA) or Guinea Pig tests. There are, however, increasing public and political concerns regarding the use of animal testing for the screening of new chemicals. Consequently, the development of *in vitro* models for predicting the sensitizing potential of new chemicals is receiving widespread interest. The COLIPA Skin Tolerance project team currently collaborate with a number of academic research groups to increase and apply our understanding of the molecular and cellular events occurring during the acquisition of skin sensitization. At present fundamental and applied research is being funded in the following key areas; chemistry/peptide binding, skin metabolism, skin bioavailability of skin sensitizing chemicals; evaluation of different biomarkers for Dendritic cell activation by chemical sensitizers; and T cell proliferation. Knowledge gained from this research is being used to support the development and pre-validation of novel *in vitro* approaches for the identification and characterization of skin sensitizing chemicals. At present three *in vitro* test methods (Direct peptide reactivity assay, MUSST and hCLAT) are being evaluated for their potential to predict skin sensitization potential within COLIPA interlaboratory ring trials.

PS 508 QRA APPROACH FOR SKIN SENSITIZATION TO HAIR DYES BY MEASURING THE CONSUMER EXPOSURE LEVEL (MCEL) *IN VITRO* .

C. Goebel[1], P. Kern[2], C. A. Ryan[2], H. Rothe[1] and G. F. Gerberick[2]. *[1]CPS, Procter & Gamble Service GmbH, Darmstadt, Germany and [2]CPS, Procter & Gamble Company, Cincinnati, OH.*

Allergy to hair dye actives is an important topic for the safety of hair dye products. QRA (quantitative risk assessment) includes the detailed knowledge of the allergenic potency and the dose response characteristics of the ingredient as well as the assessment of the consumer exposure level. We introduce an approach for experimentally measuring the skin exposure to hair dye actives. Specifically, we suggest assessing the consumer exposure level based on exposure data available from skin penetration studies. These in vitro studies (OECD guideline 428) provide direct quantification of the concentrations found on and in the skin and will be referred to as the measured consumer exposure level (mCEL) at a distinct use concentration under realistic use conditions. For example, the dermal load for p-phenylenediamine was 22 µg/cm2 determined after application of a typical hair dye product containing 2% PPD under use condition (30 min exposure time and rinsing with water and shampoo).We conclude that this approach allows for a more robust and accurate QRA for hair dyes.

PS 509 CYTOTOXICITY OF LATEX CONDOM EXTRACTS IN L929 FIBROBLASTS AND RAW 264.7 MACROPHAGES.

S. Loftin, M. Toal, C. Pollard, M. Bailey, A. Lucas, M. Stratmeyer and R. Brown. *CDRH, FDA, Silver Spring, MD.*

Extracts of natural rubber latex (NRL) medical devices (e.g., condoms) typically produce a positive response in in vitro cytotoxicity assays; however, clinical use of these devices is associated with a very low incidence of adverse effects. The positive response seen in cytotoxicity assays complicates the interpretation of these results in the preclinical biological evaluation of NRL-containing medical devices. To differentiate devices with the potential to produce adverse effects in vivo from those with an adequate safety profile, dilution cutoff values (e.g., 1:8) have been proposed to determine an acceptable level of toxicity of the extracts in cytotoxicity tests. The goal of this study is to provide an empirical basis for dilution cutoff values for acceptable levels of in vitro cytotoxicity. Sections of commercially available male condoms (2 lubricated NRL, 2 non-lubricated NRL, 2 polyurethane, and 1 lubricated NRL with spermicide) were extracted (3 cm2/ml) with RPMI-1640 media +/- 10% FBS for 24 hrs at 37C. Extracts from NRL tubing were used as positive controls. Dilutions (1:1 to 1:20) of the extracts were sterile filtered, applied to confluent 24-hour-old cultures of L929 fibroblasts and RAW 264.7 macrophages, and incubated

for 24 hrs. Cell viability was assessed using the neutral red assay. No cytotoxicity was observed following extraction of the condoms in cell culture media without FBS. Concentration-dependent cytotoxicity was seen in FBS-containing extracts from all NRL condoms and none of the FBS-containing condom extracts were toxic at a dilution more than 1:3, including extracts from the spermicide-containing NRL condom. Extracts of the non-NRL condoms were non-toxic. Concentration-dependent toxicity was seen in FBS-containing extracts from the positive control material (NRL tubing) up to a 1:10 extract dilution. These in vitro results will be compared to the results of in vivo tests (dermal irritation and systemic toxicity) to provide an empirical basis for acceptable levels of in vitro cytotoxicity produced by extracts of NRL medical devices.

PS 510 SAFETY ASSESSMENT OF OXIDATIVE DEGRADATION PRODUCTS IN HYDROCORTISONE.

H. Fikree[1], A. C. Pais[1], L. N. Sarkissian[1], N. R. Bullock[2] and L. A. Haighton[2]. *[1]Ashuren Health Sciences, Mississauga, ON, Canada and [2]CANTOX Health Science Intl., Mississauga, ON, Canada.*

Hydrocortisone, a commonly used anti-inflammatory and anti-pruritic agent, was demonstrated to be susceptible to oxidation, thus requiring qualification of the resultant degradants. A toxicological assessment was conducted to determine the potential toxicity (if any) associated with these degradants. The likely degradation products were identified as 17-deoxy-21-dehydrohydrocortisone and 21-dehydrohydrocortisone under neutral conditions and the etio-acid (an oxidative product), 17-ketosteroid, and the glycolic acid under basic conditions. Hydrocortisone formulations containing clay minerals (ingredients common to topical formulations) may be more susceptible to oxidation due to the oxidizing action of the ferric iron present at the surface of these minerals. 21 Dehydrohydrocortisone and 17-deoxy-21-dehydrohydrocortisone were characterized as immunogenic agents, and were implicated as pro-antigens in allergic reactions caused by corticosteroid preparations; however, this is a known adverse reaction of hydrocortisone itself. These 2 degradation products also contain a ketoaldehyde which is comparable to the alkyl aldehyde group, for which a structural alert for genotoxicity has been identified; however, most other chemicals with this alert are short chain aldehydes such as formaldehyde. Bulkier structures like that of 21-dehydrohydrocortisone and 17-deoxy-21-dehydrohydrocortisone could potentially buffer or diminish any potential genotoxic effects. Since clay minerals generally contain surface ferric iron, the potential for accelerating the oxidative degradation of drugs should be considered whenever clay minerals and drugs susceptible to oxidation are combined.

PS 511 COMPARISON OF SEVERAL COSMETIC PRESERVATIVES FOR MILDNESS.

A. Gill, W. Ambrister, C. Rodriguez, T. Mentilik, A. H. Dang, Y. John and B. C. Jones. *Mary Kay Inc, Dallas, TX.*

A significant number of personal care product consumers believe that they have sensitive skin. However, the concept of sensitive skin is not always consistent. It is becoming more important to evaluate objective skin irritation in addition to subject sensory irritation potential in developing cosmetic products especially for individuals with sensitive skin as also the need to adequately preserve products. A broad spectrum preservative is required to protect our formulations from the possible introduction of micro-organisms such as bacteria, yeast and mold. The ideal preservative, both effective and devoid of irritation or sensitizing potential, which can be used in all formula types, has yet to be discovered. This study investigates the use of cosmetic preservatives as single or combined ingredients by evaluating objective and subjective skin irritations in formulations specific on clinically-diagnosed sensitive skin. The method comprises of 2 parts. In part 1, we used data from the EpiOcularTM assay to predict ocular irritation potential of various preservatives. This assays measures the exposure time required for an ingredient of a product to reduce the tissue cell viability by one-half (ET50). A reduced ET50 score is indicative of a greater potential for ocular irritation in vivo. This non-cornified tissue model was selected because many of the formulations are applied repeatedly to the face increasing the susceptibility of ocular irritation. The EpiOcular tissue model is an organotypic model of human corneal epithelium cultured from normal human keratinocytes using serum free medium making it an excellent choice to determine the ocular irritancy of their products without using animals. In part 2, 14-day cumulative irritation and sensory irritation tests were performed on human subjects with sensitive skin to compare various combinations of preservatives in sensitive skin formulations. A comparison of the in vitro data and in vivo data was performed to assess the utility of the tissue model to screen potential preservative systems specifically for sensitive skin formulations.

PS 512 OPTIMIZATION OF IN VITRO MICRONUCLEUS TEST WITHOUT CYTOCHALASIN B TO EVALUATE TOTAL PARTICLE MATTER OF CIGARETTE SMOKE.

J. Nakai[1], J. Sawaguri[1], M. Ogura[1], H. Fukudomi[1], K. Hori[2], M. Tsuchitani[2], T. Sofuni[1] and K. Inada[1]. *[1]Japan Tobacco Inc., Tokyo, Japan and [2]Mitsubishi Chemical Safety Institute Ltd., Tokyo, Japan.*

In the current OECD draft guideline (3rd version) for *in vitro* micronucleus test (MN), some options were cited for several parameters (e.g. cell line, presence or absence of cytochalasin B (CB)). On the other hand, Health Canada (T503 2nd edition) specifies CHO cells and the without-CB condition for MN to evaluate the total particle matter (TPM) of cigarette smoke. CORESTA *in vitro* toxicology task force recommends to include *in vitro* genotoxicity test using mammalian cells (MN, CA or MLA) in biological test methods for TPMs, and arranged a collaborative study of MN for TPMs. However, experimental condition for MN has not been studied in detail. Therefore, we examined the conditions of CB using CHL/IU cells, and tried to find the optimal parameters for the evaluation of TPMs. Furthermore, we evaluated the accuracy and discrimination capability for the test condition using various TPMs.

The number of cells with micronucleus did not vary between the with-CB and without-CB condition at the dose range without severe cytotoxicity. In that dose range, the frequencies of mitotic cells are almost the same to that of solvent control under the without-CB condition. It is indicated that, under the without-CB condition, the micronucleus induction by the TPMs can be evaluated sufficiently. The optimal condition of parameters which we found under the without-CB condition (3-h for treatment and 21-h for recovery time) is ; 5.2×10^4 cells/mL for initial number of cells, 24 hours for preculture and 1.5% for the S9 concentration. Under this condition, it was observed that the dose responses of the micronucleus induction by three different TPMs (flue cured, burley and 3R4F) were clearly discriminated, and furthermore, the order of the activities was maintained under with and without S9 condition. In conclusion, the optimal condition of *in vitro* micronucleus test using CHL/IU cells without cytochalasin B for TPMs was established from this experiment.

PS 513 *IN VIVO* DERMAL EXPOSURE ASSESSMENT: RESOLVING THE DISPOSITION OF BOUND SKIN RESIDUES FOR LANNATE® 20SL.

W. J. Fasano and K. S. Bentley. *E.I. du Pont de Nemours & Co. Inc., Wilmington, DE.*

Nearly a decade ago, Thongsinthusak et al. (1999) published an exponential saturation model to estimate absorption of bound skin residues (BSR) in rats using cumulative excretion data. Use of a modeling approach was intended to avoid repeating the in vivo dermal exposure study with additional animals and longer recovery times. In the ten years since Thongsinthusak, little has been published on the applicability of the modeling approach. Nonetheless, the European Commission guidance, Sanco/222/2000 (2004), recommends use of modeling as part of "expert judgment" on disposition of BSR. We have evaluated BSR disposition from an original rat in vivo dermal study terminated at 66 h post-exposure with modeling and in a follow-up in vivo dermal study terminated 42 days post-exposure. Rats were exposed for 6 h to Lannate® 20SL (suspension liquid) containing methomyl active ingredient (a.i.), either a spray dilution (1.5 g a.i./L) or the neat formulation (200 g a.i./L), applied at a rate of 10 μL/cm2 to a 10.5 cm2 area on the back; at 6 h post-dose, residual formulation was removed by washing with soap and water. Excreta were collected during the exposure and post-exposure periods. For rats held until 66 h post-exposure, 17.8% and 6.04% of the applied dose was absorbed and 39.3% and 6.09% remained as BSR for the spray dilution and neat formulation, respectively. The excretion data was modeled and maximum absorption of the spray dilution and neat formulation was estimated to be 17.6% and 6.61%, respectively. For rats maintained for 42 days post-exposure, approximately 8.4% and 6.4% was absorbed systemically, for the spray dilution and neat formulation, respectively. Overall, absorption of the spray dilution, based on the 66 h post-exposure, was comparable to the model-predicted value yet higher than the 42-day results; the model estimated absorption and the 42 day results for the neat formulation were comparable to the 66 h study. These results support the conclusion that the BSR, retained in the skin following a 6 h dermal exposure to Lannate® 20SL, does not become systemically available.

PS 514 POST-MARKET CHALLENGES FOR SAFETY ASSESSMENT OF HERBAL PRODUCTS.

S. A. Jordan, S. Reid, D. Cunningham and R. Marles. *Health Canada, Ottawa, ON, Canada.*

In Canada herbal products are regulated as natural health products (NHP). Not all NHPs on the Canadian market are currently authorized for sale; however a phased-in approach ensures that all marketed NHPs will be authorized in 2010. Post-market (PM) assessment is critical for improving the safe use of all marketed products

and can influence pre-market requirements for NHPs. PM safety assessment of herbal products includes signal detection and clinical/toxicological assessment. Regulators can face difficult risk mitigation (RM) decisions due to uncertainty in the clinical and toxicological database for herbal products. Efforts at decreasing uncertainty can lead to better informed RM decisions. As part of the NHP Regulations, manufacturers must report serious adverse reactions (AR) to Health Canada (HC); practitioners are encouraged to do so voluntarily. Published reports of herbal ARs are also monitored. Challenges in clinical assessment of AR information include issues of quantity and quality. HC has taken steps to improve AR reporting: the development of on-line educational modules, and issuing publications aimed at health care practitioners and the public. Targeted stimulation of reporting has led to increased information and mitigation of risk (eg black cohosh). Scientific assessment of safety signals is also hampered by quantity and quality of toxicological information. Verification of plant species in published case reports and toxicological studies is important for determining cause and effect; however, this information is often lacking, making accurate associations difficult. With the current lack of toxicological information for many herbs, predictive toxicology can be of some use in the safety assessment of individual phytochemicals; however, herbal products are generally complex mixtures of phytochemicals. Thus, data on isolated constituents needs to be taken in context with studies using whole plants or plant extracts, such as those being conducted by the NTP. Despite challenges, combined clinical and scientific assessment of herbal safety can provide meaningful information on which to base appropriate RM activities.

PS 515 EFFECT OF SIMULATED RESPIRATORY ACIDOSIS AND HYPERTHERMIA ON THE HEMOLYTIC EFFECT OF MATERIAL EXTRACTS.

R. Brown, S. Loftin, C. Revenis, A. Trivedi, H. Baskar, Y. Das and M. Stratmeyer. *CDRH, FDA, Silver Spring, MD.*

Hemolysis testing of medical device materials is typically conducted using erythrocytes (RBCs) from healthy animals or humans (e.g., ISO 10993-4, ASTM F756); however, various disease states can potentiate the toxic effect of compounds released from medical device materials. Use of assay conditions that replicate the physiological conditions found in disease states may result in biocompatibility testing of device materials under more clinically relevant conditions than those defined in standard test methods. The goal of this study is to determine if in vitro simulated respiratory acidosis (hypoxia, acidosis, hypercapnia) and hyperthermia potentiate the hemolytic effect of material extracts. Positive (latex, neoprene, PVC, BUNA rubber) and negative (silicone) control materials were extracted at 37oC in ethanol:PBS (50:50) for 24 hrs using the surface area/volume ratios defined in ISO 10993-12. Extracts were incubated with washed cow and rat erythrocytes (Hct 1.5%) under normothermic (37C) or hyperthermic (40C) conditions for 4 hrs in control (pH 7.4) or CO2-gassed (pH 6.8) PBS. Hyperthermia potentiated the toxicity of all material extracts in both cow and rat RBCs. Simulated respiratory acidosis potentiated the toxicity of some but not all material extracts in either cow or rat RBCs. A synergistic hemolytic effect was produced by hyperthermia and acidosis for neoprene extracts in cow and rat RBCs. Other extracts produced synergistic effects in cow (PVC) but not rat, and in rat (latex, BUNA rubber) but not cow RBCs incubated under hyperthermic and acidotic conditions, suggesting that interactive hemolytic effects produced under these conditions are species dependent. Since the hemolytic effects produced by material extracts incubated in vitro under normal physiological conditions can differ from those seen under conditions consistent with disease states, the clinical relevance of the results of hemolysis tests conducted using the ISO and ASTM standards should be carefully considered for devices used in critically ill patients.

PS 516 DETERMINING THE DISTRIBUTION OF VX IN GUINEA PIG TARGET ORGANS FOLLOWING A SINGLE SUBLETHAL SUBCUTANEOUS OR PERCUTANEOUS EXPOSURE.

J. M. McGuire[1], C. E. Whalley[1], L. A. Lumley[2], E. D. Clarkson[2], E. M. Jakubowski[1], S. A. Thomson[1] and T. Shih[2]. *[1]U.S. Army Edgewood Chemical Biological Center, Aberdeen Proving Ground, MD and [2]U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Physiologically based pharmacokinetic-pharmacodynamic (PBPK-PD) models have become useful analytical tools to interpret data from chemical warfare nerve agent (CWNA) exposure scenarios for risk assessments. These models rely upon accurate databases to compare the uptake and clearance kinetics of similar CWNA doses across various routes of administration. A sensitive method for determining exposure to the chemical warfare nerve agent VX has been developed in which the biomarker ethyl methylphosphonofluoridate (VX-G) is used as a dose metric for determining tissue distribution and kinetics of VX in guinea pigs following sublethal exposures via subcutaneous (s.c.) or percutaneous (p.c.) routes. The VX-G is measured in select target organs following treatment with fluoride ion using isotope-dilution gas chromatography tandem mass spectrometry (GC-MS/MS). The aforementioned analyte and a deuterated analog were isolated via solid phase extraction and detected using ammonia chemical ionization in the multiple reaction monitoring mode. The method has been applied to the analysis of blood, skin (from the exposure site), liver, lung, and kidney tissues from guinea pigs exposed to a 0.4 LD50 s.c. or p.c. dose of VX taken at 2, 4, 6, 24, and 48 hours post exposure. For the subcutaneous exposure, VX-G levels in general showed a decreasing trend in time with the highest concentrations in liver and kidney tissues. For the percutaneous exposures, VX-G levels were highest in the skin tissues which decreased exponentially over 48 hours. These results are consistent with previous studies on p.c. application of lethal doses of VX on anesthetized and atropinized guinea pigs where the concentrations of VX in blood rose over a six hour period and then slowly decreased with implications that VX was still circulating at toxicologically relevant levels.

PS 517 EFFICACY OF NOVEL PYRIDINIUM OXIMES FOR POTENTIAL ACTIVITY IN THE CENTRAL NERVOUS SYSTEM FOR REACTIVATING PHOSPHORYLATED ACETYLCHOLINESTERASE.

A. Harmon[1], E. C. Meek[1], H. Chambers[2], J. Gearhart[3] and J. E. Chambers[1]. *[1]College of Veterinary Medicine, Mississippi State University, Mississippi State, MS, [2]Department of Entomology and Plant Pathology, Mississippi State University, Mississippi State, MS and [3]Wright-Patterson AFB, Wright-Patterson AFB, OH.*

Organophosphate (OP) poisoning resulting in the inhibition of acetylcholinesterase (AChE) traditionally has been treated with atropine sulfate and an oxime, such as 2-PAM. Currently available oximes have limited abilities to cross the blood-brain barrier, resulting in little, if any, reactivation of AChE in the brain. This study involves the testing of pyridinium oximes that have been synthesized to incorporate phenoxyalkyl moieties to increase lipophilicity to enhance the likelihood of crossing the blood-brain barrier. The new oximes, along with 2-PAM, were evaluated *in vitro* to determine the ability of the oximes to reactivate AChE in rat brain. An experimental OP was synthesized as a surrogate for sarin to test the reactivation potential of the oximes. The experimental OP, phthalimidyl isopropyl methylphosphonate (PIMP; IC50=36nM), leaves AChE phosphorylated with the same moiety as the nerve agent sarin, but degrades quickly in aqueous solution to prevent re-inhibition of reactivated AChE in *in vitro* assays. Rat brain homogenate was treated with PIMP to yield about 80% inhibition, followed by 0.1mM oxime for 30 min, and AChE activity was measured by a discontinuous spectrophotometric assay. Reactivation varied among the oximes (34-81%), with 2-PAM yielding 89% reactivation. Lipophilicity, reflecting the potential for crossing the blood-brain barrier, was determined by n-octanol/water partition coefficients and varied among the oximes with some up to 30 fold greater than 2-PAM. The partition coefficient for 2-PAM was 0.006, and those for some of the oximes were up to 0.138. A few of the novel oximes showed combined higher lipophilicity along with reactivation potential approaching that of 2-PAM, suggesting that they may be effective reactivators in the brain. Supported by Defense Threat Reduction Agency: 1.E0056_08_AHB_C

PS 518 DETERMINATION OF LCT50 IN RATS EXPOSED TO NEBULIZED NERVE AGENTS.

J. Collins, R. Lee, A. Witriol, Z. Pierre, X. Peng and A. M. Sciuto. *Analytical Toxicology Division USAMRICD, Aberdeen Proving Ground, MD.*

Studies were designed to determine the LCt50 of the organophosphate nerve agent VX (O-ethyl S-(2-(diisopropylamino)ethyl) methlyphosphonothioate) and its isomer VR using a consistent inhalation delivery system. Nerve agents pose a threat to the respiratory tract with exposure resulting in acute lung injury and death. The determination of toxicity by inhalation is important for the rational development of therapeutic countermeasures. This study was designed to deliver nebulized dilute nerve agents in a dose-response manner to investigate the extent of lethality of these non-volatile agents. Male rats (240-270g) were anesthetized intramuscularly with 10 mg/kg xylazine and 90 mg/kg ketamine. Following anesthesia, rats were intubated with a glass endotracheal tube (ET) and placed in a glove box. The ET was connected to a closed circuit nebulizer system (Aeroneb, Aerogen, Inc.) that delivered a particle size of <2.0 μm and was in series between the ventilator and the ET. Nerve agents were delivered by a small animal ventilator set for a volume of 2.5 mL x 60-80 breaths/minute. Both VX and VR were nebulized and delivered in concentrations ranging from 6.25 to 800 μg/kg over a 10 min exposure time period. Lethality by inhalation occurred either during the 10 min exposure period or less than 15 min after the start of exposure. Survivors were euthanized at 24 h post-exposure. LCt50 estimates (± 95% confidence intervals) were obtained from the se-

quential stage-wise experiments using the probit analysis of Feder et al. Probit analysis revealed that the LCt50 for VX was 110.7 μg/kg (CI 73.5-166.7) and for VR 64.2 μg/kg (CI 42.1- 97.8). Although VR is a structural isomer of VX, the compounds appear to be markedly different in terms of toxicity when delivered by nebulization and inhalation.

This project was supported by the Defense Department and the Defense Threat Reduction Agency.

PS 519 EVIDENCE OF RDX-INDUCED BRAIN INJURY USING PERIPHERAL BENZODIAZEPINE RECEPTOR (PBR)/TRANSLOCATOR PROTEIN 18KDA (TSPO) QUANTITATIVE AUTORADIOGRAPHY.

D. I. Bannon[1], J. Choi[2], R. Saul[2] and T. Guilarte[2]. *[1]Center for Health Promotion and Preventive Medicine Toxicology, U.S. Army, APG, Aberdeen, MD and [2]Department of Environmental Health Sciences Toxicology Division, Johns Hopkins University Bloomberg School of Publich Health, Baltimore, MD.*

Hexahydro-1,3,5-trinitro-1,3,5-triazine is a synthetic, high-impact, stable chemical known as Rapid Detonation Explosive (RDX) that has been used in munitions since World War II. Humans can be exposed during manufacture or when RDX leaks into groundwater from unexploded ordnance. The primary symptom of acute oral exposure to high doses in humans is transient and reversible seizures, which are also reported in experimental animals. These effects in humans are often reported in occupational settings with high RDX airborne exposures. Studies have correlated measurements of RDX in the tissue of animals with frank seizures but little work has been done on the effects of RDX at the molecular or cellular level. The peripheral benzodiazepine receptor (PBR), recently renamed translocator protein 18 kDa (TPSO) has been used as a biomarker of brain injury in a variety of animal models (Chen and Guilarte. Pharm. Ther. 118: 1-17, 2008). In this work, male Sprague-Dawley rats (165-185 g) were either given a single oral dose (68 mg/kg) of RDX suspended in water or vehicle. Within 3 hours, 21 out of 24 animals had tonic-clonic convulsions. At 1, 3, 5, 7, and 10 days after RDX administration, animals were euthanized, brains harvested and fresh frozen at -80 degrees. Autoradiography of [3H]-R-PK11195 binding to PBR/TSPO was performed in RDX-treated and control brains. We found increased [3H]-R-PK11195 specific binding to PBR/TSPO in all animals dosed with RDX relative to controls. In particular, significantly increased levels of [3H]-R-PK11195 binding were measured in the cerebral cortex, hippocampus, and cerebellum. This work quantifies the effects of RDX in specific areas of the mammalian brain and suggests widespread brain injury as a result of a single seizure-inducing dose of RDX. [Supported by Army subcontract W91ZLK-07-P-2160 and ES07062 to TRG]

PS 520 ACUTE TOXICITY, TOXICOKINETICS AND HISTOPATHOLOGY OF INHALED RICIN IN BALB/C MICE AND SPRAGUE-DAWLEY RATS.

A. Gomez, T. March, M. Wolf, E. Barr and J. Benson. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

Ricin is a ribosome-inactivating protein derived from the castor bean. Because of its ease of dissemination and potential for human morbidity following exposure, the CDC has classified ricin as a Category B bioterrorist agent. Most likely routes of human exposure are inhalation and ingestion. The purpose of this study was to compare the acute toxicity, lung clearance and histopathology of inhaled ricin in rats and mice. For the acute toxicity studies, 5 groups of 6 animals of each species were exposed nose-only to ricin aerosols (1 μm MMAD). Targeted deposited doses for the acute toxicity studies were 0.12 – 1.2 μg/kg. The observation period was 7 days, with tissues collected for histopathological evaluation at necropsy. The calculated median lethal doses for rats and mice were 0.13 and 0.56 μg/kg, respectively. For rats, mean survival time was ≤ 2 days, except for the lowest dose tested, where mean survival time was 6.2 days. Concentrations of ricin in rat lung from all but the lowest dose group ranged from 23 – 93 ng. For mice, survival time was 2 (highest dose) to 7 days (two lowest doses), with 6 – 9 ng ricin/lung found up to 3 days post exposure. Pulmonary lesions included hemorrhage, bronchiolitis, and vasculitis. Respiratory tract clearance and tissue distribution were assessed at 6 time points, up to 72 hours post exposure of rats and mice to approximately 95 ng ricin/L air for 20 min and 40 min. For rats, initial lung burdens following 20 and 40 min exposures were 52 ± 7.7 and 145 ± 25 ng/lung (45 ± 10, and 110 ± 25.2 ng/g lung) respectively. The initial lung burden following a 40 min exposure in mice was 12.6 ± 7.7 ng/lung (88.5 ± 65.9 ng/g lung). Half times for elimination of ricin from the lung were less than 24 hours for both species. Results of our studies indicate that ricin is extremely toxic following inhalation, that ricin is eliminated from the lung rapidly, and that responses of rats and mice are similar. Research conducted under NIAID contract N01-AI-40095.

PS 521 ACETYLCHOLINESTERASE ACTIVITY IN GUINEA PIG TISSUE AFTER SUB-LETHAL VX EXPOSURE: COMPARISON OF PERCUTANEOUS *VS.* SUBCUTANEOUS EXPOSURE ROUTES.

L. A. Lumley[1], J. C. O'Donnell[1], E. Clarkson[1], T. Shih[1] and C. E. Whalley[2]. *[1]USAMRICD, Aberdeen Proving Ground, MD and [2]ECBC, APG, MD.*

The nerve agent VX is a potent inhibitor of acetylcholinesterase (AChE). In contrast to the G-agents that are volatile and primarily an inhalation threat, VX has low volatility, is readily absorbed through the skin and is primarily a percutaneous (PC) threat. Data on the toxicology of PC exposure to VX are limited to evaluations in anesthetized animals. Since anesthesia may affect the absorption of VX, it is important to evaluate kinetics in un-anesthetized animals. We and other laboratories observed that there is a delay in maximum concentration of VX (or fluoride ion regenerated G-analog of VX) and a much longer plasma half-life compared to G-agents. While VX inhibition of blood AChE was robust, VX inhibition of butyrylcholinesterase was minimal. We currently report on the time-course of AChE inhibition in tissues following a single sub-lethal and asymptomatic VX dose (0.4 LD50), administered by PC or subcutaneous (SC) route to un-anesthetized guinea pigs. Tissue activities of AChE were determined between 2-48 hr after exposure. Compared to saline control animals, following SC exposure, significant inhibition occurred in heart and brain 2-48 hr and in lung and eye 2-24 hr. No significant inhibition was observed in diaphragm or kidneys. In the diaphragm, AChE activity was variable, and there was a non-significant trend for levels to be inhibited at 2 and 6 hr after exposure. However, following PC exposure, AChE inhibition was delayed, with inhibition in heart 6-24 hr, in lung 20-24 hr and in brain 24 hr. There was no significant inhibition observed in eye, kidneys or diaphragm, although there was a non-significant trend for reduced AChE activity in diaphragm at 24 hr. These data, along with VX-G concentration in tissue, will be used in mathematical models of absorption, distribution, elimination and tissue response to nerve agents to improve human toxicity estimates.

PS 522 ACUTE TOXICITY, TOXICOKINETICS, AND HISTOPATHOLOGY OF INGESTED RICIN IN BALB/C MICE.

J. Benson, A. Gomez, M. Wolf and T. March. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

Because of its ease of dissemination and potential for human morbidity following exposure, the CDC has classified ricin as a Category B bioterrorist agent. Most likely routes of human exposure from a terrorist attack are inhalation and ingestion. The purpose of this study was to compare the acute toxicity, GI tract clearance, tissue distribution, and histopathology of ricin administered to BALB/c mice by gavage. For the acute toxicity studies, 5 groups of 10 mice were administered ricin at 4.4, 7, 11, 17.5 or 28 mg/kg. Mice were observed for 7 days for morbidity and mortality. Tissues were harvested from all animals for quantitation of ricin and evaluation of morphologic changes. The calculated LD50 (95% confidence interval) was 12.1 mg/kg (8.44-17.0 mg/kg). Survival time was dose dependent, ranging from 3.3 ± 1.8 to 6.5 ± 1.6 days for the highest and lowest dose groups, respectively. The primary targets organs for ricin induced toxicity were the gastrointestinal tract (apoptosis, congestion, mucosal/submucosal granulocytic infiltrates), liver (apoptosis, congestion, heptocytic cytoplasmic vacuolization, sinusoidal granulocyte leukocytosis), spleen (lymphocytic/hematopoietic apoptosis, neutrophilic leukocytosis), and pancreas (apoptosis, congestion, granulocytic infiltrates). The kidney was less frequently affected (congestion, vacuolization). Notably, similar lesions were present in mice surviving 7 days, even at the lowest dose tested. Results were verified in a follow-up experiment with a second ricin preparation. Ricin clearance and tissue distribution were assessed at 7 time points post dosing. Ricin concentration in stomach tissue was 19.2 ± 14.4 μg (97.8 ± 65.5 μg/g tissue) 0.25 hour and 60.2 ± 77.7 ng/lung (376 ± 519 ng/g tissue) 48 hours post dosing. In conclusion, ingested ricin is several orders of magnitude less toxic by ingestion than by inhalation. Lesions persist in animals surviving seven days post exposure. Ricin clears rapidly from the stomach, but quantifiable levels persist up to 2 days post dosing. Research conducted under NIAID contract N01-AI-40095.

PS 523 NEUREGULIN-1 PROTECTS AGAINST PARAOXON-INDUCTED APOPTOSIS IN HIPPOCAMPAL SLICE CULTURES.

C. Barnhart, H. Lauridsen, D. Bruun and P. J. Lein. *CROET, Oregon Health & Science University, Portland, OR.*

Organophosphorus (OP) pesticides cause significant death world-wide each year and OP nerve agents continue to represent a credible terrorist threat in military combat and against civilian populations. Current post-exposure medical countermeasures against OPs are useful in preventing mortality, but are insufficiently effective in protecting the CNS from seizures and permanent injury. Therefore, new and

more effective medical countermeasures must be developed to facilitate better emergency treatment and protection of civilians and military personnel following exposure to OPs. The use of neuroprotective and anti-inflammatory compounds, in combination with the current antidotal drugs, has been shown to decrease toxic symptoms and inflammation-induced brain damage. The objective of this study is to evaluate the therapeutic benefit of neuregulin-1 (NRG-1), a novel neuroprotective, anti-inflammatory compound, alone or as a complement to the standard therapy for OP poisoning. Hippocampal slice cultures derived from postnatal rat pups were exposed to varying concentrations of paraoxon for 24 hr beginning on the fifth day in vitro. Two markers of neuronal damage were assessed: 1) apoptosis, which was measured by fluorometric detection of caspase-3 activity; and 2) oxidative damage, which was assessed by western blot analyses of oxidized proteins. Oxidative damage was not detected but significant increases in caspase-3 activity were observed at 0.01 and 10 μM paraoxon. Addition of NRG-1 at 0.1 and 3 μM significantly reduced paraoxon-induced apoptosis. These findings suggest that NRG-1 represents a novel neuroprotective agent that may be useful in optimizing treatment of individuals exposed to acutely toxic levels of OPs.
This work was supported by NIH (NS 057993).

PS 524 2-DICHLOROETHYL ETHYL SULFIDE STIMULATES ARACHIDONIC ACID METABOLISM IN MOUSE SKIN.

M. Huang[1], J. P. Gray[2], H. Kim[3], R. P. Casillas[4], D. R. Gerecke[5], D. L. Laskin[5], J. D. Laskin[6] and D. E. Heck[3]. *[1]Chemical Biology, Rutgers University, Piscataway, NJ, [2]Science, U.S. Coast Guard Academy, New London, CT, [3]Environmental Health Science, New York Medical College, Valhalla, NY, [4]Battelle, Columbus, OH, [5]Pharmacology & Toxicology, Rutgers University, Piscataway, NJ and [6]Environmental & Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

The chemical warfare agent sulfur mustard induces blister formation and severe inflammatory reactions in the skin. In the mouse ear vesicant model (MEVM), sulfur mustard rapidly induces edema and inflammation as well as acanthosis and hypergranulosis. In previous studies we demonstrated that in the MEVM, 2-chloroethyl ethyl sulfide (CEES), a model sulfur mustard vesicant, rapidly induces the production of the antioxidant heme oxygenase-1, as well as inducible nitric oxide synthase and the proinflammatory mediators IL-1β and IL-6. In the present studies we determined if CEES modulated production of prostaglandins and leukotrienes, two important classes of arachidonic acid-derived proinflammatory lipid mediators. CEES (65 μmoles) induced the biosynthesis of both prostaglandin E2 (PGE2) and leukotriene B4 in the skin. This was associated with increases in mRNA expression of COX-2 and PGE2 synthase, two enzymes mediating production of PGE2. Leukotrienes are derived from arachidonic acid via 5-lipoxygenase (5-LOX); CEES decreased expression of 5-LOX mRNA, but increased expression of 5-LOX activating protein (FLAP), a critical protein upregulating leukotriene biosynthesis. CEES also decreased mRNA for leukotriene A4 hydrolase and leukotriene C4 synthetase, as well as 12-lipoxygenase. Taken together these data show that in the MEVM, CEES modulates both the prostaglandin and leukotriene biosynthetic pathways and generates inflammatory mediators. PGE2 and LTB4 antagonists may be important therapeutics for sulfur mustard-induced tissue injury. Supported by NIH grants CA100994, CA093798, ES004738, ES005022, GM034310 and AR055073.

PS 525 THE EFFECTS OF LOW DOSE SARIN AT SYMPTOMATIC AND ASYMPTOMATIC DOSES ON BEHAVIOR AND CATECHOLAMINE LEVELS IN MICE.

T. L. Garrett[1], C. M. Rapp[1], M. Fernandez[1], V. Tafur[1], J. J. Schlager[2] and J. B. Lucot[1]. *[1]Pharmacology & Toxicology, Wright State University, Dayton, OH and [2]Applied Biotechnology Branch, Air Force Research Laboratory, Wright Patterson Air Force Base, Dayton, OH.*

The differences between symptomatic and asymptomatic doses of the chemical warfare agent sarin (GB) at the time of dosing are significant. Using two different types of exposure we are able to investigate the differences behaviorally and neurochemically between the two doses. In the first method of exposure we used the carboxlyesterase inhibitor CBDP to enhance the effects of GB on the mouse and allow a lower dose of GB to be administered. In the second group, a low asymptomatic dose, animals are given 2 doses of sarin 1 day apart. The first group of animals were given 1.5 mg/kg CBDP followed an hour later by 0.2 LD50 GB and the second group was given 2 doses of 0.4 LD50 GB a day a part (asymptomatic). The 2 doses of 0.4 LD50 was asymptomatic and the CBDP plus GB produced significant acetylcholinesterase inhibition, seizure and a 35% mortality rate. The animals underwent a neurobehavioral battery before being euthanized for HPLC, neurochemical measurement. There were no differences between groups in spontaneous alternation in y-maze. GB dosed animals at both doses had decreased time in the open arm in the elevated plus maze compared to control animals and displayed thigmotactic behavior in the open field environment, indicating increased aversion to stressful environments. The catecholamine levels for dopamine, HVA and DOPAC in the frontal cortex and amygdala were changed between the groups when compared to controls (see Oswal et al., 2008). These results indicate that GB does affect cognitive abilities, but there appears to be little difference between doses that are symptomatic and asymptomatic.

PS 526 ELECTRON PARAMAGNETIC RESONANCE SPECTROMETRY (EPR) AND SPIN-TRAPPING TO DETECT FREE RADICALS IN RAT LUNG AFTER SULFUR MUSTARD VAPOR EXPOSURE.

A. A. Brimfield[1], G. Murphy[2], S. D. Soni[3], W. W. Holmes[3] and D. R. Anderson[3]. *[1]Pharmacology, U.S. AMRICD, Aberdeen Proving Ground, MD, [2]Medical Toxicology, U.S. AMRICD, Aberdeen Proving Ground, MD and [3]Analytical Toxicology, U.S. AMRICD, Aberdeen Proving Ground, MD.*

Investigations of sulfur mustard metabolism have led us to conclude that flavoenzyme reductases involved in extra-mitochondrial electron transport enzymatically reduce the cyclic sulfur mustard sulfonium ions. The reduced sulfonium ions then undergo homolytic cleavage to form carbon-based free radicals. EPR spectrometry and spin-trapping using a system consisting of NADPH, a reductase, mustard and the spin trap 4-POBN (alpha-[4-pyridyl-1-oxide]-N-tert-butylnitrone) have confirmed this in vitro. We expanded our investigation to a mustard vapor model in rats with bronchoalveolar lavage to include an in vivo system, and to detect evidence for free radical-induced lung injury. Anesthetized rats were intratracheally intubated and exposed to 0.35 mg mustard vapor over 50 min. During necropsy one hour later, lungs were rinsed three times with 5 ml of the spin trap 4-POBN 0.8 M in 0.1 M KPO4 buffer, pH 7.5. The recovered lavage fluid was assayed for mustard-related carbon free radical adducts by EPR spectrometry using a Bruker EMX Plus instrument equipped with a 4119 HS cavity. Spectrometer scans of lavage fluid from exposed rats produced spectra that appeared to contain three EPR signals. One signal, a triplet of doublets with hyperfine splitting constants of aN = 15.583 G and aH = 2.812 G, closely resembled results we got using sulfur mustard in our in vitro system. The unidentified signals seemed to be overlapping groups of three singlets. Scans of lavage fluid from a diluent control contained no structure that would indicate a free radical signal. Identification of free radicals as an outcome of mustard inhalation provides a more thorough understanding of mustard-related lung injury, and may provide a new in vivo screen for therapeutic compounds.

PS 527 PURIFICATION OF HUMAN PARAOXONASE 1 AND EVALUATION OF ITS CATALYTIC ACTIVITY AGAINST NERVE AGENT SIMULANTS.

H. A. Farag[1] and M. P. Nambiar[1, 2]. *[1]Brain Dysfunction and Blast Injury, Walter Reed Army Institute of Research, Silver Spring, MD and [2]Uniformed Services University of the Health Sciences, Bethesda, MD.*

Bioscavenger prophylactic treatment for chemical warfare nerve agents (CWNA) is moving towards development of catalytic bioscavengers that are more effective in protecting troops and civilians against CWNA exposure. Paraoxonase 1 (PON1) is a 43kDa glycoprotein synthesized in liver. PON1 has been shown to degrade organophosphate nerve agents, making it a potential catalytic bioscavenger. Compared to the stoichiometric bioscavenger human butyrylcholinesterase that act in a 1:1 ratio, PON1 could degrade large amounts of CWNA and would thus require small doses and reduce the cost of treatment. We initiated a project on purifying mammalian PON1 and determining its catalytic activity against inhalation exposure to nerve agents in a guinea pig model. We measured PON1 activity in human plasma, rabbit serum and the homogenate of Trichoplusia ni (cabbage looper) larvae expressing recombinant human PON1, using para-nitrophenylacetate as a substrate and normalized the data with protein levels. Rabbit serum was found to have the highest PON1 arylesterase activity followed by human plasma and larvae homogenate. We purified human PON1 from outdated plasma (human exempt protocol WRAIR # 1453) using Cibacron-Blue agarose chromatography and two subsequent anion exchange chromatography columns as described by Gan et al (1991). Preliminary data show that the purified enzyme has a specific activity of 605 U/mg. Para-nitrophenol conjugated surrogates of soman and sarin were used to assay the catalytic activity of PON1. Our data show an activity of 537 U/mg against sarin-NO2. In contrast, the activity of purified PON1 against soman simulant was less compared to sarin simulant. PON1 pharmacokinetics using a

guinea pig model is in progress. Our next goal is to evaluate the efficacy of PON1 against inhaled soman and sarin in the guinea pig model of microinstillation inhalation exposure.

PS 528 THERAPEUTIC BENEFIT OF REACTIVATION OF SARIN-INHIBITED ACETYLCHOLINESTERASE (ACHE) IN THE CENTRAL NERVOUS SYSTEM (CNS) BY THE TERTIARY OXIME MONOISONITROSOACETONE (MINA) IN GUINEA PIGS.

J. H. McDonough, T. Shih, R. Kan, T. Myers and I. Koplovitz. *Research Division, U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

The nerve agent sarin is a potent inhibitor of the enzyme AChE which results in excessive accumulation of acetylcholine (ACh) and overstimulation of central and peripheral cholinergic receptor sites. Treatment of sarin poisoning consists of the anticholinergic atropine to block the effects of excessive ACh and an oxime such as 2-pyridinium aldoxime (2-PAM) to reactivate agent-inhibited AChE. Oximes such as 2-PAM are quaternary drugs that provide negligible reactivation of CNS AChE. The present study investigated the capacity of the tertiary oxime MINA to 1) reactivate peripheral tissue, blood and brain AChE inhibited by sarin; 2) terminate sarin-induced seizures; 3) prevent neuropathology and the neurobehavioral consequences of sarin exposure; and 4) protect against the lethal effects of sarin. MINA (22-139 mg/kg, IM) administered 15 min after 1LD50 of sarin resulted in a dose dependent reactivation of peripheral tissue, blood and brain AChE after 60 min, whereas 2-PAM (25 mg/kg, IM) reactivated only peripheral tissue AChE. MINA (18-56 mg/kg, IM) administered from 0 to 10 min after a 2LD50 sarin challenge resulted in a dose-dependent blockade of electrographic seizures, neuropathology and behavioral debilitation. These sequelae were not blocked by 2-PAM treatment. Seizure prevention or termination preserved neurobehavioral functioning in tests of shuttlebox avoidance, acoustic startle, and open field locomotion. MINA (35 or 60 mg/kg, IM) administered alone, with atropine (0.5 mg/kg), or with atropine and 2-PAM 1 min after sarin challenge increased the 24-hr LD50 of sarin 3.6- to 15-fold compared to 1- to 3.3-fold for atropine, 2-PAM or atropine plus 2-PAM treatment. The results show that reactivation of brain AChE by the tertiary oxime MINA can mitigate the lethal and adverse neurobehavioral consequences of sarin intoxication and reinforce the importance of restoring AChE activity in the CNS following nerve agent intoxication.

PS 529 EVALUATION OF DELAYED TREATMENT WITH NOVEL NERVE AGENT ANTICONVULSANTS AND THEIR EFFECTS ON BRAIN NEUROTRANSMITTERS IN A RAT MODEL.

J. A. Guarisco, T. Shih, R. Kan and J. H. McDonough. *Research Division, U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Nerve agents are potential threats for use in terrorist attacks. Administration of standard antidote drugs (atropine, pralidoxime [2-PAM], diazepam) to civilian casualties in a terrorist attack will be substantially delayed. This study developed a delayed nerve agent treatment model and evaluated standard treatments plus novel anticonvulsant adjuncts. Rats were surgically prepared with electroencephalographic (EEG) recording electrodes and a microdialysis guide cannulae directed at the basolateral amygdala (BLA) or the piriform cortex (PC). A week later the animals were challenged with the nerve agent soman (180 ug/kg, SC). EEG was monitored for seizure onset and 20 min after seizure onset the animals received standard medical countermeasures — 0.45 mg/kg atropine sulfate, 25 mg/kg 2-PAM and 2.0 mg/kg diazepam — either alone or with an adjunctive drug. The animals were monitored 6 hr after exposure. Microdialysis samples were collected at 15-min intervals at a flow rate of 1.5 ul/min during this time. At 24 hr the animals were anesthetized and perfused with saline followed by 10% formalin. The brains were examined to determine cannula placement and evidence of neuropathology. In the absence of an adjunct drug, all animals continued to display seizure activity for more than 4 hr following standard medical countermeasures and 12 of 19 (63%) were still seizing at 24 hr; all animals displayed marked weight loss and extensive brain pathology. Treatment with the anticholinergic procyclidine (5.6 mg/kg) as an adjunct to standard medical countermeasures stopped seizure activity 10.8 (+/- 0.2) min after administration in 14 of 22 (64%). Animals in which seizures were stopped by procyclidine had no brain pathology and lost significantly less weight than those where seizures were not controlled by procyclidine treatment. Adjunct treatment with procyclidine can control nerve agent-induced seizures even under delayed treatment conditions.

PS 530 MINOCYCLINE AS A NOVEL THERAPEUTIC TO ORGANOPHOSPHOROUS NERVE AGENT POISONING.

L. Wagner, C. Eisner, T. Ferrara and A. Mazza. *USAMRICD, Aberdeen Proving Ground, MD.* Sponsor: J. McDonough.

Exposure to chemical warfare nerve agents results in the accumulation of synaptic acetylcholine, exciting both peripheral and central cholinergic receptors. The resultant acute cholinergic crisis induces the synaptic release of alternative neurotransmitter systems, leading to widespread neuronal stimulation in the CNS. This progressive condition causes excitotoxic neuron injury via increased intracellular calcium and mitochondrial dysfunction, which is further exacerbated by initiation of the proinflammatory response. The focus of this study was the ability of minocycline (MIN) to mitigate neural injury. MIN has been shown to be neuroprotective during global and focal brain ischemia, traumatic brain injury, endothelin-1-induced vasoconstriction, intracerebral hemorrhage, and seizure-induced brain injury (Domercq and Matute, 2004). Rats were injected with HI-6 30 min before delivery of 1.6 LD50s of soman and atropine. Following seizure onset, rats were injected with diazepam and either MIN (22.5, 45 or 90mg/kg) or vehicle. The neuroprotective efficacy of MIN was evaluated using EEG recording and neuropathology. In the initial phase, we are assessing whether MIN treatment affects 1) tissue injury and clinical response to soman exposure, 2) soman-induced increases in permeability of the blood brain barrier, and 3) the release of pro-inflammatory cytokines. We have determined that 90 mg/kg MIN reduces seizure severity at 24 hrs post-exposure. H&E and Fluoro-Jade B staining suggest that this dose decreases cell death in the hippocampus and piriform cortex. If MIN is in fact minimizing excitotoxic neuron injury, we hypothesize that it may decrement the proinflammatory response, attenuate BBB permeability, downregulate the release of the inflammatory cytokines and reduce the presence of apoptotic markers. Our initial data suggest that MIN inhibits neuron injury in specific brain regions at 90 mg/kg, with potential to decrease seizure severity and brain injury by downregulating mediators of inflammation and apoptosis.

PS 531 *IN VIVO* PHARMACOKINETIC EVALUATION OF A NOVEL CESIUM (CS) DECORPORATION AGENT IN RATS.

J. A. Creim, W. Yantasee, S. Addleman, G. E. Fryxell and C. Timchalk. *Biological Monitoring and Modeling, Pacific Northwest National Laboratory, Richland, WA.*

Novel decorporation agents are being developed to protect against radiological terrorist attacks (i.e. dirty bombs). Nano-engineered solid sorbents for chelation therapy were developed and validated in vivo. These sorbents, known as the self-assembled monolayer on mesoporous supports (SAMMS™), are hybrid materials where differing organic moieties are grafted onto mesoporous silica (SiO2). For cesium (Cs) a Cu-FC-EDA-SAMMS was evaluated for in vivo decorporation and experiments were conducted comparing the performance of the SAMMS vs. insoluble Prussian Blue. Three groups of jugular cannulated S-D rats (4/treatment) were evaluated. Group I was administered Cs (~40 μgeq/kg) by intravenous (iv) injection and oral gavage; Group II was administered prebound SAMMS+Cs by oral gavage; and Group III was orally administered Cs (~0.06 μgeq/kg) followed by 0.1 g of either SAMMS or Prussian Blue. Following dosing the rats were maintained in metabolism cages for 72 hr and blood, urine and fecal samples were collected for Cs analysis (gamma counting), rats were humanely euthanized and liver, stomach, small and large intestine were analyzed. Orally administered Cs was well absorbed (~100% relative to iv dose), and the pharmacokinetics (blood, urine, feces & tissues) were very comparable. For both exposures the urine and feces accounted for 20 and 3% of the dose, respectively. The prebound SAMMS+Cs was retained primarily within the feces (72% of the dose), with ~1.4% detected in the urine, suggesting that the Cs remained tightly bound to SAMMS, and is extensively eliminated in the feces. SAMMS & Prussian Blue both effectively chelated available Cs in the gut with feces accounting for 80-88% of the administered dose, while less than 2% was detected in the urine. This study suggests that the functionalized SAMMS provides comparable in vivo chelation efficacy with Prussian Blue. Future studies will focus on in vivo SAMMS chelation for a complex mixture and at higher doses of radionuclides. (Supported by NIH/NIAID grant R01 AI0 74064-01)

PS 532 EFFECTS OF 4-PYRIDINEALDOXIME (4PA) ON NERVE AGENT-INHIBITED ACETYLCHOLINESTERASE ACTIVITY IN GUINEA PIGS.

T. Shih, J. A. Guarisco, J. W. Skovira, J. C. O'Donnell and J. H. McDonough. *U.S. Army Med Res Inst Chem Defn, Aberdeen Proving Ground, MD.*

The oxime methoxime (MMB-4) is being proposed as a replacement for 2-pyridinium aldoxime (2-PAM) as an antidote to reactivate nerve agent-inhibited AChE activity and alleviate toxic and lethal consequences of nerve agent exposure. 4PA is

a break-down product and a probable metabolite of MMB-4. The interaction of 4PA with AChE in vivo may complicate the pharmacological consequence of nerve agent therapy. Therefore, the purposes of this study were to determine in guinea pigs the capacity of 4PA to affect the toxicity of the nerve agent sarin and/or to interact with AChE activity in blood, brain, and peripheral tissues. Animals were pretreated with atropine methyl nitrate (AMN) (1.0 mg/kg, im) 15 min prior to sarin exposure to minimize peripheral toxic effects. AMN is a peripheral acting muscarinic receptor blocker that does not affect AChE activity. Animals were challenged with 1 x LD50 sc dose of sarin. 4PA (3.5, 7.0, or 14.0 mg/kg) was given im at 15 min (at time of maximum brain, blood and tissue AChE inhibition by 1.0 x LD50 dose of sarin) after sarin exposure. A saline/saline control group and a sarin-exposed/saline-treated group were also included. At ~13 min (before 4PA administration) and ~58 min (before termination of the experiment) after sarin injection cholinergic toxic signs were scored. Blood, brain regions, and peripheral tissues were collected at 60 min after sarin exposure for analysis of AChE activity. 4PA did not modify the severity of sarin-induced toxicity score at either time point. The AChE activity observed at 60 min after sarin exposure was not significantly affected by any of the doses of 4PA administered at 15 min following sarin challenge. The present findings indicated that 4PA at the doses tested in this study does not influence (reduce or potentiate) the toxicity of sarin or the AChE activity inhibited by sarin.

PS 533 GENOMIC ANALYSIS OF PIRIFORM CORTEX AND HIPPOCAMPUS FOLLOWING EXPOSURE TO SARIN.

K. D. Spradling[1], L. A. Lumley[2], C. L. Robison[2], J. L. Meyerhoff[3] and J. F. Dillman[1]. *[1]Cell and Molecular Biology Branch, USAMRICD, Aberdeen Proving Ground, MD, [2]Neurobehavioral Toxicology Branch, USAMRICD, Aberdeen Proving Ground, MD and [3]WRAIR, Silver Spring, MD.*

Organophosphorus nerve agents, such as sarin, are known to inhibit acetylcholinesterase; however, the biological pathways involved in nerve agent-induced neurodegeneration are not well understood. To determine these pathways, we analyzed gene expression changes following sarin exposure. Male Sprague-Dawley rats were challenged with 1.0 x LD50 sarin, using saline as a vehicle. One minute after seizure onset, the animals were treated with atropine sulfate and 2-pyridine aldoxime methylchloride (2-PAM). Thirty minutes later, they were given diazepam. Control animals received an equivalent volume of vehicle and drug treatments. The piriform cortex and hippocampus were harvested at 0.25 h, 1 h, 3 h, 6 h, and 24 h post-exposure, and total RNA was processed for microarray analysis. Principal component analysis identified the major sources of variability as seizure occurrence and the time point following seizure onset at which the tissues were harvested. An analysis of variance was performed to identify genes most significantly changed at each time point based on sarin exposure, and gene ontology analysis was used to determine the biological pathways most affected by sarin-induced seizures, as well as by sarin exposure without the occurrence of seizures. The top pathways identified as being most significant in seizing animals, such as interleukin (IL)-6 and IL-10 signaling, were indicative of an inflammatory response, while the top pathways identified in non-seizing animals, such as protein ubiquitination, represent a more general stress response. This identification of biological pathways involved in sarin-induced neurodegeneration will help determine potential therapeutic targets for the development of antidotes to counteract sarin toxicity.

PS 534 A COMPARISON OF THE SENSITIVITY OF DIFFERENT STRAINS OF MICE TO SARIN AND KAINIC ACID SEIZURES.

C. M. Rapp[1], T. L. Garrett[1], D. G. Watson[2], A. R. Kessler[1] and J. B. Lucot[1]. *[1]Pharmacology & Toxicology, Wright State University, Dayton, OH and [2]711 Human Performance Wing, Air Force Research Laboratory, Wright Patterson Air Force Base, Dayton, OH.*

Poisoning from chemical warfare agents such as sarin (GB) causes prolonged seizure activity and is associated with neuronal degeneration. To determine the effectiveness of rescue agents, we must find a mouse strain that exhibits neuronal degeneration and uses a relatively low dose of sarin. Using five strains of mice we determined the LD50 of each strain to GB. Beginning doses of GB were based on doses of kainic acid (KA) that induced seizures (McLin and Steward 2006). Using C57BL/6 mice as a baseline, a strain rated as moderately sensitive by McLin and Steward, doses were calculated up or down using the LD50 of C57BL/6 as a starting point, which we determined to be 200 μg/kg based on our shipment of GB. Initial estimates of LD50 doses in other strains based on their sensitivity to KA and extrapolated to GB proved inaccurate. Therefore dose-response curves for GB were determined to establish the LD50 for each strain. The strain sensitivity to KA in increasing order is DBA/2 > C57BL/6 > ICR > FVB/N. McLin and Steward did not get conclusive results with the Swiss-Webster (S-W) strain. The order of sensitivity to GB by strain by increasing dose is C57BL/6 > DBA/2 > ICR > S-W >FVB/N. Neuronal degeneration was illustrated by staining frozen 10 μm sections of brain with Fluoro-Jade C and examining the hippocampal region of each brain section. Of the 5 strains tested, DBA/2 and C57BL/6 did not exhibit any FJ-C staining. Based on this data and other considerations, we have chosen Swiss-Webster mice to use in subsequent studies of neuronal deficits following GB poisoning.

PS 535 EFFECTS OF SOMAN EXPOSURE ON CONTEXTUAL AND CUED FEAR CONDITIONING IN RATS.

M. Moffett and L. Lumley. *Analytical Toxicology, USAMRICD, Aberdeen Proving Grounds-EA, MD.* Sponsor: J. Yourick.

Soman (GD), an organophosphorus nerve agent, irreversibly inhibits acetylcholinesterase leading to an accumulation of acetylcholine at central and peripheral sites. The effects of cholinergic hyperactivity include hypersecretion, respiratory distress and convulsions. Current therapies increase survival rates but do not necessarily offer protection from seizure-associated brain pathology and performance deficits. The amygdala and hippocampus are affected in animals that seize extensively. Both regions are believed to play important roles in the development and expression of fear conditioning. The fear conditioning tasks are evaluated as possible behavioral correlates of the observed neuropathology. Male rats were implanted with a telemetry transmitter which continuously collects electroencephalographic activity. The rats were exposed to GD (1.0, 1.2 LD50) or saline followed 1 minute later with injections of atropine (2 mg/kg, im) and the oxime HI-6 (93.6 mg/kg, im). Diazepam (10 mg/kg, sc) was administered 30 minutes after seizure onset or 50 minutes post-exposure in rats that did not seize. Fear conditioning was conducted on post-exposure day (PED) 8. Following a 3-minute habituation period the rats were given 15 tone- (85 dB, 10s) shock (1.0 mA, 2s) pairings with 60 seconds between pairings. Twenty-four hours after conditioning the rats were returned to the test chamber and freezing behavior was recorded. Freezing behavior was measured 48 hours after conditioning in a novel context. Following a 3-minute habituation period, the rats were presented with 7 tones (85dB, 10 s) with 60 seconds between trials. Rats exposed to GD or saline froze for 40-60% of each minute when placed in the conditioning chambers. When presented with the tone, rats exposed to 1.2 LD50 GD froze less than1.0 LD50 GD and saline- treated animals. The present study indicates that fear conditioning potentially could be used as a behavioral assessment of neuropathology resulting from GD exposure. Evaluation to compare neuropathology of the GD-exposed rats with performance in the fear conditioning tasks is ongoing.

PS 536 γ-H2AX FORMATION IN THREE-DIMENSIONAL HUMAN SKIN AND CELL MODELS FOLLOWING *IN VITRO* EXPOSURE TO SULFUR MUSTARD.

A. L. Miller, O. E. Clark, E. W. Nealley, K. W. Leiter and W. J. Smith. *Research Division, USAMRICD, Aberdeen Proving Ground, MD.*

Sulfur mustard (2-2'-dichlorodiethyl sulfide, SM) is a cytotoxic chemical warfare agent known for its vesicating properties. SM exposure to human tissue results in DNA damage, eventually leading to cell and tissue death. To elucidate the genotoxic effects of SM, the presence of γ-H2AX foci was determined in several skin models. These included normal human epidermal keratinocytes (NHEK) and two commercially available multicellular skin tissue constructs, EpiDerm™ and EpiDermFT™ (MatTek Corp.). γ-H2AX is a phosphorylated derivative of the H2AX histone and is tightly bound to double strand DNA break sites, making γ-H2AX an important indicator of genotoxic injury. NHEK, EpiDerm™ and EpiDermFT™ constructs were exposed to 0, 50, 100 and 300 μM concentrations of SM. Two and 24 hrs following SM exposure, models underwent immunohistochemistry staining using a mouse anti-γ-H2AX antibody with propidium iodide (PI) as a nuclear stain. Our results show that SM exposure leads to the formation of γ-H2AX foci in the in vitro models at 24 hrs compared to the untreated controls. This in vitro model of early DNA damage will aid in the development of therapeutic compounds to prevent cell death following SM exposure.

PS 537 POLYURETHANE SPONGES CONTAINING ADDITIVES FOR DECONTAMINATING GUINEA PIGS EXPOSED TO CUTANEOUS SOMAN OR VX.

E. D. Clarkson[1], S. Schulz[1], A. Gunduz[2], R. Railer[1], K. Baker[2], L. Askins[2], S. Strating[2], J. Echazabal[2], R. Kaiser[2], B. P. Doctor[2], R. K. Gordon[2] and S. I. Baskin[1]. *[1]Medical Toxicology, U.S. Army Institute for Chemical Defense, Aberdeen Proving Grounds, MD and [2]Walter Reed, Army Institute of Research, Silver Spring, MD.*

Polyurethane sponges were very effective for the decontamination of skin following acute exposure to chemical warfare agents. The sponges were designed for ease of use and the ability to detoxify or inactivate chemical warfare agents. Detoxifying

the chemical warfare agents prevents further contamination and toxicity and extends the life of the sponge, because it can be used multiple times. Decontamination efficacy was measured by survival of guinea pigs exposed to soman (GD) and VX. GD or VX was applied to skin on the lateral flank of anesthetized guinea pigs and was removed with a wiping motion 1 minute after application. To measure detoxification of GD and VX in the sponge over a 3 h period, samples from the sponge were added to known concentrations of acetylcholinesterase (AChE). The amount of GD or VX removed by the sponge but not neutralized was measured by residual inhibition of AChE. When testing the effectiveness of oximes, sponge solutions contained 50 mM oxime in phosphate buffer. The oximes TMB-4, 2-PAM, BMO and HI-6 were tested against GD challenge and HI-6 was found to be the most effective, increasing the median lethal dose (MLD) by a factor of 7. Solutions of 10% tetraglyme or 10% triglyme were also tested against GD challenge; and each increased the MLD by a factor of 8. All additional experiments were conducted using mixtures of oximes and tetraglyme. The combination of tetraglyme and HI-6 was very successful, increasing the MLDs of GD by a factor of 14 and VX by a factor of 110. The rate at which GD and VX were neutralized in the sponges correlated well with the increased MLDs observed. In summary, the small, self-contained polyurethane sponges will provide immediate use for either the individual or buddy in the field with little additional training and enhance force protection and mobility.

PS 538 INCREASED CHEMOKINE EXPRESSION AND NEUTROPHIL INFILTRATION IN THE BRAIN FOLLOWING PROLONGED SOMAN-INDUCED STATUS EPILEPTICUS IN RATS.

E. A. Johnson, T. L. Dao, D. M. Kniffin, C. P. Tompkins, T. A. Hamilton and R. K. Kan. *USAMRICD, Aberdeen Proving Ground, MD.* Sponsor: J. Dillman.

Exposure to the toxic nerve agent soman (GD) causes neuronal cell death and impaired behavioral function dependent on the induction of status epilepticus (SE). However, little is known about this important pathological process following GD exposure. Although data exist for a small number of neuroinflammatory transcripts in the brain after GD exposure, no data on proinflammatory chemokines have been elucidated. The purpose of this study is to characterize the regional and temporal progression of early neuroinflammatory protein signals following GD-induced seizure activity in rats. Protein levels of chemokines and inflammatory cell growth factors in multiple brain regions were quantified up to 72 hours following SE onset using multiplex bead immunoassays. We observed significant concentration increases for three chemokines in the brain (CXCL1, MIP-1α and MCP-1) that peaked between 12 and 24 hours after seizure onset. Additionally, immunohistochemistry was used to identify the resident neural cell types that produce these factors at peak expression times. Lastly, because these factors affect inflammatory cell migration, neutrophil infiltration and active microglial accumulation were also investigated and correlated with chemokine expression. These data suggest that following GD-induced SE, a strong chemotactic response originates primarily in neurons and cells of the neurovascular unit to recruit circulating neutrophils and resident microglia to areas of brain damage. The induction of this inflammatory response may play a key role in the progressive brain pathology observed following GD-induced SE and greater understanding of the neuroinflammatory process may help develop better therapeutic strategies to mitigate the effects of GD exposure. This research was supported by the Defense Threat Reduction Agency – Joint Science and Technology Office, Medical S&T Division.

PS 539 RAPID RADIATION EXPOSURE ASSESSMENT ACCOMPLISHED *VIA* A HEMATOTOXICITY MATRIX.

J. C. Bemis[1], Y. Chen[2], S. Phonethepswath[1], S. Bryce[1], R. Chen[2], O. Hyrien[2], S. Peslak[2], J. Palis[2], P. Okunieff[2] and S. Dertinger[1]. *[1]Litron Laboratories, Rochester, NY and [2]University of Rochester Medical Center, Rochester, NY.*

The human health concerns associated with radiological incidents, whether accidental or intentional, are well documented. However our ability to respond on a clinical level is limited by the lack of technologies that can rapidly and reliably assess the level of radiation that a victim has received. Building on the established response of lymphocyte frequencies to irradiation (IR), the Hematotoxicity Response Matrix (HARM) assay employs flow cytometry to provide data on the absolute number and apoptotic signature of multiple hematopoietic cell types in peripheral. Undiluted whole blood is placed directly into a staining solution that labels cellular nucleic acid content and mitochondrial membrane potential (MMP). Proof-of-principle experiments in mice demonstrated the ability of the HARM assay to assess the response of several blood cell populations to radiation exposure. These studies were extended by validating the method of cell identification using phenotype-specific antibodies and comparing HARM-based blood cell counting to a standard hematological analyzer. Blood samples collected from rats exposed to ≤ 6 Gy ^{137}Cs total body irradiation revealed dose- and time-dependent reductions in lymphocyte and reticulocyte frequencies and elevations in the MMP-based apoptotic signature in these populations. Additional experiments using untreated non-human primate and human samples demonstrate the cross-species compatibility of the reagents and analytical approach. Application of statistical modeling revealed that the combinatorial use of multiple endpoints improved the dose estimating ability of the HARM assay. Our findings lay the groundwork to suggest that this method could play an important role in the triage of individuals involved in radiological incidents.

PS 540 EVALUATION OF A CAPSAICIN ANALOG AS A MODULATOR OF INFLAMMATORY CYTOKINE RELEASE IN HUMAN TISSUE MODELS.

O. E. Clark[1], E. W. Nealley[1], A. L. Miller[1], K. W. Leiter[1], Y. Jung[2] and W. J. Smith[1]. *[1]Research Division, U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD and [2]Korea Research Institute of Chemical Technology, Daejeon, Korea, South.*

We studied the mechanism of toxicity of the chemical vesicant sulfur mustard (2, 2'-dichlorodiethyl sulfide, SM) for the purpose of developing medical countermeasures to chemical threat agents. A major feature of SM tissue injury is inflammation. Capsaicin is known to block neurogenic inflammatory pathways. The capsaicin analogs have been reported to have limited ability to prevent SM damage in the mouse ear vesicant model. They have been used with cell culture models to inhibit inflammatory cytokine release and reduce cellular death. The novel capsaicin analog KR-24095 was obtained from the KRICT. Development of a potential therapeutic compound required additional information on tissue sensitivity to capsaicin analogs. We acquired three different in vitro models: 1)EpiOcular™ (MatTek) corneal model derived from normal, human epidermal keratinocytes, 2) normal human bronchial epithelial cells and 3) normal human microvascular endothelial cells derived from lung. Cells and tissue constructs were pretreated for 15 minutes with KR-24095 dissolved in distilled water and diluted in growth media. Cells and tissue constructs were exposed to SM diluted in growth media. Cytokine levels were measured with human cytokine 10-plex assay kits™ (Invitrogen) following the manufacturer's protocol. KR-24095 did not decrease inflammatory cytokine release into the media of the treated EpiOcular™ corneal model. The release of IL-10, IL-8, IL-5, IL-6, IL-2, IL-1β, IFN-γ, TNF-α, and GM-CSF induced by 300 μM SM was reduced in both the bronchial cells and human endothelial cells. We previously reported that KR-24095 protects against the loss of cell viability due to SM. Current results indicate that the same compound attenuates some inflammatory response due to SM. Thus, a capsaicin analog may serve a dual purpose of being anti-inflammatory and protecting against SM-induced cell death.

PS 541 DEVELOPMENT OF A PULMONARY INJURY MODEL OF INHALED SULFUR MUSTARD.

W. M. Weber, M. Lehman, D. Kracko, J. Benson, J. Seagrave, T. March, J. McDonald and G. Grotendorst. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

Sulfur mustard (SM) poses a considerable potential threat as a weapon or terrorism agent due to its ease of synthesis and ability to be easily distributed in a manner that would allow for a mass casualty situation. Appropriate animal models are required to understand mechanisms of effect and to validate therapeutic agents. We compared inhalation of both vapor and aerosol forms of SM in female F344 rats. Due to the extreme reactivity, nose-only inhalation of SM vapors resulted in severe nasal damage with minimal injury in the conducting airways and none in the deep lung. An aerosol formulation of SM in ethanol delivered by nose-only inhalation induced injury in the lung but still caused severe injury in the nasal cavity. IL-2, -9, -13, and -17 were elevated in BALF, and mild injury was detected in histological analysis. To bypass the nose, SM was delivered by inhalation to intubated animals. In initial studies using an injectable anesthetic mixture, the rats exposed to SM vapor recovered from anesthesia before the conclusion of the exposure and significantly earlier than animals breathing only filtered air, suggesting that reaction of SM with the anesthetic inactivated both chemical's biological activities. Chemical reaction analysis and biochemical assays of the lung tissue support this hypothesis. A second intubation system was developed to allow the addition of Isoflurane into the exposure atmosphere to maintain the rodents' anesthetized state. Isoflurane did not react chemically with SM. Grossly, lungs from rodents exposed via this exposure system showed patchy, lobar, or segmental redness and atelectasis. Current work is being conducted to deliver an aerosol via intubation in anticipation an aerosol will result in a more homogeneous lung injury model. The molecular and cellular mechanisms for these effects remain to be determined, but there are clear implications for the utility of these models to assess the utility of therapeutic agents for treatment of SM-induced pulmonary injury. This work was funded by NIH NINDS #5U54NS058185-03.

PS 542 8-OH-DPAT PROTECTS FROM DEFICITS PRODUCED BY SARIN INDUCED CONVULSIONS.

K. V. Joshi[1], C. M. Rapp[1], K. E. Irwin[1], J. J. Schlager[2] and J. B. Lucot[1]. *[1]pharmacology and toxicology, wright state university, Dayton, OH and [2]Applied Biotechnology Branch, Air Force Research Laboratory, Wright-Patterson Air Force Base, Dayton, OH.*

Sarin (GB) is a weapon of mass destruction that was released in the Gulf War and terrorist attacks in Japan. Current treatments are still not effective at protecting against long term deficits if not given within few minutes of exposure. Chemical warfare agent-induced seizures cause the release of glutamate. The excessive glutamate release produced neurotoxicity and N-methyl-D-aspartic acid (NMDA) antagonists reduce the amount of damage but are too toxic therapeutically. In vitro and in vivo, serotonin (5-HT) 1A agonist prevented toxicity from glutamate. We determined the neuroprotective capabilities of the 5-HT-1A agonist 8-hydroxy-2-(di-n-propylamino) tetralin (8-OH-DPAT), as a novel pharmacological countermeasure to chemical warfare agents. Rodents have higher amount of carboxyl-esterase enzyme and requires higher doses of sarin than other species. To address this issue we administered 1.5 mg/kg of CBDP (2-/o-cresyl/-4 H-1: 3: 2-benzodioxaphosphorin-2-oxide), which specifically blocks carboxyl esterase and makes mouse model comparable to that of human exposure. We determined the time course of neuroprotection by 8-OH-DPAT over five time points. The toxic challenge was 1.5 mg/kg of CBDP and one hour later a sarin dose which produced 35-40% mortality, followed by 1mg/kg of 8-OH-DPAT at 1,15,30,45 or 60 minutes. Mice were sacrificed at two weeks after sarin administration and left or right brain hemispheres were collected and frozen in isopentane for histological examination. There was a decrement in glial fibrillary acidic protein (GFAP) expression at least out to the 45 min time point after 1 mg/kg dose of 8-OH-DPAT plus toxic challenge group compare to toxic challenge alone in dentate gyrus.

PS 543 8-OH-DPAT REDUCES THE SEVERITY OF SEIZURES PRODUCED BY SARIN.

B. Sims[1], J. Harrod[1], D. G. Watson[2] and J. B. Lucot[1]. *[1]Wright State University, Dayton, OH and [2]711 Human Performance Wing, Air Force Research Laboratory, Wright Patterson Air Force Base, Dayton, OH.*

Sarin (GB), an organophosphorous (OP) compound, has been used as a chemical warfare and terrorist agent. Veterans of Desert Storm and the Gulf War suffered from illnesses linked to nerve agent exposure. Sarin acts by targeting the acetylcholinesterase (AChE) at its active site and interfering with neurotransmission by allowing acetylcholine to build up at nerve synapses, inducing seizures which results in severe neurological damage. 8-hydroxy-2-(di-n-propylamino) tetralin (8-OH-DPAT) is a 5-HT1A agonist that protects nerve cells from excitotoxicity by controlling the release of glutamate protecting the neurons in survivors of OP poisoning. This study tested the hypothesis that the neuroprotective effects of 8-OH-DPAT against sarin-induced neuropathology resulted from alteration of the seizure pattern. ICR mice were implanted subcutaneously (sc) with transmitters and cortical electrodes for telemetry recordings. Recordings of baseline electroencephalography (EEG) were obtained and mice were then injected with 200 μg/kg (sc) of GB and EEG recordings were taken for 4 hours unless death resulted. Another group was dosed with 200 μg/kg of GB and 1 min later DPAT (1.0 mg/kg) (sc). All of the GB dosed mice exhibited behavioral signs of seizure activity. The recordings substantiated that seizures occurred and they continued increasing in severity of spikes. There was a significant difference in the seizure activity of mice dosed with GB alone compared to the mice with GB+DPAT. The EEG of the GB dosed mice indicated seizure patterns with an intense (high amplitude), rapid spikes, a high seizure periodicity and 50% mortality rate. The seizure pattern of the GB+DPAT dosed mice revealed seizure patterns with greater intervals between spikes, had a lower amplitude and were of a shorter seizure duration. The GB+DPAT mice had 0% mortality rate. These studies demonstrate that 8-OH-DPAT influences the pattern, intensity, and duration of sarin-induced seizures in mice.

PS 544 EFFECT OF LOW-DOSE SARIN EXPOSURE ON THE NEUROCHEMISTRY OF DIFFERENT BRAIN STRUCTURES IN MICE.

D. P. Oswal[1], B. S. Izu[2], M. Morris[1] and J. B. Lucot[1]. *[1]Pharmacology and Toxicology, Wright State University, Dayton, OH and [2]Department of Surgery, Wright State University, Dayton, OH.*

Sarin (GB) is a toxic organophosphate (OP) nerve agent that was released in the Gulf war and was used in terrorist attacks in Japan. People who survive such attacks exhibit various long-term effects including alterations in neuropsychological performances. In order to understand the effect of low dose exposure to GB on physiological and behavioral functions, we analyzed the levels of catecholamines and their metabolites [dopamine (DA), dihydroxyphenyl-acetic acid (DOPAC) and homovanillic acid (HVA)] in different brain areas after exposure of mice to sublethal dose of GB. Two groups of mice (male C57BL/6) were injected subcutaneously once a day for 2 days, with 0.05 LD50 or 0.4 LD50 of GB. The mice did not show signs of cholinergic toxicity. Mice were sacrificed at 4 weeks and 8 weeks with collection of brains for neurochemical analysis. In both dose groups and time points, significant decrease in DOPAC/DA ratio and HVA/DA ratio were observed in the frontal cortex region of the brain. There was an increase in the DOPAC/DA ratio and HVA/DA ratio in the amygdala for the 4 week group but not for the 8 week group at both doses. There was no significant change observed in the caudate nucleus. The frontal cortex and the amygdala receive projections from the A10 DA cell bodies and the caudate nucleus gets the projections from the A9 DA cell bodies. Data shows that even low dose of sarin has potent long-term, region specific effects on catecholamine systems. Further experiments are necessary to evaluate the relationship between these modifications and the neuropsychological disorders reported after asymptomatic exposure to OPs.

PS 545 QUANTITATIVE ASSESSMENT OF DNA DAMAGE *VIA* COMET ASSAY IN CEES-TREATED MOUSE SKIN EPIDERMAL CELLS AND FIBROBLASTS.

S. Inturi[1], N. Tewari-Singh[1], C. Agarwal[1], C. W. White[2] and R. Agarwal[1]. *[1]Pharmaceutical Sciences, University of Colorado Denver, Aurora, CO and [2]National Jewish Medical and Research Center, Denver, CO.*

Sulfur mustard (HD) is a cytotoxic and alkylating chemical warfare agent, whose primary toxic consequence is severe skin damage with vesication linked to cell death of proliferating keratinocytes in the basal layer of the skin. HD, through alkylation reactions, forms adducts and cross links with DNA leading to its damage and further cytotoxic effects. To understand these cytotoxic effects, our recent studies employing JB6 mouse epidermal keratinocytes have identified and established injury biomarkers using 2-chloroethyl ethyl sulfide (CEES); a less toxic analog of HD. These studies showed phosphorylation of H2A.X ser139 and p53 ser15 by CEES showing its DNA damaging effects. To further quantify and assess CEES-caused DNA damage, we employed comet assay, a well known technique for the quantification of damaged DNA, in JB6 cells and neonatal SKH1 hairless mouse skin fibroblasts. This approach was selected to understand CEES-caused DNA damage in both epidermal and dermal layers of skin. Treatment of both these cells with CEES (0.1- 1mM) for 2h, showed maximum DNA damage at 0.5mM CEES concentration. In the time response study, 0.5mM CEES treatment of cells from 30min to 16h showed maximum DNA damage between 1 to 2 h. Interestingly, starting 4h of CEES treatment, DNA damage started decreasing and by 16h there was a substantial decrease suggesting a possible role of repair and rescue mechanisms. To relate cell viability with time-dependent DNA damage, we next conducted Trypan blue exclusion assay, which showed a maximum decrease in viability at 2h in JB6 cells and at 1 h in fibroblasts. Whereas further studies are underway to assess the nature of CEES-caused DNA damage and related molecular mechanisms, present findings suggest that DNA damage could be an important quantitative biological marker in agent efficacy screening studies.

PS 546 HEMORRHAGIC PULMONARY EDEMA IN THE RAT FOLLOWING ACUTE EXPOSURE TO THE NERVE AGENT SOMAN.

R. K. Kan, A. Koemeter-Cox, D. M. Kniffin, C. P. Tompkins, L. W. Mitcheltree and T. A. Hamilton. *USAMRICD, Aberdeen Proving Ground, MD.* Sponsor: J. McDonough.

Brain injury is a hallmark of chemical warfare nerve agent (CWNA) poisoning. However, pulmonary hemorrhage is a less well-known phenomenon that is observed in rats that die within minutes to hours after soman (GD) exposure. The present study investigated morphological alterations in the rat lung following a lethal injection of GD. Male Sprague-Dawley rats were pretreated with HI-6 30 min prior to GD challenge (1.6 LD50, sc) and treated with atropine methylnitrate (AMN; 2.0 mg/kg, im) one minute after agent administration. Lung tissues from rats that died after GD exposure and from those that were euthanized at 1, 3 or 6 hr after the onset of seizures were fixed in 10% formalin or 2% paraformaldehyde and 2.5% glutaraldehyde for light or transmission electron microscopy, respectively. Deceased animals showed massive pulmonary hemorrhage in all lung lobes. Histopathology revealed severe hemorrhagic pulmonary edema (HPE) indicated by alveolar accumulation of red blood cells with proteinaceous exudate. Although less severe, lung samples from rats euthanized at scheduled time points after seizure onset showed various degrees of HPE within the lung parenchyma. By transmission electron microscopy, alterations of both endothelial and epithelial cells were observed, which included thinning of the blood-air barrier, blebbing and rupture of the capillary endothelial layer, extravasation of RBCs, necrosis and rupture of type

I pneumocytes and recruitment of platelets. These ultrastructural changes led us to conclude that HPE after GD exposure could be caused by mechanical stress failure of the blood-air barrier due to pathophysiological conditions, including neurogenic pulmonary edema and pulmonary arterial hypertension.

PS 547 COUNTERMEASURES AGAINST NITROGEN MUSTARD INJURY TO THE CORNEA.

A. S. DeSantis[1], R. A. Hahn[1], J. Beloni[1], K. K. Svoboda[2], D. R. Gerecke[1], M. Babin[3] and M. K. Gordon[1]. *[1]Pharmacology and Toxicology, Rutgers University, Piscataway, NJ, [2]Biomedical Sciences, Baylor College of Dentistry, Dallas, TX and [3]Battelle, Biomedical Research Center, Columbus, OH.*

Mustards are potential terrorist agents for which there are not good countermeasures. Moderate to severe exposures to eyes have acute effects, but may also exhibit recurrent injury. To study the wound healing response in an in vitro corneal organ culture model system, scales for assessing mild and moderate injury have been developed. Countermeasures have been examined using these scales to evaluate effectiveness. Dissected rabbit corneas with scleral rims were filled with agar and placed epithelial side up in culture dishes. The corneas remained air lifted by adding medium only up to the corneal-scleral junction. Corneas remain transparent for at least 10 days in organ culture. Corneas were exposed to 100 nmol nitrogen mustard. Two hours following exposure, medium was replaced with either fresh medium, or with medium plus a counteragent. Medium plus or minus countermeasure was reapplied 3 more times over the following 22 hours. Corneas were then fixed, sectioned, stained with hematoxylin and visualized by light microscopy. Suprabasal epithelial cell nuclei stained well, but basal cell nuclei were pale, suggesting DNA damage. A modified H&E staining technique provided a color palette scale to gauge the severity of injury to basal cell nuclei. Multiple stain solution (MSS) was used to better view gaps in cell-cell and cell-membrane junctions. Corneas exposed to nitrogen mustard, then treated with doxycycline, a matrix metalloproteinase inhibitor, or with Tobradex, an antibiotic/steroid combination drug, demonstrated an improved epithelial BM-stromal interface and a healthier appearance of basal cell nuclei, as compared to corneas that received no countermeasure. These data suggest that even mild injury from mustard compounds causes DNA damage to the basal epithelial cells, with some ECM degradation. Furthermore, the adverse effects can be ameliorated by compounds such as doxycycline and Tobradex. Supported by EY009056 and AR055073.

PS 548 PROPHYLACTIC AND THERAPEUTIC EFFICACY OF GLUTATHIONE (GSH) AGAINST SULFUR MUSTARD ANALOG CEES-INDUCED SKIN INJURY.

N. Tewari-Singh[1], M. Gu[1], A. Pal[1], C. Agarwal[1], C. W. White[2] and R. Agarwal[1]. *[1]Pharmaceutical Sciences, University of Colorado Denver, Aurora, CO and [2]National Jewish Medical and Research Center, Denver, CO.*

Sulfur mustard (HD) is a cytotoxic and alkylating chemical warfare agent that inflicts incapacitating effects on skin. Effective prophylactic or therapeutic interventions against HD-caused skin injury are lacking due to incomplete knowledge of the related cellular mechanisms. Our recent findings have elaborated on the mechanisms involved in HD analog, 2-chloroethyl ethyl sulfide (CEES)-induced skin injury and established its biomarkers in mouse epidermal JB6 cells and SKH-1 hairless mouse skin. The aim of the current study was to evaluate the protective effect of GSH, an oxidative stress protecting thiol known to be depleted by HD, on CEES-induced skin toxicity employing JB6 cells and SKH-1 mouse skin model. GSH treatments at 1 and 10 mM for 1 min to 4 h both pre and post 0.35 and 0.5 mM CEES exposed JB6 cells indicated a dose-dependent reversal of CEES-induced decreases in cell viability and DNA synthesis. The CEES exposure of cells at 0.35 mM concentration resulted in 50% cell death at 24 h; however, 10 and 1 mM GSH pre- or post-CEES treatment resulted in almost complete and 60% reversal of CEES-caused cell death, respectively. In other studies, GSH treatment of cells before 0.5 mM CEES exposure was more effective in reversing CEES-induced cell death than its post-treatment. Furthermore, GSH pre or post treatment for 30 min rescued JB6 cells from 0.5 mM CEES-caused S and G2-M phase cell cycle arrest. These cell culture rescue effects of GSH were next translated into mouse skin studies. In SKH-1 hairless mice, 300 mg/kg GSH pre-treatment via oral gavage for 1 h resulted in a significant ($p<0.01$-0.001) reversal of 2 mg topical CEES-caused increase in skin bi-fold thickness, local edema and epidermal thickness. Together, these results suggest a possible role of oxidative stress in CEES-induced skin injury, and highlight the significance of further efficacy studies to develop GSH and its precursors as effective countermeasures against HD-caused skin injury.

PS 549 DOXYCYCLINE AND TOBRADEX SUPPRESS RABBIT CORNEAL BASEMENT MEMBRANE ZONE DAMAGE INDUCED BY 2-CHLOROETHYL ETHYL SULFIDE.

R. A. Hahn[1], J. J. Schlager[2], A. S. DeSantis[1], M. A. Gallo[3], D. Heck[4], P. Sinko[5], D. L. Laskin[1], J. D. Laskin[3], N. Heindel[6], R. Casillas[7], D. R. Gerecke[1], M. C. Babin[7] and M. K. Gordon[1]. *[1]Pharmacology and Toxicology, Rutgers University, Piscataway, NJ, [2]Air Force Research Laboratory, Wright-Patterson AFB, Dayton, OH, [3]Environmental and Occupational Medicine, UMDNJ, Robert Wood Johnson Medical School, Piscataway, NJ, [4]Environmental Health Science, New York Medical College, Valhalla, NY, [5]Pharmaceutics, Rutgers University, Piscataway, NJ, [6]Chemistry, Lehigh University, Bethlehem, PA and [7]Battelle, Biomedical Research Center, Columbus, OH.*

A rabbit corneal organ culture model system was used to evaluate the effects of antibiotic and steroid countermeasures against 2-chloroethyl ethyl sulfide (CEES), a model sulfur mustard vesicant. In this system, air lifted corneal organ cultures were exposed to CEES, plus or minus countermeasure, and then analyzed 24 hr later by electron microscopy to evaluate the junction between the epithelial basement membrane and the anterior stroma. In unexposed controls the lamina lucida and lamina densa were distinct, as were hemidesmosome, anchoring filaments, and anchoring fibrils. A 200 nmole CEES exposure for 2 hr caused a range of phenotypes. Some areas looked normal and intact, while adjacent regions showed vesicant effects ranging from swelling and loss of clarity of the hemidesmosomes to basal lamina integrity loss. In more damaged areas, the electron density of the hemidesmosomes faded, and the cell membrane between the hemidesmosomes retracted from the degrading basal lamina. The anterior stroma looked littered from basement membrane degradation. Corneas treated for 22 hr with doxycycline after CEES exposure were markedly improved, although in some areas the hemidesmosomes still looked swollen. The basal lamina in most sections had a clear lamina lucida and lamina densa. Similar results were found with Tobradex, although extreme retraction of epithelial cells from the stroma between the hemidesmosomes was frequently observed. Despite this, the lamina lucida and lamina densa were, for the most part, distinct. Supported by NIH grants EY009056 and AR055073.

PS 550 INVOLVEMENT OF BNIP3-MEDIATED INTRACELLULAR CALCIUM MOBILIZATION IN CYANIDE-INDUCED CELL DEATH.

L. Zhang, L. Li, H. Leavesley, X. Zhang, J. Borowitz and G. Isom. *MCMP, Purdue University, West Lafayette, IN.*

Cyanide is a potent neurotoxicant that can induce neurodegeneration in select brain areas. Sublethal cyanide intoxication can result in dopaminergic neuronal cell death in substantia niagra and has been linked to a Parkinsonism-like syndrome. In the current study, the mechanism of cyanide-induced apoptosis was determined in a dopaminergic cell line, Mes 23.5. In response to cyanide, BNIP3, a BH-3 only Bcl-2 family protein, localized in both endoplasmic reticulum (ER) and mitochondria. Elevated BNIP3 in ER caused by cyanide mobilized calcium from ER to increase mitochondrial calcium. This increase in mitochondrial calcium was blocked by Ru360, a mitochondrial Calcium uniporter inhibitor. The excess mitochondrial Calcium facilitated loss of mitochondrial membrane potential ($\Delta\Psi m$) and resulted in cell death. Either Ru 360 or cyclosporin A, a mitochondrial permeability transition pore inhibitor, preserved $\Delta\Psi m$ and provided protection from cyanide-induced cell death. Also, in response to cyanide, Bax was activated and co-localized with BNIP3 in ER and mitochondria. Forced overexpression of BNIP3 resulted in activation of Bax, whereas gene silencing of BNIP3 with RNA interfering strategy reduced Bax activity. Knockdown of Bax prevented BNIP3-mediated Calcium transfer from ER to mitochondria, thereby blocking cyanide-induced mitochondrial dysfunction and apoptosis. These findings indicate that in response to cyanide, Bax acts downstream of BNIP3 to facilitate ER Calcium release and subsequent mitochondrial Calcium overload, thereby inducing a mitochondria-mediated cell death. (This work was supported by National Institutes of Health grant ES 04140).

PS 551 RADIOPROTECTION BY ORAL ADMINISTRATION OF GENISTEIN IN MICE RECEIVING TOTAL BODY IRRADIATION.

M. R. Landauer[1], T. A. Davis[2] and S. R. Mog[1]. *[1]Armed Forces Radiobiology Research Institute, Bethesda, MD and [2]Naval Medical Research Center, Silver Spring, MD.*

Medical radiation countermeasures have applications in clinical oncology, space travel, radiation site cleanup and radiological terrorism. In the present studies, mice were pre-treated with oral genistein and exposed to a lethal dose (8.75 Gy) of cobalt-60 gamma radiation. Mice were gavaged with genistein for 4 or 6 days, either once a day (QD) with 10 mg day/mouse, or twice a day (BID) with 5 mg/mouse. Mice that received genistein for 4 or 6 days QD, had survival rates of

60% and 55%, respectively, and were not significantly different from the vehicle control group (30%). When gavaged BID for 4 or 6 days, survival rates for genistein-treated mice were 75% and 85%, respectively, significantly higher than vehicle-treated mice (30%). Based on the survival data, a separate group of mice were administered genistein (5 mg/mouse, BID) for 6 days prior to 6 Gy irradiation and evaluated for hematological recovery. Mice treated with genistein had an increase in bone marrow cellularity and a more rapid recovery of white blood cells, neutrophils, platelets, red blood cells, and reticulocytes than time-matched vehicle-treated mice. These data indicate that oral administration of genistein prior to irradiation protects mice from lethal doses of radiation by resulting in accelerated recovery of bone marrow and reducing the severity of pancytopenia in irradiated mice.

PS 552 DISRUPTION OF KERATINOCYTE - BASEMENT MEMBRANE (BM) COMPONENT INTERACTIONS BY SULFUR MUSTARD (SM) ANALOGUES.

M. P. Shakarjian[1, 4], A. M. Vetrano[1, 3], J. P. Gray[2], A. S. DeSantis[3], D. J. Riley[4], J. D. Laskin[5], Y. Chang[3], D. R. Gerecke[3] and D. E. Heck[1]. *[1]Environmental Health Science, New York Medical College, Valhalla, NY, [2]Science, U.S. Coast Guard Academy, New London, CT, [3]Pharmacology & Toxicol., Rutgers University, Piscataway, NJ, [4]Medicine, UMDNJ-RWJMS, Piscataway, NJ and [5]Env. Occ. Med., UMDNJ-RWJMS, Piscataway, NJ.*

The chemical weapon, SM, causes delayed vesication that is slowly resolving. Separation occurs at the cutaneous epidermal-dermal junction. While basal keratinocytes are sensitive cellular targets, it is unclear whether their demise occurs before or after detachment from the BM. Basal keratinocytes rely upon the BM component laminin-332 to maintain skin integrity through contact with the underlying dermis. We hypothesized that direct alkylation of laminin-332 by SM could influence keratinocyte attachment and migration, leading to cell death or protracted wound healing. Nitrogen mustard (HN2) and chloroethylethylsulfide (CEES) served as surrogates for SM; responses were measured using primary mouse epidermal keratinocyte (MEK) cultures. In examining the ability of various matrices to support cell growth and differentiation, laminin-332 was found to be most effective as determined by relative mRNA levels of the differentiation markers, MK1 and profilaggrin. Both HN2 and CEES dose-dependently reduced MEK viability, with HN2 being >100-fold more potent. When laminin-332 was directly alkylated by either CEES or HN2, the adhesion of MEKs or HT-1080 cells to the matrix was dose-dependently reduced. However, unlike their cytotoxic actions, HN2 and CEES inhibited cell adhesion in an equipotent manner. Finally, incubation of HN2 with laminin-332 led to the dose-dependent formation of high molecular weight complexes as shown by Western blotting. Our data suggest that agents like SM may inhibit cell adhesion and migration, potentially triggering cell death or reducing the rate of wound healing. However, the dose relation between direct cytotoxicity and matrix-dependent effects differs among these agents. This work is supported by ES05022, ES07148 and the NIH CounterACT Program NIAMS U54AR055073.

PS 553 INHALATION OF 2-CHLOROETHYL ETHYL SULFIDE (CEES, HALF MUSTARD) RESULTS IN MARKED INJURY AT MULTIPLE LEVELS OF THE UPPER AND LOWER RESPIRATORY TRACTS.

H. C. O'Neill[1, 2], T. B. Hendry-Hofer[2], J. E. Loader[2], L. Veress[2], R. C. Rancourt[2], D. Orlicky[1], B. J. Day[2, 1] and C. W. White[2, 1]. *[1]Department of Pharmaceutical Sciences, UCHSC, Denver, CO and [2]Pediatrics, National Jewish Health, Denver, CO.*

Sulfur mustard (bis(2-chloroethyl) sulfide, SM) is an alkylating chemical warfare agent. Exposure to SM and the SM analog 2-chloroethyl ethyl sulfide (CEES, half-mustard) results in acute injury to the skin, eyes, and respiratory tract. Rats were exposed to aerosolized 5% CEES in ethanol for 15 minutes under anesthesia and subsequently sacrificed 18 hours following exposure. Lungs were lavaged with two 5 ml passes of saline for subsequent biochemical analyses or inflation fixed at a 20 cm pressure with 4% paraformaldehyde in PBS for histopathology studies. Nasal cavities were either lavaged with two 500 µl passes of saline or retrograde flushed with 1 ml 4% paraformaldehyde through the nasopharynx and fixed for histopathology. In the lower airways, bronchoalveolar lavage (BAL) protein was significantly increased 18 hours after CEES exposure as compared to ethanol controls indicating airway damage ($p<0.05$). IgM, which is not normally found in BAL, was also significantly increased as compared to ethanol controls indicating alveolar-capillary or airway-capillary leak ($p<0.05$). Proximal tracheobronchial regions revealed variable injury at times resulting in extensive and severe epithelial sloughing (pseudomembrane formation) characteristic of exposure to a vessicating agent. Electron microscopy studies demonstrated damage to Clara cells in CEES-treated rats which was further confirmed by a decrease in epithelial immunostaining for CC-10, a major Clara cell component. In the nasal passages, increases in nasal lavage IgM also were evident in CEES-exposed animals ($p<0.05$). Periodic acid-Schiff (PAS) stained nasal sections demonstrated a decrease in PAS-positive staining in the respiratory epithelium of the middle meatus region near the septum as a result of CEES exposure.Combined, these data indicate significant damage specific regions of upper and lower airways as a result of exposure to the SM analog CEES.

PS 554 CUMULATIVE REPRODUCTIVE EFFECTS OF *IN UTERO* ADMINISTRATION OF A MIXTURE OF TEN "ANTIANDROGENS" IN MALE SD RATS: SYNERGY OR ADDITIVITY?

L. E. Gray[1], C. Rider[1, 2] and J. Furr[1]. *[1]ENDOCRINOLOGY BRANCH, NHEERL, U.S. EPA, Research Triangle Park, NC and [2]NCSU/EPA Cooperative Research Grant, North Carolina State University, Raleigh, NC.*

In 1996, the USEPA was charged under FQPA to consider the cumulative effects of chemicals in their risk assessments. We are conducting studies to provide a framework for assessing the cumulative effects of antiandrogens. In the current study, ten "antiandrogenic" chemicals were administered orally to pregnant rats on gestational days 14-18 and the reproductive development of the male offspring is being evaluated. Data were analyzed to determine if the chemicals behaved in a response-, integrated or dose-additive fashion. The experimental design is a fixed ratio mixture of ten chemicals with a control group, a top dose group and five dilutions of the top dose (100%, 80, 60, 40, 20, 10 and 0% of the top dose). The top dose included dosages of each chemical that are at or below the no observed effect level for hypospadias induction (vinclozolin - 30 mg/kg, procymidone - 30 mg/kg, linuron - 40 mg/kg, prochloraz - 60 mg/kg/d and six phthalate esters: DEHP, DBP, BBP, DiBP, DiHP -150 mg/kg/d/phthalate and DPP – 50 mg/kg/d). F1 male rats displayed retained female-like areolae at 14 days of age and reduced anogenital distance (AGD) at 3 days of age in the 20% and 40% groups and above, respectively. F1 female rat AGD was unaffected. In addition, malformed external genitalia were seen at puberty in males in the 40% and above groups. Dose addition was the only model that accurately predicted the malformations in the top three dose groups (observed and dose addition=100%; integrated addition=0-16%; response addition=0%) or retained nipples in the top four dose groups. The observation that dose- but not response- or integrated-addition models accurately predict the effects of chemical mixtures that act via diverse mechanisms suggests that dose additivity may commonly occur among chemicals that disrupt the same signaling pathway at different molecular sites during sexual differentiation. This abstract does not necessarily reflect EPA policy.

PS 555 *IN UTERO* EXPOSURE TO THE FUNGICIDE PROCYMIDONE AND DIBUTYL PHTHALATE PRODUCE DOSE-ADDITIVE DISRUPTIONS OF MALE RAT SEXUAL DIFFERENTIATION.

A. K. Hotchkiss[1, 2], K. L. Howdeshell[1], C. R. Blystone[1, 2], J. Furr[1], C. V. Rider[1, 2] and L. E. Gray[1]. *[1]Reproductive Toxicology Division, NHEERL, ORD, U.S. EPA, Research Triangle Park, NC and [2]Molecular Biomedical Sciences, NC State University, Raleigh, NC.*

Procymidone (PRO) and dibutyl phthalate (DBP) alter male rat sexual differentiation by disrupting the androgen-signaling pathway via distinctly different cellular mechanisms of toxicity. DBP inhibits fetal Leydig cell androgen production whereas PRO binds AR and blocks androgen action in the target tissues. Here, we report on two studies in which pregnant rats were treated with a mixture of PRO and DBP. We hypothesized that these chemicals would induce adverse effects on reproductive development in a dose-additive fashion. In the 1st study, SD rats were gavaged on gestational day 14-18 with either corn oil, 50 mg/kg/d PRO, 500 mg/kg/d DBP, or 50 mg/kg/d PRO + 500 mg/kg/d DBP. The 2nd study was a fixed ratio study with a control group, a top dose group mixture (PRO at 150 mg/kg/d and DBP at 1125 mg/kg/d) or seven dilutions of the top dose (83, 67, 50, 33, 17, 8, or 4%). In F1 male rats, the mixtures resulted in dose-related reductions in AGD, increased nipple retention and malformations, and reduced reproductive tissue weights. Further, these changes were accurately predicted by dose- but not by response-addition models indicating that these chemicals did not interact independently. We also found a dose-related increase in testicular interstitial cell adenomas and hyperplasia in the 67% and above groups and seminiferous tubular degeneration in the 50% and above groups; effects that could not be modeled given the absence or low incidence of similar lesions in the individual PRO and DBP studies.

Despite different mechanisms, coadministration of DBP and PRO produced dose-additive effects on androgen-dependent tissues. The data suggest that having a common mechanism should not be a requirement for conducting a cumulative risk assessment; rather it should be based on producing similar adverse effects. This abstract does not necessarily reflect US EPA policy.

PS 556 DEFINING THE BORDERS OF DOSE ADDITION: MIXTURE EFFECTS OF 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN AND DIBUTYL PHTHALATE ON MALE RAT REPRODUCTIVE TRACT DEVELOPMENT.

C. V. Rider[1, 2], J. Furr[2] and L. Gray[2]. *[1]Molecular Biomedical Sciences, NCSU, Research Triangle Park, NC and [2]RTD, NHEERL, ORD, U.S. EPA, Research Triangle Park, NC.*

In utero exposure to either dibutyl phthalate (DBP) or 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) disrupts male rat reproductive tract differentiation. However, they act via different modes of toxicity and induce distinct postnatal phenotypes. DBP exposure decreases anogenital distance (AGD), and induces nipple retention and undescended testes by reducing fetal hormone levels. TCDD delays the onset of puberty, but does not reduce fetal androgen levels. Both DBP and TCDD induce epididymal agenesis and decrease sperm counts. Our hypothesis is that observed responses for endpoints targeted by only one of the chemicals would be response additive: driven by the active chemical, while those targeted by both chemicals would be dose additive: both chemicals would contribute predictably to the observed effects. Pregnant Sprague-Dawley rats were dosed with either vehicle, DBP (500 mg/kg/d on gestational days (GD) 14-18), TCDD (2 μg/kg on GD 16), or both DBP and TCDD (High Mixture Dose (HMD) = 500 mg/kg/d DBP + 2 μg/kg TCDD or Low Mixture Dose (LMD) = 320 mg/kg/d DBP + 1.3 μg/kg TCDD). Male offspring are being assessed for reproductive development. The data generally support our hypothesis, reflecting a dose-dependent TCDD-driven delay in puberty (4d delay in LMD and a 6-8d delay with TCDD or HMD) and presence of a temporary thread along the frenulum of the penis prepuce (10% in LMD and 20-40% with TCDD or HMD) and a dose-dependent DBP-driven increase in areolae retention (2 areolae/male in LMD and 3-5 with DBP or HMD). No clear trends among the treatments were evident with AGD, pup loss, or maternal weight gain. Additional endpoints include reproductive organ weights and malformations. The results from this study will contribute to determining the limits of dose additivity among reproductive toxicants. Funding provided by NCSU/EPA Cooperative Training Program CT833235-01-0. This abstract does not necessarily reflect EPA policy.

PS 557 DOSE ADDITION PREDICTS THE EFFECTS OF A MIXTURE OF FIVE PHTHALATE ESTERS TO INHIBIT FETAL TESTOSTERONE PRODUCTION AND GENE EXPRESSION, AND POSTNATAL REPRODUCTIVE DEVELOPMENT IN THE SPRAGUE-DAWLEY RAT.

K. L. Howdeshell[1], V. S. Wilson[1], J. Furr[1], C. R. Lambright[1], C. V. Rider[2], D. Bermudez[2] and L. Gray[1]. *[1]Reproductive Toxicology Division, U.S. EPA, RTP, NC and [2]North Carolina State University/U.S. EPA Coop. #CT833235-01-0, Raleigh, NC.*

Exposure to some phthalate esters (PE) during sexual differentiation induces reproductive malformations in male and female rats. In the fetal male, these lesions result from phthalate-induced reductions in testicular testosterone (T) production and insulin-like hormone 3 (insl3) levels. We hypothesized that dose addition modelling would predict the effects of co-administration of five PEs [benzyl butyl (BBP), di(n)butyl (DBP), diethylhexyl (DEHP), diisobutyl (DiBP) and dipentyl (DPP)] on fetal testicular T production and gene expression since they act via a common mode of toxicity. First, we characterized the dose response effects of six individual PEs on gestation day (GD) 18 testicular T production following exposure to rats on GD8-18. BBP, DBP, DEHP, and DiBP were equipotent (ED50=441 mg/kg), and DPP was about 3-fold more potent (ED50=130.9 mg/kg); diethyl phthalate (DEP) had no effect. Next, dams were dosed at 100, 80, 60, 40, 20, 10, 5 or 0% of a mixture of BBP, DBP, DEHP, DiBP (300 mg/kg per chemical) and 100 mg DPP/kg; this ratio was selected so that each phthalate would contribute equally to the reduction in T. As predicted, the PE mixture dose-additively inhibited fetal T production [ED50, observed (obs)=480 vs predicted (pre)=360 mg/kg] and mRNA expression of insl3 (ED50, obs=388 vs pre=288 mg/kg) and steroidogenic genes [cyp11a (ED50, obs=345 vs pre=533 mg/kg) and StAR (ED50, obs=297 vs pre=724 mg/kg)]. In a postnatal study, dose additive effects were observed for the PE mixture on anogenital distance (ED50, obs=743 vs pre=724 mg/kg) as well as other reproductive tract endpoints. The ED50 for female malformations was 450 mg PE mixture/kg. The data demonstrate that individual PEs with a similar mechanism of action elicit dose additive effects on rat reproductive development. This abstract does not necessarily reflect USEPA policy.

PS 558 THE IMPACT OF NICOTINE EXPOSURE ON THE PHARMACOKINETICS AND PHARMACODYNAMICS OF CHLORPYRIFOS: IMPLICATIONS FOR DRUG/CHEMICAL MIXTURES.

S. Lee, T. S. Poet, A. L. Busby and C. Timchalk. *Biological Monitoring and Modeling, Pacific Northwest National Laboratory, Richland, WA.*

Chlorpyrifos (CPF) is the most widely used organophosphorus (OP) insecticide to control agricultural pests. CPF is bioactivated mainly in the liver by CYP450-mediated desulfuration to its oxon metabolite (CPF-oxon), which elicits neurotoxicity by inhibiting cholinesterases (ChE). CPF also undergoes dearylation to form 3,5,6-trichloro-2-pyridinol (TCPy). The routine use of tobacco products may modify key metabolizing systems which will further impact the metabolism of OPs. The objective of this study was to evaluate the impact of repeated nicotine administration on CPF pharmacokinetics and pharmacodynamics in male S-D rats. The influence of repeated nicotine exposure on in vivo metabolism of CPF and the level of inhibition in ChE activities in plasma, brain and diaphragm were investigated. Animals (250-300 g) were administered 1) both 1 mg nicotine/kg/day (s.c. at nape) and 5 mg CPF/kg/day (in corn oil, po) for 7 days, 2) 1 mg nicotine/kg/day for 7 days and a single dose of 35 mg CPF/kg (po) on 7th day, no-nicotine-controls were given 3) 5 mg CPF/kg/day for 7 days, or 4) 35 mg CPF/kg once. All the animals were sacrificed at 1, 4, 8, 12 or 24 hr post-last dosing of CPF. For both (single and repeated) CPF exposures, Cmax and AUC of blood TCP were increased (~2-fold) indicating a possible increase of CYP450-mediated metabolism of CPF to TCPy, which is consistent with previous in vitro data. The most significant changes in ChE activities due to nicotine pretreatments were in the brain following the daily administration of 5 mg CPF/kg, where less inhibition of ChE in the brain from nicotine groups (~71% of naive [no CPF, no nicotine]) over chlorpyrifos-only controls (~42% of naive) were observed. But there were no differences in plasma and diaphragm ChE activities due to nicotine pretreatment. The results of this study suggest that repeated nicotine exposure (i.e., from smoking) could alter the metabolism and pharmacodynamics of CPF (Funded by CDC/NIOSH grant R01-OH003629).

