Note: [Stable documentation](#) for the latest release is located at [doc](#). Documentation for [recent developments](#) is located at [devel](#).

The ARCH toolbox contains routines for:

- Univariate volatility models;
- Bootstrapping;
- Multiple comparison procedures;
- Unit root tests;
- Cointegration Testing and Estimation; and
- Long-run covariance estimation.

Future plans are to continue to expand this toolbox to include additional routines relevant for the analysis of financial data.

UNIVARIATE VOLATILITY MODELS

`arch.univariate` provides both high-level (`arch_model()`) and low-level methods (see *Mean Models*) to specify models. All models can be used to produce forecasts either analytically (when tractable) or using simulation-based methods (Monte Carlo or residual Bootstrap).

1.1 Introduction to ARCH Models

ARCH models are a popular class of volatility models that use observed values of returns or residuals as volatility shocks. A basic GARCH model is specified as

$$r_t = \mu + \epsilon_t \quad (1.1)$$

$$\epsilon_t = \sigma_t e_t \quad (1.2)$$

$$\sigma_t^2 = \omega + \alpha \epsilon_{t-1}^2 + \beta \sigma_{t-1}^2 \quad (1.3)$$

A complete ARCH model is divided into three components:

- a *mean model*, e.g., a constant mean or an *ARX*;
- a *volatility process*, e.g., a *GARCH* or an *EGARCH* process; and
- a *distribution* for the standardized residuals.

In most applications, the simplest method to construct this model is to use the constructor function `arch_model()`

```
import datetime as dt
import pandas_datareader.data as web

from arch import arch_model

start = dt.datetime(2000, 1, 1)
end = dt.datetime(2014, 1, 1)
sp500 = web.DataReader('^GSPC', 'yahoo', start=start, end=end)
returns = 100 * sp500['Adj Close'].pct_change().dropna()
am = arch_model(returns)
```

Alternatively, the same model can be manually assembled from the building blocks of an ARCH model

```
from arch import ConstantMean, GARCH, Normal

am = ConstantMean(returns)
am.volatility = GARCH(1, 0, 1)
am.distribution = Normal()
```

In either case, model parameters are estimated using

```
res = am.fit()
```

with the following output

```
Iteration:    1,   Func. Count:    6,   Neg. LLF: 5159.58323938
Iteration:    2,   Func. Count:   16,   Neg. LLF: 5156.09760149
Iteration:    3,   Func. Count:   24,   Neg. LLF: 5152.29989336
Iteration:    4,   Func. Count:   31,   Neg. LLF: 5146.47531817
Iteration:    5,   Func. Count:   38,   Neg. LLF: 5143.86337547
Iteration:    6,   Func. Count:   45,   Neg. LLF: 5143.02096168
Iteration:    7,   Func. Count:   52,   Neg. LLF: 5142.24105141
Iteration:    8,   Func. Count:   60,   Neg. LLF: 5142.07138907
Iteration:    9,   Func. Count:   67,   Neg. LLF: 5141.416653
Iteration:   10,   Func. Count:   73,   Neg. LLF: 5141.39212288

```

1.1.1 Model Constructor

While models can be carefully specified using the individual components, most common specifications can be specified using a simple model constructor.

```
arch.univariate.arch_model(y, x=None, mean='Constant', lags=0, vol='GARCH', p=1, o=0, q=1, power=2.0,
                           dist='normal', hold_back=None, rescale=None)
```

Initialization of common ARCH model specifications

Parameters

- y**
 [{`ndarray`, `Series`, `None`}] The dependent variable
- x**
 [{`np.array`, `DataFrame`}, optional] Exogenous regressors. Ignored if model does not permit exogenous regressors.
- mean**
 [`str`, optional] Name of the mean model. Currently supported options are: ‘Constant’, ‘Zero’, ‘LS’, ‘AR’, ‘ARX’, ‘HAR’ and ‘HARX’
- lags**
 [`int` or `list (int)`, optional] Either a scalar integer value indicating lag length or a list of integers specifying lag locations.
- vol**
 [`str`, optional] Name of the volatility model. Currently supported options are: ‘GARCH’ (default), ‘ARCH’, ‘EGARCH’, ‘FIGARCH’, ‘APARCH’ and ‘HARCH’
- p**
 [`int`, optional] Lag order of the symmetric innovation
- o**
 [`int`, optional] Lag order of the asymmetric innovation
- q**
 [`int`, optional] Lag order of lagged volatility or equivalent
- power**
 [`float`, optional] Power to use with GARCH and related models
- dist**
 [`int`, optional] Name of the error distribution. Currently supported options are:
- Normal: ‘normal’, ‘gaussian’ (default)
 - Students’s t: ‘t’, ‘studentst’
 - Skewed Student’s t: ‘skewstudent’, ‘skewt’
 - Generalized Error Distribution: ‘ged’, ‘generalized error’
- hold_back**
 [`int`] Number of observations at the start of the sample to exclude when estimating model parameters. Used when comparing models with different lag lengths to estimate on the common sample.
- rescale**
 [`bool`] Flag indicating whether to automatically rescale data if the scale of the data is likely to produce convergence issues when estimating model parameters. If False, the model is estimated on the data without transformation. If True, than y is rescaled and the new scale is reported in the estimation results.

Returns

model

[ARCHModel] Configured ARCH model

Notes

Input that are not relevant for a particular specification, such as *lags* when *mean='zero'*, are silently ignored.

Examples

```
>>> import datetime as dt
>>> import pandas_datareader.data as web
>>> djia = web.get_data_fred('DJIA')
>>> returns = 100 * djia['DJIA'].pct_change().dropna()
```

A basic GARCH(1,1) with a constant mean can be constructed using only the return data

```
>>> from arch.univariate import arch_model
>>> am = arch_model(returns)
```

Alternative mean and volatility processes can be directly specified

```
>>> am = arch_model(returns, mean='AR', lags=2, vol='harch', p=[1, 5, 22])
```

This example demonstrates the construction of a zero mean process with a TARCH volatility process and Student t error distribution

```
>>> am = arch_model(returns, mean='zero', p=1, o=1, q=1,
...                 power=1.0, dist='StudentsT')
```

Return type

HARCH

1.2 ARCH Modeling

This setup code is required to run in an IPython notebook

```
[1]: %matplotlib inline
import matplotlib.pyplot as plt
import seaborn

seaborn.set_style("darkgrid")
plt.rc("figure", figsize=(16, 6))
plt.rc("savefig", dpi=90)
plt.rc("font", family="sans-serif")
plt.rc("font", size=14)
```

1.2.1 Setup

These examples will all make use of financial data from Yahoo! Finance. This data set can be loaded from `arch.data.sp500`.

```
[2]: import datetime as dt

import arch.data.sp500

st = dt.datetime(1988, 1, 1)
en = dt.datetime(2018, 1, 1)
data = arch.data.sp500.load()
market = data["Adj Close"]
returns = 100 * market.pct_change().dropna()
ax = returns.plot()
xlim = ax.set_xlim(returns.index.min(), returns.index.max())
```

nbsphinx-code-borderwhite

1.2.2 Specifying Common Models

The simplest way to specify a model is to use the model constructor `arch.arch_model` which can specify most common models. The simplest invocation of `arch` will return a model with a constant mean, GARCH(1,1) volatility process and normally distributed errors.

$$r_t = \mu + \epsilon_t$$

$$\sigma_t^2 = \omega + \alpha \epsilon_{t-1}^2 + \beta \sigma_{t-1}^2$$

$$\epsilon_t = \sigma_t e_t, \quad e_t \sim N(0, 1)$$

The model is estimated by calling `fit`. The optional inputs `iter` controls the frequency of output from the optimizer, and `disp` controls whether convergence information is returned. The results class returned offers direct access to the estimated parameters and related quantities, as well as a `summary` of the estimation results.

GARCH (with a Constant Mean)

The default set of options produces a model with a constant mean, GARCH(1,1) conditional variance and normal errors.

```
[3]: from arch import arch_model
```

```
am = arch_model(returns)
res = am.fit(update_freq=5)
print(res.summary())
```

```

```
[4]: fig = res.plot(annualize="D")
```

nbsphinx-code-borderwhite

GJR-GARCH

Additional inputs can be used to construct other models. This example sets `o` to 1, which includes one lag of an asymmetric shock which transforms a GARCH model into a GJR-GARCH model with variance dynamics given by

$$\sigma_t^2 = \omega + \alpha\epsilon_{t-1}^2 + \gamma\epsilon_{t-1}^2 I_{[\epsilon_{t-1} < 0]} + \beta\sigma_{t-1}^2$$

where I is an indicator function that takes the value 1 when its argument is true.

The log likelihood improves substantially with the introduction of an asymmetric term, and the parameter estimate is highly significant.

```
[5]: am = arch_model(returns, p=1, o=1, q=1)
res = am.fit(update_freq=5, disp="off")
print(res.summary())
```

(continued from previous page)

Covariance estimator: robust

TARCH/ZARCH

TARCH (also known as ZARCH) model the *volatility* using absolute values. This model is specified using `power=1.0` since the default power, 2, corresponds to variance processes that evolve in squares.

The volatility process in a TARCH model is given by

$$\sigma_t = \omega + \alpha |\epsilon_{t-1}| + \gamma |\epsilon_{t-1}| I_{[\epsilon_{t-1} < 0]} + \beta \sigma_{t-1}$$

More general models with other powers (κ) have volatility dynamics given by

$$\sigma_t^\kappa = \omega + \alpha |\epsilon_{t-1}|^\kappa + \gamma |\epsilon_{t-1}|^\kappa I_{[\epsilon_{t-1} < 0]} + \beta \sigma_{t-1}^\kappa$$

where the conditional variance is $(\sigma_t^\kappa)^{2/\kappa}$.

The TARCH model also improves the fit, although the change in the log likelihood is less dramatic.

```

Student's T Errors

Financial returns are often heavy tailed, and a Student's T distribution is a simple method to capture this feature. The call to `arch` changes the distribution from a Normal to a Student's T.

The standardized residuals appear to be heavy tailed with an estimated degree of freedom near 10. The log-likelihood also shows a large increase.

```
[7]: am = arch_model(returns, p=1, o=1, q=1, power=1.0, dist="StudentsT")
res = am.fit(update_freq=5)

1.2.3 Fixing Parameters

In some circumstances, fixed rather than estimated parameters might be of interest. A model-result-like class can be generated using the `fix()` method. The class returned is identical to the usual model result class except that information about inference (standard errors, t-stats, etc) is not available.

In the example, I fix the parameters to a symmetric version of the previously estimated model.

```
[8]: fixed_res = am.fix([0.0235, 0.01, 0.06, 0.0, 0.9382, 8.0])
print(fixed_res.summary())
```

```

1.2.4 Building a Model From Components

Models can also be systematically assembled from the three model components:

- A mean model (`arch.mean`)
 - Zero mean (`ZeroMean`) - useful if using residuals from a model estimated separately
 - Constant mean (`ConstantMean`) - common for most liquid financial assets
 - Autoregressive (`ARX`) with optional exogenous regressors
 - Heterogeneous (`HARX`) autoregression with optional exogenous regressors
 - Exogenous regressors only (`LS`)
- A volatility process (`arch.volatility`)
 - ARCH (`ARCH`)
 - GARCH (`GARCH`)
 - GJR-GARCH (`GARCH` using `o` argument)
 - TARCH/ZARCH (`GARCH` using `power` argument set to 1)
 - Power GARCH and Asymmetric Power GARCH (`GARCH` using `power`)
 - Exponentially Weighted Moving Average Variance with estimated coefficient (`EWMAVariance`)
 - Heterogeneous ARCH (`HARCH`)
 - Parameterless Models
 - * Exponentially Weighted Moving Average Variance, known as RiskMetrics (`EWMAVariance`)
 - * Weighted averages of EWMAAs, known as the RiskMetrics 2006 methodology (`RiskMetrics2006`)
- A distribution (`arch.distribution`)
 - Normal (`Normal`)
 - Standardized Students's T (`StudentsT`)

Mean Models

The first choice is the mean model. For many liquid financial assets, a constant mean (or even zero) is adequate. For other series, such as inflation, a more complicated model may be required. These examples make use of Core CPI downloaded from the [Federal Reserve Economic Data](#) site.

```
[10]: import arch.data.core_cpi
```

```
core_cpi = arch.data.core_cpi.load()
ann_inflation = 100 * core_cpi.CPILFESL.pct_change(12).dropna()
fig = ann_inflation.plot()
```

nbsphinx-code-borderwhite

All mean models are initialized with constant variance and normal errors. For ARX models, the lags argument specifies the lags to include in the model.

```
[11]: from arch.univariate import ARX
```

```
ar = ARX(100 * ann_inflation, lags=[1, 3, 12])
print(ar.fit().summary())
```

```

Volatility Processes

Volatility processes can be added a a mean model using the volatility property. This example adds an ARCH(5) process to model volatility. The arguments iter and disp are used in fit() to suppress estimation output.

```
[12]: from arch.univariate import ARCH, GARCH
```

```
ar.volatility = ARCH(p=5)
res = ar.fit(update_freq=0, disp="off")
print(res.summary())
```

```

```

```
Covariance estimator: robust
```

Plotting the standardized residuals and the conditional volatility shows some large (in magnitude) errors, even when standardized.

```
[13]: fig = res.plot()
```

nbsphinx-code-borderwhite

Distributions

Finally the distribution can be changed from the default normal to a standardized Student's T using the `distribution` property of a mean model.

The Student's t distribution improves the model, and the degree of freedom is estimated to be near 8.

```
[14]: from arch.univariate import StudentsT

ar.distribution = StudentsT()
res = ar.fit(update_freq=0, disp="off")
print(res.summary())
```

```

Covariance estimator: robust

1.2.5 WTI Crude

The next example uses West Texas Intermediate Crude data from FRED. Three models are fit using alternative distributional assumptions. The results are printed, where we can see that the normal has a much lower log-likelihood than either the Standard Student's T or the Standardized Skew Student's T – however, these two are fairly close. The closeness of the T and the Skew T indicate that returns are not heavily skewed.

```
[15]: from collections import OrderedDict

import arch.data.wti

crude = arch.data.wti.load()
crude_ret = 100 * crude.DCOILWTICO.dropna().pct_change().dropna()
res_normal = arch_model(crude_ret).fit(dis="off")
res_t = arch_model(crude_ret, dist="t").fit(dis="off")
res_skewt = arch_model(crude_ret, dist="skewt").fit(dis="off")
lls = pd.Series(
    OrderedDict(
        (
            ("normal", res_normal.loglikelihood),
            ("t", res_t.loglikelihood),
            ("skewt", res_skewt.loglikelihood),
        )
    )
)
print(lls)
params = pd.DataFrame(
    OrderedDict(
        (
            ("normal", res_normal.params),
            ("t", res_t.params),
            ("skewt", res_skewt.params),
        )
    )
)
params
```

```
normal    -18165.858870

omega     0.055806  0.048516  0.047683
```

The standardized residuals can be computed by dividing the residuals by the conditional volatility. These are plotted along with the (unstandardized, but scaled) residuals. The non-standardized residuals are more peaked in the center indicating that the distribution is somewhat more heavy tailed than that of the standardized residuals.

```
[16]: std_resid = res_normal.resid / res_normal.conditional_volatility
unit_var_resid = res_normal.resid / res_normal.resid.std()
df = pd.concat([std_resid, unit_var_resid], 1)
df.columns = ["Std Resids", "Unit Variance Resids"]
subplot = df.plot(kind="kde", xlim=(-4, 4))
```

nbsphinx-code-borderwhite

1.2.6 Simulation

All mean models expose a method to simulate returns from assuming the model is correctly specified. There are two required parameters, `params` which are the model parameters, and `nobs`, the number of observations to produce.

Below we simulate from a GJR-GARCH(1,1) with Skew-t errors using parameters estimated on the WTI series. The simulation returns a `DataFrame` with 3 columns:

- `data`: The simulated data, which includes any mean dynamics.
- `volatility`: The conditional volatility series
- `errors`: The simulated errors generated to produce the model. The errors are the difference between the data and its conditional mean, and can be transformed into the standardized errors by dividing by the volatility.

```
[17]: res = arch_model(crude_ret, p=1, o=1, q=1, dist="skewt").fit(dispatch="off")
pd.DataFrame(res.params)
```

```
[17]:
      params
mu      0.029365

```

```
[18]: sim_mod = arch_model(None, p=1, o=1, q=1, dist="skewt")

sim_data = sim_mod.simulate(res.params, 1000)
sim_data.head()
```

```
[18]:      data  volatility  errors
0 -14.892196  11.761690 -14.921562
1   3.987987  12.115573   3.958622
2   5.809655  11.723446   5.780290
3   8.249386  11.380700   8.220021
4  -9.530404  11.120267  -9.559770
```

Simulations can be reproduced using a NumPy RandomState. This requires constructing a model from components where the RandomState instance is passed into to the distribution when the model is created.

The cell below contains code that builds a model with a constant mean, GJR-GARCH volatility and Skew t errors initialized with a user-provided RandomState. Saving the initial state allows it to be restored later so that the simulation can be run with the same random values.

```
[19]: import numpy as np
      from arch.univariate import GARCH, ConstantMean, SkewStudent

rs = np.random.RandomState([892380934, 189201902, 129129894, 9890437])
# Save the initial state to reset later
state = rs.get_state()

dist = SkewStudent(random_state=rs)
vol = GARCH(p=1, o=1, q=1)
repro_mod = ConstantMean(None, volatility=vol, distribution=dist)

repro_mod.simulate(res.params, 1000).head()
```

```
[19]:      data  volatility  errors
0   1.616836   4.787697  1.587470
1   4.106780   4.637129  4.077415
2   4.530200   4.561457  4.500834
3   2.284833   4.507739  2.255468
4   3.378519   4.381016  3.349153
```

Resetting the state using `set_state` shows that calling `simulate` using the same underlying state in the `RandomState` produces the same objects.

```
[20]: # Reset the state to the initial state
      rs.set_state(state)
      repro_mod.simulate(res.params, 1000).head()
```

```
[20]:      data  volatility  errors
0   1.616836   4.787697  1.587470
```

1.3 Forecasting

Multi-period forecasts can be easily produced for ARCH-type models using forward recursion, with some caveats. In particular, models that are non-linear in the sense that they do not evolve using squares or residuals do not normally have analytically tractable multi-period forecasts available.

All models support three methods of forecasting:

- Analytical: analytical forecasts are always available for the 1-step ahead forecast due to the structure of ARCH-type models. Multi-step analytical forecasts are only available for model which are linear in the square of the residual, such as GARCH or HARCH.
- Simulation: simulation-based forecasts are always available for any horizon, although they are only useful for horizons larger than 1 since the first out-of-sample forecast from an ARCH-type model is always fixed. Simulation-based forecasts make use of the structure of an ARCH-type model to forward simulate using the assumed distribution of residuals, e.g., a Normal or Student's t .
- Bootstrap: bootstrap-based forecasts are similar to simulation based forecasts except that they make use of the standardized residuals from the actual data used in the estimation rather than assuming a specific distribution. Like simulation-base forecasts, bootstrap-based forecasts are only useful for horizons larger than 1. Additionally, the bootstrap forecasting method requires a minimal amount of in-sample data to use prior to producing the forecasts.

This document will use a standard GARCH(1,1) with a constant mean to explain the choices available for forecasting. The model can be described as

$$r_t = \mu + \epsilon_t \quad (1.4)$$

$$\epsilon_t = \sigma_t e_t \quad (1.5)$$

$$\sigma_t^2 = \omega + \alpha \epsilon_{t-1}^2 + \beta \sigma_{t-1}^2 \quad (1.6)$$

$$e_t \sim N(0, 1) \quad (1.7)$$

In code this model can be constructed using data from the S&P 500 using

```
from arch import arch_model
import datetime as dt
import pandas_datareader.data as web
start = dt.datetime(2000,1,1)
end = dt.datetime(2014,1,1)
sp500 = web.get_data_yahoo('^GSPC', start=start, end=end)
returns = 100 * sp500['Adj Close'].pct_change().dropna()
am = arch_model(returns, vol='Garch', p=1, o=0, q=1, dist='Normal')
```

The model will be estimated using the first 10 years to estimate parameters and then forecasts will be produced for the final 5.

```
split_date = dt.datetime(2010,1,1)
res = am.fit(last_obs=split_date)
```

1.3.1 Analytical Forecasts

Analytical forecasts are available for most models that evolve in terms of the squares of the model residuals, e.g., GARCH, HARCH, etc. These forecasts exploit the relationship $E_t[\epsilon_{t+1}^2] = \sigma_{t+1}^2$ to recursively compute forecasts.

Variance forecasts are constructed for the conditional variances as

$$\sigma_{t+1}^2 = \omega + \alpha\epsilon_t^2 + \beta\sigma_t^2 \quad (1.8)$$

$$\sigma_{t+h}^2 = \omega + \alpha E_t[\epsilon_{t+h-1}^2] + \beta E_t[\sigma_{t+h-1}^2] \quad h \geq 2 \quad (1.9)$$

$$= \omega + (\alpha + \beta) E_t[\sigma_{t+h-1}^2] \quad h \geq 2 \quad (1.10)$$

```
forecasts = res.forecast(horizon=5, start=split_date)
forecasts.variance[split_date:].plot()
```

1.3.2 Simulation Forecasts

Simulation-based forecasts use the model random number generator to simulate draws of the standardized residuals, e_{t+h} . These are used to generate a pre-specified number of paths of the variances which are then averaged to produce the forecasts. In models like GARCH which evolve in the squares of the residuals, there are few advantages to simulation-based forecasting. These methods are more valuable when producing multi-step forecasts from models that do not have closed form multi-step forecasts such as EGARCH models.

Assume there are B simulated paths. A single simulated path is generated using

$$\sigma_{t+h,b}^2 = \omega + \alpha\epsilon_{t+h-1,b}^2 + \beta\sigma_{t+h-1,b}^2 \quad (1.11)$$

$$\epsilon_{t+h,b} = e_{t+h,b} \sqrt{\sigma_{t+h,b}^2} \quad (1.12)$$

where the simulated shocks are $e_{t+1,b}, e_{t+2,b}, \dots, e_{t+h,b}$ where b is included to indicate that the simulations are independent across paths. Note that the first residual, ϵ_t , is in-sample and so is not simulated.

The final variance forecasts are then computed using the B simulations

$$E_t[\epsilon_{t+h}^2] = \sigma_{t+h}^2 = B^{-1} \sum_{b=1}^B \sigma_{t+h,b}^2 \quad (1.13)$$

```
forecasts = res.forecast(horizon=5, start=split_date, method='simulation')
```

1.3.3 Bootstrap Forecasts

Bootstrap-based forecasts are virtually identical to simulation-based forecasts except that the standardized residuals are generated by the model. These standardized residuals are generated using the observed data and the estimated parameters as

$$\hat{e}_t = \frac{r_t - \hat{\mu}}{\hat{\sigma}_t} \quad (1.14)$$

The generation scheme is identical to the simulation-based method except that the simulated shocks are drawn (i.i.d., with replacement) from $\hat{e}_1, \hat{e}_2, \dots, \hat{e}_t$. so that only data available at time t are used to simulate the paths.

1.3.4 Forecasting Options

The `forecast()` method is attached to a model fit result.

- `params` - The model parameters used to forecast the mean and variance. If not specified, the parameters estimated during the call to `fit` the produced the result are used.
- `horizon` - A positive integer value indicating the maximum horizon to produce forecasts.
- `start` - A positive integer or, if the input to the mode is a DataFrame, a date (string, datetime, datetime64 or Timestamp). Forecasts are produced from `start` until the end of the sample. If not provided, `start` is set to the length of the input data minus 1 so that only 1 forecast is produced.
- `align` - One of 'origin' (default) or 'target' that describes how the forecasts aligned in the output. Origin aligns forecasts to the last observation used in producing the forecast, while target aligns forecasts to the observation index that is being forecast.
- `method` - One of 'analytic' (default), 'simulation' or 'bootstrap' that describes the method used to produce the forecasts. Not all methods are available for all horizons.
- `simulations` - A non-negative integer indicating the number of simulation to use when `method` is 'simulation' or 'bootstrap'

1.3.5 Understanding Forecast Output

Any call to `forecast()` returns a `ARCHModelForecast` object with has 3 core attributes and 1 which may be useful when using simulation- or bootstrap-based forecasts.

The three core attributes are

- `mean` - The forecast conditional mean.
- `variance` - The forecast conditional variance.
- `residual_variance` - The forecast conditional variance of residuals. This will differ from `variance` whenever the model has dynamics (e.g. an AR model) for horizons larger than 1.

Each attribute contains a DataFrame with a common structure.

```
print(forecasts.variance.tail())
```

which returns

| Date | h.1 | h.2 | h.3 | h.4 | h.5 |
|------------|----------|----------|----------|----------|----------|
| 2013-12-24 | 0.489534 | 0.495875 | 0.501122 | 0.509194 | 0.518614 |
| 2013-12-26 | 0.474691 | 0.480416 | 0.483664 | 0.491932 | 0.502419 |
| 2013-12-27 | 0.447054 | 0.454875 | 0.462167 | 0.467515 | 0.475632 |
| 2013-12-30 | 0.421528 | 0.430024 | 0.439856 | 0.448282 | 0.457368 |
| 2013-12-31 | 0.407544 | 0.415616 | 0.422848 | 0.430246 | 0.439451 |

The values in the columns `h.1` are one-step ahead forecast, while values in `h.2`, ..., `h.5` are 2, ..., 5-observation ahead forecasts. The output is aligned so that the Date column is the final data used to generate the forecast, so that `h.1` in row 2013-12-31 is the one-step ahead forecast made using data **up to and including** December 31, 2013.

By default forecasts are only produced for observations after the final observation used to estimate the model.

```
day = dt.timedelta(1)
print(forecasts.variance[split_date - 5 * day:split_date + 5 * day])
```

which produces

| | h.1 | h.2 | h.3 | h.4 | h.5 |
|------------|----------|----------|----------|----------|----------|
| Date | | | | | |
| 2009-12-28 | NaN | NaN | NaN | NaN | NaN |
| 2009-12-29 | NaN | NaN | NaN | NaN | NaN |
| 2009-12-30 | NaN | NaN | NaN | NaN | NaN |
| 2009-12-31 | NaN | NaN | NaN | NaN | NaN |
| 2010-01-04 | 0.739303 | 0.741100 | 0.744529 | 0.746940 | 0.752688 |
| 2010-01-05 | 0.695349 | 0.702488 | 0.706812 | 0.713342 | 0.721629 |
| 2010-01-06 | 0.649343 | 0.654048 | 0.664055 | 0.672742 | 0.681263 |

The output will always have as many rows as the data input. Values that are not forecast are nan filled.

1.3.6 Output Classes

| | |
|---|--|
| <code>ARCHModelForecast(index, start_index, mean, ...)</code> | Container for forecasts from an ARCH Model |
| <code>ARCHModelForecastSimulation(index, values, ...)</code> | Container for a simulation or bootstrap-based forecasts from an ARCH Model |

arch.univariate.base.ARCHModelForecast

`class arch.univariate.base.ARCHModelForecast(index, start_index, mean, variance, residual_variance, simulated_paths=None, simulated_variances=None, simulated_residual_variances=None, simulated_residuals=None, align='origin', *, reindex=False)`

Container for forecasts from an ARCH Model

Parameters

arch.univariate.base.ARCHModelForecast.mean

property ARCHModelForecast.**mean**: DataFrame

Forecast values for the conditional mean of the process

Return type

DataFrame

arch.univariate.base.ARCHModelForecast.residual_variance

property ARCHModelForecast.**residual_variance**: DataFrame

Forecast values for the conditional variance of the residuals

Return type

DataFrame

arch.univariate.base.ARCHModelForecast.simulations

property ARCHModelForecast.**simulations**: *ARCHModelForecastSimulation*

Detailed simulation results if using a simulation-based method

Returns

ARCHModelForecastSimulation

Container for simulation results

Return type

ARCHModelForecastSimulation

arch.univariate.base.ARCHModelForecast.variance

property ARCHModelForecast.**variance**: **DataFrame**

Forecast values for the conditional variance of the process

Return type

DataFrame

arch.univariate.base.ARCHModelForecastSimulation

class arch.univariate.base.**ARCHModelForecastSimulation**(*index, values, residuals, variances, residual_variances*)

Container for a simulation or bootstrap-based forecasts from an ARCH Model

Parameters

index

values

residuals

variances

residual_variances

Attributes

index

The index aligned to dimension 0 of the simulation paths

residual_variances

Simulated variance of the residuals

residuals

Simulated residuals used to produce the values

values

The values of the process

variances

Simulated variances of the values

Methods

Properties

| | |
|---------------------------|--|
| <i>index</i> | The index aligned to dimension 0 of the simulation paths |
| <i>residual_variances</i> | Simulated variance of the residuals |
| <i>residuals</i> | Simulated residuals used to produce the values |
| <i>values</i> | The values of the process |
| <i>variances</i> | Simulated variances of the values |

arch.univariate.base.ARCHModelForecastSimulation.index

property ARCHModelForecastSimulation.index: Index

The index aligned to dimension 0 of the simulation paths

Return type

Index

arch.univariate.base.ARCHModelForecastSimulation.residual_variances

property ARCHModelForecastSimulation.residual_variances: numpy.ndarray | None

Simulated variance of the residuals

Return type

Optional[ndarray]

arch.univariate.base.ARCHModelForecastSimulation.residuals

property ARCHModelForecastSimulation.residuals: numpy.ndarray | None

Simulated residuals used to produce the values

Return type

Optional[ndarray]

arch.univariate.base.ARCHModelForecastSimulation.values

property ARCHModelForecastSimulation.values: numpy.ndarray | None

The values of the process

Return type

Optional[ndarray]

arch.univariate.base.ARCHModelForecastSimulation.variances**property** ARCHModelForecastSimulation.variances: `numpy.ndarray` | `None`

Simulated variances of the values

Return typeOptional[`ndarray`]

1.4 Volatility Forecasting

This setup code is required to run in an IPython notebook

```
[1]: %matplotlib inline
import matplotlib.pyplot as plt
import seaborn as sns

sns.set_style("darkgrid")
plt.rc("figure", figsize=(16, 6))
plt.rc("savefig", dpi=90)
plt.rc("font", family="sans-serif")
plt.rc("font", size=14)
```

1.4.1 Future Forecast Shape Changes

WARNINGThe future behavior of `forecast` is changing.

Versions of `arch` before 4.19 defaulted to returning forecast values with the same shape as the data used to fit the model. While this is convenient it is also computationally wasteful. This is especially true when using `method` is `"simulation"` or `"bootstrap"`. In future version of `arch`, the default behavior will change to only returning the minimal `DataFrame` that is needed to contain the forecast results. In the current version of `arch`, calling `forecast()` without the `reindex` keyword argument produces a `FutureWarning`. You can silence the future warning by:

- Using `reindex=False` which uses the future behavior.
- Using `reindex=True` which uses the legacy behavior.
- Importing from `arch.__future__ import reindexing` which will set the default to `False` and silence the warning.

1.4.2 Data

These examples make use of S&P 500 data from Yahoo! that is available from `arch.data.sp500`.

```
[2]: import datetime as dt
import sys

import arch.data.sp500
import numpy as np
import pandas as pd
from arch import arch_model

data = arch.data.sp500.load()
market = data["Adj Close"]
returns = 100 * market.pct_change().dropna()
```

1.4.3 Basic Forecasting

Forecasts can be generated for standard GARCH(p,q) processes using any of the three forecast generation methods:

- Analytical
- Simulation-based
- Bootstrap-based

By default forecasts will only be produced for the final observation in the sample so that they are out-of-sample.

Forecasts start with specifying the model and estimating parameters.

```
[3]: am = arch_model(returns, vol="Garch", p=1, o=0, q=1, dist="Normal")
res = am.fit(update_freq=5)

Iteration:      5,   Func. Count:    35,   Neg. LLF: 6970.282172935112
Iteration:     10,   Func. Count:    63,   Neg. LLF: 6936.718477483884
Optimization terminated successfully   (Exit mode 0)
      Current function value: 6936.718476988963
      Iterations: 11
      Function evaluations: 68
      Gradient evaluations: 11
```

```
[4]: forecasts = res.forecast(reindex=False)
```

Forecasts are contained in an `ARCHModelForecast` object which has 4 attributes:

- `mean` - The forecast means
- `residual_variance` - The forecast residual variances, that is $E_t[\epsilon_{t+h}^2]$
- `variance` - The forecast variance of the process, $E_t[r_{t+h}^2]$. The variance will differ from the residual variance whenever the model has mean dynamics, e.g., in an AR process.
- `simulations` - An object that contains detailed information about the simulations used to generate forecasts. Only used if the forecast method is set to 'simulation' or 'bootstrap'. If using 'analytical' (the default), this is None.

The three main outputs are all returned in DataFrames with columns of the form `h.#` where `#` is the number of steps ahead. That is, `h.1` corresponds to one-step ahead forecasts while `h.10` corresponds to 10-steps ahead.

The default forecast only produces 1-step ahead forecasts.

```
[5]: print(forecasts.mean.iloc[-3:])
print(forecasts.residual_variance.iloc[-3:])
print(forecasts.variance.iloc[-3:])
```

```

                h.1
Date
2018-12-31  0.056353
                h.1
Date
2018-12-31  3.59647
                h.1
Date
2018-12-31  3.59647
```

Longer horizon forecasts can be computed by passing the parameter horizon.

```
[6]: forecasts = res.forecast(horizon=5, reindex=False)
print(forecasts.residual_variance.iloc[-3:])
```

```

                h.1      h.2      h.3      h.4      h.5
Date
2018-12-31  3.59647  3.568502  3.540887  3.513621  3.4867
```

If you fail to set reindex you will see a warning.

```
[7]: forecasts = res.forecast(horizon=5)
```

```
c:\git\arch\arch\__future__\utility.py:11: FutureWarning:
The default for reindex is True. After September 2021 this will change to
False. Set reindex to True or False to silence this message. Alternatively,
you can use the import comment
```

```
from arch.__future__ import reindexing
```

```
to globally set reindex to True and silence this warning.
```

```
warnings.warn(
```

When not specified, or if reindex is True, then values that are not computed are nan-filled.

```
[8]: print(forecasts.residual_variance.iloc[-3:])
```

```

                h.1      h.2      h.3      h.4      h.5
Date
2018-12-27      NaN      NaN      NaN      NaN      NaN
2018-12-28      NaN      NaN      NaN      NaN      NaN
2018-12-31  3.59647  3.568502  3.540887  3.513621  3.4867
```

1.4.4 Alternative Forecast Generation Schemes

Fixed Window Forecasting

Fixed-windows forecasting uses data up to a specified date to generate all forecasts after that date. This can be implemented by passing the entire data in when initializing the model and then using `last_obs` when calling `fit`. `forecast()` will, by default, produce forecasts after this final date.

Note `last_obs` follow Python sequence rules so that the actual date in `last_obs` is not in the sample.

```
[9]: res = am.fit(last_obs="2011-1-1", update_freq=5)
forecasts = res.forecast(horizon=5, reindex=False)
print(forecasts.variance.dropna().head())
```

```
Iteration:      5,   Func. Count:    34,   Neg. LLF: 4578.713295409127
Iteration:     10,   Func. Count:    63,   Neg. LLF: 4555.338451419905
Optimization terminated successfully   (Exit mode 0)
      Current function value: 4555.285110045323
      Iterations: 14
      Function evaluations: 83
      Gradient evaluations: 14
```

| | h.1 | h.2 | h.3 | h.4 | h.5 |
|------------|----------|----------|----------|----------|----------|
| Date | | | | | |
| 2010-12-31 | 0.381757 | 0.390905 | 0.399988 | 0.409008 | 0.417964 |
| 2011-01-03 | 0.451724 | 0.460381 | 0.468976 | 0.477512 | 0.485987 |
| 2011-01-04 | 0.428416 | 0.437236 | 0.445994 | 0.454691 | 0.463326 |
| 2011-01-05 | 0.420554 | 0.429429 | 0.438242 | 0.446993 | 0.455683 |
| 2011-01-06 | 0.402483 | 0.411486 | 0.420425 | 0.429301 | 0.438115 |

Rolling Window Forecasting

Rolling window forecasts use a fixed sample length and then produce one-step from the final observation. These can be implemented using `first_obs` and `last_obs`.

```
[10]: index = returns.index
start_loc = 0
end_loc = np.where(index >= "2010-1-1")[0].min()
forecasts = {}
for i in range(20):
    sys.stdout.write(".")
    sys.stdout.flush()
    res = am.fit(first_obs=i, last_obs=i + end_loc, disp="off")
    temp = res.forecast(horizon=3, reindex=False).variance
    fcast = temp.iloc[0]
    forecasts[fcast.name] = fcast
print()
print(pd.DataFrame(forecasts).T)
```

```
...
           h.1      h.2      h.3
2009-12-31  0.615314  0.621743  0.628133
2010-01-04  0.751747  0.757343  0.762905
2010-01-05  0.710453  0.716315  0.722142
2010-01-06  0.666244  0.672346  0.678411
```

Recursive Forecast Generation

Recursive is similar to rolling except that the initial observation does not change. This can be easily implemented by dropping the `first_obs` input.

```
[11]: import numpy as np
import pandas as pd

index = returns.index
start_loc = 0
end_loc = np.where(index >= "2010-1-1")[0].min()
forecasts = {}
for i in range(20):
    sys.stdout.write(".")
    sys.stdout.flush()
    res = am.fit(last_obs=i + end_loc, disp="off")
    temp = res.forecast(horizon=3, reindex=False).variance
    fcast = temp.iloc[0]
    forecasts[fcast.name] = fcast
print()
print(pd.DataFrame(forecasts).T)
```

1.4.5 TARCH

Analytical Forecasts

All ARCH-type models have one-step analytical forecasts. Longer horizons only have closed forms for specific models. TARCH models do not have closed-form (analytical) forecasts for horizons larger than 1, and so simulation or bootstrapping is required. Attempting to produce forecasts for horizons larger than 1 using `method='analytical'` results in a `ValueError`.

```
[12]: # TARCH specification
am = arch_model(returns, vol="GARCH", power=2.0, p=1, o=1, q=1)
res = am.fit(update_freq=5)
forecasts = res.forecast(reindex=False)
print(forecasts.variance.iloc[-1])

Iteration:      5,  Func. Count:      40,  Neg. LLF: 6846.496665348549
Iteration:     10,  Func. Count:      75,  Neg. LLF: 6822.883179474602
Optimization terminated successfully (Exit mode 0)
      Current function value: 6822.882823372691
      Iterations: 13
      Function evaluations: 93
      Gradient evaluations: 13
h.1      3.010188
Name: 2018-12-31 00:00:00, dtype: float64
```

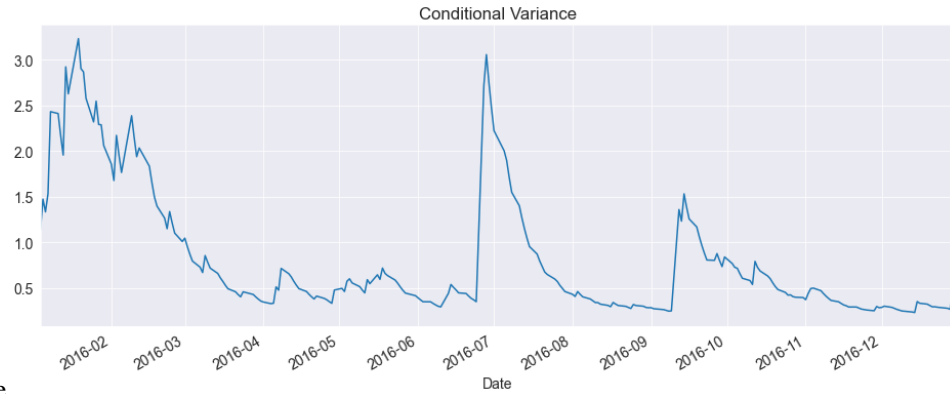

Simulation Forecasts

When using simulation- or bootstrap-based forecasts, an additional attribute of an `ARCHModelForecast` object is meaningful – `simulation`.

```
[13]: import matplotlib.pyplot as plt

fig, ax = plt.subplots(1, 1)
var_2016 = res.conditional_volatility["2016"] ** 2.0
subplot = var_2016.plot(ax=ax, title="Conditional Variance")
subplot.set_xlim(var_2016.index[0], var_2016.index[-1])

[13]: (16804.0, 17165.0)
```

nbsphinx-code-borderwhite

```
[14]: forecasts = res.forecast(horizon=5, method="simulation", reindex=False)
      sims = forecasts.simulations

      x = np.arange(1, 6)
      lines = plt.plot(x, sims.residual_variances[-1, ::5].T, color="#9cb2d6", alpha=0.5)
      lines[0].set_label("Simulated path")
      line = plt.plot(x, forecasts.variance.iloc[-1].values, color="#002868")
      line[0].set_label("Expected variance")
      plt.gca().set_xticks(x)
      plt.gca().set_xlim(1, 5)
      legend = plt.legend()
```

nbsphinx-code-borderwhite

```
[15]: import seaborn as sns

      sns.boxplot(data=sims.variances[-1])

[15]: <AxesSubplot:>
```

nbsphinx-code-borderwhite

Bootstrap Forecasts

Bootstrap-based forecasts are nearly identical to simulation-based forecasts except that the values used to simulate the process are computed from historical data rather than using the assumed distribution of the residuals. Forecasts produced using this method also return an `ARCHModelForecastSimulation` containing information about the simulated paths.

```
[16]: forecasts = res.forecast(horizon=5, method="bootstrap", reindex=False)
sims = forecasts.simulations

lines = plt.plot(x, sims.residual_variances[-1, ::5].T, color="#9cb2d6", alpha=0.5)
lines[0].set_label("Simulated path")
line = plt.plot(x, forecasts.variance.iloc[-1].values, color="#002868")
line[0].set_label("Expected variance")
plt.gca().set_xticks(x)
plt.gca().set_xlim(1, 5)
legend = plt.legend()
```

nbsphinx-code-borderwhite

1.5 Value-at-Risk Forecasting

Value-at-Risk (VaR) forecasts from GARCH models depend on the conditional mean, the conditional volatility and the quantile of the standardized residuals,

$$VaR_{t+1|t} = -\mu_{t+1|t} - \sigma_{t+1|t}q_\alpha$$

where q_α is the α quantile of the standardized residuals, e.g., 5%.

The quantile can be either computed from the estimated model density or computed using the empirical distribution of the standardized residuals. The example below shows both methods.

```
[17]: am = arch_model(returns, vol="Garch", p=1, o=0, q=1, dist="skewt")
res = am.fit(dispatch="off", last_obs="2017-12-31")
```

1.5.1 Parametric VaR

First, we use the model to estimate the VaR. The quantiles can be computed using the `ppf` method of the distribution attached to the model. The quantiles are printed below.

```
[18]: forecasts = res.forecast(start="2018-1-1", reindex=False)
cond_mean = forecasts.mean["2018":]
cond_var = forecasts.variance["2018":]
q = am.distribution.ppf([0.01, 0.05], res.params[-2:])
print(q)

[-2.64484999 -1.64965918]
```

Next, we plot the two VaRs along with the returns. The returns that violate the VaR forecasts are highlighted.

```
[19]: value_at_risk = -cond_mean.values - np.sqrt(cond_var).values * q[None, :]
value_at_risk = pd.DataFrame(value_at_risk, columns=["1%", "5%"], index=cond_var.index)
ax = value_at_risk.plot(legend=False)
xl = ax.set_xlim(value_at_risk.index[0], value_at_risk.index[-1])
rets_2018 = returns["2018:"].copy()
rets_2018.name = "S&P 500 Return"
c = []
for idx in value_at_risk.index:
    if rets_2018[idx] > -value_at_risk.loc[idx, "5%"]:
        c.append("#000000")
    elif rets_2018[idx] < -value_at_risk.loc[idx, "1%"]:
        c.append("#BB0000")
    else:
        c.append("#BB00BB")
c = np.array(c, dtype="object")
labels = {
    "#BB0000": "1% Exceedence",
    "#BB00BB": "5% Exceedence",
    "#000000": "No Exceedence",
}
markers = {"#BB0000": "x", "#BB00BB": "s", "#000000": "o"}
for color in np.unique(c):
    sel = c == color
```

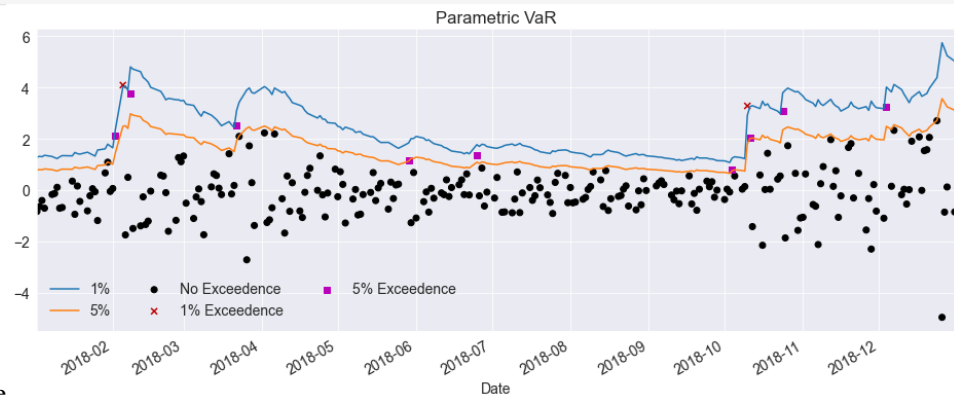

(continues on next page)

(continued from previous page)

```

ax.scatter(
    rets_2018.index[sel],
    -rets_2018.loc[sel],
    marker=markers[color],
    c=c[sel],
    label=labels[color],
)
ax.set_title("Parametric VaR")
leg = ax.legend(frameon=False, ncol=3)

```

nbsphinx-code-borderwhite

1.5.2 Filtered Historical Simulation

Next, we use the empirical distribution of the standardized residuals to estimate the quantiles. These values are very similar to those estimated using the assumed distribution. The plot below is identical except for the slightly different quantiles.

```

[20]: std_rets = (returns["2017"] - res.params["mu"]) / res.conditional_volatility
std_rets = std_rets.dropna()
q = std_rets.quantile([0.01, 0.05])
print(q)

0.01    -2.668273
0.05    -1.723352
dtype: float64

```

```

[21]: value_at_risk = -cond_mean.values - np.sqrt(cond_var).values * q.values[None, :]
value_at_risk = pd.DataFrame(value_at_risk, columns=["1%", "5%"], index=cond_var.index)
ax = value_at_risk.plot(legend=False)
xl = ax.set_xlim(value_at_risk.index[0], value_at_risk.index[-1])
rets_2018 = returns["2018":].copy()
rets_2018.name = "S&P 500 Return"
c = []
for idx in value_at_risk.index:
    if rets_2018[idx] > -value_at_risk.loc[idx, "5%"]:
        c.append("#000000")
    elif rets_2018[idx] < -value_at_risk.loc[idx, "1%"]:
        c.append("#BB0000")
    else:

```

(continues on next page)

(continued from previous page)

```

        c.append("#BB00BB")
c = np.array(c, dtype="object")
for color in np.unique(c):
    sel = c == color
    ax.scatter(
        rets_2018.index[sel],
        -rets_2018.loc[sel],
        marker=markers[color],
        c=c[sel],
        label=labels[color],
    )
ax.set_title("Filtered Historical Simulation VaR")
leg = ax.legend(frameon=False, ncol=3)

```

nbsphinx-code-borderwhite

1.6 Volatility Scenarios

Custom random-number generators can be used to implement scenarios where shock follow a particular pattern. For example, suppose you wanted to find out what would happen if there were 5 days of shocks that were larger than average. In most circumstances, the shocks in a GARCH model have unit variance. This could be changed so that the first 5 shocks have variance 4, or twice the standard deviation.

Another scenario would be to over sample a specific period for the shocks. When using the standard bootstrap method (filtered historical simulation) the shocks are drawn using iid sampling from the history. While this approach is standard and well-grounded, it might be desirable to sample from a specific period. This can be implemented using a custom random number generator. This strategy is precisely how the filtered historical simulation is implemented internally, only where the draws are uniformly sampled from the entire history.

First, some preliminaries

```

[1]: %matplotlib inline
import matplotlib.pyplot as plt
import numpy as np
import pandas as pd
import seaborn as sns
from arch.univariate import GARCH, ConstantMean, Normal

sns.set_style("darkgrid")
plt.rc("figure", figsize=(16, 6))

```

(continues on next page)

(continued from previous page)

```
plt.rc("savefig", dpi=90)
plt.rc("font", family="sans-serif")
plt.rc("font", size=14)
```

This example makes use of returns from the NASDAQ index. The scenario bootstrap will make use of returns in the run-up to and during the Financial Crisis of 2008.

```
[2]: import arch.data.nasdaq
```

```
data = arch.data.nasdaq.load()
nasdaq = data["Adj Close"]
print(nasdaq.head())
```

```
Date
1999-01-04    2208.050049
1999-01-05    2251.270020
1999-01-06    2320.860107
1999-01-07    2326.090088
1999-01-08    2344.409912
Name: Adj Close, dtype: float64
```

Next, the returns are computed and the model is constructed. The model is constructed from the building blocks. It is a standard model and could have been (almost) equivalently constructed using

```
mod = arch_model(rets, mean='constant', p=1, o=1, q=1)
```

The one advantage of constructing the model using the components is that the NumPy `RandomState` that is used to simulate from the model can be externally set. This allows the generator seed to be easily set and for the state to reset, if needed.

NOTE: It is always a good idea to scale return by 100 before estimating ARCH-type models. This helps the optimizer converge since the scale of the volatility intercept is much closer to the scale of the other parameters in the model.

```
[3]: rets = 100 * nasdaq.pct_change().dropna()
```

```
# Build components to set the state for the distribution
random_state = np.random.RandomState(1)
dist = Normal(random_state=random_state)
volatility = GARCH(1, 1, 1)

mod = ConstantMean(rets, volatility=volatility, distribution=dist)
```

Fitting the model is standard.

```
[4]: res = mod.fit(dispatch="off")
res
```

```
[4]: Constant Mean - GJR-GARCH Model Results
```

```

All GARCH specification are complete models in the sense that they specify a distribution. This allows simulations to be produced using the assumptions in the model. The forecast function can be made to produce simulations using the assumed distribution by setting method='simulation'.

These forecasts are similar to the analytical forecasts above. As the number of simulation increases towards ∞ , the simulation-based forecasts will converge to the analytical values above.

```
[6]: sim_forecasts = res.forecast(
    start="1-1-2017", method="simulation", horizon=10, reindex=False
)
print(sim_forecasts.residual_variance.dropna().head())

1.6.1 Custom Random Generators

forecast supports replacing the generator based on the assumed distribution of residuals in the model with any other generator. A shock generator should usually produce unit variance shocks. However, in this example the first 5 shocks generated have variance 2, and the remainder are standard normal. This scenario consists of a period of consistently surprising volatility where the volatility has shifted for some reason.

The forecast variances are much larger and grow faster than those from either method previously illustrated. This reflects the increase in volatility in the first 5 days.

```
[7]: import numpy as np

random_state = np.random.RandomState(1)

def scenario_rng(size):
    shocks = random_state.standard_normal(size)
    shocks[:, :5] *= np.sqrt(2)
    return shocks

scenario_forecasts = res.forecast(
    start="1-1-2017", method="simulation", horizon=10, rng=scenario_rng, reindex=False
)
print(scenario_forecasts.residual_variance.dropna().head())
```

1.6.2 Bootstrap Scenarios

forecast supports Filtered Historical Simulation (FHS) using `method='bootstrap'`. This is effectively a simulation method where the simulated shocks are generated using iid sampling from the history of the demeaned and standardized return data. Custom bootstraps are another application of `rng`. Here an object is used to hold the shocks. This object exposes a method (`rng`) that acts like a random number generator, except that it only returns values that were provided in the `shocks` parameter.

The internal implementation of the FHS uses a method almost identical to this where `shocks` contain the entire history.

```
[8]: class ScenarioBootstrapRNG(object):
    def __init__(self, shocks, random_state):
        self._shocks = np.asarray(shocks) # 1d
        self._rs = random_state
        self.n = shocks.shape[0]

    def rng(self, size):
        idx = self._rs.randint(0, self.n, size=size)
        return self._shocks[idx]

random_state = np.random.RandomState(1)
std_shocks = res.resid / res.conditional_volatility
shocks = std_shocks["2008-08-01":"2008-11-10"]
scenario_bootstrap = ScenarioBootstrapRNG(shocks, random_state)
bs_forecasts = res.forecast(
    start="1-1-2017",
    method="simulation",
    horizon=10,
    rng=scenario_bootstrap.rng,
    reindex=False,
)
print(bs_forecasts.residual_variance.dropna().head())
```

1.6.3 Visualizing the differences

The final forecast values are used to illustrate how these are different. The analytical and standard simulation are virtually identical. The simulated scenario grows rapidly for the first 5 periods and then more slowly. The bootstrap scenario grows quickly and consistently due to the magnitude of the shocks in the financial crisis.

```
[9]: import pandas as pd
```

```
df = pd.concat(
    [
        forecasts.residual_variance.iloc[-1],
        sim_forecasts.residual_variance.iloc[-1],
        scenario_forecasts.residual_variance.iloc[-1],
        bs_forecasts.residual_variance.iloc[-1],
    ],
    1,
)
df.columns = ["Analytic", "Simulation", "Scenario Sim", "Bootstrp Scenario"]
# Plot annualized vol
subplot = np.sqrt(252 * df).plot(legend=False)
legend = subplot.legend(frameon=False)
```

nbsphinx-code-borderwhite

```
[10]: subplot = np.sqrt(252 * df).plot
```

1.6.4 Comparing the paths

The paths are available on the attribute `simulations`. Plotting the paths shows important differences between the two scenarios beyond the average differences plotted above. Both start at the same point.

```
[11]: fig, axes = plt.subplots(1, 2)
colors = sns.color_palette("dark")
# The paths for the final observation
sim_paths = sim_forecasts.simulations.residual_variances[-1].T
bs_paths = bs_forecasts.simulations.residual_variances[-1].T
```

(continues on next page)

(continued from previous page)

```

x = np.arange(1, 11)
# Plot the paths and the mean, set the axis to have the same limit
axes[0].plot(x, np.sqrt(252 * sim_paths), color=colors[1], alpha=0.05)
axes[0].plot(
    x, np.sqrt(252 * sim_forecasts.residual_variance.iloc[-1]), color="k", alpha=1
)
axes[0].set_title("Model-based Simulation")
axes[0].set_xticks(np.arange(1, 11))
axes[0].set_xlim(1, 10)
axes[0].set_ylim(20, 100)

axes[1].plot(x, np.sqrt(252 * bs_paths), color=colors[2], alpha=0.05)
axes[1].plot(
    x, np.sqrt(252 * bs_forecasts.residual_variance.iloc[-1]), color="k", alpha=1
)
axes[1].set_xticks(np.arange(1, 11))
axes[1].set_xlim(1, 10)
axes[1].set_ylim(20, 100)
title = axes[1].set_title("Bootstrap Scenario")

```

1.6.5 Comparing across the year

A hedgehog plot is useful for showing the differences between the two forecasting methods across the year, instead of a single day.

```

[12]: analytic = forecasts.residual_variance.dropna()
bs = bs_forecasts.residual_variance.dropna()
fig, ax = plt.subplots(1, 1)
vol = res.conditional_volatility["2017-1-1":"2019-1-1"]
idx = vol.index
ax.plot(np.sqrt(252) * vol, alpha=0.5)
colors = sns.color_palette()
for i in range(0, len(vol), 22):
    a = analytic.iloc[i]
    b = bs.iloc[i]
    loc = idx.get_loc(a.name)
    new_idx = idx[loc + 1 : loc + 11]
    a.index = new_idx

```

(continues on next page)

(continued from previous page)

```

b.index = new_idx
ax.plot(np.sqrt(252 * a), color=colors[1])
ax.plot(np.sqrt(252 * b), color=colors[2])
labels = ["Annualized Vol.", "Analytic Forecast", "Bootstrap Scenario Forecast"]
legend = ax.legend(labels, frameon=False)
xlim = ax.set_xlim(vol.index[0], vol.index[-1])

```

nbsphinx-code-borderwhite

1.7 Forecasting with Exogenous Regressors

This notebook provides examples of the accepted data structures for passing the expected value of exogenous variables when these are included in the mean. For example, consider an AR(1) with 2 exogenous variables. The mean dynamics are

$$Y_t = \phi_0 + \phi_1 Y_{t-1} + \beta_0 X_{0,t} + \beta_1 X_{1,t} + \epsilon_t.$$

The h -step forecast, $E_T[Y_{t+h}]$, depends on the conditional expectation of $X_{0,T+h}$ and $X_{1,T+h}$,

$$E_T[Y_{T+h}] = \phi_0 + \phi_1 E_T[Y_{T+h-1}] + \beta_0 E_T[X_{0,T+h}] + \beta_1 E_T[X_{1,T+h}]$$

where $E_T[Y_{T+h-1}]$ has been recursively computed.

In order to construct forecasts up to some horizon h , it is necessary to pass $2 \times h$ values (h for each series). If using the features of `forecast` that allow many forecast to be specified, it necessary to supply $n \times 2 \times h$ values.

There are two general purpose data structures that can be used for any number of exogenous variables and any number steps ahead:

- **dict** - The values can be pass using a dict where the keys are the variable names and the values are 2-dimensional arrays. This is the most natural generalization of a pandas DataFrame to 3-dimensions.
- **array** - The vales can alternatively be passed as a 3-d NumPy array where dimension 0 tracks the regressor index, dimension 1 is the time period and dimension 2 is the horizon.

When a model contains a single exogenous regressor it is possible to use a 2-d array or DataFrame where dim0 tracks the time period where the forecast is generated and dimension 1 tracks the horizon.

In the special case where a model contains a single regressor *and* the horizon is 1, then a 1-d array of pandas Series can be used.

```

[1]: # initial setup
      %matplotlib inline

```

(continues on next page)

(continued from previous page)

```

import matplotlib.pyplot as plt
import numpy as np
import pandas as pd
import seaborn
from arch.__future__ import reindexing

seaborn.set_style("darkgrid")
plt.rc("figure", figsize=(16, 6))
plt.rc("savefig", dpi=90)
plt.rc("font", family="sans-serif")
plt.rc("font", size=14)

```

1.7.1 Simulating data

Two X variables are simulated and are assumed to follow independent AR(1) processes. The data is then assumed to follow an ARX(1) with 2 exogenous regressors and GARCH(1,1) errors.

```

[2]: from arch.univariate import ARX, GARCH, ZeroMean, arch_model

burn = 250

x_mod = ARX(None, lags=1)
x0 = x_mod.simulate([1, 0.8, 1], nobs=1000 + burn).data
x1 = x_mod.simulate([2.5, 0.5, 1], nobs=1000 + burn).data

resid_mod = ZeroMean(volatility=GARCH())
resids = resid_mod.simulate([0.1, 0.1, 0.8], nobs=1000 + burn).data

phi1 = 0.7
phi0 = 3
y = 10 + resids.copy()
for i in range(1, y.shape[0]):
    y[i] = phi0 + phi1 * y[i - 1] + 2 * x0[i] - 2 * x1[i] + resids[i]

x0 = x0.iloc[-1000:]
x1 = x1.iloc[-1000:]
y = y.iloc[-1000:]
y.index = x0.index = x1.index = np.arange(1000)

```

1.7.2 Plotting the data

```

[3]: ax = pd.DataFrame({"ARX": y}).plot(legend=False)
ax.legend(frameon=False)
_ = ax.set_xlim(0, 999)

```

nbsphinx-code-borderwhite

1.7.3 Forecasting the X values

The forecasts of Y depend on forecasts of X_0 and X_1 . Both of these follow simple AR(1), and so we can construct the forecasts for all time horizons. Note that the value in position $[i, j]$ is the time- i forecast for horizon $j+1$.

```
[4]: x0_oos = np.empty((1000, 10))
x1_oos = np.empty((1000, 10))
for i in range(10):
    if i == 0:
        last = x0
    else:
        last = x0_oos[:, i - 1]
    x0_oos[:, i] = 1 + 0.8 * last
    if i == 0:
        last = x1
    else:
        last = x1_oos[:, i - 1]
    x1_oos[:, i] = 2.5 + 0.5 * last
```

x1_oos[-1]

```
[4]: array([5.32610653, 5.16305327, 5.08152663, 5.04076332, 5.02038166,
          5.01019083, 5.00509541, 5.00254771, 5.00127385, 5.00063693])
```

1.7.4 Fitting the model

Next, the model is fit. The parameters are accurately estimated.

```
[5]: exog = pd.DataFrame({"x0": x0, "x1": x1})
mod = arch_model(y, x=exog, mean="ARX", lags=1)
res = mod.fit(dispatch="off")
print(res.summary())
```

1.7.5 Using a dict

The first approach uses a dict to pass the two variables. The key consideration here is the the keys of the dictionary must **exactly** match the variable names (`x0` and `x1` here). The dictionary here contains only the final row of the forecast values since `forecast` will only make forecasts beginning from the final in-sample observation by default.

Using DataFrame

While these examples make use of NumPy arrays, these can be DataFrames. This allows the index to be used to track the forecast origination point, which can be a helpful device.

```
[6]: exog_fcast = {"x0": x0_oos[-1:], "x1": x1_oos[-1:]}
      forecasts = res.forecast(horizon=10, x=exog_fcast)
      forecasts.mean.T.plot()
```

```
[6]: <AxesSubplot:>
```

nbsphinx-code-borderwhite

1.7.6 Using an array

An array can alternatively be used. This frees the restriction on matching the variable names although the order must match instead. The forecast values are 2 (variables) by 1 (forecast) by 10 (horizon).

```
[7]: exog_fcast = np.array([x0_oos[-1:], x1_oos[-1:]])
print(f"The shape is {exog_fcast.shape}")
array_forecasts = res.forecast(horizon=10, x=exog_fcast)
print(array_forecasts.mean - forecasts.mean)
```

```
The shape is (2, 1, 10)
      h.01 h.02 h.03 h.04 h.05 h.06 h.07 h.08 h.09 h.10
999    0.0  0.0  0.0  0.0  0.0  0.0  0.0  0.0  0.0  0.0
```

1.7.7 Producing multiple forecasts

`forecast` can produce multiple forecasts using the same fit model. Here the model is fit to the first 500 observations and then forecasting for the remaining values are produced. It must be the case that the `x` values passed for `forecast` have the same number of rows as the table of forecasts produced.

```
[8]: res = mod.fit(dispatch="off", last_obs=500)
exog_fcast = {"x0": x0_oos[-500:], "x1": x1_oos[-500:]}
multi_forecasts = res.forecast(start=500, horizon=10, x=exog_fcast)
multi_forecasts.mean.tail(10)
```

```
[8]:      h.01      h.02      h.03      h.04      h.05      h.06 \

997    9.488851    9.737583    9.891902    9.983206
998   10.532205   10.636352   10.657221   10.628546
999   13.097526   12.733225   12.363590   12.012647
```

The plot of the final 5 forecast paths shows the the mean reversion of the process.

```
[9]: _ = multi_forecasts.mean.tail().T.plot()
```

nbsphinx-code-borderwhite

The previous example made use of dictionaries where each of the values was a 500 (number of forecasts) by 10 (horizon) array. The alternative format can be used where `x` is a 3-d array with shape 2 (variables) by 500 (forecasts) by 10 (horizon).

```
[10]: exog_fcast = np.array([x0_oos[-500:], x1_oos[-500:]])
print(exog_fcast.shape)
array_multi_forecasts = res.forecast(start=500, horizon=10, x=exog_fcast)
np.max(np.abs(array_multi_forecasts.mean - multi_forecasts.mean))
```

```
(2, 500, 10)
```

```
[10]: h.01    0.0
h.02    0.0
h.03    0.0
h.04    0.0
h.05    0.0
h.06    0.0
h.07    0.0
h.08    0.0
h.09    0.0
h.10    0.0
dtype: float64
```

1.7.8 x input array sizes

While the natural shape of the `x` data is the number of forecasts, it is also possible to pass an `x` that has the same shape as the `y` used to construct the model. This may simplify tracking the origin points of the forecast. Values that are not needed are ignored. In this example, the out-of-sample values are 2 by 1000 (original number of observations) by 10. Only the final 500 are used.

WARNING

Other sizes are not allowed. The size of the out-of-sample data must either match the original data size or the number of forecasts.

```
[11]: exog_fcast = np.array([x0_oos, x1_oos])
print(exog_fcast.shape)
array_multi_forecasts = res.forecast(start=500, horizon=10, x=exog_fcast)
np.max(np.abs(array_multi_forecasts.mean - multi_forecasts.mean))
```

```
(2, 1000, 10)
[11]: h.01    0.0
      h.02    0.0
      h.03    0.0
      h.04    0.0
      h.05    0.0
      h.06    0.0
      h.07    0.0
      h.08    0.0
      h.09    0.0
      h.10    0.0
      dtype: float64
```

1.7.9 Special Cases with a single x variable

When a model consists of a single exogenous regressor, then `x` can be a 1-d or 2-d array (or `Series` or `DataFrame`).

```
[12]: mod = arch_model(y, x=exog.iloc[:, :1], mean="ARX", lags=1)
      res = mod.fit(dispatch="off")
      print(res.summary())
```

```

```

1.7.10 Simulation

forecast supports simulating paths. When forecasting a model with exogenous variables, the same value is used to in all mean paths. If you wish to also simulate the paths of the x variables, these need to be generated and then passed inside a loop.

Static out-of-sample x

This first example shows that variance of the paths when the same x values are used in the forecast. There is a sense the out-of-sample x are treated as deterministic.

```
[14]: x = {"x0": x0_oos[-1], "x1": x1_oos[-1]}
sim_fixedx = res.forecast(horizon=10, x=x, method="simulation", simulations=100)
sim_fixedx.simulations.values.std(1)

[14]: array([[0.94510757, 0.97700028, 1.13035701, 1.10824845, 1.26825095,
          1.26590793, 1.23342443, 1.18098812, 1.28265677, 1.2315994 ]])
```

Simulating the out-of-sample x

This example simulates distinct paths for the two exogenous variables and then simulates a single path. This is then repeated 100 times. We see that variance is much higher when we account for variation in the x data.

```
[15]: from numpy.random import RandomState

def sim_ar1(params: np.ndarray, initial: float, horizon: int, rng: RandomState):
    out = np.zeros(horizon)
    shocks = rng.standard_normal(horizon)
    out[0] = params[0] + params[1] * initial + shocks[0]
    for i in range(1, horizon):
        out[i] = params[0] + params[1] * out[i - 1] + shocks[i]
    return out

simulations = []
rng = RandomState(20210301)
for i in range(100):
    x0_sim = sim_ar1(np.array([1, 0.8]), x0.iloc[-1], 10, rng)
```

(continues on next page)

(continued from previous page)

```
x1_sim = sim_ar1(np.array([2.5, 0.5]), x1.iloc[-1], 10, rng)
x = {"x0": x0_sim, "x1": x1_sim}
fcast = res.forecast(horizon=10, x=x, method="simulation", simulations=1)
simulations.append(fcast.simulations.values)
```

Finally the standard deviation is quite a bit larger. This is a most accurate value for the long-run variance of the forecast residuals which should account for dynamics in the model and any exogenous regressors.

```
[16]: joined = np.concatenate(simulations, 1)
joined.std(1)
```

```
[16]: array([[3.21343234, 4.99297815, 6.29477322, 7.49884207, 8.47501636,
8.64628226, 8.72478144, 8.78606273, 9.03824963, 9.30368669]])
```

1.8 Mean Models

All ARCH models start by specifying a mean model.

| | |
|--|---|
| <code>ZeroMean</code> ([y, hold_back, volatility, ...]) | Model with zero conditional mean estimation and simulation |
| <code>ConstantMean</code> ([y, hold_back, volatility, ...]) | Constant mean model estimation and simulation. |
| <code>ARX</code> ([y, x, lags, constant, hold_back, ...]) | Autoregressive model with optional exogenous regressors estimation and simulation |
| <code>HARX</code> ([y, x, lags, constant, use_rotated, ...]) | Heterogeneous Autoregression (HAR), with optional exogenous regressors, model estimation and simulation |
| <code>LS</code> ([y, x, constant, hold_back, volatility, ...]) | Least squares model estimation and simulation |

1.8.1 arch.univariate.ZeroMean

```
class arch.univariate.ZeroMean(y=None, hold_back=None, volatility=None, distribution=None,
                               rescale=None)
```

Model with zero conditional mean estimation and simulation

Parameters

y

[{ndarray, Series}] nobs element vector containing the dependent variable

hold_back

[int] Number of observations at the start of the sample to exclude when estimating model parameters. Used when comparing models with different lag lengths to estimate on the common sample.

volatility

[VolatilityProcess, optional] Volatility process to use in the model

distribution

[Distribution, optional] Error distribution to use in the model

rescale

[bool, optional] Flag indicating whether to automatically rescale data if the scale of the data is likely to produce convergence issues when estimating model parameters. If False, the

model is estimated on the data without transformation. If True, than y is rescaled and the new scale is reported in the estimation results.

