### 6.1 Solving Equations by Using Inverse Operations

 $\frac{\text{Inverse}}{\text{others results.}} \xrightarrow{\text{Operations}} \text{"undo" or reverse each others results.}$   $\frac{\text{Examples:}}{\text{and}} \xrightarrow{\text{are inverse operations.}} \xrightarrow{\text{are inverse operations.}} \xrightarrow{\text{x}} \xrightarrow{\text{and}} \xrightarrow{\text{are inverse operations.}} \xrightarrow{\text{x}} \xrightarrow{\text{and}} \xrightarrow{\text{x}^2} \xrightarrow{\text{x}^2} \xrightarrow{\text{are inverse operations.}} \xrightarrow{\text{x}} \xrightarrow{\text{x}} \xrightarrow{\text{and}} \xrightarrow{\text{x}^2} \xrightarrow{\text{x}^2} \xrightarrow{\text{are inverse operations.}} \xrightarrow{\text{x}} \xrightarrow{x$ 

## **Example 1: Writing Then Solving One-Step Equations**

For each statement below, write then solve an equation to determine each number. Verify the solution.

a) Three times a number is 12.

$$3x = 12$$
  
 $x = 4$ 

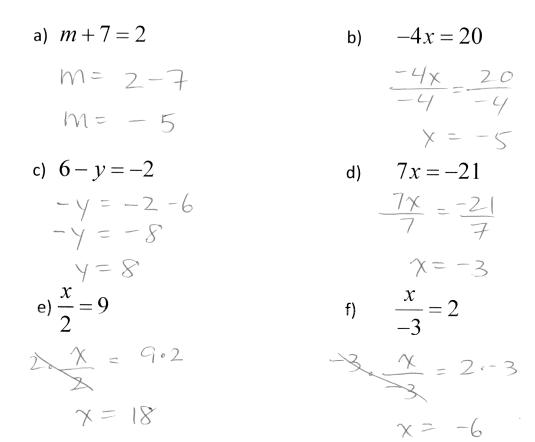

b) A number divided by 4 is 8.

$$\frac{\chi}{4} = 8 \qquad \chi = 32$$

c) A number plus 7 is 15.

$$\chi + 7 = 15$$
$$\chi = 8$$

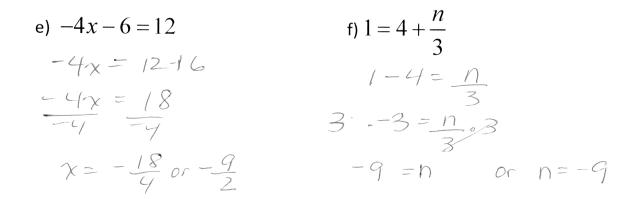

**Example 2: Solving One-Step Equations.** 

### Example 3: Solving a Two-Step Equation

- a) 2x+1=7 2x = 7-1  $\frac{2x}{2} = \frac{6}{2}$  $\chi = 3$
- c) 5m + 2m = 7 + 2 $\frac{7m}{7} = \frac{9}{7}$  $m = \frac{9}{7}$  $m = \frac{9}{7}$

b) 
$$-3x-2 = -11$$
  
 $-3x = -11 + 2$   
 $-3x = -9$   
 $-3 = -3$   
 $x = 3$   
d)  $\frac{w}{2} - 1 = 11$   
 $\frac{w}{2} = 1(+1)$   
 $2 \cdot \frac{w}{2} = 12 \cdot 2$   
 $w = 24$ 

## Example 4: Using an Equation to Model and Solve a Problem

A rectangle has length 3.7 cm and perimeter 13.2 cm.