PS 559 CRITICAL ANALYSIS OF LITERATURE ON LOW DOSE SYNERGY FOR USE IN SCREENING CHEMICAL MIXTURES FOR RISK ASSESSMENT.

M. Embry[1], C. HESI RAM Mixtures[1], R. Hertzberg[2], S. Collie[3] and D. Kopp[4]. *[1]ILSI HESI, Washington, DC, [2]Biomathematics Consulting, Atlanta, GA, [3]Synergy Toxicology, San Antonio, TX and [4]Emory University, Atlanta, GA.*

Scientists and regulators need a better understanding of the consequences of co-exposures to substances at environmentally relevant concentrations. From a safety perspective, it is essential to know if synergistic interactions can occur at these dose levels, which are typically low compared to those used in toxicological studies. Our objective was to determine if sufficient data were available to derive a synergistic factor or criteria that could be applied in a Threshold of Toxicological Concern (TTC)-based approach to screen and prioritize environmental chemical mixtures. A literature search was conducted to identify studies that demonstrated synergism in mammalian test systems, with emphasis on synergism at doses close to the individual chemicals' NOELs or LOELS. The search identified 204 unique chemicals by in-depth critical review of 90 unique references; these were compiled into a database. Based on study selection criteria, a quantitative estimate of low dose synergy was found in only a limited number of studies. Calculations of interaction magnitude were included in eleven articles, reflecting seven research programs. Their approaches differed, as did their estimates of magnitude. While the range of reported values is quite wide, from 1.1 to 107, these values are not comparable with each other because definitions of synergy and methods used to quantify synergy were different across studies. Methods varied in terms of the null hypothesis, response measured, departure point (dose at which the effect was observed), consideration of the slope of the dose-response curve, and difference between experimental results and an estimate based on the assumption of additivity. Before such data can be integrated into a TTC approach, it is recommended that: synergy be defined in terms of departure from dose additivity; uniform procedures be developed for assessing synergy at low exposures; and points of departure for calculating synergy be standardized.

PS 560 ACETYLCHOLINESTERASE INHIBITION FROM REPEATED EXPOSURES TO A MIXTURE OF TWO ORGANOPHOSPHORUS INSECTICIDES (CHLORPYRIFOS AND DIAZINON) IN RATS.

E. C. Meek, A. Coban, M. K. Davis, K. H. Lednum, S. X. Guo-Ross and J. E. Chambers. *Center for Environmental Health Sciences, College of Veteinary Medicine, Mississippi State University, Mississippi State, MS.*

Organophosphorus (OP) insecticides are widely used inhibitors of acetylcholinesterase (AChE) in both target and non-target species. Surveys have revealed the presence of urinary OP insecticide metabolites in large numbers of random survey participants. The use of many OP insecticides for a variety of applications results in many people being exposed to multiple OP insecticides repeatedly. The common mechanism of toxicity for OP insecticides requires the evaluation of risk for multiple OP exposures. A reverse dosimetry mathematical model could predict the exposure scenario through the use of biomarkers such as blood AChE inhibition data or urinary metabolites. These experiments have acquired the biomarker data that could be used for subsequent model development. Rats were exposed orally to chlorpyrifos (7.5mg/kg) and diazinon (60mg/kg) alone or a mixture of ½ the individual doses or an equal mixture of the individual doses every 4 days over a 15 day period. Brain, plasma and red blood cell (RBC) AChE and liver and serum carboxylesterase (CbxE) activities were determined spectrophotometrically. AChE inhibition was dose related, with peak inhibition in the brain of about 20% for the individual compounds and the lower dose mixture, and about 40% in the higher dose mixture 24 hours after exposure, with plasma and RBCs showing greater inhibition than in the brain. Partial recovery of AChE activity occurred between exposures; therefore, there was only a slight increase in inhibition with repeated exposures and inhibition was relatively greater in brain than in blood, suggesting faster recovery of activity in blood than brain. CbxE activity was greatly inhibited 24 hours after dosing (about 80%) with partial recovery occurring between exposures. These data sets along with urinary metabolite levels will be used to calibrate a reverse dosimetry model. Supported by EPA STAR grant RD 83345101.

PS 561 ENVIRONMENTALLY REALISTIC MIXTURES OF THE FIVE REGULATED HALOACETIC ACIDS EXHIBIT CONCENTRATION-DEPENDENT DEPARTURES FROM DOSE ADDITIVITY.

J. Simmons[1], C. Dingus[2], E. D. Wagner[3], G. Rice[4], L. K. Teuschler[4] and M. J. Plewa[4]. *[1]NHEERL/ORD, U.S. EPA, RTP, NC, [2]Battelle, Columbus, OH, [3]U of IL., Urbana, IL and [4]NCEA/ORD, U.S. EPA, Cincinnati, OH.*

Disinfection of water decreases waterborne disease. Disinfection byproducts (DBPs) are formed when oxidizing disinfectants react with inorganic and organic materials in the source water. The U.S. EPA regulates 5 haloacetic acid (HAA) DBPs as a mixture. The objective of this study was to evaluate environmentally relevant HAA mixtures under an assumption of dose addition. Mixtures were tested at an equimolar mixing ratio (EQ) and at ratios representing disinfection by postchlorination (CL) or preozonation/postchlorination (OZ/CL). The 5 individual HAAs (chloroacetic, dichloroacetic, trichloroacetic, bromoacetic (BA), dibromoacetic acid) and the HAA mixtures were evaluated in a Chinese Hamster Ovary cell chronic cytotoxicity assay at a minimum of 10 concentrations each. The individual HAA data were used to develop a smooth additivity model consistent with Berenbaum's definition of additivity. The fitted models provided reasonable fits to the experimental data. The slope of the fitted dose-response curve for each individual HAA was negative and statistically significant, indicating that cell density decreased significantly with increasing HAA concentration. BA was markedly more toxic than the other regulated HAAs. The overall test for departure from dose additivity was significant ($p<0.001$) for each mixture. Individual dose levels (with Hochberg's correction applied, alpha=0.05) demonstrated less-than-additive (antagonistic) departures from additivity in the higher portion of each mixture dose-response curve (EQ, CL, OZ/CL). In addition, the lowest two concentrations of the EQ mixture exhibited statistically significant greater-than additive departures from additivity. In summary, all 3 HAA mixtures exhibited less-than-additive toxicity in the higher dose region but only the EQ mixture, the least environmentally realistic, exhibited detectable greater-than-additive toxicity. (This abstract may not reflect EPA policy.)

PS 562 MIXTURE EFFECTS OF THREE IMIDAZOLE FUNGICIDES ON ADRENAL HORMONE SECRETION IN THE HUMAN ADRENOCORTICAL CELL LINE H295R.

E. Ullerås, √. Ohlsson and A. Oskarsson. *Biomedical Sciences and Veterinary Public Health, Swedish University of Agricultural Sciences, Uppsala, Sweden.*

Toxicological studies have focused on effects of single chemicals, but exposure to mixtures is more likely. There is a need for test systems that can address and predict effects of mixtures. Prochloraz (PRO), ketoconazole (KET) and imazalil (IMA) are imidazole fungicides that are known to bind un-specifically to cytochrome P450s (CYP). Adrenal steroidogenesis is depending on a number of CYPs and is therefore a likely target of these compounds. The human adrenocortical cell line H295R shares the pathways for aldosterone and cortisol synthesis with the normal adrenal gland and is a valuable model to test adrenal endocrine disruption. Herein, the effects of the imidazoles on adrenal hormone secretion and steroidogenic gene expression were investigated after exposure to individual chemicals and binary and tertiary mixtures. H295R cells were treated for 24 hours with PRO, KET and IMA at non-cytotoxic concentrations (0-10 μM), individually and as mixtures. Cortisol and aldosterone levels in cell culture medium were analysed by ELISA. Expression of key genes in the steroidogenic pathway was analysed by quantitative RT-PCR. A dose dependent inhibition of cortisol secretion was evident after PRO, KET and IMA treatment, both individually and as mixtures. For aldosterone secretion, a biphasic response was shown with a maximal two-fold increase following PRO treatment. The non-linear dose response for aldosterone was also observed following mixture treatment. The IC50 for the effect on cortisol were similar for the individual chemicals and the mixture. Gene expression analysis indicated that the aldosterone pathway specific gene CYP11B2 was up-regulated while other steroidogenic genes were down-regulated after imidazole treatment. In summary, the effects of the individual chemicals are similar to the effects following mixture exposure. We conclude that the H295R cells are a promising model to study endocrine disrupting effects of chemicals and mixtures.

PS 563 PROBABILISTIC ANALYSES OF UNCERTAINTY IN MIXTURE TOXICITY SUGGEST THAT ADDITIVE AND INDEPENDENCE MODELS MAY PRODUCE SIMILAR ESTIMATES OF TOXICITY.

P. Price. *Toxicology & Environmental Research & Consulting, The Dow Chemical Company, Midland, MI.*

Toxicologists have debated when additive or independence models should be used to evaluate the toxicity of mixtures. In a recent study of the toxicity of mixtures of anthropogenic compounds found in surface waters, probabilistic analyses of the uncertainty in the predictions of toxicity for additive and independence models were performed. The analyses used Monte Carlo modeling, published distributions of the inter-chemical variation in safety factors, and the mixture-specific relative proportions of each component. Traditional deterministic models of additive and independence toxicity were also performed. As expected, independence models either predicted the same or lower toxicities (larger estimates of safe doses) than the additive models. For deterministic models the ratios of the safe levels of the mixtures predicted by the two models ranged from 1.0 to 2.9 and averaged 1.5. For the probabilistic versions of models, the ratios of the lower 90% confidence limits of the safe levels for the mixtures ranged from 1.0 to 1.2 and averaged 1.1. The reason for the closer agreement between the probabilistic versions of the models is due to statistical processes that cause deterministic additive models to overestimate, and deterministic independence models to underestimate mixtures' toxicities. Specifically, additive models assume all mixture components will always be as toxic as their standards while independent models assume that no mixture component will have a higher toxicity than its standard. In the probabilistic models of mixture toxicity these assumptions are relaxed and as a result the two approaches produce results that are more similar. This analysis demonstrates the value of performing probabilistic modeling in the investigation of the risks posed by mixtures and suggests that the decisions concerning additivity versus independence may not be as critical an issue when probabilistic models are used.

PS 564 EVALUATING NEUROTOXICITY OF A MIXTURE OF FIVE OP PESTICIDES USING A COMPOSITE SCORE.

E. Nyirabahizi[1], C. Gennings[1] and V. C. Moser[2]. *[1]Biostatistics, Virginia Commonwealth University, Richmond, VA and [2]Neurotoxicology Division, U.S. EPA-NHEERL, Research Triangle Park, NC.*

The evaluation of the cumulative effects of neurotoxic pesticides often involves the analysis of both neurochemical and behavioral endpoints. Multiple statistical tests on many endpoints can greatly inflate Type I error rates. Multiple comparison adjustments are often overly conservative leading to reduced power to detect effects of interest. Furthermore, identification of the most sensitive endpoint may be chemical dependent so that neurotoxicity may be most evident on a per animal basis by evaluating many endpoints. Use of a composite score focuses the inference and avoids inflated type I error rates. Coffey et al (2007) describe the development of an overall score based on desirability functions for the many types of outcomes measured in neurobehavioral toxicology experiments. Our objective was to evaluate the neurotoxicity of a mixture of five pesticides (Moser et al, 2005). In particular, the desirability functions for neurochemical (blood and brain cholinesterase activity) and behavioral (motor activity, gait score, tail-pinch response score) endpoints were

calculated for single chemical (acephate, diazinon, dimethoate, chlorpyrifos, and malathion) and mixture dose response data, and a composite score of neurotoxicity was determined. Both an additivity model using single chemical data and a model for an environmentally-relevant fixed-ratio mixture were estimated. Focusing in the low dose region using a 5%, 10% and 20% benchmark responses (BMRs), departure from additivity was found at the 20% BMR with all five pesticides in the mixture; additivity was observed at the lower BMRs. Using the same relevant mixing ratio but without the most common chemical, malathion, we found departure from additivity at all three BMRs. Thus, malathion significantly influences the interactions of the remaining chemicals in the mixture. This methodology is therefore useful in evaluating the overall neurotoxicity of pesticide mixtures. This is an abstract of a proposed presentation and does not reflect US EPA policy.

PS 565 JOINT TOXICITY OF CHEMICAL MIXTURES OF BENZENE, TRICHLOROETHYLENE AND METHYL MERCURY NOT SIGNIFICANTLY DIFFERENT FROM INDIVIDUAL CHEMICALS IN F344 RATS, FOLLOWING PER ORAL EXPOSURE.

M. Mumtaz[1], A. P. Freidig[2], D. Jonker[2], J. J. Bogaards[2], P. Hendriksen[2], R. H. Stierum[2] and J. P. Groten[3]. [1]*Toxicology and Environmental Medicine, CDC Agency for Toxic Substances and Disease Registry, Atlanta, GA,* [2]*TNO Quality of Life, Utrechtseweg 48 3704-HE, Zeist, Netherlands and* [3]*Drug Safety Europe, Schering Plough, 5340 BH Oss, Netherlands.*

Benzene (200 or 400 mg/kg), methyl mercury (0.25 or 0.75 mg/kg) and trichloroethylene (500 or 1500 mg/kg), three important and extensively characterized environmental pollutants were studied individually and as their mixtures in male F344 rats, following per oral exposure. Several toxicity endpoints such as body/organ weights (kidneys, liver, spleen, thymus); clinical chemistry (plasma glucose, albumin, creatinine); and hematological parameters (red blood cells, white blood cells, lymphocytes) were studied. A simple classification scheme was used to categorize the observed effects into the following groups: induced by individual chemical components and their mixtures (additive); induced by individual components, but not their mixtures (antagonistic); and induced by mixtures, but not by individual components (synergistic or new). The results show subtle mixture-induced toxicity shifts in several endpoints. Decrease of plasma creatinine was observed in binary or ternary mixtures while plasma albumin levels increased in contrast to the individual components. Thus, the endpoints affected by binary and ternary mixtures generally matched those affected by the individual chemicals but were different in observed severity. In fact, none indicated a lower threshold for joint toxicity than their individual components. The implications of these findings will be discussed using a systems approach to provide insights to potential underlying mechanisms of the overall toxicity of mixtures [Funded by American Chemical Council LRI, RSK-0103].

PS 566 *IN VITRO* CHARACTERIZATION OF METABOLIC INTERACTIONS BETWEEN N-HEXANE, TOLUENE, CYCLOHEXANE AND ISOOCTANE.

I. Nechad[1], G. Charest-Tardif[2], R. Tardif[2], K. Krishnan[2] and S. Haddad[1]. [1]*sciences biologiques, TOXEN, Université du Québec à Montréal, Montr√ ©al, QC, Canada and* [2]*santé environnementale et santé au travail, Université de Montréal, Montr√ ©al, QC, Canada.*

The objective of this study was to characterize the metabolic interactions occurring between four volatile organic compounds (VOCs) associated with petroleum products, namely n-hexane (H), toluene (T), cyclohexane (C) and isooctane (I). More specifically, using liver microsomal preparations from the rat, we studied the potential inhibition of metabolism of T by H, C, and I, as well as the inhibition of H metabolism by T, C, and I. First, measurements of medium:air partition coefficients (Pm:a) were made to allow estimation of inhibitor and substrate concentrations in the incubation medium during the metabolism studies. Pm:a values obtained for H, C, I and T are 0.0922, 0.2020, 0.2286, 2.2318, respectively. Then, by measuring disappearance rates in sealed glass vials by headspace gas chromatography after incubations of 45 min for T and 4 min for H, metabolic rates were determined for these two compounds incubated alone (3 concentrations) or in presence of inhibitors (3 concentrations). Regression analyses indicate that inhibition of T by H,C and I is best described by competitive mechanism and the inhibition constants (Ki) are 0.48, 1,28 and 2.35 μM for H, C and I, respectively. The mechanisms best describing inhibition of H metabolism were uncompetitive inhibition for T (Ki=1.22 μM), and non-competitive inhibition for C (Ki=0.39 μM) and I (Ki = 1.54 μM). These in vitro data on metabolic interactions between the VOCs can be integrated within physiologically based pharmacokinetic models for predicting the internal dose resulting from mixed exposure to these chemicals. Supported by ExxonMobil and NSERC.

PS 567 URBAN PARTICULATE MATTER ACTIVATES AKT IN HUMAN LUNG CELLS.

T. L. Watterson[1], R. Martin[2] and R. A. Coulombe[1]. [1]*Toxicology Graduate Program, Utah State University, Logan, UT and* [2]*Department of Civil and Environmental Engineering, Utah State University, Logan, UT.*

The normally-picturesque Cache Valley in northern Utah gained national attention by achieving, during winter atmospheric inversions, some of the highest PM2.5 concentrations ever measured in the United States. PM is associated with a variety of cardiovascular diseases and early mortality. We and others have shown that PM2.5 induces the inflammatory response in cultured human lung cells, through mechanisms associated with Akt activation, such as induction of ER stress, activation of NF-κB, calpain, and heat shock protein (Hsp)-27, apoptosis suppression, and inflammatory cytokine release. This study was undertaken to determine whether Cache Valley PM2.5 and PM10 would cause Akt activation in human lung cells. BEAS-2B cells were treated with either PM2.5 and PM10 (12.5 and 25 and μg/ml)at time intervals up to 24 hr. PM treatment resulted in Akt activation as evidenced by phosphorylation at Thr308, and Ser473. PM treated cells showed phosphorylation of Akt related proteins PDK, and PTEN while that of GSK was reduced compared to control cells. Increases in p53 protein were observed at 1 hr post-treatment but not 24 hr. NF-κB activation was observed at 1 and 24 hr, but IκB phosphorylation occurred at 24 hr only. PM treatment lead to the release of the NF-κB related inflammatory cytokines IL-1α, and IL-6 and the chemokine IL-8 at 6 and 24 hr. These effects were independent of IRAK-1 phosphorylation, indicating a MyD88 receptor independent mechanism. Treatment with calpain inhibitor leupeptin limited Akt phosphorylation to Ser473 and reduced release of IL-1α, IL-6 and IL-8. Thus, it is possible that that calpain or similar proteases are involved in PM-induced activation of Akt leading to release of inflammatory cytokines. There were no consistent differences in these molecular events with respect to particle size. In total, our data indicate that Akt activation may play an important role in the inflammogenic response to PM exposure in human lung cells. Supported in part by the Marriner S. Eccles Foundation.

PS 568 COMPARATIVE HEALTH EFFECTS OF INHALED DIESEL AND GASOLINE EXHAUST, WOOD SMOKE, AND "DOWNWIND" COAL EMISSIONS.

J. L. Mauderly[1], E. G. Barrett[1], M. J. Campen[1], A. P. Gigliotti[1], J. D. McDonald[1], M. D. Reed[1], J. Seagrave[1] and S. K. Seilkop[2]. [1]*Lovelace Respiratory Research Institute, Albuquerque, NM and* [2]*SKS Consulting, Siler City, NC.*

Rats and mice were exposed 6 hr/day, 7 days/wk by inhalation to multiple dilutions of diesel engine exhaust, gasoline engine exhaust, hardwood smoke, or a mixture simulating downwind coal emissions. The identical health response protocols were aimed at providing a database allowing comparisons among source emissions and identification of causal pollutant species. Body and organ weights, hematology, serum chemistry, bronchoalveolar lavage and histopathology were evaluated in F344 rats exposed 1 wk or 6 mo. Body and organ weights and micronuclei in circulating reticulocytes were evaluated in A/J mice exposed 1 wk or 6 mo. Clearance of bacteria from lung was evaluated in C57BL6 mice exposed 1 wk. Heart rate and electrocardiogram were evaluated in SHR rats exposed 1 wk. Vascular responses were evaluated in ApoE-/- mice exposed 7 wk. Development of respiratory allergic responses was evaluated in BALBc mice after in utero + postnatal exposure. Exacerbation of existing allergic responses was evaluated in BALBc mice exposed 3 days. To place results on the same scale for comparisons among variables and exposures, an "effect size" (ES) parameter was calculated for each variable by dividing the exposure-response slope estimate by its standard error. The sign of ES reflected the direction of difference from control, and the magnitude reflected the significance of the effect on the same scale for all variables. Combining the magnitudes of ES with judgements on whether increases or decreases of each variable were "adverse" allowed semi-quantitative comparisons among exposure atmospheres. Overall, engine exhausts elicited stronger adverse responses than wood smoke or coal emissions, and coal emissions elicited the fewest adverse responses. Research conducted by the National Environmental Respiratory Center with government and industry support. Contents do not represent the views of any sponsor.

PS 569 ATMOSPHERIC GAS-PARTICLE INTERACTIONS CAUSE A RAPID SHIFT IN TOXICITY FROM THE GAS PHASE TO THE PARTICLE PHASE.

S. Ebersviller[1], K. de Bruijne[1], K. G. Sexton[1], Y. Lin[1], I. Jaspers[1, 2] and H. E. Jeffries[1]. [1]*UNC, Chapel Hill, NC and* [2]*CEMALB, Chapel Hill, NC.*

Researchers have attempted to determine whether particulate matter (PM) is inherently toxic, or if its toxicity can be attributed to pollutants it absorbs from the air around it. Previous experiments have measured significant changes in the chemical

composition of both gases and particles as air pollution mixtures age in sunlight, usually with an accompanying increase in toxicity. In general, these reactions create oxidized species which are less volatile than their parent compounds and are, therefore, more likely to partition to particulate matter. As a result, PM can act as a vehicle to deliver air toxics into the deep lung. Here, the long residence time of PM can greatly affect the dose of the VOCs absorbed by the body. This study is designed to investigate whether gas-particle partitioning can cause a non-toxic aerosol to become toxic. Using a continuously stirred tank reactor (CSTR), human epithelial lung cells were exposed to mixtures of gases and particles across an air-liquid interface. The CSTR was coupled to two in vitro exposure systems EAVES (Electrostatic Aerosol in Vitro Exposure System) and GIVES (Gas In Vitro Exposure System), which allow gas and particle phase exposures to occur separately. Moreover, the exposure systems maintain equilibrium between phases until delivery to the cells. Four exposure mixtures were used: clean air, mineral oil aerosol in clean air, VOCs alone (tolualdehyde and acrolein), and mineral oil aerosol mixed with VOCs. While no toxicity was measured with either of the exposures in clean air, the VOCs alone elicited a significant response from the cells exposed to the gas phase pollutants. When VOCs were mixed with the aerosol, the gas-phase response decreased, and the response from the cells exposed to the particles alone increased. Therefore, we were able to see a shift in toxicity from the gas phase to the particle phase and, as this shift occurs in a matter of seconds, these findings have important ramifications for understanding the toxicity of PM across the environment.

PS 570 ETS AND HORMONE EFFECTS ON AIRWAY RESPONSES IN A MODEL OF ALLERGIC ASTHMA.

V. L. Mitchell[1], T. J. Combs[1], W. F. Walby[2], E. S. Schelegle[2] and L. S. Van Winkle[1,2]. [1]*CHE, University of California, Davis, Davis, CA and* [2]*VM:APC, University of California, Davis, Davis, CA.*

Women have a higher incidence of adult onset asthma, COPD, and certain forms of lung cancer. All of these lung pathologies have been linked to tobacco smoke exposure. In the current study, we hypothesized that progesterone would enhance and testosterone would dampen allergic inflammation and that this would be mediated, in part, by regulation of antioxidant levels in the lung. Female 6 week BALB/c ovariectomized mice were implanted with placebo, progesterone, or testosterone time-release pellets. Mice were exposed to environmentally relevant levels of ETS for 6 weeks (6hrs/day, 5 days/week). Half of the animals were sensitized and exposed to house dust mite allergen (HDMA) aerosols for two weeks. Endpoints included bronchoalveolar lavage (BAL) for cytokine analysis followed by lung fixation in 1% paraformaldehyde or airway hyperresponsivenss testing to methacholine challenge. IL-12p40, a subunit with antagonist activity to the heterodimer IL-12p70, was significantly increased in the BAL of allergic mice vs. controls ($p=0.0002$). Within the allergic animals progesterone resulted in significantly more IL-12p40 than testosterone ($p=0.0132$). Immunohistochemistry for glutamate-cysteine ligase (GCL), a sensitive marker for oxidative stress, demonstrated strong continuous staining of the conducting airway epithelium in non-allergic mice exposed to ETS. HDMA treatment decreased GCL and resulted in focal staining on the epithelium. Progesterone treatment increased GCL staining. The decrease in GCL in the HDMA exposed animals could be due to the significant increase in mucous metaplasia in these groups. ANOVA analysis revealed a significant interaction between the allergic phenotype and hormone treatment ($p <0.0001$) with regards to airway reactivity. We conclude that hormones as well as allergic sensitization influence airway hyperresponsiveness, the local cytokine milieu of the airways and expression of key antioxidant enzymes. PS 571 SIMULTANEOUS EXPOSURE TO MULTIPLE AIR POLLUTANTS INFLUENCES ALVEOLAR EPITHELIAL CELL ION TRANSPORT.

A. J. LaGier[1], N. D. Manzo[2] and J. A. Dye[1]. [1]*NHEERL, U.S. -EPA, Research Triangle Park, NC and* [2]*North Carolina State University, Raleigh, NC.* Sponsor: G. Hatch.

Purpose. Air pollution sources generally release multiple pollutants simultaneously and yet, research has historically focused on the source-to-health linkages of individual air pollutants. We recently showed that exposure of alveolar epithelial cells to a combination of particulate matter-associated metals resulted in greater epithelial cell damage than cells exposed to each metal individually. The goal of the current study was to further assess how mixtures of air pollutants interact to alter alveolar epithelial cell health. Method. Confluent murine LA-4 cells were loaded with BCECF-AM, a cell-permeant fluorescent intracellular pH indicator. LA-4 cells were subsequently treated with increasing concentrations (0 – 100 μg/cm2) of insoluble particles, either vehicle-emitted diesel exhaust particles (DEP) or carbon black (CB), individually or in combination with an acidic insult, i.e. 100 mM ammonium chloride or acetate, a soluble toxicant associated with lung injury. Cells were treated for 15 minutes, washed and changes in fluorescence between pre- and post-exposure were assessed. Results. LA-4 cells exposed to DEP or CB individually had no significant change in fluorescence, while LA-4 cells exposed to ammonium alone had a significant loss in fluorescence, an indicator of altered intracellular pH. Alternatively, LA-4 cells exposed to increasing concentrations of DEP, but not CB, in combination with ammonium had significantly less fluorescence loss than cells treated with ammonium alone. Conclusions. Data presented here indicates that DEP alters the intracellular ion transport elicited by ammonium and suggests that DEP likely prevents mechanisms necessary to protect alveolar epithelial cells from ammonium toxicity. In this regard, this study exemplifies the importance of using combinations of pollutants for assessing effects of air pollution on health. (Abstract does not reflect USEPA policy)

S 572 OVERVIEW: BIOLOGICAL IMPORTANCE OF AROMATASE (CYP19) EXPRESSION AND FUNCTION.

S. Laws[1] and T. Sanderson[2]. [1]*Reproductive Toxicology Division, NHEERL, ORD, U.S. EPA, Research Triangle Park, NC and* [2]*INRS-Institut Armand Frappier, Laval, QC, Canada.*

During the past five years, advancements have been made in our understanding of the regulation of aromatase (CYP19) gene expression and function in humans and wildlife. This cytochrome P450 microsomal enzyme is responsible for the conversion of androgens to estrogens, and is essential for maintaining estrogen homeostasis within multiple target tissues for both males and females. The expression of the human CYP19 gene is regulated through multiple promoters and co-factors that are target tissue specific. Thus, local regulation of estrogen concentrations within various target tissues may vary significantly from that observed in circulating serum. To date, the ability of environmental chemicals to inhibit the catalytic activity of aromatase, as well as resulting adverse effects on reproductive function, have been clearly demonstrated. However, specific effects on aromatase gene expression following exposure to environmental chemicals, and the physiological impact on local and systemic levels of estrogen, remain to be elucidated. In addition, the presence of elevated aromatase expression in hormone-dependent cancers underscores the need for determining if environmental chemicals can modulate the activity and expression of aromatase in humans and wildlife. To highlight these important findings, the session will provide an overview of the current state of knowledge regarding the regulation of aromatase (CYP19) gene expression, describe the toxicological consequences of altered aromatase gene expression and function in humans and wildlife, and present novel approaches for identifying environmental chemicals that disrupt the homeostasis of estrogen biosynthesis via this mode-of-action.
This abstract does not necessarily reflect EPA policy.

S 573 REGULATION OF AROMATASE AND OTHER STEROIDOGENIC GENES IN ENDOMETRIOSIS.

S. E. Bulun. *Division of Reproductive Biology Research, Department of Obstetrics and Gynecology, Northwestern University, Chicago, IL.* Sponsor: T. Sanderson.

Endometriosis causes chronic pelvic pain and infertility in 5-10% of US women of reproductive age and is defined as the presence of endometrium-like tissue in ectopic sites outside the uterus. The biologically active estrogen, estradiol, is essential for growth of endometriosis and synthesized locally in endometriosis from cholesterol through six serial enzymatic conversions. Aromatase and other necessary steroidogenic genes are expressed *in vivo* in endometriotic stromal cells enabling this single cell type to synthesize estradiol from cholesterol *de novo*. SF1 acts as a master-switch downstream of the PGE2-cAMP pathway and coordinates induction of the steroidogenic genes, steroidogenic acute regulator protein (StAR), side chain cleavage, 3β-hydroxysteroid dehydrogenase (HSD) type II, 17-hydroxylase/17-20-lyase (P450c17) and aromatase in endometriotic stromal cells. The PGE2-dependent inductions of StAR and aromatase mRNA levels were the highest in comparison with other steroidogenic genes. In contrast, normal endometrium or endometrial stromal cells do not biosynthesize estradiol. Both endometriosis and normal endometrium contain the enzyme 17β-HSD-1 that catalyzes the final step that is the conversion of estrone to estradiol. What separates normal endometrium from endometriosis, however, is the *in vivo* lack of expression of the SF1-regulated steroidogenic genes. The clinical significance of local estradiol synthesis in endometriosis was exemplified by successful treatment of this disease using aromatase inhibitors. SF1 is the key determinant of steroidogenic gene expression in endometriosis; its mRNA levels in endometriotic stromal cells is >12,000 times higher than those in endometrial cells. We identified a classic CpG island that occupies the SF1 promoter and regulates its activity. This region was heavily methylated in normal endometrial stromal cells and unmethylated in endometriotic stromal cells. Thus, inappropriate SF1 expression in endometriosis activates multiple steroidogenic genes resulting in local production of estradiol in this pathologic tissue.

S 574 AROMATASE REGULATION IN BREAST CANCER.

C. Clyne, K. Knower, A. Chand, N. Flemming and E. Simpson. *Prince Henry's Institute of Medical Research, Clayton, VIC, Australia.* Sponsor: S. Laws.

Estrogen biosynthesis from C_{19} steroids is catalysed by the enzyme aromatase cytochrome P450. Regulation of aromatase expression is complex, involving at least 10 alternative promoters that are used in a tissue-specific manner. Aromatase is expressed in breast adipose tissue through the use of a distal promoter (pI.4) that is regulated by cytokines and glucocorticoids. In the presence of breast tumor, however, aromatase is over-expressed in response to tumor-derived factors that induce the proximal, cAMP-responsive promoter II (pII, normally active in ovary), leading to increased estrogen production that supports tumor growth and development. Nuclear receptors are central to promoter II activity. In the ovary, expression from this promoter requires the monomeric orphan receptor SF-1. However, SF-1 is not expressed in breast adipose or cancer tissue. Instead, other receptors including LRH-1 and ERRα positively regulate aromatase expression, in balance with inhibitory receptors such as COUP-TF and PPARγ. Although many of these receptors are ligand-independent, their activity can potentially be regulated by endocrine disrupting chemicals. This could provide a link between environmental factors and local aromatase activity, in turn influencing breast cancer susceptibility.

S 575 UNDERSTANDING THE EFFECTS OF ATRAZINE ON STEROIDOGENESIS IN WISTAR RATS.

N. Tinfo[1] and S. Laws[2]. *[1]College of Veterinary Medicine, NC State University, Raleigh, NC and [2]RTD, NHEERL, ORD, U.S. EPA, Research Triangle Park, NC.*

The effects of environmental chemicals on the catalytic activity of steroidogenic enzymes, including aromatase, have been well documented. However, specific effects of environmental chemicals on the expression of genes within the steroidogenic pathway, and the physiological impact on local and systemic concentrations of steroids have not yet been clearly demonstrated in laboratory animals. Recent *in vitro* studies have shown that atrazine (ATR), a chlorotriazine herbicide, induces aromatase gene expression in several human cell lines and may be associated with a stimulatory effect on NR5A receptors (SF-1, LRH-1) and second messenger signaling. Thus, these studies support the hypothesis of a specific cellular target through which ATR and potentially other environmental chemicals may alter aromatase expression, as well as other enzymes within the steroidogenic pathway. Using both animal studies and *in vitro* methods, we have evaluated the effects of ATR and metabolites on steroidogenesis. ATR (50 mg/kg/x 3 days, oral) caused a significant dose dependent increase in serum progesterone (P4), estrone and estradiol in male Wistar rats. However, no significant changes were observed in testicular aromatase activity or CYP19 mRNA in the brain or gonads, suggesting that alternative mechanisms such as substrate availability may be responsible for the elevated serum estrogens. To further investigate, we characterized the effects of ATR on steroidogenesis in rat granulosa cell cultures using different concentrations and exposure times. As with the *in vivo* studies, a consistent increase in P4 was observed, indicating that ATR (10 and 30 μM) does impact steroidogenesis in these cells. However, ATR did not significantly alter estradiol production. Additional studies are ongoing to determine the cellular mechanisms through which ATR induces P4 synthesis in this culture system. Thus, these studies support the hypothesis that ATR may have a direct effect on the rodent steroidogenic pathway.
This abstract does not necessarily reflect U.S.EPA policy.

S 576 DIFFERENTIAL REGULATION OF AROMATASE ISOFORMS AND TISSUE RESPONSES TO ENVIRONMENTAL CHEMICALS IN FISH.

L. Mills, R. Gutjahr-Gobell and G. Zaroogian. *Atlantic Ecology Division, NHEERL, ORD, U.S. EPA, Narragansett, RI.*

As in mammals, aromatase plays a basic role in fish reproduction, but unlike most mammals, fish have two distinct isoforms. One isoform, P450aromA, predominates in ovaries and controls circulating levels of estrogens that are critical to female differentiation and development. Another isoform, P450aromB, prevails in brains and controls local aromatization of testosterone into estrogen, controlling sex-specific reproductive behavior. The two isoforms, derived from distinct genes, have unique regulatory 5'-flanking promoter regions. Degradation of mRNA for the two isoforms differ. In addition, differences in amino acid sequences between isoforms relate to different levels of activity. The isoforms also have different phosphorylation sites that regulate their activity, suggesting distinct sensitivity to phosphorylation. Because of these differences, we investigated whether chemicals that modulate aromatase activity affect the two isoforms differently. Endocrine-disrupting chemicals (EDCs) have been shown to modulate aromatase activity. We compared the effects of four EDCs on reproduction and aromatase activity in brains and gonads of a marine fish, *Tautogolabrus adspersus*, treated *in vivo*. Testicular aromatase activity was low and not affected by any EDC treatment. Treatment with estradiol or ethynylestradiol significantly decreased aromatase activity in ovary and male brain, and resulted in lower egg production, viability and fertility. Treatment with octylphenol significantly increased male brain aromatase activity and decreased egg viability and fertility. An aromatase inhibitor, androstatrienedione, significantly reduced male and female brain aromatase activity, as well as egg production and fertility, but had no effect on ovarian aromatase activity. Overall, our results demonstrate that different EDCs can affect the activity of brain and ovarian isoforms differently. Furthermore, changes in reproductive parameters were associated with alterations in the activity of either isoform. *This abstract does not necessarily reflect EPA policy.*

S 577 EVALUATION OF (LPTA®) CD-1-TG(CYP19-LUC)-XEN MICE AS A BIOLUMINESCENT RESEARCH TOOL FOR THE *IN VIVO* STUDY OF ENDOCRINE DISRUPTORS.

T. Sanderson, P. Devine, S. Petrillo and P. Rivest. *INRS-Institut Armand-Frappier, Laval, QC, Canada.*

There is increasing concern that chemicals widely used in commercial and food products, and enter the environment, are affecting the endocrine system of humans and wildlife. These chemicals are suspected of causing endocrine-related diseases, such as reduced fertility, impaired fetal/child development, and hormone-dependent cancers of the breast, ovary, testis and prostate. A number of bioluminescent mouse models have recently been developed as possible tools to assess the in vivo biological potency of potential endocrine disruptors, as effects on gene expression can be monitored in real-time using an imaging system, without the need to sacrifice the mice. A potentially useful model is the Cyp19-luc mouse (Caliper LifeSciences), which expresses luciferase under control of a gonadal aromatase-promoter. Aromatase converts androgens to estrogens, and its dysregulation is associated with various pathologies. Overexpression is associated with the development of hormone-dependent cancers, whereas reduced expression/inhibition results in bone loss and infertility in females and decreased sperm production in males. Aromatase is increasingly recognized as an important target for endocrine disrupting chemicals. We are currently evaluating the Cyp19-luc mouse model (line 125) for its suitability as an in vivo tool for the study of chemicals that disrupt aromatase expression. Females expressed luciferase almost exclusively in the ovaries; males expressed it in the testes and epididymides. Luciferase expression increased as the reproductive system matured in both sexes, doubling between day 21 and 140 of age. In females, 5 IU hCG increased expression about 6-fold after 24h after which it returned to baseline levels. Dexamethasone did not affect luciferase expression in either sex, whereas forskolin, a stimulant of cyclic-AMP synthesis, increased expression about 3.5-fold after 3 days. Our results indicate that the luciferase transgene, similar to the aromatase gene, is stimulated by activators of the cAMP-dependent protein kinase A pathway in Cyp19-luc mice.

S 578 GENOMIC, NON-GENOMIC AND EPIGENETIC MECHANISMS OF NUCLEAR HORMONE RECEPTOR ACTION.

C. Walker[1] and S. Safe[2]. *[1]University of Texas MD Anderson Cancer Center, Smithville, TX and [2]Texas A&M University, College Station, TX.*

Our understanding of how nuclear hormone receptors respond to steroid hormones, endocrine disruptors and xenobiotics is rapidly evolving. Nuclear hormone receptors, which were once thought to act as simple transcription factors primarily through interaction with the DNA, are now appreciated to have equally important activities as activators of non-genomic signaling cascades within the cell and to interact with protein modifiers, such as arginine and lysine methyltransferases, to induce epigenetic modifications of chromatin in a ligand-, receptor-, co-activator and gene-specific fashion. Because of the importance of this class of receptors for many toxic responses, including those induced by xenoestrogens and xenobiotics, this session will highlight cutting-edge discoveries being made in this area that are having a major impact on the discipline of toxicology.

S 579 TRANSCRIPT PROFILING OF ESTROGEN-RESPONSIVE GENES.

G. Daston and J. Naciff. *Miami Valley Labs, Procter & Gamble, Cincinnati, OH.*

Global analysis of gene expression can provide significant information about the molecular basis of normal and abnormal biological function. Virtually every change in biological function is accompanied by changes in gene expression and the transcript profile has sufficient specificity as to be diagnostic of particular mechanisms

of action. It also provides support for the generation of hypotheses about the role of specific genes in a particular biological response. We have evaluated the effects of estrogens on gene expression in the rodent reproductive system. Exposure of rats to estrogens of varying potency produces a characteristic transcript profile that is sex- and lifestage-specific. Changes in the expression of steroid metabolizing genes are consistent across sex and lifestage, but other genes, e.g., transcription factors, have much greater specificity. We have carried out a temporal analysis of gene expression in the juvenile rat uterus after a single dose of an estrogen. Gene expression responses are consistent with what can be observed at a histological level. Early changes involve genes that are responsible for the cell proliferation, inhibition of apoptosis and fluid imbibition. This is followed by changes in genes that affect the state of cellular differentiation. Subsequently, there is an increase in expression of genes associated with inflammation and tissue remodeling, as well as an upregulation of apoptotic genes as the uterus returns to a pre-stimulus state. The expression of specific genes can be organized into models of coordinated gene action that can be stated as testable hypotheses. We have made progress in evaluating gene expression in a uterine adenoma cell line, for which the estrogen-driven transcript profiles appear sufficiently similar to in vivo that it appears that this system can be used to test hypotheses about the role of specific genes in the uterine response to estrogens. Gene expression analysis has utility as a predictor of mechanism of action and has the potential to be a significant adjunct to understanding the molecular control of biological responses

S 580 NON-CLASSICAL ER/SP ACTIVATION OF ESTROGEN RESPONSIVE GENES.

S. Safe[1, 2], F. Wu[3], K. Kim[2], I. Ivanov[1] and S. Khan[1]. [1]*Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX,* [2]*Institute of Biosciences & Technology, Texas A&M Health Science Center, Houston, TX and* [3]*Biochemistry & Biophysics, Texas A&M University, College Station, TX.*

17β-Estradiol (E2) binds the estrogen receptor (ER) and activates both genomic and non-genomic signaling pathways that increase or decrease gene expression. The classical genomic pathway involves E2-induced formation of an ER dimer that modulates gene expression through interactions with estrogen responsive elements (EREs) in target gene promoters. Research in this laboratory has focused on the non-classical genomic pathway in which E2 activates ER/specificity protein (Sp)-mediated induction or repression of genes in breast cancer cells by interacting with GC-rich Sp binding sites in E2-responsive gene promoters. Analysis of E2-dependent gene expression in breast cancer cells transfected with a non-specific oligonucleotide or a cocktail (iSp) of small inhibitory RNAs for Sp1 (iSp1), Sp3 (iSp3), or Sp4 (iSp4) demonstrates that E2 induced 62 and repressed 134 genes. Moreover, analysis of this data shows that over 62% of all genes induced or repressed by E2 were Sp-dependent. E2, pharmacological selective ER modulators (SERMs), and xenoestrogens also activate ER/Sp-dependent gene expression, and results of comparative activation of wild-type and variant ER indicate differences among xenoestrogens, suggesting that these compounds are also SERMs. Results of in vitro studies in breast cancer cells also show that activation of ER/Sp is complex and dependent on ligand structure, ER subtype (ERα or ERβ), Sp protein, promoter and cell context. In vivo studies with transgenic mice expressing a GC-rich luciferase construct confirm that ER/Sp is also activated or repressed in multiple tissues by E2 and other estrogenic compounds and this further confirms the importance of this non-classical estrogenic (ER-dependent) pathway.

S 581 LIFE, DEATH, AND TRANSFORMATION: MOVEMENTS, REPEATS, AND NCRNAS?

M. Rosenfeld. *Howard Hughes Medical Institute, University of California San Diego, San Diego, CA.* Sponsor: C. Walker.

The nuclear receptor (NR) superfamily of transcriptional regulators plays a central role in developmental homeostasis and diseases processes, and has been extensively studied as a model to identify the molecular mechanism for precise spatial and temporal control of gene expressions. Additional regulatory and sensor strategies have altered our views about mechanisms of gene regulation and disease. While the role of liganded nuclear receptors in mediating coactivator/corepressor exchange is well established, nuclear motor-dependent regulation of chromosomal organization in the three-dimensional space of the nucleus to diverse signaling events is emerging as a major parallel strategy to achieve integrated transcriptional responses revealing a key role for the modulation of nuclear architecture in orchestrating regulated gene expression programs in the mammalian nucleus, using previously unsuspected classes of sensor molecules. Thus, a network of covalent modifications and their corresponding gene fusions play important roles in many diseases of developmental and in initial steps in cancers, which is particularly well-established for leukemias, but now identified as a more general event in solid tumors. The molecular basis for these tumor translocation events is quite incompletely understood, although a prevailing model instituted by events in yeast, is that random translocations are selected by conferring growth advantage. We will present a model for the molecular logic underlying tumor translocation events, linking these translocations to evolutionarily-conserved strategies, with the liganded nuclear receptor (AR) serving as a driver of non-random and tissue-specific chromosomal translocations by inducing both the juxtaposition of the recombination sites, and based on local chromatin modification, serial recruitment of genotoxic stress induced enzymes that cause a synergistic enhancement of extended DSB at those sites in response to genomic insults, and NHEJ-dependent tumor translocations. In parallel, life, death and cell fate decisions are required for cells to avoid massive apoptotic death in response to genotoxic stress. While many of the regulatory mechanism controlling DNA damage/repair and apoptosis are well characterized, the precise molecular strategies that adjudicate DNA repair or apoptosis remain incompletely understood. A posttranslational modification that can modulate the ability of H2AX to function as an active determinant of repair/survival versus apoptotic responses to DNA damage through regulated differential recruitment of either DNA repair or pro-apoptotic factors, revealing a switch that modulates survival/cell death decisions during mammalian organogenesis will be presented.

S 582 REGULATION OF TRANSCRIPTION BY PROTEIN ARGININE METHYLTRANSFERASES.

M. Bedford. *MD Anderson Cancer Center, Smithville, TX.* Sponsor: C. Walker.

The covalent marking of protein arginine residues by methyl groups can promote recognition by a binding partner or a modulation in biological activity. A small family of eukaryotic gene products that catalyze methylation reactions (PRMTs) work in conjunction with a changing cast of associated subunits to recognize specific targets in the cell for modification. Physiological roles for protein arginine methylation have been established in signal transduction, mRNA splicing, transcriptional control, DNA repair, and protein translocation. Using different proteomic approaches, we have identified a number of PRMT substrates and methylarginine-dependent protein-protein interactions. This has helped us understand the molecular mechanisms behind the diverse biological roles of arginine methylation. Recent developments in our knowledge of how arginine methylation regulates transcription will be presented.

S 583 *IN VITRO* MODELS OF HUMAN TOXICITY PATHWAYS.

D. J. Dix. *U.S. Environmental Protection Agency, Research Triangle Park, NC.*

For toxicity testing and assessment programs to address the large numbers of substances of potential concern, a paradigm shift in the assessment of chemical hazard and risk is needed that takes advantage of advances in molecular toxicology, computational sciences, and information technology. This shift represents an evolution of toxicology from an observational science, to a predictive science built upon mechanism-based, biological observations in vitro. The progress in developing robust, quantitative in vitro models of human toxicity pathways with the potential to replace the current reliance on in vivo animal data will be presented. These in vitro models identify cellular and molecular responses associated with critical biological pathways, which can result in adverse health effects when sufficiently perturbed by chemical exposure. One of the challenges to this in vitro approach is selecting appropriate cell types and endpoints that provide a sufficient battery for predicting the response of relevant toxicity pathways. Results from these high-throughput screening (HTS) assays are being linked to historical toxicological test results to facilitate a transition in testing paradigms. The results from five laboratories and programs wherein the convergence of science, technology and regulatory need have produced initial successes in creating in vitro models of human toxicity pathways will be highlighted. Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.

S 584 EVALUATION OF THE TOXCAST SUITE OF CELLULAR AND MOLECULAR ASSAYS FOR PREDICTION OF *IN VIVO* TOXICITY.

K. A. Houck. *U.S. Environmental Protection Agency, Research Triangle Park, NC.*

Measurement of perturbation of critical signaling pathways and cellular processes using in vitro assays provides a means to predict the potential for chemicals to cause injury in the intact animal. To explore the utility of such an approach, a diverse collection of human in vitro cellular assays was used to profile the activity of 320 bioactive compounds, having known toxicities, from the EPA's ToxCast Program phase I chemical library. The assays consisted of a wide variety of technologies and endpoints and used both cell lines and primary cells. Some systems included biotransformation capacity in the form of phase I and II enzymes or primary human

hepatocytes. Results demonstrated that chemicals could be categorized with respect to mechanisms of toxicity including mitochondrial dysfunction, microtubule disruption, oxidative stress, nuclear receptor activation, DNA damage and other mechanisms. These toxicity phenotypes sometimes recapitulated the intended mechanism of action against target species for pesticide active ingredients, and other times reflected apparently unrelated activities. Together with activity profiles generated from high-throughput, biochemical screening assays against over 200 specific molecular targets, correlations with in vivo toxicity endpoints from the EPA's Toxicology Reference Database have been made. Initial toxicity signatures predictive of in vivo toxicity endpoints illustrate the utility of including both phenotypic cellular assays along with specific molecular targets in building predictive toxicity models. *Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.*

S 585 USE OF NUCLEAR REPORTER ASSAYS TO INVESTIGATE SPECIES DIFFERENCES IN TOXICITY.

R. C. Peffer[1] and J. Vanden Heuvel[2]. [1]*Product Safety, Syngenta Crop Protection, Inc., Greensboro, NC and* [2]*Indigo Biosciences, Inc., State College, PA.*

Nuclear receptors (NRs) are a diverse family of transcription factors that play a role in physiological and toxic processes. For some compounds, variation in toxicity between species may be related to differential activation of the NRs as well as differences in receptor splice variants within a species or tissue. For example, the critical role of the Constitutive Androstane Receptor (CAR) in the generation of mouse liver tumors by phenobarbital (PB) and 1,4-bis[2-(3,5-Dichloropyridyloxy)]benzene (TCPOBOP) has been demonstrated by the absence of tumors in Car-null mice (Yamamoto, 2004; Huang, 2005). A reporter assay in HEK293-T fibroblasts was developed with one of four different CAR ligand-binding domains (mouse CAR-1, rat CAR-1 human CAR-1 or human CAR-3) fused to the DNA binding domain of yeast Gal4. A luciferase reporter plasmid under control of the Gal4 response element was also present. Using a number of model substrates at a range of concentrations, phenobarbital produced no increase in luciferase activity in any of the four CAR variants, as would be predicted for an indirect CAR activator. However, mCAR was specifically activated 6-fold by TCPOBOP, whereas no activation was observed for hCAR-1, hCAR-3 or rCAR. The model hCAR activator CITCO produced a 60-fold increase with hCAR-3, but no response with the other three forms including hCAR-1. Androstane had the profile of an inverse agonist with all forms of CAR except for hCAR-3. These experiments and further literature references point to the possible species differences in responsiveness to different substrates by CAR, which could have bearing on differential toxicity.

S 586 TOWARDS NEW *IN VITRO* TOXICOLOGY STRATEGIES FOR DECISION MAKING: ACUTE TOXICITY AS A CASE STUDY.

G. Ouedraogo, R. Note, J. Eilstein, M. Thomas, D. Duche and J. Meunier. *Safety Research department, L'Oreal, Aulnay sous bois, France.* Sponsor: D. Dix.

In Europe, the REACH legislation and the 7th amendment to the European Cosmetic Directive are challenging for the safety assessment of chemicals. Both regulations are strong incentives for seeking alternative methods in hazard/risk assessment. Although single in vitro assays are valuable in providing mechanistic insight into toxicity pathways, they cannot address the complexity of events leading to toxicity in vivo. According to the 7th amendment to the cosmetic directive, 4 in vivo endpoints will be phased out starting in March 2009: skin irritation, eye irritation, genotoxicity and acute toxicity. While there are a number of alternatives for the former 3 endpoints, clues for replacing acute toxicity remain scarce. Previous initiatives like the Multi-centre Evaluation of In Vitro Cytotoxicity (MEIC), have pointed to the possibility of using in vitro cytotoxicity data to predict lethal systemic toxicity in vivo. Towards this end, l'Oréal has invested a lot of effort in the past two years trying to build up a strategy for the development and the implementation of in vivo acute toxicity. A proof of concept approach has been performed using a set of compounds with well documented values of LD50. These compounds have been selected to cover different in vivo toxicity range, as defined by the LD50 values and also a variety of mechanisms of toxic action. Other selection criteria relate to the target species and the route of administration: data generated in rats treated by gavage have been used to assess the correlation between the in vitro derived data and LD50 values. Preliminary statistical analysis has led to encouraging results. This is an exploratory work and further investigations such as assessing the relevance of such an approach in an Integrated Testing Strategy (ITS) workflow, are still in progress. This research project is in line with the strategy used by the US EPA for the ToxCast program. It is part of L'Oreal's commitment to contribute to the research effort needed for building the new paradigm of the "toxicity testing in the 21st century".

S 587 THREE-DIMENSIONAL HUMAN CELLULAR AND METABOLIZING ENZYME MICROARRAYS FOR HIGH-THROUGHPUT TOXICITY SCREENING.

J. S. Dordick[1, 3], D. S. Clark[2, 3], M. Lee[3], P. Asuri[3], J. Ryan[3], M. G. Hogg[3], B. Eker[3], S. Butt[3] and A. Ramasubramanian[1, 2]. [1]*Chemical and Biological Engineering, Rensselaer Polytechnic Institute, Troy, NY,* [2]*Chemical Engineering, University of California, Berkeley, CA and* [3]*Solidus Biosciences, Inc., Troy, NY.* Sponsor: D. Dix.

A miniaturized 3D cell-culture microarray (the Data Analysis Toxicology Assay Chip, or DataChip) has been developed for high-throughput toxicity screening of drug candidates and their cytochrome P450-generated metabolites. The DataChip consists of human cells encapsulated in 20 nL alginate gel spots arrayed on a functionalized glass slide for spatially addressable screening against multiple compounds. Similar dose responses were obtained with the DataChip and conventional 96-well plate assays, demonstrating that the near 5,000-fold miniaturization does not influence the cytotoxicity response. In combination with the MetaChip, which mimics the Phase I and II metabolism of the liver, the DataChip may therefore enable toxicity analyses of drug candidates and chemicals, and their metabolites, at throughputs compatible with the increased need for rapid, animal-free testing.

S 588 MICROSCALE LIVER MODELS FOR DRUG DEVELOPMENT AND TOXICITY SCREENING.

S. R. Khetani[1] and S. Bhatia[2, 3]. [1]*Hepregen Corporation, Medford, MA,* [2]*Health Sciences and Technology / Electrical Engineering and Computer Science, Massachusetts Institute of Technology, Cambridge, MA and* [3]*Medicine, Brighman and Women's Hospital, Boston, MA.* Sponsor: D. Dix.

Drug-induced liver disease is the leading cause of pre-launch and post-market attrition of pharmaceutical compounds. Environmental compounds can also cause drug-induced liver disease. Species-specific variations in liver-specific molecular pathways necessitate supplementation of animal data with in vitro assays to assess human responses to compounds. Isolated primary hepatocytes are considered to be the gold standard for evaluating drug disposition in vitro. However, hepatocytes from various species exhibit a precipitous decline in viability and phenotypic functions under conventional culture conditions. We have utilized microtechnology tools to optimize and miniaturize into a multi-well format (up to 96-well) in vitro models of the rodent and human livers. Specifically, primary hepatocytes were organized into colonies of prescribed, empirically optimized dimensions and subsequently surrounded by supportive stroma. Hepatocytes in these micropatterned cocultures retained in vivo-like morphology, expressed liver-specific genes, metabolized compounds using active Phase I/II drug metabolism enzymes, secreted diverse liver-specific products, and displayed functional bile canaliculi for several weeks. We demonstrate utility of our platform in drug development by quantifying drug-drug interactions and susceptibility to a panel of clinical hepatotoxins. In particular, we show that cultures responded to both continuous and intermittent treatment with prototypical drug inducers, showing elevated CYP450 activities when treated with drugs and recovery to basal enzyme levels within 72 hours following inducer removal. We also show that micropatterned co- are amenable to high content imaging readouts, such as those used to evaluate mechanisms of hepatotoxicity. In the future, improved in vitro models of liver tissue could eliminate problematic compounds earlier in drug discovery towards creating safer drugs for patients.

S 589 NITRATIVE AND OXIDATIVE STRESS IN TOXICOLOGY AND DISEASE.

R. Roberts[1] and W. Slikker[2]. [1]*Safety Assessment, AstraZeneca, Macclesfield, United Kingdom and* [2]*NCTR, U.S. FDA, Jefferson, AR.*

Persistent inflammation and the formation and actions of reactive oxygen species play pivotal roles in tissue injury during disease pathogenesis and as a reaction to toxicant exposures. The associated oxidative and nitrative stresses promote diverse biological reactions including neurodegenerative disorders, cancer, atherosclerosis and stillbirth. These effects occur via sustained cell proliferation and cell death and, in some cases, via induction of a pro-angiogenic environment. Exposure to ozone, a ubiquitous urban air pollutant, leads to the generation of reactive oxygen and nitrogen species in lung macrophages inducing inflammatory genes which play a key role in subsequent tissue damage. Similarly, the developing brain is susceptible to anesthetic-induced injury; recent studies have indicated that genes along the oxidative stress pathway are altered by this anesthetic treatment. In addition to a role in damage to the developing brain, inflammation and oxidative stress are implicated in Parkinson's disease (PD), a neurodegenerative disease characterized by the loss of dopamine neurons. Recent data suggests a mechanistic link between oxidative stress and elevated levels of DOPAL, a neurotoxin endogenous to dopamine neurons. Such work has significant implications for the development of therapeutics and

identification of novel biomarkers for PD pathogenesis. As well as a role in lung disease and neuronal injury, oxidative and nitrative stress is implicated in creating the pro-inflammatory microenvironment associated with the aggressive phenotype of inflammatory breast cancer. Targeting these pathways may help diminish the pro-inflammatory microenvironment that may contribute to the genetic instability and aggressive phenotype. Fundamental concepts and progresses to how one might create a rational plan of treatment, based on understanding derived from basic principles will be addressed. This session will appeal to both those with specialist knowledge in the field as well as to toxicologists looking to learn more about the role of nitrative and oxidative stress in toxicology.

S 590 ATTENUATION OF NEUROTOXICANT-INDUCED BRAIN INJURY ASSOCIATED WITH OXIDATIVE STRESS AND MITOCHONDRIAL DYSFUNCTION.

W. Slikker and C. Wang. *National Center for Toxicological Research, FDA, Jefferson, AR.*

The developing brain is susceptible to anesthetic-induced injury. The window of vulnerability to these neuronal effects of anesthetics is restricted to the period of rapid synaptogenesis, also known as the brain growth spurt. Similar dependencies on dose/duration of exposure and developmental stage are observed both in the non-human primate and in the rodent models. The duration of anesthesia to induce cell death as measured by minimal exposure requirements is similar (~6 hrs.) for nonhuman primate and rodent brain cells in culture and also for in vivo rodent and nonhuman primate studies. The susceptible stage or period of development has not been completely described but begins somewhere before the last quarter of pregnancy and continues to shortly after birth in the nonhuman primate. It has been postulated that up-regulation of the NR1 subunit of the N-methyl-D-aspartic acid receptor (NMDAR), a calcium channel, may be an important first step in the pathway to anesthetic-induced neurotoxicity. Importantly, NMDARs are vulnerable to glutamate concentrations within the tissues; in turn, the excitotoxic effects of glutamate may be mediated largely by increased Ca2+ influx through activated NMDARs. Associated with this increased Ca2+ influx is an increase in the generation of reactive oxygen species (ROS) that appears to originate in mitochondria. Several recent studies with oxidative stress blockers such as L-carnitine, melatonin, the superoxide dismutase mimetic, M40403 and the NOS inhibitor, 7-nitroindazole have indicated that reduction of oxidative stress may protect the developing animal from anesthetic induced brain cell death. Recent gene expression assessments indicate that genes along the oxidative stress pathway are altered by anesthetic treatment of developing animals. Together, the application of omics approaches along with traditional toxicological endpoints indicates that the susceptibility of the developing brain to anesthetics is mediated by oxidative stress.

S 591 REGULATION OF CAVEOLIN-1 EXPRESSION, NITRIC OXIDE PRODUCTION AND TISSUE INJURY BY TUMOR NECROSIS FACTOR-ALPHA.

L. Debra. *Department of Pharmacology and Toxicology, Rutgers University, Piscataway, NJ.*

Oxidative stress plays a key role in the pathogenesis of diseases such as asthma and COPD, and in lung injury following exposure to air pollutants. Oxidative stress is due to the combined effects of the injurious agent and reactive oxygen and nitrogen species (RONS) generated by inflammatory cells accumulating in the lung. We have been investigating the role of RONS generated by macrophages in the toxicity of ozone (O3), a ubiquitous urban air pollutant. We have previously demonstrated that alveolar macrophages (AM) and inflammatory mediators including nitric oxide (NO) generated via inducible NO synthase (NOSII) and TNFα contribute to the pathogenesis of tissue injury. The generation of these mediators is regulated by the transcription factor NF-κB. Our findings that NF-κB p50-/- mice are unable to generate inflammatory mediators and are protected from O3-induced lung injury demonstrate a critical role of this protein. In further studies we analyzed mechanisms regulating NF-κB activation in the lung after O3 inhalation. Treatment of WT mice with ozone (0.8 ppm, 3 h) results in a rapid increase in NF-kB activity in AM which peaked after 6-12 h. This response was attenuated in TNFα-/- mice. O3 inhalation resulted in increased p42/p44 (ERK1/2) activation in WT mice which was evident immediately after exposure. Activated ERK1/2 is known to downregulate caveolin-1 (Cav-1), a negative regulator of PI3K. O3 inhalation markedly downregulated Cav-1 expression in AM. This was directly correlated with O3-induced activation of PI3K and PKB. In contrast in TNFα-/- mice, O3 had no effect on Cav-1 or PI3K expression. These data together with our findings that TNFα suppresses Cav-1 expression in vitro, demonstrate that TNFα and downstream signaling molecules are important in activation of NF-κB and regulation of inflammatory genes important in O3 toxicity. Supported by NIH ES004738, GM034310, ES005022 and CA132624.

S 592 OXIDATION/REDUCTION RESPONSES AND TOXIC SHOCK.

C. V. Smith. *Seattle Children's Hospital Research Institute, Center for Developmental Therapeutics, Seattle, WA.*

Evidence for participation of reactive oxygen and nitrogen species in disease states is strong, but the data largely have been developed through pharmacological, immunohistochemical, and molecular biological methods, often without sufficiently critical consideration of the limitations of each of the approaches. The selectivities of specific reactive intermediates and of the methods of analysis used to study the intermediates, as well as issues arising from subcellular and other modes of compartmentalization need to be considered in such studies. The specificities and sensitivities needed for resolution of molecular mechanisms in relevant biological models are becoming possible, largely through ongoing advances in mass spectrometry, but absolute, as distinguished from relative quantitation, identification and application of appropriate biological denominators, and distinctions of causes, effects, and unrelated responses are needed. Efforts to understand oxidation and reduction reactions in biological disease states also encounter major limitations from incomplete or even incorrect understanding of redox chemistry in the application of these principles to redox toxicology. For example, myeloperoxidase-catalyzed oxidations can be distinguished from effects of reagent hypochlorous acid, yet many studies continue to be based upon the assumption that the two modes of oxidation are identical. The challenges in studies of acute exposures are formidible and are considerably more complicated in efforts to study chronic conditions, such as the relationships of inflammatory responses with neurodegenerative disorders, cancer, atherosclerosis, stillbirth, and preterm birth. Stillbirth and premature birth, which often are associated with maternal infections, account for more than twice as many human deaths worldwide each year as do AIDS, malaria, and tuberculosis combined. Animal models of stillbirth and premature birth can be induced by acute exposure to endotoxin, or other proinflammatory stimuli, and are associated with oxidant stress responses. However, contributions to causal mechanisms are not established.

S 593 OXIDATIVE AND NITROSATIVE STRESS IN REGULATION OF THE PRO-INFLAMMATORY MICROENVIRONMENT AND AGGRESSIVE PHENOTYPE OF INFLAMMATORY BREAST CANCER.

F. M. Robertson[1, 2, 3], A. Simeone[1] and M. Cristofanilli[2, 3]. [1]*Experimental Therapeutics, The University of Texas M.D. Anderson Cancer Center, Houston, TX,* [2]*Breast Medical Oncology, The University of Texas M.D. Anderson Cancer Center, Houston, TX and* [3]*The Morgan Welch Inflammatory Breast Cancer Research Program and Clinic, The University of Texas M.D. Anderson Cancer Center, Houston, TX.*
Sponsor: R. Roberts.

Inflammatory breast cancer [IBC] is the most lethal form of breast cancer, with little understood about this disease to ensure its detection and effective treatment. Patients with IBC are commonly misdiagnosed, have a significantly higher incidence of locoregional recurrence, with a 5 year overall survival rate significantly lower compared to patients with non-IBC locally advanced breast cancer. The mechanisms underlying the aggressive phenotype of IBC have not been clearly defined. Our recent studies provide first time evidence that IBC is associated with up-regulation of genes and proteins that regulate nitrosative and oxidative stress. The human SUM149 IBC breast tumor cells and IBC patient tumors express very high levels of the inducible isoform of the cyclooxygenase enzyme, Cox-2, with concomitant production of prostaglandin E2 (PGE2). The Cox-2 enzyme is a bifunctional enzyme and produces oxygen free radicals as a byproduct of its peroxidatic function. SUM149 IBC breast tumor cells also produce large amounts of nitric oxide and peroxynitrite, which is a very labile and active free radical that can rapidly damage DNA. We have found that selective inhibitors of Cox-2, prostanoid receptor antagonists, and nitric oxide inhibitors significantly reduce the levels of oxidative and nitrosative stress in SUM149 IBC breast tumor cells as well as alter the phenotype of the IBC breast tumor cells. Taken together, these observations suggest that targeting these pathways can effectively diminish the "pro-inflammatory" microenvironment that may contribute to the genetic instability and aggressive phenotype of IBC.

S 594 GENERATION OF REACTIVE INTERMEDIATES DURING DOPAMINE CATABOLISM: IMPLICATIONS FOR PARKINSON'S DISEASE.

J. A. Doorn. *Medicinal and Natural Products Chemistry, University of Iowa, Iowa City, IA.*

Parkinson's disease (PD) is a neurodegenerative disease characterized by the loss of dopamine (DA) neurons. Several factors have been implicated in the pathogenesis of PD, including inflammation and oxidative stress. However, it is unknown how

oxidative stress translates into selective degeneration of DA neurons. Recent data have suggested a link between oxidative stress and disruption of the cellular metabolism of an endogenous neurotoxin derived from DA. Catabolism of DA by monoamine oxidase (MAO), a process implicated in oxidative stress and inflammation, initially yields the toxic and protein-reactive intermediate 3,4-dihydroxyphenylacetaldehyde (DOPAL), which is further metabolized to 3,4-dihydroxyphenylacetic acid via aldehyde dehydrogenase (ALDH) or to 3,4-dihydroxyphenylethanol via reductases. Previous studies have demonstrated the high sensitivity of ALDH toward 4-hydroxynonenal (4HNE) and malondialdehyde (MDA), aldehydes generated via lipid peroxidation and associated with inflammation. The hypothesis of this research is that aldehydes generated via oxidative stress inhibit DA catabolism, yielding elevated levels of DOPAL, a neurotoxin endogenous to dopamine neurons. Both 4HNE and MDA were found to disrupt DA catabolism via inhibition of ALDH but not MAO, yielding several-fold increase in the level of cellular DOPAL. Reductases can compensate for impaired ALDH activity; however, MDA potently inhibited reductase-mediated metabolism of DOPAL. The impaired DA catabolism via lipid peroxidation products was found to yield elevated levels of DOPAL-protein adducts. In summary, these data demonstrate the sensitivity of DA catabolism toward lipid peroxidation products and implicate a mechanistic link between oxidative stress and elevated levels of DOPAL, a neurotoxin endogenous to DA neurons. Such work has significant implications for development of therapeutics and identification of novel biomarkers for PD pathogenesis.

S 595 NOVEL SIGNALING MECHANISMS THAT REGULATE DOPAMINERGIC NEURONAL SURVIVAL OR DEATH: IMPLICATIONS IN PARKINSON'S DISEASE.

Z. Xia. *University of Washington, Seattle, WA.*

Parkinson's disease (PD) is the second most common aging-related neurodegenerative disorder characterized by loss of dopaminergic neurons in the substantia nigra pars compacta (SNpc), resulting in irreversible motor symptoms including tremor, bradykinesia, and rigidity. Although the etiology of idiopathic PD, which accounts for at least 90% of all PD cases, has been elusive, epidemiological studies suggest a correlation between increased risk for PD and occupational exposure to pesticides. Consequently, treatment of cultured neuronal and rodent models with pesticides has been useful in the investigation of PD pathogenesis. However, despite extensive research in the past, molecular mechanisms underlying dopaminergic neuronal death associated with PD remain incompletely defined. Recent studies using several pesticides including rotenone, paraquat, and dieldrin as models to investigate signal transduction mechanisms that regulate dopaminergic neuronal death will be presented. Furthermore, idiopathic PD is most likely caused by multiple factors, including a complex interaction between genes and the environment. Interestingly, mutations in LRRK2 found in dominant familial PD have also been found in idiopathic PD, and the penetrance of LRRK2 mutations is incomplete. Thus, LRRK2 may provide an example whereby the onset and progression of PD may depend on gene-environment interactions. Recent advances in the role of LRRK2 mutations, many of which increase its kinase activity, in dopaminergic neuronal death are also important to address. Data is available on signal transduction pathways that promote dopaminergic neuronal survival and should be of general interest to scientists studying neurodegeneration, neurotoxicology, pesticide toxicology, signal transduction, molecular mechanisms of toxicity, and occupational and public health. Presentation of this data is likely to accelerate understanding of cell signaling mechanisms underlying environmental neurotoxicant-induced nigral degenerative processes as well as to foster the identification of novel therapeutic targets for treatment of PD.

S 596 SYNERGISTIC EFFECTS OF RISK FACTORS THAT CONVERGE ON DOPAMINE SYSTEMS: IMPLICATIONS FOR PARKINSON'S DISEASE.

D. A. Cory-Slechta[1] and M. Thiruchelvam[2]. *[1]Environmental Medicine, University of Rochester Medical School, Rochester, NY and [2]Environmental and Occupational Health Sciences Institute, Piscataway, NJ.*

Both epidemiological and animal studies suggest various pesticide exposures can serve as risk factors for the Parkinson's disease (PD) phenotype. Humans are concurrently exposed to multiple pesticides that act on brain nigrostriatal dopamine (DA) systems, a scenario likely to foster interactions. Based on this, we postulated a multiple-hit model which hypothesizes that concurrent exposure to multiple pesticides and/or other risk factors acting on DA systems at different target sites may actually enhance vulnerability relative to single risk factors or to multiple risk factors acting by a single mechanism, by constraining the ability to evoke compensatory or homeostatic processes. The combined paraquat (PQ) and maneb (MB) model of the PD phenotype was developed based on this premise. Synergisms and/or potentiation observed with the model, as demonstrated e.g., in nigral DA neuron loss, include effects of combined PQ+MB relative to PQ or MB alone. Moreover, PQ+MB effects are enhanced by altered genetic background (human α-synuclein mutations), aging, male gender, and early developmental exposures. Protection against PQ+MB is afforded by female gender and over-expression of glutathione peroxidase and superoxide dismutase. Developmental exposure of males to PQ+MB results in a progressive loss of DA nigral neurons across the life-span and enhances vulnerability associated with adult exposures, confirming silent neurotoxicity revealed by later exposures. Studies incorporating multiple risk factors that converge on the nigrostriatal DA system will assist in further testing the multiple hit hypothesis and in refining models of the PD phenotype. Such an evolution should permit more focused hypothesis testing in epidemiological and clinical studies.

S 597 MITOCHONDRIAL COMPLEX I INHIBITION IS NOT REQUIRED FOR DOPAMINERGIC NEURON DEATH INDUCED BY ROTENONE, MPP+, OR PARAQUAT.

Z. Xia. *University of Washington, Seattle, WA.*

Inhibition of mitochondrial complex I is one of the leading hypotheses for dopaminergic neuron death associated with Parkinson's disease (PD). To test this hypothesis genetically, we used a mouse strain lacking functional Ndufs4, a gene encoding a subunit required for complete assembly and function of complex I. Deletion of Ndufs4 gene abolished complex I activity in midbrain mesencephalic neurons cultured from embryonic day (E) 14 mice, but did not affect the survival of dopaminergic neurons in culture. This presentation will present data suggesting that dopaminergic neuron death induced by rotenone, MPP+, or paraquat in culture does not require complex I inhibition and bring into question the role of complex I inhibition in PD pathogenesis. Signaling mechanisms, including JNK/p38 MAP kinases, both in vitro and in vivo, regulating dopaminergic neuron death and survival using the rotenone and paraquat models will also be discussed.

S 598 NOVEL ROLES AND REGULATION OF SURVIVAL FACTOR MEF2 IN DOPAMINERGIC NEURONS.

Z. Mao. *Departments of Pharmacology and Neurology, Emory University, Atlanta, GA.* Sponsor: Z. Xia.

Mitochondrial dysfunction has long been hypothesized to contribute to the pathogenesis of Parkinson's disease (PD). MEF2 family of transcription factors have been implicated in promoting the survival of several types of CNS neurons. This presentation will discuss a role for the MEF2 proteins in neuroprotection of dopaminergic neurons and in the regulation of mitochondria function. It will present evidence to support MEF2-mediated regulation of mitochondria as a direct target for known PD-inducing toxicants such as MPP+ and Rotenone. How these mechanisms may be modulated by genetic and environmental toxic risk factors associated with PD will also be discussed. These studies reveal a novel site of action for PD toxicants and may provide insight concerning neuroprotective therapies for PD treatment.

S 599 LRRK2 SIGNALING AND NEURONAL DEATH.

M. R. Cookson. *Laboratory of Neurogenetics, National Institute on Aging, National Institutes of Health, Bethesda, MD.* Sponsor: Z. Xia.

Dominant mutations in Leucine rich repeat kinase 2 (LRRK2) are the single most common cause of inherited Parkinson's disease (PD). The gene product is a large multi-domain protein that has several protein-protein interaction domains surrounding a central enzymatic region that includes GTPase (ROC) and kinase domains separated by an intervening COR (C-terminal of ROC) domain. Definitively pathogenic mutations are found in all of the catalytic regions and may be clustered here, although there are a few mutations in the protein-protein interaction domains. Several groups have shown that LRRK2 is an active kinase, and we have recently shown that it is also a minimal dimer that autophosphorylates within each dimer unit. Some mutations (such as the common G2019S variant) seem to increase kinase activity directly, while others may influence regulation of the protein activity. For example, mutations in the GTPase domain (eg R1441C) appear to decrease GTP turnover activity. Because the GTP bound form of LRRK2 is more active than the GDP bound form, this group of mutations is likely to increase the length of time that LRRK2 is in the higher activity state. Therefore, our current model is that many of the mutations impinge on kinase activity although they may do this in different ways. Whether this is true of all mutations remains to be proven. The work of our own lab, and others, also suggests that kinase activity is a key contributor to the toxic effects of increased expression of LRRK2 at least in acute experiments in vitro. The key questions, which will be discussed in this presentation,

is what the signaling pathways are that mediate neuronal damage. At this stage, our knowledge of LRRK2 activity in the physiological state is limited but there are strong suggestions that it may be involved in the establishment and function of neurites and possibly in responses to oxidative stress.

S 600 NOVEL PKC SIGNALING IN OXIDATIVE DAMAGE IN PESTICIDE-INDUCED DOPAMINERGIC NEUROTOXICITY MODELS.

A. Kanthasamy. *Biomedical Sciences, Iowa State University, Ames, IA.*

Presentation description: Chronic exposure to neurotoxic pesticides has been implicated in PD pathogenesis. However, the cell death mechanisms underlying pesticide-induced dopaminergic neuronal degeneration have not yet been defined. This talk will present evidence for the possible role of novel PKC isoform aberrant signaling in the initiation and promotion of pesticide-induced dopaminergic degenerative processes. A translational approach for intervention of the activation of this proapoptotic kinase will also be discussed. Epidemiological and case control studies have shown a strong association between neurotoxic chemical exposure and the development of idiopathic Parkinson's disease (PD). However, understanding cellular and molecular mechanisms of the etiopathogenesis and selective nigrostriatal degeneration in PD is a formidable challenge. Recently, we uncovered a novel apoptotic pathway involving caspase-3 dependent proteolytic cleavage of a protein kinase C isoform PKCδ that mediates apoptosis in cell culture models of PD following exposure to the organochlorine pesticide dieldrin or the neurotoxic metal manganese. Exposure to these agents resulted in activation of the mitochondrial dependent apoptotic cascade, starting from cytochrome C release to caspase-3 activation, in a time- and dose-dependent manner. Interestingly, environmental toxicants induced caspase-3 dependent proteolytic cleavage of native PKCδ into a 41 kDa catalytic subunit and a 38 kDa regulatory subunit to persistently activate the kinase. The classic Parkinsonian toxin MPTP also induced proteolytic activation of PKCδ. Importantly, overexpression of the kinase-inactive PKCδ-K376R mutant, PKCδ-CRM, or PKCδ-siRNA protected against dopaminergic toxins-induced apoptotic cell death, confirming the proapoptotic function of PKCδ in dopaminergic neurodegeneration. This talk will describe some recent findings pertaining to feedback regulation and subcellular localization of PKCδ and translational strategies (supported by NIH grants ES10586 and NS38644).

S 601 REGULATION OF DRUG TRANSPORTERS IN DISEASE STATES AND ITS TOXICOLOGICAL AND CLINICAL IMPLICATIONS.

J. E. Manautou[1] and N. J. Cherrington[2]. *[1]University of Connecticut, Storrs, CT and [2]University of Arizona, Tucson, AZ.*

Drug transporters play an important role in the uptake, distribution and elimination of pharmaceuticals, environmental contaminants and endogenous compounds. In the last decade, considerable interest has been centered on regulation of drug transporters and on how chemicals and disease states alter their expression. It is clearly important to understand the pharmacological and toxicological consequences of changes in drug transporter function. Both induction and repression of transporter expression have been documented with exposure to classical drug metabolizing enzyme inducers, treatment with target organ toxicants and under a variety of pathological conditions. Many of these changes are mediated by transcription factors, including CAR, PXR, Nrf2, as well as cytokines and related inflammatory mediators. Therefore, it is important to highlight the recent knowledge gained on how transporter expression changes during non-alcoholic steatohepatitis and drug-induced hepatotoxicity, as well as regulation of blood brain barrier transporters and its implications to the management and/or treatment of central nervous system disorders. Finally, this session will address the molecular regulatory mechanisms involved and the potential functional consequences, and understanding how changes in transporter expression or function may be involved in drug-drug interactions and the implications of these effects in drug development and the clinical setting.

S 602 CHANGES IN THE EXPRESSION OF DRUG METABOLIZING ENZYMES AND TRANSPORTERS DURING FATTY LIVER DISEASE.

N. Cherrington[1], C. Fisher[1], A. Lickteig[1], M. Merrell[1], J. Jackson[1,2], S. Ferguson[2] and L. Augustine[1]. *[1]Pharmacology and Toxicology, University of Arizona, Tucson, AZ and [2]CellzDirect, Durham, NC.*

Of the more than 2 million severe adverse drug reactions that occur in the United States each year, most result from inter-individual variation in the ability to metabolize and eliminate drugs from the body. Although genetics plays an important role, the greatest source of variation comes from other environmental factors such as disease states. Nonalcoholic fatty liver disease (NAFLD) is a chronic condition that comprises a spectrum of pathophysiologic conditions ranging from simple steatosis to the more severe progressive steatohepatitis. It is estimated that up to a quarter of adults have steatosis, while ~2% of the world population have the more severe inflammatory and fibrogenic condition known as nonalcoholic steatohepatitis (NASH), which can lead to cirrhosis and significant impairment of liver function. Because the liver plays such a key role in the metabolism and disposition of so many drugs, any disease state that results in the functional impairment of the liver has the capacity to alter the fate of most drugs within the body. Drug metabolizing enzymes and transporter proteins play a key role in the uptake, metabolism and efflux of drugs required for their elimination. Our preliminary results suggest that several of the major drug metabolizing enzymes and transporters are altered in different stages of human NAFLD, as well as in diet-induced animal models of steatosis and NASH. In addition, the disposition and elimination of model substrates has been demonstrated in these animal models. Translation of these findings to patients with NAFLD is underway. Understanding the effect of NAFLD on the functional activity of individual drug metabolizing enzymes and transporters could help predict the fate of a drug in patients with these diseases.

S 603 ACETAMINOPHEN-INDUCED HEPATOTOXICITY ALTERS THE EXPRESSION OF MULTIDRUG RESISTANCE-ASSOCIATED TRANSPORT PROTEINS.

J. E. Manautou, S. N. Campion, L. M. Aleksunes and X. Gu. *Pharmaceutical Sciences, University of Connecticut, Storrs, CT.*

We have recently demonstrated that the liver responds to chemical injury by regulating the expression of multiple uptake and efflux transporters. Toxic doses of acetaminophen (APAP) and carbon tetrachloride decrease mRNA and protein levels of uptake transporters while increasing the levels of efflux transporters in mice. Similar changes are observed in human liver specimens following APAP overdose. Induction of multidrug resistance-associated proteins 3 and 4 (Mrp3/Abcc3 and Mrp4/Abcc4) by APAP occurs in centrilobular hepatocytes. This coordinated adaptive response may allow the liver to better handle subsequent toxicant exposures. In fact, upon re-challenging with a second dose of APAP, mice are highly resistant to hepatotoxicity and much greater Mrp4 induction is observed in actively replicating hepatocytes in injured zones. Toxic APAP treatment produces oxidative stress in hepatocytes and also activates Kupffer cells. These two events are known to mediate several compensatory responses to liver injury. In our studies, we investigated the role of the transcription factor nuclear factor (erythroid-derived 2)-like 2 (Nfe2l2 or Nrf2) and Kupffer cell function in mediating changes in transporter expression by APAP. Induction of Mrp3 and Mrp4 by APAP is diminished in Nrf2-null mice. Similarly, depletion of Kupffer cells using liposomal clodronate prevents increased Mrp4 expression in mice treated with APAP. Analysis of the 5' regulatory genomic sequence of human MRP4 (hMRP4) gene and reporter gene assay studies have identified additional transcription factors that regulate hMRP4 expression. Among these, nuclear respiratory factor 1 (NRF1) induces promoter activity of hMRP4 gene in HepG2 cells, whereas drosophila hairy and enhancer of split homologue 1 (HES-1) is suppressive. Collectively, our studies have led us to postulate that recovery from drug-induced liver injury involves differential expression of hepatobiliary transporters via signaling molecules with known hepatoprotective properties. Supported by NIH grant DK069557.

S 604 REGULATION OF ABC TRANSPORTER EXPRESSION AT THE BLOOD-BRAIN BARRIER.

D. S. Miller[1], A. M. Hartz[2] and B. Bauer[3]. *[1]Laboratory of Pharmacology, NIH/NIEHS, Research Triangle Park, NC, [2]Department of Biochemistry and Molecular Biology, Medical School, University of Minnesota, Duluth, MN and [3]Department of Pharmaceutical Sciences, College of Pharmacy, University of Minnesota, Duluth, MN.* Sponsor: J. Manautou.

The blood-brain barrier, which resides within the brain's capillary endothelium, is an exceptionally effective barrier to the delivery of therapeutic drugs to the central nervous system (CNS), limiting pharmacotherapy of major CNS diseases, including, neurodegenerative diseases, epilepsy, brain cancer and neuro-AIDS. Two elements are largely responsible for these barrier properties: tight junction between endothelial cells and high expression of ATP-driven drug efflux pumps. Of all the transporters expressed in the brain capillary endothelium, P-glycoprotein (MDR1, P-gp) is clearly the major obstacle to drug delivery. We have focused on understanding the signals and mechanisms that modulate P-gp expression and activity in brain capillaries. The overall goals are to understand how barrier transport function is altered in disease and to identify signaling elements that can be targeted to improve drug entry into the CNS. Using a combined in vitro/in vivo approach (intact brain capillaries from rats and mice as well as from treated animals), we have iden-

tified multiple extracellular and intracellular signals that modulate P-gp. Several extended signaling pathways have been mapped. Three pathways are triggered by the brain's innate immune response, two by xenobiotic-nuclear receptor (PXR, CAR) interactions, one by oxidative stress and one by seizures. Several pathways share common elements (TNF-alpha-receptor1, endothelin B receptor, nitric oxide synthase, protein kinase C), suggesting a regulatory network. Signaling is also spatially complex, involving autocrine/paracrine elements and the cytoskeletal machinery. Multiple steps in signaling are potential therapeutic targets that could be used to adjust P-gp activity in the clinic. Finally, some of these pathways modulate expression of other ABC transporters (BCRP, MRP1, MRP2, MRP4) as well as xenobiotic metabolizing enzymes.

S 605 APPLYING MODELS OF ALTERED TRANSPORTER FUNCTION TO MECHANISMS OF TOXICITY AND DRUG INTERACTIONS.

L. Lehman-McKeeman. *Bristol-Myers Squibb, Princeton, NJ.*

Xenobiotic transporters influence the disposition of many xenobiotics and endogenous compounds. Consequently, alterations in expression or function of influx or efflux transporters may affect target organ concentrations, the likelihood of toxicity and increase the potential for drug interactions. Several mutant models such as Mrp2-deficient rats have been widely used to evaluate transporter function, and more recently, a variety of transporter deficient mouse models have been genetically engineered. The organic anion transporting polypeptides (Oatps) are a superfamily of solute carriers that play a major role in the hepatic uptake of compounds. Null mouse models for Oatp1a1 (Oatp1), Oatp1a4 (Oatp2) and Oatp1b2 (Oatp4) have been developed. In Oatp1 and Oatp2 null mice, no compensatory changes in transporter expression have been observed. Clinically, young mice (3-4 mo) show small increases in total bilirubin that become more severe as the animals age (1 yr). In vitro functional assessments using primary hepatocytes from these mice demonstrate reduced capacity to transport substrates such as estradiol-17β-D-glucuronide, and in vivo evaluations reveal alterations in plasma clearance and tissue concentrations of numerous substrates, thereby supporting a role for these transporters in hepatic and renal uptake. In a manner consistent with sex-dependent differences in constitutive expression observed in this family of carriers, male mice lacking Oatp1 show the most significant changes in kinetic evaluations and tissue uptake. Additional phenotypic characterization using urinary or serum metabonomic evaluations provide more global evidence of transport deficiencies and potential endogenous substrates. Collectively, the development and characterization of null or mutant models of transporter deficiencies can be applied to determining transporter function in xenobiotic disposition and toxicity.

S 606 CLINICAL DRUG AND TOXICOLOGICAL INTERACTIONS INVOLVING DRUG TRANSPORTERS.

J. Polli. *Preclinical Drug Metabolism and Pharmacokinetics, GlaxoSmithKline, Inc, Research Triangle Park, NC.* Sponsor: J. Manautou.

Detailed elucidation of the role of drug transporters on the absorption, distribution, metabolism and excretion (ADME) of a drug candidate are often completed after the selection of the compound for initial clinical testing. Transporters can be effective barriers to drug exposure, be the rate determining step in the uptake and/or excretion of a compound or metabolite, and be a cause of drug-drug interactions or toxicity. The recognition of the influence of drug transporters on disposition and toxicity is driving a surge in transport-related research activities within the drug metabolism and pharmaceutical sciences. A case study for lapatinib, a tyrosine kinase inhibitor, where preclinical and clinical data support a role of drug transporters in clinically relevant drug interactions will be given to highlight the integrated preclinical development approach used to identify drug transporters involved in its disposition. Integration of data from pharmacokinetic, mass balance, whole-body autoradiography, in situ perfusion experiments and in vitro studies are utilized to determine when and which transporter is involved in the disposition of lapatinib.

W 607 AGGLOMERATION *VERSUS* DISPERSION: HOW NANOPARTICLE BEHAVIOR AFFECTS EXPOSURE AND TOXICITY *IN VITRO*, *IN VIVO*, AND IN THE REAL WORLD.

J. Tsuji[1] and C. Sayes[2]. [1]*Exponent Inc., Bellevue, WA and* [2]*Texas A&M University, College Station, TX.*

Many studies of nanoparticles have noted a tendency of these particles to agglomerate and form larger particles in air, solution, or suspension. Consequently, dispersion of nanoparticles has been a challenge for toxicity studies and pharmaceutical or medical applications, which have used various means, both chemical and physical to deliver nanoparticles to cells, tissues, or organisms. Such methods are important in evaluating free nanoparticles. However, clumping of nanoparticles, or particle agglomerates, is a real world phenomenon that is relevant to understanding risks posed by nanomaterials. In some systems, agglomeration of particles in air or solution/suspension appears to increase with particle concentration and decreasing size. The solution's ionic strength and electrolyte concentration can affect agglomeration and surface characteristics. Particle characteristics can in turn affect agglomeration. Other factors, such as dispersants used in sunscreens or dissolved organic matter in aquatic environments may prevent clumping. Consequences of agglomeration include exclusion by biological barriers. Agglomerated carbon nanotubes have also been shown to exhibit different effects in the lungs than their more dispersed counterparts. Studies with aquatic organisms indicate less toxicity with increasing size of particle agglomerates, although agglomerated nanoparticles are not necessarily similar in toxicity to micron-sized particles. Therefore, it is important to explore determinants of nano-sized particle-to-particle interactions, including particle properties, environmental conditions, consequences of change in size on fate in the environment and within organisms, its effects on toxicity, and the real world consequences of such particle behavior on health and environmental risks. Our ncrease in the understanding of nanoparticle exposure and toxicity in recent years is enabling inferences on certain aspects of nanoparticles that may help us design and interpret toxicity studies to better assess the health risks and beneficial applications of nanomaterials.

W 608 PHYSICAL & CHEMICAL CHARACTERISTICS AFFECTING NANOPARTICLE BEHAVIOR IN TOXICOLOGY AND ECO-TOXICOLOGY STUDIES.

C. M. Sayes. *Vet. Phys. & Pharmacology, Texas A&M University, College Station, TX.*

Relevant nanomaterial characterization profiles is essential for the successful development of various nanotechnologies, including pharmaceutical & medicinal research, toxicology, environmental sciences and engineering, and regulatory and policy decisions. In this talk, we will discuss some of the most common physical and chemical properties often reported in both scientific literature and industrial specification sheets. Further, we will identify some of the nano-properties most relevant to toxicological assessments in cell cultures, whole animals, and ecological systems. Particles such as metal nano-colloids (silver), metal oxide nanoparticles (aluminum oxide), and carbon-based nanostructures (C60). By varying concentration (0.001 - 1000 mg/L), changing solvent conditions in various aqueous media, and assessing nanoparticle characteristics at different time points after suspension (minutes, hours, weeks, and months), we have studied changes in the aggregation potential of each nanoparticle system. Results showed that, depending on the nanoparticle system and its concentration, the aggregation potential for each of material changes over time. Some systems show evidence of de-aggregation as well as changes in surface charge, pH, and iso-electric point depending on solvent (medium) and time duration in suspension. Further, for some systems, the particle sizing data demonstrated that the nano-sized particles aggregate to a greater extent than the fine-sized particles. This study presents our results regarding material characterization of nano and fine-sized particles in aqueous media, a review of the current literature, and suggestions for relevant and adequate characterization defining the "nano" properties in reference to eco-toxicity assessments of particle systems.

W 609 EFFECTS OF PARTICLE AGGLOMERATION ON PULMONARY TOXICITY.

V. Castranova. *National Institute for Occupational Safety and Health, Morgantown, WV.*

Nanoparticles tend to agglomerate into um-sized structures upon suspension in biologically compatible media such as phosphate-buffered saline (PBS), due to the high ionic strength and near neutral pH of the media. Dispersion of nanoparticles in chemical surfactants is effective but is problematic because of bio-incompatibility or alteration of the nanoparticle surface. The effectiveness of albumin, phospholipid, dilute alveolar lining fluid, and an "artificial dispersion fluid" containing a phospholipid/albumin/PBS mixture in suspending ultrafine carbon black, ultrafine titanium dioxide, and multi-walled carbon nanotubes has been evaluated with dilute alveolar lining fluid and the "artificial dispersion fluid" proven to significantly enhance dispersion. Evidence indicates that at the low concentration used dispersion fluid does not mask the activity of the nanoparticle surface. Improved dispersion significantly increases the inflammatory potential of ultrafine carbon black in an intratracheal instilled rat model. Evaluation of the pulmonary responses to poorly dispersed vs well dispersed preparations of single-walled carbon nanotules (SWCNT) in a pharyngeal aspiration mouse model indicates that granulomas form at deposition sites of agglomerates, while more dispersed SWCNT structures avoid phagocytosis by alveolar macrophages, rapidly cross the alveolar epithelial lining

and enter the interstitium where a persistent fibrotic response is initiated. Inhalation studies with SWCNT indicate that pharyngeal aspiration of dispersed SWCNT more closely mimics inhalation a dry aerosol of SWCNT than aspiration of a poorly dispersed suspension.

W 610 STABILITY OF NANOPARTICLES FOR BIOMEDICAL APPLICATIONS.

M. Philbert. *School of Public Health, University of Michigan, Ann Arbor, MI.*

A great deal of attention has been paid to agglomeration and aggregation of nanomaterials due to the exponential increase in surface area to volume ratios at radii below 50nm. Aggregation of nanoparticles may be enhanced by surface modifications intended for enhancing targeting and/or functionality or the incorporation of ferromagnetic moieties for MR imaging. The resulting increase in particle size alone may hamper the ability of the nanoparticle to reach its intended target, to be sequestered by immune cells or accumulate in the interstitial compartment. Charged polymer chains have been successfully used to reduce such particle-to-particle interactions. Modulation of surface charge, however, may alter the final disposition and fate of nanoparticles independent of their intrinsic chemical identities. Other potential complications include disintegration of composite nanoparticles with unintended and premature release of active components. Depending on composition, release of active components prior to administration results in reduction/loss of efficacy and increases the possibility of collateral toxicity. Formulations incorporating photoactive components must be stable with respect to minimal quenching of reactive oxygen species, inactivation of the photodynamic moiety and retention in the body of the nanoparticle. While many of the available analytical techniques provide adequate determination of particle integrity in vitro, new measurement technologies will have to be developed for intravital and in vivo quantification of stability. W 611 NANOPARTICLE-MACROMOLECULE INTERACTIONS AND THEIR IMPACT ON THE RATE AND EXTENT OF PARTICLE AGGLOMERATION.

G. Lowry. *Civil & Environmental Engineering, Carnegie Mellon University, Pittsburgh, PA.* Sponsor: J. Tsuji.

Most nanoparticles rapidly aggregate or agglomerate in air and water. The rate and extent of aggregation/agglomeration is typically greater in biological fluids (e.g. physiological buffer) due to the high salt concentration and presence of divalent cations (e.g. Ca2+). This physical transformation of nanoparticles can affect their reactivity (e.g. ROS generation), mobility in the environment, translocation in organisms, and their overall toxicity. A fundamental understanding of the behavior of nanoparticles in fluids, and the relationship between the particle surface properties and the rate and extent of agglomeration of those particles is needed to determine the mechanisms of nanoparticle toxicity. Medium and high molecular weight macromolecules such as proteins and DNA adsorb to nanoparticle surfaces with high affinity so even very low concentrations of these compounds in solution can lead to significant adsorbed mass. Both the adsorbed mass and the layer conformation of the adsorbed macromolecule affect the magnitude of the attractive and repulsive forces afforded by the adsorbed macromolecule, and therefore the aggregation and agglomeration behavior of the particles. These molecular scale interaction forces can be measured and correlated with the macroscopic behavior of nanoparticle suspensions (e.g. agglomeration and sedimentation). Even for highly attractive particles expected to aggregate into a primary minimum, adsorbed macromolecules lead to agglomeration in a secondary minimum at separation distances of ~100nm. These agglomerates are more readily detached and resuspended as individual nanoparticles than aggregated particles. Exposure studies conducted with highly stabilized particles can decrease contact of those particles with plated cells, and alter the properties of the particles contacting the cells. Measurements of the agglomeration and sedimentation rate are therefore a required step toward identifying the mechanisms of toxicity.

W 612 APPLICATION OF TOXICOLOGY STUDIES FOR RISK ASSESSMENT IN THE REAL WORLD.

J. Tsuji[1] and F. Mowat[2]. *[1]Exponent, Bellevue, WA and [2]Exponent, Menlo Park, CA.*

Risk assessment of nanotechnology applications must consider the relevance of laboratory studies for worker, consumer, or environmental exposures. Studies on nanomaterials typically use high doses delivered in vitro to cells or tissue cultures, short-term in vivo by injection or bolus dosing (e.g., intratracheal instillation, gavage), or in small test chambers for aquatic or environmental studies. Particle behavior under these conditions can differ dramatically from behavior in the real world, thereby complicating dose-response assessments and evaluation of effects. Nanoparticles readily agglomerate in air particularly at higher concentrations, posing challenges for inhalation studies, but indicating limits to higher "real-life" nanoscale particle exposures. Studies of more well dispersed carbon nanotubes in the lungs of rats via pharyngeal aspiration indicate that fibrosis or systemic effects (e.g., cardiovascular) may be more relevant than granuloma formation in risk assessment of chronic exposure to nanoparticles in the workplace or in the environment. High exposure to nanoparticles in aquatic environments may be limited by increased agglomeration with higher concentration and smaller particle size, as shown for fullerenes and titanium dioxide. Although agglomerated nanoparticles may have greater reactivity than similar-sized solid particles, larger size may restrict translocation of agglomerated nanoparticles from nose to brain via axon transport or through cell membranes, according to research indicating a 200 nm upper limit for such transport. Conversely, surface coatings, dispersants (e.g., in sunscreens, organic matter in water), and functional groups on nanoparticles can reduce or alter agglomeration behavior. Dose-response assessments need to incorporate the complexities of nanoparticle behavior for specific compounds and conditions at relevant dose ranges for nanomaterials in consumer products, pharmaceuticals, and other applications.

PL 613 IDENTIFICATION OF SELENOCYSTEINE ADDUCTS IN THIOREDOXIN REDUCTASE BY 2-CHLOROETHYL ETHYL SULFIDE (CEES), A MODEL SULFUR MUSTARD VESICANT.

Y. Jan[1], J. P. Gray[2], D. R. Gerecke[3], H. Zheng[3], R. P. Casillas[4], D. E. Heck[5], D. L. Laskin[3] and J. D. Laskin[1]. *[1]Environmental & Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, [2]Science, U.S. Coast Guard Academy, New London, CT, [3]Pharmacology & Toxicology, Rutgers University, Piscataway, NJ, [4]Battelle, Columbus, OH and [5]Environmental Health, New York Medical College, Valhalla, NY.*

Thioredoxin reductase (TrxR), a selenocysteine-containing flavoprotein that catalyzes the reduction of oxidized thioredoxin, is a critical target for CEES. Previously, we reported that CEES effectively inhibited purified TrxR and TrxR in type II lung epithelial cells. CEES was significantly less effective in inhibiting mutant TrxR in which selenocysteine was replaced by cysteine indicating that the vesicant reacts with the C-terminal redox center of TrxR. In the present studies alkylation sites in TrxR modified by CEES were identified. Rat TrxR was reacted with CEES, purified by SDS-PAGE, cleaved by in gel Lys-C digestion, and subjected to LC-MS/MS. Based on distinct isotope patterns of selenium-containing peptides and searching for critical b and y ions in MS/MS, several specific alkylated selenium-containing peptides were identified in CEES-treated enzyme. One of the alkylated selenium-containing peptides, a doubly charged ion at m/z 723.22, corresponded to a mass addition of 145 Da as compared with the mass of unmodified peptide. MS/MS sequence analysis revealed that a cysteine residue is alkylated by a single carbamoylmethyl group (+ 57 Da) and a selenocysteine residue is alkylated by a single ethylthioethyl group (+ 88 Da). No peaks with mass increases corresponding to two ethylthioethyl-modifications were detected, suggesting that CEES specifically alkylated the selenocysteine, but not cysteine residues, in the C-terminal redox motif of TrxR. Taken together, these data demonstrate that mustard vesicants target TrxR by selectively forming selenocysteine adducts. Inhibiting adduct formation may be an important mechanism to counter vesicant toxicity. Supported by CA100994, CA093798, ES004738, ES005022, GM034310 and AR055073.

PL 614 CALCIUM SIGNALING IN NEURONAL CELLS EXPOSED TO THE MUNITIONS COMPOUND CYCLOTRIMETHYLENETRINITRAMINE (RDX).

X. Wu[1], M. Ehrich[1], S. Werre[1], M. A. Majors[2], W. C. McCain[2] and G. Reddy[2]. *[1]Virginia Maryland Regional College of Veterinary Medicine, Blacksburg, VA and [2]Directorate of Toxicology, U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD.*

Cyclotrimethylenetrinitramine (RDX) has use as an explosive. Past studies in animals have demonstrated spontaneous seizures as an adverse effect of oral administration. Mechanisms for seizure production, however, have not been described. In the present study we examined the ability of RDX applied to human neuroblastoma SH-SY5Y cells to increase cellular calcium, as increased calcium levels are a possible contributing mechanism for excitotoxicity. For these experiments, cells were loaded with calcium-indicating fluorescent dye one hour before application of RDX in concentrations between 1.5 μM and 7.5 mM. Fluorescence was immediately measured on a kinetic fluorescent microplate reader with autoinject, and recordings were made for a total of 30 cycles of 11 seconds each. A concentration response was noted, with even the lowest concentration of RDX tested capable of

raising calcium fluorescence above baseline. A return toward baseline was noted by the end of the observation period. The rise in calcium levels were similar to that noted with 200 nM carbachol, and could be prevented by pretreatment with 10 mM of the calcium chelator tetrasodium EGTA. Partial attenuation of the carbachol- and the RDX-induced increases in calcium were evident after exposure to the calcium channel blocker verapamil (20 uM), the sarcoplasmic reticulum CaATPase inhibitor thapsigargin (5 uM), and the general membrane stabilizer lidocaine (10 mM), although the latter was only effective in medium containing serum. Results suggest that RDX has capability to transiently increase intracellular calcium levels and that multiple mechanisms may be involved.

PL 615 MODIFICATION OF NADPH CYTOCHROME P450 REDUCTASE BY 2-CHLOROETHYL ETHYL SULFIDE (CEES) STIMULATES PRODUCTION OF REACTIVE OXYGEN SPECIES.

V. Mishin[1], J. P. Gray[2], D. E. Heck[3], R. P. Casillas[4], D. R. Gerecke[1], D. L. Laskin[1] and J. D. Laskin[5]. *[1]Pharmacology & Toxicology, Rutgers University, Piscataway, NJ, [2]Science, United States Coast Guard Academy, New London, CT, [3]Environmental Health, New York Medical College, Valhalla, NY, [4]Battelle, Columbus, OH and [5]Environmental & Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

NADPH-cytochrome P450 reductase, a flavin-containing electron donor protein for cytochrome P450's, is a crucial enzyme in xenobiotic metabolism. Disruption of xenobiotic metabolism is known to lead to oxidative stress and toxicity. Sulfur mustard and related vesicants are known to target the cytochrome P450 system and inhibit drug metabolism. In previous studies we demonstrated that the sulfur mustard analog 2-chloroethyl ethyl sulfide (CEES) causes a time- and concentration-dependent inhibition of NADPH-cytochrome P450 reductase activity in MLE-15 lung epithelial cells. Effects were maximal after 1 hr with concentrations of CEES ranging from 0.1-10 mM. In the present studies, we analyzed the effects of CEES on a recombinant human cytochrome P450 system. We found that CEES inhibited the reduction of cytochrome c as well as cytochrome P450 1A1 activity. Despite this inhibition, NADPH consumption and electron flow through the flavin cofactors of the reductase were not affected as measured by NADPH utilization and the reduction of 2,6-dichlorophenolindophenol (DCPIP), respectively. NADPH-cytochrome P450 reductase also generates reactive oxygen intermediates (ROI) via oxidation of NADPH. We quantified ROI production by the reductase by measuring hydrogen peroxide production in the Amplex-Red assay. Surprisingly, CEES markedly enhanced the generation of ROI by the reductase. These data demonstrate that CEES can selectively target multiple sites within cytochrome P450 reductase. Enhanced formation of ROI by the enzyme following CEES treatment can lead to 'uncoupling' of xenobiotic metabolism and increased oxidative stress and may contribute to the toxicity of sulfur mustard. Supported by CA100994, CA093798, ES004738, ES005022, GM034310 and AR055073.

PL 616 INHALED SULFUR MUSTARD PRODUCES SEVERE LEUKOCYTE DEPLETION IN AN ANIMAL MODEL: COMPARISON WITH HALF-MUSTARD.

J. Seagrave, J. Benson, M. Lehman, T. March, J. McDonald, W. Weber and G. Grotendorst. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

Sulfur mustard (SM) is a chemical threat vesicant which causes skin blistering and long-term pulmonary dysfunction. Severe leukopenia has been reported in humans believed to have been exposed to SM aerosols during warfare. However, exposure levels and confounding effects of exposure to other agents are unknown for these subjects. This study evaluated this effect in an animal model where the exposures were well defined, and compared the effects of SM with chloroethylethyl sulfide (CEES, half-mustard). Briefly, F344 rats were conditioned to nose-only exposure tubes, then exposed to aerosols generated using a Swirler nebulizer from solutions of SM or CEES in ethanol. Aerosol concentrations were determined by gas chromatography. Exposures to SM were for 5, 10 or 15 min at 190 $\mu g/m^3$ or for 30 or 60 min at 10 or 97 $\mu g/m^3$. Exposures to CEES were 254 or 1200 $\mu g/m^3$ for 5, 10 or 15 min. At intervals following the exposure, the rats were humanely killed. Blood was collected and analyzed for hematological parameters using an Advia automated system. SM exposure caused dose-dependent suppression of most types of leukocytes and reticulocytes 24 h later, without substantial alterations in the erythrocytes. Recovery studies indicated that lymphocytes recovered by 3d after exposure to 10 $\mu g/m^3$ SM for 30 min. Depletion of other leukocytes and reticulocytes was more sustained but recovered by 10d. CEES at 254 $\mu g/m^3$ for up to 15 min had little effect at 24 hr, but exposure to 1200 $\mu g/m^3$ CEES suppressed lymphocytes at 24 hr similarly to exposure to 190 $\mu g/m3$ HD. However, in contrast to HD, CEES exposure did not affect monocytes; and neutrophils, reticulocytes, and erythrocytes were elevated. These results suggest differences between the effects of CEES and HD. The mechanisms for these effects and the differences between the two agents are not known, but there are clear implications for protection of humans exposed through acts of war or terrorism from secondary infections. Funded by Cooperative Agreement NIH NINDS 5U54NS058185-03.

