# **1.0 Introduction**

The U.S. Environmental Protection Agency (USEPA) has initiated remedial design (RD) efforts for groundwater contamination at the Ace Services site near Colby, Kansas. The RD process is the methodology that the Superfund program has established for remediating risks posed by uncontrolled hazardous waste sites. Documents detailing the methodology for preliminary RD activities at the Ace Services site consist of a work plan (WP) (BVSPC, 1999a and 1999f), a field sampling plan (FSP) (BVSPC, 1999b and 2000a), a site management plan (SMP) (BVSPC, 1999e), a quality assurance project plan (QAPP) (BVSPC, 1999c and 2000b), and a health and safety plan (HSP) (BVSPC, 1999d and 2000c).

This Addendum No. 1 to the RD sampling activities technical memorandum presents a description of field activities performed in July, August, and September 2000, as preliminary RD activities at the Ace Services site. It describes the following items:

- Installation and development of groundwater extraction and observation wells.
- Survey of newly installed extraction and observation wells.
- Analytical results of existing groundwater monitoring wells, recovery wells, water supply wells, and residential wells (September 2000).
- Description of the sampling methodologies for the various media.
- Procedures for managing derived wastes.
- Nature and extent of groundwater contamination.
- Pump test results of contaminated aquifer zones.
- Groundwater flow modeling results and extraction well field design.

The previous RD sampling activities technical memorandum (BVSPC, 2000d) presents a description of activities performed in October 1999 (Phase 1) and February 2000 (Phase 2) and should be referred to for supplemental information. Comments provided by EPA and KDHE were incorporated into the document and are included in Appendix J. The previous RD Sampling Activities Technical Memorandum describes the following items:

- Installation, development, and sampling of new groundwater wells.
- Analytical results of existing groundwater monitoring wells, recovery wells, water supply wells, and residential wells (October 1999 and February 2000).
- Descriptions of the sampling methodologies for the various media.
- Procedures for managing derived wastes.
- Evaluation of subsurface soils in historical lagoon area.
- Nature and extent of groundwater contamination.

• Survey of new monitoring wells.

#### **1.1 Site Location and History**

The Ace Services site is located near the east edge of Colby, Kansas, at 345 Convesse Street in Thomas County. The geographic coordinates for the site are approximately 100°02'10" West Longitude and 39° 23' 47" North Latitude. The site lies in the southeast quarter of Section 31, Township 7 South, Range 33 West. The facility is next to the Thomas County Mental Health Center and a hardware store. The Thomas County courthouse is approximately 2-1/2 blocks west of the site. The surrounding property is primarily light industrial and commercial, although there are some residential properties within 2 blocks of the site. A railroad right-of-way, aligned north-south, is approximately 1 block west of the site.

Northwest Manufacturing Company operated a chromium plating facility at the site from 1954 to 1969, when Ace Services was formed and began operating an electroplating facility. Ace Services operated the facility until 1989 when it forfeited its corporate status and abandoned the facility.

# 1.2 Purpose and Scope

The purpose and scope of this report is to describe the results of the preliminary RD investigation activities and describe revised proposed activities based on the results.

# 2.0 Investigation Objectives

The objective of the preliminary RD sampling efforts was to complete characterization of the chromium groundwater plume and complete characterization of aquifer characteristics. The data acquired during the preliminary RD activities will be used for design of groundwater remediation systems. The scope of the preliminary RD activities included:

- Installing and sampling new monitoring wells.
- Sampling existing monitoring wells.
- Sampling existing recovery and water supply wells.
- Sampling residential wells.
- Installing groundwater extraction and observation wells.
- Evaluation of subsurface soils in historical lagoon area.
- Survey of newly installed groundwater monitoring wells.
- Performing pumping tests of contaminated aquifer zones and measuring groundwater levels.
- Collecting subsurface soil samples for geotechnical evaluation.
- Performing a ground survey to develop a base map for design drawings.

The objectives identified above have been completed at the time of this memorandum except for the objectives listed below:

- Installing and sampling monitoring wells.
- Collecting subsurface soil samples for geotechnical evaluation.
- Performing a ground survey to develop a base map for design drawings.

Two additional groundwater monitoring well nests consisting of shallow and intermediate depth wells are to be installed south of the railroad tracks near monitoring well nests MW-11 and MW-12. Final locations of the wells will be controlled by property access restrictions and technical adequacy.

Additional subsurface soil samples may need to be collected and evaluated for geotechnical properties. The existing onsite machine shop is to be used to house the treatment system, therefore, a separate building will not be constructed. However, geotechnical information concerning the site may be needed for other structures.

The ground survey for the base map will be performed after property access has been granted by all required property owners. The base map will be provided under separate cover.

# 3.0 Investigation Activities

Field investigation activities for the preliminary RD efforts are discussed in this section. The following subtasks are discussed:

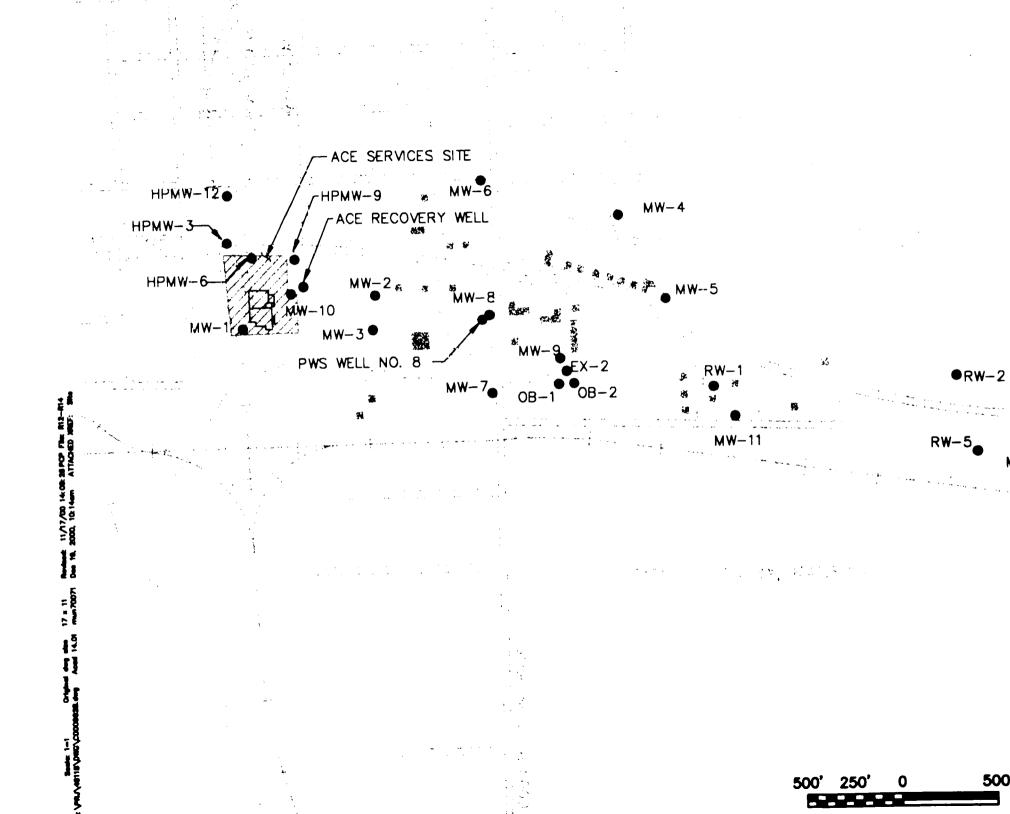

- Well Installation.
- Groundwater Sampling Locations and Analyses.
- Groundwater Sampling Procedures.
- Decontamination Procedures.
- Treatability Study Groundwater Sampling.
- Aquifer Pump Test.
- Numerical Computer Modeling of Groundwater Flow.