Notes

The zero mean model is described by

$$y_t = \epsilon_t$$

Examples

```
>>> import numpy as np
>>> from arch.univariate import ZeroMean
>>> y = np.random.randn(100)
>>> zm = ZeroMean(y)
>>> res = zm.fit()
```

Attributes

distribution

Set or gets the error distribution

name

The name of the model.

num_params

Returns the number of parameters

volatility

Set or gets the volatility process

x

Gets the value of the exogenous regressors in the model

y

Returns the dependent variable

Methods

| | |
|--|--|
| <i>bounds()</i> | Construct bounds for parameters to use in non-linear optimization |
| <i>compute_param_cov</i> (params[, backcast, robust]) | Computes parameter covariances using numerical derivatives. |
| <i>constraints()</i> | Construct linear constraint arrays for use in non-linear optimization |
| <i>fit</i> ([update_freq, disp, starting_values, ...]) | Estimate model parameters |
| <i>fix</i> (params[, first_obs, last_obs]) | Allows an ARCHModelFixedResult to be constructed from fixed parameters. |
| <i>forecast</i> (params[, horizon, start, align, ...]) | Construct forecasts from estimated model |
| <i>parameter_names()</i> | List of parameters names |
| <i>resids</i> (params[, y, regressors]) | Compute model residuals |
| <i>simulate</i> (params[, nobs[, burn, ...]) | Simulated data from a zero mean model |
| <i>starting_values()</i> | Returns starting values for the mean model, often the same as the values returned from fit |

arch.univariate.ZeroMean.bounds

ZeroMean.**bounds**()

Construct bounds for parameters to use in non-linear optimization

Returns

bounds

[list (2-tuple of float)] Bounds for parameters to use in estimation.

Return type

list[tuple[float, float]]

arch.univariate.ZeroMean.compute_param_cov

ZeroMean.**compute_param_cov**(*params*, *backcast=None*, *robust=True*)

Computes parameter covariances using numerical derivatives.

Parameters

params

[ndarray] Model parameters

backcast

[float] Value to use for pre-sample observations

robust

[bool, optional] Flag indicating whether to use robust standard errors (True) or classic MLE (False)

Return type

ndarray

arch.univariate.ZeroMean.constraints

ZeroMean.**constraints**()

Construct linear constraint arrays for use in non-linear optimization

Returns

a

[ndarray] Number of constraints by number of parameters loading array

b

[ndarray] Number of constraints array of lower bounds

Notes

Parameters satisfy $a \cdot \text{parameters} - b \geq 0$

Return type

`tuple[ndarray, ndarray]`

arch.univariate.ZeroMean.fit

`ZeroMean.fit(update_freq=1, disp='final', starting_values=None, cov_type='robust', show_warning=True, first_obs=None, last_obs=None, tol=None, options=None, backcast=None)`

Estimate model parameters

Parameters

update_freq

`[int, optional]` Frequency of iteration updates. Output is generated every *update_freq* iterations. Set to 0 to disable iterative output.

disp

`[{bool, "off", "final"}]` Either 'final' to print optimization result or 'off' to display nothing. If using a boolean, False is "off" and True is "final"

starting_values

`[ndarray, optional]` Array of starting values to use. If not provided, starting values are constructed by the model components.

cov_type

`[str, optional]` Estimation method of parameter covariance. Supported options are 'robust', which does not assume the Information Matrix Equality holds and 'classic' which does. In the ARCH literature, 'robust' corresponds to Bollerslev-Wooldridge covariance estimator.

show_warning

`[bool, optional]` Flag indicating whether convergence warnings should be shown.

first_obs

`[{int, str, datetime, Timestamp}]` First observation to use when estimating model

last_obs

`[{int, str, datetime, Timestamp}]` Last observation to use when estimating model

tol

`[float, optional]` Tolerance for termination.

options

`[dict, optional]` Options to pass to *scipy.optimize.minimize*. Valid entries include 'ftol', 'eps', 'disp', and 'maxiter'.

backcast

`[{float, ndarray}, optional]` Value to use as backcast. Should be measure σ_0^2 since model-specific non-linear transformations are applied to value before computing the variance recursions.

Returns

results

`[ARCHModelResult]` Object containing model results

Notes

A `ConvergenceWarning` is raised if SciPy's optimizer indicates difficulty finding the optimum.

Parameters are optimized using SLSQP.

Return type

`ARCHModelResult`

`arch.univariate.ZeroMean.fix`

`ZeroMean.fix(params, first_obs=None, last_obs=None)`

Allows an `ARCHModelFixedResult` to be constructed from fixed parameters.

Parameters

`params`

`[{ndarray, Series}]` User specified parameters to use when generating the result. Must have the correct number of parameters for a given choice of mean model, volatility model and distribution.

`first_obs`

`[{int, str, datetime, Timestamp}]` First observation to use when fixing model

`last_obs`

`[{int, str, datetime, Timestamp}]` Last observation to use when fixing model

Returns

`results`

`[ARCHModelFixedResult]` Object containing model results

Notes

Parameters are not checked against model-specific constraints.

Return type

`ARCHModelFixedResult`

`arch.univariate.ZeroMean.forecast`

`ZeroMean.forecast(params, horizon=1, start=None, align='origin', method='analytic', simulations=1000, rng=None, random_state=None, *, reindex=None, x=None)`

Construct forecasts from estimated model

Parameters

`params`

`[{ndarray, Series}]` Parameters required to forecast. Must be identical in shape to the parameters computed by fitting the model.

`horizon`

`[int, optional]` Number of steps to forecast

`start`

`[{int, datetime, Timestamp, str}, optional]` An integer, datetime or str indicating the first observation to produce the forecast for. Datetimes can only be used with pandas

inputs that have a datetime index. Strings must be convertible to a date time, such as in '1945-01-01'.

align

[*str*, optional] Either 'origin' or 'target'. When set of 'origin', the t-th row of forecasts contains the forecasts for t+1, t+2, ..., t+h. When set to 'target', the t-th row contains the 1-step ahead forecast from time t-1, the 2 step from time t-2, ..., and the h-step from time t-h. 'target' simplified computing forecast errors since the realization and h-step forecast are aligned.

method

[{'analytic', 'simulation', 'bootstrap'}] Method to use when producing the forecast. The default is analytic. The method only affects the variance forecast generation. Not all volatility models support all methods. In particular, volatility models that do not evolve in squares such as EGARCH or TARCH do not support the 'analytic' method for horizons > 1.

simulations

[*int*] Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[*callable()*, optional] Custom random number generator to use in simulation-based forecasts. Must produce random samples using the syntax *rng(size)* where size the 2-element tuple (simulations, horizon).

random_state

[*RandomState*, optional] NumPy RandomState instance to use when method is 'bootstrap'

reindex

[*bool*, optional] Whether to reindex the forecasts to have the same dimension as the series being forecast. Prior to 4.18 this was the default. As of 4.19 this is now optional. If not provided, a warning is raised about the future change in the default which will occur after September 2021.

New in version 4.19.

x

[{*dict*[*label*, *numpy:array_like*], *numpy:array_like*}] Values to use for exogenous regressors if any are included in the model. Three formats are accepted:

- 2-d array-like: This format can be used when there is a single exogenous variable. The input must have shape (nforecast, horizon) or (nobs, horizon) where nforecast is the number of forecasting periods and nobs is the original shape of y. For example, if a single series of forecasts are made from the end of the sample with a horizon of 10, then the input can be (1, 10). Alternatively, if the original data had 1000 observations, then the input can be (1000, 10), and only the final row is used to produce forecasts.
- A dictionary of 2-d array-like: This format is identical to the previous except that the dictionary keys must match the names of the exog variables. Requires that the exog variables were passed as a pandas DataFrame.
- A 3-d NumPy array (or equivalent). In this format, each panel (0th axis) is a 2-d array that must have shape (nforecast, horizon) or (nobs,horizon). The array x[j] corresponds to the j-th column of the exogenous variables.

Due to the complexity required to accommodate all scenarios, please see the example notebook that demonstrates the valid formats for x.

New in version 4.19.

Returns

arch.univariate.base.ARCHModelForecast

Container for forecasts. Key properties are mean, variance and residual_variance.

Notes

The most basic 1-step ahead forecast will return a vector with the same length as the original data, where the t-th value will be the time-t forecast for time t + 1. When the horizon is > 1, and when using the default value for *align*, the forecast value in position [t, h] is the time-t, h+1 step ahead forecast.

If model contains exogenous variables (model.x is not None), then only 1-step ahead forecasts are available. Using horizon > 1 will produce a warning and all columns, except the first, will be nan-filled.

If *align* is 'origin', forecast[t,h] contains the forecast made using y[:t] (that is, up to but not including t) for horizon h + 1. For example, y[100,2] contains the 3-step ahead forecast using the first 100 data points, which will correspond to the realization y[100 + 2]. If *align* is 'target', then the same forecast is in location [102, 2], so that it is aligned with the observation to use when evaluating, but still in the same column.

Examples

```
>>> import pandas as pd
>>> from arch import arch_model
>>> am = arch_model(None, mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> sim_data = am.simulate([0.1, 0.4, 0.3, 0.2, 1.0], 250)
>>> sim_data.index = pd.date_range('2000-01-01', periods=250)
>>> am = arch_model(sim_data['data'], mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> res = am.fit()
>>> fig = res.hedgehog_plot()
```

Return type

ARCHModelForecast

arch.univariate.ZeroMean.parameter_names

ZeroMean.parameter_names()

List of parameters names

Returns

names

[list (str)] List of variable names for the mean model

Return type

list[str]

arch.univariate.ZeroMean.resids

`ZeroMean.resids`(*params*, *y=None*, *regressors=None*)

Compute model residuals

Parameters**params**

[`ndarray`] Model parameters

y

[`ndarray`, optional] Alternative values to use when computing model residuals

regressors

[`ndarray`, optional] Alternative regressor values to use when computing model residuals

Returns**resids**

[`ndarray`] Model residuals

Return type

Union[`ndarray`, `Series`]

arch.univariate.ZeroMean.simulate

`ZeroMean.simulate`(*params*, *nobs*, *burn=500*, *initial_value=None*, *x=None*, *initial_value_vol=None*)

Simulated data from a zero mean model

Parameters**params**

[`{ndarray, DataFrame}`] Parameters to use when simulating the model. Parameter order is [volatility distribution]. There are no mean parameters.

nobs

[`int`] Length of series to simulate

burn

[`int`, optional] Number of values to simulate to initialize the model and remove dependence on initial values.

initial_value

[`None`] This value is not used.

x

[`None`] This value is not used.

initial_value_vol

[`{ndarray, float}`, optional] An array or scalar to use when initializing the volatility process.

Returns**simulated_data**

[`DataFrame`] DataFrame with columns data containing the simulated values, volatility, containing the conditional volatility and errors containing the errors used in the simulation

Examples

Basic data simulation with no mean and constant volatility

```
>>> from arch.univariate import ZeroMean
>>> import numpy as np
>>> zm = ZeroMean()
>>> params = np.array([1.0])
>>> sim_data = zm.simulate(params, 1000)
```

Simulating data with a non-trivial volatility process

```
>>> from arch.univariate import GARCH
>>> zm.volatility = GARCH(p=1, o=1, q=1)
>>> sim_data = zm.simulate([0.05, 0.1, 0.1, 0.8], 300)
```

Return type

DataFrame

arch.univariate.ZeroMean.starting_values

ZeroMean.starting_values()

Returns starting values for the mean model, often the same as the values returned from fit

Returns

sv
[ndarray] Starting values

Return type

ndarray

Properties

| | |
|---------------------|---|
| <i>distribution</i> | Set or gets the error distribution |
| <i>name</i> | The name of the model. |
| <i>num_params</i> | Returns the number of parameters |
| <i>volatility</i> | Set or gets the volatility process |
| <i>x</i> | Gets the value of the exogenous regressors in the model |
| <i>y</i> | Returns the dependent variable |

arch.univariate.ZeroMean.distribution**property** ZeroMean.distribution: *Distribution*

Set or gets the error distribution

Distributions must be a subclass of Distribution

Return type*Distribution***arch.univariate.ZeroMean.name****property** ZeroMean.name: `str`

The name of the model.

Return type`str`**arch.univariate.ZeroMean.num_params****property** ZeroMean.num_params: `int`

Returns the number of parameters

arch.univariate.ZeroMean.volatility**property** ZeroMean.volatility: *VolatilityProcess*

Set or gets the volatility process

Volatility processes must be a subclass of VolatilityProcess

Return type*VolatilityProcess***arch.univariate.ZeroMean.x****property** ZeroMean.x: `Optional[Union[ndarray, DataFrame]]`

Gets the value of the exogenous regressors in the model

Return type`Union[ndarray, DataFrame, None]`**arch.univariate.ZeroMean.y****property** ZeroMean.y: `Optional[Union[ndarray, DataFrame, Series]]`

Returns the dependent variable

Return type`Union[ndarray, DataFrame, Series, None]`

1.8.2 arch.univariate.ConstantMean

```
class arch.univariate.ConstantMean(y=None, hold_back=None, volatility=None, distribution=None,
                                   rescale=None)
```

Constant mean model estimation and simulation.

Parameters

y

[[[ndarray](#), [Series](#)]] nobs element vector containing the dependent variable

hold_back

[[int](#)] Number of observations at the start of the sample to exclude when estimating model parameters. Used when comparing models with different lag lengths to estimate on the common sample.

volatility

[[VolatilityProcess](#), optional] Volatility process to use in the model

distribution

[[Distribution](#), optional] Error distribution to use in the model

rescale

[[bool](#), optional] Flag indicating whether to automatically rescale data if the scale of the data is likely to produce convergence issues when estimating model parameters. If False, the model is estimated on the data without transformation. If True, than y is rescaled and the new scale is reported in the estimation results.

Notes

The constant mean model is described by

$$y_t = \mu + \epsilon_t$$

Examples

```
>>> import numpy as np
>>> from arch.univariate import ConstantMean
>>> y = np.random.randn(100)
>>> cm = ConstantMean(y)
>>> res = cm.fit()
```

Attributes

distribution

Set or gets the error distribution

name

The name of the model.

num_params

Returns the number of parameters

volatility

Set or gets the volatility process

- x**
Gets the value of the exogenous regressors in the model
- y**
Returns the dependent variable

Methods

| | |
|---|--|
| <code>bounds()</code> | Construct bounds for parameters to use in non-linear optimization |
| <code>compute_param_cov(params[, backcast, robust])</code> | Computes parameter covariances using numerical derivatives. |
| <code>constraints()</code> | Construct linear constraint arrays for use in non-linear optimization |
| <code>fit([update_freq, disp, starting_values, ...])</code> | Estimate model parameters |
| <code>fix(params[, first_obs, last_obs])</code> | Allows an ARCHModelFixedResult to be constructed from fixed parameters. |
| <code>forecast(params[, horizon, start, align, ...])</code> | Construct forecasts from estimated model |
| <code>parameter_names()</code> | List of parameters names |
| <code>resids(params[, y, regressors])</code> | Compute model residuals |
| <code>simulate(params, nobs[, burn, ...])</code> | Simulated data from a constant mean model |
| <code>starting_values()</code> | Returns starting values for the mean model, often the same as the values returned from fit |

arch.univariate.ConstantMean.bounds

ConstantMean.**bounds**()

Construct bounds for parameters to use in non-linear optimization

Returns

bounds

[list (2-tuple of float)] Bounds for parameters to use in estimation.

Return type

list[tuple[float, float]]

arch.univariate.ConstantMean.compute_param_cov

ConstantMean.**compute_param_cov**(params, backcast=None, robust=True)

Computes parameter covariances using numerical derivatives.

Parameters

params

[ndarray] Model parameters

backcast

[float] Value to use for pre-sample observations

robust

[bool, optional] Flag indicating whether to use robust standard errors (True) or classic MLE (False)

Return type
`ndarray`

arch.univariate.ConstantMean.constraints

`ConstantMean.constraints()`

Construct linear constraint arrays for use in non-linear optimization

Returns

- a**
`[ndarray]` Number of constraints by number of parameters loading array
- b**
`[ndarray]` Number of constraints array of lower bounds

Notes

Parameters satisfy $a \cdot \text{parameters} - b \geq 0$

Return type
`tuple[ndarray, ndarray]`

arch.univariate.ConstantMean.fit

`ConstantMean.fit(update_freq=1, disp='final', starting_values=None, cov_type='robust', show_warning=True, first_obs=None, last_obs=None, tol=None, options=None, backcast=None)`

Estimate model parameters

Parameters

- update_freq**
`[int, optional]` Frequency of iteration updates. Output is generated every *update_freq* iterations. Set to 0 to disable iterative output.
- disp**
`[{bool, "off", "final"}]` Either 'final' to print optimization result or 'off' to display nothing. If using a boolean, False is "off" and True is "final"
- starting_values**
`[ndarray, optional]` Array of starting values to use. If not provided, starting values are constructed by the model components.
- cov_type**
`[str, optional]` Estimation method of parameter covariance. Supported options are 'robust', which does not assume the Information Matrix Equality holds and 'classic' which does. In the ARCH literature, 'robust' corresponds to Bollerslev-Wooldridge covariance estimator.
- show_warning**
`[bool, optional]` Flag indicating whether convergence warnings should be shown.
- first_obs**
`[{int, str, datetime, Timestamp}]` First observation to use when estimating model

last_obs

[{int, str, datetime, Timestamp}] Last observation to use when estimating model

tol

[float, optional] Tolerance for termination.

options

[dict, optional] Options to pass to *scipy.optimize.minimize*. Valid entries include ‘ftol’, ‘eps’, ‘disp’, and ‘maxiter’.

backcast

[{float, ndarray}, optional] Value to use as backcast. Should be measure σ_0^2 since model-specific non-linear transformations are applied to value before computing the variance recursions.

Returns**results**

[ARCHModelResult] Object containing model results

Notes

A ConvergenceWarning is raised if SciPy’s optimizer indicates difficulty finding the optimum.

Parameters are optimized using SLSQP.

Return type

ARCHModelResult

arch.univariate.ConstantMean.fix

ConstantMean.**fix**(*params*, *first_obs=None*, *last_obs=None*)

Allows an ARCHModelFixedResult to be constructed from fixed parameters.

Parameters**params**

[{ndarray, Series}] User specified parameters to use when generating the result. Must have the correct number of parameters for a given choice of mean model, volatility model and distribution.

first_obs

[{int, str, datetime, Timestamp}] First observation to use when fixing model

last_obs

[{int, str, datetime, Timestamp}] Last observation to use when fixing model

Returns**results**

[ARCHModelFixedResult] Object containing model results

Notes

Parameters are not checked against model-specific constraints.

Return type

ARCHModelFixedResult

arch.univariate.ConstantMean.forecast

ConstantMean.**forecast**(*params*, *horizon=1*, *start=None*, *align='origin'*, *method='analytic'*,
simulations=1000, *rng=None*, *random_state=None*, *, *reindex=None*, *x=None*)

Construct forecasts from estimated model

Parameters

params

[{*ndarray*, *Series*}] Parameters required to forecast. Must be identical in shape to the parameters computed by fitting the model.

horizon

[*int*, optional] Number of steps to forecast

start

[{*int*, *datetime*, *Timestamp*, *str*}, optional] An integer, datetime or str indicating the first observation to produce the forecast for. Datetimes can only be used with pandas inputs that have a datetime index. Strings must be convertible to a date time, such as in '1945-01-01'.

align

[*str*, optional] Either 'origin' or 'target'. When set of 'origin', the t-th row of forecasts contains the forecasts for t+1, t+2, ..., t+h. When set to 'target', the t-th row contains the 1-step ahead forecast from time t-1, the 2 step from time t-2, ..., and the h-step from time t-h. 'target' simplified computing forecast errors since the realization and h-step forecast are aligned.

method

[{ 'analytic', 'simulation', 'bootstrap' }] Method to use when producing the forecast. The default is analytic. The method only affects the variance forecast generation. Not all volatility models support all methods. In particular, volatility models that do not evolve in squares such as EGARCH or TARARCH do not support the 'analytic' method for horizons > 1.

simulations

[*int*] Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[*callable()*, optional] Custom random number generator to use in simulation-based forecasts. Must produce random samples using the syntax *rng(size)* where size the 2-element tuple (simulations, horizon).

random_state

[*RandomState*, optional] NumPy RandomState instance to use when method is 'bootstrap'

reindex

[*bool*, optional] Whether to reindex the forecasts to have the same dimension as the series being forecast. Prior to 4.18 this was the default. As of 4.19 this is now optional. If not

provided, a warning is raised about the future change in the default which will occur after September 2021.

New in version 4.19.

x

[{*dict*[label, numpy:array_like], numpy:array_like}] Values to use for exogenous regressors if any are included in the model. Three formats are accepted:

- 2-d array-like: This format can be used when there is a single exogenous variable. The input must have shape (nforecast, horizon) or (nobs, horizon) where nforecast is the number of forecasting periods and nobs is the original shape of y. For example, if a single series of forecasts are made from the end of the sample with a horizon of 10, then the input can be (1, 10). Alternatively, if the original data had 1000 observations, then the input can be (1000, 10), and only the final row is used to produce forecasts.
- A dictionary of 2-d array-like: This format is identical to the previous except that the dictionary keys must match the names of the exog variables. Requires that the exog variables were passed as a pandas DataFrame.
- A 3-d NumPy array (or equivalent). In this format, each panel (0th axis) is a 2-d array that must have shape (nforecast, horizon) or (nobs,horizon). The array x[j] corresponds to the j-th column of the exogenous variables.

Due to the complexity required to accommodate all scenarios, please see the example notebook that demonstrates the valid formats for x.

New in version 4.19.

Returns

arch.univariate.base.ARCHModelForecast

Container for forecasts. Key properties are mean, variance and residual_variance.

Notes

The most basic 1-step ahead forecast will return a vector with the same length as the original data, where the t-th value will be the time-t forecast for time t + 1. When the horizon is > 1, and when using the default value for *align*, the forecast value in position [t, h] is the time-t, h+1 step ahead forecast.

If model contains exogenous variables (model.x is not None), then only 1-step ahead forecasts are available. Using horizon > 1 will produce a warning and all columns, except the first, will be nan-filled.

If *align* is 'origin', forecast[t,h] contains the forecast made using y[:t] (that is, up to but not including t) for horizon h + 1. For example, y[100,2] contains the 3-step ahead forecast using the first 100 data points, which will correspond to the realization y[100 + 2]. If *align* is 'target', then the same forecast is in location [102, 2], so that it is aligned with the observation to use when evaluating, but still in the same column.

Examples

```
>>> import pandas as pd
>>> from arch import arch_model
>>> am = arch_model(None, mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> sim_data = am.simulate([0.1, 0.4, 0.3, 0.2, 1.0], 250)
>>> sim_data.index = pd.date_range('2000-01-01', periods=250)
>>> am = arch_model(sim_data['data'], mean='HAR', lags=[1, 5, 22], vol='Constant')
```

(continues on next page)

(continued from previous page)

```
>>> res = am.fit()
>>> fig = res.hedgehog_plot()
```

Return type*ARCHModelForecast***arch.univariate.ConstantMean.parameter_names**ConstantMean.**parameter_names**()

List of parameters names

Returns**names***[list (str)]* List of variable names for the mean model**Return type***list[str]***arch.univariate.ConstantMean.resids**ConstantMean.**resids**(*params, y=None, regressors=None*)

Compute model residuals

Parameters**params***[ndarray]* Model parameters**y***[ndarray, optional]* Alternative values to use when computing model residuals**regressors***[ndarray, optional]* Alternative regressor values to use when computing model residuals**Returns****resids***[ndarray]* Model residuals**Return type***Union[ndarray, Series]***arch.univariate.ConstantMean.simulate**ConstantMean.**simulate**(*params, nobs, burn=500, initial_value=None, x=None, initial_value_vol=None*)

Simulated data from a constant mean model

Parameters**params***[numpy:array_like]* Parameters to use when simulating the model. Parameter order is *[mean volatility distribution]*. There is one parameter in the mean model, *mu*.

nobs

[int] Length of series to simulate

burn

[int, optional] Number of values to simulate to initialize the model and remove dependence on initial values.

initial_value

[None] This value is not used.

x

[None] This value is not used.

initial_value_vol

[{ndarray, float}, optional] An array or scalar to use when initializing the volatility process.

Returns**simulated_data**

[DataFrame] DataFrame with columns data containing the simulated values, volatility, containing the conditional volatility and errors containing the errors used in the simulation

Examples

Basic data simulation with a constant mean and volatility

```
>>> import numpy as np
>>> from arch.univariate import ConstantMean, GARCH
>>> cm = ConstantMean()
>>> cm.volatility = GARCH()
>>> cm_params = np.array([1])
>>> garch_params = np.array([0.01, 0.07, 0.92])
>>> params = np.concatenate((cm_params, garch_params))
>>> sim_data = cm.simulate(params, 1000)
```

Return type

DataFrame

arch.univariate.ConstantMean.starting_values

ConstantMean.starting_values()

Returns starting values for the mean model, often the same as the values returned from fit

Returns**sv**

[ndarray] Starting values

Return type

ndarray

Properties

| | |
|---------------------|---|
| <i>distribution</i> | Set or gets the error distribution |
| <i>name</i> | The name of the model. |
| <i>num_params</i> | Returns the number of parameters |
| <i>volatility</i> | Set or gets the volatility process |
| <i>x</i> | Gets the value of the exogenous regressors in the model |
| <i>y</i> | Returns the dependent variable |

arch.univariate.ConstantMean.distribution

property ConstantMean.distribution: *Distribution*

Set or gets the error distribution

Distributions must be a subclass of Distribution

Return type

Distribution

arch.univariate.ConstantMean.name

property ConstantMean.name: `str`

The name of the model.

Return type

`str`

arch.univariate.ConstantMean.num_params

property ConstantMean.num_params: `int`

Returns the number of parameters

arch.univariate.ConstantMean.volatility

property ConstantMean.volatility: *VolatilityProcess*

Set or gets the volatility process

Volatility processes must be a subclass of VolatilityProcess

Return type

VolatilityProcess

arch.univariate.ConstantMean.x**property** ConstantMean.x: `Optional[Union[ndarray, DataFrame]]`

Gets the value of the exogenous regressors in the model

Return type`Union[ndarray, DataFrame, None]`**arch.univariate.ConstantMean.y****property** ConstantMean.y: `Optional[Union[ndarray, DataFrame, Series]]`

Returns the dependent variable

Return type`Union[ndarray, DataFrame, Series, None]`**1.8.3 arch.univariate.ARX****class** arch.univariate.ARX(*y=None, x=None, lags=None, constant=True, hold_back=None, volatility=None, distribution=None, rescale=None*)

Autoregressive model with optional exogenous regressors estimation and simulation

Parameters**y**`[{ndarray, Series}]` nobs element vector containing the dependent variable**x**`[{ndarray, DataFrame}, optional]` nobs by k element array containing exogenous regressors**lags**`[scalar, 1-d array, optional]` Description of lag structure of the HAR. Scalar included all lags between 1 and the value. A 1-d array includes the AR lags `lags[0]`, `lags[1]`, ...**constant**`[bool, optional]` Flag whether the model should include a constant**hold_back**`[int]` Number of observations at the start of the sample to exclude when estimating model parameters. Used when comparing models with different lag lengths to estimate on the common sample.**volatility**`[VolatilityProcess, optional]` Volatility process to use in the model**distribution**`[Distribution, optional]` Error distribution to use in the model**rescale**`[bool, optional]` Flag indicating whether to automatically rescale data if the scale of the data is likely to produce convergence issues when estimating model parameters. If False, the model is estimated on the data without transformation. If True, than y is rescaled and the new scale is reported in the estimation results.

Notes

The AR-X model is described by

$$y_t = \mu + \sum_{i=1}^p \phi_{L_i} y_{t-L_i} + \gamma' x_t + \epsilon_t$$

Examples

```
>>> import numpy as np
>>> from arch.univariate import ARX
>>> y = np.random.randn(100)
>>> arx = ARX(y, lags=[1, 5, 22])
>>> res = arx.fit()
```

Estimating an AR with GARCH(1,1) errors

```
>>> from arch.univariate import GARCH
>>> arx.volatility = GARCH()
>>> res = arx.fit(update_freq=0, disp='off')
```

Attributes

distribution

Set or gets the error distribution

name

The name of the model.

num_params

Returns the number of parameters

volatility

Set or gets the volatility process

x

Gets the value of the exogenous regressors in the model

y

Returns the dependent variable

Methods

| | |

arch.univariate.ARX.bounds

ARX.bounds()

Construct bounds for parameters to use in non-linear optimization

Returns

bounds

[list (2-tuple of float)] Bounds for parameters to use in estimation.

Return type

list[tuple[float, float]]

arch.univariate.ARX.compute_param_cov

ARX.compute_param_cov(params, backcast=None, robust=True)

Computes parameter covariances using numerical derivatives.

Parameters

params

[ndarray] Model parameters

backcast

[float] Value to use for pre-sample observations

robust

[bool, optional] Flag indicating whether to use robust standard errors (True) or classic MLE (False)

Return type

ndarray

arch.univariate.ARX.constraints

ARX.constraints()

Construct linear constraint arrays for use in non-linear optimization

Returns

- a**
[ndarray] Number of constraints by number of parameters loading array
- b**
[ndarray] Number of constraints array of lower bounds

Notes

Parameters satisfy $a \cdot \text{parameters} - b \geq 0$

Return type

tuple[ndarray, ndarray]

arch.univariate.ARX.fit

ARX. **fit**(*update_freq=1, disp='final', starting_values=None, cov_type='robust', show_warning=True, first_obs=None, last_obs=None, tol=None, options=None, backcast=None*)

Estimate model parameters

Parameters

update_freq

[int, optional] Frequency of iteration updates. Output is generated every *update_freq* iterations. Set to 0 to disable iterative output.

disp

[{bool, "off", "final"}] Either 'final' to print optimization result or 'off' to display nothing. If using a boolean, False is "off" and True is "final"

starting_values

[ndarray, optional] Array of starting values to use. If not provided, starting values are constructed by the model components.

cov_type

[str, optional] Estimation method of parameter covariance. Supported options are 'robust', which does not assume the Information Matrix Equality holds and 'classic' which does. In the ARCH literature, 'robust' corresponds to Bollerslev-Wooldridge covariance estimator.

show_warning

[bool, optional] Flag indicating whether convergence warnings should be shown.

first_obs

[{int, str, datetime, Timestamp}] First observation to use when estimating model

last_obs

[{int, str, datetime, Timestamp}] Last observation to use when estimating model

tol

[float, optional] Tolerance for termination.

options

[`dict`, `optional`] Options to pass to `scipy.optimize.minimize`. Valid entries include ‘ftol’, ‘eps’, ‘disp’, and ‘maxiter’.

backcast

[`{float, ndarray}`, `optional`] Value to use as backcast. Should be measure σ_0^2 since model-specific non-linear transformations are applied to value before computing the variance recursions.

Returns**results**

[`ARCHModelResult`] Object containing model results

Notes

A `ConvergenceWarning` is raised if SciPy’s optimizer indicates difficulty finding the optimum.

Parameters are optimized using SLSQP.

Return type

`ARCHModelResult`

arch.univariate.ARX.fix

`ARX.fix(params, first_obs=None, last_obs=None)`

Allows an `ARCHModelFixedResult` to be constructed from fixed parameters.

Parameters**params**

[`{ndarray, Series}`] User specified parameters to use when generating the result. Must have the correct number of parameters for a given choice of mean model, volatility model and distribution.

first_obs

[`{int, str, datetime, Timestamp}`] First observation to use when fixing model

last_obs

[`{int, str, datetime, Timestamp}`] Last observation to use when fixing model

Returns**results**

[`ARCHModelFixedResult`] Object containing model results

Notes

Parameters are not checked against model-specific constraints.

Return type

`ARCHModelFixedResult`

arch.univariate.ARX.forecast

ARX.forecast(*params*, *horizon=1*, *start=None*, *align='origin'*, *method='analytic'*, *simulations=1000*, *rng=None*, *random_state=None*, *, *reindex=None*, *x=None*)

Construct forecasts from estimated model

Parameters

params

[{`ndarray`, `Series`}] Parameters required to forecast. Must be identical in shape to the parameters computed by fitting the model.

horizon

[`int`, optional] Number of steps to forecast

start

[{`int`, `datetime`, `Timestamp`, `str`}, optional] An integer, datetime or str indicating the first observation to produce the forecast for. Datetimes can only be used with pandas inputs that have a datetime index. Strings must be convertible to a date time, such as in '1945-01-01'.

align

[`str`, optional] Either 'origin' or 'target'. When set of 'origin', the t-th row of forecasts contains the forecasts for t+1, t+2, ..., t+h. When set to 'target', the t-th row contains the 1-step ahead forecast from time t-1, the 2 step from time t-2, ..., and the h-step from time t-h. 'target' simplified computing forecast errors since the realization and h-step forecast are aligned.

method

[{'analytic', 'simulation', 'bootstrap'}] Method to use when producing the forecast. The default is analytic. The method only affects the variance forecast generation. Not all volatility models support all methods. In particular, volatility models that do not evolve in squares such as EGARCH or TARCH do not support the 'analytic' method for horizons > 1.

simulations

[`int`] Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[`callable()`, optional] Custom random number generator to use in simulation-based forecasts. Must produce random samples using the syntax `rng(size)` where `size` the 2-element tuple (simulations, horizon).

random_state

[`RandomState`, optional] NumPy `RandomState` instance to use when method is 'bootstrap'

reindex

[`bool`, optional] Whether to reindex the forecasts to have the same dimension as the series being forecast. Prior to 4.18 this was the default. As of 4.19 this is now optional. If not provided, a warning is raised about the future change in the default which will occur after September 2021.

New in version 4.19.

x

[{`dict`[`label`, `numpy:array_like`], `numpy:array_like`}] Values to use for exogenous regressors if any are included in the model. Three formats are accepted:

- 2-d array-like: This format can be used when there is a single exogenous variable. The input must have shape (nforecast, horizon) or (nobs, horizon) where nforecast is the number of forecasting periods and nobs is the original shape of y. For example, if a single series of forecasts are made from the end of the sample with a horizon of 10, then the input can be (1, 10). Alternatively, if the original data had 1000 observations, then the input can be (1000, 10), and only the final row is used to produce forecasts.
- A dictionary of 2-d array-like: This format is identical to the previous except that the dictionary keys must match the names of the exog variables. Requires that the exog variables were passed as a pandas DataFrame.
- A 3-d NumPy array (or equivalent). In this format, each panel (0th axis) is a 2-d array that must have shape (nforecast, horizon) or (nobs,horizon). The array x[j] corresponds to the j-th column of the exogenous variables.

Due to the complexity required to accommodate all scenarios, please see the example notebook that demonstrates the valid formats for x.

New in version 4.19.

Returns

arch.univariate.base.ARCHModelForecast

Container for forecasts. Key properties are mean, variance and residual_variance.

Notes

The most basic 1-step ahead forecast will return a vector with the same length as the original data, where the t-th value will be the time-t forecast for time t + 1. When the horizon is > 1, and when using the default value for *align*, the forecast value in position [t, h] is the time-t, h+1 step ahead forecast.

If model contains exogenous variables (model.x is not None), then only 1-step ahead forecasts are available. Using horizon > 1 will produce a warning and all columns, except the first, will be nan-filled.

If *align* is 'origin', forecast[t,h] contains the forecast made using y[:t] (that is, up to but not including t) for horizon h + 1. For example, y[100,2] contains the 3-step ahead forecast using the first 100 data points, which will correspond to the realization y[100 + 2]. If *align* is 'target', then the same forecast is in location [102, 2], so that it is aligned with the observation to use when evaluating, but still in the same column.

Examples

```
>>> import pandas as pd
>>> from arch import arch_model
>>> am = arch_model(None, mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> sim_data = am.simulate([0.1, 0.4, 0.3, 0.2, 1.0], 250)
>>> sim_data.index = pd.date_range('2000-01-01', periods=250)
>>> am = arch_model(sim_data['data'], mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> res = am.fit()
>>> fig = res.hedgehog_plot()
```

Return type

ARCHModelForecast

arch.univariate.ARX.parameter_names

ARX.parameter_names()

List of parameters names

Returns

names
[list (str)] List of variable names for the mean model

Return type

list[str]

arch.univariate.ARX.resids

ARX.resids(params, y=None, regressors=None)

Compute model residuals

Parameters

params
[ndarray] Model parameters

y
[ndarray, optional] Alternative values to use when computing model residuals

regressors
[ndarray, optional] Alternative regressor values to use when computing model residuals

Returns

resids
[ndarray] Model residuals

Return type

Union[ndarray, Series]

arch.univariate.ARX.simulate

ARX.simulate(params, nobs, burn=500, initial_value=None, x=None, initial_value_vol=None)

Simulates data from a linear regression, AR or HAR models

Parameters

params
[numpy:array_like] Parameters to use when simulating the model. Parameter order is [mean volatility distribution] where the parameters of the mean model are ordered [constant lag[0] lag[1] ... lag[p] ex[0] ... ex[k-1]] where lag[j] indicates the coefficient on the jth lag in the model and ex[j] is the coefficient on the jth exogenous variable.

nobs
[int] Length of series to simulate

burn
[int, optional] Number of values to simulate to initialize the model and remove dependence on initial values.

initial_value

[{`ndarray`, `float`}, optional] Either a scalar value or *max(lags)* array set of initial values to use when initializing the model. If omitted, 0.0 is used.

x

[{`ndarray`, `DataFrame`}, optional] nobs + burn by k array of exogenous variables to include in the simulation.

initial_value_vol

[{`ndarray`, `float`}, optional] An array or scalar to use when initializing the volatility process.

Returns**simulated_data**

[`DataFrame`] `DataFrame` with columns data containing the simulated values, volatility, containing the conditional volatility and errors containing the errors used in the simulation

Examples

```
>>> import numpy as np
>>> from arch.univariate import HARX, GARCH
>>> harx = HARX(lags=[1, 5, 22])
>>> harx.volatility = GARCH()
>>> harx_params = np.array([1, 0.2, 0.3, 0.4])
>>> garch_params = np.array([0.01, 0.07, 0.92])
>>> params = np.concatenate((harx_params, garch_params))
>>> sim_data = harx.simulate(params, 1000)
```

Simulating models with exogenous regressors requires the regressors to have nobs plus burn data points

```
>>> nobs = 100
>>> burn = 200
>>> x = np.random.randn(nobs + burn, 2)
>>> x_params = np.array([1.0, 2.0])
>>> params = np.concatenate((harx_params, x_params, garch_params))
>>> sim_data = harx.simulate(params, nobs=nobs, burn=burn, x=x)
```

Return type

`DataFrame`

arch.univariate.ARX.starting_values**ARX.starting_values()**

Returns starting values for the mean model, often the same as the values returned from fit

Returns**sv**

[`ndarray`] Starting values

Return type

`ndarray`

Properties

arch.univariate.ARX.volatility

property ARX.volatility: *VolatilityProcess*

Set or gets the volatility process

Volatility processes must be a subclass of VolatilityProcess

Return type

VolatilityProcess

arch.univariate.ARX.x**property** ARX.x: `Optional[Union[ndarray, DataFrame]]`

Gets the value of the exogenous regressors in the model

Return type`Union[ndarray, DataFrame, None]`**arch.univariate.ARX.y****property** ARX.y: `Optional[Union[ndarray, DataFrame, Series]]`

Returns the dependent variable

Return type`Union[ndarray, DataFrame, Series, None]`**1.8.4 arch.univariate.HARX****class** arch.univariate.HARX(*y=None, x=None, lags=None, constant=True, use_rotated=False, hold_back=None, volatility=None, distribution=None, rescale=None*)

Heterogeneous Autoregression (HAR), with optional exogenous regressors, model estimation and simulation

Parameters**y**`[[ndarray, Series]]` nobs element vector containing the dependent variable**x**`[[ndarray, DataFrame], optional]` nobs by k element array containing exogenous regressors**lags**`[[scalar, ndarray], optional]` Description of lag structure of the HAR.

- Scalar included all lags between 1 and the value.
- A 1-d n-element array includes the HAR lags `1:lags[0]+1, 1:lags[1]+1, ... 1:lags[n]+1`.
- A 2-d (2,n)-element array that includes the HAR lags of the form `lags[0,j]:lags[1,j]+1` for all columns of lags.

constant`[bool, optional]` Flag whether the model should include a constant**use_rotated**`[bool, optional]` Flag indicating to use the alternative rotated form of the HAR where HAR lags do not overlap**hold_back**`[int]` Number of observations at the start of the sample to exclude when estimating model parameters. Used when comparing models with different lag lengths to estimate on the common sample.**volatility**`[VolatilityProcess, optional]` Volatility process to use in the model**distribution**`[Distribution, optional]` Error distribution to use in the model

rescale

[bool, optional] Flag indicating whether to automatically rescale data if the scale of the data is likely to produce convergence issues when estimating model parameters. If False, the model is estimated on the data without transformation. If True, than y is rescaled and the new scale is reported in the estimation results.

Notes

The HAR-X model is described by

$$y_t = \mu + \sum_{i=1}^p \phi_{L_i} \bar{y}_{t-L_{i,0}:L_{i,1}} + \gamma' x_t + \epsilon_t$$

where $\bar{y}_{t-L_{i,0}:L_{i,1}}$ is the average value of y_t between $t - L_{i,0}$ and $t - L_{i,1}$.

Examples

Standard HAR with average lags 1, 5 and 22

```
>>> import numpy as np
>>> from arch.univariate import HARX
>>> y = np.random.RandomState(1234).randn(100)
>>> harx = HARX(y, lags=[1, 5, 22])
>>> res = harx.fit()
```

A standard HAR with average lags 1 and 6 but holding back 10 observations

```
>>> from pandas import Series, date_range
>>> index = date_range('2000-01-01', freq='M', periods=y.shape[0])
>>> y = Series(y, name='y', index=index)
>>> har = HARX(y, lags=[1, 6], hold_back=10)
```

Models with equivalent parametrizations of lags. The first uses overlapping lags.

```
>>> harx_1 = HARX(y, lags=[1, 5, 22])
```

The next uses rotated lags so that they do not overlap.

```
>>> harx_2 = HARX(y, lags=[1, 5, 22], use_rotated=True)
```

The third manually specified overlapping lags.

```
>>> harx_3 = HARX(y, lags=[[1, 1, 1], [1, 5, 22]])
```

The final manually specified non-overlapping lags

```
>>> harx_4 = HARX(y, lags=[[1, 2, 6], [1, 5, 22]])
```

It is simple to verify that these are the equivalent by inspecting the R2.

```
>>> models = [harx_1, harx_2, harx_3, harx_4]
>>> print([mod.fit().rsquared for mod in models])
0.085, 0.085, 0.085, 0.085
```

Attributes*distribution*

Set or gets the error distribution

name

The name of the model.

num_params

Returns the number of parameters

volatility

Set or gets the volatility process

x

Gets the value of the exogenous regressors in the model

y

Returns the dependent variable

Methods

| | |
|--|--|
| <i>bounds()</i> | Construct bounds for parameters to use in non-linear optimization |
| <i>compute_param_cov</i> (params[, backcast, robust]) | Computes parameter covariances using numerical derivatives. |
| <i>constraints()</i> | Construct linear constraint arrays for use in non-linear optimization |
| <i>fit</i> ([update_freq, disp, starting_values, ...]) | Estimate model parameters |
| <i>fix</i> (params[, first_obs, last_obs]) | Allows an ARCHModelFixedResult to be constructed from fixed parameters. |
| <i>forecast</i> (params[, horizon, start, align, ...]) | Construct forecasts from estimated model |
| <i>parameter_names()</i> | List of parameters names |
| <i>resids</i> (params[, y, regressors]) | Compute model residuals |
| <i>simulate</i> (params, nobs[, burn, ...]) | Simulates data from a linear regression, AR or HAR models |
| <i>starting_values()</i> | Returns starting values for the mean model, often the same as the values returned from fit |

arch.univariate.HARX.bounds**HARX.bounds()**

Construct bounds for parameters to use in non-linear optimization

Returns**bounds**

[list (2-tuple of float)] Bounds for parameters to use in estimation.

Return type

list[tuple[float, float]]

arch.univariate.HARX.compute_param_cov

HARX.**compute_param_cov**(*params*, *backcast=None*, *robust=True*)

Computes parameter covariances using numerical derivatives.

Parameters

params

[*ndarray*] Model parameters

backcast

[*float*] Value to use for pre-sample observations

robust

[*bool*, optional] Flag indicating whether to use robust standard errors (True) or classic MLE (False)

Return type

ndarray

arch.univariate.HARX.constraints

HARX.**constraints**()

Construct linear constraint arrays for use in non-linear optimization

Returns

a

[*ndarray*] Number of constraints by number of parameters loading array

b

[*ndarray*] Number of constraints array of lower bounds

Notes

Parameters satisfy $a \cdot \text{parameters} - b \geq 0$

Return type

tuple[*ndarray*, *ndarray*]

arch.univariate.HARX.fit

HARX.**fit**(*update_freq=1*, *disp='final'*, *starting_values=None*, *cov_type='robust'*, *show_warning=True*, *first_obs=None*, *last_obs=None*, *tol=None*, *options=None*, *backcast=None*)

Estimate model parameters

Parameters

update_freq

[*int*, optional] Frequency of iteration updates. Output is generated every *update_freq* iterations. Set to 0 to disable iterative output.

disp

[{*bool*, "off", "final"}] Either 'final' to print optimization result or 'off' to display nothing. If using a boolean, False is "off" and True is "final"

starting_values

[`ndarray`, optional] Array of starting values to use. If not provided, starting values are constructed by the model components.

cov_type

[`str`, optional] Estimation method of parameter covariance. Supported options are ‘robust’, which does not assume the Information Matrix Equality holds and ‘classic’ which does. In the ARCH literature, ‘robust’ corresponds to Bollerslev-Wooldridge covariance estimator.

show_warning

[`bool`, optional] Flag indicating whether convergence warnings should be shown.

first_obs

[`{int, str, datetime, Timestamp}`] First observation to use when estimating model

last_obs

[`{int, str, datetime, Timestamp}`] Last observation to use when estimating model

tol

[`float`, optional] Tolerance for termination.

options

[`dict`, optional] Options to pass to `scipy.optimize.minimize`. Valid entries include ‘ftol’, ‘eps’, ‘disp’, and ‘maxiter’.

backcast

[`{float, ndarray}`, optional] Value to use as backcast. Should be measure σ_0^2 since model-specific non-linear transformations are applied to value before computing the variance recursions.

Returns**results**

[`ARCHModelResult`] Object containing model results

Notes

A `ConvergenceWarning` is raised if SciPy’s optimizer indicates difficulty finding the optimum.

Parameters are optimized using SLSQP.

Return type

`ARCHModelResult`

arch.univariate.HARX.fix

`HARX.fix(params, first_obs=None, last_obs=None)`

Allows an `ARCHModelFixedResult` to be constructed from fixed parameters.

Parameters**params**

[`{ndarray, Series}`] User specified parameters to use when generating the result. Must have the correct number of parameters for a given choice of mean model, volatility model and distribution.

first_obs

[`{int, str, datetime, Timestamp}`] First observation to use when fixing model

last_obs

[{int, str, datetime, Timestamp}] Last observation to use when fixing model

Returns**results**

[ARCHModelFixedResult] Object containing model results

Notes

Parameters are not checked against model-specific constraints.

Return type

ARCHModelFixedResult

arch.univariate.HARX.forecast

HARX.forecast(*params*, *horizon=1*, *start=None*, *align='origin'*, *method='analytic'*, *simulations=1000*, *rng=None*, *random_state=None*, *, *reindex=None*, *x=None*)

Construct forecasts from estimated model

Parameters**params**

[{ndarray, Series}] Parameters required to forecast. Must be identical in shape to the parameters computed by fitting the model.

horizon

[int, optional] Number of steps to forecast

start

[{int, datetime, Timestamp, str}, optional] An integer, datetime or str indicating the first observation to produce the forecast for. Datetimes can only be used with pandas inputs that have a datetime index. Strings must be convertible to a date time, such as in '1945-01-01'.

align

[str, optional] Either 'origin' or 'target'. When set of 'origin', the t-th row of forecasts contains the forecasts for t+1, t+2, ..., t+h. When set to 'target', the t-th row contains the 1-step ahead forecast from time t-1, the 2 step from time t-2, ..., and the h-step from time t-h. 'target' simplified computing forecast errors since the realization and h-step forecast are aligned.

method

[{'analytic', 'simulation', 'bootstrap'}] Method to use when producing the forecast. The default is analytic. The method only affects the variance forecast generation. Not all volatility models support all methods. In particular, volatility models that do not evolve in squares such as EGARCH or TARARCH do not support the 'analytic' method for horizons > 1.

simulations

[int] Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[callable(), optional] Custom random number generator to use in simulation-based forecasts. Must produce random samples using the syntax *rng(size)* where size the 2-element tuple (simulations, horizon).

random_state

[`RandomState`, optional] NumPy `RandomState` instance to use when method is ‘bootstrap’

reindex

[`bool`, optional] Whether to reindex the forecasts to have the same dimension as the series being forecast. Prior to 4.18 this was the default. As of 4.19 this is now optional. If not provided, a warning is raised about the future change in the default which will occur after September 2021.

New in version 4.19.

x

[{`dict`[`label`, `numpy:array_like`], `numpy:array_like`}] Values to use for exogenous regressors if any are included in the model. Three formats are accepted:

- 2-d array-like: This format can be used when there is a single exogenous variable. The input must have shape (nforecast, horizon) or (nobs, horizon) where nforecast is the number of forecasting periods and nobs is the original shape of y. For example, if a single series of forecasts are made from the end of the sample with a horizon of 10, then the input can be (1, 10). Alternatively, if the original data had 1000 observations, then the input can be (1000, 10), and only the final row is used to produce forecasts.
- A dictionary of 2-d array-like: This format is identical to the previous except that the dictionary keys must match the names of the exog variables. Requires that the exog variables were passed as a pandas DataFrame.
- A 3-d NumPy array (or equivalent). In this format, each panel (0th axis) is a 2-d array that must have shape (nforecast, horizon) or (nobs,horizon). The array `x[j]` corresponds to the j-th column of the exogenous variables.

Due to the complexity required to accommodate all scenarios, please see the example notebook that demonstrates the valid formats for x.

New in version 4.19.

Returns***arch.univariate.base.ARCHModelForecast***

Container for forecasts. Key properties are `mean`, `variance` and `residual_variance`.

Notes

The most basic 1-step ahead forecast will return a vector with the same length as the original data, where the t-th value will be the time-t forecast for time t + 1. When the horizon is > 1, and when using the default value for `align`, the forecast value in position [t, h] is the time-t, h+1 step ahead forecast.

If model contains exogenous variables (model.x is not None), then only 1-step ahead forecasts are available. Using horizon > 1 will produce a warning and all columns, except the first, will be nan-filled.

If `align` is ‘origin’, `forecast[t,h]` contains the forecast made using `y[:t]` (that is, up to but not including t) for horizon h + 1. For example, `y[100,2]` contains the 3-step ahead forecast using the first 100 data points, which will correspond to the realization `y[100 + 2]`. If `align` is ‘target’, then the same forecast is in location [102, 2], so that it is aligned with the observation to use when evaluating, but still in the same column.

Examples

```
>>> import pandas as pd
>>> from arch import arch_model
>>> am = arch_model(None, mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> sim_data = am.simulate([0.1, 0.4, 0.3, 0.2, 1.0], 250)
>>> sim_data.index = pd.date_range('2000-01-01', periods=250)
>>> am = arch_model(sim_data['data'], mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> res = am.fit()
>>> fig = res.hedgehog_plot()
```

Return type

ARCHModelForecast

arch.univariate.HARX.parameter_names

HARX.parameter_names()

List of parameters names

Returns

names

[list(str)] List of variable names for the mean model

Return type

list[str]

arch.univariate.HARX.resids

HARX.resids(params, y=None, regressors=None)

Compute model residuals

Parameters

params

[ndarray] Model parameters

y

[ndarray, optional] Alternative values to use when computing model residuals

regressors

[ndarray, optional] Alternative regressor values to use when computing model residuals

Returns

resids

[ndarray] Model residuals

Return type

Union[ndarray, Series]

arch.univariate.HARX.simulate

HARX.simulate(*params*, *nobs*, *burn=500*, *initial_value=None*, *x=None*, *initial_value_vol=None*)

Simulates data from a linear regression, AR or HAR models

Parameters

params

[numpy:array_like] Parameters to use when simulating the model. Parameter order is [mean volatility distribution] where the parameters of the mean model are ordered [constant lag[0] lag[1] ... lag[p] ex[0] ... ex[k-1]] where lag[j] indicates the coefficient on the jth lag in the model and ex[j] is the coefficient on the jth exogenous variable.

nobs

[int] Length of series to simulate

burn

[int, optional] Number of values to simulate to initialize the model and remove dependence on initial values.

initial_value

[{ndarray, float}, optional] Either a scalar value or *max(lags)* array set of initial values to use when initializing the model. If omitted, 0.0 is used.

x

[{ndarray, DataFrame}, optional] nobs + burn by k array of exogenous variables to include in the simulation.

initial_value_vol

[{ndarray, float}, optional] An array or scalar to use when initializing the volatility process.

Returns

simulated_data

[DataFrame] DataFrame with columns data containing the simulated values, volatility, containing the conditional volatility and errors containing the errors used in the simulation

Examples

```

>>> import numpy as np
>>> from arch.univariate import HARX, GARCH
>>> harx = HARX(lags=[1, 5, 22])
>>> harx.volatility = GARCH()
>>> harx_params = np.array([1, 0.2, 0.3, 0.4])
>>> garch_params = np.array([0.01, 0.07, 0.92])
>>> params = np.concatenate((harx_params, garch_params))
>>> sim_data = harx.simulate(params, 1000)

```

Simulating models with exogenous regressors requires the regressors to have nobs plus burn data points

```

>>> nobs = 100
>>> burn = 200
>>> x = np.random.randn(nobs + burn, 2)
>>> x_params = np.array([1.0, 2.0])
>>> params = np.concatenate((harx_params, x_params, garch_params))
>>> sim_data = harx.simulate(params, nobs=nobs, burn=burn, x=x)

```

Return type
 DataFrame

arch.univariate.HARX.starting_values

HARX.starting_values()

Returns starting values for the mean model, often the same as the values returned from fit

Returns

sv
 [ndarray] Starting values

Return type
 ndarray

Properties

| | |
|---------------------|---|
| <i>distribution</i> | Set or gets the error distribution |
| <i>name</i> | The name of the model. |
| <i>num_params</i> | Returns the number of parameters |
| <i>volatility</i> | Set or gets the volatility process |
| <i>x</i> | Gets the value of the exogenous regressors in the model |
| <i>y</i> | Returns the dependent variable |

arch.univariate.HARX.distribution

property HARX.distribution: *Distribution*

Set or gets the error distribution

Distributions must be a subclass of Distribution

Return type
Distribution

arch.univariate.HARX.name

property HARX.name: **str**

The name of the model.

Return type
 str

arch.univariate.HARX.num_params**property** HARX.num_params: `int`

Returns the number of parameters

arch.univariate.HARX.volatility**property** HARX.volatility: *VolatilityProcess*

Set or gets the volatility process

Volatility processes must be a subclass of VolatilityProcess

Return type*VolatilityProcess***arch.univariate.HARX.x****property** HARX.x: `Optional[Union[ndarray, DataFrame]]`

Gets the value of the exogenous regressors in the model

Return type`Union[ndarray, DataFrame, None]`**arch.univariate.HARX.y****property** HARX.y: `Optional[Union[ndarray, DataFrame, Series]]`

Returns the dependent variable

Return type`Union[ndarray, DataFrame, Series, None]`

1.8.5 arch.univariate.LS

class arch.univariate.LS(*y=None, x=None, constant=True, hold_back=None, volatility=None, distribution=None, rescale=None*)

Least squares model estimation and simulation

Parameters**y**`[{ndarray, Series}]` nobs element vector containing the dependent variable**x**`[{ndarray, DataFrame}, optional]` nobs by k element array containing exogenous regressors**constant**`[bool, optional]` Flag whether the model should include a constant**hold_back**`[int]` Number of observations at the start of the sample to exclude when estimating model parameters. Used when comparing models with different lag lengths to estimate on the common sample.

volatility

[VolatilityProcess, optional] Volatility process to use in the model

distribution

[Distribution, optional] Error distribution to use in the model

rescale

[bool, optional] Flag indicating whether to automatically rescale data if the scale of the data is likely to produce convergence issues when estimating model parameters. If False, the model is estimated on the data without transformation. If True, than y is rescaled and the new scale is reported in the estimation results.

Notes

The LS model is described by

$$y_t = \mu + \gamma' x_t + \epsilon_t$$

Examples

```
>>> import numpy as np
>>> from arch.univariate import LS
>>> y = np.random.randn(100)
>>> x = np.random.randn(100,2)
>>> ls = LS(y, x)
>>> res = ls.fit()
```

Attributes***distribution***

Set or gets the error distribution

name

The name of the model.

num_params

Returns the number of parameters

volatility

Set or gets the volatility process

x

Gets the value of the exogenous regressors in the model

y

Returns the dependent variable

Methods

| | |
|--|--|
| <i>bounds()</i> | Construct bounds for parameters to use in non-linear optimization |

arch.univariate.LS.bounds

LS.bounds()

Construct bounds for parameters to use in non-linear optimization

Returns

bounds

[list (2-tuple of float)] Bounds for parameters to use in estimation.

Return type

list[tuple[float, float]]

arch.univariate.LS.compute_param_cov

LS.compute_param_cov(params, backcast=None, robust=True)

Computes parameter covariances using numerical derivatives.

Parameters

params

[ndarray] Model parameters

backcast

[float] Value to use for pre-sample observations

robust

[bool, optional] Flag indicating whether to use robust standard errors (True) or classic MLE (False)

Return type

ndarray

arch.univariate.LS.constraints

LS.constraints()

Construct linear constraint arrays for use in non-linear optimization

Returns

- a**
[ndarray] Number of constraints by number of parameters loading array
- b**
[ndarray] Number of constraints array of lower bounds

Notes

Parameters satisfy $a \cdot \text{parameters} - b \geq 0$

Return type

tuple[ndarray, ndarray]

arch.univariate.LS.fit

LS.fit(*update_freq=1, disp='final', starting_values=None, cov_type='robust', show_warning=True, first_obs=None, last_obs=None, tol=None, options=None, backcast=None*)

Estimate model parameters

Parameters

update_freq

[int, optional] Frequency of iteration updates. Output is generated every *update_freq* iterations. Set to 0 to disable iterative output.

disp

[{bool, "off", "final"}] Either 'final' to print optimization result or 'off' to display nothing. If using a boolean, False is "off" and True is "final"

starting_values

[ndarray, optional] Array of starting values to use. If not provided, starting values are constructed by the model components.

cov_type

[str, optional] Estimation method of parameter covariance. Supported options are 'robust', which does not assume the Information Matrix Equality holds and 'classic' which does. In the ARCH literature, 'robust' corresponds to Bollerslev-Wooldridge covariance estimator.

show_warning

[bool, optional] Flag indicating whether convergence warnings should be shown.

first_obs

[{int, str, datetime, Timestamp}] First observation to use when estimating model

last_obs

[{int, str, datetime, Timestamp}] Last observation to use when estimating model

tol

[float, optional] Tolerance for termination.

options

[`dict`, `optional`] Options to pass to `scipy.optimize.minimize`. Valid entries include ‘ftol’, ‘eps’, ‘disp’, and ‘maxiter’.

backcast

[`float`, `ndarray`], `optional`] Value to use as backcast. Should be measure σ_0^2 since model-specific non-linear transformations are applied to value before computing the variance recursions.

Returns**results**

[`ARCHModelResult`] Object containing model results

Notes

A `ConvergenceWarning` is raised if SciPy’s optimizer indicates difficulty finding the optimum.

Parameters are optimized using SLSQP.

Return type

ARCHModelResult

arch.univariate.LS.fix

LS.**fix**(*params*, *first_obs=None*, *last_obs=None*)

Allows an `ARCHModelFixedResult` to be constructed from fixed parameters.

Parameters**params**

[`ndarray`, `Series`] User specified parameters to use when generating the result. Must have the correct number of parameters for a given choice of mean model, volatility model and distribution.

first_obs

[`int`, `str`, `datetime`, `Timestamp`] First observation to use when fixing model

last_obs

[`int`, `str`, `datetime`, `Timestamp`] Last observation to use when fixing model

Returns**results**

[`ARCHModelFixedResult`] Object containing model results

Notes

Parameters are not checked against model-specific constraints.

Return type

ARCHModelFixedResult

arch.univariate.LS.forecast

`LS.forecast(params, horizon=1, start=None, align='origin', method='analytic', simulations=1000, rng=None, random_state=None, *, reindex=None, x=None)`

Construct forecasts from estimated model

Parameters

params

[`ndarray`, `Series`] Parameters required to forecast. Must be identical in shape to the parameters computed by fitting the model.

horizon

[`int`, optional] Number of steps to forecast

start

[`int`, `datetime`, `Timestamp`, `str`], optional] An integer, datetime or str indicating the first observation to produce the forecast for. Datetimes can only be used with pandas inputs that have a datetime index. Strings must be convertible to a date time, such as in '1945-01-01'.

align

[`str`, optional] Either 'origin' or 'target'. When set of 'origin', the t-th row of forecasts contains the forecasts for t+1, t+2, ..., t+h. When set to 'target', the t-th row contains the 1-step ahead forecast from time t-1, the 2 step from time t-2, ..., and the h-step from time t-h. 'target' simplified computing forecast errors since the realization and h-step forecast are aligned.

method

[`'analytic'`, `'simulation'`, `'bootstrap'`] Method to use when producing the forecast. The default is analytic. The method only affects the variance forecast generation. Not all volatility models support all methods. In particular, volatility models that do not evolve in squares such as EGARCH or TARCH do not support the 'analytic' method for horizons > 1.

simulations

[`int`] Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[`callable()`, optional] Custom random number generator to use in simulation-based forecasts. Must produce random samples using the syntax `rng(size)` where `size` the 2-element tuple (simulations, horizon).

random_state

[`RandomState`, optional] NumPy `RandomState` instance to use when method is 'bootstrap'

reindex

[`bool`, optional] Whether to reindex the forecasts to have the same dimension as the series being forecast. Prior to 4.18 this was the default. As of 4.19 this is now optional. If not provided, a warning is raised about the future change in the default which will occur after September 2021.

New in version 4.19.

x

[`{dict[label, numpy:array_like], numpy:array_like}`] Values to use for exogenous regressors if any are included in the model. Three formats are accepted:

- 2-d array-like: This format can be used when there is a single exogenous variable. The input must have shape (nforecast, horizon) or (nobs, horizon) where nforecast is the number of forecasting periods and nobs is the original shape of y. For example, if a single series of forecasts are made from the end of the sample with a horizon of 10, then the input can be (1, 10). Alternatively, if the original data had 1000 observations, then the input can be (1000, 10), and only the final row is used to produce forecasts.
- A dictionary of 2-d array-like: This format is identical to the previous except that the dictionary keys must match the names of the exog variables. Requires that the exog variables were passed as a pandas DataFrame.
- A 3-d NumPy array (or equivalent). In this format, each panel (0th axis) is a 2-d array that must have shape (nforecast, horizon) or (nobs,horizon). The array x[j] corresponds to the j-th column of the exogenous variables.

Due to the complexity required to accommodate all scenarios, please see the example notebook that demonstrates the valid formats for x.

New in version 4.19.

Returns

arch.univariate.base.ARCHModelForecast

Container for forecasts. Key properties are mean, variance and residual_variance.

Notes

The most basic 1-step ahead forecast will return a vector with the same length as the original data, where the t-th value will be the time-t forecast for time t + 1. When the horizon is > 1, and when using the default value for *align*, the forecast value in position [t, h] is the time-t, h+1 step ahead forecast.

If model contains exogenous variables (model.x is not None), then only 1-step ahead forecasts are available. Using horizon > 1 will produce a warning and all columns, except the first, will be nan-filled.

If *align* is 'origin', forecast[t,h] contains the forecast made using y[:t] (that is, up to but not including t) for horizon h + 1. For example, y[100,2] contains the 3-step ahead forecast using the first 100 data points, which will correspond to the realization y[100 + 2]. If *align* is 'target', then the same forecast is in location [102, 2], so that it is aligned with the observation to use when evaluating, but still in the same column.

Examples

```
>>> import pandas as pd
>>> from arch import arch_model
>>> am = arch_model(None, mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> sim_data = am.simulate([0.1, 0.4, 0.3, 0.2, 1.0], 250)
>>> sim_data.index = pd.date_range('2000-01-01', periods=250)
>>> am = arch_model(sim_data['data'], mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> res = am.fit()
>>> fig = res.hedgehog_plot()
```

Return type

ARCHModelForecast

arch.univariate.LS.parameter_names

LS.parameter_names()

List of parameters names

Returns

names
[list (str)] List of variable names for the mean model

Return type

list[str]

arch.univariate.LS.resids

LS.resids(*params*, *y=None*, *regressors=None*)

Compute model residuals

Parameters

params
[ndarray] Model parameters

y
[ndarray, optional] Alternative values to use when computing model residuals

regressors
[ndarray, optional] Alternative regressor values to use when computing model residuals

Returns

resids
[ndarray] Model residuals

Return type

Union[ndarray, Series]

arch.univariate.LS.simulate

LS.simulate(*params*, *nobs*, *burn=500*, *initial_value=None*, *x=None*, *initial_value_vol=None*)

Simulates data from a linear regression, AR or HAR models

Parameters

params
[numpy:array_like] Parameters to use when simulating the model. Parameter order is [mean volatility distribution] where the parameters of the mean model are ordered [constant lag[0] lag[1] ... lag[p] ex[0] ... ex[k-1]] where lag[j] indicates the coefficient on the jth lag in the model and ex[j] is the coefficient on the jth exogenous variable.

nobs
[int] Length of series to simulate

burn
[int, optional] Number of values to simulate to initialize the model and remove dependence on initial values.

initial_value

[{`ndarray`, `float`}, optional] Either a scalar value or *max(lags)* array set of initial values to use when initializing the model. If omitted, 0.0 is used.

x

[{`ndarray`, `DataFrame`}, optional] nobs + burn by k array of exogenous variables to include in the simulation.

initial_value_vol

[{`ndarray`, `float`}, optional] An array or scalar to use when initializing the volatility process.