- a) Write an equation that can be used to determine the width of the rectangle.
- b) Solve and verify the equation.

a) 
$$\chi = \frac{3.7 \text{ cm}}{\text{N}} \times \frac{13.7 \text{ cm}}{\text{P} = 13.2 \text{ cm}} \times \frac{13.2 \text{ cm}}{\text{P} = 2 \times + 7.4} = 13.7 \text{ b) } 2 \times +7.4 \text{ cm} = 13.2 \text{ cm} \times \frac{13.2 \text{ cm}}{\text{P} = 2 \times + 7.4} = 2 \times +7.4 \text{ cm} \times \frac{2 \times -5.8}{2} \text{ cm} \times \frac{2 \times -5.8}{2} \text{ cm} \times \frac{13.2 \text{ cm}}{2} = 2 \times +7.4 \text{ cm} \times \frac{2 \times -5.8}{2} \text{ cm} \times \frac{13.2 \text{ cm}}{2} \text{ c$$

### Example 5: Using an Equation to Solve a Percent Problem

a) 7% of a number is 56.7. Find the number.

$$7\% = 56.7$$
  
 $0.07x = 56.7$   
 $0.07x = 56.7$

## 6.2 Solving Equations by Using Balance Strategies

### Investigate: Try the Balance Puzzle.

When solving linear equations, think of the equation as a <u>balance</u>, with the <u>sign</u> as the middle or <u>fulcrum</u>.

When an operation is done to one side of an equation, it must be done to the other in order to keep balance.

The idea is to isolate <u>Variables</u> on one side and <u>Constants</u> on the other side.

## **Example 1: Modelling Equations with Variables on Both Sides**

a) $6x + 2 = 10 + 4x$	b) $7x + 1 = 2x - 6$
6x - 4x = 10 - 2	7x - 2x = -6 - 1
$2\chi = 8$	5x = -7
$\chi = 4$	$\chi = -\frac{7}{5}$
c) $-3x+1 = -4x+4$	d) $8c + 2c = 3c + 9$
-3x + 4x = 4 - 1	10C = 3C + 9
$\chi = 3$	10c - 3c = 9 $7c = 9$
	C = 9/7
e) $-8m + 7 = -6m + 3$	f) $-8y + 2 = 8y + 3$
-8m + 6m = 3 - 7 -2m = -4	-8y - 8y = 3 - 2
m = 2	-16y = 1
	$y = \frac{-1}{10}$

Use the distributive property to remove brackets and then solve.

g) 2(x+1) = 7 2x + 2 = 7 2x = 7 - 2 -3x - 2x = -8 + 3 -5x = -5 x = 5/2x = 1

i) 
$$4(x+2)+2(x+1) = 7$$
  
 $4x+8+2x+2 = 7$   
 $6x+10 = 7$   
 $6x = 7-10$   
 $6x = -3$   
 $\chi = -\frac{3}{6} = -\frac{1}{2}$ 

$$5(c+3) - (c+4) = 1$$
  

$$5(c+15 - c - 4 = 1)$$
  

$$4c + 11 = 1$$
  

$$4c = -10$$
  

$$c = -\frac{10}{4} = -\frac{5}{2}$$

k) 
$$3(m-3)-2(m+4)=6$$
  
 $3m-9-2m-8=6$   
 $m-17=6$   
 $m=6+17$   
 $m=23$ 

# Example 2: Solving Equations with Rational Coefficients (Fractions)

To get rid of a fraction, multiply each term by the <u>Common</u> <u>denominator</u>.

a) 
$$\frac{2x}{3} = \frac{4x}{5} + 7$$
 (15)  $\frac{2\gamma}{3} = (15) \frac{4\gamma}{5} + (15) 7$   
LCD = 15  $10\chi = 12\chi + 105$   
 $10\chi = 12\chi + 105$   
 $10\chi - 12\chi = 105$   $\chi = -105$   
b)  $\frac{x}{2} - \frac{3x}{4} = 1$  (4)  $\frac{\gamma}{2} - \frac{(4)}{3\chi} = (4) 1$   
LCD =  $4$   $2\chi - 3\chi = 4$   
 $-1\chi = 4$   $\chi = -4$ 