A site map illustrating the locations of all wells is presented as Figure 3-1. Final well locations were agreed to by EPA, KDHE, and the City of Colby.

The RD investigation activities discussed in this memorandum were conducted in July, August, and September 2000. Well nests EX-2, OB-1, and OB-2 were installed and developed during July 10, 2000 to July 19, 2000. Pump tests for the shallow, intermediate, and deep aquifer zones were conducted from July 31, 2000 to August 10, 2000. Groundwater sampling activities were conducted from September 18, 2000 to September 22, 2000.

#### 3.1 Well Installation

The groundwater well construction details are described in this section. The drilling and well installation was conducted by Woofter Pump and Well, Inc., of Hoxie, Kansas, a drilling subcontractor licensed in the State of Kansas. The wells installed as part of the Phase 2 remedial design sampling activities are listed in Table 3-1. At all times during the progress of the work, precautions were used to prevent tampering with the well or the entrance of foreign material into the well. Runoff was prevented from entering the well during construction. The completed wells have a sanitary seal to prevent material from entering the wells.

RAC VII Ace Services Site Addendum No. 1 - TM

#### 3.1.1 Observation Wells

Observation wells installed for the preliminary RD efforts are listed in Table 3-1. The observation wells were constructed using 4 inch diameter, polyvinyl chloride (PVC) riser pipe and screen. The riser pipe was Schedule 40 PVC. The well screens were 20-foot-long, Schedule 40 PVC with 0.020-inch slots.

Observation wells were installed in a nested fashion and consist of three wells at various depths to respectively evaluate shallow (110 to 130 feet), intermediate (172 to 195 foot) and deep (215 to 235 feet) aquifer zones. The water table ranged in depth from approximately 108 to 113 feet below ground surface (bgs) and impermeable shale bedrock (Pierre Shale Formation) was encountered at approximately 235 feet bgs.

A test hole for each well nest was drilled from the ground surface to bedrock and logged by the onsite geologist. The lithologic information was used to select the specific screen depth for each water bearing zone and monitoring well. Screen lengths for the wells were field determined and each well was installed within the selected water bearing zone at each well nest location.

Wells within the well nest were installed so that the shallow well is upgradient of the intermediate well and the intermediate well is upgradient of the deep well. Individual wells were installed approximately 15 feet apart.

The annular space around well screens was backfilled with a silica sand filter pack that conformed to screen gradation analysis requirements of not less than 95 percent of the sand passing US Standard Sieve No. 10 and not more than 5 percent passing US Standard Sieve No. 20. The filter pack extended from the bottom of the borehole to a minimum of 3 feet above the top of the screen. The annular space above the filter pack was backfilled with a minimum of 5 feet of bentonite chips. The annular space above the bentonite chips to the surface was backfilled with cement/bentonite grout tremied into place. A locking above ground or, where required, flush mount cover was installed to secure the well head.

#### 3.1.2 Extraction Wells

Extraction wells installed for the preliminary RD efforts are listed in Table 3-1. Extraction well EX-2-S was constructed using 6 inch diameter PVC riser pipe and screen. Extraction wells EX-2-I and EX-2-D were constructed using 8 inch diameter PVC riser pipe and screen. The riser pipe was Schedule 40 PVC. The well screen was constructed of Schedule 40 PVC with 0.032-inch slots.

Extraction wells were installed in a nested fashion and consist of a maximum of three wells at various depths to respectively extract contaminated groundwater at shallow (100 to 130 feet), intermediate (145 to 190 foot) and deep (195 to 235 feet) aquifer zones. Results from the plume characterization study were used to determine which aquifer zones are contaminated.

A test hole for the well nest was drilled first and logged by the onsite geologist. The boring log information was used to select the specific screen depth for each extraction well. Screen length for the wells was field determined and installed within the selected water bearing zone at each extraction well location.

Wells within the well nest were installed with the shallow well upgradient of the intermediate well and the intermediate well, upgradient of the deep well. Individual wells were installed approximately 15 feet apart. A detailed location map for observation well nests OB-1 and OB-2 and extraction well nest EX-2 is presented in Figure 3-2.

The annular space around the screen was backfilled with No. 1 Fine Washed Silica Sand filter pack. The filter pack extended from the bottom of the borehole to a minimum of 3 feet above the top of the screen. The annular space above the filter pack was backfilled with a minimum of 5 feet of bentonite chips. Remaining annular space about the bentonite seal was backfilled to the ground surface with bentonite grout. A locking flush mount cover was installed to secure the well head.

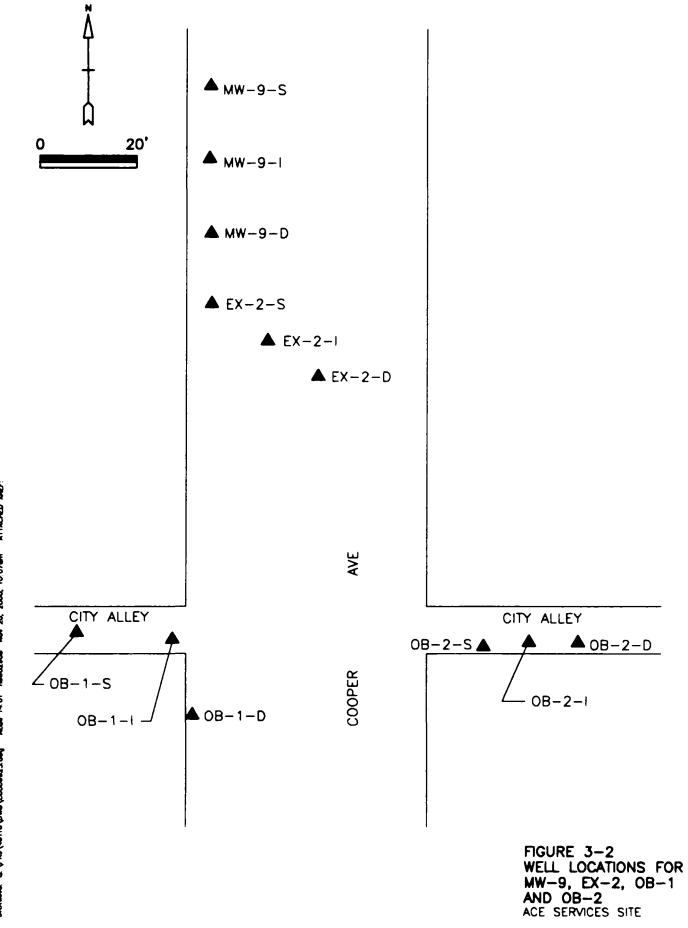

#### 3.1.3 Boring Logs and Well Construction Logs

Boring logs and well construction logs for wells listed in Table 3-1 are provided in Appendix A and Appendix B, respectively.