Returns**simulated_data**

[`DataFrame`] `DataFrame` with columns data containing the simulated values, volatility, containing the conditional volatility and errors containing the errors used in the simulation

Examples

```
>>> import numpy as np
>>> from arch.univariate import HARX, GARCH
>>> harx = HARX(lags=[1, 5, 22])
>>> harx.volatility = GARCH()
>>> harx_params = np.array([1, 0.2, 0.3, 0.4])
>>> garch_params = np.array([0.01, 0.07, 0.92])
>>> params = np.concatenate((harx_params, garch_params))
>>> sim_data = harx.simulate(params, 1000)
```

Simulating models with exogenous regressors requires the regressors to have nobs plus burn data points

```
>>> nobs = 100
>>> burn = 200
>>> x = np.random.randn(nobs + burn, 2)
>>> x_params = np.array([1.0, 2.0])
>>> params = np.concatenate((harx_params, x_params, garch_params))
>>> sim_data = harx.simulate(params, nobs=nobs, burn=burn, x=x)
```

Return type

`DataFrame`

arch.univariate.LS.starting_values**LS.starting_values()**

Returns starting values for the mean model, often the same as the values returned from fit

Returns**sv**

[`ndarray`] Starting values

Return type

`ndarray`

Properties

| | |
|---------------------|---|
| <i>distribution</i> | Set or gets the error distribution |
| <i>name</i> | The name of the model. |
| <i>num_params</i> | Returns the number of parameters |
| <i>volatility</i> | Set or gets the volatility process |
| <i>x</i> | Gets the value of the exogenous regressors in the model |
| <i>y</i> | Returns the dependent variable |

arch.univariate.LS.distribution

property `LS.distribution`: *Distribution*

Set or gets the error distribution

Distributions must be a subclass of *Distribution*

Return type

Distribution

arch.univariate.LS.name

property `LS.name`: `str`

The name of the model.

Return type

`str`

arch.univariate.LS.num_params

property `LS.num_params`: `int`

Returns the number of parameters

arch.univariate.LS.volatility

property `LS.volatility`: *VolatilityProcess*

Set or gets the volatility process

Volatility processes must be a subclass of *VolatilityProcess*

Return type

VolatilityProcess

arch.univariate.LS.x**property** `LS.x`: `Optional[Union[ndarray, DataFrame]]`

Gets the value of the exogenous regressors in the model

Return type`Union[ndarray, DataFrame, None]`**arch.univariate.LS.y****property** `LS.y`: `Optional[Union[ndarray, DataFrame, Series]]`

Returns the dependent variable

Return type`Union[ndarray, DataFrame, Series, None]`

1.8.6 (G)ARCH-in-mean Models

(G)ARCH-in-mean models allow the conditional variance (or a transformation of it) to enter the conditional mean.

`ARCHInMean`(`y`, `x`, `lags`, `constant`, ...)(G)ARCH-in-mean model and simulation

arch.univariate.ARCHInMean**class** `arch.univariate.ARCHInMean`(`y=None`, `x=None`, `lags=None`, `constant=True`, `hold_back=None`, `volatility=None`, `distribution=None`, `rescale=None`, `form='vol'`)

(G)ARCH-in-mean model and simulation

Parameters**y**`[[ndarray, Series]]` nobs element vector containing the dependent variable**x**`[[ndarray, DataFrame], optional]` nobs by k element array containing exogenous regressors**lags**`[{scalar, 1-d array}, optional]` Description of lag structure of the HAR. Scalar included all lags between 1 and the value. A 1-d array includes the AR lags `lags[0]`, `lags[1]`, ...**constant**`[bool, optional]` Flag whether the model should include a constant**hold_back**`[int, optional]` Number of observations at the start of the sample to exclude when estimating model parameters. Used when comparing models with different lag lengths to estimate on the common sample.**volatility**`[VolatilityProcess, optional]` Volatility process to use in the model. `volatility.updateable` must return `True`.**distribution**`[Distribution, optional]` Error distribution to use in the model

rescale

[**bool**, **optional**] Flag indicating whether to automatically rescale data if the scale of the data is likely to produce convergence issues when estimating model parameters. If **False**, the model is estimated on the data without transformation. If **True**, than y is rescaled and the new scale is reported in the estimation results.

form

[{"log", "vol", "var", **int**, **float**}] The form of the conditional variance that appears in the mean equation. The string names use the log of the conditional variance ("log"), the square-root of the conditional variance ("vol") or the conditional variance. When specified using a float, interpreted as σ_t^{form} so that 1 is equivalent to "vol" and 2 is equivalent to "var". When using a number, must be different from 0.

Notes

The (G)arch-in-mean model with exogenous regressors (-X) is described by

$$y_t = \mu + \kappa f(\sigma_t^2) + \sum_{i=1}^p \phi_{L_i} y_{t-L_i} + \gamma' x_t + \epsilon_t$$

where $f(\cdot)$ is the function specified by `form`.

Examples

```
>>> import numpy as np
>>> from arch.univariate import ARCHInMean, GARCH
>>> from arch.data.sp500 import load
>>> sp500 = load()
>>> rets = 100 * sp500["Adj Close"].pct_change().dropna()
>>> gim = ARCHInMean(rets, lags=[1, 2], volatility=GARCH())
>>> res = gim.fit()
```

Attributes**distribution**

Set or gets the error distribution

form

The form of the conditional variance in the mean

name

The name of the model.

num_params

Returns the number of parameters

volatility

Set or gets the volatility process

x

Gets the value of the exogenous regressors in the model

y

Returns the dependent variable

Methods

| | |
|---|--|
| <code>bounds()</code> | Construct bounds for parameters to use in non-linear optimization |
| <code>compute_param_cov(params[, backcast, robust])</code> | Computes parameter covariances using numerical derivatives. |
| <code>constraints()</code> | Construct linear constraint arrays for use in non-linear optimization |
| <code>fit([update_freq, disp, starting_values, ...])</code> | Estimate model parameters |
| <code>fix(params[, first_obs, last_obs])</code> | Allows an ARCHModelFixedResult to be constructed from fixed parameters. |
| <code>forecast(params[, horizon, start, align, ...])</code> | Construct forecasts from estimated model |
| <code>parameter_names()</code> | List of parameters names |
| <code>resids(params[, y, regressors])</code> | Compute model residuals |
| <code>simulate(params, nobs[, burn, ...])</code> | Simulates data from a linear regression, AR or HAR models |
| <code>starting_values()</code> | Returns starting values for the mean model, often the same as the values returned from fit |

arch.univariate.ARCHInMean.bounds

ARCHInMean.bounds()

Construct bounds for parameters to use in non-linear optimization

Returns

bounds

[list (2-tuple of float)] Bounds for parameters to use in estimation.

Return type

list[tuple[float, float]]

arch.univariate.ARCHInMean.compute_param_cov

ARCHInMean.compute_param_cov(params, backcast=None, robust=True)

Computes parameter covariances using numerical derivatives.

Parameters

params

[ndarray] Model parameters

backcast

[float] Value to use for pre-sample observations

robust

[bool, optional] Flag indicating whether to use robust standard errors (True) or classic MLE (False)

Return type

ndarray

arch.univariate.ARCHInMean.constraints

ARCHInMean.constraints()

Construct linear constraint arrays for use in non-linear optimization

Returns

- a**
[ndarray] Number of constraints by number of parameters loading array
- b**
[ndarray] Number of constraints array of lower bounds

Notes

Parameters satisfy $a \cdot \text{parameters} - b \geq 0$

Return type

tuple[ndarray, ndarray]

arch.univariate.ARCHInMean.fit

ARCHInMean.fit(*update_freq=1, disp='final', starting_values=None, cov_type='robust', show_warning=True, first_obs=None, last_obs=None, tol=None, options=None, backcast=None*)

Estimate model parameters

Parameters

update_freq

[int, optional] Frequency of iteration updates. Output is generated every *update_freq* iterations. Set to 0 to disable iterative output.

disp

[{bool, "off", "final"}] Either 'final' to print optimization result or 'off' to display nothing. If using a boolean, False is "off" and True is "final"

starting_values

[ndarray, optional] Array of starting values to use. If not provided, starting values are constructed by the model components.

cov_type

[str, optional] Estimation method of parameter covariance. Supported options are 'robust', which does not assume the Information Matrix Equality holds and 'classic' which does. In the ARCH literature, 'robust' corresponds to Bollerslev-Wooldridge covariance estimator.

show_warning

[bool, optional] Flag indicating whether convergence warnings should be shown.

first_obs

[{int, str, datetime, Timestamp}] First observation to use when estimating model

last_obs

[{int, str, datetime, Timestamp}] Last observation to use when estimating model

tol

[float, optional] Tolerance for termination.

options

[`dict`, `optional`] Options to pass to `scipy.optimize.minimize`. Valid entries include ‘ftol’, ‘eps’, ‘disp’, and ‘maxiter’.

backcast

[`float`, `ndarray`], `optional`] Value to use as backcast. Should be measure σ_0^2 since model-specific non-linear transformations are applied to value before computing the variance recursions.

Returns**results**

[`ARCHModelResult`] Object containing model results

Notes

A `ConvergenceWarning` is raised if SciPy’s optimizer indicates difficulty finding the optimum.

Parameters are optimized using SLSQP.

Return type

`ARCHModelResult`

arch.univariate.ARCHInMean.fix

`ARCHInMean.fix(params, first_obs=None, last_obs=None)`

Allows an `ARCHModelFixedResult` to be constructed from fixed parameters.

Parameters**params**

[`ndarray`, `Series`] User specified parameters to use when generating the result. Must have the correct number of parameters for a given choice of mean model, volatility model and distribution.

first_obs

[`int`, `str`, `datetime`, `Timestamp`] First observation to use when fixing model

last_obs

[`int`, `str`, `datetime`, `Timestamp`] Last observation to use when fixing model

Returns**results**

[`ARCHModelFixedResult`] Object containing model results

Notes

Parameters are not checked against model-specific constraints.

Return type

`ARCHModelFixedResult`

arch.univariate.ARCHInMean.forecast

ARCHInMean.**forecast**(*params*, *horizon=1*, *start=None*, *align='origin'*, *method='analytic'*,
simulations=1000, *rng=None*, *random_state=None*, *, *reindex=None*, *x=None*)

Construct forecasts from estimated model

Parameters

params

[`ndarray`, `Series`] Parameters required to forecast. Must be identical in shape to the parameters computed by fitting the model.

horizon

[`int`, optional] Number of steps to forecast

start

[`int`, `datetime`, `Timestamp`, `str`], optional] An integer, datetime or str indicating the first observation to produce the forecast for. Datetimes can only be used with pandas inputs that have a datetime index. Strings must be convertible to a date time, such as in '1945-01-01'.

align

[`str`, optional] Either 'origin' or 'target'. When set of 'origin', the t-th row of forecasts contains the forecasts for t+1, t+2, ..., t+h. When set to 'target', the t-th row contains the 1-step ahead forecast from time t-1, the 2 step from time t-2, ..., and the h-step from time t-h. 'target' simplified computing forecast errors since the realization and h-step forecast are aligned.

method

[`'analytic'`, `'simulation'`, `'bootstrap'`] Method to use when producing the forecast. The default is analytic. The method only affects the variance forecast generation. Not all volatility models support all methods. In particular, volatility models that do not evolve in squares such as EGARCH or TARARCH do not support the 'analytic' method for horizons > 1.

simulations

[`int`] Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[`callable()`, optional] Custom random number generator to use in simulation-based forecasts. Must produce random samples using the syntax `rng(size)` where size the 2-element tuple (simulations, horizon).

random_state

[`RandomState`, optional] NumPy `RandomState` instance to use when method is 'bootstrap'

reindex

[`bool`, optional] Whether to reindex the forecasts to have the same dimension as the series being forecast. Prior to 4.18 this was the default. As of 4.19 this is now optional. If not provided, a warning is raised about the future change in the default which will occur after September 2021.

New in version 4.19.

x

[`dict`[`label`, `numpy:array_like`], `numpy:array_like`] Values to use for exogenous regressors if any are included in the model. Three formats are accepted:

- 2-d array-like: This format can be used when there is a single exogenous variable. The input must have shape (nforecast, horizon) or (nobs, horizon) where nforecast is the number of forecasting periods and nobs is the original shape of y. For example, if a single series of forecasts are made from the end of the sample with a horizon of 10, then the input can be (1, 10). Alternatively, if the original data had 1000 observations, then the input can be (1000, 10), and only the final row is used to produce forecasts.
- A dictionary of 2-d array-like: This format is identical to the previous except that the dictionary keys must match the names of the exog variables. Requires that the exog variables were passed as a pandas DataFrame.
- A 3-d NumPy array (or equivalent). In this format, each panel (0th axis) is a 2-d array that must have shape (nforecast, horizon) or (nobs,horizon). The array x[j] corresponds to the j-th column of the exogenous variables.

Due to the complexity required to accommodate all scenarios, please see the example notebook that demonstrates the valid formats for x.

New in version 4.19.

Returns

arch.univariate.base.ARCHModelForecast

Container for forecasts. Key properties are mean, variance and residual_variance.

Notes

The most basic 1-step ahead forecast will return a vector with the same length as the original data, where the t-th value will be the time-t forecast for time t + 1. When the horizon is > 1, and when using the default value for *align*, the forecast value in position [t, h] is the time-t, h+1 step ahead forecast.

If model contains exogenous variables (model.x is not None), then only 1-step ahead forecasts are available. Using horizon > 1 will produce a warning and all columns, except the first, will be nan-filled.

If *align* is 'origin', forecast[t,h] contains the forecast made using y[:t] (that is, up to but not including t) for horizon h + 1. For example, y[100,2] contains the 3-step ahead forecast using the first 100 data points, which will correspond to the realization y[100 + 2]. If *align* is 'target', then the same forecast is in location [102, 2], so that it is aligned with the observation to use when evaluating, but still in the same column.

Examples

```
>>> import pandas as pd
>>> from arch import arch_model
>>> am = arch_model(None, mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> sim_data = am.simulate([0.1, 0.4, 0.3, 0.2, 1.0], 250)
>>> sim_data.index = pd.date_range('2000-01-01', periods=250)
>>> am = arch_model(sim_data['data'], mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> res = am.fit()
>>> fig = res.hedgehog_plot()
```

Return type

ARCHModelForecast

arch.univariate.ARCHInMean.parameter_names**ARCHInMean.parameter_names()**

List of parameters names

Returns**names**`[list (str)]` List of variable names for the mean model**Return type**`list[str]`**arch.univariate.ARCHInMean.resids****ARCHInMean.resids**(*params*, *y=None*, *regressors=None*)

Compute model residuals

Parameters**params**`[ndarray]` Model parameters**y**`[ndarray, optional]` Alternative values to use when computing model residuals**regressors**`[ndarray, optional]` Alternative regressor values to use when computing model residuals**Returns****resids**`[ndarray]` Model residuals**Return type**`Union[ndarray, Series]`**arch.univariate.ARCHInMean.simulate****ARCHInMean.simulate**(*params*, *nobs*, *burn=500*, *initial_value=None*, *x=None*, *initial_value_vol=None*)

Simulates data from a linear regression, AR or HAR models

Parameters**params**`[numpy:array_like]` Parameters to use when simulating the model. Parameter order is [mean volatility distribution] where the parameters of the mean model are ordered [constant lag[0] lag[1] ... lag[p] ex[0] ... ex[k-1]] where lag[j] indicates the coefficient on the jth lag in the model and ex[j] is the coefficient on the jth exogenous variable.**nobs**`[int]` Length of series to simulate**burn**`[int, optional]` Number of values to simulate to initialize the model and remove dependence on initial values.

initial_value

[{`ndarray`, `float`}, optional] Either a scalar value or *max(lags)* array set of initial values to use when initializing the model. If omitted, 0.0 is used.

x

[{`ndarray`, `DataFrame`}, optional] nobs + burn by k array of exogenous variables to include in the simulation.

initial_value_vol

[{`ndarray`, `float`}, optional] An array or scalar to use when initializing the volatility process.

Returns**simulated_data**

[`DataFrame`] `DataFrame` with columns data containing the simulated values, volatility, containing the conditional volatility and errors containing the errors used in the simulation

Examples

```
>>> import numpy as np
>>> from arch.univariate import HARX, GARCH
>>> harx = HARX(lags=[1, 5, 22])
>>> harx.volatility = GARCH()
>>> harx_params = np.array([1, 0.2, 0.3, 0.4])
>>> garch_params = np.array([0.01, 0.07, 0.92])
>>> params = np.concatenate((harx_params, garch_params))
>>> sim_data = harx.simulate(params, 1000)
```

Simulating models with exogenous regressors requires the regressors to have nobs plus burn data points

```
>>> nobs = 100
>>> burn = 200
>>> x = np.random.randn(nobs + burn, 2)
>>> x_params = np.array([1.0, 2.0])
>>> params = np.concatenate((harx_params, x_params, garch_params))
>>> sim_data = harx.simulate(params, nobs=nobs, burn=burn, x=x)
```

Return type

`DataFrame`

arch.univariate.ARCHInMean.starting_values**ARCHInMean.starting_values()**

Returns starting values for the mean model, often the same as the values returned from fit

Returns**sv**

[`ndarray`] Starting values

Return type

`ndarray`

Properties

| | |
|---------------------|---|
| <i>distribution</i> | Set or gets the error distribution |
| <i>form</i> | The form of the conditional variance in the mean |
| <i>name</i> | The name of the model. |
| <i>num_params</i> | Returns the number of parameters |
| <i>volatility</i> | Set or gets the volatility process |
| <i>x</i> | Gets the value of the exogenous regressors in the model |
| <i>y</i> | Returns the dependent variable |

arch.univariate.ARCHInMean.distribution

property ARCHInMean.distribution: *Distribution*

Set or gets the error distribution

Distributions must be a subclass of Distribution

Return type

Distribution

arch.univariate.ARCHInMean.form

property ARCHInMean.form: `Union[int, float, Literal['log', 'vol', 'var']]`

The form of the conditional variance in the mean

Return type

`Union[int, float, Literal['log', 'vol', 'var']]`

arch.univariate.ARCHInMean.name

property ARCHInMean.name: `str`

The name of the model.

Return type

`str`

arch.univariate.ARCHInMean.num_params

property ARCHInMean.num_params: `int`

Returns the number of parameters

arch.univariate.ARCHInMean.volatility**property** ARCHInMean.volatility: *VolatilityProcess*

Set or gets the volatility process

Volatility processes must be a subclass of VolatilityProcess

Return type*VolatilityProcess***arch.univariate.ARCHInMean.x****property** ARCHInMean.x: *Optional[Union[ndarray, DataFrame]]*

Gets the value of the exogenous regressors in the model

Return type*Union[ndarray, DataFrame, None]***arch.univariate.ARCHInMean.y****property** ARCHInMean.y: *Optional[Union[ndarray, DataFrame, Series]]*

Returns the dependent variable

Return type*Union[ndarray, DataFrame, Series, None]***Special Requirements**

Not all volatility processes support application to AIM modeling. Specifically, the property `updateable` must be `True`.

```
In [1]: from arch.univariate import GARCH, EGARCH
```

```
In [2]: GARCH().updateable
```

```
Out[2]: True
```

```
In [3]: EGARCH().updateable
```

```
Out[3]: True
```

1.8.7 Writing New Mean Models

All mean models must inherit from `:class:ARCHModel` and provide all public methods. There are two optional private methods that should be provided if applicable.

```
ARCHModel([y, volatility, distribution, ...])
```

Abstract base class for mean models in ARCH processes.

arch.univariate.base.ARCHModel

class arch.univariate.base.**ARCHModel**(*y=None, volatility=None, distribution=None, hold_back=None, rescale=None*)

Abstract base class for mean models in ARCH processes. Specifies the conditional mean process.

All public methods that raise `NotImplementedError` should be overridden by any subclass. Private methods that raise `NotImplementedError` are optional to override but recommended where applicable.

Attributes

distribution

Set or gets the error distribution

name

The name of the model.

num_params

Number of parameters in the model

volatility

Set or gets the volatility process

y

Returns the dependent variable

Methods

arch.univariate.base.ARCHModel.bounds

ARCHModel.bounds()

Construct bounds for parameters to use in non-linear optimization

Returns

bounds

[list (2-tuple of float)] Bounds for parameters to use in estimation.

Return type

list[tuple[float, float]]

arch.univariate.base.ARCHModel.compute_param_cov

ARCHModel.compute_param_cov(params, backcast=None, robust=True)

Computes parameter covariances using numerical derivatives.

Parameters

params

[ndarray] Model parameters

backcast

[float] Value to use for pre-sample observations

robust

[bool, optional] Flag indicating whether to use robust standard errors (True) or classic MLE (False)

Return type

ndarray

arch.univariate.base.ARCHModel.constraints

ARCHModel.constraints()

Construct linear constraint arrays for use in non-linear optimization

Returns

a

[ndarray] Number of constraints by number of parameters loading array

b

[ndarray] Number of constraints array of lower bounds

Notes

Parameters satisfy $a \cdot \text{parameters} - b \geq 0$

Return type

`tuple[ndarray, ndarray]`

arch.univariate.base.ARCHModel.fit

`ARCHModel.fit(update_freq=1, disp='final', starting_values=None, cov_type='robust', show_warning=True, first_obs=None, last_obs=None, tol=None, options=None, backcast=None)`

Estimate model parameters

Parameters

update_freq

[`int`, optional] Frequency of iteration updates. Output is generated every *update_freq* iterations. Set to 0 to disable iterative output.

disp

[`bool`, “off”, “final”] Either ‘final’ to print optimization result or ‘off’ to display nothing. If using a boolean, False is “off” and True is “final”

starting_values

[`ndarray`, optional] Array of starting values to use. If not provided, starting values are constructed by the model components.

cov_type

[`str`, optional] Estimation method of parameter covariance. Supported options are ‘robust’, which does not assume the Information Matrix Equality holds and ‘classic’ which does. In the ARCH literature, ‘robust’ corresponds to Bollerslev-Wooldridge covariance estimator.

show_warning

[`bool`, optional] Flag indicating whether convergence warnings should be shown.

first_obs

[`int`, `str`, `datetime`, `Timestamp`] First observation to use when estimating model

last_obs

[`int`, `str`, `datetime`, `Timestamp`] Last observation to use when estimating model

tol

[`float`, optional] Tolerance for termination.

options

[`dict`, optional] Options to pass to `scipy.optimize.minimize`. Valid entries include ‘ftol’, ‘eps’, ‘disp’, and ‘maxiter’.

backcast

[`float`, `ndarray`], optional] Value to use as backcast. Should be measure σ_0^2 since model-specific non-linear transformations are applied to value before computing the variance recursions.

Returns

results

[`ARCHModelResult`] Object containing model results

Notes

A `ConvergenceWarning` is raised if SciPy's optimizer indicates difficulty finding the optimum.

Parameters are optimized using SLSQP.

Return type

ARCHModelResult

arch.univariate.base.ARCHModel.fix

`ARCHModel.fix(params, first_obs=None, last_obs=None)`

Allows an `ARCHModelFixedResult` to be constructed from fixed parameters.

Parameters

params

`[{ndarray, Series}]` User specified parameters to use when generating the result. Must have the correct number of parameters for a given choice of mean model, volatility model and distribution.

first_obs

`[{int, str, datetime, Timestamp}]` First observation to use when fixing model

last_obs

`[{int, str, datetime, Timestamp}]` Last observation to use when fixing model

Returns

results

[ARCHModelFixedResult] Object containing model results

Notes

Parameters are not checked against model-specific constraints.

Return type

ARCHModelFixedResult

arch.univariate.base.ARCHModel.forecast

abstract `ARCHModel.forecast(params, horizon=1, start=None, align='origin', method='analytic', simulations=1000, rng=None, random_state=None, *, reindex=None, x=None)`

Construct forecasts from estimated model

Parameters

params

`[{ndarray, Series}]` Parameters required to forecast. Must be identical in shape to the parameters computed by fitting the model.

horizon

`[int, optional]` Number of steps to forecast

start

[`{int, datetime, Timestamp, str}`, optional] An integer, datetime or str indicating the first observation to produce the forecast for. Datetimes can only be used with pandas inputs that have a datetime index. Strings must be convertible to a date time, such as in '1945-01-01'.

align

[`str`, optional] Either 'origin' or 'target'. When set of 'origin', the t-th row of forecasts contains the forecasts for t+1, t+2, ..., t+h. When set to 'target', the t-th row contains the 1-step ahead forecast from time t-1, the 2 step from time t-2, ..., and the h-step from time t-h. 'target' simplified computing forecast errors since the realization and h-step forecast are aligned.

method

[`{'analytic', 'simulation', 'bootstrap'}`] Method to use when producing the forecast. The default is analytic. The method only affects the variance forecast generation. Not all volatility models support all methods. In particular, volatility models that do not evolve in squares such as EGARCH or TARCH do not support the 'analytic' method for horizons > 1.

simulations

[`int`] Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[`callable()`, optional] Custom random number generator to use in simulation-based forecasts. Must produce random samples using the syntax `rng(size)` where size the 2-element tuple (simulations, horizon).

random_state

[`RandomState`, optional] NumPy RandomState instance to use when method is 'bootstrap'

reindex

[`bool`, optional] Whether to reindex the forecasts to have the same dimension as the series being forecast. Prior to 4.18 this was the default. As of 4.19 this is now optional. If not provided, a warning is raised about the future change in the default which will occur after September 2021.

New in version 4.19.

x

[`{dict[label, numpy:array_like], numpy:array_like}`] Values to use for exogenous regressors if any are included in the model. Three formats are accepted:

- 2-d array-like: This format can be used when there is a single exogenous variable. The input must have shape (nforecast, horizon) or (nobs, horizon) where nforecast is the number of forecasting periods and nobs is the original shape of y. For example, if a single series of forecasts are made from the end of the sample with a horizon of 10, then the input can be (1, 10). Alternatively, if the original data had 1000 observations, then the input can be (1000, 10), and only the final row is used to produce forecasts.
- A dictionary of 2-d array-like: This format is identical to the previous except that the dictionary keys must match the names of the exog variables. Requires that the exog variables were passed as a pandas DataFrame.
- A 3-d NumPy array (or equivalent). In this format, each panel (0th axis) is a 2-d array that must have shape (nforecast, horizon) or (nobs,horizon). The array `x[j]` corresponds to the j-th column of the exogenous variables.

Due to the complexity required to accommodate all scenarios, please see the example notebook that demonstrates the valid formats for `x`.

New in version 4.19.

Returns

arch.univariate.base.ARCHModelForecast

Container for forecasts. Key properties are `mean`, `variance` and `residual_variance`.

Notes

The most basic 1-step ahead forecast will return a vector with the same length as the original data, where the t -th value will be the time- t forecast for time $t + 1$. When the horizon is > 1 , and when using the default value for `align`, the forecast value in position $[t, h]$ is the time- t , $h+1$ step ahead forecast.

If model contains exogenous variables (`model.x` is not `None`), then only 1-step ahead forecasts are available. Using horizon > 1 will produce a warning and all columns, except the first, will be nan-filled.

If `align` is 'origin', `forecast[t,h]` contains the forecast made using `y[:t]` (that is, up to but not including t) for horizon $h + 1$. For example, `y[100,2]` contains the 3-step ahead forecast using the first 100 data points, which will correspond to the realization `y[100 + 2]`. If `align` is 'target', then the same forecast is in location `[102, 2]`, so that it is aligned with the observation to use when evaluating, but still in the same column.

Examples

```
>>> import pandas as pd
>>> from arch import arch_model
>>> am = arch_model(None, mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> sim_data = am.simulate([0.1, 0.4, 0.3, 0.2, 1.0], 250)
>>> sim_data.index = pd.date_range('2000-01-01', periods=250)
>>> am = arch_model(sim_data['data'], mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> res = am.fit()
>>> fig = res.hedgehog_plot()
```

Return type

ARCHModelForecast

arch.univariate.base.ARCHModel.parameter_names

abstract `ARCHModel.parameter_names()`

List of parameters names

Returns

names

`[list(str)]` List of variable names for the mean model

Return type

`list[str]`

arch.univariate.base.ARCHModel.resids

abstract ARCHModel.**resids**(*params*, *y=None*, *regressors=None*)

Compute model residuals

Parameters

params

[ndarray] Model parameters

y

[ndarray, optional] Alternative values to use when computing model residuals

regressors

[ndarray, optional] Alternative regressor values to use when computing model residuals

Returns

resids

[ndarray] Model residuals

Return type

Union[ndarray, Series]

arch.univariate.base.ARCHModel.simulate

abstract ARCHModel.**simulate**(*params*, *nobs*, *burn=500*, *initial_value=None*, *x=None*,
initial_value_vol=None)

Return type

DataFrame

arch.univariate.base.ARCHModel.starting_values

ARCHModel.**starting_values**()

Returns starting values for the mean model, often the same as the values returned from fit

Returns

sv

[ndarray] Starting values

Return type

ndarray

Properties

| | |
|---------------------|------------------------------------|
| <i>distribution</i> | Set or gets the error distribution |
| <i>name</i> | The name of the model. |
| <i>num_params</i> | Number of parameters in the model |
| <i>volatility</i> | Set or gets the volatility process |
| <i>y</i> | Returns the dependent variable |

arch.univariate.base.ARCHModel.distribution**property** ARCHModel.distribution: *Distribution*

Set or gets the error distribution

Distributions must be a subclass of Distribution

Return type*Distribution***arch.univariate.base.ARCHModel.name****property** ARCHModel.name: `str`

The name of the model.

Return type`str`**arch.univariate.base.ARCHModel.num_params****property** ARCHModel.num_params: `int`

Number of parameters in the model

arch.univariate.base.ARCHModel.volatility**property** ARCHModel.volatility: *VolatilityProcess*

Set or gets the volatility process

Volatility processes must be a subclass of VolatilityProcess

Return type*VolatilityProcess***arch.univariate.base.ARCHModel.y****property** ARCHModel.y: `Optional[Union[ndarray, DataFrame, Series]]`

Returns the dependent variable

Return type`Union[ndarray, DataFrame, Series, None]`

1.9 Volatility Processes

A volatility process is added to a mean model to capture time-varying volatility.

| | |
|---|---|
| <i>ConstantVariance</i> () | Constant volatility process |
| <i>GARCH</i> ([p, o, q, power]) | GARCH and related model estimation |
| <i>FIGARCH</i> ([p, q, power, truncation]) | FIGARCH model |
| <i>EGARCH</i> ([p, o, q]) | EGARCH model estimation |
| <i>HARCH</i> ([lags]) | Heterogeneous ARCH process |
| <i>MIDASHyperbolic</i> ([m, asym]) | MIDAS Hyperbolic ARCH process |
| <i>ARCH</i> ([p]) | ARCH process |
| <i>APARCH</i> ([p, o, q, delta, common_asym]) | Asymmetric Power ARCH (APARCH) volatility process |

1.9.1 arch.univariate.ConstantVariance

class arch.univariate.ConstantVariance

Constant volatility process

Notes

Model has the same variance in all periods

Attributes

name

The name of the volatility process

num_params

The number of parameters in the model

start

Index to use to start variance subarray selection

stop

Index to use to stop variance subarray selection

updateable

Flag indicating that the volatility process supports update

volatility_updater

Get the volatility updater associated with the volatility process

Methods

| | |
|---|---|
| <i>backcast</i> (resids) | Construct values for backcasting to start the recursion |
| <i>backcast_transform</i> (backcast) | Transformation to apply to user-provided backcast values |
| <i>bounds</i> (resids) | Returns bounds for parameters |
| <i>compute_variance</i> (parameters, resids, sigma2, ...) | Compute the variance for the ARCH model |
| <i>constraints</i> () | Construct parameter constraints arrays for parameter estimation |
| <i>forecast</i> (parameters, resids, backcast, ...) | Forecast volatility from the model |
| <i>parameter_names</i> () | Names of model parameters |
| <i>simulate</i> (parameters, nobs, rng[, burn, ...]) | Simulate data from the model |
| <i>starting_values</i> (resids) | Returns starting values for the ARCH model |
| <i>update</i> (index, parameters, resids, sigma2, ...) | Compute the variance for a single observation |
| <i>variance_bounds</i> (resids[, power]) | Construct loose bounds for conditional variances. |

arch.univariate.ConstantVariance.backcast

ConstantVariance.**backcast**(*resids*)

Construct values for backcasting to start the recursion

Parameters

resids
[*ndarray*] Vector of (approximate) residuals

Returns

backcast
[*float*] Value to use in backcasting in the volatility recursion

Return type

float | *ndarray*

arch.univariate.ConstantVariance.backcast_transform

ConstantVariance.**backcast_transform**(*backcast*)

Transformation to apply to user-provided backcast values

Parameters

backcast
[*{float, ndarray}*] User-provided backcast that approximates $\sigma^2[0]$.

Returns

backcast
[*{float, ndarray}*] Backcast transformed to the model-appropriate scale

Return type

float | *ndarray*

arch.univariate.ConstantVariance.bounds

ConstantVariance.**bounds**(*resids*)

Returns bounds for parameters

Parameters

resids
[*ndarray*] Vector of (approximate) residuals

Returns

bounds
[*list[tuple[*float*,*float*]]*] List of bounds where each element is (lower, upper).

Return type

*list[tuple[*float*, *float*]]*

arch.univariate.ConstantVariance.compute_variance

ConstantVariance.**compute_variance**(*parameters*, *resids*, *sigma2*, *backcast*, *var_bounds*)

Compute the variance for the ARCH model

Parameters

parameters

[`ndarray`] Model parameters

resids

[`ndarray`] Vector of mean zero residuals

sigma2

[`ndarray`] Array with same size as `resids` to store the conditional variance

backcast

[`{float, ndarray}`] Value to use when initializing ARCH recursion. Can be an `ndarray` when the model contains multiple components.

var_bounds

[`ndarray`] Array containing columns of lower and upper bounds

Return type

`ndarray`

arch.univariate.ConstantVariance.constraints

ConstantVariance.**constraints**()

Construct parameter constraints arrays for parameter estimation

Returns

A

[`ndarray`] Parameters loadings in constraint. Shape is number of constraints by number of parameters

b

[`ndarray`] Constraint values, one for each constraint

Notes

Values returned are used in constructing linear inequality constraints of the form $A \cdot \text{parameters} - b \geq 0$

Return type

`tuple[ndarray, ndarray]`

arch.univariate.ConstantVariance.forecast

`ConstantVariance.forecast(parameters, resids, backcast, var_bounds, start=None, horizon=1, method='analytic', simulations=1000, rng=None, random_state=None)`

Forecast volatility from the model

Parameters**parameters**

[`ndarray`, `Series`] Parameters required to forecast the volatility model

resids

[`ndarray`] Residuals to use in the recursion

backcast

[`float`] Value to use when initializing the recursion

var_bounds

[`ndarray`, 2-d] Array containing columns of lower and upper bounds

start

[`None`, `int`] Index of the first observation to use as the starting point for the forecast. Default is `len(resids)`.

horizon

[`int`] Forecast horizon. Must be 1 or larger. Forecasts are produced for horizons in `[1, horizon]`.

method

[`'analytic'`, `'simulation'`, `'bootstrap'`] Method to use when producing the forecast. The default is `analytic`.

simulations

[`int`] Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[`callable()`] Callable random number generator required if method is `'simulation'`. Must take a single shape input and return random samples numbers with that shape.

random_state

[`RandomState`, optional] NumPy `RandomState` instance to use when method is `'bootstrap'`

Returns**forecasts**

[`VarianceForecast`] Class containing the variance forecasts, and, if using simulation or bootstrap, the simulated paths.

Raises**NotImplementedError**

- If method is not supported

ValueError

- If the method is not known

Notes

The analytic method is not supported for all models. Attempting to use this method when not available will raise a `ValueError`.

Return type

`VarianceForecast`

`arch.univariate.ConstantVariance.parameter_names`

`ConstantVariance.parameter_names()`

Names of model parameters

Returns

names

`[list (str)]` Variables names

Return type

`list[str]`

`arch.univariate.ConstantVariance.simulate`

`ConstantVariance.simulate(parameters, nobs, rng, burn=500, initial_value=None)`

Simulate data from the model

Parameters

parameters

`[{ndarray, Series}]` Parameters required to simulate the volatility model

nobs

`[int]` Number of data points to simulate

rng

`[callable()]` Callable function that takes a single integer input and returns a vector of random numbers

burn

`[int, optional]` Number of additional observations to generate when initializing the simulation

initial_value

`[{float, ndarray}, optional]` Scalar or array of initial values to use when initializing the simulation

Returns

resids

`[ndarray]` The simulated residuals

variance

`[ndarray]` The simulated variance

Return type

`tuple[ndarray, ndarray]`

arch.univariate.ConstantVariance.starting_values

ConstantVariance.**starting_values**(*resids*)

Returns starting values for the ARCH model

Parameters**resids**

[`ndarray`] Array of (approximate) residuals to use when computing starting values

Returns**sv**

[`ndarray`] Array of starting values

Return type

`ndarray`

arch.univariate.ConstantVariance.update

ConstantVariance.**update**(*index, parameters, resids, sigma2, backcast, var_bounds*)

Compute the variance for a single observation

Parameters**index**

[`int`] The numerical index of the variance to compute

variance_params

[`ndarray`] The variance model parameters

resids

The residual array. Only uses `resids[:index]` when computing `sigma2[index]`

sigma2

[`ndarray`] The array containing the variances. Only uses `sigma2[:index]` when computing `sigma2[index]`. The computed value is stored in `sigma2[index]`.

backcast

[`{float, ndarray}`] Value to use when initializing the recursion

var_bounds

[`ndarray`] Array containing columns of lower and upper bounds

Returns**float**

The variance computed for location index

Return type

`float`

arch.univariate.ConstantVariance.variance_bounds

ConstantVariance.**variance_bounds**(*resids*, *power=2.0*)

Construct loose bounds for conditional variances.

These bounds are used in parameter estimation to ensure that the log-likelihood does not produce NaN values.

Parameters

resids

[[ndarray](#)] Approximate residuals to use to compute the lower and upper bounds on the conditional variance

power

[[float](#), [optional](#)] Power used in the model. 2.0, the default corresponds to standard ARCH models that evolve in squares.

Returns

var_bounds

[[ndarray](#)] Array containing columns of lower and upper bounds with the same number of elements as *resids*

Return type

[ndarray](#)

Properties

| | |
|---------------------------|---|
| <i>name</i> | The name of the volatility process |
| <i>num_params</i> | The number of parameters in the model |
| <i>start</i> | Index to use to start variance subarray selection |
| <i>stop</i> | Index to use to stop variance subarray selection |
| <i>updateable</i> | Flag indicating that the volatility process supports update |
| <i>volatility_updater</i> | Get the volatility updater associated with the volatility process |

arch.univariate.ConstantVariance.name

property ConstantVariance.**name**: [str](#)

The name of the volatility process

Return type

[str](#)

arch.univariate.ConstantVariance.num_params**property** ConstantVariance.num_params: `int`

The number of parameters in the model

Return type`int`**arch.univariate.ConstantVariance.start****property** ConstantVariance.start: `int`

Index to use to start variance subarray selection

Return type`int`**arch.univariate.ConstantVariance.stop****property** ConstantVariance.stop: `int`

Index to use to stop variance subarray selection

Return type`int`**arch.univariate.ConstantVariance.updateable****property** ConstantVariance.updateable: `bool`

Flag indicating that the volatility process supports update

Return type`bool`**arch.univariate.ConstantVariance.volatility_updater****property** ConstantVariance.volatility_updater: *VolatilityUpdater*

Get the volatility updater associated with the volatility process

Returns**VolatilityUpdater**

The updater class

Raises**NotImplementedError**

If the process is not updateable

Return type*VolatilityUpdater*

1.9.2 arch.univariate.GARCH

`class arch.univariate.GARCH(p=1, o=0, q=1, power=2.0)`

GARCH and related model estimation

The following models can be specified using GARCH:

- ARCH(p)
- GARCH(p,q)
- GJR-GARCH(p,o,q)
- AVARCH(p)
- AVGARCH(p,q)
- TARCH(p,o,q)
- Models with arbitrary, pre-specified powers

Parameters

p

[int] Order of the symmetric innovation

o

[int] Order of the asymmetric innovation

q

[int] Order of the lagged (transformed) conditional variance

power

[float, optional] Power to use with the innovations, $\text{abs}(e) ** \text{power}$. Default is 2.0, which produces ARCH and related models. Using 1.0 produces AVARCH and related models. Other powers can be specified, although these should be strictly positive, and usually larger than 0.25.

Notes

In this class of processes, the variance dynamics are

$$\sigma_t^\lambda = \omega + \sum_{i=1}^p \alpha_i |\epsilon_{t-i}|^\lambda + \sum_{j=1}^o \gamma_j |\epsilon_{t-j}|^\lambda I[\epsilon_{t-j} < 0] + \sum_{k=1}^q \beta_k \sigma_{t-k}^\lambda$$

Examples

```
>>> from arch.univariate import GARCH
```

Standard GARCH(1,1)

```
>>> garch = GARCH(p=1, q=1)
```

Asymmetric GJR-GARCH process

```
>>> gjr = GARCH(p=1, o=1, q=1)
```

Asymmetric TARCH process

```
>>> tarch = GARCH(p=1, o=1, q=1, power=1.0)
```

Attributes

name

The name of the volatility process

num_params

The number of parameters in the model

start

Index to use to start variance subarray selection

stop

Index to use to stop variance subarray selection

updateable

Flag indicating that the volatility process supports update

volatility_updater

Get the volatility updater associated with the volatility process

Methods

| | |
|---|---|
| <i>backcast</i> (resids) | Construct values for backcasting to start the recursion |
| <i>backcast_transform</i> (backcast) | Transformation to apply to user-provided backcast values |

| <i>update</i> (index, parameters, resids, sigma2, ...) | Compute the variance for a single observation |
| <i>variance_bounds</i> (resids[, power]) | Construct loose bounds for conditional variances. |

arch.univariate.GARCH.backcast

GARCH.**backcast**(*resids*)

Construct values for backcasting to start the recursion

Parameters

resids

[*ndarray*] Vector of (approximate) residuals

Returns

backcast

[*float*] Value to use in backcasting in the volatility recursion

Return type

float | *ndarray*

arch.univariate.GARCH.backcast_transform

GARCH.**backcast_transform**(*backcast*)

Transformation to apply to user-provided backcast values

Parameters

backcast

[{float, ndarray}] User-provided backcast that approximates $\sigma^2[0]$.

Returns

backcast

[{float, ndarray}] Backcast transformed to the model-appropriate scale

Return type

float | ndarray

arch.univariate.GARCH.bounds

GARCH.**bounds**(*resids*)

Returns bounds for parameters

Parameters

resids

[ndarray] Vector of (approximate) residuals

Returns

bounds

[list[tuple[float, float]]] List of bounds where each element is (lower, upper).

Return type

list[tuple[float, float]]

arch.univariate.GARCH.compute_variance

GARCH.**compute_variance**(*parameters*, *resids*, *sigma2*, *backcast*, *var_bounds*)

Compute the variance for the ARCH model

Parameters

parameters

[ndarray] Model parameters

resids

[ndarray] Vector of mean zero residuals

sigma2

[ndarray] Array with same size as *resids* to store the conditional variance

backcast

[{float, ndarray}] Value to use when initializing ARCH recursion. Can be an ndarray when the model contains multiple components.

var_bounds

[ndarray] Array containing columns of lower and upper bounds

Return type
`ndarray`

arch.univariate.GARCH.constraints

`GARCH.constraints()`

Construct parameter constraints arrays for parameter estimation

Returns

- A**
`[ndarray]` Parameters loadings in constraint. Shape is number of constraints by number of parameters
- b**
`[ndarray]` Constraint values, one for each constraint

Notes

Values returned are used in constructing linear inequality constraints of the form $A \cdot \text{parameters} - b \geq 0$

Return type
`tuple[ndarray, ndarray]`

arch.univariate.GARCH.forecast

`GARCH.forecast(parameters, resids, backcast, var_bounds, start=None, horizon=1, method='analytic', simulations=1000, rng=None, random_state=None)`

Forecast volatility from the model

Parameters

- parameters**
`[{ndarray, Series}]` Parameters required to forecast the volatility model
- resids**
`[ndarray]` Residuals to use in the recursion
- backcast**
`[float]` Value to use when initializing the recursion
- var_bounds**
`[ndarray, 2-d]` Array containing columns of lower and upper bounds
- start**
`[{None, int}]` Index of the first observation to use as the starting point for the forecast. Default is `len(resids)`.
- horizon**
`[int]` Forecast horizon. Must be 1 or larger. Forecasts are produced for horizons in `[1, horizon]`.
- method**
`[{'analytic', 'simulation', 'bootstrap'}]` Method to use when producing the forecast. The default is `analytic`.

simulations

[`int`] Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[`callable()`] Callable random number generator required if method is 'simulation'. Must take a single shape input and return random samples numbers with that shape.

random_state

[`RandomState`, optional] NumPy `RandomState` instance to use when method is 'bootstrap'

Returns**forecasts**

[`VarianceForecast`] Class containing the variance forecasts, and, if using simulation or bootstrap, the simulated paths.

Raises**`NotImplementedError`**

- If method is not supported

`ValueError`

- If the method is not known

Notes

The analytic method is not supported for all models. Attempting to use this method when not available will raise a `ValueError`.

Return type

`VarianceForecast`

`arch.univariate.GARCH.parameter_names`

`GARCH.parameter_names()`

Names of model parameters

Returns**names**

[`list (str)`] Variables names

Return type

`list[str]`

arch.univariate.GARCH.simulate

`GARCH.simulate(parameters, nobs, rng, burn=500, initial_value=None)`

Simulate data from the model

Parameters**parameters**

[`ndarray`, `Series`] Parameters required to simulate the volatility model

nobs

[`int`] Number of data points to simulate

rng

[`callable`()] Callable function that takes a single integer input and returns a vector of random numbers

burn

[`int`, `optional`] Number of additional observations to generate when initializing the simulation

initial_value

[`float`, `ndarray`], `optional`] Scalar or array of initial values to use when initializing the simulation

Returns**resids**

[`ndarray`] The simulated residuals

variance

[`ndarray`] The simulated variance

Return type

`tuple`[`ndarray`, `ndarray`]

arch.univariate.GARCH.starting_values

`GARCH.starting_values(resids)`

Returns starting values for the ARCH model

Parameters**resids**

[`ndarray`] Array of (approximate) residuals to use when computing starting values

Returns**sv**

[`ndarray`] Array of starting values

Return type

`ndarray`

arch.univariate.GARCH.update

GARCH.**update**(*index*, *parameters*, *resids*, *sigma2*, *backcast*, *var_bounds*)

Compute the variance for a single observation

Parameters

index

[int] The numerical index of the variance to compute

variance_params

[ndarray] The variance model parameters

resids

The residual array. Only uses `resids[:index]` when computing `sigma2[index]`

sigma2

[ndarray] The array containing the variances. Only uses `sigma2[:index]` when computing `sigma2[index]`. The computed value is stored in `sigma2[index]`.

backcast

[{float, ndarray}] Value to use when initializing the recursion

var_bounds

[ndarray] Array containing columns of lower and upper bounds

Returns

float

The variance computed for location `index`

Return type

float

arch.univariate.GARCH.variance_bounds

GARCH.**variance_bounds**(*resids*, *power=2.0*)

Construct loose bounds for conditional variances.

These bounds are used in parameter estimation to ensure that the log-likelihood does not produce NaN values.

Parameters

resids

[ndarray] Approximate residuals to use to compute the lower and upper bounds on the conditional variance

power

[float, optional] Power used in the model. 2.0, the default corresponds to standard ARCH models that evolve in squares.

Returns

var_bounds

[ndarray] Array containing columns of lower and upper bounds with the same number of elements as `resids`

Return type

ndarray

Properties

| | |
|---------------------------|---|
| <i>name</i> | The name of the volatility process |
| <i>num_params</i> | The number of parameters in the model |

| <i>updateable</i> | Flag indicating that the volatility process supports update |
| <i>volatility_updater</i> | Get the volatility updater associated with the volatility process |

arch.univariate.GARCH.name

property GARCH.name: `str`

The name of the volatility process

Return type

`str`

arch.univariate.GARCH.num_params

property GARCH.num_params: `int`

The number of parameters in the model

Return type

`int`

arch.univariate.GARCH.start

property GARCH.start: `int`

Index to use to start variance subarray selection

Return type

`int`

arch.univariate.GARCH.stop

property GARCH.stop: `int`

Index to use to stop variance subarray selection

Return type

`int`

arch.univariate.GARCH.updateable**property** GARCH.updateable: `bool`

Flag indicating that the volatility process supports update

Return type`bool`**arch.univariate.GARCH.volatility_updater****property** GARCH.volatility_updater: *VolatilityUpdater*

Get the volatility updater associated with the volatility process

Returns**VolatilityUpdater**

The updater class

Raises**NotImplementedError**

If the process is not updateable

Return type*VolatilityUpdater*

1.9.3 arch.univariate.FIGARCH

class arch.univariate.FIGARCH(*p=1, q=1, power=2.0, truncation=1000*)

FIGARCH model

Parameters**p**

[[0, 1]] Order of the symmetric innovation

q

[[0, 1]] Order of the lagged (transformed) conditional variance

power`[float, optional]` Power to use with the innovations, $\text{abs}(e) ** \text{power}$. Default is 2.0, which produces FIGARCH and related models. Using 1.0 produces FIAVARCH and related models. Other powers can be specified, although these should be strictly positive, and usually larger than 0.25.**truncation**`[int, optional]` Truncation point to use in ARCH(∞) representation. Default is 1000.

Notes

In this class of processes, the variance dynamics are

$$h_t = \omega + [1 - \beta L - \phi L(1 - L)^d] \epsilon_t^2 + \beta h_{t-1}$$

where L is the lag operator and d is the fractional differencing parameter. The model is estimated using the ARCH(∞) representation,

$$h_t = (1 - \beta)^{-1} \omega + \sum_{i=1}^{\infty} \lambda_i \epsilon_{t-i}^2$$

The weights are constructed using

$$\begin{aligned} \delta_1 &= d \\ \lambda_1 &= d - \beta + \phi \end{aligned}$$

and the recursive equations

$$\begin{aligned} \delta_j &= \frac{j-1-d}{j} \delta_{j-1} \\ \lambda_j &= \beta \lambda_{j-1} + \delta_j - \phi \delta_{j-1}. \end{aligned}$$

When *power* is not 2, the ARCH(∞) representation is still used where ϵ_t^2 is replaced by $|\epsilon_t|^p$ and p is the power.

Examples

```
>>> from arch.univariate import FIGARCH
```

Standard FIGARCH

```
>>> figarch = FIGARCH()
```

FIARCH

```
>>> fiarch = FIGARCH(p=0)
```

FIAVGARCH process

| <i>starting_values</i> (resids) | Returns starting values for the ARCH model |
| <i>update</i> (index, parameters, resids, sigma2, ...) | Compute the variance for a single observation |
| <i>variance_bounds</i> (resids[, power]) | Construct loose bounds for conditional variances. |

arch.univariate.FIGARCH.backcast

FIGARCH.**backcast**(*resids*)

Construct values for backcasting to start the recursion

Parameters

resids
[*ndarray*] Vector of (approximate) residuals

Returns

backcast
[*float*] Value to use in backcasting in the volatility recursion

Return type

float | *ndarray*

arch.univariate.FIGARCH.backcast_transform

FIGARCH.**backcast_transform**(*backcast*)

Transformation to apply to user-provided backcast values

Parameters

backcast
[*{float, ndarray}*] User-provided backcast that approximates sigma2[0].

Returns

backcast
[*{float, ndarray}*] Backcast transformed to the model-appropriate scale

Return type`float | ndarray`**arch.univariate.FIGARCH.bounds****FIGARCH.bounds**(*resids*)

Returns bounds for parameters

Parameters**resids**`[ndarray]` Vector of (approximate) residuals**Returns****bounds**`[list[tuple[float,float]]]` List of bounds where each element is (lower, upper).**Return type**`list[tuple[float, float]]`**arch.univariate.FIGARCH.compute_variance****FIGARCH.compute_variance**(*parameters, resids, sigma2, backcast, var_bounds*)

Compute the variance for the ARCH model

Parameters**parameters**`[ndarray]` Model parameters**resids**`[ndarray]` Vector of mean zero residuals**sigma2**`[ndarray]` Array with same size as *resids* to store the conditional variance**backcast**`[{float, ndarray}]` Value to use when initializing ARCH recursion. Can be an `ndarray` when the model contains multiple components.**var_bounds**`[ndarray]` Array containing columns of lower and upper bounds**Return type**`ndarray`

arch.univariate.FIGARCH.constraints

FIGARCH.constraints()

Construct parameter constraints arrays for parameter estimation

Returns

A

[ndarray] Parameters loadings in constraint. Shape is number of constraints by number of parameters

b

[ndarray] Constraint values, one for each constraint

Notes

Values returned are used in constructing linear inequality constraints of the form $A \cdot \text{parameters} - b \geq 0$

Return type

tuple[ndarray, ndarray]

arch.univariate.FIGARCH.forecast

FIGARCH.**forecast**(*parameters*, *resids*, *backcast*, *var_bounds*, *start=None*, *horizon=1*, *method='analytic'*, *simulations=1000*, *rng=None*, *random_state=None*)

Forecast volatility from the model

Parameters

parameters

[{ndarray, Series}] Parameters required to forecast the volatility model

resids

[ndarray] Residuals to use in the recursion

backcast

[float] Value to use when initializing the recursion

var_bounds

[ndarray, 2-d] Array containing columns of lower and upper bounds

start

[{None, int}] Index of the first observation to use as the starting point for the forecast. Default is len(resids).

horizon

[int] Forecast horizon. Must be 1 or larger. Forecasts are produced for horizons in [1, horizon].

method

[{'analytic', 'simulation', 'bootstrap'}] Method to use when producing the forecast. The default is analytic.

simulations

[int] Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[`callable()`] Callable random number generator required if method is ‘simulation’. Must take a single shape input and return random samples numbers with that shape.

random_state

[`RandomState`, optional] NumPy `RandomState` instance to use when method is ‘bootstrap’

Returns**forecasts**

[`VarianceForecast`] Class containing the variance forecasts, and, if using simulation or bootstrap, the simulated paths.

Raises**NotImplementedError**

- If method is not supported

ValueError

- If the method is not known

Notes

The analytic method is not supported for all models. Attempting to use this method when not available will raise a `ValueError`.

Return type

`VarianceForecast`

arch.univariate.FIGARCH.parameter_names

`FIGARCH.parameter_names()`

Names of model parameters

Returns**names**

[`list (str)`] Variables names

Return type

`list[str]`

arch.univariate.FIGARCH.simulate

`FIGARCH.simulate(parameters, nobs, rng, burn=500, initial_value=None)`

Simulate data from the model

Parameters**parameters**

[`{ndarray, Series}`] Parameters required to simulate the volatility model

nobs

[`int`] Number of data points to simulate

rng

[`callable()`] Callable function that takes a single integer input and returns a vector of random numbers

burn

[`int`, `optional`] Number of additional observations to generate when initializing the simulation

initial_value

[`{float, ndarray}`, `optional`] Scalar or array of initial values to use when initializing the simulation

Returns**resids**

[`ndarray`] The simulated residuals

variance

[`ndarray`] The simulated variance

Return type

`tuple[ndarray, ndarray]`

arch.univariate.FIGARCH.starting_values

`FIGARCH.starting_values(resids)`

Returns starting values for the ARCH model

Parameters**resids**

[`ndarray`] Array of (approximate) residuals to use when computing starting values

Returns**sv**

[`ndarray`] Array of starting values

Return type

`ndarray`

arch.univariate.FIGARCH.update

`FIGARCH.update(index, parameters, resids, sigma2, backcast, var_bounds)`

Compute the variance for a single observation

Parameters**index**

[`int`] The numerical index of the variance to compute

variance_params

[`ndarray`] The variance model parameters

resids

The residual array. Only uses `resids[:index]` when computing `sigma2[index]`

sigma2

[`ndarray`] The array containing the variances. Only uses `sigma2[:index]` when computing `sigma2[index]`. The computed value is stored in `sigma2[index]`.

backcast

[`{float, ndarray}`] Value to use when initializing the recursion

var_bounds

[`ndarray`] Array containing columns of lower and upper bounds

Returns

`float`

The variance computed for location `index`

Return type

`float`

arch.univariate.FIGARCH.variance_bounds

`FIGARCH.variance_bounds(resids, power=2.0)`

Construct loose bounds for conditional variances.

These bounds are used in parameter estimation to ensure that the log-likelihood does not produce NaN values.

Parameters

resids

[`ndarray`] Approximate residuals to use to compute the lower and upper bounds on the conditional variance

power

[`float, optional`] Power used in the model. 2.0, the default corresponds to standard ARCH models that evolve in squares.

Returns

var_bounds

[`ndarray`] Array containing columns of lower and upper bounds with the same number of elements as `resids`

Return type

`ndarray`

property FIGARCH.truncation: **int**

Truncation lag for the ARCH-infinity approximation

Return type

int

arch.univariate.FIGARCH.updateable

property FIGARCH.updateable: **bool**

Flag indicating that the volatility process supports update

Return type

bool

arch.univariate.FIGARCH.volatility_updater**property** FIGARCH.volatility_updater: *VolatilityUpdater*

Get the volatility updater associated with the volatility process

Returns**VolatilityUpdater**

The updater class

Raises**NotImplementedError**

If the process is not updateable

Return type*VolatilityUpdater***1.9.4 arch.univariate.EGARCH****class** arch.univariate.EGARCH(*p=1, o=0, q=1*)

EGARCH model estimation

Parameters**p***[int]* Order of the symmetric innovation**o***[int]* Order of the asymmetric innovation**q***[int]* Order of the lagged (transformed) conditional variance**Notes**

In this class of processes, the variance dynamics are

$$\ln \sigma_t^2 = \omega + \sum_{i=1}^p \alpha_i \left(|e_{t-i}| - \sqrt{2/\pi} \right) + \sum_{j=1}^o \gamma_j e_{t-j} + \sum_{k=1}^q \beta_k \ln \sigma_{t-k}^2$$

where $e_t = \epsilon_t / \sigma_t$.**Examples**

```
>>> from arch.univariate import EGARCH
```

Symmetric EGARCH(1,1)

```
>>> egarch = EGARCH(p=1, q=1)
```

Standard EGARCH process

```
>>> egarch = EGARCH(p=1, o=1, q=1)
```

Exponential ARCH process

```
>>> earch = EGARCH(p=5)
```

arch.univariate.EGARCH.backcast

EGARCH.**backcast** (*resids*)

Construct values for backcasting to start the recursion

Parameters

resids

[*ndarray*] Vector of (approximate) residuals

Returns

backcast

[*float*] Value to use in backcasting in the volatility recursion

Return type
float | ndarray

arch.univariate.EGARCH.backcast_transform

EGARCH.**backcast_transform**(*backcast*)

Transformation to apply to user-provided backcast values

Parameters

backcast
[`{float, ndarray}`] User-provided backcast that approximates $\sigma^2[0]$.

Returns

backcast
[`{float, ndarray}`] Backcast transformed to the model-appropriate scale

Return type
float | ndarray

arch.univariate.EGARCH.bounds

EGARCH.**bounds**(*resids*)

Returns bounds for parameters

Parameters

resids
[`ndarray`] Vector of (approximate) residuals

Returns

bounds
[`list[tuple[float, float]]`] List of bounds where each element is (lower, upper).

Return type
`list[tuple[float, float]]`

arch.univariate.EGARCH.compute_variance

EGARCH.**compute_variance**(*parameters, resids, sigma2, backcast, var_bounds*)

Compute the variance for the ARCH model

Parameters

parameters
[`ndarray`] Model parameters

resids
[`ndarray`] Vector of mean zero residuals

sigma2
[`ndarray`] Array with same size as *resids* to store the conditional variance

backcast
[`{float, ndarray}`] Value to use when initializing ARCH recursion. Can be an ndarray when the model contains multiple components.

var_bounds

[[ndarray](#)] Array containing columns of lower and upper bounds

Return type

[ndarray](#)

arch.univariate.EGARCH.constraints

EGARCH.**constraints**()

Construct parameter constraints arrays for parameter estimation

Returns

A

[[ndarray](#)] Parameters loadings in constraint. Shape is number of constraints by number of parameters

b

[[ndarray](#)] Constraint values, one for each constraint

Notes

Values returned are used in constructing linear inequality constraints of the form $A \cdot \text{dot}(\text{parameters}) - b \geq 0$

Return type

[tuple](#)[[ndarray](#), [ndarray](#)]

arch.univariate.EGARCH.forecast

EGARCH.**forecast**(*parameters*, *resids*, *backcast*, *var_bounds*, *start=None*, *horizon=1*, *method='analytic'*, *simulations=1000*, *rng=None*, *random_state=None*)

Forecast volatility from the model

Parameters

parameters

[[ndarray](#), [Series](#)] Parameters required to forecast the volatility model

resids

[[ndarray](#)] Residuals to use in the recursion

backcast

[[float](#)] Value to use when initializing the recursion

var_bounds

[[ndarray](#), 2-d] Array containing columns of lower and upper bounds

start

[[None](#), [int](#)] Index of the first observation to use as the starting point for the forecast. Default is len(resids).

horizon

[[int](#)] Forecast horizon. Must be 1 or larger. Forecasts are produced for horizons in [1, horizon].

method

[{'analytic', 'simulation', 'bootstrap'}] Method to use when producing the forecast. The default is analytic.

simulations

[int] Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[callable()] Callable random number generator required if method is 'simulation'. Must take a single shape input and return random samples numbers with that shape.

random_state

[RandomState, optional] NumPy RandomState instance to use when method is 'bootstrap'

Returns**forecasts**

[VarianceForecast] Class containing the variance forecasts, and, if using simulation or bootstrap, the simulated paths.

Raises**NotImplementedError**

- If method is not supported

ValueError

- If the method is not known

Notes

The analytic method is not supported for all models. Attempting to use this method when not available will raise a ValueError.

Return type

VarianceForecast

arch.univariate.EGARCH.parameter_names

EGARCH.parameter_names()

Names of model parameters

Returns**names**

[list (str)] Variables names

Return type

list[str]

arch.univariate.EGARCH.simulate

EGARCH.**simulate**(*parameters*, *nobs*, *rng*, *burn=500*, *initial_value=None*)

Simulate data from the model

Parameters

parameters

[`ndarray`, `Series`] Parameters required to simulate the volatility model

nobs

[`int`] Number of data points to simulate

rng

[`callable`()] Callable function that takes a single integer input and returns a vector of random numbers

burn

[`int`, `optional`] Number of additional observations to generate when initializing the simulation

initial_value

[`float`, `ndarray`], `optional`] Scalar or array of initial values to use when initializing the simulation

Returns

resids

[`ndarray`] The simulated residuals

variance

[`ndarray`] The simulated variance

Return type

`tuple`[`ndarray`, `ndarray`]

arch.univariate.EGARCH.starting_values

EGARCH.**starting_values**(*resids*)

Returns starting values for the ARCH model

Parameters

resids

[`ndarray`] Array of (approximate) residuals to use when computing starting values

Returns

sv

[`ndarray`] Array of starting values

Return type

`ndarray`

arch.univariate.EGARCH.update

`EGARCH.update(index, parameters, resids, sigma2, backcast, var_bounds)`

Compute the variance for a single observation

Parameters

index

[int] The numerical index of the variance to compute

variance_params

[ndarray] The variance model parameters

resids

The residual array. Only uses `resids[:index]` when computing `sigma2[index]`

sigma2

[ndarray] The array containing the variances. Only uses `sigma2[:index]` when computing `sigma2[index]`. The computed value is stored in `sigma2[index]`.

backcast

[{float, ndarray}] Value to use when initializing the recursion

var_bounds

[ndarray] Array containing columns of lower and upper bounds

Returns

float

The variance computed for location `index`

Return type

float

arch.univariate.EGARCH.variance_bounds

`EGARCH.variance_bounds(resids, power=2.0)`

Construct loose bounds for conditional variances.

These bounds are used in parameter estimation to ensure that the log-likelihood does not produce NaN values.

Parameters

resids

[ndarray] Approximate residuals to use to compute the lower and upper bounds on the conditional variance

power

[float, optional] Power used in the model. 2.0, the default corresponds to standard ARCH models that evolve in squares.

Returns

var_bounds

[ndarray] Array containing columns of lower and upper bounds with the same number of elements as `resids`

Return type

ndarray

Flag indicating that the volatility process supports update

Return type`bool`**arch.univariate.EGARCH.volatility_updater****property** EGARCH.volatility_updater: *VolatilityUpdater*

Get the volatility updater associated with the volatility process

Returns**VolatilityUpdater**

The updater class

Raises**NotImplementedError**

If the process is not updateable

Return type*VolatilityUpdater*

1.9.5 arch.univariate.HARCH

class arch.univariate.HARCH(*lags=1*)

Heterogeneous ARCH process

Parameters**lags**[[`list`, `array`, `int`]] List of lags to include in the model, or if scalar, includes all lags up the value**Notes**

In a Heterogeneous ARCH process, variance dynamics are

$$\sigma_t^2 = \omega + \sum_{i=1}^m \alpha_{l_i} \left(l_i^{-1} \sum_{j=1}^{l_i} \epsilon_{t-j}^2 \right)$$

In the common case where lags=[1,5,22], the model is

$$\sigma_t^2 = \omega + \alpha_1 \epsilon_{t-1}^2 + \alpha_5 \left(\frac{1}{5} \sum_{j=1}^5 \epsilon_{t-j}^2 \right) + \alpha_{22} \left(\frac{1}{22} \sum_{j=1}^{22} \epsilon_{t-j}^2 \right)$$

A HARCH process is a special case of an ARCH process where parameters in the more general ARCH process have been restricted.

Examples

```
>>> from arch.univariate import HARCH
```

Lag-1 HARCH, which is identical to an ARCH(1)

```
>>> harch = HARCH()
```

More useful and realistic lag lengths

```
>>> harch = HARCH(lags=[1, 5, 22])
```

Attributes

arch.univariate.HARCH.backcast

HARCH.**backcast**(*resids*)

Construct values for backcasting to start the recursion

Parameters

resids
[`ndarray`] Vector of (approximate) residuals

Returns

backcast
[`float`] Value to use in backcasting in the volatility recursion

Return type

`float` | `ndarray`

arch.univariate.HARCH.backcast_transform

HARCH.**backcast_transform**(*backcast*)

Transformation to apply to user-provided backcast values

Parameters

backcast
[`{float, ndarray}`] User-provided backcast that approximates $\sigma^2[0]$.

Returns

backcast
[`{float, ndarray}`] Backcast transformed to the model-appropriate scale

Return type

`float` | `ndarray`

arch.univariate.HARCH.bounds

HARCH.**bounds**(*resids*)

Returns bounds for parameters

Parameters

resids
[`ndarray`] Vector of (approximate) residuals

Returns

bounds
[`list[tuple[float, float]]`] List of bounds where each element is (lower, upper).