c) 
$$\frac{2x+1}{4} + \frac{3x-2}{3} = 2$$
  
LCD = 12  
d)  $\frac{(x-4)}{7} = \frac{(2x+1)}{3}$   
LCD = 12  
 $\frac{12(2x+1)}{4} + \frac{12(3x-2)}{3} = 12(2)$   
 $\frac{12(2x+1)}{4} + \frac{12(3x-2)}{3} = 12(2)$   
 $\frac{12(2x+1)}{4} + \frac{12(3x-2)}{3} = 24$   
 $\frac{12(2x+1)}{18x-2} = 24$   
 $\frac{18x-29}{18}$ 

LCD=21

$$\frac{21(x-4)}{7} = \frac{21(2x+1)}{3} - 11x = 19$$
  

$$\frac{3(x-4)}{3x-12} = 7(2x+1) \qquad \boxed{x = -19}{11}$$
  

$$\frac{3x-12}{3x-14x} = 7+12$$

Example 3: Using an Equation to Model and Solve a Problem

A cell phone company offers two plans.

Plan A: 120 free minutes, \$0.75 per additional minute Plan B: 30 free minutes, \$0.25 per additional minute

Which time for calls will result in the same cost for both plans?

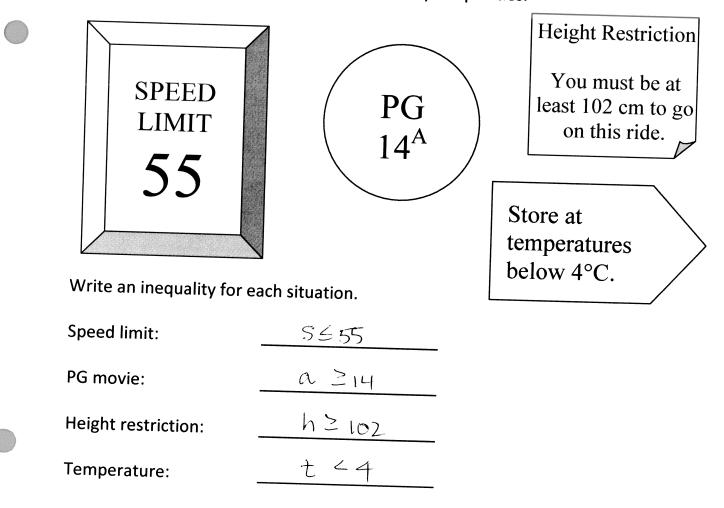

Model the problem with an equation and solve the problem.  $|\ell + \chi = t_{i} m \ell_{i}$ 

A: 0.75(x - 120) B: 0.25(x - 30) 0.75(x - 120) = 0.25(x - 30) 0.75x - 90 = 0.25x - 7.5 0.75x - 0.25x = -7.5 + 90 0.5x = 82.5x = 165 min.

## Recall the following symbols:

Investigate:

Many real-world situations can be modeled by inequalities.

## Example 1: Writing an Inequality to Describe a Situation

Define a variable and write an inequality to describe each situation.

a) Contest entrants must be at least 18 years old.  $\alpha \geq 18$ 

b) The temperature has been below -5°C for the last week.

c) You must have 7 items or less to use the express checkout line.

d) Scientists have identified over 400 species of dinosaurs. S > 400

+. L -5

 $\leq 7$ 

We use an <u>inequality</u> to describe a <u>range</u> of numbers instead of a single number.

A linear equation is true for only <u>One</u> value of the variable.

A linear inequality may be true for <u>many</u> values of the variable. There are usually too many values to list, so we show them on a <u>number line</u>.

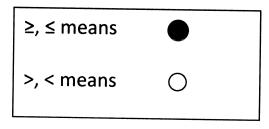

## Example 2: Determining Whether a Number Is a Solution of an Inequality

a) Consider  $x \ge -4$ . Which number is part of the solution?