#### 3.1.4 Well Development

Well development consisted of surging and pumping the well using an electric submersible pump. The temperature, pH, specific conductivity, turbidity, dissolved oxygen (DO), and oxidation reduction potential (ORP) was monitored during pumping. Well development data was recorded in the field data sheets (Appendix C). Pumping continued until the field parameters stabilized and the water was clear and free of fines.

In all cases, care was taken not to collapse well screens during development activities, and at least half as much water as was introduced during drilling was removed during development and construction of each well. Development fluids (fluids recovered from the wells during development) were collected and managed as described in Section 4.0.

# 3.2 Sampling Locations and Analyses

The scope of the preliminary RD investigation included groundwater sampling and analysis for newly installed wells (Table 3-1) and currently existing wells (Table 3-2). The locations of the wells are shown on Figure 3-1. Groundwater samples were analyzed for total chromium (Cr). Samples from wells representative of extracted groundwater were analyzed for total chromium and hexavalent chromium. Groundwater samples were collected separately for treatability study purposes from wells EX-2-S, EX-2-I, EX-2-D, RW-6, and a composite sample from several monitoring wells. The treatability study samples were analyzed for several wet chemistry and metals parameters. Results of the samples will be discussed in the treatability study report. All samples were unfiltered.

Analytical parameters, analytical methods, sample container requirements, preservation methods, and holding times are summarized by sample media in Table 3-3. The total number of samples collected during the investigation including duplicates, blanks, and other quality control samples are summarized by sample media in Table 3-4.

# 3.3 Groundwater and Soil Sampling Procedures

The following general procedures were practiced when sampling:

- A clean pair of new, disposable surgical gloves were worn each time a sample was collected and equipment was deontaminated or replaced with new material between each sample.
- During the course of the field investigation, all samples were properly documented, as described in the FSP (BVSPC, 1999b), FSP Addendum (BVSPC, 2000a), QAPP (BVSPC, 1999c), and QAPP Addendum (BVSPC, 2000b). Documentation included completion of chain of custody (COC) forms, field logbook documentation, and sample labels for sample containers.
- Samples were immediately sealed, kept out of the sun, and kept cool by ice after collection.
- All samples for hexavalent chromium analysis were shipped "Next Day Air-Early A.M." by UPS for 7:30 A.M. delivery to meet the 24 hour holding time.

#### 3.3.1 Water Level Measurement

Water levels for existing wells were measured prior to any intrusive work. The water level, time of measurement, and date were recorded.

# Table 3-2Existing Wells Sampled as part of the Remedial Design (September 2000)Ace Services Site<br/>Remedial Design

#### 3.3.2 Well Purging/Development and Groundwater Sample Collection

Before sampling, the depth to water was measured and recorded. Using information from the well construction logs, the total volume of water in the well casing was determined. The subcontractor (Woofter Pump and Well, Inc., Hoxie, Kansas) purged the wells prior to collecting groundwater samples. The monitoring wells and the Ace Recovery Well were purged and sampled using a submersible pump and Public Water Supply Well No. 8 was sampled using its dedicated turbine pump. A water truck was used to store and transport the purge water so it could be discharged to the City of Colby's sanitary sewer system.

In addition to the collection of primary samples, quality assurance/quality control (QA/QC) samples such as equipment rinsate blanks, duplicate samples, and matrix spike (MS), and matrix spike duplicate (MSD) samples were collected.

Monitoring well purging/development data sheets were completed for each well that was developed or sampled and are provided in Appendix C.

**3.3.2.1** Existing Monitoring Well Purging and Sample Collection. Most of the existing monitoring wells were purged using a high capacity (~15 gpm) submersible pump.

The remaining existing monitoring wells and the three screened intervals of the Ace Recovery Well were micropurged. The wells were micropurged at a rate less than the recharge rate of the well. The water level in the well was monitored for drawdown during micropurging. Micropurging was performed at a rate so that minimal drawdown occurred. Micropurging was performed at approximately one liter per minute (0.26 gallons per minute). The wells were micropurged from the midpoint of the screened intervals.

Field parameters (temperature, pH, specific conductivity, ORP, turbidity, and DO) were measured and recorded during both purging processes. Measurements were recorded periodically until stabilization occurred at which time purging was complete and the sample collected.

#### 3.3.2.2 Public Supply Well No. 8 Purging and Sample Collection

The subcontractor (Woofter Pump and Well, Inc.) purged the well prior to collecting groundwater samples. The public water supply well was sampled using its dedicated turbine pump. Field parameters (temperature, pH, specific conductivity, ORP, DO, and turbidity) were measured and recorded during the purging process.

**3.3.2.3 Residential Well Purging and Sample Collection.** The residential wells sampled during the groundwater sampling activity are listed in Table 3-2. Addresses for the residential wells are provided on Table 3-5. The residential wells are equipped with dedicated pumps. The samples were collected from an outside tap prior to any water treatment system. Purging and sample collection procedure for the residential wells was as follows:

- (1) The tap was opened and allowed to flow prior to sample collection. The field parameters (temperature, pH, specific conductivity, ORP, turbidity, and DO) were measured periodically. Purging was considered complete when the field parameters stabilized.
- (2) Following the purging procedure, the flow from the tap was reduced for sample collection in order to minimize agitation and aeration.
- (3) The sampler donned a clean pair of surgical gloves.
- (4) At the end of the purging interval, the sample containers were filled directly from the tap.
- (5) Following sample collection, sample documentation (i.e., sample number, chain-ofcustody record) was completed and noted in the field logbook.
- (6) The samples were placed in a cooler on ice.

#### 3.3.3 Subsurface Soil Sampling

Soil samples were collected from drill cuttings for IDW characterization as discussed in Section 4.0. The samples were analyzed for total chromium.

#### 3.3.4 Equipment Rinsate Blanks

Rinsate blanks were used to measure the effectiveness of pump decontamination procedures. Equipment rinsate blanks were prepared from the submersible pumps after the pumps had been decontaminated. The rinsate blanks were identified with a sample identification number. The rinsate blank number, time, and date of collection was documented in the field logbook.