Return type

`list[tuple[float, float]]`

arch.univariate.HARCH.compute_variance

HARCH.**compute_variance**(*parameters*, *resids*, *sigma2*, *backcast*, *var_bounds*)

Compute the variance for the ARCH model

Parameters

parameters

[ndarray] Model parameters

resids

[ndarray] Vector of mean zero residuals

sigma2

[ndarray] Array with same size as resids to store the conditional variance

backcast

[{float, ndarray}] Value to use when initializing ARCH recursion. Can be an ndarray when the model contains multiple components.

var_bounds

[ndarray] Array containing columns of lower and upper bounds

Return type

ndarray

arch.univariate.HARCH.constraints

HARCH.**constraints**()

Construct parameter constraints arrays for parameter estimation

Returns

A

[ndarray] Parameters loadings in constraint. Shape is number of constraints by number of parameters

b

[ndarray] Constraint values, one for each constraint

Notes

Values returned are used in constructing linear inequality constraints of the form $A \cdot \text{dot}(\text{parameters}) - b \geq 0$

Return type

tuple[ndarray, ndarray]

arch.univariate.HARCH.forecast

HARCH.forecast(*parameters*, *resids*, *backcast*, *var_bounds*, *start=None*, *horizon=1*, *method='analytic'*, *simulations=1000*, *rng=None*, *random_state=None*)

Forecast volatility from the model

Parameters**parameters**

[`ndarray`, `Series`] Parameters required to forecast the volatility model

resids

[`ndarray`] Residuals to use in the recursion

backcast

[`float`] Value to use when initializing the recursion

var_bounds

[`ndarray`, 2-d] Array containing columns of lower and upper bounds

start

[`None`, `int`] Index of the first observation to use as the starting point for the forecast. Default is `len(resids)`.

horizon

[`int`] Forecast horizon. Must be 1 or larger. Forecasts are produced for horizons in `[1, horizon]`.

method

[`'analytic'`, `'simulation'`, `'bootstrap'`] Method to use when producing the forecast. The default is `analytic`.

simulations

[`int`] Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[`callable()`] Callable random number generator required if method is `'simulation'`. Must take a single shape input and return random samples numbers with that shape.

random_state

[`RandomState`, optional] NumPy `RandomState` instance to use when method is `'bootstrap'`

Returns**forecasts**

[`VarianceForecast`] Class containing the variance forecasts, and, if using simulation or bootstrap, the simulated paths.

Raises**NotImplementedError**

- If method is not supported

ValueError

- If the method is not known

Notes

The analytic method is not supported for all models. Attempting to use this method when not available will raise a `ValueError`.

Return type

`VarianceForecast`

`arch.univariate.HARCH.parameter_names`

`HARCH.parameter_names()`

Names of model parameters

Returns

names

`[list (str)]` Variables names

Return type

`list[str]`

`arch.univariate.HARCH.simulate`

`HARCH.simulate(parameters, nobs, rng, burn=500, initial_value=None)`

Simulate data from the model

Parameters

parameters

`[{ndarray, Series}]` Parameters required to simulate the volatility model

nobs

`[int]` Number of data points to simulate

rng

`[callable()]` Callable function that takes a single integer input and returns a vector of random numbers

burn

`[int, optional]` Number of additional observations to generate when initializing the simulation

initial_value

`[{float, ndarray}, optional]` Scalar or array of initial values to use when initializing the simulation

Returns

resids

`[ndarray]` The simulated residuals

variance

`[ndarray]` The simulated variance

Return type

`tuple[ndarray, ndarray]`

arch.univariate.HARCH.starting_values**HARCH.starting_values**(*resids*)

1.9.6 arch.univariate.MIDASHyperbolic

class arch.univariate.MIDASHyperbolic(*m=22, asym=False*)

MIDAS Hyperbolic ARCH process

Parameters

m

[int] Length of maximum lag to include in the model

asym

[bool] Flag indicating whether to include an asymmetric term

Notes

In a MIDAS Hyperbolic process, the variance evolves according to

$$\sigma_t^2 = \omega + \sum_{i=1}^m (\alpha + \gamma I[\epsilon_{t-j} < 0]) \phi_i(\theta) \epsilon_{t-i}^2$$

where

$$\phi_i(\theta) \propto \Gamma(i + \theta) / (\Gamma(i + 1)\Gamma(\theta))$$

where Γ is the gamma function. $\{\phi_i(\theta)\}$ is normalized so that $\sum \phi_i(\theta) = 1$

References

Examples

```
>>> from arch.univariate import MIDASHyperbolic
```

22-lag MIDAS Hyperbolic process

```
>>> harch = MIDASHyperbolic()
```

Longer 66-period lag

```
>>> harch = MIDASHyperbolic(m=66)
```

Asymmetric MIDAS Hyperbolic process

```
>>> harch = MIDASHyperbolic(asym=True)
```

Attributes

name

The name of the volatility process

num_params

The number of parameters in the model

start

Index to use to start variance subarray selection

stop

Index to use to stop variance subarray selection

updateable

Flag indicating that the volatility process supports update

volatility_updater

Get the volatility updater associated with the volatility process

Methods

| | |
|---|--|
| <i>backcast</i> (resids) | Construct values for backcasting to start the recursion |
| <i>backcast_transform</i> (backcast) | Transformation to apply to user-provided backcast values |
| <i>bounds</i> (resids) | Returns bounds for parameters |
| <i>compute_variance</i> (parameters, resids, sigma2, ...) | Compute the variance for the ARCH model |
| <i>constraints</i> () | Constraints |
| <i>forecast</i> (parameters, resids, backcast, ...) | Forecast volatility from the model |
| <i>parameter_names</i> () | Names of model parameters |
| <i>simulate</i> (parameters, nobs, rng[, burn, ...]) | Simulate data from the model |
| <i>starting_values</i> (resids) | Returns starting values for the ARCH model |
| <i>update</i> (index, parameters, resids, sigma2, ...) | Compute the variance for a single observation |
| <i>variance_bounds</i> (resids[, power]) | Construct loose bounds for conditional variances. |

arch.univariate.MIDASHyperbolic.backcast

MIDASHyperbolic.**backcast**(*resids*)

Construct values for backcasting to start the recursion

Parameters

resids

[*ndarray*] Vector of (approximate) residuals

Returns

backcast

[*float*] Value to use in backcasting in the volatility recursion

Return type

float | *ndarray*

arch.univariate.MIDASHyperbolic.backcast_transform

MIDASHyperbolic.**backcast_transform**(*backcast*)

Transformation to apply to user-provided backcast values

Parameters

backcast

[{*float*, *ndarray*}] User-provided backcast that approximates sigma2[0].

Returns

backcast

[{float, ndarray}] Backcast transformed to the model-appropriate scale

Return type

float | ndarray

arch.univariate.MIDASHyperbolic.bounds

MIDASHyperbolic.**bounds**(*resids*)

Returns bounds for parameters

Parameters**resids**

[ndarray] Vector of (approximate) residuals

Returns**bounds**

[list[tuple[float, float]]] List of bounds where each element is (lower, upper).

Return type

list[tuple[float, float]]

arch.univariate.MIDASHyperbolic.compute_variance

MIDASHyperbolic.**compute_variance**(*parameters*, *resids*, *sigma2*, *backcast*, *var_bounds*)

Compute the variance for the ARCH model

Parameters**parameters**

[ndarray] Model parameters

resids

[ndarray] Vector of mean zero residuals

sigma2

[ndarray] Array with same size as resids to store the conditional variance

backcast

[{float, ndarray}] Value to use when initializing ARCH recursion. Can be an ndarray when the model contains multiple components.

var_bounds

[ndarray] Array containing columns of lower and upper bounds

Return type

ndarray

arch.univariate.MIDASHyperbolic.constraints

MIDASHyperbolic.constraints()

Constraints

Notes

Parameters are (omega, alpha, gamma, theta)

$A \cdot \text{dot}(\text{parameters}) - b \geq 0$

1. $\omega > 0$
2. $\alpha > 0$ or $\alpha + \gamma > 0$
3. $\alpha < 1$ or $\alpha + 0.5 \cdot \gamma < 1$
4. $\theta > 0$
5. $\theta < 1$

Return type

`tuple[ndarray, ndarray]`

arch.univariate.MIDASHyperbolic.forecast

MIDASHyperbolic.forecast(parameters, resids, backcast, var_bounds, start=None, horizon=1, method='analytic', simulations=1000, rng=None, random_state=None)

Forecast volatility from the model

Parameters

parameters

`[{ndarray, Series}]` Parameters required to forecast the volatility model

resids

`[ndarray]` Residuals to use in the recursion

backcast

`[float]` Value to use when initializing the recursion

var_bounds

`[ndarray, 2-d]` Array containing columns of lower and upper bounds

start

`[{None, int}]` Index of the first observation to use as the starting point for the forecast. Default is `len(resids)`.

horizon

`[int]` Forecast horizon. Must be 1 or larger. Forecasts are produced for horizons in `[1, horizon]`.

method

`[{'analytic', 'simulation', 'bootstrap'}]` Method to use when producing the forecast. The default is `analytic`.

simulations

`[int]` Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[`callable()`] Callable random number generator required if method is 'simulation'. Must take a single shape input and return random samples numbers with that shape.

random_state

[`RandomState`, optional] NumPy `RandomState` instance to use when method is 'bootstrap'

Returns**forecasts**

[`VarianceForecast`] Class containing the variance forecasts, and, if using simulation or bootstrap, the simulated paths.

Raises**NotImplementedError**

- If method is not supported

ValueError

- If the method is not known

Notes

The analytic method is not supported for all models. Attempting to use this method when not available will raise a `ValueError`.

Return type

`VarianceForecast`

arch.univariate.MIDASHyperbolic.parameter_names

`MIDASHyperbolic.parameter_names()`

Names of model parameters

Returns**names**

[`list (str)`] Variables names

Return type

`list[str]`

arch.univariate.MIDASHyperbolic.simulate

`MIDASHyperbolic.simulate(parameters, nobs, rng, burn=500, initial_value=None)`

Simulate data from the model

Parameters**parameters**

[`{ndarray, Series}`] Parameters required to simulate the volatility model

nobs

[`int`] Number of data points to simulate

rng

[`callable()`] Callable function that takes a single integer input and returns a vector of random numbers

burn

[`int`, `optional`] Number of additional observations to generate when initializing the simulation

initial_value

[`{float, ndarray}`, `optional`] Scalar or array of initial values to use when initializing the simulation

Returns**resids**

[`ndarray`] The simulated residuals

variance

[`ndarray`] The simulated variance

Return type

`tuple[ndarray, ndarray]`

arch.univariate.MIDASHyperbolic.starting_values

`MIDASHyperbolic.starting_values(resids)`

Returns starting values for the ARCH model

Parameters**resids**

[`ndarray`] Array of (approximate) residuals to use when computing starting values

Returns**sv**

[`ndarray`] Array of starting values

Return type

`ndarray`

arch.univariate.MIDASHyperbolic.update

`MIDASHyperbolic.update(index, parameters, resids, sigma2, backcast, var_bounds)`

Compute the variance for a single observation

Parameters**index**

[`int`] The numerical index of the variance to compute

variance_params

[`ndarray`] The variance model parameters

resids

The residual array. Only uses `resids[:index]` when computing `sigma2[index]`

sigma2

[`ndarray`] The array containing the variances. Only uses `sigma2[:index]` when computing `sigma2[index]`. The computed value is stored in `sigma2[index]`.

backcast

[`{float, ndarray}`] Value to use when initializing the recursion

var_bounds

[`ndarray`] Array containing columns of lower and upper bounds

Returns

`float`

The variance computed for location `index`

Return type

`float`

arch.univariate.MIDASHyperbolic.variance_bounds

MIDASHyperbolic.`variance_bounds`(*resids*, *power=2.0*)

Construct loose bounds for conditional variances.

These bounds are used in parameter estimation to ensure that the log-likelihood does not produce NaN values.

Parameters

resids

[`ndarray`] Approximate residuals to use to compute the lower and upper bounds on the conditional variance

power

[`float`, optional] Power used in the model. 2.0, the default corresponds to standard ARCH models that evolve in squares.

Returns

var_bounds

[`ndarray`] Array containing columns of lower and upper bounds with the same number of elements as `resids`

Return type

`ndarray`

Index to use to stop variance subarray selection

Return type`int`**arch.univariate.MIDASHyperbolic.updateable****property** MIDASHyperbolic.updateable: `bool`

Flag indicating that the volatility process supports update

Return type`bool`**arch.univariate.MIDASHyperbolic.volatility_updater****property** MIDASHyperbolic.volatility_updater: *VolatilityUpdater*

Get the volatility updater associated with the volatility process

Returns**VolatilityUpdater**

The updater class

Raises**NotImplementedError**

If the process is not updateable

Return type*VolatilityUpdater*

1.9.7 arch.univariate.ARCH

class arch.univariate.ARCH(*p=1*)

ARCH process

Parameters**p**

[int] Order of the symmetric innovation

Notes

The variance dynamics of the model estimated

$$\sigma_t^2 = \omega + \sum_{i=1}^p \alpha_i \epsilon_{t-i}^2$$

Examples

ARCH(1) process

```
>>> from arch.univariate import ARCH
```

ARCH(5) process

```
>>> arch = ARCH(p=5)
```

| <i>variance_bounds</i> (resids[, power]) | Construct loose bounds for conditional variances. |

arch.univariate.ARCH.backcast

ARCH.**backcast**(*resids*)

Construct values for backcasting to start the recursion

Parameters

resids

[`ndarray`] Vector of (approximate) residuals

Returns

backcast

[`float`] Value to use in backcasting in the volatility recursion

Return type

`float` | `ndarray`

arch.univariate.ARCH.backcast_transform

ARCH.**backcast_transform**(*backcast*)

Transformation to apply to user-provided backcast values

Parameters

backcast

[`{float, ndarray}`] User-provided backcast that approximates `sigma2[0]`.

Returns

backcast

[`{float, ndarray}`] Backcast transformed to the model-appropriate scale

Return type

`float` | `ndarray`

arch.univariate.ARCH.bounds

ARCH.**bounds**(*resids*)

Returns bounds for parameters

Parameters

resids
[ndarray] Vector of (approximate) residuals

Returns

bounds
[list[tuple[float,float]]] List of bounds where each element is (lower, upper).

Return type

list[tuple[float, float]]

arch.univariate.ARCH.compute_variance

ARCH.**compute_variance**(*parameters, resids, sigma2, backcast, var_bounds*)

Compute the variance for the ARCH model

Parameters

parameters
[ndarray] Model parameters

resids
[ndarray] Vector of mean zero residuals

sigma2
[ndarray] Array with same size as resids to store the conditional variance

backcast
[float, ndarray] Value to use when initializing ARCH recursion. Can be an ndarray when the model contains multiple components.

var_bounds
[ndarray] Array containing columns of lower and upper bounds

Return type

ndarray

arch.univariate.ARCH.constraints

ARCH.**constraints**()

Construct parameter constraints arrays for parameter estimation

Returns

A
[ndarray] Parameters loadings in constraint. Shape is number of constraints by number of parameters

b
[ndarray] Constraint values, one for each constraint

Notes

Values returned are used in constructing linear inequality constraints of the form $A \cdot \text{dot}(\text{parameters}) - b \geq 0$

Return type

`tuple[ndarray, ndarray]`

arch.univariate.ARCH.forecast

ARCH. **forecast**(*parameters, resids, backcast, var_bounds, start=None, horizon=1, method='analytic', simulations=1000, rng=None, random_state=None*)

Forecast volatility from the model

Parameters

parameters

`[{ndarray, Series}]` Parameters required to forecast the volatility model

resids

`[ndarray]` Residuals to use in the recursion

backcast

`[float]` Value to use when initializing the recursion

var_bounds

`[ndarray, 2-d]` Array containing columns of lower and upper bounds

start

`[{None, int}]` Index of the first observation to use as the starting point for the forecast. Default is `len(resids)`.

horizon

`[int]` Forecast horizon. Must be 1 or larger. Forecasts are produced for horizons in `[1, horizon]`.

method

`[{'analytic', 'simulation', 'bootstrap'}]` Method to use when producing the forecast. The default is `analytic`.

simulations

`[int]` Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

`[callable()]` Callable random number generator required if method is `'simulation'`. Must take a single shape input and return random samples numbers with that shape.

random_state

`[RandomState, optional]` NumPy `RandomState` instance to use when method is `'bootstrap'`

Returns

forecasts

`[VarianceForecast]` Class containing the variance forecasts, and, if using simulation or bootstrap, the simulated paths.

Raises

`NotImplementedError`

- If method is not supported

ValueError

- If the method is not known

Notes

The analytic method is not supported for all models. Attempting to use this method when not available will raise a ValueError.

Return type

VarianceForecast

arch.univariate.ARCH.parameter_names

ARCH.**parameter_names**()

Names of model parameters

Returns

names

[list (str)] Variables names

Return type

list[str]

arch.univariate.ARCH.simulate

ARCH.**simulate**(*parameters, nobs, rng, burn=500, initial_value=None*)

Simulate data from the model

Parameters

parameters

[{ndarray, Series}] Parameters required to simulate the volatility model

nobs

[int] Number of data points to simulate

rng

[callable()] Callable function that takes a single integer input and returns a vector of random numbers

burn

[int, optional] Number of additional observations to generate when initializing the simulation

initial_value

[{float, ndarray}, optional] Scalar or array of initial values to use when initializing the simulation

Returns

resids

[ndarray] The simulated residuals

variance
 [ndarray] The simulated variance

Return type
 tuple[ndarray, ndarray]

arch.univariate.ARCH.starting_values

ARCH.**starting_values**(*resids*)

Returns starting values for the ARCH model

Parameters

resids
 [ndarray] Array of (approximate) residuals to use when computing starting values

Returns

sv
 [ndarray] Array of starting values

Return type
 ndarray

arch.univariate.ARCH.update

ARCH.**update**(*index, parameters, resids, sigma2, backcast, var_bounds*)

Compute the variance for a single observation

Parameters

index
 [int] The numerical index of the variance to compute

variance_params
 [ndarray] The variance model parameters

resids
 The residual array. Only uses `resids[:index]` when computing `sigma2[index]`

sigma2
 [ndarray] The array containing the variances. Only uses `sigma2[:index]` when computing `sigma2[index]`. The computed value is stored in `sigma2[index]`.

backcast
 [{float, ndarray}] Value to use when initializing the recursion

var_bounds
 [ndarray] Array containing columns of lower and upper bounds

Returns

float
 The variance computed for location `index`

Return type
 float

arch.univariate.ARCH.variance_bounds

ARCH.**variance_bounds**(*resids*, *power=2.0*)

Construct loose bounds for conditional variances.

These bounds are used in parameter estimation to ensure that the log-likelihood does not produce NaN values.

Parameters

resids

[[ndarray](#)] Approximate residuals to use to compute the lower and upper bounds on the conditional variance

power

[[float](#), [optional](#)] Power used in the model. 2.0, the default corresponds to standard ARCH models that evolve in squares.

Returns

var_bounds

[[ndarray](#)] Array containing columns of lower and upper bounds with the same number of elements as *resids*

Return type

[ndarray](#)

arch.univariate.ARCH.name

property ARCH.**name**: [str](#)

The name of the volatility process

Return type

[str](#)

arch.univariate.ARCH.num_params**property** ARCH.num_params: `int`

The number of parameters in the model

Return type`int`**arch.univariate.ARCH.start****property** ARCH.start: `int`

Index to use to start variance subarray selection

Return type`int`**arch.univariate.ARCH.stop****property** ARCH.stop: `int`

Index to use to stop variance subarray selection

Return type`int`**arch.univariate.ARCH.updateable****property** ARCH.updateable: `bool`

Flag indicating that the volatility process supports update

Return type`bool`**arch.univariate.ARCH.volatility_updater****property** ARCH.volatility_updater: *VolatilityUpdater*

Get the volatility updater associated with the volatility process

Returns**VolatilityUpdater**

The updater class

Raises**NotImplementedError**

If the process is not updateable

Return type*VolatilityUpdater*

1.9.8 arch.univariate.APARCH

class arch.univariate.**APARCH**(*p=1, o=1, q=1, delta=None, common_asym=False*)

Asymmetric Power ARCH (APARCH) volatility process

Parameters

p

[int] Order of the symmetric innovation. Must satisfy $p \geq 0$.

o

[int] Order of the asymmetric innovation. Must satisfy $o \leq p$.

q

[int] Order of the lagged (transformed) conditional variance

delta

[float, optional] Value to use for a fixed delta in the APARCH model. If not provided, the value of delta is jointly estimated with other model parameters. User provided delta is restricted to lie in (0.05, 4.0).

common_asym

[bool, optional] Restrict all asymmetry terms to share the same asymmetry parameter. If False (default), then there are no restrictions on the o asymmetry parameters.

Notes

In this class of processes, the variance dynamics are

$$\sigma_t^\delta = \omega + \sum_{i=1}^p \alpha_i (|\epsilon_{t-i}| - \gamma_i I_{[o \geq i]} \epsilon_{t-i})^\delta + \sum_{k=1}^q \beta_k \sigma_{t-k}^\delta$$

If `common_asym` is True, then all of γ_i are restricted to have a common value.

Examples

```
>>> from arch.univariate import APARCH
```

Symmetric Power ARCH(1,1)

```
>>> aparch = APARCH(p=1, q=1)
```

Standard APARCH process

```
>>> aparch = APARCH(p=1, o=1, q=1)
```

Fixed power parameters

```
>>> aparch = APARCH(p=1, o=1, q=1, delta=1.3)
```

Attributes

common_asym

The value of delta in the model.

delta

The value of delta in the model.

name

The name of the volatility process

num_params

The number of parameters in the model

start

Index to use to start variance subarray selection

stop

Index to use to stop variance subarray selection

updateable

Flag indicating that the volatility process supports update

volatility_updater

Get the volatility updater associated with the volatility process

Methods

| | |
|---|---|
| <i>backcast</i> (resids) | Construct values for backcasting to start the recursion |
| <i>backcast_transform</i> (backcast) | Transformation to apply to user-provided backcast values |

| <i>update</i> (index, parameters, resids, sigma2, ...) | Compute the variance for a single observation |
| <i>variance_bounds</i> (resids[, power]) | Construct loose bounds for conditional variances. |

arch.univariate.APARCH.backcast**APARCH.backcast**(resids)

Construct values for backcasting to start the recursion

Parameters**resids**

[ndarray] Vector of (approximate) residuals

Returns**backcast**

[float] Value to use in backcasting in the volatility recursion

Return type

float | ndarray

arch.univariate.APARCH.backcast_transform

APARCH.**backcast_transform**(*backcast*)

Transformation to apply to user-provided backcast values

Parameters

backcast

[{float, ndarray}] User-provided backcast that approximates $\sigma^2[0]$.

Returns

backcast

[{float, ndarray}] Backcast transformed to the model-appropriate scale

Return type

float | ndarray

arch.univariate.APARCH.bounds

APARCH.**bounds**(*resids*)

Returns bounds for parameters

Parameters

resids

[ndarray] Vector of (approximate) residuals

Returns

bounds

[list[tuple[float, float]]] List of bounds where each element is (lower, upper).

Return type

list[tuple[float, float]]

arch.univariate.APARCH.compute_variance

APARCH.**compute_variance**(*parameters*, *resids*, *sigma2*, *backcast*, *var_bounds*)

Compute the variance for the ARCH model

Parameters

parameters

[ndarray] Model parameters

resids

[ndarray] Vector of mean zero residuals

sigma2

[ndarray] Array with same size as *resids* to store the conditional variance

backcast

[{float, ndarray}] Value to use when initializing ARCH recursion. Can be an ndarray when the model contains multiple components.

var_bounds

[ndarray] Array containing columns of lower and upper bounds

Return type
`ndarray`

arch.univariate.APARCH.constraints

`APARCH.constraints()`

Construct parameter constraints arrays for parameter estimation

Returns

- A**
`[ndarray]` Parameters loadings in constraint. Shape is number of constraints by number of parameters
- b**
`[ndarray]` Constraint values, one for each constraint

Notes

Values returned are used in constructing linear inequality constraints of the form $A \cdot \text{parameters} - b \geq 0$

Return type
`tuple[ndarray, ndarray]`

arch.univariate.APARCH.forecast

`APARCH.forecast(parameters, resids, backcast, var_bounds, start=None, horizon=1, method='analytic', simulations=1000, rng=None, random_state=None)`

Forecast volatility from the model

Parameters

- parameters**
`[{ndarray, Series}]` Parameters required to forecast the volatility model
- resids**
`[ndarray]` Residuals to use in the recursion
- backcast**
`[float]` Value to use when initializing the recursion
- var_bounds**
`[ndarray, 2-d]` Array containing columns of lower and upper bounds
- start**
`[{None, int}]` Index of the first observation to use as the starting point for the forecast. Default is `len(resids)`.
- horizon**
`[int]` Forecast horizon. Must be 1 or larger. Forecasts are produced for horizons in `[1, horizon]`.
- method**
`[{'analytic', 'simulation', 'bootstrap'}]` Method to use when producing the forecast. The default is `analytic`.

simulations

[`int`] Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[`callable()`] Callable random number generator required if method is 'simulation'. Must take a single shape input and return random samples numbers with that shape.

random_state

[`RandomState`, optional] NumPy `RandomState` instance to use when method is 'bootstrap'

Returns**forecasts**

[`VarianceForecast`] Class containing the variance forecasts, and, if using simulation or bootstrap, the simulated paths.

Raises**`NotImplementedError`**

- If method is not supported

`ValueError`

- If the method is not known

Notes

The analytic method is not supported for all models. Attempting to use this method when not available will raise a `ValueError`.

Return type

`VarianceForecast`

`arch.univariate.APARCH.parameter_names`

`APARCH.parameter_names()`

Names of model parameters

Returns**names**

[`list (str)`] Variables names

Return type

`list[str]`

arch.univariate.APARCH.simulate

APARCH.simulate(*parameters*, *nobs*, *rng*, *burn=500*, *initial_value=None*)

Simulate data from the model

Parameters**parameters**

[`ndarray`, `Series`] Parameters required to simulate the volatility model

nobs

[`int`] Number of data points to simulate

rng

[`callable`()] Callable function that takes a single integer input and returns a vector of random numbers

burn

[`int`, `optional`] Number of additional observations to generate when initializing the simulation

initial_value

[`float`, `ndarray`], `optional`] Scalar or array of initial values to use when initializing the simulation

Returns**resids**

[`ndarray`] The simulated residuals

variance

[`ndarray`] The simulated variance

Return type

`tuple`[`ndarray`, `ndarray`]

arch.univariate.APARCH.starting_values

APARCH.starting_values(*resids*)

Returns starting values for the ARCH model

Parameters**resids**

[`ndarray`] Array of (approximate) residuals to use when computing starting values

Returns**sv**

[`ndarray`] Array of starting values

Return type

`ndarray`

arch.univariate.APARCH.update

`APARCH.update(index, parameters, resids, sigma2, backcast, var_bounds)`

Compute the variance for a single observation

Parameters

index

[int] The numerical index of the variance to compute

variance_params

[ndarray] The variance model parameters

resids

The residual array. Only uses `resids[:index]` when computing `sigma2[index]`

sigma2

[ndarray] The array containing the variances. Only uses `sigma2[:index]` when computing `sigma2[index]`. The computed value is stored in `sigma2[index]`.

backcast

[{float, ndarray}] Value to use when initializing the recursion

var_bounds

[ndarray] Array containing columns of lower and upper bounds

Returns

float

The variance computed for location `index`

Return type

float

arch.univariate.APARCH.variance_bounds

`APARCH.variance_bounds(resids, power=2.0)`

Construct loose bounds for conditional variances.

These bounds are used in parameter estimation to ensure that the log-likelihood does not produce NaN values.

Parameters

resids

[ndarray] Approximate residuals to use to compute the lower and upper bounds on the conditional variance

power

[float, optional] Power used in the model. 2.0, the default corresponds to standard ARCH models that evolve in squares.

Returns

var_bounds

[ndarray] Array containing columns of lower and upper bounds with the same number of elements as `resids`

Return type

ndarray

| <i>updateable</i> | Flag indicating that the volatility process supports update |
| <i>volatility_updater</i> | Get the volatility updater associated with the volatility process |

arch.univariate.APARCH.common_asym

property APARCH.common_asym: **bool**

The value of delta in the model. NaN is delta is estimated.

Return type

bool

arch.univariate.APARCH.delta

property APARCH.delta: **float**

The value of delta in the model. NaN is delta is estimated.

Return type

float

arch.univariate.APARCH.name

property APARCH.name: **str**

The name of the volatility process

Return type

str

arch.univariate.APARCH.num_params

property APARCH.num_params: **int**

The number of parameters in the model

Return type

int

arch.univariate.APARCH.start

property APARCH.start: `int`

Index to use to start variance subarray selection

Return type

`int`

arch.univariate.APARCH.stop

property APARCH.stop: `int`

Index to use to stop variance subarray selection

Return type

`int`

arch.univariate.APARCH.updateable

property APARCH.updateable: `bool`

Flag indicating that the volatility process supports update

Return type

`bool`

arch.univariate.APARCH.volatility_updater

property APARCH.volatility_updater: *VolatilityUpdater*

Get the volatility updater associated with the volatility process

Returns

VolatilityUpdater

The updater class

Raises

NotImplementedError

If the process is not updateable

Return type

VolatilityUpdater

1.9.9 Parameterless Variance Processes

Some volatility processes use fixed parameters and so have no parameters that are estimable.

| | |
|--|--|
| <i>EWMAVariance</i> ([lam]) | Exponentially Weighted Moving-Average (RiskMetrics) Variance process |
| <i>RiskMetrics2006</i> ([tau0, tau1, kmax, rho]) | RiskMetrics 2006 Variance process |

arch.univariate.EWMAVariance

class arch.univariate.EWMAVariance(*lam=0.94*)

Exponentially Weighted Moving-Average (RiskMetrics) Variance process

Parameters

lam

[{float, None}, optional] Smoothing parameter. Default is 0.94. Set to None to estimate lam jointly with other model parameters

Notes

The variance dynamics of the model

$$\sigma_t^2 = \lambda\sigma_{t-1}^2 + (1 - \lambda)\epsilon_{t-1}^2$$

When lam is provided, this model has no parameters since the smoothing parameter is treated as fixed. Set lam to None to jointly estimate this parameter when fitting the model.

Examples

Daily RiskMetrics EWMA process

```
>>> from arch.univariate import EWMAVariance
>>> rm = EWMAVariance(0.94)
```

Attributes

name

The name of the volatility process

num_params

The number of parameters in the model

start

Index to use to start variance subarray selection

stop

Index to use to stop variance subarray selection

updateable

Flag indicating that the volatility process supports update

volatility_updater

Get the volatility updater associated with the volatility process

Methods

| | |
|---|---|
| <i>backcast</i> (resids) | Construct values for backcasting to start the recursion |
| <i>backcast_transform</i> (backcast) | Transformation to apply to user-provided backcast values |
| <i>bounds</i> (resids) | Returns bounds for parameters |
| <i>compute_variance</i> (parameters, resids, sigma2, ...) | Compute the variance for the ARCH model |
| <i>constraints</i> () | Construct parameter constraints arrays for parameter estimation |
| <i>forecast</i> (parameters, resids, backcast, ...) | Forecast volatility from the model |
| <i>parameter_names</i> () | Names of model parameters |
| <i>simulate</i> (parameters, nobs, rng[, burn, ...]) | Simulate data from the model |
| <i>starting_values</i> (resids) | Returns starting values for the ARCH model |
| <i>update</i> (index, parameters, resids, sigma2, ...) | Compute the variance for a single observation |
| <i>variance_bounds</i> (resids[, power]) | Construct loose bounds for conditional variances. |

arch.univariate.EWMAVariance.backcast

`EWMAVariance.backcast(resids)`

Construct values for backcasting to start the recursion

Parameters

resids
[ndarray] Vector of (approximate) residuals

Returns

backcast
[float] Value to use in backcasting in the volatility recursion

Return type

float | ndarray

arch.univariate.EWMAVariance.backcast_transform

`EWMAVariance.backcast_transform(backcast)`

Transformation to apply to user-provided backcast values

Parameters

backcast
[float, ndarray] User-provided backcast that approximates sigma2[0].

Returns

backcast
[float, ndarray] Backcast transformed to the model-appropriate scale

Return type

float | ndarray

arch.univariate.EWMAVariance.bounds`EWMAVariance.bounds(resids)`

Returns bounds for parameters

Parameters**resids**
[ndarray] Vector of (approximate) residuals**Returns****bounds**
[list[tuple[float,float]]] List of bounds where each element is (lower, upper).**Return type**

list[tuple[float, float]]

arch.univariate.EWMAVariance.compute_variance`EWMAVariance.compute_variance(parameters, resids, sigma2, backcast, var_bounds)`

Compute the variance for the ARCH model

Parameters**parameters**
[ndarray] Model parameters**resids**
[ndarray] Vector of mean zero residuals**sigma2**
[ndarray] Array with same size as resids to store the conditional variance**backcast**
[float, ndarray] Value to use when initializing ARCH recursion. Can be an ndarray when the model contains multiple components.**var_bounds**
[ndarray] Array containing columns of lower and upper bounds**Return type**

ndarray

arch.univariate.EWMAVariance.constraints`EWMAVariance.constraints()`

Construct parameter constraints arrays for parameter estimation

Returns**A**
[ndarray] Parameters loadings in constraint. Shape is number of constraints by number of parameters**b**
[ndarray] Constraint values, one for each constraint

Notes

Values returned are used in constructing linear inequality constraints of the form $A \cdot \text{dot}(\text{parameters}) - b \geq 0$

Return type

`tuple[ndarray, ndarray]`

`arch.univariate.EWMAVariance.forecast`

`EWMAVariance.forecast(parameters, resids, backcast, var_bounds, start=None, horizon=1, method='analytic', simulations=1000, rng=None, random_state=None)`

Forecast volatility from the model

Parameters

parameters

`[{ndarray, Series}]` Parameters required to forecast the volatility model

resids

`[ndarray]` Residuals to use in the recursion

backcast

`[float]` Value to use when initializing the recursion

var_bounds

`[ndarray, 2-d]` Array containing columns of lower and upper bounds

start

`[{None, int}]` Index of the first observation to use as the starting point for the forecast. Default is `len(resids)`.

horizon

`[int]` Forecast horizon. Must be 1 or larger. Forecasts are produced for horizons in `[1, horizon]`.

method

`[{'analytic', 'simulation', 'bootstrap'}]` Method to use when producing the forecast. The default is `analytic`.

simulations

`[int]` Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

`[callable()]` Callable random number generator required if method is `'simulation'`. Must take a single shape input and return random samples numbers with that shape.

random_state

`[RandomState, optional]` NumPy `RandomState` instance to use when method is `'bootstrap'`

Returns

forecasts

`[VarianceForecast]` Class containing the variance forecasts, and, if using simulation or bootstrap, the simulated paths.

Raises

`NotImplementedError`

- If method is not supported

ValueError

- If the method is not known

Notes

The analytic method is not supported for all models. Attempting to use this method when not available will raise a ValueError.

Return type

VarianceForecast

arch.univariate.EWMAVariance.parameter_names

EWMAVariance.**parameter_names**()

Names of model parameters

Returns

names
[list (str)] Variables names

Return type

list[str]

arch.univariate.EWMAVariance.simulate

EWMAVariance.**simulate**(*parameters*, *nobs*, *rng*, *burn=500*, *initial_value=None*)

Simulate data from the model

Parameters

parameters
[*ndarray*, *Series*] Parameters required to simulate the volatility model

nobs
[*int*] Number of data points to simulate

rng
[*callable*()] Callable function that takes a single integer input and returns a vector of random numbers

burn
[*int*, *optional*] Number of additional observations to generate when initializing the simulation

initial_value
[*float*, *ndarray*], *optional*] Scalar or array of initial values to use when initializing the simulation

Returns

resids
[*ndarray*] The simulated residuals

variance
[ndarray] The simulated variance

Return type
tuple[ndarray, ndarray]

arch.univariate.EWMAVariance.starting_values

EWMAVariance.starting_values(*resids*)

Returns starting values for the ARCH model

Parameters

resids
[ndarray] Array of (approximate) residuals to use when computing starting values

Returns

sv
[ndarray] Array of starting values

Return type
ndarray

arch.univariate.EWMAVariance.update

EWMAVariance.update(*index, parameters, resids, sigma2, backcast, var_bounds*)

Compute the variance for a single observation

Parameters

index
[int] The numerical index of the variance to compute

variance_params
[ndarray] The variance model parameters

resids
The residual array. Only uses `resids[:index]` when computing `sigma2[index]`

sigma2
[ndarray] The array containing the variances. Only uses `sigma2[:index]` when computing `sigma2[index]`. The computed value is stored in `sigma2[index]`.

backcast
[`{float, ndarray}`] Value to use when initializing the recursion

var_bounds
[ndarray] Array containing columns of lower and upper bounds

Returns

float
The variance computed for location `index`

Return type
float

arch.univariate.EWMAVariance.variance_bounds

`EWMAVariance.variance_bounds(resids, power=2.0)`

Construct loose bounds for conditional variances.

These bounds are used in parameter estimation to ensure that the log-likelihood does not produce NaN values.

Parameters

resids

[`ndarray`] Approximate residuals to use to compute the lower and upper bounds on the conditional variance

power

[`float`, optional] Power used in the model. 2.0, the default corresponds to standard ARCH models that evolve in squares.

Returns

var_bounds

[`ndarray`] Array containing columns of lower and upper bounds with the same number of elements as `resids`

Return type

`ndarray`

Properties

| | |
|---------------------------------|---|
| <code>name</code> | The name of the volatility process |
| <code>num_params</code> | The number of parameters in the model |

| <code>stop</code> | Index to use to stop variance subarray selection |
| <code>updateable</code> | Flag indicating that the volatility process supports update |
| <code>volatility_updater</code> | Get the volatility updater associated with the volatility process |

arch.univariate.EWMAVariance.name

property `EWMAVariance.name`: `str`

The name of the volatility process

Return type

`str`

arch.univariate.EWMAVariance.num_params

property EWMAVariance.num_params: `int`

The number of parameters in the model

Return type

`int`

arch.univariate.EWMAVariance.start

property EWMAVariance.start: `int`

Index to use to start variance subarray selection

Return type

`int`

arch.univariate.EWMAVariance.stop

property EWMAVariance.stop: `int`

Index to use to stop variance subarray selection

Return type

`int`

arch.univariate.EWMAVariance.updateable

property EWMAVariance.updateable: `bool`

Flag indicating that the volatility process supports update

Return type

`bool`

arch.univariate.EWMAVariance.volatility_updater

property EWMAVariance.volatility_updater: *VolatilityUpdater*

Get the volatility updater associated with the volatility process

Returns

VolatilityUpdater

The updater class

Raises

NotImplementedError

If the process is not updateable

Return type

VolatilityUpdater

arch.univariate.RiskMetrics2006

```
class arch.univariate.RiskMetrics2006(tau0=1560, tau1=4, kmax=14, rho=1.4142135623730951)
```

RiskMetrics 2006 Variance process

Parameters

tau0

[{int, float}, optional] Length of long cycle. Default is 1560.

tau1

[{int, float}, optional] Length of short cycle. Default is 4.

kmax

[int, optional] Number of components. Default is 14.

rho

[float, optional] Relative scale of adjacent cycles. Default is $\sqrt{2}$

Notes

The variance dynamics of the model are given as a weighted average of kmax EWMA variance processes where the smoothing parameters and weights are determined by tau0, tau1 and rho.

This model has no parameters since the smoothing parameter is fixed.

Examples

Daily RiskMetrics 2006 process

```
>>> from arch.univariate import RiskMetrics2006
>>> rm = RiskMetrics2006()
```

Attributes

name

The name of the volatility process

num_params

The number of parameters in the model

| <code>variance_bounds(resids[, power])</code> | Construct loose bounds for conditional variances. |

arch.univariate.RiskMetrics2006.backcast

RiskMetrics2006.**backcast**(*resids*)

Construct values for backcasting to start the recursion

Parameters

resids

[`ndarray`] Vector of (approximate) residuals

Returns

backcast

[`ndarray`] Backcast values for each EWMA component

Return type

`float` | `ndarray`

arch.univariate.RiskMetrics2006.backcast_transform

RiskMetrics2006.**backcast_transform**(*backcast*)

Transformation to apply to user-provided backcast values

Parameters

backcast

[`{float, ndarray}`] User-provided backcast that approximates `sigma2[0]`.

Returns

backcast

[`{float, ndarray}`] Backcast transformed to the model-appropriate scale

Return type

`float` | `ndarray`

arch.univariate.RiskMetrics2006.bounds

`RiskMetrics2006.bounds`(*resids*)

Returns bounds for parameters

Parameters

resids
[`ndarray`] Vector of (approximate) residuals

Returns

bounds
[`list[tuple[float, float]]`] List of bounds where each element is (lower, upper).

Return type

`list[tuple[float, float]]`

arch.univariate.RiskMetrics2006.compute_variance

`RiskMetrics2006.compute_variance`(*parameters*, *resids*, *sigma2*, *backcast*, *var_bounds*)

Compute the variance for the ARCH model

Parameters

parameters
[`ndarray`] Model parameters

resids
[`ndarray`] Vector of mean zero residuals

sigma2
[`ndarray`] Array with same size as *resids* to store the conditional variance

backcast
[`{float, ndarray}`] Value to use when initializing ARCH recursion. Can be an `ndarray` when the model contains multiple components.

var_bounds
[`ndarray`] Array containing columns of lower and upper bounds

Return type

`ndarray`

arch.univariate.RiskMetrics2006.constraints

`RiskMetrics2006.constraints`()

Construct parameter constraints arrays for parameter estimation

Returns

A
[`ndarray`] Parameters loadings in constraint. Shape is number of constraints by number of parameters

b
[`ndarray`] Constraint values, one for each constraint

Notes

Values returned are used in constructing linear inequality constraints of the form $A \cdot \text{parameters} - b \geq 0$

Return type

`tuple[ndarray, ndarray]`

`arch.univariate.RiskMetrics2006.forecast`

`RiskMetrics2006.forecast(parameters, resids, backcast, var_bounds, start=None, horizon=1, method='analytic', simulations=1000, rng=None, random_state=None)`

Forecast volatility from the model

Parameters

parameters

`[{ndarray, Series}]` Parameters required to forecast the volatility model

resids

`[ndarray]` Residuals to use in the recursion

backcast

`[float]` Value to use when initializing the recursion

var_bounds

`[ndarray, 2-d]` Array containing columns of lower and upper bounds

start

`[{None, int}]` Index of the first observation to use as the starting point for the forecast. Default is `len(resids)`.

horizon

`[int]` Forecast horizon. Must be 1 or larger. Forecasts are produced for horizons in `[1, horizon]`.

method

`[{'analytic', 'simulation', 'bootstrap'}]` Method to use when producing the forecast. The default is `analytic`.

simulations

`[int]` Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

`[callable()]` Callable random number generator required if method is `'simulation'`. Must take a single shape input and return random samples numbers with that shape.

random_state

`[RandomState, optional]` NumPy `RandomState` instance to use when method is `'bootstrap'`

Returns

forecasts

`[VarianceForecast]` Class containing the variance forecasts, and, if using simulation or bootstrap, the simulated paths.

Raises

`NotImplementedError`

- If method is not supported

ValueError

- If the method is not known

Notes

The analytic method is not supported for all models. Attempting to use this method when not available will raise a ValueError.

Return type

VarianceForecast

arch.univariate.RiskMetrics2006.parameter_names

RiskMetrics2006.**parameter_names**()

Names of model parameters

Returns

names

[list (str)] Variables names

Return type

list[str]

arch.univariate.RiskMetrics2006.simulate

RiskMetrics2006.**simulate**(*parameters, nobs, rng, burn=500, initial_value=None*)

Simulate data from the model

Parameters

parameters

[{ndarray, Series}] Parameters required to simulate the volatility model

nobs

[int] Number of data points to simulate

rng

[callable()] Callable function that takes a single integer input and returns a vector of random numbers

burn

[int, optional] Number of additional observations to generate when initializing the simulation

initial_value

[{float, ndarray}, optional] Scalar or array of initial values to use when initializing the simulation

Returns

resids

[ndarray] The simulated residuals

variance

[ndarray] The simulated variance

Return type

tuple[ndarray, ndarray]

arch.univariate.RiskMetrics2006.starting_values

RiskMetrics2006.**starting_values**(*resids*)

Returns starting values for the ARCH model

Parameters

resids

[ndarray] Array of (approximate) residuals to use when computing starting values

Returns

sv

[ndarray] Array of starting values

Return type

ndarray

arch.univariate.RiskMetrics2006.update

RiskMetrics2006.**update**(*index, parameters, resids, sigma2, backcast, var_bounds*)

Compute the variance for a single observation

Parameters

index

[int] The numerical index of the variance to compute

variance_params

[ndarray] The variance model parameters

resids

The residual array. Only uses `resids[:index]` when computing `sigma2[index]`

sigma2

[ndarray] The array containing the variances. Only uses `sigma2[:index]` when computing `sigma2[index]`. The computed value is stored in `sigma2[index]`.

backcast

[{float, ndarray}] Value to use when initializing the recursion

var_bounds

[ndarray] Array containing columns of lower and upper bounds

Returns

float

The variance computed for location `index`

Return type

float

arch.univariate.RiskMetrics2006.variance_bounds

RiskMetrics2006.**variance_bounds**(*resids*, *power=2.0*)

Construct loose bounds for conditional variances.

These bounds are used in parameter estimation to ensure that the log-likelihood does not produce NaN values.

Parameters

resids

[`ndarray`] Approximate residuals to use to compute the lower and upper bounds on the conditional variance

power

[`float`, optional] Power used in the model. 2.0, the default corresponds to standard ARCH models that evolve in squares.

Returns

var_bounds

[`ndarray`] Array containing columns of lower and upper bounds with the same number of elements as `resids`

Return type

`ndarray`

arch.univariate.RiskMetrics2006.name

property RiskMetrics2006.**name**: `str`

The name of the volatility process

Return type

`str`

`arch.univariate.RiskMetrics2006.num_params`

property `RiskMetrics2006.num_params`: `int`

The number of parameters in the model

Return type

`int`

`arch.univariate.RiskMetrics2006.start`

property `RiskMetrics2006.start`: `int`

Index to use to start variance subarray selection

Return type

`int`

`arch.univariate.RiskMetrics2006.stop`

property `RiskMetrics2006.stop`: `int`

Index to use to stop variance subarray selection

Return type

`int`

`arch.univariate.RiskMetrics2006.updateable`

property `RiskMetrics2006.updateable`: `bool`

Flag indicating that the volatility process supports update

Return type

`bool`

`arch.univariate.RiskMetrics2006.volatility_updater`

property `RiskMetrics2006.volatility_updater`: *VolatilityUpdater*

Get the volatility updater associated with the volatility process

Returns

VolatilityUpdater

The updater class

Raises

NotImplementedError

If the process is not updateable

Return type

VolatilityUpdater

1.9.10 FixedVariance

The `FixedVariance` class is a special-purpose volatility process that allows the so-called zig-zag algorithm to be used. See the example for usage.

| | |
|--|--------------------------|
| <code>FixedVariance(variance[, unit_scale])</code> | Fixed volatility process |
|--|--------------------------|

arch.univariate.FixedVariance

class `arch.univariate.FixedVariance`(*variance*, *unit_scale=False*)

Fixed volatility process

Parameters

variance

[`array`, `Series`] Array containing the variances to use. Should have the same shape as the data used in the model.

unit_scale

[`bool`, `optional`] Flag whether to enforce a unit scale. If `False`, a scale parameter will be estimated so that the model variance will be proportional to `variance`. If `True`, the model variance is set of `variance`

Notes

Allows a fixed set of variances to be used when estimating a mean model, allowing GLS estimation.

Attributes

name

The name of the volatility process

num_params

The number of parameters in the model

start

Index to use to start variance subarray selection

stop

Index to use to stop variance subarray selection

updateable

Flag indicating that the volatility process supports update

volatility_updater

Get the volatility updater associated with the volatility process

Methods

| | |
|--|---|
| <code>backcast(resids)</code> | Construct values for backcasting to start the recursion |
| <code>backcast_transform(backcast)</code> | Transformation to apply to user-provided backcast values |
| <code>bounds(resids)</code> | Returns bounds for parameters |
| <code>compute_variance(parameters, resids, sigma2, ...)</code> | Compute the variance for the ARCH model |
| <code>constraints()</code> | Construct parameter constraints arrays for parameter estimation |
| <code>forecast(parameters, resids, backcast, ...)</code> | Forecast volatility from the model |
| <code>parameter_names()</code> | Names of model parameters |
| <code>simulate(parameters, nobs, rng[, burn, ...])</code> | Simulate data from the model |
| <code>starting_values(resids)</code> | Returns starting values for the ARCH model |
| <code>update(index, parameters, resids, sigma2, ...)</code> | Compute the variance for a single observation |
| <code>variance_bounds(resids[, power])</code> | Construct loose bounds for conditional variances. |

arch.univariate.FixedVariance.backcast

FixedVariance.**backcast**(*resids*)

Construct values for backcasting to start the recursion

Parameters

resids
[ndarray] Vector of (approximate) residuals

Returns

backcast
[float] Value to use in backcasting in the volatility recursion

Return type

float | ndarray

arch.univariate.FixedVariance.backcast_transform

FixedVariance.**backcast_transform**(*backcast*)

Transformation to apply to user-provided backcast values

Parameters

backcast
[{{float, ndarray}}] User-provided backcast that approximates sigma2[0].

Returns

backcast
[{{float, ndarray}}] Backcast transformed to the model-appropriate scale

Return type

float | ndarray

arch.univariate.FixedVariance.bounds

FixedVariance.**bounds**(*resids*)

Returns bounds for parameters

Parameters

resids
[ndarray] Vector of (approximate) residuals

Returns

bounds
[list[tuple[float,float]]] List of bounds where each element is (lower, upper).

Return type

list[tuple[float, float]]

arch.univariate.FixedVariance.compute_variance

FixedVariance.**compute_variance**(*parameters, resids, sigma2, backcast, var_bounds*)

Compute the variance for the ARCH model

Parameters

parameters
[ndarray] Model parameters

resids
[ndarray] Vector of mean zero residuals

sigma2
[ndarray] Array with same size as resids to store the conditional variance

backcast
[float, ndarray] Value to use when initializing ARCH recursion. Can be an ndarray when the model contains multiple components.

var_bounds
[ndarray] Array containing columns of lower and upper bounds

Return type

ndarray

arch.univariate.FixedVariance.constraints

FixedVariance.**constraints**()

Construct parameter constraints arrays for parameter estimation

Returns

A
[ndarray] Parameters loadings in constraint. Shape is number of constraints by number of parameters

b
[ndarray] Constraint values, one for each constraint

Notes

Values returned are used in constructing linear inequality constraints of the form $A \cdot \text{parameters} - b \geq 0$

Return type

`tuple[ndarray, ndarray]`

`arch.univariate.FixedVariance.forecast`

`FixedVariance.forecast(parameters, resids, backcast, var_bounds, start=None, horizon=1, method='analytic', simulations=1000, rng=None, random_state=None)`

Forecast volatility from the model

Parameters

parameters

`[ndarray, Series]` Parameters required to forecast the volatility model

resids

`[ndarray]` Residuals to use in the recursion

backcast

`[float]` Value to use when initializing the recursion

var_bounds

`[ndarray, 2-d]` Array containing columns of lower and upper bounds

start

`[None, int]` Index of the first observation to use as the starting point for the forecast. Default is `len(resids)`.

horizon

`[int]` Forecast horizon. Must be 1 or larger. Forecasts are produced for horizons in `[1, horizon]`.

method

`['analytic', 'simulation', 'bootstrap']` Method to use when producing the forecast. The default is `analytic`.

simulations

`[int]` Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

`[callable()]` Callable random number generator required if method is `'simulation'`. Must take a single shape input and return random samples numbers with that shape.

random_state

`[RandomState, optional]` NumPy `RandomState` instance to use when method is `'bootstrap'`

Returns

forecasts

`[VarianceForecast]` Class containing the variance forecasts, and, if using simulation or bootstrap, the simulated paths.

Raises

`NotImplementedError`

- If method is not supported

ValueError

- If the method is not known

Notes

The analytic method is not supported for all models. Attempting to use this method when not available will raise a ValueError.

Return type

VarianceForecast

arch.univariate.FixedVariance.parameter_names

FixedVariance.**parameter_names**()

Names of model parameters

Returns

names

[list (str)] Variables names

Return type

list[str]

arch.univariate.FixedVariance.simulate

FixedVariance.**simulate**(parameters, nobs, rng, burn=500, initial_value=None)

Simulate data from the model

Parameters

parameters

[{ndarray, Series}] Parameters required to simulate the volatility model

nobs

[int] Number of data points to simulate

rng

[callable()] Callable function that takes a single integer input and returns a vector of random numbers

burn

[int, optional] Number of additional observations to generate when initializing the simulation

initial_value

[{float, ndarray}, optional] Scalar or array of initial values to use when initializing the simulation

Returns

resids

[ndarray] The simulated residuals

variance
[ndarray] The simulated variance

Return type
tuple[ndarray, ndarray]

arch.univariate.FixedVariance.starting_values

FixedVariance.**starting_values**(*resids*)

Returns starting values for the ARCH model

Parameters

resids
[ndarray] Array of (approximate) residuals to use when computing starting values

Returns

sv
[ndarray] Array of starting values

Return type
ndarray

arch.univariate.FixedVariance.update

FixedVariance.**update**(*index, parameters, resids, sigma2, backcast, var_bounds*)

Compute the variance for a single observation

Parameters

index
[int] The numerical index of the variance to compute

variance_params
[ndarray] The variance model parameters

resids
The residual array. Only uses `resids[:index]` when computing `sigma2[index]`

sigma2
[ndarray] The array containing the variances. Only uses `sigma2[:index]` when computing `sigma2[index]`. The computed value is stored in `sigma2[index]`.

backcast
[`{float, ndarray}`] Value to use when initializing the recursion

var_bounds
[ndarray] Array containing columns of lower and upper bounds

Returns

float
The variance computed for location `index`

Return type
float

arch.univariate.FixedVariance.variance_bounds

FixedVariance.**variance_bounds**(*resids*, *power=2.0*)

Construct loose bounds for conditional variances.

These bounds are used in parameter estimation to ensure that the log-likelihood does not produce NaN values.

Parameters

resids

[`ndarray`] Approximate residuals to use to compute the lower and upper bounds on the conditional variance

power

[`float`, optional] Power used in the model. 2.0, the default corresponds to standard ARCH models that evolve in squares.

Returns

var_bounds

[`ndarray`] Array containing columns of lower and upper bounds with the same number of elements as *resids*

Return type

`ndarray`

Properties

| | |
|---------------------------|---|
| <i>name</i> | The name of the volatility process |
| <i>num_params</i> | The number of parameters in the model |
| <i>start</i> | Index to use to start variance subarray selection |
| <i>stop</i> | Index to use to stop variance subarray selection |
| <i>updateable</i> | Flag indicating that the volatility process supports update |
| <i>volatility_updater</i> | Get the volatility updater associated with the volatility process |

arch.univariate.FixedVariance.name

property FixedVariance.**name**: `str`

The name of the volatility process

Return type

`str`

arch.univariate.FixedVariance.num_params

property FixedVariance.num_params: `int`

The number of parameters in the model

Return type

`int`

arch.univariate.FixedVariance.start

property FixedVariance.start: `int`

Index to use to start variance subarray selection

Return type

`int`

arch.univariate.FixedVariance.stop

property FixedVariance.stop: `int`

Index to use to stop variance subarray selection

Return type

`int`

arch.univariate.FixedVariance.updateable

property FixedVariance.updateable: `bool`

Flag indicating that the volatility process supports update

Return type

`bool`

arch.univariate.FixedVariance.volatility_updater

property FixedVariance.volatility_updater: *VolatilityUpdater*

Get the volatility updater associated with the volatility process

Returns

VolatilityUpdater

The updater class

Raises

NotImplementedError

If the process is not updateable

Return type

VolatilityUpdater

1.9.11 Writing New Volatility Processes

All volatility processes must inherit from *VolatilityProcess* and provide all public methods.

| | |
|-----------------------------|--------------------------------------|
| <i>VolatilityProcess</i> () | Abstract base class for ARCH models. |
|-----------------------------|--------------------------------------|

arch.univariate.volatility.VolatilityProcess

class arch.univariate.volatility.VolatilityProcess

Abstract base class for ARCH models. Allows the conditional mean model to be specified separately from the conditional variance, even though parameters are estimated jointly.

Attributes

- name*
The name of the volatility process
- num_params*
The number of parameters in the model
- start*
Index to use to start variance subarray selection
- stop*
Index to use to stop variance subarray selection
- updateable*
Flag indicating that the volatility process supports update
- volatility_updater*
Get the volatility updater associated with the volatility process

Methods

| | |
|---|---|
| <i>backcast</i> (resids) | Construct values for backcasting to start the recursion |
| <i>backcast_transform</i> (backcast) | Transformation to apply to user-provided backcast values |
| <i>bounds</i> (resids) | Returns bounds for parameters |
| <i>compute_variance</i> (parameters, resids, sigma2, ...) | Compute the variance for the ARCH model |
| <i>constraints</i> () | Construct parameter constraints arrays for parameter estimation |
| <i>forecast</i> (parameters, resids, backcast, ...) | Forecast volatility from the model |
| <i>parameter_names</i> () | Names of model parameters |
| <i>simulate</i> (parameters, nobs, rng[, burn, ...]) | Simulate data from the model |
| <i>starting_values</i> (resids) | Returns starting values for the ARCH model |
| <i>update</i> (index, parameters, resids, sigma2, ...) | Compute the variance for a single observation |
| <i>variance_bounds</i> (resids[, power]) | Construct loose bounds for conditional variances. |

arch.univariate.volatility.VolatilityProcess.backcast

`VolatilityProcess.backcast`(*resids*)

Construct values for backcasting to start the recursion

Parameters

resids
[`ndarray`] Vector of (approximate) residuals

Returns

backcast
[`float`] Value to use in backcasting in the volatility recursion

Return type

`float` | `ndarray`

arch.univariate.volatility.VolatilityProcess.backcast_transform

`VolatilityProcess.backcast_transform`(*backcast*)

Transformation to apply to user-provided backcast values

Parameters

backcast
[`{float, ndarray}`] User-provided backcast that approximates $\sigma^2[0]$.

Returns

backcast
[`{float, ndarray}`] Backcast transformed to the model-appropriate scale

Return type

`float` | `ndarray`

arch.univariate.volatility.VolatilityProcess.bounds

abstract `VolatilityProcess.bounds`(*resids*)

Returns bounds for parameters

Parameters

resids
[`ndarray`] Vector of (approximate) residuals

Returns

bounds
[`list[tuple[float, float]]`] List of bounds where each element is (lower, upper).

Return type

`list[tuple[float, float]]`

arch.univariate.volatility.VolatilityProcess.compute_variance**abstract** VolatilityProcess.compute_variance(*parameters*, *resids*, *sigma2*, *backcast*, *var_bounds*)

Compute the variance for the ARCH model

Parameters**parameters**`[ndarray]` Model parameters**resids**`[ndarray]` Vector of mean zero residuals**sigma2**`[ndarray]` Array with same size as `resids` to store the conditional variance**backcast**`[{float, ndarray}]` Value to use when initializing ARCH recursion. Can be an ndarray when the model contains multiple components.**var_bounds**`[ndarray]` Array containing columns of lower and upper bounds**Return type**`ndarray`**arch.univariate.volatility.VolatilityProcess.constraints****abstract** VolatilityProcess.constraints()

Construct parameter constraints arrays for parameter estimation

Returns**A**`[ndarray]` Parameters loadings in constraint. Shape is number of constraints by number of parameters**b**`[ndarray]` Constraint values, one for each constraint**Notes**Values returned are used in constructing linear inequality constraints of the form $A \cdot \text{dot}(\text{parameters}) - b \geq 0$ **Return type**`tuple[ndarray, ndarray]`

arch.univariate.volatility.VolatilityProcess.forecast

`VolatilityProcess.forecast(parameters, resids, backcast, var_bounds, start=None, horizon=1, method='analytic', simulations=1000, rng=None, random_state=None)`

Forecast volatility from the model

Parameters**parameters**

`[[ndarray, Series]]` Parameters required to forecast the volatility model

resids

`[ndarray]` Residuals to use in the recursion

backcast

`[float]` Value to use when initializing the recursion

var_bounds

`[ndarray, 2-d]` Array containing columns of lower and upper bounds

start

`[[None, int]]` Index of the first observation to use as the starting point for the forecast. Default is `len(resids)`.

horizon

`[int]` Forecast horizon. Must be 1 or larger. Forecasts are produced for horizons in `[1, horizon]`.

method

`['analytic', 'simulation', 'bootstrap']` Method to use when producing the forecast. The default is `analytic`.

simulations

`[int]` Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

`[callable()]` Callable random number generator required if method is `'simulation'`. Must take a single shape input and return random samples numbers with that shape.

random_state

`[RandomState, optional]` NumPy `RandomState` instance to use when method is `'bootstrap'`

Returns**forecasts**

`[VarianceForecast]` Class containing the variance forecasts, and, if using simulation or bootstrap, the simulated paths.

Raises**NotImplementedError**

- If method is not supported

ValueError

- If the method is not known

Notes

The analytic method is not supported for all models. Attempting to use this method when not available will raise a `ValueError`.

Return type

`VarianceForecast`

`arch.univariate.volatility.VolatilityProcess.parameter_names`

abstract `VolatilityProcess.parameter_names()`

Names of model parameters

Returns

names

`[list (str)]` Variables names

Return type

`list[str]`

`arch.univariate.volatility.VolatilityProcess.simulate`

abstract `VolatilityProcess.simulate(parameters, nobs, rng, burn=500, initial_value=None)`

Simulate data from the model

Parameters

parameters

`[{ndarray, Series}]` Parameters required to simulate the volatility model

nobs

`[int]` Number of data points to simulate

rng

`[callable()]` Callable function that takes a single integer input and returns a vector of random numbers

burn

`[int, optional]` Number of additional observations to generate when initializing the simulation

initial_value

`[{float, ndarray}, optional]` Scalar or array of initial values to use when initializing the simulation

Returns

resids

`[ndarray]` The simulated residuals

variance

`[ndarray]` The simulated variance

Return type

`tuple[ndarray, ndarray]`

arch.univariate.volatility.VolatilityProcess.starting_values**abstract** VolatilityProcess.starting_values(*resids*)

Returns starting values for the ARCH model

Parameters**resids**`[ndarray]` Array of (approximate) residuals to use when computing starting values**Returns****sv**`[ndarray]` Array of starting values**Return type**`ndarray`**arch.univariate.volatility.VolatilityProcess.update**VolatilityProcess.update(*index*, *parameters*, *resids*, *sigma2*, *backcast*, *var_bounds*)

Compute the variance for a single observation

Parameters**index**`[int]` The numerical index of the variance to compute**variance_params**`[ndarray]` The variance model parameters**resids**The residual array. Only uses `resids[:index]` when computing `sigma2[index]`**sigma2**`[ndarray]` The array containing the variances. Only uses `sigma2[:index]` when computing `sigma2[index]`. The computed value is stored in `sigma2[index]`.**backcast**`[{float, ndarray}]` Value to use when initializing the recursion**var_bounds**`[ndarray]` Array containing columns of lower and upper bounds**Returns****float**The variance computed for location `index`**Return type**`float`

arch.univariate.volatility.VolatilityProcess.variance_bounds

VolatilityProcess.**variance_bounds**(*resids*, *power=2.0*)

Construct loose bounds for conditional variances.

These bounds are used in parameter estimation to ensure that the log-likelihood does not produce NaN values.

Parameters

resids

[[ndarray](#)] Approximate residuals to use to compute the lower and upper bounds on the conditional variance

power

[[float](#), optional] Power used in the model. 2.0, the default corresponds to standard ARCH models that evolve in squares.

Returns

var_bounds

[[ndarray](#)] Array containing columns of lower and upper bounds with the same number of elements as *resids*

Return type

[ndarray](#)

Properties

| | |
|---------------------------|---|
| <i>name</i> | The name of the volatility process |
| <i>num_params</i> | The number of parameters in the model |
| <i>start</i> | Index to use to start variance subarray selection |
| <i>stop</i> | Index to use to stop variance subarray selection |
| <i>updateable</i> | Flag indicating that the volatility process supports update |
| <i>volatility_updater</i> | Get the volatility updater associated with the volatility process |

arch.univariate.volatility.VolatilityProcess.name

property VolatilityProcess.**name**: [str](#)

The name of the volatility process

Return type

[str](#)

arch.univariate.volatility.VolatilityProcess.num_params

property VolatilityProcess.num_params: `int`

The number of parameters in the model

Return type

`int`

arch.univariate.volatility.VolatilityProcess.start

property VolatilityProcess.start: `int`

Index to use to start variance subarray selection

Return type

`int`

arch.univariate.volatility.VolatilityProcess.stop

property VolatilityProcess.stop: `int`

Index to use to stop variance subarray selection

Return type

`int`

arch.univariate.volatility.VolatilityProcess.updateable

property VolatilityProcess.updateable: `bool`

Flag indicating that the volatility process supports update

Return type

`bool`

arch.univariate.volatility.VolatilityProcess.volatility_updater

property VolatilityProcess.volatility_updater: *VolatilityUpdater*

Get the volatility updater associated with the volatility process

Returns

VolatilityUpdater

The updater class

Raises

NotImplementedError

If the process is not updateable

Return type

VolatilityUpdater

They may optionally expose a *VolatilityUpdater* class that can be used in *ARCHInMean* estimation.

| | |
|-----------------------------|--|
| <i>VolatilityUpdater</i> () | Base class that all volatility updaters must inherit from. |
|-----------------------------|--|

arch.univariate.recursions_python.VolatilityUpdater

class arch.univariate.recursions_python.VolatilityUpdater

Base class that all volatility updaters must inherit from.

Notes

See the implementation available for information on modifying `__init__` to capture model-specific parameters and how `initialize_update` is used to precompute values that change in each likelihood but not each iteration of the recursion.

When writing a volatility updater, it is recommended to follow the examples in `recursions.pyx` which use Cython to produce a C-callable update function that can then be used to improve performance. The subclasses of this abstract metaclass are all pure Python and model estimation performance is poor since loops are written in Python.

Methods

| | |
|---|--|
| <i>initialize_update</i> (parameters, backcast, nobs) | Initialize the recursion prior to calling update |
| <i>update</i> (t, parameters, resids, sigma2, var_bounds) | Update the current variance at location t |

arch.univariate.recursions_python.VolatilityUpdater.initialize_update

abstract VolatilityUpdater.*initialize_update*(*parameters*, *backcast*, *nobs*)

Initialize the recursion prior to calling update

Parameters

parameters

[ndarray] The model parameters.

backcast

[{float, ndarray}] The backcast value(s).

nobs

[int] The number of observations in the sample.

Notes

This function is called once per likelihood evaluation and can be used to pre-compute expensive parameter transformations that do not change with each call to `update`.

Return type

None

`arch.univariate.recursions_python.VolatilityUpdater.update`

abstract `VolatilityUpdater.update(t, parameters, resids, sigma2, var_bounds)`

Update the current variance at location `t`

Parameters

t

[int] The index of the value of `sigma2` to update. Assumes but does not check that update has been called recursively for $0, 1, \dots, t-1$.

parameters

[ndarray] Model parameters

resids

[ndarray] Residuals to use in the recursion

sigma2

[ndarray] Conditional variances with same shape as `resids`

var_bounds

[ndarray] nobs by 2-element array of upper and lower bounds for conditional variances for each time period

Notes

The update to `sigma2` occurs inplace.

Return type

None

1.10 Using the Fixed Variance process

The `FixedVariance` volatility process can be used to implement zig-zag model estimation where two steps are repeated until convergence. This can be used to estimate models which may not be easy to estimate as a single process due to numerical issues or a high-dimensional parameter space.