PL 617 SULFUR MUSTARD-INDUCED ENDOPLASMIC RETICULUM STRESS RESPONSE IN THE MOUSE EAR VESICANT MODEL.

D. Gerecke[1], M. Soriano[1], R. P. Casillas[2], C. L. Sabourin[2], M. K. Gordon[1] and Y. Chang[1]. *[1]Pharmacology & Toxicology, Rutgers University, Piscataway, NJ and [2]Battelle Biomedical Research Center, Columbus, OH.*

Topical exposure to the chemical agent, bis(2-chloroethyl) sulfide (SM) in the mouse ear vesicant model (MEVM) resulted in time-related changes in the histopathology of the skin. Changes included increasing edema over time, detachment of the epidermis from the dermis, and upregulation of laminin-332, a skin glycoprotein required for both basal keratinocyte adhesion in undamaged skin, and keratinocyte migration after wounding. Homeostatic dysfunction caused endoplasmic reticulum stress response (ESR), as observed by confocal microscopy. ESR is activated to increase the capacity of the ER to fold and process proteins. These perturbations occur when the lumen either accumulates misfolded proteins or when it has lipid imbalances. ESR can also occur after excessive internal ionic changes. Confocal microscopy experiments and microarray data suggested that ER stress occurs very quickly in the MEVM. Microarray analysis accompanied by confirmatory RT-PCR experiments indicated there was upregulation of several heat shock proteins and folding chaperones in the ER. Some of these included calreticulin, immunoglobulin-binding protein, and protein disulfide isomerase. The accumulation of laminin γ2 protein, one of the chains of laminin-332, in the ER was visualized by confocal microscopy and colocalized with several of the ER chaperones. This accumulation appeared specifically in the migrating, but not proliferating cells. These observations are consistent with recent reports that laminin-332 is found in migrating, transformed epithelial cells that have left the cell cycle, but not in proliferating cells. Taken together, these results suggest that laminin γ2 is misfolded after SM treatment, resulting in decreased secretion and reduced overall amounts of laminin-332 in the extracellular matrix. This would explain the observation that there is a delayed wound healing response evident in this wound model. Supported by ES005022, ES004738, EY09056, and the NIH CounterACT Program through NIAMS U54AR055073.

PL 618 EXPOSURE TO CEES INDUCES OXIDATIVE STRESS AND PRODUCES AN INFLAMMATORY RESPONSE IN SKH-1 HAIRLESS MOUSE SKIN.

A. Pal[1], N. Tewari-Singh[1], M. Gu[1], C. W. White[2] and R. Agarwal[1]. *[1]Pharmaceutical Sciences, University of Colorado Denver, Aurora, CO and [2]National Jewish Medical and Research Center, Denver, CO.*

CEES, 2-chloroethyl ethyl sulfide, is an analog of sulfur mustard (HD) that induces tissue damage similar to HD. Our recent findings have shown that topical application of CEES on to the dorsal skin of female SKH-1 hairless mice causes skin inflammatory response measured as bi-fold thickness, edema, hyperplasia, together with a strong activation of transcription factors AP1 and NF-κB via upstream signaling pathways including MAPKs and Akt. Based on these outcomes, the major objective of present study was to assess: 1) whether CEES exposure of skin causes an oxidative stress that could be responsible for the activation of signaling pathways and transcription factors, and 2) what are the effector inflammatory molecules which are induced, possibly through CEES-caused activation of transcription factors, and play a role in overall inflammatory and blistering effects of CEES in skin. CEES exposure of SKH1 hairless mice at different doses and treatment times resulted in oxidative stress as measured by immunoblotting of skin tissue samples, which showed 4-HNE- and DMPO-adducted protein modifications. Parallel to 4-HNE and DMPO adduct formation, we also observed by immunoblotting that protein oxidation is significantly increased following CEES exposure in a dose- and time-dependent manner. Our results also showed that topical CEES exposure of mice induces both COX-2 and iNOS expression at protein level in skin, providing a convincing link with well known inflammatory activity of CEES. We also studied the expression of MMP-2 (gelatinase A) and -9 (gelatinase B) in CEES-exposed mice to determine their role in tissue blistering injury. A dose- and time-dependent increase in overall gelatinase activity was observed in CEES-treated skin epidermis. Collectively, our results suggest that topical application of CEES to SKH-1 hairless mouse skin induces inflammatory responses through COX-2 and iNOS and skin blistering through MMP-2 & -9 via CEES-induced oxidative stress.

PL 619 MODULATION OF GENE EXPRESSION BY MMP INHIBITORS IN SULFUR MUSTARD EXPOSED MOUSE SKIN.

Y. Chang[1], R. P. Casillas[2], C. L. Sabourin[2], M. K. Gordon[1] and D. Gerecke[1]. *[1]Pharmacology & Toxicology, Rutgers University, Piscataway, NJ and [2]Battelle Biomedical Reseach Center, Columbus, OH.*

Skin exposure to sulfur mustard(SM) causes detachment of the epidermis from the dermis within hours. Damage may be enhanced by matrix metalloproteinases (MMPs), zinc-dependent proteinases involved in the degradation and remodeling of extracellular matrix proteins. Several MMP inhibitors were selected for evaluation as potential therapeutic countermeasures to SM-induced injury. MMP-2/MMP-9 Inhibitor I, Ilomastat, and GM1489 were used as pretreatments in time course studies (24h, 72h, and 168h post-SM treatment) to evaluate their therapeutic effectiveness. Histological examination was used to assess the gross pathology and Draize scores were assigned to the samples. Microarray analysis was performed to identify subtle gene changes. Only the Ilomastat pretreatment in conjunction with SM exposure coincided with a slightly improved Draize score. All three inhibitors showed improvement in overall tissue structure and a reduction in edema by 72 hours post-treatment as determined by histological examination. Affymetrix microarray and ANOVA analysis (false discovery rate of 0.05) was used to create gene profile lists for each of the compounds tested. KEGG library pathways analysis for each time period was performed and the data assigned Fisher p values. The most common pathways affected by inhibitor treatments included: apoptosis, immune system and signal transduction pathways for 24h, cytokine-cytokine receptor interaction and various metabolic pathways for 72h, and wound repair pathways for 168h. Results were verified by RT-PCR. *This work is supported by ES05022, ES07148, EY09056, and the NIH CounterAct Program NIAMS U54AR055073. PL 620 TRPA1 MEDIATES THE ACUTE NOXIOUS EFFECTS OF INDUSTRIAL ISOCYANATES AND TEAR GASES.

B. F. Bessac, S. E. Jordt, M. Sivula, C. von Hehn and A. I. Caceres. *Pharmacology, Yale University School of Medicine, New Haven, CT.*

The release of the methyl isocyanate in Bhopal, India, caused the worst industrial accident in history. Exposures to industrial isocyanates induce lacrimation, pain, airway irritation and edema. Similar responses are elicited by chemicals used as tear gases. Despite of frequent exposures the biological targets of isocyanates and tear gases in vivo have not been identified, precluding the development of effective countermeasures. We use Ca2+ imaging and electrophysiology to show that the noxious effects of isocyanates and all major tear gas agents are caused by activation of Ca2+ influx and membrane currents in mustard oil-sensitive sensory neurons. These responses are mediated by Transient Receptor Potential Ankyrin 1 (TRPA1), an ion channel serving as a detector for reactive chemicals. We identify 2-chlorobenzylidene malononitrile (CS tear gas agent) as the most potent TRPA1 agonists known to date (EC50=7±1 nM). In mice, genetic ablation or pharmacological inhibition of TRPA1 dramatically reduces isocyanate- and tear gas-induced nocifensive behavior following both ocular and cutaneous exposures. We conclude that isocyanates and tear gas agents target the same neuronal receptor, TRPA1. TRPA1 antagonists can prevent and alleviate the adverse health effects of exposures to a wide range of toxic noxious chemicals.

PL 621 MAP KINASES REGULATE CHANGES IN ANTIOXIDANT AND INFLAMMATORY MEDIATOR EXPRESSION IN MOUSE KERATINOCYTES INDUCED BY THE VESICANT 2-CHLOROETHYL ETHYL SULFIDE.

A. T. Black[1], L. B. Joseph[1], C. R. Gardner[1], J. P. Gray[1], R. P. Casillas[2], D. E. Heck[3], D. R. Gerecke[1], D. L. Laskin[1] and J. D. Laskin[4]. *[1]Pharmacology & Toxicology, Rutgers University, Piscataway, NJ, [2]Battelle, Columbus, OH, [3]Environmental Health, New York Medical College, Valhalla, NY and [4]Environmental & Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

Skin exposure to sulfur mustard causes marked inflammation and tissue injury. These effects are associated with changes in expression of antioxidants and cytokines in the skin which regulate inflammatory reactions and oxidative stress. In the present studies we characterized mechanisms regulating changes in expression of these mediators using an in vitro skin construct model in which mouse keratinocytes were grown at an air-liquid interface and exposed directly to 100-1000 μM 2-chloroethyl ethyl sulfide (CEES), a model sulfur mustard vesicant. CEES was found to cause marked increases in Cu,Zn superoxide dismutase, catalase, thioredoxin reductase and the glutathione-S-transferases, GSTA1-2, GSTP1 and mGST2. CEES also upregulated TGF-β and IL-1α, as well as several enzymes important in the synthesis of prostaglandins, including COX-2, microsomal prostaglandin E synthase-2 (mPGES-2) and prostaglandin D synthase (PGDS). CEES readily activated keratinocyte JNK and p38 MAP kinase signaling pathways which are known to regulate expression of antioxidants and prostaglandin synthases. Inhibition of p38 MAP kinase suppressed expression of GSTA1-2, COX-2, mPGES-2 and PGDS while JNK inhibition suppressed PGDS and GSTP1. CEES also induced caveolin-1, a membrane protein known to interact with MAP kinases and regulate their activity. These data indicate that CEES modulates antioxidants and inflammatory mediators by distinct mechanisms. Alterations in expression of these mediators are likely to be important mechanisms regulating inflammation and/or protection of the skin from CEES-induced oxidative stress. Supported by CA100994, CA093798, ES004738, ES005022, GM034310 and AR055073.

PL 622 DEVELOPMENTAL EFFECTS OF PM DURING POST-NATAL LUNG GROWTH.

C. J. Johnston, G. Oberdörster, R. Gelein and J. N. Finkelstein. *University of Rochester, Rochester, NY.*

Early childhood exposures to environmental contaminants may contribute to diseases, either during childhood or later in life, both because children's exposures may be higher and because they may be more vulnerable to the toxic effects of the contaminants. We hypothesize that early life exposure to ambient ultrafine particles alters lung response and structural development; furthermore re-exposure as adults will lead to increased sensitivity. These studies will (1) Identify critical time points in the differential response of newborn vs. adult lung to inhaled environmental particles. (2) Compare effects of age on uptake efficiency and particle distribution after exposure. C57Bl/6J mice at 2 and 56 days old were exposed to concentrated ambient "Real World" particles from ultrafine particle concentrator (HUCAP) for a duration of 4 hours a day for 4 consecutive days and compared to sham controls for either 1 week or 2 weeks and examined at the end of exposure or allowed to recover until 8 weeks of age. At that time mice were either sacrificed or exposed to ambient concentrated particles for 4 days and examined at the end of exposure. Additional studies compared particle distribution in the lung and whole-body translocation in HUCAP exposed mice exposed to ~ 10nm Au ultrafine particles for 4 hours and examined 24 hours later. Lungs harvested from mice exposed starting at 2 days of age to HUCAPs for 4 hours a day for 4 consecutive days showed increased mRNAs encoding MnSOD. Mice exposed to HUCAPs for two consecutive weeks early in development and re-exposed as adults to HUCAPs for 4 hours a day on 4 consecutive days demonstrated decreases in mRNAs encoding TNFα and RANTES compared to mice that were exposed only as adults. Early life exposures to ambient ultrafine particles induce antioxidant defenses and activate cell cycle and inflammatory systems. Re-exposure as adults demonstrated decreases in inflammatory genes which may suggest a suppression of the immune system in response to subsequent particle exposure. Supported by EPA Star PM Center R-827354 and P30 ES-01247.

PL 623 THE EFFECTS OF HIGH FAT DIET INDUCED GESTATIONAL DIABETES ON MOUSE METABOLIC DISORDER AND SKELETAL MALFORMATION.

C. Liang[1], M. E. Oest[1], J. C. Jones[1] and R. M. Prater[2, 1]. *[1]Biomedical Science and Pathobiology, Virginia Tech, Blacksburg, VA and [2]Edward VIA Virginia College of Osteopathic Medicine, Blacksburg, VA.*

Adult diets rich in saturated fat augment LDL cholesterol, elevate oxidative stress (OS), and increase risk of cardiovascular disease, obesity, cancer, and osteoporosis. However, the contribution of gestational high saturated fat diet (HFD) and OS to metabolic disease and skeletal dysfunction in perinates and adult offspring is not known. Animal models show deleterious effects of maternal HFD during pregnancy, including excessive OS, placental and vascular dysfunction, insulin resistance, and metabolic syndrome. Pathophysiologic mechanisms linking gestational HFD, OS, and insulin resistance to perinatal development and adult-onset skeletal and metabolic dysfunction are explored in the present study. Female C57BL/6 mice were fed "cafeteria-style" rodent diet HFD which including 32.1% saturated fat for one month prior to conception, and throughout gestation. Dam body weight increased from gestation day 0 (GD0) to GD19 by 41% with HFD, as compared to 23% in control dams; GD19 placental OS was 87% higher in HFD vs. control mice. HFD dams also developed hyperglycemia and insulin resistance. Results of this study also demonstrate for the first time a marked reduction in GD19 perinatal bone mineral density (BMD; 20%), total bone volume (45%), and crown-to rump length (12%) in progeny of dams who consumed HFD, as compared to controls. Additionally, offspring that were fed conventional rodent chow exhibited lifelong effects of gestational HFD, including hyperglycemia, insulin resistance, obesity, lower femoral epiphyseal BMD (HFD offspring were 87% of control), and

dysregulation of distal femoral trabecular architecture at 6 months of age, as measured by micro-computed tomographic image analysis. Collectively, these data suggest that offspring of dams who consume HFD during pregnancy are at increased risk of permanent skeletal malformation and adult-onset fragility fractures, as well as metabolic dysfunction.

PL 624 DIOXIN SUPPRESSION OF DUCT FORMATION AND BRANCHING IN AN ENGINEERED 3D *IN VITRO* MODEL OF THE HUMAN MAMMARY GLAND.

J. Reiners[1, 2], M. Sameni[2] and B. Sloane[2]. [1]*Institute Environmental Health Sciences, Wayne State University, Detroit, MI and* [2]*Department of Pharmacology, Wayne State University School of Medicine, Detroit, MI.*

Mammary gland development is a carefully orchestrated, chronological process that is influenced by a variety of environmental agents including 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (dioxin). Exposure of pregnant rodents to dioxin in late gestation profoundly suppresses mammary duct development and branching in female progeny. The mechanisms by which dioxin suppresses mammary duct development and branching, let alone the signaling processes involved in normal duct development, are not known. To address these issues, we have developed a Cultrex™-based 3-dimensional *in vitro* model in which the co-culturing of single cell suspensions of human mammary epithelial and myoepithelial cell lines, plus/minus human myofibroblasts, give rise to structures (> 1 mm), within 10 days, consisting of primary and secondary ducts with attached alveoli-like lobular units. Structure development was monitored by differential interference constrast microscopy, and 3D reconstruction of confocal image stacks of the phalloidin stained actin cytoskeleton, and immunostained laminin-5. Duct branching, but not alveoli development, was impaired when epithelial and myoepithelial cells were cultured in the presence of 10 nM dioxin. The co-culturing of mammary and myoepithelial cells on a layer of myofibroblasts (embedded in a solidified matrix of type 1 collagen) did not affect gland development. Inclusion of 10 nM dioxin in the tri-cell co-culture model did not affect alveoli development, but severely suppressed duct development and eliminated ductal branching. These effects of dioxin on duct development and branching in the co-culture model mimic what occurs *in vivo* following fetal exposure. These data suggest that the Cultrex™-based 3D mammary gland culture model maybe useful for the screening of putative modifiers of mammary gland development, elucidation of cell types responsible for toxicant effects, and unraveling mechanisms of action. Supported by CA56586 and a pilot award from ES06639.

PL 625 PERSISTENT MODULATION OF T CELL AND B CELL MATURATION AND FUNCTION IN 48-WEEK-OLD C57BL/6 MICE DEVELOPMENTALLY EXPOSED TO TCDD.

S. D. Holladay[2], A. Mustafa[1], S. Witonsky[1], R. Kerr[1], C. M. Reilly[3], D. P. Sponenberg[1] and R. M. Gogal[1, 2]. [1]*Biomedical Sciences & Pathobiology, Virginia Tech, Blacksburg, VA,* [2]*Anatomy and Radiology, University of Georgia, Athens, GA and* [3]*Biomedical Sciences, Virginia College of Osteopathic Medicine, Blacksburg, VA.*

The extent to which prenatal TCDD exposure can permanently alter immunity and affect disease progression during aging is unknown. Preliminary experiments showed altered immune development, enhanced immune complex formation, and lupus-like lesions in 24-week-old C57BL/6 mice after a single prenatal exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). In this study, 48 week-old offspring of high affinity AhR C57BL/6 dams prenatally exposed to oral TCDD (0, 2.5 or 5.0 μg/kg) were evaluated for changes in T cell and B cell maturation and function as well as the progression of immune-mediated renal disease. As at 24 weeks, TCDD-treated females continued to display decreased thymic weight and cellularity. TCDD-treated male offspring had increased percentages of autoreactive CD3+Vβ3 TcR+ T cells in axillary and inguinal lymph nodes. Con-A stimulated splenocytes from prenatal TCDD-treated female mice produced increased IL-12 and IFN-γ and diminished IL-4, while males showed increased IL-10 and IL-12. Alterations in bone marrow lymphopoiesis were seen in both sexes. Splenic transitional-2 B cells (CD21intCD24hi) were increased in males while transitional-1 B cells (CD23neg CD1neg) were increased in females. Autoantibodies to cardiolipin were significantly increased in the TCDD-treated males. Anti-IgG and anti-C3 immune complex renal deposition was significantly increased in TCDD-treated males, and enhanced in the TCDD-treated females. These collective findings suggest that developmental TCDD exposure permanently and differently alters the immune system function based on sex. This immune dysregulation appears to include a sustained type III hypersensitivity, lupus-like autoimmune-mediated disease in this genetically non-predisposed murine strain.

PL 626 TCDD DECREASES β-CATENIN DEPENDENT SOX9 EXPRESSION DURING PROSTATIC BUD INHIBITION IN MOUSE UROGENITAL SINUS.

C. M. Vezina[1], H. A. Hardin[1], A. Lashua[2], X. Sun[2], R. L. Tanguay[3] and R. E. Peterson[1, 4]. [1]*School of Pharmacy, University of Wisconsin, Madison, WI,* [2]*Laboratory of Genetics, University of Wisconsin, Madison, WI,* [3]*Department of Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR and* [4]*Molecular and Environmental Toxicology Center, University of Wisconsin, Madison, WI.*

The developing mouse prostate is a model for androgen-dependent prostate growth. 2,3,7,8-Tetrachlorodibenzo-*p*-dioxin (TCDD) interferes with the earliest stage of prostate morphogenesis by impairing formation of prostatic buds from the fetal prostate anlage, the urogenital sinus (UGS). *In utero* TCDD exposure completely prevents buds from forming on the ventral UGS surface and causes buds on the lateral UGS surface to form in an inappropriate dorsal position. In search of a mechanism, we considered SOX9, a transcription factor required for prostatic bud formation and reduced in abundance by TCDD in the developing zebrafish jaw and regenerating fin. *In utero* TCDD exposure (5 μg/kg, maternal dose) on mouse embryonic day (E) 15.5 reduced SOX9 protein levels on E16.5 in the same UGS epithelial cell layer where *Cyp1a1* was induced. To identify a mechanism, we tested the hypothesis that SOX9 is regulated by β-catenin-dependent transcription. The β-catenin null UGS did not form prostatic buds and did not express detectable levels of SOX9 protein. However, *in utero* TCDD exposure did not alter β-catenin abundance or distribution in the UGS epithelium of wild type mice. Therefore, it appears that TCDD acts downstream of β-catenin to repress SOX9, and this may be the mechanism by which TCDD impairs prostatic bud formation in mice. (Supported by NIH grants F32 ES014284, R37 ES01332, and ES 10820).

PL 627 ASSESSING THE METHYLATION STATUS OF EMBRYOS TREATED WITH VALPROIC ACID AS A POSSIBLE MECHANISM OF TERATOGENESIS.

E. W. Tung[1] and L. M. Winn[1, 2]. [1]*Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada and* [2]*School of Environmental Studies, Queen's University, Kingston, ON, Canada.*

Exposure to the anticonvulsant drug valproic acid (VPA) in utero is associated with a 1-2% increase in neural tube defects (NTDs), however the molecular mechanisms by which VPA induces NTDs are unknown. VPA is a histone deacetylase (HDAC) inhibitor and has been shown to increase histone acetylation in embryos 1 hour after maternal administration of the drug. Chromatin structure and DNA methylation are tightly correlated. Open chromatin is associated with unmethylated DNA, and HDACs can trigger demethylation of hyperacetylated genes. Previously in our laboratory, we demonstrated that folic acid pre- and co-administrated with VPA was protective against the teratogenic effects caused by VPA, indicating that one-carbon metabolism may be disrupted. The purpose of this study was to evaluate the methylation status of exencephalic embryos exposed to VPA during gestation using the cytosine extension assay. On gestational day (GD) 9.0, pregnant dams were injected with 400 mg/kg VPA or saline subcutaneously. On GD 10.5, embryos were removed and categorized by treatment groups and neural tube closure status. The cytosine extension assay was then used to assess the degree of hypomethylation in these embryos. Results indicate that methylation is unchanged in VPA treated embryos with closed neural tubes (n=6) and VPA treated embryos with exencephaly (n=6) when compared with saline treated embryos (n=5). In addition, western blotting did not show any changes in the expression of DNA methyltransferase (DNMT) 1 or hyperacetylated histone H4 on GD 10.5. Currently, we are evaluating methylation changes 1 hour and 6 hours after exposure to VPA. Western blotting will also be completed for DNMTs 3a and 3b, the methylated DNA binding protein MeCP2, and acetylated histone H3 (Support: CIHR).

PL 628 PRENATAL EXPOSURE TO B(A)P IMPAIRS LATER-LIFE NEURONAL FUNCTION AND BEHAVIOR IN CPR MICE.

D. B. Hood[1], S. Liu[3], M. M. McCallister[1], M. Maguire[1], A. Ramesh[2], Q. Aimin[1], H. Khoshbouei[1], M. Aschner[2], F. F. Ebner[4] and P. Levitt[5]. [1]*Molecular and Behavioral Neuroscience, Meharry Medical College, Nashville, TN,* [2]*Department of Cancer Biology, Meharry Medical College, Nashville, TN,* [3]*Center in Molecular Toxicology, Vanderbilt University Nashville, TN,* [4]*Cognitive and Integrative Neuroscience, Vanderbilt University, Nashville, TN and* [5]*Kennedy Center, Vanderbilt University Nashville, TN.*

Exposure to toxicants during the critical window of cortical neurogenesis may contribute to alterations in the developing brain with respect to the neuropathology of autism spectrum disorders. To characterize the impact of prenatal B(a)P exposure on the development of a metabolite burden that degrades cortical neuronal activity and function; pregnant Cpr+/+ mice were exposed to B(a)P (0, 150, 300 and

600ug/kg BW) by oral gavage on gestational days 14 through 17. Metabolite disposition was quantified during the preweaning period. Primary cortical neuronal cultures were prepared from PND 0 control and B(a)P-exposed Cpr+/+ pups, patch clamp analysis was performed and revealed significant decreases in the magnitude of inward current in neuronal cultures from exposed Cpr+/+ mice. Immunohistochemical analysis of primary cortical neuronal cultures also revealed significant shifts in peak mRNA and protein expression period for MET receptor tyrosine kinase and NR2B derived from B(a)P-exposed Cpr+/+ offspring as compared to cultures from control Cpr+/+ offspring. Alterations in MET expression have been linked with the neuropathology of autism spectrum disorders. Additionally, in B(a)P-exposed Cpr+/+ offspring, a dose-dependent decrease in the expression profile of cerebrocortical MET was observed. Behavioral analysis of B(a)P-exposed Cpr+/+ offspring using the 2-choice novel object recognition task also revealed a robust reduction in novelty index scores as compared to control Cpr+/+ offspring. The results obtained corroborate previous findings conducted in rat models. Prenatal exposure to B(a)P results in deficits in cortical neuronal activity and behavior at a time when synapses are forming for the first time in sensory pathways.

PL 629 PLACENTAL AND NEURAL TUBE DEFECTS AFTER MATERNAL FUMONISIN OR FTY720 EXPOSURE.

J. Gelineau-van Waes[1], J. Maddox[1], J. Wilberding[1], K. Voss[2] and R. T. Riley[2]. [1]*Department of Genetics, Cell Biology & Anatomy, University of Nebraska Medical Center, Omaha, NE and* [2]*Toxicology & Mycotoxin Research Unit, USDA-ARS, Athens, GA.*

Fumonisin B1 (FB1) is a mycotoxin produced by a common fungal contaminant of maize. Increased neural tube defect (NTD) risk is observed in human populations that rely heavily on maize as a dietary staple. FB1 inhibition of ceramide synthase results in elevated sphingoid bases. FTY720 is a sphingoid base analog currently in Phase III human clinical trials. Phosphorylated FTY720 acts as an immunosuppressant by modulating S1P receptor-mediated pathways involved in lymphocyte chemotaxis. FB1 (20mg/kg/day ip, E7.5-8.5) or FTY720 (10mg/kg/day po, E6.5-8.5) were administered to pregnant inbred SWV and LM/Bc mice. Maternal plasma and whole blood were collected on E10.5, embryonic phenotype was recorded, and placental/embryonic tissues were collected for histology, or LC-ESI-MS analysis of sphingoid base 1-phosphates. Trophoblast cells were labeled with cytokeratin, and uterine natural killer (uNK) cells were identified with DBA lectin. Strain and/or treatment-specific differences in sphingolipid gene expression were analyzed by qRT-PCR. Maternal FB1 or FTY720 resulted in elevation of bioactive sphinganine-1-P or FTY720-1-P in maternal blood and placental tissue, and increased NTDs and/or resorptions. Sphingosine kinase gene expression was significantly elevated in placental tissue from treated dams. Placentas from exencephalic embryos had a shallow ectoplacental cone, fewer uNK at the implant site, proliferative and invasive giant trophoblast cells, and a disorganized vascular labyrinth. Maternal FB1 or FTY720 exposure results in accumulation of bioactive sphingoid base-1-P in maternal and fetal tissue, altered migration of uNK cells, abnormal formation of the placenta, and increased risk for NTDs. Sa-1-P and FTY720-1-P act as agonists or functional antagonists on G protein-coupled S1P receptors. Elevated levels of Sa-1-P or FTY720-1-P may therefore alter S1P-receptor-mediated signaling pathways involved in uNK migration, placental formation, and neural tube closure.

PL 630 EPIGENETIC ALTERATIONS DURING TCDD-INDUCED INHIBITION OF B CELL DIFFERENTIATION.

E. A. McClure[1, 2], C. M. North[2, 3], N. E. Kaminski[2, 3] and J. I. Goodman[2, 3]. [1]*MMG, MSU, East Lansing, MI,* [2]*PHM/Toxicology MSU, East Lansing, MI and* [3]*CIT, MSU, East Lansing, MI.*

B cells within the splenocyte population, isolated from mice treated with lipopolysaccharides (LPS), differentiate into antibody-producing plasma cells in vitro. Pretreatment with TCDD inhibits differentiation. We hypothesize that altered DNA methylation, an epigenetic event, plays a key role in this inhibition. DNA was isolated from splenocytes prepared 6 days post experiment initiation from 5-6wk old female C57BL/6 mice dosed with: TCDD, 30µg/kg, on day 0; or LPS, 25µg/mouse, on day 4; or sequentially with TCDD and then LPS on days 0 and 4, respectively. To discern regions of altered DNA methylation (RAMs), DNA was restricted with HpaII (a methylation sensitive enzyme), followed by arbitrarily primed PCR and capillary electrophoresis. LPS or TCDD alone resulted in 39 and 42 RAMs, respectively, while LPS+TCDD resulted in 34 RAMs. Interestingly, the combined treatment lead to 4 RAMs seen with LPS alone, 4 RAMs seen with TCDD alone, and 19 RAMs observed only in the co-treatment group. These data indicate treatment with LPS or TCDD can alter DNA methylation in splenocytes. The combined TCDD+LPS leads to RAMs that are unique: we do not simply observe the sum of the RAMs that form from the individual treatments. PCR products representing a number of the RAMs observed were cloned, sequenced and annotated. Those unique to the LPS-TCDD combination include: Bank1 (involved in B cell receptor-induced Ca2+ mobilization); Adcy5 (membrane-bound calcium-inhibitable adenylyl cyclase); Arvcf (involved in protein-protein interactions); CtBP2 (corepressor targeting diverse transcription regulators), Lingo2 (leucine-rich repeat and immunoglobulin-like domain-containing nogo receptor-interacting protein 2; Pctk3 (may play a role in signal transduction cascades); Krr1 (involved in nucleolar processing of pre-18S ribosomal RNA and ribosomal assembly). Unique RAMs in the TCDD+LPS group indicate crosstalk between the actions of LPS to induce B cell differentiation and Ah receptor signaling which, presumably, mediates the inhibitory effect of TCDD. (P42 ES04911)

PL 631 EXAMINATION OF IMPRINTED GENES AS EARLY INDICATORS OF METHYLATION CHANGES IN RESPONSE TO RODENT CARCINOGENS.

J. Klapacz, M. J. LeBaron, R. Rasoulpour, H. M. Hollnagel and B. B. Gollapudi. *TERC, The Dow Chemical Company, Midland, MI.*

Imprinting is an epigenetic modification of the genome that results in differential expression of maternal or paternal alleles in somatic cells. Since imprinting involves precise allele expression controlled by DNA methylation and histone modifications, these epigenetic machineries may be especially sensitive to dysregulation by environmental factors. Loss of genomic imprinting (LOI) has been associated with a number of human diseases, mammalian developmental abnormalities and cancer. The goal of this study was to determine whether LOI could serve as a useful biomarker of rodent carcinogenesis. Liver from male Big Blue® Fischer 344 rats treated for 28 days with the genotoxicant 2-acetylaminoflouorene (AAF, 3 mg/kg/day) or non-genotoxicant phenobarbital (PB, 100 mg/kg/day) was examined. Robust changes in gene expression were observed as a result of treatment (Seidel et al. *Int J Toxicol*. 2006). DNA isolated from four representative animals per group was modified with bisulfite to differentiate between methylated and unmethylated cytosines within CpGs. Bisulfite sequencing (BS) and methylation specific PCR (MSP) were used to characterize DNA methylation of selected genes. *Lac I* was confirmed to be extensively methylated in controls and was unchanged after 28-day treatment with the carcinogens. Rat *H-Ras* promoter was hypomethylated in controls and unchanged by AAF or PB treatment. Differentially methylated regions (DMRs) of the insulin-like growth factor 2 gene (*Igf2*) and the non-coding RNA gene *H19*, two imprinted genes often associated with cancer, were investigated and compared to controls. Treatment with AAF or PB did not alter methylation status within *Igf2* DMRs. The extent of methylation within the *H19* promoter decreased (AAF>>PB) after treatment with both carcinogens. Taken together, this study demonstrates that assaying DNA methylation within CpG islands of imprinted genes could be a useful biomarker of liver tumorigenesis.

PL 632 GENOME-WIDE ANALYSIS OF DNA METHYLATION PROFILES IN A PRECLINICAL ANIMAL MODEL OF NONGENOTOXIC CARCINOGENESIS.

Epigenetics defines heritable changes in gene function that occur without alterations in DNA sequence. Unique patterns of epigenetic marks form the molecular basis for developmental and cell-specific gene expression, resulting in distinct cellular phenotypes. Current literature suggests that epigenetic perturbations may also precede the adverse effects associated with some drugs and toxicants, including nongenotoxic carcinogens. The working hypothesis for this investigation is that epigenetic modifications, namely DNA methylation, will provide insights into the early molecular mechanisms associated with nongenotoxic carcinogenesis. Our initial objective is to evaluate the sensitivity and specificity of genome-wide and locus-specific DNA methylation assays in rodent tissues. B6C3F1 mice were treated for 4 weeks with the nongenotoxic liver carcinogen phenobarbital. Methylated DNA from liver and kidney was isolated using the MeDIP assay for immunoprecipitation of 5-methylcytosine, and applied to promoter/CpG island microarrays from Nimblegen, which include all UCSC-annotated CpG islands and 1.8 kb promoter regions for all RefSeq genes. Promoter regions of genes that exhibit low expression in liver (e.g. Pdzk2) or kidney (e.g. Cyp2c44) are found to be highly methylated

using this method. In addition, phenobarbital induces specific alterations in promoter methylation patterns in liver (target tissue) as compared to kidney (non-target tissue). The application of this approach for identifying early mechanism-based markers of nongenotoxic carcinogenesis may ultimately increase the quality of cancer risk assessments for candidate drugs and ensure a lower attrition rate during late-phase development.

PL 633 EVALUATION OF TOXIC POTENTIAL BASED ON CYTOTOXICITY AND EPIGENETIC TOXICITY OF CHEMICALS IN MOUSE HEPATOMA CELLS.

S. Jeong, J. Kang, H. Shin, J. Cho, B. Choi, E. Kim, Y. Lee and G. Chung. *Toxicology Division, National Veterinary Research & Quarantine Service, Anyang, KyungGi, Korea, South.*

Epigenetic mechanism is understood to determine gene expression with DNA base sequence. This study was performed to estimate toxic potential of chemicals based on cytotoxicity and global DNA methylation. Phenylbutazone, bisphenol A and chloramphenicol which are carcinogens or suspected to link with cancer are assessed with positive controls, 5-aza-2deoxycytidine (5Aza) and sodium butyrate, which are inducers of hypo- or hyper- global DNA methylation in mouse hepatoma cells (Hepa1c1c7). The toxic potential of phenylbutazone, cholramphenicol, and bisphenol A was estimated by employing the results of global DNA methylation combined with cytolethality data (MTT, ATP and Cell proliferation assay). In vitro cytotoxicity assessments showed cytolethal and non-cytolethal concentration (CL, NCL) of phenylbutazone as 0.55mM and 0.065mM. CL and NCL of chloramphenicol were determined as 0.3mM and 0.03mM. The CL and NCL of bisphenol A were 0.08 and 0.045mM. The CL and NCL of 5Aza and sodium butyrate were 0.25 and 0.0025mM and 6.5 and 1.5mM, respectively. Global methylation status in hepatoma cell treated with CL and NCL of these chemicals were measured. Hypermethylation at CL but hypomethylation at NCL were observed for phenylbutazone. Choramphenicol did not change global DNA methylation at both doses of CL and NCL. Bisphenol A led to reduction of global methylation levels at CL. 5Aza at CL led to hypomethylation but sodium butyrate induced hypermethylation at NCL. Finally, we estimated toxic potential rankings following to cytotoxicity and global DNA methylation. Phenylbutazone and Bisphenol A ranked the highest position for they presented changed DNA methylation at NCL or high cytotoxicity with change of DNA methylation at CL. 5Aza and sodium butyrate ranked second one for they showed moderate cytotoxicity with changed DNA methylation at CL or NCL. Chloramphenicol was allotted at the lowest toxic position for moderate cytotoxicity with un-changed DNA methylation.

PL 634 ONTOGENIC EXPRESSION OF HEPATIC MICRORNAS CORRELATES WITH HISTONE H3K4 DI-METHYLATION DURING MOUSE LIVER DEVELOPMENT.

Y. Cui, X. Zhong and C. D. Klaassen. *Department of Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

MicroRNAs are short, endogenously-expressed non-coding RNAs that down-regulate gene translation by base-pairing to corresponding target mRNAs. Most studies have focused on the role of microRNAs in carcinogenesis. Recent evidence suggests that microRNAs also have critical functions in regulating normal development, as well as xeno- and endobiotic metabolism in liver. Although many microRNA targets have been identified, the in vivo regulation of microRNAs themselves is poorly understood. The purpose of the present study was to characterize the ontogenic expression patterns of microRNAs in mouse liver, and determine the epigenetic mechanisms for their expression during postnatal development. C57BL/6 mouse livers were collected from 2 days prenatal to 45 days of age. The ontogenic profiles of microRNAs were characterized by microarray, and confirmed by the Multiplex Suspension Array. Of the 574 verified mouse microRNAs, 79 microRNAs are expressed in liver, falling into three distinct patterns: fetal-, neonatal-, and adult-specific. In addition, the microRNAs sharing a similar expression pattern are usually closely located as a cluster on a chromosome (<10kb), suggesting a common regulatory mechanism may exist. ChIP-on-chip analysis performed on mouse chromosomes 5, 12, and 15 demonstrated that DNA methylation and histone H3K27 trimethylation, the two major epigenetic marks for gene suppression, were consistently low in regions encoding microRNAs expressed in liver. In contrast, enrichment of histone H3K4 di-methylation, a hallmark for gene activation, occurred in the vicinity of microRNA clusters at ages when microRNAs were highly expressed. Regression analysis demonstrated a strong correlation between enrichment of histone H3K4 di-methylation and microRNA ontogenic expression. Collectively,ontogenic expression patterns of microRNAs correlate with histone H3K4 dimethylation during mouse liver development (Supported by NIH grants ES09716, ES07079, ES013714, ES09649, and RR021940).

PL 635 THE BENZENE METABOLITE, HYDROQUINONE ALTERS GLOBAL DNA METHYLATION AND SPECIFIC GENE PROMOTER METHYLATION IN HUMAN TK6 CELLS.

Z. Ji, C. M. McHale, L. Zhang and M. T. Smith. *School of Public Health, University of California at Berkeley, Berkeley, CA.*

DNA methylation, the addition of a methyl group at the C-5 position of cytosine in CpG dinucleotides, plays a critical role in maintaining genome stability and in controlling gene expression. Aberrant DNA methylation patterns have been frequently observed in human leukemia and other cancers. Benzene is an established human carcinogen, to which chronic exposure causes leukemia and other hematological cancers. In one recent study (Cancer Res, 67:876, 2007), global DNA hypomethylation and hyper- and hypomethylation of gene-specific promoters was detected in healthy individuals exposed to low levels of benzene slightly above background. In order to further explore the effects of benzene exposure on DNA methylation, we conducted a study in vitro to examine whether or not hydroquinone (HQ), a major metabolite of benzene, altered global DNA methylation and gene-specific promoter methylation in the human lymphoblastoid TK6 cell line. TK6 cells were treated with HQ at 0 - 20 μM for 48 hours. The DNA methylation inhibitor, 5-aza-2'-deoxycytidine, served as positive control. Global DNA methylation was determined by immunocytochemistry using flow cytometry. Methylation of specific gene promoters was detected by Illumina's GoldenGate Methylation Cancer Panel I assay, in which 1505 loci on 807 genes were analyzed. As expected, 5-aza-2'-deoxycytidine reduced global DNA methylation and had a demethylating effect on many genes. After HQ treatment, global DNA methylation was reduced in a dose-dependent manner. Methylation of specific gene promoters was also altered, with certain genes hypermethylated and other genes hypomethylated. In conclusion, HQ reduced global DNA methylation and induced hyper- and hypomethylation of multiple gene promoters in TK6 cells. These DNA methylation alterations might lead to genomic instability, the abnormal expression of certain genes and may be one of the mechanisms producing leukemogenesis from benzene exposure.

PL 636 EPIGENETIC CONTROL OF MAMMALIAN LINE-1 RETROTRANSPOSON BY RETINOBLASTOMA PROTEINS.

D. E. Montoya-Durango[1, 2], Y. Liu[3, 4], T. Kalbfleisch[1, 2], I. Teneng[1, 2] and K. S. Ramos[1, 2]. *[1]Biochemistry, University of Louisville, Louisville, KY, [2]Center for Genetics and Molecular Medicine, University of Louisville, Louisville, KY, [3]J.G. Brown Cancer Center, University of Louisville, Louisville, KY and [4]Ophthalmology and Visual Sciences, University of Louisville, Louisville, KY.*

Long interspersed nuclear elements (LINEs or L1 elements) are targeted for epigenetic silencing during early embryonic development and remain inactive in most cells and tissues. Although DNA methyl transferases (DNMTs) contribute to L1 silencing via CpG-rich regions hypermethylation, the exact epigenetic mechanisms involved in L1 silencing remain largely unknown. Since E2F/Rb protein complexes localize to highly repetitive pericentromeric regions we sought to determine if L1 epigenetic regulation is E2F/Rb-mediated. Here we show that E2F/Rb family complexes participate in L1 epigenetic regulation via nucleosomal histone modifications and recruitment of histone deacetylases (HDACs) HDAC1 and HDAC2. ChIP experiments demonstrated that (i) Rb and E2F interact with human and mouse L1 elements, (ii) L1 elements are deficient in both heterochromatin-associated histone marks H3 tri methyl K9 and H4 tri methyl K20 in Rb family triple knock out fibroblasts (TKO), (iii) L1 promoter exhibits increased histone H3 acetylation in the absence of HDAC1 and HDAC2 recruitment, (iv) L1 expression in TKO fibroblasts is upregulated compared to wild type counterparts, (v) treatment of TKO cells with the genotoxic stressor benzo-a-pyrene B(a)P induces an exacerbated L1 expression. On the basis of these findings we propose a model in which L1 sequences throughout the genome serve as centers for heterochromatin formation in an Rb family-dependent manner. As such, Rb proteins and L1 elements may play key roles in heterochromatin formation beyond pericentromeric chromosomal regions. This model predicts that LINE-1 reactivation in tumor cells is caused by a failure of co-repressor protein recruitment by Rb that reflects loss of histone epigenetic marks, heterochromatin formation, and increased histone H3 acetylation.

PL 637 USE OF IL-18 PRODUCTION IN A HUMAN KERATINOCYTE CELL LINE TO DISCRIMINATE CONTACT SENSITIZERS FROM IRRITANTS AND LOW MOLECULAR WEIGHT RESPIRATORY ALLERGENS.

E. Corsini[1], M. Mitjans[2], L. Lucchi[1], C. L. Galli[1] and M. Marinovich[1]. [1]*Department fo Pharmacological Sciences, University of Milan, Milan, Italy and* [2]*Departament de Fisiologia, Facultat de Farmàcia, Universitat de Barcelona, Barcelona, Spain.*

Assessment of allergenic potency of low molecular weight compounds is generally performed using animal models, such as the murine local lymph node assay. Progress in understanding the mechanisms of skin sensitization, including effects on the production of cytokines by the different cell types within the skin, provides us with the opportunity to develop in vitro tests as an alternative to in vivo sensitization testing. The aim of the present study was to evaluate the possibility to use cytokine production, namely interleukin-18 (IL-18), by human keratinocytes to assess in vitro the contact sensitization potential of low molecular weight chemicals. In the present study, the human keratinocyte cell line NCTC 2455 was used. IL-18 has been demonstrated to favor Th-1 type immune response by enhancing the secretion of pro-inflammatory mediators such as TNF-α, IL-8 and IFN-γ, and to play a key proximal role in the induction of allergic contact dermatitis. Cells were exposed to contact allergens (dinitrochlorobenzene, cinnamaldehyde, tetramethylthiuram disulfide, eugenol, isoeugenol, paraphenylediamine, resorcinol), to respiratory allergens (diphenylmethane diisocyanate, trimellitic anhydride, ammonium hexachloroplatinate) and to irritants (sodium lauryl sulphate, salicylic acid, phenol). Cell associated IL-18 were evaluated 24 later by a commercially available ELISA kit. At not cytotoxic concentrations (cell viability higher of 80% as assessed by MTT reduction assay), all contact sensitizers induced a dose-related increase in IL-18, whereas both irritants and respiratory failed. Results obtained indicated that cell-associated IL-18 may provide an in vitro tool for identification and discrimination of contact versus respiratory allergens and/or irritants. PL 638 RECOMBINANT LACTOFERRIN INHIBITS SPECIFICALLY IGE ANTIBODY RESPONSES PROVOKED BY NATIVE LACTOFERRIN.

R. Almond[1], B. F. Flanagan[1], I. Kimber[2] and R. J. Dearman[2]. [1]*University of Liverpool, Liverpool, United Kingdom and* [2]*Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom.*

Intraperitoneal administration of human native lactoferrin (nLF) to BALB/c strain mice stimulated relatively high titer IgG and IgE antibody responses at doses of 0.2% to 1%. In contrast, exposure to recombinant lactoferrin (rLF; produced in rice) failed to provoke vigorous antibody responses, even at concentrations as high as 5%. The two proteins have identical amino acid sequences but differ with respect to glycosylation patterns. In subsequent experiments, the impact of exposure to rLF on the development of IgE antibody responses has been examined. Mice were immunized with rLF (1%) or nLF (0.2%) alone or in combination. Control mice were immunized with the unrelated allergens ovalbumin or peanut lectin (both at 0.2%) alone or in combination with 1% rLF. Sera were analyzed for protein-specific IgE by homologous passive cutaneous anaphylaxis assay (PCA). Administration of nLF alone induced high titer specific IgE (1/16), whereas treatment with rLF alone failed to provoke detectable IgE antibody. The combination of rLF and nLF resulted in a very marked down-regulation of anti-LF IgE antibody production in 2 independent experiments (with a titer of 1 recorded in both experiments). In contrast, rLF was without effect on anti-OVA IgE antibody responses, with a titer of 1/4 achieved regardless of the presence of rLF. There was also no impact of co-administration of rLF on the relatively vigorous IgE antibody responses stimulated by treatment with peanut lectin, with titers of 1 in 16 achieved regardless of the presence of rLF. The selective inhibition of anti-LF IgE antibody responses demonstrates that rLF is influencing the induction phase of the specific IgE antibody response. These data suggest that the glycosylation pattern of the protein influences uptake, processing and/or presentation of antigen such that the immune response is skewed away from conditions that are permissive for the development of a type 2 phenotype and IgE antibody production.

PL 639 STRAIN-DEPENDENT ALLERGIC RESPONSES IN A MOUSE MODEL FOR PEANUT FOOD ALLERGY.

R. Pieters, J. Smit, M. Marcondes Rezende, R. Bleumink, I. Hassing and M. Bol. *IRAS, Utrecht University, Utrecht, Netherlands.*

Food allergy is the leading cause of hospitalization for anaphylactic reactions in westernized countries. Mouse models for food allergy have proved to be an excellent tool to elucidate the mechanisms underlying food allergy. In addition, murine models could provide an opportunity to study the genetic factors underlying food allergy. In the present study, the allergic responses of 3 strains of mice were studied in a model of peanut allergy. C3H/HeOuJ (C3H), C57BL/6 and BALB/c mice were orally exposed to peanut extract (PE) combined with cholera toxin (CT) to induce PE sensitization, and challenged with PE only 27 days after the initial oral exposure. Mice were sacrificed on day 28. PE sensitisation induced the highest PE-specific IgE levels in C57BL/6 and BALB/c mice. Levels of PE-specific IgG1 were highest in C57BL/6 mice whereas levels of IgG2a were highest in C3H mice. Unexpectedly, serum levels of MMCP-I, a measure of mast cell degranulation, were significantly elevated in C3H and BALB/c but not in C57BL/6 mice. Th2 cytokines (IL-4, IL-5, and IL-13) and Th1 (IFN-γ) cytokines induced in isolated mesenterial lymphnode-or spleen-derived cultures by PE incubation were highest in BALB/c mice, and significantly less in C3H/HeOuJ or C57BL/6 mice. Anaphylactic symptoms after i.p. challenge with PE were highest in C3H/HeOuJ and C57BL/6 but completely absent in BALB/c mice. These data demonstrate that three mouse strains significantly differ in their allergic responses in a peanut allergy model. BALB/c mice demonstrate the highest cytokine and IgE response but no anaphylaxis. C57BL/6 mice demonstrate moderate IgE and cytokine responses, but no mast cell degranulation. C3H/HeOuJ demonstrate moderate IgE and cytokine responses, but high levels of mast cell degranulation and anaphylaxis. This demonstrates that the different components of the allergic cascade are differently regulated in different strains, leading to a differential outcome in allergic disease. In conclusion, genetic predisposition to food allergy is not simply linked to a more or less dominant Th2 or Th1 type responses.

PL 640 DENDRITIC GENE MARKERS UNRAVEL PIECES OF THE SKIN SENSITIZATION PUZZLE.

N. Lambrechts, P. De Boever, J. Hooyberghs, H. Witters, R. Van Den Heuvel, I. Nelissen and G. Schoeters. *VITO, Mol, Belgium.* Sponsor: B. De Wever.

Dendritic cells derived from CD34+ progenitor cells in cord blood (CD34-DC) are a promising in vitro alternative for skin sensitization testing. Transcriptomic analyses revealed 13 marker genes that are differentially expressed in CD34-DC after exposure to skin sensitizers. Based on their differential expression, a preliminary classification model (VITOSENS®) has been developed to identify chemicals as (non)sensitizing1. The goal of this study was to increase our understanding of the role of the marker genes (e.g. CREM, CCR2, and PTGS2) in skin sensitization and to explore their use for potency testing. Using Ingenuity Pathways Analysis (Ingenuity Systems, Inc.), the marker genes were fit into a literature-based interactome containing members that are possible mediators in DC mediated skin sensitization. The outcome of the pathway analysis was tested in the in vitro VITOSENS® model. Three additional gene transcripts (TNF-α, NF-κβ1, and CREB1) were effectively expressed in CD34-DC as suggested by the pathway analysis, and TNF-α was significantly stimulated by sensitizing exposure. Furthermore, we assessed whether the marker genes corresponded with functional proteins using FACS analysis. In addition, we tested if the marker genes in the VITOSENS® assay were able to range the chemicals2 according to their in vivo potency. Initial evaluation showed that the VITOSENS® test system is effective to rate chemicals according to their potency, and that the selected gene markers were translated to functional proteins in the dendritic cell. 1Hooyberghs et al., Toxicol. Appl. Pharmacol. 2008, 231:103-111.
2Chemicals: dinitrobenzenesulfonic acid, dinitrochlorobenzene, dinitrofluorobenzene, mercaptobenzothiazole, nickel sulphate, cinnemaldehyde, tetramethylthiuram disulfide, ammonium hexachloroplatinate IV and eugenol

PL 641 REACTIVITY PROFILING STRATEGY: COVALENT MODIFICATION OF SINGLE NUCLEOPHILE PEPTIDES.

M. Aleksic, E. Thain, D. Roger, O. Saib, S. Jacquoilleot, J. Li, M. Davies and R. Zazzeroni. *Safety & Environmental Assurance Centre, Unilever, Bedford, United Kingdom.* Sponsor: P. Hepburn.

Covalent modification of proteins by sensitising chemicals is a key step in the induction of skin sensitisation. The exact nature of the relevant *in vivo* protein modifications is currently unknown. Qualitative and quantitative measurements of chemical reactivity with single protein nucleophiles provide a useful dataset for screening and future risk assessments. To gain maximum information about chemical reactivity we developed a peptide reactivity profiling strategy. The model peptide portfolio contains six peptides: five with generic sequence AcFAAXAA, (X=C, K, Y, H or R) and peptide H_2N-FAAAAA. Using LC-MS/MS strategies, we investigated reactivity of model peptides with chemicals following incubation at optimum pH and 1:100 concentration ratio of peptide to chemical at 37°C for 24 h. The depletion of unchanged peptide(s) was determined and detailed structural elucidation of adduct(s) performed. Further quantitative measurements of rate of reac-

tion were obtained and an addition of skin-relevant metabolic activation system was investigated. We present reactivity profiles of forty chemicals of known sensitising potential. The data show that peptide depletion above 10% is likely to be due to covalent modification. However, peptide depletion below this value does not always correlate with observation of adduct(s) and is often inconclusive. It is therefore necessary to additionally confirm the reactivity by identifying the adduct(s). The approach enables investigation of reactivity that may arise from the presence of impurities or a combination of chemicals. By optimising the incubation conditions we achieved high levels of confidence in detection of non-reactive chemicals. The data is analysed using mathematical and statistical approaches to obtain a rank order of reactivity based on specificity, reaction rate, mechanism(s) and complexity. This *in chemico* dataset will be integrated with outputs from other predictive *in vitro* assays in the future, to help make decisions about the safe use of chemicals without using animal tests.

PL 642 MOUSE MESENTERIC LYMPH NODE GENE EXPRESSION PROFILES DURING SENSITIZATION, AND EAR-SWELLING, HISTAMINE, AND IMMUNOGLOBULIN RESPONSE DURING ELICITATION IN RESPONSE TO COMMON FOOD ALLERGENS.

M. Husain[1], H. J. Boermans[2] and N. A. Karrow[1]. *[1]Department of Animal & Poultry Science, University of Guelph, Guelph, ON, Canada and [2]Department of Biomedical Sciences, University of Guelph, Guelph, ON, Canada.*

The development of novel foods, including genetically modified (GM) foods, has amplified the risk of food allergy in certain individuals. Therefore, there is a need to evaluate the potential allergenicity of novel foods before they reach consumers. In the following study, Balb/c mice were sensitized and then challenged with common food allergens {0.2% peanut agglutinin (PNA), 2% egg ovalbumin (OVA) or 2% beta lactoglobulin (BLG)} to test the hypothesis that gene expression profiling during sensitization can be used to predict allergenicity during elicitation. For the elicitation phase, female Balb/c mice were sensitized i.p. with allergen or saline for 2 d, and 2 wk later challenged with the respective allergen on the dorsal side of the ear to measure the ear swelling response 0, 0.5, 1, 2, 6 and 24 hr post challenge. Blood was collected from one group of mice 20 min after challenge to measure histamine levels, and 24 hr after challenge in another group to measure the IgG1 and IgE. For the sensitization phase, mice were sensitized as described above and then euthanized 24 and 48 hr later to measure mesenteric lymph node (MLN) gene expression profiles using a mouse oligoarray (Mouse 22.4K ESTs). During elicitation, PNA (38% increase) and OVA (38% increase) induced a stronger ear swelling response than BLG (29% increase). Histamine levels were 2 to 17 times higher in the allergen challenged mice compared to the control mice. Lastly, levels of IgG1 and IgE in the allergen challenged mice were 2 to 6 times higher than the control mice. During sensitization, a number of genes were induced in the MLN in response to the various allergens, and the expression of these genes is being correlated with endpoints measured during the elicitation phase.

PL 643 COMPARISON OF CONTACT ALLERGEN-INDUCED GENE EXPRESSION CHANGES IN HUMAN PERIPHERAL BLOOD MONONUCLEAR CELL-DERIVED DENDRITIC CELLS AND DC-SURROGATE CELL LINES.

C. Ryan[1], S. Python[2], F. Python[2], P. Aeby[2] and F. Gerberick[1]. *[1]Procter & Gamble Company, Cincinnati, OH and [2]Procter & Gamble Company, Marly, Switzerland.*

To help identify predictive endpoint measures for use in an in vitro cell based assay(s) for assessing the skin sensitization potential of chemicals, we focused on a genomics approach to identify genes that are regulated in human peripheral blood-derived dendritic cells (PBMC-DC) following chemical allergen exposure. A list of 29 potentially predictive genes was derived using PBMC-DC which has been evaluated with 26 chemicals using a multiplexed bead assay for measuring gene expression. With PBMC-DC, 14 out of 29 genes are consistently positive in response to 5 mM DNBS with very little donor-to-donor variability. Excluding DNBS, no genes were consistently positive with all allergens tested and some allergens induced changes in only a few genes. These same genes have been evaluated in two DC-surrogate cell lines, THP1, U937 with a smaller number of chemicals. These cell lines show few changes in the expression of the 29 genes following allergen treatment. In U937 cells the few positive responses observed were minimal with only 2-6 fold changes over control except for a maximal response of 8.5-fold increase in one gene, ISG15. A few more gene changes are observed in the THP1 cells. Only one gene was positive in THP1 cells with all of the allergens tested, AKR1C2. There are clear differences between PBMC-DC and the U937 and THP1 cell lines in the allergen-induced expression changes of these 29 genes. PBMC-DC appear to be the cells of choice for use in this gene expression-based method.

PL 644 DISTINGUISHING CONTACT SENSITIZERS, RESPIRATORY SENSITIZERS, AND IRRITANTS IN THE LOCAL LYMPH NODE ASSAY (LLNA): A TOXICOGENOMIC APPROACH.

D. R. Boverhof, B. B. Gollapudi, J. A. Hotchkiss and M. R. Woolhiser. *Toxicology and Environmental Research & Consulting, The Dow Chemical Company, Midland, MI.*

Genomic approaches have the potential to enhance existing toxicology endpoints, including those for chemical sensitization. The present study was conducted to identify gene expression responses with the ability to distinguish between irritants, contact sensitizers and respiratory sensitizers. The evaluated chemicals included the contact sensitizers dinitrochlorobenzene (DNCB) and hexyl cinnamic aldehyde (HCA), the respiratory sensitizers ortho-phthalaldehyde (OPA) and trimellitic anhydride (TMA), and the non-sensitizing irritants methyl salicylate (MS) and nonanoic acid (NA). Female Balb/C mice received three doses of each chemical as per the standard LLNA dosing regimen. Auricular lymph nodes were analyzed for both 3HTdR incorporation and gene expression responses. All chemicals induced dose-dependent increases in stimulation index values with EC3 values of 0.09%, 8.6%, 0.01%, 0.15%, 52%, and 18.9% for DNCB, HCA, OPA, TMA, MA and NA, respectively. Analysis of the gene expression data indicated that all chemicals induced a dose-dependent increase in the number of active responses with a strong correlation to the corresponding stimulation indices. Genes such as IL-4, IL-21 and IFN-gamma were similarly modulated by all chemicals and appear to lack any discriminating potential. The majority of the genes modulated by the irritants were similarly regulated by the sensitizers, consistent with the irritating effects of the sensitizers at high doses. A select number of responses were unique to the sensitizers and therefore offer the ability to distinguish sensitizers from irritants. In addition, a small subset of genes was identified that appeared to be unique to the respiratory sensitizers. Collectively, the data suggest that gene expression responses observed in the mouse LLNA may serve as useful biomarkers to distinguish irritants from sensitizers and respiratory sensitizers from contact sensitizers.

PL 645 THE CHEMICAL SENSITIZER NICKEL SULFATE INDUCES THE PRODUCTION OF INTERLEUKIN-12: COOPERATION AMONG P38MAPK, NF-κB AND IRF-1 PATHWAYS.

D. Antonios, P. Rousseau, S. Kerdine-Romer, A. Larange and M. Pallardy. *Univ Paris Sud, INSERM UMR-S 749, Faculté de Pharmacie, Châtenay-Malabry, France.*

Allergic contact dermatitis, caused by metallic ions such as nickel, is a T cell-mediated inflammatory skin disease. Interleukin-12 (IL-12) is considered to be important in the generation of the allergen-specific T cell response. IL-12p70, the bioactive form of IL-12, is a heterodimeric protein composed of two subunits IL-12p40 and IL-12p35. Dendritic cells (DC) are professional antigen presenting cells that are involved in the induction of primary immune responses as they possess the ability to stimulate naïve T cells. In this study we address the question whether NiSO4 by itself or in synergy with other signals can induce the secretion of IL-12p70 by human monocytes derived DC (Mo-DCs). Mo-DC were obtained from human monocytes purified from peripheral blood and cultured in the presence of GM-CSF and IL-4 for 5 days. Nickel sulfate by itself induced the production of IL-12p40 in a dose dependent manner but was unable to induce the production of IL-12p70. The concomitant presence of IFN-γ and nickel was necessary to induce the production of IL-12p70. Both signals were required for the expression of the p35 subunit of IL-12 as shown by RT-PCR. Interestingly, we found that in addition to the activation of MAPK (Mitogen-activated protein kinase) and NF-κB (Nuclear factor kappa B) pathways, nickel sulfate by itself induced the activation of IRF-1 (a member of the family of transcription factors IRF (Interferon Regulatory Factors)). To test the impact of these signaling pathways in IL-12 production, we used well known pharmacological inhibitors of MAPK and NF-κB pathways and RNA interference-mediated silencing of IRF-1. Results suggested that p38MAPK and NF-κB but not JNK are involved in IL-12p40 production induced by nickel. Moreover, specific IRF-1 silencing nearly totally abrogated IL-12p40 and IL-12p70 production provoked by nickel or nickel plus interferon-gamma. Finally, our results indicate that p38MAPK, NF-κB and IRF-1 cooperate in IL-12p70 induced by nickel sulfate and interferon-γ.

PL 646 MULTIPLEXED QUANTITATIVE HIGH CONTENT SCREENING ASSAYS REVEAL THAT CIGARETTE SMOKE CONDENSATE ACTIVATES NUCLEAR FACTOR-KAPPA B AND INDUCES CELL DEATH IN HUMAN BRONCHIAL EPITHELIAL CELLS.

C. A. Carter[1] and J. T. Hamm[2]. [1]*Life Sciences, Lorillard Tobacco Company, Greensboro, NC and* [2]*Integrated Laboratory Systems, Inc., Research Triangle Park, NC.*

Human bronchial cells are one of the first cell types exposed to inhalable environmental toxins. Nuclear transcription factor-κB (NF-κB) responds to environmental stress as a ubiquitous transcription factor that regulates the inflammatory response, cell proliferation, apoptosis and disrupts the F-actin cytoskeleton. The effects of cigarette smoke condensate (CSC) on NF-κB, F-actin, and apoptosis were evaluated in BEAS-2B immortalized human bronchial epithelial cells. We hypothesized that CSC would activate NF-κB, disrupt the F-actin cytoskeleton and induce apoptosis. NF-κB translocates from the cytoplasm to the nucleus upon activation. This translocation is observed when BEAS-2B cells are treated with doses above 20μg/ml CSC for 24 hrs. As NF-κB is activated, cell number and nuclear size decrease. Cell structural alterations often accompany toxic insults to cells. CSC treatment of BEAS-2B cells induces a rearrangement of F-actin such that stress fibers are no longer prominent at the cell periphery and throughout the cells, but relocalize to perinuclear regions. Because toxins induce F-actin relocalization to perinuclear areas and perinuclear F-actin is associated with apoptosis, we evaluated the effects of CSC on apoptosis. CSC induces apoptosis in BEAS-2B cells evidenced by an increase in caspase 3. CSC doses above 10μg/ml induce a significant increase in caspase 3 when cells are treated for 1- or 24 hrs compared to DMSO controls. Caspase 3 levels are twice that of DMSO controls when cells are treated with 40μg/ml CSC for 1- or 24 hrs. As caspase 3 increases, cell number decreases. After treatment for 24 hrs, there is a dose-dependent decrease in cell number with an average of 85% remaining when cells are treated with 10μg/ml CSC while only 46% remain when treated with 40μg/ml CSC. CSC activates NF-κB in BEAS-2B cells and induces cell death with a concomitant disruption of the F-actin cytoskeleton.

PL 647 UP-REGULATION AND NUCLEAR ACCUMULATION OF P53 PROTEIN IN HUMAN BRONCHIAL EPITHELIAL CELLS EXPOSED TO 4-(METHYLNITROSAMINO)-1-(3-PYRIDYL)-1-BUTANONE.

L. Chen[1], C. Shao[1], E. Cobos[2], J. Wang[3] and W. Gao[1]. [1]*Environmental Toxicology, The Institute of Environmental and Human Health (TIEHH), Texas tech university, Lubbock, TX,* [2]*Texas Tech University Health Sciences Center, lubbock, TX and* [3]*The University of Georgia, Athens, GA.*

Our previous study showed that 150 μM of 4-(methylnitro-samino)-1-(3-pyridyl)-1-butanone (NNK), a tobacco specific lung carcinogen, inhibited cell proliferation and down-regulated the expression of chromosomal region maintenance 1 (CRM1) in human bronchial epithelial cells (BEAS-2B). CRM1 is an exporter for leucine-rich nuclear export signal proteins including p53, a critical tumor suppressor gene product that plays an important role in lung carcinogenesis. In the present study, we hypothesize that NNK exposure not only changes the expression level of p53 protein, but also alters p53 subcellular localization due to CRM1 down-regulation. BEAS-2B cells were treated with 150 μM NNK for 24 and 72 h. The expression of p53 was examined by western blot analysis and cellular localization of p53 was evaluated by immunocytochemistry. Expression of p53 was significantly up-regulated following treatment with NNK for 72 h (1.23 fold increase; p=0.02, t test) but not for 24 h (p=0.27, t test). Furthermore, the proportion of cells that had higher p53 staining in nucleus than cytoplasm was increased in NNK-treated cells for both 24 h (~40%) and 72 h (~70%) as compared to the vehicle-treated control (20~30%). These findings suggest that p53 expression can be up-regulated and accumulated in the nucleus after NNK exposure that may cause DNA damage and further trigger apoptosis through activating p53. In addition, p53 nuclear accumulation induced by NNK exposure might result from CRM1 down-regulation that will diminish p53 export from nucleus. Further studies will focus on evaluating the role of CRM1 in modulating the p53 shuttling between nucleus and cytoplasm.

PL 648 BENZO[A]PYRENE INDUCES DEDIFFERENTIATION OF HUMAN BRONCHIAL EPITHELIAL BEAS-2B CELLS.

H. Gao[1, 2] and K. S. Ramos[1, 2]. [1]*Biochemistry and Molecular Biology, University of Louisville, Louisville, KY and* [2]*Center for Genetics and Molecular Medicine, University of Louisville, Louisville, KY.*

Although extensive studies have shown that benzo[a]pyrene (BaP), a ubiquitous environmental carcinogen, is closely associated with multiple human pulmonary diseases, molecular mechanisms of BaP toxicity are still not fully understood. Given that epithelial to mesenchymal transition (EMT) in the lung has been observed in response to environmental injury, and this type of transition has been linked to the onset and progression of pulmonary diseases, we hypothesized that BaP induces pulmonary disease via EMT. To examine the possible role of BaP in EMT, we examined a reliable epithelial marker, E-cadherin, in human bronchial epithelial BEAS-2B cells following BaP challenge. Our results showed that BaP (0.3 and 30 μM) decreased protein levels of E-cadherin in a concentration dependent manner. The loss of E-cadherin was specific since other cellular markers remained unchanged. BaP at 30 μM significantly altered the normal structure of cytokeratin, another marker of epithelial functional integrity, as assessed by immunostaining. The molecular basis for the shift toward mesenchymal phenotype is currently under investigation.

PL 649 EFFECTS OF SIDE STREAM TOBACCO SMOKE IN DNA DAMAGE REPAIR AND GSH-DEFICIENT MICE.

M. L. Yamamoto[1], A. Westbrook[1], J. H. Miller[2] and R. H. Schiestl[1]. [1]*Molecular Toxicology, University of California, Los Angeles, Los Angeles, CA and* [2]*Microbiology, Immunology, and Molecular Genetics, University of California, Los Angeles, Los Angeles, CA.*

Side stream tobacco smoke (SSTS), the main component of secondhand smoke, is classified as a human carcinogen, but has been difficult to study in animal models. Cigarette smoke causes free radicals and inflammation, both leading to DNA damage. Thus, animals with inadequate oxidative DNA damage repair, with the propensity to develop spontaneous lung tumors, may be more sensitive to the biological activity of SSTS. Likewise, animals with a decreased capacity to combat oxidative stress may also be susceptible to SSTS-induced damage. We used mice lacking the gene Ogg1, Myh, or double mutant mice, both of which are involved in base excision repair, removing oxidatively damaged DNA bases. We also used Gclm-deficient mice, which have decreased levels of glutathione (GSH). We have found that DNA strand breaks are increased immediately after a 4-hour exposure to 55.8 mg/m^3 total particulate matter (TPM) of SSTS in wildtype, Ogg1, and Myh single mutant mice. Moreover, micronucleated cells in the peripheral blood are increased in Ogg1-deficient but not in wildtype mice indicating that while strand breaks are repaired in wildtype mice, they seem less easily repaired in Ogg1-deficient mice. Our results may clarify the roles of oxidative stress and oxidative DNA damage-repair in SSTS-induced cancers as well as elucidate the role of genetic polymorphisms in SSTS disease susceptibility. Understanding gene-environment interactions in SSTS as well as the interactions of oxidative stress and DNA damage will aid in the development of chemoprevention and treatment of lung cancer.

PL 650 LUNG GLUTATHIONE ADAPTIVE RESPONSE TO CIGARETTE SMOKE.

N. Gould[1, 3], C. Kariya[1, 3], R. Martin[3], H. Chu[3] and B. J. Day[1, 2, 3]. [1]*Pharmaceutical Sciences, University of Colorado Health Sciences Center, Aurora, CO,* [2]*Medicine, University of Colorado Health Sciences Center, Aurora, CO and* [3]*Medicine, National Jewish Health, Denver, CO.*

Chronic obstructive pulmonary disease (COPD), which includes chronic bronchitis and emphysema, is largely associated with a history of chronic tobacco use. It is interesting that only 10-20 percent of chronic smokers actually develop COPD. This suggests that the lung has very effective adaptive responses to limit the potential damaging effects of chronic smoking. Glutathione is a major endogenous thiol antioxidant involved in the adaptive response in the air surface fluids with exposure to cigarette smoke (CS). Mouse strains show differential sensitivity of lung damage towards chronic CS exposure and we tested whether they have different GSH adaptive responses. Using one sensitive strain (AKRJ) and two resistant strains (C57/B6 and BALB/c), we compared the GSH adaptive responses in the epithelial lining fluid to CS. After two weeks of CS the C57/B6 and BALB/c mice had similar responses while AKRJ mice had diminished GSH adaptive response and higher GSSG levels. Next we examined if the GSH response occurs immediately or only after multiple days of exposure to CS. Using C57/B6 mice the GSH response was examined after 1d, 3d, and 2 weeks of CS exposure. It was found that GSH in the epithelial lining fluid (ELF) is greatly increased (up to 6-fold) after just one day of CS exposure, while the GSH levels are only about 2-fold at 3d and 14d. To investigate the role of the GSH biosynthesis enzymes, airway epithelial cells were treated with cigarette smoke extract (CSE) and BSO, BCNU, or acivicin to inhibit GCL, GR, or GGT respectively. We found that inhibiting the synthesis, catabolism, or recycling or GSH prevented the increased levels of apical GSH stimulated by the CSE. This would indicate that diminished activity of these enzymes or possible genetic mutations could prevent a GSH adaptive response and predispose an individual to CS induced COPD.

PL 651 GLUTATHIONE S-TRANSFERASE P PROTECTS AGAINST ENDOTHELIAL DYSFUNCTION INDUCED BY EXPOSURE TO TOBACCO SMOKE AND ACROLEIN.

D. J. Conklin[1], P. Haberzettl[1], R. A. Prough[2] and A. Bhatnagar[1]. *[1]Inst. Mol. Card., University of Louisville, Louisville, KY and [2]Department Biochem., University of Louisville, Louisville, KY.*

Exposure to tobacco smoke impairs endothelium-dependent arterial dilation. Although the mechanism by which tobacco smoke induces endothelial dysfunction is unclear, reactive constituents of cigarette smoke are metabolized and detoxified by glutathione S-transferases (GSTs). Polymorphisms in GST genes are associated with the risk of cancer in smokers, yet the role of these enzymes in regulating the cardiovascular effects of smoking has not been studied. Because short-chain, unsaturated aldehydes, such as acrolein or crotonaldehyde, are excellent substrates of the GSTP isozyme, we tested if $GSTP^{-/-}$ mice were more sensitive than $GSTP^{+/+}$ mice to inhaled tobacco smoke and acrolein. The GSTP protein and activity were present in high abundance in mouse lung and aorta. Because GSTP also affects cell stress signaling, we determined MAPK activation in lungs of tobacco smoke- or acrolein-exposed mice. JNK activation was apparent after 5h exposure although no change in the level of ERK or p38 phosphorylation was detected. Aortic rings isolated from tobacco smoke-exposed $GSTP^{-/-}$ mice (3 day) showed greater attenuation of acetylcholine-evoked relaxation than those from similarly exposed $GSTP^{+/+}$ mice although no change in the sodium nitroprusside-induced relaxation was observed in either $GSTP^{+/+}$ or $GSTP^{-/-}$ mice. Similarly, aortic rings prepared from $GSTP^{-/-}$ mice inhaling acrolein (1 ppm, 5h/day, 3 days) or those exposed to acrolein (10 μM) in the organ bath showed diminished acetylcholine-induced relaxation more strongly than $GSTP^{+/+}$ mice. Endothelial dysfunction due to acrolein was prevented by pretreating the isolated aorta with N-acetylcysteine. These results indicate that GSTP protects against the endothelial dysfunction induced by exposure to tobacco smoke and that this protection could be related to the detoxification of acrolein or other related electrophilic cigarette smoke constituents. This work supported by ES11860 (AB), HL89380 (DJC), AHAF/NHF (DJC), and a Philip Morris grant(AB).

PL 652 THIOREDOXIN MEDIATES TGF-β1 AGAINST OXIDATIVE STRESS OF CIGARETTE SMOKE IN HUMAN AIRWAY EPITHELIUM.

Y. Huang[1], C. Chuang[2], F. Sung[1,3], C. Chen[1] and C. Chou[4]. *[1]Institute of Environmental Health, National Taiwan University, Taipei, Taiwan, [2]Biomedical Engineering and Environmental Sciences, National Tsing Hua University, Hsinchu, Taiwan, [3]Institute of Environmental Health, China Medical University, Taichung, Taiwan and [4]College of Veterinary Medicine, National Chung-Hsing University, Taichung, Taiwan.*

Cigarette smoke (CS) contains reactive oxygen species (ROS) to cause oxidative damage, inflammation, and dysfunction of repair process in airway cells. Thioredoxin (TRX) has anti-oxidation capability against oxidative stress, and involves in cell growth and differentiation. Transforming growth factor (TGF)-β is found to regulate the growth of normal epithelial cells and initiate a signaling pathway that suppresses the early development of cancer cells. As airway epithelium provides a protective barrier against external environment, this study was to investigate how TRX mediates oxidative stress of CS in human bronchial epithelial cells and its following signaling transduction of stress-activated mitogen-activated protein kinases (MAPK) in the regulation of TGF-β1. Results showed that CS caused intracellular ROS generation and apoptosis, and induced TRX but attenuated TGF-β1 expression in human bronchial epithelial (BEAS-2B) cells. Additionally, the constructed TRX-overexpressing BEAS-2B cells could repress CS-induced apoptosis and enhance TGF-β1 expression. After neutralized with anti-TGF-β1 antibody, TRX-overexpressing BEAS-2B cells exposed to CS decreased TRX expression. These represented TRX regulated TGF-β1 expression in CS exposure. TRX suppressed CS-induced c-Jun-N-terminal kinase (JNK) to prevent from apoptosis. This study demonstrated that oxidative stress of CS induced MAPK signaling, and TRX mediated TGF-β1 against oxidative stress of CS in human airway epithelial cells.

PL 653 ENHANCEMENT OF NNK METABOLISM BY ARSENIC AS THE MECHANISM OF INCREASED CIGARETTE SMOKE LUNG CARCINOGENICITY BY ARSENIC.

L. W. Chang, P. P. Lin and S. H. Lee. *Division of Environmental Health & Occup. Medicine, National Health Research Institutes, Zhunan Town, Taiwan.*

Mounting epidemiological evidences indicated that interaction between cigarette smoke and arsenic increased lung and liver cancer risks among cigarette smokers in arseniasis areas. We believe that the metabolism of NNK, a specific and known carcinogenic component in cigarette smoke, can be enhanced by arsenic leading to increased NNK metabolites, harmful DNA adducts and eventual carcinogenic risk. Young male ICR mice were exposed to single injection of NNK (1 mg/kg). These animals were also co-exposed to arsenite (10 mg/kg) or saline via gavage for 10 days. All animals, in groups of 3, were housed in metabolic cages for urine collections. Changes in hepatic P450 enzyme,Cyp2a5/6, a specific P450 enzyme for NNK metabolism, and urinary NNK metabolites were assayed with LC/MS/MS analytical method. Significant increased hepatic Cyp2a enzyme expression and activity were found in all arsenic treated animals. All NNK metabolites in the urine were also found to be elevated. More importantly, O6- and N7-MeG DNA-adducts in the liver were also found to be highly elevated in all arsenic treated animals. Our findings affirmed that arsenic can increase NNK metabolism. The increased NNK metabolites and the formations of DNA damaging O6- and N7-MeG adducts would enhance carcinogenic risk. Our findings also provide the needed scientific base for the epidemiological observations.

PL 654 ENVIRONMENTAL TOBACCO SMOKE-INDUCED ENDOTHELIAL DYSFUNCTION: ROLE OF ACROLEIN AND PROTEIN-ACROLEIN ADDUCTS.

P. Haberzettl, D. J. Conklin and A. Bhatnagar. *Inst. Mol. Card., University of Louisville, Louisville, KY.*

This study delineates the contribution of unsaturated aldehydes, such as acrolein to endothelial dysfunction after environmental tobacco smoke (ETS) exposure. We exposed 12-week old male C57BL/6 mice to air or ETS (average TSP ~91 mg/m^3, over 2 separate experiments) for three consecutive days (5h/day). To evaluate the effects of an unsaturated aldehyde scavenger, mice were treated with water or N-acetylcysteine (NAC, 200 mg/kg, i.p.) at 0.5h before exposure each day. Animals were sacrificed 24h after the 3rd exposure following an 8h fast. ETS exposure decreased endothelium function in isolated mouse aorta and NAC pretreatment prevented the loss of endothelium-dependent acetylcholine-induced (ACh) relaxation supporting the role of ETS-derived unsaturated aldehydes as mediators of endothelial injury. NAC pretreatment did not enhance endogenous endothelium function in air-exposed mice because ACh-induced relaxation of phenylephrine-precontracted (PE) thoracic aortic rings was similar in air-exposed mice with or without NAC pretreatment (ACh EC_{50}, Air = 243±23nM; Air+NAC = 413±98nM; n=3,3; ACh % relaxation, Air = -83±1; Air+NAC = -96±5; n=3,3). ACh relaxation of NAC-pretreated ETS-exposed mice (-78±4%) was significantly greater than in ETS-exposed mice (-50±5%). Aortic sensitivity to PE was greater in ETS-exposed mice compared with all other groups perhaps due to underlying endothelium dysfunction. To elucidate the role of potential reactive electrophiles in ETS responsible for endothelial dysfunction, the presence of acrolein-protein adducts was determined by Western blotting in lysates of lung tissue and plasma. In ETS-exposed mice the quantity of acrolein-protein adducts in lung (~70/75 and ~150 kDa) and plasma (~150 kDa) was significantly increased compared with air-exposed animals. These data support the hypothesis that acrolein in ETS is delivered systemically and could directly cause endothelial dysfunction, a condition prevented by addition of a thiol aldehyde scavenger. This work supported by PO1 ES11860 (AB) and a Phillip Morris grant (AB).

R 655 LEVERAGING NONCLINICAL DISEASE MODELS FOR EARLY PERSPECTIVE ON SAFETY AND RISK DURING DRUG DISCOVERY.

M. Otieno[1], M. Yakes[3], A. Bell[2], S. Adams[1], B. Gemzik[1] and M. Graham[2]. *[1]Bristol Myers Squibb, Princeton, NJ, [2]AstraZeneca Pharmaceuticals, Alderley Park, United Kingdom and [3]Exelixis, Inc, South San Francisco, CA.*

Preclinical toxicity contributes to ~ 70% of compound failure during the drug discovery process, suggesting that approaches that reduce attrition due to pharmacology or chemistry can lead to successful selection of candidate drugs. The use of animal disease models to test for toxicity presents a unique opportunity for toxicologists to explore liabilities early in the drug discovery process. Rodent models, including tumor xenograft, metabolic, and inflammation models are especially attractive for combined efficacy/toxicology testing due to their repeat-dose testing paradigm and study duration. Thus, this forum will highlight the successes and challenges in the use of nonclinical disease models to evaluate safety endpoints. Thorough parallel testing in xenograft tumor models that includes acute and subchronic dosing paradigms, MTD determination, histological evaluation of tumor and normal tissue, and DMPK profiling can inform on both safety and efficacy of lead compounds. In addition, information obtained from such studies can often be applied toward a biomarker strategy or dose-scheduling plan for nonclinical and clinical development. Metabolic and chronic inflammatory disease models have altered physiology needs to be considered, as this may modulate the toxicological response. A robust analysis of the impact of disease phenotype on toxicity should be based on a reductive mechanistic model of an aspect of the human disease that has

common mechanisms with nonclinical models. Creative ways to generate early tolerability data for CNS molecules include an understanding of target pharmacology and interactions with other receptors, ion channels, and transporters. Behavioral or physiological changes (e.g., altered activity, stereotype, body temperature) can be evaluated in early pharmacokinetic studies. Combining receptor occupancy from pharmacology models, behavioral, and pharmacokinetic data can provide an integrated assessment for potential CNS side effects.

R 656 ROLE OF REGULATORY COOPERATIVE EFFORTS IN FOOD PROTECTION.

J. Vodela[1] and K. Dearfield[2]. *[1]Residue Branch, USDA/FSIS, Washington DC, DC and [2]United States Food Safety Inspection Service, United States Department of Agriculture, Washingto DC, DC.*

Chemical and microbial risk assessments are widely used in food safety decision making, in identifying data needs, and in implementing the Hazard Analysis and Critical Control Point (HACCP) Program. The HACCP Program is an excellent example of a collaborative effort between the U.S. Department of Agriculture and the Food and Drug Administration. Collaboration among all food safety bodies, including state, federal and global partners provides a robust system for continued protection and preparedness of the food protection system. The chemical and microbial risk assessment communities benefit from this on-going collaboration and cooperation. Collaboration has led to advancements in the food safety information infrastructure, data mining, data sharing and the development of sophisticated risk assessment models (risk assessments, vulnerability assessments, etc.) to guide the creation of preventive measures as part of food protection efforts. Leaders from state, federal and international bodies will discuss cooperative and innovative approaches for chemical and microbiological risk assessments in order to provide the safest food supply to the consumer.

R 657 WEIGHT OF EVIDENCE ADVANCEMENTS IN RISK ASSESSMENT: CONCEPTUAL FRAMEWORKS AND CASE STUDIES ILLUSTRATING FUNDAMENTALS OF APPLICATION.

P. J. Spencer[1], J. G. Seed[2], B. Meek[3], J. C. Lipscomb[4], J. A. Swenberg[5] and R. A. Corley[6]. *[1]TERC, The Dow Chemical Company, Midland, MI, [2]Risk Assessment Division OPPT, U.S. EPA, Washington DC, DC, [3]McLaughlin Centre for Population Health Risk Assessment, University of Ottawa, Ottawa, ON, Canada, [4]National Center for Environmental Assessment, ORD, U.S. EPA, Cincinnati, OH, [5]Department of Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC and [6]Pacific Northwest National Laboratory, Richland, WA.*

Chemicals interact with biological targets ultimately at the molecular level producing key, necessary and causative events. Identification and quantification of these events leads to understanding of a toxicant's mode of action (MOA). Weight of evidence (WOE) approaches consider relevant scientific data, underlying assumptions and correlations to characterize the overall support for a hypothesized MOA. Frameworks for WOE analyses for MOA in animals and their associated human relevance (HR) have been developed by the International Life Sciences Institute (ILSI) and International Programme on Chemical Safety (IPCS). Information reviewed as a basis for consideration of the WOE of MOA and its HR can be applied to refine the dose-response relationship and with sufficient data may be used in the derivation of Chemical Specific Adjustment Factors (CSAF), as outlined in the guidance developed by the IPCS. This includes using PBPK modeling to develop quantitative data to replace default assumptions for inter- and intra-species differences in tissue dosimetry. The principles for WOE considerations embodied in the HRF can potentially be extended to other areas to refine human health risk assessments. Characterizing the MOA and determining its relevance to the human system provides the foundation for developing non-default, CSAFs for application in health risk assessment. Therefore, it is important to provide a forum for discussion on how one might extend the framework into other areas with chemical specific case studies that use the MOA-HRF for analyzing cancer mode of action in animals, characterizing human dose-response and development of a CSAF.

EC 658 GRANTSMANSHIP FORUM: TOOLS AND SKILLS NEEDED TO NAVIGATE TOXICOLOGY RESEARCH FUNDING.

S. S. Nadadur[1], J. Hiendel[1], R. T. Okita[2], S. O'connor[3] and E. M. Cannon[4]. *[1]Division of Extramural Research & Taining, NIEHS, Research Triangle Park, NC, [2]Pharmacology, Physiology & Biochemistry, National Institute of General Medical Sciences, Bethesda, MD, [3]Biological Infrastructure, National Science Foundation, Arlington, VA and [4]PhRMA Foundation, Washington, DC.*

Toxicology research at academic institutions is supported by various extramural research funding mechanisms, of which the most common are research grants and fellowships. These research grants can be obtained either by investigator-initiated, generally unsolicited, or in response to research funding announcements by various funding agencies. Traditionally, the major research support for understanding the impact of toxic substances on public health is supported by the National Institute of Health (NIH) and its 26 different Institutes or Centers. While the National Institute of Environmental Health Sciences (NIEHS) supports toxicology research efforts to understand the impact of environmental pollutants, the National Institute of General Medical Sciences (NIGMS) supports research grants for a wide variety of agents including pharmaceuticals. Some of the federal agencies, such as the National Science Foundation, support research in the areas of environmental biology. Numerous non-profit organizations including the Pharmaceutical Research and Manufacturers of America (PhRMA) Foundation also provide research grant support, starting from pre-doctoral to sabbatical opportunities in pharmacology, toxicology and informatics. A representative Program Director from NIGMS, NIEHS, NSF and PhRMA Foundation will present the opportunities, tools, and skills needed for successful research funding. In highlighting this important funding opportunity available, one presentation will focus exclusively on successful grant writing noting specific requirements such as the correct mix of scientific knowledge and salesmanship to enable your to navigate NIH funding.

R 659 BIOMARKERS OF CARDIAC HYPERTROPHY AND SKELETAL MUSCLE TOXICITY – SUCCESSES AND CHALLENGES RELATED TO THEIR IMPLEMENTATION IN DRUG DEVELOPMENT.

D. Watson[1] and W. Glaab[2]. *[1]Investigative Toxicology and Pathology, GlaxoSmithKline, Research Triangle Park, NC and [2]Investigative Toxicology, Lilly Research Laboratories, Greenfield, IN.*

Drug-related injury to cardiac and/or skeletal muscle is a common cause of safety-related attrition in drug development, and has resulted in the withdrawal of several efficacious pharmaceutical agents from the market. Improving our ability to detect muscle injuries should improve patient safety. Case studies are presented on successes and challenges related to the implementation in drug development of serological biomarkers of skeletal muscle necrosis, including differentiation of injury to Type I versus Type II muscle fibers; cardiac myocyte injury, including comparisons of the performance of cardiac troponins with other serological biomarkers and histopathology; and cardiac hypertrophy, including serological concentrations of natriturectic peptides, and their relationship to hemodynamic and structural changes in the heart. Scientific challenges that limit the broader application of these biomarkers are also addressed in a presentation on the changes in muscle structure and biochemistry that are driven by physiological and pathological processes, including those related to exercise, muscle atrophy, and drug toxicity in human muscle.

R 660 THE REGULATORY FRONTIER: ADDRESSING PRODUCTS OF NANOTECHNOLOGY.

T. Woodruff[1], K. Dreher[2], J. Pendergrass[3], D. Berube[4], J. Sass[5] and T. L. Medley[6]. *[1]Obstetrics, Gynecology & Reproductive Sciences, University of California San Francisco, San Francisco, CA, [2]National Health and Environmental Effects Research Laboratory, U.S. Environmental Protection Agency, Research Triangle Park, NC, [3]Environmental Law Institute, Washington, DC, [4]Department of Communication, North Carolina State University, Raleigh, NC, [5]Natural Resources Defense Council, Washington, DC and [6]Environment and Sustainable Growth Center, Dupont, Willmington, DE.*

Nanomaterials, typically defined as manufactured materials that have at least 1 dimension <100 nanometers, are being increasingly produced worldwide. Nanomaterials have been used or proposed for use in a variety of products, ranging from computers, clothing, cosmetics, medical devices, coatings and fuel cells, to new technologies for environmental clean up. Use is expected to increase and it is estimated that by 2015 about 10% of output from the chemicals sector will have some influence from nanotechnology, greatly increasing opportunities for human exposures . There has been some evaluation of potential health risks from nanomaterials, but to date, but these have not been pursued in a systematic way. Nanomaterials pose new challenges and opportunities to the regulatory and policy structure. There is an increasing number of regulatory and policy decisions being discussed or made at the state, federal and international level. Given that this is still a new and emerging technology, there are opportunities to consider how to address potential health risks in the regulatory and policy framework prior to widespread use and adoption. This symposium will present an overview of nanomaterials, the current state of regulations and policies for addressing nanomaterials and a discussion of how various entities propose the government move forward to address nanomaterials.

HH 661 DIOXIN, FORTY YEARS OF SCIENCE: ARE WE ANY CLOSER TO ASSESSING POTENTIAL RISK?

W. Brock[1] and A. Faqi[2]. *[1]Brock Scientific Consulting, Gaithersburg, MD and [2]MPI Research, Mattawan, MI.*

The word dioxin conjures up fears when another article appears in the media. Since the 1970s, there have been scientific publications reporting the potential environmental and human health hazards of exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD; dioxin) and possible mechanisms of toxicity. Numerous epidemiological studies have reported on Vietnam veterans, residents of towns in Italy and Missouri as well as workers in plants that produce the substances containing TCDD. Identification of possible health hazards has been the basis of toxicological research with an examination of possible reproductive effects, immunotoxicity, hepatic effects, cancer and a number of endpoints. Early mechanistic work identified the Ah receptor (AHR) and the role of this receptor in toxicity and changes in metabolic processes. AHR receptor research and the awareness that there is likely to be endogenous and naturally occurring AHR ligands that govern normal physiological processes has shed new light on the significance of the AHR. The EPA report of the 1980s examined the extent of environmental contamination leading to greater interest in environmental analysis of dioxin and the potential for accumulation into the food chain. However, because of regulatory and voluntary efforts subsequently introduced, the levels of dioxin in the environment and food chain have significantly declined. The margin of exposures should continue to increase as additional controls on dioxin emissions are enacted and environmental levels dissipate. The available scientific data have improved our understanding of the strengths and weaknesses of toxicity equivalency factors used in dioxin risk assessment. The NAS evaluation of EPA's draft dioxin reassessment identified a number of important uncertainties and errors of how dioxin risks were managed. This session will focus on the research that has been reported over the last 40+ years, the principles of mechanistic toxicology learned from this research and what the future of research into the human health and environmental effects of this particularly toxic compound.

IS 662 NIH GENES, ENVIRONMENT AND HEALTH INITIATIVE: BIOMARKERS AND BIOSENSORS FOR DETECTING RESPONSE TO ENVIRONMENTAL STRESS.

D. Shaughnessy. *DERT/SPHB, NIEHS, Research Triangle Park, NC.* Sponsor: M. Smith.

The NIH established the Genes, Environment, and Health Initiative (GEI) in 2006 with a goal of establishing a foundation for large-scale gene environment interaction studies. A central component of this initiative is the Exposure Biology Program, led by the National Institute of Environmental Health Sciences in collaboration with the National Cancer Institute, National Heart, Lung, and Blood Institute, National Institute for Drug Abuse, and other NIH Institutes and Centers. The Exposure Biology Program aims to develop a new generation of tools for comprehensive exposure assessment. These tools stem from the efforts of four complementary program areas focused on improving detection of individual exposures to traditional environmental toxicants, assessing psychosocial stress and addictive substances, assessing diet and physical activity, and measuring biological responses to these factors. This activity is focused on the development and validation of new tools, approaches, and biomarkers that will enable fundamentally new directions in environmental epidemiology and the exploration of gene environment interactions. An overview of the GEI Exposure Biology Program will be presented by grantees from the Biological Response Indicators Program. The evolution of these new biomarkers and biosensors and how they may be used to assess early but persistent changes in key physiological pathways known to be involved in disease pathogenesis will be the primary focus. In addition, the application of new technologies and methodologies for improved detection of patterns of response to different chemical and lifestyle stressors in pathways that include oxidative stress, inflammation, and DNA damage will be highlighted. Presentations will cover transcriptomic and DNA adduct markers of tobacco smoke exposure, epigenetic alterations in breast stem/progenitor cells from endocrine disrupting chemicals, gene expression patterns from specific PCB congeners, and new biosensors for detecting protein adducts and genetic damage resulting from chemical exposures.

S 663 DOES METAL TOXICITY PLAY A ROLE IN THE ETIOLOGY OF ALZHEIMER'S.

N. H. Zawia. *Biomedical, University of Rhode Island, Kingston, RI.*

Alzheimer's disease (AD) is a progressive neurodegenerative disorder whose clinical manifestations appear with advancing age. One of the pathological hallmarks found in brains of AD patients is a buildup of extracellular amyloid plagues that are rich in beta amyloid which is derived from the amyloid precursor protein (APP). Studies have shown that beta amyloid is a metalloprotein which binds zinc (Zn), copper (Cu) and iron (Fe). Exposure to low levels of lead (Pb) in early life has been linked to abnormal regulation and expression of APP, possibly by the reprogramming of APP expression. An epigenetic study of Pb-exposed subjects and work on beta-amyloid clearance from the brain following Pb exposure also provides evidence for a possible role for Pb in the etiology of AD. Manganese (Mn) exposure in primates has been recently shown to result in diffuse beta-amyloid plaques in the frontal cortex of young non-human primates. Experts in metal toxicology, neurotoxicology, and environmental epidemiology, who have performed pioneering work to address this newly emerging research area in metal neurotoxicology will address these issues.

S 664 EVIDENCE FOR LEAD AS AN ENVIRONMENTAL STRESSOR OF ALZHEIMER'S DISEASE AND THE ROLE OF EPIGENETICS.

H. Hu. *School of Public Health, University of Michigan, Ann Arbor, MI.*

Lead is well-known to toxicologists and the public health community as a potent neurobehavioral toxicant in children. More recently, a critical mass of studies has developed using molecular and biomarker epidemiology to demonstrate that, if the dose received is chronic over many years, lead is both a potent neurobehavioral toxicant in community-exposed adults as well as a trans-generational neurotoxicant resulting from the mobilization of maternal skeletal lead stores during pregnancy. This presentation will review this recent work, emphasizing the multi-disciplinary studies conducted by the Michigan-Harvard Metals Epidemiology Research Group on the Normative Aging Study (NAS) and the Early Life Exposures in Mexico to Environmental Toxicants (ELEMENT) Study. Attention will be particularly focused on studies demonstrating that (A) cumulative lead exposure assessed by K-x-ray fluorescence (KXRF) measures of lead in bone are associated with functional deficits in cognition that are (i) modified by genetic polymorphisms related to the regulation of iron; and (ii) associated with evidence of gliosis in the hippocampus as reflected by myo-inositol to creatine ratios measured by proton magnetic resonance spectroscopy (MRS); (B) prenatal lead exposure results in neurobehavioral deficits that are long-lasting; (C) preliminary epidemiologic analyses demonstrating that lead exposure is inversely associated with global DNA methylation within ALU elements, reducing DNA methyation and underscoring the potential for lead exposure to result in epigenetic changes that may contribute towards Alzheimers pathology.

S 665 PROMOTION OF ALZHEIMER'S DISEASE DUE TO EXPOSURE TO LEAD (PB)EARLY IN LIFE.

N. H. Zawia. *BPS, University of Rhode Island, Kingston, RI.*

The sporadic nature of most AD cases strongly argues for an environmental link that may drive AD pathogenesis; however, it is not clear when this may occur. This presentation will present evidence that exposure to Pb in early life promotes AD-like pathogenesis in old age and will argue for both an environmental link and a developmental-basis for AD. Furthermore, the epigenetic mechanisms involved as well as potential novel therapeutic approaches will be discussed.

S 666 CLEARANCE OF BRAIN BETA-AMYLOID FROM THE CEREBROSPINAL FLUID: ROLE OF THE CHOROID PLEXUS AND EFFECT OF PB POISONING.

W. Zheng. *Purdue University, West Lafayette, IN.*

Accumulation of beta-amyloid peptides (Abeta) in brain extracellular fluids is the key event in the amyloid cascade leading to neuronal cell damage in the etiology of Alzheimer's disease (AD). Excess amounts of extracellular Abeta may result from an overproduction, inadequate metabolic clearance, and/or imbalanced import and export of Abeta by brain barrier systems. The choroid plexus (CP) constitutes a barrier between the blood and cerebrospinal fluid (CSF). Clinical evidences have shown elevated Abeta levels in the CSF of AD patients, a marked deposition of Abeta in the CP of postmortem AD brains, and an age-related buildup of lead (Pb) in human CP. To understand relations between CSF Abeta, CP functions and Pb exposure, we examined (1) kinetics of Abeta uptake and transport by rat CP, (2) proteins that are critical to Abeta degradation and transport in the CP, and (3) Abeta accumulation in the CP as the consequence of acute Pb poisoning. Results show that the CP accumulates Abeta with 3 distinct characteristics: a) the CP takes up the intact Abeta, but not its small fragments; b) the uptake occurs rapidly and by a non-diffusive process; and c) the CP has a large capacity in accumulating Abeta. In Transwell transport studies with primary CP cells, the efflux transport of Abeta (from the CSF to blood) is greater than the influx (from the blood to CSF). The CP expresses proteins/enzymes involving in Abeta production, i.e., amyloid precursor

protein and beta-secretase, and in Abeta degradation, i.e., insulin degrading enzyme (IDE1), endothelin-converting enzyme-1 (ECE1), and neprilysin. After rats were injected ip with 50 mg Pb/kg, an evident increase in Abeta stains in the CP tissues was observed at 24 hrs. Acute Pb exposure also mobilized the low density lipoprotein receptor protein-1 (LRP1) from CP cytosol to the apical surface facing the CSF. These data suggest that the CP selectively cleanses Abeta from the CSF, potentially reducing Abeta from the brain. Pb exposure may alter these functions, leading to a halted clearance of Abeta by the CP and a subsequent elevation of Abeta in the CSF.

S 667 INCREASED BRAIN AMYLOID STAINS IN NON-HUMAN PRIMATES FOLLOWING CHRONIC MANGANESE EXPOSURE: A POSSIBLE RELATIONSHIP TO AD?

T. R. Guilarte. *School of Public Health, Johns Hopkins University, Baltimore, MD.*

Recent studies from our laboratory have shown that chronic exposure to manganese (Mn) produces increased levels of amyloid-beta precursor-like protein-1 (APLP1), a member of the APP family, and diffuse amyloid-beta plaques in the frontal cortex of non-human primates. These changes in APLP1 and amyloid-beta were associated with neuronal degeneration including hypertrophic nuclei, intracytoplasmic vacuolization, increased silver staining and apoptosis. These novel findings suggest that chonic Mn exposure dysregulates the APP processing leading to increased amyloid-beta production and diffuse amyloid-beta plaques in the non-human primate brain.

S 668 EARLY–LIFE EVENTS MAY TRIGGER BIOCHEMICAL PATHWAYS FOR ALZHEIMER 'S DISEASE: THE "LEARN" MODEL.

D. K. Lahiri. *Indiana University School of Medicine, Indianapolis, IN.* Sponsor: N. Zawia.

Alzheimer's disease (AD), the most common form of dementia among the elderly. In addition to genes, environmental factors, including diet, metals and life style, play an important role in the development of disease phenotype. To explain the etiology of AD, we have recently proposed and tested the "Latent Early Associated Regulation" (LEARn) model, which postulates a latent expression of specific genes triggered at the developmental stage. This model integrates both the neuropathological features and environmental factors associated with the disease. The LEARn model operates through the regulatory region (promoter) of the gene and by affecting the methylation status within the promoter of specific genes.

S 669 EPIGENETIC IMPLICATIONS TO TOXICOLOGY.

R. Rasoulpour[1], K. Gabrielson[2], J. Goodman[3], M. Costa[4], R. Jirtle[5], J. Herman[6], S. Ho[7] and C. Harris[8]. *[1]The Dow Chemical Company, Midland, MI, [2]Johns Hopkins University, Baltimore, MD, [3]Michigan State University, East Lansing, MI, [4]New York University School of Medicine, New York, NY, [5]Duke University, Durham, NC, [6]Johns Hopkins University, Baltimore, MD, [7]University of Cincinnati, Cincinnati, OH and [8]National Institutes of Health, Bethesda, MD.*

The emerging field of epigenetics may profoundly impact the future of toxicology. Epigenetics can be defined as heritable changes in gene expression that do not involve genetic mutations and are propagated without continued stimulus. Discrete chemical modifications of the chromatin can regulate gene expression or repression and can be transmitted to daughter cells or future generations due to epigenetic memory. Although potentially reversible, these heritable changes may be classified as transgenerational, mitotic, or meiotic, implicating the wide-ranging impact of epigenetic control in cellular function. These epigenetic processes play fundamental roles in cell proliferation, differentiation, cancer development and toxicities. Epigenetic processes that occur in the cell include DNA methylation/demethylation at CpG islands, small nuclear RNA processes and protein acetylation/deacetylation. Understanding how these modifications are inherited from mother cells to daughter cells or from an organism to its progeny remains a major scientific challenge. Recently, there has been a growing concern that epigenetic events may play a role in chemically and/or nutritionally driven adverse health effects, with particular focus toward reproductive toxicity and non-genotoxic carcinogenesis. For example, changes in DNA methylation which target tumor suppressor and DNA repair genes for silencing is a well established and valid step in cancer etiology. Overall, although the current literature consists of relatively few studies, there has been considerable interest by the popular press, government agencies, and the scientific community. Therefore, it is important to provide an introduction to epigenetic mechanisms and to highlight the current state-of-the-science in epigenetic toxicology.

S 670 EPIGENETIC MECHANISMS OF NICKEL ION CARCINOGENESIS.

M. Costa and H. Chen. *NYU School of Medicine, New York, NY.*

Water insoluble nickel (Ni) compounds are carcinogenic due to delivery of high concentrations of Ni ions into cells by phagocytosis and dissolution. The major target of Ni ions in cells is the iron-, ascorbate-, oxoglutarate-dependent dioxygenase enzymes. Examples of these enzymes include the HIF prolyl hydroxylases, the Alk B DNA repair enzyme homolog's including the FTO and the newly-discovered histone H3 demethylases. The specificity in Ni inhibition is because all these enzymes contain loosely bound Fe within a 2-His-1-carboxylate triad termed in some enzymes the JMJC domain. Since Fe binding to this domain is required for catalytic activity and Ni ions readily displace Fe from all of these enzymes, Ni exposure results in essentially inactive enzyme. Ni ions were found to induce global DNA and H3K9 methylation by inhibiting the H3K9 histone demethylase of which JHDM2A is an example. Preincubation of recombinant JHDM2A with 5 uM Ni ions essentially inactivated the enzyme since even 2000 uM Fe ions were not able to displace the Ni ions from the active site of the enzyme. A ratio of Ni ions to enzyme molecules of ~1:1 was required for complete inhibition. Since Ni ions are one of the least toxic metal ions, this ratio was easily achievable at non-toxic levels. Transfection of flag-tagged JHDM2A resulted in a loss of H3K9 Dimethylation which was prevented when cells were treated with Ni ions, indicating that this enzyme was a target of Ni ions in intact cells. Ni ion exposure as well as knockdown of JHDM2A resulted in the down-regulation of a number of genes which remained low in expression for as much as 25 days after Ni ions were removed from the media, suggesting that there is epigenetic inheritance of gene expression changes brought about by Ni ion exposure. The genes most stably downregulated by Ni ion exposure had greater H3K9 Dimethylation changes in their promoter based upon Chip assays. Chip on chip using H3K9 di me and H3K4 tri me antibodies mapped the coordinates on the promoter of genes that were up or down regulated and these changes were correlated with down regulation (H3K9 di me) or up regulation (H3K4 tri me) marks in their promoters.

S 671 EPIGENETICS: THE NEW GENETICS OF TOXICOLOGY.

R. Jirtle. *Department of Radiation Oncology, Duke University, Durham, NC.*

This presentation will be in two parts: 1) present data on a recently development computer-learning algorithm that predicts 600 imprinted genes in mice versus 156 in humans with a mere 30% overlap between the two; and, 2) show data on how in utero maternal dietary supplementation with various compounds causes an alteration in expression of the metastable Avy allele as a sensor for epigenetic changes.

S 672 EPIGENETIC REGULATION IN DEVELOPMENT: IMPLICATIONS IN STEM CELL BIOLOGY AND TOXICITIES.

J. Herman. *Department of Oncology, Johns Hopkins University, Baltimore, MD.* Sponsor: K. Gabrielson.

Epigenetic mechanisms are important in cancer stem cell biology. Environmental toxins such as NNK have been shown to alter DNA methylation patterns. This presentation will review the epigenetic mechanisms involved in gene expression modulation of cancer stem cells by alkylating agents including NNK, a nitrosamine component of cigarette smoke.

S 673 IS THERE A COMMON "E-EPIGENOME"?

S. Ho. *Department of Environmental Health, University of Cincinnati, Cincinnati, OH.*

Estrogen and estrogen mimics are now known to have distinct epigenetic effects on various reproductive end organs. Focusing on DNA methylation changes induced by the natural estrogen or its mimics in the environment, we asked the question of whether there is a common set of genes whose methylation status is affected by estrogens/estrogen mimics in a convergent manner that transcends tissue specificity. The effects of estradiol-17beta, bisphenol A, diethylstilbestrol, soy-estrogens were investigated for their epigenetic effects on the prostate, uterus, and breast to determine if an "e-epigenome" could be identified and/or constructed.

S 674 MICRORNA EPIGENETIC REGULATION.

C. C. Harris. *Chief, Laboratory of HUman Carcinogenesis, CCR, NCI, National Institutes of Health, Bethesda, MD.* Sponsor: K. Gabrielson.

Infection and chronic inflammation contribute to about 1 in 4 of all cancer cases. Mediators of the inflammatory response, e.g., cytokines, free radicals, prostaglandins and growth factors, can induce epigenetic changes influencing tumor suppressor gene expression. Recent discovery of an interaction between microRNAs and innate immunity during inflammation has further strengthened the association between inflammation and cancer. This presentation will review microRNA molecules as they regulate gene expression important in the pathogenesis of toxicities and carcinogenesis.

S 675 IMMUNOMODULATION DURING COMPLEMENTARY AND ALTERNATIVE MEDICINE (CAM) THERAPY: RISKS AND BENEFITS.