#### 3.3.5 Duplicate Samples

The purpose of duplicate samples is to assess laboratory QA/QC. Duplicate samples were collected in the field by alternately filling appropriate sample containers for the primary

# Table 3-5 Residential Well Sample Codes Ace Services Site Remedial Design

| Code | Residential Well Description |
|------|------------------------------|
| RW-1 | 175 Thompson                 |
| RW-2 | 1655 E. 4th                  |
| RW-3 | 1765 E. 4th                  |
| RW-4 | 1795 E. 4th                  |
| RW-5 | 1680 E. 4th                  |
| RW-6 | 1940 E. 4th                  |
| RW-7 | 2040 E. 4th                  |
| RW-8 | 1888 County Road 21          |
| RW-9 | 2580 E. 4th                  |

and duplicate samples. The primary sample and the duplicate samples were placed in identical containers, preserved in the same manner, and submitted for the same analyses. The duplicate groundwater samples were identified with a sample identification number. The sample location, number, and date and time of collection was documented in the field logbook.

#### 3.3.6 Matrix Spike/Matrix Spike Duplicates

The purpose of MS/MSD samples is to evaluate effects of the sample matrix on the accuracy of the analysis. MS/MSD samples were collected in the field by alternately filling appropriate sample containers for the primary, MS, and MSD sample from the discharge hose of the pump. The primary sample, the MS sample, and the MSD samples were placed in identical containers, preserved in the same manner, and submitted for the same analyses. The MS/MSD samples were identified with a sample identification number. The sample location, number, and date and time of collection was documented in the field logbook.

#### 3.4 Sample Numbering System

A sample numbering system was used to identify each sample submitted for chemical analysis. The purpose of the numbering system was to provide a tracking system for retrieval of information on each sample. The sample identification numbers allocated for all sampling efforts were used on sample labels, chain-of-custody records, and all other applicable documentation used during the sampling activity. A listing of all sample identification numbers was maintained in the field logbook by the field team representative.

Sample identification numbers consist of four components: a media code, a well code, the date, and the sample characteristic code. The following is an example of a completely numbered sample, with each component identified:

W-MW-1-S-091900-P.

where

MW = well type code (i.e., monitoring well),

1 = well number code

S = well interval code (shallow)

091900 = sample date code (month, day, and year sample was collected), and

RAC VII Ace Services Site Addendum No. 1 - TM

W = water

3-14

46118 126-03

P = sample characteristic code (i.e., primary).

The media codes consist of W for water or S for subsurface soil. The well type code identifies the well type: MW for monitoring well, PWS for public water supply, RW for residential well, ACE for Ace recovery well, EX for extraction wells, OB for observation wells, and HPMW for HI-Plains Coop monitoring wells. The well number code identifies the well number. The well interval code identifies the aquifer zone monitored: P for perched, S for shallow, I for intermediate, and D for deep. The sample date code identifies the data the sample was collected: 091900 is September 19, 2000. The sample characteristic code indicates whether the sample is a primary sample (P), an equipment rinsate blank (R), duplicate (D), a matrix spike (MS), or a matrix spike duplicate (MSD) sample.

# 3.5 Documentation

Documentation was a vital aspect of the site investigation. This section discusses pertinent documentation activities.

#### 3.5.1 Field Logbook

Bound field logbooks were maintained by the sampling team to provide a detailed record of significant events, observations, and measurements taken during the field investigation. The field log books are intended to provide sufficient data and observations to enable the field team to reconstruct events that occurred during the project. Copies of the field logbooks kept by field personnel are presented in Appendix D.

#### 3.5.2 Sample Labels

An adhesive sample label was placed on each sample container submitted for chemical analysis. The following information was included on each sample label:

- Site name.
- Sample number.
- Name of sampler.
- Sample collection date and time.
- Analysis requested and preservatives added.

#### 3.5.3 Chain-of-Custody Record

Chain-of-custody procedures were employed to maintain and document continuous sample possession. A sample was considered under a person's custody if it was in that

person's physical possession, within visual sight of that person after taking physical possession, secured by that person so that the sample could not be tampered with, or secured by that person in an area that was restricted from unauthorized personnel.

A chain-of-custody record was completed for each sample shipment. Standard laboratory chain-of-custody records were used. After completion of the chain-of-custody-record, one carbonless copy of the chain-of-custody record was retained by the field crew and the remaining copies and the original were enclosed in a sealable plastic bag and secured to the inside of the shipping container lid. A separate chain-of-custody record was completed for each shipping container. Shipping containers were secured, and custody seals were placed across the container openings. The chain-of-custody record was sealed inside the shipping container, and the custody seals remained intact; therefore, the commercial carrier was not required to sign the chain-of-custody record. Copies of the chain-of-custody records are included in Appendix E.

#### 3.5.4 Custody Seals

Custody seals were used to ensure the integrity of the samples when they remained unattended or when they were relinquished to the delivery service until they were opened by the laboratory. All samples were shipped in an insulated shipping container, and each shipping container was sealed with at least two custody seals. The seals were affixed to each shipping container so that it was necessary to break the seals to open the shipping container.

#### 3.5.5 Airbills

An airbill was completed for each sample shipment. Priority 7:30 a.m. overnight delivery was used for samples collected in the morning and late morning delivery was used for samples collected in the afternoon to achieve the analytical holding time (24 hours) for hexavalent chromium analysis. Copies of the completed airbills are included in Appendix F.

#### 3.6 Decontamination Procedures

Procedures for equipment decontamination were implemented to avoid cross-contamination of subsurface strata and samples of various media that are to be submitted for chemical analysis. Sampling equipment was thoroughly cleaned and decontaminated before initial use and between sample locations.

#### 3.6.1 Initial Decontamination

Initial decontamination of the drill rig, sampling equipment, and electric pump before any wells were purged and sampled included the following:

- (1) Steam clean with potable water.
- (2) Circulate and rinse pump with potable water.
- (3) Rinse pump with distilled water.

Initial decontamination of the split-spoon sampler included alconox wash followed by potable and distilled water rinses.

#### 3.6.2 Intermediate Decontamination

Intermediate decontamination of the sampling equipment was required between sampling attempts. The intermediate decontamination procedures for sampling equipment was the same as those outlined in the initial decontamination.

#### 3.6.3 Final Decontamination

Final decontamination was performed on all equipment used to drill, purge, or sample wells. The procedures used during initial decontamination were utilized during final contamination.

#### 3.7 Site Survey Data

A location survey was conducted by Zerr Engineering of Colby, Kansas, as part of the preliminary RD investigation. Items surveyed included newly installed monitoring wells. At monitoring well locations, top of casing (TOC) elevations were measured to the closest 0.01 foot using the notched reference point for monitoring wells. Ground elevations were measured to the closest 0.01 foot. Location coordinates were also determined for the wells and are referenced to the State Plane Coordinate System. Elevations are referenced to mean sea level (msl), specifically to the National Geodetic Vertical Datum of 1929. Survey data for the wells are presented in Appendix G.