This setup code is required to run in an IPython notebook

```
[1]: %matplotlib inline
import matplotlib.pyplot as plt
import seaborn

seaborn.set_style("darkgrid")
plt.rc("figure", figsize=(16, 6))
plt.rc("savefig", dpi=90)
```

(continues on next page)

(continued from previous page)

```
plt.rc("font", family="sans-serif")
plt.rc("font", size=14)
```

1.10.1 Setup

Imports used in this example.

```
[2]: import datetime as dt
import numpy as np
```

Data

The VIX index will be used to illustrate the use of the FixedVariance process. The data is from FRED and is provided by the arch package.

```
[3]: import arch.data.vix

vix_data = arch.data.vix.load()
vix = vix_data.vix.dropna()
vix.name = "VIX Index"
ax = vix.plot(title="VIX Index")
```

nbsphinx-code-borderwhite

Initial Mean Model Estimation

The first step is to estimate the mean to filter the residuals using a constant variance.

```
[4]: from arch.univariate.mean import HARX, ZeroMean
from arch.univariate.volatility import GARCH, FixedVariance

mod = HARX(vix, lags=[1, 5, 22])
res = mod.fit()
print(res.summary())
```

```

Initial Volatility Model Estimation

Using the previously estimated residuals, a volatility model can be estimated using a ZeroMean. In this example, a GJR-GARCH process is used for the variance.

```
[5]: vol_mod = ZeroMean(res.resid.dropna(), volatility=GARCH(p=1, o=1, q=1))
vol_res = vol_mod.fit(dispatch="off")
print(vol_res.summary())
```

```

nbsphinx-code-borderwhite

Re-estimating the mean with a FixedVariance

The `FixedVariance` requires that the variance is provided when initializing the object. The variance provided should have the same shape as the original data. Since the variance estimated from the GJR-GARCH model is missing the first 22 observations due to the HAR lags, we simply fill these with 1. These values will not be used to estimate the model, and so the value is not important.

The summary shows that there is a single parameter, `scale`, which is close to 1. The mean parameters have changed which reflects the GLS-like weighting that this re-estimation imposes.

```
[7]: variance = np.empty_like(vix)
variance.fill(1.0)
variance[22:] = vol_res.conditional_volatility**2.0
fv = FixedVariance(variance)
mod = HARX(vix, lags=[1, 5, 22], volatility=fv)
res = mod.fit()
print(res.summary())
```

Covariance estimator: robust

1.11 Distributions

A distribution is the final component of an ARCH Model.

| | |
|--|---|
| <i>Normal</i> ([random_state, seed]) | Standard normal distribution for use with ARCH models |
| <i>StudentsT</i> ([random_state, seed]) | Standardized Student's distribution for use with ARCH models |
| <i>SkewStudent</i> ([random_state, seed]) | Standardized Skewed Student's distribution for use with ARCH models |
| <i>GeneralizedError</i> ([random_state, seed]) | Generalized Error distribution for use with ARCH models |

1.11.1 arch.univariate.Normal

class arch.univariate.**Normal**(random_state=None, *, seed=None)

Standard normal distribution for use with ARCH models

Parameters

random_state

[[RandomState](#), optional] Deprecated since version 5.0: random_state is deprecated. Use seed instead.

seed

[{int, Generator, [RandomState](#)}, optional] Random number generator instance or int to use. Set to ensure reproducibility. If using an int, the argument is passed to `np.random.default_rng`. If not provided, `default_rng` is used with system-provided entropy.

Attributes

generator

The NumPy Generator or RandomState attached to the distribution

name

The name of the distribution

random_state

The NumPy RandomState attached to the distribution

Methods

| | |
|--|---|
| <i>bounds</i> (resids) | Parameter bounds for use in optimization. |
| <i>cdf</i> (resids[, parameters]) | Cumulative distribution function |
| <i>constraints</i> () | Construct arrays to use in constrained optimization. |
| <i>loglikelihood</i> (parameters, resids, sigma2[, ...]) | Computes the log-likelihood of assuming residuals are normally distributed, conditional on the variance |
| <i>moment</i> (n[, parameters]) | Moment of order n |
| <i>parameter_names</i> () | Names of distribution shape parameters |
| <i>partial_moment</i> (n[, z, parameters]) | Order n lower partial moment from -inf to z |
| <i>ppf</i> (pits[, parameters]) | Inverse cumulative density function (ICDF) |
| <i>simulate</i> (parameters) | Simulates i.i.d. |
| <i>starting_values</i> (std_resid) | Construct starting values for use in optimization. |

arch.univariate.Normal.bounds

Normal.**bounds**(*resids*)

Parameter bounds for use in optimization.

Parameters

resids

[`ndarray`] Residuals to use when computing the bounds

Returns

bounds

[`list`] List containing a single tuple with (lower, upper) bounds

Return type

`list[tuple[float, float]]`

arch.univariate.Normal.cdf

Normal.**cdf**(*resids*, *parameters=None*)

Cumulative distribution function

Parameters

resids

[`ndarray`] Values at which to evaluate the cdf

parameters

[`ndarray`] Distribution parameters. Use `None` for parameterless distributions.

Returns

f

[`ndarray`] CDF values

Return type

`ndarray`

arch.univariate.Normal.constraints

Normal.**constraints**()

Construct arrays to use in constrained optimization.

Returns

A

[`ndarray`] Constraint loadings

b

[`ndarray`] Constraint values

Notes

Parameters satisfy the constraints $A \cdot \text{dot}(\text{parameters}) - b \geq 0$

Return type

`tuple[ndarray, ndarray]`

arch.univariate.Normal.loglikelihood

`Normal.loglikelihood(parameters, resids, sigma2, individual=False)`

Computes the log-likelihood of assuming residuals are normally distributed, conditional on the variance

Parameters

parameters

`[ndarray]` The normal likelihood has no shape parameters. Empty since the standard normal has no shape parameters.

resids

`[ndarray]` The residuals to use in the log-likelihood calculation

sigma2

`[ndarray]` Conditional variances of resids

individual

`[bool, optional]` Flag indicating whether to return the vector of individual log likelihoods (True) or the sum (False)

Returns

ll

`[float]` The log-likelihood

Notes

The log-likelihood of a single data point x is

$$\ln f(x) = -\frac{1}{2} \left(\ln 2\pi + \ln \sigma^2 + \frac{x^2}{\sigma^2} \right)$$

Return type

`float | ndarray`

arch.univariate.Normal.moment

`Normal.moment(n, parameters=None)`

Moment of order n

Parameters

n

`[int]` Order of moment

parameters

`[ndarray, optional]` Distribution parameters. Use None for parameterless distributions.

Returns

float

Calculated moment

Return type

float

arch.univariate.Normal.parameter_namesNormal.**parameter_names**()

Names of distribution shape parameters

Returns**names**

[list (str)] Parameter names

Return type

list[str]

arch.univariate.Normal.partial_momentNormal.**partial_moment**(*n*, *z=0.0*, *parameters=None*)Order *n* lower partial moment from -inf to *z***Parameters****n**

[int] Order of partial moment

z

[float, optional] Upper bound for partial moment integral

parameters

[ndarray, optional] Distribution parameters. Use None for parameterless distributions.

Returns**float**

Partial moment

NotesThe order *n* lower partial moment to *z* is

$$\int_{-\infty}^z x^n f(x) dx$$

See [1] for more details.

References

[1]

Return type
float

arch.univariate.Normal.ppf

Normal.ppf(*pits*, *parameters=None*)

Inverse cumulative density function (ICDF)

Parameters

pits
[`float`, `ndarray`] Probability-integral-transformed values in the interval (0, 1).

parameters
[`ndarray`, `optional`] Distribution parameters. Use `None` for parameterless distributions.

Returns

i
[`float`, `ndarray`] Inverse CDF values

Return type
`ndarray`

arch.univariate.Normal.simulate

Normal.simulate(*parameters*)

Simulates i.i.d. draws from the distribution

Parameters

parameters
[`ndarray`] Distribution parameters

Returns

simulator
[`callable()`] Callable that take a single output size argument and returns i.i.d. draws from the distribution

Return type
`Callable[[int | tuple[int, ...]], ndarray]`

arch.univariate.Normal.starting_values

`Normal.starting_values(std_resid)`

Construct starting values for use in optimization.

Parameters

std_resid

[`ndarray`] Estimated standardized residuals to use in computing starting values for the shape parameter

Returns

sv

[`ndarray`] The estimated shape parameters for the distribution

Notes

Size of `sv` depends on the distribution

Return type

`ndarray`

Properties

| | |
|---------------------|---|
| <i>generator</i> | The NumPy Generator or RandomState attached to the distribution |
| <i>name</i> | The name of the distribution |
| <i>random_state</i> | The NumPy RandomState attached to the distribution |

arch.univariate.Normal.generator

property `Normal.generator`: `numpy.random.mtrand.RandomState` | `numpy.random._generator.Generator`

The NumPy Generator or RandomState attached to the distribution

Return type

`RandomState` | `Generator`

arch.univariate.Normal.name

property `Normal.name`: `str`

The name of the distribution

Return type

`str`

arch.univariate.Normal.random_state

property `Normal.random_state`: `numpy.random.mtrand.RandomState` | `numpy.random._generator.Generator`

The NumPy RandomState attached to the distribution

Deprecated since version 5.0: `random_state` is deprecated. Use `generator` instead.

Return type

`RandomState` | `Generator`

1.11.2 arch.univariate.StudentsT

class `arch.univariate.StudentsT`(`random_state=None`, *, `seed=None`)

Standardized Student's distribution for use with ARCH models

Parameters

`random_state`

[`RandomState`, optional] Deprecated since version 5.0: `random_state` is deprecated. Use `seed` instead.

`seed`

[{`int`, `Generator`, `RandomState`}, optional] Random number generator instance or int to use. Set to ensure reproducibility. If using an int, the argument is passed to `np.random.default_rng`. If not provided, `default_rng` is used with system-provided entropy.

Attributes

`generator`

The NumPy Generator or RandomState attached to the distribution

`name`

The name of the distribution

`random_state`

The NumPy RandomState attached to the distribution

Methods

Returns**A**`[ndarray]` Constraint loadings**b**`[ndarray]` Constraint values

Notes

Parameters satisfy the constraints $A \cdot \text{parameters} - b \geq 0$

Return type

`tuple[ndarray, ndarray]`

arch.univariate.StudentsT.loglikelihood

`StudentsT.loglikelihood(parameters, resids, sigma2, individual=False)`

Computes the log-likelihood of assuming residuals are have a standardized (to have unit variance) Student's t distribution, conditional on the variance.

Parameters

parameters

`[ndarray]` Shape parameter of the t distribution

resids

`[ndarray]` The residuals to use in the log-likelihood calculation

sigma2

`[ndarray]` Conditional variances of resids

individual

`[bool, optional]` Flag indicating whether to return the vector of individual log likelihoods (True) or the sum (False)

Returns

ll

`[float]` The log-likelihood

Notes

The log-likelihood of a single data point x is

$$\ln \Gamma\left(\frac{\nu+1}{2}\right) - \ln \Gamma\left(\frac{\nu}{2}\right) - \frac{1}{2} \ln(\pi(\nu-2)\sigma^2) - \frac{\nu+1}{2} \ln(1+x^2/(\sigma^2(\nu-2)))$$

where Γ is the gamma function.

Return type

`float | ndarray`

arch.univariate.StudentsT.moment

`StudentsT.moment(n, parameters=None)`

Moment of order n

Parameters

n

`[int]` Order of moment

parameters

`[ndarray, optional]` Distribution parameters. Use None for parameterless distributions.

Returns

`float`
Calculated moment

Return type

`float`

arch.univariate.StudentsT.parameter_names

`StudentsT.parameter_names()`

Names of distribution shape parameters

Returns

names
`[list (str)]` Parameter names

Return type

`list[str]`

arch.univariate.StudentsT.partial_moment

`StudentsT.partial_moment(n, z=0.0, parameters=None)`

Order n lower partial moment from -inf to z

Parameters

n
`[int]` Order of partial moment

z
`[float, optional]` Upper bound for partial moment integral

parameters
`[ndarray, optional]` Distribution parameters. Use None for parameterless distributions.

Returns

`float`
Partial moment

Notes

The order n lower partial moment to z is

$$\int_{-\infty}^z x^n f(x) dx$$

See [1] for more details.

References

[1]

Return type
float

arch.univariate.StudentsT.ppf

StudentsT.**ppf**(*pits*, *parameters=None*)

Inverse cumulative density function (ICDF)

Parameters

pits
[`float`, `ndarray`] Probability-integral-transformed values in the interval (0, 1).

parameters
[`ndarray`, `optional`] Distribution parameters. Use `None` for parameterless distributions.

Returns

i
[`float`, `ndarray`] Inverse CDF values

Return type
`ndarray`

arch.univariate.StudentsT.simulate

StudentsT.**simulate**(*parameters*)

Simulates i.i.d. draws from the distribution

Parameters

parameters
[`ndarray`] Distribution parameters

Returns

simulator
[`callable()`] Callable that take a single output size argument and returns i.i.d. draws from the distribution

Return type
`Callable[[int | tuple[int, ...]], ndarray]`

arch.univariate.StudentsT.starting_values

StudentsT.starting_values(*std_resid*)

Construct starting values for use in optimization.

Parameters

std_resid

[ndarray] Estimated standardized residuals to use in computing starting values for the shape parameter

Returns

sv

[ndarray] Array containing starting valuer for shape parameter

Notes

Uses relationship between kurtosis and degree of freedom parameter to produce a moment-based estimator for the starting values.

Return type

ndarray

Properties

| | |
|---------------------|---|
| <i>generator</i> | The NumPy Generator or RandomState attached to the distribution |
| <i>name</i> | The name of the distribution |
| <i>random_state</i> | The NumPy RandomState attached to the distribution |

arch.univariate.StudentsT.generator

property StudentsT.generator: `numpy.random.mtrand.RandomState` | `numpy.random._generator.Generator`

The NumPy Generator or RandomState attached to the distribution

Return type

RandomState | Generator

arch.univariate.StudentsT.name

property StudentsT.name: `str`

The name of the distribution

Return type

str

arch.univariate.StudentsT.random_state

property StudentsT.**random_state**: `numpy.random.mtrand.RandomState` | `numpy.random._generator.Generator`

The NumPy RandomState attached to the distribution

Deprecated since version 5.0: `random_state` is deprecated. Use `generator` instead.

Return type

`RandomState` | `Generator`

1.11.3 arch.univariate.SkewStudent

class arch.univariate.**SkewStudent**(*random_state=None*, *, *seed=None*)

Standardized Skewed Student's distribution for use with ARCH models

Parameters

random_state

[`RandomState`, optional] Deprecated since version 5.0: `random_state` is deprecated. Use `seed` instead.

seed

[{`int`, `Generator`, `RandomState`}, optional] Random number generator instance or int to use. Set to ensure reproducibility. If using an int, the argument is passed to `np.random.default_rng`. If not provided, `default_rng` is used with system-provided entropy.

Notes

The Standardized Skewed Student's distribution ([1]) takes two parameters, η and λ . η controls the tail shape and is similar to the shape parameter in a Standardized Student's t. λ controls the skewness. When $\lambda = 0$ the distribution is identical to a standardized Student's t.

References

[1]

Attributes

generator

The NumPy Generator or RandomState attached to the distribution

arch.univariate.SkewStudent.bounds

SkewStudent.**bounds**(*resids*)

Parameter bounds for use in optimization.

Parameters

resids

[ndarray] Residuals to use when computing the bounds

Returns

bounds

[list] List containing a single tuple with (lower, upper) bounds

Return type

list[tuple[float, float]]

arch.univariate.SkewStudent.cdf

SkewStudent.**cdf**(*resids*, *parameters=None*)

Cumulative distribution function

Parameters

resids

[ndarray] Values at which to evaluate the cdf

parameters

[ndarray] Distribution parameters. Use None for parameterless distributions.

Returns

f

[ndarray] CDF values

Return type

ndarray

arch.univariate.SkewStudent.constraints

SkewStudent.constraints()

Construct arrays to use in constrained optimization.

Returns

A
[ndarray] Constraint loadings

b
[ndarray] Constraint values

Notes

Parameters satisfy the constraints $A \cdot \text{parameters} - b \geq 0$

Return type

tuple[ndarray, ndarray]

arch.univariate.SkewStudent.loglikelihood

SkewStudent.loglikelihood(parameters, resids, sigma2, individual=False)

Computes the log-likelihood of assuming residuals are have a standardized (to have unit variance) Skew Student's t distribution, conditional on the variance.

Parameters

parameters
[ndarray] Shape parameter of the skew-t distribution

resids
[ndarray] The residuals to use in the log-likelihood calculation

sigma2
[ndarray] Conditional variances of resids

individual
[bool, optional] Flag indicating whether to return the vector of individual log likelihoods (True) or the sum (False)

Returns

ll
[float] The log-likelihood

Notes

The log-likelihood of a single data point x is

$$\ln \left[\frac{bc}{\sigma} \left(1 + \frac{1}{\eta - 2} \left(\frac{a + bx/\sigma}{1 + \text{sgn}(x/\sigma + a/b)\lambda} \right)^2 \right)^{-(\eta+1)/2} \right],$$

where $2 < \eta < \infty$, and $-1 < \lambda < 1$. The constants a , b , and c are given by

$$a = 4\lambda c \frac{\eta - 2}{\eta - 1}, \quad b^2 = 1 + 3\lambda^2 - a^2, \quad c = \frac{\Gamma(\frac{\eta+1}{2})}{\sqrt{\pi(\eta-2)}\Gamma(\frac{\eta}{2})},$$

and Γ is the gamma function.

Return type
`ndarray`

arch.univariate.SkewStudent.moment

`SkewStudent.moment(n, parameters=None)`

Moment of order n

Parameters

n
`[int]` Order of moment

parameters
`[ndarray, optional]` Distribution parameters. Use None for parameterless distributions.

Returns

`float`
Calculated moment

Return type
`float`

arch.univariate.SkewStudent.parameter_names

`SkewStudent.parameter_names()`

Names of distribution shape parameters

Returns

names
`[list (str)]` Parameter names

Return type
`list[str]`

arch.univariate.SkewStudent.partial_moment

`SkewStudent.partial_moment(n, z=0.0, parameters=None)`

Order n lower partial moment from -inf to z

Parameters

n
`[int]` Order of partial moment

z
`[float, optional]` Upper bound for partial moment integral

parameters
`[ndarray, optional]` Distribution parameters. Use None for parameterless distributions.

Returns

`float`

Partial moment

Notes

The order n lower partial moment to z is

$$\int_{-\infty}^z x^n f(x) dx$$

See [1] for more details.

References

[1]

Return type

`float`

`arch.univariate.SkewStudent.ppf`

`SkewStudent.ppf(pits, parameters=None)`

Inverse cumulative density function (ICDF)

Parameters

`pits`

`[{float, ndarray}]` Probability-integral-transformed values in the interval (0, 1).

`parameters`

`[ndarray, optional]` Distribution parameters. Use `None` for parameterless distributions.

Returns

`i`

`[{float, ndarray}]` Inverse CDF values

Return type

`float | ndarray`

`arch.univariate.SkewStudent.simulate`

`SkewStudent.simulate(parameters)`

Simulates i.i.d. draws from the distribution

Parameters

`parameters`

`[ndarray]` Distribution parameters

Returns

`simulator`

`[callable()]` Callable that take a single output size argument and returns i.i.d. draws from the distribution

Return type

Callable[[int | tuple[int, ...]], ndarray]

arch.univariate.SkewStudent.starting_valuesSkewStudent.starting_values(*std_resid*)

Construct starting values for use in optimization.

Parameters**std_resid**

[ndarray] Estimated standardized residuals to use in computing starting values for the shape parameter

Returns**sv**

[ndarray] Array containing starting value for shape parameter

Notes

Uses relationship between kurtosis and degree of freedom parameter to produce a moment-based estimator for the starting values.

Return type

ndarray

Properties

arch.univariate.GeneralizedError.bounds

GeneralizedError.**bounds**(*resids*)

Parameter bounds for use in optimization.

Parameters

resids

[ndarray] Residuals to use when computing the bounds

Returns

bounds

[list] List containing a single tuple with (lower, upper) bounds

Return type

list[tuple[float, float]]

arch.univariate.GeneralizedError.cdf

GeneralizedError.**cdf**(*resids*, *parameters=None*)

Cumulative distribution function

Parameters

resids

[ndarray] Values at which to evaluate the cdf

parameters

[ndarray] Distribution parameters. Use None for parameterless distributions.

Returns

f

[ndarray] CDF values

Return type

ndarray

arch.univariate.GeneralizedError.constraints

`GeneralizedError.constraints()`

Construct arrays to use in constrained optimization.

Returns

A
[ndarray] Constraint loadings

b
[ndarray] Constraint values

Notes

Parameters satisfy the constraints $A \cdot \text{parameters} - b \geq 0$

Return type

tuple[ndarray, ndarray]

arch.univariate.GeneralizedError.loglikelihood

`GeneralizedError.loglikelihood(parameters, resids, sigma2, individual=False)`

Computes the log-likelihood of assuming residuals are have a Generalized Error Distribution, conditional on the variance.

Parameters

parameters
[ndarray] Shape parameter of the GED distribution

resids
[ndarray] The residuals to use in the log-likelihood calculation

sigma2
[ndarray] Conditional variances of resids

individual
[bool, optional] Flag indicating whether to return the vector of individual log likelihoods (True) or the sum (False)

Returns

ll
[float] The log-likelihood

Notes

The log-likelihood of a single data point x is

$$\ln \nu - \ln c - \ln \Gamma\left(\frac{1}{\nu}\right) - \left(1 + \frac{1}{\nu}\right) \ln 2 - \frac{1}{2} \ln \sigma^2 - \frac{1}{2} \left| \frac{x}{c\sigma} \right|^\nu$$

where Γ is the gamma function and $\ln c$ is

$$\ln c = \frac{1}{2} \left(\frac{-2}{\nu} \ln 2 + \ln \Gamma\left(\frac{1}{\nu}\right) - \ln \Gamma\left(\frac{3}{\nu}\right) \right).$$

Return type

ndarray

arch.univariate.GeneralizedError.moment

GeneralizedError.**moment**(*n*, *parameters=None*)

Moment of order *n*

Parameters**n**

[int] Order of moment

parameters

[ndarray, optional] Distribution parameters. Use None for parameterless distributions.

Returns**float**

Calculated moment

Return type

float

arch.univariate.GeneralizedError.parameter_names

GeneralizedError.**parameter_names**()

Names of distribution shape parameters

Returns**names**

[list (str)] Parameter names

Return type

list[str]

arch.univariate.GeneralizedError.partial_moment

GeneralizedError.**partial_moment**(*n*, *z=0.0*, *parameters=None*)

Order *n* lower partial moment from $-\infty$ to *z*

Parameters**n**

[int] Order of partial moment

z

[float, optional] Upper bound for partial moment integral

parameters

[ndarray, optional] Distribution parameters. Use None for parameterless distributions.

Returns**float**

Partial moment

Notes

The order n lower partial moment to z is

$$\int_{-\infty}^z x^n f(x) dx$$

See [1] for more details.

References

[1]

Return type
float

arch.univariate.GeneralizedError.ppf

GeneralizedError.**ppf**(*pits*, *parameters=None*)

Inverse cumulative density function (ICDF)

Parameters

pits

[{float, ndarray}] Probability-integral-transformed values in the interval (0, 1).

parameters

[ndarray, optional] Distribution parameters. Use None for parameterless distributions.

Returns

i

[{float, ndarray}] Inverse CDF values

Return type

ndarray

arch.univariate.GeneralizedError.simulate

GeneralizedError.**simulate**(*parameters*)

Simulates i.i.d. draws from the distribution

Parameters

parameters

[ndarray] Distribution parameters

Returns

simulator

[callable()] Callable that take a single output size argument and returns i.i.d. draws from the distribution

Return type

Callable[[int | tuple[int, ...]], ndarray]

arch.univariate.GeneralizedError.starting_values

GeneralizedError.starting_values(*std_resid*)

Construct starting values for use in optimization.

Parameters

std_resid

[[ndarray](#)] Estimated standardized residuals to use in computing starting values for the shape parameter

Returns

sv

[[ndarray](#)] Array containing starting valuer for shape parameter

Notes

Defaults to 1.5 which is implies heavier tails than a normal

Return type

[ndarray](#)

Properties

| | |
|---------------------|---|
| <i>generator</i> | The NumPy Generator or RandomState attached to the distribution |
| <i>name</i> | The name of the distribution |
| <i>random_state</i> | The NumPy RandomState attached to the distribution |

arch.univariate.GeneralizedError.generator

property GeneralizedError.generator: [numpy.random.mtrand.RandomState](#) | [numpy.random._generator.Generator](#)

The NumPy Generator or RandomState attached to the distribution

Return type

[RandomState](#) | [Generator](#)

arch.univariate.GeneralizedError.name

property GeneralizedError.name: [str](#)

The name of the distribution

Return type

[str](#)

arch.univariate.GeneralizedError.random_state

property GeneralizedError.random_state: `numpy.random.mtrand.RandomState` | `numpy.random._generator.Generator`

The NumPy RandomState attached to the distribution

Deprecated since version 5.0: random_state is deprecated. Use generator instead.

Return type

`RandomState` | `Generator`

1.11.5 Writing New Distributions

All distributions must inherit from `:class:Distribution` and provide all public methods.

| | |
|--|-------------------------------|
| <i>Distribution</i> ([random_state, seed]) | Template for subclassing only |
|--|-------------------------------|

arch.univariate.distribution.Distribution

class arch.univariate.distribution.Distribution(*random_state=None*, *, *seed=None*)

Template for subclassing only

Attributes

generator

The NumPy Generator or RandomState attached to the distribution

name

The name of the distribution

random_state

The NumPy RandomState attached to the distribution

Methods

| | |
|--|--|
| <i>bounds</i> (resids) | Parameter bounds for use in optimization. |
| <i>cdf</i> (resids[, parameters]) | Cumulative distribution function |
| <i>constraints</i> () | Construct arrays to use in constrained optimization. |
| <i>loglikelihood</i> (parameters, resids, sigma2[, ...]) | Loglikelihood evaluation. |
| <i>moment</i> (n[, parameters]) | Moment of order n |
| <i>parameter_names</i> () | Names of distribution shape parameters |
| <i>partial_moment</i> (n[, z, parameters]) | Order n lower partial moment from -inf to z |
| <i>ppf</i> (pits[, parameters]) | Inverse cumulative density function (ICDF) |
| <i>simulate</i> (parameters) | Simulates i.i.d. |
| <i>starting_values</i> (std_resid) | Construct starting values for use in optimization. |

arch.univariate.distribution.Distribution.bounds

abstract `Distribution.bounds(resids)`

Parameter bounds for use in optimization.

Parameters

resids

[`ndarray`] Residuals to use when computing the bounds

Returns

bounds

[`list`] List containing a single tuple with (lower, upper) bounds

Return type

`list[tuple[float, float]]`

arch.univariate.distribution.Distribution.cdf

abstract `Distribution.cdf(resids, parameters=None)`

Cumulative distribution function

Parameters

resids

[`ndarray`] Values at which to evaluate the cdf

parameters

[`ndarray`] Distribution parameters. Use `None` for parameterless distributions.

Returns

f

[`ndarray`] CDF values

Return type

`ndarray`

arch.univariate.distribution.Distribution.constraints

abstract `Distribution.constraints()`

Construct arrays to use in constrained optimization.

Returns

A

[`ndarray`] Constraint loadings

b

[`ndarray`] Constraint values

Notes

Parameters satisfy the constraints $A \cdot \text{parameters} - b \geq 0$

Return type

`tuple[ndarray, ndarray]`

`arch.univariate.distribution.Distribution.loglikelihood`

abstract `Distribution.loglikelihood(parameters, resids, sigma2, individual=False)`

Loglikelihood evaluation.

Parameters

parameters

`[ndarray]` Distribution shape parameters

resids

`[ndarray]` nobs array of model residuals

sigma2

`[ndarray]` nobs array of conditional variances

individual

`[bool, optional]` Flag indicating whether to return the vector of individual log likelihoods (True) or the sum (False)

Notes

Returns the loglikelihood where `resids` are the “data”, and `parameters` and `sigma2` are inputs.

Return type

`float | ndarray`

`arch.univariate.distribution.Distribution.moment`

abstract `Distribution.moment(n, parameters=None)`

Moment of order `n`

Parameters

n

`[int]` Order of moment

parameters

`[ndarray, optional]` Distribution parameters. Use `None` for parameterless distributions.

Returns

float

Calculated moment

Return type

`float`

arch.univariate.distribution.Distribution.parameter_names**abstract** `Distribution.parameter_names()`

Names of distribution shape parameters

Returns**names**
[`list` (`str`)] Parameter names**Return type**`list`[`str`]**arch.univariate.distribution.Distribution.partial_moment****abstract** `Distribution.partial_moment`(*n*, *z=0.0*, *parameters=None*)Order *n* lower partial moment from -inf to *z***Parameters****n**
[`int`] Order of partial moment**z**
[`float`, optional] Upper bound for partial moment integral**parameters**
[`ndarray`, optional] Distribution parameters. Use `None` for parameterless distributions.**Returns****float**
Partial moment**Notes**The order *n* lower partial moment to *z* is

$$\int_{-\infty}^z x^n f(x) dx$$

See [1] for more details.

References

[1]

Return type
`float`

arch.univariate.distribution.Distribution.ppf

abstract `Distribution.ppf`(*pits*, *parameters=None*)

Inverse cumulative density function (ICDF)

Parameters

pits

[{float, ndarray}] Probability-integral-transformed values in the interval (0, 1).

parameters

[ndarray, optional] Distribution parameters. Use None for parameterless distributions.

Returns

i

[{float, ndarray}] Inverse CDF values

Return type

float | ndarray

arch.univariate.distribution.Distribution.simulate

abstract `Distribution.simulate`(*parameters*)

Simulates i.i.d. draws from the distribution

Parameters

parameters

[ndarray] Distribution parameters

Returns

simulator

[callable()] Callable that take a single output size argument and returns i.i.d. draws from the distribution

Return type

Callable[[int | tuple[int, ...]], ndarray]

arch.univariate.distribution.Distribution.starting_values

abstract `Distribution.starting_values`(*std_resid*)

Construct starting values for use in optimization.

Parameters

std_resid

[ndarray] Estimated standardized residuals to use in computing starting values for the shape parameter

Returns

sv

[ndarray] The estimated shape parameters for the distribution

Notes

Size of `sv` depends on the distribution

Return type
`ndarray`

Properties

| | |
|---------------------|---|
| <i>generator</i> | The NumPy Generator or RandomState attached to the distribution |
| <i>name</i> | The name of the distribution |
| <i>random_state</i> | The NumPy RandomState attached to the distribution |

`arch.univariate.distribution.Distribution.generator`

property `Distribution.generator`: `numpy.random.mtrand.RandomState` | `numpy.random._generator.Generator`

The NumPy Generator or RandomState attached to the distribution

Return type
`RandomState` | `Generator`

`arch.univariate.distribution.Distribution.name`

property `Distribution.name`: `str`

The name of the distribution

Return type
`str`

`arch.univariate.distribution.Distribution.random_state`

property `Distribution.random_state`: `numpy.random.mtrand.RandomState` | `numpy.random._generator.Generator`

The NumPy RandomState attached to the distribution

Deprecated since version 5.0: `random_state` is deprecated. Use `generator` instead.

Return type
`RandomState` | `Generator`

1.12 Model Results

All model return the same object, a results class (`ARCHModelResult`). When using the `fix` method, a (`ARCHModelFixedResult`) is produced that lacks some properties of a (`ARCHModelResult`) that are not relevant when parameters are not estimated.

| | |
|---|---|
| <code>ARCHModelResult</code> (params, param_cov, r2, ...) | Results from estimation of an ARCHModel model |
| <code>ARCHModelFixedResult</code> (params, resid, ...) | Results for fixed parameters for an ARCHModel model |

1.12.1 `arch.univariate.base.ARCHModelResult`

```
class arch.univariate.base.ARCHModelResult(params, param_cov, r2, resid, volatility, cov_type, dep_var,  
names, loglikelihood, is_pandas, optim_output, fit_start,  
fit_stop, model)
```

Results from estimation of an ARCHModel model

Parameters

params

[`ndarray`] Estimated parameters

param_cov

[`{ndarray, None}`] Estimated variance-covariance matrix of params. If none, calls method to compute variance from model when parameter covariance is first used from result

r2

[`float`] Model R-squared

resid

[`ndarray`] Residuals from model. Residuals have same shape as original data and contain nan-values in locations not used in estimation

volatility

[`ndarray`] Conditional volatility from model

cov_type

[`str`] String describing the covariance estimator used

dep_var

[`Series`] Dependent variable

names

[`list (str)`] Model parameter names

loglikelihood

[`float`] Loglikelihood at estimated parameters

is_pandas

[`bool`] Whether the original input was pandas

optim_output

[`OptimizeResult`] Result of log-likelihood optimization

fit_start

[`int`] Integer index of the first observation used to fit the model

fit_stop

[`int`] Integer index of the last observation used to fit the model using slice notation
fit_start:fit_stop

model

[`ARCHModel`] The model object used to estimate the parameters

Attributes***aic***

Akaike Information Criteria

bic

Schwarz/Bayesian Information Criteria

conditional_volatility

Estimated conditional volatility

convergence_flag

scipy.optimize.minimize result flag

fit_start

Start of sample used to estimate parameters

fit_stop

End of sample used to estimate parameters

loglikelihood

Model loglikelihood

model

Model instance used to produce the fit

nobs

Number of data points used to estimate model

num_params

Number of parameters in model

optimization_result

Information about the convergence of the loglikelihood optimization

param_cov

Parameter covariance

params

Model Parameters

pvalues

Array of p-values for the t-statistics

resid

Model residuals

rsquared

R-squared

rsquared_adj

Degree of freedom adjusted R-squared

scale

The scale applied to the original data before estimating the model.

std_err

Array of parameter standard errors

std_resid

Residuals standardized by conditional volatility

tvalues

Array of t-statistics testing the null that the coefficient are 0

Methods

| | |
|--|--|
| <i>arch_lm_test</i> ([lags, standardized]) | ARCH LM test for conditional heteroskedasticity |
| <i>conf_int</i> ([alpha]) | Parameter confidence intervals |
| <i>forecast</i> ([params, horizon, start, align, ...]) | Construct forecasts from estimated model |
| <i>hedgehog_plot</i> ([params, horizon, step, ...]) | Plot forecasts from estimated model |
| <i>plot</i> ([annualize, scale]) | Plot standardized residuals and conditional volatility |
| <i>summary</i> () | Constructs a summary of the results from a fit model. |

arch.univariate.base.ARCHModelResult.arch_lm_test

ARCHModelResult.**arch_lm_test**(lags=None, standardized=False)

ARCH LM test for conditional heteroskedasticity

Parameters

lags

[int, optional] Number of lags to include in the model. If not specified,

standardized

[bool, optional] Flag indicating to test the model residuals divided by their conditional standard deviations. If False, directly tests the estimated residuals.

Returns

result

[WaldTestStatistic] Result of ARCH-LM test

Return type

WaldTestStatistic

arch.univariate.base.ARCHModelResult.conf_int

ARCHModelResult.**conf_int**(alpha=0.05)

Parameter confidence intervals

Parameters

alpha

[float, optional] Size (prob.) to use when constructing the confidence interval.

Returns

ci

[DataFrame] Array where the ith row contains the confidence interval for the ith parameter

Return type

DataFrame

arch.univariate.base.ARCHModelResult.forecast

ARCHModelResult.**forecast**(*params=None, horizon=1, start=None, align='origin', method='analytic', simulations=1000, rng=None, random_state=None, *, reindex=None, x=None*)

Construct forecasts from estimated model

Parameters**params**

[*ndarray*, optional] Alternative parameters to use. If not provided, the parameters estimated when fitting the model are used. Must be identical in shape to the parameters computed by fitting the model.

horizon

[*int*, optional] Number of steps to forecast

start

[{*int*, *datetime*, *Timestamp*, *str*}, optional] An integer, datetime or str indicating the first observation to produce the forecast for. Datetimes can only be used with pandas inputs that have a datetime index. Strings must be convertible to a date time, such as in '1945-01-01'.

align

[*str*, optional] Either 'origin' or 'target'. When set of 'origin', the t-th row of forecasts contains the forecasts for t+1, t+2, ..., t+h. When set to 'target', the t-th row contains the 1-step ahead forecast from time t-1, the 2 step from time t-2, ..., and the h-step from time t-h. 'target' simplified computing forecast errors since the realization and h-step forecast are aligned.

method

[{'analytic', 'simulation', 'bootstrap'}, optional] Method to use when producing the forecast. The default is analytic. The method only affects the variance forecast generation. Not all volatility models support all methods. In particular, volatility models that do not evolve in squares such as EGARCH or TARCH do not support the 'analytic' method for horizons > 1.

simulations

[*int*, optional] Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[*callable*() , optional] Custom random number generator to use in simulation-based forecasts. Must produce random samples using the syntax *rng(size)* where *size* the 2-element tuple (simulations, horizon).

random_state

[*RandomState*, optional] NumPy RandomState instance to use when method is 'bootstrap'

reindex

[*bool*, optional] Whether to reindex the forecasts to have the same dimension as the series being forecast. Prior to 4.18 this was the default. As of 4.19 this is now optional. If not provided, a warning is raised about the future change in the default which will occur after September 2021.

New in version 4.19.

x

[{**dict**[label, numpy:array_like], numpy:array_like}] Values to use for exogenous regressors if any are included in the model. Three formats are accepted:

- 2-d array-like: This format can be used when there is a single exogenous variable. The input must have shape (nforecast, horizon) or (nobs, horizon) where nforecast is the number of forecasting periods and nobs is the original shape of y. For example, if a single series of forecasts are made from the end of the sample with a horizon of 10, then the input can be (1, 10). Alternatively, if the original data had 1000 observations, then the input can be (1000, 10), and only the final row is used to produce forecasts.
- A dictionary of 2-d array-like: This format is identical to the previous except that the dictionary keys must match the names of the exog variables. Requires that the exog variables were pass as a pandas DataFrame.
- A 3-d NumPy array (or equivalent). In this format, each panel (0th axis) is a 2-d array that must have shape (nforecast, horizon) or (nobs,horizon). The array x[j] corresponds to the j-th column of the exogenous variables.

Due to the complexity required to accommodate all scenarios, please see the example notebook that demonstrates the valid formats for x.

New in version 4.19.

Returns

arch.univariate.base.ARCHModelForecast

Container for forecasts. Key properties are mean, variance and residual_variance.

Notes

The most basic 1-step ahead forecast will return a vector with the same length as the original data, where the t-th value will be the time-t forecast for time t + 1. When the horizon is > 1, and when using the default value for *align*, the forecast value in position [t, h] is the time-t, h+1 step ahead forecast.

If model contains exogenous variables (*model.x is not None*), then only 1-step ahead forecasts are available. Using horizon > 1 will produce a warning and all columns, except the first, will be nan-filled.

If *align* is 'origin', forecast[t,h] contains the forecast made using y[:t] (that is, up to but not including t) for horizon h + 1. For example, y[100,2] contains the 3-step ahead forecast using the first 100 data points, which will correspond to the realization y[100 + 2]. If *align* is 'target', then the same forecast is in location [102, 2], so that it is aligned with the observation to use when evaluating, but still in the same column.

Return type

ARCHModelForecast

arch.univariate.base.ARCHModelResult.hedgehog_plot

ARCHModelResult.hedgehog_plot(*params=None, horizon=10, step=10, start=None, plot_type='volatility', method='analytic', simulations=1000*)

Plot forecasts from estimated model

Parameters

params

[{`ndarray`, `Series`}] Alternative parameters to use. If not provided, the parameters computed by fitting the model are used. Must be 1-d and identical in shape to the parameters computed by fitting the model.

horizon

[`int`, optional] Number of steps to forecast

step

[`int`, optional] Non-negative number of forecasts to skip between spines

start

[`int`, `datetime` or `str`, optional] An integer, datetime or str indicating the first observation to produce the forecast for. Datetimes can only be used with pandas inputs that have a datetime index. Strings must be convertible to a date time, such as in '1945-01-01'. If not provided, the start is set to the earliest forecastable date.

plot_type

[{'volatility', 'mean'}] Quantity to plot, the forecast volatility or the forecast mean

method

[{'analytic', 'simulation', 'bootstrap'}] Method to use when producing the forecast. The default is analytic. The method only affects the variance forecast generation. Not all volatility models support all methods. In particular, volatility models that do not evolve in squares such as EGARCH or TARCH do not support the 'analytic' method for horizons > 1.

simulations

[`int`] Number of simulations to run when computing the forecast using either simulation or bootstrap.

Returns**fig**

[`figure`] Handle to the figure

Examples

```
>>> import pandas as pd
>>> from arch import arch_model
>>> am = arch_model(None, mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> sim_data = am.simulate([0.1, 0.4, 0.3, 0.2, 1.0], 250)
>>> sim_data.index = pd.date_range('2000-01-01', periods=250)
>>> am = arch_model(sim_data['data'], mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> res = am.fit()
>>> fig = res.hedgehog_plot(plot_type='mean')
```

Return type

`Figure`

arch.univariate.base.ARCHModelResult.plot

ARCHModelResult.plot(*annualize=None, scale=None*)

Plot standardized residuals and conditional volatility

Parameters

annualize

[str, optional] String containing frequency of data that indicates plot should contain annualized volatility. Supported values are 'D' (daily), 'W' (weekly) and 'M' (monthly), which scale variance by 252, 52, and 12, respectively.

scale

[float, optional] Value to use when scaling returns to annualize. If scale is provided, annualize is ignored and the value in scale is used.

Returns

fig

[figure] Handle to the figure

Examples

```
>>> from arch import arch_model
>>> am = arch_model(None)
>>> sim_data = am.simulate([0.0, 0.01, 0.07, 0.92], 2520)
>>> am = arch_model(sim_data['data'])
>>> res = am.fit(update_freq=0, disp='off')
>>> fig = res.plot()
```

Produce a plot with annualized volatility

```
>>> fig = res.plot(annualize='D')
```

Override the usual scale of 252 to use 360 for an asset that trades most days of the year

```
>>> fig = res.plot(scale=360)
```

Return type

Figure

arch.univariate.base.ARCHModelResult.summary

ARCHModelResult.summary()

Constructs a summary of the results from a fit model.

Returns

summary

[Summary instance] Object that contains tables and facilitated export to text, html or latex

Return type

Summary

arch.univariate.base.ARCHModelResult.aic

property ARCHModelResult.aic: float

Akaike Information Criteria

$-2 * \text{loglikelihood} + 2 * \text{num_params}$

arch.univariate.base.ARCHModelResult.bic

property ARCHModelResult.bic: float

Schwarz/Bayesian Information Criteria

$-2 * \text{loglikelihood} + \log(\text{nobs}) * \text{num_params}$

arch.univariate.base.ARCHModelResult.conditional_volatility

property ARCHModelResult.conditional_volatility: pandas.core.series.Series | numpy.ndarray

Estimated conditional volatility

Returns

conditional_volatility

[{ndarray, Series}] nobs element array containing the conditional volatility (square root of conditional variance). The values are aligned with the input data so that the value in the t-th position is the variance of t-th error, which is computed using time-(t-1) information.

arch.univariate.base.ARCHModelResult.convergence_flag

property ARCHModelResult.convergence_flag: int

scipy.optimize.minimize result flag

arch.univariate.base.ARCHModelResult.fit_start

property ARCHModelResult.fit_start: int

Start of sample used to estimate parameters

arch.univariate.base.ARCHModelResult.fit_stop

property ARCHModelResult.fit_stop: int

End of sample used to estimate parameters

arch.univariate.base.ARCHModelResult.loglikelihood

property ARCHModelResult.loglikelihood: float

Model loglikelihood

arch.univariate.base.ARCHModelResult.model

property ARCHModelResult.model: ARCHModel

Model instance used to produce the fit

arch.univariate.base.ARCHModelResult.nobs

property ARCHModelResult.nobs: `int`
Number of data points used to estimate model

arch.univariate.base.ARCHModelResult.num_params

property ARCHModelResult.num_params: `int`
Number of parameters in model

arch.univariate.base.ARCHModelResult.optimization_result

property ARCHModelResult.optimization_result: `OptimizeResult`
Information about the convergence of the loglikelihood optimization

Returns

optim_result
[OptimizeResult] Result from numerical optimization of the log-likelihood.

Return type

`OptimizeResult`

arch.univariate.base.ARCHModelResult.param_cov

property ARCHModelResult.param_cov: `DataFrame`
Parameter covariance

arch.univariate.base.ARCHModelResult.params

property ARCHModelResult.params: `Series`
Model Parameters

arch.univariate.base.ARCHModelResult.pvalues

property ARCHModelResult.pvalues: `Series`
Array of p-values for the t-statistics

arch.univariate.base.ARCHModelResult.resid

Model residuals

arch.univariate.base.ARCHModelResult.rsquared

property ARCHModelResult.rsquared: float
R-squared

arch.univariate.base.ARCHModelResult.rsquared_adj

property ARCHModelResult.rsquared_adj: float
Degree of freedom adjusted R-squared

arch.univariate.base.ARCHModelResult.scale

property ARCHModelResult.scale: float
The scale applied to the original data before estimating the model.
If scale=1.0, the the data have not been rescaled. Otherwise, the model parameters have been estimated on scale * y.

arch.univariate.base.ARCHModelResult.std_err

property ARCHModelResult.std_err: Series
Array of parameter standard errors

arch.univariate.base.ARCHModelResult.std_resid

property ARCHModelResult.std_resid: numpy.ndarray | pandas.core.series.Series
Residuals standardized by conditional volatility

arch.univariate.base.ARCHModelResult.tvalues

property ARCHModelResult.tvalues: Series
Array of t-statistics testing the null that the coefficient are 0

1.12.2 arch.univariate.base.ARCHModelFixedResult

class arch.univariate.base.ARCHModelFixedResult(*params, resid, volatility, dep_var, names, loglikelihood, is_pandas, model*)

Results for fixed parameters for an ARCHModel model

Parameters

params

[ndarray] Estimated parameters

resid

[ndarray] Residuals from model. Residuals have same shape as original data and contain nan-values in locations not used in estimation

volatility

[ndarray] Conditional volatility from model

dep_var
 [Series] Dependent variable

names
 [list (str)] Model parameter names

loglikelihood
 [float] Loglikelihood at specified parameters

is_pandas
 [bool] Whether the original input was pandas

model
 [ARCHModel] The model object used to estimate the parameters

Attributes

aic
 Akaike Information Criteria

bic
 Schwarz/Bayesian Information Criteria

conditional_volatility
 Estimated conditional volatility

loglikelihood
 Model loglikelihood

model
 Model instance used to produce the fit

nobs
 Number of data points used to estimate model

num_params
 Number of parameters in model

params
 Model Parameters

resid
 Model residuals

std_resid
 Residuals standardized by conditional volatility

Methods

| <code>summary()</code> | Constructs a summary of the results from a fit model. |

arch.univariate.base.ARCHModelFixedResult.arch_lm_test

ARCHModelFixedResult.**arch_lm_test**(lags=None, standardized=False)

ARCH LM test for conditional heteroskedasticity

Parameters

lags

[int, optional] Number of lags to include in the model. If not specified,

standardized

[bool, optional] Flag indicating to test the model residuals divided by their conditional standard deviations. If False, directly tests the estimated residuals.

Returns

result

[WaldTestStatistic] Result of ARCH-LM test

Return type

WaldTestStatistic

arch.univariate.base.ARCHModelFixedResult.forecast

ARCHModelFixedResult.**forecast**(params=None, horizon=1, start=None, align='origin', method='analytic', simulations=1000, rng=None, random_state=None, *, reindex=None, x=None)

Construct forecasts from estimated model

Parameters

params

[ndarray, optional] Alternative parameters to use. If not provided, the parameters estimated when fitting the model are used. Must be identical in shape to the parameters computed by fitting the model.

horizon

[int, optional] Number of steps to forecast

start

[{int, datetime, Timestamp, str}, optional] An integer, datetime or str indicating the first observation to produce the forecast for. Datetimes can only be used with pandas inputs that have a datetime index. Strings must be convertible to a date time, such as in '1945-01-01'.

align

[str, optional] Either 'origin' or 'target'. When set of 'origin', the t-th row of forecasts contains the forecasts for t+1, t+2, ..., t+h. When set to 'target', the t-th row contains the 1-step ahead forecast from time t-1, the 2 step from time t-2, ..., and the h-step from time t-h. 'target' simplified computing forecast errors since the realization and h-step forecast are aligned.

method

[{'analytic', 'simulation', 'bootstrap'}, optional] Method to use when producing the forecast. The default is analytic. The method only affects the variance forecast generation. Not all volatility models support all methods. In particular, volatility models that do not evolve in squares such as EGARCH or TARCH do not support the 'analytic' method for horizons > 1.

simulations

[`int`, optional] Number of simulations to run when computing the forecast using either simulation or bootstrap.

rng

[`callable()`, optional] Custom random number generator to use in simulation-based forecasts. Must produce random samples using the syntax `rng(size)` where `size` the 2-element tuple (simulations, horizon).

random_state

[`RandomState`, optional] NumPy `RandomState` instance to use when method is 'bootstrap'

reindex

[`bool`, optional] Whether to reindex the forecasts to have the same dimension as the series being forecast. Prior to 4.18 this was the default. As of 4.19 this is now optional. If not provided, a warning is raised about the future change in the default which will occur after September 2021.

New in version 4.19.

x

[{`dict`[`label`, `numpy:array_like`], `numpy:array_like`}] Values to use for exogenous regressors if any are included in the model. Three formats are accepted:

- 2-d array-like: This format can be used when there is a single exogenous variable. The input must have shape (nforecast, horizon) or (nobs, horizon) where nforecast is the number of forecasting periods and nobs is the original shape of `y`. For example, if a single series of forecasts are made from the end of the sample with a horizon of 10, then the input can be (1, 10). Alternatively, if the original data had 1000 observations, then the input can be (1000, 10), and only the final row is used to produce forecasts.
- A dictionary of 2-d array-like: This format is identical to the previous except that the dictionary keys must match the names of the exog variables. Requires that the exog variables were pass as a pandas DataFrame.
- A 3-d NumPy array (or equivalent). In this format, each panel (0th axis) is a 2-d array that must have shape (nforecast, horizon) or (nobs,horizon). The array `x[j]` corresponds to the `j`-th column of the exogenous variables.

Due to the complexity required to accommodate all scenarios, please see the example notebook that demonstrates the valid formats for `x`.

New in version 4.19.

Returns***arch.univariate.base.ARCHModelForecast***

Container for forecasts. Key properties are `mean`, `variance` and `residual_variance`.

Notes

The most basic 1-step ahead forecast will return a vector with the same length as the original data, where the t -th value will be the time- t forecast for time $t + 1$. When the horizon is > 1 , and when using the default value for *align*, the forecast value in position $[t, h]$ is the time- t , $h+1$ step ahead forecast.

If model contains exogenous variables (*model.x is not None*), then only 1-step ahead forecasts are available. Using horizon > 1 will produce a warning and all columns, except the first, will be nan-filled.

If *align* is 'origin', forecast $[t,h]$ contains the forecast made using $y[t]$ (that is, up to but not including t) for horizon $h + 1$. For example, $y[100,2]$ contains the 3-step ahead forecast using the first 100 data points, which will correspond to the realization $y[100 + 2]$. If *align* is 'target', then the same forecast is in location $[102, 2]$, so that it is aligned with the observation to use when evaluating, but still in the same column.

Return type

ARCHModelForecast

arch.univariate.base.ARCHModelFixedResult.hedgehog_plot

`ARCHModelFixedResult.hedgehog_plot`(*params=None, horizon=10, step=10, start=None, plot_type='volatility', method='analytic', simulations=1000*)

Plot forecasts from estimated model

Parameters

params

[*ndarray, Series*] Alternative parameters to use. If not provided, the parameters computed by fitting the model are used. Must be 1-d and identical in shape to the parameters computed by fitting the model.

horizon

[*int, optional*] Number of steps to forecast

step

[*int, optional*] Non-negative number of forecasts to skip between spines

start

[*int, datetime or str, optional*] An integer, datetime or str indicating the first observation to produce the forecast for. Datetimes can only be used with pandas inputs that have a datetime index. Strings must be convertible to a date time, such as in '1945-01-01'. If not provided, the start is set to the earliest forecastable date.

plot_type

[{'volatility', 'mean'}] Quantity to plot, the forecast volatility or the forecast mean

method

[{'analytic', 'simulation', 'bootstrap'}] Method to use when producing the forecast. The default is analytic. The method only affects the variance forecast generation. Not all volatility models support all methods. In particular, volatility models that do not evolve in squares such as EGARCH or TARCH do not support the 'analytic' method for horizons > 1 .

simulations

[*int*] Number of simulations to run when computing the forecast using either simulation or bootstrap.

Returns

fig

[*figure*] Handle to the figure

Examples

```
>>> import pandas as pd
>>> from arch import arch_model
>>> am = arch_model(None, mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> sim_data = am.simulate([0.1, 0.4, 0.3, 0.2, 1.0], 250)
>>> sim_data.index = pd.date_range('2000-01-01', periods=250)
>>> am = arch_model(sim_data['data'], mean='HAR', lags=[1, 5, 22], vol='Constant')
>>> res = am.fit()
>>> fig = res.hedgehog_plot(plot_type='mean')
```

Return type

Figure

arch.univariate.base.ARCHModelFixedResult.plot

ARCHModelFixedResult.plot(*annualize=None, scale=None*)

Plot standardized residuals and conditional volatility

Parameters

annualize

[str, optional] String containing frequency of data that indicates plot should contain annualized volatility. Supported values are ‘D’ (daily), ‘W’ (weekly) and ‘M’ (monthly), which scale variance by 252, 52, and 12, respectively.

scale

[float, optional] Value to use when scaling returns to annualize. If scale is provided, annualize is ignored and the value in scale is used.

Returns

fig

[figure] Handle to the figure

Examples

```
>>> from arch import arch_model
>>> am = arch_model(None)
>>> sim_data = am.simulate([0.0, 0.01, 0.07, 0.92], 2520)
>>> am = arch_model(sim_data['data'])
>>> res = am.fit(update_freq=0, disp='off')
>>> fig = res.plot()
```

Produce a plot with annualized volatility

```
>>> fig = res.plot(annualize='D')
```

Override the usual scale of 252 to use 360 for an asset that trades most days of the year

```
>>> fig = res.plot(scale=360)
```

Return type

Figure

arch.univariate.base.ARCHModelFixedResult.summary

`ARCHModelFixedResult.summary()`

Constructs a summary of the results from a fit model.

Returns

summary

[Summary instance] Object that contains tables and facilitated export to text, html or latex

Return type

Summary

Properties

| | |
|-------------------------------|--|
| <i>aic</i> | Akaike Information Criteria |
| <i>bic</i> | Schwarz/Bayesian Information Criteria |
| <i>conditional_volatility</i> | Estimated conditional volatility |
| <i>loglikelihood</i> | Model loglikelihood |
| <i>model</i> | Model instance used to produce the fit |
| <i>nobs</i> | Number of data points used to estimate model |
| <i>num_params</i> | Number of parameters in model |
| <i>params</i> | Model Parameters |
| <i>resid</i> | Model residuals |
| <i>std_resid</i> | Residuals standardized by conditional volatility |

arch.univariate.base.ARCHModelFixedResult.aic

property `ARCHModelFixedResult.aic`: float

Akaike Information Criteria

$-2 * \text{loglikelihood} + 2 * \text{num_params}$

arch.univariate.base.ARCHModelFixedResult.bic

property `ARCHModelFixedResult.bic`: float

Schwarz/Bayesian Information Criteria

$-2 * \text{loglikelihood} + \log(\text{nobs}) * \text{num_params}$

arch.univariate.base.ARCHModelFixedResult.conditional_volatility

property `ARCHModelFixedResult.conditional_volatility`: `pandas.core.series.Series` | `numpy.ndarray`

Estimated conditional volatility

Returns

conditional_volatility

[{`ndarray`, `Series`}] `nobs` element array containing the conditional volatility (square root of conditional variance). The values are aligned with the input data so that the value in the `t`-th position is the variance of `t`-th error, which is computed using time-`(t-1)` information.

arch.univariate.base.ARCHModelFixedResult.loglikelihood

property ARCHModelFixedResult.loglikelihood: `float`
Model loglikelihood

arch.univariate.base.ARCHModelFixedResult.model

property ARCHModelFixedResult.model: `ARCHModel`
Model instance used to produce the fit

arch.univariate.base.ARCHModelFixedResult.nobs

property ARCHModelFixedResult.nobs: `int`
Number of data points used to estimate model

arch.univariate.base.ARCHModelFixedResult.num_params

property ARCHModelFixedResult.num_params: `int`
Number of parameters in model

arch.univariate.base.ARCHModelFixedResult.params

property ARCHModelFixedResult.params: `Series`
Model Parameters

arch.univariate.base.ARCHModelFixedResult.resid

property ARCHModelFixedResult.resid: `numpy.ndarray` | `pandas.core.series.Series`
Model residuals

arch.univariate.base.ARCHModelFixedResult.std_resid

property ARCHModelFixedResult.std_resid: `numpy.ndarray` | `pandas.core.series.Series`
Residuals standardized by conditional volatility

1.13 Utilities

Utilities that do not fit well on other pages.

1.13.1 Test Results

class `arch.utility.testing.WaldTestStatistic`(*stat*, *df*, *null*, *alternative*, *name*="")

Test statistic holder for Wald-type tests

Parameters

stat

[float] The test statistic

df

[int] Degree of freedom.

null

[str] A statement of the test's null hypothesis

alternative

[str] A statement of the test's alternative hypothesis

name

[str, default ""] (empty) Name of test

Attributes

alternative

critical_values

Critical values test for common test sizes

null

Null hypothesis

pval

P-value of test statistic

stat

Test statistic

property `critical_values`: `dict[str, float]`

Critical values test for common test sizes

property `null`: `str`

Null hypothesis

Return type

`str`

property `pval`: `float`

P-value of test statistic

property `stat`: `float`

Test statistic

Return type

`float`

1.14 Theoretical Background

To be completed

BOOTSTRAPPING

The bootstrap module provides both high- and low-level interfaces for bootstrapping data contained in NumPy arrays or pandas Series or DataFrames.

All bootstraps have the same interfaces and only differ in their name, setup parameters and the (internally generated) sampling scheme.

2.1 Bootstrap Examples

This setup code is required to run in an IPython notebook

```
[1]: %matplotlib inline
import matplotlib.pyplot as plt
import seaborn

seaborn.set_style("darkgrid")
plt.rc("figure", figsize=(16, 6))
plt.rc("savefig", dpi=90)
plt.rc("font", family="sans-serif")
plt.rc("font", size=14)
```

2.1.1 Sharpe Ratio

The Sharpe Ratio is an important measure of return per unit of risk. The example shows how to estimate the variance of the Sharpe Ratio and how to construct confidence intervals for the Sharpe Ratio using a long series of U.S. equity data.

```
[2]: import arch.data.frenchdata
import numpy as np
import pandas as pd

ff = arch.data.frenchdata.load()
```

The data set contains the Fama-French factors, including the excess market return.

```
[3]: excess_market = ff.iloc[:, 0]
print(ff.describe())
```

| | Mkt-RF | SMB | HML | RF |
|-------|-------------|-------------|-------------|-------------|
| count | 1109.000000 | 1109.000000 | 1109.000000 | 1109.000000 |
| mean | 0.659946 | 0.206555 | 0.368864 | 0.274220 |
| std | 5.327524 | 3.191132 | 3.482352 | 0.253377 |
| min | -29.130000 | -16.870000 | -13.280000 | -0.060000 |
| 25% | -1.970000 | -1.560000 | -1.320000 | 0.030000 |
| 50% | 1.020000 | 0.070000 | 0.140000 | 0.230000 |
| 75% | 3.610000 | 1.730000 | 1.740000 | 0.430000 |
| max | 38.850000 | 36.700000 | 35.460000 | 1.350000 |

The next step is to construct a function that computes the Sharpe Ratio. This function also return the annualized mean and annualized standard deviation which will allow the covariance matrix of these parameters to be estimated using the bootstrap.

```
[4]: def sharpe_ratio(x):
      mu, sigma = 12 * x.mean(), np.sqrt(12 * x.var())
      values = np.array([mu, sigma, mu / sigma]).squeeze()
      index = ["mu", "sigma", "SR"]
      return pd.Series(values, index=index)
```

The function can be called directly on the data to show full sample estimates.

```
[5]: params = sharpe_ratio(excess_market)
      params
[5]: mu          7.919351
      sigma      18.455084
      SR         0.429115
      dtype: float64
```

2.1.2 Reproducibility

All bootstraps accept the keyword argument `seed` which can contain a NumPy Generator or `RandomState` or an `int`. When using an `int`, the argument is passed `np.random.default_rng` to create the core generator. This allows the same pseudo random values to be used across multiple runs.

Warning

The bootstrap chosen must be appropriate for the data. Squared returns are serially correlated, and so a time-series bootstrap is required.

Bootstraps are initialized with any bootstrap specific parameters and the data to be used in the bootstrap. Here the 12 is the average window length in the Stationary Bootstrap, and the next input is the data to be bootstrapped.

```
[6]: from arch.bootstrap import StationaryBootstrap

      # Initialize with entropy from random.org
      entropy = [877788388, 418255226, 989657335, 69307515]
      seed = np.random.default_rng(entropy)

      bs = StationaryBootstrap(12, excess_market, seed=seed)
      results = bs.apply(sharpe_ratio, 2500)
```

(continues on next page)

(continued from previous page)

```
SR = pd.DataFrame(results[:, -1:], columns=["SR"])
fig = SR.hist(bins=40)
```

nbsphinx-code-borderwhite

```
[7]: cov = bs.cov(sharpe_ratio, 1000)
cov = pd.DataFrame(cov, index=params.index, columns=params.index)
print(cov)
se = pd.Series(np.sqrt(np.diag(cov)), index=params.index)
se.name = "Std Errors"
print("\n")
print(se)
```

| | mu | sigma | SR |
|-------|-----------|-----------|-----------|
| mu | 3.837196 | -0.638431 | 0.224722 |
| sigma | -0.638431 | 3.019569 | -0.105762 |
| SR | 0.224722 | -0.105762 | 0.014915 |

| | |
|-------|----------|
| mu | 1.958876 |
| sigma | 1.737691 |
| SR | 0.122126 |

Name: Std Errors, dtype: float64

```
[8]: ci = bs.conf_int(sharpe_ratio, 1000, method="basic")
ci = pd.DataFrame(ci, index=["Lower", "Upper"], columns=params.index)
print(ci)
```

| | mu | sigma | SR |
|-------|-----------|-----------|----------|
| Lower | 4.367662 | 14.780547 | 0.166759 |
| Upper | 11.958503 | 21.735752 | 0.659350 |

Alternative confidence intervals can be computed using a variety of methods. Setting `reuse=True` allows the previous bootstrap results to be used when constructing confidence intervals using alternative methods.

```
[9]: ci = bs.conf_int(sharpe_ratio, 1000, method="percentile", reuse=True)
ci = pd.DataFrame(ci, index=["Lower", "Upper"], columns=params.index)
print(ci)
```

| | mu | sigma | SR |
|-------|-----------|-----------|----------|
| Lower | 3.880198 | 15.174416 | 0.198880 |
| Upper | 11.471040 | 22.129620 | 0.691471 |

Optimal Block Length Estimation

The function `optimal_block_length` can be used to estimate the optimal block lengths for the Stationary and Circular bootstraps. Here we use the squared market return since the Sharpe ratio depends on the mean and the variance, and the autocorrelation in the squares is stronger than in the returns.

```
[10]: from arch.bootstrap import optimal_block_length
```

```
opt = optimal_block_length(excess_market**2)
print(opt)
```

```
          stationary   circular
Mkt-RF    47.766787   54.679322
```

We can repeat the analysis above using the estimated optimal block length. Here we see that the extremes appear to be slightly more extreme.

```
[11]: # Reinitialize using the same entropy
rs = np.random.default_rng(entropy)

bs = StationaryBootstrap(opt.loc["Mkt-RF", "stationary"], excess_market, seed=seed)
results = bs.apply(sharpe_ratio, 2500)
SR = pd.DataFrame(results[:, -1:], columns=["SR"])
fig = SR.hist(bins=40)
```

nbsphinx-code-borderwhite

2.1.3 Probit (statsmodels)

The second example makes use of a Probit model from `statsmodels`. The demo data is university admissions data which contains a binary variable for being admitted, GRE score, GPA score and quartile rank. This data is downloaded from the internet and imported using `pandas`.

```
[12]: import arch.data.binary
```

```
binary = arch.data.binary.load()
binary = binary.dropna()
print(binary.describe())
```

```
count    admit      gre      gpa      rank
mean     0.317500  587.700000  3.389900  2.48500
std      0.466087  115.516536   0.380567  0.94446
```

(continues on next page)

(continued from previous page)

| | | | | |
|-----|----------|------------|----------|----------|
| min | 0.000000 | 220.000000 | 2.260000 | 1.000000 |
| 25% | 0.000000 | 520.000000 | 3.130000 | 2.000000 |
| 50% | 0.000000 | 580.000000 | 3.395000 | 2.000000 |
| 75% | 1.000000 | 660.000000 | 3.670000 | 3.000000 |
| max | 1.000000 | 800.000000 | 4.000000 | 4.000000 |

Fitting the model directly

The first steps are to build the regressor and the dependent variable arrays. Then, using these arrays, the model can be estimated by calling `fit`

```
[13]: import statsmodels.api as sm

endog = binary[["admit"]]
exog = binary[["gre", "gpa"]]
const = pd.Series(np.ones(exog.shape[0]), index=endog.index)
const.name = "Const"
exog = pd.DataFrame([const, exog.gre, exog.gpa]).T

# Estimate the model
mod = sm.Probit(endog, exog)
fit = mod.fit(displ=0)
params = fit.params
print(params)
```

```
Const    -3.003536
gre         0.001643
gpa         0.454575
dtype: float64
```

The wrapper function

Most models in `statsmodels` are implemented as classes, require an explicit call to `fit` and return a class containing parameter estimates and other quantities. These classes cannot be directly used with the bootstrap methods. However, a simple wrapper can be written that takes the data as the only inputs and returns parameters estimated using a `Statsmodel` model.

```
[14]: def probit_wrap(endog, exog):
      return sm.Probit(endog, exog).fit(displ=0).params
```

A call to this function should return the same parameter values.

```
[15]: probit_wrap(endog, exog)
```

```
[15]: Const    -3.003536
      gre         0.001643
      gpa         0.454575
      dtype: float64
```

The wrapper can be directly used to estimate the parameter covariance or to construct confidence intervals.

```
[16]: from arch.bootstrap import IIDBootstrap

bs = IIDBootstrap(endog=endog, exog=exog)
cov = bs.cov(probit_wrap, 1000)
cov = pd.DataFrame(cov, index=exog.columns, columns=exog.columns)
print(cov)
```

| | Const | gre | gpa |
|-------|-----------|---------------|-----------|
| Const | 0.397473 | -6.641971e-05 | -0.102525 |
| gre | -0.000066 | 4.467596e-07 | -0.000058 |
| gpa | -0.102525 | -5.815162e-05 | 0.039859 |

```
[17]: se = pd.Series(np.sqrt(np.diag(cov)), index=exog.columns)
print(se)
print("T-stats")
print(params / se)
```

| | |
|-------|----------|
| Const | 0.630455 |
| gre | 0.000668 |
| gpa | 0.199647 |

dtype: float64

T-stats

| | |
|-------|-----------|
| Const | -4.764077 |
| gre | 2.457413 |
| gpa | 2.276894 |

dtype: float64

```
[18]: ci = bs.conf_int(probit_wrap, 1000, method="basic")
ci = pd.DataFrame(ci, index=["Lower", "Upper"], columns=exog.columns)
print(ci)
```

| | Const | gre | gpa |
|-------|-----------|----------|----------|
| Lower | -4.214157 | 0.000360 | 0.005706 |
| Upper | -1.622607 | 0.002906 | 0.871725 |

Speeding things up

Starting values can be provided to fit which can save time finding starting values. Since the bootstrap parameter estimates should be close to the original sample estimates, the full sample estimated parameters are reasonable starting values. These can be passed using the `extra_kwargs` dictionary to a modified wrapper that will accept a keyword argument containing starting values.

```
[19]: def probit_wrap_start_params(endog, exog, start_params=None):
        return sm.Probit(endog, exog).fit(start_params=start_params, disp=0).params
```

```
[20]: bs.reset() # Reset to original state for comparability
cov = bs.cov(
    probit_wrap_start_params, 1000, extra_kwargs={"start_params": params.values}
)
cov = pd.DataFrame(cov, index=exog.columns, columns=exog.columns)
print(cov)
```

| | Const | gre | gpa |
|-------|-----------|---------------|-----------|
| Const | 0.397473 | -6.641971e-05 | -0.102525 |
| gre | -0.000066 | 4.467596e-07 | -0.000058 |
| gpa | -0.102525 | -5.815162e-05 | 0.039859 |

2.1.4 Bootstrapping Uneven Length Samples

Independent samples of uneven length are common in experiment settings, e.g., A/B testing of a website. The `IIDBootstrap` allows for arbitrary dependence within an observation index and so cannot be naturally applied to these data sets. The `IndependentSamplesBootstrap` allows datasets with variables of different lengths to be sampled by exploiting the independence of the values to separately bootstrap each component. Below is an example showing how a confidence interval can be constructed for the difference in means of two groups.

```
[21]: from arch.bootstrap import IndependentSamplesBootstrap

def mean_diff(x, y):
    return x.mean() - y.mean()

rs = np.random.RandomState(0)
treatment = 0.2 + rs.standard_normal(200)
control = rs.standard_normal(800)

bs = IndependentSamplesBootstrap(treatment, control, seed=seed)
print(bs.conf_int(mean_diff, method="studentized"))

[[0.19450863]
 [0.49723719]]
```

2.2 Confidence Intervals

The confidence interval function allows three types of confidence intervals to be constructed:

- Nonparametric, which only resamples the data
- Semi-parametric, which use resampled residuals
- Parametric, which simulate residuals

Confidence intervals can then be computed using one of 6 methods:

- Basic (`basic`)
- Percentile (`percentile`)
- Studentized (`studentized`)
- Asymptotic using parameter covariance (`norm`, `var` or `cov`)
- Bias-corrected (`bc`, `bias-corrected` or `debiased`)
- Bias-corrected and accelerated (`bca`)

- *Setup*
- *Confidence Interval Types*
 - *Nonparametric Confidence Intervals*
 - *Semi-parametric Confidence Intervals*
 - *Parametric Confidence Intervals*
- *Confidence Interval Methods*
 - *Basic (basic)*
 - *Percentile (percentile)*

 - *Studentized (studentized)*
 - *Bias-corrected (bc, bias-corrected or debiased)*
 - *Bias-corrected and accelerated (bca)*

2.2.1 Setup

All examples will construct confidence intervals for the Sharpe ratio of the S&P 500, which is the ratio of the annualized mean to the annualized standard deviation. The parameters will be the annualized mean, the annualized standard deviation and the Sharpe ratio.