P. S. Nagarkatti. *Pathology, Microbiology and Immunology, University of South Carolina School of Medicine, Columbia, SC.*

There are over 40 million Americans who suffer from some form of degenerative disease and it is estimated that approximately one third of them will attempt using complementary and alternative medicine (CAM) to alleviate pain and suffering. Of the various CAM therapies, the use of plant products remains popular. However, there is lack of sufficient experimental and clinical proof that they are safe and effective. In 1998, the National Center for Complementary and Alternative Medicine (NCCAM) was established by the U.S. Congress as one of the NIH Institutes to provide funds to investigate if the popular CAM modalities are truly beneficial. In the United States, while drugs must be approved by the FDA as being safe and effective before they can be sold, the FDA is not authorized to evaluate the safety or efficacy of dietary supplements. However, the FDA can ban the sale of supplements that are shown to be unsafe. On the other hand, the immunosuppressive properties of plant products, if found safe, can also be used to develop new therapeutic modality against inflammatory and autoimmune diseases. Herbal and plant-derived compounds are widely available in the market that claim to sustain, restore or enhance immunity. To begin addressing this issue an overview of CAM therapy with an emphasis on herbal and plant-derived compounds and their potential risks/benefits will be highlighted for their immunomodulatory properties. Benefits versus the risks of using certain plant-derived products that constitute CAM will be discussed including Cat's Claw, Echinacea, Ginseng, Thunder God Vine, Aristolochia, Kava, Ephedra and St. John's Wart.(Supported in part by NIH grants R01-DA016545, R01-ES09098, R01-AI053703, R01-AI058300, R01-HL058641, and P01-AT003961).

S 676 IMMUNE MODULATION BY PLANT-DERIVED CANNABINOID COMPOUNDS.

B. L. Kaplan[1, 2] and N. E. Kaminski[1, 2]. *[1]Center for Integrative Toxicology, Michigan State University, East Lansing, MI and [2]Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

Cannabinoids are a group of more than 60 plant-derived compounds from the plant Cannabis sativa, more commonly known as marijuana. Use of marijuana for medicinal purposes is an ongoing debate in the United States, although the mechanisms by which it exerts any therapeutic benefits are not fully elucidated. Further complicating our understanding of the risk/benefit ratio of medical marijuana use is the demonstration that many plant-derived cannabinoid compounds, such as Δ^9-tetrahydrocannabinol (Δ^9-THC) and cannabidiol (CBD), also modulate immune function. For example, CBD either stimulated or suppressed interleukin-2 (IL-2) or interferon-γ (IFN-γ) protein production from primary mouse splenocytes depending on the magnitude with which the leukocytes were stimulated. The objective of these studies was to characterize the molecular mechanisms by which plant-derived cannabinoid compounds modulate immune function. Using phorbol ester plus calcium ionophore (PMA/Io) to stimulate the splenocytes "optimally" (40 nM PMA/0.5 μM Io), CBD suppressed IL-2 and IFN-γ steady state mRNA levels. In contrast, CBD enhanced IL-2 and IFN-γ steady state mRNA levels in splenocytes stimulated "suboptimally" (4 nM PMA /0.05 μM Io). Concordant with this, NFAT transcriptional activation was either suppressed or enhanced by CBD when human Jurkat T cells were stimulated optimally or suboptimally, respectively. Interestingly, CBD enhanced intracellular calcium in resting cells, which was further enhanced with PMA/Io regardless of the magnitude of stimulation. Overall, these results suggest that the plant-derived cannabinoid, CBD, might affect immune function differentially depending on the magnitude with which the immune system is stimulated.

S 677 MECHANISMS OF RESVERATROL-INDUCED IMMUNOMUDULATION AND ITS POTENTIAL USE IN THE TREATMENT OF INFLAMMATORY AND AUTOIMMUNE DISEASES.

P. S. Nagarkatti and M. Nagarkatti. *Pathology, Microbiology and Immunology, University of South Carolina School of Medicine, Columbia, SC.*

Resveratrol (3,5,4'-trihydroxystilbene), which is found in many plants, including mulberries, red grapes and peanuts, possesses anti-cancer and anti-inflammatory properties. Recent studies from our laboratory have demonstrated that resveratrol activates AhR and ER thereby triggering apoptosis in activated T cells. In vitro studies on the mechanism of action revealed that resveratrol triggered high levels of apoptosis in activated T cells and to a lesser extent in unactivated T cells. Moreover, resveratrol-induced apoptosis was mediated through up-regulation of AhR, Fas, and FasL expression. In addition, resveratrol-induced apoptosis in primary T cells correlated with cleavage of caspase-8, caspase-9, caspase-3, poly(ADP-ribose) polymerase, and release of cytochrome c. In vivo, resveratrol was also found to decrease the induction of Th17 cells while increasing the generation of FoxP3+ Tregs. We have shown that resveratrol can suppress a wide range of inflammatory disorders including the murine model of multiple sclerosis, known as experimental autoimmune encephalomyelitis (EAE). Resveratrol administration also led to significant down-regulation of certain cytokines and chemokines in EAE-induced mice including tumor necrosis factor-alpha, interferon-gamma, interleukin (IL)-2, IL-9, IL-12, IL-17, macrophage inflammatory protein-1alpha (MIP-1alpha), monocyte chemoattractant protein-1 (MCP-1), RANTES, and Eotaxin. Resveratrol was also effective on a wide range of inflammatory disorders including colitis, bacterial super antigen-induced lung injury and graft-versus-host disease. These studies demonstrate, for the first time, the ability of resveratrol to trigger apoptosis in activated T cells and its potential use in the treatment of inflammatory and autoimmune diseases including, MS (Supported in part by NIH grants R01-DA016545, R01-ES09098, R01-AI053703, R01-AI058300, R01-HL058641, and P01-AT003961).

S 678 IMMUNOMODULATION BY N-3 POLYUNSATURATERD FATTY ACIDS.

J. Pestka[1, 2]. *[1]Center for Integrative Toxicology, Michigan State University, East Lansing, MI and [2]Microbiology and Molecular Biology, Michigan State University, East Lansing, MI.*

Clinical studies suggest that consumption of n-3 polyunsaturated fatty acids (PUFAs) derived from marine sources and algal fermentation might be efficacious for both prophylaxis and treatment of inflammatory diseases. Although nearly 26 million Americans over 18 years of age currently consume n–3 PUFAs, mechanisms of action of these supplements remain incompletely understood. Critical gaps exist in our knowledge of how n-3 PUFAs attenuate immune gene expression and impact responses to pathogens. This gap impairs: (1) prediction of which inflammatory diseases n-3 PUFAs would be most effective; (2) knowledge of required n-3 PUFA therapeutic concentrations in tissues and corresponding dosages to achieve these; and (3) mechanism-based safety assessment of n-3 PUFAs. Recent studies in our laboratory have focused on the mechanisms by which n-3 PUFAs modulate abnormal pathologic and normal requisite IgA production in the mouse. n-3 ameliorative effects on pathologic IgA was addressed using an experimental IgA nephropathy model induced by feeding the mycotoxin, deoxynivalenol (DON). Responses to gut mucosal infection by reovirus were used to gauge n-3 suppression of the normal IgA response. The results of these studies provide insight into therapeutic ratio for n-3 PUFA suppression of pathologic effects relative to impairment of normal immune response.

S 679 IMMUNOMODULATION BY 3.3'-DIINDOLYLMETHANE.

L. Bjeldanes[1] and J. Pestka[2]. *[1]Department of Nutritional Sciences and Toxicology, University of California, Berkeley, Berkeley, CA and [2]Department of Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI.*

3,3'-Diindolylmethane (DIM) is a natural autolytic product present in food plants of the Brassica genus. The anticarcinogenic effects of DIM are well established in rodent models and the compound is currently in several clinical trials. In a series of studies of the effects of DIM on immune function, we observed that DIM activated the interferon gamma (IFNγ) signal transduction pathway in human breast cancer cells. MCF-7 cells were found to express IFNγ mRNA and to secrete IFNγ protein into the culture medium, in response to DIM treatment. DIM treatment also activated the expression of the IFNγ receptor (IFNGR1) and the IFNγ responsive genes, p56 and p69-OAS. DIM also produced a synergistic activation with IFNγ of interferon-inducible-reporter constructs in transfected cells. Combined treatment with DIM and IFNγ produced a synergistic increase in level of MHC-I expressed

on the cytosolic membrane, as well as increased levels of mRNAs of associated proteins and transporters. In a subsequent study we used promoter deletion constructs to determine that DIM can activate IFNγ expression by a mechanism that involves stimulation of JNK and p38 stress signaling pathways and displacement of the negative regulatory factor, CREB, from a specific IFNγ promoter regulatory element. Finally, in rodent studies we found that DIM induced proliferation of splenic lymphocytes, augmented mitogen- and IL-2-induced splenic lymphocyte proliferation. DIM also stimulated the production of ROS by murine peritoneal macrophage cultures. Oral administration of DIM, but not intraperitoneal injection, induced elevation of serum cytokines in mice, including interleukin (IL)-6, granulocyte-colony stimulating factor (G-CSF), IL-12 and IFN-γ, enhanced both clearance of reovirus from the GI tract and the subsequent mucosal IgA response. Thus, DIM is a potent stimulator of immune function in both tumor cells and in the response of rodents to immune challenge.

S 680 EOTAXIN-1 INHIBITION BY 7, 4-DIHYDROXY FLAVONE ISOLATED FROM GLYCYRRHIZA URALENSIS.

X. Li. *Department of Pediatrics and Immunobiology, Mt. Sinai School of Medicine, New York, NY.* Sponsor: B. Kaplan.

Eosinophilic inflammation plays an important role in pathological mechanisms of asthma. Eotaxin, a CC chemokine, stimulates the migration of eosinophils from blood into the lungs by acting on the CC chemokine receptor CCR3. The human lung fibroblast cell line (HFL-1 cell), which produces eotaxin, has been widely used to investigate of mechanisms of inflammation and anti-inflammatory therapy. There is an increasing interest in investigating botanical products for treatment of allergy and asthma. In a controlled clinical study, we showed that an anti-asthma herbal medicine intervention (ASHMI) significantly improved lung function, reduced symptom scores and reduced beta-2 agonist use. We recently showed that ASHMI suppressed eotaxin production by HFL-1 cells. Glycyrrhiza uralensis (G. uralensis) Chinese licorice (Gan-Cao), is one of the most commonly used herbs in Traditional Chinese Medicine and is a constituent in ASHMI. Previous study showed that glyrrhyzin, a compound isolated from G. uralensis had an inhibitory effect on eotaxin production. Here we report the structure and biological activities of flavonoids isolated from G. uralensis, and compare the potency of these flavonoids with glyrrhyzin. We demonstrated that 7, 4-dihydroxy flavone from G. uralensis suppressed eotaxin production in vitro and airway eosinophilic inflammation in a murine model of allergic asthma. Studies on pure compounds will enhance our understanding of the pharmacological mechanisms G. uralensis and may lead to a novel therapy for asthma and perhaps other inflammatory diseases.

S 681 NANOTOXICOLOGY AND DRUG DELIVERY.

C. Somps and R. Chapin. *Drug Safety, Pfizer Global R&D, Groton, CT.*

The biopharmaceutical industry is looking at the rapidly developing, multifaceted field of nanotechnology as an opportunity for improved approaches to drug development. A good example is the ongoing effort to exploit the unique physical and chemical properties of nanoscale materials for the purpose of improved drug delivery. Using nanoparticles with targeting ligands to precisely deliver a drug payload to a specific diseased tissue, while by-passing all other parts of the body, would clearly represent a game changing approach to drug development. However, before that future vision can be realized, significant unknowns and gaps in our understanding of the toxicology of nanoscale drug delivery platforms will need to be addressed. Academic and industry researchers, as well as government regulators, interested in the unique safety issues confronting drug developers will explore the use of nanomaterials for improved drug delivery. The program will consider the design and development of nanomaterials compatible with the unique requirements for drug delivery and therapy, focusing on material distribution and safety when intentionally delivered into physiologic systems. Special emphasis will be placed on properties that influence absorption, distribution, metabolism and excretion of nanomaterials, including immune system interactions, and properties that influence the toxicity of nanomaterials and their degradation products. Finally, we will explore the FDA's current activities toward developing a regulatory framework to support the development and safe use of nanomedicine products, including nanoscale drug delivery platforms.

S 682 DESIGNING FAVORABLE ELIMINATION FEATURES INTO NANOSCALE DRUG DELIVERY SYSTEMS.

P. J. Sinko. *Rutgers University, Piscataway, NJ.* Sponsor: C. Somps.

Our lab has been involved in the design, synthesis, characterization and evaluation of targeted PEG-based nanocarriers for the treatment of AIDS and certain other types of cancers (e.g., DCIS breast cancer). Nanoscale drug delivery allows for the precise control of drug concentrations and exposure times in target organs, tissues and in specific cell types. This is a major advantage since therapy is maximized (i.e., high local concentrations of drug can be achieved) while drug toxicity is minimized (i.e., healthy tissues are not being exposed unnecessarily to drug). However, unlike conventional macroscale dosage forms where excipients are either not absorbed into the body or are readily eliminated, the biological fate of the materials comprising nanoscale delivery systems is not fully understood. The physical, chemical and biological properties of biocompatible materials that are known or suspected to influence elimination from the body will be briefly reviewed and several case studies will be discussed. Following this, our efforts to design biodegradable dimeric nanocarriers will be described. These flexible nanocarriers have features that are counterintuitive to currently used PEGylation approaches (i.e., they have been designed to enter into cells not remain in the blood, deliver their cargo then selectively degrade into components that can be readily eliminated via the kidneys). Several features will be discussed including target cell uptake, blood and target cell persistence, toxicity and effectiveness in in vitro and in vivo models. Finally, a detailed analysis of the "enhanced elimination" design elements relating to the selective intracellular degradation of the dimeric nanocarriers will be presented followed by results supporting our hypothesis.

S 683 EVALUATION OF CANCER NANOTHERAPEUTICS' STABILITY AND DISPOSITION.

S. T. Stern. *Nanotechnology Characterization Laboratory, SAIC-Frederick, Inc., NCI-Frederick, Frederick, MD.*

Nanotechnology is finding increasing application in cancer therapy. Nanotechnology-based drug delivery platforms offer the potential to rejuvenate traditional chemotherapeutics by improving safety and efficacy profiles. For example, nanotechnology platforms can target drugs to tumor sites via passive mechanisms, resulting from the inherent leakiness of the tumor vasculature, and via active ligand-receptor dependent targeting mechanisms. Nanotechnology can also eliminate the need for the toxic vehicles required for administration of hydrophobic drug entities. Platforms presently undergoing evaluation include nanoemulsions, nanoliposomes, and metal, polymeric and carbon-based nanoparticles. Critical parameters that can influence the success of nanotechnology platforms include stability, clearance and tissue permeability. This presentation will specifically address the importance and challenges of monitoring the disposition and in vivo integrity of nanotechnology platforms, using preclinical and clinical case studies to demonstrate the analytical methodologies and the pharmacokinetic models employed. Examples will include radiolabel, elemental analysis, ELISA, LC and imaging techniques, with resulting data analyzed by both compartmental and noncompartmental methods. Funded by NCI Contract N01-CO-12400

S 684 SAFE DESIGN OF NANOPARTICLES FOR THERAPY AND IMAGING: PHYSICAL AND CHEMICAL CHARACTERISTICS.

M. A. Philbert. *University of Michigan, Ann Arbor, MI.*

A variety of nanoparticles are under development for medical imaging and therapy. Particle chemistries for imaging vary from metals and metalloids to polymer/metal or polymer/metal chelate composites. Therapeutic nanoparticles include nanometer-sized crystals of drug, dendrimer polymers containing drugs and/or photosensitizers and other polymers housing combinations of drug and/or photosenitizers. The surfaces of each of these nanoparticle formulations may be further modified to enable targeting (peptides, antibodies, nucleotide polymers, etc.), to prevent agglomeration or to avoid the reticulo-endothelial system. Each of these modifications may have unintended biological, pharmacological and toxicological consequences. This presentation will address a range of issues associated with the safe development of nanoparticles for imaging and photodynamic therapy and will examine the effects of particle modifications on ADME and therapeutic efficacy. Acknowledgements: NIEHS-ES08854; NCI-N01-CO-37123, Air Force-FA9550-06-1-0098.

S 685 NANOPARTICLE INTERACTIONS WITH IMMUNE SYSTEM.

M. A. Dobrovolskaia. *ATP, NCL, SAIC-Frederick, NCI-Frederick, Frederick, MD.* Sponsor: S. Stern.

The unique physicochemical properties of nanosized particles make them attractive candidate drugs or drug carriers. A nanoparticle's interaction with immune cells and plasma proteins may influence its biodistribution and drug delivery, so understanding the physicochemical properties which determine this interaction is an important part of preclinical development of nanoparticle-based drugs. This presentation discusses recent advances in our understanding of nanoparticle effects on the immune system; reviews in vitro methods for identifying the properties of nanopar-

ticles which influence immune recognition; gives an overview of some of the properties that have been shown to influence immune system biocompatibility thus far, and details current challenges in the preclinical immunological evaluation of nanoparticles. Funded by NCI Contract N01-CO-12400

S 686 SAFETY CONSIDERATIONS FOR THE REGULATION OF NANOMATERIAL-CONTAINING THERAPEUTICS.

N. Sadrieh. *FDA, SilverSpring, MD.*

Products containing nanomaterials are being investigated for potential applications as therapeutics. While some of these nanomaterials are nanoscale versions of larger materials used in approved products, other nanomaterials are novel and have never been used in drug products. Meanwhile, the regulatory requirements to ensure preclinical safety for products containing such novel materials, remain identical to those requirement for products that do not contain nanoparticles. There are various reasons why there are no "nano-specific" requirements at this time. One reason is that the preclinical studies currently required of sponsors are very comprehensive, and include many studies that measure endpoints that should pick up injury in most organs. Another reason is that, while some have suggested that the current preclinical screening tests might need to be tailored for nanomaterial-containing products, no one has clearly communicated in what respect the current requirements might be lacking in their capacity to assess safety concerns from nanomaterial-containing products, and what are other available tests that might improve the predictive value of the current regulatory preclinical requirements. Nevertheless, it is widely accepted that there are unique features associated with nanotherapeutic products, and these unique features may lead to future challenges for the development, manufacturing, safety evaluation and review of these products. These challenges are both for the sponsor of nanotechnology-based products, as well as for regulatory agencies, who must regulate these products. The FDA must ensure the safety and efficacy of nanomaterial containing products, yet, it must also promote innovation in order provide the public with access to the best medical products. With this goal in mind, the Agency is working on future guidance documents to help industry bring to fruition the promise of nanotechnology in drug applications.

W 687 LOW-DOSE NON-LINEARITY: WHAT CAN EMERGING TECHNOLOGIES TELL U.S. ?

J. S. Bus[1] and W. Slikker[2]. *[1]Toxicology & Environmental Research & Consulting, The Dow Chemical Company, Midland, MI and [2]U.S. FDA /NCTR, Jefferson, AR.*

Characterization of dose-response, as captured in the *Paracelsus* phrase, "The dose makes the poison", is a central tenant to the field of toxicology and risk assessment. Until recently, methodological limitations have prevented comprehensive examination of many of the fundamental biological phenomena underlying both toxicological responses and risk assessment assumptions at or below the low end of traditionally-defined toxicity dose-response curves. Relatively recent and rapid advances in cellular, biochemical, toxicogenomic, and analytical technologies, however, are now presenting opportunities to more accurately and comprehensively characterize the nature of dose-response curves, including its shape in low-dose ranges that are more relevant to actual, real-world human exposures. To this end, and pursuant to the recent recommendations proposed by the National Academies/National Research Council Report and a joint SETAC-SOT sponsored Pellston Conference (NAS, "Applications of Toxicogenomic Technologies to Predictive Toxicology and Risk Assessment, 2007; DiGiulio and Benson, "Genomic Approaches to Cross-Species Extrapolation in Toxicology," 2007), the practice of applying emerging technologies to characterize toxicant-induced responses in the low-dose range and shape of the dose-response are now being realized. Importantly, application of these molecular-level technologies may allow a more complete and predictive analysis of responses and/or associated risk assessment assumptions that are key to understanding human relevance of responses observed at the low end of the dose-response curve, i.e., decisions of whether to apply linear versus non-linear risk assessment approaches. Low-end dose-response analysis using emerging technologies on a number of diverse-acting compounds such as direct genotoxicants, cytotoxicants, and receptor-mediated and undefined-acting toxicants, and will discuss the evidence for the existence, or lack thereof, of thresholds and non-linearity for genomic and other biological responses to xenobiotics will be addressed.

W 688 THE POTENTIAL OF GENOMIC DOSE-RESPONSE DATA TO DEFINE MODE-OF-ACTION AND LOW-DOSE BEHAVIOR OF CHEMICAL TOXICANTS.

R. S. Thomas[1], B. C. Allen[2], L. Yang[1], H. J. Clewell[1] and M. E. Andersen[1]. *[1]The Hamner Institutes for Health Sciences, Research Triangle Park, NC and [2]Bruce Allen Consulting, Chapel Hill, NC.*

There is increasing acceptance within the toxicology community that high dose animal studies are not predictive of low dose risks in humans or even in the test animals themselves. New genomic technologies now provide a unique opportunity to evaluate the relevance of current low dose default assumptions used in chemical risk assessment and identify dose-dependent transitions in modes of action. In this presentation, we describe the application of benchmark dose analysis to gene expression microarray data collected following ninety day exposures to five different lung and liver carcinogens. The benchmark dose methods were used to estimate doses at which different cellular processes are altered and showed that benchmark dose values for certain processes mirrored the tumor response in a two-year rodent bioassay. The results show that dose-response changes in gene expression, when related to higher-order biological processes and pathways, reflect the dose dependent changes in key events in the carcinogenic process and can support nonlinear modeling of the events in the low dose region within the framework of a mode of action risk assessment.

W 689 TRANSCRIPT PROFILING TO ELUCIDATE RESPONSES TO ESTROGENS AT DOSE LEVELS BELOW THE TRADITIONAL NO OBSERVED ADVERSE EFFECT LEVEL.

G. Daston and J. Naciff. *Miami Valley Labs, Procter & Gamble, Cincinnati, OH.*

The nature of the dose-response curve at levels below the no-observed adverse effect level is a contentious issue in risk assessment. Resolution of the debate has been difficult because the resolving power of most experimental methods is too limited to support conclusions about response at very low doses. One controversy has been the possibility of non-monotonic dose-response curves for estrogens on the developing male reproductive system. Some labs report effects on prostate or testis development at dose levels well below the NOAEL from standard toxicity studies. Other labs have been unable to replicate these findings. An NTP panel concluded that it is impossible to dismiss the former results because the magnitude of the effect is small and subject to sources of variability that could hinder detection at the limits of resolution. We have applied genome-wide analysis of gene expression to this problem. Gene expression analysis is particularly amenable to this question because 1) it has sub-attomolar sensitivity; 2) virtually every toxic response is accompanied by changes in gene expression; and 3) it is unbiased because expression of every gene in the genome is evaluated. We treated pregnant SD rats with ethynyl estradiol, genistein or bisphenol A at dosages ranging from 0.001-10 ug/kg/day, 0.001-100 mg/kg/day, or 0.002-400 mg/kg/day, respectively, from GD11-20. mRNA from fetal testes was isolated and evaluated on Affymetrix microarrays. All three treatments produced significant changes in gene expression. The dose-response curves for all three were monotonic, with numbers of genes and magnitude of change decreasing with decreasing dose. There was no evidence of non-monotonicity or of unique sets of genes for which expression changed at very low doses and there were apparent thresholds of expression. This result supports the conclusion of monotonicity in the shape of the dose-response curve, and of lack of effect at low doses, and demonstrates the power of microarray analysis to elucidate dose-response behavior below the traditional NOAEL.

W 690 PHENOTYPIC ANCHORING OF CARCINOGEN-INDUCED GENE EXPRESSION TO DNA ADDUCT LEVELS REVEALS A COINCIDENCE BETWEEN THE NO TRANSCRIPTIONAL EFFECT LEVEL (NOTEL) AND THE NO DETECTABLE ADDUCT LEVEL (NODAL).

H. Zarbl[1], K. Yeung[2], J. Glick[3], C. Ceailles[3], Q. Wang[1] and P. Vouros[3]. *[1]Robert Wood Johnson Medical School, UMDNJ, Piscataway, NJ, [2]University of Washington, Seattle, WA and [3]Northeastern University, Boston, MA.*

We previously described a toxicogenomic approach to explore the relationship between the DNA adduct formation and the transcriptional responses in cells exposed to decreasing doses of genotoxic carcinogens. For *in vitro* studies, logarithmically growing human BEAS-2B bronchial epithelial cells were dosed with the active metabolite of PhIP (N-hydroxy-PhIP) or benzo[a]pyrene-r-7,t-8-dihydrodiol-t-9,10-expoxide (BPDE) at concentrations ranging from 10^{-5} to 10^{-11} M. The toxicity and mutagenicity of the compounds were assessed at each dose. Total RNA and DNA were simultaneously isolated from each of the exposed cultures using the Qiagen AllPrep™ kit. Microarray data were extracted and analyzed for changes in gene expression as a function of carcinogen dose. Transcriptional profiles were analyzed using both frequentist and Bayesian approaches, and assessed using various biochemical pathway mapping tools. For measurements of adduct formation, genomic DNA was digested to mononucleosides and the adducted bases enriched by snake venom phosphodiesterase. DNA adduct levels were measured using an Agilent ion trap MS with a HPLC Chip Cube interface. Using this approach, adducts were detected in the dosing range of 10^{-5} to 10^{-8} M N-hydroxy-PhIP concentrations. Significantly, doses of carcinogen that failed to yield detectable DNA

adduct levels (NODAL) corresponded closely to the doses that had no observable effect on the cells gene expression profile (NOTEL). Analyses of similar *in vivo* experiments using Fischer 344 rats exposed to deceasing, non-tumorigenic doses of N-nitroso-N-methylurea (NMU) are in progress. Our findings have significant implications for the use of linear low dose extrapolations in risk assessment for genotoxic compounds and carcinogens, and suggest that toxicogenomic assays may provide useful endpoints for benchmark dose modeling.

W 691 LOW-DOSE GENOTOXICITY ASSESSMENT USING BIOMARKERS OF INTERNAL DOSE AND FLOW CYTOMETRY-BASED MICRONUCLEUS ASSAY: LOW-DOSE ACRYLAMIDE STUDY IN MICE.

L. Recio[1], E. Zeiger[2], T. R. Fennell[3], J. Haseman[4], R. W. Snyder[3] and M. Friedman[5]. *[1]ILS, Inc., RTP, NC, [2]Errol Zieger Consulting, Chapel Hill, NC, [3]RTI International, RTP, NC, [4]J.K. Haseman Consulting, Raleigh, NC and [5]University of Louisville School of Medicine, Louisville, LA.*

Low-dose genotoxicity studies require robust measures of dose and response. Measures of internal dose based on PB-PK dosimetry, hemoglobin adducts or DNA adducts and a "high content" flow cytometry-based micronucleus (MN) assay are useful for low-dose genotoxicity assessments. The MN response in mouse bone marrow, and the shape of the dose-response curve was evaluated in mice administered low doses of acrylamide. B6C3F1 mice were dosed orally with acrylamide for 28 days using logarithmically spaced doses from 0.125-24.0 mg/kg/day, and micronuclei were assessed in peripheral blood reticulocytes and erythrocytes by flow cytometry. Liver glycidamide DNA adducts, and acrylamide and glycidamide N-terminal valine hemoglobin adducts were also determined. Acrylamide produced a weak MN response, with statistical significance at 6.0 mg/kg/day, or greater, in micronucleated reticulocytes (MN-RET) and at 4.0 mg/kg/day or greater in normochromatic erythrocytes (MN-NCE). The MN responses at the lower doses (from 0.125-2.0 mg/kg/day) were indistinguishable from the concurrent and historical controls. When the MN-NCE values were compared to administered dose, the response was consistent with a linear model. However, when hemoglobin or DNA adducts were used as the dose metric, the response was significantly non-linear, and models that assumed a point of departure (POD) of 1 or 2 mg/kg/day provided a better fit than a linear model. The MN-RET dose-response had greater variability than the MN-NCE response, and was consistent with both linearity and with a POD at 1 or 2 mg/kg/day, regardless of the dose metric. These data suggest a threshold below the POD for acrylamide using the in vivo mouse MN assay and provides a framework to assess the shape of the dose-response curve at low doses for genotoxicity.

W 692 BIOLOGICAL THRESHOLDS AND NONLINEAR DOSE-RESPONSES FOR MULTIPLE ENDPOINTS IN METHYL METHANESULFONATE (MMS)-TREATED RATS.

M. J. LeBaron, H. L. Kan, D. R. Geter, L. H. Pottenger, F. Zhang, M. R. Schisler, M. J. Bartels and B. B. Gollapudi. *Toxicology & Environmental Research & Consulting, The Dow Chemical Company, Midland, MI.*

The existence of thresholds for DNA reactive agents is a contentious topic. Using the well-characterized alkylating agent MMS, we sought to evaluate the relationship between dose (administered, systemic, and target), changes in liver transcriptome profile, and genotoxicity (peripheral blood micronuclei) in male Fischer 344 rats. Six animals per group were dosed orally for 4 consecutive days at 0 (DMSO vehicle), 0.5, 1, 5, 25, or 50 mg MMS/kg bw/day (mkd). Characterization of systemic and liver doses was based on hemoglobin (Hbβ) and hepatic DNA adduct levels, respectively. N-terminal methyl (Me)-Hbβ adducts, quantified as signature peptides by HPLC/ESI-MS/MS, demonstrated linear dose-response. Analysis of hepatic DNA for O^6- and N7-methylguanine (MeG) adducts as performed by LC/pESI-MS/MS identified N7-MeG adducts as NQ (not quantifiable; >0.8/10^6 nt and <2.0/10^6 nt), NQ, 2.89, 9.30, 31.8, and 67.9/10^6 nt for control, 0.5, 1, 5, 25, and 50 mkd, respectively. O^6-MeG adducts, however, were NQ (<2.0/10^6 nt) at any dose. Gene expression from hepatic RNA was evaluated, and under the experimental conditions used, there were no significantly altered genes in the 0.5, 1, or 5 mkd dose groups when compared to vehicle control, whereas this number was 20 and 121 at 25 and 50 mkd, respectively. Interestingly, the ratio of altered genes compared to systemic or liver adducts was nearly identical, suggesting optimal MMS activity. Thus, although MMS was systemically available (as evidenced by Hbβ adducts), there were clear thresholds for the induction of hepatic DNA adducts and gene expression changes. Furthermore, genotoxicity data collected from the same treated animals showed a NOEL at an administered dose of 5 mkd and elevated MN frequency at 25 and 50 mkd (p<0.05). Collectively, these results provide evidence for the existence of thresholds for biologically significant events from DNA-reactive agents.

W 693 MATERNAL TOXICITY AND ITS IMPACT ON STUDY DESIGN AND DATA INTERPRETATION.

B. K. Beyer[1] and J. Kim[2]. *[1]Drug Safety Evaluation, sanofi-aventis, Malvern, PA and [2]ILSI Health and Environmental Sciences Institute, Washington, DC.*

Assessing maternal toxicity in DART studies is important because it can potentially influence the study's outcome, thus impacting risk assessment and regulatory decisions. Some degree of maternal/parental toxicity is required in developmental and reproductive toxicity (DART) studies by regulatory agencies. However, excessive maternal/parental toxicity is a confounding factor in study design and data interpretation. There is no clear consensus on levels of toxicity that are high enough to meet regulatory requirements but low enough to avoid confounding data interpretation. In addition, there is a need to distinguish true toxicity from exaggerated pharmacology. It also appears that there may be some differences in species susceptibility to maternal toxicity, with the rabbit being more sensitive than the rat in certain cases. Finally, there are conflicting reports in the literature about the relationship between maternal toxicity and fetal abnormalities. Current views of the issues as they impact study design and interpretation and discussion of these areas in which more knowledge is needed will be addressed.

W 694 OVERVIEW AND BACKGROUND.

R. D. Hood[1, 2]. *[1]Ronald D. Hood & Associates, Tuscaloosa, AL and [2]Department of Biological Sciences, The University of Alabama, Tuscaloosa, AL.*

Adverse effects on the offspring seen only at maternally toxic dosages may be caused by direct effects, indirect (maternally-mediated) effects, or a combination of the two. Effects on developing offspring can also result from maternal stress, as well as (or perhaps in addition to) maternal toxicity. Determining which, if any, of these alternatives is operative in a given study is difficult, typically requiring additional studies to even attempt to make a supportable determination. The issue is complex, and its interpretation can be subject to bias. Thus it remains an area of controversy. Background information will be presented, together with examples of studies where maternal toxicity apparently influenced fetal findings, as well as studies with severe maternal toxicity and few or no obvious effects on the offspring. Current regulatory views of how fetal findings seen at maternally toxic dosages should be interpreted will also be addressed.

W 695 EXAGGERATED PHARMACOLOGY *VERSUS* TRUE TOXICITY.

B. R. Danielsson[1, 2] and M. S. Rocca[3]. *[1]Department of Biopharmaceutical Sciences, Uppsala University, Stockholm, Sweden, [2]Uppsala and Pharmanet Consulting, Stockholm, Sweden and [3]Global Safety, Amgen Inc., Thousand Oaks, CA.*

Maternal toxicity is important in setting doses and interpreting results from embryo-fetal toxicity studies. This is a particular challenge for therapeutic biologics that have a very targeted mechanism of action. Maternal effects may range from no effect at any dose, to effects at all doses, to maternal toxicity due to on-target exaggerated pharmacology. Examples including study designs, dose selection, and results will be presented.

Oxygen is essential for development, and periods of interrupted oxygen supply result in stage-specific malformations and embryonic death. Several drugs are believed to produce embryonic hypoxia and malformations due to vasoconstriction of uterine vessels on the maternal side. Antihypertensives, such as nifedine and felodipine, are associated with hypoxia-related teratogenicity via dilation of peripheral vessels and a diversion of blood flow from central (i.e., uterine) to peripheral vessels in the mother, resulting in a decrease in utero-placental blood. A large number of drugs (> 100) have the potential to cause QT changes on the ECG and cardiac arrhythmia in adults of many species (e.g., humans, rabbits, and dogs, but not rodents) via blockade of the cardiac repolarisation ion channel, IKr. IKr seems to be very important for cardiac rhythm regulation in all species in embryonic life, including the mouse, rat, rabbit, and human. Reviewing scientific and regulatory teratology studies allows the following conclusions to be made: 1) IKr blockers cause embryotoxicity / teratogenicity as a result of embryonic cardiac arrhythmia and hypoxia, 2) toxicity signs due to maternal cardiac arrhythmia occur in the rabbit at lower dosages than in rats because of species differences in IKr expression, 3) embryotoxicity by IKr blockers is often explained by observed maternal toxicity (e.g.,

slight weight changes) even when a direct effect on the embryonic heart is more likely, and 4) high incidences of embryonic death may mask the teratogenic potential of IKr blockers.

W 696 RELATIONSHIPS OF MATERNAL AND FETAL WEIGHT CHANGES IN DEVELOPMENTAL TOXICOLOGY BIOASSAYS.

N. Chernoff. *U.S. Environmental Protection Agency, Research Triangle Park, NC.*
Sponsor: J. Kim.

Standard developmental toxicology bioassays are designed to identify agents with the potential to induce adverse effects in the embryo/fetus. Guidelines require the inclusion of a dose level(s) that induces "overt maternal toxicity". The common occurrence of dose levels at which both maternal and fetal toxicity has been observed has led to a number of attempts to characterize possible toxicological relationships between these endpoints. An analysis of 125 developmental toxicity bioassays in the mouse, rat, and rabbit conducted by the National Toxicology Program from 1982 to 2004 allows a number of general conclusions to be made: 1) most Lowest Observable Adverse Effect Levels (LOAELs) were determined by reduced maternal gestational weight gain or fetal weight at term, 2) maternal weight reductions are associated with reduced food intake for a variety of dissimilar test agents, 3) lower fetal weights were associated with reduced maternal weight gains late in gestation, and 4) the degree of fetal weight reduction is correlated with the extent of the maternal weight loss. In a substantial number of the studies, reduced term fetal weights may, therefore, be due to maternal undernutrition caused by general toxicity rather than direct developmental insult. Consequently, such test agents may be erroneously classified as primary developmental toxicants. There are experimental approaches that can test the hypothesis that maternal undernutrition in standard developmental toxicology bioassays may be responsible for significant term fetal weight decrements.

W 697 POSTNATAL CONSEQUENCES OF MATERNAL TOXICITY.

A. R. Scialli. *Sciences International Inc., Alexandria, VA.*

Exposures that cause human developmental toxicity in the presence of maternal toxicity include maternal alcoholism and therapy with methotrexate and some anticonvulsant medications. There is little evidence that the developmental toxicity is secondary to the maternal toxicity in these cases, but in some cases, the developmental effects appear to be exaggerations of the pharmacological effects of the medication. There are also examples of maternal illnesses that may be associated with developmental toxicity, including diabetes mellitus, hypertension, autoimmune disorders, and nutritional deficiencies. These illnesses may offer an opportunity to study the role of maternal toxicity in developmental toxicity.

W 698 REGULATORY PERSPECTIVES AND CASE STUDIES.

K. L. Davis-Bruno[1] and W. A. Harrouk[2]. *[1]Division of Metabolism and Endocrinology Products, U.S. FDA, Silver Spring, MD and [2]Division of Nonprescription Clinical Evaluation, Office of Nonprescription Products, U.S. FDA, Silver Spring, MD.*

Maternal toxicity can be a confounding factor in DART study design and interpretation. Conflicting published literature exists in describing the relationship between maternal toxicity and fetal abnormalities in DART studies. The regulatory perspective, based on illustrative case studies will be presented, and interpretation of such findings relative to potential clinical relevance and risk will be discussed.

W 699 PESTICIDE MIXTURES: EXPERIMENTAL EVALUATION AND COMPUTATIONAL MODELING.

J. E. Chambers[1] and V. C. Moser[2]. *[1]Mississippi State University, Mississippi State, MS and [2]U.S. EPA, Research Triangle Park, NC.*

Pesticides are applied in the environment to kill insects, weeds, fungi, or other pests. They may be applied in mixtures, or, because of overlapping pest pressures, may result in environmental mixtures because of the proximity of times and spaces over which they are applied. Exposures of humans and other non-target organisms to currently registered pesticides and/or persistent legacy pesticides will, therefore, likely be to pesticide mixtures. Because of the vast number of potential mixtures, predicting the effects of pesticide mixtures for risk assessment purposes is ultimately best accomplished through the use of computational models that are based upon experimental results with defined mixtures. Recent research conducted on the neurotoxic or immunotoxic effects of pesticide mixtures and the mathematical approaches to predictive modeling of the resultant data will be reviewed. Modeling approaches include the use of biomarker data produced for some of these pesticides. We will address exposures to the anticholinesterase insecticides, i.e., the organophosphorus and N-methyl carbamate classes of insecticides and the results in serine esterase inhibition. The levels of inhibition of some of these serine esterases, such as blood cholinesterase, is routinely used, in laboratory animal experiments and in worker exposure monitoring, to assess the level of exposure and potential toxicity. To fully understant these experimental results, biomarker data in terms of experimental results and the use of biomarker data in constructing the computational models will be highlighted.

W 700 CELLULAR SIGNALING PATHWAYS AS A TARGET OF A PESTICIDE MIXTURE.

S. Pruett. *Department of Basic Sciences, Mississippi State University, Mississippi State, MS.*

Dieldrin, a persistent organochlorine insecticide, which is now banned, is still present in the food supply, and a majority of people in the U.S. are exposed at levels greater than the reference dose. Atrazine is the most abundantly used conventional pesticide in the U.S. Risk assessments for these pesticides have been done without considering the probability of concomitant exposure to both compounds. These risk assessments would be quite different if this was considered and these (or any) compounds acted additively or synergistically. In the present study, interactions between these compounds with regard to activation of TLR4 signaling and resultant cytokine production were evaluated. The results demonstrate a greater than additive suppression of IL-6 production and inhibition of NF-kappaB activation in peritoneal macrophages from mice treated with the TLR4 ligand, bacterial lipopolysaccharide (LPS). Inhibition of AP-1 by these agents was essentially additive. Another pro-inflammatory cytokine, IL-12, was affected in a manner similar to IL-6. These changes in cellular activation and cytokine production were not caused by cell death, as indicated by an MTT cell viability/proliferation assay. Initial results indicate that LPS induces a complex between NF-kappaB and AP-1 in this experimental system, and other investigators report that this complex induces much higher levels of transcription that either transcription factor alone. Mathematical modeling with ordinary differential equations was done with the idea that a complex of NF-kappaB and AP-1 binds to the response element for NF-kappaB and increases transcription much more than NF-kappaB alone. A key assumption is that the formation of the complex is reversible and driven by mass action. Modeling based on these concepts predicted levels of IL-6 production very similar to those measured experimentally, indicating that the overall structure of the model is acceptable. Future studies will allow refinement as hard data become available for more parameters. This work was funded in part by grant ES0913708 from NIEHS.

W 701 EVALUATION OF CHOLINESTERASE-INHIBITING PESTICIDE MIXTURES USING A DOSE-ADDITIVE MODEL.

V. C. Moser. *NTD/NHEERL, U.S. EPA, Research Triangle Park, NC.*

Environmental exposures to pesticides generally occur with more than one chemical at a time and through multiple pathways. Cholinesterase-inhibiting pesticides are presumed to act through a common mode of action, that is, inhibition of the acetylcholinesterase enzyme at cholinergic nerve terminals. As such, mixtures of these pesticides are assumed to contribute to the overall response in a dose-additive manner. Statistical models are now available to test such assumptions using mixtures of several to many chemicals. We have used an additivity model based on single-chemical dose-response data to provide predictions of the response of defined mixtures. The predicted response can then be statistically compared to experimentally determined data. The statistical model allows flexibility in the number or mixing ratios of the components, and the pesticides may be combined at levels that reflect environmental exposures, usage patterns, relative potency, etc. We have evaluated behavioral and cholinesterase-inhibitory effects of pesticide mixtures in adult and 17-day old Long-Evans rats. The organophosphorus pesticide mixtures (four or five pesticides) produce significant greater-than-additive responses for most of the endpoints, whereas additivity was observed with some mixtures of N-methyl carbamates (three or seven pesticides). These approaches for studying pesticide mixtures improve evaluations of potential toxicity under varying conditions that may mimic human exposures.
This is an abstract of a proposed presentation and does not reflect US EPA policy.

W 702 *IN VITRO* AND *IN VIVO* EFFECTS OF SEVERAL LOW-DOSE BINARY MIXTURES OF ORGANOPHOSPHORUS INSECTICIDES.

J. E. Chambers. *College of Veterinary Medicine, Mississippi State University, Mississippi State, MS.*

The primary neurochemical target of the organophosphorus (OP) insecticides, acetylcholinesterase (AChE), varies in its sensitivity to inhibition by the various insecticides or their oxon metabolites. The sensitivity to inhibition of protective non-target esterases, such as carboxylesterases, and the efficiency of catalytic detoxifying enzymes, such as paraoxonase (A-esterase), also vary among the various compounds. The response of an organism's AChE (i.e., level and time course of inhibition and recovery) following exposure of any given OP insecticide cannot be predicted by the anticholinesterase potency alone, since the efficiencies of both these protective mechanisms and any required bioactivation will also influence the magnitude and time course of the responses. Prior inhibition of target and non-target esterases from one OP compound will influence the level of response to a second OP compound. Experiments in vitro with preparations of rat brain, where OP detoxication potential is minimal, have indicated that inhibition of AChE to binary or ternary mixtures of low concentrations of OP compounds can be predicted by non-linear mass action models using ordinary differential equations. However these models were not always effective at predicting inhibition of the non-target esterases from binary mixtures in vitro in liver and serum where substantial detoxication mechanisms were present for some OP compounds. Patterns of inhibition of brain AChE following in vivo treatment of rats with low and moderate levels of binary mixtures of OP insecticides could frequently be predicted based upon the potencies of the oxon as an inhibitor of AChE or carboxylesterases, lipophilicity, and likelihood of detoxication by paraoxonase. Thus the in vitro information can be useful in developing predictive models for responses of AChE following exposures to mixtures of OP insecticides. Supported by American Chemistry Council grant 0161 00080636 and US Environmental Protection Agency grant RD 83345101.

W 703 OP INSECTICIDE MIXTURE EXPOSURE: INTEGRATING COMPUTATIONAL APPROACHES AND BIOMARKERS TO RECONSTRUCT DOSE.

B. Reisfeld[1, 2, 3]. [1]*Department of Chemical and Biological Engineering, Colorado State University, Fort Collins, CO,* [2]*Department of Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO and* [3]*School of Biomedical Engineering, Colorado State University, Fort Collins, CO.*

Although various biomarkers have been used to assess exposure to and poisoning from organophosphorus (OP) pesticides/insecticides, the complexity of OP absorption, distribution, metabolism, and elimination, especially for mixtures of these chemicals, warrants integration of computational modeling tools with the biomarker data for more accurate quantitation and assessment of actual whole body exposures and target tissue dosimetry.

In this presentation, we detail the development of a computer-assisted framework to aid in the identification, characterization, and understanding of biomarkers resulting from human exposure to mixtures of OP insecticides, using chlorpyrifos and diazinon as the initial test compounds. The framework uses existing human biomarker data and data from our own intermittent-dose studies, along with information about population and exposure variability and uncertainty, to reconstruct absorbed dose and exposure scenarios. The software may also be used to predict levels of biomarkers resulting from known exposures to these chemicals. Ultimately, we anticipate that the software tool developed, and targeted data acquired, will be useful in informing the cumulative risk assessment process for mixtures of organophosphorus insecticides.

PL 704 *IN VITRO* TO *IN VIVO* CONCORDANCE OF A HIGH THROUGHPUT ASSAY OF BONE MARROW TOXICITY ACROSS A DIVERSE SET OF DRUG CANDIDATES.

A. J. Olaharski[1], H. Uppal[1], D. Goldstein[2], M. Cooper[1], S. Platz[1], T. Zabka[1], J. Jin[1] and K. Kolaja[1]. [1]*Roche Palo Alto, Palo Alto, CA and* [2]*Medicinal Chemistry, Roche Palo Alto LLC, Palo Alto, CA.*

Drug-induced bone marrow toxicity can hinder or derail drug candidate development. The colony forming assay (CFA) has been the most commonly used in vitro method to address this toxicity prior to running in vivo studies, but the associated cost, technical difficulty, and requirement for highly-trained personnel have limited its broader implementation. New platforms that assess hemotoxicity via luminescence is an alternative approach by which the CFA can be run in a high-throughput manner without the requirement for highly trained personnel. This novel assay, the CFC-GEMM HALO® was used to identify bone marrow toxicity in vitro across a structurally diverse set of 56 compounds that have known in vivo toxicological profiles. Concordance of the in vitro assay with in vivo toxicity data, depends upon how the in vitro toxicity limits are set (i.e. should an IC50 value of 5 or 30 μM be considered toxic?). Utilizing various in vitro toxicity classification thresholds, it was identified that a 20 μM in vitro classification provided the highest combination of sensitivity and specificity to in vivo bone marrow toxicity (76 and 73%, respectively). Interestingly, a 1 μM toxicity limit provided the highest specificity (100%) with a moderate level of sensitivity (45%), indicating that if a compound tested below 1 μM in the HALO® assay then there was a perfect prediction of in vivo bone marrow toxicity. The information obtained by the high-throughput CFC-GEMM HALO® assay can be used to rank compounds at earlier stages of development in order to reduce the likelihood of failure at later stages due to bone marrow toxicity.

PL 705 INTERACTIVE EFFECTS OF SEX HORMONES AND PRO-INFLAMMATORY CYTOKINES ON A CULTURED HUMAN HEPATOCYTE CELL LINE.

T. J. Flynn[1] and M. S. Ferguson[2]. [1]*Toxicology, U.S. FDA, Laurel, MD and* [2]*Public Health and Biostatistics, U.S. FDA, College Park, MD.*

Women are more susceptible than men to acute liver injury from hepatotoxic drugs, dietary supplements and other xenobiotics. The underlying biological mechanisms for this gender difference are unknown, but known sex differences in steroid hormone levels and immune response could play a role. A human hepatocyte cell line, HepG2/C3A, was cultured for 8 days in either a male hormone, female hormone, or sex hormone-free medium. The cells were then exposed to a mixture of pro-inflammatory cytokines (IL-1β, IL-6, TNFα) for 72 hours to simulate acute inflammation. Various metabolic functions (e.g., reactive oxygen species, neutral and polar lipid accumulation, CYP activities) were measured fluorometrically, and acute phase proteins were measured in culture medium by ELISA. The effects of cytokines on cell viability (4-8% decrease), generation of reactive oxygen species (8-12% increase) cytochrome P450-1A1/2 activity (20-30% decrease) and acute phase protein production (albumin 10% decrease, IL-1ra 500% increase) were comparable regardless of hormonal environment. However, there were marked gender hormone-related differences in the cellular accumulation of neutral lipids. In the absence of cytokines, relative to the hormone-free group male hormones significantly reduced neutral lipid storage while female hormones significantly increased neutral lipid storage. In the presence of cytokines, relative to the hormone-free group male hormones significantly increased neutral lipid storage while female hormones had no significant effect. These findings suggest that sex hormones and pro-inflammatory cytokines can interact to alter normal liver metabolism in ways that may contribute to the marked gender difference in susceptibility to chemical-induced acute liver injury.

PL 706 SCREENING OF PESTICIDE TOXICITY USING A *C. ELEGANS* HIGH-THROUGHPUT GROWTH ASSAY.

W. A. Boyd[3, 1], M. V. Smith[2], J. R. Rice[3] and J. H. Freedman[1, 3]. [1]*NIEHS, RTP, NC,* [2]*SRA International, RTP, NC and* [3]*NTP, RTP, NC.*

The need for alternative models for assessing the adverse effects of chemicals has been well established. Government agencies are developing the means to effectively prioritize and screen chemicals using high-throughput and alternative toxicological methods. We have developed several endpoints of toxicity using the nematode *Caenorhabditis elegans. C. elegans* is an ideal alternative model organism for toxicological studies because they are inexpensive and simple to use, as well as the large extent of biological knowledge and conservation of many stress responses with higher organisms. Nematodes develop through four larval stages, L1 to L4, before maturing to gravid adult. Our growth assay measures the change in optical density of control nematodes from the L1 to L4 stage over 48h using a COPAS Biosort, a flow cytometer designed to measure *C. elegans*. A library of 320 pesticides was selected for the EPA's ToxCast program, a project designed to collate the results of hundreds of toxicological assays to prioritize future toxicity testing in mammals. After screening the ToxCast library, two approaches were taken to describe the toxicity of the chemicals to *C. elegans*: classification of the toxic effects of chemicals (i.e., hit, safe, borderline) and scoring the relative toxicity of chemicals. Approximately half of the chemicals caused severe decreases in *C. elegans* growth over 48h and were termed 'hits'. Another quarter of the chemicals did not affect growth and were referred to as 'safe'. Of the remaining chemicals, classifications were not always clear for several reasons and were therefore called 'borderline'. In general, nematodes exposed to borderline chemicals exhibited slightly decreased growth but with considerable overlap with the control population. To score chemical toxicities, the relative change in the median optical density of exposed nematodes from t=0 to 48h was calculated for each group. These results demonstrate that *C. elegans* growth can be used to rapidly screen large numbers of chemicals for as part of a tiered toxicity testing approach.

PL 707 TOXICITY SCREENING OF THE TOXCAST CHEMICAL LIBRARY USING A ZEBRAFISH DEVELOPMENTAL ASSAY.

S. Padilla[1], D. L. Hunter[1], B. Padnos[1], D. Corum[2], D. J. Dix[2], K. A. Houck[2], T. B. Knudsen[2] and M. T. Martin[2]. *[1]NTD, NHEERL, U.S. EPA, RTP, NC and [2]NCCT, U.S. EPA, RTP, NC.*

As part of the chemical screening and prioritization research program of the U.S. Environmental Protection Agency, the toxicity of the 320 ToxCast™ Phase I chemicals were assessed using a vertebrate screen of developmental toxicity. Zebrafish embryos/larvae (*Danio rerio*) were exposed from late blastula stage (approximately 6hr post fertilization, pf) to day 5pf (1 day post hatch). The 320 chemicals tested here included 309 unique chemicals, most of which are pesticide actives and metabolites, and several replicates for quality control. All exposures were by immersion, continuously, at a single concentration of 80 µM. On day 5pf, fish were removed from the exposure solution to a control solution without chemicals, and on day 6pf were assessed for death and structural defects (n=4 independent embryos per chemical). Gross structural abnormalities or death was observed with 61% of the 309 chemicals. The developmental toxicity of the chemicals varied by chemical class. Classes in which all members caused either structural defects or lethality included: antiobiotics (mectins and strobins, 7 tested); conazoles (imidazoles and triazoles, 16 tested); organochlorines (4 tested); dithiocarbamates (11 tested); and pyrethroids (12 tested). Other chemical classes showed a range of positive and negative results: 4 of 10 carbamates showed no toxicity; 5 of 36 organophosphates showed no toxicity; and 2 of 6 phthalates showed no toxicity. The 6 neo-nicotinoids tested did not produce any toxicity in the developing zebrafish embryo. In conclusion, the early development of zebrafish is sensitive to many pesticides following exposure at 80 µM, and that sensitivity seems to vary by chemical class. Efforts are underway to compare the response in zebrafish embryos with prenatal developmental toxicity in mammalian systems captured within the U.S. EPA ToxRefDB database. *This abstract may not necessarily reflect official Agency policy.*

PL 708 ASSESSMENT OF OTOTOXICITY AND OTOPROTECTION IN A ZEBRAFISH HAIR CELL MODEL.

W. L. Seng, I. Ezedi, M. Haldi and P. McGrath. *Phylonix, Cambridge, MA.*

Drug-induced ototoxicity from antibiotics and chemotherapeutics can cause hearing loss and vestibular disorders. Conventional histological and auditory functional methods are costly and labor intensive. The structure and function of zebrafish neuromasts, which are arranged in a stereotypical pattern along the head, body and tail, have been shown to be similar to inner ear hair cells in mammals. To facilitate identification of ototoxic and otoprotective agents, we developed a quantitative in vivo zebrafish assay that relies on staining with a live fluorescent dye (DASPEI) followed by image based morphometric analysis (Ton and Parng; Hearing res. (2005). In this study, we first developed a zebrafish gentamicin based ototoxicity model and then screened ~300 potential protectants from the Natural Product Collection (MicroSource Discovery Systems). Zebrafish were exposed to test compound and gentamicin simultaneously by semi-static immersion from day 5 to day 6 post fertilization. At the end of drug treatment, 20, day 6 zebrafish were mounted on depression slides for examination and image capture (NIH Image). Treatment with gentamicin alone caused hair cell loss and neuromast fluorescence intensity decreased to approximately 15% of untreated control. "Hit" criteria" for identifying protential protectants was: "% Protection > 20% and P-value < 0.05". In this screen, four compounds: Angolensic Acid, Methyl Esther, Retusin 7-Methyl Ether, Irigenol, and Juglone exhibited >30% protection against gentamicin induced hair cell damage. The transparency, ease of drug treatment, small amount of compound required and use of statistically significant number of animals per experiment are significant advantages for high throughput morphological and functional analysis of hair cells after drug treatment. Furthermore, results of ototoxicity and otoprotection in zebrafish correlated with results in mammals, underscoring the high degree of conservation among species and supporting use of zebrafish for preclinical drug screening.

PL 709 CARDIAC CHANNEL PANELTM: A CRITICAL PATH TOOL FOR UNDERSTANDING CARDIAC RISK.

G. E. Kirsch, J. Brimecombe, J. W. Kramer and A. M. Brown. *ChanTest Corporation, Cleveland, OH.*

Drug-induced Torsades de Pointes (TdP) is always associated with delayed repolarization (DR; prolonged QT/APD) but DR may not be associated with TdP. Likewise, drug-induced DR may be associated with block of hERG, but hERG block may not be associated with DR. We surveyed 118 drugs that we tested with the hERG assay and for DR using the Purkinje fiber APD assay and the QT in paced, isolated rabbit hearts. We used an IC50 for hERG block of ≤ 1µM, an increase of APD90 ≥10% and an increase of paced QT ≥10% as positives. We found 24% discordance, 16% with positive hERG and negative DR (Type 1 discordance) and 8% with negative HERG and positive DR (Type 2 discordance). The discordances may be resolved by assuming that many drugs act on cardiac channels in addition to or in the absence of effects on hERG. To test this hypothesis, we have assembled a Cardiac Channel PanelTM whose members may include cell lines over-expressing hERG, KvLQT1/minK, Kv1.5, Kv4.3, Kir2.1, Nav1.5, Cav1.2, Cav3.1, HCN2 and HCN4. These cell lines have been validated using manual patch clamp, PatchXpress, QPatch and Ion Works Quattro. We have screened the Cardiac Channel PanelTM using these instruments and have identified effects that explain concordance and both types of discordance. Examples for each case are presented. With automation, the Cardiac Channel PanelTM can be screened accurately, quickly and inexpensively. We propose that screening the Cardiac Channel PanelTM is a Critical Path Tool for understanding and predicting cardiac risk.

PL 710 INCREASED PREDICTIVE VALUE OF STUDIES IN RABBITS WITH VENTRICULAR HYPERTROPHY AND HEART FAILURE FOR PREDICTING ARRHYTHMOGENICITY OF DRUGS IN MAN.

R. Hamlin[1, 2]. *[1]Veterinary Biosciences, The Ohio State University, Columbus, OH and [2]Safety Assessment, QTest Labs, Columbus, OH.*

It is well-known that arrhythmias occur more prevalently in humans with ventricular hypertrophy (VH) and/or heart failure (HF), therefore this study was conducted to demonstrate that rabbits with VH and/or HF serve as models to predict arrhythmia in man. VH was produced by banding of the pulmonary trunk and/or aorta and HF was produced by ligating 1 major and 2 minor coronary arteries. These rabbits and normals were challenged with a drug (dofetilide) which produces torsades de pointes or with programmed electrical stimulation (PES) that produces reentrany arrhythmia. Increased arrhythmogenicity was demonstrated in the following order: HF>(RV+LV)>LVH>RVH>control.Thus, as in man, prexisting heart disease increases likelihood of drug-induced arrhythmia, and rabbits with iatrogenic heart disease may increase predictive value for arrhythomogencity in man. These studies must be extended to include more arrhythmogens and non-arrythmogens to demonsrtate both sensitiviy and specificity.

PL 711 ANALYSIS OF GENE EXPRESSION DATA USING A SYSTEMS BIOLOGY APPROACH: CONCORDANCE OF MODEL PREDICTIONS AND CLINICAL OBSERVATIONS.

K. Subramanian[1], A. R. Bhat[1], A. Radhakrishnan[1], M. K. Narasimha[1], R. Srivatsan[1], R. Kumar[1], R. Radhakrishnan[1], S. Das[1], S. Raghavan[1], V. Gupta[1], H. Ellinger[2], K. Meyer[3], T. Steger-Hartmann[3] and J. Jacob[1]. *[1]Strand Life Sciences, Bangalore, India, [2]Bayer Healthcare AG, Wuppertal, Germany and [3]Bayer Schering Pharmacology AG, Berlin, Germany.* Sponsor: H. Ahr.

A systems model of the rat hepatocyte was created using enzyme and transporter kinetics of proteins belonging to several essential pathways, such as energy metabolism, antioxidant metabolism, bile and lipid homeostasis and cytoskeletal organization, which are known to suffer derangement in the liver during drug-induced toxicity. This approach was found to accurately reproduce liver-like behavior under several physiological and drug-treated situations. The model was tested for its ability to interface with "omics" data. Towards this end, microarray gene expression data from the livers of rats treated with two compounds, BAY 16-4749 from Bayer Healthcare AG, a compound having been dropped out from development, and pyridine as hepatotoxic model compound, were analyzed. Using well-established statistical methods, lists of differentially expressed genes were extracted for both compounds. The analysis yielded a set of 366 genes for BAY 16-4749 and 158 genes for pyridine. This gene list was overlapped with the list of enzymes, transporters and other proteins in the pathways represented in the model to get a subset of proteins whose activities could be considered as altered due to drug exposure. Subsequently, simulations were carried out using the altered activities of these proteins. The gene signatures were taken to reflect protein activity profiles, i.e., the fold change in mRNA was treated as equal to the fold change in protein expression. The model predicted transient cholestasis for BAY 16-4749 and a susceptibility to necrosis for pyridine. The results of the simulations were found to be in concordance with pre-clinical observations

PL 712 V-LIVER: SIMULATING HEPATIC TISSUE LESIONS AS VIRTUAL CELLULAR SYSTEMS.

I. Shah[1], J. R. Pirone[1], K. Houck[1], B. Vallanat[1, 2], C. Corton[2], M. DeVito[2], R. Judson[1], D. Dix[1], T. Knudsen[1] and R. Conolly[1]. *[1]NCCT, U.S. EPA, RTP, NC and [2]NHEERL, U.S. EPA, RTP, NC.*

The US EPA Virtual Liver (v-Liver) project is aimed at reducing uncertainty in estimating the risk of toxic outcomes in humans by simulating the dose-dependent effects of environmental chemicals *in silico*. The v-Liver embodies an emerging field

of research in computational tissue modeling that integrates molecular and cellular scales to simulate adverse outcomes. At its current phase of development v-Liver is a cellular systems model of a complex liver acinus: parenchymal and non-parenchymal cells represented as autonomous biological entities ("agents") connected and spatially organized according to lobular morphology. The tissue microenvironment is dynamically modeled with portal to centrilobular blood flow. Each agent autonomously processes inputs from the microenvironment using biological rules to generate a response. The biological rules and agent responses are derived from prior knowledge and experimental data on hepatocyte (HC) and Kupffer cell (KC) physiology. This includes a range of cellular inputs leading to HC adaptation, HC injury, KC migration, HC necrosis, apoptosis and proliferation. The v-Liver system enables in silico investigation of liver lesions as emergent tissue-level outcomes. We demonstrate the use of the v-Liver to analyze the formation of pre-neoplastic and neoplastic lesions by: (a) selecting non-genotoxic carcinogens, (b) encoding knowledge about carcinogenic MoA as biological rules, and (c) calibrating quantitative agent responses using cell-level *in vitro* data from ToxCast and *ex vivo* tissue samples. In the long-term the v-Liver will aid decision support through *in silico* experiments on new environmental chemicals to qualitatively and quantitatively explore mode-of-action (MoA) knowledge in concert with targeted *in vitro* studies. *This work was reviewed by EPA and approved for publication but does not necessarily reflect official agency policy.*

PL 713 BIOSIMULATION OF DRUG-INDUCED LIVER INJURY.

A. T. De Souza, C. I. Pearson and M. Gishizky. *Entelos Inc., Foster City, CA.*
Sponsor: R. Ulrich.

Drug-induced liver injury (DILI) is the most common cause of regulatory action for new drugs. In its Critical Path Initiative, the FDA identified computer modeling and simulation as important new methods for early prediction of efficacy and safety through a systems-level, mechanistic understanding of human biology. As part of this initiative, the FDA and Entelos are developing a mechanism-based computer model of liver homeostasis and drug-induced injury (the DILI PhysioLab® platform). Data in the public domain provides a basis for building the DILI model. Drug responses from clinical trials and the Entelos DrugMatrix® database (which links rodent gene expression data for 600 compounds to preclinical pharmacology, toxicology and pathology measurements) are also key for model calibration and validation. The model will reproduce both preclinical and clinical responses to specific drugs. The first generation platform is expected to include: (1) representations of healthy rat and human liver physiology, unhealthy states such as necrosis and cholestasis, and injury responses such as fibrosis and inflammation; (2) a reference rat phenotype and three observed human clinical phenotypes (tolerator, adaptor, susceptible); and (3) a dual-species architecture that allows quantitative translation of animal and human responses by incorporating species-specific representations of liver function and response. The platform is expected to advance our understanding of the molecular mechanisms of DILI, including adverse events in pre- and post-regulatory approval. By guiding the selection and validation of preclinical assays and clinical biomarkers that better predict human response, the platform is also expected to improve the concordance between animal data and the results of human clinical trials. Ultimately, the platform will provide mechanistic insights and candidate biomarkers to help optimize clinical trials and better predict "idiosyncratic" DILI adverse events, increasing confidence in promising drug candidates.

PL 714 BIOKINETIC CONSIDERATIONS IN *IN VITRO* TOXICOLOGY.

B. Blaauboer. *Div Toxicology, Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands.*

The current practice in toxicological risk assessment is to assess human health or environmental risk of chemicals on the basis of clinical or histopathological endpoints in animal studies. These apical endpoints do normally not take into account the mechanism(s) of toxic action. In vitro studies have much better possibilities to study these mechanisms in great detail. Such data are normally expressed as the concentrations giving a certain degree of effect, e.g. the concentration resulting in 50% of the maximal effect (EC50). However, the extrapolation of in vitro toxicity data to the in vivo situation needs a number of considerations too. The interpretation of these results in terms of risk requires the "translation" of the data towards the expected exposure in an intact organism. Thus, EC50s, expressed as molar concentrations will need to be converted to the amount (i.e. the dose) to which the organism is exposed. These biokinetic aspects can now be studied in detail with the help of (physiologically-based) biokinetic (PBBK) models. Such a model allows the calculation of concentrations in tissues given a certain exposure scenario. When used in a reverse way, it thus also allows the calculation of a dose (or exposure scenario) resulting in a concentration in target tissues that would give a toxicologically relevant effect in an in vitro system. Similar models can also be used to study the biokinetic behaviour of compounds in the in vitro system, i.e. "biokinetics in vitro". Evaluating the kinetics of a compound in the cell culture is greatly increasing the relevance of the in vitro toxicity findings, e.g. by taking into account the actual (free) concentration to which the cells in an in vitro system are exposed to. It may also show any relevant differences in the conditions of exposure at a cellular level between the in vitro systems and the situation in vivo, e.g. in relation to protein binding. Making use of these models, a conversion was calculated of the EC50 values for cytotoxicity to toxic doses (LD50s). It was shown that the correlations with the experimentally determined LD50 in rodents improved.

PL 715 A PBPK MODELING TOOL TO PREDICT INFANT INTERNAL EXPOSURE TO PERSISTANT ORGANIC CHEMICALS AND ASSESS CRITICAL PERIODS OF SUSCEPTIBILITY.

M. Verner[1], P. Ayotte[2], G. Muckle[2], M. Charbonneau[3] and S. Haddad[1]. *[1]sciences biologiques, TOXEN, Université du Québec à Montréal, Montr√©al, QC, Canada, [2]Centre de recherche du CHUQ-CHUL, Université Laval, Qu√©bec, QC, Canada and [3]INRS-Institut Armand-Frappier, Université du Québec, Laval, QC, Canada.*

Uncertainty still remains in regards to the association between postnatal exposure to persistent organic pollutants (POPs) and adverse effects in infants. This may be partly because exposure assessment in epidemiologic studies was limited to snapshot measurements of breast milk and/or infant blood POP levels, yielding only partial insights into infant lifetime toxicokinetic profiles and hence preventing the determination of critical windows of susceptibility. Our goals were to i) build a generic physiologically-based pharmacokinetic (PBPK) model for POPs, and ii) validate the model using data on POP levels from longitudinal study on Inuit mothers and infants. A previously published PBPK model for mothers was modified to better assess mother-infant transfer. Using the model and measured maternal blood POP levels, exposure to p,p'-DDE, p,p'-DDT, HCB, β-HCH, PCB138, PCB153 and PCB180 in mothers was estimated to subsequently simulate infant plasma, breast milk and cord blood concentration. Simulations were compared to corresponding measured levels through Spearman correlation analyses. Model predictions were highly correlated with measured concentrations for PCB153, PCB180, PCB138, HCB and p,p'-DDE (r=0.83 to 0.96). Weaker correlations were observed for p,p'-DDT and β-HCH for which levels were close to the limits of detection. This is the first PBPK model for POPs to be validated on such a large scale. An approach using the maximum concentration (and the time when this concentration is reached) as well as the area under the curve for different time frames might provide crucial information on critical windows of exposure as well as dose-response relationships.

PL 716 EXAMINING MODELS FOR THE PHARMACOKINETICS OF PERFLUOROOCTANOIC ACID.

J. F. Wambaugh, H. A. Barton and W. Setzer. *National Center for Computational Toxicology, U.S. EPA, Research Triangle Park, NC.*

Perfluorooctanoate (PFOA) is a man-made surfactant used in a variety of industrial and consumer applications. Because of its wide-spread environmental distribution and stability, PFOA is found in human blood from the general population (Calafat et al., 2007). PFOA pharmacokinetics (PK) are complicated: plasma concentration indicates a long half life but also rapidly achieves steady-state. Attempts to address this have included using variable volumes of distribution and saturable renal resorption (Andersen et al., 2006) in which PFOA is cleared from the plasma into a kidney filtrate compartment from which it is either excreted or resorbed by a process with a Michaelis-Menten form. Lou et al. (2008) examined the renal resorption model for mice and though the model described the plasma data, the parameter uncertainty was large and the estimated flow through the filtrate was too large to be biologically consistent. In this work we investigated alternative model structures, including a modified two-compartment model in which transport from the deep tissue back to the plasma is saturable. To discriminate between models we applied maximum likelihood and Bayesian statistical approaches that, for example, balance the prediction likelihood with model flexibility. For the Lou et al. (2008) data the renal resorption model predicts that after 600 hours, 30% of a 1 mg/kg dose remains while only 5% remains for a 60 mg/kg dose. For the saturable deep tissue transport model the plasma predictions are similar, but PFOA is accumulated in deep tissue at high doses: 4% remains of a 1 mg/kg dose after 600 hours, while for a 60 mg/kg dose the deep tissue compartment holds 76%. Determining the body-burden of PFOA will require biological models for tissues other than plasma. Careful statistical analysis provides a needed crucible for data-driven development of these models. EPA reviewed this work but it does not necessarily reflect official Agency policy. Andersen et al. (2006), Tox. 227,156-164. Calafat et al. (2007) Env. Health Pers. 115, 1596-1602. Lou et al. (2008), Tox. Sci., in press.

PL 717 AN IMPROVED MODEL OF HUMAN RESPONSE TO AEROSOL CHEMICAL AND BIOLOGICAL AGENT HAZARDS.

K. Millage[1], J. Bergman[1], G. McClellan[1], S. Watson[1], S. Langford[1], B. Asgharian[2] and O. Price[2]. [1]*Applied Research Associates, Inc., Arlington, VA and* [2]*The Hamner Institutes For Health Sciences, Research Triangle Park, NC.*

An improved mathematical model for predicting the probability of infection or injury from exposure to aerosol chemical and biological (CB) agent hazards is being developed for the CB defense community. Many models currently assume that only particles reaching the lung are of concern and therefore estimating the inhalation of 1-5 micron "respirable' particles is adequate; however, coarse particle deposition must be included. Coarse particle deposition in the nose, mouth and throat may pose a substantial health risk, particularly for infectious agents. The Multiple Path Particle Dosimetry (MPPD) model (The Hamner Institutes For Health Sciences, RTP NC, V2.01) is used to estimate the respiratory dose associated with the inhalation hazard. Several modifications were made to MPPD to extend the range of applicability for predicting the deposition pattern for aerosol particle size distributions of interest. Changes included extending the upper bound of particle size to 100 micrometers and implementing new inhalability curves to include outdoor environments with non-zero wind speeds. Other changes were made to the dosimetry model to allow for better integration with existing atmospheric transport and dispersion models. An uncertainty analysis based on the stochastic lung models in MPPD was performed to provide a level of confidence in the deposition results. These changes to MPPD improved its applicability to particle size distributions of interest to the CB defense community and provided a solid foundation for improving the human response model.

PL 718 UPTAKE OF C60 FULLERENE NANOPARTICLES IN ISOLATED PERFUSED PORCINE SKIN FLAPS.

T. Leavens, X. Xia, H. Lee, N. Monteiro-Riviere, J. Brooks and J. Riviere. *Center for Chemical Toxicology Research and Pharmacokinetics, NCSU, Raleigh, NC.*

Nanomaterials are increasingly playing a role in society for uses ranging from biomedicine to microelectronics. While research concerning their applications is extensive, studies necessary to evaluate their potential toxicity are limited. In particular information on nanoparticle disposition will be necessary for human health risk assessments of exposure to the materials. Tissue distribution, one component of pharmacokinetics, can be assessed by quantifying arterial extraction of materials by isolated perfused porcine skin flaps (IPPSF). The purpose of this study was to determine the extent of tissue uptake of C60 fullerene nanoparticles (C60) by IPPSF. IPPSF were infused first for 4 hr with regular or IgG-free media that contained 1-2 ug/ml C60 and then for 4 hr with media only during a washout phase. Arterial and venous concentrations of C60 were measured in the media by HPLC-UV-vis chromatography. The size distribution of the C60 nanoparticles used for the experiments in regular and IgG-free media was analyzed by a Zetasizer. Steady-state differences in the arterial and venous C60 concentrations were compared to determine tissue extraction from the vascular space of the IPPSF, and the venous C60 washout concentrations were used to calculate compartmental pharmacokinetic parameters. The steady-state differences in the arterial and venous concentrations in the IPPSF were small; extraction ratios ranged from 0 to 15.8% with a mean of 6.3%. During the washout phase greater than 95% of C60 was eliminated with a mean half life of 1.2 min. Although the Zetasizer analysis indicated agglomeration of C60 nanoparticles in media containing IgG, there was no statistically significant difference in the extraction ratio or pharmacokinetic parameters between the C60 particles in regular versus IgG-free media. Based on the extraction ratios and rapid elimination of C60 from the vascular space of the IPPSF, the tissue uptake of C60 in this system appears to be limited. (Supported by BioChemics, Inc., Danvers, MA)

PL 719 COMPARISON OF QUANTUM DOT BIODISTRIBUTION WITH BLOOD FLOW-LIMITED PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL.

H. A. Lee, T. L. Leavens, S. E. Mason, N. A. Monteiro-Riviere and J. E. Riviere. *Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.*

Physiologically based pharmacokinetic (PBPK) modeling is a widely used tool to simulate chemical biodistribution in complex biological systems and for dose-response modeling in human health risk assessments. Their applicability to nanomaterial biodistribution has not been assessed. Models predicting the biodistribution of nanoparticles such as quantum dots (QD) will be important since systemic disposition of the nanoparticle following absorption may influence the site and magnitude of toxicity. The purpose of this study was to compare a general blood flow-limited PBPK model with QD distribution to determine the model's predictive ability across QD types, species, and exposure routes. The distribution of QD from blood to tissue was flow-limited, and all compartments (blood, kidney, liver, muscle and skin) were non-eliminating (QD > 10nm). Tissue-to-blood partition coefficients were estimated from a study of mice administered QD705 (Yang et al., 2007, Environ. Health Perspect. 115, 1339-1343). The model with estimated partition coefficients was used to simulate QD biodistribution in the liver and kidney from published studies. Although model simulations were consistent with constant QD concentrations in tissues at later time points, the predicted elimination from the blood and accumulation in the tissue compartments was too rapid. In addition, the percentage of initial dose per g of tissue varied among the studies used for the comparison; therefore, the estimated partition coefficients were not predictive of liver and kidney concentrations for the various QD types, species or exposure routes. Since the partition coefficients represent the movement of the QD from the vascular to extracellular space or uptake by cells, more complex models that incorporate physiological differences among tissues and physicochemical information for particular QD will be needed to account for pharmacokinetic differences among QD types and animal species.

PL 720 MICRORNA BIOMARKERS FOR CARCINOGEN ARISTOLOCHIC ACID EXPOSURE IN RATS.

T. Chen, Z. Li and M. Pearce. *Division of Genetic and Reproductive Toxicology, National Center for Toxicological Research, Jefferson, AR.*

MicroRNAs (miRNAs) are small non-coding RNAs that negatively regulate gene expression and control cellular mechanisms. However, the functional significance of each miRNA is mostly unknown. Despite the postulated involvement of miRNAs in carcinogenesis, there are only a few experimental examples that support an oncogene or a tumor suppressor is a miRNA target. Aristolochic acid (AA) is a model human carcinogen and has been associated with the development of urothelial cancer in humans, and kidney tumors in rodents. To investigate the potential miRNA biomarkers for chemical carcinogens, we determined miRNA expression profiles by microarray from the kidneys of rats treated with a similar dose protocol that produce kidney tumors. In addition, the genomic gene expression data generated from the same samples were analyzed to explore whether miRNA alterations were related to carcinogenesis of AA. A number of miRNAs were significantly altered by AA treatment. Among them, two miRNAs, miR-34a and miR-21, were further analyzed and confirmed by QPCR. Many miR-34a and miR-21 target genes were significantly altered by AA treatment concurrently. Most of these genes are involved in cancer-related functions like DNA repair, cell apoptosis and cell growth. Our results suggest miR-34a and miR-21 are oncogenic miRNAs and increases of their expressions may be early indicators of carcinogenic insulation. Thus, these miRNAs can become potential biomarkers for exposure of carcinogens.

PL 721 METABOLOMIC APPROACHES TO CHARACTERIZING CHANGES IN TRANSFER RNA SECONDARY MODIFICATIONS IN CELLULAR RESPONSES TO TOXINS.

T. Chan[1], K. Taghizadeh[2], T. J. Begley[3] and P. C. Dedon[4]. [1]*Chemistry, Massachusetts Institute of Technology, Cambridge, MA,* [2]*Center for Environmental Health Sciences, Massachusetts Institute of Technology, Cambridge, MA,* [3]*Department of Biomedical Sciences, Gen*NY*sis Center for Excellence in Cancer Genomics, University at Albany, State University of New York, Rensselaer, NY and* [4]*Department of Biological Engineering, Massachusetts Institute of Technology, Cambridge, MA.*

It has been known for several decades that there are ~90 different non-canonical nucleobase structures in rRNA and tRNA, yet the precise physiological functions of most of these modifications have not been established. Recent evidence suggests that the modifications play a role in cellular responses to toxins and other stimuli, with changes contributing to translational regulation of gene expression. To test this hypothesis, we have developed a coupled liquid chromatography-triple quadrupole mass spectrometry (LC/MS-MS) approach to characterize and quantify changes in the spectrum of the secondary modifications of tRNA in S. cerevisiae exposed to different toxic agents such as hydrogen peroxide and methyl methane sulfonate This analytical method should be generally applicable to characterize modifications in all RNA species, including rRNA, mRNA and micro-RNAs. Results from our analysis revealed that exposure of cells to hydrogen peroxide leads to an increase in levels of several tRNA modifications, including 5-methylcytidine (m5C), 2'-O-methyluridine (Cm), and N2,N2-dimethylguanosine (m22G). In parallel, we also showed that cell strains deficient in methyl transferase enzymes responsible for these modifications were more sensitive to hydrogen peroxide exposure than the wild-type strain. These results suggest that these modifications are involved in modulating the toxicity of hydrogen peroxide. Also, they demonstrated changes in the spectrum of tRNA modifications have the potential to serve as biomarkers of cellular exposures to toxins.

PL 722 IMMUNOGLOBULIN SWITCH TRANSCRIPTS ARE NON-INVASIVE SURROGATE BIOMARKERS OF ADAPTIVE IMMUNE FUNCTION AND BACTERIAL INFECTION.

E. R. Fedyk[1], E. Izmailova[2], C. Simpson[3], E. Koenig[3], J. Gray[3], V. Csizmadia[1], C. Milch[4] and C. L. Alden[1]. *[1]Drug Safety Evaluation, Millennium Pharmaceuticals Inc., Cambridge, MA, [2]Molecular Medicine, Millennium Pharmaceuticals Inc., Cambridge, MA, [3]Molecular Technologies, Millennium Pharmaceuticals Inc., Cambridge, MA and [4]Inflammation Clinical Research, Millennium Pharmaceuticals Inc., Cambridge, MA.*

Effective therapeutic intervention in autoimmune disease requires inhibiting innate and adaptive immunity, but not to an extent that predisposes subjects to infection. In developing an anti-inflammatory therapeutic for autoimmune disease, we repeatedly encountered atrophy of follicular germinal centers in secondary lymphoid organs, impaired T cell-dependent antibody responses (TDAR) and bacterial infection in a subset of Cynomolgus macaques in the high dose groups of one and three month chronic toxicology investigations. Other indicators of immunotoxicity were not present, such as the frequency of leukocyte subsets, levels of immunoglobulin and functional activity of complement, granulocytes, monocytes and natural killer cells. Further molecular and cellular investigations revealed that the therapeutic inhibited the differentiation of B lymphocytes in Cynomolgous macaques, rats and mice. The levels of more labile (i.e. short half-life) products of B cell differentiation, specifically immunoglobulin isotype class switching transcripts (switch transcripts) and post-germinal center B lymphocytes, did correlate with atrophy of follicular germinal centers, impaired TDAR and the incidence of bacterial infection, in both secondary lymphoid organs and peripheral blood. Decreases in the level of switch transcripts and post-germinal center B lymphocytes also preceded the onset of clinical signs of infection. We therefore conclude that blood switch transcripts and post-germinal center B lymphocytes are noninvasive, surrogate biomarkers of adaptive immune function and hence, could guide more effective clinical dosing.

PL 723 ASSESSING CIRCULATING ENDOTHELIAL CELL PROGENITORS AS A SOURCE FOR POTENTIAL BIOMARKERS OF DRUG-INDUCED CARDIOVASCULAR TOXICITY IN THE RAT.

R. A. Thomas, D. C. Pietrzak, M. S. Scicchitano, D. C. McFarland, K. S. Frazier and H. C. Thomas. *Safety Assessment, GlaxoSmithKline, King of Prussia, PA.*

There are currently no widely accepted noninvasive detection methods for drug-induced vascular damage. Circulating endothelial progenitor cell (CEPC) enumeration has recently gained attention as a potential biomarker of vascular injury and endothelial damage/dysfunction. The rat is commonly used in preclinical drug development toxicity testing and, as in human, lacks a consensus noninvasive methodology for immunophenotypic identification of CEPCs. We have recognized and characterized CEPCs in rat blood using cell culture, fluorescence microscopy, flow cytometry, and gene expression analysis. A modified colony forming unit (CFU)-Hill assay confirmed the existence of immature phenotype CEPCs in peripheral blood. Extended in vitro culture resulted in a morphology and immunophenotype consistent with mature endothelial cells as noted by positive staining for CD31, von Willebrand factor, and rat endothelial cell antigen, and negative staining for smooth muscle cell α-actin. CEPC populations (comprised of diI-Ac-LDL or CD36 positive cells negative for CD11b) sorted from lysed whole blood revealed heterogeneity in surface protein expression of CD31 and vWF by flow cytometry. Cell sorting of CEPC populations for subsequent gene expression analysis compared relative expression levels of nine endothelial-related and four progenitor-cell-related genes to determine endothelial and progenitor genotypes. Sorted populations were consistently positive for PECAM1, EDN1, FLK1, VWF, ITGAD, CCR1, IP30, and MMP2. Taken together, our data suggests that CEPCs, as identified in rat blood by these methods, express cell-surface and gene expression markers consistent with endothelial cells and endothelial progenitor cell populations. These methods enable peripheral blood sampling of phenotypically and genotypically consistent populations of cells for use as a source for potential endothelial biomarkers of cardiovascular injury in the rat after drug administration.

PL 724 URINARY LBPA TRACKS WITH ONSET AND REVERSAL OF DRUG-INDUCED PHOSPHOLIPIDOSIS.

J. A. Phillips[1], V. V. Papov[2], J. H. Stoltz[1], A. M. Mineo[1], K. N. Locke[1] and S. Jayadev[1]. *[1]Toxicology and Safety Assessment, Boehringer Ingelheim, Ridgefield, CT and [2]Analytical Sciences, Boehringer Ingelheim, Ridgefield, CT.*

Phospholipidosis (PLD) is characterized by the intracellular accumulation of phospholipids. The current study assesses the value of lyso-bis-phosphatidic acid (LBPA) as a biomarker to track the onset and reversal of PLD. LBPA changes were evaluated and compared to histopathology from exposure to amiodarone, a known phospholipidogenic agent. Sprague Dawley rats were dosed with vehicle (control), 15 mg/kg/day amiodarone (low-dose) or 150 mg/kg/day amiodarone (high-dose) for 14 days. Additionally, a subset of control and high-dose rats were maintained for a 12 day recovery period. Liver, lung and peripheral leukocytes were collected for histopathology evaluations. Blood was collected weekly for serum and hematology analysis. Urine was collected daily for measurement of LBPA and creatinine (Cr). Control and low-dose animals showed no significant changes in urinary LBPA:Cr ratios, as compared to pretest values. Microscopic analysis of the lungs, liver and leukocytes showed no evidence of PLD in the control animals, but one animal in the low-dose group exhibited minimal PLD in the lung macrophages. In contrast, high-dose group urinary LBPA:Cr levels increased steadily from drug day (DD) 2 to DD7, representing an approximately 10-fold change above corresponding pretest levels. Foamy alveolar macrophages were observed microscopically in the lung in 5/5 high-dose animals on DD14. A substantial increase in % leukocyte vacuolation was also observed in the high-dose group at the end of the drug-phase. After discontinuation of amiodarone dosing on day 14 in the high-dose group animals there was a precipitous decrease in urinary LBPA:Cr, returning to pretest levels within 10 days. Decreased LBPA:Cr levels in recovery paralleled the absence or marked depletion of foamy alveolar macrophages in the lungs and decrease in % leukocyte vacuolation. Collectively, these data suggest that LBPA could serve as a correlative urinary marker of drug-induced PLD.

PL 725 CARDIAC BIOMARKER EXPRESSION IN THE URINE OF COCAINE USERS.

M. M. Bourgeois and I. S. Richards. *EOH, USF COPH, Tampa, FL.*

Cocaine is a powerful sympathomimetic capable of increasing heart rate, blood pressure, contractility, respiration, myocardial oxygen demand and body temperature. Its use has been associated with acute myocardial ischemia and infarction, sudden death, vasoconstriction and rhabdomyolysis. This is accompanied with the release of cardiac biomarkers into blood, urine and other body fluids when the heart or its attendant structures are damaged. Detection of these biomarkers is used to diagnose, evaluate, and monitor patients with suspected acute coronary syndrome, acute myocardial infarction, acute cardiac ischemia or other symptoms of cardiac dysfunction. In recent years, attempts have been made to improve risk stratification using a combination of biomarkers that reflect myocardial cell damage, left ventricular dysfunction, renal failure, and inflammation. The multimarker approach is gaining acceptance in clinical settings. This study describes the effect of cocaine use on cardiac biomarker expression in the urine of cocaine users compared to non-users. Specimens were assayed for myeloperoxidase, vascular endothelial growth factor, heat shock proteins, microalbumin, aldosterone, myoglobin, creatinine, pro atrial natriuretic peptide and C-reactive protein using enzyme-linked immunosorbent assays. Many of these markers have been assayed exclusively in serum specimens; urine specimens are non-invasive and are traditionally used to test for illicit substances. Increased expression of these markers is associated, in varying degrees of specificity, with cardiac damage, oxidative stress and inflammation. Establishing a link between biomarker expression in urine and cocaine-induced cardiac damage is the first step in developing a diagnostic tool that may permit rapid diagnosis and selection of an appropriate clinical intervention. Our research suggests that biomarkers in the urine may be an important non-invasive way to assess cardiovascular damage in users of illicit substances.

This work has been supported in part by the Agency for Community Treatment and Services of Tampa.

PL 726 IDENTIFICATION OF AUTOANTIBODIES AGAINST TUMOR-DERIVED ANTIGENS AS BIOMARKERS FOR EARLY DETECTION AND DIAGNOSIS OF ESOPHAGEAL CANCER.

C. Shao[1], L. Chen[1], E. Cobos[2], J. Wang[3] and W. Gao[1]. *[1]Environmental Toxicology, The Institute of Environmental and Human Health (TIEHH), Texas Tech University, Lubbock, TX, [2]Texas Tech University Health Sciences Center, Lubbock, TX and [3]The University of Georgia, Athens, GA.*

Autoantibodies against specific tumor-associated antigens in circulating blood are potential biomarkers for early detection and diagnosis of various cancers. The serological proteome analysis (SERPA) integrating two dimensional (2D) gel electrophoresis, western blots, and mass spectrometry (MS) is a powerful tool to identify novel autoantibodies in sera of cancer patients. In this study, SERPA was used to screen autoantibodies for esophageal squamous cell carcinoma (ESCC). Proteins from human ESCC cell line, KYSE-150, were separated by 2D gels, followed by hybridization with sera from 28 subjects (14 primary ESCC patients and 14 age-matched healthy controls) as sources of primary antibodies. Immunoblots were quantified and analyzed by ImageQuant software. Non-parametric test was per-

formed to compare the levels of autoantibody expression between cases and controls. Eleven protein spots were found to be significantly higher in sera of cases than controls, with six of them being detectable only in cancer patients (Wilcoxon rank-sum test, P<0.05). Further identification of these protein spots with MS showed that levels of autoantibodies against three isoforms of α-enolase were significantly increased in sera of ESCC patients. The autoantibody against phosphorylated α-enolase was the most discriminative marker that was detectable only in cases (6/14, 43%). α-enolase is a ubiquitous cytoplasmic glycolytic enzyme that has been shown to be overexpressed in various tumor tissues from different organ sites, including esophagus. Our initiative proteomics-based analysis suggested that α-enolase is potentially immunogenic and the autoantibody against the phosphorylated α-enolase present in the sera may be a potential biomarker for early detection, diagnosis, and treatment of ESCC.

PL 727 STEM CELL SELECTION FACILITATES ARSENIC-INDUCED MALIGNANT TRANSFORMATION *VIA* INNATE RESISTANCE, HYPER-ADAPTABILITY AND OVER-PRODUCTION.

E. J. Tokar[1], W. Qu[1], J. Liu[1], W. Liu[2], J. Phang[2] and M. P. Waalkes[1]. *[1]Inorganic Carcinogenesis Section, LCC, NCI at NIEHS, Research Triangle Park, NC and [2]Metabolism and Cancer Susceptibility Section, LCC, NCI-Frederick, Frederick, MD.*

Arsenic is a carcinogen that targets the urogenital system (UGS). Although mechanisms are undefined, arsenic drives aberrant accumulation of stem cells (SCs) *in vivo* and *in vitro*, indicating this is a key target population. Disruption of SC population dynamics is thought to be a critical factor in acquisition of malignant phenotype. Here, we test the hypothesis that UGS SCs have a survival selection advantage during arsenic exposure favoring accumulation and facilitating malignant conversion. Innate and acquired resistance to acute and chronic arsenite-induced cytolethality and apoptosis were assessed in the human UGS SC line, WPE-stem, and compared to its mature, parental cell line, RWPE-1. Real time RT-PCR and Western blot analysis defined selected gene expression. Arsenic-, cadmium-, and *N*-methyl-*N*-nitrosourea (MNU)-induced isogenic malignant transformants of RWPE-1 cells were also compared for acquisition of cancer SC (CSC) qualities. WPE-stem showed remarkable innate resistance to arsenic-induced cytolethality (LC_{50} = 26.9 μM) and apoptosis compared to parental RWPE-1 cells (14.6 μM) involving general apoptotic- (Bcl-2, Bax, caspases) and stress-related (Nrf2, HO-1, HIF-1α, PRODH) genes, as well as arsenic-specific adaptation genes (ABCC1, GST-π, MT). After chronic, pre-transformation (6 wks) arsenic exposure at levels (5 μM) eventually inducing malignant phenotype, WPE-stem showed a hyper-adaptability with a 282% increase in LC_{50} (102.8 μM) while RWPE-1 increased only 95% (28.4 μM). Quantitative assessment of CSCs in isogenic RWPE-1 transformants clearly showed a stunning overproduction of CSCs that was unique to acquired malignant phenotype after arsenic exposure but not after cadmium or MNU. These data strongly indicate that a SC survival selection during arsenic-induced malignant transformation manifests itself as a specific CSC over-abundance after acquisition of malignant phenotype.

PL 728 CELLULAR UPTAKE OF PLATINUM NANOPARTICLES IN HUMAN COLON CARCINOMA CELLS AND THEIR IMPACT ON CELLULAR REDOX SYSTEMS AND DNA INTEGRITY.

D. Marko[1], J. Pelka[1], H. Gehrke[1], M. Esselen[1], M. Türk[2], M. Crone[2], S. Bräse[3], T. Muller[3], W. Send[4], V. Zibat[4], P. Brenner[4], R. Schneider[4] and D. Gerthsen[4]. *[1]Institut für Angewandte Biowissenschaften, Universität Karlsruhe (TH), Karlsruhe, Germany, [2]Institut für Technische Thermodynamik und Kältetechnik, Universität Karlsruhe (TH), Karlsruhe, Germany, [3]Institut für Organische Chemie, Universität Karlsruhe (TH), Karlsruhe, Germany and [4]Laboratorium für Elektronenmikroskopie, Universität Karlsruhe (TH), Karlsruhe, Germany.*

Supercritical fluid reactive deposition (SFRD) was used for the deposition of highly dispersed platinum nanoparticles with controllable metal content and particle size distribution on β-cyclodextrin. The average particle size and size distribution were steered by the precursor reduction conditions, resulting in particle preparations < 20 nm, <100 nm and > 100 nm as characterized by TEM and SEM. These particle preparations of different size distribution were used to address the question as whether metallic platinum particles are able to invade cells of the gastrointestinal tract as exemplified for the human colon carcinoma cell line HT29 and thus affect the cellular redox status and DNA integrity. Combined focussed ion beam (FIB) and SEM demonstrated that platinum nanoparticles were taken up into HT29 cells in their particulate form. The chemical composition of the particles within the cells was confirmed by energy-dispersive X-ray spectroscopy (EDX). The potential influence of platinum nanoparticles on cellular redoxsystems was determined in the DCF assay, on the translocation of Nrf-2 and by monitoring of the intracellular glutathione (GSH) levels. The impact on DNA integrity was investigated by single cell electrophoresis (comet assay) including the formation of sites sensitive to formamidopyrimidine-DNA-glycosylase (FPG). Platinum nanoparticles were found to decrease the cellular GSH level and to impair DNA integrity with a maximal effect at 1 ng/cm2. These effects were correlated with the particle size in an inverse manner and were enhanced with increasing incubation time but appeared not to be based on the formation of reactive oxygen species.

PL 729 CADMIUM-INDUCED ACQUISITION OF CANCER STEM CELL-LIKE CHARACTERISTICS DURING CARCINOGENIC TRANSFORMATION OF HUMAN PANCREATIC DUCTAL CELLS.

W. Qu, E. J. Tokar, A. J. Kim, M. Bell and M. P. Waalkes. *ICS, LCC, NCI at NIEHS, Research Triangle Park, NC.*

Emerging evidence suggests that tumor initiation and growth may be due to a small subset of pluripotent tumor cells with high proliferative potential. Termed cancer stem cells (CSCs), they are thought to arise from transformation of either normal stem cells (NSC) or their immediate progeny through dysregulation of normally tightly regulated, but complex process of NSC self-renewal. In light of the recent isolation of pancreatic CSCs, this study examined whether cadmium targets stem cells during pancreatic cell transformation. Normal human pancreatic ductal epithelial (HPDE) cells were exposed to a non-cytotoxic level of cadmium (5 μM; ≥ 12 wk) and compared to passage-matched control cells. Floating "pancreaspheres" of viable cells, shown in other cell types contain an abundance of either NSCs or CSCs, were isolated from control and chronic cadmium exposed (CCE) cells. Cadmium treatment increased floating sphere formation 3-fold and invasion 2.8-fold. Significant increases in matrix metalloproteinase 9 (MMP-9), a biomarker for tumor cells, were seen in pancreaspheres from CCE cells as early as 3 weeks of cadmium exposure, while levels in adherent cells remained constant over the course of 12 weeks. Our prior work shows that increased MMP-9 secretion occurs in treated adherent cells at 29 weeks. By real-time PCR, both treated and control floating cells showed significantly higher expression than their adherent counterparts for various genetic markers for pancreatic NCS/CSCs and/or pancreatic cancer progression/aggressiveness such as S100P, Oct4, PSCA, and CXCR4. Time course analysis revealed a cadmium-induced time-dependent increase in these markers, possibly as a prelude to malignant transformation. These data suggest that cadmium may act to promote and maintain a CSC-like population in human pancreatic cells during transformation. This study also reinforces the general importance of CSCs in the initiation and progression of the carcinogenic process, even with inorganic carcinogens.

PL 730 TUMORS AND PROLIFERATIVE LESIONS IN MICE INDUCED BY TRANSPLACENTAL INORGANIC ARSENIC COMBINED WITH DIMETHYLARSENIC ACID IN ADULTHOOD.

M. P. Waalkes[1] and B. A. Diwan[2]. *[1]ICS, LCC, NCI at NIEHS, Research Triangle Park, NC and [2]SAIC-Frederick Inc., NCI at Frederick, Frederick, MD.*

Arsenic is a multi-site human carcinogen and may have transplacental activity. In mice, inorganic arsenic (iAs) is a transplacental carcinogen and fetal exposure also initiates lesions promotable by other agents later in life. Dimethylarsinic acid (DMA), a methylation product of iAs, can act as a tumor promoter. Thus, we studied the promoting effects of DMA given in adulthood on carcinogenesis initiated by fetal iAs exposure. Pregnant CD1 mice (20/group) received drinking water with 0 or 85 ppm iAs (as sodium arsenite) from gestation day 8 to 18. After birth and weaning, male offspring received drinking water with 0 or 200 ppm DMA for up to 2 years. Survival and body weights were not reduced by treatment. The number of mice/group analyzed histologically was: control 49; iAs alone 45; DMA alone 25; iAs + DMA 23. Renal tumors did not occur in control or DMA alone groups but fetal iAs alone mice had 2 (a renal cell carcinoma [RCC] and adenoma) and iAs + DMA induced 4 ($p < 0.05$ versus control; 3 RCC, 1 adenoma). Both iAs alone (13%) and iAs + DMA (35%) had increased renal total proliferative lesions (TPL; incidence of cystic atypical hyperplasia, adenoma or RCC) over control (0%) while DMA alone (8%) did not. Fetal iAs alone (38%), DMA alone (32%) and iAs + DMA (44%) induced similar levels of urinary bladder TPL (incidence of hyperplasia, papilloma or transitional cell carcinoma [TCC]) versus control (2%). Two papilloma (iAs + DMA) and 2 TCC (iAs alone) were seen with arsenicals. RCC and TCC are rare in mice and TCC occur in arsenic exposed humans. Compared to control (6%), iAs alone (20%) tripled the rate of hepatocellular carcinoma, and iAs + DMA doubled this rate again (39%), but DMA alone (8%) had no effect. DMA alone (24%), iAs alone (38%), and iAs + DMA (48%) increased adrenal adenomas versus control (0%). Overall, DMA in adulthood promoted tumors and/or proliferative lesions initiated by fetal iAs exposure in the kidney and liver, but acted independently in the bladder and adrenal.

PL 731 DEPLETED URANIUM INDUCES TRANSFORMATION IN HUMAN BRONCHIAL EPITHELIAL CELLS.

C. LaCerte[1, 2, 3], H. Xie[1, 2, 3] and J. P. Wise[1, 2, 3]. Depleted uranium (DU) has been extensively used in military, industrial and medical applications. Thus, exposure of soldiers and non-combatants is potentially frequent and widespread, and is now becoming a major international public health concern. Previous studies have shown the DU has both chemical and radiological toxicity, and that the primary route of exposure of DU to humans is through inhalation and ingestion. However, there is limited research information on the potential health hazards of DU exposure to human bronchial cells. Therefore the purpose of this study is to improve our current understanding of DU's potential toxicity to human lung bronchial cells. We determined the cytotoxicity, clastogenicity and potential transforming ability of water-insoluble DU to human bronchial epithelial cells (BEP2D). We observed cytotoxicity, foci formation and loss of contact inhibition in cells exposed to DU after 24 h. The DU-transformed cells acquired anchorage-independent growth in soft agar suggesting that DU may be tumorigenic. We are currently characterizing DU-induced transformed cell lines in which some cell lines are showing an increase in plating efficiency, sensitivity to exposure to DU, and a transformed phenotype. Our study demonstrates that transformation of human bronchial cells can be induced by depleted uranium. This work was supported by ARO grants # W911NF-04-1-0240 and W911NF-08-0333 (J.P.W.).

PL 732 HUMAN CANCER RISK OF SOLUBLE COBALT: BIOKINETIC EXTRAPOLATION FROM RODENT BIOASSAY DATA.

K. T. Bogen. *Exponent Health & Environmental, Oakland, CA.*

Soluble cobalt (Co), tungsten-Co alloy, and tungsten-carbide-Co particles are cytotoxic, genotoxic and carcinogenic. Alloys and ceramics wear/corrode in vivo, generating soluble-Co exposures above essential baseline levels. Exposure to Co or related hard metal dusts increases lung cancer risk in workers, but epidemiological data are currently unsuitable for risk assessment. To quantify potential human cancer risk of soluble Co, an existing rodent PK model for nickel was applied to estimate Co concentration in lung (CoL) in NTP (1998) male and female rats and mice exposed for 2 years to different concentrations of CoSO4 hexahydrate aerosols. All the exposed rodents had >90% incidence of alveolar lesions and elevated risk of alveolar/ bronchiolar tumors; the male mouse data yielded the greatest upper-bound estimate of human-equivalent cancer potency (q1* = 2.8 per ppmw CoL). The Leggett (2008) human biokinetic model for Co was then used to estimate corresponding human-equivalent tissue-specific risks per microgram (mcg) of systemically released Co (CoS), including 0.19 and 2.2 per million per mcg CoS for human lung and kidney, respectively. These bioassay-extrapolated risks predict that 10-year exposures to CoS levels previously estimated for Co-alloy implant patients (5 to 25 mcg/day) impose cancer risks (e.g., 0.37 to 1.7% for lung, and 4.0 to 20% for kidney) that appear to be inconsistent with cancer rates experienced in these types of patients. The inconsistency may only reflect conservatism in the linearized multistage approach used to extrapolate q1* from NTP bioassay data. Alternatively or additionally, the linear extrapolations may be invalid because they do not address "hot spot" microdosimetry issues posed by the >1000-fold difference in Co concentrations expected (albeit transiently) between rare cell(s) proximate to each pure CoSO4 hexahydrate particle inhaled onto an alveolar or terminal airway surface, and all other cells that experienced only much lower, tissue-equilibrium concentrations of Co.

PL 733 CADMIUM-INDUCED GENE EXPRESSION IN HUMAN LUNG EPITHELIAL CELLS AND POTENTIAL ROLE IN THE INITATION OF LUNG CANCER.

K. Davis[1, 2, 3] and J. Cates[3]. [1]*Pharmacology & Toxicology, University of Louisville, Louisville, KY,* [2]*James Graham Brown Cancer Center, University of Louisville, Louisville, KY and* [3]*Owensboro Cancer Research Program, Owensboro, KY.*

Smoking is a major cause of lung cancer and may be the primary factor in 80-90% of lung cancers reported. Tobacco smoke contains a number of known carcinogens, including the potent nitrosamines and metals such as cadmium (Cd). Cd may contribute to cancer development by inhibiting DNA repair and modulating signaling pathways important for cell cycle control, the response to oxidative stress, and the activation of resistance to apoptotic signals. Few studies have comprehensively examined gene expression changes associated with Cd exposure and functionally test which of these changes may promote lung cancer. Moreover, very little is known about how Cd interacts with other tobacco-derived carcinogens and whether these interactions affect the initiation and progression of lung cancer. We have established immortalized human lung epithelial cells (HBE-135) as an *in vitro* model to examine genome-wide gene expression changes in response to Cd. We have shown that HBE-135 cells exhibit decreased viability at Cd concentrations >5 μM and that known Cd-induced genes such as JUN, HspA6, and HMOX1 are induced in a dose-dependent manner, with some genes being strongly induced at 1-3 μM Cd. Preliminary expression analysis using Agilent whole genome microarrays have identified ~150 genes with altered expression patterns at 3 and 6 h after treatment with 3 μM Cd. Additional studies demonstrated that sub-μM doses of the tobacco-derived carcinogen nitrosamine 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK) enhance Cd effects on cell viability. Current studies are focused on whole genome microarray studies of HBE-135 cells treated with Cd alone, and a combination of Cd and NNK. These results will allow us to characterize the interaction of Cd and NNK at the molecular level and provide the basis for a functional analysis of specific Cd/Cd-NNK modulated genes that may be involved in the initiation and progression of lung cancer.

PL 734 DEPLETED URANIUM HAS GENOTOXIC AND EPIGENETIC EFFECTS IN HUMAN LUNG EPITHELIAL CELLS.

H. Xie[2, 3, 1], C. LaCerte[2, 3, 1] and J. P. Wise[2, 3, 1]. [1]*Applied Medical Sciences, University of Southern Maine, Portland, ME,* [2]*Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME and* [3]*Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME.*

Depleted uranium is commonly used in military applications and is also used in civilian industry and thus exposure of soldiers and others is frequent and widespread. There is limited research information on the potential health hazards of depleted uranium exposure. Previous studies have shown that depleted uranium has both chemical and radiological toxicity. In our study we used the human bronchial epithelial cell line (BEP2D) to study the potential cytotoxic and carcinogenic hazard of depleted uranium. After a 24 h exposure we observed a concentration-dependent increase in cytotoxicity with 0.25, 2.5 and 25 μg/cm2 depleted uranium inducing 79, 74 and 36% relative survival, respectively. We also found that depleted uranium was genotoxic in a concentration–dependent manner with these doses inducing with an average of 1.3, 3.0 and 9.7 DNA double strand breaks per cell (measured as H2A.X foci). Our previous study demonstrated that transformation of human bronchial cells can be induced by depleted uranium. We hypothesized that depleted uranium may also have epigenetic effects, which may contribute to its carcinogenic activity. We found that the level of dimethylated histone H3 lysine 9 (H3K9), a critical mark for DNA methylation and gene silencing, was indeed increased in human lung cells after depleted uranium exposure. This work was supported by ARO grants # W911NF-04-1-0240 and W911NF-08-0333 (J.P.W.).

PL 735 PARTICULATE CHROMATE INDUCED DNA DOUBLE STRAND BREAKS ARE ASSOCIATED WITH XPF GENE ACTIVITY IN HUMAN LUNG CELLS.