A survey of the site will be performed after all wells are installed and the site area is defined. A site map will be developed from the survey data. The site map will include locations of the wells, utilities, cultural features, and topography which will be used as a base map for engineering drawings.

#### 3.8 Data Validation

Samples collected in October 1999 and February 2000 were sent to Analytical Management Laboratories, Inc. of Olathe, Kansas, for analyses. Once samples were received at the lab, the specified analyses were performed, and results in the form of raw laboratory data were generated. Data validation and evaluation was then performed on the raw laboratory data in accordance with FPA Contract Laboratory Program (CLP) National Functional Guidelines by Heartland Environmental Services, Inc. of St. Charles, Missouri.

Samples collected in September 2000 were sent to Southwest Laboratories of Oklahoma in Broken Arrow, Oklahoma. Once samples were received at the lab, the specified analyses were performed, and results in the form of raw laboratory data were generated. Data validation and evaluation was then performed on the raw laboratory data in accordance with EPA Contract Laboratory Program (CLP) National Functional Guidelines by Validata Chemical Services, Inc. of Lilburn, Georgia.

The objective of the data validation was to review analytical laboratory procedures and QC results to evaluate whether the data met project data quality objectives (DQOs) established in the site specific QAPP (BVSPC, 1999c and 2000b).

Results of the laboratory data assessment for the samples collected in October 1999 and February 2000 are presented in the *Data Validation Report* dated January 10, 2000 and April 20, 2000 (BVSPC, 2000e and 2000f) and the *PARCCs Report and Data Evaluation Technical Memorandum* dated June 28, 2000 (BVSPC, 2000g).

Results of the laboratory data assessment for the samples collected in September 2000 are presented in the *Data Validation Report* dated December 12, 2000 (BVSPC 2000h) and the *PARCCs Report and Data Evaluation Technical Memorandum* dated December 18, 2000 (BVSPC 2000i).

Results of the data validation and evaluation process have determined the data are defensible, were collected in accordance with the site specific QAPP and FSP, and are useable for the intended purposes.

# 3.9 Aquifer Pump Test

An objective of the preliminary RD efforts was to perform pump tests within the three aquifer zones. Hydrogeologic data for the pump tests were used to develop a computer flow model of groundwater flow of the site. The model results were used to estimate the number, location, and extraction rates necessary to achieve remedial action objectives.

Three pump tests were performed in July and August 2000, and evaluated in September 2000. Pump test procedures and results are discussed in the *Pump Test Results Ace Services Site Memorandum*, November 13, 2000, which is presented in Appendix H.

# 3.10 Groundwater Modeling

An objective of the preliminary RD efforts was to develop a numerical computer model of groundwater flow of the site. The model results were used to estimate the number, location, and extraction rates necessary to achieve remedial action objectives.

Numerical computer modeling efforts of groundwater flow of the site was performed in October and November 2000. Modeling procedures and results are discussed in the *Groundwater Modeling Activities Ace Services Site Memorandum*, December 14, 2000, which is presented in Appendix I.

# 4.0 Investigation Derived Waste

Investigation derived wastes (IDW) included decontamination fluids, groundwater removed from monitoring wells, drill cuttings, fluids, plastic sheeting, and personal protective equipment.

#### 4.1 Liquids

Purging fluids, development water, and decontamination solution and rinses were collected and stored in a water tank. The fluids were then transported and discharged into the City of Colby's sanitary sewer system.

# 4.2 Personal Protective Equipment

All personal protective equipment (PPE) such as surgical gloves, paper towels, plastic sheeting, etc., was double bagged and disposed of as solid waste.

# 4.3 Drill Cuttings

Drill cuttings were placed in containment structures for characterization prior to disposal. Care was taken to exclude or remove any free liquid. A composite drill-cuttings sample was collected from the cuttings of each well nest and analyzed for total chromium for hazardous waste determination purposes. Results of the soil cuttings analyses are summarized in Table 4-1.

Analytical results determined the cuttings to be non-hazardous (i.e., less than 100 mg/kg total chromium). Once results indicated the soils were non-hazardous, the soil cuttings were spread to the ground per agreement with KDHE Bureau of Waste Management-Solid Waste Section.

#### 5.0 Remedial Design Investigation Results

This section presents, evaluates, and interprets data collected during the preliminary RD efforts performed from July 2000 to September 2000.

#### 5.1 Water Level Data

The Ogallala Formation is an unconfined aquifer in the Colby area. The Ogallala aquifer is the sole source of potable water for the City of Colby.

Water level data for the monitoring wells are presented in Tables 5-1 and 5-2. The groundwater elevations were determined using location survey data and water level data collected during previous RI and RD investigation activities. The predominant groundwater flow direction for September 22, 2000, for the shallow, intermediate, and deep zones is illustrated on Figures 5-1 through 5-3 respectively. Depth to groundwater in the site area is approximately 100 to 120 feet bgs. Plots of the groundwater elevation data on site maps indicate the groundwater flow direction in the three zones in the site area is predominantly to the east-southeast. Detailed hydrogeologic data are presented in Appendices H and I.

## 5.2 Geochemical and Biochemical Groundwater Data

Basic water quality parameters were analyzed or measured on groundwater samples to evaluate the geochemical and biochemical quality of the groundwater. The geochemical and biochemical data will be used in the design of the groundwater treatment process. Results of field parameters are presented in Table 5-3. Analytical results of samples collected specifically for design criteria will be discussed in the Treatability Study Report which will be prepared as part of the RD efforts.

## 5.3 Nature and Extent of Groundwater Contamination

The nature and extent of contamination in groundwater at the site was evaluated from 54 primary groundwater samples. A list of the wells sampled and the analytical results are presented in Table 5-3. Results for the duplicate samples are also included.

Analytical results of the groundwater samples indicate the presence of chromium in groundwater. Comparing results of the total chromium and hexavalent chromium analyses indicates that most or all of the total chromium is in the hexavalent state. Hexavalent chromium (Cr (VI)) typically occurs in the dissolved state while trivalent chromium (Cr (III)) typically occurs as a precipitate or solid. The detected concentration of hexavalent chromium may exceed the total chromium concentration because the parameters were analyzed using two different methods. Data validation procedures have determined that results for both methods are within acceptable ranges of the methodologies.

The total chromium concentrations have been contoured on Figures 5-4 through 5-6 to illustrate the horizontal extent of total chromium in the aquifer in the shallow, intermediate, and deep zones. The vertical extent of hexavalent chromium in the groundwater is illustrated in Figure 5-7.

Historical results for total chromium are presented in Table 5-4.