The setup makes use of return data downloaded from Yahoo!

```
import datetime as dt

import pandas as pd
import pandas_datareader.data as web

start = dt.datetime(1951, 1, 1)
end = dt.datetime(2014, 1, 1)
sp500 = web.DataReader('^GSPC', 'yahoo', start=start, end=end)
low = sp500.index.min()
high = sp500.index.max()
monthly_dates = pd.date_range(low, high, freq='M')
monthly = sp500.reindex(monthly_dates, method='ffill')
returns = 100 * monthly['Adj Close'].pct_change().dropna()
```

The main function used will return a 3-element array containing the parameters.

```
def sharpe_ratio(x):
    mu, sigma = 12 * x.mean(), np.sqrt(12 * x.var())
    return np.array([mu, sigma, mu / sigma])
```

Note: Functions must return 1-d NumPy arrays or Pandas Series.

2.2.2 Confidence Interval Types

Three types of confidence intervals can be computed. The simplest are non-parametric; these only make use of parameter estimates from both the original data as well as the resampled data. Semi-parametric mix the original data with a limited form of resampling, usually for residuals. Finally, parametric bootstrap confidence intervals make use of a parametric distribution to construct “as-if” exact confidence intervals.

Nonparametric Confidence Intervals

Non-parametric sampling is the simplest method to construct confidence intervals.

This example makes use of the percentile bootstrap which is conceptually the simplest method - it constructs many bootstrap replications and returns order statistics from these empirical distributions.

```
from arch.bootstrap import IIDBootstrap

bs = IIDBootstrap(returns)
ci = bs.conf_int(sharpe_ratio, 1000, method='percentile')
```

Note: While returns have little serial correlation, squared returns are highly persistent. The IID bootstrap is not a good choice here. Instead a time-series bootstrap with an appropriately chosen block size should be used.

Semi-parametric Confidence Intervals

See *Semiparametric Bootstraps*

Parametric Confidence Intervals

See *Parametric Bootstraps*

2.2.3 Confidence Interval Methods

Note: `conf_int` can construct two-sided, upper or lower (one-sided) confidence intervals. All examples use two-sided, 95% confidence intervals (the default). This can be modified using the keyword inputs `type` ('upper', 'lower' or 'two-sided') and `size`.

Basic (basic)

Basic confidence intervals construct many bootstrap replications $\hat{\theta}_b^*$ and then constructs the confidence interval as

$$\left[\hat{\theta} + \left(\hat{\theta} - \hat{\theta}_u^* \right), \hat{\theta} + \left(\hat{\theta} - \hat{\theta}_l^* \right) \right]$$

where $\hat{\theta}_l^*$ and $\hat{\theta}_u^*$ are the $\alpha/2$ and $1 - \alpha/2$ empirical quantiles of the bootstrap distribution. When θ is a vector, the empirical quantiles are computed element-by-element.

```
from arch.bootstrap import IIDBootstrap

bs = IIDBootstrap(returns)
ci = bs.conf_int(sharpe_ratio, 1000, method='basic')
```

Percentile (percentile)

The percentile method directly constructs confidence intervals from the empirical CDF of the bootstrap parameter estimates, $\hat{\theta}_b^*$. The confidence interval is then defined.

$$\left[\hat{\theta}_l^*, \hat{\theta}_u^* \right]$$

where $\hat{\theta}_l^*$ and $\hat{\theta}_u^*$ are the $\alpha/2$ and $1 - \alpha/2$ empirical quantiles of the bootstrap distribution.

```
from arch.bootstrap import IIDBootstrap

bs = IIDBootstrap(returns)
ci = bs.conf_int(sharpe_ratio, 1000, method='percentile')
```

Asymptotic Normal Approximation (norm, cov or var)

The asymptotic normal approximation method estimates the covariance of the parameters and then combines this with the usual quantiles from a normal distribution. The confidence interval is then

$$\left[\hat{\theta} + \hat{\sigma}\Phi^{-1}(\alpha/2), \hat{\theta} - \hat{\sigma}\Phi^{-1}(\alpha/2), \right]$$

where $\hat{\sigma}$ is the bootstrap estimate of the parameter standard error.

```
from arch.bootstrap import IIDBootstrap

bs = IIDBootstrap(returns)
ci = bs.conf_int(sharpe_ratio, 1000, method='norm')
```

Studentized (studentized)

The studentized bootstrap may be more accurate than some of the other methods. The studentized bootstrap makes use of either a standard error function, when parameter standard errors can be analytically computed, or a nested bootstrap, to bootstrap studentized versions of the original statistic. This can produce higher-order refinements in some circumstances.

The confidence interval is then

$$\left[\hat{\theta} + \hat{\sigma}\hat{G}^{-1}(\alpha/2), \hat{\theta} + \hat{\sigma}\hat{G}^{-1}(1 - \alpha/2), \right]$$

where \hat{G} is the estimated quantile function for the studentized data and where $\hat{\sigma}$ is a bootstrap estimate of the parameter standard error.

The version that uses a nested bootstrap is simple to implement although it can be slow since it requires B inner bootstraps of each of the B outer bootstraps.

```

from arch.bootstrap import IIDBootstrap

bs = IIDBootstrap(returns)
ci = bs.conf_int(sharpe_ratio, 1000, method='studentized')

```

In order to use the standard error function, it is necessary to estimate the standard error of the parameters. In this example, this can be done using a method-of-moments argument and the delta-method. A detailed description of the mathematical formula is beyond the intent of this document.

```

def sharpe_ratio_se(params, x):
    mu, sigma, sr = params
    y = 12 * x
    e1 = y - mu
    e2 = y ** 2.0 - sigma ** 2.0
    errors = np.vstack((e1, e2)).T
    t = errors.shape[0]
    vcv = errors.T.dot(errors) / t
    D = np.array([[1, 0],
                  [0, 0.5 * 1 / sigma],
                  [1.0 / sigma, - mu / (2.0 * sigma**3)]
                  ])
    avar = D.dot(vcv / t).dot(D.T)
    return np.sqrt(np.diag(avar))

```

The studentized bootstrap can then be implemented using the standard error function.

```

from arch.bootstrap import IIDBootstrap
bs = IIDBootstrap(returns)
ci = bs.conf_int(sharpe_ratio, 1000, method='studentized',
                 std_err_func=sharpe_ratio_se)

```

Note: Standard error functions must return a 1-d array with the same number of element as params.

Note: Standard error functions must match the patters `std_err_func(params, *args, **kwargs)` where `params` is an array of estimated parameters constructed using `*args` and `**kwargs`.

Bias-corrected (bc, bias-corrected or debiased)

The bias corrected bootstrap makes use of a bootstrap estimate of the bias to improve confidence intervals.

```

from arch.bootstrap import IIDBootstrap
bs = IIDBootstrap(returns)
ci = bs.conf_int(sharpe_ratio, 1000, method='bc')

```

The bias-corrected confidence interval is identical to the bias-corrected and accelerated where $a = 0$.

Bias-corrected and accelerated (bca)

Bias-corrected and accelerated confidence intervals make use of both a bootstrap bias estimate and a jackknife acceleration term. BCa intervals may offer higher-order accuracy if some conditions are satisfied. Bias-corrected confidence intervals are a special case of BCa intervals where the acceleration parameter is set to 0.

```
from arch.bootstrap import IIDBootstrap

bs = IIDBootstrap(returns)
ci = bs.conf_int(sharpe_ratio, 1000, method='bca')
```

The confidence interval is based on the empirical distribution of the bootstrap parameter estimates, $\hat{\theta}_b^*$, where the percentiles used are

$$\Phi \left(\Phi^{-1}(\hat{b}) + \frac{\Phi^{-1}(\hat{b}) + z_\alpha}{1 - \hat{a}(\Phi^{-1}(\hat{b}) + z_\alpha)} \right)$$

where z_α is the usual quantile from the normal distribution and \hat{b} is the empirical bias estimate,

$$\hat{b} = \# \{ \hat{\theta}_b^* < \hat{\theta} \} / B$$

\hat{a} is a skewness-like estimator using a leave-one-out jackknife.

2.3 Covariance Estimation

The bootstrap can be used to estimate parameter covariances in applications where analytical computation is challenging, or simply as an alternative to traditional estimators.

This example estimates the covariance of the mean, standard deviation and Sharpe ratio of the S&P 500 using Yahoo! Finance data.

```
import datetime as dt
import pandas as pd
import pandas_datareader.data as web

start = dt.datetime(1951, 1, 1)
end = dt.datetime(2014, 1, 1)
sp500 = web.DataReader('^GSPC', 'yahoo', start=start, end=end)
low = sp500.index.min()
high = sp500.index.max()
monthly_dates = pd.date_range(low, high, freq='M')
monthly = sp500.reindex(monthly_dates, method='ffill')
returns = 100 * monthly['Adj Close'].pct_change().dropna()
```

The function that returns the parameters.

```
def sharpe_ratio(r):
    mu = 12 * r.mean(0)
    sigma = np.sqrt(12 * r.var(0))
    sr = mu / sigma
    return np.array([mu, sigma, sr])
```

Like all applications of the bootstrap, it is important to choose a bootstrap that captures the dependence in the data. This example uses the stationary bootstrap with an average block size of 12.

```
import pandas as pd
from arch.bootstrap import StationaryBootstrap

bs = StationaryBootstrap(12, returns)
param_cov = bs.cov(sharpe_ratio)
index = ['mu', 'sigma', 'SR']
params = sharpe_ratio(returns)
params = pd.Series(params, index=index)
param_cov = pd.DataFrame(param_cov, index=index, columns=index)
```

The output is

```
>>> params
mu          8.148534
sigma      14.508540
SR          0.561637
dtype: float64

>>> param_cov
           mu      sigma      SR
mu    3.729435 -0.442891  0.273945
sigma -0.442891  0.495087 -0.049454
SR     0.273945 -0.049454  0.020830
```

Note: The covariance estimator is centered using the average of the bootstrapped estimators. The original sample estimator can be used to center using the keyword argument `recenter=False`.

2.4 Low-level Interfaces

2.4.1 Constructing Parameter Estimates

The bootstrap method apply can be use to directly compute parameter estimates from a function and the bootstrapped data.

This example makes use of monthly S&P 500 data.

```
import datetime as dt

import pandas as pd
import pandas_datareader.data as web

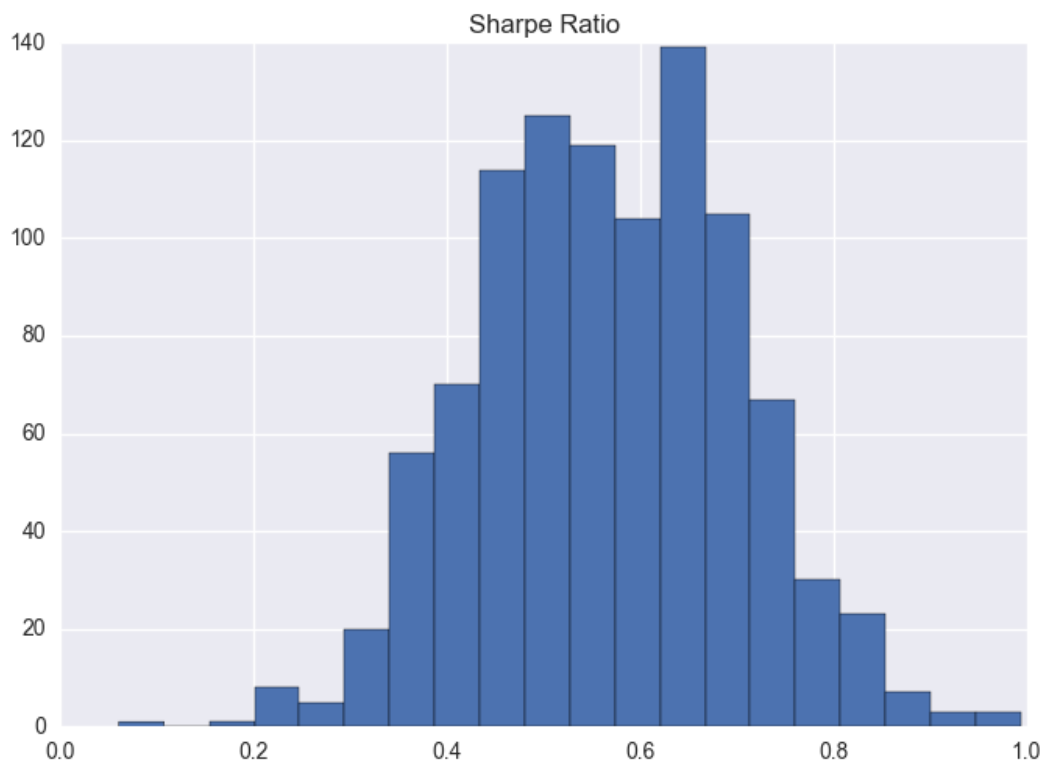

start = dt.datetime(1951, 1, 1)
end = dt.datetime(2014, 1, 1)
sp500 = web.DataReader('^GSPC', 'yahoo', start=start, end=end)
low = sp500.index.min()
high = sp500.index.max()
monthly_dates = pd.date_range(low, high, freq='M')
monthly = sp500.reindex(monthly_dates, method='ffill')
returns = 100 * monthly['Adj Close'].pct_change().dropna()
```

The function will compute the Sharpe ratio – the (annualized) mean divided by the (annualized) standard deviation.

```
import numpy as np
def sharpe_ratio(x):
    return np.array([12 * x.mean() / np.sqrt(12 * x.var())])
```

The bootstrapped Sharpe ratios can be directly computed using *apply*.

```
import seaborn
from arch.bootstrap import IIDBootstrap
bs = IIDBootstrap(returns)
sharpe_ratios = bs.apply(sr, 1000)
sharpe_ratios = pd.DataFrame(sharpe_ratios, columns=['Sharpe Ratio'])
sharpe_ratios.hist(bins=20)
```

2.4.2 The Bootstrap Iterator

The lowest-level method to use a bootstrap is the iterator. This is used internally in all higher-level methods that estimate a function using multiple bootstrap replications. The iterator returns a two-element tuple where the first element contains all positional arguments (in the order input) passed when constructing the bootstrap instance, and the second contains the all keyword arguments passed when constructing the instance.

This example makes uses of simulated data to demonstrate how to use the bootstrap iterator.

```
import pandas as pd
import numpy as np
```

(continues on next page)

(continued from previous page)

```

from arch.bootstrap import IIDBootstrap

x = np.random.randn(1000, 2)
y = pd.DataFrame(np.random.randn(1000, 3))
z = np.random.rand(1000, 10)
bs = IIDBootstrap(x, y=y, z=z)

for pos, kw in bs.bootstrap(1000):
    xstar = pos[0] # pos is always a tuple, even when a singleton
    ystar = kw['y'] # A dictionary
    zstar = kw['z'] # A dictionary

```

2.5 Semiparametric Bootstraps

Functions for semi-parametric bootstraps differ from those used in nonparametric bootstraps. At a minimum they must accept the keyword argument `params` which will contain the parameters estimated on the original (non-bootstrap) data. This keyword argument must be optional so that the function can be called without the keyword argument to estimate parameters. In most applications other inputs will also be needed to perform the semi-parametric step - these can be input using the `extra_kwargs` keyword input.

For simplicity, consider a semiparametric bootstrap of an OLS regression. The bootstrap step will combine the original parameter estimates and original regressors with bootstrapped residuals to construct a bootstrapped regressand. The bootstrap regressand and regressors can then be used to produce a bootstrapped parameter estimate.

The user-provided function must:

- Estimate the parameters when `params` is not provided
- Estimate residuals from bootstrapped data when `params` is provided to construct bootstrapped residuals, simulate the regressand, and then estimate the bootstrapped parameters

```

import numpy as np
def ols(y, x, params=None, x_orig=None):
    if params is None:
        return np.linalg.pinv(x).dot(y).ravel()

    # When params is not None
    # Bootstrap residuals
    resids = y - x.dot(params)
    # Simulated data
    y_star = x_orig.dot(params) + resids
    # Parameter estimates
    return np.linalg.pinv(x_orig).dot(y_star).ravel()

```

Note: The function should return a 1-dimensional array. `ravel` is used above to ensure that the parameters estimated are 1d.

This function can then be used to perform a semiparametric bootstrap

```
from arch.bootstrap import IIDBootstrap
x = np.random.randn(100, 3)
e = np.random.randn(100, 1)
b = np.arange(1, 4)[: , None]
y = x.dot(b) + e
bs = IIDBootstrap(y, x)
ci = bs.conf_int(ols, 1000, method='percentile',
                sampling='semi', extra_kwarg={'x_orig': x})
```

2.5.1 Using partial instead of extra_kwarg

`functools.partial` can be used instead to provide a wrapper function which can then be used in the bootstrap. This example fixed the value of `x_orig` so that it is not necessary to use `extra_kwarg`.

```
from functools import partial
ols_partial = partial(ols, x_orig=x)
ci = bs.conf_int(ols_partial, 1000, sampling='semi')
```

2.5.2 Semiparametric Bootstrap (Alternative Method)

Since semiparametric bootstraps are effectively bootstrapping residuals, an alternative method can be used to conduct a semiparametric bootstrap. This requires passing both the data and the estimated residuals when initializing the bootstrap.

First, the function used must account for this structure.

```
def ols_semi_v2(y, x, resid=None, param=None, x_orig=None):
    if param is None:
        return np.linalg.pinv(x).dot(y).ravel()

    # Simulated data if param provided
    y_star = x_orig.dot(param) + resid
    # Parameter estimates
    return np.linalg.pinv(x_orig).dot(y_star).ravel()
```

This version can then be used to *directly* implement a semiparametric bootstrap, although ultimately it is not meaningfully simpler than the previous method.

```
resid = y - x.dot(ols_semi_v2(y,x))
bs = IIDBootstrap(y, x, resid=resid)
bs.conf_int(ols_semi_v2, 1000, sampling='semi', extra_kwarg={'x_orig': x})
```

Note: This alternative method is more useful when computing residuals is relatively expensive when compared to simulating data or estimating parameters. These circumstances are rarely encountered in actual problems.

2.6 Parametric Bootstraps

Parametric bootstraps are meaningfully different from their nonparametric or semiparametric cousins. Instead of sampling the data to simulate the data (or residuals, in the case of a semiparametric bootstrap), a parametric bootstrap makes use of a fully parametric model to simulate data using a pseudo-random number generator.

Warning: Parametric bootstraps are model-based methods to construct exact confidence intervals through integration. Since these confidence intervals should be exact, bootstrap methods which make use of asymptotic normality are required (and may not be desirable).

Implementing a parametric bootstrap, like implementing a semi-parametric bootstrap, requires specific keyword arguments. The first is `params`, which, when present, will contain the parameters estimated on the original data. The second is `rng` which will contain the `numpy.random.RandomState` instance that is used by the bootstrap. This is provided to facilitate simulation in a reproducible manner.

A parametric bootstrap function must:

- Estimate the parameters when `params` is not provided
- Simulate data when `params` is provided and then estimate the bootstrapped parameters on the simulated data

This example continues the OLS example from the semiparametric example, only assuming that residuals are normally distributed. The variance estimator is the MLE.

```
def ols_para(y, x, params=None, state=None, x_orig=None):
    if params is None:
        beta = np.linalg.pinv(x).dot(y)
        e = y - x.dot(beta)
        sigma2 = e.T.dot(e) / e.shape[0]
        return np.r_[beta.ravel(), sigma2.ravel()]

    beta = params[:-1]
    sigma2 = params[-1]
    e = state.standard_normal(x_orig.shape[0])
    ystar = x_orig.dot(beta) + np.sqrt(sigma2) * e

    # Use the plain function to compute parameters
    return ols_para(ystar, x_orig)
```

This function can then be used to form parametric bootstrap confidence intervals.

```
bs = IIDBootstrap(y, x)
ci = bs.conf_int(ols_para, 1000, method='percentile',
                sampling='parametric', extra_kwargs={'x_orig': x})
```

Note: The parameter vector in this example includes the variance since this is required when specifying a complete model.

2.7 Independent, Identical Distributed Data (i.i.d.)

IIDBootstrap is the standard bootstrap that is appropriate for data that is either i.i.d. or at least not serially dependent.

| | |
|---|------------------------------------|
| <i>IIDBootstrap</i> (*args[, random_state, seed]) | Bootstrap using uniform resampling |
|---|------------------------------------|

2.7.1 arch.bootstrap.IIDBootstrap

class arch.bootstrap.IIDBootstrap(*args, random_state=None, seed=None, **kwargs)

Bootstrap using uniform resampling

Parameters

args

Positional arguments to bootstrap

seed

[{Generator, RandomState, int}, optional] Seed to use to ensure reproducible results. If an int, passes the value to value to np.random.default_rng. If None, a fresh Generator is constructed with system-provided entropy.

random_state

[RandomState, optional] RandomState to use to ensure reproducible results. Cannot be used with seed

Deprecated since version 5.0: The random_state keyword argument has been deprecated. Use seed instead.

kwargs

Keyword arguments to bootstrap

See also:

[*arch.bootstrap.IndependentSamplesBootstrap*](#)

Notes

Supports numpy arrays and pandas Series and DataFrames. Data returned has the same type as the input data.

Data entered using keyword arguments is directly accessible as an attribute.

To ensure a reproducible bootstrap, you must set the seed attribute after the bootstrap has been created. See the example below. Note that seed is a reserved keyword and any variable passed using this keyword must be an integer, a Generator or a RandomState.

Examples

Data can be accessed in a number of ways. Positional data is retained in the same order as it was entered when the bootstrap was initialized. Keyword data is available both as an attribute or using a dictionary syntax on `kw_data`.

```
>>> from arch.bootstrap import IIDBootstrap
>>> from numpy.random import standard_normal
>>> y = standard_normal((500, 1))
>>> x = standard_normal((500, 2))
>>> z = standard_normal(500)
>>> bs = IIDBootstrap(x, y=y, z=z)
>>> for data in bs.bootstrap(100):
...     bs_x = data[0][0]
...     bs_y = data[1]['y']
...     bs_z = bs.z
```

Set the seed if reproducibility is required

```
>>> from numpy.random import default_rng
>>> seed = default_rng(1234)
>>> bs = IIDBootstrap(x, y=y, z=z, seed=seed)
```

This is equivalent to

```
>>> bs = IIDBootstrap(x, y=y, z=z, seed=1234)
```

Attributes

`data`

[[tuple](#)] Two-element tuple with the `pos_data` in the first position and `kw_data` in the second (`pos_data`, `kw_data`)

`pos_data`

[[tuple](#)] Tuple containing the positional arguments (in the order entered)

`kw_data`

[[dict](#)] Dictionary containing the keyword arguments

Methods

| | |
|--|--|
| <code>apply(func[, reps, extra_kwargs])</code> | Applies a function to bootstrap replicated data |
| <code>bootstrap(reps)</code> | Iterator for use when bootstrapping |
| <code>clone(*args[, seed])</code> | Clones the bootstrap using different data with a fresh prng. |
| <code>conf_int(func[, reps, method, size, tail, ...])</code> | |
| Parameters | |
| <code>cov(func[, reps, recenter, extra_kwargs])</code> | Compute parameter covariance using bootstrap |
| <code>get_state()</code> | Gets the state of the bootstrap's random number generator |
| <code>reset([use_seed])</code> | Resets the bootstrap to either its initial state or the last seed. |
| <code>seed(value)</code> | Reseeds the bootstrap's random number generator |
| <code>set_state(state)</code> | Sets the state of the bootstrap's random number generator |
| <code>update_indices()</code> | Update indices for the next iteration of the bootstrap. |
| <code>var(func[, reps, recenter, extra_kwargs])</code> | Compute parameter variance using bootstrap |

arch.bootstrap.IIDBootstrap.apply

IIDBootstrap.**apply**(*func*, *reps=1000*, *extra_kwargs=None*)

Applies a function to bootstrap replicated data

Parameters

func

[[callable\(\)](#)] Function the computes parameter values. See Notes for requirements

reps

[[int](#), default 1000] Number of bootstrap replications

extra_kwargs

[[dict](#), default [None](#)] Extra keyword arguments to use when calling `func`. Must not conflict with keyword arguments used to initialize bootstrap

Returns

ndarray

reps by nparam array of computed function values where each row corresponds to a bootstrap iteration

Notes

When there are no extra keyword arguments, the function is called

`func(params, *args, **kwargs)`

where `args` and `kwargs` are the bootstrap version of the data provided when setting up the bootstrap. When extra keyword arguments are used, these are appended to `kwargs` before calling `func`

Examples

```
>>> import numpy as np
>>> x = np.random.randn(1000,2)
>>> from arch.bootstrap import IIDBootstrap
>>> bs = IIDBootstrap(x)
>>> def func(y):
...     return y.mean(0)
>>> results = bs.apply(func, 100)
```

Return type
ndarray

arch.bootstrap.IIDBootstrap.bootstrap

IIDBootstrap.**bootstrap**(*reps*)

Iterator for use when bootstrapping

Parameters

reps
[int] Number of bootstrap replications

Returns

generator
Generator to iterate over in bootstrap calculations

Notes

The iterator returns a tuple containing the data entered in positional arguments as a tuple and the data entered using keywords as a dictionary

Examples

The key steps are problem dependent and so this example shows the use as an iterator that does not produce any output

```
>>> from arch.bootstrap import IIDBootstrap
>>> import numpy as np
>>> bs = IIDBootstrap(np.arange(100), x=np.random.randn(100))
>>> for posdata, kwdata in bs.bootstrap(1000):
...     # Do something with the positional data and/or keyword data
...     pass
```

Note: Note this is a generic example and so the class used should be the name of the required bootstrap

Return type
Generator[tuple[tuple[Union[ndarray, DataFrame, Series], ...], dict[str, Union[ndarray, DataFrame, Series]]], None, None]

arch.bootstrap.IIDBootstrap.clone

`IIDBootstrap.clone(*args, seed=None, **kwargs)`

Clones the bootstrap using different data with a fresh prng.

Parameters

args

Positional arguments to bootstrap

seed

The seed value to pass to the closed generator

kwargs

Keyword arguments to bootstrap

Returns

bs

Bootstrap instance

Return type

IIDBootstrap

arch.bootstrap.IIDBootstrap.conf_int

`IIDBootstrap.conf_int(func, reps=1000, method='basic', size=0.95, tail='two', extra_kwargs=None, reuse=False, sampling='nonparametric', std_err_func=None, studentize_reps=1000)`

Parameters

func

[`callable()`] Function the computes parameter values. See Notes for requirements

reps

[`int`, default 1000] Number of bootstrap replications

method

[`str`, default “basic”] One of ‘basic’, ‘percentile’, ‘studentized’, ‘norm’ (identical to ‘var’, ‘cov’), ‘bc’ (identical to ‘debiased’, ‘bias-corrected’), or ‘bca’

size

[`float`, default 0.95] Coverage of confidence interval

tail

[`str`, default “two”] One of ‘two’, ‘upper’ or ‘lower’.

reuse

[`bool`, default `False`] Flag indicating whether to reuse previously computed bootstrap results. This allows alternative methods to be compared without rerunning the bootstrap simulation. Reuse is ignored if reps is not the same across multiple runs, func changes across calls, or method is ‘studentized’.

sampling

[`str`, default “nonparametric”] Type of sampling to use: ‘nonparametric’, ‘semi-parametric’ (or ‘semi’) or ‘parametric’. The default is ‘nonparametric’. See notes about the changes to func required when using ‘semi’ or ‘parametric’.

extra_kwargs

[dict, default None] Extra keyword arguments to use when calling func and std_err_func, when appropriate

std_err_func

[callable(), default None] Function to use when standardizing estimated parameters when using the studentized bootstrap. Providing an analytical function eliminates the need for a nested bootstrap

studentize_reps

[int, default 1000] Number of bootstraps to use in the inner bootstrap when using the studentized bootstrap. Ignored when std_err_func is provided

Returns**ndarray**

Computed confidence interval. Row 0 contains the lower bounds, and row 1 contains the upper bounds. Each column corresponds to a parameter. When tail is 'lower', all upper bounds are inf. Similarly, 'upper' sets all lower bounds to -inf.

Notes

When there are no extra keyword arguments, the function is called

```
func(*args, **kwargs)
```

where args and kwargs are the bootstrap version of the data provided when setting up the bootstrap. When extra keyword arguments are used, these are appended to kwargs before calling func.

The standard error function, if provided, must return a vector of parameter standard errors and is called

```
std_err_func(params, *args, **kwargs)
```

where params is the vector of estimated parameters using the same bootstrap data as in args and kwargs.

The bootstraps are:

- 'basic' - Basic confidence using the estimated parameter and difference between the estimated parameter and the bootstrap parameters
- 'percentile' - Direct use of bootstrap percentiles
- 'norm' - Makes use of normal approximation and bootstrap covariance estimator
- 'studentized' - Uses either a standard error function or a nested bootstrap to estimate percentiles and the bootstrap covariance for scale
- 'bc' - Bias corrected using estimate bootstrap bias correction
- 'bca' - Bias corrected and accelerated, adding acceleration parameter to 'bc' method

Examples

```
>>> import numpy as np
>>> def func(x):
...     return x.mean(0)
>>> y = np.random.randn(1000, 2)
>>> from arch.bootstrap import IIDBootstrap
>>> bs = IIDBootstrap(y)
>>> ci = bs.conf_int(func, 1000)
```

Return type
ndarray

arch.bootstrap.IIDBootstrap.cov

`IIDBootstrap.cov(func, reps=1000, recenter=True, extra_kwargs=None)`

Compute parameter covariance using bootstrap

Parameters

func

[callable()] Callable function that returns the statistic of interest as a 1-d array

reps

[int, default 1000] Number of bootstrap replications

recenter

[bool, default True] Whether to center the bootstrap variance estimator on the average of the bootstrap samples (True) or to center on the original sample estimate (False). Default is True.

extra_kwargs

[dict, default None] Dictionary of extra keyword arguments to pass to func

Returns

ndarray

Bootstrap covariance estimator

Notes

func must have the signature

```
func(params, *args, **kwargs)
```

where params are a 1-dimensional array, and **args* and ***kwargs* are data used in the the bootstrap. The first argument, params, will be none when called using the original data, and will contain the estimate computed using the original data in bootstrap replications. This parameter is passed to allow parametric bootstrap simulation.

Examples

Bootstrap covariance of the mean

```
>>> from arch.bootstrap import IIDBootstrap
>>> import numpy as np
>>> def func(x):
...     return x.mean(axis=0)
>>> y = np.random.randn(1000, 3)
>>> bs = IIDBootstrap(y)
>>> cov = bs.cov(func, 1000)
```

Bootstrap covariance using a function that takes additional input

```
>>> def func(x, stat='mean'):
...     if stat=='mean':
...         return x.mean(axis=0)
...     elif stat=='var':
...         return x.var(axis=0)
>>> cov = bs.cov(func, 1000, extra_kwargs={'stat':'var'})
```

Note: Note this is a generic example and so the class used should be the name of the required bootstrap

Return type

float | ndarray

arch.bootstrap.IIDBootstrap.get_state

`IIDBootstrap.get_state()`

Gets the state of the bootstrap's random number generator

Returns

dict

Dictionary containing the state.

Return type

Union[Tuple[str, ndarray, int, int, float], Mapping[str, Any]]

arch.bootstrap.IIDBootstrap.reset

`IIDBootstrap.reset(use_seed=True)`

Resets the bootstrap to either its initial state or the last seed.

Parameters

use_seed

[bool, default True] Flag indicating whether to use the last seed if provided. If False or if no seed has been set, the bootstrap will be reset to the initial state. Default is True

Return type

None

arch.bootstrap.IIDBootstrap.seed

IIDBootstrap.**seed**(*value*)

Reseeds the bootstrap's random number generator

Parameters

value

[*int*, *List[int]*, *ndarray*] Value to use as the seed.

Return type

None

arch.bootstrap.IIDBootstrap.set_state

IIDBootstrap.**set_state**(*state*)

Sets the state of the bootstrap's random number generator

Parameters

state

[*dict*] Dictionary or tuple containing the state.

Return type

None

arch.bootstrap.IIDBootstrap.update_indices

IIDBootstrap.**update_indices**()

Update indices for the next iteration of the bootstrap. This must be overridden when creating new bootstraps.

Return type

Union[ndarray, Tuple[ndarray, ...], Tuple[List[ndarray], Dict[str, ndarray]]]

arch.bootstrap.IIDBootstrap.var

IIDBootstrap.**var**(*func*, *reps=1000*, *recenter=True*, *extra_kwargs=None*)

Compute parameter variance using bootstrap

Parameters

func

[*callable*()] Callable function that returns the statistic of interest as a 1-d array

reps

[*int*, default 1000] Number of bootstrap replications

recenter

[*bool*, default *True*] Whether to center the bootstrap variance estimator on the average of the bootstrap samples (*True*) or to center on the original sample estimate (*False*). Default is *True*.

extra_kwargs: dict, default None

Dictionary of extra keyword arguments to pass to *func*

Returns

ndarray

Bootstrap variance estimator

Notes

func must have the signature

```
func(params, *args, **kwargs)
```

where params are a 1-dimensional array, and **args* and ***kwargs* are data used in the the bootstrap. The first argument, params, will be none when called using the original data, and will contain the estimate computed using the original data in bootstrap replications. This parameter is passed to allow parametric bootstrap simulation.

Examples

Bootstrap covariance of the mean

```
>>> from arch.bootstrap import IIDBootstrap
>>> import numpy as np
>>> def func(x):
...     return x.mean(axis=0)
>>> y = np.random.randn(1000, 3)
>>> bs = IIDBootstrap(y)
>>> variances = bs.var(func, 1000)
```

Bootstrap covariance using a function that takes additional input

```
>>> def func(x, stat='mean'):
...     if stat=='mean':
...         return x.mean(axis=0)
...     elif stat=='var':
...         return x.var(axis=0)
>>> variances = bs.var(func, 1000, extra_kwargs={'stat': 'var'})
```

Note: Note this is a generic example and so the class used should be the name of the required bootstrap

Return type

float | ndarray

Properties

| | |
|---------------------|--------------------------------------|
| <i>generator</i> | Set or get the instance PRNG |
| <i>index</i> | The current index of the bootstrap |
| <i>random_state</i> | Set or get the instance random state |
| <i>state</i> | Set or get the generator's state |

arch.bootstrap.IIDBootstrap.generator

property IIDBootstrap.generator: `numpy.random._generator.Generator` | `numpy.random.mtrand.RandomState`

Set or get the instance PRNG

Parameters

seed

[{`Generator`, `RandomState`}, optional] Generator or `RandomState` used to produce the pseudo-random values used in the bootstrap

Returns

{`Generator`, `RandomState`}

The instance of the `Generator` or `RandomState` instance used by bootstrap

Return type

`Generator` | `RandomState`

arch.bootstrap.IIDBootstrap.index

property IIDBootstrap.index: `Union[ndarray, Tuple[ndarray, ...], Tuple[List[ndarray], Dict[str, ndarray]]]`

The current index of the bootstrap

Return type

`Union[ndarray, Tuple[ndarray, ...], Tuple[List[ndarray], Dict[str, ndarray]]]`

arch.bootstrap.IIDBootstrap.random_state

property IIDBootstrap.random_state: `numpy.random._generator.Generator` | `numpy.random.mtrand.RandomState`

Set or get the instance random state

Parameters

random_state

[`RandomState`] `RandomState` instance used by bootstrap

Returns

`RandomState`

`RandomState` instance used by bootstrap

Return type

`Generator` | `RandomState`

arch.bootstrap.IIDBootstrap.state

property IIDBootstrap.state: Union[Tuple[str, ndarray, int, int, float], Mapping[str, Any]]

Set or get the generator's state

Returns

{tuple, dict}

A tuple or dictionary containing the generator's state. If using a RandomState, the value returned is a tuple. Otherwise it is a dictionary.

Return type

Union[Tuple[str, ndarray, int, int, float], Mapping[str, Any]]

2.8 Independent Samples

IndependentSamplesBootstrap is a bootstrap that is appropriate for data is totally independent, and where each variable may have a different sample size. This type of data arises naturally in experimental settings, e.g., website A/B testing.

IndependentSamplesBootstrap(*args[, ...]) Bootstrap where each input is independently resampled

2.8.1 arch.bootstrap.IndependentSamplesBootstrap

class arch.bootstrap.IndependentSamplesBootstrap(*args, random_state=None, seed=None, **kwargs)

Bootstrap where each input is independently resampled

Parameters

args

Positional arguments to bootstrap

kwargs

Keyword arguments to bootstrap

See also:

[*arch.bootstrap.IIDBootstrap*](#)

Notes

This bootstrap independently resamples each input and so is only appropriate when the inputs are independent. This structure allows bootstrapping statistics that depend on samples with unequal length, as is common in some experiments. If data have cross-sectional dependence, so that observation *i* is related across all inputs, this bootstrap is inappropriate.

Supports numpy arrays and pandas Series and DataFrames. Data returned has the same type as the input data.

Data entered using keyword arguments is directly accessible as an attribute.

To ensure a reproducible bootstrap, you must set the `random_state` attribute after the bootstrap has been created. See the example below. Note that `random_state` is a reserved keyword and any variable passed using this keyword must be an instance of `RandomState`.

Examples

Data can be accessed in a number of ways. Positional data is retained in the same order as it was entered when the bootstrap was initialized. Keyword data is available both as an attribute or using a dictionary syntax on `kw_data`.

```
>>> from arch.bootstrap import IndependentSamplesBootstrap
>>> from numpy.random import standard_normal
>>> y = standard_normal(500)
>>> x = standard_normal(200)
>>> z = standard_normal(2000)
>>> bs = IndependentSamplesBootstrap(x, y=y, z=z)
>>> for data in bs.bootstrap(100):
...     bs_x = data[0][0]
...     bs_y = data[1]['y']
...     bs_z = bs.z
```

Set the `random_state` if reproducibility is required

```
>>> from numpy.random import RandomState
>>> rs = RandomState(1234)
>>> bs = IndependentSamplesBootstrap(x, y=y, z=z, random_state=rs)
```

Attributes

`data`

[tuple] Two-element tuple with the `pos_data` in the first position and `kw_data` in the second (`pos_data`, `kw_data`)

`pos_data`

[tuple] Tuple containing the positional arguments (in the order entered)

`kw_data`

[dict] Dictionary containing the keyword arguments

Methods

| | |
|--|--|
| <code>apply(func[, reps, extra_kwargs])</code> | Applies a function to bootstrap replicated data |
| <code>bootstrap(reps)</code> | Iterator for use when bootstrapping |
| <code>clone(*args[, seed])</code> | Clones the bootstrap using different data with a fresh prng. |
| <code>conf_int(func[, reps, method, size, tail, ...])</code> | |
| Parameters | |
| <code>cov(func[, reps, recenter, extra_kwargs])</code> | Compute parameter covariance using bootstrap |
| <code>get_state()</code> | Gets the state of the bootstrap's random number generator |
| <code>reset([use_seed])</code> | Resets the bootstrap to either its initial state or the last seed. |
| <code>seed(value)</code> | Reseeds the bootstrap's random number generator |
| <code>set_state(state)</code> | Sets the state of the bootstrap's random number generator |
| <code>update_indices()</code> | Update indices for the next iteration of the bootstrap. |
| <code>var(func[, reps, recenter, extra_kwargs])</code> | Compute parameter variance using bootstrap |

arch.bootstrap.IndependentSamplesBootstrap.apply

IndependentSamplesBootstrap.**apply**(*func*, *reps*=1000, *extra_kwargs*=None)

Applies a function to bootstrap replicated data

Parameters**func**

[*callable*()] Function the computes parameter values. See Notes for requirements

reps

[*int*, default 1000] Number of bootstrap replications

extra_kwargs

[*dict*, default None] Extra keyword arguments to use when calling *func*. Must not conflict with keyword arguments used to initialize bootstrap

Returns**ndarray**

reps by nparam array of computed function values where each row corresponds to a bootstrap iteration

Notes

When there are no extra keyword arguments, the function is called

```
func(params, *args, **kwargs)
```

where *args* and *kwargs* are the bootstrap version of the data provided when setting up the bootstrap. When extra keyword arguments are used, these are appended to *kwargs* before calling *func*

Examples

```
>>> import numpy as np
>>> x = np.random.randn(1000,2)
>>> from arch.bootstrap import IIDBootstrap
>>> bs = IIDBootstrap(x)
>>> def func(y):
...     return y.mean(0)
>>> results = bs.apply(func, 100)
```

Return type

ndarray

arch.bootstrap.IndependentSamplesBootstrap.bootstrap

IndependentSamplesBootstrap.bootstrap(*reps*)

Iterator for use when bootstrapping

Parameters

reps
[int] Number of bootstrap replications

Returns

generator
Generator to iterate over in bootstrap calculations

Notes

The iterator returns a tuple containing the data entered in positional arguments as a tuple and the data entered using keywords as a dictionary

Examples

The key steps are problem dependent and so this example shows the use as an iterator that does not produce any output

```
>>> from arch.bootstrap import IIDBootstrap
>>> import numpy as np
>>> bs = IIDBootstrap(np.arange(100), x=np.random.randn(100))
>>> for posdata, kwdata in bs.bootstrap(1000):
...     # Do something with the positional data and/or keyword data
...     pass
```

Note: Note this is a generic example and so the class used should be the name of the required bootstrap

Return type

Generator[tuple[tuple[Union[ndarray, DataFrame, Series], ...], dict[str, Union[ndarray, DataFrame, Series]]], None, None]

arch.bootstrap.IndependentSamplesBootstrap.clone

IndependentSamplesBootstrap.clone(*args, seed=None, **kwargs)

Clones the bootstrap using different data with a fresh prng.

Parameters

args
Positional arguments to bootstrap

seed
The seed value to pass to the closed generator

kwargs
Keyword arguments to bootstrap

Returns

bs
Bootstrap instance

Return type

IIDBootstrap

arch.bootstrap.IndependentSamplesBootstrap.conf_int

`IndependentSamplesBootstrap.conf_int(func, reps=1000, method='basic', size=0.95, tail='two', extra_kwargs=None, reuse=False, sampling='nonparametric', std_err_func=None, studentize_reps=1000)`

Parameters

func
[`callable()`] Function the computes parameter values. See Notes for requirements

reps
[`int`, default 1000] Number of bootstrap replications

method
[`str`, default “basic”] One of ‘basic’, ‘percentile’, ‘studentized’, ‘norm’ (identical to ‘var’, ‘cov’), ‘bc’ (identical to ‘debiased’, ‘bias-corrected’), or ‘bca’

size
[`float`, default 0.95] Coverage of confidence interval

tail
[`str`, default “two”] One of ‘two’, ‘upper’ or ‘lower’.

reuse
[`bool`, default `False`] Flag indicating whether to reuse previously computed bootstrap results. This allows alternative methods to be compared without rerunning the bootstrap simulation. Reuse is ignored if reps is not the same across multiple runs, func changes across calls, or method is ‘studentized’.

sampling
[`str`, default “nonparametric”] Type of sampling to use: ‘nonparametric’, ‘semi-parametric’ (or ‘semi’) or ‘parametric’. The default is ‘nonparametric’. See notes about the changes to func required when using ‘semi’ or ‘parametric’.

extra_kwargs
[`dict`, default `None`] Extra keyword arguments to use when calling func and std_err_func, when appropriate

std_err_func
[`callable()`, default `None`] Function to use when standardizing estimated parameters when using the studentized bootstrap. Providing an analytical function eliminates the need for a nested bootstrap

studentize_reps
[`int`, default 1000] Number of bootstraps to use in the inner bootstrap when using the studentized bootstrap. Ignored when std_err_func is provided

Returns

`ndarray`
Computed confidence interval. Row 0 contains the lower bounds, and row 1 contains the

upper bounds. Each column corresponds to a parameter. When tail is 'lower', all upper bounds are inf. Similarly, 'upper' sets all lower bounds to -inf.

Notes

When there are no extra keyword arguments, the function is called

```
func(*args, **kwargs)
```

where args and kwargs are the bootstrap version of the data provided when setting up the bootstrap. When extra keyword arguments are used, these are appended to kwargs before calling func.

The standard error function, if provided, must return a vector of parameter standard errors and is called

```
std_err_func(params, *args, **kwargs)
```

where params is the vector of estimated parameters using the same bootstrap data as in args and kwargs.

The bootstraps are:

- 'basic' - Basic confidence using the estimated parameter and difference between the estimated parameter and the bootstrap parameters
- 'percentile' - Direct use of bootstrap percentiles
- 'norm' - Makes use of normal approximation and bootstrap covariance estimator
- 'studentized' - Uses either a standard error function or a nested bootstrap to estimate percentiles and the bootstrap covariance for scale
- 'bc' - Bias corrected using estimate bootstrap bias correction
- 'bca' - Bias corrected and accelerated, adding acceleration parameter to 'bc' method

Examples

```
>>> import numpy as np
>>> def func(x):
...     return x.mean(0)
>>> y = np.random.randn(1000, 2)
>>> from arch.bootstrap import IIDBootstrap
>>> bs = IIDBootstrap(y)
>>> ci = bs.conf_int(func, 1000)
```

Return type

ndarray

arch.bootstrap.IndependentSamplesBootstrap.cov

IndependentSamplesBootstrap.cov(*func*, *reps*=1000, *recenter*=True, *extra_kwargs*=None)

Compute parameter covariance using bootstrap

Parameters

func

[callable()] Callable function that returns the statistic of interest as a 1-d array

reps

[int, default 1000] Number of bootstrap replications

recenter

[bool, default True] Whether to center the bootstrap variance estimator on the average of the bootstrap samples (True) or to center on the original sample estimate (False). Default is True.

extra_kwargs

[dict, default None] Dictionary of extra keyword arguments to pass to func

Returns

ndarray

Bootstrap covariance estimator

Notes

func must have the signature

```
func(params, *args, **kwargs)
```

where params are a 1-dimensional array, and *args and **kwargs are data used in the the bootstrap. The first argument, params, will be none when called using the original data, and will contain the estimate computed using the original data in bootstrap replications. This parameter is passed to allow parametric bootstrap simulation.

Examples

Bootstrap covariance of the mean

```
>>> from arch.bootstrap import IIDBootstrap
>>> import numpy as np
>>> def func(x):
...     return x.mean(axis=0)
>>> y = np.random.randn(1000, 3)
>>> bs = IIDBootstrap(y)
>>> cov = bs.cov(func, 1000)
```

Bootstrap covariance using a function that takes additional input

```
>>> def func(x, stat='mean'):
...     if stat=='mean':
...         return x.mean(axis=0)
...     elif stat=='var':
```

(continues on next page)

(continued from previous page)

```
...         return x.var(axis=0)
>>> cov = bs.cov(func, 1000, extra_kwargs={'stat': 'var'})
```

Note: Note this is a generic example and so the class used should be the name of the required bootstrap

Return type`float | ndarray`**arch.bootstrap.IndependentSamplesBootstrap.get_state**`IndependentSamplesBootstrap.get_state()`

Gets the state of the bootstrap's random number generator

Returns`dict`

Dictionary containing the state.

Return type`Union[Tuple[str, ndarray, int, int, float], Mapping[str, Any]]`**arch.bootstrap.IndependentSamplesBootstrap.reset**`IndependentSamplesBootstrap.reset(use_seed=True)`

Resets the bootstrap to either its initial state or the last seed.

Parameters**use_seed**

[`bool`, `default True`] Flag indicating whether to use the last seed if provided. If `False` or if no seed has been set, the bootstrap will be reset to the initial state. Default is `True`

Return type`None`**arch.bootstrap.IndependentSamplesBootstrap.seed**`IndependentSamplesBootstrap.seed(value)`

Reseeds the bootstrap's random number generator

Parameters**value**

[`{int, List[int], ndarray}`] Value to use as the seed.

Return type`None`

arch.bootstrap.IndependentSamplesBootstrap.set_state

`IndependentSamplesBootstrap.set_state(state)`

Sets the state of the bootstrap's random number generator

Parameters

state
[dict] Dictionary or tuple containing the state.

Return type

None

arch.bootstrap.IndependentSamplesBootstrap.update_indices

`IndependentSamplesBootstrap.update_indices()`

Update indices for the next iteration of the bootstrap. This must be overridden when creating new bootstraps.

Return type

tuple[list[ndarray], dict[str, ndarray]]

arch.bootstrap.IndependentSamplesBootstrap.var

`IndependentSamplesBootstrap.var(func, reps=1000, recenter=True, extra_kwargs=None)`

Compute parameter variance using bootstrap

Parameters

func
[callable()] Callable function that returns the statistic of interest as a 1-d array

reps
[int, default 1000] Number of bootstrap replications

recenter
[bool, default True] Whether to center the bootstrap variance estimator on the average of the bootstrap samples (True) or to center on the original sample estimate (False). Default is True.

extra_kwargs: dict, default None
Dictionary of extra keyword arguments to pass to func

Returns

ndarray
Bootstrap variance estimator

Notes

func must have the signature

```
func(params, *args, **kwargs)
```

where params are a 1-dimensional array, and **args* and ***kwargs* are data used in the the bootstrap. The first argument, params, will be none when called using the original data, and will contain the estimate computed using the original data in bootstrap replications. This parameter is passed to allow parametric bootstrap simulation.

Examples

Bootstrap covariance of the mean

```
>>> from arch.bootstrap import IIDBootstrap
>>> import numpy as np
>>> def func(x):
...     return x.mean(axis=0)
>>> y = np.random.randn(1000, 3)
>>> bs = IIDBootstrap(y)
>>> variances = bs.var(func, 1000)
```

Bootstrap covariance using a function that takes additional input

```
>>> def func(x, stat='mean'):
...     if stat=='mean':
...         return x.mean(axis=0)
...     elif stat=='var':
...         return x.var(axis=0)
>>> variances = bs.var(func, 1000, extra_kwargs={'stat': 'var'})
```

Note: Note this is a generic example and so the class used should be the name of the required bootstrap

Return type

float | ndarray

Properties

| | |
|---------------------|--|
| <i>generator</i> | Set or get the instance PRNG |
| <i>index</i> | Returns the current index of the bootstrap |
| <i>random_state</i> | Set or get the instance random state |
| <i>state</i> | Set or get the generator's state |

arch.bootstrap.IndependentSamplesBootstrap.generator

property IndependentSamplesBootstrap.generator: `numpy.random._generator.Generator` | `numpy.random.mtrand.RandomState`

Set or get the instance PRNG

Parameters**seed**

[{Generator, RandomState}, optional] Generator or RandomState used to produce the pseudo-random values used in the bootstrap

Returns

{Generator, RandomState}

The instance of the Generator or RandomState instance used by bootstrap

Return type

Generator | RandomState

arch.bootstrap.IndependentSamplesBootstrap.index

property IndependentSamplesBootstrap.index: `Union[ndarray, Tuple[ndarray, ...], Tuple[List[ndarray], Dict[str, ndarray]]]`

Returns the current index of the bootstrap

Returns

`tuple[list[ndarray], dict[str, ndarray]]`

2-element tuple containing a list and a dictionary. The list contains indices for each of the positional arguments. The dictionary contains the indices of keyword arguments.

Return type

`Union[ndarray, Tuple[ndarray, ...], Tuple[List[ndarray], Dict[str, ndarray]]]`

arch.bootstrap.IndependentSamplesBootstrap.random_state

property IndependentSamplesBootstrap.random_state: `numpy.random._generator.Generator` | `numpy.random.mtrand.RandomState`

Set or get the instance random state

Parameters**random_state**

[RandomState] RandomState instance used by bootstrap

Returns

RandomState

RandomState instance used by bootstrap

Return type

Generator | RandomState

arch.bootstrap.IndependentSamplesBootstrap.state

property IndependentSamplesBootstrap.state: Union[Tuple[str, ndarray, int, int, float], Mapping[str, Any]]

Set or get the generator's state

Returns

{tuple, dict}

A tuple or dictionary containing the generator's state. If using a RandomState, the value returned is a tuple. Otherwise it is a dictionary.

Return type

Union[Tuple[str, ndarray, int, int, float], Mapping[str, Any]]

2.9 Time-series Bootstraps

Bootstraps for time-series data come in a variety of forms. The three contained in this package are the stationary bootstrap (*StationaryBootstrap*), which uses blocks with an exponentially distributed lengths, the circular block bootstrap (*CircularBlockBootstrap*), which uses fixed length blocks, and the moving block bootstrap which also uses fixed length blocks (*MovingBlockBootstrap*). The moving block bootstrap does *not* wrap around and so observations near the start or end of the series will be systematically under-sampled. It is not recommended for this reason.

| | |
|--|---|
| <i>StationaryBootstrap</i> (block_size, *args[, ...]) | Politis and Romano (1994) bootstrap with expon distributed block sizes |
| <i>CircularBlockBootstrap</i> (block_size, *args[, ...]) | Bootstrap using blocks of the same length with end-to-start wrap around |
| <i>MovingBlockBootstrap</i> (block_size, *args[, ...]) | Bootstrap using blocks of the same length without wrap around |
| <i>optimal_block_length</i> (x) | Estimate optimal window length for time-series bootstraps |

2.9.1 arch.bootstrap.StationaryBootstrap

class arch.bootstrap.StationaryBootstrap(block_size, *args, random_state=None, seed=None, **kwargs)

Politis and Romano (1994) bootstrap with expon distributed block sizes

Parameters

block_size

[int] Average size of block to use

args

Positional arguments to bootstrap

seed

[{Generator, RandomState, int}], optional] Seed to use to ensure reproducible results. If an int, passes the value to value to np.random.default_rng. If None, a fresh Generator is constructed with system-provided entropy.

random_state

[RandomState, optional] RandomState to use to ensure reproducible results. Cannot be used with seed

Deprecated since version 5.0: The `random_state` keyword argument has been deprecated. Use `seed` instead.

kwargs

Keyword arguments to bootstrap

See also:

arch.bootstrap.optimal_block_length

Optimal block length estimation

arch.bootstrap.CircularBlockBootstrap

Circular (wrap-around) bootstrap

Notes

Supports numpy arrays and pandas Series and DataFrames. Data returned has the same type as the input data.

Data entered using keyword arguments is directly accessible as an attribute.

To ensure a reproducible bootstrap, you must set the `random_state` attribute after the bootstrap has been created. See the example below. Note that `random_state` is a reserved keyword and any variable passed using this keyword must be an instance of `RandomState`.

Examples

Data can be accessed in a number of ways. Positional data is retained in the same order as it was entered when the bootstrap was initialized. Keyword data is available both as an attribute or using a dictionary syntax on `kw_data`.

```
>>> from arch.bootstrap import StationaryBootstrap
>>> from numpy.random import standard_normal
>>> y = standard_normal((500, 1))
>>> x = standard_normal((500, 2))
>>> z = standard_normal(500)
>>> bs = StationaryBootstrap(12, x, y=y, z=z)
>>> for data in bs.bootstrap(100):
...     bs_x = data[0][0]
...     bs_y = data[1]['y']
...     bs_z = bs.z
```

Set the `random_state` if reproducibility is required

```
>>> from numpy.random import RandomState
>>> rs = RandomState(1234)
>>> bs = StationaryBootstrap(12, x, y=y, z=z, random_state=rs)
```

Attributes

data

[tuple] Two-element tuple with the `pos_data` in the first position and `kw_data` in the second (`pos_data`, `kw_data`)

pos_data

[tuple] Tuple containing the positional arguments (in the order entered)

kw_data

[dict] Dictionary containing the keyword arguments

Methods

| | |
|--|--|
| <code>apply(func[, reps, extra_kwargs])</code> | Applies a function to bootstrap replicated data |
| <code>bootstrap(reps)</code> | Iterator for use when bootstrapping |
| <code>clone(*args[, seed])</code> | Clones the bootstrap using different data with a fresh prng. |
| <code>conf_int(func[, reps, method, size, tail, ...])</code> | |
| Parameters | |
| <code>cov(func[, reps, recenter, extra_kwargs])</code> | Compute parameter covariance using bootstrap |
| <code>get_state()</code> | Gets the state of the bootstrap's random number generator |
| <code>reset([use_seed])</code> | Resets the bootstrap to either its initial state or the last seed. |
| <code>seed(value)</code> | Reseeds the bootstrap's random number generator |
| <code>set_state(state)</code> | Sets the state of the bootstrap's random number generator |
| <code>update_indices()</code> | Update indices for the next iteration of the bootstrap. |
| <code>var(func[, reps, recenter, extra_kwargs])</code> | Compute parameter variance using bootstrap |

arch.bootstrap.StationaryBootstrap.apply

StationaryBootstrap.**apply**(*func*, *reps=1000*, *extra_kwargs=None*)

Applies a function to bootstrap replicated data

Parameters

func

[[callable\(\)](#)] Function the computes parameter values. See Notes for requirements

reps

[[int](#), default 1000] Number of bootstrap replications

extra_kwargs

[[dict](#), default [None](#)] Extra keyword arguments to use when calling `func`. Must not conflict with keyword arguments used to initialize bootstrap

Returns

ndarray

reps by nparam array of computed function values where each row corresponds to a bootstrap iteration

Notes

When there are no extra keyword arguments, the function is called

`func(params, *args, **kwargs)`

where `args` and `kwargs` are the bootstrap version of the data provided when setting up the bootstrap. When extra keyword arguments are used, these are appended to `kwargs` before calling `func`

Examples

```

>>> import numpy as np
>>> x = np.random.randn(1000,2)
>>> from arch.bootstrap import IIDBootstrap
>>> bs = IIDBootstrap(x)
>>> def func(y):
...     return y.mean(0)
>>> results = bs.apply(func, 100)

```

Return type
ndarray

arch.bootstrap.StationaryBootstrap.bootstrap

StationaryBootstrap.**bootstrap**(*reps*)

Iterator for use when bootstrapping

Parameters

reps
[int] Number of bootstrap replications

Returns

generator
Generator to iterate over in bootstrap calculations

Notes

The iterator returns a tuple containing the data entered in positional arguments as a tuple and the data entered using keywords as a dictionary

Examples

The key steps are problem dependent and so this example shows the use as an iterator that does not produce any output

```

>>> from arch.bootstrap import IIDBootstrap
>>> import numpy as np
>>> bs = IIDBootstrap(np.arange(100), x=np.random.randn(100))
>>> for posdata, kwdata in bs.bootstrap(1000):
...     # Do something with the positional data and/or keyword data
...     pass

```

Note: Note this is a generic example and so the class used should be the name of the required bootstrap

Return type
Generator[tuple[tuple[Union[ndarray, DataFrame, Series], ...], dict[str, Union[ndarray, DataFrame, Series]]], None, None]

arch.bootstrap.StationaryBootstrap.clone

`StationaryBootstrap.clone(*args, seed=None, **kwargs)`

Clones the bootstrap using different data with a fresh prng.

Parameters

args

Positional arguments to bootstrap

seed

The seed value to pass to the closed generator

kwargs

Keyword arguments to bootstrap

Returns

bs

Bootstrap instance

Return type

CircularBlockBootstrap

arch.bootstrap.StationaryBootstrap.conf_int

`StationaryBootstrap.conf_int(func, reps=1000, method='basic', size=0.95, tail='two',
extra_kwargs=None, reuse=False, sampling='nonparametric',
std_err_func=None, studentize_reps=1000)`

Parameters

func

[`callable()`] Function the computes parameter values. See Notes for requirements

reps

[`int`, default 1000] Number of bootstrap replications

method

[`str`, default “basic”] One of ‘basic’, ‘percentile’, ‘studentized’, ‘norm’ (identical to ‘var’, ‘cov’), ‘bc’ (identical to ‘debiased’, ‘bias-corrected’), or ‘bca’

size

[`float`, default 0.95] Coverage of confidence interval

tail

[`str`, default “two”] One of ‘two’, ‘upper’ or ‘lower’.

reuse

[`bool`, default `False`] Flag indicating whether to reuse previously computed bootstrap results. This allows alternative methods to be compared without rerunning the bootstrap simulation. Reuse is ignored if reps is not the same across multiple runs, func changes across calls, or method is ‘studentized’.

sampling

[`str`, default “nonparametric”] Type of sampling to use: ‘nonparametric’, ‘semi-parametric’ (or ‘semi’) or ‘parametric’. The default is ‘nonparametric’. See notes about the changes to func required when using ‘semi’ or ‘parametric’.

extra_kwargs

[dict, default None] Extra keyword arguments to use when calling func and std_err_func, when appropriate

std_err_func

[callable(), default None] Function to use when standardizing estimated parameters when using the studentized bootstrap. Providing an analytical function eliminates the need for a nested bootstrap

studentize_reps

[int, default 1000] Number of bootstraps to use in the inner bootstrap when using the studentized bootstrap. Ignored when std_err_func is provided

Returns**ndarray**

Computed confidence interval. Row 0 contains the lower bounds, and row 1 contains the upper bounds. Each column corresponds to a parameter. When tail is 'lower', all upper bounds are inf. Similarly, 'upper' sets all lower bounds to -inf.

Notes

When there are no extra keyword arguments, the function is called

```
func(*args, **kwargs)
```

where args and kwargs are the bootstrap version of the data provided when setting up the bootstrap. When extra keyword arguments are used, these are appended to kwargs before calling func.

The standard error function, if provided, must return a vector of parameter standard errors and is called

```
std_err_func(params, *args, **kwargs)
```

where params is the vector of estimated parameters using the same bootstrap data as in args and kwargs.

The bootstraps are:

- 'basic' - Basic confidence using the estimated parameter and difference between the estimated parameter and the bootstrap parameters
- 'percentile' - Direct use of bootstrap percentiles
- 'norm' - Makes use of normal approximation and bootstrap covariance estimator
- 'studentized' - Uses either a standard error function or a nested bootstrap to estimate percentiles and the bootstrap covariance for scale
- 'bc' - Bias corrected using estimate bootstrap bias correction
- 'bca' - Bias corrected and accelerated, adding acceleration parameter to 'bc' method

Examples

```
>>> import numpy as np
>>> def func(x):
...     return x.mean(0)
>>> y = np.random.randn(1000, 2)
>>> from arch.bootstrap import IIDBootstrap
>>> bs = IIDBootstrap(y)
>>> ci = bs.conf_int(func, 1000)
```

Return type

`ndarray`

`arch.bootstrap.StationaryBootstrap.cov`

`StationaryBootstrap.cov(func, reps=1000, recenter=True, extra_kwags=None)`

Compute parameter covariance using bootstrap

Parameters

func

[`callable()`] Callable function that returns the statistic of interest as a 1-d array

reps

[`int`, default 1000] Number of bootstrap replications

recenter

[`bool`, default `True`] Whether to center the bootstrap variance estimator on the average of the bootstrap samples (`True`) or to center on the original sample estimate (`False`). Default is `True`.

extra_kwags

[`dict`, default `None`] Dictionary of extra keyword arguments to pass to `func`

Returns

`ndarray`

Bootstrap covariance estimator

Notes

`func` must have the signature

```
func(params, *args, **kwags)
```

where `params` are a 1-dimensional array, and `*args` and `**kwags` are data used in the the bootstrap. The first argument, `params`, will be `None` when called using the original data, and will contain the estimate computed using the original data in bootstrap replications. This parameter is passed to allow parametric bootstrap simulation.

Examples

Bootstrap covariance of the mean

```
>>> from arch.bootstrap import IIDBootstrap
>>> import numpy as np
>>> def func(x):
...     return x.mean(axis=0)
>>> y = np.random.randn(1000, 3)
>>> bs = IIDBootstrap(y)
>>> cov = bs.cov(func, 1000)
```

Bootstrap covariance using a function that takes additional input

```
>>> def func(x, stat='mean'):
...     if stat=='mean':
...         return x.mean(axis=0)
...     elif stat=='var':
...         return x.var(axis=0)
>>> cov = bs.cov(func, 1000, extra_kwargs={'stat': 'var'})
```

Note: Note this is a generic example and so the class used should be the name of the required bootstrap

Return type

float | ndarray

arch.bootstrap.StationaryBootstrap.get_state

StationaryBootstrap.get_state()

Gets the state of the bootstrap's random number generator

Returns

dict

Dictionary containing the state.

Return type

Union[Tuple[str, ndarray, int, int, float], Mapping[str, Any]]

arch.bootstrap.StationaryBootstrap.reset

StationaryBootstrap.reset(*use_seed=True*)

Resets the bootstrap to either its initial state or the last seed.

Parameters

use_seed

[bool, default True] Flag indicating whether to use the last seed if provided. If False or if no seed has been set, the bootstrap will be reset to the initial state. Default is True

Return type

None

arch.bootstrap.StationaryBootstrap.seed

StationaryBootstrap.**seed**(*value*)

Reseeds the bootstrap's random number generator

Parameters

value

[*int*, *List[int]*, *ndarray*] Value to use as the seed.

Return type

None

arch.bootstrap.StationaryBootstrap.set_state

StationaryBootstrap.**set_state**(*state*)

Sets the state of the bootstrap's random number generator

Parameters

state

[*dict*] Dictionary or tuple containing the state.