Q. Qin[1, 2, 3], H. Xie[1, 2, 3], A. Jeevaragen[4], W. Wallace[4], D. Hammond[4], T. Shehata[5] and J. P. Wise[1, 2, 3]. [1]*1Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME,* [2]*Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME,* [3]*Department of Applied Medical Science, University of Southern Maine, Portland, ME,* [4]*NASA Johnson Space Center, Houston, TX and* [5]*Maine Space Grant Consortium, Augusta, ME.*

It has been established that hexavalent chromium Cr(VI) can cause lung cancer in humans. The most potent carcinogenic form of Cr(VI) is the particulates which deposit and persist in the respiratory tract after inhalation. The particle-derived Cr(VI) ion enters the cell and reduces to reactive intermediates producing numerous types of DNA damage. Cell culture studies show that Cr(VI) intermediates form ternary DNA adducts that can be processed by nucleotide excision repair (NER) machinery and produce a DNA double strand break. However the mechanisms underlying these effects are poorly understood. We investigated the relationship of Cr(VI)-induced DNA damage and key genes involved in the repair of Cr adducts. Chronic exposure to zinc chromate caused persistent DNA double strand breaks in human lung cells. Cells exposed to 400 ng/cm^2 zinc chromate for 24, 48, 72, 96 and 120 hours induced 15, 20, 10, 11 and 13 DNA double strand breaks per cell, respectively. We next focused on the XPF gene, which is involved in NER and forms a complex with ERCC1, which exhibits endonuclease activity and is responsible for the 5' incision. During DNA replication, the 5' incision of Cr-DNA adducts results in DNA double strand breaks. We found that 24 hour exposure to zinc chromate did not change the protein expression of XPF. However, chronic ex-

posure to zinc chromate in XPF deficient human lung cells induced less DNA double strand breaks than normal human lung cells, which indicate that XPF may play a key role in generating DNA double strand breaks without changing its protein expression. This work is supported by a NASA EPSCoR grant through the Maine Space Grant Consortium (JPW), and the Maine Center for Toxicology and Environmental Health.

PL 736 ROLE OF ARNT BINDING AND TRANSACTIVATION IN THE LIGAND DEPENDENT AND INDEPENDENT DEGRADATION OF THE AH RECEPTOR.

R. S. Pollenz[1], J. Jones[1] and E. J. Dougherty[2]. *[1]Biology, University of South Florida, Tampa, FL and [2]Clinical Endocrinology Branch, NIH, Bethesda, MD.*

The Ah receptor (AHR) is rapidly degraded both in vivo and in vitro following binding to ligands typified by 2,3,7,8-tetrachlorodibenzo[p]dioxin (TCDD). The AHR is also degraded after cells are exposed to compounds such a geldanamycin (GA) that disrupt or modify the association of the hsp90 chaperone proteins with the AHR. Previous studies suggest that the TCDD-induced degradation mechanism requires the AHR to associate with ARNT and DNA and contain a functional transactivation domain(TAD). Thus, mutagenesis was used to create an AHR with a mutation at R39 (AHR-R39A) so that DNA binding would be reduced. A similar approach was used to mutate L69 and L71 (AHR-L69/71A) to reduce dimerization with ARNT. Retroviral expression vectors were used to generate stable cell lines expressing the various AHRs as well as wild type protein (AHR-WT) in the Hepa-1 cell background. Western analysis confirmed that all stable lines expressed levels of AHR protein and ARNT that were similar. However, cell lines expressing AHR-R39A or AHR-L69/71A showed greatly reduced levels of TCDD-inducible CYP1A1 protein, confirming that the AHR-mediated signaling pathway had been disrupted. When the level of AHR protein was evaluated following short or long term exposure to TCDD, the AHR-R39A and AHR-L69/71A proteins showed greatly reduced levels of degradation when compared AHR-WT. Importantly, when the various lines were treated with GA, the degradation of the AHR was similar in all the stable lines. To investigate the role of the TAD domain, the AHR was truncated at amino acid 500 and expressed with a variety of TAD domains from other proteins including HIF-1, ARNT, ARNT2 and VP-16. These chimeric proteins were expressed in the Hepa-1 line and the level of TCDD and GA-mediated degradation evaluated. Collectively the results support a hypothesis that ARNT dimerization, DNA binding and a functional TAD domain are required for the ligand-dependent degradation of the AHR. Supported by NIEHSES015481

PL 737 HYPOXIA POTENTIATES TCDD INDUCTION OF CYP1A1 IN DIFFERENTIATING CHONDROCYTES.

M. H. Kung[1, 2], J. Puzas[1, 2], R. J. O'Keefe[2] and M. J. Zuscik[2]. *[1]Environmental Medicine, University of Rochester, Rochester, NY and [2]Orthopaedics, University of Rochester, Rochester, NY.*

Hypoxia has been shown to be a key regulator of chondrogenesis [1, 2]. Because both AhR and Hif pathways converge with their binding partner ARNT, we postulate that ligand-activated AhR signaling may disrupt normal hypoxia signaling. The purpose of this study is to investigate crosstalk between the Hif and AhR pathways in differentiating chondrocytes. Primary E11.5 murine limb buds were cultured in micromass for 5 days under basal conditions. To investigate the effects of TCDD on hypoxic signaling, cells were treated with varying doses of TCDD for 18h. At this time, cells were either left in normoxia or placed in hypoxia (5% O2) for 24h. To test the effects of hypoxia on AhR signaling, cells were cultured in 20% or 5% O2 for 18h. TCDD was added to cultures for 4h. We quantified mRNA by qRT-PCR. TCDD does not interfere with hypoxic induction of VEGF. 24h hypoxia exposure increased VEGF mRNA levels. Surprisingly, hypoxia increases AhR target gene induction. TCDD-induced Cyp1a1 mRNA levels were 1.92, 1.76, and 1.96-fold higher in the hypoxia group for 1, 5, 10nM doses, respectively. In this study we present the novel finding that hypoxia has the ability to increase AhR-responsiveness in primary differentiating chondrocytes. These findings are contrary to the negative regulation by Hif-AhR interaction as reported in several studies [3-7]. These preliminary results suggest an undefined mechanism by which the AhR and Hif pathways converge in differentiating chondrocytes, but not competitively. 1.Robins, J.C. et al., Bone, 2005. 37(3): p. 313-22. 2.Wan, C., et al. PL 738 TCDD, CO-PLANAR PCBs AND PAHS INDUCE COMMON AH RECEPTOR-DEPENDENT EPIGENETIC SIGNATURES IN THE CYP1A1 PROMOTER.

J. L. Ovesen, M. Schnekenburger and A. Puga. *Environmental Health, University Of Cincinnati, Cincinnati, OH.*

Dioxin and dioxin like compounds (DLCs) are environmental contaminants released during many industrial processes including combustion. The most toxic of these compounds, 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), has been identified as a possible human carcinogen and as an immuno- and developmental toxicant. TCDD, DLCs and the polycyclic aromatic hydrocarbons like benzo[a]pyrene (B[a]P), transactivate the heterodimeric transcriptional complex formed by ligand-bound Ah receptor (AHR) and the ARNT protein. As a consequence, several cytochrome P450 genes, including CYP1A1, CYP1B1, CYP1A2 and CYP2S1 become transcriptionally induced. Previously, we have shown that recruitment of the B[a]P-activated AHR to the Cyp1a1 promoter of mouse Hepa1 cells requires dissociation of bound histone deacetylase-1 and modification of several histone marks. Here we find that the Cyp1a1 gene of C57Bl/6J mouse embryonic fibroblasts shows a similar pattern of histone modifications accompanying gene induction, including trimethylation of histone H3 K4 and hyperacetylation of H3 K14, strongly implying that this mechanism of response to Ah receptor ligands is ubiquitous. Because DLCs have toxic effects similar to those of TCDD, albeit with different Toxic Equivalency Factors (TEF), we used chromatin immunoprecipitation to determine that TCDD, 3MC, βNF, and various DLCs causes fingerprints of epigenetic modification similar to those elicited by B[a]P. In addition, dose response experiments indicate that various co-planar polychlorinated biphenyls (PCBs) caused recruitment of AHR to the Cyp1a1 promoter and increased Cyp1a1 transcription at levels proportional to their TEF, whereas PCB153, a non-coplanar PCB, showed no AHR recruitment. These results not only imply a correlation between chromatin recruitment of AHR and the resultant toxicity but also delineate an epigenetic signature for AHR-mediated gene activation. (Supported by NIH R01ES6273, NIH R01ES10807, and NIH P30 ES06096).

PL 739 INVOLVEMENT OF AMINOLEVULINIC ACID SYNTHASE IN DIOXIN-INDUCED GLYCOGEN DEPLETION IN HEPG2 CELLS.

Y. Sakata, S. Ohsako and C. Tohyama. *Laboratory of Environmental Health Sciences, Center for Disease Biology and Integrative Medicine, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan.*

Laboratory animals exposed to 2,3,7,8-teterachlorodibenzo-p-dioxin (TCDD) develop wasting syndrome, and it has been thought that glycogen depletion and CYP1A1, a hemoprotein, in the liver are involved in the onset of this syndrome. Heme and hemoproteins have essential roles in various cell functions, and a possible relationship between heme biosynthesis and glucose metabolism has been suggested. Treatment by glucose was found to clinically ameliorate hepatic porphyria, caused by disorders of heme biosynthetic pathway, and porphyria patients were reported by epidemiological studies to be accompanied with hyperinsulinemia. Using microarray, we found that mRNA of aminolevulinic acid synthase (ALAS), the rate limiting enzyme in the heme synthesis pathway, was dose-dependently induced by TCDD exposure in the liver from three kinds of mouse strains. We here investigated how ALAS is involved in glycogen metabolism and/or gluconeogenesis.

When HepG2, a human hepatoma cell line, was exposed to 1-100 nM TCDD, glycogen amounts in the cells were decreased dose-dependently, and ALAS mRNA and protein was induced. However, transfection of ALAS specific siRNA suppressed the TCDD-induced decrease in glycogen amounts. In addition, overexpression of ALAS in HepG2 reduced glycogen amounts indifferent from TCDD exposure. Furthermore, TCDD exposure was found to enhance the phosphorylation of GSK3-β protein, a downstream protein of insulin signal, and induce mRNAs of PEPCK and PGC-1α, the both of which are involved in the regulation of gluconeogenesis. On the other hand, ALAS siRNA-transfection abolished TCDD-dependent phosphorylation of GSK3-β protein and significantly decreased the mRNA levels of PEPCK and PGC-1α that are induced by TCDD. In conclusion, the present results suggest that ALAS is involved in the regulation of glycogen metabolism and gluconeogenesis in the TCDD-exposed cells.

PL 740 HYPOXIA-MIMETIC CHEMICALS AND MICROBIAL STIMULI INTERACT TO PRODUCE A PRO-ANGIOGENIC PHENOTYPE IN HUMAN LUNG FIBROBLASTS (HLF).

C. Mathias, K. Brant and J. P. Fabisiak. *Environmental & Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Several chemical stimuli can mimic the cellular response to hypoxia via the activation of HIF-1α transcription factor-dependent changes in gene expression. Hypoxia stimulates angiogenesis, which is regulated via the action of multiple angiogenic (CXCL8, VEGF) and angiostatic (CXCL10) factors. As several of these

factors also act as chemokines during infection we considered how microbial stimuli impact the expression of angiogenic mediators following chemical exposure. We previously showed that Ni, a hypoxia-mimetic metal, can synergistically amplify CXCL8 (IL-8) but attenuate CXCL10 (IP-10) release by HLF when exposed in the presence of a mycoplasma-derived TLR-2 agonist, MALP-2. Here we tested if the hypoxia-mimetics, deferoxamine (DFO) and cobalt chloride (CoCl2,) could similarly interact with MALP-2 to alter the angiogenic mediators in HLF. Accumulation of HIF-1α protein was observed within 4 hrs exposure to Ni, Co, or DFO alone. Exposure to DFO or CoCl2 alone failed to stimulate CXCL8 and IP-10. Both, however, enhanced CXCL8 expression in response to MALP-2, but antagonized the MALP-2-dependent induction of IP-10. Time course experiments showed that despite an early induction of HIF-1α, most of the amplified CXCL-8 release after Ni/MALP-2 or DFO/MALP-2 co-exposure occurred between 24 – 48 hrs and coincided with a synergistic induction of COX-2 protein and PGE2 release implying an autocrine modulatory role for endogenous prostanoids. Like Ni, DFO or CoCl2 stimulated the release of VEGF which was less affected by the addition of MALP-2. These data suggest that like Ni, other hypoxia-mimetics like Co and DFO can interact with MALP-2 to promote a pro-angiogenic phenotype in HLF. These data point to a functional role for HIF-1α in modulating the changes in expression of fibroblast-derived gene products with potential to modulate endothelial cell angiogenic behavior in the lung during co-exposure to chemical and microbial stimuli. Supported by NIH grant R01 ES11986.

PL 741 POTENTIAL NEGATIVE FEEDBACK LOOP BETWEEN NOVEL COREGULATOR KC101 AND TARGET NUCLEAR RECEPTORS.

I. Gurevich, C. C. Zhang, C. P. Struzynski and B. J. Aneskievich. *Pharmaceutical Sciences, University of Connecticut, Storrs, CT.* Sponsor: J. Manautou.

Epidermis serves as the interface between the body and the environment and is central for protection from cutaneous toxic assaults. Peroxisome proliferators (PPs) and retinoids play important roles in maintenance and regulation of epidermal barrier function, and may themselves have toxic effects. These chemicals exert their effects through distinct classes of nuclear receptors (NRs) – ligand driven transcription factors which rely on coregulator proteins to activate or repress transcription of target genes. We conducted a yeast two-hybrid screen of keratinocyte library in which we isolated a novel NR interacting protein KC101. Interaction studies revealed that KC101 associates with PP activated receptors (PPARs) and retinoic acid receptors (RARs) in the presence of their ligands, typically a feature of NR coactivators, but reduces receptors' activity. This makes KC101 an unusual NR coregulator – a ligand dependent corepressor, which may function in combinatorial regulation of gene expression in the epidermis and other tissues. To examine the regulation of the KC101 expression, we cloned a ~6000 base pair promoter fragment and carried out in silico analysis to identify putative transcription factor binding sites which predicted several PPAR response elements (PPREs) and retinoic acid response elements (RAREs). Transcriptional activation studies revealed that KC101 promoter is positively regulated by PPARs and RARs. Electrophoretic mobility shift assays showed PPAR and RAR binding at distinct sites in the distal portion of the KC101 promoter. Promoter-luciferase reporter studies confirmed these as response elements. Our findings reveal a potential regulatory feedback loop where KC101 expression is increased by PPARs and RARs which, in turn, attenuates their activity. Such regulatory feedback loops between coregulators and their target NRs may serve to buffer cells against extremes of hormone-regulated signaling, such as the presence of toxic ligand levels, or cells being exposed to ligand at inappropriate times.

PL 742 TRANSCRIPTIONAL REGULATION OF HUMAN MULTIDRUG RESISTANCE ASSOCIATED PROTEIN 4 GENE EXPRESSION.

X. Gu and J. E. Manautou. *Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT.*

Multidrug resistance associated protein 4 (MRP4, ABCC4) is an efflux transporter that plays an important role in cellular communication, signaling and drug resistance. Liver Mrp4 induction in mice is associated with enhanced resistance to acetaminophen hepatotoxicity. Studies in mice have shown that Nfe2l2, Kupffer cell function and the nuclear receptors PPARα and CAR, all contribute to hepatic Mrp4 induction under certain pathological conditions and chemical treatments. Liver Mrp4 induction is also seen in humans overdosed with APAP. In this study, bioinformatics and biochemical genetics approaches were used to investigate the regulation of human MRP4 gene expression at the transcriptional level. MatInspector analysis showed the presence of more than 1,000 transcription factor binding sites for over 100 transcription factors in the proximal 10 kb 5' regulatory sequence of the MRP4 gene. Reporter gene assays in HepG2 cells showed that the basal transcription activity of the promoter-proximal region was constitutively active and that the first 100 bp are required for maximal activity. Overexpression of transcription factors NRF1, NFE2L2, SP2, STAT1, KLF10 and TFAP2A in HepG2 cells up-regulates MRP4 reporter gene expression; while HES1, KLF15 and ZFP161 are repressive. Overexpression of a dominant negative form of NRF1 or site-directed mutations in putative NRF1 binding sites suppressed MRP4 gene expression. Scanning deletion analysis of the promoter-proximal region showed the presence of a short module associated with HES1 function. Although the interaction between the multiple transcription factors examined and the 5' regulatory region of MRP4 needs further characterization, these observations suggest complex regulatory mechanisms for hepatic MRP4 gene expression. The interplay between the different transcription factors that regulate MRP4 gene expression in response to toxic acetaminophen treatment, oxidative stress and other stimuli remains to be elucidated. This work was supported by The National Institutes of Health Grant DK069557.

PL 743 CRITICAL ROLE OF RALDH2 EXPRESSION IN EPIMORPHIC TISSUE REGENERATION.

S. Sengupta, L. K. Mathews, J. A. Franzosa, J. Perry, J. La Du, E. A. Andreasen and R. L. Tanguay. *Environmental & Molecular Toxicology, Environmental Health Sciences Center, Oregon State University, Corvallis, OR.*

Tissue regeneration is an orchestrated spatio-temporal co-ordination of multiple signaling events. Identification of signaling pathways that promote tissue regeneration will enable their modulation for therapeutic purpose. The emerging field of regenerative medicine is advancing through the evaluation of regenerative mechanisms in model organisms. Zebrafish have the ability to regenerate a number of tissues including the heart and both adult and larval caudal fin. Regeneration of these tissues despite significant structural differences, suggests conservation of the molecular pathways critical for tissue regeneration. Comparative genomic analysis across regenerating adult heart, caudal fin and larval caudal fin revealed a number of transcripts with similar expression changes. We identified retinaldehyde dehydrogenase or raldh2, a rate limiting enzyme for the formation of retinoic acid, as one of the highly induced transcripts across the three regenerative platforms. In situ localization and other functional studies using chemical probes revealed that raldh2 expression is necessary for wound epithelium and blastema formation. We report that Wnt, Fgf and ActβA pathways, some of the key players of tissue regeneration, are also modulators of raldh2 expression during caudal fin regeneration. This is the first report indicating a role for retinoic acid signaling in early regenerative events. Our progress demonstrates that the larval zebrafish is an ideal platform to identify and define the molecular pathways underlying complex in vivo processes. Supported by NSF #0641409, NIH R01 ES10820, and NIH P30 ES00210.

PS 744 FURAN IN FOOD: 28 DAY ORAL TOXICITY AND CELL PROLIFERATION IN MALE F344/N RATS.

A. Mally[1], C. Graff[1], S. Moro[1], C. Hamberger[1], U. M. Schauer[1], J. Brück[2], S. Özden[1], M. Sieber[1], U. Steger[1], G. C. Hard[3], J. K. Chipman[4], D. Schrenk[2] and W. Dekant[1]. *[1]University of Wuerzburg, Wuerzburg, Germany, [2]University of Kaiserslautern, Kaiserslautern, Germany, [3]Private Consultant, Tairua, New Zealand and [4]The University of Birmingham, Birmingham, United Kingdom.*

Furan, a potent hepatotoxicant and liver carcinogen in rodents, was recently shown to be present in a wide variety of heat-treated foods. Although data on human intake of furan are limited, it appears that there is a relatively narrow margin between human exposure and doses which cause liver tumors in rodents, suggesting that the presence of furan in food may present a potential risk to human health. The aim of this study was to characterize furan toxicity by assessing clinical chemistry, individual bile acids, metabonomics, histopathological and proliferative changes in rat liver after repeated oral administration of furan at doses close to human exposure. Male F344/N rats were treated with furan at doses of 0, 0.1, 0.5 and 2 mg/kg bw by gavage for up to 28 days (5d/wk). No effects on body weight and no clinical signs of toxicity were evident throughout the study. Routine clinical chemistry and metabonomics (1H-NMR and GC-MS) did not reveal signs of hepatotoxicity, other than a mild, dose-dependent increase in serum cholesterol after 28 days treatment with furan. Serum concentrations of deoxycholic acid, lithocholic acid and hyodeoxycholic acid were significantly increased in rats treated with 2 mg/kg bw, suggesting functional changes in hepatobiliary transport. Significant histopathological alterations and changes in BrdU labeling index in response to furan treatment were restricted to some parts along the edge of the left and caudate liver lobes. In these areas, a dose- and time-dependent increase in hepatocyte proliferation, accompanied by very thin foci of non-specific inflammation, was observed. In summary, results from this study suggest that even short-term treatment with low doses

of furan may induce functional (2 mg/kg bw) and proliferative changes (0.1 mg/kg bw) in rat liver. This work was supported by FP6 of the European Union (SSPE-CT-2006-44393) and DFG (MA 3323/3-1).

PS 745 MODULATION OF HEPATIC GENE EXPRESSION INDEPENDENT OF DNA METHYLATION IN FURAN TREATED F344/N RATS.

T. Chen[1], A. Mally[2], S. Ozden[2], W. Dekant[2] and K. Chipman[1]. [1]*School of Biosciences, The University of Birmingham, Birmingham, United Kingdom and* [2]*Department of Toxicology, University of Würzburg, Würzburg, Germany.*

Furan is a liver carcinogen in rodents and has been found in a variety of heated food products. To better understand the mechanism of furan carcinogenicity, time- and dose-related effects of furan on the expression of genes related to apoptosis and cell cycle were assessed by qRT-PCR arrays in livers of F344/N rats treated with furan at an oral dose of 0, 0.1 and 2 mg/kg b.w., 5-days per week for up to 28 days. Of 86 cell cycle-related genes, a total of 15 were statistically significantly upregulated at 0.1 mg/kg b.w. and this response was more evident than at the higher dose. In contrast, of 86 apoptosis-related genes, the greatest response was at 2 mg/kg b.w. (11 genes upregulated). There was little evidence of down regulation of any genes throughout. We found that very few gene expression changes occurred within 5 days and the changes observed at 28 days were largely reversible after a subsequent 2-weeks off-dose. The DNA methylation status of Bid3, Prlr and Cdkn2b (p15) (which were highly upregulated) as well as Cdkn2a (p16), Connexin 32 and c-Myc were investigated further by MSP and/or COBRA at 2mg/kg b.w.. Using LC-MS we also measured global DNA methylation following the treatments. No global DNA methylation or gene-specific methylation changes were found at either dose level. Our results indicate that, with time after repeat dosing of furan at a relatively low dose, induction of cell cycle and apoptosis related gene expression occurs. However the modulation is reversible and epigenetic DNA methylation appears not to be a mechanism under the current experimental conditions.

PS 746 A 13-WEEK ORAL TOXICITY STUDY OF L-SERINE IN RATS.

K. Hayamizu[1], I. Kaneko[1], L. Han[1] and A. Liang[2]. [1]*FANCL Research Institute, Yokohama, Kanagawa, Japan and* [2]*Center of Safety Evaluation for Chinese Materia Medica, Institute of Chinese Materia Medica, Beijing, China.*

L-Serine, the nonessential amino acid, is synthesized mainly from metabolic intermediates of the glycolysis system or partially from glycine. Recently, L-Serine was reported anti-stress and anti-sleep disorder activities, and it is expected as dietary supplement for sleep-inducer. A subchronic oral toxicity study was conducted to evaluate the safety of L-serine in Sprague-Dawley rats. The test article was administered once daily by gavage in male and female rats at dose levels of 0, 500, 1500 and 3000 mg/kg body weight/day for 13 weeks. Daily clinical observations, body weight, food and water consumption were not affected by the ingestion of the test article. There were no treatment-related adverse effect on clinical chemistry, hematology, urinalysis, organ weights, gross and histopathological examination. In conclusion, the administration of L-serine at levels up to 3000 mg/kg bw/day for 13 weeks was well tolerated without any signs of toxicity.

PS 747 SAFETY AND THERAPEUTIC EFFICACY OF A NOVEL CHROMIUM(III) DINICOCYSTEINATE (CDNC).

D. Bagchi[1,2], S. K. Jain[3], F. C. Lau[2] and M. Bagchi[2]. [1]*Pharmaceutical & Pharmacological Sciences, University of Houston, Houston, TX,* [2]*Research & Development, InterHealth Research Center, Benicia, CA and* [3]*Department of Pediatrics, Louisiana State University Health Sciences Center, Shreveport, LA.*

Chromium(III) supplementation is widely used as an adjuvant therapy to improve glucose metabolism. It also helps in energy production and increasing lean body mass. This study was focused on determining the broad spectrum safety and efficacy of CDNC. Acute oral, acute dermal, primary dermal irritation, primary eye irritation and a dose-dependent 90-day sub-chronic toxicity studies were conducted. Both acute oral and dermal LD50s and of CDNC were found to be greater than 2000 mg/kg body weight in both male and female Sprague Dawley rats. The primary skin irritation study in New Zealand Albino rabbits demonstrated CDNC as slightly irritating. The eye irritation study exhibited that CDNC is moderately irritating. A dose-dependent 90-day subchronic toxicity study demonstrated no significant toxicity of CDNC. In efficacy studies, Zucker diabetic fatty (ZDF) rats were supplemented with CDNC (400 mcg elemental chromium(III)/kg body weight/day) over a period of 8 weeks. CDNC significantly lowered blood glucose (24%), HbA1c (11%), CRP (20%), MCP-1 (49%), ICAM (10%) and Lipid peroxidation (20%), respectively, compared to control rats. Taken together, these results demonstrate the broad spectrum safety and efficacy of a novel Chromium(III) Dinicocysteinate.

PS 748 GENE EXPRESSION PROFILING IN PRENATALLY-EXPOSED MICE TO STUDY THE POTENTIAL OF SELENIUM TO AMELIORATE DEVELOPMENTAL METHYLMERCURY NEUROTOXICITY.

S. Jayashankar[1], C. N. Glover[3], K. I. Folven[1], C. Hogstrand[2,1], T. Brattelid[1] and A. Lundebye[1]. [1]*Seafood safety, National Institute of Nutrition and Seafood Research, Bergen, Hordaland, Norway,* [2]*Nutritional Sciences, King's College London, London, United Kingdom and* [3]*School of Biological Sciences, University of Canterbury, Christchurch, New Zealand.* Sponsor: T. Syversen.

Controversy remains regarding the safety of consuming seafood, particularly during pregnancy. While seafood is the main source of environmental contaminants such as methylmercury (MeHg), it is also rich in vital nutrients. These nutrients have important roles in health, including brain development in the foetus, but may also offset effects of seafood toxicants. Selenium (Se) is a nutrient hypothesized to ameliorate MeHg toxicity. The aim of this study was to ascertain the impact of Se on MeHg-induced gene expression in a mammalian model.

Whole brain microarray analysis was performed in 15d-old mice which had been exposed throughout development via the maternal diet. The three exposure groups included: MeHg (4 mg/kg), Se (1.3 mg/kg), and MeHg+Se (4 mg/kg +1.3 mg/kg). MeHg was presented as a cysteinate form, and Se as Se-methionine, the elemental species occurring naturally in seafood.

Genes related to calcium binding and prolactin, key targets of MeHg neurotoxicity were significantly differentially-regulated following MeHg exposure. These genes did not appear in the combined MeHg + Se exposure, suggesting that these pathways of toxic action/response were ameliorated by the presence of Se. Instead MeHg + Se exposure resulted in significant differential expression of genes involved in cell adhesion and those possessing an immunoglobin domain. These functional clusters were also distinct from pathways regulated on exposure to Se alone. The differences were not related to changes in MeHg accumulation, as this was not significantly different between these exposure groups. Changes in gene expression were accompanied by improvement in some neurobehavioural indicators of MeHg-induced toxicity. These results suggest potentially novel mechanisms by which Se may ameliorate the negative effects of MeHg-associated with seafood consumption.

PS 749 SIMULTANEOUS DETERMINATION OF BISPHENOL A, OCTYLPHENOL AND NONYLPHENOL BY PRESSURIZED LIQUID EXTRACTION AND LIQUID CHROMATOGRAPHY–TANDEM MASS SPECTROMETRY IN INFANT FORMULAS.

G. Font[1], J. Mañes[1], E. Ferrer[1], G. Sagratini[2], E. Santoni[2], S. Vittori[2] and A. Anadon[3]. [1]*Department of Bromatology And Toxicology, Faculty of Pharmacy, Universitat de Valencia, Valencia, Valencia, Spain,* [2]*Department of Chemical Sciences, Faculty of Pharmacy, University of Camerino, Camerino, Camerino, Italy and* [3]*Department of Toxicology and Pharmacology, Faculty of Veterinary Medicine, Universidad Complutense, Madrid, Spain.*

Bisphenol A (BPA) is a substance widely used for the manufacture of polycarbonate plastics and epoxy resins, which are used in plastic food containers, such as baby bottles. Nonylphenol (NP) and Octylphenol (OP) are the environmental contaminants used as intermediates to produce anionic and non-ion surfactants. Some recent reports determined the occurrence of these endocrine disruptor compounds in foods from different markets or containers [1, 2]. The aim of this work is to develop a new rapid, sensitive and reproducible analytical strategy for determining BPA, OP and NP contents in powdered infant formulas using pressurized liquid extraction (PLE) and liquid chromatography-tandem mass spectrometry (LC–MS/MS) with a triple quadrupole (QqQ) mass analyzer. For the extraction of the sample a comparative study was carried out using as dispersing agent C18 powder, and acetone/hexane mixtures as solvents. The separation was carried out on a reverse phase C18 column using as mobile phase methanol/acetonitrile/water containing 0.1% ammonia. LC-MS/MS studies were performed using a QqQ equipped with an electrospray ionization (ESI) source operating in negative mode. Calibration curves, calculated in the range 0.05-5 μg ml-1, showed excellent linearity (r2>0.998). The recoveries ranged from 63 to 91% with an RSD< 12%; limits of quantification (LOQs) were in the range 0.0005-0.0025μg ml-1. PLE coupled with LC-ESI-MS/MS enables rapid and accurate determination of BPA, NP and OP in infant formulas. This work was supported by the Science and Education Spanish Ministry (AGL2007-61493).

PS 750 RELATIVE PHOTOMUTAGENIC POTENCY OF FUROCOUMARINS AND LIMETTIN.

N. Raquet and D. Schrenk. *Food Chemistry and Toxicology, University of Kaiserslautern, Kaiserslautern, Germany.*

Furocoumarins occur in plants used as food (e.g. grapefruit, lime, parsley, parsnip) or in phytomedicines (Ammi majus, Angelica archangelica). In combination with UV light they can lead to photomutagenic effects. The latter are caused, e.g., by UV-induced covalent binding of furocoumarins to pyrimidine bases of the DNA. In contrast, a photomutagenic potency of limettin, a coumarin occurring in citrus products, has not been established so far.
We performed the hPRT mutagenicity assay in order to detect possible DNA damage resulting in hereditary mutations of the hPRT (hypoxanthine-P-ribosyl-transferase) locus. Therefore, V79 cells were incubated with furocoumarins (5-MOP, 8-MOP, angelicin) or limettin (5,7-dimethoxycoumarin), and irradiated with various doses of UVA-light (0-200 mJ/cm2). In the absence of light, no significant genotoxic effects were detectable with any of the compounds. At various levels of 5-MOP, an increase in mutagenicity with increasing UVA dose was observed. All furocoumarins tested and limettin led to a linear increase in mutagenicity with increasing concentrations at a given UVA-dose of 125 mJ/cm2. The slopes of these linear relationships allowed the calculation of photomutagenicity equivalency factors (PMEF) setting the PMEF of 5-MOP at 1.0. The PMEFs were calculated as 0.3 for 8-MOP, 0.02 for angelicin, and 0.02 for limettin, clearly demonstrating the photomutagenic potency of this compound.

PS 751 MAIZE GRAIN FROM HERBICIDE-TOLERANT TRANSGENIC EVENT DP-Ø9814Ø-6: SUBCHRONIC ORAL TOXICITY IN RATS.

L. M. Appenzeller[1], S. M. Munley[2], D. Hoban[2], G. P. Sykes[2], L. A. Malley[2], R. Essner[1] and B. Delaney[1]. *[1]Pioneer, A DuPont Company, Johnston, IA and [2]DuPont Haskell Global Centers for Health and Environmental Sciences, Newark, DE.*

This 90-day rat feeding study was conducted as part of the pre-market safety assessment of genetically-modified (GM), herbicide-tolerant maize DP-Ø9814Ø-6 (98140; Optimum® GAT®, registered trademark of Pioneer, A DuPont Company). Metabolic inactivation of the herbicidal active ingredient glyphosate is conferred by genomic integration and expression of a gene-shuffled acetylase coding sequence, *gat4621*, from *Bacillus licheniformis*; tolerance to ALS-inhibiting herbicides is conferred by overexpression of a modified allele (*zm-hra*) of the endogenous maize acetolactate synthase enzyme that is resilient to inactivation. Diets nutritionally comparable to PMI® Certified Rodent LabDiet® 5002 were formulated by substitution (at 35-38% w/w) of milled maize grain from untreated (98140) and herbicide-treated (98140+Gly/SU) plants, the conventional non-transgenic, near-isogenic control (091), and three commercial non-transgenic reference hybrids (33J56, 33P66, and 33R77). To evaluate the potential health effects from long-term consumption of Optimum® GAT® maize grain, the experimental diets were fed to young adult SD rats (12/sex/group) for at least 91 consecutive days. Compared with rats fed diets containing grain from the conventional near-isogenic control maize, no diet-related adverse effects were observed in rats fed diets containing grain from 98140 or 98140+Gly/SU maize with respect to standard nutritional performance metrics and OECD 408 response variables (body weight/gain, food consumption/efficiency, mortality, clinical signs of toxicity, ophthalmological observations, neurobehavioral assessments, organ weights, and clinical and anatomic pathology). No health hazards were identified, supporting the comparative safety and nutritional value of maize grain from genetically modified Optimum® GAT® and conventional, non-transgenic hybrid field corn.

PS 752 HYDROLYZED FUMONISIN B_1 (HFB_1) DID NOT INDUCE NEURAL TUBE DEFECTS IN LM/Bc MICE.

K. A. Voss[1], T. D. Burns[2], M. E. Snook[1], R. T. Riley[1] and J. B. Gelineau-van Waes[3]. *[1]Toxicology & Mycotoxin Research Unit, USDA Agricultural Research Service, Athens, GA, [2]Interdisciplinary Toxicology Program, University of Georgia, Athens, GA and [3]Department of Genetics, Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE.*

Fumonisins are mycotoxins produced by *Fusarium verticillioides*. They are found in corn-based foods and are toxic and carcinogenic to rodents. There is evidence suggesting that consumption of corn tortillas containing fumonisins contributed to an enigmatic cluster of neural tube defects (NTDs) in southern Texas during 1990-91. Fumonisin B_1 (FB_1) causes NTDs when given intraperitoneally (ip) at doses of ≥ 5 mg/kg (≥ 7 μmol/kg) body weight to pregnant LM/Bc mice on embryonic days (E) 7-8, the critical window for neural tube closure. To test the teratogenic potential of hydrolyzed fumonisins, which are found in tortillas and other alkaline cooked corn products, pregnant LM/Bc mice were given (ip) 2.5, 5.0, 10 or 20 mg/kg (≤ 49 μmol/kg) body weight HFB_1 on E7-8. Negative and positive control groups were given vehicle or 10 mg/kg (14 μmol/kg) body weight FB_1, respectively. NTDs were not found (E16) in the groups given HFB_1 and no significant differences were found among negative control and HFB_1-exposed litters (n=8-9/group) for the following (mean ± S.D.): number of implants (9.9 ± 3.9 to 11.8 ± 2.0), viable fetuses (8.6 ± 3.6 to 10.0 ± 2.0), early resorptions (0.9 ± 1.0 to 1.7 ± 2.0), late deaths (0.3 ± 0.5 to 0.7±1.0) and average weight of viable fetuses (0.47 ± 0.09 to 0.55 ± 0.05 g). NTDs were found in all positive control litters (n=10): the mean number/litter was 4.7 ± 2.8, which equaled 66 ± 24% of the fetuses. The mean number of implantations/litter (11.4 ± 2.1) was similar to the other groups; however, early resorptions (4.6 ± 3.0/litter) and fetal deaths (3.0 ± 0.9) were increased ($p < 0.05$) and the number (3.9 ± 2.1) and weight (0.33 ± 0.7 g) of viable fetuses decreased ($p < 0.05$). These findings indicate that HFB_1 does not cause NTDs in LM/Bc mice at doses up to 7-fold higher (μmol/kg body weight basis) than the reported LOAEL for FB_1.

PS 753 IN VITRO ANALYSIS OF ZEARALENONE BINDERS INCLUDED IN ANIMAL FEEDS IN MEXICO AND INITIAL STEPS FOR STANDARDIZATION OF OCHRATOXIN SORPTION ASSAYS.

A. G. Marroquin-Cardona[1], M. J. Berg[2], N. M. Johnson[1], C. M. Sayes[2], A. Robinson[1], J. F. Taylor[1] and T. D. Phillips[1]. *[1]Veterinary Integrative Biosciences, Texas A&M University, College Station, TX and [2]Veterinary Physiology and Pharmacology, Texas A&M University, College Station, TX.*

Six commercially available Zearalenone (ZEN) binders from Mexico were analyzed by equilibrium isothermal analysis to compare their adsorption capacity for ZEN at pH 2 and 6.5. Nitrogen BET surface area was determined to investigate a potential correlation with sorption capacity. The binders included Zeotek, Duotek (Nutek), Mexsil (Karluis), Mycosorb (Alltech), Toxinor (Norel) and Mycoad (Avimex). Binders were compared to Activated Carbon (AC), Cetylpyridinium-Low pH Montmorillonite (CP-LPHM) (+ controls) and NovaSil (Engelhard) (- control). Experiments to evaluate solubility and stability of Ochratoxin A (OTA) were performed as a preliminary step for the isothermal sorption analysis of ZEN/OTA binders. Isotherms for ZEN were run in triplicate for 11 different concentrations of ZEN with 0.05 mg of each binder, while water and ZEN (4 ppm) were used as controls. Computer-generated isotherm data were analyzed and the semi-empirical parameters of Q_{max} and K_d were calculated. C-shaped curve characteristics were observed for most of the binders at pH 2 and 6.5 with varied r^2 values. AC and CP-LPHM showed different patterns of sorption (L-shaped), suggestive of more effective binding properties. With OTA, 4 and 8 ppm solutions in water:acetonitrile (124.9:0.1) were stable for 1 week (with maximum absorbance observed at 333 nm) when protected from light and stored at a 2-8 °C. In conclusion, 1) none of the binders showed an effective pattern of sorption for ZEN, 2) BET data could not be correlated with Q_{max} values; however, it provided important insight regarding the composition of matter of the binders, and 3) OTA water:acetonitrile solutions may be appropriate for sorption analysis of OTA. Further determination of surface area using water vapor as a more suitable method for analysis of these materials is ongoing. (Supported by NIEHS P42 ES04917, PROMEP 103.5/05/1673)

PS 754 PREDOMINANCE OF AFLATOXIN EXPOSURE IN RURAL RESIDENTS OF SOUTHERN GUANGXI, CHINA.

L. Xu[1], L. Tang[1, 2], G. Qian[1], J. Su[3] and J. Wang[1]. *[1]Department of Environmental Health Science, University of Georgia, Athens, GA, [2]Jiangnan University, Wuxi, China and [3]Guangxi Cancer Institute, Nanning, China.*

Aflatoxin B_1 (AFB_1) is the predominant and most toxic form of natural mycotoxins frequently found in cereal grains and oilseeds. AFB_1 contamination in food is considered as an unavoidable public health problem worldwide, especially in developing countries. As a known human carcinogen (Group 1, IARC), the linkage between dietary AFB_1 exposure and hepatocellular carcinoma (HCC) has been firmly established. To further assess human risks exposed to AFB_1, development and validation of sensitive, accurate, and easy-to-use, and inter-laboratory comparable methods for reliable AFB_1 biomarkers and longitudinal biomonitoring are of importance. In this study conducted in rural southern Guangxi area, China, serum samples collected from both healthy individuals and HCC patients, matched with gender, age and residence, were measured for AFB_1-lysine adducts by a recently developed HPLC method. Out of 136 samples analyzed from healthy people, 97.1% (132/136) had detectable levels of AFB_1-lysine adduct ranging from 0.29 to 157.83 pg/mg albumin with the average level of 7.46 ± 9.27 (mean ± SD) pg/mg albumin and a median, 3.69 pg/mg albumin. Of 68 serum samples analyzed from HCC patients, 91.2% (62/68) had detectable levels of AFB_1-lysine adduct ranging from 0.54 to 66.26 pg/mg albumin with the average level of 7.34±16.59 (mean ± SD) pg/mg albumin and a median, 4.97 pg/mg albumin. AFB_1-lysine levels in HCC pa-

tients were marginally higher than those in healthy individuals (p=0.087) and has no change after adjusting sex and age. These results indicated that dietary AFB_1 exposure was prevalent in this high risk population, which is consistent with previous study in this area. (Supported by NCI CA90997)

PS 755 SERUM LEVELS OF AFLATOXIN B_1-LYSINE ADDUCT IN A U.S. POPULATION COMPARED TO A HIGH RISK POPULATION IN CHINA.

G. Qian[1], L. Tang[1], L. Xu[1], N. M. Johnson[2], D. Tietze[2], M. Rodriguez[3], L. Kaufman[3], K. Cunningham[3], J. Wittmer[3], F. Guerra[3], K. C. Donelly[2], T. D. Phillips[2] and J. S. Wang[1]. *[1]College of Public Health, University of Georgia, Athens, GA, [2]College of Veterinary Medicine, Texas A&M University, College Station, TX and [3]San Antonio Metropolitan Health District, San Antonio, TX.*

Aflatoxins are a group of mycotoxins that have long been recognized as hazardous contaminants of food. Aflatoxin B_1 (AFB_1) is the most significant hepatotoxic and genotoxic agent. Acute dietary exposure to high levels of AFB_1 causes aflatoxicosis and chronic exposure to low levels of AFB_1 is one of the major risk factors for human hepatocellular carcinoma (HCC) in several regions of Africa and Southeast Asia. In this study, the levels of AFB_1-lysine adduct were measured in serum samples collected from participants in a predominantly Hispanic population in a maize consuming region of Texas known to have an increased incidence of HCC. This cross-sectional study was conducted within adult volunteers from three zip code regions in San Antonio, Texas. In addition to a sociodemographic survey, serum samples were analyzed for AFB_1-lysine adduct by a recently developed HPLC method. Out of the total 151 serum samples analyzed, 17.2% (26/151) had detectable levels of AFB_1-lysine adduct with the average level at 4.57 ± 3.28 ranging from 1.69-16.57 pg/mg albumin. Results from this study were compared to our previous findings in a southern Guangxi population known to be at high risk for AFB_1 exposure. Of the total 136 samples collected from participants in Fusui County, 97.1% (132/136) had detectable levels of AFB_1-lysine adduct ranging from 0.28 to 157.83 pg/mg albumin. These findings suggest that the study population in San Antonio had low dietary aflatoxin exposure. (Supported by NIEHS ES 09106 and NCI CA90997)

PS 756 INITIAL EVALUATION OF PROTEIN EXPRESSION PATTERNS IN HUMAN LIVER CELLS TREATED WITH AFLATOXIN B1.

L. Tang[1, 2, 3], Y. Zhou[2], Y. Yang[2] and J. Wang[1, 2]. *[1]Environmental Health Science, The University of Georgia, Athens, GA, [2]Enviromental Toxicology, Texas Tech University, Lubbock, TX and [3]Food Safety and Nutrition, Jiangna University, Wuxi, China.*

Aflatoxin B1 (AFB1) is the most significant hepatotoxic and genotoxic mycotoxin. Acute dietary exposure to high levels of AFB1 causes severe liver damage (aflatoxicosis) and chronic exposure to low levels of AFB1 can induce hepatocellular carcinoma (HCC) in animals and humans. Many toxicological researches had focused on evaluation of AFB1 toxic effects on single DNA or protein target; however, the overall toxicogenomic and toxicoproteomic profile of AFB1 toxicity is largely unknown. In this study, 2-dimensional gel electrophoresis based proteomic analysis was undertaken to assess the dose response and time course of the protein expression in human HCC cells (HepG2) following treatment with AFB1 at 1μM and 5μM for 24, 48, and 72 h. The differentially expressed proteins were classified according to the image analysis with ImageQuant software. No significant inhibition on overall protein expression was found in cells treated with AFB1 concentration at 1μM or 5μM up to 72 h, as evidenced by similar numbers of total protein spots detected. However, HepG2 cells treated with AFB1 had different protein expression profiling as compared to the non-treated control cells. A total of 30 distinctive protein spots (2-fold or higher or lower than controls in density) was found in cells treated with 1μM or 5μM AFB1 for 24 h. More distinctive protein expression changes were found in cells treated with AFB1 for 72 h: 60 protein spots were detected in 1μM AFB1-treated cells and 74 protein spots, in 5μM AFB1-treated cells. Both up- or down-regulations were found in protein expression profiles. Majority changes were found in proteins with their isoelectrofocusing at pH 5-7. Future work will use mass spectrometry to identify these proteins. (Supported by DOD RDECOM W911SR-07-C-0069).

PS 757 BENZOCAINE-INDUCED METHEMOGLOBINEMIA IN AN ACUTE EXPOSURE RAT MODEL.

L. S. VonTungeln[1], F. A. Beland[1], K. A. Woodling[1], D. R. Doerge[1], K. J. Greenlees[2] and T. Zhou[2]. *[1]Division of Biochemical Toxicology, FDA/NCTR, Jefferson, AR and [2]Office of New Animal Drug Evaluation, FDA/CVM, Rockville, MD.*

Tricaine methanesulfonate, a widely used anesthetic for temporarily immobilizing food producing fin fish, has a 21-day withdrawal time. The anesthetic benzocaine has been proposed as an alternative to tricaine methanesulfonate because it is hoped that an extended withdrawal period would not be required. Benzocaine has been known to induce methemoglobinemia in a number of mammals including humans. This poses a potential concern for humans consuming fish containing residues of benzocaine. We have assessed the potential in rats for methemoglobin formation resulting from treating rats with single oral doses of benzocaine. Initially, male and female Sprague-Dawley rats (3/sex/time point) were given a single gavage administration of 64 mg benzocaine hydrochloride per kg body weight (bw) and then euthanized at 12-min intervals up to 120 min after treatment. Plasma levels of benzocaine, as determined by UPLC-ES-MS/MS, were relatively low and constant (~0.1 μM) at all time points, whereas the mean methemoglobin value peaked at 20% at 24 min and then declined. Based upon these data, additional rats (5/sex/treatment group) were orally gavaged with 0-1024 mg benzocaine hydrochloride per kg bw and euthanized 24 min after treatment. Plasma levels of benzocaine increased in a linear manner from 0.01 μM at 2 mg/kg bw to 2.9 μM at 1024 mg/kg bw. Methemoglobin levels did not differ from control values (0.8%) at doses up to 32 mg/kg bw in females and 64 mg/kg bw in males, whereupon the value increased to 80% at 1024 mg/kg bw. These data indicate that oral doses of benzocaine hydrochloride <32 mg/kg bw do not cause an increase in methemoglobin in this acute exposure animal model.

PS 758 ISOLATION AND CHARACTERIZATION OF 1-DEOXYSPHINGANINE, A NOVEL SPHINGOID BASE THAT ACCUMULATES IN CELLS FOLLOWING FUMONISIN B1 INHIBITION OF CERAMIDE SYNTHASE.

N. C. Zitomer[1], T. Mitchell[1], K. A. Voss[1], S. T. Pruett[2], E. Garnier[3], L. S. Liebeskind[3], H. Park[4], E. Wang[4], C. Sullards[4], A. H. Merrill[4] and R. T. Riley[1]. *[1]Toxicology and Mycotoxin Research Unit, USDA-ARS, Athens, GA, [2]Yerkes National Primate Research Center, Emory University Biomarkers Core Lab, Atlanta, GA, [3]Department of Chemistry, Emory University, Atlanta, GA and [4]School of Biology and the Petit Institute for Bioengineering and Bioscience, Georgia Institute of Technology, Atlanta, GA.*

Fumonisin B1 (FB1) is a fungal toxin found in maize worldwide. It is hepato- and nephrotoxic in many species, a liver and kidney carcinogen in rodents, and suspected to be involved in human disease. Its mechanism of action is disruption of sphingolipid metabolism consequent to inhibition of ceramide synthases (CerS). In cultured cells, inhibition of CerS by FB1 increases sphinganine (Sa), Sa 1-phosphate and a previously unidentified metabolite, believed to be a novel sphingoid base. In this study, the metabolite was analysed by mass spectrometry (MS) and assigned a m/z =286.3123 in positive ionization mode, consistent with a 1- or 3-deoxysphinganine (deoxySa), $C_{18}H_{40}NO$. Based on the calculated formula, it was hypothesized that the putative deoxySa was either produced from Sa via a dehydroxylase or was formed from the utilization of alanine by serine palmitoyl transferase (SPT), the first and rate-limiting enzyme in sphingolipid biosynthesis. Comparison with a synthetic standard using liquid chromatography tandem MS (LC-MS/MS) identified the metabolite as 1-deoxySa based on LC mobility and production of a distinctive m/z 44 fragment ion ($CH_3CH{=}NH_2$+) upon collision-induced dissociation. By comparison, Sa produced a distinctive m/z 60 fragment ion ($HOCH_2CH{=}NH_2$+). Inhibition of SPT with myriocin blocked the formation of both Sa and 1-deoxySA. Labeling studies using L-alanine-U-$^{13}C_3$ and L-serine-U-$^{13}C_3$ showed the preferential incorporation of alanine into 1-deoxySa, confirming that 1-deoxySA arises from condensation of alanine with palmitoyl-CoA via SPT.

PS 759 ACCUMULATION OF 1-DEOXYSPHINGANINE IN MAMMALIAN CELLS AND TISSUES FOLLOWING FUMONISIN INHIBITION OF CERAMIDE SYNTHASE: A NOVEL CATEGORY OF BIOACTIVE SPHINGOID BASES AND 1-DEOXYDIHYDROCERAMIDES.

R. T. Riley[1], N. C. Zitomer[1], T. Mitchell[1], K. A. Voss[1], G. S. Bondy[2], S. T. Pruett[3], E. Garnier[4], L. S. Liebeskind[4], H. Park[5], E. Wang[5], C. Sullards[5] and A. H. Merrill Jr[5]. *[1]Toxicology and Mycotoxin Research Unit, USDA-ARS, Athens, GA, [2]Food Directorate Health Products and Food Branch, Health Canada, Ottawa, ON, Canada, [3]Yerkes National Primate Research Center, Emory University, Atlanta, GA, [4]Department of Chemistry, Emory University, Atlanta, GA and [5]School of Biology and the Petit Institute for Bioengineering and Bioscience, Georgia Institute of Technology, Atlanta, GA.*

Fumonisin B1(FB) is a mycotoxin that inhibits ceramide synthases (CerS) and causes kidney and liver toxicity and other disease. CerS inhibition increases sphinganine (Sa), Sa 1-phosphate and a novel sphingoid base, 1-deoxysphinganine (1-deoxySa). The purpose of this study was to i) determine the cytotoxicity of 1-deoxySa, ii) verify that 1-deoxySa can become elevated in tissues of animals exposed

to FB, and iii) determine if endogenous 1-deoxySa is N-acylated by CerS. In LLC-PK_1 cells, Vero cells, and other cell lines, 1-deoxySa accumulated to high levels after treatment with FB. 1-DeoxySa was also detected in liver and kidney of P53N5 mice and increased in mice fed FB diets. 1-DeoxySa displayed a similar toxicity as Sa in dividing LLC-PK_1 cells. FB alone and FB plus 10 μM sphinganine co-treatment caused a slight elevation in 1-deoxySa compared to the control, whereas cells treated with FB plus 10 μM 1-deoxySa showed a 25-fold elevation in 1-deoxySa compared to the FB-only treated cells and a 42-fold elevation compared to the cultures treated with only 10 μM 1-deoxySa. Conversely, in LLC-PK_1 cells treated with 10 μM 1-deoxySa, the level of total N-acyl-1-deoxySa (i.e., 1-deoxydihydroceramides) went from 32.2 to 4,634 pmol/mg protein. Co-treatment with FB reduced the increase to 396 pmol/mg protein, indicating that the endogenous 1-deoxySa is acylated by CerS. 1-Deoxydihydroceramides were also easily detected in mouse liver. These findings implicate 1-deoxy sphingoid bases in diseases caused by FB, and they may play important roles in cell regulation.

PS 760 IMPROVED REAL-TIME PCR QUANTITATION OF RICIN AND OTHER RIBOSOME-INACTIVING PROTEINS.

W. B. Melchior and W. H. Tolleson. *Division of Biochemical Toxicology, NCTR, Jefferson, AR.*

We previously reported an assay for ricin and other ribosome inactivating proteins that uses quantititative real-time PCR (qPCR). The assay measures the single base change in the rRNA sequence after Moloney murine leukemia virus reverse transcriptase (MMLV-RT) preferentially inserts an adenosine in the cDNA opposite the specific abasic RNA site created by the toxin. We now report an improvement of this assay that decreases the number of steps, the amount of supplies, and the time needed for the entire process. The assay described previously involved three separate steps: (1) RNA incubation with ricin; (2) reverse transcription of the treated RNA; and (3) qPCR determination of the amount of altered sequence. We have now shown that the assay can be simplified by using "one-step" quantitative reverse-transcriptase PCR (qRT-PCR): toxin-treated RNA is added to the qRT-PCR reaction mix, incubated in a real-time PCR instrument for a few minutes at 50° C for the RT step (using a reverse transcriptase based on MMLV-RT, like the original assay), and then amplified; both the RT reaction and the qPCR amplification are handled by a single program in the instrument. As in the original assay, reactions are done with two primer sets: one to measure the sequence change and the other, for a sequence close to but not including the site of ricin action, to measure the total amount of rRNA. Enzyme activity is determined by comparing these two reactions performed on the same sample. The primer used by the RT step must not extend into the site of ricin reaction so that the polymerase can insert an adenine opposite the abasic site. The other primer, therefore, must be the one that matches the altered base. This assay has been shown to detect a variety of ribosome inactivating proteins: type II toxins ricin, abrin, and shiga toxin 1; and type I toxins pokeweed toxin and ricin A chain. It detects the enzymatic activity of the ribosome inactivating proteins, is rapid and sufficiently sensitive to detect bioterrorism-contaminated materials and equipment, and complements immunochemical and cell-based assays.

PS 761 SAFETY ASSESSMENT OF SCLAREOLIDE AS A FOOD INGREDIENT.

I. Carabin[1] and G. A. Burdock[2]. *[1]Women's Health Sciences Group, Vero Beach, FL and [2]Marketing, Burdock Group, Orlando, FL.*

Sclareolide (CAS # 564-20-5) is a synthetic sesquiterpene. In the food industry, sclareolide is used as a flavoring agent to enhance the organoleptic properties of foodstuffs, as partial fat replacer in dairy products, and as a modulator to reduce or eliminate the aftertaste of artificial sweeteners used in food and beverages. Sclereolide has been approved for use as a flavor ingredient by the Flavor and Extract Manufacturers' Association (FEMA). Sclareolide is structurally similar to sclareol, and it is synthesized by degradation of a manoyl derivative and by ozonization of 12α-hydroxy-13-epinanoyl oxide. No toxicological studies have been conducted with sclareolide, however, some studies have been performed with sclareol. Because of the structural similarity, the results obtained from toxicological studies performed with sclareol are likely to approximate the toxicity of sclareolide. Sclareol was practically non-toxic in acute studies. The oral LD50 in rats and the dermal LD50 in rabbits exceeding 5 g/kg. At a concentration as high as 10% in petrolatum, sclareol did not produce irritation when applied to the skin of human subjects. Sclareolide was tested and found to have antibacterial activity and demonstrated cytotoxicity against breast (MCF-7), colon (CKCO-1), lung (H-1299) and skin (HT-144) human cancer cell lines. Sclareolide has a long history of use and is presumed safe. FEMA Expert Panel established the safe use of sclareolide at 0.05 mg/day.

PS 762 DISPOSITION OF [2, 3-14C]ACRYLAMIDE ORALLY DOSED TO JUVENILE AND ADULT FEMALE RATS.

H. Kurebayashi[1], N. Nanbu[2], Y. Hamai[2], A. Shigematsu[2], T. Imai[1], K. Nakazawa[1] and Y. Ohno[1]. *[1]NIHS, japan, Tokyo, Japan and [2]Institute of Whole Body Metabolism, Chiba, Japan.* Sponsor: A. Nishikawa.

Acrylamide (ACR) was reported for testicular toxicity, neurotoxicity and carcinogenicity. International Agency for Research on Cancer (IARC 1994) labeled ACR as a probable human carcinogen. Recently, much scientific as well as public attention has been focused on chemicals such as ACR formation during food processing, and the consumption of ACR from food is estimated to be higher in children than in adults. Another apprehension is the sensibility of children to ACR toxicity. There were some reports on the disposition of ACR in male rats in relation to its testicular toxicity, but few reports in female ones. Until now there has been no report on the metabolism of 14C-ACR in juvenile female rats. For risk assessment purposes, we have studied on the disposition of [2,3-14C]ACR (14C-ACR) in juvenile and adult female rats. Female SD rats of 4 and 14 wk were administered by a single oral dose of 14C-ACR 2.5mg/kg, 50-140μCi/kg. 14C-ACR was rapidly absorbed and excreted because 65-80% of radioactivity was excreted into urine within 72 h and fecal excretion was smaller (9–10%). 14C-ACR was rapidly distributed over the rat and most of organs showed the maximum concentrations at 30 or 60 min, except for blood. The radioactivity eliminated rapidly from most of organs, but very slowly from the blood. There was not specific tissue retention in nerve cells or mammary glands but in blood cells after 72 h. 14C-ACR seemed more rapidly absorbed and excreted in juvenile rats than in adult rats.

PS 763 RELATIVE QUANTIFICATION OF SEED PROTEIN ALLERGENS FROM NONTRANSGENIC SOYBEAN VARIETIES BY LIQUID CHROMATOGRAPHY-TANDEM MASS SPECTROMETRY.

S. E. Stevenson[1], J. J. Thelen[1] and G. S. Ladics[2]. *[1]Interdisciplinary Plant Group and Department of Biochemistry, University of Missouri, Columbia, MO and [2]Crop Genetics, DuPont Co., Wilmington, DE.*

Use of proteomic techniques to identify and evaluate endogenous levels of proteins is increasing. Data are lacking on the natural variability of levels of different proteins (allergens) across varieties and different environmental conditions. These data are critical for interpreting differences in protein levels between crop varieties. A current approach to evaluate proteins is to separate them by two-dimensional gel electrophoresis (2-DE) and analyze protein spots by either MALDI-TOF or tandem mass spectrometry (MS/MS). The 2-DE approach is laborious and has reproducibility issues that render it a more qualitative than quantitative approach. The objective was to develop and evaluate a higher-throughput and potentially more quantitative approach to analyze complex protein samples that does not employ gels or chemical labeling. The approach involves C18 analytical liquid chromatography (LC) separation of peptides obtained by in-solution protein trypsin digestion, coupled to online nanospray ionization MS/MS; a technique commonly referred to as LC-MS/MS. Using contemporary, fast-scanning MS the frequency of MS/MS scans (representing individual peptides as protein surrogates) is a theoretical reflection of the relative protein abundance in the original sample, termed spectral counting. After validating the linear dynamic range and reproducibility of this approach using protein standards, soybean proteins were analyzed to compare the relative abundance of allergenic proteins across soy varieties from multiple U.S. locations. Most of the major soy allergens: glycinins (genInfo identifier 121276, 121277, 121278, 121279, 75221455), beta-conglycinin alpha chain (121281), Kunitz-type trypsin inhibitor (125020), Gly m Bd 28K (12697782), and 34 kDa maturing seed protein (84371705) were identified from 1 μg of injected protein suggesting this could be a potentially viable, high-throughput approach for monitoring variation in protein allergen levels in plants.

PS 764 SAFETY OF GERANIUM OIL AS A FOOD INGREDIENT.

C. Crincoli and G. A. Burdock. *Burdock Group, Orlando, FL.*

Geranium oil is the steam-derived essential oil obtained from the geranium plant, Pelargonium graveolens, and is used by both the fragrance and food industries. It is a popular constituent of soaps and detergents because, unlike other fragrance oils, it is not adversely affected by the alkaline nature of soaps. Primary constituents of geranium oil have been anecdotally used for their anti-inflammatory and antioxidant activity, making them good candidates for dietary supplement use. As a flavoring agent it is GRAS for food use by FDA, Flavor and Extract Manufacturers' Association (FEMA) and by the Council of Europe with no set use limits defined. The National Academy of Science and FEMA consumption calculations estimate the per capita consumption level to be 0.234 mg/day (0.00387 mg/kg/day) and

0.149 mg/day (0.00387 mg/kg/day), respectively, which, although lower than the ADI value of 0.0288 mg/kg/day suggested by FEMA, consumer exposure could increase significantly with use as a dietary supplement. The ADI for geranium oil is based on a minimal set of studies using geranium oil. The oral LD50 in rats is greater than the highest dose tested (5 mg/kg body weight). Dermal toxicity studies conducted in rabbits and guinea pigs resulted in LD50 levels of 2.5 g/kg and >5 g/kg, respectively. Dermal irritation studies produced mixed results ranging from "non-irritating" to "moderate" at full strength. However, based on the lack of toxicity shown in the animal model as well as the long history of human exposure as a fragrance and in food as an added flavoring, geranium oil as an added food ingredient is considered safe at present use levels.

PS 765 COMPARISON OF EXPOSURE ASSESSMENT MODELS IN DETERMINING ESTIMATED HUMAN DIETARY EXPOSURE TO N-ACETYLASPARTATE FROM FOODSTUFFS.

C. A. Mathesius[1], R. Layton[1], B. Delaney[1], A. O. Hession[2], E. G. Esrey[2], R. A. Croes[2] and C. A. Maxwell[2]. *[1]Pioneer, A DuPont Company, Johnston, IA and [2]DuPont Agriculture and Nutrition, Wilmington, DE.*

A recent study reported finding N-Acetylaspartate (NAA) in various foodstuffs including fruits, vegetables, meats, grains, milk, coffee, tea and cocoa. In order to estimate human dietary exposure to NAA, concentrations of NAA in the foodstuffs were entered into two models: GEMS/Food Regional Diets (GEMS/Food) and DEEM™ - FCID (Exponent Inc., Washington, DC). The GEMS/Food model is based on a high level per capita estimate of food commodity utilization within a cluster of countries with similar diets. The DEEM model is based on actual U.S. consumption data. The DEEM model has the advantage of supporting subpopulation analyses. The GEMS/Food model does not allow for subpopulation analyses but can be used for comparison across countries clustered by consumption patterns. Both models have numerous food categories, but the GEMS/Food model has fewer categories and cannot utilize food processing or other adjustment factors. A comparison of results from the two models indicated that the GEMS/Food model overestimates exposure. The estimated exposure from GEMS/Food for country cluster M (which contains the U.S.) was approximately 3X higher for NAA than the DEEM U.S. population mean analysis at 0.0264 and 0.0094 mg/kg of BW/d, respectively. This comparison highlights the differences between two models which should be considered when determining a model to use in regulatory arenas for risk assessment of food safety.

PS 766 COMPARATIVE STUDY OF THE TWO DETECTION METHODS FOR CIGUATOXINS.

J. H. Yuan, K. Zhao, J. Liu, J. Cheng and Z. Zhuang. *Toxicology Laboratory, Shenzhen Center for Disease Control and Prevention, ShenZhen, Guangdong, China.*
Sponsor: K. Ramos.

Objective: To establish the detection methods of cytotoxicity assay and mouse bioassay for ciguatoxins, comparing and evaluating the two methods. Methods: The toxicity curvilinear relationship between the toxin dosage and cytoactive was established by the use of toxin standard samples(P-CTX-1)in different concentration and conjugated Ouabain and Veratridine. At the same time, the detection standard of mouse bioassay was established through detecting the ciguatera toxin medial lethal dose LD50 to Kunming mouse and the relation equation between toxin dosage and death time of Kunming mouse, in addition, the detection results of the two methods were explored by detecting toxin extractive from the 32 portions fish samples in different months. Result: There was certain dependability between the detection results of cytotoxicity assay and the detection results of mouse bioassay, however, the detection sensitivity of cytotoxicity assay was better than mouse bioassay. Conclusion: The detection methods of cytotoxicity assay is applicable to screen considerable samples preliminarily, nevertheless, mouse bioassay could be a kind of important reference method for detection of ciguatoxins.

PS 767 IMMUNOTOXICITY OF DEOXYNIVALENOL IN BALB/C MICE: EFFECTS ON CIRCULATING AND SPLENIC LEUKOCYTE AND CELL MIGRATION MARKERS WITH TIME COURSE AND Dose-Response .

X. Wu[1], J. Cunnick[2], M. Kohut[3] and S. Hendrich[1]. *[1]Food Science and Human Nutrition, Iowa State University, Ames, IA, [2]Animal Science, Iowa State University, Ames, IA and [3]Kinesiology, Iowa State University, Ames, IA.*

The hypothesis in our study was that deoxynivalenol (DON) could change leukocyte subset number and their migration potential in peripheral blood with interactions of age and sex, which could be sensitive biomarkers to predict DON exposure for human epidemiological screening. After BALB/c mice were fed DON at 1.0 and 2.0 ppm, age, sex and feeding intervals all disrupted immune response, as measured by flow cytometry for markers of peripheral blood and spleen leukocyte subpopulations and chemokine receptor and integrin expression. In 2.5-3 mo old female mice after feeding DON for 14 d, peripheral blood (PB) granulocytes were increased at 1 and 2 ppm DON, and percentage of PB CD4+ cells and CD11b+ (macrophages) in spleen were decreased by 2.0 ppm DON. Increased percentage of CD19+ cells occurred with 2.0 ppm DON at both 14 and 28 d. After 16 mo old females were fed DON, reduced CXCR5+ B cells were noted in peripheral blood at 2.0 ppm after 14 d, and reduced splenic CD11b+ cell % at 1.0 ppm, but not at 2.0 ppm. In 16 mo old male mice fed 2.0 ppm DON increased granulocytes, CD29+CD11a+ neutrophils and CCR9+ T cytotoxic cells suggested that digestive system inflammation occurred. In 2.5-3 mo old male mice, reduced body weight gain at 1.0 ppm DON after 14 d only suggested that mice adapted to DON exposure or to their environment. As a conclusion, low-dose DON changed leukocyte balance in peripheral blood and spleen, and also altered B cell, neutrophil, and T cells migration. Sex and age also interacted with DON exposure.

PS 768 RISK ASSESSMENT OF DANDELION ROOT EXTRACT SOLID AS A FOOD INGREDIENT.

R. A. Matulka. *Burdock Group, Orlando, FL.*

A risk assessment of food ingredients should be comprehensive in nature, taking into account both the preclinical studies conducted on the food ingredient and its constituents, as well as the history of use. This is the case for dandelion root extract solid, obtained from the root of the Taraxacum officinale G.H. Weber ex. Wiggers plant. Substances found in dandelion roots include inulin (up to 40% of the root), sesquiterpene lactones of the eudesmanolide and germacranolide chemical families, as well as caffeic acid, chicoric acid, and β-sitosterol, as well as palmitic, linoleic, and linolenic fatty acids. Dandelion roots have had a long history as a coffee substitute and a diuretic, dating back hundreds of years. Current uses for dandelion root extract include alcoholic and nonalcoholic beverages, baked goods, frozen dairy products, and soft candy. Oral administration of the major constituent inulin has been found to decrease tumor formation in preclinical studies. Acute oral toxicity, dermal sensitization, and anti-tumor studies have been conducted on dandelion extracts, with the results indicating a low level of toxicity. Recent per capita consumption estimates find that dandelion root extract is consumed as a food ingredient at 0.0014 mg/kg body weight/day. Based on studies on dandelion root extract and its individual components, as well as the long history of human consumption, dandelion root extract can be considered safe when consumed at current use levels.

PS 769 PAIN REDUCTION MEASURED BY GROUND FORCE PLATE IN ARTHRITIC DOGS TREATED WITH TYPE-II COLLAGEN.

R. C. Gupta[1], M. Barnes[1], J. Minniear[1], J. Lindley[1], J. T. Goad[1], T. D. Canerdy[1], M. Bagchi[2] and D. Bagchi[2]. *[1]Toxicology, Murray State University, Hopkinsville, KY and [2]InterHealth Research center, Benicia, CA.*

Presently, one in four of 77 million pet dogs in the United States is diagnosed with some form of arthritis. In dogs, osteoarthritis is more common than rheumatoid arthritis and pain is the number one complaint. This investigation evaluated therapeutic efficacy and safety of glycosylated undenatured type II collagen (UC-II) in moderately arthritic dogs that received daily placebo or 40 mg type II collagen (10 mg active UC-II) for a period of 120 days, followed by a 30 day withdrawal. On a monthly basis, dogs were evaluated for overall pain, pain upon limb manipulation, and pain after physical exertion. In addition, pain was measured using Ground Force Plate (peak force and impulse area). Dogs on placebo exhibited no significant change in arthritic conditions. Following 120 days treatment with UC-II, dogs showed significant decreases in overall pain (77%) and pain after limb manipulation (83%) and exercise (84%). With Ground Force Plate, peak force value elevated from 7.26 to 9.49 Newtons/kg body wt, and impulse area elevated from 1.36 to 2.08 Newtons.Sec/kg body wt, suggesting increase in g force and decrease in level of pain. Dogs receiving placebo or UC-II showed no adverse effects in liver, kidney and heart functions (bilirubin, ALT, creatinine, BUN and CK), or changes in body weight, heart rate, respiration rate, or temperature. In conclusion, UC-II significantly reduced arthritic pain and is well tolerated.

PS 770 SUBCHRONIC ORAL TOXICITY ASSESSMENT OF N-ACETYL-L-ASPARTIC ACID IN RATS.

S. Karaman[1], B. Delaney[1], J. Barnett[2] and A. Hoberman[2]. *[1]Pioneer Hi-Bred International, Johnston, IA and [2]Charles River Laboratories, Horsham, PA.*

N-Acetyl-L-aspartic acid (NAA) is an abundant substance in the mammalian CNS and is also present at low concentrations in many foods. In the current study, the potential effects of subchronic (90 day) dietary exposure to NAA at three doses;

100, 250 and 500 mg/kg of body weight/day were investigated in Sprague Dawley rats (10/sex/group). A negative control group was administered feed without supplemental NAA and an additional control group was administered 500 mg/kg of body weight/day of the parent amino-acid, L-aspartic acid for comparative purposes. No biologically significant differences were observed between groups for any of the response variables that were examined including body weight gain, feed consumption/efficiency, mortality, clinical signs, ophthalmology, neurobehavioral assessment, hematology, coagulation, clinical chemistry, organ weights, or gross and microscopic pathology. Based on the results of this study the NOAEL of NAA following oral exposure for 90 days is >500 mg/kg of body weight/day.

PS 771 APOPTOSIS IN RAW264.7 MACROPHAGE CELLS EXPOSED TO MELAMINE.

W. H. Tolleson. *Division of Biochemical Toxicology, Food and Drug Administration, National Center for Toxicological Research, Jefferson, AR.*

Lethal acute renal failure syndromes occurred in 2004 and 2007 in Asia and N. America, respectively, among pets that consumed pet food products contaminated with the triazines melamine, ammeline, ammelide, and cyanuric acid. Triazine contamination precipitated the recall of over 1,000 types of pet food products during 2007. Melamine-contaminated infant formula has been linked with 54,000 illnesses among infants exposed in China; 13,000 cases required hospitalization for renal failure and at least four cases resulted in deaths. Post-renal failure in animals exposed to melamine and cyanuric acid was assigned to blockage of renal tubules by unique, birefringent melamine- and cyanuric acid-containing renal calculi. Histological examination of kidneys from affected pets revealed the intracellular uptake of birefringent material by interstitial macrophages. In vitro experiments were performed to examine the biochemical toxicology of melamine and cyanuric acid. In the current study, neither melamine nor cyanuric acid exhibited toxicity to human ACHN renal carcinoma or COLO205 colon carcinoma epithelial cell lines - selected as representative of the sites of adsorption and deposition of triazines consumed orally. In contrast, melamine, but not cyanuric acid, was cytotoxic to RAW264.7 murine macrophage cells. The toxicity of melamine in RAW264.7 cells was potentiated slightly by divalent transition metal ions (copper, iron, and zinc) and by cyanuric acid. Exposure of RAW264.7 cells to melamine also induced caspase-3/7 activity and apoptotic morphology. RAW264.7 cells treated with melamine exhibited increased oxidative stress, measured in situ via oxidation of dichlorodihydrofluorescein diacetate. The addition of exogenous antioxidants blocked melamine-induced oxidative stress but did not protect RAW264.7 cells from decreased viability. The direct toxicity of melamine to interstitial macrophage cells in the kidney could contribute to enhanced inflammation and edema that exacerbate the acute renal failure syndrome produced by melamine and cyanuric acid.

PS 772 EFFECT OF PH ON THE THERMAL STABILITY OF RICIN.

Z. Zhang[1, 2, 3], W. H. Tolleson[1], W. B. Melchior[1], L. S. Jackson[3] and P. Varelis[2, 3]. *[1]National Center for Toxicological Research, Jefferson, AR, [2]Illinois Institute of Technology, Summit-Argo, IL and [3]National Center for Food Safety and Technology, Summit-Argo, IL.*

Ricin is a potent AB heterodimeric toxin produced by the castor plant, *Ricinis communis*. Ricin A-chain (RTA) encodes the 28S rRNA-specific adenosine N-glycosidase activity responsible for ribosome degradation and inhibition of protein synthesis. Ricin B-chain (RTB) encodes a galactose-binding lectin that facilitates cellular uptake. The potency, resistance to heat-inactivation, and ease of isolation has led to the designation of ricin as a Category B Select Agent for bioterrorism by the HHS and created the impetus to evaluate the effects of selected food matrices and manufacturing procedures on the stability of ricin. Our previous studies showed that the rate of thermal inactivation for ricin holotoxin varied in acidic fruit juices and infant formulas in a pH-dependent manner. Four analytical strategies were exploited in the current study to probe the effect of pH on ricin thermal inactivation kinetics. Exponential decays were observed with each method for the thermal inactivation of ricin holotoxin at 85° C and pH intervals between pH 3.0 and pH 9.0. The rate of ricin unfolding was monitored via the quenching of tryptophan fluorescence, conformation-dependent ELISA, adenosine N-glycosidase activity, and cytotoxicity activity using RAW264.7 macrophage cells. Because RTA and RTB contain one and nine TRP residues, respectively, fluorescence quenching emphasizes effects on RTB. In contrast, effects on RTA chain were followed by the decay in A-chain dependent enzyme activity and by ELISA using A-chain specific antibodies. Cytotoxicity assays revealed the net effect on both peptides. Our results show that the rate of ricin inactivation at 85° C increases exponentially as the pH decreases from pH 7.5 to pH 3.0 and also increased rapidly as the pH increases from pH 7.5 to pH 9.0. These results suggest that ricin may exhibit greater thermal stability in pH-neutral foods like milk, black olives, peas, or corn.

PS 773 SIMULTANEOUS DETERMINATION OF MELAMINE AND CYANURIC ACID IN PET FOOD USING A UV/EC DUAL DETECTION SYSTEM.

C. Chou[1], C. Liao[2], J. Liao[3], J. Zen[2] and C. Chuang[4]. *[1]Veterinary Medicine, National Chung-Hsing University, Taichung, Taiwan, [2]Chemistry, NCHU, Taichung, Taiwan, [3]Veterinary Pathology, NCHU, Taichung, Taiwan and [4]Biomedical Engineering and Environmental Sciences, NTHU, Hsinchu, Taiwan.*

Outbreaks of pet food associated renal failure in companion animals occurred in Asia and North America in 2004 and 2007. While the mechanisms of nephrotoxicity were mostly unknown, it has becoming clear that the presence of melamine (M) and cyanuric acid (CA) is critical for the acute renal failure and the severity of renal toxicity was associated with the ratio of these 2 compounds. Recently, powdered milk tainted with M has been blamed for killing 4 Chinese babies and sickening thousands more for kidney problems, causing a global withdrawal of hundreds of products containing Chinese milk and vegetable-based proteins. To facilitate surveillances of human and pet food safety, it is imperative to detect M and CA simultaneously with satisfactory sensitivity and short analysis time. The current best HPLC-UV method for M detection has a limit of detection (LOD) around 1 ppm at 220 nm, but for CA the LOD is only about 70-90 ppm. By employing an electrochemical detection (HPLC-EC) using copper electrode in an alkaline mobile phase (acetonitrile in 0.1 M PBS, pH 8), we have improved the LOD for CA to 1 ppm. In addition, by connecting a flow injection analysis system to the sample outlet of UV detector, M and CA can be detected in 10 min by UV and EC detector, respectively, in one single injection/run. The dual detection method was used to analyze pet food sample (lot No. L-107) suspected of causing renal failure in 2004 and found that an estimation of 900 ppm CA and 6,000 ppm M (a ratio of 1:6.7) were present. No detectable levels of the two were found in newer batch of pet food (lot No. PB03) produced from the same manufacturer. The method also successfully detected the presence of 20-200 ppm of M in imported powdered milk and coffee mixes. Because most M adulteration in food is at ppm level, the first dual detection method we developed is suitable for routine and efficient monitoring of M and CA in food products.

PS 774 EFFECTS OF PREPUBERTAL EXPOSURE TO ACRYLAMIDE ON *N*-METHYL-*N*-NITROSOUREA INDUCED MULTI-ORGAN CARCINOGENESIS IN RATS.

S. Takami[1], T. Imai[1], Y. Cho[1], M. Maeda[1], M. Hirose[2] and A. Nishikawa[1]. *[1]Division of Pathology, National Institute of Health Sciences, Tokyo, Japan and [2]Food Safety Commission, Cabinet Office, Tokyo, Japan.*

Acrylamide (AA) has been reported to be formed in fried and baked foods with various concentrations, and human exposure levels to AA from cooked foods in childhood are estimated to be higher than those in adults. It has been documented that AA shows carcinogenic properties in several organs such as thyroid, mammary gland and tunica vaginalis in rats as well as genotoxicities in various *in vitro* and *in vivo* systems including cultured thyroid follicular cells. In the present study, to evaluate effects of the genotoxic carcinogenesis actions of AA exposed during childhood, we conducted a medium-term carcinogenicity study with prepubertal administration of AA followed by treatments of a multi-organ carcinogen and a promoting agent for thyroid carcinogenesis in rats. A total of 36 postpartum F344 rats were given drinking water containing AA at 0, 20, 40 or 80 ppm for 3 weeks in lactation period, and their weaned offspring received the same AA-mixed water for 3 weeks. Offspring were then injected with *N*-methyl-*N*-nitrosourea (40 mg/kg body weight, i.p.) once at week 7. Half of the animals of 0 and 40 ppm groups were additionally treated with sulfadimethoxine (125 ppm), an antithyroid agent, in drinking water thereafter. Offspring were autopsied at week 50. The brain, spinal cord (cervical region), thyroids, thymus, lungs, liver, spleen, kidneys, stomach, intestines, mesenteric lymph nodes, urinary bladder, mammary gland and macroscopic abnormalities were excised and examined histopathologically. There is no treatment-related change in the incidences of preneoplastic and neoplastic lesions in target organs of AA, including brain, spinal cord, oral cavity, pituitary, thyroids, adrenals, uterus, mammary gland, clitoral gland and tunica vaginalis. The results indicate that prepubertal exposure to AA in rats does not influence the carcinogenesis in any organs.

PS 775 THE EFFECT OF AQUEOUS EXTRACT OF CNIDOSCOLUS ACONITIFOLIUS ON PARACETAMOL INDUCED HAPATIC DAMAGE IN RATS.

A. A. Oyagbemi, A. A. Odetola and T. A. Akinola. *Veterinary Physiology, Biochemistry and pharmacology, University of Ibadan, Ibadan, Oyo, Nigeria.*
Sponsor: O. Farombi.

The study was designed to evaluate the possible hepato-protective effect on Cnidoscolus aconitifolius on Paracetamol poisoning in rats. Twenty five male Wistar albino rats were used in this study. They were placed groups of five rats.

Group A & B received normal saline (0.9% physiological saline). Animal in groups C, D and E were administered Cnidoscolus aconitifolius at 100mg/kg, 500mg/kg and 1,000mg respectively for seven days. All animal in groups B, C, D and E were given paracetamol 3g/kg body with by intubations on days 8 and 9. Animals were sacrificed by cervical dislocation on day 10 after an over night fast. Blood was collected through retro-orbital venous plexus and analyzed for plasma alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), total protein, total bilirubin, albumin, triglycerides (TAG), total cholesterol (T.C), high density lipoprotein (HDL), low density lipoproteins (LDL), urea, creatinine, sodium ion (Na+), potassium (K+), chloride anion (Cl-), and bicarbonate anion (HCO3-). Paracetamol overdose caused significant increase ($P<0.01$) in the plasma ALT, AST, ALP, total protein, TAG and TG when compared with values in the normal control group. Pre-treatment with Cnidoscolus aconitifolius extract at 100mg and 500mg/kg led to significant increase in plasma ALP, AST and LDL when compared with the PCM treated control rats whereas pre-treatment with 1000mg/kg caused and significant reduction in ALP, TP, ALB, TC and HDL to values that were not significantly different from those in normal rats. In summary, the results obtained in this study show that lower dosages (100mg/kg and 500mg/kg) of Cnidoscolus aconitifolius may potentiate the toxicity associated with Paracetamol overdose while high dosage (1000mg/kg body weight) of the extract showed promising hepato-protective effect against hepatic damage induced by Paracetamol poisoning.

PS 776 NATURE AND CHARACTERISTICS OF THE TIMING OF REACTIVITY TO GLUTEN IN CELIAC DISEASE.

S. A. Assimon and P. M. Bolger. *CFSAN, FDA, College Park, MD.*

Celiac disease (CD) is a permanent hypersensitivity reaction triggered by ingestion of wheat, barley or rye, or the plant storage proteins of these grains. The grain proteins that elicit this reaction are often collectively referred to as "gluten." Exposure to gluten in individuals with CD results in an immune-mediated enteropathy which is associated with morphological damage to the lining of the small intestine. A diverse array of clinical signs and symptoms are also often associated with exposure to gluten in those that develop CD. Available published studies that performed oral food challenge tests in individuals susceptible to the development of CD and that included dose-response information on adverse health effects of gluten were analyzed. The pattern of the timing of the adverse effects and the nature of the toxicity exhibited in response to the gluten challenges in CD subjects were examined within a toxicological framework. Tremendous variability in the timing of the adverse reactions to gluten existed between those afflicted with CD. The reactions occurred after acute, subchronic and chronic exposure durations to this substance and this response pattern was present at the lowest doses tested. These differences in the timeframes of the reaction by individuals to gluten ingestion were found both between CD subjects within the same study and across CD subjects in different studies. This differing individual reactivity was also seen in studies that performed the gluten challenge tests on children and studies that performed them on adult subjects. The adverse reactions that emerged after acute, subchronic and chronic durations of exposure to gluten included adverse morphological changes in the small intestine and/or a range of clinical signs and symptoms associated with CD. In sum, an analysis of findings from food challenge tests in those with CD indicates that gluten can be an acute, subchronic and chronic toxin with respect to both morphological and clinical adverse health effects. Also, the timing and characteristics of this responsiveness of CD sufferers to gluten emerges as being "individualistic" in nature.

PS 777 EVALUATION OF URINARY FUMONISIN B1 AS A BIOMARKER OF EXPOSURE IN A WEST AFRICAN POPULATION HIGHLY EXPOSED TO AFLATOXINS.

A. Robinson[1], N. Johnson[1], J. T. Taylor[1], A. Marroquin-Cardona[1], E. Afriyie-Gyawu[1], N. Ankrah[2], J. H. Willaims[5], J. S. Wang[3], P. Jolly[4] and T. D. Phillips[1]. *[1]College of Veterinary Medicine, Texas A&M University, College Station, TX, [2]Noguchi MIMR, University of Ghana, Accra, Ghana, [3]College of Public Health, University of Georgia, Athens, GA, [4]School of Public Health, University of Alabama, Birmingham, AL and [5]Peanut CRSP, University of Georgia, Griffin, GA.*

Chronic exposure to Fumonisin B1 (FB1), a toxin produced by Fusarium fungi, has been correlated with an increased incidence of esophageal cancer in regions of China and South Africa. Previous animal studies have suggested FB1 may act to enhance aflatoxin (AF) carcinogenicity; moreover, FB1 has been found in foods co-contaminated with AFs. Thus, the major objectives of the present study were to validate a urinary biomarker for FB1 and use this method to assess individual exposures to FB1 in a West African population highly exposed to AFs and considered at high risk for aflatoxicosis. Urine samples (n=49) were collected from participants in the Ejura-Sekyedumase district, Ashanti region of Ghana and were evaluated using parent FB1 in the urine as a dosimetry biomarker. This method utilized immunoaffinity clean-up columns (Vicam), methanol/water (80:20) as the elution phase and naphthalene-2, 3-dicarboxaldehyde (NDA) as a derivatization agent. The separation, identification, and quantitation of urinary FB1 peaks were carried out using HPLC analysis with fluorescence detection at 252 nm excitation and 483 nm emission and a flow rate of 1.0 ml/min. Retention time for the FB1 peak ranged from 22-23 min. The NDA derivative was determined to be linear and stable with a limit of detection and quantitation of 0.33 ng and 1.25 ng, respectively. Importantly, FB1 peaks were detected in 69.4% of the samples evaluated. Mean and median quantities of FB1 were 6.53 ng/ml and 6.69 ng/ml urine, respectively. Studies are ongoing to standardize these values to creatinine excretion. The potential impact of this FB1 exposure along with aflatoxin is yet to be determined. (Supported by USAID LAG-G-00-96-90013-00)

PS 778 SAFETY ASSESSMENT OF N-ACETYLGLUTAMATE.

M. S. Harper[1], E. van de Mortel[1], A. Myhre[1], A. Shen[1], J. Barnett[2], A. Hoberman[2], B. Krsmanovic[3], L. Nicholson[3] and B. Delaney[1]. *[1]Pioneer, A DuPont Company, Johnston, IA, [2]Charles River Laboratories, Horsham, PA and [3]BioReliance Laboratories, Rockville, MD.*

N-acetylglutamate (NAG) is an endogenously produced mammalian substance and minor constituent of commonly consumed foods. The current study reports the outcome of mutagenicity, acute and repeated dose dietary toxicology studies conducted with NAG. No evidence of mutagenicity was observed with NAG in a bacterial reverse mutation assay or in a bone marrow micronucleus assay conducted in ICR mice. In the acute toxicity study, no mortalities or evidence of adverse effects was observed in rats (n = 5/sex) following acute oral gavage with NAG at a dose of 2000 mg/kg of body weight. A repeated dose dietary toxicity study was conducted by addition of NAG to the diets of Sprague-Dawley rats (n = 10/sex/group) at concentrations corresponding to daily doses of 100, 500, or 1000 mg/kg/day for 28 days. All rats survived until scheduled sacrifice and no differences in body weights, feed consumption, clinical signs, ophthalmologic examinations, hematology, coagulation, clinical chemistry, or organ weights or histopathology of any of the treatment groups. Based on these results, it was concluded that NAG is not mutagenic or acutely toxic and the no-observed-adverse-effect-level (NOAEL) from repeated dose dietary exposure to NAG under conditions of this study was 1000 mg/kg/day.

PS 779 ASSESSMENT OF THE TOXICITY AND MUTAGENICITY OF A NOVEL SOLUBLE POLYSACCHARIDE.

R. A. Matulka[1], G. A. Burdock[1], S. Wood[2], M. Lyon[2] and P. A. Marone[3]. *[1]Burdock Group, Orlando, FL, [2]Canadian Centre for Functional Medicine, Coquitlam, BC, Canada and [3]Eurofins-PDL, Dayton, NJ.*

Viscous fiber has several demonstrable effects on the body, including delaying gastric emptying time, slowing insulin release, and altering the absorption of dietary fat and cholesterol. PGX® is composed of a proprietary agglomeration of food-grade, water-soluble polysaccharides. These polysaccharides produce a novel ingredient with an interlocking matrix that leads to a viscosity higher than any of the individual components. As a potential new food ingredient, PGX has been evaluated in a subchronic study in rats and in a genotoxicity Ames assay. Sprague-Dawley rats (10/sex/group) consumed 0, 1.25, 2.5, or 5.0% PGX in the diet for 90 days and were evaluated for toxicological effects. There were no test substance-related changes in viability, behavior, clinical signs, body weight, food consumption, mean organ weight, organ-to-body weight, or organ-to-brain weight values between controls and treated animals. Hematology, clinical chemistry and urinalysis parameters evaluated revealed a significant decrease in red blood cell count and increased aspartate and alanine aminotransferase levels and triglyceride levels in males administered 5% PGX, although these effects were not seen in female rats. In female rats, 5% PGX significantly decreased serum sodium, potassium and chloride concentrations. These results were within historical control values, and did not correlate with any histopathological changes. In both sexes fed 5% PGX, a significant increase in urinary volume was noted. Clinical pathology changes were considered only adaptive in nature and, as such, it is concluded that the NOAEL for PGX is 5% of the diet. PGX was also investigated for its potential to induce gene mutations using Salmonella typhimurium and Escherichia coli strains. No toxic effects or biologically relevant increases in mutations were noted in any of the five strains at up to 100 μg/plate, which indicated that PGX is nonmutagenic in the bacterial reverse mutation assay. Overall, these data indicate a low level of toxicity for PGX.

PS 780 ASSSESSMENT OF THE TERATOGENICITY AND MUTAGENICITY OF REBAUDIOSIDE A.

L. D. Williams[1], E. Ford[2], A. M. Hoberman[3], J. Rochowicz[1] and G. A. Burdock[1]. *[1]Burdock Group, Orlando, FL, [2]Corn Product International, Westchester, IL and [3]Charles River Laboratories, Horsham, PA.*

Rebaudioside A (Reb A) is a steviol glycoside isolated from the leaves of Stevia rebaudiana. This non-nutritive, natural sweetener is reported to be 300-400 times sweeter than sucrose and has potential for wide use in the US diet, as it is used in Japan and South America today. The safety of rebaudioside A has been investigated in several studies, but until now, no teratogenicity studies have been reported and the information on genotoxicity is incomplete. In our teratogenicity study (conducted according to OECD guidelines), Reb A was administered to pregnant rabbits daily on Days 6-28 of gestation via gavage at 0, 350, 700, and 1400 mg/kg bw/day. There were no deaths or treatment related adverse effects in the 0, 350 or 700 mg/kg bw/day dose groups. However, in the 1400 mg/kg bw/day dose group, the does exhibited marked gastrointestinal distress which resulted in a statistically significant decrease in feed consumption and body weight, as well as 12 maternal deaths and three abortions. Gastrointestinal distress is typical in rabbits administered high doses of poorly absorbed compounds such as Reb A, therefore the observed deaths and abortions were not considered to be toxic effects of Reb A. Evaluation of fetuses from the control and treatment groups revealed no teratogenic effects at any of the doses tested. Reb A was also investigated for its potential genotoxicity in three in vitro and two in vivo assays (conducted according to OECD guidelines). Reb A was non-mutagenic in an Ames test using Salmonella typhimurium and Escherichia coli, in a chromosomal aberration test using Chinese Hamster V79 cells and in a mouse lymphoma assay using L5178Y +/- cells, all at concentrations up 5000 μg/ml with and without metabolic activation. Also, Reb A was non-genotoxic in a bone marrow micronucleus test in mice at doses up 750 mg/kg bw and in an unscheduled DNA synthesis test in rats at 2000 mg/kg bw. Taken together, these studies provide evidence that Reb A is not teratogenic or genotoxic at the doses tested.

PS 781 EFFECTS OF ORAL MONOSODIUM GLUTAMATE (MSG) IN ASTHMATIC MICE.

R. Sakai, K. Chin, K. Torii and J. Yoneda. *Institute of Life Sceinces, Ajinomoto Co., Inc., Kawasaki-shi, Japan.*

Rationale: Multicenter, double-blind, placebo controlled clinical studies testing the effects of large doses of monosodium glutamate (MSG) intake in asthmatics concluded neither consistent nor sever reactions after MSG ingestion. However, no detailed analysis have not been conducted yet using experimental animals. Thus, present study aimed to investigate the effects of MSG ingestion on development of allergic reactions using well-established murine model for asthma. Methods: Bronchial inflammation was induced in BALB/c mice by means of intraperitoneal sensitization and inhalation challenge to ovalbumin. Bronchoalveolar lavage fluid, blood and lung specimens were harvested 24 h after the last inhalation. Some of the animals were used for the measurement of airway obstruction to assess airway hyperresponsiveness to methacoline. Results: Dietary administration of MSG (0.5, 5%, w/w) for the whole experimental period did not affect either pulmonary eosinophil infiltration, production of Th2 cytokines such as IL-4 and IL-5, circulating IgE concentrations or airway hyperresponsiveness. No effects of MSG ingestion on pulmonary inflammation including secondary changes in the asthmatic mice were confirmed by histological examination. Oral gavage of MSG solution (0.5, 5%, w/w) 30 min before the assessment did not exert any acute effects either on lung inflammation or on airway hyperresponsiveness in the asthmatic mice. Conclusions: There was no involvement of MSG ingestion either in development of allergic reactions or in acute responses in asthmatic model mice. These results were consistent with previous clinical studies indicating safety of MSG intake in asthmatics.

PS 782 IS THERE AN EFFECT OF FOOD MATRICES ON THE BIOAVAILABILITY OF ACRYLAMIDE?

M. Baum, F. Berger, J. Feld and G. Eisenbrand. *Food Chemistry and Toxicology, University of Kaiserslautern, Kaiserslautern, Germany.*

Acrylamide (AA) is classified by IARC as probably carcinogenic to humans (group IIa). The biological activity of AA is considered to be mainly determined by its metabolic activation into genotoxic glycidamide (GA). However, bioavailability of AA ingested with food might also be of relevance. Up to now, only few data are available to assess whether the bioavailability of AA is influenced by the food matrix. In this study we investigated to which extent French fries and bread crust, with AA contents up to 2800 μg/kg, affect the bioavailability of AA as compared to AA uptake via drinking water. Rats were daily fed with the AA containing foods and a separate group received AA in drinking water (AA-DW group) over time periods between 1-9 days. Urine and feces were collected over 24h after the last feeding, then the animals were sacrificed and blood and liver samples isolated. Levels of AAMA and GAMA reflected daily intake without evidence for cumulation. Levels of AA-val-Hb-adducts increased in correlation with cumulated intake. Mercapturic acid excretion (40-60% of total dose) and AA-val-adduct formation in the French fries groups were similar to the AA-DW group while slightly reduced AA-val-Hb adducts and mercapturic acids (20%) were determined in the bread crust group. Under all conditions GA-val-Hb-adduct levels did not exceed those of the untreated control. The comet assay did not show significant induction of DNA damage in blood or liver cells. In summary, the bioavailability of AA after oral ingestion in French fries is comparable to that after intake in water. Hb adduct formation indicates that AA is systemically distributed whereas GA, as soon as it was metabolically generated in the liver became efficiently coupled to glutathione to be excreted as mercapturic acid in the urine. Bioavailability of AA from bread crust was slightly reduced. Thus, in rat a very effective first pass effect through the liver appears to prevent systemic bioavailability of GA. Supported by AiF, FEI and BLL

PS 783 BERGAMOTTIN INHIBITS PMA-MEDIATED MATRIX METALLOPROTEINASE-9 ACTIVATION THROUGH DOWN-REGULATING OF NUCLEAR FACTOR-KB.

H. Pil and H. Jeong. *BK 21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South.*

Matrix metalloproteinase-9 (MMP-9) plays an important role in the invasion and metastasis of cancer cells. In this study, we examined the inhibitory effect of bergamottin (BGM) from Citrus paradis on phorbol myristate acetate (PMA)-induced MMP-9 expression in HT1080 human fibrosarcoma cells. BGM significantly suppressed PMA-induced MMP-9 expression in HT-1080 cells. Furthermore, as evidenced by MMP-9 promoter, BGM specifically inhibited MMP-9 gene expression by blocking PMA-stimulated activation of NF-kB. In addition, BGM suppressed PMA-induced phosphorylation of JNK and p38 mitogen-activated protein kinase (MAPK), upstream factors involved in NF-kB, whereas the phosphorylation of extracellular signal-regulated kinase (ERK) was not affected by BMG, suggesting that the primary target of BGM for suppression of the NF-kB induction is present in upstream of JNK or p38 MAPK signaling pathway. These results suggest that the suppression of MMP-9 expression, at least in part, contributes to the antitumor activity of BGM.

PS 784 PRUNELLA VULGARIS INHIBITS TUMOR CELL METASTASIS AND GROWTH BY MODULATING EXPRESSIONS OF MATRIX METALLOPROTEINASE-9.

J. Seo[1], J. Choi[2], Y. Chung[1] and H. Jeong[2]. *[1]Division of Food Science, International University of Korea, Jinju, Jinju, Korea, South and [2]BK21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South.*

Metastasis of cancer cells to distant sites is one of the major deciding factors in cancer outcome. In fact, prognosis of cancer is mainly determined by the invasiveness of the tumor and its ability to metastasize. In this study, we assayed the preventive and therapeutic effects of Prunella vulgaris on the experimental lung metastasis induced by B16F10 melanoma cells and solid tumor induced by B16F1 melanoma cells in C57BL/6 mice. The antimetastatic properties of Prunella vulgaris were investigated by evaluating matix metalloproteinase-9 (MMP-9) production in HT-1080 cells. The level of secreted MMP-9 was determined by gelatin zymography and protein expression. In B16F10 melanoma lung metastasis experiment, Prunella vulgaris showed a great inhibition effect on the number of lung metastatic colonization in a dose-dependent manner. In B16F1 melanoma solid tumor growth experiment, Prunella vulgaris showed remarkable inhibitory effects on the solid tumor growth in a dose-dependent manner. In HT-1080 fibrosarcoma antimetastatic experiment, Prunella vulgaris showed remarkable inhibitory effects on the MMP-9 activity and expression in a dose-dependent manner. The results demonstrate that Prunella vulgaris possess an anti-tumor activity. Taken together, the results of our study provide evidence that Prunella vulgaris possess an anti-metastatic activity and anti-tumor activity.

PS 785 EUPATILIN EXHIBITS A NOVEL ANTI-TUMOR ACTIVITY THROUGH THE INDUCTION OF CELL CYCLE ARREST AND DIFFERENTIATION OF GASTRIC CARCINOMA AGS CELLS.

E. Choi and S. Kim. *school of medicine kyungpook national university, Daegu, Korea, South.*

In many cases, the process of cancer cell differentiation is associated with the programmed cell death. In the present study, interestingly, we found that eupatilin, one of the pharmacologically active ingredients of Artemisia asiatica that has been re-

ported to induce apoptosis in human gastric cancer AGS cells, also triggers differentiation of these cells. Treatment of AGS cells with eupatilin induced cell cycle arrest at the G1 phase with the concomitant induction of p21cip1, a cell cycle inhibitor. This led us to test whether eupatilin may trigger AGS cells to differentiate into the matured phenotypes of epithelial cells and this phenomenon may be coupled to the apoptosis. Eupatilin induced changes of AGS cells to a more flattened morphology with increased cell size and granularity. It also markedly induced trefoil factor 1 (TFF1), a gene responsible for the gastrointestinal cell differentiation. Eupatilin dramatically induced redistribution of tight junction proteins such as occludin and ZO-1, and F-actin at the junctional region between cells. It also induced phosphorylation of extracellular signal-regulated kinase 2 and p38 kinase. Blockade of ERK signaling by PD098059 or the dominant-negative ERK2 significantly reduced eupatilin-induced TFF1 and p21 expression as well as ZO-1 redistribution. These findings indicate that ERK cascades may mediate eupatilin-induced AGS cell differentiation. Collectively, our results suggest that eupatilin acts as a novel antitumor agent by inducing differentiation of gastrointestinal cancer cells rather than its direct role in inducing apoptotic cell death.
This work was supported by the Brain Korea 21 Project in 2008

PS 786 SUPPRESSION OF P-GLYCOPROTEIN EXPRESSION BY PUERARIN IN BREAST CANCER CELL MCF-7/ADR.

H. Thi, H. Kim and H. Jeong. *BK21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South.*

P-glycoprotein accounts for the most intrinsic and acquired cancer multidrug resistance (MDR). To inhibit the expression of P-glycoprotein is one of the effective ways to reverse cancer drug resistance. Puerarin, an isoflavonoid found in Pueraria Radix, has been reported to possess antiatherogenic, antihyperglycemic and antioxidant activities. In the present study, we identified that puerarin down-regulated the expression of P-glycoprotein at mRNA and protein levels in MCF7/adrimycin (MCF7/ADR), a human breast MDR cancer cell line. Puerarin suppressed the activity of MDR1 gene promoter. Furthermore, puerarin treatment significantly increases in intracellular accumulation of fluorescent P-gp substrate rhodamine 123, indicating that puerarin treatment leads to reversal of the MDR phenotype resulting from an increased accumulation of anticancer drugs by inhibiting drug efflux function of P-gp. These results suggest that the puerarin can be a new adjuvant agent for human breast cancer chemotherapy.

PS 787 ALLOSE GALLATES INHIBIT MULTIDRUG RESISTANCE THROUGH DOWN-REGULATION OF P-GLYCOPROTEIN EXPRESSION.

S. Lee and S. Kim. *Pharmacology, Kyungpook National University, Daegu, Korea, South.*

The major reason for the failure of cancer therapy is the development of multidrug resistance (MDR). The MDR of cancer cells can be mediated by the overexpression of P-glycoprotein (P-gp). P-gp is known to function as energy-dependent efflux pumps of chemotherapeutic agents by decreasing their intracellular drug accumulation. We studied the effects of 1, 2, 6-tri-O-galloyl-beta-D-allopyranose (GT23), a gallotannin isolated and purified from the Euphorbia species, on MDR function in P-gp overexpressing AML-2/DX250 cells. The doxorubicin-resistant AML-2/DX250 was selected from the AML-2/WT by chronic exposure to doxorubicin on an intermittent dosage schedule at sufficient intervals to permit the expression of resistance phenotypes. We found GT23 having inhibitory effect of MDR in P-gp overexpressing AML-2/DX250 cells. Although GT23 was showed low cytotoxicity, GT23 decreased cell viability as chemosensitizing effects in presence of doxorubicin. Flow cytometry data showed that GT23 increased drug accumulation in a concentration-dependent manner. In addition, GT23 decreased the levels of mRNA and protein of P-gp through mitogen-activated protein kinase (MAPK) in AML-2/DX250 cells. Taken together, these results suggest that GT23 has a chemosensitizing effects by down-regulation of P-gp expression and advancing the intracellular accumulation of drugs.

PS 788 EXPOSURE TO A PROANTHOCYANIDIN MIXTURE SIGNFICANTLY REDUCES DIMETHYLNITROSAMINE (DMN) – INDUCED NEPHROCARCINOGENESIS *IN VIVO* .

I. Khodos and S. Ray. *Mol. Toxicology Labs, Division of Pharmacology Scs., AMS Coll. of Pharmacology & Health Scs., Brooklyn, NY.*

CDC has ranked kidney cancer as the 7th leading cause of cancer mortality in 2004, and surprisingly, NCI estimates new cases and deaths from kidney cancer could be 54, 390 and 13,010 respectively in 2008 alone. Prime factors that precipitate this scenario include air and water pollution, food-borne toxic exposures, malnutrition, and lack of exercise. Constant encounters to toxic end products for clearance make the kidneys extremely vulnerable to toxic/carcinogenic changes. Although kidney's complex anatomy is designed to handle such consequences, a significant drop in tissue antioxidant levels can potentially navigate the cells to a wrong path. In this context, antioxidants appear to be instrumental in cellular defense mechanisms, and numerous publications attest to the fact that diets rich in antioxidant phytochemicals could potentially prevent cancer. This study explored whether continuous exposure to a powerful antioxidant proanthocyanidin mixture (PM) would reduce nephrocarcinogenic potential of DMN in male B6C3F1 mice. Animals were divided into four groups (GrI: Control; GrII: PM alone; GrIII: DMN alone; GrIV: PM+DMN). GrI and GrIII were on control diet, whereas GrII and GrIV were on PM-diet. In order to initiate kidney cancer, GrIII and GrIV received DMN (5 mg/kg: 0-8 weeks; 10 mg/kg: 4 weeks, ip) between 0-3 months. Animals were sacrificed every 3 months for serum chemistry and evaluation of carcinogenic changes in the kidneys. Tissue biochemistry and histopathology revealed DMN-induced orderly neoplastic changes and presence of nuclei of diverse morphology (apoptotic, necrotic and apocrotic). Co-exposure to PM alongwith DMN reduced animal mortality and carcinogenic changes in the kidneys. Minor changes in BUN/creatinine levels and DNA fragmentation (less than 2-fold increase at 3, 6, 9 & 12 months) were observed. These results suggest that long term exposure to a proanthocyanidin mixture alone does not induce any change, whereas in combination with DMN, it may delay, reduce or counteract DMN-induced nephrocarcinogenesis in vivo.

PS 789 EFFECTIVENESS OF SOYA ISOFLAVONES AND VITAMIN D IN BREAST CANCER PREVENTION.

R. Marik[1], S. Sukumar[2], M. A. Zeiger[1], V. Stearns[2] and C. B. Umbricht[1]. *[1]SOM, Johns Hopkins, Baltimore, MD and [2]SKCC, Johns Hopkins, Baltimore, MD.*

Abstract: Drug toxicity is a major problem of chemotherapy in breast as well as other cancers. Recently, it is been reported that dietary Soya isoflavones Daidzein (Da) and Genistein (Ge) possess similar effects like other toxic chemotherapeutic drugs used in prostrate cancer cells. They possess structures similar to estrogen, and may mimic or antagonize estrogen effects in different tissues. Da and Ge may also be involved in gene regulation by modulating epigenetic events such as DNA methylation, directly or through an estrogen receptor dependent process. We hypothesized these isoflavones would be able to act as demethylating drug to retard breast cancer like other chemotherapeutic toxic drug 5'deoxy-azacytidine (AZA). Methods: We treated three breast cancer cell lines (MCF7, 21PT and T47D) with daidzein and genistein alone and in combination with cellular differentiating vitamin D3 (VTD) for 96 hours. Effects were then compared to those seen with the known methyltransferase inhibitor AZA. Results: Da and Ge inhibited the growth of all the three breast cancer cell lines in a dose dependent manner. The combination of VTD with isoflavones showed an additive effect. We have found that Isoflavone treatment caused reversal of methylation of several breast cancer marker genes including Hin-1, RAR beta and Rass-F1, associated with an induction of their expression levels and combination therapy of VTD showed additive activation of expression of those genes. Furthermore, Da or Ge treatment resulted in a significant decrease of estrogen receptor alpha (ERA) level and its downstream signaling as well as an increase in ER beta (ERB) levels. Indeed, recent studies indicate that high ERB levels are associated with a reduced breast cancer risk and that ERB is an important modulator of proliferation and invasion of breast cancer cells. Conclusion: These isoflavones alone and in combination with VTD can retard the growth of the above three breast cancer cell lines by acting as a dietary non-toxic demethylating chemotherapeutic food drug at the same level of AZA.