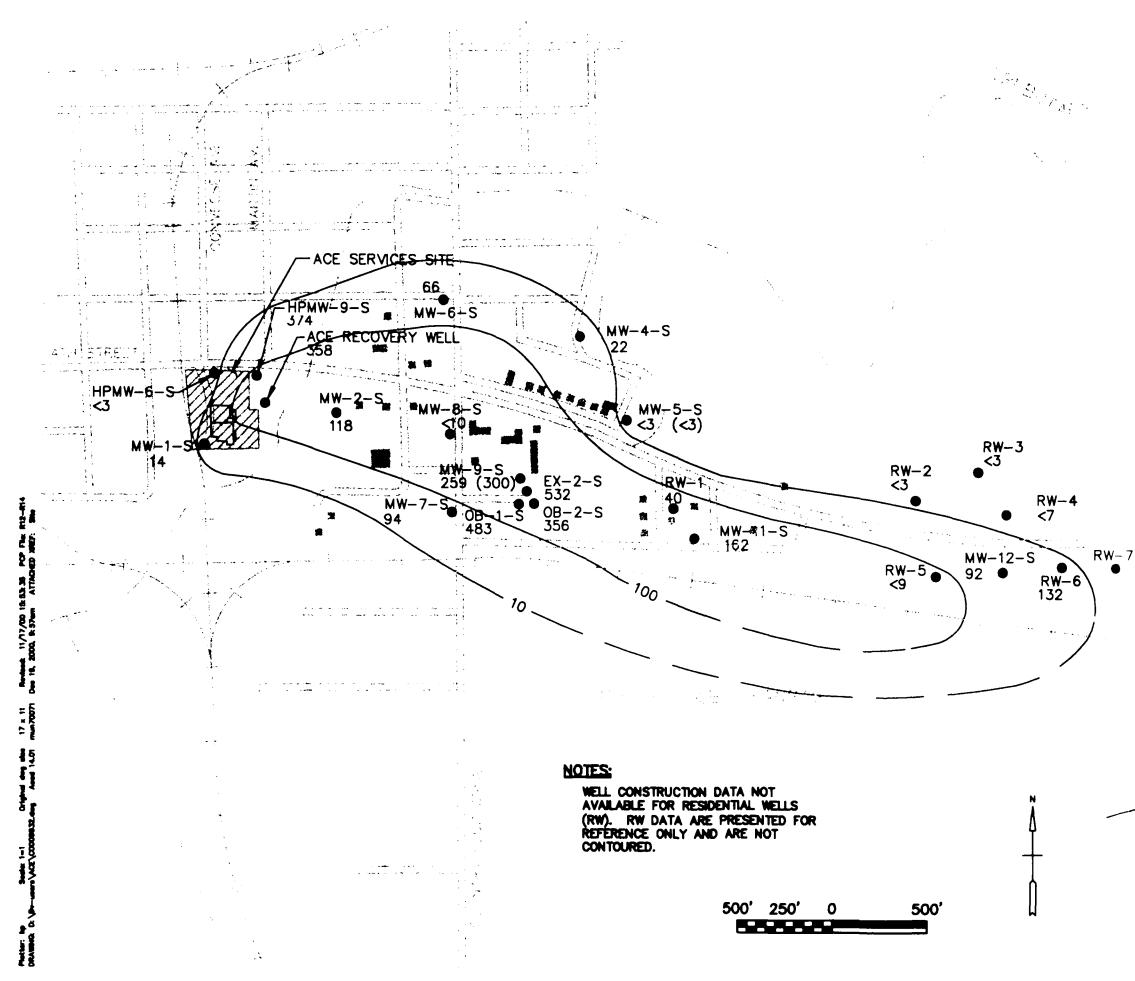

#### 5.4 Remaining Preliminary RD Activities

Efforts for completing preliminary RD objectives are described in the RD WP (BVSPC, 1999a; 1999f), FSP (BVSPC, 1999b; 2000a), and QAPP (BVSPC 1999c; 2000b). Initial efforts were planned using information and site data available at that time. Completion in October 1999 of Phase 1 of the preliminary RD activities indicated additional monitoring wells were needed to complete characterization of the nature and extent of contamination. Completion in February 2000 of Phase 2 activities also indicated additional monitoring wells were needed to complete objectives. Phase 3 of the preliminary RD activities was completed in November 2000, results of which are discussed in this report. However, two additional monitoring well nests remain to be installed pending property access.

Phase 3 investigation activities have provided additional and more complete information concerning site characteristics and the nature and extent of contamination. The remaining preliminary RD activities include:

- Installation of two monitoring well nests; and
- Geotechnical borings
- Survey of site area to develop a base map for engineering design drawings.

Two additional monitoring well nests are to be installed to confirm the downgradient extent of the chromium plume (MW-13 and MW-14). Each monitoring well nest will consist of a shallow and intermediate well. The well nests will be installed south of the railroad tracks. Proposed locations for the two well nests are illustrated on Figure 5-8. Final locations of the wells were selected with consideration to property access restrictions.

The site survey base map will include the area identified as part of the site. The site survey base map will include areas where additional extraction well nests may need to be installed to achieve the active remediation goal defined in the ROD for the site.

Appendix B Well Construction Logs

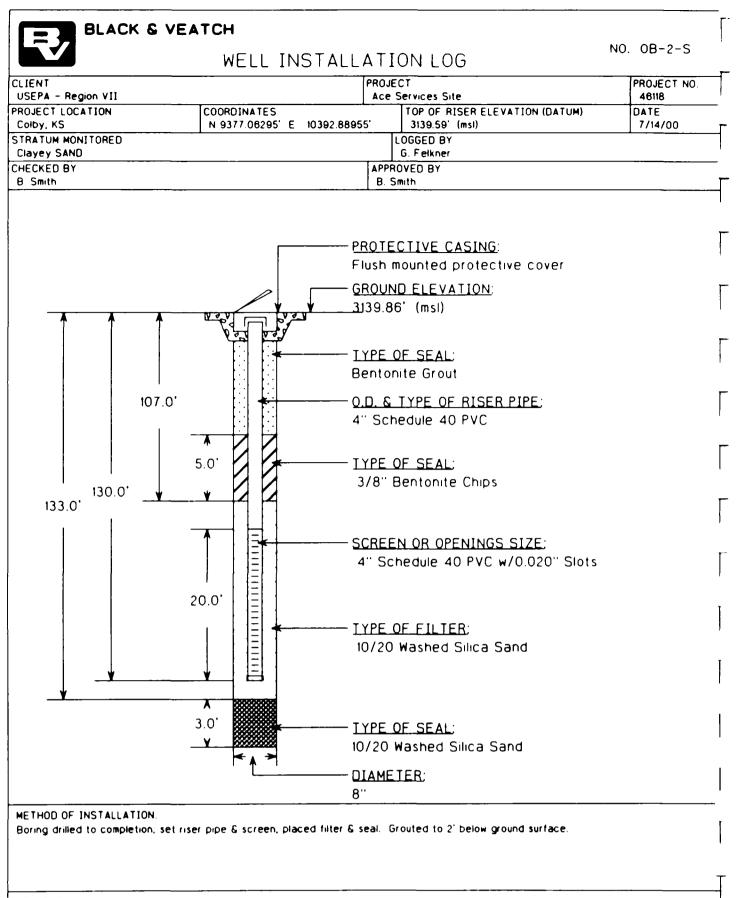

• ~

۰.