Return type

None

arch.bootstrap.StationaryBootstrap.update_indices

StationaryBootstrap.**update_indices**()

Update indices for the next iteration of the bootstrap. This must be overridden when creating new bootstraps.

Return type

ndarray

arch.bootstrap.StationaryBootstrap.var

StationaryBootstrap.**var**(*func*, *reps=1000*, *recenter=True*, *extra_kwargs=None*)

Compute parameter variance using bootstrap

Parameters

func

[*callable*()] Callable function that returns the statistic of interest as a 1-d array

reps

[*int*, default 1000] Number of bootstrap replications

recenter

[*bool*, default *True*] Whether to center the bootstrap variance estimator on the average of the bootstrap samples (*True*) or to center on the original sample estimate (*False*). Default is *True*.

extra_kwargs: dict, default None

Dictionary of extra keyword arguments to pass to *func*

Returns

ndarray

Bootstrap variance estimator

Notes

func must have the signature

```
func(params, *args, **kwargs)
```

where params are a 1-dimensional array, and **args* and ***kwargs* are data used in the the bootstrap. The first argument, params, will be none when called using the original data, and will contain the estimate computed using the original data in bootstrap replications. This parameter is passed to allow parametric bootstrap simulation.

Examples

Bootstrap covariance of the mean

```
>>> from arch.bootstrap import IIDBootstrap
>>> import numpy as np
>>> def func(x):
...     return x.mean(axis=0)
>>> y = np.random.randn(1000, 3)
>>> bs = IIDBootstrap(y)
>>> variances = bs.var(func, 1000)
```

Bootstrap covariance using a function that takes additional input

```
>>> def func(x, stat='mean'):
...     if stat=='mean':
...         return x.mean(axis=0)
...     elif stat=='var':
...         return x.var(axis=0)
>>> variances = bs.var(func, 1000, extra_kwargs={'stat': 'var'})
```

Note: Note this is a generic example and so the class used should be the name of the required bootstrap

Return type

float | ndarray

Properties

| | |
|---------------------|--------------------------------------|
| <i>generator</i> | Set or get the instance PRNG |
| <i>index</i> | The current index of the bootstrap |
| <i>random_state</i> | Set or get the instance random state |
| <i>state</i> | Set or get the generator's state |

arch.bootstrap.StationaryBootstrap.generator

property StationaryBootstrap.generator: `numpy.random._generator.Generator` | `numpy.random.mtrand.RandomState`

Set or get the instance PRNG

Parameters

seed

[{`Generator`, `RandomState`}, optional] Generator or `RandomState` used to produce the pseudo-random values used in the bootstrap

Returns

{`Generator`, `RandomState`}

The instance of the `Generator` or `RandomState` instance used by bootstrap

Return type

`Generator` | `RandomState`

arch.bootstrap.StationaryBootstrap.index

property StationaryBootstrap.index: `Union[ndarray, Tuple[ndarray, ...], Tuple[List[ndarray], Dict[str, ndarray]]]`

The current index of the bootstrap

Return type

`Union[ndarray, Tuple[ndarray, ...], Tuple[List[ndarray], Dict[str, ndarray]]]`

arch.bootstrap.StationaryBootstrap.random_state

property StationaryBootstrap.random_state: `numpy.random._generator.Generator` | `numpy.random.mtrand.RandomState`

Set or get the instance random state

Parameters

random_state

[`RandomState`] `RandomState` instance used by bootstrap

Returns

`RandomState`

`RandomState` instance used by bootstrap

Return type

`Generator` | `RandomState`

arch.bootstrap.StationaryBootstrap.state

property StationaryBootstrap.state: Union[Tuple[str, ndarray, int, int, float], Mapping[str, Any]]

Set or get the generator's state

Returns

{tuple, dict}

A tuple or dictionary containing the generator's state. If using a RandomState, the value returned is a tuple. Otherwise it is a dictionary.

Return type

Union[Tuple[str, ndarray, int, int, float], Mapping[str, Any]]

2.9.2 arch.bootstrap.CircularBlockBootstrap

class arch.bootstrap.CircularBlockBootstrap(*block_size*, *args, random_state=None, seed=None, **kwargs)

Bootstrap using blocks of the same length with end-to-start wrap around

Parameters

block_size

[int] Size of block to use

args

Positional arguments to bootstrap

seed

[[{Generator, RandomState, int}], optional] Seed to use to ensure reproducible results. If an int, passes the value to value to np.random.default_rng. If None, a fresh Generator is constructed with system-provided entropy.

random_state

[RandomState, optional] RandomState to use to ensure reproducible results. Cannot be used with seed

Deprecated since version 5.0: The random_state keyword argument has been deprecated. Use seed instead.

kwargs

Keyword arguments to bootstrap

See also:

[arch.bootstrap.optimal_block_length](#)

Optimal block length estimation

[arch.bootstrap.StationaryBootstrap](#)

Politis and Romano's bootstrap with exp. distributed block lengths

Notes

Supports numpy arrays and pandas Series and DataFrames. Data returned has the same type as the input data.

Data entered using keyword arguments is directly accessible as an attribute.

To ensure a reproducible bootstrap, you must set the `random_state` attribute after the bootstrap has been created. See the example below. Note that `random_state` is a reserved keyword and any variable passed using this keyword must be an instance of `RandomState`.

Examples

Data can be accessed in a number of ways. Positional data is retained in the same order as it was entered when the bootstrap was initialized. Keyword data is available both as an attribute or using a dictionary syntax on `kw_data`.

```
>>> from arch.bootstrap import CircularBlockBootstrap
>>> from numpy.random import standard_normal
>>> y = standard_normal((500, 1))
>>> x = standard_normal((500, 2))
>>> z = standard_normal(500)
>>> bs = CircularBlockBootstrap(17, x, y=y, z=z)
>>> for data in bs.bootstrap(100):
...     bs_x = data[0][0]
...     bs_y = data[1]['y']
...     bs_z = bs.z
```

Set the `random_state` if reproducibility is required

```
>>> from numpy.random import RandomState
>>> rs = RandomState(1234)
>>> bs = CircularBlockBootstrap(17, x, y=y, z=z, random_state=rs)
```

Attributes

data

[tuple] Two-element tuple with the `pos_data` in the first position and `kw_data` in the second
(`pos_data`, `kw_data`)

pos_data

[tuple] Tuple containing the positional arguments (in the order entered)

kw_data

[dict] Dictionary containing the keyword arguments

Methods

| | |
|--|--|
| <code>apply(func[, reps, extra_kwargs])</code> | Applies a function to bootstrap replicated data |
| <code>bootstrap(reps)</code> | Iterator for use when bootstrapping |
| <code>clone(*args[, seed])</code> | Clones the bootstrap using different data with a fresh prng. |
| <code>conf_int(func[, reps, method, size, tail, ...])</code> | |
| Parameters | |
| <code>cov(func[, reps, recenter, extra_kwargs])</code> | Compute parameter covariance using bootstrap |
| <code>get_state()</code> | Gets the state of the bootstrap's random number generator |
| <code>reset([use_seed])</code> | Resets the bootstrap to either its initial state or the last seed. |
| <code>seed(value)</code> | Reseeds the bootstrap's random number generator |
| <code>set_state(state)</code> | Sets the state of the bootstrap's random number generator |
| <code>update_indices()</code> | Update indices for the next iteration of the bootstrap. |
| <code>var(func[, reps, recenter, extra_kwargs])</code> | Compute parameter variance using bootstrap |

arch.bootstrap.CircularBlockBootstrap.apply

CircularBlockBootstrap.**apply**(*func*, *reps*=1000, *extra_kwargs*=None)

Applies a function to bootstrap replicated data

Parameters

func

[`callable()`] Function the computes parameter values. See Notes for requirements

reps

[`int`, default 1000] Number of bootstrap replications

extra_kwargs

[`dict`, default `None`] Extra keyword arguments to use when calling `func`. Must not conflict with keyword arguments used to initialize bootstrap

Returns

ndarray

reps by nparam array of computed function values where each row corresponds to a bootstrap iteration

Notes

When there are no extra keyword arguments, the function is called

```
func(params, *args, **kwargs)
```

where `args` and `kwargs` are the bootstrap version of the data provided when setting up the bootstrap. When extra keyword arguments are used, these are appended to `kwargs` before calling `func`

Examples

```
>>> import numpy as np
>>> x = np.random.randn(1000,2)
>>> from arch.bootstrap import IIDBootstrap
>>> bs = IIDBootstrap(x)
>>> def func(y):
...     return y.mean(0)
>>> results = bs.apply(func, 100)
```

Return type
ndarray

arch.bootstrap.CircularBlockBootstrap.bootstrap

CircularBlockBootstrap.**bootstrap**(*reps*)

Iterator for use when bootstrapping

Parameters

reps
[int] Number of bootstrap replications

Returns

generator
Generator to iterate over in bootstrap calculations

Notes

The iterator returns a tuple containing the data entered in positional arguments as a tuple and the data entered using keywords as a dictionary

Examples

The key steps are problem dependent and so this example shows the use as an iterator that does not produce any output

```
>>> from arch.bootstrap import IIDBootstrap
>>> import numpy as np
>>> bs = IIDBootstrap(np.arange(100), x=np.random.randn(100))
>>> for posdata, kwdata in bs.bootstrap(1000):
...     # Do something with the positional data and/or keyword data
...     pass
```

Note: Note this is a generic example and so the class used should be the name of the required bootstrap

Return type

Generator[tuple[tuple[Union[ndarray, DataFrame, Series], ...], dict[str, Union[ndarray, DataFrame, Series]]], None, None]

arch.bootstrap.CircularBlockBootstrap.clone

`CircularBlockBootstrap.clone(*args, seed=None, **kwargs)`

Clones the bootstrap using different data with a fresh prng.

Parameters**args**

Positional arguments to bootstrap

seed

The seed value to pass to the closed generator

kwargs

Keyword arguments to bootstrap

Returns**bs**

Bootstrap instance

Return type

CircularBlockBootstrap

arch.bootstrap.CircularBlockBootstrap.conf_int

`CircularBlockBootstrap.conf_int(func, reps=1000, method='basic', size=0.95, tail='two', extra_kwargs=None, reuse=False, sampling='nonparametric', std_err_func=None, studentize_reps=1000)`

Parameters**func**

[`callable()`] Function the computes parameter values. See Notes for requirements

reps

[`int`, default 1000] Number of bootstrap replications

method

[`str`, default “basic”] One of ‘basic’, ‘percentile’, ‘studentized’, ‘norm’ (identical to ‘var’, ‘cov’), ‘bc’ (identical to ‘debiased’, ‘bias-corrected’), or ‘bca’

size

[`float`, default 0.95] Coverage of confidence interval

tail

[`str`, default “two”] One of ‘two’, ‘upper’ or ‘lower’.

reuse

[`bool`, default `False`] Flag indicating whether to reuse previously computed bootstrap results. This allows alternative methods to be compared without rerunning the bootstrap simulation. Reuse is ignored if reps is not the same across multiple runs, func changes across calls, or method is ‘studentized’.

sampling

[`str`, default “nonparametric”] Type of sampling to use: ‘nonparametric’, ‘semi-parametric’ (or ‘semi’) or ‘parametric’. The default is ‘nonparametric’. See notes about the changes to func required when using ‘semi’ or ‘parametric’.

extra_kwargs

[dict, default None] Extra keyword arguments to use when calling func and std_err_func, when appropriate

std_err_func

[callable(), default None] Function to use when standardizing estimated parameters when using the studentized bootstrap. Providing an analytical function eliminates the need for a nested bootstrap

studentize_reps

[int, default 1000] Number of bootstraps to use in the inner bootstrap when using the studentized bootstrap. Ignored when std_err_func is provided

Returns**ndarray**

Computed confidence interval. Row 0 contains the lower bounds, and row 1 contains the upper bounds. Each column corresponds to a parameter. When tail is 'lower', all upper bounds are inf. Similarly, 'upper' sets all lower bounds to -inf.

Notes

When there are no extra keyword arguments, the function is called

```
func(*args, **kwargs)
```

where args and kwargs are the bootstrap version of the data provided when setting up the bootstrap. When extra keyword arguments are used, these are appended to kwargs before calling func.

The standard error function, if provided, must return a vector of parameter standard errors and is called

```
std_err_func(params, *args, **kwargs)
```

where params is the vector of estimated parameters using the same bootstrap data as in args and kwargs.

The bootstraps are:

- 'basic' - Basic confidence using the estimated parameter and difference between the estimated parameter and the bootstrap parameters
- 'percentile' - Direct use of bootstrap percentiles
- 'norm' - Makes use of normal approximation and bootstrap covariance estimator
- 'studentized' - Uses either a standard error function or a nested bootstrap to estimate percentiles and the bootstrap covariance for scale
- 'bc' - Bias corrected using estimate bootstrap bias correction
- 'bca' - Bias corrected and accelerated, adding acceleration parameter to 'bc' method

Examples

```
>>> import numpy as np
>>> def func(x):
...     return x.mean(0)
>>> y = np.random.randn(1000, 2)
>>> from arch.bootstrap import IIDBootstrap
>>> bs = IIDBootstrap(y)
>>> ci = bs.conf_int(func, 1000)
```

Return type

ndarray

arch.bootstrap.CircularBlockBootstrap.cov

CircularBlockBootstrap.cov(*func*, *reps*=1000, *recenter*=True, *extra_kwargs*=None)

Compute parameter covariance using bootstrap

Parameters

func

[callable()] Callable function that returns the statistic of interest as a 1-d array

reps

[int, default 1000] Number of bootstrap replications

recenter

[bool, default True] Whether to center the bootstrap variance estimator on the average of the bootstrap samples (True) or to center on the original sample estimate (False). Default is True.

extra_kwargs

[dict, default None] Dictionary of extra keyword arguments to pass to func

Returns

ndarray

Bootstrap covariance estimator

Notes

func must have the signature

```
func(params, *args, **kwargs)
```

where params are a 1-dimensional array, and **args* and ***kwargs* are data used in the the bootstrap. The first argument, params, will be none when called using the original data, and will contain the estimate computed using the original data in bootstrap replications. This parameter is passed to allow parametric bootstrap simulation.

Examples

Bootstrap covariance of the mean

```
>>> from arch.bootstrap import IIDBootstrap
>>> import numpy as np
>>> def func(x):
...     return x.mean(axis=0)
>>> y = np.random.randn(1000, 3)
>>> bs = IIDBootstrap(y)
>>> cov = bs.cov(func, 1000)
```

Bootstrap covariance using a function that takes additional input

```
>>> def func(x, stat='mean'):
...     if stat=='mean':
...         return x.mean(axis=0)
...     elif stat=='var':
...         return x.var(axis=0)
>>> cov = bs.cov(func, 1000, extra_kwargs={'stat':'var'})
```

Note: Note this is a generic example and so the class used should be the name of the required bootstrap

Return type

float | ndarray

arch.bootstrap.CircularBlockBootstrap.get_state

CircularBlockBootstrap.get_state()

Gets the state of the bootstrap's random number generator

Returns

dict

Dictionary containing the state.

Return type

Union[Tuple[str, ndarray, int, int, float], Mapping[str, Any]]

arch.bootstrap.CircularBlockBootstrap.reset

CircularBlockBootstrap.reset(*use_seed=True*)

Resets the bootstrap to either its initial state or the last seed.

Parameters

use_seed

[bool, default True] Flag indicating whether to use the last seed if provided. If False or if no seed has been set, the bootstrap will be reset to the initial state. Default is True

Return type

None

arch.bootstrap.CircularBlockBootstrap.seed

CircularBlockBootstrap.**seed**(*value*)

Reseeds the bootstrap's random number generator

Parameters

value

[*int*, *List[int]*, *ndarray*] Value to use as the seed.

Return type

None

arch.bootstrap.CircularBlockBootstrap.set_state

CircularBlockBootstrap.**set_state**(*state*)

Sets the state of the bootstrap's random number generator

Parameters

state

[*dict*] Dictionary or tuple containing the state.

Return type

None

arch.bootstrap.CircularBlockBootstrap.update_indices

CircularBlockBootstrap.**update_indices**()

Update indices for the next iteration of the bootstrap. This must be overridden when creating new bootstraps.

Return type

ndarray

arch.bootstrap.CircularBlockBootstrap.var

CircularBlockBootstrap.**var**(*func*, *reps=1000*, *recenter=True*, *extra_kwargs=None*)

Compute parameter variance using bootstrap

Parameters

func

[*callable*()] Callable function that returns the statistic of interest as a 1-d array

reps

[*int*, default 1000] Number of bootstrap replications

recenter

[*bool*, default *True*] Whether to center the bootstrap variance estimator on the average of the bootstrap samples (*True*) or to center on the original sample estimate (*False*). Default is *True*.

extra_kwargs: dict, default None

Dictionary of extra keyword arguments to pass to *func*

Returns

ndarray

Bootstrap variance estimator

Notes

func must have the signature

```
func(params, *args, **kwargs)
```

where params are a 1-dimensional array, and **args* and ***kwargs* are data used in the the bootstrap. The first argument, params, will be none when called using the original data, and will contain the estimate computed using the original data in bootstrap replications. This parameter is passed to allow parametric bootstrap simulation.

Examples

Bootstrap covariance of the mean

```
>>> from arch.bootstrap import IIDBootstrap
>>> import numpy as np
>>> def func(x):
...     return x.mean(axis=0)
>>> y = np.random.randn(1000, 3)
>>> bs = IIDBootstrap(y)
>>> variances = bs.var(func, 1000)
```

Bootstrap covariance using a function that takes additional input

```
>>> def func(x, stat='mean'):
...     if stat=='mean':
...         return x.mean(axis=0)
...     elif stat=='var':
...         return x.var(axis=0)
>>> variances = bs.var(func, 1000, extra_kwargs={'stat': 'var'})
```

Note: Note this is a generic example and so the class used should be the name of the required bootstrap

Return type

float | ndarray

Properties

| | |
|---------------------|--------------------------------------|
| <i>generator</i> | Set or get the instance PRNG |
| <i>index</i> | The current index of the bootstrap |
| <i>random_state</i> | Set or get the instance random state |
| <i>state</i> | Set or get the generator's state |

arch.bootstrap.CircularBlockBootstrap.generator

property CircularBlockBootstrap.generator: `numpy.random._generator.Generator` | `numpy.random.mtrand.RandomState`

Set or get the instance PRNG

Parameters**seed**

[{Generator, RandomState}, optional] Generator or RandomState used to produce the pseudo-random values used in the bootstrap

Returns

{Generator, RandomState}

The instance of the Generator or RandomState instance used by bootstrap

Return type

Generator | RandomState

arch.bootstrap.CircularBlockBootstrap.index

property CircularBlockBootstrap.index: `Union[ndarray, Tuple[ndarray, ...], Tuple[List[ndarray], Dict[str, ndarray]]]`

The current index of the bootstrap

Return type

`Union[ndarray, Tuple[ndarray, ...], Tuple[List[ndarray], Dict[str, ndarray]]]`

arch.bootstrap.CircularBlockBootstrap.random_state

property CircularBlockBootstrap.random_state: `numpy.random._generator.Generator` | `numpy.random.mtrand.RandomState`

Set or get the instance random state

Parameters**random_state**

[RandomState] RandomState instance used by bootstrap

Returns

RandomState

RandomState instance used by bootstrap

Return type

Generator | RandomState

arch.bootstrap.CircularBlockBootstrap.state

property `CircularBlockBootstrap.state`: `Union[Tuple[str, ndarray, int, int, float], Mapping[str, Any]]`

Set or get the generator's state

Returns

`{tuple, dict}`

A tuple or dictionary containing the generator's state. If using a `RandomState`, the value returned is a tuple. Otherwise it is a dictionary.

Return type

`Union[Tuple[str, ndarray, int, int, float], Mapping[str, Any]]`

2.9.3 arch.bootstrap.MovingBlockBootstrap

class `arch.bootstrap.MovingBlockBootstrap`(*block_size*, **args*, *random_state*=None, *seed*=None, ***kwargs*)

Bootstrap using blocks of the same length without wrap around

Parameters

block_size

[`int`] Size of block to use

args

Positional arguments to bootstrap

seed

[`{Generator, RandomState, int}`], optional] Seed to use to ensure reproducible results. If an `int`, passes the value to `value to np.random.default_rng`. If `None`, a fresh `Generator` is constructed with system-provided entropy.

random_state

[`RandomState`, optional] `RandomState` to use to ensure reproducible results. Cannot be used with `seed`

Deprecated since version 5.0: The `random_state` keyword argument has been deprecated. Use `seed` instead.

kwargs

Keyword arguments to bootstrap

Politis and Romano's bootstrap with exp. distributed block lengths

[`arch.bootstrap.CircularBlockBootstrap`](#)

Circular (wrap-around) bootstrap

Notes

Supports numpy arrays and pandas Series and DataFrames. Data returned has the same type as the input data.

Data entered using keyword arguments is directly accessible as an attribute.

To ensure a reproducible bootstrap, you must set the `random_state` attribute after the bootstrap has been created. See the example below. Note that `random_state` is a reserved keyword and any variable passed using this keyword must be an instance of `RandomState`.

Examples

Data can be accessed in a number of ways. Positional data is retained in the same order as it was entered when the bootstrap was initialized. Keyword data is available both as an attribute or using a dictionary syntax on `kw_data`.

```
>>> from arch.bootstrap import MovingBlockBootstrap
>>> from numpy.random import standard_normal
>>> y = standard_normal((500, 1))
>>> x = standard_normal((500, 2))
>>> z = standard_normal(500)
>>> bs = MovingBlockBootstrap(7, x, y=y, z=z)
>>> for data in bs.bootstrap(100):
...     bs_x = data[0][0]
...     bs_y = data[1]['y']
...     bs_z = bs.z
```

Set the `random_state` if reproducibility is required

```
>>> from numpy.random import RandomState
>>> rs = RandomState(1234)
>>> bs = MovingBlockBootstrap(7, x, y=y, z=z, random_state=rs)
```

Attributes

data

[tuple] Two-element tuple with the `pos_data` in the first position and `kw_data` in the second (`pos_data`, `kw_data`)

pos_data

[tuple] Tuple containing the positional arguments (in the order entered)

kw_data

[dict] Dictionary containing the keyword arguments

Methods

| | |
|--|--|
| <code>apply(func[, reps, extra_kwargs])</code> | Applies a function to bootstrap replicated data |
| <code>bootstrap(reps)</code> | Iterator for use when bootstrapping |
| <code>clone(*args[, seed])</code> | Clones the bootstrap using different data with a fresh prng. |
| <code>conf_int(func[, reps, method, size, tail, ...])</code> | |
| Parameters | |
| <code>cov(func[, reps, recenter, extra_kwargs])</code> | Compute parameter covariance using bootstrap |
| <code>get_state()</code> | Gets the state of the bootstrap's random number generator |
| <code>reset([use_seed])</code> | Resets the bootstrap to either its initial state or the last seed. |
| <code>seed(value)</code> | Reseeds the bootstrap's random number generator |
| <code>set_state(state)</code> | Sets the state of the bootstrap's random number generator |
| <code>update_indices()</code> | Update indices for the next iteration of the bootstrap. |
| <code>var(func[, reps, recenter, extra_kwargs])</code> | Compute parameter variance using bootstrap |

arch.bootstrap.MovingBlockBootstrap.apply

MovingBlockBootstrap.**apply**(*func*, *reps*=1000, *extra_kwargs*=None)

Applies a function to bootstrap replicated data

Parameters

func

[[callable\(\)](#)] Function the computes parameter values. See Notes for requirements

reps

[[int](#), default 1000] Number of bootstrap replications

extra_kwargs

[[dict](#), default [None](#)] Extra keyword arguments to use when calling func. Must not conflict with keyword arguments used to initialize bootstrap

Returns

ndarray

reps by nparam array of computed function values where each row corresponds to a bootstrap iteration

Notes

When there are no extra keyword arguments, the function is called

`func(params, *args, **kwargs)`

where args and kwargs are the bootstrap version of the data provided when setting up the bootstrap. When extra keyword arguments are used, these are appended to kwargs before calling func

Examples

```

>>> import numpy as np
>>> x = np.random.randn(1000,2)
>>> from arch.bootstrap import IIDBootstrap
>>> bs = IIDBootstrap(x)
>>> def func(y):
...     return y.mean(0)
>>> results = bs.apply(func, 100)

```

Return type
ndarray

arch.bootstrap.MovingBlockBootstrap.bootstrap

MovingBlockBootstrap.**bootstrap**(*reps*)

Iterator for use when bootstrapping

Parameters

reps
[int] Number of bootstrap replications

Returns

generator
Generator to iterate over in bootstrap calculations

Notes

The iterator returns a tuple containing the data entered in positional arguments as a tuple and the data entered using keywords as a dictionary

Examples

The key steps are problem dependent and so this example shows the use as an iterator that does not produce any output

```

>>> from arch.bootstrap import IIDBootstrap
>>> import numpy as np
>>> bs = IIDBootstrap(np.arange(100), x=np.random.randn(100))
>>> for posdata, kwdata in bs.bootstrap(1000):
...     # Do something with the positional data and/or keyword data
...     pass

```

Note: Note this is a generic example and so the class used should be the name of the required bootstrap

Return type
Generator[tuple[tuple[Union[ndarray, DataFrame, Series], ...], dict[str, Union[ndarray, DataFrame, Series]]], None, None]

arch.bootstrap.MovingBlockBootstrap.clone

`MovingBlockBootstrap.clone(*args, seed=None, **kwargs)`

Clones the bootstrap using different data with a fresh prng.

Parameters

args

Positional arguments to bootstrap

seed

The seed value to pass to the closed generator

kwargs

Keyword arguments to bootstrap

Returns

bs

Bootstrap instance

Return type

CircularBlockBootstrap

arch.bootstrap.MovingBlockBootstrap.conf_int

`MovingBlockBootstrap.conf_int(func, reps=1000, method='basic', size=0.95, tail='two',
extra_kwargs=None, reuse=False, sampling='nonparametric',
std_err_func=None, studentize_reps=1000)`

Parameters

func

[`callable()`] Function the computes parameter values. See Notes for requirements

reps

[`int`, default 1000] Number of bootstrap replications

method

[`str`, default “basic”] One of ‘basic’, ‘percentile’, ‘studentized’, ‘norm’ (identical to ‘var’, ‘cov’), ‘bc’ (identical to ‘debiased’, ‘bias-corrected’), or ‘bca’

size

[`float`, default 0.95] Coverage of confidence interval

tail

[`str`, default “two”] One of ‘two’, ‘upper’ or ‘lower’.

reuse

[`bool`, default `False`] Flag indicating whether to reuse previously computed bootstrap results. This allows alternative methods to be compared without rerunning the bootstrap simulation. Reuse is ignored if reps is not the same across multiple runs, func changes across calls, or method is ‘studentized’.

sampling

[`str`, default “nonparametric”] Type of sampling to use: ‘nonparametric’, ‘semi-parametric’ (or ‘semi’) or ‘parametric’. The default is ‘nonparametric’. See notes about the changes to func required when using ‘semi’ or ‘parametric’.

extra_kwargs

[dict, default None] Extra keyword arguments to use when calling func and std_err_func, when appropriate

std_err_func

[callable(), default None] Function to use when standardizing estimated parameters when using the studentized bootstrap. Providing an analytical function eliminates the need for a nested bootstrap

studentize_reps

[int, default 1000] Number of bootstraps to use in the inner bootstrap when using the studentized bootstrap. Ignored when std_err_func is provided

Returns**ndarray**

Computed confidence interval. Row 0 contains the lower bounds, and row 1 contains the upper bounds. Each column corresponds to a parameter. When tail is 'lower', all upper bounds are inf. Similarly, 'upper' sets all lower bounds to -inf.

Notes

When there are no extra keyword arguments, the function is called

```
func(*args, **kwargs)
```

where args and kwargs are the bootstrap version of the data provided when setting up the bootstrap. When extra keyword arguments are used, these are appended to kwargs before calling func.

The standard error function, if provided, must return a vector of parameter standard errors and is called

```
std_err_func(params, *args, **kwargs)
```

where params is the vector of estimated parameters using the same bootstrap data as in args and kwargs.

The bootstraps are:

- 'basic' - Basic confidence using the estimated parameter and difference between the estimated parameter and the bootstrap parameters
- 'percentile' - Direct use of bootstrap percentiles
- 'norm' - Makes use of normal approximation and bootstrap covariance estimator
- 'studentized' - Uses either a standard error function or a nested bootstrap to estimate percentiles and the bootstrap covariance for scale
- 'bc' - Bias corrected using estimate bootstrap bias correction
- 'bca' - Bias corrected and accelerated, adding acceleration parameter to 'bc' method

Examples

```
>>> import numpy as np
>>> def func(x):
...     return x.mean(0)
>>> y = np.random.randn(1000, 2)
>>> from arch.bootstrap import IIDBootstrap
>>> bs = IIDBootstrap(y)
>>> ci = bs.conf_int(func, 1000)
```

Return type
ndarray

arch.bootstrap.MovingBlockBootstrap.cov

MovingBlockBootstrap.cov(*func*, *reps*=1000, *recenter*=True, *extra_kwargs*=None)

Compute parameter covariance using bootstrap

Parameters

func

[callable()] Callable function that returns the statistic of interest as a 1-d array

reps

[int, default 1000] Number of bootstrap replications

recenter

[bool, default True] Whether to center the bootstrap variance estimator on the average of the bootstrap samples (True) or to center on the original sample estimate (False). Default is True.

extra_kwargs

[dict, default None] Dictionary of extra keyword arguments to pass to func

Returns

ndarray

Bootstrap covariance estimator

Notes

func must have the signature

```
func(params, *args, **kwargs)
```

where params are a 1-dimensional array, and **args* and ***kwargs* are data used in the the bootstrap. The first argument, params, will be none when called using the original data, and will contain the estimate computed using the original data in bootstrap replications. This parameter is passed to allow parametric bootstrap simulation.

Examples

Bootstrap covariance of the mean

```
>>> from arch.bootstrap import IIDBootstrap
>>> import numpy as np
>>> def func(x):
...     return x.mean(axis=0)
>>> y = np.random.randn(1000, 3)
>>> bs = IIDBootstrap(y)
>>> cov = bs.cov(func, 1000)
```

Bootstrap covariance using a function that takes additional input

```
>>> def func(x, stat='mean'):
...     if stat=='mean':
...         return x.mean(axis=0)
...     elif stat=='var':
...         return x.var(axis=0)
>>> cov = bs.cov(func, 1000, extra_kwargs={'stat':'var'})
```

Note: Note this is a generic example and so the class used should be the name of the required bootstrap

Return type

float | ndarray

arch.bootstrap.MovingBlockBootstrap.get_state

MovingBlockBootstrap.get_state()

Gets the state of the bootstrap's random number generator

Returns

dict
Dictionary containing the state.

Return type

Union[Tuple[str, ndarray, int, int, float], Mapping[str, Any]]

arch.bootstrap.MovingBlockBootstrap.reset

MovingBlockBootstrap.reset(*use_seed=True*)

Resets the bootstrap to either its initial state or the last seed.

Parameters

use_seed
[bool, default True] Flag indicating whether to use the last seed if provided. If False or if no seed has been set, the bootstrap will be reset to the initial state. Default is True

Return type

None

arch.bootstrap.MovingBlockBootstrap.seed

MovingBlockBootstrap.**seed**(*value*)

Reseeds the bootstrap's random number generator

Parameters

value

[*int*, *List[int]*, *ndarray*] Value to use as the seed.

Return type

None

arch.bootstrap.MovingBlockBootstrap.set_state

MovingBlockBootstrap.**set_state**(*state*)

Sets the state of the bootstrap's random number generator

Parameters

state

[*dict*] Dictionary or tuple containing the state.

Return type

None

arch.bootstrap.MovingBlockBootstrap.update_indices

MovingBlockBootstrap.**update_indices**()

Update indices for the next iteration of the bootstrap. This must be overridden when creating new bootstraps.

Return type

ndarray

arch.bootstrap.MovingBlockBootstrap.var

MovingBlockBootstrap.**var**(*func*, *reps=1000*, *recenter=True*, *extra_kwargs=None*)

Compute parameter variance using bootstrap

Parameters

func

[*callable*()] Callable function that returns the statistic of interest as a 1-d array

reps

[*int*, default 1000] Number of bootstrap replications

recenter

[*bool*, default *True*] Whether to center the bootstrap variance estimator on the average of the bootstrap samples (*True*) or to center on the original sample estimate (*False*). Default is *True*.

extra_kwargs: *dict*, default *None*

Dictionary of extra keyword arguments to pass to *func*

Returns

ndarray

Bootstrap variance estimator

Notes

func must have the signature

```
func(params, *args, **kwargs)
```

where params are a 1-dimensional array, and **args* and ***kwargs* are data used in the the bootstrap. The first argument, params, will be none when called using the original data, and will contain the estimate computed using the original data in bootstrap replications. This parameter is passed to allow parametric bootstrap simulation.

Examples

Bootstrap covariance of the mean

```
>>> from arch.bootstrap import IIDBootstrap
>>> import numpy as np
>>> def func(x):
...     return x.mean(axis=0)
>>> y = np.random.randn(1000, 3)
>>> bs = IIDBootstrap(y)
>>> variances = bs.var(func, 1000)
```

Bootstrap covariance using a function that takes additional input

```
>>> def func(x, stat='mean'):
...     if stat=='mean':
...         return x.mean(axis=0)
...     elif stat=='var':
...         return x.var(axis=0)
>>> variances = bs.var(func, 1000, extra_kwargs={'stat': 'var'})
```

Note: Note this is a generic example and so the class used should be the name of the required bootstrap

Return type

float | ndarray

Properties

| | |
|---------------------|--------------------------------------|
| <i>generator</i> | Set or get the instance PRNG |
| <i>index</i> | The current index of the bootstrap |
| <i>random_state</i> | Set or get the instance random state |
| <i>state</i> | Set or get the generator's state |

arch.bootstrap.MovingBlockBootstrap.generator

property MovingBlockBootstrap.generator: `numpy.random._generator.Generator` | `numpy.random.mtrand.RandomState`

Set or get the instance PRNG

Parameters

seed

[{`Generator`, `RandomState`}, optional] Generator or `RandomState` used to produce the pseudo-random values used in the bootstrap

Returns

{`Generator`, `RandomState`}

The instance of the `Generator` or `RandomState` instance used by bootstrap

Return type

`Generator` | `RandomState`

arch.bootstrap.MovingBlockBootstrap.index

property MovingBlockBootstrap.index: `Union[ndarray, Tuple[ndarray, ...], Tuple[List[ndarray], Dict[str, ndarray]]]`

The current index of the bootstrap

Return type

`Union[ndarray, Tuple[ndarray, ...], Tuple[List[ndarray], Dict[str, ndarray]]]`

arch.bootstrap.MovingBlockBootstrap.random_state

property MovingBlockBootstrap.random_state: `numpy.random._generator.Generator` | `numpy.random.mtrand.RandomState`

Set or get the instance random state

Parameters

random_state

[`RandomState`] `RandomState` instance used by bootstrap

Returns

`RandomState`

`RandomState` instance used by bootstrap

Return type

`Generator` | `RandomState`

arch.bootstrap.MovingBlockBootstrap.state

property MovingBlockBootstrap.state: Union[Tuple[str, ndarray, int, int, float], Mapping[str, Any]]

Set or get the generator's state

Returns

{tuple, dict}

A tuple or dictionary containing the generator's state. If using a RandomState, the value returned is a tuple. Otherwise it is a dictionary.

Return type

Union[Tuple[str, ndarray, int, int, float], Mapping[str, Any]]

2.9.4 arch.bootstrap.optimal_block_length

arch.bootstrap.optimal_block_length(x)

Estimate optimal window length for time-series bootstraps

Parameters

x

[numpy:array_like] A one-dimensional or two-dimensional array-like. Operates columns by column if 2-dimensional.

Returns

DataFrame

A DataFrame with two columns b_{sb} , the estimated optimal block size for the Stationary Bootstrap and b_{cb} , the estimated optimal block size for the circular bootstrap.

See also:

[*arch.bootstrap.StationaryBootstrap*](#)

Politis and Romano's bootstrap with exp. distributed block lengths

[*arch.bootstrap.CircularBlockBootstrap*](#)

Circular (wrap-around) bootstrap

Notes

Algorithm described in ([1]) its correction ([2]) depends on a tuning parameter m , which is chosen as the first value where k_n consecutive autocorrelations of x are all inside a conservative band of $\pm 2\sqrt{\log_{10}(n)/n}$ where n is the sample size. The maximum value of m is set to $\lceil \sqrt{n} + k_n \rceil$ where $k_n = \max(5, \log_{10}(n))$. The block length is then computed as

$$b_i^{OPT} = \left(\frac{2g^2}{d_i} n \right)^{\frac{1}{3}}$$

where

$$g = \sum_{k=-m}^m h\left(\frac{k}{m}\right) |k| \hat{\gamma}_k$$
$$h(x) = \min(1, 2(1 - |x|))$$
$$d_i = c_i (\hat{\sigma}^2)^2$$
$$\hat{\sigma}^2 = \sum_{k=-m}^m h\left(\frac{k}{m}\right) \hat{\gamma}_k$$
$$\hat{\gamma}_i = n^{-1} \sum_{k=i+1}^n (x_k - \bar{x})(x_{k-i} - \bar{x})$$

and the two remaining constants c_i are 2 for the Stationary bootstrap and 4/3 for the Circular bootstrap.

Some of the tuning parameters are taken from Andrew Patton's MATLAB program that computes the optimal block length. The block lengths do not match this implementation since the autocovariances and autocorrelations are all computed using the maximum sample length rather than a common sampling length.

Articles used in the creation of this module include

MULTIPLE COMPARISON PROCEDURES

This module contains a set of bootstrap-based multiple comparison procedures. These are designed to allow multiple models to be compared while controlling a the [Familywise Error Rate](#), which is similar to the size of a test.

3.1 Multiple Comparisons

This setup code is required to run in an IPython notebook

```
[1]: %matplotlib inline
import matplotlib.pyplot as plt
import seaborn

seaborn.set_style("darkgrid")
plt.rc("figure", figsize=(16, 6))
plt.rc("savefig", dpi=90)
plt.rc("font", family="sans-serif")
plt.rc("font", size=14)
```

```
[2]: # Reproducibility
import numpy as np

gen = np.random.default_rng(23456)
# Common seed used throughout
seed = gen.integers(0, 2**31 - 1)
```

The multiple comparison procedures all allow for examining aspects of superior predictive ability. There are three available:

- SPA - The test of Superior Predictive Ability, also known as the Reality Check (and accessible as `RealityCheck`) or the bootstrap data snooper, examines whether any model in a set of models can outperform a benchmark.
- StepM - The stepwise multiple testing procedure uses sequential testing to determine which models are superior to a benchmark.
- MCS - The model confidence set which computes the set of models which with performance indistinguishable from others in the set.

All procedures take **losses** as inputs. That is, smaller values are preferred to larger values. This is common when evaluating forecasting models where the loss function is usually defined as a positive function of the forecast error that is increasing in the absolute error. Leading examples are Mean Square Error (MSE) and Mean Absolute Deviation (MAD).

3.1.1 The test of Superior Predictive Ability (SPA)

This procedure requires a t -element array of benchmark losses and a t by k -element array of model losses. The null hypothesis is that no model is better than the benchmark, or

$$H_0 : \max_i E[L_i] \geq E[L_{bm}]$$

where L_i is the loss from model i and L_{bm} is the loss from the benchmark model.

This procedure is normally used when there are many competing forecasting models such as in the study of technical trading rules. The example below will make use of a set of models which are all equivalently good to a benchmark model and will serve as a *size study*.

Study Design

The study will make use of a measurement error in predictors to produce a large set of correlated variables that all have equal expected MSE. The benchmark will have identical measurement error and so all models have the same expected loss, although will have different forecasts.

The first block computed the series to be forecast.

```
[3]: import statsmodels.api as sm
      from numpy.random import randn

      t = 1000
      factors = randn(t, 3)
      beta = np.array([1, 0.5, 0.1])
      e = randn(t)
      y = factors.dot(beta)
```

The next block computes the benchmark factors and the model factors by contaminating the original factors with noise. The models are estimated on the first 500 observations and predictions are made for the second 500. Finally, losses are constructed from these predictions.

```
[4]: # Measurement noise
      bm_factors = factors + randn(t, 3)
      # Fit using first half, predict second half
      bm_beta = sm.OLS(y[:500], bm_factors[:500]).fit().params
      # MSE loss
      bm_losses = (y[500:] - bm_factors[500:].dot(bm_beta)) ** 2.0
      # Number of models
      k = 500
      model_factors = np.zeros((k, t, 3))
      model_losses = np.zeros((500, k))
      for i in range(k):
          # Add measurement noise
          model_factors[i] = factors + randn(1000, 3)
          # Compute regression parameters
          model_beta = sm.OLS(y[:500], model_factors[i, :500]).fit().params
          # Prediction and losses
          model_losses[:, i] = (y[500:] - model_factors[i, 500:].dot(model_beta)) ** 2.0
```

Finally the SPA can be used. The SPA requires the **losses** from the benchmark and the models as inputs. Other inputs allow the bootstrap seed to be changed or for various options regarding studentization of the losses. `compute` does the real work, and then `pvalues` contains the probability that the null is true given the realizations.

In this case, one would not reject. The three p-values correspond to different re-centerings of the losses. In general, the consistent p-value should be used. It should always be the case that

$$lower \leq consistent \leq upper.$$

See the original papers for more details.

```
[5]: from arch.bootstrap import SPA

spa = SPA(bm_losses, model_losses, seed=seed)
spa.compute()
spa.pvalues
```

```
[5]: lower          0.005
consistent        0.005
upper            0.005
dtype: float64
```

The same blocks can be repeated to perform a simulation study. Here I only use 100 replications since this should complete in a reasonable amount of time. Also I set `reps=250` to limit the number of bootstrap replications in each application of the SPA (the default is a more reasonable 1000).

```
[6]: # Save the pvalues
pvalues = []
b = 100
seeds = gen.integers(0, 2**31 - 1, b)
# Repeat 100 times
for j in range(b):
    if j % 10 == 0:
        print(j)
    factors = randn(t, 3)
    beta = np.array([1, 0.5, 0.1])
    e = randn(t)
    y = factors.dot(beta)

    # Measurement noise
    bm_factors = factors + randn(t, 3)
    # Fit using first half, predict second half
    bm_beta = sm.OLS(y[:500], bm_factors[:500]).fit().params
    # MSE loss
    bm_losses = (y[500:] - bm_factors[500:].dot(bm_beta)) ** 2.0
    # Number of models
    k = 500
    model_factors = np.zeros((k, t, 3))
    model_losses = np.zeros((500, k))
    for i in range(k):
        model_factors[i] = factors + randn(1000, 3)
        model_beta = sm.OLS(y[:500], model_factors[i, :500]).fit().params
        # MSE loss
        model_losses[:, i] = (y[500:] - model_factors[i, 500:].dot(model_beta)) ** 2.0
    # Lower the bootstrap replications to 250
    spa = SPA(bm_losses, model_losses, reps=250, seed=seeds[j])
    spa.compute()
    pvalues.append(spa.pvalues)
```

```
0
10
20
30
40
50
60
70
80
90
```

Finally the pvalues can be plotted. Ideally they should form a 45° line indicating the size is correct. Both the consistent and upper perform well. The lower has too many small p-values.

```
[7]: import pandas as pd

pvalues = pd.DataFrame(pvalues)
for col in pvalues:
    values = pvalues[col].values
    values.sort()
    pvalues[col] = values
# Change the index so that the x-values are between 0 and 1
pvalues.index = np.linspace(0.005, 0.995, 100)
fig = pvalues.plot()
```

nbsphinx-code-borderwhite

Power

The SPA also has power to reject then the null is violated. The simulation will be modified so that the amount of measurement error differs across models, and so that some models are actually better than the benchmark. The p-values should be small indicating rejection of the null.

```
[8]: # Number of models
k = 500
model_factors = np.zeros((k, t, 3))
model_losses = np.zeros((500, k))
for i in range(k):
    scale = (2500.0 - i) / 2500.0
    model_factors[i] = factors + scale * randn(1000, 3)
    model_beta = sm.OLS(y[:500], model_factors[i, :500]).fit().params
    # MSE loss
```

(continues on next page)

(continued from previous page)

```

model_losses[:, i] = (y[500:] - model_factors[i, 500:].dot(model_beta)) ** 2.0

spa = SPA(bm_losses, model_losses, seed=seed)
spa.compute()
spa.pvalues

```

```

[8]: lower          0.039
      consistent    0.049
      upper          0.050
      dtype: float64

```

Here the average losses are plotted. The higher index models are clearly better than the lower index models – and the benchmark model (which is identical to model.0).

```

[9]: model_losses = pd.DataFrame(model_losses, columns=["model." + str(i) for i in range(k)])
      avg_model_losses = pd.DataFrame(model_losses.mean(0), columns=["Average loss"])
      fig = avg_model_losses.plot(style=["o"])

```

nbsphinx-code-borderwhite

3.1.2 Stepwise Multiple Testing (StepM)

Stepwise Multiple Testing is similar to the SPA and has the same null. The primary difference is that it identifies the set of models which are better than the benchmark, rather than just asking the basic question if any model is better.

```

[10]: from arch.bootstrap import StepM

stepm = StepM(bm_losses, model_losses)
stepm.compute()
print("Model indices:")
print([model.split(".")[1] for model in stepm.superior_models])

Model indices:
['379', '466', '475']

```

```

[11]: better_models = pd.concat([model_losses.mean(0), model_losses.mean(0)], 1)
      better_models.columns = ["Same or worse", "Better"]
      better = better_models.index.isin(stepm.superior_models)
      worse = np.logical_not(better)
      better_models.loc[better, "Same or worse"] = np.nan
      better_models.loc[worse, "Better"] = np.nan
      fig = better_models.plot(style=["o", "s"], rot=270)

```

nbsphinx-code-borderwhite

3.1.3 The Model Confidence Set

The model confidence set takes a set of **losses** as its input and finds the set which are not statistically different from each other while controlling the familywise error rate. The primary output is a set of p-values, where models with a pvalue above the size are in the MCS. Small p-values indicate that the model is easily rejected from the set that includes the best.

```
[12]: from arch.bootstrap import MCS

# Limit the size of the set
losses = model_losses.iloc[:, ::20]
mcs = MCS(losses, size=0.10)
mcs.compute()
print("MCS P-values")
print(mcs.pvalues)
print("Included")
included = mcs.included
print([model.split(".")[-1] for model in included])
print("Excluded")
excluded = mcs.excluded
print([model.split(".")[-1] for model in excluded])
```

```
MCS P-values
      Pvalue

nbsphinx-code-borderwhite

3.2 Module Reference

3.2.1 Test of Superior Predictive Ability (SPA), Reality Check

The test of Superior Predictive Ability (Hansen 2005), or SPA, is an improved version of the Reality Check (White 2000). It tests whether the best forecasting performance from a set of models is better than that of the forecasts from a benchmark model. A model is “better” if its losses are smaller than those from the benchmark. Formally, it tests the null

$$H_0 : \max_i E[L_i] \geq E[L_{bm}]$$

where L_i is the loss from model i and L_{bm} is the loss from the benchmark model. The alternative is

$$H_1 : \min_i E[L_i] < E[L_{bm}]$$

This procedure accounts for dependence between the losses and the fact that there are potentially alternative models being considered.

Note: Also callable using `RealityCheck`

| | |
|--|--|
| <code>SPA(benchmark, models[, block_size, reps, ...])</code> | Test of Superior Predictive Ability (SPA) of White and Hansen. |
|--|--|

arch.bootstrap.SPA

```
class arch.bootstrap.SPA(benchmark, models, block_size=None, reps=1000, bootstrap='stationary',
                        studentize=True, nested=False, *, seed=None)
```

Test of Superior Predictive Ability (SPA) of White and Hansen.

The SPA is also known as the Reality Check or Bootstrap Data Snooper.

Parameters

benchmark

`[{ndarray, Series}]` T element array of benchmark model *losses*

models

`[{ndarray, DataFrame}]` T by k element array of alternative model *losses*

block_size

`[int, optional]` Length of window to use in the bootstrap. If not provided, `sqrt(T)` is used. In general, this should be provided and chosen to be appropriate for the data.

reps

`[int, optional]` Number of bootstrap replications to uses. Default is 1000.

bootstrap

`[str, optional]` Bootstrap to use. Options are 'stationary' or 'sb': Stationary bootstrap (Default) 'circular' or 'cbb': Circular block bootstrap 'moving block' or 'mbb': Moving block bootstrap

studentize

`[bool]` Flag indicating to studentize loss differentials. Default is True

nested=False

Flag indicating to use a nested bootstrap to compute variances for studentization. Default is False. Note that this can be slow since the procedure requires k extra bootstraps.

seed

`[{int, Generator, RandomState}, optional]` Seed value to use when creating the bootstrap used in the comparison. If an integer or None, the NumPy `default_rng` is used with the seed value. If a Generator or a RandomState, the argument is used.

See also:

[StepM](#)

Notes

The three p-value correspond to different re-centering decisions.

- Upper : Never recenter to all models are relevant to distribution
- Consistent : Only recenter if closer than a $\log(\log(t))$ bound
- Lower : Never recenter a model if worse than benchmark

See [1] and [2] for details.

References

[1], [2]

Attributes

pvalues

P-values corresponding to the lower, consistent and upper p-values.

Methods

| | |
|--|---|
| <i>better_models</i> ([pvalue, pvalue_type]) | Returns set of models rejected as being equal-or-worse than the benchmark |
| <i>compute</i> () | Compute the bootstrap pvalue. |
| <i>critical_values</i> ([pvalue]) | Returns data-dependent critical values |
| <i>reset</i> () | Reset the bootstrap to its initial state. |
| <i>seed</i> (value) | Seed the bootstrap's random number generator |
| <i>subset</i> (selector) | Sets a list of active models to run the SPA on. |

arch.bootstrap.SPA.better_models

SPA.**better_models**(*pvalue*=0.05, *pvalue_type*='consistent')

Returns set of models rejected as being equal-or-worse than the benchmark

Parameters

pvalue

[float, optional] P-value in (0,1) to use when computing superior models

pvalue_type

[str, optional] String in 'lower', 'consistent', or 'upper' indicating which critical value to use.

Returns

indices

[list] List of column names or indices of the superior models. Column names are returned if models is a DataFrame.

Notes

List of superior models returned is always with respect to the initial set of models, even when using `subset()`.

Return type

`ndarray` | `list[Hashable]`

`arch.bootstrap.SPA.compute`

`SPA.compute()`

Compute the bootstrap pvalue.

Notes

Must be called before accessing the pvalue.

Return type

`None`

`arch.bootstrap.SPA.critical_values`

`SPA.critical_values(pvalue=0.05)`

Returns data-dependent critical values

Parameters

pvalue

[`float`, optional] P-value in (0,1) to use when computing the critical values.

Returns

crit_vals

[`Series`] Series containing critical values for the lower, consistent and upper methodologies

Return type

`Series`

`arch.bootstrap.SPA.reset`

`SPA.reset()`

Reset the bootstrap to its initial state.

Return type

`None`

arch.bootstrap.SPA.seed**SPA.seed**(*value*)

Seed the bootstrap's random number generator

Parameters**value**[`int`, `List[int]`, `ndarray[int]`] Integer to use as the seed**Return type**

None

arch.bootstrap.SPA.subset**SPA.subset**(*selector*)

Sets a list of active models to run the SPA on. Primarily for internal use.

Parameters**selector**[`ndarray`] Boolean array indicating which columns to use when computing the p-values. This is primarily for use by StepM.**Return type**

None

Properties

pvalues

P-values corresponding to the lower, consistent and upper p-values.

arch.bootstrap.SPA.pvalues**property** SPA.pvalues: **Series**

P-values corresponding to the lower, consistent and upper p-values.

Returns**pvals**[`Series`] Three p-values corresponding to the lower bound, the consistent estimator, and the upper bound.**Return type**`Series`

3.2.2 Stepwise Multiple Testing (StepM)

The Stepwise Multiple Testing procedure (Romano & Wolf (2005)) is closely related to the SPA, except that it returns a set of models that are superior to the benchmark model, rather than the p-value from the null. They are so closely related that *StepM* is essentially a wrapper around *SPA* with some small modifications to allow multiple calls.

| | |
|--|---|
| <code>StepM(benchmark, models[, size, block_size, ...])</code> | StepM multiple comparison procedure of Romano and Wolf. |
|--|---|

arch.bootstrap.StepM

```
class arch.bootstrap.StepM(benchmark, models, size=0.05, block_size=None, reps=1000,
                           bootstrap='stationary', studentize=True, nested=False, *, seed=None)
```

StepM multiple comparison procedure of Romano and Wolf.

Parameters

benchmark

`[{ndarray, Series}]` T element array of benchmark model *losses*

models

`[{ndarray, DataFrame}]` T by k element array of alternative model *losses*

size

`[float, optional]` Value in (0,1) to use as the test size when implementing the comparison. Default value is 0.05.

block_size

`[int, optional]` Length of window to use in the bootstrap. If not provided, \sqrt{T} is used. In general, this should be provided and chosen to be appropriate for the data.

reps

`[int, optional]` Number of bootstrap replications to uses. Default is 1000.

bootstrap

`[str, optional]` Bootstrap to use. Options are 'stationary' or 'sb': Stationary bootstrap (Default) 'circular' or 'cbb': Circular block bootstrap 'moving block' or 'mbb': Moving block bootstrap

studentize

`[bool, optional]` Flag indicating to studentize loss differentials. Default is True

nested

`[bool, optional]` Flag indicating to use a nested bootstrap to compute variances for studentization. Default is False. Note that this can be slow since the procedure requires k extra bootstraps.

seed

`[{int, Generator, RandomState}, optional]` Seed value to use when creating the bootstrap used in the comparison. If an integer or None, the NumPy default_rng is used with the seed value. If a Generator or a RandomState, the argument is used.

See also:

[SPA](#)

Notes

The size controls the Family Wise Error Rate (FWER) since this is a multiple comparison procedure. Uses SPA and the consistent selection procedure.

See [1] for detail.

Attributes

superior_models

List of the indices or column names of the superior models

Methods

| | |
|--------------------|--|
| <i>compute()</i> | Compute the set of superior models. |
| <i>reset()</i> | Reset the bootstrap to it's initial state. |
| <i>seed(value)</i> | Seed the bootstrap's random number generator |

arch.bootstrap.StepM.compute

StepM.**compute**()

Compute the set of superior models.

Return type

None

arch.bootstrap.StepM.reset

StepM.**reset**()

Reset the bootstrap to it's initial state.

Return type

None

arch.bootstrap.StepM.seed

StepM.**seed**(*value*)

Seed the bootstrap's random number generator

Parameters

value

[[int, List[int], ndarray[int]]] Integer to use as the seed

Return type

None

Properties

| | |
|------------------------|--|
| <i>superior_models</i> | List of the indices or column names of the superior models |
|------------------------|--|

arch.bootstrap.StepM.superior_models

property StepM.superior_models: list[Hashable]

List of the indices or column names of the superior models

Returns

list

List of superior models. Contains column indices if models is an array or contains column names if models is a DataFrame.

Return type

list[Hashable]

3.2.3 Model Confidence Set (MCS)

The Model Confidence Set (Hansen, Lunde & Nason (2011)) differs from other multiple comparison procedures in that there is no benchmark. The MCS attempts to identify the set of models which produce the same expected loss, while controlling the probability that a model that is worse than the best model is in the model confidence set. Like the other MCPs, it controls the Familywise Error Rate rather than the usual test size.

| | |
|--|--|
| <i>MCS</i> (losses, size[, reps, block_size, ...]) | Model Confidence Set (MCS) of Hansen, Lunde and Nason. |
|--|--|

arch.bootstrap.MCS

class arch.bootstrap.MCS(*losses, size, reps=1000, block_size=None, method='R', bootstrap='stationary', *, seed=None*)

Model Confidence Set (MCS) of Hansen, Lunde and Nason.

Parameters

losses

[{ndarray, DataFrame}] T by k array containing losses from a set of models

size

[float, optional] Value in (0,1) to use as the test size when implementing the mcs. Default value is 0.05.

block_size

[int, optional] Length of window to use in the bootstrap. If not provided, sqrt(T) is used. In general, this should be provided and chosen to be appropriate for the data.

method

[{'max', 'R'}, optional] MCS test and elimination implementation method, either 'max' or 'R'. Default is 'R'.

reps

[`int`, optional] Number of bootstrap replications to uses. Default is 1000.

bootstrap

[`str`, optional] Bootstrap to use. Options are 'stationary' or 'sb': Stationary bootstrap (Default) 'circular' or 'cbb': Circular block bootstrap 'moving block' or 'mbb': Moving block bootstrap

seed

[{`int`, `Generator`, `RandomState`}, optional] Seed value to use when creating the bootstrap used in the comparison. If an integer or None, the NumPy `default_rng` is used with the seed value. If a `Generator` or a `RandomState`, the argument is used.

Notes

See [1] for details.

References

Attributes*excluded*

List of model indices that are excluded from the MCS

included

List of model indices that are included in the MCS

pvalues

Model p-values for inclusion in the MCS

Methods

| | |
|--------------------------|--|
| <code>compute()</code> | Compute the set of models in the confidence set. |
| <code>reset()</code> | Reset the bootstrap to it's initial state. |
| <code>seed(value)</code> | Seed the bootstrap's random number generator |

arch.bootstrap.MCS.compute**MCS.compute()**

Compute the set of models in the confidence set.

Return type

None

arch.bootstrap.MCS.reset

MCS.reset()

Reset the bootstrap to it's initial state.

Return type

None

arch.bootstrap.MCS.seed

MCS.seed(*value*)

Seed the bootstrap's random number generator

Parameters

value

[{int, List[int], ndarray[int]}] Integer to use as the seed

Return type

None

Properties

| | |
|-----------------|--|
| <i>excluded</i> | List of model indices that are excluded from the MCS |
| <i>included</i> | List of model indices that are included in the MCS |
| <i>pvalues</i> | Model p-values for inclusion in the MCS |

arch.bootstrap.MCS.excluded

property MCS.excluded: list[Hashable]

List of model indices that are excluded from the MCS

Returns

excluded

[list] List of column indices or names of the excluded models

Return type

list[Hashable]

arch.bootstrap.MCS.included

property MCS.included: list[Hashable]

List of model indices that are included in the MCS

Returns

included

[list] List of column indices or names of the included models

Return type

list[Hashable]

arch.bootstrap.MCS.pvalues

property `MCS.pvalues`: `DataFrame`

Model p-values for inclusion in the MCS

Returns

`pvalues`

[`DataFrame`] `DataFrame` where the index is the model index (column or name) containing the smallest size where the model is in the MCS.

Return type

`DataFrame`

Articles used in the creation of this module include

UNIT ROOT TESTING

Many time series are highly persistent, and determining whether the data appear to be stationary or contains a unit root is the first step in many analyses. This module contains a number of routines:

- Augmented Dickey-Fuller (*ADF*)
- Dickey-Fuller GLS (*DFGLS*)
- Phillips-Perron (*PhillipsPerron*)
- KPSS (*KPSS*)
- Zivot-Andrews (*ZivotAndrews*)
- Variance Ratio (*VarianceRatio*)
- Automatic Bandwidth Selection (*auto_bandwidth()*)

The first four all start with the null of a unit root and have an alternative of a stationary process. The final test, KPSS, has a null of a stationary process with an alternative of a unit root.

4.1 Introduction

All tests expect a 1-d series as the first input. The input can be any array that can *squeeze* into a 1-d array, a pandas *Series* or a pandas *DataFrame* that contains a single variable.

All tests share a common structure. The key elements are:

- *stat* - Returns the test statistic
- *pvalue* - Returns the p-value of the test statistic
- *lags* - Sets or gets the number of lags used in the model. In most test, can be `None` to trigger automatic selection.
- *trend* - Sets or gets the trend used in the model. Supported trends vary by model, but include:
 - `'nc'`: No constant
 - `'c'`: Constant
 - `'ct'`: Constant and time trend
 - `'ctt'`: Constant, time trend and quadratic time trend
- *summary()* - Returns a summary object that can be printed to get a formatted table

4.1.1 Basic Example

This basic example show the use of the Augmented-Dickey fuller to test whether the default premium, defined as the difference between the yields of large portfolios of BAA and AAA bonds. This example uses a constant and time trend.

```
import datetime as dt

import pandas_datareader.data as web
from arch.unitroot import ADF

start = dt.datetime(1919, 1, 1)
end = dt.datetime(2014, 1, 1)

df = web.DataReader(["AAA", "BAA"], "fred", start, end)
df['diff'] = df['BAA'] - df['AAA']
adf = ADF(df['diff'])
adf.trend = 'ct'

print(adf.summary())
```

which yields

```
Augmented Dickey-Fuller Results
=====
Test Statistic           -3.448
P-value                   0.045
Lags                      21
-----

Trend: Constant and Linear Time Trend
Critical Values: -3.97 (1%), -3.41 (5%), -3.13 (10%)
Null Hypothesis: The process contains a unit root.
Alternative Hypothesis: The process is weakly stationary.
```

4.2 Unit Root Testing

This setup code is required to run in an IPython notebook

```
[1]: import warnings

warnings.simplefilter("ignore")

%matplotlib inline
import matplotlib.pyplot as plt
import seaborn

seaborn.set_style("darkgrid")
plt.rc("figure", figsize=(16, 6))
plt.rc("savefig", dpi=90)
plt.rc("font", family="sans-serif")
plt.rc("font", size=14)
```

4.2.1 Setup

Most examples will make use of the Default premium, which is the difference between the yields of BAA and AAA rated corporate bonds. The data is downloaded from FRED using pandas.

```
[2]: import arch.data.default
import pandas as pd
import statsmodels.api as sm

default_data = arch.data.default.load()
default = default_data.BAA.copy()
default.name = "default"
default = default - default_data.AAA.values
fig = default.plot()
```

nbsphinx-code-borderwhite

The Default premium is clearly highly persistent. A simple check of the autocorrelations confirms this.

```
[3]: acf = pd.DataFrame(sm.tsa.stattools.acf(default), columns=["ACF"])
fig = acf[1:].plot(kind="bar", title="Autocorrelations")
```

nbsphinx-code-borderwhite

4.2.2 Augmented Dickey-Fuller Testing

The Augmented Dickey-Fuller test is the most common unit root test used. It is a regression of the first difference of the variable on its lagged level as well as additional lags of the first difference. The null is that the series contains a unit root, and the (one-sided) alternative is that the series is stationary.

By default, the number of lags is selected by minimizing the AIC across a range of lag lengths (which can be set using `max_lag` when initializing the model). Additionally, the basic test includes a constant in the ADF regression.

These results indicate that the Default premium is stationary.

```
[4]: from arch.unitroot import ADF
```

```
adf = ADF(default)
print(adf.summary().as_text())
```

```

Augmented Dickey-Fuller Results
=====
Test Statistic          -3.356
P-value                  0.013
Lags                     21
-----

Trend: Constant
Critical Values: -3.44 (1%), -2.86 (5%), -2.57 (10%)
Null Hypothesis: The process contains a unit root.
Alternative Hypothesis: The process is weakly stationary.
```

The number of lags can be directly set using `lags`. Changing the number of lags makes no difference to the conclusion.

Note: The ADF assumes residuals are white noise, and that the number of lags is sufficient to pick up any dependence in the data.

Setting the number of lags

```
[5]: adf = ADF(default, lags=5)
print(adf.summary().as_text())
```

```

Augmented Dickey-Fuller Results
=====
Test Statistic          -3.582
P-value                  0.006
Lags                     5
-----

Trend: Constant
Critical Values: -3.44 (1%), -2.86 (5%), -2.57 (10%)
Null Hypothesis: The process contains a unit root.
Alternative Hypothesis: The process is weakly stationary.
```

Deterministic terms

The deterministic terms can be altered using `trend`. The options are:

- 'nc' : No deterministic terms
- 'c' : Constant only
- 'ct' : Constant and time trend
- 'ctt' : Constant, time trend and time-trend squared

Changing the type of constant also makes no difference for this data.

```
[6]: adf = ADF(default, trend="ct", lags=5)
print(adf.summary().as_text())
```

```
Augmented Dickey-Fuller Results
=====
Test Statistic          -3.786
P-value                 0.017
Lags                    5
-----

Trend: Constant and Linear Time Trend
Critical Values: -3.97 (1%), -3.41 (5%), -3.13 (10%)
Null Hypothesis: The process contains a unit root.
Alternative Hypothesis: The process is weakly stationary.
```

Regression output

The ADF uses a standard regression when computing results. These can be accessed using `regression`.

```
[7]: reg_res = adf.regression
print(reg_res.summary().as_text())
```

```

Notes:

- [1] Standard Errors assume that the covariance matrix of the errors is correctly specified.
- [2] The condition number is large, 5.7e+03. This might indicate that there are strong multicollinearity or other numerical problems.

```
[8]: import matplotlib.pyplot as plt
import pandas as pd
```

```
resids = pd.DataFrame(reg_res.resid)
resids.index = default.index[6:]
resids.columns = ["resids"]
fig = resids.plot()
```

nbsphinx-code-borderwhite

Since the number lags was directly set, it is good to check whether the residuals appear to be white noise.

```
[9]: acf = pd.DataFrame(sm.tsa.stattools.acf(reg_res.resid), columns=["ACF"])
fig = acf[1:].plot(kind="bar", title="Residual Autocorrelations")
```

nbsphinx-code-borderwhite

4.2.3 Dickey-Fuller GLS Testing

The Dickey-Fuller GLS test is an improved version of the ADF which uses a GLS-detrending regression before running an ADF regression with no additional deterministic terms. This test is only available with a constant or constant and time trend (`trend='c'` or `trend='ct'`).

The results of this test agree with the ADF results.

```
[10]: from arch.unitroot import DFGLS
```

```
dfgls = DFGLS(default)
print(dfgls.summary().as_text())
```

```

      Dickey-Fuller GLS Results

-----

Trend: Constant
Critical Values: -2.59 (1%), -1.96 (5%), -1.64 (10%)
Null Hypothesis: The process contains a unit root.
Alternative Hypothesis: The process is weakly stationary.
```

The trend can be altered using `trend`. The conclusion is the same.

```
[11]: dfgls = DFGLS(default, trend="ct")
print(dfgls.summary().as_text())
```

```

      Dickey-Fuller GLS Results
=====
Test Statistic          -3.464
P-value                 0.009
Lags                    21
-----

Trend: Constant and Linear Time Trend
Critical Values: -3.43 (1%), -2.86 (5%), -2.58 (10%)
Null Hypothesis: The process contains a unit root.
Alternative Hypothesis: The process is weakly stationary.
```

4.2.4 Phillips-Perron Testing

The Phillips-Perron test is similar to the ADF except that the regression run does not include lagged values of the first differences. Instead, the PP test fixed the t-statistic using a long run variance estimation, implemented using a Newey-West covariance estimator.

By default, the number of lags is automatically set, although this can be overridden using `lags`.

```
[12]: from arch.unitroot import PhillipsPerron
```

```
pp = PhillipsPerron(default)
print(pp.summary().as_text())
```

```

Phillips-Perron Test (Z-tau)
=====
Test Statistic          -3.898
P-value                 0.002
Lags                    23
-----

Trend: Constant
Critical Values: -3.44 (1%), -2.86 (5%), -2.57 (10%)
Null Hypothesis: The process contains a unit root.
Alternative Hypothesis: The process is weakly stationary.

```

It is important that the number of lags is sufficient to pick up any dependence in the data.

```
[13]: pp = PhillipsPerron(default, lags=12)
print(pp.summary().as_text())
```

```

Phillips-Perron Test (Z-tau)
=====
Test Statistic          -4.024
P-value                 0.001
Lags                    12
-----

Trend: Constant
Critical Values: -3.44 (1%), -2.86 (5%), -2.57 (10%)
Null Hypothesis: The process contains a unit root.
Alternative Hypothesis: The process is weakly stationary.