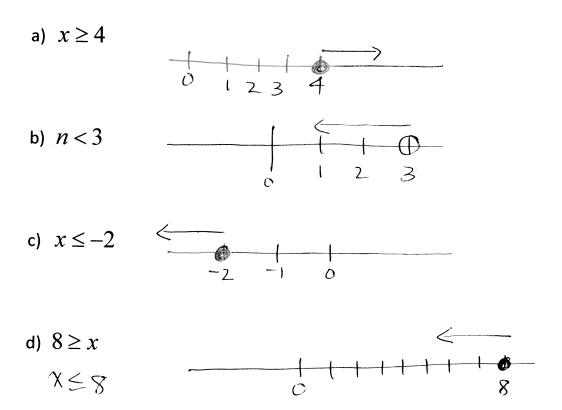

-8 × -3.5 / -4 / -4.5 × 0 / b) Consider x < 9. Which number is part of the solution?

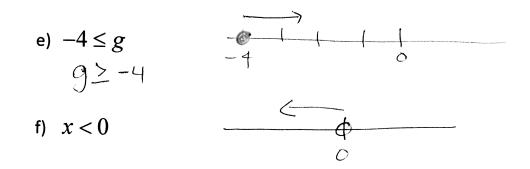

17 × 0 ✓ -2 ✓ 9 × 12 ×

When graphing inequalities on a number line, a <u>closed</u> <u>circle(shaded)</u> or dot will indicate the inclusion of that point and an <u>Open circle(non-shaded)</u> or hole will indicate the non-inclusion of that point.

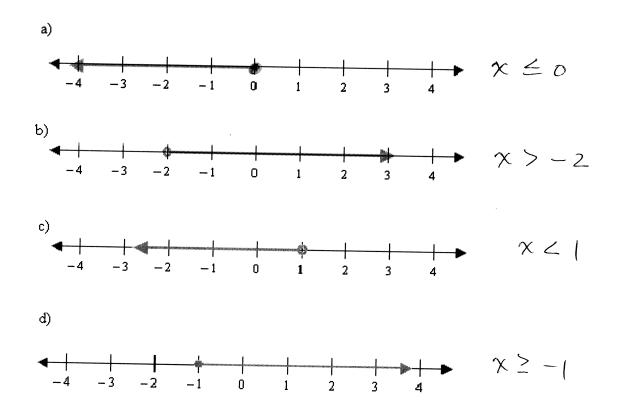

## Example 3: Graphing Inequalities on a Number Line

Now give the inequality for each number line below.

## 6.4 Solving Linear Inequalities by Using Addition and Subtraction

### **Solving an Inequality**

When the same number is added to or subtracted from each side of an inequality, the resulting inequality is still true.

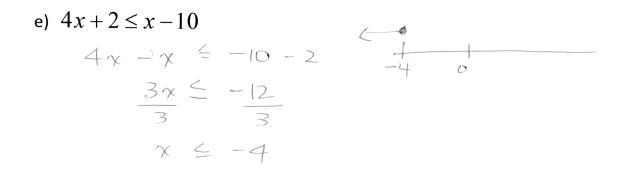

For Example:

$$3 < 7$$
  
 $3 + 1 < 7 + 1$   $4 < 8$   $\checkmark$  Stall true!  
or  
 $3 - 6 < 7 - 6$   $- 3 < 1$   $\checkmark$  Stall true!

**Example 1: Solving and Inequality** 

a) 2x + 1 < 3ax < 3-1  $\frac{\partial \chi}{\partial z} < \frac{2}{2}$ XLI b)  $6x - 7 \ge 8$  $\frac{\chi \ge 15}{6} \text{ or } \chi \ge \frac{5}{2} \text{ or } \chi \ge 2.5$ 6x 2 8+7  $6x \ge 15$  $\xrightarrow{ 0 \rightarrow }$ c) 3x+1>93x> 9-1  $\frac{3x>8}{3}$  $\chi > 8_{/3}$ 

d) 5x + 1 < 2x - 7 5x - 2x < -7 - 1  $\frac{3x}{3} < \frac{-8}{3}$ x < -8/3.