PS 790 LACK OF EFFECTS OF SULFORAPHANE (SFN) ON BASELINE CYP3A4 ACTIVITY IN HEALTHY HUMAN VOLUNTEERS.

E. M. Poulton[1], D. L. Eaton[1] and J. W. Lampe[2]. *[1]DEOHS, University of Washington, Seattle, WA and [2]Epidemiology, University of Washington, Seattle, WA.*

SFN is a chemoprotective compound that occurs naturally at relatively high concentrations in broccoli, and is an established inducer of phase II enzymes (e.g. sulfotransferases, glutathione S-transferases, and quinone oxidoreductases) through the NRF2/Keap1 pathway. We reported previously that SFN acts as an antagonist to the human Pregnane X Receptor (PXR), preventing induction of CY3A4 and other PXR-regulated genes via rifampicin and other PXR ligands. CYP3A4 plays a key role in the metabolism of many pharmaceuticals. In primary cultures of human hepatocytes, SFN significantly down regulated basal CYP3A4. To determine if SFN caused a clinically relevant decrease in constitutive CYP3A4 activity in humans, we measured midazolam (MDZ) clearance, an marker of CYP3A4 activity, in 5 healthy volunteers following dietary SFN intake. Subjects were placed on a crucifer

free diet for 1 week, then given a cheese soup with or without broccoli sprout extract containing 100 mmoles of SFN for 7 days. A cross-over design was used allowing each subject to serve as their own control. The soup was well tolerated with no adverse affects reported. On days 2 and day 9 of each period blood samples were collected at 15-30 minute intervals over 6 hrs, and MDZ and 6-OH-MDZ were measured by LCMS. The Areas Under the Plasma Concentration vs. time curve (AUC) of MDZ and 6-OH-MDZ were measured using WinNonLin. MDZ clearance values were within the range of values seen in other studies. CYP3A4 levels were variable between individuals, but no difference was noted in MDZ clearance after a week of daily consumption of sprout extract. Total urinary isothiocyanate levels showed excretion of the majority of the dose given. Thus, at the dose and time frame in this study, SFN did not cause a clinically significant change in CYP3A4 activity. A more complete study is now underway examining the effects of SFN and RIF interaction on MDZ metabolism. If SFN is to be developed as a chemoproventive agent then information on its interactions with other drugs is necessary.

PS 791 TOXIC AND GENOTOXIC STUDIES OF WOOD DUSTS.

M. Wilson[1], R. Rando[1, 4], C. Miller[1, 2, 3] and X. Tan[1]. *[1]Environmental Health Sciences, Tulane University, New Orleans, LA, [2]Tulane Cancer Center, Tulane University, New Orelans, LA, [3]Center for Bioenvironmental Research, Tulane University, New Orleans, LA and [4]Environmental Medicine, Tulane University, New Orleans, LA.*

The National Toxicology Program and the International Agency for Research on Cancer have generally classified wood dust as a known human carcinogen. This classification is based on epidemiologic studies that have clearly linked an increased risk of nasal adenocarcinoma with chronic occupational exposures to wood dusts. However, few reports have addressed which wood dusts are of the greatest concern, and the potential mechanisms of wood dust action are relatively unexplored. To address some of these informational gaps we used a panel of in vitro assays to investigate the toxic and genotoxic potential of dusts from different hard and soft woods and wood products. Our studies indicated that dusts from specific woods and wood products contained a soluble compound(s) that 1) potently activated aryl hydrocarbon receptor signaling, 2) generated changes in mammalian cell ploidy, and 3) induced mutations in a target transgenic gpt gene in mammalian cells. Additional studies to identify the mutation spectra and the cell transformation capability of wood dusts are ongoing. We conclude that some wood dusts are particularly genotoxic and thus may pose potentially greater health risks than others. Teak wood dust may be of particular concern to woodworkers because it always displayed the most activity in these in vitro assays.

PS 792 *IN VITRO* ANTI-ESTROGENIC AND ANTI-ANDROGENIC PROPERTIES OF LAMELLARINS.

M. van den Berg[1], S. M. Nijmeijer[1], P. Ploypradith[2], M. Chittchang[2], S. Ruchirawat[2], M. S. Denison[3] and M. B. Van Duursen[1]. *[1]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands, [2]Laboratory of Medicinal Chemistry, Chulabhorn Research Institute, Bangkok, Thailand, Bangkok, Thailand and [3]University of California at Davis, Davis, CA.*

Lamellarins (LAMs) are natural compounds of marine origin with properties that are promising with respect to cancer chemoprevention. In the present study six LAM congeners (K, M, L, N, Y and Y-DB) were synthesized. These LAMs contain hydroxyl and methoxy groups on different positions which are known to modulate their biological and toxicological activities. Using the BG-1 pGudluc7ERE and T47 pGudLucARE CALUX cell lines, the LAMs were studied for their (anti)estrogenic and (anti)androgenic properties. None of the LAMs were cytotoxic up to 10 uM as measured by an MTT assay in both cell systems. Estrogenic response of these LAMs differed depending on the position of the hydroxyl and methoxy groups in the BG-1 ERE CALUX cells. Some congeners only showed antagonistic behavior, while other LAMs showed agonist behavior at low concentrations (0.3-1 uM) and antagonistic effects at higher concentrations (1-30 uM). Combination experiments with these compounds and 20 pM 17β estradiol (E2) showed significant antiestrogenic activity for LAMs K and M, with reduction of 50-75% of the induced estrogenic activity. In the T47D ARE CALUX cells LAMs were tested for (anti)androgenicity. Up to 1 uM none of the LAMs showed androgenicity, but significant anti-androgenicity was already present around 300 nM for some LAMs (K, L and M). When co-exposed to 20 nM testosterone again significant anti-androgenicity was observed at concentrations even below 300 nM for all LAMs. The tested LAMS were even found to be more or equally potent as the antiandrogens flutamide and cyproterone. Based on the anti-estrogenic and antiandrogenic properties in combination with their low cytotoxicity in these cell systems, the tested LAMs appear to be promising chemopreventive agents.

PS 793 BORIC ACID AS A NOVEL STORAGE CALCIUM RELEASE ANTAGONIST AND ENDOPLASMIC RETICULUM MODULATOR IN DU-145 PROSTATE CANCER CELLS.

K. Henderson[1], S. Kobylewski[1], S. Stella[2] and C. Eckhert[1]. *[1]Molecular Toxicology, UCLA, Los Angeles, CA and [2]Pharmacology, UCLA, Los Angeles, CA.*

Men living in countries with low and high risk for prostate cancer both exhibit microscopic prostate cancer in their 40's. However, as a consequence of local environments they exhibit more than a 100 fold difference in disease in later life. Boric acid intake from water and food content reflect local soils, geology, and dietary practices. We have reported that prostate cancer is reduced by 54% in U.S. men with the highest boric acid diets and 37% in men in regions with the highest boron groundwater concentrations in Texas. In vitro studies showed that boric acid reduced NAD+ stimulated Ca2+ release in DU-145 prostate cancer cells within seconds. Here we show that boric acid induces endoplasmic reticulum stress. In addition, physiological concentrations of boric acid inhibit the release of ryanodine receptor (RYR) and inositol 1,4,5-triphosphate receptor (IP3R) sensitive Ca2+ stores. We show that physiological concentrations of boric acid inhibit Ca2+ release in response to RYR agonists, caffeine and 4-chloro-m-cresol, as well as in response to the IP3 generating compound, m-3m3FBS. In addition, prolonged treatment also lowers overall storage Ca2+ levels. Boric acid's antagonistic actions were less effective in LNCaP prostate cancer cells and PWR1E non-tumor cells. Given the central role of Ca2+ storage and signaling in cell functions, our observations show that boric acid has promise as a cancer preventative agent and treatment as well as possible implications beyond cancer.

PS 794 THE SUSCEPTIBILITY OF VARIOUS STRAINS OF MICE TO THE TOXICITY OF METHYLLYCACONITINE.

K. Welch, B. Green, K. Panter, D. Gardner, J. Pfister, D. Cook, B. Stegelmeier and Z. Davis. *Poisonous Plant Research Laboratory, USDA-ARS, Logan, UT.*

Although the mechanism of action for larkspur (Delphinium) alkaloids has been described, there is little information on the variation of the physiological response of individual animals to larkspur alkaloids. Anecdotal observations and pilot studies in cattle indicate that there is animal-to-animal variation in response to larkspur toxicity. The objective of this study was to determine if there is variation in susceptibility of different strains of mice to larkspur toxicity and to identify factors responsible for the variation that could then be used as a model for studies in cattle. The acute toxicity of methyllycaconitine (MLA) in ten different inbred strains of mice was compared. The rank order of susceptibility was A/J > B10 > FVB > BALB/c > C57Bl/6 > NZW > C3H > DBA > 129. The toxicokinetic profiles of MLA in the susceptible A/J and resistant 129 strains were compared in order to determine if their differences in susceptibility are simply due to differences in their ability to eliminate MLA. The differences in toxicokinetic parameters observed did not explain the differences in susceptibility. The protein expression of various nAChR subunits was also compared between the resistant 129 and susceptible A/J strains. The 129 strain of mice had twice the amount of alpha 7 nAChR subunit expression as the A/J strain, which was in direct proportion to the approximate two fold difference in LD50. There was also a significant difference in the expression of the alpha 3 and alpha 5 nAChR subunits between the 129 and A/J strains, with the 129 strain having a higher expression in each case. These data suggest that the increased susceptibility of the A/J mice could be due to a lower expression of nAChR subunits. The identification of factors that regulate the differences in susceptibility to larkspur poisoning between breeds of cattle would provide livestock producers with knowledge to use in their breeding, culling, and grazing management programs to reduce or prevent larkspur poisoning on rangelands.

PS 795 INDUCTION OF HEME OXYGENASE-1 EXPRESSION BY SAPONINS DERIVED FROM ROOTS OF PLATYCODON GRANDIFLORUM IN HEPA1C1C7 CELLS.

B. Park[1], Y. Hwang[2], Y. Chung[3] and H. Jeong[2]. *[1]Jangsaeng Doraji Research Institute of Biotechnology, Jangsaeng Doraji Co., Ltd., Jinju, Jinju, Korea, South, [2]BK21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South and [3]Division of Food Science, International University of Korea, Jinju, Jinju, Korea, South.*

Platycodon grandiflorum A. DC (Campanulaceae) is used as a traditional oriental medicine and also as a food in Korea. Previous studies reported that the Platycodon grandiflorum, Changkil, saponin (CKS) has antioxidant activity. Nrf2 is a transcription factor involved in the cellular protection against oxidative stress through antioxidant response element (ARE) or electrophile-response element (EpRE)-directed induction of several phase II detoxifying and antioxidant enzymes. Heme oxygenase-1 (HO-1) is known as a stress-inducible protein and functions as an an-

tioxidant enzyme. It has been shown that HO-1 is induced rapidly by a variety of chemical and physical stimuli. In this work, we assessed the ability of CKS from the roots of Platycodon grandiflorum A. to up-regulate HO-1 gene expression via activation of Nrf2 in cultured hepa1c1c7 cells. HO-1 enzyme activity and protein expression in the hepa1c1c7 cells was significantly increases by CKS. Furthermore, transfection studies using a human HO-1 ARE/EpRE reporter construct demonstrated that CKS activated the ARE/EpRE. CKS induced nuclear localization of the Nrf2 transcription factor. Taken together, these results demonstrate that induction of HO-1 expression by CKS required the activation of the Nrf2/ARE pathway.

PS 796 PROTECTIVE EFFECT OF THE ARALIA CONTINENTALIS ON CARBON TETRACHLORIDE-INDUCED HEPATOTOXICITY IN MICE.

C. Ho, Y. Hwang and H. Jeong. *BK 21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South.*

The root of Aralia continentalis Kitagawa has been used in traditional Korean medicine to relieve pain and to treat inflammation. The purpose of this study was to investigate the protective effects of the extract of Aralia continentalis roots (AC) against hepatotoxicity induced by carbon tetrachloride (CCl4) and the mechanism of its hepatoprotective effect. In mice, pretreatment with AC prior to the administration of CCl4 significantly prevented the increased serum enzymatic activity of ALT and AST as well as the formation of hepatic malondialdehyde. Histopathological evaluation of the livers also revealed that AC reduced the incidence of liver lesions induced by CCl4. In addition, pretreatment with AC significantly prevented both the depletion of reduced glutathione (GSH) content and the decrease in glutathione S-transferase (GST) activity in the liver of CCl4-intoxicated mice. Hepatic GSH levels and GST activity were increased by treatment with AC alone. Heme oxygenase-1 (HO-1) is known to be induced by oxidative stress and to confer protection against oxidative tissue injuries. AC markedly up-regulated hepatic HO-1 expression in CCl4-treated mice, which might provide anti-oxidative activity in the liver. These results indicate that AC plays a critical protective role in CCl4-induced acute liver injury by promoting anti-oxidative protein expression.

PS 797 IMMUNOSTIMULATORY ACTIVITY OF AQUEOUS EXTRACT ISOLATED FROM PRUNELLA VULGARIS.

E. Han[1], J. Park[1], Y. Chung[2], J. Seo[2] and H. Jeong[1]. *[1]BK 21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South and [2]Division of Food Science, International University of Korea, Jinju, Jinju, Korea, South.*

Prunella vulgaris (P. vulgaris) has been used as a traditional medicine in the clinical treatment of herpetic keratitis and for its antioxidative and antimicrobial activities. In this study, we examined the immunostimulatory and antitumor activity of P. vulgaris in murine macrophage RAW 264.7 cells. We found that PVAE stimulated macrophage phagocytic activity, nitric oxide (NO) production and cytostatic activity. In addition, PVAE induced gene expression and production of macrophage-related cytokines such as TNF-alpha, IL-1beta and IL-6. Transient transfection revealed that NF-kB mediated the PVAE-induced increases in macrophage-related cytokine expression levels. Mitogen-activated protein kinases (MAP Kinase) were also significantly activated by the PVAE-induced NF-kB activation. Pretreatment with NF-kB inhibitor and MAP Kinase inhibitors inhibited the NO production and the phagocytic activity induced by PVAE. This demonstrates that PVAE stimulates macrophage activation via NF-kB transactivation and MAP kinase activation.

PS 798 EFFECTS OF CHEMICALLY CHARACTERIZED FRACTIONS FROM A COMMERCIAL *ECHINACEA* HERBAL PRODUCT AND AERIAL PARTS OF *ECHINACEA PURPUREA* AND *ANGUSTIFOLIA* PLANTS ON MYELOPOIESIS.

S. Ramasahayam[1], H. N. Baraka[2], F. M. Abdel Bar[2], K. A. El Sayed[2] and S. A. Meyer[1]. *[1]Toxicology, University of Louisiana-Monroe, Monroe, LA and [2]Basic Pharmaceutical Sciences, University of Louisiana-Monroe, Monroe, LA.*

Herbal *Echinacea* products are widely used for their perceived beneficial effects on immune function. Components prevalent in *Echinacea* - alkylamides, caffeic acid derivatives, and polysaccharides - have been shown to have various immunomodulatory effects. However, commercialized products often contain other ingredients in addition to plant-derived material that may alter activity of *Echinacea* active components. We have evaluated activity of an ethanolic extract from a commercial preparation of dried aerial parts of *Echinacea purpurea* (Spring Valley by IdeaSphere Inc., American Fork, UT) on content and growth of hematopoietic progenitor cells of CFU-GMs from bone marrow of treated rats. This was then compared to activity of ethanolic extracts from cultivars of *E. angustifolia* (PI 649029 and PI 649040) and *E. purpurea* (PI 649026) obtained from the USDA North Central Regional Plant Introduction Station (Ames, IA). Analysis for constituent classes by proton and APT NMR techniques indicated the presence of alkylamides and caffeic acids in ethanolic extracts of both the commercial material and cultivars. Rats were gavaged daily for 7 days with ethanolic extracts at 50 mg dry weight/kg/d of the commercial preparation and 50 and 100 mg dry weight/kg/d of cultivars. Nucleated bone marrow cells from femurs were separated and CFU-GMs were measured with the HALO assay (Hemogenix, Colorado Springs, CO). The commercial ethanolic extract caused a significant 70% increase in CFU-GMs compared to vehicle control and *E. angustifolia* (PI 649040) and *E. purpurea* (PI 649026) at 100 mg dry wt/kg/d caused a significant 85% increase in CFU-GMs. *E.angustifolia* (PI 649029) was without effect. In conclusion, our results indicated that a myelostimulatory activity of the ethanolic extract of the commercial product is due to plant-derived constituents.

PS 799 GALLOTANNINS DECREASE NITIRIC OXIDE PRODUCTION THROUGH INHIBITION OF NF-κB AND DOWNSTREAM INOS EXPRESSION IN MACROPHAGES.

M. Kim and S. Kim. *Department of Pharmacology School of medicine Kyungpook National University, Daegu, Korea, South.*

Tannins are plant secondary metabolites and the term widely applied to large polyphenolic compound containing sufficient hydroxyls and other suitable groups to form strong complexes with proteins and other macromolecules. Based on their structural characteristics, tannins can be separated into four major groups: gallotannins, ellagitannins, condensed tannins and complex tannins. The gallotannins from Euphorbia species (Euphorbiaceae) are water-soluble polyphenols with wide-ranging biological activities. Nitric oxide (NO) is a widely recognized mediator of inflammatory signal transmission and could be produced by stimulation of LPS. In the present study, we examined the inhibitory effects of seven gallotannins on the LPS-induced NO production and underlying mechanisms of action. Among the seven gallotannins, 1,2,3,4,6-penta-o-galloyl-beta-d-glucose (GT15) and 1,2,6-trio-galloyl-beta-d-allopyanose (GT23) significantly reduced LPS-induced NO production in mouse macrophage cells (J774A.1). GT15 and GT23 dose-dependently decreased gene expression and production of nitiric oxide synthase (iNOS). The transcriptional activator protein, NF-κB plays a key role in immune and inflammatory responses to infection. Activated macrophages express iNOS and produce excessive amounts of NO. GT15 and GT23 also inhibited LPS-induced activation of NF-κB as indicated by inhibition of degradation of I-κBα, nuclear translocation of NF-κB, and NF-κB-dependent gene reporter assay. Our results suggested that gallotannins may have an inhibitory effect on the LPS-induced inflammatory reaction. This work was supported by the Brain Korea 21 Project in 2008

PS 800 METHODOLOGY TO ASSESS THE INHIBITION OF α-AMYLASE BY PLANT EXTRACTS WITH ANTI-DIABETIC POTENTIAL.

A. M. Rodriguez-Nassif and J. Gavillan-Suarez. *Chemistry, University of Puerto Rico at Cayey, Cayey, PR.*

Diabetes is a severe chronic disease caused by insufficient production of or resistance to insulin, which results in abnormal metabolism of carbohydrates, fats, and proteins. The inhibition of α-amylase activity has been suggested as a strategy for diabetes and obesity management by reducing sugar levels in blood. In this study we examined the inhibition of α-amylase by the plant flavonoid Quercetin, the tetrasacharide Acarbose (Glucobay®), and methanolic and aqueous extracts of Tapeinochilus ananassae (Costaceae). This plant has ethnomedicinal use in Puerto Rico and is known as "insulina". In this study, we determined the percent of reaction of α-amylase following the production of maltose from starch at λ = 540 nm after reaction with DNS color reagent, the percent of inhibition of test compounds and extracts and the IC50 for α-amylase inhibition. Results showed that methanolic and aqueous extracts of Tapeinochilus ananassae promote α-amylase activity whereas Quercetin and Acarbose are inhibitors of the enzyme at the concentrations tested [18-290 μg/mL] with IC50 207.8 μg/mL, and 808.2μg/mL, respectively. The activity observed for T. ananassae extracts has been reported with extracts of Lypinus luteus and Pharbitis nil during the study of their plant growth stimulating activity. Acarbose is known as a non-competitive inhibitor of α-amylase activity (IC50 36 μg/mL, 19.4 μg/mL). The in vitro activity of Quercetin as inhibitor of α-amylase activity has not been reported previously. Further, in terms of using T. ananassae as α-amylase inhibitor this finding should be of importance.

PS 801 TOXICOLOGICAL CHANGES ASSOCIATED WITH ADMINISTRATION OF EXTRACT OF LAGENARIA BREVIFLORA IN WISTAR RATS.

A. B. Saba and O. A. Oridupa. *Veterinary Physiology, Biochemistry & Pharmacology, University of Ibadan, Ibadan, Nigeria.* Sponsor: O. Farombi.

Lagenaria breviflora Roberts is employed as antiviral herbal remedy in West Africa and its therapeutic effect has been confirmed by Scientists. Its toxicological effects as observed from serum and reproductive parameters of male Wistar rats administered with the plant extract was studied. 25 male rats were equally and randomly divided into a control and four test groups. 0.9%Physiological saline was administered orally into rats in the control group, while rats in the test groups were administered with extract of 1000mg, 2000mg, 4000mg and 8000mg/kg bwt respectively once daily for 14 days. There was a significant ($P<0.05$) dose dependent increase in the serum glucose level.Higher doses of the extract increased the serum levels of triglycerides and LDL-Cholesterol, and lowered HDL-Cholesterol level in the serum. The mean serum sodium, phosphate ions, creatinine and BUN levels increased, while bicarbonate, potassium, and calcium ions decreased in the test groups. Serum enzymes AST and ALT levels in the rats were non-significantly different from that of the control group. There was significant reduction of sperm count and motility accompanied by secondary sperm cell abnormalities. Histopathological findings revealed no hepatocellular changes but marked renal and seminiferous tubular degeneration in the test rats. The extract caused hyperglycaemia and dyslipidaemia in the test animals which suggest that its continued use can predispose to diabetes mellitus and atherosclerosis. There was also evidence of electrolyte imbalance; the decreased serum bicarbonate levels may precipitate metabolic acidosis. Significant elevation of serum creatinine and BUN indicate renal injury caused by the extract.The renal injury is believed to be responsible for alterations of the serum biochemistry in the test rats. It is therefore, recommended that ethno-medicinal use of the plant be discouraged.

PS 802 APPLICATION OF THE THRESHOLD OF TOXICOLOGICAL CONCERN APPROACH FOR THE SAFETY EVALUATION OF CALENDULA FLOWER (CALENDULA OFFICINALIS) PETALS AND EXTRACTS USED IN COSMETIC AND PERSONAL CARE PRODUCTS.

T. A. Re[1], D. Mooney[1], E. Dufour[2], E. Antignac[2], I. Bark[1] and V. Srinivasan[1]. *[1]Product Safety, L'Oreal USA, Clark, NJ and [2]L'Oreal, Recherche, Asnl ®res-sur-Seine Cedex, France.*

Calendula Flower (Calendula officinalis) (CF) has been used in herbal medicine because its anti-inflammatory activity. CF and Calendula officinalis Extracts (CFE) are used as a skin conditioning agents in cosmetics. Although data on topical safety are available, their potential systemeic effects following dermal application have not been fully charecterized. The Threshold of Toxicological Concern (TTC) is a pragmatic, risk assessment based approach that has gained regulatory acceptance. Recently it has been adapted to address cosmetic ingredients safety. The purpose of this paper is to determine if the safe use of CF and CFE can be established based upon this concept. For each chemical constituent the maximum known concentration in the plant/extract, the molecular weight, and the estimated skin penetration potential were used to estimate a maximal daily systemic exposure which was then compared to its TTC value. Since the composition of plant extracts are variable, back calculation was used to determine the maximum allowable concentration of a given chemical in an extract of CF. The exposure values derived using the TTC approach are greatly conservative and are at least one to three orders of magnitude below the acceptable allowable daily exposures that rely on the classical "margin of safety" approach using published NOEL's for some of the components of the plant. It is also a rapid and convenient method that allows evaluations of extracts where certain major components have been enriched through adjusted extractions methods or concentrated via HPLC or other methods. Using CF and CFE as examples, we have been able to clearly demonstrate the practical utility of the TTC approach to support the safe cosmetic use of a complex organic mixture such as a plant part or extract.

PS 803 *IN VITRO* EVALUATION OF TECOMA STANS (BIGNONIACEAE) LEAF EXTRACTS USING HUMAN LIVER CELLS.

J. Zhu, E. Roland and E. E. Smith. *Department of Environmental Toxicology, TIEHH, TTU, Lubbock, TX.*

Tecoma Stans (Bignoniaceae) a natural herd is used in complementary and alternative medicine for reducing blood glucose concentration. Natural remedies are not entirely safe and their side effects should be clearly determined. Furthermore, the anti-diabetic mechanism of Tecoma Stans has not been elucidated. The aim of this study was to investigate the cytotoxicity of aqueous extracts of this herb in human hepatoblastoma (HepG2) and normal liver cells (THLE-2) in vitro. Cytotoxicity and IC50 values were measured by formazan3-(4, 5-dimethyl-thiazol-2-yl) -2,5-diphenyl-tetrazolium bromide (MTT) assay. Hepatic cell glucose uptake was also measured to evaluate the potential hypoglycemic activity in response to treatment with T. Stans using a glucose assay kit. Lyophilized T. Stans leaf extract (0.25, 0.5, 1, 1.5, 2, 2.5, 3, 4 mg/mL) was dissolved into cell culture medium with and without Fetal Bovine Serum (FBS). The endpoints were determined following incubation for 2, 24, 48 and 72 h. Cytotoxicity and glucose uptake were dose and time dependent ($p<0.001$) following exposure to T Stans without FBS. Significant inhibitory effects were observed at all concentrations of T. Stans above 0.5 mg/ml from 24 to 72 h for HepG2. In contrast, T. Stans inhibited THLE-2 above 1.5mg/ml from 24 to 72 h. The addition of FBS to the culture media increased the toxic concentration of T. Stans from 0.5mg/ml to 1mg/mL for HepG2 and from 1.5mg/ml to 2mg/mL for THLE-2 after 24 h exposure. The results indicate that while T. Stans might provide positive therapeutic benefits in glucose uptake as a complementary herbal extract, further studies are needed to determine the indication that nutrition, concentration, and duration of exposure can potentially influence the toxicity of T. Stans.

PS 804 HEPATOPROTECTIVE EFFECTS OF THE ANTHOCYANIN FROM PURPLE-FLESHED SWEET POTATO AGAINST ACETAMINOPHEN-INDUCED TOXICITY IN MICE.

C. Choi[2], J. Choi[1], Y. Chung[2] and H. Jeong[1]. *[1]BK21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South and [2]Division of Food Science, International University of Korea, Jinju, Jinju, Korea, South.*

The protective effects of the anthocyanin fraction (AF) obtained from Purple-Fleshed sweet potato on acetaminophen (APAP)-induced hepatotoxicities, and to determine the mechanism involved in mice. Pretreatment with AF prior to the administration of APAP significantly prevented the increased serum enzymatic activities of alanine and aspartate aminotransferase and hepatic lipid peroxidation in a dose-dependent manner. In addition, pretreatment with AF protected the APAP-induced depletion of hepatic glutathione (GSH) levels. Hepatic GSH levels and glutathione-S-transferase (GST) activities were increased by treatment with AF alone. APAP-induced hepatotoxicity was also prevented by pretreatment with AF, as indicated by liver histopathology. The effect of AF on cytochrome P450 (CYP) 2E1, the major isozyme involved in APAP bioactivation, was investigated. Treatment of the mice with AF resulted in a significant decrease in the CYP2E1-dependent aniline hydroxylation and CYP2El protein levels in does dependent manner. AF exhibited antioxidant effects on FeCl2-ascorbate induced lipid peroxidation in mice liver homogenates, and in superoxide radical scavenging activity. Our results suggest that the protective effects of AF against the APAP-induced hepatotoxicity possibly involve mechanisms related to its ability to block CYP2El-mediated APAP bioactivation and induction of hepatic GSH levels and free radical scavenging effects.

PS 805 THE EFFECTS OF RAYLESS GOLDENROD ON SPANISH GOATS.

Z. Davis, B. Stegelmeier, B. Green, S. Lee and K. Welch. *Poisonous Plant Research Laboratory, USDA-ARS, Logan, UT.*

Rayless Goldenrod (Happlopappus Heterophyllus) has been known to be toxic to livestock in the southwestern United States since the 1800's. The putative toxic compound in Rayless Goldenrod has been named tremetol (a mixture of ketones and alchohols). Animals poisoned by eating Rayless Goldenrod become depressed, lethargic, stiff gaited, stand in a humped up position, and decline to move, which is indicative of muscle damage. Some livestock develop muscle tremors, especially after exercise. The objectives of this study were to determine the dose and the duration required to develop clinical signs of toxicosis in Spanish goats. Four groups of four goats were dosed twice daily with dried, ground Rayless Goldenrod by oral gavage to give a daily dose of 0.5, 1, 2, and 3 percent of their body weight. Goats were exercised daily on a treadmill and EKG's were recorded prior to, during, and following exercise. Serum enzyme concentrations of ALT, AST and CK were monitored daily. Goats dosed with 0.5 and 1% of their body weight showed no clinical signs and serum enzyme activities remained normal throughout the study. After 6 days of dosing with Rayless Goldenrod at 2 and 3% of their body weight many goats became weak, reluctant to exercise, and when forced they would stand with post-like straight legs and flexed backs and their tails flexed vertically. These animals had increases in ALT, AST and CK activities of 3, 10 and 15-fold, respectively. These severely affected animals also had nearly a two-fold increase in resting heart rate, as well as a prolonged recovery time to normal heart rate following exercise.

After 7 days of dosing the animals were euthanized, necropsies and tissues were collected for further studies. Histologic, ultrastructural, toxicokinetic, and additional biochemical studies are underway. In conclusion we were able to reproduce Rayless Goldenrod toxicity in a goat model. This model will be used to definitively identify the toxin, define the pathogenesis of poisoning, describe the effect of poisoning and develop models to formulate prognoses for previously poisoned animals.

PS 806 SUPPRESSIVE EFFECT OF THE WATER EXTRACTS OF HOUTTUYNIA CORDATA ON ANAPHYLACTIC REACTION AND IMMUNOGLOBULIN E-MEDIATED ALLERGIC RESPONSE IN MAST CELLS.

J. Park, J. Park, E. Han and H. Jeong. *BK 21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South.*

Mast cells are key effector cells in the early phase allergic inflammation and in diverse immunological and pathological processes. Houttuynia cordata water extract (HCWE) has been used as a traditional medicine in Korea and is known to have an antioxidant, anti-cancer and anti-allergic activities. The precise effect of HCWE, however, remains unknown. In this study, we investigated the effects of HCWE on anti-allergic effect on RBL-2H3 rat mast cells and on IgE-mediated passive cutaneous anaphylaxis (PCA) in mice. HCWE reduced the anti-dinitrophenyl (DNP) IgE-induced beta-hexosaminidase and histamine release in RBL-2H3 cells. Also, the oral administration of HCWE inhibited IgE-induced ear swelling was significantly reduced systemic passive cutaneous anaphylaxis reaction in mice. HCWE inhibited activating phosphorylation of Syk kinase, indicating that HCWE inhibits the activity of Src-family kinases in mast cells. In addition, HCWE inhibited NF-kB activation and MAP kinases, which are critical for the production of various pro-inflammatory cytokines in mast cells. Taken together, these findings suggested that HCWE has an anti-allergic activity and this might be useful for the clinical application to treat allergic diseases such as atopic dermatitis.

PS 807 IDENTIFICATION OF NOVEL MYCOTOXIN AND ITS CYTOTOXIC EFFECT ON HUMAN LYMPHOCYTE CELLS IN COMPARISON TO SOME OTHER MYCOTOXINS.

P. B. Njobeh[1], M. F. Dutton[1], S. H. Koch[2], P. A. Steenkamp[3] and S. D. Stoev[1]. *[1]Food, Environment and Health Research Group, University of Johannesburg, Johannesburg, Gauteng, South Africa, [2]Plant Protection Research Institute, Agricultural Research Council, Pretoria, Gauteng, South Africa and [3]Biosciences, Council for Scientific and Industrial Research, Pretoria, Gauteng, South Africa.*

A hydrophobic novel metabolite was recently isolated from P. polonicum cultures. Its molecular mass and empirical formula were established as 390.2770 and C24H38O4, respectively, by means of chromatographic and mass spectrometric methods applied on liquid chromatography-tandem mass spectrophotometer (LC-MS/MS). The potential cytoxicity of this novel compound was further tested, in vitro, using the methylthiazol diphenyltetrazolium bromide (MTT) method against cultured human mononuclear lymphocyte cells over 18-hr period in comparison to that of some well known mycotoxins including ochratoxin A and T-2. At low concentrations (0.15, 0.31 and 0.63 μg/ml), the toxicity of the novel metabolite did not significantly differ from that of T-2 toxin, but was found significantly less toxic ($p<0.01$) than ochratoxin A. In all the cases, increasing concentration levels from 0.15 to 5.0 μg/ml significantly ($R2 = 0.8$; $p<0.001$) decreased cell viability. These findings indicate that the newly identified compound has an influence on lymphocyte cell viability probably by interfering with cell membrane of the lymphocyte cells due to the presence of the keto group it contains that is very active in effect. Having in mind that this novel mycotoxin might be a health risk and is commonly associated with Cameroonian food commodities and Bulgarian animal feeds, further studies are required on the impact of chronic dose administration of this mycotoxin on human and animal health, as well as, the various mechanisms of apoptosis for toxicity and carcinogenicity.

PS 808 HPLC FRACTIONATION OF AN EXTRACT OF COLA ACUMINATA.

K. Harris[1], K. Fontenot[1] and W. Gray[1, 2]. *[1]Chemistry, Southern University and A&M College, Baton Rouge, LA and [2]Environmental Toxicology, Southern University and A&M College, Baton Rouge, LA.*

Cola Acuminata or Bizzy nut is a bitter, caffeine-containing nut found in the rainforests of Africa. It is used as a stimulant, an appetite suppressant, an aphrodisiac, to restore vitality and to ease hunger pains. In Jamaica, Bizzy nuts are grated and made into a tea by the ETTU people. The Bizzy nut has garnered a reputation as a remedy for a plethora of illnesses and diseases including asthma, menstrual cramps, headache, gout and diabetes, as well as a form of birth control. Due to the direct or indirect hormonal dependence of several of the diseases and illnesses affected by the Bizzy nut, it is believed that the medicinal effects may be a result of the estrogenic and androgenic properties of non-steroidal estrogenic chemicals (phytoestrogens) found in the Bizzy nut. Recently, we confirmed that Bizzy exhibits steroid-like activity. In order to gain more insight into the mode of action of the Bizzy nut and to identify its medicinally active compounds, we are developing a high throughput HPLC screening method. A sample of dried Bizzy nut was ground and then subjected to a series of organic extractions. One of the extracts was then selected and further separated using reversed-phase HPLC analysis. A 1000 ppm sample of extract in DMSO/MeOH (1:9) was fractionated using a gradient of 30 – 90% Acetonitrile/Isopropanol/Formic Acid (70:30:0.05) over 40 min on a preparative column. The absorbance was monitored and wavelength spectra were simultaneously collected at 5 points on each peak. The chromatograph showed five distinct peaks all eluting within the first 25 minutes of the run. The corresponding wavelength spectra showed 4 to 5 compounds in each of the peaks from the chromatograph. This procedure has resulted in optimal separation and recovery of several chromatographic peaks. In vitro bioassays, monitoring cytotoxicity and gene expression, have been performed on the crude extract and the HPLC fractions, resulting in interesting and unique results for each fraction.

PS 809 INHIBITORY EFFECTS OF THE SAPONINS DERIVED FROM ROOTS OF PLATYCODON GRANDIFLORUM ON MAST CELL ACTIVATION.

H. Jeong[1], E. Han[1], J. Park[1] and Y. Chung[2]. *[1]BK 21 Project Team, Pharmacy, Chosun University, Gwangju, Gwangju, Korea, South and [2]Division of Food Science, International University of Korea, Jinju, Jinju, Korea, South.*

Mast cells are key effectors cells in the early phase allergic inflammation and in diverse immunological and pathological processes. In this study, we investigated the anti-allergic effect of the saponins isolated from the roots of Platycodon grandiflorum (Changkil saponins, CKS) in RBL-2H3 rat mast cells and mice. CKS reduced the anti-dinitrophenyl (DNP) IgE antibody-induced beta-hexosaminidase and histamine release in RBL-2H3 cells. Also, CKS significantly reduced ear swelling on IgE-mediated passive cutaneous anaphylaxis (PCA) in mice. CKS inhibited phosphorylation of antigen-induced Syk kinase in mast cells, indicating that CKS inhibits the activity of Src-family kinases. CKS also suppressed antigen-induced MAP kinases, which are critical for the production of various pro-inflammatory cytokines in mast cells. The present results suggest that the anti-allergic activity of CKS is mediated through reducing degranulation by inhibition of Src-family kinase in mast cells and it may be useful for the treatment of mast cell-related immediate and delayed allergic diseases.

PS 810 INHIBITION OF THE SODIUM-IODIDE SYMPORTER BY PERCHLORATE: AN EVALUATION OF LIFESTAGE SENSITIVITY USING PBPK MODELING.

E. D. McLanahan[1], R. B. Conolly[2], D. Tillman[3], M. E. Gilbert[4], P. White[5], L. Flowers[5] and P. M. Schlosser[1]. *[1]ORD/NCEA, U.S. EPA, RTP, NC, [2]ORD/NCCT, U.S. EPA, RTP, NC, [3]ORD/OSP, U.S. EPA, Washington, DC, [4]ORD/NHEERL, U.S. EPA, RTP, NC and [5]ORD/NCEA, U.S. EPA, Washington, DC.*

Perchlorate (ClO_4^-) competitively inhibits uptake of iodide by the sodium-iodide symporter (NIS) in laboratory animals and humans. NIS is found in many tissues, but is primarily responsible for sequestering iodide into the thyroid, enabling biosynthesis of thyroid hormones. The National Academy of Sciences (NAS, 2005) recommended the use of thyroidal radioactive iodide uptake (RAIU) inhibition as the critical effect for determination of a reference dose (RfD) for ClO_4^-. An uncertainty factor of 10 was applied to the point of departure (0.007 mg/kg-day) to protect the most sensitive population, which was identified as the fetuses of pregnant women who might be hypothyroid or iodide deficient, to obtain an RfD of 0.0007 mg/kg-day. U.S. EPA's Integrated Risk Information System (IRIS) Program adopted the recommendations of the NAS in 2005. The present work evaluated physiologically based-pharmacokinetic models (Clewell et al., 2007; Merrill et al., 2005) to assess lifestage relative sensitivity for use in human health risk assessment by evaluating model predicted percent RAIU inhibition by ClO_4^-. A six-step framework for model evaluation (Chiu et al., 2007; Clark et al., 2004) was followed, and the structures were determined to be suitable for potential use in risk assessment. A limited sensitivity analysis of model parameters was conducted and minor modifications were made to model codes. Parameters describing urinary excretion of ClO_4^- and iodide were found to be particularly important in prediction of RAIU inhibition; therefore, a range of biologically plausible values in peer-reviewed literature was evaluated. This draft analysis indicates that the near-term fetus (gestation week 40) is approximately 5-fold more sensitive at 7000 ng ClO_4^-/kg body weight to RAIU inhibition than the average adult. (The views expressed are those of the authors and do not necessarily reflect the views or policies of U.S. EPA).

PS 811 CHLOROFORM INHALATION HEALTH ASSESSMENT USING BENCHMARK DOSE MODELING: A COMPARISON OF ALTERNATIVE POINTS OF DEPARTURE.

Z. Li, T. Berner, D. Wong, S. Jones and S. Rieth. *National Center For Environmental Assessment, EPA, Washington DC, DC.*

The current Integrated Risk Information System (IRIS) database entry for chloroform contains a reference value for chloroform via oral exposure only. Because chloroform is relatively volatile, humans can be exposed via inhalation to chloroform vapor. Chloroform is currently undergoing assessment within IRIS, which includes development of an inhalation reference value. Benchmark dose (BMD) modeling was used to quantitatively assess the impact of alternative choices on the point of departure (POD). These alternatives included the choice of endpoints selected for human extrapolation, which data sets to use as the basis for BMD estimation, and selection of the benchmark response (BMR) based on considerations of biological significance and severity of the endpoint. Data sets from a Japan Bioassay Research Center (JBRC) chronic study, three subchronic studies, and a developmental study were considered. Endpoints associated with chloroform inhalation exposure within these studies include lesions in the nasal cavity, kidney and liver, and malformation/growth retardation in the fetus. Various dose-response models available in EPA's BMD software (BMDS) were fit to these study/endpoint combinations to establish PODs. BMD modeling generated a BMDL10 of 2.2 ppm for the nasal cavity endpoint (Kasai et al., 2002), a BMDL10 of 20.1 ppm for liver lesions (Yamamoto et al., 2002), a BMDL10 of 4.2 for kidney lesions (Yamamoto et al., 2002), and a BMDL5 of 0.97 ppm for developmental effects (Baeder and Hofmann, 1991). A BMR of 5%, rather than 10%, was used for the developmental endpoint because, as noted in EPA's benchmark dose technical guidance (U.S. EPA, 2000), "[r]eproductive and developmental studies having nested study designs often have greater sensitivity, and for such studies a BMR of 5% has typically been used". [Disclaimer: The findings and conclusions in this abstract are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA.]

PS 812 COMPARISON OF POINTS OF DEPARTURE FOR NONCANCER ENDPOINTS IN HUMANS AND ANIMALS FROM INHALATION EXPOSURE TO ACRYLONITRILE.

D. Wong and T. Berner. *ORD/NCEA, U.S. EPA, Washington, DC.*

Acrylonitrile (AN) is widely used in the production of acrylic fibers, acrylonitrile-styrene resins, nitrile rubbers and as an intermediate in the production of other chemicals. The potential health hazard from inhalation exposure to AN has been evaluated in both epidemiological studies of occupationally exposed workers and animal studies. Neurobehavioral effects were identified as critical noncancer effects in occupational exposure studies. A LOAEL of 0.24 mg/m3 was determined, based on statistically significant performance deficits in a World Health Organization (WHO)-recommended Neurobehavioral Core Test Battery for mood, attention and speed, auditory memory, visual perception and memory, and motor steadiness in exposed workers. The LOAEL, adjusted to exposure for 24 hours/day, 7 days/week, was 0.086 mg/m3. Critical noncancer effects were also observed in a 2-year inhalation bioassay of AN in Sprague-Dawley rats. Statistically significantly increased incidences of inflammatory and degenerative nasal lesions (hyperplasia of mucus-secreting cells in males and flattening of respiratory epithelium in females) occurred in rats exposed to the lowest level of 20 ppm AN in this chronic bioassay (6 hours/day, 5 days/week). Other nonneoplastic lesions with elevated incidences at the 80 ppm exposure level were gliosis and perivascular cuffing in the brain of males and females, focal nephrosis and thyroid cysts in males, and hepatic necrosis in females (which was also elevated at 20 ppm). Benchmark dose modeling was conducted on human equivalent concentrations converted from animal exposure data. The 95% lower bounds on the benchmark concentrations for 10% extra risk (BMCL10s) were determined to be 0.082 mg/m3 and 0.059 mg/m3 for nasal effects in male and female rats, respectively, and were identified as possible points of departure (POD). The PODs obtained from animal and human studies were similar.
(The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA.)

PS 813 EVALUATION OF REPRODUCTIVE AND DEVELOPMENTAL TOXICITY STUDIES OF VANADIUM PENTOXIDE FOR DERIVATION OF THE REFERENCE DOSE (RFD).

G. Backus and S. Diwan. *ORD/NCEA, U.S. EPA, Washington, DC.*

The reference dose (RfD) currently listed on IRIS for vanadium pentoxide is 9×10^{-3} mg/kg-day (IRIS, 1996). This RfD is based on decreased hair cystine as a critical effect in an unpublished study (Stokinger et. al., 1953). Decreased hair cystine may serve as a biomarker of exposure but its toxicological significance is uncertain. The available database for the oral route of exposure is limited to a rat subchronic study by Mountain et. al. (1953). This study reported a biologically significant reduction in RBC count (21%) at an average dose of 10.1 mg/kg-day in male Wistar rats. A NOAEL of 6.5 mg/kg-day could be established. Hemoglobin was decreased in orally dosed rats compared to controls at 6.5 mg/kg-day (5%) and 10.1 mg/kg-day (10%). These related findings may correlate with erythropenia and anemia. The authors did not examine comprehensive hematological parameters. Furthermore, Zaporowska et al (1993) reported similar hematological effects in rats dosed orally to ammonium metavanadate (NH_4VO_3). Given the uncertainty and low confidence associated with Mountain et. al. (1953) study, we further evaluated oral exposure studies of related vanadium compounds ($NaVO_3$, Na_3VO_4). Elfant and Keen (1987) reported significant decreases in percent litter survival at 7.0 mg/kg-day $NaVO_3$ in rats. Significantly increased amounts of vanadium in fetal blood and increased litter resorption were observed at 34 mg/kg-day (Ganguli et. al., 1994). Sanchez et. al. (1991) reported significant delay in fetal skeletal ossification at 30 mg/kg-day $NaVO_3$ in mice. These studies seem inappropriate surrogates for selection of a critical study for vanadium pentoxide but provide support for the proposal of 6.5 mg/kg-day (Mountain et. al. 1953) as the point of departure and decreased RBC count as the critical effect for the derivation of the RfD. Studies using related vanadium compounds confirm that adverse effects may occur above an oral dose of 6.5 mg/kg-day. [Disclaimer: The views expressed are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA].

PS 814 A NEW CHRONIC MINIMAL RISK LEVEL FOR INHALED INORGANIC MANGANESE.

J. D. Garey[3], M. Williams[2] and P. R. McClure[1]. *[1]Environmental Science, SRC, N. Syracuse, NY, [2]Agency for Toxic Substances and Disease Registry, Atlanta, GA and [3]Environmental Science, SRC, Arlington, VA.*

Manganese (Mn) is an abundant element, an essential human nutrient, and a widely used component of many consumer products, including steel, fireworks, alkaline batteries, certain paints and the gasoline additive, methylcyclopentadienyl manganese tricarbonyl (MMT). In the workplace, high levels of chronic inhalation exposure to inorganic Mn have been associated with a Parkinsonian-type syndrome known as manganism which may or may not be reversible with cessation of exposure. Lower Mn exposure levels have been associated with more subtle health effects, including declines in cognitive, motor skill or male reproductive performance and cardiac difficulties. The 2000 ATSDR Toxicological Profile for Mn derived a chronic minimal risk level (MRL) for inhaled inorganic Mn of 0.4 ug/m3 using data from a study of 92 male workers in a dry alkaline battery plant exposed to manganese dioxide dust (Roels et al. 1992). An updated toxicological profile for Mn was released for public comment in October 2008. A newly revised MRL is derived from the Roels et al. (1992) study, using EPA Benchmark Dose methods to achieve a best fit to the incidence data for abnormal eye-hand coordination scores. The best-fitting model generated a BMCL10 of 0.1426 mg Mn/m3, which was selected as the new point of departure for deriving an MRL. Following adjustment to a continuous exposure basis, the point of departure was divided by a combined uncertainty factor of 100 (10 for human variability and 10 for limitations/uncertainties of the database). The new MRL of 0.3 ug/m3 is supported by results from a substantial number of other epidemiological studies of workers exposed to air concentrations ranging from about 0.1 to 2 mg Mn/m3. Significant associations with impaired performance on neurobehavioral tests were found in seven out of 10 of these epidemiological studies.

PS 815 ORAL MINIMAL RISK LEVEL (MRL) FOR HEXAVALENT CHROMIUM.

J. M. Klotzbach[1], L. Ingerman[1], S. B. Wilbur[2] and G. Diamond[1].
[1]Environmental Science, SRC, N. Syracuse, NY and [2]Agency for Toxic Substances and Disease Registry, Atlanta, GA.

The general population is exposed to chromium by inhaling ambient air, ingesting food, and drinking water containing chromium. Chromium in food and water consists of mixtures of valence states that include chromium(III) and Cr(VI). Effects in humans associated with acute intoxication from ingestion of high doses of Cr(VI) include caustic burns and hemorrhage of the gastrointestinal tract, metabolic acidosis, hepatic effects and renal failure. However, studies of outcomes of longer-term exposures to humans are limited to ecological epidemiology studies that do not provide dose-response relationships suitable for derivation of oral MRLs. Studies in animals exposed to oral Cr(VI) for intermediate (e.g., subchronic) durations have reported hematological, gastrointestinal, hepatic, lymphatic and reproductive effects, with hematological effects (microcytic, hypochromic anemia) occurring at the lowest exposure levels. Microcytic, hypochromic anemia, characterized by decreased mean cell volume (MCV), mean cell hemoglobin (MCH), hematocrit (Hct), and hemoglobin (Hgb), has been reported in rats and mice exposed to

Cr(VI) compounds in drinking water or feed for exposure durations ranging from 22 days to 6 months. ATSDR derived an intermediate-duration MRL of 0.005 mg/kg/day for Cr(VI) based on microcytic, hypochromic anemia. Dose-related, statistically significant decreases in MCV, MCH, Hct, and Hgb in male rats exposed to sodium dichromate dehydrate in drinking water for 22 days in a 2-year NTP study were identified as the critical effects. Benchmark dose modeling was conducted for MCV, MCH, Hct, and Hgb to derive the lower confidence limit (95%) on the benchmark dose associated with a change of 2 standard deviations from the control (BMDL2sd). Adequate model fit was obtained for MCV, MCH, and Hgb, but not for Hct. The intermediate oral MRL was derived based on the average BMDL2sd values for MCV, MCH, and Hgb, with application of a composite uncertainty factor of 100 (10 for extrapolation from animals to humans and 10 for human variability).

PS 816 CHRONIC MINIMAL RISK LEVELS (MRLS) FOR CADMIUM.

L. Ingerman[1], G. Diamond[1] and O. Faroon[2]. *[1]Syracuse Research Corp, N. Syracuse, NY and [2]Agency for Toxic Substances and Disease Registry, Atlanta, GA.*

For the general, non-smoking, population, dietary cadmium is the most likely route of exposure. The estimated daily intake of cadmium in nonsmoking adults living in the U.S. is 0.30-0.35 μg/kg. The most sensitive targets of cadmium toxicity in environmentally exposed populations and cadmium workers appear to be the kidney and bone following oral exposure and kidney and lung following inhalation exposure. Adverse effect levels for renal effects appear to be similar to those observed for skeletal and respiratory effects and renal effects were used as the basis for ATSDR's chronic oral and inhalation MRLs. The earliest indication of cadmium-induced kidney damage in humans is an increased excretion of low molecular weight proteins (e.g., β2-microglobulin, human complex forming glycoprotein (pHC), and retinol binding protein) or intracellular enzymes (e.g., NAG). MRLs were based on a point of departure estimated from analysis of dose-response relationships from epidemiological studies of environmental exposures. Dose-response functions from each study were implemented to arrive at estimates of the internal dose corresponding to probabilities of 10% excess risk of low molecular weight proteinuria (urinary cadmium dose, UCD10). The 95% lower confidence limit of this value (UCDL10), 0.5 μg/g creatinine, was transformed into estimates of chronic cadmium intake that would result in the UCDL10 at age 55 using a modification of the Nordberg-Kjellström (KN) model. The estimated dietary cadmium intake of 0.33 μg/kg/day was divided by an uncertainty factor of 3 for human variability resulting in a chronic-duration oral MRL of 0.1 μg/kg/day. For the inhalation MRL, an airborne cadmium concentration (combined with average cadmium dietary intake) which would result in a urinary cadmium level of 0.5 μg/g creatinine (UCDL10) was predicted using the ICRP Human Respiratory Tract and KN models. This air concentration of 0.1 μg Cd/m3 was divided by an uncertainty factor of 3 for human variability and modifying factor of 3 resulting in a chronic inhalation MRL of 0.01 μg/m3.

PS 817 REFERENCE EXPOSURE LEVEL FOR 1-BROMOPROPANE, PROPOSED AS A SUBSTITUTE FOR PERCHLOROETHYLENE IN DRY CLEANING.

J. F. Collins, A. G. Salmon and M. A. Marty. *OEHHA, CalEPA, Oakland, CA.*

Concern about the contribution of perchloroethylene to smog has led regulators in California to ban the use of perchloroethylene in dry cleaning by 2023. Candidate replacements, some already in use, include liquid carbon dioxide, mineral spirits, decamethylpentacyclosiloxane (D5), specific glycol ethers, and 1-bromopropane. An advantage of 1-bromopropane is that it can be used in existing perchloroethylene machines with little modification. It is not listed as a federal Hazardous Air Pollutant or as a California Toxic Air Contaminant. However, it is listed under Proposition 65 as a chemical known to the State of California as causing reproductive toxicity. Animal studies have found neurotoxic, reproductive, and developmental effects. Several reports have documented mild to serious neurotoxicity, including the need for hospitalization, in American and Chinese workers manufacturing the chemical or using it to manufacture furniture. Chinese women (n=27), who had worked 27±31 months producing 1-bromopropane at a geometric mean TWA exposure of 2.92 ppm (range 0.34-49.19 ppm), had reduced vibration sensation in the feet, significantly longer distal latency in the tibial nerve, and increased tension, depression, anxiety, fatigue, and confusion compared with matched controls. Using these results and a recently approved methodology that incorporates specifically the protection of infants and children, we developed a chronic Reference Exposure Level (cREL) of 0.7 ppb (4 $\mu g/m^3$). A cREL is a concentration of a chemical at or below which adverse noncancer health effects are not anticipated to occur during long-term exposure. Although derived by approved methodology, the proposed cREL for 1-bromopropane has not undergone external peer review.

PS 818 ANALYSIS OF EMISSIONS SOURCE CONTRIBUTIONS OF ARSENIC, MANGANESE, AND MERCURY AND THEIR IMPLICATIONS FOR THE PROPOSED OEHHA NONCANCER REFERENCE EXPOSURE LEVELS.

M. Suh and D. HaMai. *Exponent, Irvine, CA.*

The Office of Environmental Health Hazard Assessment (OEHHA) is in the process of finalizing the 2007 draft guidance Air Toxics Hot Spots Program Technical Support Document for the Derivation of Noncancer Reference Exposure Levels (RELs). In this guidance, OEHHA proposed revisions to the methodology for deriving public health protective acute, eight-hour, and chronic inhalation RELs and increased the stringency of health protective levels for six chemical compounds, three of which are metals. The RELs are health-based values used to evaluate noncancer risk within the risk assessment process. For hazard identification of air releases, the California Air Resource Board (CARB) maintains an inventory of toxic and criteria data for large point sources, areawide sources, and over a 100 mobile sources. The annual mass contribution by source categories were differentiated to identify high emission sources of arsenic, manganese, and mercury, thereby, facilitating the attribution of risk from relevant source exposures. To locate high emission regions of arsenic, manganese, and mercury, the proposed RELs were compared to statewide and regional air quality data. For regions with ambient air concentrations that exceeded the RELs, the 2006 California Toxics Inventory was analyzed to rank source categories by emissions release. Statewide background concentrations were above the RELs for manganese, and exceedances were detected in counties throughout northern and southern California. For arsenic, background concentrations exceeded the RELs in Imperial and San Bernadino counties of Salton Sea and South Coast air basins, respectively. For all three metals, areawide sources were identified as generating higher rates of emissions release and more probable in contributing a greater extent to health risk than those of large point and mobile sources. Efforts to mitigate human health risk from the emissions of these metals will require coordination among diverse industries associated with areawide sources that include petroleum refinement and agricultural processes.

PS 819 PROVISIONAL ADVISORY LEVELS (PALS) FOR TITANIUM TETRACHLORIDE ($TiCl_4$).

C. M. Troxel[1], M. McClanahan[2], D. Dorman[3] and F. Adeshima[4]. *[1]CMTox., Inc., Lander, WY, [2]Retired; Centers for Disease Control and Prevention, Chamblee, GA, [3]NCSU, Raleigh, NC and [4]U.S. EPA, Washington, DC.*

PAL values developed by the U.S. EPA represent general public emergency exposure limits for oral and inhalation exposures for hazardous materials corresponding to three severity levels and durations of 24 hrs, 30 and 90 d, and 2 yrs. PAL 1, 2, and 3 severity levels represent the threshold for mild effects, serious/irreversible/escape-impairing effects, and lethal effects, respectively. The PAL protocol has been applied to estimate oral and inhalation exposure limits for $TiCl_4$.
$TiCl_4$ is used in the manufacturing of titanium dioxide pigments, titanium metal, artificial pearls, and iridescent glass; in the production of Ziegler-Natto catalysts; and as a military smoke screen. $TiCl_4$ is highly corrosive, hydrolyzing upon contact with moisture releasing heat, hydrochloric acid, and orthotitanic acids, thereby causing direct tissue damage in the lung. Data indicate that the fine particulate oxychloride intermediates generated from $TiCl_4$ hydrolysis are able to penetrate deep into the lung where hydrolysis is completed, resulting in direct contact irritation and producing bronchitis or pneumonia. Data were insufficient for derivation of oral PAL values. Data were available for deriving inhalation PAL 1, 2, and 3 values for 24 h, 30 d, 90 d, and 2 yrs; these will be presented.

PS 820 PROVISIONAL ADVISORY LEVEL (PAL) DEVELOPMENT FOR INORGANIC ARSENIC.

P. B. Selby[1], D. Dorman[2], L. Koller[3] and F. Adeshina[4]. *[1]Oak Ridge National Laboratory, Oak Ridge, TN, [2]North Carolina State University, Raleigh, NC, [3]Environmental Health and Toxicology, Corvallis, OR and [4]U.S. Environmental Protection Agency, Washington, DC.*

PAL values developed for hazardous materials by the US EPA represent general public emergency exposure limits for oral and inhalation exposures corresponding to three different severity levels (1, 2, and 3) for 24-hour, 30-day, 90-day, and 2-year durations. PAL 1 represents the threshold for mild effects; PAL 2 represents the threshold for serious, irreversible or escape-impairing effects; PAL 3 represents the threshold for lethal effects. PALS have not been promulgated nor have they been formally issued as regulatory guidance. They are intended to be used at the discretion of risk managers in emergency situations when site-specific risk assessments are not available. Application of PAL protocols has been performed for inorganic arsenic to estimate oral and inhalation exposure limits, to the degree supported by the available data. Oral and inhalation PAL values were derived from vast amounts of

data available from human exposures (medical and forensic experience as well as subacute or chronic poisonings from inorganic arsenic in drinking water or food) and from very limited experiments on rats, respectively. PAL estimates for inorganic arsenic will be presented.

PS 821 PROVISIONAL ADVISORY LEVELS (PALS) FOR PHOSPHINE (PH_3).

K. A. Davidson[1], L. Koller[2], D. Gardner[3] and F. Adeshina[4]. [1]*Oak Ridge National Laboratory, Oak Ridge, TN,* [2]*Environmental Health & Toxicology, Corvallis, OR,* [3]*Inhalation Toxicology Associates, Savannah, GA and* [4]*U.S. EPA, Washington, DC.*

PAL values developed by the US EPA represent general public emergency exposure limits for oral and inhalation exposures for hazardous materials corresponding to three severity levels and durations of 24 hrs, 30 and 90 d, and 2 yrs. PAL 1, 2, and 3 severity levels represent the threshold for mild effects, serious/irreversible/escape-impairing effects, and lethal effects, respectively. The PAL protocol has been applied to estimate oral and inhalation exposure limits for PH_3.
PH_3 is a pesticide released as vapor from aluminum phosphide tablets used to fumigate bulk grain or it is incorporated into rodent bait as zinc phosphide and released in the gastrointestinal tract. PH_3 is highly toxic by the oral and inhalation routes in humans and in animals. It is absorbed very rapidly from the respiratory and gastrointestinal tracts and inhibits mitochondrial respiration via non-competitive inhibition of cytochrome c oxidase. Although PH_3 affects many organ systems in the body, its primary targets are the gastrointestinal tract, cardio-respiratory systems, and the central nervous system. Data were available for deriving a 24-h oral PAL 3 value and inhalation PAL 1, 2, and 3 values for 24 h, 30 d, 90 d, and 2 years; these will be presented.

PS 822 PROVISIONAL ADVISORY LEVEL (PAL) DEVELOPMENT FOR METHYL ISOCYANATE (MIC).

C. Wood[1], L. Koller[2], E. McConnell[3] and F. Adeshina[4]. [1]*Oak Ridge National Lab, Oak Ridge, TN,* [2]*Environmental Health & Toxicology, Corvallis, OR,* [3]*ToxPath, Inc, Raleigh, NC and* [4]*U.S. EPA, Washington, DC.*

PAL values developed for hazardous materials by the US EPA represent general public emergency exposure limits for oral and inhalation exposures corresponding to three different severity levels (1, 2, and 3) for 24-hr, 30-d, 90-d, and 2-yr durations. PAL 1 represents the threshold for mild effects; PAL 2 represents the threshold for serious, irreversible or escape-impairing effects; PAL 3 represents the threshold for lethal effects. PALs have not been promulgated nor have they been formally issued as regulatory guidance. They are intended to be used at the discretion of risk managers in emergency situations when site specific risk assessments are not available. Application of PAL protocols has been performed for MIC to estimate oral and inhalation exposure limits, as data permit.
MIC is one of the most reactive of all isocyanates and is used as an intermediate in the synthesis of certain insecticides and herbicides. No data from oral exposure of humans and only limited data from oral exposure of laboratory animals were found. An LD50 of 71 mg/kg was reported for male rats with deaths occurring in 1-5 days. Signs of severe respiratory tract irritation were reported for victims of the Bhopal disaster; the cause of death was pulmonary edema. Increased spontaneous abortion and decreased number of live births among women pregnant at the time have been reported. Numerous animal studies corroborate the epidemiological findings in humans and the results show little species variability. Developmental and reproductive toxicity has also been shown in rats and mice following inhalation exposure to MIC. Increases in stillbirths observed in mice following multiple inhalation exposures did not appear as increased resorptions following single exposures. Unlike other isocyanates, MIC is not a sensitizer. PAL estimates were based on evaluation of experimental data in humans and rats. PAL estimates were approved by the Expert Consultation Panel for Provisional Advisory Levels in April 2008 and will be presented.

PS 823 PROVISIONAL ADVISORY LEVELS (PALS) DEVELOPMENT FOR MEVINPHOS.

J. L. Rayner[1], D. Dorman[2], M. McClanahan[3] and F. Adeshina[4]. [1]*Oak Ridge National Laboratory, Oak Ridge, TN,* [2]*North Carolina State University, Raleigh, NC,* [3]*Retired; Centers for Disease Control and Prevention, Chamblee, GA and* [4]*U.S. EPA, Washington, DC.*

PAL values developed for hazardous materials by the U.S. EPA represent general public emergency exposure limits for oral and inhalation exposures corresponding to three different severity levels (1, 2, and 3) for 24-hr, 30-d, 90-d, and 2-yr durations. PAL 1 represents the threshold for mild effects; PAL 2 represents the threshold for serious, irreversible or escape-impairing effects; PAL 3 represents the threshold for lethal effects. PALS have not been promulgated nor have they been formally issued as regulatory guidance. They are intended to be used at the discretion of risk managers in emergency situations when site specific risk assessments are not available. Application of PAL protocols has been performed for mevinphos to estimate oral and inhalation exposure limits, as experimental data permit. Mevinphos is a restricted use organophosphate pesticide that inhibits plasma, erythrocyte, and brain cholinesterase activity in several species. Lethal reports of mevinphos poisoning in humans show that exposure results in tremors, convulsions, and pulmonary congestion and edema. Short-term non-lethal doses cause inhibition in plasma and erythrocyte cholinesterase activity, increased Achilles tendon reflex force, and decreased slow muscle fiber nerve conduction velocity. No clinical signs of intoxication were observed at non-lethal experimental doses. In rats, mevinphos exposure causes generalized tremors, miosis, salivation, lacrimation, impaired mobility, convulsions, respiratory failure. At higher concentrations, the symptoms are more pronounced and severe. Oral PAL estimates were recommended at each severity level and duration. Inhalation PAL 2 and 3 estimates were recommended for the 24-hr duration. Insufficient data were available to derive inhalation PAL values for 30-d, 90-d, and 2-yr durations. PAL estimates were approved by the Expert Consultation Panel for PALs in July 2008 and will be presented.

PS 824 HEALTH RISK ASSESSMENT OF 2-ETHYLHEXANOL IN DRINKING WATER.

C. English, C. Lee, C. J. McLellan and G. L. Ball. *NSF International, Ann Arbor, MI.*

Acceptable levels of 2-ethylhexanol in drinking water were determined based on Annex A of NSF/ANSI 61 (2007a). 2-Ethylhexanol is detected in the extract water of plastic pipes that convey drinking water. While limited toxicity data for 2-ethylhexanol in humans were identified, numerous studies have evaluated the toxicity of oral exposure to 2-ethylhexanol in laboratory animals. Repeated gavage exposure with 2-ethylhexanol was associated with reductions in mean body weight and altered organ weights in rats and mice in the absence of specific target organ toxicity. Rats were more sensitive than mice, since the body weight reduction occurred at lower dose levels in rats. Developmental toxicity after 2-ethylhexanol included skeletal malformation and retardation with reduced fetal body weight accompanied by signs of maternal toxicity in dams. Lifetime exposure of female mice to 2-ethylhexanol by gavage was associated with an increase in the incidence of hepatocellular carcinomas that exceeded the concurrent control incidence, but were within the historical control range for gavage studies reported by the NTP. There was no significant difference in hepatocellular adenomas or carcinomas in treated male mice or male or female F344 rats. 2-Ethylhexanol is a peroxisome proliferator, and this mode of action may be related to or influence the development of hepatocellular carcinomas. While some rodents are highly susceptible to peroxisome proliferation, humans and other primates are resistant. The weight of genotoxic evidence suggests that 2-ethylhexanol is not mutagenic or clastogenic. It was concluded that the data are inadequate for an assessment of human carcinogenic potential under U.S. EPA (2005) guidelines. The RfD of 0.1 mg/kg-day 2-ethylhexanol was based on the NOAEL of 36 mg/kg-day for reduced mean body weight and altered organ weights in rats and mice with a total uncertainty factor of 300x to account for inter- and intraspecies extrapolation and the lack of a two-generation reproduction study. The RfD was used to determine the Total Allowable Concentration in drinking water of 0.8 mg/L.

PS 825 THE CHALLENGE OF SETTING REFERENCE DOSES (RFDS) FOR POLYOLS THAT ARE CONSTITUENTS OF FOODS, BEVERAGES, DRUGS, AND MUNITIONS.

T. Zewdie, M. S. Hutcheson and C. Smith. *Office of Research and Standards, Massachusetts Department of Environmental Protection, Boston, MA.*

Pentaerythritol (PE) was detected in a private well in Massachusetts at a concentration of 500 mg/L. In order to assess the potential human health hazard from domestic use of the well water, we sought toxicological information on PE to support derivation of an RfD. PE is a sugar alcohol or polyol that is manufactured for use in explosives, pharmaceuticals and various other products. Since the toxicological database on PE was limited, toxicological data on a structurally related compound, erythritol, was
also assessed to derive an RfD for PE. Erythritol belongs to a class of polyols whose toxicity has been extensively studied in both animals and humans because they are commonly used as food additives and sugar substitutes. Both compounds are well absorbed and excreted in the urine unchanged, and both seem to have similar adverse effects on the gastrointestinal (GI) tract and the kidney. The GI effects include mainly diarrhea and increased cecal weight, while the effects in the kidney include diuresis and increased water consumption, serum and urine electrolyte

imbalance, and changes in kidney weight and structure, including renal calcification. The estimated chronic RfDs based on animal studies are 15 mg/kg/d for PE and 17 mg/kg/d for erythritol. The chronic RfD for erythritol based on a human study is 22 mg/kg/d. The RfD for PE can be used to derive an allowable drinking water concentration. Typically, drinking water values are calculated using a standardized approach based on a 70 kg person consuming 2 liters of water per day and a default source apportionment factor of 20%. The challenge regarding the application of a source apportionment factor, however, is that the reported 50th and 90th percentile total daily consumption of polyols from dietary sources, as these compounds are widely used in foods and beverages, ranges from 14 to 86 and 57 to 228 mg/kg/d respectively. These values are close to or much higher than the RfD estimated for PE.

PS 826 PFOA IN NEW JERSEY DRINKING WATER: OCCURRENCE, EXPOSURE SIGNIFICANCE, AND HEALTH-BASED GUIDANCE.

G. B. Post[1], K. R. Cooper[2] and B. J. Boros-Russo[1]. *[1]NJ Department of Environmental Protection, Trenton, NJ and [2]Rutgers University, New Brunswick, NJ.*

Perfluorooctanoic acid (PFOA) is ubiquitous in the blood of humans, with a mean serum concentration in the US of about 4 ug/L. Sources of PFOA exposure include food, house dust, consumer products, and drinking water. Human exposure is of concern because of PFOA's long half-life and toxicity. Little is known about the general occurrence of PFOA in drinking water or its contribution to total human exposure. PFOA was found in 24 of 30 (80%) of NJ public water supplies tested at levels ranging from <0.004-0.19 ug/L. These concentrations may contribute significantly to total human exposure, based on an approximate 100:1 ratio between the concentration of PFOA in serum and in drinking water observed in OH and WV communities with both high (>3 ug/L) and low (<0.1 ug/L) drinking water levels. A lifetime drinking water guidance for PFOA was developed based on evaluation of NOAELs and LOAELs, as well as cancer data, from animal studies identified in a USEPA draft risk assessment (2005). Since the half-life of PFOA in humans is much longer than in animals, the drinking water guidance was based on comparison of blood levels in animals and humans, rather than on administered doses. The 100:1 ratio between serum and drinking water concentrations of PFOA was used to develop health-based drinking water concentrations for non-cancer and cancer endpoints. The most sensitive endpoints were decreased body weight and hematological effects in a chronic study in female rats. The guidance value based on these endpoints is 0.04 ug/L, while the drinking water concentration based on cancer at the 1 x 10-6 risk level is 0.06 ug/L. Recent data from animal and human studies not considered in the USEPA risk assessment, including developmental effects in mice and decreased birth weight and other measures of fetal growth in humans, further support this health-based drinking water guidance. While PFOA in most NJ water supplies was below the health-based drinking water guidance of 0.04 ug/L, several NJ water supplies exceeded this concentration.

PS 827 HEALTH RISK ASSESSMENT OF INDOOR AIR QUALITY AT A PUBLIC HOUSING PROJECT.

S. Dwyer[1], M. E. Pate[2] and R. J. Keenan[3]. *[1]Kleinfelder, Bellevue, WA, [2]Kleinfelder, Diamond Bar, CA and [3]Kleinfelder, Redlands, CA.*

A 300-unit public housing project is located on a portion of a former petroleum storage facility that had occupied more than 100 acres in Southern California. The petroleum storage facility operated for about 40 years, closing in 1965, and the housing project was constructed in the early 1970s. Concerns about potential health effects among the housing project residents triggered several rounds of environmental site investigation beginning in the 1990s. In 2007, a regulatory agency order required a detailed investigation of soil, soil vapor, and groundwater contamination and a site-specific human health risk assessment. Because indoor air quality was a primary health concern, soil vapor, indoor air, and outdoor air samples were concurrently collected for analysis by EPA Method TO-15. Soil vapor analysis revealed petroleum hydrocarbon constituents (e.g., benzene) at concentrations of health concern. The highest concentrations occurred in the deepest soil vapor samples (32 feet below ground surface, bgs) and concentrations declined in the samples from intermediate (15 feet bgs) and shallow depths (5 feet bgs). Of the 13 volatile organic chemicals (VOCs) detected in soil vapor samples, only five were also detected in indoor air, which indicated that chemicals in soil vapor were not migrating to indoor air. Comparison of indoor air and outdoor air samples revealed that an identical suite of chemicals was detected in each medium and that the concentrations of these chemicals were equivalent. Furthermore, the indoor air and outdoor air concentrations from the subject site were equivalent to the concentrations reported for ambient air in an extensive study of background VOC concentrations in the regional air shed. In conclusion, these data indicate that residual petroleum hydrocarbon constituents in soil vapor are not migrating to indoor air at levels of health concern and indoor air quality at the public housing project is consistent with the ambient background air quality of the region.

PS 828 HUMAN HEALTH RISK ASSESSMENT OF EXPOSURE TO PESTICIDES IN PARLIER, CALIFORNIA.

J. D. Roberts[1] and R. Reiss[2]. *[1]Health Sciences Practice, Center of Exposure and Dose Reconstruction, Exponent ®, Wood Dale, IL and [2]Health Sciences Practice, Center of Exposure and Dose Reconstruction, Exponent ®, Alexandria, VA.*

As part of the California Environmental Protection Agency (Cal/EPA) Environmental Justice Action Plan, the Department of Pesticide Regulation (DPR) has set a goal to analyze the ambient air in a variety of communities in California for traces of pesticidal compounds. DPR selected Parlier, a small community in Fresno County and collected environmental data. Air monitoring was performed throughout the year of 2006 with the purpose of being able to determine if residents were exposed to pesticidal compounds in the ambient air at levels of concern. Thirty pesticides and breakdown products, 25 volatile organic compound (VOCs), and 29 metals/non-metals were evaluated. The VOCs and metals/non-metals were monitored at two sites. DPR sampled for twelve pesticides at the Martinez, Chavez and Benavidez Schools. Using the estimated air concentrations, a human health risk assessment was conducted to assess the potential non-carcinogenic effects of the pesticidal compounds evaluated by Cal/EPA at Parlier. The Cal/EPA acute screening levels (ACL), as well as, the chronic reference exposure levels (REL), when available, were used as reference values to determine hazard quotients (HQ). Using the maximum air exposure estimate, the only pesticide that was found to have an HQ above 1.0 (unity) was diazinon at the Chavez School. All of the VOC acute HQs were either well below 1.0 or could not be determined with the exception of acrolein, which ranged from 6.8 to 26.5. Likewise, the VOC chronic HQs identified formaldehyde to be present in ambient air concentrations at levels above the Cal/EPA REL. None of the metals/non-metals acute HQs were estimated above 1.0. However, the chronic HQ for chlorine was found to be a value of 1.2. Among all of the pesticidal compounds evaluated, it was found that the majority (92.5%) of compounds that the Parlier residents were exposed to were well below the reference levels considered "safe".

PS 829 HUMAN HEALTH RISK ASSESSMENT OF CONSUMPTION OF FISH FROM THE LOWER PASSAIC RIVER.

J. Urban[1], J. Tachovsky[1], D. Staskal[1], L. Haws[1] and M. Harris[2]. *[1]ToxStrategies, Austin, TX and [2]ToxStrategies, Houston, TX.*

The Lower Passaic River (LPR) in New Jersey has been substantially impacted by various human activities for more than two centuries. We conducted a human health risk assessment (HHRA) of fish consumption along the LPR in New Jersey by incorporating site-specific information in lieu of default exposure assumptions. Fish consumption information gathered during a year-long, intercept-style creel angler survey conducted along the LPR and representative LPR fish tissue concentrations for more than 150 chemicals of potential concern (COPCs) obtained from USEPA's analytical LPR fish data publically available on OurPassaic.org were used as the basis for the risk assessment. This HHRA is comprised of two phases: (1) identification of COPC groups that contribute to the majority of overall excess cancer risk and hazard estimates using deterministic and probabilistic methods, and (2) probabilistic characterization of risk using distributions of chemical concentration and cooking loss for those compounds identified in Phase 1. Phase 1 relied on CT and RME point estimates of COPC concentrations and demonstrated that PCDD/Fs and PCBs (dioxin-like and non-dioxin-like) are the greatest contributors to cancer risk, while non-dioxin-like PCBs are the primary contributors to non-cancer hazard estimates. Phase 1 results for total excess cancer risks for child and adult receptors were within USEPA's acceptable excess cancer risk range, with the exception of RME child ($3.4x10^{-4}$ and $1.4x10^{-4}$ for deterministic and probabilistic approaches, respectively). Phase 2 focused on PCDD, PCDF, and PCBs and used distributions of chemical concentrations in fish, taking into account cooking loss. The results showed that all excess cancer risk estimates were within the acceptable risk range, although non-cancer hazard estimates for PCBs slightly exceeded a Hazard Index of 1. This HHRA of LPR fish consumption represents the most comprehensive evaluation conducted to date and demonstrates that measured COPCs are not likely to pose a health risk to people who currently consume fish from the LPR.

PS 830 HUMAN HEALTH RISK ASSESSMENT FOR ENVIRONMENTAL APPLICATIONS OF STEEL SLAG: DIFFERENCES BETWEEN MATERIAL-SPECIFIC AND DEFAULT APPROACHES.

D. Proctor and D. HaMai. *Exponent, Irvine, CA.*

Steel slag is generated from steel production, consisting of the minerals that are incompatible with steel. Its use commercially for construction and agriculture results in the potential for exposure to human populations. Certain metals in steel slag

occur at concentrations that are higher than in soils, and manganese (Mn) levels in slag are of potential human health concern. Although some metals exceed screening levels for metals in soil, there are several physical/chemical properties of slag which limit environmental mobility and bioaccessibility. These factors should be quantified in any material-specific risk assessment. Metals in slag exist as metal oxides tightly bound to the slag matrix, and heavy metals are concentrated in larger slag particles, such that concentrations lessen with decreasing particle size. A comparative health risk assessment of environmental steel slag applications, focused on incidental ingestion for a residential application, was conducted to evaluate the difference in calculated potential hazards using material-specific factors relative to default ones. Important risk assessment parameters include the use of appropriate exposure point concentrations (EPCs), considerations of bioaccessibility, factoring frequencies of exposure to slag applications, and the use of the EPA modifying factor (MF) with the Mn RfD. The assessment was conducted using EPCs based on reliable analytical methods, exposure frequencies based on time-use data, and slag-specific measures of the bioaccessibility of Mn and vanadium ranging from 20% to 70% and of 20% to 30%, respectively. Exposures to metals were quantified and compared to the EPA Mn RfD without use of the MF because Mn in steel slag is not associated with drinking water exposures or exposures to neonates, and uptake of Mn is tightly regulated by homeostatic controls. The comparative assessment demonstrated that exposures to metals in slag are below the level of potential concern with a hazard index of 0.8, and that hazards are approximately 10-times lower than that estimated using default approaches.

PS 831 AN ASSESSMENT OF THE POTENTIAL HEALTH HAZARDS ASSOCIATED WITH EXPOSURES TO CHRYSOTILE ASBESTOS IN DRYWALL ACCESSORY PRODUCTS.

A. D. Phelka and K. S. Franke. *ChemRisk, Boulder, CO.*

Historically, short fiber chrysotile asbestos was added to industrial joint compounds and consumer spackling and patching compounds to serve as a reinforcing agent designed to control shrinkage and cracking as the materials dried. As is the case with numerous historic asbestos-containing products, some concerns have emerged regarding the potential health risks associated with former use of these compounds. In this study, we summarize: 1) the published and unpublished literature describing fiber type and fiber length data for historic drywall accessory products, 2) animal toxicology data involving inhalation exposures to short-fiber chrysotile, and 3) epidemiology data available for career drywaller cohorts and other occupations exposed primarily to short-fiber chrysotile. The results of our analysis indicate that: 1) the vast majority of asbestos fibers in joint compound were likely to have been less than five microns in length, and were, therefore, too short to pose a risk of disease, 2) laboratory animal studies evaluating long-term exposures to short chrysotile fibers consistently report an absence of asbestos-related diseases, even at exposures in great excess of those experienced by career drywallers, and 3) mortality studies of drywall workers do not indicate an increase in mortality from asbestos-related disease. We conclude that the weight of evidence suggests that drywallers and, consequently bystanders to drywalling activities, were not historically at risk for developing asbestos-related disease.

PS 832 EVALUATION OF RISK FOR FETAL LIMB DEFECTS FROM OCCUPATIONAL EXPOSURE TO MANCOZEB AND ETHYLENE THIOUREA DURING PREGNANCY.

A. S. Lewis, S. N. Sax, S. Thakali and B. D. Beck. *Gradient Corporation, Cambridge, MA.*

Ethylene thiourea (ETU) and Mancozeb, which metabolizes to ETU in the environment, are two pesticides used on tomato farms. ETU is associated with developmental toxicity in rats, including some forms of limb defects, while Mancozeb is associated with fetal effects, but only at maternally toxic doses. We evaluated the potential for these pesticides to cause limb defects in human fetuses from maternal exposures to a hypothetical farm worker. Using information about recommended application rates, treatment regimens, and the environmental fate of the applied pesticides, we estimated potential worst-case maternal exposures during the critical period for limb development (gestation days 28-42) and compared to doses that cause developmental toxicity in animals. To estimate maternal dose we examined the following exposure pathways: 1) inhalation of sprayed pesticides, 2) dermal exposure to sprayed pesticide, 3) incidental ingestion of soil, 4) dermal contact with soil, 5) incidental ingestion of residue on plant, 6) dermal exposure to residue on plant, and 7) inhalation of fugitive dust. The United States Environmental Protection Agency (US EPA) air dispersion model, AERMOD was used to determine pesticide concentration in air (for inhalation exposure) and deposition rate (for dermal exposure). To evaluate potential risk, we used a margin of exposure (MOE) approach. Using our multi-exposure pathway analysis, we demonstrated that MOEs for Mancozeb for each pathway ranged from over a 1,000 to over 30,000,000 and that MOEs for ETU for each pathway ranged from over 3,000 to over 4,000,000, indicating a negligible risk of fetal limb defects from occupational exposure (via maternal exposures) to these pesticides.

PS 833 POTENTIAL FOR OCCUPATIONAL EXPOSURES OF HAIRDRESSERS TO VINYL CHLORIDE IN HAIRSPRAY (1967-1974).

D. M. Cowan[1], J. Sahmel[1], K. Unice[2], P. Scott[2] and D. Paustenbach[3]. *[1]ChemRisk, Boulder, CO, [2]ChemRisk, Pittsburgh, PA and [3]ChemRisk, San Francisco, CA.*

Vinyl chloride was used as a propellant in a small percentage of aerosol hairspray products in the U.S. from approximately 1967 to 1973. Since that time, questions have arisen regarding whether occupational exposures of hairdressers to vinyl chloride in hair salons would be sufficient to increase the risk for developing hepatic angiosarcoma (HAS) which has been linked definitively with vinyl chloride exposures among industrial workers with significant chronic vinyl chloride exposures. Since the hairspray products used during this time are no longer available to use for simulation purposes and existing measurement data are sparse, a modeling approach was used to estimate the potential for exposures to hairdressers during his time period. A transient two-zone model along with comparison estimates from the steady-state imperfect mixing model were used to estimate the airborne concentration of vinyl chloride for both individual hairdressers spraying hairspray and background concentrations of vinyl chloride in hair salons over time, because the emission rate of hairspray was not constant. Near field and far field concentrations of vinyl chloride were modeled over time for representative small, medium, and large salons as well as a representative home salon. Ventilation and air movement characteristics, air exchange rates, salon size, the number of hairdressers, and the number of customers were determined using published literature and variability in these parameters was also considered using Monte Carlo techniques. The modeling results were also compared against airborne exposure measurements in the literature for a number of products with the potential to produce airborne concentrations in hair salons. The results indicate that the lifetime cumulative doses via inhalation of vinyl chloride for hairdressers for the time period in which it was used in hairspray products are more than 10 to 100 fold lower than those found among industrial manufacturing workers who developed HAS.

PS 834 INHALATION RISKS OF MERCURY IN INDOOR AIR FROM BENEFICIAL USE OF COAL COMBUSTION PRODUCTS (CCPS) IN BUILDING MATERIALS.

C. M. Long, A. S. Lewis and S. N. Sax. *Gradient Corporation, Cambridge, MA.*

Coal combustion products (CCPs), including coal fly ash (CFA) and flue gas desulfurization (FGD) residues, are receiving increasing use as substitutes for traditional substances in building materials. For example, approximately 30% of U.S. wallboard is now manufactured from FGD synthetic gypsum, while CFA has gained widespread usage as a partial replacement for Portland cement in concrete. Given concerns that have been raised regarding the presence of mercury (Hg) in CCPs and the potential for Hg releases from CCP building materials into indoor air, we conducted a screening-level assessment to estimate worst-case inhalation risks from indoor air exposures to Hg for two CCP utilization scenarios: (1) FGD synthetic gypsum wallboard used in a school classroom or home, and (2) CFA concrete blocks used in a school classroom. For CFA concrete, we relied on data from recent laboratory studies of Hg emissions during dry curing of concrete at near-ambient temperatures to calculate two Hg release rates to indoor air, one based on the maximum 28-day curing rate from these studies to represent worst-case emissions and one based on extrapolated long-term emissions to represent upper-bound, long-term emissions. For wallboard, we calculated a Hg release rate based on laboratory flux chamber measurements for synthetic gypsum wallboard samples. We estimated indoor air Hg concentrations using these Hg release rates and conservative values for other parameters (e.g., air exchange rates, material loading ratios) in a steady-state indoor air model. Even using parameters intended to overstate potential exposures, we predicted indoor air Hg concentrations that are generally consistent with or below ambient background Hg levels. Moreover, predicted indoor Hg concentrations were well below established inhalation toxicity criteria (hazard indices ranged from 0.0002 to 0.016). Thus, based on our findings, we conclude that CCPs in concrete and wallboard building materials are unlikely to result in Hg exposures in either classroom settings or in residential homes that pose a health concern.

PS 835 INHALATION RISKS OF MERCURY FROM USE OF COAL COMBUSTION PRODUCTS (CCPS) AS STRUCTURAL FILL AND FROM DISPOSAL OF CCP BUILDING MATERIALS IN LANDFILLS.

S. Sax, A. Lewis and C. Long. *Gradient Corp, Cambridge, MA.*

The beneficial use of coal combustion products (CCPs) conserves natural resources, reduces landfill waste, and may also improve the quality and performance of construction materials. Concerns remain, however, about potential exposures to Hg in CCPs, including coal fly ash (CFA) used in concrete and structural fill, as well as flue gas desulfurization (FGD) used in wallboard. Moreover, with potential future regulation that requires Hg emission reductions, Hg concentrations in CCPs are likely to increase. Therefore, to examine potential exposures to Hg emissions from CCPs, we conducted a screening-level risk assessment to determine worst-case inhalation exposures to Hg for two outdoor exposure scenarios: (1) CFA used as structural fill material, and (2) CCP concrete and wallboard disposed of in a construction & demolition (C&D) landfill. For the structural fill scenario, we considered both fugitive dust emissions containing inorganic Hg and volatilization of elemental Hg from the CFA. For the landfill scenario, we considered only volatilization of elemental Hg from CCPs in concrete and wallboard. We estimated outdoor Hg air concentrations using US Environmental Protection Agency's (US EPA's) Wind Erosion Model and the Screen 3 Model applying conservative, worst-case assumptions. To estimate potential risks, we compared the modeled air concentrations to toxicity criteria to determine if exposures to children and adults were above a level of health concern. Our results showed that Hg exposures via inhalation from the CCP materials are near or below ambient Hg levels, and several orders of magnitude lower than health-based toxicity criteria. Our findings thus indicate that upper-end exposures to Hg from the beneficial use of CCPs in structural fills, and from disposal of building materials containing CCPs, are not expected to pose an inhalation health risk.

PS 836 EFFECTS OF ACUTE EXPOSURE TO AIRBORNE METHYL ISOTHIOCYANATE (MITC): A COMPARISON OF IRRITANT RISKS.

M. L. Dourson[1], M. J. Kohrman[1] and W. S. Cain[2]. [1]*TERA, Cincinnati, OH and* [2]*University of California - San Diego, San Diego, CA.*

Methyl isothiocyanate (MITC) is the degradate that provides the pesticidal properties of a number of field applied fumigants (e.g. metam sodium). Airborne MITC can drift off-site and potentially affect bystanders, in addition to field workers and pesticide handlers. Based on a review and synthesis of literature, eye irritation, mediated through stimulation of the trigeminal nerve, appears to be the most sensitive endpoint after acute exposure. Risk assessment for exposure can therefore rely on studies of eye irritation to determine the point of departure for acute inhalation studies. We used a human study by Russell and Rush (1996) and assessed the risk for acute exposure based on the outcome variables of perceived irritation, blink rate, and tearing. We analyzed the hazards through concentration-time (CxT) analyses, computed benchmark concentrations (BMCs) and determined a BMCL of 0.20 ppm. Because the derived BMC is based on human data, no uncertainty factor (UF) for extrapolation from experimental animals is necessary. Similarly, since the lower limits to the BMCs are NOAEL surrogates, no UF is needed for extrapolation from LOAEL to NOAEL, nor is a database uncertainty factor needed. A UF for human variability is, however, necessary. Based on the available information, we concluded that a UF of 1 is appropriate because there is minimal intraspecies variability for direct contact effects (i.e. eye irritation) since only dynamic, not kinetic, variability is relevant, and because the Russell and Rush (1996) study included a sensitive population. We compared the key events and effects of MITC to those of other irritant chemicals that likely act via trigeminal nerve stimulation (e.g. chloropicrin) to provide further evidence that, through trigeminal nerve stimulation, eye effects will occur at lower concentrations, and within shorter periods of time, than respiratory effects. The best estimate of a health protective concentration for MITC, based on this assessment, is 0.8 ppm for 14 minutes and 0.2 ppm for 4 hours and longer.

PS 837 ASSESSMENT OF POTENTIAL HUMAN HEALTH AND ECOLOGICAL RISKS ASSOCIATED WITH PRESENCE OF LINDANE IN PHARMACEUTICAL PRODUCTS.

L. Sweet and K. Unice. *ChemRisk, Pittsburgh, PA.*

Use and disposal of household pharmaceutical products have become important topics within the field of risk assessment. Lindane based medications are used in the prescription treatment of scabies and lice. Although lindane medications have over 50 years of clinical use, public concern about the potential environmental and human health risks associated with the use and disposal of lindane containing products continues. The purpose of this assessment was to evaluate the potential health risks associated with lindane generated as a result of lindane medication use and disposal in drains connected to wastewater treatment systems. Using conservative models (EFAST) and input parameters, our risk assessment revealed that down the drain disposal of lindane containing medications results in exposures well below predicted or currently available no effect health benchmarks. Conservatively predicted water concentrations for lindane were below respective health screening criteria by orders of magnitude. Overall, these results suggest a large margin of safety for the secondary exposure to lindane in treated tapwater, wastewater, and surface water derived from household drain disposal of lindane medications. These findings show that household usage of bleach contributes a negligible fraction of lindane to surface water if any, and would not necessitate further risk management measures. As such, this assessment demonstrates that potential lindane levels present as a result residential lindane medication usage are highly unlikely to cause adverse health or ecological effects. Margins of exposure are adequate for the protection of environmental and human health when lindane medications are used as directed.

PS 838 EVALUATION OF THE PUBLIC HEALTH RISKS ASSOCIATED WITH FORMER MANUFACTURED GAS PLANTS (MGP).

R. B. DeHate, G. T. Johnson and R. D. Harbison. *Department of Environmental Occupational Health, University of South Florida, Tampa, FL.*

Regulatory agencies have recently focused on assessing the potential for soil vapor intrusion (SVI) and risk posed to occupants of residential and commercial properties overlying and surrounding former MGP. This study evaluated the potential for SVI at 10 commercial buildings and 26 single and multi-family residential properties overlying and/or adjacent to 3 former MGPs. The potential for SVI exposure was categorized into three groupings according to vadose zone: no vadose zone; 0 - 6 feet, and 6 to 25 feet. Indoor and outdoor air and soil vapor samples were collected and analyzed for VOCs by Method TO-15. These findings were compared to federal and state regulatory background data sets. The results did not identify evidence of MGP-related soil vapor intrusion from any of the 36 sites regardless of depth to water table or proximity to MGP source tar or dissolved phase plumes. In addition, comparative risks were calculated based on maximum and mean concentrations for benzene, toluene, ethylbenzene, and xylenes measured in all samples. These chemicals were selected based on frequency of detection within the data sets. Hazard Indexes were calculated using the study results and the mean, maximum and 95th percentile concentrations from regulatory data bases. Carcinogenic risks associated with benzene were calculated using both the measured mean and maximum study results and the mean, maximum and 95th percentile concentrations from state and federal data bases. The calculated Hazard Indexes were less than 1 or were comparable to mean and maximum background levels. Cancer risks for residential exposures ranged from 1.93x10-6 to 3.68x10-5. However background residential benzene exposure not related to former MGP sites ranged from 9.9x10-6 to 3.59x10-3. Cancer risk and exposures to indoor air, soil vapor or ambient air concentrations were equivalent or less than a normal resident in the northeast United States. No increased public health risks were associated with occupied residential or commercial properties overlying or surrounding MGPs.

PS 839 MODE OF ACTION (MOA) EVALUATION AND DERIVATION OF A CANCER AND NON-CANCER REFERENCE VALUE FOR 4-VINYLCYCLOHEXENE.

C. Bevan[1], M. Gargas[1], C. Kirman[2] and J. Vergnes[3]. [1]*The Sapphire Group, Inc., Dayton, OH,* [2]*The Sapphire Group, Inc., Cleveland, OH and* [3]*International Specialty Products, Wayne, NJ.*

4-Vinylcyclohexene (VCH) induces follicular loss and tumors in the ovaries of mice, but not rats. Alternative MOAs for the mouse ovarian tumors were evaluated using the modified Hill criteria for causality in the IPCS Human Relevance Framework. There is a high degree of confidence that VCH acts through a non-genotoxic, non-linear (threshold) MOA in producing mouse ovarian tumors. The critical event is the destruction of ovarian primordial and primary follicles by VCH diepoxide through an apoptotic mechanism. Complete oocyte loss results in ovarian failure, which increases plasma FSH levels from the loss of negative feedback from 17β-estradiol and inhibin on the hypothalamus/pituitary. Ovarian tumor development occurs from the elevated plasma FSH levels, perhaps through alteration in signaling pathways affecting cell growth. The MOA is relevant to humans, but due to metabolic differences between mice and humans, humans are expected to be less susceptible than mice to the ovarian effects from comparable VCH doses. Although there are limited in vitro data indicating genotoxic potential from the VCH epoxide metabolites, particularly VCH diepoxide, the weight of evidence is not compelling that genotoxicity is important in the MOA for mouse ovarian tumors. A 13-week mouse inhalation study was considered to be the key study, and a

critical adverse effect (ovarian toxicity) with a clear NOAEL of 250 ppm (47 ppm when adjusted for continuous exposure) was identified. A benchmark dose evaluation also resulted in a BMDL value of 49 ppm. A total uncertainty factor of 100 was used: 10 (intraspecies variability), 10 (subchronic to chronic), and 1 (interspecies) because of mouse/human differences in VCH diepoxide production and similarity between VCH and 1,3-butadiene metabolism. A non-cancer reference value of 0.47 ppm (470 ppb) was derived. Based on the proposed MOA, this value is expected to be adequately protective against ovarian tumors.

PS 840 EMISSIONS-WEIGHTED TOXICITY RANKING OF AIRPORT-RELATED HAZARDOUS AIR POLLUTANTS.

M. Seeley[1], E. Wood[2], S. Herndon[2], R. Miake-Lye[2] and D. Nelson[2]. *[1]Gradient Corporation, Cambridge, MA and [2]Aerodyne, Inc., Billerica, MA.*

Emissions related to airport operations, including particulate matter and gas-phase hazardous air pollutants (HAPs), can affect local air quality, and may pose a health concern for individuals at the airport and in surrounding communities. Airport managers are increasingly asked to evaluate potential health risks for airport employees and nearby residents. However, for many HAPs, there are insufficient data to adequately conduct such evaluations. The aim of this analysis was to prioritize airport HAPs in terms of emissions and toxicity, to identify areas for future research. Emissions were estimated for 56 HAPs emitted from aircraft and ground service equipment. We calculated risk-based concentrations (RBCs) for cancer and noncancer endpoints for 30 HAPs, using published toxicity criteria along with standard methodology recommended by the U.S. EPA. We then quantitatively ranked these 30 HAPs based on the quotient of emissions relative to the RBC. For airport-related HAPs without published toxicity criteria, we searched for published, peer-reviewed toxicity information, or for surrogate compounds with published toxicity criteria. For nine of these HAPs, we identified sufficient information, or toxicity criteria for suitable surrogates, to qualitatively assess emissions relative to potential toxicity. For the 30 HAPs with published toxicity criteria, the quantitative ranking indicates that acrolein represents the most significant health risk. Additional prioritized HAPs include formaldehyde, 1,3-butadiene, naphthalene, benzene, acetaldehyde and ethylbenzene. A significant finding was that several HAPs without published toxicity criteria may, in terms of emissions and potential toxicity, pose a health risk comparable to that of the prioritized HAPs. These HAPs include the following aldehydes: crotonaldehyde, glyoxal, methylglyoxal and propanal. Additional toxicology studies for these aldehydes would provide valuable information for conducting more rigorous, quantitative analyses. (Analysis funded by ACRP Project 02-03).

PS 841 ASSESSMENT OF THE POTENTIAL HUMAN HEALTH AND ECOLOGICAL RISKS ASSOCIATED WITH RESIDENTIAL SODIUM HYPOCHLORITE (BLEACH) DISPOSAL INTO DRAINS.

L. Sweet[1], K. Unice[1], E. Shay[1] and A. K. Madl[2]. *[1]ChemRisk, Pittsburgh, PA and [2]ChemRisk, San Francisco, CA.*

Use and disposal of household consumer products have become important topics within the field of risk assessment. Sodium hypochlorite (bleach) is used in a variety of consumer cleaning products. Although bleach has been used as a household cleaner for over 50 years, public concern about the potential environmental risks associated with the use of bleach-based cleaning products continues. The purpose of this assessment was to evaluate the potential human and ecological health risks associated with halogenated and other chemical byproducts that are generated as a result of liquid bleach disposal in drains connected to wastewater treatment systems. A total of 23 halogenated organic and two inorganic (chlorate, perchlorate) compounds were considered in this human and ecological health risk assessment. Using conservative models (EFAST and EUSES) and input parameters, our risk assessment revealed that down the drain disposal of bleach results in exposures well below predicted or currently available no effect health benchmarks. Conservatively predicted tapwater, surface water, soil, and sediment concentrations for the halogenated organics and inorganics were below their respective health screening criteria by a factor of at least 10 to 1000 times for the vast majority of chemicals evaluated. Underlying uncertainties were evaluated for chemicals within a factor of 10. Overall, these results suggest a large margin of safety for the secondary exposure to halogenated organics in treated tapwater, wastewater, surface water, soil, and sediment derived from household drain disposal of liquid bleach. These findings show that household usage of bleach contributes a negligible fraction of halogenated organics to surface water as compared to municipal and industrial wastewater treatment processes and would not necessitate further testing or risk reduction. As such, this assessment demonstrates that halogenated organic byproducts formed as a result of residential bleach usage are highly unlikely to cause adverse health or ecological effects.

PS 842 HAZARD EVALUATION OF 6-2 FLUOROTELOMER ALCOHOL (6-2 FTOH), 1, 1, 2, 2-TETRAHYDROPERFLUOROOCTANOL.

T. Serex[1], S. Munley[1], C. Carpenter[1], M. Donner[1], R. Hoke[1], R. Buck[2] and S. E. Loveless[1]. *[1]DuPont Haskell Global Centers for Health and Environmental Sciences, Newark, DE and [2]DuPont Chemical Solutions Enterprise, Wilmington, DE.*

6-2 Fluorotelomer alcohol (6-2 FTOH) was evaluated for acute, genetic, subchronic, reproductive, developmental, and aquatic toxicity. 6-2 FTOH was slightly toxic by the oral and dermal routes with an oral LD50 of 1750 mg/kg and a dermal LD50 > 5000 mg/kg in rats, and did not produce a dermal sensitization response in mice. 6-2 FTOH was not mutagenic in the bacterial reverse mutation test or in the mouse lymphoma assay and was not clastogenic in a chromosome aberration assay in human lymphocytes. 6-2 FTOH was moderately toxic to aquatic organisms. The 96-hour LC50 in fathead minnows was 4.8 mg/L, 48-hour EC50 in Daphnia magna was 7.8 mg/L, and 72-hr EC50 in Pseudokirchneriella subcapitata was 4.5mg/L. In subchronic, one-generation reproductive, and developmental toxicity studies, 6-2 FTOH was administered to rats by oral gavage. Mortality was observed in the subchronic study at 125 and 250 mg/kg/day; the deaths occurred after about three weeks of dosing and continued sporadically. Other effects observed at these doses included decreased body weights, changes in organ weights, and pathological findings involving the liver and kidneys as well as effects on the teeth. Observations at 125 and 250 mg/kg/day in the reproductive study included reduced litter size, increased pup mortality during lactation, reduced uterine weights, and reduced offspring weights. Effects in the developmental study were limited to increased incidences of skeletal variations, lower maternal body weights and food consumption at 125 and 250 mg/kg/day. There was no maternal mortality nor were there any test substance-related gross observations in the developmental study. There was no effect on fetal body weight or litter sex ratio and there were no effects on the incidences of fetal resorptions or malformations at any dose level. These data indicate 25 mg/kg/day is the NOAEL for this test substance; ongoing histopathological evaluations will clarify.

PS 843 PROBABILISTIC LEAD RISK ASSESSMENT FOR A COMMUNITY WITH AN OPERATING SMELTER.

R. Schoof and E. Lorenzen. *Integral Consulting Inc., Mercer Island, WA.*

Human health exposure assessment in communities with major operating air emission sources requires consideration of unique site conditions when using generic intake models. A U.S.EPA probabilistic lead model was used to estimate the contribution of lead via multiple exposure pathways for children. Site-specific data from a community in a developing country with an operating smelter were incorporated into the model for estimating lead intake from the diet, drinking water, dust, air and soil. Due to the unique living conditions of this community and on-going dust emissions from the operating smelter, the model was modified to account for intake of lead via indoor and outdoor dust. Default lead bioavailability values were not modified. Blood lead data collected for children under the age of six were used to calibrate the model and to back-calculate soil and dust ingestion rates. In the community closest to the smelter, intake of lead via ingestion of outdoor and indoor dust was estimated to contribute approximately 69% and 14%, respectively, of total lead intake while soil ingestion had an estimated contribution of 5%. Dietary intake of lead was measured in a duplicate diet study and contributed approximately 9% of total lead intake, greater than intakes reported in developed countries. The modified model was then used to predict future blood lead levels if smelter emissions were reduced. An update to the risk assessment conducted after stack and fugitive lead emissions were reduced showed good agreement with the significant observed decline in blood lead levels of young children. In the updated model, intake of lead via ingestion of outdoor dust was reduced relative to other pathways and was estimated to contribute 56%. The indoor dust and soil contributions increased to 23% and 12%, respectively. Dietary intake decreased to approximately 6% and the contributions of air and water were nominal.

PS 844 PROBABILISTIC RISK ASSESSMENT OF INCREMENTAL RISK BETWEEN SITE AND BACKGROUND ARSENIC IN SOIL.

P. Zieber, R. Schoof and L. Tolbert. *Integral Consulting, Inc., Mercer Island, WA.*

A site in the Northeastern United States with soil arsenic concentrations resulting from natural background conditions and contamination from chemical manufacturing activities was evaluated through deterministic and probabilistic risk assessments. The deterministic risk assessment using default assumptions found that even background arsenic levels ranging up to 20 mg/kg would be of concern for cancer risks, making it difficult to identify areas requiring remediation. Thus, a probabilistic risk assessment (PRA) was performed to yield more useful quantitative and qual-

itative risk information to compare site and background conditions and to support the remediation process. Background conditions were estimated using data from a nearby town not impacted by chemical manufacturing activities and considering differential land use weighting (e.g., proportion of historical orchard use because arsenical pesticides are often used in orchards). Background samples were divided into land use subsets (orchard, wooded-agricultural, commercial-industrial, and residential-public) and each subset was tested for distribution goodness-of-fit. Following selection of an appropriate distribution, a larger data subset of 1,000 forecast values was generated for each land use category using Oracle's Crystal Ball® software. Finally, a background condition data set of the same size as the site data set was generated by sampling from each of the forecast data subsets according to property type/land usage weighting factors based on historical land use in the site study area. Central tendency exposures (CTE) and reasonable maximum exposures (RME) were identified as the 50th and 95th percentiles of the distributions, respectively. RME based on PRA was substantially lower than RME based on deterministic risk assessment. The incremental risks between site and background conditions were calculated for CTE and RME as the difference between site risks and background risks. Incremental risks were substantially lower than total risks, providing critical perspective in the remedy selection process.

PS 845 INHIBITION OF CHOLINESTERASE (CHE) IN RATS FOLLOWING ACUTE INHALATION EXPOSURE TO CARBARYL.

A. Blacker[1], C. Lunchick[1], G. Mihlan[1], J. Weinberg[2] and M. Beck[2]. *[1]Bayer CropScience, Research Triangle Park, NC and [2]WIL Research Laboratories, Ashland, OH.*

Due to rapid recovery of ChE inhibition following exposure to carbaryl, acute exposure has been the focus of risk assessments. To refine the assessment via inhalation, red blood cell (RBC) and brain ChE activity was determined following acute exposure to a dust aerosol of carbaryl. Immediately after exposure, animals were euthanized, and blood and brains were sampled. ChE activity was analyzed using a Hitachi 912 Serum Chemistry Analyzer. The assay method used was based on a modification of the Ellman reaction. The time to peak inhibition was determined in a time-course study with male rats exposed to 300 mg/m3. Both RBC and brain ChE was significantly and rapidly inhibited after 15 minutes of exposure (54 and 28%, respectively) with a plateau being reached following 1.5 hours of exposure. Subsequently, groups of 5 male and 5 female albino rats were exposed to concentrations of 240, 120, 60, 30, 10 and 0 mg/m3 for 3 hours to determine the No-Observed-Adverse-Effect-Level (NOAEL). Aerosol particle size during exposures ranged from 1.4–1.7 microns (MMAD). Mean RBC and brain ChE activity for males and females showed a dose-related decrease at exposure levels of 60, 30, 10 and 0 mg/m3, with a saturated response at levels of 240 and 120 mg/m3. At the lowest exposure level of 10 mg/m3 (0.01 mg/L), ChE activity was considered comparable to control based on less than approximately 10% inhibition and lack of any statistical difference. This exposure level is equivalent to 1.0 and 1.4 mg/kg body weight for males and females, respectively. Prior to the conduct of this study, the risk from inhalation exposure associated with residential use of a dust formulation was extrapolated using the oral toxicity NOAEL of 1.1 mg/kg/day. However the extrapolation from an oral route toxicity study to exposure from inhalation introduced uncertainty in the risk assessment. The results of this study demonstrated comparable toxicity between the inhalation and oral routes of exposure thus reducing the route specific uncertainty.

PS 846 DEVELOPMENT OF A SAFE DOSE FOR CHLORPYRIFOS: FOCUS ON HUMAN KINETIC VARIABILITY.