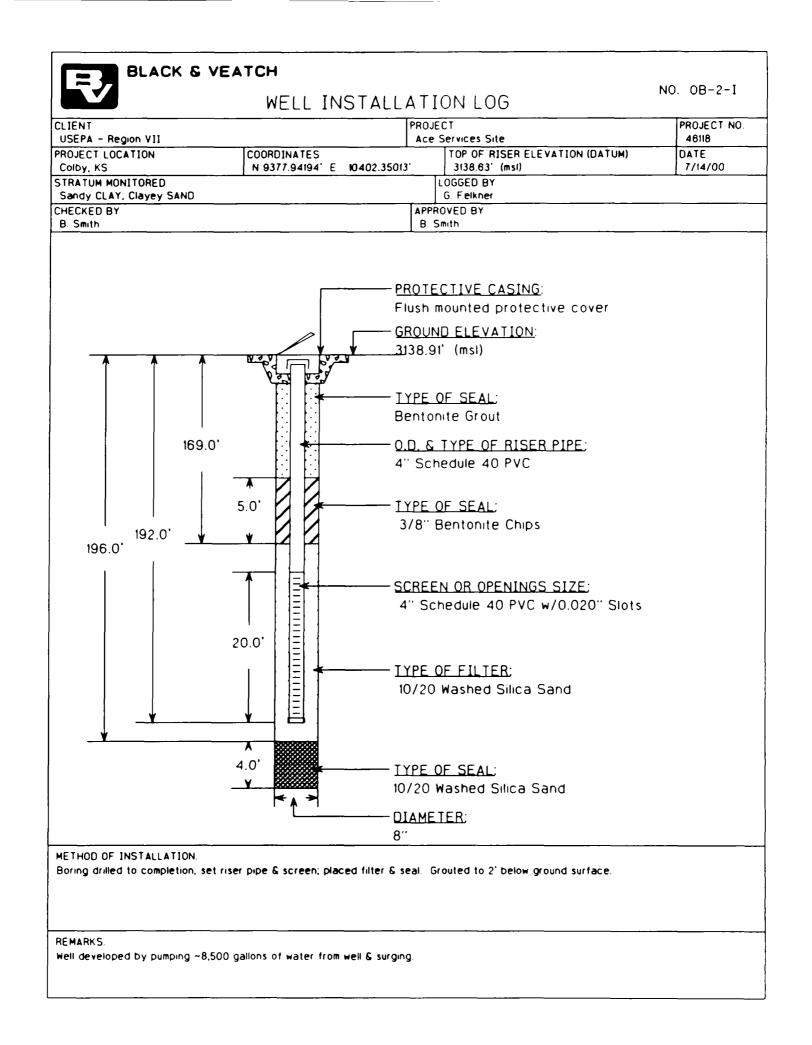

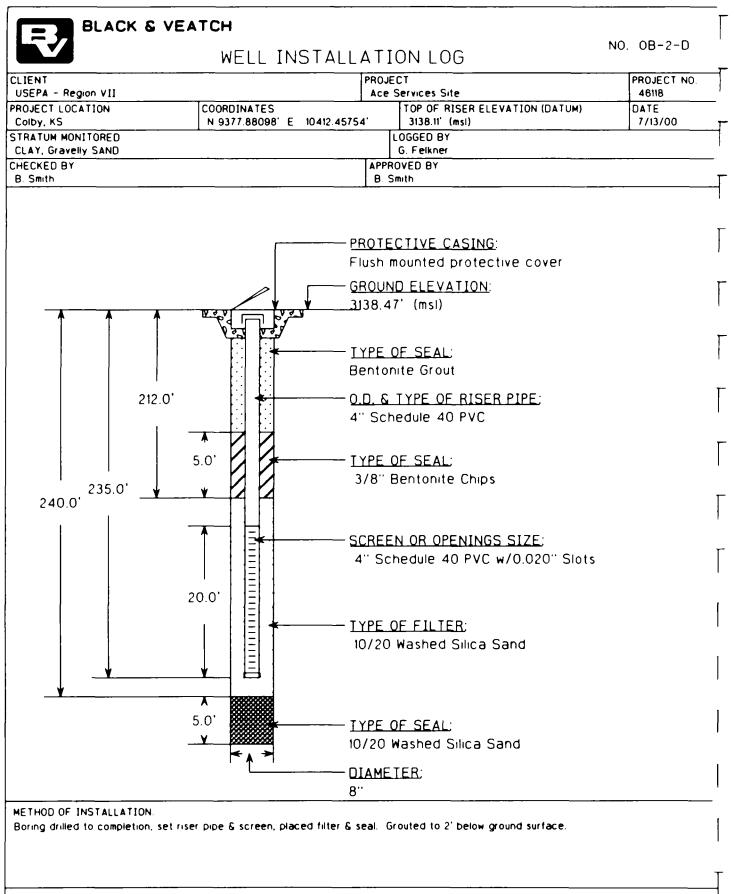

REMARKS.