## Example 2: Using an Inequality to Model and Solve a Problem

Jake plans to board his dog while he is away on vacation. Boarding House A charges \$90 plus \$5 per day. Boarding House B charges \$100 plus \$4 per day. For how many days must Jake board his dog for Boarding House A to be **less** expensive than Boarding House B?

a) Choose a variable and write an inequality. Let x = ho of days.

- b) Solve the problem.
- c) Graph on a number line.

a) A: 
$$90 + 5x$$
 A less than B  
B:  $100 + 4x$   
 $90 + 5x < 100 + 4x$   
 $90 - 100 < 4x - 5x$   
 $10 < -1x$   
 $10 < -1x$   
 $1x < 10$   
 $10 < 1x$   
 $1x < 10$

## 6.5 Solving Linear Inequalities by Using Multiplication and Division

### Investigate:

8 > 3 Now multiply both sides by 2.

16 > 6 This is still true.

8 > 3 Now multiply both sides by -2.

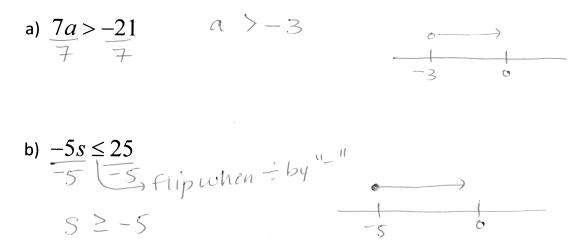

-16 > -6 This is not true.

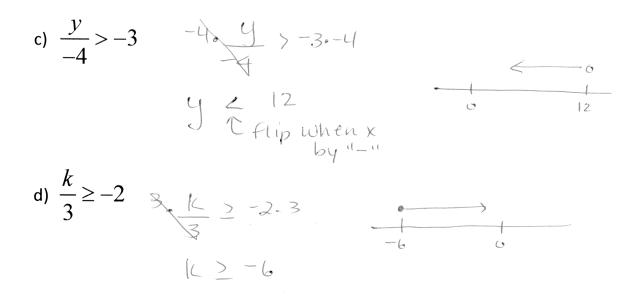

To overcome this, follow the following properties of inequalities:

- When each side of an inequality is multiplied or divided by the same positive number, the resulting inequality is still true.
- When each side of the inequality is multiplied or divided by the same negative number, the inequality sign must be **reversed** for the inequality to remain true.

So from above, -16 < -6 This is now true.

### **Example 1: Solving a One-Step Inequality**

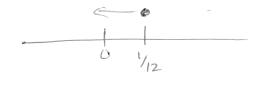

#### **Example 2: Solving a Multi-Step Inequality**

a) 
$$3x+1 > 6x+4$$
  
 $3x - 6x > 4-1$   
 $\frac{-3x}{-3} > \frac{3}{-3}$  flip!  
 $x < -1$ 

b)  $-5x+2 \ge 7x+1$   $-5x-7x \ge 1-2$   $-1ax \ge -1$  -1ax = -1 -1ax = -1-1ax =

c) -2(x+1) < 3(x-2) distribute first! -2x-3x < -6+2 -5x < -4 + 1x > 4/5

## Example 3: Using an Inequality to Model and Solve a Problem

A super-slide charges \$1.25 to rent a mat and \$0.75 per ride. Haru has \$10.25. How many rides can she go on?

- a) Choose a variable, then write an inequality to solve this problem.
- b) Solve the problem.
- c) Graph the solution.

a) let n= number of rides.  
1.25 
$$\pm$$
 0.75 n  $\leq$  10.25  
b) 0.75 n  $\leq$  10.25 -1.25  
 $\frac{0.75 n}{.75} \leq \frac{9}{.75}$   
n  $\leq$  12  
She can go on 12 rides or less