L. T. Haber, B. K. Gadagbui and M. L. Dourson. *Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH.*

Chlorpyrifos (CPF) is a widely used pesticide that inhibits cholinesterase (ChE). ChE inhibition by the CPF metabolite, CPF-oxon, is believed to be the most sensitive effect in all animal species evaluated and in humans from previous evaluations. Three human studies (i.e., Coulston et al., 1972; Kisciki et al., 1999; Nolan et al., 1984) form an adequate basis for determining the safe level, and the resulting point of departure is a NOAEL for RBC cholinesterase inhibition of 0.1 mg/kg-day in the Coulston et al. (1972) study. There is considerable variability in activity of paraoxonase 1 (PON1), the enzyme that metabolizes CPF-oxon, due to genetic polymorphisms and variability in gene expression. We considered the impact of this variability, together with other sources of variability, on the tissue dose of CPF-oxon, and thus on the kinetic component of the human variability uncertainty factor. Published (Timchalk et al. 2002) PBPK simulations have found that variability in PON1 in adults due to the Q192/R genetic polymorphism, coupled with variability in enzyme levels, had minimal impact on the dose of CPF-oxon at doses in the range of the current or any proposed RfD. Unpublished simulations submitted to EPA (Poet and Timchalk 2008) that took into account infant levels of PON1 and the metabolic status of pregnant women found <50% impact on an effect measure (BuChE inhibition) in these potentially sensitive populations at doses in the range of the RfD. The actual impact of low PON1 levels is likely to be lower than the estimates from these studies, since the PBPK model did not account for the recent finding that human serum albumin is also able to detoxify CPF-oxon and can compensate for low levels of PON1 (Sogorb et al. 2008). Based on these considerations, the default uncertainty factor of 3 for kinetic variability is more than adequate, but the data are not sufficient to use chemical-specific data for a data-derived extrapolation factor. A health-protective RfD can be derived from the NOAEL of 0.1 mg/kg-day and a factor of 10 for human variability.

PS 847 A RISK MANAGEMENT BASED APPROACH TO THE EVALUATION OF SYNERGY.

E. W. Carney and P. Price. *Toxicology & Environmental Research and Consulting, The Dow Chemical Company, Midland, MI.*

The potential for synergy between chemicals has been a concern for toxicologists assessing mixture toxicity for many decades. This poster presents a simple and flexible framework for determining the impact of specific findings of synergy on the management of risks posed by mixtures. The framework was developed by asking the question "What characteristics of synergistic effects are required to cause the current system for managing the chronic human non-cancer effects of mixtures to underestimate toxicity?" To answer this question the models of mixture toxicity that do not consider synergy (additive and independence models) are examined and the doses of mixture components permitted under each model are determined. This is performed in a two step process of first looking at the prediction of safe levels for test animals and then extrapolating to the predictions of the safe levels for sensitive humans. This approach demonstrates that both additive and independence models keep doses of components of mixtures to small fractions of their corresponding no effect levels in sensitive humans. The framework allows assessors to determine if a study showing synergy would change risk management decisions either directly (showing that effects would occur at doses permitted under additive or independence models) or indirectly (showing that synergy at higher doses is also likely to occur at the permitted doses). A graphical description of this framework was developed and applied to the Moser et al. (Toxicol Sci 92:235-45, 2006) finding of synergy. Using the framework, the permitted doses were shown to be 36 (independence model) and 78 (additive model) fold lower than the lowest tested dose by Moser et al. and that the observed synergy declined with dose. This framework enables one to clearly and easily distinguish between mixtures where synergistic effects are a concern from those where current risk management systems already afford ample protection.

PS 848 IN VITRO METABOLISM OF BISPHENOL A BY HUMAN AND RAT LIVER MICROSOMES.

S. Ye, L. L. Needham and A. M. Calafat. *Centers for disease control and prevention, Atlanta, GA.* Sponsor: B. Fowler.

Bisphenol A (BPA) has been widely used in manufacturing both polycarbonate plastics and epoxy resins. BPA is considered an endocrine disruptor, according to a series of in-vitro and in-vivo studies. The toxic effects of BPA in humans are unknown, but because of its widespread uses, the potential for human exposure is high. Therefore, understanding the metabolic fate of BPA is necessary for risk assessments. Results from animal studies demonstrate that BPA glucuronide conjugate is a major BPA metabolite found in urine and feces. Thus, BPA and its conjugate can be good biomarkers for assessing human exposure to BPA. Since free-form BPA is a pharmacologically active species, measuring the free form of this compound in biological fluids (e.g., blood, serum, and milk) would be particularly important for risk assessments. However, BPA may be present in numerous consumer and household products, and the potentially contaminated samples with BPA could pose a challenge for measuring free-form BPA. Therefore, looking for different BPA metabolites is scientifically interesting. We investigated the in-vitro metabolism of BPA using rat liver and human liver microsomes (BD GentestTM, Woburn, MA). After incubating BPA with the microsomal preparations, the BPA metabolites were first extracted by on-line solid phase extraction, and then separated and detected by high-performance liquid chromatography-tandem mass spectrometry. Based on their chromatographic behavior and mass spectral fragmentation patterns, we tentatively identified several BPA metabolites and oxidative products. One of the products is believed to be a hydroxylated BPA with a hydroxyl functional group on the ring (catechol BPA). We also compared the metabolism pathways and kinetics data of BPA with rat enzymes and human enzymes. Our findings suggest that in addition to BPA glucuronide, oxidized BPA metabolites may potentially be used as biomarkers to assess exposure to BPA.

PS 849 GUIDANCE FOR SELECTING CRITICAL STUDIES AND UTILIZING CHILD SAFETY FACTORS IN DEVELOPING CHILD SPECIFIC REFERENCE DOSES (CHRDS) FOR CALIFORNIA SCHOOL-SITE RISK ASSESSMENT.

D. Chan, S. A. Knadle, D. Qiao, J. Carlisle and D. Siegel. *IRAB, OEHHA, Cal/EPA, Sacramento, CA.*

California Health & Safety code 901(g) promulgated in 2000 a policy to protect school children from harmful exposure to environmental contaminants. The law directs the Office of Environmental Health Hazard Assessment (OEHHA) to identify chemical contaminants commonly found at school sites which are of concern because of child-specific physiological sensitivities, and to develop child-specific health guidance values for school-site risk assessment. Developing child-specific health standards in the form of chRDs is new and there is no national science policy to provide guidance. Therefore, OEHHA formulated the following guidance for chRD development: 1) Use the most sensitive species and developing organs as endpoints, 2) target perinatal and pubertal studies in organs during critical windows 3) also consider chemicals that interfere with specific cellular migration, differentiation, and proliferation pathways to produce functional deficits as adults, as well as producing pathological changes, 4) integrate information from EPA, FIFRA, and peer–reviewed studies to comprehend the mechanism disrupting a normal physiological process in young animals to determine the appropriate critical study for the chRD, and (5) if only adult studies are available, add child safety factors (cSF). Default cSF are expedient when numerous chemicals need child-protective values at once. Emphasizing mechanisms in children has allowed OEHHA to focus on pharmacodynamic (PD) and pharmacokinetic (PK) differences in the developing organs of children compared to adults on a case-by-case basis. Studies in young animals do not usually require cSFs because PK and PD are already incorporated. A cSF is only used if critical studies 1) employ adults, or 2) have a high LOAEL, and other studies in young animals with less robust data indicate a lower LOAEL for that chemical. This approach informs the concept of child safety factors with a scientific basis. OEHHA will present cases illustrating use of this guidance in our chRDs.

PS 850 HAZARD EVALUATION OF FLUOROTELOMER-BASED URETHANE POLYMERIC PRODUCTS.

S. E. Loveless[1], S. MacKenzie[1], C. Carpenter[1], T. Serex[1] and R. Buck[2]. [1]*DuPont Haskell Global Centers for Health and Environmental Sciences, Newark, DE and* [2]*DuPont Chemical Solutions Enterprise, Wilmington, DE.*

The objective of these studies was to evaluate the acute, genetic, and ecotoxicity of three fluorotelomer-based urethane polymeric products derived from short-chain raw materials (A, B, C). In addition, the subchronic, reproductive, and developmental toxicity in rats of the fluorotelomer-based urethane polymeric product (C) used as a stain and soil-resistance finish for textiles was also evaluated. All three products have low acute toxicity (oral LD50>5000 mg/kg; not classifiable for skin or eye irritation; not a skin sensitizer). At the highest achievable aerosol concentration of 1363 mg/m3, a single exposure to Product B resulted in no deaths. Products B and C were negative in the bacterial reverse mutation test and mouse lymphoma assay (Product C). Product C exhibited low concern for aquatic hazard in fish and green algae and moderate concern in Daphnia, whereas Product B exhibited low concern in Daphnia. In a 10-day biopersistence screen, there was very low uptake of Product C. Levels in the blood of male rats days were generally very low and only slightly above the estimated limit of quantification and tissue concentrations in liver and fat were marginally higher. Product C was administered neat by oral gavage at dosages of 0, 50, 250, or 1000 mg/kg/day (90-day subchronic toxicity and one-generation reproduction), and at the same dosages on gestation days 6-20 (developmental toxicity). The NOAEL for subchronic and reproductive toxicity was 1000 mg/kg/day, based on no test substance-related effects on in-life, neurobehavioral, ophthalmological, or anatomic pathology parameters, or on any reproductive parameter in P1 or F1 rats dosed up to 1000 mg/kg/day. In the developmental toxicity study, the NOAEL for both maternal and fetal toxicity was 1000 mg/kg/day, based on a lack of test substance-related effects on any maternal or fetal parameter. No fetal malformations were observed. Overall, these materials are considered to have low potential to produce human health effects.

PS 851 EVALUATION OF THE SUBCHRONIC TOXICITY OF A PURIFIED FLUOROTELOMER ALCOHOL MIXTURE.

C. Carpenter[1], T. Serex[1], R. Frame[1], R. Buck[2] and S. E. Loveless[1]. [1]*DuPont Haskell Global Centers for Health and Environmental Sciences, Newark, DE and* [2]*2DuPont Chemical Solutions Enterprise, Wilmington, DE.*

The objective of this study was to evaluate the subchronic toxicity of a purified fluorotelomer alcohol mixture in male and female rats. The commercial mixture was processed to remove trace levels of raw materials and perfluorinated carboxylic acid impurities. Test substance was administered by gavage at 0, 25, 100, or 250 mg/kg/day for approximately 90 days. Rats designated for recovery were held without dosing for an additional 1 or 3 months. The NOAEL for male rats was 100 mg/kg/day based on atrophy of the ameloblastic layer of the incisor teeth in males dosed at 250 mg/kg/day. The NOAEL for female rats was 25 mg/kg/day based on atrophy of the ameloblastic layer of the incisor teeth in females dosed at 100 and 250 mg/kg/day. This finding was reversible in males and females after a 3-month recovery period. Other adverse effects at 250 mg/kg/day were flattened teeth, teeth curved inwards, broken teeth, absent teeth, decreased body weight gain (males only), and decreased food efficiency (males only). The test substance was a moderate inducer of hepatic peroxisomal β-oxidation activity in males and females dosed at 100 and 250 mg/kg/day. No adverse effects were observed on ophthalmology, clinical pathology parameters, neurobehavioral parameters, organ weights, or gross pathology in any male or female dose group. Increased plasma fluoride was observed at the end of the dosing period in males and females dosed at 100 or 250 mg/kg/day. After a 1-month recovery, mean plasma fluoride in males and females dosed at 250 mg/kg/day remained elevated. After a 3-month recovery, mean plasma fluoride levels were similar to the respective control group levels. Increased excreted fluoride (urine fluoride) observed in males and females dosed at 25, 100, or 250 mg/kg/day is an expected finding consistent with exposure to and metabolism of a fluoride-containing test substance.

PS 852 IN VITRO EFFECTS OF A NOVEL NANOPARTICLE, ZIRCONIUM PHOSPHATE.

T. Liberati[1], E. Perkins[2], R. Gairani[1] and L. Vermeulen[2, 3]. [1]*Internal Medicine, SIU School of Medicine, Springfield, IL,* [2]*Chemistry, SIU, Carbondale, IL and* [3]*West Chester University, West Chester, PA.*

Synthetic zirconium phosphate ($Zr(O_3POH)_2$; ZiP) particles have a layered inorganic framework with high surface area and are candidate carriers for drug delivery. ZiP particles are prepared by refluxing a zirconium salt and phosphoric acid in the presence of HF at a ratio of 1:4:2 for 6 days. Because ZiP particles are 60 nm in length in one dimension, they can be classed as nanoparticles. X-ray diffraction analysis showed formation of a crystalline α-ZrP phase. The structure of ZiP resembles that of naturally occurring nontoxic clays, however, its toxicity profile in a biological system had not been evaluated. We used human cell lines (A549, lung epithelium; AGS, gastric epithelium) to evaluate the toxicity of ZiP *in vitro*. Cells were cultured to a subconfluent state and were then exposed for 24 or 48 h to ZiP suspensions ranging from 0.5 to 100 μg/ml (0.13 to 26.3 $\mu g/cm^2$). Control cells were untreated or treated with Aeroxide® TiO_2 P25 (Degussa) or Min-U-Sil 5 (US Silica). Cytotoxicity was evaluated using MTT assay and LDH release. In A549 and AGS cells, ZiP particles caused a greater dose-dependent decrease in mitochondrial activity than did TiO_2 or silica. Like nanosized TiO_2, ZiP particles showed marked aggregation that progressed over time in culture at pH 7.4. Scanning electron microscopy of ZiP particles that were suspended in medium and then dried confirmed this aggregation. LDH release occurred in a dose-dependent manner in A549 and AGS cells but was variable across trials, probably because particle aggregation reduced the effective dose. Low concentrations of ZiP particles reduced apoptosis in AGS cell cultures as evidenced by reduced levels of caspase 3 and 7 but did not affect A549 cells. At high ZiP concentrations, caspase levels were comparable to those of control cells. Thus, apoptosis may not underlie the observed reduction in cell proliferation. In general, additional *in vitro* studies and treatment of the ZiP particles to decrease aggregation at physiologic pH is essential prior to their *in vivo* use.

PS 853 UNDERSTANDING THE SIZE AND SHAPE DEPENDENCE GENO, CYTO AND PHOTOTOXIC EFFECTS OF FRESHLY PREPARED SILVER NANOMATERIAL.

W. Lu, S. Wang, D. Senapati, O. Tovmachenko, H. Yu and P. Ray. *Jackson State University, Jackson State University, MS.* Sponsor: P. Anita.

Silver nanomaterials are rapidly becoming a part of our daily life in the form of cosmetics, food packaging, bandage, shocks, clothing and laundry detergents and others. As the nanotechnology field continues to develop, assessing nanoparticle toxicity is very important for advancing nanoparticles for day to day life application. Here we report geno and cytotoxicity of silver nanomaterial of different size and shape on HaCaT keratinocytes, cell line using Comet and MTT assay. We also compare the results with the toxicity of AgNO3, which is the starting material for silver nanomaterial synthesis and also non-nano counterparts. Since exposure of UV light on intake of silver products in skin cell may produce argyria, we also reported the photo-toxicity of silver nanomaterial of different size and shape in presence of UVA light for 30 minutes exposure and compare the results with non-nano counterpart. Our data suggest that spherical silver nanoparticle and silver nanoprism with different sizes are not geno or cyto toxic even after 48 hours incu-

bation with 100 uM concentration and also not phototoxic even after 30 minutes of UVA light exposure. On the other hand our data sows silver nitrate is highly toxic even at the concentration of 10 uM. We have also shown that silver nanorods are highly toxic due to the presence of CTAB as coating material, where as PSS coated nanorod is not toxic.

PS 854 INCREASED INTRACELLULAR CALCIUM CONCENTRATIONS IN HUMAN BRONCHIAL EPITHELIAL CELLS EXPOSED TO ULTRAFINE ZINC OXIDE PARTICLES.

C. Huang[1], R. S. Aronstam[1, 3], D. Chen[2] and Y. Huang[1]. *[1]Biological Sciences, Missouri University of Science and Technology, Rolla, MO, [2]Energy, Environmental and Chemical Engineering, Washington University in St. Louis, St. Louis, MO and [3]Biological Sciences and cDNA Resource Center, Missouri University of Sciences and Technology, Rolla, MO.*

Zinc oxide nanoparticles caused a dose- and time-dependent cytotoxicity in a human bronchial epithelial cell line, BEAS-2B. This toxicity was observed at concentrations as low as 5-6 μg/mL; there was a steep decline in cell numbers at ZnO concentrations between 6-10 μg/mL. Exposure to ZnO nanoparticles increased intracellular calcium levels in a dose- and time-dependent manner. Treatment with an antioxidant N–acetylcysteine (NAC) prevented cell loss and diminished the increase in intracellular calcium concentration, findings consistent with an oxidative stress-mediated cytotoxicity. Calcium concentrations were elevated by as much as four fold compared to control cells, and the elevation went down when the cells were subsequently treated with NAC. Nifedipine, an L-type voltage-gated calcium channel blocker, attenuated the intracellular calcium elevation caused by ZnO toxicity, suggesting that the elevation of intracellular calcium concentration depended on an influx of extracellular calcium. Thus, these findings indicate that exposure of BEAS-2B cells to 20 nm ZnO particles causes a dose- and time- dependent cytotoxicity reflected in cell viability reduction, elevated oxidative stress and increased calcium content that is dependent on the influx of extracellular calcium.

PS 855 ZINC OXIDE NANOPARTICLES: IT'S THE CONTACT THAT KILLS.

P. J. Moos, K. Chung, D. Woessner, M. Honeggar and J. M. Veranth.
Pharmacology & Toxicology, University of Utah, Salt Lake City, UT.

Previously, we evaluated the toxicity and transcriptional responses to 6 manufactured nanoparticles in colon cell lines. These manufactured nanoparticles are used in consumer products, and therefore, there could be considerable occupational exposure. NanoZnO displayed the most toxicity and demonstrated the most pronounced transcriptional response. This transcriptional response suggested exposure to elemental Zn, and therefore, perhaps the toxicity was Zn toxicity. Therefore, we sought to determine if the nanoZnO toxicity was due to the dissolution of ZnO to elemental Zn and determine the mechanism of the cell death upon exposure to the nanoZnO. In addition, we utilized two size ranges of ZnO particulate matter to evaluate the effects of size/surface area. First, we set out to determine; 1) if cell and particulate matter contact was required for ZnO toxicity, and 2) if ZnO dissolution to free Zn was dependent on the cells. We used a set of three experimental conditions; 1) the ZnO was separated from cellular contact using a dialysis device with a 10 kD cutoff to ensure no ZnO particulate matter could interact directly with cells, 2) transwells with 0.4 micron pores that would allow greater interactions with cellular products but still separate the cells and the particulate matter, and 3) ZnO particulate matter in direct contact with the cells. We measured the Zn concentrations in the media by ICP spectrometry and cell viability by PI exclusion. We found that the ZnO toxicity was only observed when the particles were in contact with the cells irrespective of Zn levels in the media, suggesting that contact and potentially uptake is required for cellular toxicity. We have found that ZnO induces apoptosis as measured by Annexin V cytometric analysis. We have found that ZnO disrupts mitochondrial function and induces superoxide production in the mitochondria. In addition, all of the toxic effects are dependent on particle size as the larger ZnO particulate matter always demonstrated reduced toxicity compared to the smaller ZnO nanoparticles.

PS 856 MACROPHAGE TARGETED MULTIVALENT MANNOSYLATED PEPTIDE BACKBONE PEG NANOCARRIERS: UPTAKE INTO J774-E CELLS.

P. Chen, S. Pooyan, S. Gunaseelan, X. Zhang, S. Stein and P. Sinko.
Pharmaceutical Science, Rutgers University, Piscataway, NJ.

In order to evaluate the uptake into macrophage-like J774-E cells, multivalent peptidic nanocarriers consisting of PEG and multiple copies of a targeting agent, mannose, were synthesized. These novel nanocarriers were prepared by coupling mannose and polyethylene glycol (PEG) to a peptide backbone. The peptidic backbone synthesized for obtaining the nanocarrier was Fluorescein-Lys-β-Ala-β-Ala-Lys-β-Ala-Cys-OH. The Fluorescein tag was attached to the N-terminus of the Lys in solid phase. The two ε-NH2 of Lysine were used for stoichiometric attachment of D–Mannopyranosylphenyl isothiocyanate. The β-alanine moieties were introduced to reduce stearic hinderance for mannosylated reaction. The mannosylation reaction was performed in sodium bicarbonate (1M, pH= 9): DMSO/5:1 for 24 hours. Results showed the complete mannosylation where 2-copy mannose was successfully attached. The thiol moiety of cysteine was used to link to different sizes m-PEGX-Maleimide (X= 5, 12, 20 kDa).The PEGylation reactions were performed in phosphate buffer 100 mM, pH=7.4: DMSO (1:1) for 24 hours. Both the mannosylation and PEGylation of the peptidic core were confirmed by MALDI-TOF/MS. The uptake studies of these labeled nanocarriers in fully differentiated macrophage J774-E cells were qualitatively higher than uptake of the control nanocarrier without mannose moieties as shown by fluorescence microscopy. These nanocarriers have the potential to be biologically inactive except when reaching and interacting with macrophage mannose receptor.

PS 857 VERSATILE AND BIODEGRADABLE PEGYLATED PEPTIDE-BASED NOVEL NANOCARRIERS.

S. Pooyan, S. Gunaseelan, P. Chen, M. Samizadeh, S. Stein and P. Sinko.
Rutgers University, Piscataway, NJ. Sponsor: D. Laskin.

Novel PEGylated peptide-based nanocarriers that are both versatile and biodegradable have been developed. Their structure utilizes a central peptidic core that provides for attachment of PEGs and drugs in a stoichiometric manner. As an example, we have used as the peptidic core: CH3CO-(Lys-βAla-βAla)X-Cys-CONH2 (X= 2, 4). The copy number of lysine provides for varying the PEG content in the nanocarriers. The β-alanine moieties are used to reduce stearic hindrance for the PEGylation reaction. The β-alanines may also improve protease resistance. The thiol moiety of cysteine is used to make biodegradable disulfide linkages to another PEGylated peptidic core (to form a homodimer) or to a different peptidic core carrying ligands or drugs (to form a hetrodimeric nanocarrier). In this study we used Texas red as a form of surrogate drug in the hetrodimeric nanocarrier. The PEGylation reaction was optimized using 3 molar excess of NHS-PEG5000-Fluorescein in 100 mM phosphate buffer pH 7.0 with 70% DMSO (v:v). Homodimerization and heterodimerization were performed by reacting thiopyridine protected Fluorescein-PEGylated 2-arm peptidic core and thiopyridine protected Texas Red-4-arm peptidic core respectively with unprotected Fluorescein-PEGylated 2-arm peptidic core in 100 mM phosphate buffer pH 7.0. Optimum conditions for PEGylation of peptidic core, purifications, and dimerization have been investigated. The biodegradability of doubly labeled heterodimeric nanocarrier in a reducing environment (3 mM glutathione, representing intracellular levels) demonstrated complete release to monomer components in seven minutes. However, the same nanocarrier in 10 μM reduced glutathione (representing blood levels) demonstrated a much lower rate of biodegradation. The current results demonstrate the potential of maintaining adequate body-blood retention until the nanocarrier gets to the active site where it is rapidly converted to a form that can be readily eliminated from the body.

PS 858 NOVEL EX VIVO OVARIAN FOLLICLE ASSAY TO TEST NANOMATERIALS FOR THEIR POTENTIAL TO INTERFERE WITH FISH REPRODUCTION.

R. Weil[1, 2], K. Kroll[2], S. Brown[3], C. Martyniuk[2], D. Barber[2] and N. Denslow[2].
[1]Pharmacology and Therapeutics, University of Florida, Gainesville, FL, [2]Physiological Sciences, University of Florida, Gainesville, FL and [3]Particle Engineering Research Group, University of Florida, Gainesville, FL.

Nanomaterials are particles with one side less then 100nm, and are widely used in electronics, paints, cosmetics as well as the biomedical and pharmaceutical industries. Due to their widespread applications, nanomaterials will inevitably be released in the aquatic systems, and to date, toxicity testing for nanomaterials in fish has been very limited. In a physiological system, plasma proteins adhere to foreign particles such as nanoparticles, and studies have shown that the organism's response to foreign materials is highly dependent on the proteins coating the particles. The goal of this study was to determine whether female plasma protein adsorption to the surface of nanoparticles facilitates their uptake into developing eggs. Rhodamine- and rubpy- doped silica particles were characterized for zeta potential (-40 mV and -25 mV, respectively, in pH 5.8 water with 1 mM NaCl electrolyte) and were used to treat fathead minnow ovarian tissues ex-vivo. Fragments (15-30 mg) of ovarian tissues were incubated in serum-free L15 growth medium for 24h in the presence and absence of the nanomaterials that were either pre-incubated with plasma containing 26 mg/ml vitellogenin or with just growth media. Rubpy-doped nanoparticles, coated with plasma, entered later stage vitellogenic oocytes while the rhodamine-doped particles did not. The rubpy particles on their own did not enter the developing oocytes. Moreover, pre-vitellogenic oocytes did not appear to have taken up

the rubpy-doped particles, indicating that plasma Vtg may have adhered to the particles and facilitated their uptake into the developing eggs via vitellogenin receptor mediated endocytosis. The rubpy-doped particles appeared to be concentrated in yolk granules, as determined by confocal microscopy. This novel assay can be used to screen nanomaterials for their potential to interfere with egg development and embryogenesis.

PS 859 SERUM PROTEIN COATED GOLD NANOPARTICLES IN THE PERFUSED HUMAN TERM PLACENTA.

A. Rinderknecht, G. Oberdörster, K. de Mesy Bentley, R. Gelein, A. Elder, K. Brewer and R. K. Miller. *University of Rochester, Rochester, NY.*

Nanoparticles (NPs) have become incorporated in our daily lives from environmental to medicinal exposures. Unfortunately, pregnant women have not been a focus of health risk assessment. NPs that enter the systemic circulation become coated with serum proteins, e.g., human serum albumin (HSA) and immunoglobulin G (IgG). During pregnancy, the placenta plays a critical role as a conduit or filter for xenobiotics. HYPOTHESIS: Gold (Au) NPs pre-coated with HSA or IgG (F105) will interact with the human placenta in a manner consistent with the catabolism of HSA or the receptor-mediated placental transfer of IgG. HSA or IgG proteins were adsorbed onto the surface of 5 nm citrated Au NPs. Au NPs (3ug Au/ml; hydrodynamic diameter for HSA- or IgG-Au NPs = 8.4 or 7.3 nm, respectively) were transfused at 2,6 & 10 hrs into the maternal circuit of the dually perfused human term placental lobule in vitro. Perfusions were performed for 14 hrs with an initial control period of 2 hrs followed by maternal and fetal transfusions. HSA and IgG NP exposures did not significantly alter the blood gases, net fetal oxygen transfer, flow rates and fetal perfusion pressure compared with control values or control perfusions. Human chorionic gonadotropin measured in maternal and fetal perfusates matched controls. Circulating Au NPs significantly decreased in the maternal circuit depending upon the protein coating; IgG-Au NPs decrease 9.83±0.65% (n=2), while HSA-Au NPs decreased 1.92±1.1% (n=3). We conclude that (i) perfusion of the placenta with nanogold particles did not alter normal placental function, and (ii) protein coatings of the NPs do influence their distribution in the perfused placenta. (Supported in part by NIEHS ES07026; Eastman Kodak)

PS 860 NANOPARTICLE SIZE AND COMPOSITION AFFECT ADSORPTION OF HUMAN PLASMA PROTEINS.

D. S. Barber[1], S. Stevens[3], S. Wasdo[1], A. Feswick[1], P. Carpinone[2], N. Denslow[1], K. Powers[2] and S. M. Roberts[1]. *[1]Center for Environmental and Human Toxicology, University of Florida, Gainesville, FL, [2]Particle Research Center, University of Florida, Gainesville, FL and [3]University of South Florida, Tampa, FL.*

On contact with biological fluids, nanomaterials will adsorb proteins that modify their surface and play an important role in cellular recognition and response. Developing an understanding of the processes that affect binding of specific proteins and the relationship of protein binding and response will improve our ability to predict biocompatibility of absorbed nanomaterials. To investigate these questions, label-free proteomic techniques were used to identify and quantify proteins bound to 3.5, 20, and 40 nm gold particles as well as DeGussa P-25 titania particles after incubation in human plasma. Results demonstrate dramatic differences in the human plasma proteins that bind to gold and titania nanoparticles. F2 prothrombin, complement factor 1 and 4, and kininogen 1 were highly enriched on titania nanoparticles and were nearly absent on gold particles. Albumin, serotransferrin and alpha-2 macroglobulin were much more abundant on gold particles. Comparing binding of proteins to various sizes of gold particles revealed 32 proteins for which particle size statistically affected binding. Several proteins exhibited increased adsorption to smaller particles, including fibrinogen, serpinG1 and a 104kDa protein (IPI00790993). Other proteins exhibited decreased binding to smaller particles, including apolipoproteinB100, paraoxonase, complement C9, and clusterin. These results clearly demonstrate that nanoparticle size and composition affect their protein corona and are likely to impact biological response. These studies were supported by funds from the Center for Nano-Bio Sensors at the University of Florida.

PS 861 *IN VITRO* HEMOLYSIS TESTING OF SILVER NANOPARTICLES IN HUMAN BLOOD.

J. Choi[1, 2, 3], V. Reipa[3], V. M. Hitchins[1], P. L. Goering[1] and R. A. Malinauskas[1]. *[1]Center for Devices and Radiological Health, U.S. FDA, Silver Spring, MD, [2]Department of Chemical and Biomolecular Engineering, Univ of Maryland, College Park, MD and [3]Biochemical Science Division NIST, Gaithersburg, MD.*

Materials used in blood-contacting medical devices must be evaluated for their potential to damage red blood cells since released hemoglobin may induce toxic effects to the kidneys and other organs. Due to its antimicrobial efficacy, silver is increasingly being used in these medical devices. The objective of this study was to evaluate the hemolytic properties of silver nanoparticles using procedures outlined in the new ASTM standard: E2524-08 (Standard Test Method for Analysis of Hemolytic Properties of Nanoparticles), and to relate hemolysis levels to particle properties. Suspensions of three different sizes of silver particles (nanoparticles: ~30 and 90 nm diam., microparticles: ~1 μm diam.) were prepared in water. Each particle solution was characterized using transmission electron microscopy, dynamic light scattering, Raman and X-ray energy dispersive spectroscopy, and zeta potential measurement. Different mass concentrations of each silver particle suspension were added to heparinized human blood diluted in phosphate buffered saline (PBS) and incubated for 3.5 hours at 37 deg C. Silver ion concentration was measured with an ion-selective electrode on particles similarly incubated in PBS. Silver nanoparticles (diam. <100 nm) were significantly more hemolytic compared to micron-sized particles regardless of surface chemical composition. A concentration-dependent effect on hemolysis was observed with substantive hemolysis (>10 %) occurring at the highest nanoparticle concentrations (> 220 μg/ml). Silver ion release in PBS particle solutions was 20–100 times greater for the nanoparticles compared to the microparticles. These data suggest that the increased surface area and release of silver ions from silver nanoparticles may contribute to hemolysis. Thus, blood-contacting medical devices that use silver nanoparticles need to be carefully monitored for their hemolytic potential.

PS 862 NOVEL MOLECULAR PATHWAYS INDUCED IN FUNCTIONALIZED FULLERENE EXPOSED HUMAN EPIDERMAL KERATINOCYTES (HEK).

J. Gao and R. Iyer. *Bioscience Division, Los Alamos National Laboratory, Los Alamos, NM.*

Engineered nanomaterials have been extensively used for diagnostic, therapy and drug delivery based on their unique physicochemical properties. Since native C60 is hydrophobic, many hydrophilic C60 fullerene derivatives have been synthesized to facilitate clinical applications. However, the interaction of fullerenes with biological systems is not completely understood. In the present study, we investigated the bioimpact of three chemically modified fullerene derivatives, hexa carboxyl fullerene adduct (Hexa-C60), tris carboxyl adduct fullerene adduct (Tris-C60) and gamma (γ)-cyclodextrin caged C60 (CD-C60). Key biological responses, such as cellular viability, ROS generation, proliferation and cell cycle responses were evaluated in HEK cells to simulate the primary route of occupational dermal exposure. Our data indicate that all three fullerene derivatives can protect against induced-apoptosis, and that tris-C60 can reduce necrotic cell death in HEK cells. The reduced proliferative capacity, ROS generation and cytokine production were observed in tris-C60 treated cells as well. Moreover, cell morphology and growth characteristics were significantly altered only in the tris-C60 treated cells. Further evaluation of these responses using flow cytometric analysis demonstrated that tris-C60 induced cell cycle arrest at G1 phase. This inhibition of cell cycle progression was not observed in either CD-C60 or hexa-C60 treated cells. To understand the molecular mechanisms of this response we examined the expression of genes involved in cell cycle progression. Interestingly, a significant decrease in the expression levels of HERC5 and GADD45 was noted in the tris-C60 treated cells. GADD45 is a growth arrest and DNA damage responsive gene whereas HERC5 is an ubiquitin ligase of the HERC family. Abrogation of HERC5 has been shown to inhibit the conjugation of ISG15 to its target genes. ISG15 is implicated to be involved in innate immune responses to viral and bacterial infections. Our studies suggest a unique molecular and cellular response to derivatized fullerenes.

PS 863 IN VITRO METHODS TO PREDICT IMMUNE-MEDIATED TOXICITIES OF DEXTRAN-BASED NANOMATERIAL PRECURSORS IN RATS.

S. Casinghino[1], L. Gauthier[1], D. McClintock[2], E. Boldenow[2], C. Nauman[2], G. B. Freeman[1], M. L. Mirsky[1], R. M. Shanker[3], C. J. Somps[1] and T. T. Kawabata[1]. *[1]Drug Safety R&D, Pfizer Inc., Groton, CT, [2]Bend Research Inc., Bend, OR and [3]Pharmaceutical Sciences, Pfizer Inc., Groton, CT.*

While nanomaterials hold great promise as drug delivery platforms, biological consequences resulting from the interaction of nanomaterials with the immune system have not been fully elucidated. Initial *in vivo* toxicity studies with hydrophobic derivatives of dextrans of different molecular weights were conducted in Sprague-Dawley rats. Intravenous injections for seven consecutive days resulted in dose-related toxicity with 5000 MW and 10000 MW dextran derivatives. Toxicities ranged from an increase in the number of circulating neutrophils and lymphocytes, to death after 3 days in the highest dose group of the 5000 MW derivative. Renal glomerular thrombosis was observed in the high dose group and disseminated intravascular coagulation was suspected. We hypothesized that complement and macrophage activation contributed to these observed effects, and our goal was to

develop *in vitro* screening methods to predict immune-mediated toxicities. Human plasma was incubated with PBS, dextran controls or dextran derivatives, and complement fragments C3a and C5b-9 were quantitated by ELISA. Results showed that both dextran derivatives significantly increased C3a and C5b-9 levels when compared to PBS and dextran controls. Activation of rat plasma was also investigated, however, ELISAs to measure C5b-9 were not adequately sensitive to low to moderate increases in C5b-9 generation. To address macrophage activation, the dextran formulations were incubated with rat (NR8383) and human (THP-1) cell lines, and TNFα levels were quantitated by ELISA. TNFα generation in dextran derivative-exposed cells was significantly increased in both cell lines when compared to controls. In conclusion, our screening methods may prove useful for selection of appropriate components for nanoparticle drug delivery systems.

PS 864 UPTAKE AND TOXICITY OF TRI-N-OCTYLPHOSPHINE OXIDE, POLY(MALEIC ANHYDRIDE-ALT-1-TETRADECENE COATED CDSE QUANTUM DOTS IN THP-1 HUMAN MACROPHAGES.

D. Botta[1], C. C. White[1], H. Wilkerson[1], X. Hu[2], X. Gao[2] and T. J. Kavanagh[1]. *[1]Environmental and Occupational Health Sciences, University of Washington, Seattle, WA and [2]Bioengineering, University of Washington, Seattle, WA.*

Nanotechnology is one of the largest growing industries today. Hundreds of different engineered nanoparticles are being developed and used in such things as LED displays, cosmetics and biomedical applications. Presently there are no regulations in place that specifically regulates manufacturing or use of products containing nanoparticles. Quantum dots (QDs) are semiconductor nanoparticles, usually 5 - 10 nm in size and of various shapes. Their fluorescent properties make them ideal for potential use in biomedical imaging, and targeting organs for delivery of therapies. Little is known about the toxicity of these particles and their impact on human health. We used a human monocytic cell line (THP1) differentiated to macrophages to study the uptake and toxicity of trioctylphosphine oxide, poly(maleic anhydride-alt-1-tetradecene (TOPO-PMAT) coated CdSe QD particles in vitro. Uptake of these QDs by THP1 cells, as measured by fluorescence microscopy and flow cytometry, was time and dose dependent. QDs were moderately toxic, causing decreases in mitochondrial dehydrogenase activity (MTT assay) of 18% and 31% with 20 nM and 40 nM QDs, respectively after 24 hrs exposure. Inflammatory cytokine analyses revealed an increase in secretion of IL-1β, IL-10 and MIP-1α proteins 6 hrs after exposure to 40 nM QDs, but no change in TNFα or MCP1. IL-8 expression was suppressed at 24 hrs. These data indicate that TOPO-PMAT modified QDs, although not likely to be acutely toxic, could nonetheless incite an inflammatory response in vivo. This work was supported by NIEHS grants R01ES016189 and P30ES07033.

PS 865 OVEREXPRESSION OF MICROSOMAL GLUTATHIONE TRANSFERASE 1 PROTECTS AGAINST CYTOTOXIC EFFECTS OF SILICA NANOPARTICLES.

J. Shi[1], N. Kupferschmidt[4], K. Johansson[1], V. Gogvadze[1], K. Hultenby[2], R. Morgenstern[1], V. Kagan[3], A. Garcia-Bennett[4] and B. Fadeel[1]. *[1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Department of Laboratory Medicine, Karolinska University Hospital, Stockholm, Sweden, [3]Department of Occupational and Environmental Health, University of Pittsburgh, Pittsburgh, PA and [4]Department of Engineering Sciences, University of Uppsala, Uppsala, Sweden.*

Silica-based mesoporous materials offer great promises in biomedical applications, such as vehicles for drug delivery, in transfection devices, and so on. However, there is increasing concern about the putative adverse effects of nanomaterials on biological systems. The induction of oxidative stress has been postulated as a common paradigm for cytotoxicity of engineered nanomaterials. Moreover, our recent studies have shown that microsomal glutathione transferase 1 (MGST1) may protect cells against a variety of cytostatic drugs and pro-oxidant stimuli. Here, we hypothesized that MGST1 can also protect against oxidative stress caused by engineered nanomaterials. To this end, a comparison was made between commercial Ludox® colloidal silica and de novo synthesized mesoporous silica particles. Structural and textural characterization of the particles was performed using powder X-ray diffraction and transmission and scanning electron microscopy, and size distribution and surface charge was determined by dynamic light scattering and zeta potential measurements, respectively. No obvious cytotoxic effects were observed for mesoporous silica particles in the nano- and micron-size range using the human breast cancer cell line, MCF-7 as a model system. Ludox® silica particles, on the other hand, induced dose- and time- dependent toxicity, as assessed by Trypan Blue exclusion and the MTT assay. Importantly, the toxic effect of colloidal silica particles was reversed by overexpression of MGST1. The protective role of MGST1 was further examined by detection of oxidative DNA damage. Overall, our studies contribute to the understanding of the toxicity of nanoparticles, and point to potential anti-oxidant strategies to overcome such toxicity.

PS 866 ASSESSMENT OF QUANTUM DOT (QD) UPTAKE AND TOXICITY IN SVEC4-10 MURINE ENDOTHELIAL CELLS.

D. Cox[1], C. C. White[1], X. Hu[2], X. Gao[2] and T. J. Kavanagh[1]. *[1]Center for Ecogenetic and and Environmental Health, Environmental and Occupational Health Sciences, University of Washington, Seattle, WA and [2]Department of Bioengineering, University of Washington, Seattle, WA.*

Semiconductor quantum dots have emerged as a new class of fluorescent nanoparticles. Control over the physical and chemical properties during the production of QD's has made them a popular choice for use in optoelectronics, photovoltaics, and probes in biomedical imaging. With an increase in QD production and availability, questions regarding QD toxicity have arisen as a major concern. A growing base of literature has emerged identifying important parameters for QD persistence and toxicity in biological systems; specifically that size and unique chemical structure dictates QD toxicity. The goal of this research was to assess the in vitro toxicity of amphiphilic polymer stabilized QD (QD-TOPO-PMAT) toward murine endothelial SVEC4-10 cells. QD uptake was measured at 6 and 24h using both flow cytometry (FACS) and fluorescent microscopy showing a time and dose-dependent increase. Alterations in cell viability (MTT) were measured yielding no effect of up to 200 nM QD for 24h of exposure. Subsequent analysis using FACS showed no signs of necrosis or apoptosis using 7-AAD and Annexin V probes. Cell glutathione (GSH) levels following exposure to QD at 2.5 and 20 nM for 24h were measured using either monochlorobimane (MCB; conjugated to GSH by glutathione-S-transferase (GST) by FACS, or biochemical assay. Interestingly, neither NAD(P)H (by FACS) nor GSH levels (biochemical assay) showed any differences over 24h suggesting that GST activity may be down-regulated or compromised following QD exposure. The preliminary results of this study suggest that polymer stabilized QD are readily taken up and have no adverse affect on viability in SVEC4-10 endothelial cells but may compromise GST function. This work was supported by NIEHS Grant R01ES016189, T32ES07032 and P30ES07033.

PS 867 SHAPE MATTERS: DIFFERENTIAL CYTOTOXICITY OBSERVED IN GOLD NANOSPHERES AND NANORODS.

N. M. Schaeublin[1], L. K. Braydich-Stolle[1], R. I. MacCuspie[2], K. W. Park[2], R. A. Vaia[2] and S. M. Hussain[1]. *[1]711 HPW/ RHPB, AFRL, Wright-Patterson AFB, OH and [2]AFRL/RXBN, AFRL, Wright-Patterson AFB, OH.*

Gold nanoparticles are being used in sensing, imaging, and treatment of certain cancers and as novel gene and drug delivery agents due to their unique physical and chemical properties. Despite being easily accessible and found in a wide range of consumer products, the cytotoxicity of these nanomaterials has not been thoroughly examined. Many of the unique properties that must be evaluated prior to making claims of biocompatibility are size, surface area, morphology, shape, surface charge, crystal structure, etc. The majority of nanotoxicity studies have focused on size and very few have assessed the role that shape plays in determining nanoparticle toxicity. This study evaluated the cytotoxicity of gold nanoparticles with different shapes. Gold nanorods 51 nm in length with varying diameters were compared to gold nanospheres 12 nm in size and toxicity was assessed in the human keratinocyte (HaCaT) cell line. The cells were treated with varying concentrations (0-100 μg/ml) of the gold nanomaterials for 24 h and then biocompatibility was tested using cell viability and membrane integrity as endpoints. The MTS assay which measured mitochondrial function and directly relates to cell proliferation demonstrated that the 12 nm nanospheres did not disrupt cell proliferation while the nanorods regardless of size reduced proliferation. A similar trend was observed with the LDH membrane leakage assay which measures membrane integrity. In addition, the nanorods were toxic at very low doses and did not display much of a dose-dependent effect. Four out of the six nanorods were toxic at the lowest dose of 5 μg/ml with the other two displaying toxicity as early as 10 and 25 μg/ml respectively. Based on the initial observations of this study, shape seems to play a role in contributing to nanomaterial toxicity.

PS 868 OXIDATIVE STRESS-RELATED TOXICITY OF SILICON DIOXIDE, CERIUM OXIDE AND SILVER NANOPARTICLES IN HUMAN CELL LINES.

J. Choi and H. Eom. *Environmental Engineering, University of Seoul, Seoul, Korea, South.* Sponsor: D. Ryu.

In this study, we investigated the potential harmful effect of the exposure to silicon dioxide (SiO2) and cerium oxide (CeO2) and silver nanoparticles through in vitro toxicity assay using human cells, with a focus on the involvement of oxidative stress

as the toxic mechanism. Nanoparticle-induced oxidative stress was assessed by examining formation of reactive oxygen species (ROS), apoptosis, and the induction of antioxidant enzymes, such as superoxide dismutase (SOD) and heme oxygenase-1 (HO-1). Subsequently, to understand the molecular mechanism of nanoparticle-induced oxidative stress, the involvement of oxidative stress-responding transcription factors, such as, nuclear factor-kappaB (NF-κB) and nuclear factor -E2-related factor-2 (Nrf-2), and mitogen-activated protein (MAP) kinase signal transduction pathway was studied. Taking the overall results into account, nanoparticles exert their toxicity through oxidative stress as they cause a significant increase in cellular H2O2 concentrations. However, SiO2 nanoparticles lead a moderate induction of HO-1 via the Nrf-2- extracellular signal-regulating kinase (ERK) MAP kinase pathway, whereas exposure to CeO2 nanoparticles leads to a strong induction of HO-1 via the Nrf-2-p38 MAP kinase pathway. Further studies on the mechanism by which nanoparticles induce the Nrf2- MAP kinase pathway are warranted to better understand the nanoparticle-induced oxidative stress, as are studies with dose-response and time-course studies. The characterizations of nanoparticle in test media (i.e. aggregated- or single forms, intensity of uptake into the cells) and their influence on cytotoxicity need to be investigated. Acknowledgment: This work was accomplished through the supports of the Ministry of Environment as "The Eco-technopia 21 project"

PS 869 IMMUNE SUPPRESSION IN MRSA- INFECTED HUMAN ALVEOLAR CO-CULTURES TREATED WITH ALUMINUM NANOPARTICLES.

L. K. Braydich-Stolle[1], J. Speshock[1], M. Smith[2], C. Bunker[2], D. R. Mattie[1] and S. M. Hussain[1]. *[1]711 HPW; RHPB, Air Force Research Labs, Wright Patterson, OH and [2]AFRL/RZPF, AFRL, Wright-Patterson AFB, OH.*

The goal of this study was to evaluate the biological response following exposure to aluminum nanoparticles (Al NP). Based on their uses in jet fuels and munitions, the most likely scenario for exposure is inhalation. Since nanoparticles have been shown to be capable of penetrating deep into the alveolar regions of the lung, we cultured human alveolar macrophages (U937) with human type I pneumocytes (A549) and then exposed them to Al NPs (0-500 μg/ml) dispersed in an artificial lung surfactant to create an *in vitro* model which simulated the lung microenvironment. Three types of Al NPs were evaluated and they were aluminum (Al), aluminum oxide (Al_2O_3) and aluminum oleic acid (Al-OA). Following a 24 h incubation, cell viability was assessed using MTS, to evaluate mitochondrial function, and Biovision's Live Cell/Dead Cell kit. This data illustrated that there was mild toxicity at higher doses and that the cells affected by the NPs were the macrophages. Since the immune cells in the lung protect the epithelial cells, the co-cultures were exposed to a benign concentration of Al NPs and then infected with the pathogen MRSA. Phagocytosis assays demonstrated the Al and Al-OA impaired phagocytic function. Furthermore, NFκB and cytokine PCR arrays demonstrated that all three types of Al NPs altered the activation of the normal immune response. This change was further confirmed by ELISA assays which evaluated the secretion of IL-6, IL-8, IL-10, IL-1β, and TNFα. In all cases, the presence of all types of Al NPs repressed the co-cultures' ability to secrete cytokines.

PS 870 COMPARATIVE *IN VITRO* STUDIES ON THE PROINFLAMMATORY EFFECT OF CARBON BLACK PARTICLES ON MACROPHAGES AND DENDRITIC CELLS.

M. Steenhof, M. Brouwer and R. Pieters. *Toxicology, Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Utrecht, Netherlands.*

Previously, we have shown that nano size (14 and 40 nm in diameter) carbon black particles (CBP) induce airway inflammation in vivo. In order to better understand how CBP affect lung health, two main airway cell types likely to interact with inhaled particles, alveolar macrophages (AM) and dendritic cells (DC), have been exposed to CBP in vitro and followed for proinflammatory endpoints and/or maturation.
Mouse AM (RAW 264.7 cell line) and DC (bone marrow–derived dendritic cells from BALB/c mice) were exposed to different concentrations of CBP, phosphate buffered saline (PBS; vehicle control) or lipopolysaccharide (LPS, positive control) for 4 and 24 hours. The inflammatory mediators nitric oxide (NO) and tumor necrosis factor alpha (TNFalpha) together with cytotoxicity (MTT test) were measured in AM cultures. DC maturation and activation was determined by expression of costimulatory molecules (CD40, CD80 and CD86), and by cytokine production (IL-10 and IL-12).
The exposure of AM to both 14 and 40 nm CBP induced a clear dose- dependent increase in TNFalpha production when compared to PBS exposure. In contrast, only 40 nm CBP induced a dose-dependent upregulation of costimulatory molecules in DC. None of the CBP induced NO production in AM, or IL-10 or IL-12 production in DC. No endotoxin contamination could be detected in any of the particles used as determined by Limulus Amebocyte Lysate assay.
In general, present data indicate that the proinflammatory effects of CBP on AM as observed in vitro correspond to the previously observed in vivo effects. DC activation however depends on the particles size. It needs to be determined whether proinflammatory nanoparticles of different size also affect macrophages and DC differently in vivo.

PS 871 CHARACTERIZATION AND BIOCOMPATIBILITY OF GREEN SYNTHESIZED SILVER NANOPARTICLES.

M. C. Moulton[1], S. Kunzelman[1], L. K. Braydich-Stolle[1], R. Varma[2] and S. Hussain[1]. *[1]711 HPW; RHPB, Air Force Research Labs, Wright Patterson, OH and [2]NRMRLS, U.S. E.P.A, Cincinnati, OH.*

There are currently ~1,000 commercially available products which contain some form of silver nanotechnology, ranging from topological creams and cosmetics, to anti-microbial socks and household cleansers. Previous studies have indicated that silver nanoparticles (Ag NPs) have a size dependent cytotoxicity where the smaller particles are the most toxic; however, it has also been shown that coating the Ag NPs dramatically alters the toxicity. In light of these studies and the ever increasing probability for dermal and inhalation exposure to Ag NPs, it is imperative to create nanoparticles which can be synthesized in a cost effect, environmentally friendly manner, and pose minimal threat to workers. Therefore, the goal of this study was to synthesize biocompatible and environmentally friendly Ag NPs. Ag NPs were synthesized using wet chemistry with epinephrine (Epi) as a reducing agent, and biocompatibility was assessed using the human keratinocyte cell line (HaCaT) and rat alveolar macrophages as in vitro models for dermal and inhalation exposure, respectively. Characterization was performed using transmission electron microscopy (TEM) to yield the primary particle size and morphology, and dynamic light scattering (DLS) was used to identify agglomeration in the exposure media (EM). Biocompatibility was evaluated using Cytoviva imaging to determine internalization, the MTS assay to assess cell proliferation, and the LDH assay to evaluate membrane integrity at concentrations of 0, 50, and 100 μg/ml. The EpiAg NPs had a primary particle size of 11.5± 4.7nm, 25.8 ± 15.8nm, 11.9 ± 3.9nm, 17.3 ± 7.0nm, and 24.2 ± 6.5nm depending on the ratio of Ag to reducing agent (1:1, 2:1, 10:3, 10:1, and 20:1). Furthermore, all of the EpiAg NPs agglomerate to some degree once dispersed in EM. Overall, the Epi Ag NPs regardless of reducing agent ratio or size appeared to not disrupt cell proliferation (over how long???) despite being internalized by the cells with minor membrane disruption.

PS 872 NANOSILICAS WITH VARIOUS SURFACE CHARGE INDUCE THE DIFFERENT PROFILE OF CYTOKINE PRODUCTION ON MACROPHAGE.

Y. Yoshioka[1, 2], A. Tanabe[2], Y. Mukai[2], N. Okada[2], Y. Tsutsumi[3, 4] and S. Nakagawa[1, 2]. *[1]The Center for Advanced Medical Engineering and Informatics, Osaka University, Osaka, Japan, [2]Department of Biotechnology and Therapeutics, Graduate School of Pharmaceutical Sciences, Osaka University, Osaka, Japan, [3]Department of Toxicology, Graduate School of Pharmaceutical Sciences, Osaka University, Osaka, Japan and [4]Laboratory of Pharmaceutical Proteomics, National Institute of Biomedical Innovation, Osaka, Japan.* Sponsor: Y. Yoshioka.

Nanotechnology has produced a diverse array of nanomaterials such as carbon nanotubes, fullerene derivatives and quantum dots. The advent of nanomaterials has provided incredible opportunities for biomedical applications. For example, nano scaled silica (NS) is used in various fields such as engineering, electronics, foods, and drugs. On the other hand, the potential adverse effects of nanomaterials, such as NS, on human health remain to be established. We have tried to clarify the property and safety of nanomaterials in vivo and in vitro. In this study, we compared the effect of various NSs with different surface charge on innate immune responses using Raw264.7 cells, mouse macrophage cell lines. We used the NSs with a diameter of 70 nm with neutral (NS70(±)), anionic (NS70(-)) and cationic (NS70(+)) charge on the surface. At first, we examined the effect of NSs on the production of proinflamatory cytokines, TNF-α, in macrophage. NS70(±) alone induced the significant level of TNF-α. Next, we examined the effect of NSs on the production of proinflamatory cytokines in LPS-stimulated macrophage. LPS-induced activation resulted in elevated levels of IL-6 and TNF-α compared with unstimulated Raw264.7 cells. NS70(+) and NS70(-) enhanced LPS-induced production of TNF-α, whereas NS70(±) suppressed LPS-induced TNF-α production. In contrast, all NS70s suppressed LPS-induced IL-6 production significantly. These results indicated that NSs modified the immune responses and surface charge was important factor.

PS 873 CHARACTERIZATION OF SELECTED NANOPARTICLES AND THEIR RELATIONSHIP TO TOXICITY IN LUNG EPITHELIAL CELL LINE.

K. O. Yu[1], J. Harber[1], R. C. Murdock[1], E. Klier[2], H. Maupin[2], B. Klotz[3], D. Mattie[1], J. J. Schlager[1] and S. M. Hussain[1]. *[1]711 HPW; RHPB, Air Force Research Labs, Wright Patterson, OH, [2]U.S. Army Research Laboratory, Aberdeen Proving Ground, MD and [3]Dynamic Science, Inc., Aberdeen, MD.*

The aim of this study was to investigate the relationship between characterization of selected nanoparticles (NPs) (Boron, B; Copper, Cu and Tungsten, W) and their toxicity in human alveolar basal epithelial cells (A549). Various sizes of these particles were suspended in water, phosphate buffered saline (PBS) and 0.9% saline at room temperature for Dynamic Light Scattering measurements. All NPs in de-ionized water showed the smallest hydrodynamic aggregate sizes while PBS produced 2-3X larger sizes and 0.9% saline the largest values of 3-9X size in water. Since the major route of exposure of these materials would be inhalation while handling NPs at work places and in manufacturing settings, lung epithelial cells were chosen as a simple model to study effects of nanoparticles on lung cells. The cells were exposed with different concentrations (0, 10, 50, 100 and 200 μg/mL) of particles (Cu <100nm; B 1μm; 60 nm and 4, 9, and 26 μm W powder). Results of MTS assay for cell viability of Cu revealed that dose-dependent MTS reductions were observed at 30 min post exposure; at 5, 10, 20, 40, 60 and 80 μg /mL. MTS reductions were 20, 35, 60, 80, 85, and 90% reduction of control, respectively. No MTS reduction was observed in B and micron sizes of W. Reactive oxygen species (ROS) generation was studied to see if these NPs induced oxidative stress. Nano and micron sizes W showed several fold increases of ROS production, especially 60 nm W which displayed ~4 fold increase at 6 hr time point. No significant increase in ROS was observed in B and Cu. In summary, nanoparticles studied showed induction of ROS generation except Cu, which could cause oxidative stress in the cells when exposed with these particles. In summary, these data showed that the nanoparticles under studied exhibited chemical-, size- and concentration-dependent and specific toxicity.

PS 874 ASSESSMENT OF THE BIOLOGICAL EFFECTS OF SILVER NANOPARTICLES IN CULTURED HUMAN CELLS.

N. Miura and S. Koizumi. *National Institute of Occupational Safety and Health, Japan (JNIOSH), Kawasaki, Japan.* Sponsor: M. Satoh.

Silver nanoparticles (nano Ag), whose antimicrobial properties are well known, have been extensively used as antibacterial agents and deodorants. Despite the widespread use of nano Ag products, relatively few studies have been undertaken to determine the biological effects of nano Ag exposure. We evaluated the toxicity of nano Ag and examined influences on the expression of several genes by nano Ag. We observed apparent cytotoxicity in HeLa cells exposed to nano Ag (5-10 nm) or silver nitrate for 24 h. The IC50 values for nano Ag and silver nitrate were 92 and 17 μg Ag/ml, respectively. Furthermore, nano Ag as well as silver nitrate induced apoptosis in HeLa cells. These results indicate nano Ag possesses an obvious cytotoxic ability. To obtain the clue to the mechanism of action, we examined the expression of typical stress response genes coding for metallothionein-2A (*MT-2A*), heme oxygenase-1 (*HO-1*) and 70 kDa heat shock protein (*HSP70*) after nano Ag exposure. Nano Ag induced the expression of *MT-2A* and *HO-1* almost as effectively as Cd, known to be a strong inducer of these genes. *HSP70* expression was slightly increased by nano Ag. These results may suggest the occurrence of metal ion, oxidative stress and/or protein denaturation by nano Ag exposure.

PS 875 LIMITATIONS AND RELATIVE UTILITY OF SCREENING ASSAYS TO ASSESS ENGINEERED NANOPARTICLE TOXICITY IN A HUMAN CELL LINE.

A. O. Inman, N. A. Monteiro-Riviere and L. W. Zhang. *Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.*

Carbon black (CB), single-walled carbon nanotubes (SWCNT), fullerenes (C_{60}), nC_{60}, and quantum dots (QD) were used in vitro to determine their cytotoxicity with classical toxicity assays. Classical dye-based viability assays such as neutral red (NR) and MTT produce invalid results when treated with some nanomaterials (NM) due to interactions and/or adsorption of the dye or dye product. In this study, human epidermal keratinocytes (HEK) were exposed in vitro to CB, SWCNT, C_{60}, nC_{60}, QD, and Min-U-Sil 5 that served as a particle control to assess viability with Trypan Blue (TB), Live/Dead (LD), calcein AM (CAM), NR, MTT, Celltiter 96® AQueous One (96 AQ), alamar Blue (aB), Celltiter-Blue® (CTB), CytoTox OneTM (CTO), and flow cytometry. Viability linearity (R^2 value) for each assay was determined with HEK plated at concentrations ranging from 0 to 25,000 cells per well in 96 well plates. HEK were treated with serial dilutions of each NM for 24 h and assessed with each of the viability assays above. Dye-based assays varied a great deal, depending on the interactions of the dye/dye product with the type of NM. Based on the above studies, the optimal assay was 96 AQ. Unlike small molecules, NM can interact with different assay markers to cause variable results with these classical assays and might not be suitable for assessing cytotoxicity of engineered NM. Therefore, multiple assays may be required when determining nanoparticle cytotoxicity for risk assessment. (Supported by the US Air Force Office of Scientific Research, FA 9950-08-1-0182)

PS 876 ARE CELLULOSE NANOPARTICLES TOXIC TO HUMANS AND FISH?

J. Wise[1, 2], C. LaCerte[1, 2, 3], H. Xie[1, 2, 3], J. Huang[1, 2], J. McKay[1, 2], M. Bickford[1, 2], M. Okeny[1, 2], D. Bousfield[4], M. Mason[2, 4] and J. P. Wise[1, 2, 3]. *[1]Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME, [2]Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME, [3]Department of Applied Medical Science, University of Southern Maine, Portland, ME and [4]Department of Chemical and Biological Engineering, University of Maine, Orono, ME.*

Nanoparticles are estimated to be a $1 trillion per year industry by 2010. One of the particular interests for industry is in extracting cellulose nanoparticles from wood to be used as reinforcing agents in bioplastics, and to replace the plastic presently used in frozen desserts. The Toxicity of cellulose nanoparticles is currently unknown therefore it is important to assess its potential harm to humans and the environment. In our study we used human skin fibroblast cells (BJhTERT), and medaka fish fin cells (OLHN-12) to test the potential cytotoxicity of cellulose nanoparticles. We exposed the cells to a wide range of potentially usable concentrations of cellulose ranging from 0.5-1000 μg/cm^2 for a period of 24 hours. The fish cells were exposed to another range of 50-1000 μg/cm^2 for a period of 24 hours and a period of 120 hours. Currently we have observed mild cytotoxicity from cellulose nanoparticles to human skin cells at doses of 50-1000 μg/cm^2. For the fish cells we found moderate cytotoxicity at 1000 μg/cm^2 for 24 and 120 hours. Due to the lack of much significant toxicity on human skin cells and that the only toxicity on fish cells is an extremely high dose; the data suggests that cellulose may be suitable for use on consumer products. This work is supported by the Educational Outreach Award of the Maine EPSCoR FBRI Research Project (J.P.W.).

PS 877 MECHANISM OF QUANTUM DOT NANOPARTICLE UPTAKE IN A HUMAN CELL LINE.

L. W. Zhang and N. A. Monteiro-Riviere. *Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.*

Quantum dots (QD) have been used in biological and medical applications, but the mechanism of QD cell uptake remains unknown. Soluble QD655 nanoparticles consist of a CdSe core and a ZnS shell with a carboxylic acid surface coating. These QD are ellipsoid in shape and have a hydrodynamic diameter of 18nm-22nm. Clathrin, caveolae, lipid rafts, early endosomes, late endosomes, and lysosomes were labeled to observe their co-localization with QD. The mechanism of QD655 uptake by human epidermal keratinocytes (HEK) was investigated with 27 endocytic inhibitors associated with seven classical and very specific endocytic pathways for HEK. Clathrin and eps15 did not co-localize with QD at 1h, but co-localization occurred between QD and lipid rafts. QD655-COOH partially co-localized with EEA1 at 1h and gradually translocated into CD63/LAMP1-positive compartments indicating that early/late endosomes participated in QD uptake. Inhibitor experiments supported that QD endocytosis by HEK was not related to the clathrin-mediated pathway, macropinocytosis or HEK specific melanosome transfer pathway, but was highly dependent on the low density lipoprotein receptor/scavenger receptor mediated pathway and may be regulated by lipid rafts or G-protein linked pathway. Finally, at the high concentration of 20nM QD, minor toxicity was detected at 24h by the Live/Dead assay, and actin filaments increased in the cytoplasm. Here, we report on the QD endocytic pathway mechanism for HEK. Size, surface coating and charge of the QD nanoparticles are extremely important parameters to determine QD uptake in mammalian cells and may help to develop rational targeted nanotherapeutics. (Supported by U.S. Air Force Office of Scientific Research, FA 9950-08-1-0182)

PS 878 ASSESSMENT OF FULLERENE TOXICITY IN A DYNAMIC ROTATING CELL CULTURE SYSTEM IN A HUMAN CELL LINE.

K. M. Evaul and N. A. Monteiro-Riviere. *Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.*

In vitro screening methods with adherent cell cultures have been used to assess the toxicity of numerous chemicals and pharmaceuticals. However, repetitive dosing for long periods of time is difficult to conduct in regular in vitro cell culture models due to the limitations of cell growth. We have used a rotating cell culture system

to study the effects of microgravity and biological interactions of C_{60} fullerenes with human epidermal keratinocyte (HEK). The cells are in constant motion (dynamic) without direct contact of large agglomerates of nanomaterials sitting directly on the cell surface. A single dose of 0.1mg/ml, 0.2 mg/ml, or 0.4mg/ml of C_{60} was studied in proliferating HEK for 10 days, assayed for viability, and cellular morphology and C_{60} uptake evaluated by transmission electron microscopy (TEM). Additional studies were conducted to assess the effects of repetitive daily dosing using this rotating system with the medium dose of 0.2mg/ml C_{60} for 10 days. Samples were taken every 48 h for TEM and cellular viability was assessed by MTT. The single dose study showed a slight decrease in viability, with a statistically significant (53.4% ±0.6) decrease in viability after daily dosing for 10 days. Ultrastructural evaluation depicted the C_{60} within cytoplasmic vacuoles of the cells with a slight increase in uptake over 10 days. Control cells had normal morphology and growth. These findings demonstrate that cells in a microgravity environment can extend the life span of the cells so repetitive daily dosing can be conducted to assess longer exposure times for the study of nanomaterials to mimic multiple exposures scenarios in an occupational setting. (Supported by the US Air Force Office of Scientific Research, FA 9950-08-1-0182)

PS 879 OXIDATIVE STRESS AND APOPTOSIS IN HUMAN CELLS EXPOSED TO AG AND TIO2 NANOPARTICLES.

R. Foldbjerg[1], P. Olesen[1], D. Dang[1], F. Besenbacher[2] and H. Autrup[1]. *[1]Institute of Public Health, University of Aarhus, Aarhus, Denmark and [2]iNano Center, University of Aarhus, Aarhus, Denmark.*

The objective of this project is to study the mode of action of nanoparticles (NP)in in vitro systems and investigate the toxicity as a function of particle number and surface area. The toxicity of Ag NP(PVP coated;length: 81 nm; aspects ratio = 1.2) and TiO NP(anatase; 7.5,12 and 18 nm) were investigated in A549 human lung epithelial and THP-1 monocytic cells. Cellular toxicity was assessed by the MTT and LDH assays. Induction of reactive oxygen species (ROS) was determined by DCFH-DA and by expression of heme oxygenase (HO-1) by RT-PCR. Apotosis was measured by the Annexin V and tunnel assays using flowcytometry. Ag NP induced toxicity in A549 cells in a dose-dependent manner (10-100 ug/ml)after 24 hrs incubation, whereas toxicity was only observed above 50 ug/ml after 4 hrs incubation. Ag NP increased ROS in a dose-dependent manner after 4 hrs incubation. The induction of ROS was dependent on the ratio of particles/cell number. Ag NP also induced significantly the expression of HO-1 at doses above 10 ug/ml, whereas other genes involved in cellular defence against oxidative stress, e.g. catalase was not induced. The toxicity of all 3 TiO NPs in A549 increased in a dose dependent manner expressed as ug/ml, and highest toxicity was observed for the smallest particles. However, when toxicity was compared by same surface area, the small NPs were slightly less toxic than the larger NP. The TiO NPs also induced ROS after 24 hrs incubation in a dose(ug/ml) and surface area (200-10000 mm2/ml)dependent manner. Using the annexin V/propidium iodide (PI) assay, Ag NP was found to induce both apoptosis and necrosis in THP-1 cells in a dose,time and cell number dependent manner. Using the tunnel assay a significant effect was observed after 6 hrs at concentrations higher than 30 ug/ml. Summary: Ag and TiO NP induced ROS and loss of cell viability in a dose dependent manner, and cell death occurs primarily by apoptosis. In case of TiO, our results suggest that the toxicity should be expressed not alone by mass.

PS 880 ASSESSMENT OF SILVER NANOPARTICLES IN HUMAN EPIDERMAL KERATINOCYTES AND *IN VIVO* PIG SKIN.

M. E. Samberg[1], A. R. Siekkinen[2], S. J. Oldenburg[2] and N. A. Monteiro-Riviere[1]. *[1]Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC and [2]nanoComposix, San Diego, CA.*

Products utilizing the antimicrobial properties of silver (Ag) nanoparticles range from surgical tool coatings, surface and personal sanitizing sprays, toothbrushes, and infant pacifiers. The purpose of this study was to evaluate the cytotoxic effects of nanosilver in human epidermal keratinocytes (HEK) in vitro. Ag samples included: uncoated, unwashed colloidal 20nm, 50nm and 80nm of 0.2mg/ml in deionized water; uncoated, washed colloidal 20nm (2.86mg/ml), 50nm (3.45mg/ml) and 80nm (2.79mg/ml) in deionized water and 25 and 35nm carbon coated. Concentrations ranging from 1.7 to 0.000544μg/ml were studied and cell viability assessed using MTT, alamar Blue and Celltiter 96 Aqueous One (96AQ), and for the proinflammatory cytokines for IL-1β, IL-6, IL-8, IL-10, and TNF-α. Topical applications of 34, 3.4, and 0.34μg/ml of Ag were assessed in porcine skin. After 24 h exposure, the viability of uncoated, unwashed Ag indicated a significant dose dependent decrease ($p<0.05$) at 0.068μg/ml with MTT and at 0.34μg/ml with alamar Blue and 96AQ. However, the 20nm, 50nm and 80nm uncoated, washed Ag and the 25 and 35nm carbon coated Ag showed no significant decrease ($p<0.05$) in viability for any of the concentrations assessed by each assay. Cytokines IL-1β, IL-6, and IL-8 showed a significant increase with all sizes of uncoated, unwashed Ag. TNF-α showed an increase with the 20 and 80nm uncoated, unwashed Ag, while IL-10 had no effect. TEM depicted localization of all Ag samples in cytoplasmic vacuoles of the HEK. The 20 and 50nm unwashed uncoated colloidal Ag was compared to the respective washed uncoated colloidal Ag in vivo for 14 days. No gross irritation was evident in pigs and penetration was evaluated by TEM. (Supported by the US Air Force Office of Scientific Research, FA 9950-08-1-0182)

PS 881 EFFECTS OF SILVER NANOPARTICLES (AG-45) UPON CORONARY ENDOTHELIAL CELLS.

H. Rosas-Hernandez[1], S. Jimenez-Badillo[1], E. Garcia-Espino[2], H. Terrones[2], M. Terrones[2], N. Sadovova[3], X. Zou[3], C. Wang[3], J. J. Schlager[4], S. M. Hussain[4], S. F. Ali[3] and C. Gonzalez[1]. *[1]Faculty of Chemistry Sciences, Autonomous University of San Lous Potosi, San Lous Potosi, Mexico, [2]Advance Material Department, IPICyT, San Lous Potosi, Mexico, [3]Division of Neurotoxicology, NCTR, Jefferson, AR and [4]Applied Biotechnology Branch, Human Effectiveness Directorate, AFRL, WPARF, OH.*

Nanoparticles (NP) are small scale engineered materials (<100 nm) with unique beneficial, physical, chemical and mechanical properties, however, their potential to produces adverse or beneficial effects is still not been fully evaluated. This investigation was designed to determine whether silver nanoparticles (Ag-45 nm) induce any selective and specific biological effects upon coronary endothelial cells (CEC), such as proliferation, cytotoxicity, and nitric oxide production (NO). CEC were cultured and exposed to increasing concentrations (0.1–100 ug/ml) of Ag-45 nm for 24 hrs. Ag-45 induced dual effect upon cellular proliferation, an inhibition at low concentrations and stimulation at high concentrations, and these actions were directly associated with NO production and inversely related with cytotoxicity. Confocal microscopy studies showed that Ag-45 nm exposure, did not change CEC morphology, and were distributed widely in cellular surface, even with high concentrations of this agglomerate nanomaterial (NM). In addition, physical characterization of these Ag-45 nm, using TEM, demonstrated that the real range of this NM, compromise a heterogeneous group of silver sizes, from 10-90 nm. These results clearly demonstrate that Ag-45 nm show selective and specific effects on this vascular bed, depending on the concentration, and that opposite effect could be result of the heterogeneity of sizes. However, the protective effects we found could be mediated by the production of NO, a free radical produced mostly by endothelium from blood vessels and, mediated angiogenesis and vascular tone.

PS 882 DESIGN, SYNTHESIS, & BIOLOGICAL EVALUATION OF NANOPARTICLE DRUG DELIVERY SYSTEMS.

A. H. Faraji[1], I. I. Vlasova[2], N. V. Konduru[2], W. Feng[2], V. E. Kagan[2] and P. Wipf[1, 3]. *[1]Chemistry, University of Pittsburgh, Pittsburgh, PA, [2]Environmental & Occupational Health, University of Pittsburgh, Pittsburgh, PA and [3]Pharmaceutical Sciences, University of Pittsburgh, Pittsburgh, PA.*

The prevalence of nanotechnology in medicine has grown exponentially in recent years; moreover, intense exploration into the toxicology of nanomaterials has paralleled this growth. It is known that inorganic nanoparticles – such as those made from silica – catalyze the production of damaging free radicals. This undesirable toxicity limits the medical applications of inorganic nanoparticles. However, functionalization of the reactive nanoparticle surface may mask the potential for free radical generation. Free radical scavengers – in particular, 2,2,6,6-tetramethylpiperidine-N-oxyl (TEMPO) – may be covalently attached to nanoparticles via an acid-labile oxazoline moiety, which selectively hydrolyzes to release the antioxidant payload upon lysosomal incorporation. This new release strategy may increase the biocompatibility of inorganic nanoparticles via reduction of oxidative stress pathways. As an extension, the oxazoline release mechanism may be utilized to deliver a myriad of small molecule drugs, as it is amenable to drug attachment via peptide coupling and esterification. Silica nanoparticles were prepared and their surfaces were functionalized with the oxazoline-TEMPO antioxidant release system. In addition, the nanoparticles were conjugated to fluorescein, thus permitting to monitor subcellular localization via fluorescence microscopy. The nanoparticles were coated with phosphatidylserine to allow for efficient uptake. Macrophages (RAW264.7) were incubated with these nanoparticles; rapid and extensive uptake was seen within 0.5-1 hours. The nanoparticles concentrated in lysosomes and mitochondria, with a significant reduction in superoxide generation. In summary, the toxicity associated with inorganic nanoparticles may be mitigated by surface modification with small molecule antioxidants, thus increasing their biocompatibility and prevalence in medicine and drug delivery. Supported by NIAID U19AI068021 & NIOSH OH008282.

PS 883 ASSESSMENT OF ALUMINUM NANOPARTICLE INTERACTIONS IN HUMAN EPIDERMAL KERATINOCYTES.

N. A. Monteiro-Riviere[1], K. M. Evaul[1] and S. J. Oldenburg[2]. [1]*Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC and* [2]*nanoComposix, San Diego, CA.*

Aluminum nanoparticles (Al NP) have been used in drug delivery, as a surface coating, as an ingredient for solid rocket fuel, and in military explosives and artillery. Although Al NP have been suggested for many civilian and military applications, the health and safety of these nano size particles are not known. Size characterization was determined by dynamic light scattering and transmission electron microscopy (TEM). To understand the biological activity of Al NP, human epidermal keratinocytes (HEK) were exposed to 50nm and 80nm nanoparticles ranging in concentrations from 0.0004mg/ml to 4.0mg/ml in a humidified 5% CO_2 atmosphere at 37°C. Media was harvested at 24 h to assess the inflammatory mediator interleukin (IL)-8. HEK viability was determined with MTT, alamar Blue, and Celltiter 96® AQueous One (96 AQ) assays. There was no significant decrease ($p<0.05$) in viability relative to the controls with the 50nm and the 80nm Al NP at all treatment concentrations in the three assays, which suggests that the Al NP are not cytotoxic to HEK. TEM depicted Al NP localized within the cytoplasmic vacuoles of the cells. IL-8 data normalized to the cell viability was variable, indicating possible nanoparticle interactions with the cytokine assay. (Funded by the US Air Force Office of Scientific Research, FA 9550-08-1-0182)

PS 884 PREPARATION AND STABILITY TESTING OF ORAL FULLERENE C60 FORMULATIONS WITH PARTICLES IN THE NANOMETER AND MICROMETER SIZE RANGES.

S. Graves[1], T. Cristy[1], V. Godfrey[2], C. Smith[2] and N. Walker[2]. [1]*Toxicology Columbus, Battelle, Columbus, OH and* [2]*NTP, Research Triangle Park, NC.*

To allow for studies of the effect of size on the toxicity of nanoscale materials there is a need for the control and characterization of the size of materials in the dosing formulations used in toxicity studies. The purpose of this study was to develop methods for the preparation of oral gavage formulations of C60 with two different particle size ranges in support of studies as part of the NTP Nantechnology Safety Initiative. The C60 as received was made up of 10 – 20 μm particles agglomerated into clusters approximately 100 μm in diameter. Several methods for reducing the particle size of the material into the desired ranges were attempted. All of the methods, except grinding in oil, resulted in reagglomeration of the C60. A formulation with nanometer-sized particles was produced by grinding C60 in Cremophor® EL for 7 days followed by dilution to a final formulation of approximately 1:1:8 Cremophor:ethanol:water. The formulation was filtered through a series of filters with descending pore sizes. The formulation with micrometer-sized particles was prepared similarly, except it was only ground for approximately 15 minutes and was not filtered. Both formulations were analyzed for particle size by laser diffraction and concentration by HPLC/UV. The nanometer and micrometer-sized C60 formulations were found to have an average particle sizes of 211 nm and 16.6 μm, respectively. Both formulations were homogeneous at concentrations of approximately 30 mg/mL. The formulations were reanalyzed for concentration and particle size after 42 days of storage at room temperature and no significant changes in either were observed. This study shows that homogenous, stable, oral gavage formulations of the fullerene C60 with different particle sizes can be prepared in a mixure of Cremophor, ethanol, and water. This work was supported by NTP Contract N01-ES-05456.

PS 885 SILICA-BASED NANOPARTICLE UPTAKE AND CELLULAR RESPONSE IN PRIMARY MICROGLIA.

J. Choi[1], Q. Zheng[2], J. Bai[2], H. E. Katz[2] and T. R. Guilarte[1]. [1]*Environmental Health Sciences, Johns Hopkins School of Public Health, Baltimore, MD and* [2]*Material Sciences & Engineering, Johns Hopkins University, Baltimore, MD.*

Silica-based nanoparticles are currently being developed for imaging and diagnostic applications in medicine. Nanoparticles have been used to visualize brain tumors, thus they are able to cross the blood-brain barrier and enter the brain parenchyma. Silica-based nanoparticles are more biocompatible than quantum dots that contain toxic metals like cadmium, however, there is a paucity of knowledge on their cellular target(s) in the brain and how they affect cellular function(s). Microglia are the immune-competent cells of the brain. They have neuroprotective and immunocompetent functions in order to maintain neuronal health. In this study, primary microglia from rat brain were used to determine if silica-based nanoparticles are phagocytized and if they affect microglia function. Primary microglia were isolated and plated at a density of 250,000 cells per plate. After overnight incubation, they were exposed to 10^3, 10^5, or 10^7 silica-based nanoparticles per plate. These silica-based nanoparticles are embedded with a fluorescent dansylamide dye, allowing tracking of cellular uptake. Fluorescent confocal microscopy of nanoparticle-exposed microglia indicated that there was intracellular accumulation at all concentrations tested. Using a MTS assay, the concentration of nanoparticles tested produced no significant effect on cell viability. However, exposure to nanoparticles resulted in a dose-dependent increase in the generation of reactive oxygen species in microglia. Microglia are known to express inflammatory cytokines and enzymes such as TNF-α and COX-2, respectively. Analysis of TNF-α and COX-2 gene expression using real-time quantitative PCR showed a reduction in TNF-α gene expression at all concentrations tested and a significant increase in COX-2 gene expression only at the highest concentration. The consequences of these changes to microglia function are currently under investigation. [Supported by the Institute for NanoBiotechnology at Johns Hopkins and NIEHS-T32 ES07141]

PS 886 THE TRANSPORT OF TIO2 NANOPARTICLES IN HUMAN LUNG EPITHELIAL CELLS AND ALVEOLAR MACROPHAGES: HOW DOES AGGREGATION STATE INFLUENCE CELLULAR UPTAKE MECHANISMS?

J. M. Berg, R. A. Zebda and C. M. Sayes. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

The use of nanomaterials in today's society is increasing at a rapid pace. However, with the uses of a new technology come the hazards and risks associated with its exposure. Here, a previously well-characterized titanium dioxide (TiO2) nanoparticle sample is further examined to determine the toxic properties associated with cellular uptake in human lung epithelial cells and alveolar macrophages. Literature shows a variety of mechanisms associated with the uptake of nanoparticles; however, we suggest that nanoparticle aggregates (termed nanoaggregates) and defined primary nanoparticles (those particles that have little to no aggregation) yield differing cellular responses. A time-course study incorporating transmission electron microscopy (TEM) was used to examine the aggregation state of the nanoparticles upon cellular translocation. In addition, a variety of cellular uptake mechanisms (i.e. transmembrane diffusion vs. endocytosis) were examined. Furthermore, the fate of the particles and time for clearance was studied. Results indicate that the TiO2 nanoparticles enter the epithelial cells or macrophages in either of two forms (aggregates or primary particles). It was found that larger aggregates were incorporated into vesicles such as endosomes, while primary particles were found in the cytosol. Ongoing studies will determine if these cytosolic nanoparticles interact with proteins or other charged subcellular components due to their unique electron configuration and surface charges. The chemical identity of TiO2 inside the cells was confirmed using energy dispersive X-ray spectroscopy (EDS). Elucidating the interaction between cellular substrates and nanoparticles is crucial to developing a mechanistic approach to the conflicting toxic responses of TiO2 and other nanoparticles.

PS 887 NANOCHEMISTRY, *IN VITRO*: A NEW DIMENSION TO NANOTOXICOLOGY USING NANO-SIZED CARBON BLACK AND IRON OXIDE.

R. A. Zebda, J. Berg and C. M. Sayes. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Exposure to a variety of different classes of nanomaterials is significant to both consumers and the environment. Little effort has been put forth on the hazard assessments of co-exposure to nanomaterials, i.e. exposure to two or more nano-sized materials (as consumer product usage or occupational exposure scenarios). This study was designed to investigate the effects of the chemical reactions between nano-sized carbon black and nano-sized iron oxide in both ex vivo and in vitro conditions. We exposed human lung epithelial cells and alveolar macrophages to nanocarbon black and nano-iron oxide alone, as well as in co-exposures. We expected that the carbon black and iron oxide co-exposures would induce a greater cytotoxicity and oxidative stress than in single nanoparticle exposures. Additionally, we characterized the carbon black and iron oxide nanoparticles in an effort to develop a structure-activity relationship. To assess cytotoxicity in culture, we used enzymatic and metabolic indicators (Resazurin and MTT dyes) and cell counts (Coulter counter) to evaluate cell viability. Protein, membrane, and DNA oxidation was used as indicators of oxidative stress. Results show that in cell-free conditions the physical and chemical characterization profiles of nano-carbon black and nano-iron oxide are different. A decreased cytotoxic response of cells exposed to nano-iron oxide alone versus co-exposure with nano-carbon black was apparent. In regard to the REDOX chemistry, the reaction between carbon black and iron oxide resulted in a reduced form of iron in solution (namely Fe2+), causing a significant increase in cellular oxidation. These results illustrate the need to not only identify the toxic

profiles of single nanoparticle exposures, but in order to effectively cope with health and environmental concerns, we must also know how these sole nanoparticles interact with other particles in biological and ecological environments.

PS 888 GENERATION OF REACTIVE OXYGEN SPECIES BY SILICON NANOWIRES.

R. S. Chapman, J. R. Roberts, V. Castranova and S. S. Leonard. *NIOSH, Morgantown, WV.*

Silicon nanowires (NW) are anisotropic crystals with semi-conductor capabilities and are currently being utilized in the production of biosensors, gas sensors, and field electric transistors. Because of their composition and large length to diameter ratio, silicon NW-induced toxicity may differ from other forms of nanoparticles. A variety of different forms of nanoparticles have been shown to produce toxic effects in cellular and animal models through the induction of oxidative stress. The potential for oxidative damage after exposure to silicon NW has not been investigated. The goal of this study was to assess the generation of free radicals by silicon NW. Electron spin resonance (ESR) was used to monitor hydroxyl radical production in an acellular system by measuring Fenton-like reactions in the presence of hydrogen peroxide. In addition, the ability to produce radicals after cellular exposure was also determined by ESR. These measures of particle surface reactivity of silicon NW (20 nm diameter x 10 μm length) at two different concentrations (0.2 mg/ml or 0.1mg/ml), were compared to those of titanium dioxide (TiO_2) NW (0.1 mg/ml or 0.05 mg/ml), amosite asbestos fibers (0.2 mg/ml or 0.1 mg/ml), and lead chromate particles ($PbCrO_4$) as a positive control (0.5 mg/ml). For *in vitro* studies, two cell types were used to measure reactive oxygen species (ROS) production, primary rat macrophages harvested from the lungs of male Sprague-Dawley rats and the RAW 264.7 macrophage cell line. ESR results showed no presence of hydroxyl radical or ROS production with silicon NW, in either the acellular or cellular systems. Hydroxyl radicals were observed in $PbCrO_4$ and amosite asbestos. However, radicals were not seen in TiO_2 NW. These findings indicate that silicon NW may not induce a significant increase in oxidative stress and associated damage.

PS 889 UNANTICIPATED BREAKDOWN PRODUCTS FORMED USING DMSO AS A SOLVENT TO STUDY THE AGGREGATION EFFECTS OF TIO2 ON MARINE MICROORGANISMS.

K. Rogers[1], M. Patra[1], Y. Ding[1], D. Hatchett[2] and S. Steinberg[2]. *[1]NERL, U.S. EPA, Las Vegas, NV and [2]Chemistry, University of Nevada-Las Vegas, Las Vegas, NV.* Sponsor: C. Dary.

In contrast to chemical stressors, most nanomaterials have a tendency to aggregate in aqueous environments. The aggregation behavior and solubility of suspensions of these materials in aqueous media are typically mediated by pH, ionic strength, and the presence of organic solvents as well as by physical mixing techniques such as ultrasonication. It is herein shown that the use of sonication to decrease aggregation and increase the suspension of TiO2 (rutile) in DMSO results in the degradation of DMSO and formation of sulfonic and sulfinic acids. The concentrations of sulfonic and sulfinic acids in DMSO as shown by ion chromatography and features in FTIR spectra, increase with sonication time both in the presence and absence of TiO2 (rutile). The presence of TiO2 increases the concentration of these breakdown products over a 3 hr time frame. Due to the toxicity of sulfonic and sulfinic acids, resulting from the sonication, DMSO became unsuitable as a solvent to study the effects of aggregation of TiO2 on the marine organism Vibrio fisceri. It is further suggested that the use of sonication to suspend nanomaterials in DMSO may produce unanticipated results for toxicity studies in other organisms.

PS 890 CYTOKINES EXPRESSION *IN VITRO* AFTER EXPOSURE OF CO-CULTURES TO NANOSIZED MONODISPERSE SILICA PARTICLES.

D. Napierska[1], L. Thomassen[2], L. Gonzalez[3], V. Rabolli[4], D. Lison[4], M. Kirsch-Volders[3], B. Nemery[1] and P. Hoet[1]. *[1]Lung Toxicology Research Unit, K.U.Leuven, Leuven, Belgium, [2]Centre for Surface Chemistry and Catalysis, K.U.Leuven, Leuven, Belgium, [3]Laboratory of Cell Genetics, Free University of Brussels, Brussels, Belgium and [4]Industrial Toxicology and Occupational Medicine Unit, Catholic University of Louvain, Brussels, Belgium.*

We have previously shown that the cytotoxicity of monodisperse amorphous silica nanoparticles in human endothelial cells (EAHY926 cell line) was strongly related to particle size. The aim of the present study was to test the influence of nanoparticles size on the cytokines expression using co-cultures of pulmonary epithelial cells with macrophages and endothelium cells using a two compartment system.

We used amorphous (monodisperse) spherical silica nanoparticles with a diameter ranging from 2, 16, 60, 104 to 340 nm. Particles were incubated with epithelial cells and macrophages (A549 + THP-1) at a concentration of 5 $\mu g/cm^2$ cell cultures surface or at 10 cm^2 particle surface area/cm^2 for 24 h whether or not in the presence of confluent EAHY926 cells in an insert introduced above the biculture after 12 h. At 24 h, supernatants were recovered and TNFalpha, IL-6, IL-8, MIP-1alpha and MIP-1beta were measured by means of a bead assay.
Quantification using the FACS array system showed significant increases for TNFalpha, IL-6, IL-8, MIP-1alpha for the 2 nm particles in all conditions tested. The larger particles did not induce cytokine expression at 5 $\mu g/cm^2$, but at dosing 10 cm^2 particle surface area/cm^2 (and thus a large mass) also the larger particles induced a response. In the bicultures, TNFalpha, IL-8 and IL-6 were most prominent, while in the EAHY926 cells also MIP-1beta was significant increased.
This work clearly shows the role of size and surface area in response to nano-silica.
Work was financed by the Belgian Ministry of Scientific Policy in the frame of the 'Science for sustainable development' programme (S^2NANO project, contract number SD/HE/02A).

PS 891 *IN VITRO* TRANSLOCATION OF QUANTUM DOTS AND INFLUENCE OF OXIDATIVE STRESS.

J. Geys, B. Nemery and P. H. Hoet. *Lung Toxicology Research Unit, K.U.Leuven, Leuven, Belgium.*

BACKGROUND: Translocation of inhaled nanoparticles to the circulation has been demonstrated in vivo. However, the interaction of nanoparticles with the lung epithelium and how they translocate through the cell layer is not understood.
AIM & METHODS: In this study we investigated, in vitro, the translocation of nano-sized quantum dots (QDs) (25 pmol/ml) through a tight monolayer of primary rat type II pneumocytes. The influence of surface charge on translocation was examined by using non-functionalized QDs, amine-QDs and carboxyl-QDs. The interaction between the nanoparticles and the lung epithelium were monitored by repeatedly measuring the "transepithelial electrical resistance" (TEER) and by examining the cell layer with confocal microscopy. The effect of oxidative stress was tested by culturing the cells together with tert-butyl hydroperoxide and the antioxidant N-Acetyl-L-cysteine was used to assess the role of particle-mediated oxidative stress.
RESULTS: Using the different types of QDs, no translocation through a tight monolayer of primary rat type II pneumocytes was observed. In general, an increase in TEER was found after incubation with QDs. A condition of low oxidative stress did not enhance translocation. In contrast, conditions of high oxidative stress with disruption of the cell layer, as shown in a decreased TEER, resulted in 30% translocation, regardless of the type of QDs.
CONCLUSIONS: No translocation of QDs was found through a tight monolayer of primary rat type II pneumocytes, regardless of the QDs surface charge. In addition, QDs did not impair the barrier function of the epithelial cells. In conditions of high oxidative stress with disruption of the cell-cell barrier, 30% translocation was observed.

PS 892 MECHANISTIC APPROACH TO COMPARE TOXICITY OF THREE UNIQUE NANO-SIZED METAL COLLOIDAL SUSPENSIONS TO LIVER CELL CULTURE SYSTEMS.

N. Banerjee, E. Nalley, Y. Tian and C. M. Sayes. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Nano-sized metal colloids are studied for both industrial and medicinal purposes. To resolve some of the outstanding toxicity concerns, we are utilizing a model that more accurately mimics the response of the liver in an ex vivo cell culture system, namely co-cultures of primary hepatocytes, Kupffer's cells, and lymphocytes isolated from C57BL6 mice. The manufactured inorganic metal nanomaterials include colloidal silver (Ag), copper (Cu), and nickel (Ni). The sizes, characterized in the dry state using BET surface area analyses and in the wet phase using dynamic light scattering and electron microscopy, vary with time, temperature, and media. Further, the pH of each suspension changes over time. We also found metal ions leaching from each material via atomic emission spectroscopy. These dynamic physico-chemical properties influence the biological response in two distinct pathways: a heavy metal cationic effect versus a nano-size effect. Cells were exposed to the three metal nanomaterials, independently. Post-exposure time points ranged from 4 hr to 1 wk. Colorimetric cytotoxicity was measured using MTT and resazurin dyes. Inflammatory response was determined by cytokine profiles (TNF-alpha and IL-6). A stable PXR-transfected luciferase reporter cell line (JBC, Gu) was used to test the effects of the nanomaterials on the pregnane X transcription activity. Nano colloidal Ag, Cu, and Ni treatment enhanced the PXR ligand RIF-induced reporter gene activity, suggesting an alteration of the xenobiotic metabolism. The mechanism for the interaction will be further analyzed. Results from cells ex-

posed to Ag exhibit no significant change in cytotoxicity; decrease in IL-6; increase in TNF-alpha. Cells exposed to Cu and Ni exhibit increase in cytotoxicity, IL-6 and TNF-alpha. We conclude that all three nano metal colloidal systems behave differently in physico-chemical properties and immune-toxicological responses.

PS 893 SYNTHESIS, CHARACTERIZATION, AND CYTOTOXIC EFFECTS OF MANGANESE NANOPARTICLES.

S. F. Ali[1], M. C. Moulton[2], L. K. Braydish-Stolle[2], C. Murdock[2], H. Jiang[3], L. Rongzhu[3], D. Milatovic[3], M. Aschner[3], J. J. Schlager[2] and S. M. Hussain[2]. *[1]Division of Neurotoxicology, NCTR, Jefferson, AR, [2]Applied Biotechnology Branch, AFRL, Wright-Patterson AFB, OH and [3]Deaprtment of Pediatrics, Vanderbilt University Medical Center, Nashville, TN.*

Recently we have shown that nanoparticles such as Mn, Ag and Cu can be neurotoxic by generating ROS and depleting dopamine concentration in PC-12 cells. We have also found significant changes in genes associated with oxidative stress and apoptotic pathways. In the present study we synthesized Mn nanoparticles (Mn-NP) using different solvents (decaffeinated tea, isopropyl alcohol and caffeine). These NP were subsequently characterized using Dynamic Light Scattering, Laser Doppler Velocimetry and TEM. Mn-NP when reduced with different solvents produced semi-spherical, poly-dispersed particles with an average size of 97.6 nm in tea, 32 nm in isopropyl alcohol, and 23 nm in caffeine. Astrocytes respond to the synaptic release of various neurotransmitters, and their dysfunction has been implicated in Mn-induced neurotoxicity. Therefore, we evaluated the cytotoxicity of Mn-NP using astrocytes and neuronal cultured cell. Mn-NP (5-40 ug/ml) produced a concentration-dependent decrease in MTT, and increased LDH release from cultured astrocytes and neuronal cultured cells. Mn-NP also produced a time-dependent increase in the expression of nuclear factor erythroid 2-related factor 2 (Nrf2), a transcription factor with a key role in regulating oxidative stress response. Morphological evaluation showed a time-dependent effect of Mn-NP on cell morphology. The most interesting effect was found in cells treated with Mn-NP in tea. Eight hrs post-treatment, astrocytes appeared deformed and increased in size by 24 hrs. However, with other media, the effects were not as pronounced. Similar effects were found in neuronal cultures, where Mn-NP in tea produced the most pronounced dysmorphic effects. These data suggest Mn-NP effectively produce neurotoxicity by affecting astrocytic and neuronal functions, most likely by generating oxidative stress and neurotoxicity.

PS 894 THE ENDOTHELIAL AND ADIPOCYTE CELL SPECIFIC ROLE OF PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR (PPAR)γ IN DMBA-MEDIATED BREAST TUMOURIGENESIS.

A. L. Reid[1], N. Peterson[2], S. K. Sengupta[2], F. J. Gonzalez[3] and C. J. Nicol[1, 2, 4]. *[1]Pharmacology & Toxicology, Queen's University, Kingston, ON, Canada, [2]Pathology & Molecular Medicine, Queen's University, Kingston, ON, Canada, [3]Center for Cancer Research, NCI, Bethesda, MD and [4]Division of Cancer Biology & Genetics, CRI, Queen's University, Kingston, ON, Canada.*

Peroxisome proliferator-activated receptor (PPAR)γ plays a role in tumourigenesis. Previous studies with PPARγ(+/-) mice suggest PPARγ normally suppresses dimethylbenz[a]anthracene (DMBA)-induced breast, and other, tumour progression; however, the mechanisms remain unknown. Conditional adipocyte (A) and endothelial (E) cell-specific PPARγ knockout mice (PPARγ-A KO and PPARγ-E KO respectively) were used to evaluate whether PPARγ signaling normally acts to prevent DMBA-mediated breast tumour progression in a stromal cell-specific manner. Twelve week old PPARγ KO mice and their congenic wild-type (WT) controls were randomly assigned to one of two treatment groups. All mice were treated by gavage once/week for 6 weeks with 1 mg DMBA and maintained on a normal chow diet. At week 7, mice in each group were divided into those continuing normal chow, and those receiving a PPARγ ligand (rosiglitazone, 4mg/kg/day) supplemented diet for the duration of the 25 week study, and monitored weekly. Tumour and tissue samples were collected at necropsy, and portions of each were fixed and frozen for future analysis. Preliminary data suggests that among DMBA Only treated groups, both PPARγ A-KO and E-KO mice present with more malignant tumours, and have a greater multiplicity and larger DMBA-mediated mammary tumours compared to PPARγ WT controls. In contrast, DMBA+Rosi treated PPARγ WT, but not PPARγ A-KO or E-KO mice, appear to be protected from these effects. These results: 1) suggest that normal PPARγ signaling in adipocytes and endothelial cells may contribute to the suppression of DMBA-mediated breast tumour growth; 2) add evidence supporting a protective role for PPARγ activation in reducing environmental chemical-mediated breast tumour progression; and 3) may facilitate development of more effective drugs against breast cancer.

PS 895 RAT CARCINOGENICITY STUDY WITH GW501516, A PPAR DELTA AGONIST.

L. E. Geiger[1], W. S. Dunsford[2], D. J. Lewis[2], C. Brennan[3], K. C. Liu[3] and S. J. Newsholme[1]. *[1]Safety Assessment, GlaxoSmithKline, King of Prussia, PA, [2]Safety Assessment, GlaxoSmithKline, Ware, United Kingdom and [3]Huntingdon Life Sciences, Huntingdon, United Kingdom.*

GW501516, a non-genotoxic PPARδ agonist, was assessed for carcinogenic potential by daily administration (oral gavage) to Han Wistar rats for a period of 104 weeks. Males were given 0, 5, 15 or 30 mg/kg/day for the first 6 weeks of the study. For the remainder of the study males were given 0, 5, 20 or 40 mg/kg/day. Females were given 0, 3, 10 or 20 mg/kg/day for the entire study. GW501516 produced test article-related neoplastic findings in multiple tissues at all doses. Increased mortality was seen with females given GW501516 at all doses and uterine endometrial adenocarcinoma contributed to death in a high proportion of these animals. Neoplasms considered test-article related occurred in the liver (hepatocellular adenoma at ≥ 10 mg/kg/day), urinary bladder (transitional cell carcinoma in males given 20 and 40 mg/kg/day), thyroid (follicular cell adenoma at ≥ 3 mg/kg/day and carcinoma in males at ≥ 20 mg/kg/day), tongue (squamous cell papilloma in males at 5 mg/kg/day and 40 mg/kg/day), stomach (squamous cell papilloma in males at ≥ 5 mg/kg/day and a female at 20 mg/kg/day, and carcinoma in a male at 40 mg/kg/day and a female at 3 mg/kg/day), skin (inverted squamous cell papilloma in males at ≥ 5 mg/kg/day and females at 3 or 20 mg/kg/day), Harderian glands (adenoma in males at ≥ 5 mg/kg/day and adenocarcinoma in a male at 40 mg/kg/day), testes (interstitial cell adenoma at 40 mg/kg/day), ovary (Sertoli cell adenoma at ≥ 10 mg/kg/day) and uterus (polyp and endometrial adenocarcinoma at ≥ 3 mg/kg/day). Some of the tumor types observed in this study have not been reported with either PPARα or PPARγ agonists and may reflect tumor promotion mediated through PPARδ agonism.

PS 896 MOUSE CARCINOGENICITY STUDY WITH GW501516, A PPAR DELTA AGONIST.

S. J. Newsholme[1], W. S. Dunsford[2], T. Brodie[2], C. Brennan[3], M. Brown[3] and L. E. Geiger[1]. *[1]Safety Assessment, GlaxoSmithKline, King of Prussia, PA, [2]Safety Assessment, GlaxoSmithKline, Ware, United Kingdom and [3]Huntingdon Life Sciences, Huntingdon, United Kingdom.*

GW501516, a non-genotoxic PPARδ agonist, was assessed for carcinogenic potential by daily administration (oral gavage) to CD1 mice for 104 weeks at doses of 0, 10, 30, 60 or 80 mg/kg/day. Survival was decreased at doses ≥ 30 mg/kg/day. Neoplasms considered related to test article occurred in liver (hepatocellular carcinoma at ≥ 30 mg/kg/day and adenoma at ≥ 10 mg/kg/day), stomach (squamous cell carcinoma at all doses) and combined squamous cell tumours at all doses (squamous cell papilloma and carcinoma, and keratoacanthoma). There have been conflicting reports in the literature regarding the effects of PPARδ on epithelial cell proliferation. The results of this study demonstrate an increase in proliferation in certain epithelial cell populations, but do not support a role for PPARδ in colon carcinogenesis. The squamous cell tumors observed in this study have not been reported with either PPARα or PPARγ agonists and may reflect tumor promotion mediated through PPARδ agonism.

PS 897 LIGAND-ACTIVATION OF PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR-BETA/DELTA INHIBITS THE PROLIFERATION OF HUMAN PANCREATIC CANCER CELLS.

J. D. Coleman and J. Vanden Heuvel. *Pennsylvania State University, State College, PA.*

Pancreatic cancer is the fourth leading cause of cancer-related deaths in the United States, owing to its extremely aggressive nature and resistance to chemotherapeutic regimens. In the present study we report that activation of the nuclear receptor PPAR-β/δ decreases human pancreatic cancer cell growth. The proliferation of three human pancreatic cancer cell lines - BxPc-3 (high COX-2 expression), Panc-1 and MIA PaCa-2 (COX-2 negative) - was inhibited by the PPAR-α and PPAR-γ-selective agonists, Ciprofibrate and Rosiglitazone, respectively, but most effectively by the PPAR-β/δ-selective agonist GW501516. Treatment of pancreatic cancer cells with a PPAR-β/δ-selective agonist significantly decreased mRNA levels of the cell cycle regulatory gene, cyclin D2, compared with control cells at 24 hours. Furthermore, GW501516 treatment significantly reduced the TNF-α-induced mRNA expression of pro-inflammatory mediators in MIA PaCa-2 and BxPc-3 cells, several of which are known to influence cell proliferation. PPAR-β/δ interacts with NF-κB p50 subunit, although this was not dependent on ligand. PPAR-β/δ is unique among the PPAR isoforms in its association with the transcriptional repressor, Bcl-6. We hypothesize that PPAR-β/δ activation results in Bcl-6 shuttling from the receptor complex to its known consensus sequence in the cyclin D2 promoter where it influences pancreatic cancer cell proliferation.

PS 898 COMBINING LIGAND ACTIVATION OF PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR-β/δ (PPARβ/δ) AND INHIBITION OF CYCLOOXYGENASE-2 (COX2) ACTIVITY EXERTS BOTH CHEMOPREVENTIVE AND CHEMOTHERAPEUTIC EFFECTS ON SKIN TUMORIGENESIS.

B. Zhu[1], M. T. Bility[1], N. Blazanin[1], A. B. Glick[1], B. Kang[1], F. J. Gonzalez[2] and J. M. Peters[1]. [1]*Veterinary and Biomedical Sciences, The Pennsylvania state university, University Park, PA and* [2]*Laboratory of Metabolism, NCI, Bethesda, MD.*

PPARβ/δ-null mice exhibit exacerbated skin tumorigenesis and ligand activation of PPARβ/δ can inhibit chemically-induced skin tumorigenesis. In the present studies, the effect of combining ligand activation of PPARβ/δ with inhibition of COX2 activity on skin tumorigenesis was examined using in vitro and in vivo methods. Modest chemopreventive effects of the COX2 inhibitor nimesulide were observed in wild-type mice but not in similarly treated PPARβ/δ-null mice. In addition, better chemopreventive effects of the PPARβ/δ ligand GW0742 were observed in wild-type than PPARβ/δ-null mice. Increased efficacy of chemoprevention was also observed by combining GW0742 with nimesulide, and a significant decrease in tumor multiplicity was only observed in wild-type mice following co-administration of GW0742 and nimesulide. In wild-type mice with pre-existing papillomas, co-administration of GW0742 and nimesulide caused an increase in the efficacy of decreasing tumor multiplicity and this effect was not seen in similarly treated PPARβ/δ-null mice. No effects on tumor size were seen in the above experiments. Treatment of neoplastic mouse keratinocyte cell lines with a combination of GW0742 and COX2 inhibitors resulted in enhanced inhibition of cell proliferation. Results from these studies demonstrate that combining ligand activation of PPARβ/δ with inhibition of COX2 activity can increase the efficacy of attenuation of skin carcinogenesis. These results also suggest that this approach may be suitable for both chemoprevention and chemotherapy.

PS 899 OVEREXPRESSION OF THE PROSTAGLANDIN E2 RECEPTOR SUBTYPE 1 (EP1) PROMOTES SKIN TUMOR DEVELOPMENT THROUGH COX-2 INDUCTION.

I. Surh[1, 2] and S. Fischer[1]. [1]*Carcinogenesis, U.T.M.D.Anderson Cancer Center, Smithville, TX and* [2]*University of Texas at Austin, Austin, TX.*

Prostaglandin E2 (PGE2) has been shown to promote skin tumor development. EP1 is one of four PGE2 receptors. EP1 mRNA levels were increased after a single or four topical treatments of 12-O-tetradecanoylphorbol 13-acetate (TPA) on skin as well as in 7,12 dimethylbenz[a]anthracene (DMBA)/TPA-induced tumors. To determine whether the EP1 receptor levels affect skin tumor development, we generated BK5.EP1 transgenic mice which overexpress EP1 in the basal layer of the epidermis. The skins of these mice are histologically indistinguishable from wild type mice. To determine the role of EP1 in skin tumor development, a DMBA/TPA skin carcinogenesis protocol was used. EP1 transgenic mice had a reduced tumor multiplicity and a reduced tumor incidence compared to wild type mice, but had a higher papilloma to carcinoma conversion rate. In DMBA only skin carcinogenesis protocol, EP1 transgenic mice developed more tumors than wild type mice. The effect of EP1 on cell proliferation was measured in vivo. After TPA treatment, cell proliferation was induced in both EP1 transgenic mice and wild type mice to a similar extent. However, 5 days after DMBA treatment, there was about 2 fold more Ki67 positive cells in the basal layer of the epidermis of EP1 transgenic mouse skin than wild type mice. To confirm that the enhanced tumor formation in transgenic mice is in fact PGE2 dependent, mice were given the selective cyclooxygenase-2 inhibitor Celecoxib or a control diet starting 1 week before DMBA treatment. Surprisingly, there was no lesion formation at all on mice that were fed Celecoxib. Histological sections of skin from Celecoxib fed mice showed a fairly normal skin structure 2 weeks after DMBA treatment compared to pronounced pseudocarcinomatous hyperplasia in control mice. By western blotting, COX-2 and phospho-c-jun were increased in untreated EP1 transgenic mice skin. Therefore, it can be concluded that EP1 signaling increases PGE2 production through c-jun and COX-2 induction and promotes tumor development. Supported by CA100140.

PS 900 PPARβ/δ REGULATES AHR SIGNALING IN SKIN.