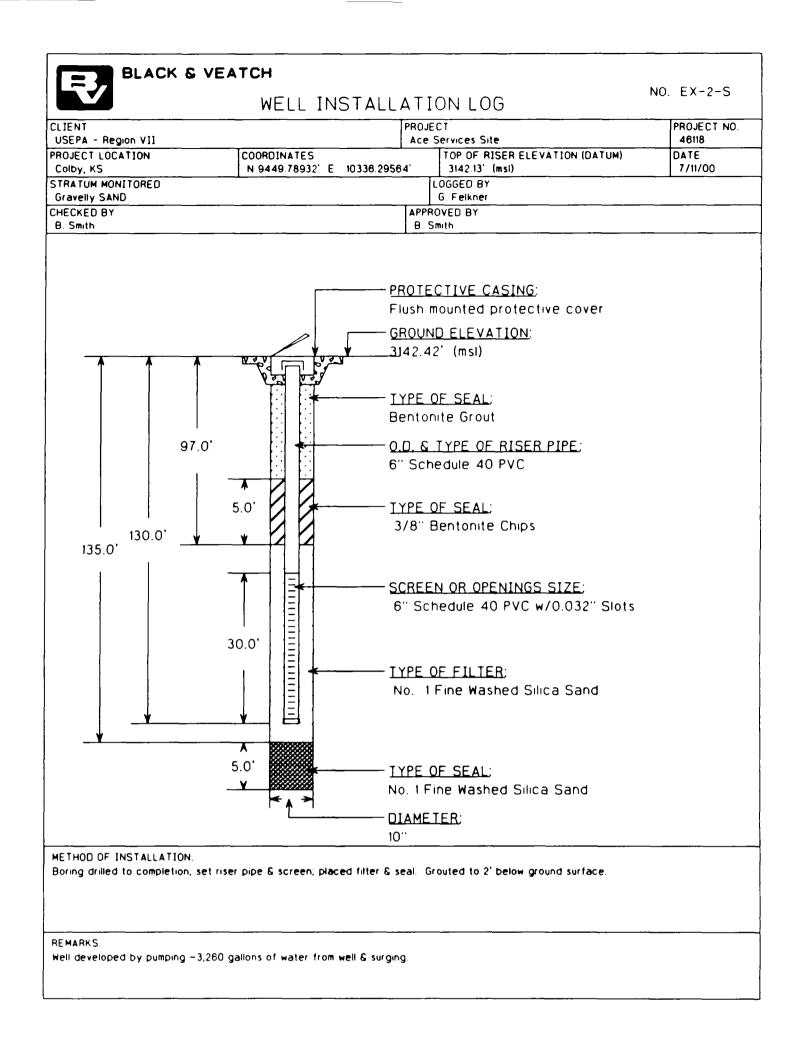

Well developed by pumping ~2,900 gallons of water from well & surging.

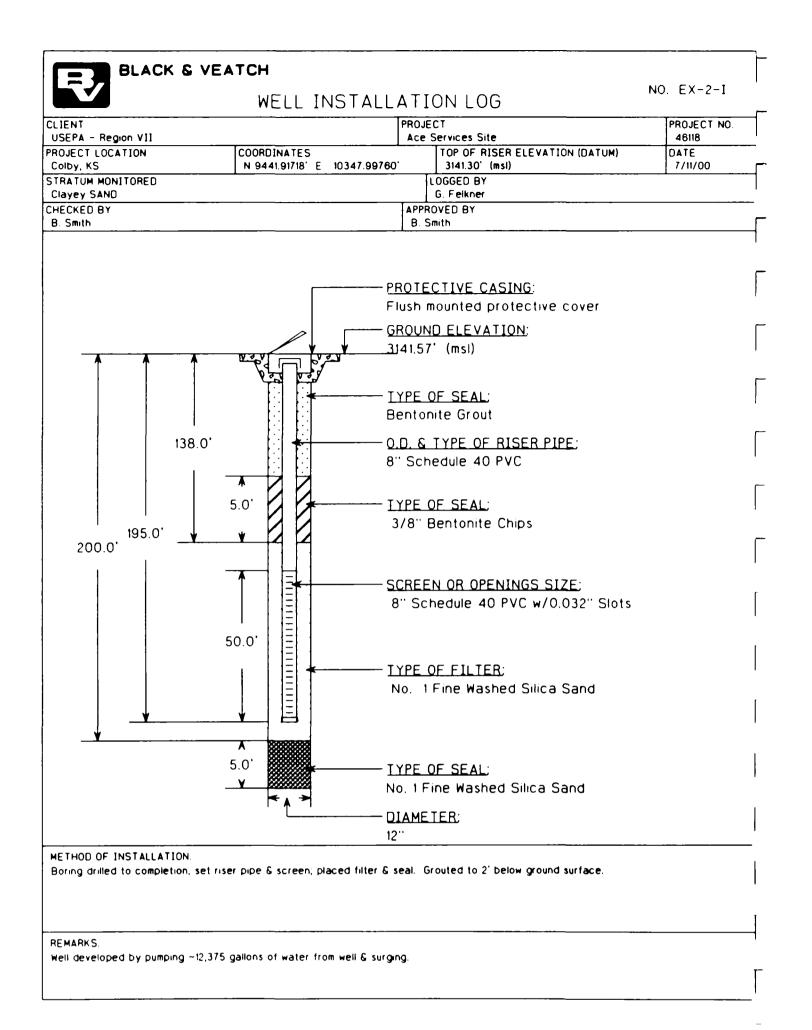

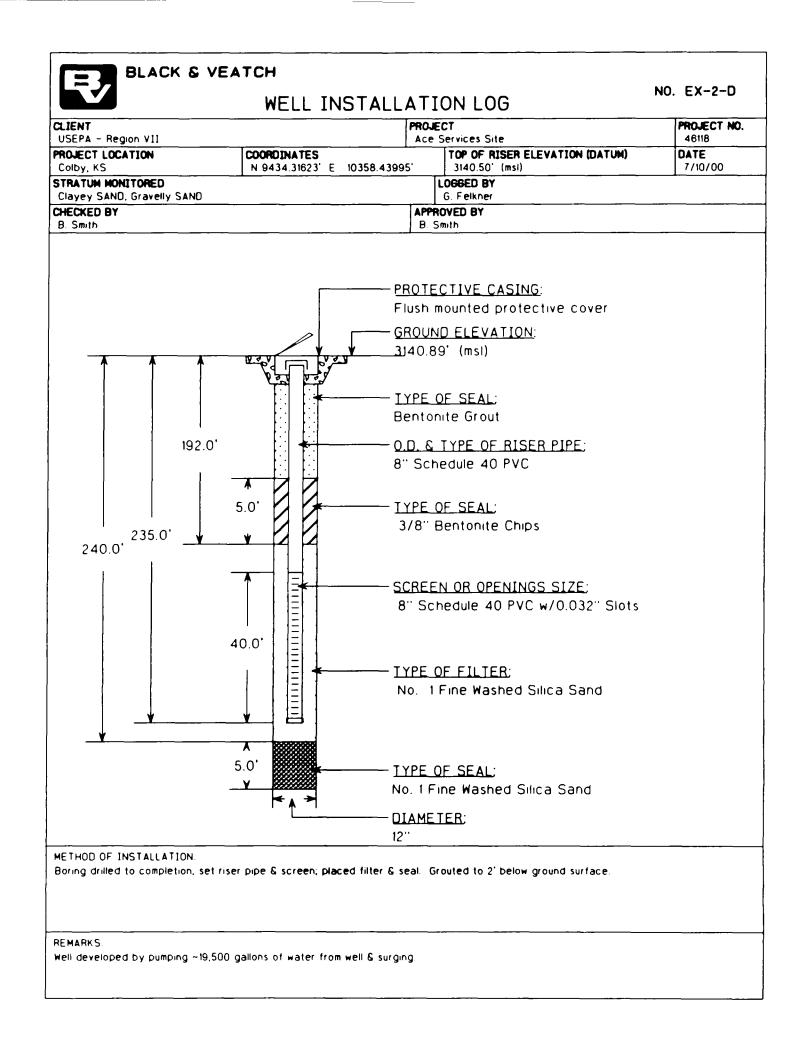

REMARKS.

Well developed by pumping ~4,680 gallons of water from well & surging.

Appendix C Well Development/Purging Data Sheets