M. G. Borland[1], M. T. Bility[1], F. J. Gonzalez[2], G. H. Perdew[1] and J. M. Peters[1]. [1]*Department of Veterinary and Biomedical Sciences, The Pennsylvania State University, University Park, PA and* [2]*Laboratory of Metabolism, NCI, Bethesda, MD.*

Peroxisome proliferator-activated receptors (PPARs) are ligand activated transcription factors with cell-specific biological functions. Previous evidence has shown that PPARβ/δ can attenuate skin tumorigenesis, which could be due in part to modulation of carcinogen metabolism. This hypothesis was examined using PPARβ/δ–null mouse models, and surprisingly, PPARβ/δ-null mouse skin and primary keratinocytes were refractory to 7,12-dimethylbenz[a]anthracene (DMBA)-dependent induction of cytochrome P450 1A1 (CYP1A1) or CYP1B1 mRNA and protein. Similar results were obtained with the human HaCaT keratinocyte cell line stably expressing shRNA against PPARβ/δ. The difference in CYP1A1/1B1 expression was also observed with other polycyclic aromatic hydrocarbons (PAHs), and this effect did not appear to be due to differences in the relative level of the AhR or accessory proteins, which are known regulators of CYP expression. Interestingly, Phase II and other non-AhR-dependent genes show a similar expression profile upon PAH treatment in the absence of PPARβ/δ expression. To begin to delineate the mechanism by which PPARβ/δ regulates AhR signaling, ligand binding and the nuclear translocation of AhR were examined, but no difference in these responses were observed between genotypes. Glutathione S-transferase (GST) pull-down of AhR with PPARβ/δ suggests there is not a functional interaction between the two receptors, although this must be more thoroughly examined in detail. The occupancy of the CYP1A1 promoter in response to PAH was examined by chromatin immunoprecipitation (ChIP), and in the absence of PPARβ/δ expression, reduced AhR occupancy of the CYP1A1 promoter was observed. These findings suggest a novel mechanism in mouse and human skin where PPARβ/δ modulates AhR-dependent signaling and potentially alters the carcinogenic effect induced by PAH, likely through modifying the balance between bioactivation and clearance of PAH. (Supported by CA97999, CA124533 [J.M.P], ES04869 [G.H.P], and an NSF GRFP).

PS 901 INVOLVEMENT OF REACTIVE OXYGEN SPECIES AND MACROPHAGES IN TGOGLITAZONE (TGZ)-INDUCED HEMANGIOSARCOMAS.

Z. Wang, S. Zhou and J. E. Klaunig. *Department of Pharmacology and Toxicology, Center for Environmental Health, Indiana University School of Medicine, Indianapolis, IN.*

Hemangiosarcomas are malignant vascular tumors, rare in humans but relatively common in mice (especially in liver). In mice, these tumors are inducible by both genotoxic and non-genotoxic agents. The mechanism for hemangiosarcoma induction remains unclear. We have previously demonstrated that Kupffer cell (the macrophage of the liver) activation secondary to chronic hemolysis, and ROS and VEGF production are involved in 2-butoxy ethanol induced hemangiosarcomas. In the present study, we investigated whether macrophages and ROS are also involved in troglitazone (TGZ) (an anti-diabetic drug) induced hemangiosarcomas. Exposure to TGZ directly stimulated growth of endothelial cells and macrophages at 30 μM and 1 μM, respectively. Co-culture of endothelial cells with macrophages alone or macrophages pretreated with TGZ (1 μM, 4 hr) increased endothelial cell growth by 26 % and 30 %, respectively. We further found that TGZ induced ROS in endothelial cells but inhibited ROS production in macrophages. Macrophages alone did not induce ROS in endothelial cells, while macrophages pretreated with TGZ significantly increased ROS generation in endothelial cells. In addition, we investigated the VEGF gene expression status using real-time PCR. Following exposure to TGZ, the mRNA level of VEGF in endothelial cells increased 1.4-fold at 24 hr, and 2.6-fold at 48 hr. The increase of VEGF levels were 1.7- and 4.9-fold in endothelial cells co-cultured with macrophages only and macrophages pretreated with TGZ for 48 hr, respectively. Taken together, these results suggest that TGZ stimulates endothelial cell growth through induction of ROS and upregulation of VEGF gene expression. In addition, these findings support the involvement of ROS and macrophages in TGZ-induced hemangiosarcomas. Supported in part by NIH CA100908 to JEK.

PS 902 EVALUATION OF THE EFFECTS OF THE PPARγ AGONIST TROGLITAZONE ON CYTOTOXICITY AND MITOGENESIS OF ENDOTHELIAL CELLS: DIFFERENCES BETWEEN HUMAN AND MOUSE.

S. Kakiuchi-Kiyota[1], R. K. Singh[1], J. A. Vetro[2], M. L. Varney[1], H. Han[2], S. Suzuki[1], K. L. Pennington[1], L. L. Arnold[1] and S. M. Cohen[1]. [1]*Pathology and Microbiology, University of Nebraska Medical Center, Omaha, NE and* [2]*Pharmaceutical Sciences, University of Nebraska Medical Center, Omaha, NE.*

Long-term treatment with high doses of troglitazone (TG) increased the incidence of hemangiosarcomas in various tissues in mice. We observed increased endothelial cell (EC) proliferation in the liver and brown and white adipose tissues in female B6C3F1 mice treated with 400 and 800 mg/kg for 4 weeks. The purpose of this study was to determine if TG directly increases EC proliferation in human (HMEC1) and in mouse (MFP MVEC) microvascular endothelial cells. Cytotoxicity occurred in a dose dependent manner in HMEC1 and MFP MVEC at high doses of TG. The LC50 on day 3 was 17.4 μM in HMEC1 and 92.2 μM in

MFP MVEC. No changes were observed by MTT assay when HMEC1 cultured with low concentrations of growth factors were treated with TG (0.001 to 20 μM) for 1, 3 and 6 days. In contrast, an increase in viability was observed when MFP MVEC cultured with a low FBS concentration (1%) were treated with low doses of TG (5 to 10 μM). DNA synthesis measured by thymidine incorporation decreased after day 1 in MFP MVEC cultured with 1% FBS and without TG. In contrast, DNA synthesis persisted in MFP MVEC cultured with low doses of TG until day 3. To investigate possible effects on apoptosis, the percentage of apoptotic cells was compared under the same culture conditions by flow cytometry using Annexin V and PI staining. Low doses of TG reduced the total number of apoptotic cells, primarily in late apoptosis. In summary, 1) TG induces increased EC proliferation in vivo in mice; 2) TG is cytotoxic both to human and mouse EC at high concentrations, but mouse EC are more resistant to TG; 3) when growth factors are reduced in the medium, TG increases the viability of mouse microvascular EC but not humans by increased cell proliferation and suppression of apoptosis. Thus, TG may induce hemangiosarcomas in mice, at least in part, through direct effects on mouse microvascular EC.

PS 903 OPTIMIZATION OF *IN VITRO* TESTING TO ENHANCE THE PREDICTIVITY OF PRE-CLINICAL DATA: D, L-SOTALOL.

D. Salvail, I. Parent, V. Lessard, A. Bouchard and C. E. Laurent. *IPS Therapeutique Inc., Sherbrooke, QC, Canada.*

Limitations inherent to preclinical safety pharmacology models, especially those used for cardiovascular safety testing have confined their ability to predict drug induced prolonged QT (LQT) to qualitative assessments. However, methods are being refined and results are accumulating which suggest that these preclinical models, when used in carefully designed studies, can adequately quantify cardiac risk and provide reliable safety margins for compounds in development. This investigation attempted to further refine study designs in order to obtain a better correlation between clinical events and preclinical data for d,l-sotalol, a beta adrenergic blocker with class-III antiarrhythmic actions known for causing LQT. Modified hERG inhibition and rabbit action potential duration (APD) assays using various stimulation protocols were used to obtain a better correlation with isolated heart data as well as published clinical data. Action potential-clamp of hERG-expressing HEK293 cells yielded an IC50 value of 85 μM for d,l-sotalol. The same 85 μM caused a 42% prolongation of the APD90 in rabbit mid-myocardial cells stimulated at 0.7 Hz. The effect was reverse-rate dependent, increasing to 53% at 0.3 Hz stimulation rate. The effect was further enhanced to 59% in hypokalemic conditions. In rabbit Langendorff hearts, 13 out of 20 hearts exhibited arrhythmia following exposure to 85 μM sotalol, a ratio which increased to 16 out of 20 hearts when the hearts were slowed by co-perfusion with 1 μM acetylcholine, and further increased to 18 out of 20 hearts in hypokalemic conditions. QT intervals were prolonged by 34 ms, 50 ms (+ acetylcholine) and 63 ms (acetylcholine + hypokalemia). These results suggest that in-vitro testing can be made more predictive by fine-tuning the conditions of experimentation to better mimic clinical factors, in order to obtain a closer correlation between pre-clinical in-vitro models and clinical data.

PS 904 BLOOD PRESSURE MEASUREMENTS IN JUVENILE BEAGLE DOGS: DIRECT AND INDIRECT.

J. Perron, H. Penton, V. Frenette and C. Copeman. *Toxicology, Charles River, Senneville, QC, Canada.* Sponsor: M. V√©zina.

The requirement for conduct of preclinical studies in juvenile populations for drugs which may be intended for use in juvenile human populations is increasing. In our laboratories, monitoring blood pressure (BP) is frequently required during the conduct of this type of study, and therefore, methods of direct and indirect blood pressure measurement were investigated to accomplish this objective. Indirect BP measurement: Juvenile beagle dogs were acclimated to the sling and cuff prior to data collection, and appropriately restrained during the monitoring period. Indirect BP measurements were recorded using a cuff, placed on the thigh of the dogs, and Mini Torr Plus or Minipack 911 monitor. Direct BP measurement: Instrumentation of juvenile dogs, involving the placement a DSI TL11M2 D70 PCT transmitter implant, took place at least one week prior to data recording. Direct BP recordings were collected using the Life Science Suite™ Ponemah Physiology Platform P3 software system (version 4.1) via Data Sciences International (DSI) Open A.R.T. version 2.3. Animals remained in their cages and were not restrained during the monitoring period. Results: Mean blood pressure recorded using the indirect method in this juvenile beagle dog population generally ranged between 80 to 160 mmHg, though occasionally rising as high as slightly above 200 mmHg. Mean blood pressure recorded using the direct method provided ranges of approximately 120 to 160 mmHg when the animal was resting, with occasional peaks corresponding to periods of activity, generally ranging from 160 to 200 mmHg. Conclusion: Collection of either direct or indirect blood pressure is feasible during the conduct of preclinical toxicology studies in juvenile animals. Overall, the data collected is comparable using both methods, however, the variability observed in the data is reduced when using the direct BP method.

PS 905 INHIBITORY EFFECTS OF OXYSTEROLS AND SATURATED AND UNSATURATED FATTY ACIDS ON HUMAN CARBOXYLESTERASE 1 AND THP1 MONOCYTE/MACROPHAGE HYDROLYTIC ACTIVITIES.

M. K. Ross[1], K. Herring[1], S. Xie[1], P. M. Potter[2] and J. A. Crow[1]. [1]*Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS and* [2]*Molecular Pharmacology, St. Jude Children's Hospital, Memphis, TN.*

Macrophage reverse cholesterol transport halts the progression of atherosclerosis and promotes its regression. Hydrolysis of cholesteryl esters in macrophages is the rate limiting step in this process. The best candidate enzyme for this hydrolase activity is cholesteryl ester hydrolase (CEH), also known as carboxylesterase 1 (CES1). CES1 has an important role in xenobiotic metabolism. Here, we studied the inhibitory effects of several oxysterols, cholesterol, and fatty acids of physiological relevance on the carboxylesterase activity of THP1 cell lysates and pure recombinant human CES1. Our results for oxysterols using THP1 cells show: (1) 27-hydroxycholesterol is a potent inhibitor (IC_{50} ~8nM); (2) 24(S),25-epoxycholesterol has moderate inhibitory activity (IC_{50} ~5μM); (3) 22(R)-hydroxycholesterol, 24-hydroxycholesterol, 25-hydroxycholesterol, and 7-ketocholesterol all exhibit minimal inhibitory activity; (4) cholesterol has no inhibitory effect. 27-Hydroxycholesterol appears to act as a noncompetitive inhibitor of pure CES1 with K_i ~7nM. Furthermore, unsaturated fatty acids are better inhibitors of CES1 than saturated fatty acids, with arachidonic acid being the most potent fatty acid tested (IC_{50} ~1.7μM). The degree of unsaturation seems to correlate with inhibition potency (rank order of unsaturated fatty acids: arachidonic>γ-linolenic≈linoleic>oleic). In general, short-chain saturated fatty acids are better inhibitors than long-chain saturated fatty acids. Our results suggest that oxysterols and fatty acids might influence cholesterol metabolism in macrophages by directly inhibiting the cholesteryl ester hydrolase activity of CES1, thus reducing the rate of cholesterol efflux from these cells. [Supported by NIH 1R15ES015348]

PS 906 EVALUATION OF ELECTROCARDIOGRAMS IN TOXICOLOGY STUDIES: HOW MUCH IS ENOUGH?

A. Jenkins, A. Mitchell, T. Cleven, D. Gumpf and R. Sarazan. *Covance Laboratories Inc., Madison, WI.*

In a typical toxicology study, approximately one minute of electrocardiographic (ECG) data is obtained at specified time points while the animals are either physically restrained or anesthetized. The emergence of noninvasive ECG monitoring devices has enabled continuous monitoring for an extended period of time; from two hours up to 24 hours continuously or ranging from 120 to 1400 one-minute intervals. These novel techniques enable the collection of more than 100 times the typical study data thereby increasing the amount of time and effort it takes to analyze the data for a study. The hypothesis formulated is does the sensitivity increase by detecting changes in measured intervals of continuous data collection when compared to the measured intervals of only a few ECG complexes. In this study, 32 cynomolgus monkeys (n=4/group/sex) were given a single oral dose of 0, 10, 50, 175 mg of moxifloxacin/kg of body weight. ECG data were evaluated by measuring 20 consecutive ECG complexes within each one minute segment for each pre-determined time point: predose, 2, 4, 6, 18, and 24 hours postdose. A comparison was made between the data set of 20 consecutive measured ECG complexes versus the data set generated with five minute averages of measured ECG complexes. Measurements for the five minute averages were achieved with the use of semi-automated ECG template analysis software. The 20 consecutive measured ECG complexes resulted in the mean covariate differences of QTc ranging from 26 to 50 msec (or ~8 to 15% increase). However, the five minute averages of measured ECG complexes resulted in the mean covariate differences of QTc ranging from 12 to 62 msec (or ~4 to 19% increase). This indicates that by increasing the number of measured ECG complexes from 20 consecutive waveforms to five minute averages, the sensitivity to detect QTc increases.

PS 907 PLASMA NITRITES, ENDOTHELIAL FUNCTION AND THE EFFECTS OF DIESEL INHALATION.

A. P. Pettit[1, 2], J. Allen[3], S. Gandhi[2], H. Kipen[2] and A. Gow[1]. [1]*Toxicology, Rutgers University, Piscataway, NJ,* [2]*UMDNJ-RWJMS, Piscataway, NJ and* [3]*Duke University, Durham, NC.*

Plasma nitrite(NO2-) has been proposed as a biochemical marker of endothelial function.The rapid oxidation of NO2- to nitrate brings into question its usefulness in clinical studies.In order to determine the viability of NO2- as a biomarker, we

have assessed its stability in plasma over time and the effect of sample storage.By addition of exogenous NO2- to freshly prepared human plasma we have determined that NO2- consumption is second order and that the rate is low below 1μm at 4°C.As human plasma NO2- concentrations are approximately nM, one would predict that samples can be kept on ice for at least 3 hours.We have confirmed this using plasma from healthy subjects.Here we show that snap freezing at -80°C and thawing did not significantly reduce NO2- concentration;indicating that samples can be stored for later analysis.Brachial artery occlusion and release, a hyperemic stimulus, we demonstrate increased plasma NO2- in healthy subjects;similar to the physiologic measure of endothelial function,brachial artery forearm-mediated dilation. Nitrite levels prior to hyperemic stimulus are similar in diabetic and healthy subjects.Following stimulus diabetics do not significantly increase NO2-.Endothelial dysfunction may also occur in response to particulate exposure, such as diesel, which may be exacerbated in the presence of disease.As diesel exhaust contains oxides of nitrogen, inhalation may lead to artifactual changes in NO2-.Therefore,we determined if these oxides contribute to plasma NO2- in the absence of stimulus.Analysis of 29 healthy subjects post diesel exposure revealed no significant change in plasma NO2-.Therefore, diesel exhaust inhalation does not artificially increase NO2- levels.In the future we will examine the effects of diesel on NO2- responses to hyperemic stimulus in control and diabetic subjects.These studies demonstrate the usefulness of plasma NO2- responses as a marker of endothelial function in healthy and diabetic subjects; and the potential for using this marker as a measure of diesel-exposure induced dysfunction.

PS 908 INHIBITION OF ISCHEMIA-INDUCED ANGIOGENESIS BY BENZO[A]PYRENE IN A MANNER DEPENDENT ON THE ARYL HYDROCARBON RECEPTOR.

S. Ichihara[2, 1], Y. Yamada[2], G. Ichihara[1], T. Nakajima[1], F. J. Gonzalez[3] and T. Murohara[4]. *[1]Occupational and Environmental Health, Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Department of Human Functional Genomics, Mie University Life Science Research Center, Tsu, Mie, Japan, [3]Laboratory of Metabolism, National Cancer Institute, NIH, Bethesda, MD and [4]Cardiology, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Objective: Smoking is an important risk factor for ischemic heart disease and peripheral vascular disease. We have investigated the effect of benzo[a]pyrene (B[a]P), a carcinogen of tobacco smoke and an agonist for the aryl hydrocarbon receptor (AHR), on hypoxia-induced angiogenesis. Methods and Results: Ischemia was induced by femoral artery ligation in wild-type and AHR-null mice, and the animals were subjected to oral administration of B[a]P (125 mg/kg) once a week. Exposure to B[a]P up-regulated the expression of metallothionein in the ischemic hindlimb and markedly inhibited ischemia-induced angiogenesis in wild-type mice. The amounts of interleukin-6 and of vascular endothelial growth factor (VEGF) mRNA in the ischemic hindlimb of wild-type mice were reduced by exposure to B[a]P. These various effects of B[a]P were markedly attenuated in AHR-null mice. Conclusions: B[a]P inhibited ischemia-induced angiogenesis in mice, and this effect was greatly diminished by ablation of the AHR. Our observations suggest that the loss of the inhibitory effect of B[a]P on ischemia-induced angiogenesis apparent in AHR-null mice may be attributable to maintenance of interleukin-6 expression and consequent promotion of angiogenesis through up-regulation of VEGF expression.

PS 909 NUCLEOSIDE REVERSE TRANSCRIPTASE INHIBITORS OF ALL SUBCLASSES INDUCE ENDOTHELIAL DYSFUNCTION AND COMPROMISE MITOCHONDRIAL FUNCTION.

V. Y. Hebert, S. Xue, B. Jiang, A. L. Khandelwal, J. A. Zavecz and T. R. Dugas. *Pharmacology, Toxicology & Neuroscience, LSU Health Sciences Center, Shreveport, LA.*

Nucleoside reverse transcriptase inhibitors (NRTI) are an important component of highly active antiretroviral therapy for HIV patients. Despite its effectiveness, a long-term use of NRTI leads to cardiovascular complications likely resulting from drug-induced mitochondrial toxicity. Our prior studies demonstrated that NRTI impair endothelial cell function in the vasculature via an increased production of mitochondria-derived reactive oxygen species. In this study, we investigated the effects of three subclasses of NRTI: thymidine analogues like AZT and stavidine (d4T); cytidine analogues, such as lamivudine (3TC); and adenosine analogues like didanosine (ddI). In mice orally administered pharmacologically relevant doses of NRTI for 2 weeks, endothelium-dependent vasorelaxation following acetylcholine administration and endothelium-independent relaxation by sodium nitroprusside was determined. In addition, we determined the mitochondrial locus of injury by measuring the activity of mitochondrial electron transport chain complexes in human umbilical vein endothelial cells (HUVEC) treated with equimolar doses of NRTI or their phosphorylated metabolites. Our in vivo data suggests that all three subclasses of NRTI impaired endothelium-dependent vasodilation, with the cytidine analog lamivudine having the most profound effect. The in vitro experiments showed direct inhibition for one or more mitochondrial complexes, and this effect was observed across all NRTI subclasses. Ongoing studies are aimed at determining the mechanism by which NRTI mediate mitochondrial electron transport.

PS 910 INHIBITORS OF NADPH OXIDASE, APOCYNIN AND DIPHENYLENEIODONIUM, MITIGATE OXIDATIVE STRESS BUT NOT CYTOTOXICITY IN H9C2 CARDIOMYOCYTES EXPOSED TO CHOLESTEROL SECOALDEHYDE.

L. Laynes, A. C. Raghavamenon and R. M. Uppu. *Environmental Toxicology and the Health Research Center, Southern University and A&M College, Baton Rouge, LA.*

Cholesterol secoaldehyde (ChSeco), a putative product of cholesterol ozonation in aqueous environments, has been shown to induce apoptosis in rat embryonic cardiomyocytes (H9c2). Depletion of intracellular glutathione and associated increase in the formation of reactive oxygen species (or *vice versa*) have been suggested to be the initial events that lead to activation of both extrinsic and intrinsic pathways of apoptosis in these cells. In an attempt to understand the significance of the plasma membrane NADPH oxidase system, we pretreated the H9c2 cells with apocynin, diphenyleneiodonium chloride (DPI), and admixtures of apocynin and DPI for 1 h and then exposed to ChSeco at concentrations close to IC^{50}. There was a significant decrease in the production of intracellular peroxide-like substances (DCF fluorescence) in the H9c2 cells treated with apocynin and DPI followed by exposure to ChSeco. However, it was found that in H9c2 cells pretreated with apocynin and DPI, the cytotoxic potential of ChSeco, measured based on MTS reduction, increased marginally instead of an expected decrease. It is plausible that, in addition to the plasma membrane NADPH oxidase system, there are other important sources (presumably mitochondria) of reactive oxygen species (ROS) that contribute to the enhanced oxidative stress status in the H9c2 cells exposed to ChSeco. Alternatively, the 'so-called' inhibitors of NADPH oxidase may have antioxidant and yet other unknown activities that need further investigation. [Funding support from NSF (grant number HRD 0450375) and NIH (grant number P20 RR 16456) to RMU is acknowledged; Corresponding author, e-mail: rao_uppu@subr.edu.]

PS 911 INVESTIGATION OF INTRACELLULAR CALCIUM CHANGE IN CULTURED CARDIOMYOCYTES USING LASER SCANNING CYTOMETRY.

C. Hu, K. French and K. Frazier. *Safety Assessment, GlaxoSmithKline, King of Prussia, PA.*

Increased intracellular Ca^{2+} concentration is involved in several separate mechanisms of drug-induced cardiac ventricular arrhythmia. We developed and optimized an *in vitro* model for evaluating intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) using the mouse cardiomyocyte cell line HL-5 by laser scanning cytometry and Fluo-4 AM as a fluorescent indicator. Ionomycin (INM), a Ca^{2+} ionophore, was used as an assay control and compared with effects elicited by the positive controls, Bay-K 8644 (BK, an L-type Ca^{2+} channel activator), and thapsigargin (TG, a sarcoplasmic reticulum Ca^{2+} ATPase inhibitor). Both instant and delayed effects on $[Ca^{2+}]_i$ were assessed. Instant effects on $[Ca^{2+}]_i$ were measured at 30 sec intervals ranging 2 min before and after treatments. Delayed effects were assessed at 0.5, 30, 120 and 360 min post treatment. In instant assays, INM robustly increased $[Ca^{2+}]_i$ by 80% compared with vehicle control. BK and TG instantly increased $[Ca^{2+}]_i$ by 40%. The effect with BK treatment was more sustained than with TG. In delayed assays, treatment with INM immediately prior to measurement at each timepoint increased $[Ca^{2+}]_i$ to similar levels, ensuring functionality of the model. BK caused a rapid increase of $[Ca^{2+}]_i$, which slowly decreased over 360 min. TG caused similar $[Ca^{2+}]_i$ increase but it diminished to the vehicle level by 30 min. TG induced cytotoxicity by 120 min and cell death at 360 min. This novel, sensitive *in vitro* imaging method successfully detects changes in $[Ca^{2+}]_i$ in HL-5 cells occurring via different mechanisms, and has the potential for use in addressing cardiac toxicity issues arising in drug development.

PS 912 MAINSTREAM CIGARETTE SMOKE (MS) AFFECTS THE CARDIOVASCULAR SYSTEM OF SPONTANEOUSLY HYPERTENSIVE RATS (SHR).

R. R. Schleef[1], K. Meurrens[2], A. Berges[2], K. Stolle[3], C. Eggert[3], S. Diehl[3], T. Wallerath[3] and M. Lietz[3]. *[1]Life Sciences, Altria Client Services, Richmond, VA, [2]Philip Morris Research Laboratories bvba, Leuven, Belgium and [3]Philip Morris Research Laboratories GmbH, Cologne, Germany.* Sponsor: G. Patskan.

Cigarette smoking elevates the risk for cardiovascular disease. This study investigates the effects of MS [450, 900, and 1350 ug total particulate matter (TPM)/day; 5 days/week; 90 days] on cardiac functional and phenotypic changes, as well as on

cardiovascular gene expression. Langendorff analysis of heart function revealed a statistically significant decrease in baseline perfusion pressure for the SHR groups exposed to 900 and 1350 ug TPM/day in comparison to sham ($p \leq 0.05$). Exposure of SHR to 900 ug TPM/day resulted in a statistically significant reduction in post-ischemic recovery after 30 minutes of global ischemia compared to sham ($p \leq 0.05$). Ratios of both heart weight and left ventricular weight to (1) body weight, (2) brain weight, and (3) tibia weight were statistically significantly increased for the 900 and 1350 ug TPM/day groups compared to sham ($p \leq 0.05$). Affymetrix gene chip analysis indicated that MS induced changes in a panel of ventricular genes. This was confirmed by PCR analysis (e.g., increased tissue inhibitor of metallopeptidase 1 in the 1350 ug TPM/day compared to sham animals; $p \leq 0.05$). Multi-analyte profiling of 67 serum proteins revealed statistically significant changes in several markers after exposure to 900 ug TPM/day including increases in interleukin 10, macrophage chemoattractant proteins 1 and 3, stem cell factor, and tissue inhibitor of metalloproteinase ($p \leq 0.05$ versus sham). A statistically significant increase in the platelet activation marker 2, 3 dinor thromboxane B1 was detected in urine of SHR exposed to 1350 ug TPM/day compared to sham ($p \leq 0.05$). The data suggest that this model system may be useful in dissecting the mechanisms involved in smoke-induced cardiovascular disease and potentially for screening reduced-risk tobacco products.

PS 913 GENDER DIFFERENCES IN THE PULMONARY REGENERATIVE RESPONSE TO NAPHTHALENE-INDUCED BRONCHIOLAR EPITHELIAL CELL INJURY.

J. R. Oliver[1, 2] and J. Hu[1, 2]. [1]*Physiology and Experimental Medicine, Hospital for Sick Children, Toronto, ON, Canada and* [2]*Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada.*

Substantial epidemiological evidence suggests that gender affects the incidence and severity of several pulmonary diseases, such as chronic obstructive pulmonary disease and lung cancer, which are more common in non-smoking females than in non-smoking males. Previous studies have shown gender differences in the susceptibility to naphthalene-induced lung injury in mice where the damage to non-ciliated secretory bronchiolar epithelial (Clara) cells was found to occur earlier and to be more extensive in females than in males. However, very little is known about whether there are any gender differences in the subsequent lung repair response. The aim of this study was to investigate whether gender plays an important role in the pulmonary regenerative response to naphthalene-induced Clara cell ablation. Adult male and female mice were injected ip with either a low (50 mg/kg), medium (100 mg/kg), or high (200 mg/kg) dose of naphthalene, and lung tissue regeneration was examined by immunohistochemical staining for the cell proliferation marker: Ki-67 and the mitosis marker: phosphohistone-3. Histopathological analysis showed that Clara cell injury was more prominent in the lungs of female mice as compared to male mice after injection with any of the three different naphthalene doses. Cell proliferation and mitosis in both the terminal bronchiolar epithelium and peribronchiolar interstitium of female mice was found to be significantly greater than that of male mice after treatment with the low and medium doses. However, after treatment with the high dose, lung regeneration was attenuated and delayed in female mice, while male mice mounted an adequate and timely regenerative response. Taken together, these findings show that there are clear gender differences in naphthalene-induced lung injury and repair.

PS 914 PULMONARY EMBOLI AND DOSE-RELATED IMPAIRMENT OF CARDIOPULMONARY FUNCTION BY THE INTRAVENOUS INJECTION OF PRECIPITATED CALCIUM SALTS IN ANESTHETIZED RATS.

S. Toyoshima, T. Nakagawa, M. Suzue, Y. Hayami, N. Emi, O. Sawamoto, S. Masumi and Y. Nakashima. *Research and Development Center, Otsuka Pharmaceutical Factory, Inc., Tokushima, Japan.* Sponsor: T. Satoh.

If chemical incompatibility exists, crystals may precipitate in intravenous admixture solutions. Respiratory distress and pulmonary emboli secondary to accidental infusion of precipitates of calcium salt have been reported in patients receiving parenteral nutrition. However, the relationship between the amount of precipitate and its effects has not been studied. In this study, we examined the effects of intravenous injection of calcium salt reagents on cardiopulmonary function in rats. Anesthetized rats (n = 5) were injected intravenously with calcium hydrogen phosphate suspension ($CaHPO_4$, 10, 30, or 60 mg/kg), calcium carbonate suspension ($CaCO_3$, 10, 30, or 60 mg/kg), or saline solution. Respiratory rate, heart rate, arterial pressures, and arterial blood gases were measured for 90 min after injection. Histopathological changes in the lungs were evaluated at 90 min. The injection of $CaHPO_4$ resulted in dose-related decreases in arterial pressures and oxygen partial pressures in arterial blood (PaO_2) at 30 and 60 mg/kg and death in three of five animals at 60 mg/kg, although the effects were insignificant at 10 mg/kg. Dose-dependently, the $CaHPO_4$ also caused increases in lung weight, and histopathologically, crystals obstructed the pulmonary microvasculature at all the dose levels. No significant changes were observed in other parameters. The effects of $CaCO_3$ were similar but weaker than those of $CaHPO_4$ and no animals died. It was concluded that intravenous injection of precipitated calcium salts caused pulmonary emboli and dose-related impairment of cardiopulmonary function in anesthetized rats.

PS 915 ARSENATE AUGMENTS CHROMIUM–EVOKED PULMONARY INJURIES AND SIGNALING IN MICE.

T. Yoshida, H. Tajima, A. Ohnuma, T. Fukuyama, K. Hayashi, S. Yamaguchi, R. Ohtsuka, M. Tomita, S. Kojima, M. Takeda, T. Kosaka, N. Nakashima, K. Ebino and T. Harada. *Toxicology, Institute of Environmental Toxicology, Joso, Ibaraki, Japan.*

Chromated copper arsenate (CCA) has been used worldwide as a wood preservative that can cause adverse impacts on human health. Although chromium (Cr) and arsenic (As) are known to cause respiratory diseases in human, combined effects of these metals have not been elucidated in vivo. Herein, male C57BL/6J mice were intratracheally instilled arsenate (As(V)), Cr(VI) and/or their mixture and sacrificed 2, 7, or 14 days after instillation to determine pulmonary toxic injuries. We found that the cotreatment of Cr(VI) with As(V) caused pulmonary inflammation and subsequent fibrosis, as assessed by lung histopathology, mRNA expression (type I collagen and CCR2), and leukocyte count and cytokine/chemokine expression (IL-6, MCP-1, MIP-1beta, RANTES, and IL-10) in bronchoalveolar lavage (BAL). Exposure to Cr(IV) rather than As(V) had a potential to induce pulmonary toxicity, although each metal resulted in no overt impact. Concurrent As(V) exposure worsened Cr(VI)-induced acute pulmonary injuries with increases in IL-6 level and LDH activity in BAL, and neutrophil sequestration and caspase activities in the lung. We further provide evidence that oxidative stress and MAPK signaling were involved in response to combined treatments: enhanced ROS generation and increased both reduced and oxidized glutathione contents, along with increases in mRNA levels of catalytic subunit of glutamylcysteine ligase, glutathione peroxidase 2, and heme oxygenase-1; and phosphorylation of ERK and JNK. These findings suggest that acute pulmonary responses were enhanced by co-administering Cr(VI) with As(V), followed by the development of fibrosis, and these effects might be associated with oxidative stress and MAPK signaling.

PS 916 UNDERSTANDING THE GENETIC BASIS OF OZONE SENSITIVITY IN THE NEONATAL MOUSE LUNG USING AN INTEGRATIVE GENETIC AND GENOMIC APPROACH.

E. M. Vancza, A. Gunnison, K. Galdanes, J. Lyon and T. Gordon. *Environmental Medicine, New York University School of Medicine, Tuxedo, NY.*

Ozone (O_3) is a powerful oxidant and respiratory irritant that leads to airway inflammation and pulmonary dysfunction. Although a greater susceptibility to inhaled O_3 in children is not established, rodent studies have shown neonates to be more sensitive than adults. Further, mouse studies in our lab showed clear and quantitative age and interstrain differences in response to O_3 inhalation, and classic and *in silico* linkage analyses revealed significant quantitative trait loci (QTLs) associated with O_3-induced lung inflammation and injury in neonates (15 to 16d old). Using micro-array technology in the current study, we integrated gene expression data with our QTLs to name candidate genes that may play a role in age-related, O_3 sensitivity. Adult and neonatal mice from resistant (A/J) and sensitive (Balb/cJ, SJL/J) strains were exposed to 5h 0.8ppm O_3 or air. One hour later, lungs were removed and snap-frozen, RNA was extracted, and cDNA was prepared and hybridized to Affy Mouse 430 2.0 gene chips (n=9 mice/group; 3 samples pooled/chip (3 chips/group); 36 total chips). Expression fold-changes (O_3/Air) were calculated and analyzed using MeVv4.1 software. A 2-way ANOVA revealed significant age:strain interactions for 3200 of 40,000 gene probes. Post-hoc testing coupled with linear expression matrix (LEM) visualization of our QTL regions narrowed this list to <50 genes, some of which (Foxp1 and 2 (chr 6), Adm and Swap70 (chr 7)) were identified in our *in silico* haplotype mapping study. Validation of these candidate genes through RT-RTPCR is currently underway along with further expression analysis using DAVIDv6 to identify biological pathways and functions associated with these genes. Transgenic and KO mouse models are also being planned. Overlapping genetic and genomic studies to examine age-related O_3-sensitivity in mice has given us greater insight into the gene-specific etiology of this complex trait and may provide us with a deeper understanding of comparable pulmonary disease in children.

PS 917 DIESEL EXHAUST PARTICLE EXPOSURE INDUCES ANGIOGENESIS.

Q. Sun[1], N. Kherada[1], A. Wang[1], X. Hong[3], L. Zheng[1], J. Deiuliis[1], C. Quan[2], T. Kampfrath[1], L. Chen[2] and S. Rajagopalan[1]. [1]*The Ohio State University, Columbus, OH,* [2]*New York University, Tuxedo, NY and* [3]*Dongfang Hospital, Fuzhou, China.*

Background: Epidemiologic studies have shown a strong link between air pollution exposure and cancer morbidity and mortality. Although multiple mechanisms have been proposed, there are no studies mechanistically evaluating the impact of diesel exhaust, primarily generated from automobile sources, on angiogenesis that cancers are dependent upon for their growth. We hypothesized that exposure to diesel exhaust particles (DEP) induces angiogenesis both *in vivo* and *in vitro*. Methods: C57BL/6 mice that underwent unilateral hindlimb ischemia surgery were exposed with to either DEP or filtered air 6 hr/d, 5 d/wk in a whole body exposure chamber for 2 months. In vitro studies of capillary sprouting were done by exposing aortic rings and confluent human umbilical vein endothelial cells (HUVECs) to various concentration of DEP (5, 15, 30 μg/ml). Gene expression of major angiogenesis regulators vascular endothelial growth factor (VEGF) and Heme oxygenase (HO)-1 was performed using quantitative RT-PCR. Results: DEP exposure induced 6-fold increase in vascular volume in the ischemic hindlimbs and 4-fold increase in the non-ischemic hindlimbs compared to the filtered air by micro-CT imaging. DEP exposure also enhanced CD31, α-smooth muscle actin, and NG2 proteoglycan expression in the ischemic hindlimb muscle demonstrated by immunohistochemical staining. Capillary sprouting assay showed marked increase in capillary tube numbers (dose dependant) and tube length (non dose dependant) when aortic rings were incubated with DEP *in vitro* compared to the controls. DEP exposure also increased VEGF and HO-1 mRNA expression in *in vitro* endothelial cell experiment co-cultured with DEPs via RT-PCR. Conclusion: DEP exposure induces angiogenesis through upregulation of VEGF and HO-1.

PS 918 DOWNREGULATION OF POLYAMINE BIOSYNTHESIS BY DIETARY RESTRICTION ATTENUATES BLEOMYCIN-INDUCED PULMONARY FIBROSIS.

N. M. Elsayed[1, 2] and D. F. Tierney[3]. [1]*Early Drug Development, Toxicology, Celgene Corp, Summit, NJ,* [2]*Anatomy and Cell Biology, SUNY Downstate Medical Center, Brooklyn, NY and* [3]*Respiratory Disease, University of California, Los Angeles, CA.*

We have observed previously that bleomycin (BLM) administration results in upregulation of lung polyamine (PA) and hydroxyproline (HP) biosynthesis suggesting that BLM-induced pulmonary fibrosis may be associated with PA metabolism. Thus, we postulated that PA downregulation may reduce BLM pulmonary toxicity. However, studies using the metabolic inhibitor difluoromethylornithine to deplete PA were unsuccessful and enhanced BLM toxicity. In an earlier report (Elsayed et al, 1988), we observed that food restriction (FR) downregulate PA metabolism and cell replication and reduce oxygen toxicity in the lung. In this study we examined whether FR would attenuate pulmonary BLM toxicity. Sprague-Dawley rats were freely fed (FF) or food restricted (FR) to 20% of the average FF animals' dietary intake for 7 (FR-7) or 21 days (FR-21) followed by intratracheal instillation of BLM (1.5 unit/rat) or saline. After treatment, all rats were FF for an additional 14 days recovery then euthanized. We found that with BLM treatment, body weight decreased 40% and 20%, $p<0.05$ in FF and FR-7, respectively, but remained unchanged in FR-21 rats compared to saline controls. Lung weight was significantly elevated with BLM treatment in all animals, 82% and 97%, in FF and FR-7 rats, but only 40% in FR-21 rats. Lung PA metabolism including ornithine decarboxylase and S-adenosylmethionine decarboxylase enzyme activities, and putrescine, spermidine and spermine contents was significantly upregulated in BLM-treated FF and FR-7 rats, but was unchanged in FR-21 rats. Concomitantly, lung HP content was significantly increased, 207% in FF and 98% in FR-7 ($P<0.05$), but only 16% (NS) in FR-21 rats. These results suggest that FR for at least 21 days may attenuate pulmonary BLM toxicity, in part, by downregulating PA biosynthesis.

PS 919 ACONITINE CHALLENGE TEST REVEALS A SINGLE EXPOSURE TO AIR POLLUTION CAUSES INCREASED CARDIAC ARRHYTHMIA RISK IN HYPERTENSIVE RATS.

M. S. Hazari, N. Haykal-Coates, D. W. Winsett, D. L. Costa and A. K. Farraj. *Experimental Toxicology Division, Environmental Protection Agency, Research Triangle Park, NC.*

Epidemiological studies demonstrate a significant association between arrhythmias and air pollution exposure. Sensitivity to aconitine-induced arrhythmia has been used repeatedly to examine the factors that increase the risk of such cardiac electrical dysfunction. In this study, we are the first to use a technique known to elicit arrhythmia to examine whether inhalation exposure to particulate air pollutants or gaseous irritants increases the risk of arrhythmia being triggered in a rat model of hypertension. Spontaneously hypertensive rats implanted with radiotelemeters were exposed for 3 hours to 3mg/m3 (high), 1mg/m3 (med) or 0.45mg/m3 (low) metal-rich synthetic residual oil fly ash (s-ROFA), 3ppm acrolein, or filtered air. Arrhythmogenesis was assessed 24 hours later in urethane-anesthetized animals by continuous intravenous infusion of aconitine while heart rate, ECG and ventilatory parameters were monitored. Sensitivity to arrhythmia was measured as the threshold dose of aconitine required to produce ventricular premature beats (VPB), ventricular tachycardia (VT), and ventricular fibrillation (VF). Rats exposed to filtered air developed VPB's, VT, and VF successively during aconitine infusion. Rats exposed to low, med and high s-ROFA, and acrolein developed VPB's, VT, and VF at significantly lower doses of aconitine than air-exposed animals. The cumulative dose of aconitine required to elicit these responses was lowest in animals exposed to acrolein followed by high s-ROFA. Paradoxically, arrhythmia was elicited at lower doses of aconitine in low s-ROFA-exposed animals than med S-ROFA. These findings suggest that a single exposure to a toxic air pollutant, whether particulate or gaseous, can increase the sensitivity of the cardiac electrical conduction system and trigger arrhythmia; which poses a particular health risk to individuals with cardiovascular disease. (This abstract does not reflect EPA policy.)

PS 920 DETERMINATION OF THE SENSORY IRRITANT POTENTIAL OF UCAR™ N-PROPYL AND UCAR™ N-BUTYL PROPIONATE IN SWISS WEBSTER MICE.

S. M. Krieger, W. M. Snellings, K. M. Anklam and J. A. Hotchkiss. *The Dow Chemical Company, Midland, MI.*

UCAR™ n-propyl and UCAR™ n-butyl propionate are solvents commonly used in automotive refinishes, OEM coatings, appliance coatings, cleaning fluids, and printing inks, and as polymerization solvents for high solids acrylic resins. Since these products are not expected to be used by consumers and tight engineering controls during manufacturing limit exposure, the human irritation response has not been well characterized. To better understand potential levels for irritation an RD_{50} assay (RD_{50} = concentration causing a 50% reduction in baseline respiration rate; ASTM Method E 981-04), was conducted to determine the sensory irritant potential in mice. The RD_{50} value can be used to evaluate occupational exposure limits (OELs) and empirical evidence indicates that the threshold limit value (TLV) for many irritant chemicals falls within 0.01 - 0.1 RD_{50}. Preliminary studies indicated that the RD_{50} in Swiss Webster mice was 535 ppm for n-propyl propionate. Lethality was observed at the highest exposure levels; however mice exhibited no clinical signs, including no signs of sedation or other central nervous systems (CNS) effects, at any exposure concentration. Sensory irritants stimulate nasal trigeminal C-fibers and decrease breathing rate. At high doses capsaicin induces receptor-mediated degeneration of sensory neurons, thus blocking irritant-induced respiratory depression. Groups of mice, with and without intravenous capsaicin pretreatment, were exposed to 0, 535 or 1000 ppm n-propyl propionate according to ASTM Method E 981-04. Exposures to chlorine and formaldehyde were included as controls to evaluate previously determined values. The response to chlorine and formaldehyde indicated that the capsaicin pretreatment was effective in attenuating chlorine- and formaldehyde-induced respiratory depression in Swiss Webster mice. Capsaicin pretreatment also attenuated the n-propyl propionate response indicating that the irritant properties of this chemical act through the trigeminal sensory irritant pathway.

PS 921 PREVENTION OF BLEOMYCIN-INDUCED LUNG FIBROSIS AND DYSFUNCTION BY PROSTAGLANDIN E_2

J. W. Card[1, 2], J. W. Voltz[2], L. M. DeGraff[2], F. B. Lih[2], G. P. Flake[2], K. B. Tomer[2] and D. C. Zeldin[2]. [1]*Cantox Health Sciences International, Mississauga, ON, Canada and* [2]*Division of Intramural Research, National Institute of Environmental Health Sciences, National Institutes of Health, Research Triangle Park, NC.*

Experimental and clinical data support the involvement of cyclooxygenase-derived eicosanoids in the pathogenesis of lung fibrosis. The present study determined the effects of increasing the circulating concentration of the potentially anti-fibrotic prostaglandin E_2 (PGE_2) in an experimental model of lung fibrosis and dysfunction. Male C57BL/6 mice were implanted subcutaneously with osmotic minipumps designed to deliver PGE_2 (1.44 μg/hour) or vehicle (15% ethanol in saline) continuously for 28 days. Seven days after pump implantation, mice were given a single dose of bleomycin (1 mg/kg body weight) or saline by oropharyngeal aspiration. Lung mechanics and indicators of lung inflammation and fibrosis were assessed 21 days following dosing with bleomycin or saline. Pilot studies revealed that serum PGE_2 was increased two- to three-fold for up to 28 days following implantation of minipumps containing PGE_2, confirming the utility of this method of prolonged administration. Compared to mice dosed with saline, mice dosed with

bleomycin had increased bronchoalveolar lavage fluid inflammatory cell content, increased histopathological lung fibrosis scores and a decline in static compliance indicative of lung stiffening (all $p<0.05$). Systemic PGE_2 administration did not appreciably alter airway inflammatory cell content but did result in lower histopathological scores and prevented the decline in static compliance in mice treated with bleomcyin (all $p<0.05$). These data reveal a protective effect of exogenous PGE_2 on bleomycin-induced lung fibrosis and dysfunction and suggest that targeted modulation of eicosanoid levels may prove beneficial in the treatment of lung fibrosis and associated functional decline.

PS 922 TOXICOLOGIC COMPARISON BETWEEN LIBBY AMPHIBOLE AND AMOSITE ASBESTOS FOLLOWING INTRATRACHEAL INSTILLATION IN RATS.

D. J. Padilla-Carlin[1], M. J. Schladweiler[2], U. P. Kodavanti[2], J. H. Shannahan[1], J. H. Richards[2], R. H. Jaskot[2], A. D. Ledbetter[2] and S. H. Gavett[2]. *[1]Curriculum in Toxicology, University of North Carolina-School of Medicine, Chapel Hill, NC and [2]Pulmonary Toxicology Branch, ETD, NHEERL, ORD, U.S. Environmental Protection Agency, Research Triangle Park, NC.*

An abnormally high incidence of asbestosis and mesothelioma has been reported in residents of Libby, Montana, after exposure to amphibole-contaminated vermiculite. However, the mechanistic basis for the toxicity of the Libby amphibole (LA) remains unclear. In the present study, LA and amosite (positive control) with aerodynamic diameter < 2.5 μm were prepared by a water elutriation technique. Male Fisher 344 rats (~235 g) were exposed to single bolus doses of either saline (SAL), amosite (0.5 mg/rat), or LA (0.5 or 5 mg/rat) by intratracheal instillation (n = 8/group). Animals were sacrificed 1 d or 2 wk after exposure and bronchoalveolar lavage (BAL) was performed. BAL from animals killed 1 d after amosite instillation had increased parameters of lung toxicity compared to SAL, which returned to baseline levels at 2 wk. Total cell counts, neutrophils, eosinophils, protein, lactate dehydrogenase (LDH), glutathione (GSH), albumin, n-acetyl glucosaminidase, and gamma-glutamyl transferase were increased in a concentration-dependent fashion at 1 d in BAL of rats exposed to LA compared to SAL. Most parameters returned to baseline levels for both LA groups at 2 wk, but protein, LDH, GSH, and albumin were elevated in the high dose LA group at 2 wk. Furthermore, increased ferritin, iron, transferrin, unsaturated iron-binding capacity, and total iron-binding capacity were detected in BAL after 1 d of exposure to amosite and LA (5 mg/rat), but at 2 wk, ferritin, heme, and transferrin remained elevated only in the high-dose LA group. These data indicate exposure to 0.5 mg amosite caused a higher degree of pulmonary injury and inflammation than at the same dose of LA; instillation of 5 mg LA resulted in increased parameters of lung toxicity at least 2 wk after exposure. Funding: EPA/UNC CR833237. Abstract does not reflect USEPA policy.

PS 923 SENSITIZATION OF THE SENSORY IRRITATION RESPONSE BY ADENOSINE.

D. N. Willis and J. B. Morris. *Toxicology Program, University of Connecticut, Storrs, CT.*

Our previous studies have suggested adenosine signaling pathways may be involved in initiation of the sensory irritation response. This response, characterized by decreased breathing frequency due to braking in the early phase of expiration, results from stimulation of nasal trigeminal nerves. The current study was performed to determine if nasal trigeminal responsiveness to irritants was increased through adenosine receptor-dependent pathways. Toward this end, sensory irritant responsiveness was measured in female C57Bl/6J mice immediately following subcutaneous injection of the adenosine precursor, adenosine 5'-monophosphate (AMP) or vehicle. To quantify the sensory irritation response, the time of expiratory braking was measured during irritant exposure by non-invasive plethysmography. Styrene (50 ppm) and capsaicin (0.2 mg/m3) were used as prototypical irritants. As assessed by plethysmography, both styrene and capsaisin induced a mild sensory nerve response (time of braking approximately 100 msec). For both irritants, the response was increased 2-4 fold in animals pretreated with AMP indicating sensitization of trigeminal nerves occurred. The AMP-sensitization was blocked by pretreatment with the broad acting adenosine receptor antagonist theophylline (20 mg/kg). The AMP-sensitization was also blocked by pretreatment with the adenosine A2 receptor antagonist 3,7-dimethyl-1-propargylxanthine (1 mg/kg). These results suggest adenosine A2 receptor stimulation leads to trigeminal nerve sensitization and enhanced sensory irritant responsiveness in the mouse. Airway mucosal adenosine levels are elevated in allergic airway disease. Adenosine A2 receptor signaling pathways may, therefore, represent a potential mechanism for the enhanced irritant responsiveness associated with allergic airway disease.

PS 924 COMPARATIVE EFFECTS OF DIESEL EXHAUST AND AMBIENT PARTICLES ON CARDIOVASCULAR SYSTEM.

C. Quan[1], Q. Sun[2], M. Lippmann[1] and L. Chen[1]. *[1]Environmental Medicine, New York University, Tuxedo Park, NY and [2]Environmental Health Sciences, Ohio State University, Columbus, OH.*

Air pollution has been associated with cardiovascular diseases (CVD) by many epidemiology studies. However, the components of air pollution that are responsible for the CVD are unknown and the mechanisms underlying the associations need to be elucidated. The objectives of this study were to investigate 1) whether subchronic inhalation of ambient particulate matter (PM), whole diesel exhaust (WDE), or diesel exhaust gases (DEG), leads to exacerbation of atherosclerosis, alteration of endothelial function, and pulmonary/systemic inflammation; 2) to what extent do WDE, and DEG, contribute to air pollution enhanced CVD; 3) whether there is interaction between DEG and ambient PM in inducing/enhancing cardiovascular effects. ApoE-/- mice were exposed via inhalation for 5 h/d, 4 d/wk, for up to 5 months (mo) to 5 different exposure atmospheres, including: 1) filtered air (FA), 2) concentrated ambient fine particles PM2.5 (CAPs, av. conc. 105 μg/m3), 3) WDE (436 μg/m3), 4) DEG (same as gases in WDE at 436 μg/m3), and 5) CAPs+DEG (PM: 113 μg/m3; Gas: same as WDE at 436 μg/m3). After 3 mo and 5 mo of exposure, lung lavage fluid and blood sera were analyzed for inflammation, and atherosclerotic plaques were quantified using 3 methods: non-invasive serial ultrasound imaging, H&E histology stain, and en-face Sudan IV stain. Vascular functions were assessed after 5 mo of exposure. The results of this study show: 1) Subchronic inhalation of CAPs, WDE and DEG all increased the serum VCAM-1 expression and enhanced the PE-induced vasoconstriction to a similar level; 2) For plaque exacerbation, the effects of CAPs > WDE >DEG = FA, indicating that PM (rather than gases), especially some components of the ambient PM (not present in WDE), were more responsible for the plaque development; 3) There were no interactive effects between CAPs and DEG on plaque exacerbation, vasomotor dysfunction, and pulmonary/systemic inflammation.

PS 925 COMPARISON OF INHALATION TOXICITY OF GENTAMICIN SOLUTION IN RATS AND DOGS.

H. Persson[1], R. Wolff[1] and M. Reed[2]. *[1]Nektar Therapeutics, San Carlos, CA and [2]Lovelace Respiratory Research Institute, Albuquerque, NM.*

Nebulized gentamicin solution was administered to rats (nose-only) and dogs (face mask) for 14 days followed by a 14 day recovery period. Mean inhaled doses were 0, 39, 123, and 245 mg/kg for rats over 30, 90, and 180 minutes, respectively, at 2 mg/L aerosol concentrations (MMAD 1.6- 2.9 μm). Because dogs would not tolerate exposures as long as rats, inhaled doses were limited to 0, 7, 14, and 41 mg/kg over 15, 30, and 60 minutes, respectively, at 1.2- 1.7 mg/L aerosol concentrations (MMAD 1.9- 2.5 μm). Therefore, comparable inhaled doses were achieved only at the low dose for rats and the high dose for dogs. Serum AUCs [14 ± 2 μg/mL*h (mean ± SD)] at 39 mg/kg in rats and 11 ± 7 μg/mL*h at 41 mg/kg in dogs] showed comparable exposure between the two species implying similar absorbed doses and hence indicating similar deposited lung doses. Rat exposures resulted in dose-related lung pathology manifest as an irritant reaction in the upper respiratory tract as well as alveolar histiocytosis, inflammation, airway epithelial metaplasia, and associated lymphomegaly in the lung tissue. This pathology was associated with high lung tissue gentamicin levels in rats measured 24 hours post dose on Day 14 (375 ± 33 μg/g at 39 mg/kg). Dose related kidney tubular necrosis, a well-known toxicity of parenteral gentamicin, was also observed. A No Observed Adverse Effect Level (NOAEL) was not established in the rat. The NOAEL for gentamicin in dogs was 14 mg/kg due to kidney tubular regeneration observed at 41 mg/kg. There were no test-article related effects on lung histopathology in dogs even at the highest inhaled dose of 41 mg/kg, in contrast to test-article related lung effects in rats at a similar inhaled dose of 39 mg/kg. The absence of any significant lung effects in the dog was associated with much lower lung tissue gentamicin levels 24 hours post dose on Day 14 (42 ± 11 μg/g at 41 mg/kg) compared to those measured in the rat. These results suggest that increased lung retention of gentamicin in rats vs dogs plays a role in the differential pathological findings.

PS 926 AN EVALUATION OF THE PERMISSIBLE EXPOSURE LIMIT OF INHALED SYNTROLEUM S-8 SYNTHETIC JET FUEL IN MICE.

S. S. Wong[1], A. N. Thomas[1], T. J. Desmarais[1], R. Lantz[2] and M. L. Witten[1]. *[1]Pediatrics, University of Arizona, Tucson, AZ and [2]Cell Biology and Anatomy, University of Arizona, Tucson, AZ.*

No current studies have examined pulmonary health effects associated with Syntroleum S-8 synthetic jet fuel. In order to gain an understanding about the cytotoxic effects, varied S-8 concentrations were used to determine the threshold concentration in which lung injury is observed. Methods and procedures were duplicated from a previous JP-8 jet fuel study to evaluate S-8 in contrast to JP-8.

C57BL/6 male mice were nose-only exposed to S-8 synthetic jet fuel for 1 hr/day for 7 days at average concentrations of 93, 352, and 616 mg/m3. Pulmonary function and respiratory permeability tests were performed 24 hours after the final exposures. No significant effects were observed at 93 mg/m3 S-8, but significant decreases were detected in expiratory lung resistance and a significant increase was observed with total lung compliance of the 357 mg/m3 group. Morphological examination and morphometric analysis of distal lung tissue revealed cellular damage in alveolar type II epithelial cells and terminal bronchial epithelial cells, with significant increases in volume density of lamellar bodies/vacuoles at 357 and 616 S-8 mg/m3. These results indicate increased surfactant production, which implicates damage. Evidence of lung injury was observed at relatively low concentrations, suggesting if synthetic jet fuel is utilized, the current permissible exposure limit (PEL) of 350 mg/m3 for S-8 jet fuel should be substantially evaluated (Supported by AFOSR).

PS 927 PERMEABILITY CHANGES - A SENSITIVE MARKER OF LUNG INJURY MEASURED WITH INHALED HORSERADISH PEROXIDASE (HRP) IN THE PERFUSED AND VENTILATED RAT LUNG (IPL).

E. Selg[1], F. Acevedo[1], B. Blomgren[2], √. Ryrfeldt[3] and P. Gerde[1, 3]. *[1]Inhalation Sciences AB, Stockholm, Sweden, [2]AstraZeneca, S√∂dert√§lje, Sweden and [3]Karolinska Institutet, Stockholm, Sweden.*

Macromolecule absorption from the lung is a largely unknown process. The intact alveolar epithelium with tight junctions (TJ) between pulmonary epithelial cells, is the major permeability barrier to passage of macromolecules through the alveolar-capillary membrane. In this study, the pulmonary absorption of the 40 kDa protein HRP was measured in the rat IPL. The DustGun aerosol technology was used for a well-controlled delivery of HRP as respirable dry powder aerosols (mass median aerodynamic diameter 0.7 μm) to the rat IPL. The lung perfusate was repeatedly sampled until 125 min after the HRP exposure. The amount of the active HRP that was cleared with the perfusate or retained in the lung tissue was measured with an enzymatic assay. Following inhalation, the penetration of HRP was rapid and the time to peak concentration (Tmax) was 218±39 s (mean±SD, n=13). After this time, the rate of penetration of HRP remained almost constant. After 2 h, 2.1±0.3 μg HRP (mean±SD, n=5) had cleared to the perfusate. This constitutes only 0.32 % of the initially deposited dose of 675±91 μg HRP per exposure. The effect of a transient opening of TJ on HRP absorption was studied by exposing the IPL to a nebulised aerosol of 0.2% poly-L-Arginine (PLA) (mean MW 42.5 kDa) in PBS, at between 40 and 45 min after the previously used HRP exposure. The concentration of HRP in the perfusate jumped eightfold from 2±1 ng/mL before to 16±5 ng/mL immediately after the PLA treatment. In the PLA-treated lungs, the total amount of HRP cleared to the perfusate was 16±8 μg or 2.2±1% (mean±SD, n=3) of the total initial dose of 747±146 μg HRP per exposure. Thus, the pulmonary absorption of HRP is very slow and inhalation of respirable HRP aerosols can be used as a sensitive marker of permeability changes induced by toxic insults to the alveolar epithelium. This inhalation technique can also be of great use in studying the pulmonary absorption of biopharmaceuticals in general.

PS 928 SYSTEMIC DELIVERY OF COTININE THUROUGH INHALATION EXPOSURE.

S. Hu, M. Muzzio and N. Rajendran. *IIT Research Institute, Chicago, IL.* Sponsor: W. Johnson.

Cotinine, a primary metabolite of nicotine, is a potential pharmacological agent for the treatment of various psychiatric syndroms such as Alzheimer's disease. The objective of this study is to develop a method for systemic delivery of cotinine using the lung as a portal of entry. Specifically, two cynomolgus monkeys (one male and one female) were exposed to a test atmosphere containing respirable nicotine aerosol (MMAD=3 um, GSD=1.6) at the concentration of 75 mg nicotine/m3 for two hours. Respiratory function (i.e., tidal volume, breathing rate and minute volume) was measured during the exposure using Fleisch #1 pneumotachograph attached to the mask. Upon exposure termination, blood samples were collected via the femoral artery at twelve discrete time points and analyzed for quantification of nicotine, cotinine, and trans-3'-hydroxycotinine concentrations in plasma using high performance liquid chromatography-mass spectrometry-mass spectrometry (LC-MS-MS). Pharmacokinetic parameters (i.e., AUC, Cmax, Tmax, elimination half-life, apparent clearance, and apparent volume of distribution) determined using WinNonlin software are reported. The results showed that following inhalation exposure, plasma cotinine level reached a maximum at 1-2 hours post-exposure whereas nicotine level reached a maximum within 0.25 hour. Plasma levels of cotinine decreased at much slower rate compared to nicotine. Compared to nicotine, pharmacokinetic parameters Cmax and AUC for cotinine were significantly greater and elimination half-life was significantly longer. This suggests that administration of nicotine aerosol via inhalation may be a viable method for maintaining cotinine concentrations at levels suitable for exploring therapeutic opportunities.

PS 929 CIGARETTE SMOKE-INDUCED MOUSE EMPHYSEMA MODEL USING A DIRECT PUMP EXPOSURE SYSTEM.

K. M. Lee[1], B. MacIsaac[1], S. Harbo[1], L. Staska[1], R. Meng[1], D. Kobayashi[2], S. Shapiro[3] and K. Gideon[1]. *[1]Battelle TNW, Richland, WA, [2]Washington University St. Louis School of Medicine, St. Louis, MO and [3]University of Pittsburgh Medical School, Pittsburgh, PA.*

Various animal models are evaluated for the chronic obstructive pulmonary disease investigation and among others, mouse emphysema models following chronic cigarette smoke (CS) exposures are most common. In the CS models, different exposure regimens are reported using diluted/continuous exposures or undiluted/intermittent exposures. The latter systems are widely used in research community but operational details are limited in literature. In this study, one of representative direct-pump exposure systems was tested to expose CS to mice for 24 wks and its smoke characteristics and biological endpoints associated with emphysema development were evaluated. Female AKR mice were exposed to mainstream smoke from 2R4F reference cigarettes (filter removed), 2-4 cig/d, 6 d/wk for 24 wks. Smoke was analyzed for WTPM, CO, and nicotine. Blood samples were collected postexposure and analyzed for nicotine and cotinine. There were notable inter- and intra-machine variability in smoke delivery. At Wks 4 and 24, groups of mice were subjected to lung function measurement or sacrificed for lung collection (for histopathology/morphometry; bronchoalveolar lavage (BAL); transcriptomics). Mild emphysema was confirmed morphometrically (increases in the mean Lm and chord length at Wk 24). A minimal increase in quasi-static compliance was observed at Wk 4. Pulmonary inflammation was detected as increased BAL protein, macrophages at Wk 4 and neutrophils at Wk 24, while lung GSH levels were slightly but consistently reduced at Wks 4 and 24. The background lymphoma was observed for both control and exposed groups at Wk 24. There were more differentially expressed genes at Wk 4 compared to Wk 24. In summary, chronic smoke exposures using the undiluted/intermittent direct-pump smoking system induced mild emphysema with chronic inflammation in AKR mice. (Funded by Battelle Biology and Health Science Initiative)

PS 930 HISTOCHEMICAL STUDY OF INTESTINAL MUCINS AFTER ADMINISTRATION OF SILVER NANOPARTICLES IN SPRAGUE-DAWLEY RATS.

G. Jeong[2], M. Song[1], H. Ryu[1], Y. Kim[1], U. Jo[2] and I. Yu[1]. *[1]Biosafety Evaluation Headquarter, KEMTI, Incheon, Korea, South and [2]Biology Education, Busan University, Busan, Korea, South.*

To investigate the effects of silver nanoparticles (NPs) on the histological structure and properties of mucosubstances of the intestinal mucosa, Sprague-Dawley rats were administrated to silver NPs (60 nm) at concentration of 1000 mg/kg for 28 days, following OECD test guideline 407 with GLP application. Control sections contained no silver NPs. Experimental samples showed luminal and surface particles and also contained silver NPs within the tissue. Accumulation of silver NPs was observed in increased numbers in the lamina propria both small and large intestine. It did show in the tip of upper villi in the ileum and in the protruding surface of fold in the colon. In the silver NPs-treated rats, numbers of goblet cells which have released their mucus granules were higher than those in controls and there were also large mucus materials in the crypt lumen and ileal lumen. Moreover, shedding of cell at the tip of the villi was frequent. The amount of neutral and acidic mucins in goblet cells in the silver NPs was decreased. In the properticis of acidic mucins, amount of sialomucins was increased while that of sulfomucins was decreased. Particularly, in colon, sialyated mucins were detected in the lamina propria, connective tissue under the epithelia, which was not found in the control rats. Therefore, the present results suggest that silver NPs induce the discharge of mucus granule and abnormal mucus composition of goblet cells in the intestines.

PS 931 SYSTEMIC TRANSLOCATION OF 70ZN FOLLOWING PULMONARY EXPOSURE IN RATS.

J. G. Wallenborn[1], K. D. Kovalcik[2], J. K. McGee[3], M. S. Landis[2] and U. P. Kodavanti[3]. *[1]SPH, UNC, Chapel Hill, NC, [2]NERL, U.S. EPA, Durham, NC and [3]PTB, ETD, NHEERL, U.S. EPA, Durham, NC.*

Mechanisms of particulate matter (PM)-induced cardiotoxicity are not fully understood. Zinc, an essential element, is a common metal in ambient PM. It has been speculated to mediate cardiotoxicity of PM via direct translocation from the lungs

into systemic circulation; however this has not been shown. We hypothesized that following a single intratracheal instillation (IT), zinc translocates through the pulmonary circulation, directly reaching the heart. To test this, we used high resolution magnetic sector field inductively coupled plasma mass spectrometry to measure levels of five stable isotopes of zinc (64Zn, 66Zn, 67Zn, 68Zn, 70Zn), and total copper in lungs, plasma, heart, liver, spleen, and kidney of male Wistar Kyoto rats (13 wks old, 250-300 g), 1, 4, 24, and 48 h following a single IT or oral gavage of saline or 0.7 μmol/rat 70Zn (as ZnSO4), using a solution enriched with 76.6% 70Zn. Natural abundance of 70Zn is 0.6%, making it an easily detectable tracer following exposure. In IT rats, lung 70Zn was highest 1 h post IT and declined by 48 h. Liver endogenous zinc was increased 24 and 48 h post IT. 70Zn was detected in all extrapulmonary organs, with levels higher following IT than following gavage. In the hearts of IT rats, 70Zn not only was increased, but seemed to accumulate, with cardiac 70Zn highest 48 h post IT. Conversely, following gavage of Zn, cardiac 70Zn only modestly increased, and did not accumulate. Liver, spleen and kidney 70Zn peaked 4 h following gavage, and 24 h following IT. 70Zn IT exposure elicited changes in copper homeostasis in all tissues. Pulmonary exposure to zinc results in selectively higher cardiac zinc levels relative to oral exposure. Following IT, soluble zinc directly moves from the lungs into circulation and accumulates in the heart, causing changes in copper homeostasis. This provides biological plausibility to the suggestion that soluble zinc possibly mediates cardiovascular effects from exposure to zinc-rich PM. Abstract does not reflect USEPA policy. Funded in part by UNC/EPA CT829471.

PS 932 TOXICITY OF PARTICULATE MATTER GENERATED BY PYROTECHNIC DISPLAYS.

C. A. Hickey, C. Gordon, L. Chen, M. Blaustein and T. Gordon.
Environmental Medicine, New York University School of Medicine, Tuxedo, NY.

Particle samplers were used to collect emissions from 14 different pyrotechnic displays in a stainless steel exposure chamber. To address our hypothesis that pyrotechnic displays emit toxic particulates which can affect human health, collected particles were used to treat a human pulmonary microvascular endothelial cell line (HPMEC-ST1.6R) and a human bronchial epithelial cell line (BEAS-2B), which is stably transfected with a NF-κB luciferase reporter gene. Cells were dosed for 24 hr with 10, 50 and 100 μg/ml of PM10 for each pyrotechnical display particle type, as well as size-fractioned particles for selected displays. Cytotoxicity was measured as release of LDH, and no significant toxicity was measured for any dose in either cell line. Reactive oxygen species (ROS) levels were measured by intracellular oxidation of a fluorescent dye. In both cell types, PM10 from less than half of the particle types elicited ROS production in a dose dependent manner. These results indicate that the composition of particles resulting from each display varied and that dose can impact in vitro cellular responses. One display, "Black Cuckoo" yielded a high response in both cell types and upon further investigation; it was shown to cause a dose-dependent response in both. Examination of the size-fractioned particles show that coarse particulate matter (PM10-2.5) caused the greatest production of ROS in HPMEC-ST1.6R cells and equal or greater production than the fine fraction (PM2.5) in BEAS-2B cells, while ultrafine PM caused the least response in both cell types. Each display particle type also impacted NF-κB levels in BEAS-2B cells, which was measured by luciferase expression. Interestingly, changes in NF-κB levels did not correlate with ROS production, suggesting that an alternative mechanism may be involved. Ongoing studies are aimed at verifying our findings in a murine model, and correlating our findings to specific components of the particulate matter produced by pyrotechnic displays.

PS 933 SUPPRESSION OF WNT /BETA-CATENIN SIGNALING IN BONE OF FEMALE RATS EXPOSED TO ETHANOL POST-LACTATION.

J. Chen[3, 2], O. P. Lazarenko[4, 2], K. Shankar[3, 2], M. L. Blackburn[3, 2], T. M. Badger[3, 2] and M. J. Ronis[1, 2]. *[1]Pharmacology & Toxicology, University of Arkansas Medical Sciences, Little Rock, AR, [2]Arkansas Children's Nutrition Center, Little Rock, AR, [3]Pediatrics, University of Arkansas for Medical Sciences, Little Rock, AR and [4]Physiology & Biophysics, University of Arkansas Medical Sciences, Little Rock, AR.*

The mechanism through which chronic alcohol intake induces bone loss remain unclear but oxidative stress might be the key event in skeletal injury. We chronically infused ethanol (EtOH, 12g/kg/day) into post-lactational female Sprague-Dawley rats for 4 weeks using total enteral nutrition. EtOH decreased bone mineral density compared to control animals during this period of bone rebuilding ($P < 0.05$). EtOH -induced bone loss was blocked by administration of the antioxidant N-acetylcysteine (NAC) at 1.2 g/kg/d ($P < 0.05$). NAC was able to reverse down-regulation of the bone formation markers alkaline phosphatase and osteocalcin in serum and gene expression in bone tissue ($P < 0.05$). RNA isolated from bone tissue and specific wnt real time array analysis revealed that the majority of wnt signaling components were down-regulated by chronic EtOH infusion ($P < 0.05$). Real-time PCR confirmed down-regulated gene expression in a subset of the wnt signaling components by EtOH, however, the wnt antagonist DKK1 was up-regulated by EtOH ($P < 0.05$). Western blot showed that the key canonical wnt signaling molecule β-catenin protein expression as well as glycogen synthase kinase-3-β were inhibited by EtOH in bone, and these actions of EtOH were blocked by NAC ($P < 0.05$). Finally, we transfected TCF/LEF-dependent transcription of a luciferase reporter gene TOPFLASH and β-catenin plasmid into osteoblastic UMR-106 cells. We found that EtOH trans-inactivated TCF/LEF gene transcription and blocked β-catenin nuclear translocation in osteoblasts. All of these effects of EtOH in vitro in osteoblasts were also eliminated by NAC pre-treatment. These observations strongly suggest that EtOH can inhibit bone formation through its novel action on suppression of wnt signaling. Supported in Part in R01 AA12928 (M.J.R.).

PS 934 THIOREDOXIN REDUCTASE DEPLETION INHIBITS NFKB SIGNALING BY A THIOREDOXIN INDEPENDENT MECHANISM.

J. M. Heilman and W. H. Watson. *Environmental Health Sciences, Johns Hopkins School of Public Health, Baltimore, MD.*

Nuclear factor-kappaB (NFkB) is a redox sensitive transcription factor involved in cell survival, proliferation, and inflammation. Certain inhibitors of NFkB signaling are also known to inhibit thioredoxin reductase (TR1), an enzyme important for processes such as oxidative insult defense and DNA replication. In the present study we tested the hypothesis that TR1 inhibition prevents cellular NFkB signaling through a build-up of oxidized thioredoxin (Trx1), a major substrate of TR1 that has been implicated in the redox maintenance of NFkB. To test this hypothesis, HeLa cells were depleted of TR1 using siRNA. Following a 90% knock-down of TR1 protein and activity and stimulation with TNF, there was a 40% decrease, compared to controls, in both NFkB activity as measured using reporter constructs and expression of the NFkB target gene I-kappaB-alpha. In contrast, an 80% knock-down of Trx1 did not result in significant inhibition of NFkB activity. Furthermore, TR1 knock-down did not result in oxidation of either cytosolic or nuclear Trx1, suggesting that TR1 is necessary for NFkB signaling and has a role that is independent of Trx1.

PS 935 TRANSCRIPTIONAL REGULATORY RELATIONSHIPS INVOLVING GLUTATHIONE S-TRANSFERASE (GST) AND OXIDATIVE STRESS RELATED GENE PRODUCTS: TARGETS INFLUENCING MELANOTOXICITY OF SUBSTITUTED PHENOLS.

G. Acquaah-Mensah, K. A. Hoey, S. Kerr and R. Sarangarajan. *Massachusetts College of Pharmacy and Health Sciences, Worcester, MA.*

Substituted phenolic substrates of tyrosinase (the enzyme responsible for melanin synthesis) are selectively toxic to melanocytes in the skin. It is suggested that tyrosinase catalyzed formation of phenol-o-quinone derivatives generates oxidative stress and melanocyte toxicity. We have demonstrated previously that cytotoxicity of 4-tertiary butylphenol (4-TBP, a prototypical substituted phenolic substrate of tyrosinase) in melanoma cells is directly associated with GST activity. In this study, computational techniques were used to determine transcriptional regulatory relationships between GST expression and oxidative stress in melanoma cells. Using the Algorithm for the Reconstruction of Accurate Cellular Networks and probesets representing genes involved in cellular response to oxidative stress, a transcriptional regulatory network was reverse-engineered from 207 publicly available melanoma microarrays. Combination of toxicity and RT-PCR studies demonstrate that 1,2-epoxy-3-(p-nitrophenoxy) propane (ENPP) mediated inhibition of GSTT1 sensitizes melanoma cells to 4-TBP induced toxicity compared to other GST isoforms. The expression of GSTT1 was found to be tied to the expressions of 31 other genes including those of GSTP1, NQO1 and GPX3 which are involved in detoxification of quinones. There are direct statistical dependencies between the expressions of the GSTM isoforms and that of GSTP1 but not GSTT1. However, the expression of GSTA1 is directly tied to expressions of both GSTP1 and GSTT1. Feed-forward loops involving hubs in the network: GSTT1, GSTP1 and GPX3 (whose average expression is higher in primary melanomas than metastatic melanomas), or GSR (whose average expression is higher in metastatic melanomas) were established. This analysis identifies molecular targets validation of which will provide insights on their ability to influence toxicity of 4-TBP selectively in melanocytic cells.

PS 936 OXIDATIVE LIPIDOMICS OF MACROPHAGE ACTIVATION AND APOPTOSIS INDUCED BY PHAGOCYTOSIS OF PARTICLES AND PATHOGENS.

W. Feng[1], V. A. Tyurin[1], K. L. Go[1], Y. Y. Tyurina[1], N. A. Stewart[2], F. Fazzi[1], E. R. Kisin[3], A. R. Murray[3], A. A. Shvedova[3], B. Pitt[1], L. A. Ortiz[1] and V. E. Kagan[1]. *[1]EOH, University of Pittsburgh, Pittsburgh, PA, [2]Medicine, University of Pittsburgh, Pittsburgh, PA and [3]Pathology/Physiology, NIOSH, Morgantown, WV.*

Macrophages are essential to the innate immune system in eliminating invading microorganisms and as major orchestrators of the inflammatory response. As pathogens undergo phagocytosis and intracellular digestion; this mechanism can lead to apoptosis of the phagocyte. However, the mechanisms of apoptosis and its links with phagocytosis are largely unknown. We hypothesized that triggering of phagocytosis and activation of macrophages – including NADPH oxidase generated derived reactive oxygen species - mediates selective oxidation of phospholipids participating in the execution of apoptotic program. To approach this, zymosan, silica particles and carbon nanotubes were utilized as different types of pathogens/particles capable of activating macrophage in vitro and/or in vivo. Macrophage cell lines (RAW 264.7 and IC-21) as well as C57Bl/6 mice were treated with one of the above and NADPH oxidase activation, superoxide generation, cytochrome c release, PS externalization and caspase 3/7 activity were used to confirm the apoptotic cell death. Oxidation of major classes of phospholipids - phosphatidylcholine (PC), phosphatidylethanolamine (PE), phosphatidylserine (PS), phosphatidylinositol (PI), and cardiolipin (CL) - was determined by electro-spray ionization mass spectrometry as well as by fluorescence HPLC/Amplex Red assay. The results demonstrated that robust and selective peroxidation of anionic phospholipids (CL>> PS >PI) accompanied macrophage apoptosis in vitro. Moreover, oxidation of the same species of anionic phospholpipids was detected in lungs of mice exposed to single walled carbon nanotubes via pharengeal inhalation. We conclude that anionic phospholipid-mediated signaling may participate in phagocytosis induced macrophage apoptosis. Supported by NIOSH OH008282, NORA 927000Y, NIH HL70755, ES010859 and the 7th Framework Program of the European Commission.

PS 937 SIRT1 IS POST-TRANSLATIONALLY MODIFIED BY ALDEHYDES AND CIGARETTE SMOKE IN LUNG EPITHELIAL CELLS.

S. W. Caito[1], S. Rajendrasozhan[1], S. Chung[1], P. Brookes[2] and I. Rahman[1]. *[1]Environmental Medicine, University of Rochester, Rochester, NY and [2]Pharmacology and Physiology, University of Rochester, Rochester, NY.* Sponsor: N. Ballatori.

Rationale: Sirtuin1 (SIRT1), a class III histone/protein deacetylase, is involved in stress responses and regulation of inflammation, apoptosis and aging. We have previously shown that SIRT1 protein levels are decreased in lungs of smokers and patients with COPD leading to increased NF-κB-dependent inflammation. As oxidative modification of proteins can alter both a protein's function and level, we hypothesized that oxidative modification of SIRT1 by cigarette smoke (CS) and oxidants leads to down regulation of SIRT1 activity and protein level. ***Methods:*** Human bronchial (BEAS-2B) and primary airway epithelial cells were exposed to different concentrations of cigarette smoke extract (CSE 0.5-1%), H_2O_2 (150 μM), or acrolein (10 and 30 μM) for 6 hours. Lysates were used to measure SIRT1 activity (*Color de Lys assay*, Biomol) and oxidative modifications using biotin switch assay. ***Results:*** SIRT1 activity was significantly decreased by CSE, acrolein, and H_2O_2. However, only CSE and acrolein dose-dependently decreased SIRT1 levels. Pre-treatment with N-acetyl-L-cysteine (2 mM) attenuated CSE depletion of SIRT1 levels and activity. Labeling cell lysates with maleimide-biotin revealed that SIRT1 was modified on cysteine residues in response to CSE, and that NAC could prevent these modifications. Treatment of cells with N-ethylmaleimide (100 μM) decreased SIRT1 activity as well as protein levels further implicating modification of cysteines in SIRT1 regulation. Furthermore, SIRT1 is degraded by proteasome as proteasomal inhibitors (5 μM ALLN and 10 μM MG-132) attenuated CSE-mediated reduction of SIRT1. ***Conclusions:*** Post-translational modification of SIRT1 by carbonylation on cysteine residues inactivates the enzyme and renders it for proteasomal degradation. These data may have implications for stress responses and abnormal inflammation in response to environmental stimuli and oxidants.

PS 938 IMPACT OF PEROXIREDOXIN 6 GENE DELETION AND OVER-EXPRESSION ON ETHANOL-MEDIATED LIVER DAMAGE IN MICE.

J. Roede[1], A. B. Fisher[2] and D. R. Petersen[1]. *[1]Pharmaceutical Sciences, University of Colorado Denver, Aurora, CO and [2]University of Pennsylvania, Philadelphia, PA.*

Oxidative stress is implicated in the etiology of many diseases including alcoholic liver disease (ALD). Peroxiredoxin 6 is a cytosolic peroxidase that has been demonstrated to protect various tissues, such as skin, lung and cardiac muscle, against acute oxidative insults. Taken together, peroxiredoxin 6 was hypothesized to also protect the liver from oxidative stress generated during the process of chronic ethanol metabolism. To test this, both peroxiredoxin 6 knockout mice (KO) and transgenic, peroxiredoxin 6 over-expressing mice (TG) were fed an ethanol containing diet and various biomarkers of ALD were assessed along with the effects of chronic ethanol consumption on the antioxidant defenses. After 9 weeks of ethanol consumption all backgrounds exhibited increased plasma ALT activity, steatosis, CYP2E1 induction and lipid peroxidation. Differences in antioxidant protein expression and activity were also observed. Significantly induced catalase and glutathione S-transferase activity in ethanol-fed KO and TG mice along with elevated levels of glutathione peroxidase activity were noted. These results could be attributed to either compensatory responses due to the genetic manipulations or ethanol-mediated responses. It can then be concluded that both ethanol-fed KO and ethanol-fed TG mice developed early stage ALD and that oxidative stress and overall pathology were not exacerbated by the absence of peroxiredoxin 6 and not prevented or attenuated by its over-expression.

PS 939 OXIDATIVE STRESS IS THE MECHANISM OF PPAR-INDUCED SKELETAL MYOPATHY IN RATS.

W. Casey[1], H. Colton[1], E. Bingham[2] and S. Ritchie[2]. *[1]GlaxoSmithKline, Durham, NC and [2]Phenomenome Discoveries Inc, Saskatoon, SK, Canada.* Sponsor: P. Kwanyuen.

The PPAR-alpha receptor is activated by fibrates which causes proliferation of peroxisomes, hepatomegaly and hepatocarcinogenesis in rodents. Skeletal muscle is also a major site of PPAR-alpha and delta expression and represents a principal tissue responsible for lipid uptake and utilization. Skeletal myopathy, and rhabdomyolysis have been reported with administration of fibrates. The aim of this study was to determine the mechanism by which PPAR (alpha/delta) agonists induce skeletal myopathy in rats. Sprague Dawley rats were treated with GW610742X, a dual pharmacologic agonist of PPAR (alpha/delta) nuclear receptors, over a time course study with animals sacrificed at 6 hrs, 24 hrs, 2, 4, 6, and 10 days. The soleus muscle, extensor digitorum longus muscle, heart, liver, whole blood and serum were collected at each time point. In addition to standard clinical chemistry and histopathology, samples were analyzed using transcriptomic (Affymetrix) and metabolomic (Fourier transform mass spectroscopy) techniques. Minimal skeletal myopathy was first noted in soleus (type I) muscle of some animals on Day 4, with the lesions becoming progressively more severe and homogeneous over the remainder of the time course. Development of skeletal myopathy was preceded by hepatic peroxisome proliferation, increased plasmalogens (antioxidant lipids) and lipid peroxides in the serum, and decreased GSH in liver, whole blood and skeletal muscle. The onset of myopathy was also preceded by increased fatty acid beta-oxidation in the soleus, and was coincident with a strong induction of genes associated with oxidative stress. Based on these data, we propose that PPAR-induced skeletal myopathy in rats is the result of a combination of two pharmacological effects; hepatic peroxisome proliferation which results in systemic GSH deficiency, and increased beta-oxidation in Type I skeletal muscle. Together, these effects result in oxidative stress which leads to the observed skeletal myopathy.

PS 940 INDICATORS OF OXIDATIVE STRESS AND APOPTOSIS FOLLOWING EXPOSURE TO STYRENE AND ITS METABOLITES IN MOUSE WHOLE LUNG AND CLARA CELLS.

J. A. Harvilchuck[1], X. Pu[2], J. E. Klaunig[2] and G. P. Carlson[1]. *[1]Health Sciences, Purdue University, West Lafayette, IN and [2]Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Styrene causes both acute and chronic toxicity in humans. In mice, styrene is both hepato- and pneumo-toxic and causes lung tumors. One possible explanation for the tumorigenicity is oxidative stress/damage. Decreases in glutathione levels, linked to increases in apoptosis, occur in lung homogenates and isolated Clara cells 3 hrs following styrene or styrene oxide (SO) administration. Since low levels of reactive oxygen species (ROS) have been linked with increased apoptosis, ROS levels following administration of styrene and its metabolites were measured in vitro and in vivo. Both in vitro and in vivo measurements showed significant increases in ROS 3 hrs after styrene, R-SO, S-SO, and racemic SO administration. None were seen with styrene or R-SO at 12 hrs or beyond. Ratios of bax/bcl-2 mRNA expression were determined at time periods from 3 to 240 hrs following exposure to styrene and R-SO. The mRNA expression ratio increased at 12 and 24 hrs following R-SO and at 120 hrs following styrene administration. Since a consequence of oxidative stress can be 8-hydroxydeoxyguanosine (8OHdG) adduct formation, levels were measured in mouse lung homogenates 3 hrs and 12 hrs after the administration of 600 mg/kg styrene or 300 mg/kg R-SO. Significant increases in 8OHdG with both compounds were seen at 3 hrs, but not at 12 hrs. Thus both ROS and

8OHdG formation increased 3 hrs following treatment with styrene and R-SO, with increases in bax/bcl-2 mRNA ratios occurring later. This increased oxidative stress may be responsible for the increased susceptibility to lung tumorigenesis in mice. Additional studies using TUNEL staining for DNA fragmentation and analysis of caspase activity are needed to complement these studies. (Supported in part by a grant from the Styrene Information and Research Center (GPC) and NIH grant (R01 CA100908; JEK)).

PS 941 CELLULAR ADAPTIVE RESPONSE TO ENVIRONMENTAL OXIDATIVE STRESS PERTURBS PANCREATIC BETA-CELL FUNCTION.

J. Pi, J. Fu, C. G. Woods, S. Collins, M. E. Andersen and Q. Zhang. *The Hamner Institutes fro Health Sciences, RTP, NC.*

Accumulating evidence indicates that many environmental factors are involved in the incidence of Type 2 diabetes (T2D). It is clear that insulin resistance plays an early role in the pathogenesis of T2D, and defects in insulin secretion by pancreatic beta-cells are instrumental in the progression to hyperglycemia. In contrast to what has been a prevailing view that increased oxidative stress play prominent roles in beta-cell dysfunction in T2D, we proposed previously that acute and transient glucose-triggered ROS contribute to glucose-stimulated insulin secretion (GSIS) in beta-cells. In the current study, we test the hypothesis in vitro and in silico that induction of antioxidant enzymes in response to chronic environmental oxidative stress interferes with these 'ROS signals' that are involved in GSIS. Exposure of INS-1(832/13) cells or isolated mouse islets to non-cytotoxic levels of oxidative stressors, including arsenic, H2O2, high glucose or palmitate led to decreased GSIS in a dose- and time-dependent fashion. The impaired GSIS was associated with increases in a battery of cellular adaptive response genes including antioxidant enzymes. Accordingly, the increased antioxidant activity significantly inhibited net glucose-stimulated intracellular H2O2 accumulation, which as already stated is a component of GSIS. To understand the quantitative nature of 'ROS signaling', we resorted to an ordinary differential equation-based model which describes the Nrf2-mediated adaptive response to oxidative stress. Our simulation indicates that in the absence of oxidative stress, a stimulus mimicking glucose treatment causes a large spike in intracellular H2O2 concentration. However, when the cell is under continuous oxidative stress, the same glucose-mimicking stimulus triggers a much smaller increase in H2O2. Taken together, these integrated approaches demonstrate that chronic oxidative stress can blunt 'ROS signaling' by adaptively upregulating overall antioxidant capacity. (Supported by NIH-R01ES016005 and K01DK076788).

PS 942 TCDD INDUCES HEPATIC Nqo1 IN MICE *VIA* AhR AND Nrf2.

R. L. Yeager, S. A. Reisman, L. M. Aleksunes and C. D. Klaassen. *Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

2, 3, 7, 8-Tetrachlorodibenzo-*p*-dioxin (TCDD) induces genes via the aryl hydrocarbon receptor (AhR), but whether TCDD also induces genes via nuclear factor erythroid 2-related factor 2 (Nrf2) remains unclear. Despite previous reports of transcriptional interactions between AhR and Nrf2, Nrf2-mediated gene regulation is rarely considered in TCDD studies. Preliminary work indicates that the AhR is required for TCDD induction of the quinone reducing enzyme NAD(P)H: quinone oxidoreductase 1 (Nqo1). Moreover, it has been demonstrated that chemical induction of Nqo1 mRNA and protein is Nrf2-dependent. The present study addresses whether Nrf2 mediates TCDD-induced Nqo1 expression *in vivo*. C57BL/6 wild-type (WT) and Nrf2-null mice (C57BL/6 Background, >99% congenic) were administered a single dose of TCDD (50 μg/kg, i.p.), and livers were collected 24 h later. TCDD markedly increased hepatic Cyp1a1/2 mRNA in both WT and Nrf2-null mice. In WT mice, TCDD increased the mRNA expression of Nrf2 by 248% and its target gene Nqo1 by 619%. In contrast, TCDD-treated Nrf2-null mice did not exhibit increased mRNA expression of Nrf2 or Nqo1. Collectively, the present study demonstrates that Nrf2 is essential for mediating TCDD-induced Nqo1 expression *in vivo*. (Supported by NIH grants ES09716, ES07079, ES013714, ES09649, and RR021940).

PS 943 ROLE OF NF-κB IN LUNG INFLAMMATION INDUCED BY IRON AND SELENIUM.

P. A. Potnis, K. S. Squibb and A. Elnabawi. *Toxicology, University of Maryland, Baltimore, Baltimore, MD.*

Epithelial cells lining the lung face a constant threat of sustaining damage caused by inhaled atmospheric pollutants. Metals present in ambient particulate matter have been strongly implicated in causing lung inflammatory diseases. We studied the effects of Fe or Se, at environmentally relevant concentrations, on induction of oxidative stress and generation of the chemokine MCP-1 in cultured human lung alveolar epithelial A549 cells. To characterize the underlying mechanisms of induction of the inflammatory response, we investigated the influence of these metals on the activation of the nuclear factor kappa B (NF-κB) intracellular signaling pathway. Exposure to Fe or Se increased cellular ROS levels measured by the fluorescent probe DCFH-DA as early as 30 min after exposure, with enhanced release of MCP-1 at 24h. Immunoblotting of cytosolic and nuclear extracts for p65 (NF-κB dimer) showed that both Fe and Se induced the nuclear translocation of NF-κB. MCP-1 levels in response to Fe were significantly suppressed in the presence of the antioxidant N-acetylcysteine (NAC); similar effects were obtained in response to Se. In the presence of BMS-345541, a specific inhibitor of NF-κB, Fe- and Se-induced release of MCP-1 was significantly decreased, indicating the involvement of NF-κB in the metal-induced chemokine release. Results indicate that both Fe and Se posses the potential for inducing lung inflammation via an oxidative stress pathway, and that the induction of NF-κB activity is, at least in part, responsible for up-regulating genes encoding for inflammatory chemokines. [Supported by: MD DHMH CH605CRT]

PS 944 INCREASED NRF2 ACTIVATION IN KEAP1-KNOCKDOWN MICE INCREASES HEPATIC CYTOPROTECTIVE GENES THAT DETOXIFY ELECTROPHILES BUT NOT REACTIVE OXYGEN SPECIES.

C. D. Klaassen, R. L. Yeager and S. A. Reisman. *University of Kansas Medical Center, Kansas City, KS.*

Nuclear factor erythroid 2-related factor 2 (Nrf2) is a transcription factor critical for protection against electrophilic and oxidative stress. A recently engineered mouse with knockdown of Keap1 (Keap1-kd mice), the cytosolic repressor of Nrf2, has a 55% decrease in Keap1 mRNA and a 200% increase in Nrf2 protein in liver. Many experiments with Nrf2-null mice demonstrate the effects of a lack of Nrf2. However, little is known about the biological effects of more Nrf2 activation, accordingly, the phenotype of Keap1-kd mice, as well as mRNA expression of detoxifying and antioxidant genes were compared with Nrf2-null and wild-type mice. Messenger RNA quantification by multiplex suspension array identified three distinct patterns of gene expression among wild-type, Nrf2-null, and Keap1-kd mice. The first pattern encompassed genes that were lower in Nrf2-null mice and considerably higher in Keap1-kd mice than wild-type mice, and included genes mainly responsible for the detoxification and elimination of electrophiles, such as NAD(P)H:quinone oxidoreductase 1, and glutathione-S-transferases (Gst), as well as multidrug resistance-associated proteins. The second pattern encompassed genes that were lower in Nrf2-null mice, not increased in Keap1-kd mice, and included genes, such as epoxide hydrolase-1, UDP-glucuronosyltransferases, aldehyde dehydrogenases, as well as genes important in the detoxification of reactive oxygen species, such as superoxide dismutase 1 and 2, catalase, and peroxiredoxin 1. The third pattern encompassed genes that were not different among wild-type, Nrf2-null, and Keap1-kd mice and included genes such as glutathione peroxidase, microsomal Gsts, heme oxygenase-1, and uptake transporters. In conclusion, the present study suggests that hepatic Nrf2 is more important for the detoxification and elimination of electrophiles rather than reactive oxygen species. (Supported by NIH grants ES09716, ES07079, ES013714, ES09649, and RR021940)

PS 945 EXOGENOUS HYDROGEN PEROXIDE RESCUES HYPEROXIA-INDUCED MACROPHAGE DYSFUNCTION OF BACTERIAL KILLING BY INHIBITION OF HMGB1 RELEASE.

B. D. Phan[1], T. Entezari-Zaher[1] and L. L. Mantell[1, 2]. *[1]Department of Pharmaceutical Sciences, College of Pharmacy and Allied Health Professions, St.John's University, Queens, NY and [2]Cardiopulmonary Research, Department of Surgery, North Shore University Hospital, the Feinstein Institute for Medical Research, North Shore-Long Island Jewish Health System, Manhasset, NY.*

Mechanical ventilation with hyperoxia is necessary to treat critically ill patients. However, prolonged exposure to hyperoxia can cause acute inflammatory lung injury and contribute significantly to ventilator-associated pneumonia. Our previous studies show that high-mobility group box 1 (HMGB1) protein, a novel inflammatory cytokine plays a pivotal role in mediating hyperoxia-induced inflammatory lung injury and macrophage dysfunction. In addition, hydrogen peroxide (H2O2) can rescue hyperoxia-induced macrophage impairment in phagocytosis of Pseudomonas aeruginosa. The aim of this study is to determine whether HMGB1 is involved in the mechanisms of H2O2 in rescueing hyperoxia-induced macrophage dysfunction. Following the exposure of RAW 264.7 cells to 95% oxygen for 24h, the cells were treated with various concentrations of H2O2 ranging from 50μM to 750μM for one hour. Corresponding to the rescuing effect on hyperoxia-impaired macrophage functions, H2O2 at moderate concentrations increased the ability of hyperoxic macrophage to kill the Pseudomonas aeruginosa significantly and reduced markedly the release of HMGB1 into extracellular milieu,

which is required for its proinflammatory function. Analysis of subcellular localization of HMGB1 via immunofluorescent examination indicates that moderate concentrations of H2O2 inhibited HMGB1 cytoplasmic translocation. However, H2O2 at higher concentrations exacerbated hyperoxia-induced cytotoxicity on macrophages triggering more HMGB1 cytoplasmic translocation and more HMGB1 release, and impairing macrophage's ability to kill Pseudomonas aeruginosa. The study provides evidence that HMGB1 plays a critical role in the effects of H2O2 in rescuing of macrophage dysfunctions under hyperoxic conditions.

PS 946 SERINE 374 C-FOS MEDIATES OXIDANT INDUCED C-FOS PROTEIN STABILIZATION.

E. Sheveleva and Q. M. Chen. *Pharmacology, University of Arizona, Tucson, AZ.*

The c-Fos protein, a component of the AP-1 transcription factor, is crucial for cellular adaptation to many disease states involving oxidative stress. Previous study from our laboratory found that oxidants induce c-Fos protein phosphorylation downstream of JNK activation. c-Fos protein phosphorylation results in resistance against proteasome mediated c-Fos degradation. Here we test whether Ser 374, a consensus phosphorylation site of MAKPs, mediates oxidant induced c-Fos protein stabilization. When wild type or Ser374 replacement mutant c-Fos was transfected into HEK293 cells, the phosphomimic mutant (374-Asp) of c-Fos has a higher basal level of c-Fos protein, which is further elevated by H2O2 treatment compared with the wild type c-Fos. The phospho eliminating mutant (374-Ala) had a lower basal or H2O2 induced level of c-Fos protein. The c-Fos protein increases in the absence of c-fos mRNA increase, suggesting a role protein stabilization in H2O2 induced c-Fos protein elevation. Inhibiting protein synthesis with cycloheximide caused a rapid decrease of 374-Ala by 90% within 1 hr of H2O2 treatment, while wild type c-Fos decreased by 50% and 374-Asp mutant decreased only 10%. The proteasomal inhibitor MG132 caused an accumulation of c-Fos protein. Our data suggest that 374-Ser residue plays a critical role in H2O2 induced c-Fos protein stabilization.

PS 947 INHIBITION OF NFκB ATTENUATES HYPEROXIA-INDUCED HMGB1 RELEASE FROM MACROPHAGES.

M. G. Muralidhar[1], T. Zaher[1], K. J. Tracy[2] and L. L. Mantell[1, 2]. [1]*St Johns University, New York, NY and* [2]*The Feinstein Institute for Medical Research, North Shore-LIJ Health System, New York, NY.*

Mechanical ventilation and therapy with high concentrations of oxygen (hyperoxia) is a life saving intervention in patients with respiratory insufficiency including sepsis. However, exposure to hyperoxia is associated with pulmonary toxicity. Our previous studies demonstrate that HMGB1 can be released from macrophages exposed to prolonged hyperoxia and contributes to hyperoxia-induced inflammatory lung injury. The objective of this study was to elucidate whether pro-inflammatory transcription factor NFκB mediates the release of HMGB1 under hyperoxic conditions from macrophages using RAW 264.7 cells (a macrophage-like cell line). Bay 11-7821, a selective and irreversible inhibitor of NFκB activation, was first used in this study. Raw 264.7 cells were exposed simultaneously to a series of concentrations of Bay 11-7821 and hyperoxia (95% O2) for 24hr. Nuclear translocation and HMGB1 release were determined by immunofluorescence and Western Blotting analyses. The release of HMGB1 under hyperoxic conditions was inhibited by the treatment with Bay 11-7821 in a dose-dependent manner. To further confirm that NFκB is mediating hyperoxia-induced HMGB1 release, Ethacrynic acid (EA), a diuretic which inhibits NFκB signaling, was also used. Inhibition of HMGB1 release was also seen with EA (1-2-4μM). Immunofluorescence analysis showed that the inhibition of HMGB1 release with both Bay 11-7821 and EA was a result of nuclear localization of HMGB1. Corresponding to the decreased release of HMGB1, Bay 11-7821 and EA significantly improved macrophage's ability to migrate under hyperoxia. These results indicate that HMGB1 release from macrophages under hyperoxia is at least partly mediated by NFκB, which may be used as a potential therapeutic target to minimize HMGB1 induced pulmonary inflammation and macrophage dysfunction.

PS 948 15-DEOXY-Δ12, 14 PROSTAGLANDIN J2-INDUCED HEME OXYGENASE-1 IN MEGAKARYOCYTES REGULATES THROMBOPOIESIS.

Platelet production is an intricate process that is poorly understood. Recently, we demonstrated that the natural peroxisome proliferator-activated receptor gamma (PPARγ) ligand, 15-deoxy-Δ12,14 prostaglandin J2 (15d-PGJ2), augments platelet numbers by increasing platelet release from megakaryocytes through the induction of reactive oxygen species (ROS) (O'Brien, Blood, 2008). 15d-PGJ2 can exert effects independent of PPARγ, such as increasing oxidative stress. Heme oxygenase-1 (HO-1) is a potent antioxidant and may influence platelet production. To further investigate the influence of 15d-PGJ2 on megakaryocytes and to understand whether HO-1 plays a role in platelet production, Meg-01 cells (a primary human megakaryoblastic cell line) and primary human megakaryocytes derived from cord blood were used to examine the effects of 15d-PGJ2 on HO-1 expression in megakaryocytes and their daughter platelets. 15d-PGJ2 potently induced HO-1 protein expression in Meg-01 cells and primary human megakaryocytes. The platelets produced from these megakaryocytes also expressed elevated levels of HO-1. 15d-PGJ2-induced HO-1 was independent of PPARγ, but could be replicated using other electrophilic prostaglandins, suggesting that the electrophilic properties of 15d-PGJ2 were important for HO-1 induction. Interestingly, inhibiting HO-1 activity enhanced ROS generation and augmented 15d-PGJ2-induced platelet production, which could be attenuated by antioxidants. These new data reveal that HO-1 negatively regulates thrombopoiesis by inhibiting ROS.

PS 949 OXIDATIVE LIPIDOMICS OF ACUTE LUNG INJURY INDUCED BY HYPEROXIA AND GAMMA-IRRADIATION.

Pulmonary endothelium is the locus of early structural and functional changes in acute lung injury induced by toxins, hyperoxia and irradiation. Apoptosis of pulmonary endothelium is a contributing factor to genesis of acute lung injury and maintenance of delayed responses. Signaling roles of phospholipid (PL) oxidation products in endothelial apoptosis in the lung have not been studied. C57BL/6NHsd female mice were subjected to total body irradiation (TBI) (5, 10 and 15 Gy, sacrificed 24 h, 125 days thereafter) or to hyperoxia (99% oxygen, sacrificed 72 h thereafter). We found that both hyperoxia and irradiation caused apoptosis, as revealed by caspase-3/7 activation. Using a lipidomics approach, we established that pulmonary lipids undergo non-random peroxidation after acute injury: two anionic PLs – mitochondria-specific cardiolipin (CL) and plasma membrane phosphatidylserine (PS) – are the two major oxidized PLs while more abundant PLs such as phosphatidylcholine (PC) and phosphatidylethanolamine (PE) – remain non-oxidized. Similar to lung injury in vivo, LC-MS analysis revealed the formation of several oxygenation products in the same two anionic PLs – CL and PS - in mouse pulmonary endothelial cells (MLECs) after exposure to dose of either hyperoxia (95% oxygen), or irradiation (15 Gy). This oxidation of MLEC phospholipids was accompanied by significant activation of caspases 3/7. Two most abundant MLEC PLs - PC and PE - did not reveal any oxidation products in spite of the presence of highly oxidizable polyunsaturated fatty acid residues in them. We speculate that cyt c driven oxidation of CL and PS is associated with the execution of apoptosis in pulmonary endothelial cells thus contributing to endothelial cell dysfunction in acute lung injury. PS 950 DETECTION OF ACETAMINOPHEN PHARMACOKINETICS USING MASS SPECTROMETRY BASED METABONOMICS.

R. D. Beger, J. Sun and L. K. Schnackenberg. *National Center for Toxicological Research, Jefferson, AR.*

Understanding of a drug's pharmacokinetics is extremely important for drug discovery and development. Liquid chromatography coupled with mass spectrometry with exact mass accuracy combined with multivariate statistical principal component analysis (PCA) can provide rapid detection of drug metabolites lowering both the cost and time associated with the drug discovery process. The strategy described here using acetaminophen (APAP) as a model compound shows the capability to detect APAP metabolites in urine samples. The PCA scores plot shows a clear separation in groups 8 hrs post-dosing with vehicle (control), acute administration (rats treated with acute single dose of 400 mg/kg or 1600 mg/kg APAP) and chronic dosing (rats dosed daily with 200, 400 or 800 mg/kg APAP). Using this approach, APAP, APAP-sulfate, APAP-glucuroninide, APAP-N-acetyl-L-cysteine (APAP-NAC) APAP-cysteine, APAP-SOCH3 and APAP-S-S-APAP were detected. After an APAP overdose, glutathione (GSH) can deactivate N-acetyl-p-benzoquinone imine (NAPQI, reactive intermediate responsible for tissue damage) to form an APAP conjugate (APAP-GSH). The corresponding conjugates including APAP-NAC, APAP-cysteine, APAP-SOCH3 and APAP-S-S-APAP are breakdown products of APAP-GSH. Results show that APAP eliminated in urine as APAP-NAC

was extremely low in the animals dosed with sub-toxic concentrations of APAP, but was extremely high in the group administered a toxic dose on day 2, which is consistent with histopathology data that showed tissue damage only in the high dosed animals on day 2. Large amounts of APAP-NAC were present in urine from both low dosed and high dosed animals on day 1, while on day 2, only urine samples from high dosed rats had a larger concentration of APAP-NAC. APAP-NAC levels were also consistent with the decreased concentration of S-adenosylmethionine in urine for both the low dosed and high dosed animals. This approach is of importance for the rapid detection of drug candidate pharmacokinetics in biofluids during drug screening and development.

PS 951 PHARMACOKINETIC AND PHARMACODYNAMIC PROFILES OF THE ASPIRIN METABOLITE SALICYLATE FOLLOWING ORAL GAVAGE AND DIETARY ADMINISTRATION OF ASPIRIN IN RATS.

D. M. Tessier[1], I. M. Kapetanovic[2], K. S. Bauer[3], M. O. Lindeblad[1], A. D. Zakharov[1], R. Lubet[2] and A. Lyubimov[1]. *[1]Toxicology Research Laboratory, University of Illinois Chicago, Chicago, IL, [2]Division of Cancer Prevention, National Cancer Institute, Bethesda, MD and [3]School of Pharmacy, University of Maryland, Baltimore, MD.*

The aim of this study was to compare oral gavage and dietary administration of aspirin in a pharmacokinetic / pharmacodynamic study in rats. The non-steroidal anti-inflammatory drug (NSAID), aspirin, is the subject of intense study as an agent in the prevention of cardiovascular disease and cancer. In animal models, an untested assumption is that exposure and the resultant pharmacological effects are similar for both gavage and dietary administration. However, for another NSAIDs, Sundilac, the route of administration significantly alters pharmacokinetic and pharmicodynamic profiles. This study examined and compared time-dependent plasma and colon mucosal concentrations of aspirin metabolite salicylate, plasma thromboxane B2 (TXB2), and colon mucosal prostaglandin E2 (PGE2) concentration following the two different dosing paradigms. Diet dosing yielded relatively constant plasma and colon salicylate concentration vs. time profiles. Oral gavage dosing led to a rapid peak followed by a fast decline in salicylate concentration in both plasma and colon. Nevertheless, the exposures as measured by the area under the concentration-time curve (AUC0-24h) of salicylate was linearly related to dose irrespective of the dosing method. Linear relationships were also observed between colon and plasma salicylate AUC0-24h and between colon PGE2 and plasma TXB2 AUC0-24h. This study therefore demonstrated that: 1.) For aspirin, which is rapidly absorbed and metabolized in the rat, the choice of gavage vs. dietary administration does not impact plasma or colon AUC's for the salycilate metabolite, nor does it impact the pharmacodynamic marker; and 2.) The more easily accessible plasma salicylate and TXB2 concentrations were representative of the salicylate exposure and the PGE2 pharmacodynamic biomarker in the colon target tissue.

PS 952 DISPOSITION OF DOUBLE-RADIOLABELED LIPOPOLYSACCHARIDE (LPS) IN THE RAT BRAIN AND PERIPHERAL ORGANS.