```

The trend can be changed as well.

```
[14]: pp = PhillipsPerron(default, trend="ct", lags=12)
print(pp.summary().as_text())
```

```

Phillips-Perron Test (Z-tau)
=====
Test Statistic          -4.262
P-value                 0.004
Lags                    12
-----

Trend: Constant and Linear Time Trend
Critical Values: -3.97 (1%), -3.41 (5%), -3.13 (10%)
Null Hypothesis: The process contains a unit root.
Alternative Hypothesis: The process is weakly stationary.

```

Finally, the PP testing framework includes two types of tests. One which uses an ADF-type regression of the first difference on the level, the other which regresses the level on the level. The default is the tau test, which is similar to an ADF regression, although this can be changed using `test_type='rho'`.

```
[15]: pp = PhillipsPerron(default, test_type="rho", trend="ct", lags=12)
print(pp.summary().as_text())
```

```

Phillips-Perron Test (Z-rho)
=====

```

(continues on next page)

(continued from previous page)

```

Test Statistic      -36.114
P-value             0.002
Lags                12
-----

```

```

Trend: Constant and Linear Time Trend
Critical Values: -29.16 (1%), -21.60 (5%), -18.17 (10%)
Null Hypothesis: The process contains a unit root.
Alternative Hypothesis: The process is weakly stationary.

```

4.2.5 KPSS Testing

The KPSS test differs from the three previous in that the null is a stationary process and the alternative is a unit root.

Note that here the null is rejected which indicates that the series might be a unit root.

```
[16]: from arch.unitroot import KPSS
```

```

kpss = KPSS(default)
print(kpss.summary().as_text())

```

```

      KPSS Stationarity Test Results
=====
Test Statistic      1.088
P-value             0.002
Lags                20
-----

```

```

Trend: Constant
Critical Values: 0.74 (1%), 0.46 (5%), 0.35 (10%)
Null Hypothesis: The process is weakly stationary.
Alternative Hypothesis: The process contains a unit root.

```

Changing the trend does not alter the conclusion.

```
[17]: kpss = KPSS(default, trend="ct")
print(kpss.summary().as_text())
```

```

      KPSS Stationarity Test Results
=====
Test Statistic      0.393
P-value             0.000
Lags                20
-----

```

```

Trend: Constant and Linear Time Trend
Critical Values: 0.22 (1%), 0.15 (5%), 0.12 (10%)
Null Hypothesis: The process is weakly stationary.
Alternative Hypothesis: The process contains a unit root.

```

4.2.6 Zivot-Andrews Test

The Zivot-Andrews test allows the possibility of a single structural break in the series. Here we test the default using the test.

```
[18]: from arch.unitroot import ZivotAndrews
```

```
za = ZivotAndrews(default)
print(za.summary().as_text())
```

```

          Zivot-Andrews Results
=====
Test Statistic          -4.900
P-value                 0.040
Lags                    21
-----

Trend: Constant
Critical Values: -5.28 (1%), -4.81 (5%), -4.57 (10%)
Null Hypothesis: The process contains a unit root with a single structural break.
Alternative Hypothesis: The process is trend and break stationary.
```

4.2.7 Variance Ratio Testing

Variance ratio tests are not usually used as unit root tests, and are instead used for testing whether a financial return series is a pure random walk versus having some predictability. This example uses the excess return on the market from Ken French's data.

```
[19]: import arch.data.frenchdata
import numpy as np
import pandas as pd
```

```
ff = arch.data.frenchdata.load()
excess_market = ff.iloc[:, 0] # Excess Market
print(ff.describe())
```

| | Mkt-RF | SMB | HML | RF |
|-------|-------------|-------------|-------------|-------------|
| count | 1109.000000 | 1109.000000 | 1109.000000 | 1109.000000 |
| mean | 0.659946 | 0.206555 | 0.368864 | 0.274220 |
| std | 5.327524 | 3.191132 | 3.482352 | 0.253377 |
| min | -29.130000 | -16.870000 | -13.280000 | -0.060000 |
| 25% | -1.970000 | -1.560000 | -1.320000 | 0.030000 |
| 50% | 1.020000 | 0.070000 | 0.140000 | 0.230000 |
| 75% | 3.610000 | 1.730000 | 1.740000 | 0.430000 |
| max | 38.850000 | 36.700000 | 35.460000 | 1.350000 |

The variance ratio compares the variance of a 1-period return to that of a multi-period return. The comparison length has to be set when initializing the test.

This example compares 1-month to 12-month returns, and the null that the series is a pure random walk is rejected. Negative values indicate some positive autocorrelation in the returns (momentum).

```
[20]: from arch.unitroot import VarianceRatio
```

(continues on next page)

(continued from previous page)

```
vr = VarianceRatio(excess_market, 12)
print(vr.summary().as_text())
```

```

Variance-Ratio Test Results
=====
Test Statistic          -5.029
P-value                 0.000
Lags                    12
-----

```

Computed with overlapping blocks (de-biased)

By default the VR test uses all overlapping blocks to estimate the variance of the long period's return. This can be changed by setting `overlap=False`. This lowers the power but does not change the conclusion.

```
[21]: warnings.simplefilter("always") # Restore warnings
```

```
vr = VarianceRatio(excess_market, 12, overlap=False)
print(vr.summary().as_text())
```

```

Variance-Ratio Test Results
=====
Test Statistic          -6.206
P-value                 0.000
Lags                    12
-----

```

Computed with non-overlapping blocks

```
c:\git\arch\arch\unitroot\unitroot.py:1679: InvalidLengthWarning:
The length of y is not an exact multiple of 12, and so the final
4 observations have been dropped.
```

```
warnings.warn(
```

Note: The warning is intentional. It appears here since when it is not possible to use all data since the data length is not an integer multiple of the long period when using non-overlapping blocks. There is little reason to use `overlap=False`.

4.3 The Unit Root Tests

| | |
|--|---|
| <i>ADF</i> (y[, lags, trend, max_lags, method, ...]) | Augmented Dickey-Fuller unit root test |
| <i>DFGLS</i> (y[, lags, trend, max_lags, method, ...]) | Elliott, Rothenberg and Stock's ([1]) GLS detrended Dickey-Fuller |
| <i>PhillipsPerron</i> (y[, lags, trend, test_type]) | Phillips-Perron unit root test |
| <i>ZivotAndrews</i> (y[, lags, trend, trim, ...]) | Zivot-Andrews structural-break unit-root test |
| <i>VarianceRatio</i> (y[, lags, trend, debiased, ...]) | Variance Ratio test of a random walk. |
| <i>KPSS</i> (y[, lags, trend]) | Kwiatkowski, Phillips, Schmidt and Shin (KPSS) stationarity test |

4.3.1 arch.unitroot.ADF

class arch.unitroot.ADF(*y*, *lags=None*, *trend='c'*, *max_lags=None*, *method='aic'*, *low_memory=None*)

Augmented Dickey-Fuller unit root test

Parameters

y

[{*ndarray*, *Series*}] The data to test for a unit root

lags

[*int*, optional] The number of lags to use in the ADF regression. If omitted or *None*, *method* is used to automatically select the lag length with no more than *max_lags* are included.

trend

[{"n", "c", "ct", "ctt"}, optional] The trend component to include in the test

- "n" - No trend components
- "c" - Include a constant (Default)
- "ct" - Include a constant and linear time trend
- "ctt" - Include a constant and linear and quadratic time trends

max_lags

[*int*, optional] The maximum number of lags to use when selecting lag length

method

[{"AIC", "BIC", "t-stat"}, optional] The method to use when selecting the lag length

- "AIC" - Select the minimum of the Akaike IC
- "BIC" - Select the minimum of the Schwarz/Bayesian IC
- "t-stat" - Select the minimum of the Schwarz/Bayesian IC

low_memory

[*bool*] Flag indicating whether to use a low memory implementation of the lag selection algorithm. The low memory algorithm is slower than the standard algorithm but will use 2-4% of the memory required for the standard algorithm. This options allows automatic lag selection to be used in very long time series. If *None*, use automatic selection of algorithm.

Notes

The null hypothesis of the Augmented Dickey-Fuller is that there is a unit root, with the alternative that there is no unit root. If the pvalue is above a critical size, then the null cannot be rejected that there and the series appears to be a unit root.

The p-values are obtained through regression surface approximation from MacKinnon (1994) using the updated 2010 tables. If the p-value is close to significant, then the critical values should be used to judge whether to reject the null.

The autolag option and maxlag for it are described in Greene.

Attributes

alternative_hypothesis

The alternative hypothesis

critical_values

Dictionary containing critical values specific to the test, number of observations and included deterministic trend terms.

lags

Sets or gets the number of lags used in the model.

max_lags

Sets or gets the maximum lags used when automatically selecting lag

nobs

The number of observations used when computing the test statistic.

null_hypothesis

The null hypothesis

pvalue

Returns the p-value for the test statistic

regression

Returns the OLS regression results from the ADF model estimated

stat

The test statistic for a unit root

trend

Sets or gets the deterministic trend term used in the test.

valid_trends

List of valid trend terms.

y
Returns the data used in the test statistic

arch.unitroot.ADF.y

property ADF.y: Union[ndarray, DataFrame, Series]

Returns the data used in the test statistic

Return type
Union[ndarray, DataFrame, Series]

4.3.2 arch.unitroot.DFGLS

class `arch.unitroot.DFGLS`(*y*, *lags=None*, *trend='c'*, *max_lags=None*, *method='aic'*, *low_memory=None*)
Elliott, Rothenberg and Stock's ([1]) GLS detrended Dickey-Fuller

Parameters

- y**
[[`ndarray`, `Series`]] The data to test for a unit root
- lags**
[`int`, optional] The number of lags to use in the ADF regression. If omitted or `None`, *method* is used to automatically select the lag length with no more than *max_lags* are included.
- trend**
[{"c", "ct"}, optional] The trend component to include in the test
- "c" - Include a constant (Default)
 - "ct" - Include a constant and linear time trend
- max_lags**
[`int`, optional] The maximum number of lags to use when selecting lag length. When using automatic lag length selection, the lag is selected using OLS detrending rather than GLS detrending ([2]).
- method**
[{"AIC", "BIC", "t-stat"}, optional] The method to use when selecting the lag length
- "AIC" - Select the minimum of the Akaike IC
 - "BIC" - Select the minimum of the Schwarz/Bayesian IC
 - "t-stat" - Select the minimum of the Schwarz/Bayesian IC

Notes

The null hypothesis of the Dickey-Fuller GLS is that there is a unit root, with the alternative that there is no unit root. If the pvalue is above a critical size, then the null cannot be rejected and the series appears to be a unit root.

DFGLS differs from the ADF test in that an initial GLS detrending step is used before a trend-less ADF regression is run.

Critical values and p-values when trend is "c" are identical to the ADF. When trend is set to "ct", they are from ...

4.3.3 arch.unitroot.PhillipsPerron

```
class arch.unitroot.PhillipsPerron(y, lags=None, trend='c', test_type='tau')
```

Phillips-Perron unit root test

Parameters

y

[[`ndarray`, `Series`]] The data to test for a unit root

lags

[`int`, optional] The number of lags to use in the Newey-West estimator of the long-run covariance. If omitted or `None`, the lag length is set automatically to $12 * (\text{nobs}/100)^{1/4}$

trend

[{"n", "c", "ct"}, optional] The trend component to include in the test

- "n" - No trend components
- "c" - Include a constant (Default)
- "ct" - Include a constant and linear time trend

test_type

[{"tau", "rho"}] The test to use when computing the test statistic. "tau" is based on the t-stat and "rho" uses a test based on nobs times the re-centered regression coefficient

Notes

The null hypothesis of the Phillips-Perron (PP) test is that there is a unit root, with the alternative that there is no unit root. If the pvalue is above a critical size, then the null cannot be rejected that there and the series appears to be a unit root.

Unlike the ADF test, the regression estimated includes only one lag of the dependant variable, in addition to trend terms. Any serial correlation in the regression errors is accounted for using a long-run variance estimator (currently Newey-West).

The p-values are obtained through regression surface approximation from MacKinnon (1994) using the updated 2010 tables. If the p-value is close to significant, then the critical values should be used to judge whether to reject the null.

| <i>stat</i> | The test statistic for a unit root |
| <i>test_type</i> | Gets or sets the test type returned by stat. |
| <i>trend</i> | Sets or gets the deterministic trend term used in the test. |
| <i>valid_trends</i> | List of valid trend terms. |
| <i>y</i> | Returns the data used in the test statistic |

arch.unitroot.PhillipsPerron.alternative_hypothesis

property PhillipsPerron.alternative_hypothesis: **str**

The alternative hypothesis

Return type

str

arch.unitroot.PhillipsPerron.critical_values**property** `PhillipsPerron.critical_values`: `dict[str, float]`

Dictionary containing critical values specific to the test, number of observations and included deterministic trend terms.

Return type`dict[str, float]`**arch.unitroot.PhillipsPerron.lags****property** `PhillipsPerron.lags`: `int`

Sets or gets the number of lags used in the model. When bootstrap use DF-type regressions, lags is the number of lags in the regression model. When bootstrap use long-run variance estimators, lags is the number of lags used in the long-run variance estimator.

Return type`int`**arch.unitroot.PhillipsPerron.nobs****property** `PhillipsPerron.nobs`: `int`

The number of observations used when computing the test statistic. Accounts for loss of data due to lags for regression-based bootstrap.

Return type`int`**arch.unitroot.PhillipsPerron.null_hypothesis****property** `PhillipsPerron.null_hypothesis`: `str`

The null hypothesis

Return type`str`**arch.unitroot.PhillipsPerron.pvalue****property** `PhillipsPerron.pvalue`: `float`

Returns the p-value for the test statistic

Return type`float`

arch.unitroot.PhillipsPerron.regression

property PhillipsPerron.regression: `RegressionResults`

Returns OLS regression results for the specification used in the test

The results returned use a Newey-West covariance matrix with the same number of lags as are used in the test statistic.

Return type

`RegressionResults`

arch.unitroot.PhillipsPerron.stat

property PhillipsPerron.stat: `float`

The test statistic for a unit root

Return type

`float`

arch.unitroot.PhillipsPerron.test_type

property PhillipsPerron.test_type: `str`

Gets or sets the test type returned by stat. Valid values are “tau” or “rho”

Return type

`str`

arch.unitroot.PhillipsPerron.trend

property PhillipsPerron.trend: `str`

Sets or gets the deterministic trend term used in the test. See `valid_trends` for a list of supported trends

Return type

`str`

arch.unitroot.PhillipsPerron.valid_trends

property PhillipsPerron.valid_trends: `list[str]`

List of valid trend terms.

Return type

`list[str]`

arch.unitroot.PhillipsPerron.y

property `PhillipsPerron.y`: `Union[ndarray, DataFrame, Series]`

Returns the data used in the test statistic

Return type

`Union[ndarray, DataFrame, Series]`

4.3.4 arch.unitroot.ZivotAndrews

class `arch.unitroot.ZivotAndrews`(*y*, *lags=None*, *trend='c'*, *trim=0.15*, *max_lags=None*, *method='aic'*)

Zivot-Andrews structural-break unit-root test

The Zivot-Andrews test can be used to test for a unit root in a univariate process in the presence of serial correlation and a single structural break.

Parameters

y
[numpy:array_like] data series

lags
[int, optional] The number of lags to use in the ADF regression. If omitted or None, *method* is used to automatically select the lag length with no more than *max_lags* are included.

trend
[{"c", "t", "ct"}, optional] The trend component to include in the test

- "c" - Include a constant (Default)
- "t" - Include a linear time trend
- "ct" - Include a constant and linear time trend

trim
[float] percentage of series at begin/end to exclude from break-period calculation in range [0, 0.333] (default=0.15)

max_lags
[int, optional] The maximum number of lags to use when selecting lag length

method
[{"AIC", "BIC", "t-stat"}, optional] The method to use when selecting the lag length

- "AIC" - Select the minimum of the Akaike IC
- "BIC" - Select the minimum of the Schwarz/Bayesian IC
- "t-stat" - Select the minimum of the Schwarz/Bayesian IC

Notes

H0 = unit root with a single structural break

Algorithm follows Baum (2004/2015) approximation to original Zivot-Andrews method. Rather than performing an autolag regression at each candidate break period (as per the original paper), a single autolag regression is run up-front on the base model (constant + trend with no dummies) to determine the best lag length. This lag length is then used for all subsequent break-period regressions. This results in significant run time reduction but also slightly more pessimistic test statistics than the original Zivot-Andrews method,

No attempt has been made to characterize the size/power trade-off.

Return type`float`

arch.unitroot.ZivotAndrews.trend**property** ZivotAndrews.trend: `str`Sets or gets the deterministic trend term used in the test. See `valid_trends` for a list of supported trends**Return type**`str`**arch.unitroot.ZivotAndrews.valid_trends****property** ZivotAndrews.valid_trends: `list[str]`

List of valid trend terms.

Return type`list[str]`**arch.unitroot.ZivotAndrews.y****property** ZivotAndrews.y: `Union[ndarray, DataFrame, Series]`

Returns the data used in the test statistic

Return type`Union[ndarray, DataFrame, Series]`

4.3.5 arch.unitroot.VarianceRatio

class arch.unitroot.VarianceRatio(*y*, *lags*=2, *trend*='c', *debiased*=True, *robust*=True, *overlap*=True)

Variance Ratio test of a random walk.

Parameters**y**`[{ndarray, Series}]` The data to test for a random walk**lags**`[int]` The number of periods to used in the multi-period variance, which is the numerator of the test statistic. Must be at least 2**trend**`[{"n", "c"}, optional]` "c" allows for a non-zero drift in the random walk, while "n" requires that the increments to *y* are mean 0**overlap**`[bool, optional]` Indicates whether to use all overlapping blocks. Default is True. If False, the number of observations in *y* minus 1 must be an exact multiple of lags. If this condition is not satisfied, some values at the end of *y* will be discarded.**robust**`[bool, optional]` Indicates whether to use heteroskedasticity robust inference. Default is True.**debiased**`[bool, optional]` Indicates whether to use a debiased version of the test. Default is True. Only applicable if `overlap` is True.

Notes

The null hypothesis of a VR is that the process is a random walk, possibly plus drift. Rejection of the null with a positive test statistic indicates the presence of positive serial correlation in the time series.

arch.unitroot.VarianceRatio.vr**property** VarianceRatio.vr: float

The ratio of the long block lags-period variance to the 1-period variance

Return type

float

arch.unitroot.VarianceRatio.y**property** VarianceRatio.y: Union[ndarray, DataFrame, Series]

Returns the data used in the test statistic

Return type

Union[ndarray, DataFrame, Series]

4.3.6 arch.unitroot.KPSS

class arch.unitroot.KPSS(y, lags=None, trend='c')

Kwiatkowski, Phillips, Schmidt and Shin (KPSS) stationarity test

Parameters**y**

[[ndarray, Series]] The data to test for stationarity

lags[int, optional] The number of lags to use in the Newey-West estimator of the long-run covariance. If omitted or None, the number of lags is calculated with the data-dependent method of Hobijn et al. (1998). See also Andrews (1991), Newey & West (1994), and Schwert (1989). Set lags=-1 to use the old method that only depends on the sample size, $12 * (\text{nobs}/100) ** (1/4)$.**trend**

[{"c", "ct"}, optional]

The trend component to include in the ADF test

"c" - Include a constant (Default) "ct" - Include a constant and linear time trend

Notes

The null hypothesis of the KPSS test is that the series is weakly stationary and the alternative is that it is non-stationary. If the p-value is above a critical size, then the null cannot be rejected that there and the series appears stationary.

The p-values and critical values were computed using an extensive simulation based on 100,000,000 replications using series with 2,000 observations.

4.3.7 Automatic Bandwidth Selection

`auto_bandwidth(y[, kernel])`Automatic bandwidth selection of Andrews (1991) and Newey & West (1994).

arch.unitroot.auto_bandwidth`arch.unitroot.auto_bandwidth(y, kernel='ba')`

Automatic bandwidth selection of Andrews (1991) and Newey & West (1994).

Parameters**y**
[ndarray, Series] Data on which to apply the bandwidth selection**kernel**
[str] The kernel function to use for selecting the bandwidth

- “ba”, “bartlett”, “nw”: Bartlett kernel (default)
- “pa”, “parzen”, “gallant”: Parzen kernel

- “qs”, “andrews”: Quadratic Spectral kernel

Returns

`float`

The estimated optimal bandwidth.

Return type

`float`

COINTEGRATION ANALYSIS

The module extended the single-series unit root testing to multiple series and cointegration testing and cointegrating vector estimation.

- Cointegrating Testing
 - Engle-Granger Test (*engle_granger*)
 - Phillips-Ouliaris Tests (*phillips_ouliaris*)
- Cointegrating Vector Estimation
 - Dynamic OLS (*DynamicOLS*)
 - Fully Modified OLS (*FullyModifiedOLS*)
 - Canonical Cointegrating Regression (*CanonicalCointegratingReg*)

5.1 Cointegration Testing

This setup code is required to run in an IPython notebook

```
[1]: %matplotlib inline
import matplotlib.pyplot as plt
import seaborn

seaborn.set_style("darkgrid")
plt.rc("figure", figsize=(16, 6))
plt.rc("savefig", dpi=90)
plt.rc("font", family="sans-serif")
plt.rc("font", size=14)
```

We will look at the spot prices of crude oil measured in Cushing, OK for West Texas Intermediate Crude, and Brent Crude. The underlying data in this data set come from the [U.S. Energy Information Administration](#).

```
[2]: import numpy as np
from arch.data import crude

data = crude.load()
log_price = np.log(data)

ax = log_price.plot()
xl = ax.set_xlim(log_price.index.min(), log_price.index.max())
```

nbsphinx-code-borderwhite

We can verify these both of these series appear to contains unit roots using Augmented Dickey-Fuller tests. The p-values are large indicating that the null cannot be rejected.

```
[3]: from arch.unitroot import ADF
```

```
ADF(log_price.WTI, trend="c")
```

```
[3]: <class 'arch.unitroot.unitroot.ADF'>
      """
      Augmented Dickey-Fuller Results
      =====
      Test Statistic          -1.780
      P-value                  0.391
      Lags                     1
      -----

      Trend: Constant
      Critical Values: -3.45 (1%), -2.87 (5%), -2.57 (10%)
      Null Hypothesis: The process contains a unit root.
      Alternative Hypothesis: The process is weakly stationary.
      """
```

```
[4]: ADF(log_price.Brent, trend="c")
```

```
[4]: <class 'arch.unitroot.unitroot.ADF'>
      """
      Augmented Dickey-Fuller Results
      =====
      Test Statistic          -1.655
      P-value                  0.454
      Lags                     1
      -----

      Trend: Constant
      Critical Values: -3.45 (1%), -2.87 (5%), -2.57 (10%)
      Null Hypothesis: The process contains a unit root.
      Alternative Hypothesis: The process is weakly stationary.
      """
```

The Engle-Granger test is a 2-step test that first estimates a cross-sectional regression, and then tests the residuals from this regression using an Augmented Dickey-Fuller distribution with modified critical values. The cross-sectional

regression is

$$Y_t = X_t\beta + D_t\gamma + \epsilon_t$$

where Y_t and X_t combine to contain the set of variables being tested for cointegration and D_t are a set of deterministic regressors that might include a constant, a time trend, or a quadratic time trend. The trend is specified using `trend` as

- "n": No trend
- "c": Constant
- "ct": Constant and time trend
- "ctt": Constant, time and quadratic trends

Here we assume that that cointegrating relationship is exact so that no deterministic are needed.

```
[5]: from arch.unitroot import engle_granger

eg_test = engle_granger(log_price.WTI, log_price.Brent, trend="n")
eg_test
```

```
[5]: Engle-Granger Cointegration Test
Statistic: -3.4676471998477267
P-value: 0.006860702109284017
Null: No Cointegration, Alternative: Cointegration
ADF Lag length: 0
Trend: c
Estimated Root (+1): 0.9386946007157646
Distribution Order: 1
ID: 0x2352eeb6e50
```

The plot method can be used to plot the model residual. We see that while this appears to be mean 0, it might have a trend in it.

```
[6]: fig = eg_test.plot()
```

nbsphinx-code-borderwhite

The estimated cointegrating vector is exposed through the `cointegrating_vector` property. Here we see it is very close to $[1, -1]$, indicating a simple no-arbitrage relationship.

```
[7]: eg_test.cointegrating_vector
```

```
[7]: WTI      1.000000
Brent    -1.000621
dtype: float64
```

We can rerun the test with both a constant and a time trend to see how this affects the conclusion. We firmly reject the null of no cointegration even with this alternative assumption.

```
[8]: eg_test = engle_granger(log_price.WTI, log_price.Brent, trend="ct")
      eg_test
```

```
[8]: Engle-Granger Cointegration Test
      Statistic: -5.83664970914174
      P-value: 2.3286206215070878e-05
      Null: No Cointegration, Alternative: Cointegration
      ADF Lag length: 0
      Trend: c
      Estimated Root (+1): 0.8400729995315473
      Distribution Order: 1
      ID: 0x235285d7340
```

```
[9]: eg_test.cointegrating_vector
```

```
[9]: WTI      1.000000
      Brent  -0.931769
      const  -0.296939
      trend   0.000185
      dtype: float64
```

The residuals are clearly mean zero but show evidence of a structural break around the financial crisis of 2008.

```
[10]: fig = eg_test.plot()
```

nbsphinx-code-borderwhite

To investigate the changes in the 2008 financial crisis, we can re-run the test on only the pre-crisis period.

```
[11]: eg_test = engle_granger(log_price[:"2008"].WTI, log_price[:"2008"].Brent, trend="n")
      eg_test
```

```
[11]: Engle-Granger Cointegration Test
      Statistic: -4.962489476284803
      P-value: 2.054007070920808e-05
      Null: No Cointegration, Alternative: Cointegration
      ADF Lag length: 0
      Trend: c
      Estimated Root (+1): 0.8246009342909095
      Distribution Order: 1
      ID: 0x2352f312f70
```

These residuals look quite a bit better although it is possible the break in the cointegrating vector happened around 2005 when oil prices first surged.

```
[12]: fig = eg_test.plot()
ax = fig.get_axes()[0]
title = ax.set_title("Pre-2009 Cointegration Residual")
```

nbsphinx-code-borderwhite

5.1.1 Phillips-Ouliaris

The Phillips-Ouliaris tests consists four distinct tests. Two are similar to the Engle-Granger test, only using a Phillips & Perron-like approach replaces the lags in the ADF test with a long-run variance estimator. The other two use variance-ratio like approaches to test. In both cases the test stabilizes when there is no cointegration and diverges due to singularity of the covariance matrix of the $I(1)$ time series when there is cointegration.

- Z_t - Like PP using the t-stat of the AR(1) coefficient in an AR(1) of the residual from the cross-sectional regression.
- Z_α - Like PP using $T(\alpha - 1)$ and a bias term from the same AR(1)
- P_u - A univariate variance ratio test.
- P_z - A multivariate variance ratio test.

The four test statistics all agree on the crude oil data.

The Z_t and Z_α test statistics are both based on the quantity $\gamma = \rho - 1$ from the regression $y_t = d_t \Delta + \rho y_{t-1} + \epsilon_t$. The null is rejected in favor of the alternative when $\gamma < 0$ so that the test statistic is *below* its critical value.

5.2 Cointegration Tests

| | |
|--|---|
| <code>engle_granger(y, x[, trend, lags, max_lags, ...])</code> | Test for cointegration within a set of time series. |
| <code>phillips_ouliaris(y, x[, trend, test_type, ...])</code> | Test for cointegration within a set of time series. |

5.2.1 arch.unitroot.cointegration.EngleGranger

arch.unitroot.cointegration.EngleGranger(y, x, trend='c', *, lags=None, max_lags=None, method='bic')

Test for cointegration within a set of time series.

Parameters

y
[numpy:array_like] The left-hand-side variable in the cointegrating regression.

x
[numpy:array_like] The right-hand-side variables in the cointegrating regression.

trend
[{"n", "c", "ct", "ctt"}, default "c"] Trend to include in the cointegrating regression. Trends are:

- "n": No deterministic terms
- "c": Constant
- "ct": Constant and linear trend
- "ctt": Constant, linear and quadratic trends

lags
[int, default None] The number of lagged differences to include in the Augmented Dickey-Fuller test used on the residuals of the

max_lags
[int, default None] The maximum number of lags to consider when using automatic lag-length in the Augmented Dickey-Fuller regression.

method: {"aic", "bic", "tstat"}, default "bic"
The method used to select the number of lags included in the Augmented Dickey-Fuller regression.

Returns

EngleGrangerTestResults
Results of the Engle-Granger test.

See also:

arch.unitroot.ADF
Augmented Dickey-Fuller testing.

arch.unitroot.PhillipsPerron
Phillips & Perron's unit root test.

arch.unitroot.cointegration.phillips_ouliaris
Phillips-Ouliaris tests of cointegration.

Notes

The model estimated is

$$Y_t = X_t\beta + D_t\gamma + \epsilon_t$$

where $Z_t = [Y_t, X_t]$ is being tested for cointegration. D_t is a set of deterministic terms that may include a constant, a time trend or a quadratic time trend.

The null hypothesis is that the series are not cointegrated.

The test is implemented as an ADF of the estimated residuals from the cross-sectional regression using a set of critical values that is determined by the number of assumed stochastic trends when the null hypothesis is true.

Return type

EngleGrangerTestResults

5.2.2 arch.unitroot.cointegration.phillips_ouliaris

`arch.unitroot.cointegration.phillips_ouliaris`(*y*, *x*, *trend*='c', *, *test_type*='Zt', *kernel*='bartlett', *bandwidth*=None, *force_int*=False)

Test for cointegration within a set of time series.

Parameters

y

[numpy:array_like] The left-hand-side variable in the cointegrating regression.

x

[numpy:array_like] The right-hand-side variables in the cointegrating regression.

trend

[{"n", "c", "ct", "ctt"}, default "c"] Trend to include in the cointegrating regression. Trends are:

- "n": No deterministic terms
- "c": Constant
- "ct": Constant and linear trend
- "ctt": Constant, linear and quadratic trends

test_type

[{"Za", "Zt", "Pu", "Pz"}, default "Zt"] The test statistic to compute. Supported options are:

- "Za": The Z test based on the the debiased AR(1) coefficient.
- "Zt": The Zt test based on the t-statistic from an AR(1).
- "Pu": The P variance-ratio test.
- "Pz": The Pz test of the trace of the product of an estimate of the long-run residual variance and the inner-product of the data.

See the notes for details on the test.

kernel

[str, default "bartlett"] The string name of any of any known kernel-based long-run covariance estimators. Common choices are "bartlett" for the Bartlett kernel (Newey-West), "parzen" for the Parzen kernel and "quadratic-spectral" for the Quadratic Spectral kernel.

bandwidth

[`int`, default `None`] The bandwidth to use. If not provided, the optimal bandwidth is estimated from the data. Setting the bandwidth to 0 and using “unadjusted” produces the classic OLS covariance estimator. Setting the bandwidth to 0 and using “robust” produces White’s covariance estimator.

force_int

[`bool`, default `False`] Whether the force the estimated optimal bandwidth to be an integer.

Returns

PhillipsOuliarisTestResults

Results of the Phillips-Ouliaris test.

See also:

arch.unitroot.ADF

Augmented Dickey-Fuller testing.

arch.unitroot.PhillipsPerron

Phillips & Perron’s unit root test.

arch.unitroot.cointegration.engle_granger

Engle & Granger’s cointegration test.

Notes

Warning: The critical value simulation is on-going and so the critical values may change slightly as more simulations are completed. These are still based on far more simulations (minimum 2,000,000) than were possible in 1990 (5000) that are reported in [1].

Supports 4 distinct tests.

Define the cross-sectional regression

$$y_t = x_t\beta + d_t\gamma + u_t$$

where d_t are any included deterministic terms. Let $\hat{u}_t = y_t - x_t\hat{\beta} + d_t\hat{\gamma}$.

The Z and Zt statistics are defined as

$$\hat{Z}_\alpha = T \times z$$

$$\hat{Z}_t = \frac{\hat{\sigma}_u}{\hat{\omega}^2} \times \sqrt{T}z$$

$$z = (\hat{\alpha} - 1) - \hat{\omega}_1^2 / \hat{\sigma}_u^2$$

where $\hat{\sigma}_u^2 = T^{-1} \sum_{t=2}^T \hat{u}_t^2$, $\hat{\omega}_1^2$ is an estimate of the one-sided strict autocovariance, and $\hat{\omega}^2$ is an estimate of the long-run variance of the process.

The \hat{P}_u variance-ratio statistic is defined as

$$\hat{P}_u = \frac{\hat{\omega}_{11 \cdot 2}}{\hat{\sigma}_u^2}$$

where $\hat{\sigma}_u^2 = T^{-1} \sum_{t=1}^T \hat{u}_t^2$ and

$$\hat{\omega}_{11 \cdot 2} = \hat{\omega}_{11} - \hat{\omega}'_{21} \hat{\Omega}_{22}^{-1} \hat{\omega}_{21}$$

and

$$\hat{\Omega} = \begin{bmatrix} \hat{\omega}_{11} & \hat{\omega}'_{21} \\ \hat{\omega}_{21} & \hat{\Omega}_{22} \end{bmatrix}$$

is an estimate of the long-run covariance of ξ_t , the residuals from an VAR(1) on $z_t = [y_t, z_t]$ that includes and trends included in the test.

$$z_t = \Phi z_{t-1} + \xi_t$$

The final test statistic is defined

$$\hat{P}_z = T \times \text{tr}(\hat{\Omega} M_{zz}^{-1})$$

where $M_{zz} = \sum_{t=1}^T \tilde{z}'_t \tilde{z}_t$, \tilde{z}_t is the vector of data $z_t = [y_t, x_t]$ detrended using any trend terms included in the test, $\tilde{z}_t = z_t - d_t \hat{\kappa}$ and $\hat{\Omega}$ is defined above.

The specification of the \hat{P}_z test statistic when trend is “n” differs from the expression in [1]. We recenter z_t by subtracting the first observation, so that $\tilde{z}_t = z_t - z_1$. This is needed to ensure that the initial value does not affect the distribution under the null. When the trend is anything other than “n”, this set is not needed and the test statistics is identical whether the first observation is subtracted or not.

5.3 Cointegrating Vector Estimation

| | |
|---|---|
| <i>DynamicOLS</i> (y, x[, trend, lags, leads, ...]) | Dynamic OLS (DOLS) cointegrating vector estimation |
| <i>FullyModifiedOLS</i> (y, x[, trend, x_trend]) | Fully Modified OLS cointegrating vector estimation. |
| <i>CanonicalCointegratingReg</i> (y, x[, trend, x_trend]) | Canonical Cointegrating Regression cointegrating vector estimation. |

5.3.1 arch.unitroot.cointegration.DynamicOLS

class arch.unitroot.cointegration.**DynamicOLS**(y, x, trend='c', lags=None, leads=None, common=False, max_lag=None, max_lead=None, method='bic')

Dynamic OLS (DOLS) cointegrating vector estimation

Parameters

y

[numpy:array_like] The left-hand-side variable in the cointegrating regression.

x

[numpy:array_like] The right-hand-side variables in the cointegrating regression.

trend

[{"n","c","ct","ctt"}, default "c"] Trend to include in the cointegrating regression. Trends are:

- “n”: No deterministic terms
- “c”: Constant
- “ct”: Constant and linear trend
- “ctt”: Constant, linear and quadratic trends

lags

[int, default None] The number of lags to include in the model. If None, the optimal number of lags is chosen using method.

leads

[int, default None] The number of leads to include in the model. If None, the optimal number of leads is chosen using method.

common

[bool, default False] Flag indicating that lags and leads should be restricted to the same value. When common is None, lags must equal leads and max_lag must equal max_lead.

max_lag

[int, default None] The maximum lag to consider. See Notes for value used when None.

max_lead

[int, default None] The maximum lead to consider. See Notes for value used when None.

method

[{"aic","bic","hqic"}, default "bic"] The method used to select lag length when lags or leads is None.

- “aic” - Akaike Information Criterion
- “hqic” - Hannan-Quinn Information Criterion
- “bic” - Schwartz/Bayesian Information Criterion

Notes

The cointegrating vector is estimated from the regression

$$Y_t = D_t\delta + X_t\beta + \Delta X_t\gamma + \sum_{i=1}^p \Delta X_{t-i}\kappa_i + \sum_{j=1}^q \Delta X_{t+j}\lambda_j + \epsilon_t$$

where p is the lag length and q is the lead length. D_t is a vector containing the deterministic terms, if any. All specifications include the contemporaneous difference ΔX_t .

When lag lengths are not provided, the optimal lag length is chosen to minimize an Information Criterion of the form

$$\ln(\hat{\sigma}^2) + k\frac{c}{T}$$

where c is 2 for Akaike, $2 \ln \ln T$ for Hannan-Quinn and $\ln T$ for Schwartz/Bayesian.

See [1] and [2] for further details.

Methods

| | |
|--|-------------------------------------|
| <code>fit(cov_type, kernel, bandwidth, ...)</code> | Estimate the Dynamic OLS regression |
|--|-------------------------------------|

`arch.unitroot.cointegration.DynamicOLS.fit`

`DynamicOLS.fit(cov_type='unadjusted', kernel='bartlett', bandwidth=None, force_int=False, df_adjust=False)`

Estimate the Dynamic OLS regression

Parameters

cov_type

[`str`, default “unadjusted”] Either “unadjusted” (or is equivalent “homoskedastic”) or “robust” (or its equivalent “kernel”).

kernel

[`str`, default “bartlett”] The string name of any of any known kernel-based long-run covariance estimators. Common choices are “bartlett” for the Bartlett kernel (Newey-West), “parzen” for the Parzen kernel and “quadratic-spectral” for the Quadratic Spectral kernel.

bandwidth

[`int`, default `None`] The bandwidth to use. If not provided, the optimal bandwidth is estimated from the data. Setting the bandwidth to 0 and using “unadjusted” produces the classic OLS covariance estimator. Setting the bandwidth to 0 and using “robust” produces White’s covariance estimator.

force_int

[`bool`, default `False`] Whether the force the estimated optimal bandwidth to be an integer.

df_adjust

[`bool`, default `False`] Whether the adjust the parameter covariance to account for the number of parameters estimated in the regression. If true, the parameter covariance estimator is multiplied by $T/(T-k)$ where k is the number of regressors in the model.

Returns

DynamicOLSResults

The estimation results.

See also:

arch.unitroot.cointegration.engle_granger

Cointegration testing using the Engle-Granger methodology

statsmodels.regression.linear_model.OLS

Ordinal Least Squares regression.

Notes

When using the unadjusted covariance, the parameter covariance is estimated as

$$T^{-1} \hat{\sigma}_{HAC}^2 \hat{\Sigma}_{ZZ}^{-1}$$

where $\hat{\sigma}_{HAC}^2$ is an estimator of the long-run variance of the regression error and $\hat{\Sigma}_{ZZ} = T^{-1} Z'Z$. Z_t is a vector the includes all terms in the regression (i.e., deterministics, cross-sectional, leads and lags) When using the robust covariance, the parameter covariance is estimated as

$$T^{-1} \hat{\Sigma}_{ZZ}^{-1} \hat{S}_{HAC} \hat{\Sigma}_{ZZ}^{-1}$$

where \hat{S}_{HAC} is a Heteroskedasticity-Autocorrelation Consistent estimator of the covariance of the regression scores $Z_t \epsilon_t$.

Return type

DynamicOLSResults

5.3.2 arch.unitroot.cointegration.FullyModifiedOLS

class arch.unitroot.cointegration.FullyModifiedOLS(*y*, *x*, *trend*='c', *x_trend*=None)

Fully Modified OLS cointegrating vector estimation.

Parameters

- y**
[numpy:array_like] The left-hand-side variable in the cointegrating regression.
- x**
[numpy:array_like] The right-hand-side variables in the cointegrating regression.
- trend**
[{"n", "c", "ct", "ctt"}], default "c"] Trend to include in the cointegrating regression. Trends are:
 - "n": No deterministic terms
 - "c": Constant
 - "ct": Constant and linear trend
 - "ctt": Constant, linear and quadratic trends
- x_trend**
[None, "c", "ct", "ctt"], default None] Trends that affects affect the x-data but do not appear in the cointegrating regression. *x_trend* must be at least as large as *trend*, so that if *trend* is "ct", *x_trend* must be either "ct" or "ctt".

Notes

The cointegrating vector is estimated from the regressions

$$\begin{aligned} Y_t &= D_{1t} \delta + X_t \beta + \eta_{1t} \\ X_t &= D_{1t} \Gamma_1 + D_{2t} \Gamma_2 + \epsilon_{2t} \\ \eta_{2t} &= \Delta \epsilon_{2t} \end{aligned}$$

or if estimated in differences, the last two lines are

$$\Delta X_t = \Delta D_{1t}\Gamma_1 + \Delta D_{2t}\Gamma_2 + \eta_{2t}$$

Define the vector of residuals as $\eta = (\eta_{1t}, \eta_{2t})'$, and the long-run covariance

$$\Omega = \sum_{h=-\infty}^{\infty} E[\eta_t \eta'_{t-h}]$$

and the one-sided long-run covariance matrix

$$\Lambda_0 = \sum_{h=0}^{\infty} E[\eta_t \eta'_{t-h}]$$

The covariance matrices are partitioned into a block form

$$\Omega = \begin{bmatrix} \omega_{11} & \omega_{12} \\ \omega'_{12} & \Omega_{22} \end{bmatrix}$$

The cointegrating vector is then estimated using modified data

$$Y_t^* = Y_t - \hat{\omega}_{12} \hat{\Omega}_{22} \hat{\eta}_{2t}$$

as

$$\hat{\theta} = \begin{bmatrix} \hat{\gamma}_1 \\ \hat{\beta} \end{bmatrix} = \left(\sum_{t=2}^T Z_t Z_t' \right)^{-1} \left(\sum_{t=2}^t Z_t Y_t^* - T \begin{bmatrix} 0 \\ \lambda_{12}^* \end{bmatrix} \right)$$

where the bias term is defined

$$\lambda_{12}^* = \hat{\lambda}_{12} - \hat{\omega}_{12} \hat{\Omega}_{22} \hat{\omega}_{21}$$

See [1] for further details.

|---|------------------------------------|

`arch.unitroot.cointegration.FullyModifiedOLS.fit`

FullyModifiedOLS.`fit(kernel='bartlett', bandwidth=None, force_int=True, diff=False, df_adjust=False)`

Estimate the cointegrating vector.

Parameters

`diff`

[bool, default False] Use differenced data to estimate the residuals.

kernel

[*str*, default “bartlett”] The string name of any of any known kernel-based long-run covariance estimators. Common choices are “bartlett” for the Bartlett kernel (Newey-West), “parzen” for the Parzen kernel and “quadratic-spectral” for the Quadratic Spectral kernel.

bandwidth

[*int*, default *None*] The bandwidth to use. If not provided, the optimal bandwidth is estimated from the data. Setting the bandwidth to 0 and using “unadjusted” produces the classic OLS covariance estimator. Setting the bandwidth to 0 and using “robust” produces White’s covariance estimator.

force_int

[*bool*, default *False*] Whether the force the estimated optimal bandwidth to be an integer.

df_adjust

[*bool*, default *False*] Whether the adjust the parameter covariance to account for the number of parameters estimated in the regression. If true, the parameter covariance estimator is multiplied by $T/(T-k)$ where k is the number of regressors in the model.

Returns

CointegrationAnalysisResults

The estimation results instance.

Return type

CointegrationAnalysisResults

5.3.3 arch.unitroot.cointegration.CanonicalCointegratingReg

class arch.unitroot.cointegration.**CanonicalCointegratingReg**(*y*, *x*, *trend*='c', *x_trend*=*None*)

Canonical Cointegrating Regression cointegrating vector estimation.

Parameters**y**

[*numpy:array_like*] The left-hand-side variable in the cointegrating regression.

x

[*numpy:array_like*] The right-hand-side variables in the cointegrating regression.

trend

[{"n", "c", "ct", "ctt"}], default “c”] Trend to include in the cointegrating regression. Trends are:

- “n”: No deterministic terms
- “c”: Constant
- “ct”: Constant and linear trend
- “ctt”: Constant, linear and quadratic trends

x_trend

[{None, “c”, “ct”, “ctt”}], default *None*] Trends that affects affect the x-data but do not appear in the cointegrating regression. *x_trend* must be at least as large as *trend*, so that if *trend* is “ct”, *x_trend* must be either “ct” or “ctt”.

Notes

The cointegrating vector is estimated from the regressions

$$\begin{aligned} Y_t &= D_{1t}\delta + X_t\beta + \eta_{1t} \\ X_t &= D_{1t}\Gamma_1 + D_{2t}\Gamma_2 + \epsilon_{2t} \\ \eta_{2t} &= \Delta\epsilon_{2t} \end{aligned}$$

or if estimated in differences, the last two lines are

$$\Delta X_t = \Delta D_{1t}\Gamma_1 + \Delta D_{2t}\Gamma_2 + \eta_{2t}$$

Define the vector of residuals as $\eta = (\eta_{1t}, \eta_{2t})'$, and the long-run covariance

$$\Omega = \sum_{h=-\infty}^{\infty} E[\eta_t \eta_{t-h}']$$

and the one-sided long-run covariance matrix

$$\Lambda_0 = \sum_{h=0}^{\infty} E[\eta_t \eta_{t-h}']$$

The covariance matrices are partitioned into a block form

$$\Omega = \begin{bmatrix} \omega_{11} & \omega_{12} \\ \omega_{12}' & \Omega_{22} \end{bmatrix}$$

The cointegrating vector is then estimated using modified data

$$\begin{aligned} X_t^* &= X_t - \hat{\Lambda}_2' \hat{\Sigma}^{-1} \hat{\eta}_t \\ Y_t^* &= Y_t - (\hat{\Sigma}^{-1} \hat{\Lambda}_2 \hat{\beta} + \hat{\kappa})' \hat{\eta}_t \end{aligned}$$

where $\hat{\kappa} = (0, \hat{\Omega}_{22}^{-1} \hat{\Omega}_{12}')'$ and the regression

$$Y_t^* = D_{1t}\delta + X_t^*\beta + \eta_{1t}^*$$

See [1] for further details.

Methods

summary()

Summary of the model, containing estimated parameters and std.

arch.unitroot.cointegration.CointegrationAnalysisResults.summary

CointegrationAnalysisResults.**summary**()

Summary of the model, containing estimated parameters and std. errors

Returns

Summary

A summary instance with method that support export to text, csv or latex.

Return type

Summary

Properties

| | |
|--------------------------|---|
| <i>bandwidth</i> | The bandwidth used in the parameter covariance estimation |
| <i>cov</i> | The estimated parameter covariance of the cointegrating vector |
| <i>kernel</i> | The kernel used to estimate the covariance |
| <i>long_run_variance</i> | Long-run variance estimate used in the parameter covariance estimator |
| <i>params</i> | The estimated parameters of the cointegrating vector |
| <i>pvalues</i> | P-value of the parameters in the cointegrating vector |
| <i>resid</i> | The model residuals |
| <i>residual_variance</i> | The variance of the regression residual. |
| <i>rsquared</i> | The model R ² |
| <i>rsquared_adj</i> | The degree-of-freedom adjusted R ² |
| <i>std_errors</i> | Standard errors of the parameters in the cointegrating vector |
| <i>tvalues</i> | T-statistics of the parameters in the cointegrating vector |

arch.unitroot.cointegration.CointegrationAnalysisResults.bandwidth

property CointegrationAnalysisResults.**bandwidth**: **float**

The bandwidth used in the parameter covariance estimation

Return type

float

arch.unitroot.cointegration.CointegrationAnalysisResults.cov

property CointegrationAnalysisResults.**cov**: **DataFrame**

The estimated parameter covariance of the cointegrating vector

Return type

DataFrame

arch.unitroot.cointegration.CointegrationAnalysisResults.kernel

property CointegrationAnalysisResults.kernel: `str`

The kernel used to estimate the covariance

Return type

`str`

arch.unitroot.cointegration.CointegrationAnalysisResults.long_run_variance

property CointegrationAnalysisResults.long_run_variance: `float`

Long-run variance estimate used in the parameter covariance estimator

Return type

`float`

arch.unitroot.cointegration.CointegrationAnalysisResults.params

property CointegrationAnalysisResults.params: `Series`

The estimated parameters of the cointegrating vector

Return type

`Series`

arch.unitroot.cointegration.CointegrationAnalysisResults.pvalues

property CointegrationAnalysisResults.pvalues: `Series`

P-value of the parameters in the cointegrating vector

arch.unitroot.cointegration.CointegrationAnalysisResults.resid

property CointegrationAnalysisResults.resid: `Series`

The model residuals

Return type

`Series`

arch.unitroot.cointegration.CointegrationAnalysisResults.residual_variance

property CointegrationAnalysisResults.residual_variance: `float`

The variance of the regression residual.

Returns

`float`

The estimated residual variance.

Notes

The residual variance only accounts for the short-run variance of the residual and does not account for any autocorrelation. It is defined as

$$\hat{\sigma}^2 = T^{-1} \sum_{t=p}^{T-q} \hat{\epsilon}_t^2$$

If `df_adjust` is True, then the estimator is rescaled by $T/(T-m)$ where m is the number of regressors in the model.

Return type
float

`arch.unitroot.cointegration.CointegrationAnalysisResults.rsquared`

property `CointegrationAnalysisResults.rsquared`: float

The model R^2

Return type
float

`arch.unitroot.cointegration.CointegrationAnalysisResults.rsquared_adj`

property `CointegrationAnalysisResults.rsquared_adj`: float

The degree-of-freedom adjusted R^2

Return type
float

`arch.unitroot.cointegration.CointegrationAnalysisResults.std_errors`

property `CointegrationAnalysisResults.std_errors`: Series

Standard errors of the parameters in the cointegrating vector

`arch.unitroot.cointegration.CointegrationAnalysisResults.tvalues`

property `CointegrationAnalysisResults.tvalues`: Series

T-statistics of the parameters in the cointegrating vector

`arch.unitroot.cointegration.DynamicOLSResults`

class `arch.unitroot.cointegration.DynamicOLSResults`(*params, cov, resid, lags, leads, cov_type, kernel_est, num_x, trend, reg_results, df_adjust*)

Estimation results for Dynamic OLS models

Parameters

params
[Series] The estimated model parameters.

cov
[DataFrame] The estimated parameter covariance.

resid
[Series] The model residuals.

lags
[int] The number of lags included in the model.

leads
[int] The number of leads included in the model.

cov_type
[str] The type of the parameter covariance estimator used.

kernel_est
[CovarianceEstimator] The covariance estimator instance used to estimate the parameter covariance.

reg_results
[RegressionResults] Regression results from fitting statsmodels OLS.

df_adjust
[bool] Whether to degree of freedom adjust the estimator.

Attributes

bandwidth
The bandwidth used in the parameter covariance estimation

cov
The estimated parameter covariance of the cointegrating vector

cov_type
The type of parameter covariance estimator used

full_cov
Parameter covariance of the all model parameters, incl.

full_params
The complete set of parameters, including leads and lags

kernel
The kernel used to estimate the covariance

lags
The number of lags included in the model

leads
The number of leads included in the model

long_run_variance
The long-run variance of the regression residual.

params
The estimated parameters of the cointegrating vector

pvalues
P-value of the parameters in the cointegrating vector

resid
The model residuals

residual_variance

The variance of the regression residual.

rsquared

The model R^2

rsquared_adj

The degree-of-freedom adjusted R^2

std_errors

Standard errors of the parameters in the cointegrating vector

tvalues

T-statistics of the parameters in the cointegrating vector

Methods

| | |
|-------------------------|--|
| <i>summary</i> ([full]) | Summary of the model, containing estimated parameters and std. |
|-------------------------|--|

arch.unitroot.cointegration.DynamicOLSResults.summary

DynamicOLSResults.**summary**(full=False)

Summary of the model, containing estimated parameters and std. errors

Parameters

full

[bool, default False] Flag indicating whether to include all estimated parameters (True) or only the parameters of the cointegrating vector

Returns

Summary

A summary instance with method that support export to text, csv or latex.

Return type

Summary

Properties

| | |
|--------------------------|--|
| <i>bandwidth</i> | The bandwidth used in the parameter covariance estimation |
| <i>cov</i> | The estimated parameter covariance of the cointegrating vector |
| <i>cov_type</i> | The type of parameter covariance estimator used |
| <i>full_cov</i> | Parameter covariance of the all model parameters, incl. |
| <i>full_params</i> | The complete set of parameters, including leads and lags |
| <i>kernel</i> | The kernel used to estimate the covariance |
| <i>lags</i> | The number of lags included in the model |
| <i>leads</i> | The number of leads included in the model |
| <i>long_run_variance</i> | The long-run variance of the regression residual. |
| <i>params</i> | The estimated parameters of the cointegrating vector |
| <i>pvalues</i> | P-value of the parameters in the cointegrating vector |

arch.unitroot.cointegration.DynamicOLSResults.bandwidth

property `DynamicOLSResults.bandwidth`: `float`

The bandwidth used in the parameter covariance estimation

Return type
`float`

arch.unitroot.cointegration.DynamicOLSResults.cov

property `DynamicOLSResults.cov`: `DataFrame`

The estimated parameter covariance of the cointegrating vector

Return type
`DataFrame`

`arch.unitroot.cointegration.DynamicOLSResults.cov_type`

property `DynamicOLSResults.cov_type`: `str`

The type of parameter covariance estimator used

Return type

`str`

`arch.unitroot.cointegration.DynamicOLSResults.full_cov`

property `DynamicOLSResults.full_cov`: `DataFrame`

Parameter covariance of the all model parameters, incl. leads and lags

Return type

`DataFrame`

`arch.unitroot.cointegration.DynamicOLSResults.full_params`

property `DynamicOLSResults.full_params`: `Series`

The complete set of parameters, including leads and lags

Return type

`Series`

`arch.unitroot.cointegration.DynamicOLSResults.kernel`

property `DynamicOLSResults.kernel`: `str`

The kernel used to estimate the covariance

Return type

`str`

`arch.unitroot.cointegration.DynamicOLSResults.lags`

property `DynamicOLSResults.lags`: `int`

The number of lags included in the model

Return type

`int`

`arch.unitroot.cointegration.DynamicOLSResults.leads`

property `DynamicOLSResults.leads`: `int`

The number of leads included in the model

Return type

`int`

arch.unitroot.cointegration.DynamicOLSResults.long_run_variance**property** `DynamicOLSResults.long_run_variance`: `float`

The long-run variance of the regression residual.

Returns`float`

The estimated long-run variance of the residual.

Notes

The long-run variance is estimated from the model residuals using the same kernel used to estimate the parameter covariance.

If `df_adjust` is True, then the estimator is rescaled by $T/(T-m)$ where m is the number of regressors in the model.

Return type`float`**arch.unitroot.cointegration.DynamicOLSResults.params****property** `DynamicOLSResults.params`: `Series`

The estimated parameters of the cointegrating vector

Return type`Series`**arch.unitroot.cointegration.DynamicOLSResults.pvalues****property** `DynamicOLSResults.pvalues`: `Series`

P-value of the parameters in the cointegrating vector

arch.unitroot.cointegration.DynamicOLSResults.resid**property** `DynamicOLSResults.resid`: `Series`

The model residuals

Return type`Series`**arch.unitroot.cointegration.DynamicOLSResults.residual_variance****property** `DynamicOLSResults.residual_variance`: `float`

The variance of the regression residual.

Returns`float`

The estimated residual variance.

Notes

The residual variance only accounts for the short-run variance of the residual and does not account for any autocorrelation. It is defined as

$$\hat{\sigma}^2 = T^{-1} \sum_{t=p}^{T-q} \hat{\epsilon}_t^2$$

If `df_adjust` is True, then the estimator is rescaled by $T/(T-m)$ where m is the number of regressors in the model.

Return type
float

`arch.unitroot.cointegration.DynamicOLSResults.rsquared`

property `DynamicOLSResults.rsquared`: float

The model R^2

Return type
float

`arch.unitroot.cointegration.DynamicOLSResults.rsquared_adj`

property `DynamicOLSResults.rsquared_adj`: float

The degree-of-freedom adjusted R^2

Return type
float

`arch.unitroot.cointegration.DynamicOLSResults.std_errors`

property `DynamicOLSResults.std_errors`: Series

Standard errors of the parameters in the cointegrating vector

`arch.unitroot.cointegration.DynamicOLSResults.tvalues`

property `DynamicOLSResults.tvalues`: Series

T-statistics of the parameters in the cointegrating vector

`arch.unitroot.cointegration.EngleGrangerTestResults`

class `arch.unitroot.cointegration.EngleGrangerTestResults`(*stat, pvalue, crit_vals, null='No Cointegration', alternative='Cointegration', trend='c', order=2, adf=None, xsection=None*)

Results class for Engle-Granger cointegration tests.

Parameters

- stat**
[float] The Engle-Granger test statistic.
- pvalue**
[float] The pvalue of the Engle-Granger test statistic.
- crit_vals**
[Series] The critical values of the Engle-Granger specific to the sample size and model dimension.
- null**
[str] The null hypothesis.
- alternative**
[str] The alternative hypothesis.
- trend**
[str] The model's trend description.
- order**
[int] The number of stochastic trends in the null distribution.
- adf**
[ADF] The ADF instance used to perform the test and lag selection.
- xsection**
[RegressionResults] The OLS results used in the cross-sectional regression.

Attributes

- alternative_hypothesis***
The alternative hypothesis
- cointegrating_vector***
The estimated cointegrating vector.
- critical_values***
Critical Values
- distribution_order***
The number of stochastic trends under the null hypothesis.
- lags***
The number of lags used in the Augmented Dickey-Fuller regression.
- max_lags***
The maximum number of lags used in the lag-length selection.
- name***
Sets or gets the name of the cointegration test
- null_hypothesis***
The null hypothesis
- pvalue***
The p-value of the test statistic.
- resid***
The residual from the cointegrating regression.
- rho***
The estimated coefficient in the Dickey-Fuller Test

stat

The test statistic.

trend

The trend used in the cointegrating regression

Methods

| | |
|----------------------------------|--|
| <code>plot([axes, title])</code> | Plot the cointegration residuals. |
| <code>summary()</code> | Summary of test, containing statistic, p-value and critical values |

arch.unitroot.cointegration.EngleGrangerTestResults.plot

`EngleGrangerTestResults.plot(axes=None, title=None)`

Plot the cointegration residuals.

Parameters

axes

[Axes, default None] matplotlib axes instance to hold the figure.

title

[str, default None] Title for the figure.

Returns

Figure

The matplotlib Figure instance.

Return type

Figure

arch.unitroot.cointegration.EngleGrangerTestResults.summary

`EngleGrangerTestResults.summary()`

Summary of test, containing statistic, p-value and critical values

Return type

Summary

Properties

| | |
|-------------------------------|--|
| <i>alternative_hypothesis</i> | The alternative hypothesis |
| <i>cointegrating_vector</i> | The estimated cointegrating vector. |
| <i>critical_values</i> | Critical Values |
| <i>distribution_order</i> | The number of stochastic trends under the null hypothesis. |
| <i>lags</i> | The number of lags used in the Augmented Dickey-Fuller regression. |
| <i>max_lags</i> | The maximum number of lags used in the lag-length selection. |
| <i>name</i> | Sets or gets the name of the cointegration test |
| <i>null_hypothesis</i> | The null hypothesis |
| <i>pvalue</i> | The p-value of the test statistic. |
| <i>resid</i> | The residual from the cointegrating regression. |
| <i>rho</i> | The estimated coefficient in the Dickey-Fuller Test |
| <i>stat</i> | The test statistic. |
| <i>trend</i> | The trend used in the cointegrating regression |

arch.unitroot.cointegration.EngleGrangerTestResults.alternative_hypothesis

property EngleGrangerTestResults.alternative_hypothesis: **str**

The alternative hypothesis

Return type

str

arch.unitroot.cointegration.EngleGrangerTestResults.cointegrating_vector

property EngleGrangerTestResults.cointegrating_vector: **Series**

The estimated cointegrating vector.

Return type

Series

arch.unitroot.cointegration.EngleGrangerTestResults.critical_values

property EngleGrangerTestResults.critical_values: **Series**

Critical Values

Returns

Series

Series with three keys, 1, 5 and 10 containing the critical values of the test statistic.

Return type

Series

arch.unitroot.cointegration.EngleGrangerTestResults.distribution_order**property** EngleGrangerTestResults.distribution_order: **int**

The number of stochastic trends under the null hypothesis.

Return type**int****arch.unitroot.cointegration.EngleGrangerTestResults.lags****property** EngleGrangerTestResults.lags: **int**

The number of lags used in the Augmented Dickey-Fuller regression.

Return type**int****arch.unitroot.cointegration.EngleGrangerTestResults.max_lags****property** EngleGrangerTestResults.max_lags: **int | None**

The maximum number of lags used in the lag-length selection.

Return type**Optional[int]****arch.unitroot.cointegration.EngleGrangerTestResults.name****property** EngleGrangerTestResults.name: **str**

Sets or gets the name of the cointegration test

Return type**str****arch.unitroot.cointegration.EngleGrangerTestResults.null_hypothesis****property** EngleGrangerTestResults.null_hypothesis: **str**

The null hypothesis

Return type**str****arch.unitroot.cointegration.EngleGrangerTestResults.pvalue****property** EngleGrangerTestResults.pvalue: **float**

The p-value of the test statistic.

Return type**float**

arch.unitroot.cointegration.EngleGrangerTestResults.resid**property** EngleGrangerTestResults.resid: `Series`

The residual from the cointegrating regression.

Return type`Series`**arch.unitroot.cointegration.EngleGrangerTestResults.rho****property** EngleGrangerTestResults.rho: `float`

The estimated coefficient in the Dickey-Fuller Test

Returns`float`

The coefficient.

NotesThe value returned is $\hat{\rho} = \hat{\gamma} + 1$ from the ADF regression

$$\Delta y_t = \gamma y_{t-1} + \sum_{i=1}^p \delta_i \Delta y_{t-i} + \epsilon_t$$

Return type`float`**arch.unitroot.cointegration.EngleGrangerTestResults.stat****property** EngleGrangerTestResults.stat: `float`

The test statistic.

Return type`float`**arch.unitroot.cointegration.EngleGrangerTestResults.trend****property** EngleGrangerTestResults.trend: `str`

The trend used in the cointegrating regression

Return type`str`

arch.unitroot.cointegration.PhillipsOuliarisTestResults

```
class arch.unitroot.cointegration.PhillipsOuliarisTestResults(stat, pvalue, crit_vals, null='No Cointegration', alternative='Cointegration', trend='c', order=2, xsection=None, test_type='Za', kernel_est=None, rho=0.0)
```

Attributes***alternative_hypothesis***

The alternative hypothesis

bandwidth

Bandwidth used by the long-run covariance estimator

cointegrating_vector

The estimated cointegrating vector.

critical_values

Critical Values

distribution_order

The number of stochastic trends under the null hypothesis.

kernel

Name of the long-run covariance estimator

name

Sets or gets the name of the cointegration test

null_hypothesis

The null hypothesis

pvalue

The p-value of the test statistic.

resid

The residual from the cointegrating regression.

stat

The test statistic.

trend

The trend used in the cointegrating regression

Methods

| | |
|-----------------------------|--|
| <i>plot</i> ([axes, title]) | Plot the cointegration residuals. |
| <i>summary</i> () | Summary of test, containing statistic, p-value and critical values |

arch.unitroot.cointegration.PhillipsOuliarisTestResults.plot

PhillipsOuliarisTestResults.**plot**(*axes=None, title=None*)

Plot the cointegration residuals.

Parameters**axes**

[Axes, default None] matplotlib axes instance to hold the figure.

title

[str, default None] Title for the figure.

Returns**Figure**

The matplotlib Figure instance.

Return type

Figure

arch.unitroot.cointegration.PhillipsOuliarisTestResults.summary

PhillipsOuliarisTestResults.**summary**()

Summary of test, containing statistic, p-value and critical values

Return type

Summary

Properties

| | |
|-------------------------------|--|
| <i>alternative_hypothesis</i> | The alternative hypothesis |
| <i>bandwidth</i> | Bandwidth used by the long-run covariance estimator |
| <i>cointegrating_vector</i> | The estimated cointegrating vector. |
| <i>critical_values</i> | Critical Values |
| <i>distribution_order</i> | The number of stochastic trends under the null hypothesis. |

`arch.unitroot.cointegration.PhillipsOuliarisTestResults.alternative_hypothesis`

property `PhillipsOuliarisTestResults.alternative_hypothesis`: `str`

The alternative hypothesis

Return type

`str`

`arch.unitroot.cointegration.PhillipsOuliarisTestResults.bandwidth`

property `PhillipsOuliarisTestResults.bandwidth`: `float`

Bandwidth used by the long-run covariance estimator

Return type

`float`

`arch.unitroot.cointegration.PhillipsOuliarisTestResults.cointegrating_vector`

property `PhillipsOuliarisTestResults.cointegrating_vector`: `Series`

The estimated cointegrating vector.

Return type

`Series`

`arch.unitroot.cointegration.PhillipsOuliarisTestResults.critical_values`

property `PhillipsOuliarisTestResults.critical_values`: `Series`

Critical Values

Returns

`Series`

Series with three keys, 1, 5 and 10 containing the critical values of the test statistic.

Return type

`Series`

`arch.unitroot.cointegration.PhillipsOuliarisTestResults.distribution_order`

property `PhillipsOuliarisTestResults.distribution_order`: `int`

The number of stochastic trends under the null hypothesis.

Return type

`int`

arch.unitroot.cointegration.PhillipsOuliarisTestResults.kernel**property** `PhillipsOuliarisTestResults.kernel: str`

Name of the long-run covariance estimator

Return type`str`**arch.unitroot.cointegration.PhillipsOuliarisTestResults.name****property** `PhillipsOuliarisTestResults.name: str`

Sets or gets the name of the cointegration test

Return type`str`**arch.unitroot.cointegration.PhillipsOuliarisTestResults.null_hypothesis****property** `PhillipsOuliarisTestResults.null_hypothesis: str`

The null hypothesis

Return type`str`**arch.unitroot.cointegration.PhillipsOuliarisTestResults.pvalue****property** `PhillipsOuliarisTestResults.pvalue: float`

The p-value of the test statistic.

Return type`float`**arch.unitroot.cointegration.PhillipsOuliarisTestResults.resid****property** `PhillipsOuliarisTestResults.resid: Series`

The residual from the cointegrating regression.

Return type`Series`**arch.unitroot.cointegration.PhillipsOuliarisTestResults.stat****property** `PhillipsOuliarisTestResults.stat: float`

The test statistic.

Return type`float`

arch.unitroot.cointegration.PhillipsOuliarisTestResults.trend

property PhillipsOuliarisTestResults.trend: `str`

The trend used in the cointegrating regression

Return type

`str`

LONG-RUN COVARIANCE ESTIMATION

6.1 Long-run Covariance Estimators

| | |
|---|---|
| <i>Andrews</i> (x[, bandwidth, df_adjust, center, ...]) | Alternative name of the QuadraticSpectral covariance estimator. |
| <i>Bartlett</i> (x[, bandwidth, df_adjust, center, ...]) | Bartlett's (Newey-West) kernel covariance estimation. |
| <i>Gallant</i> (x[, bandwidth, df_adjust, center, ...]) | Alternative name for Parzen covariance estimator. |
| <i>NeweyWest</i> (x[, bandwidth, df_adjust, center, ...]) | Alternative name for Bartlett covariance estimator. |
| <i>Parzen</i> (x[, bandwidth, df_adjust, center, ...]) | Parzen's kernel covariance estimation. |
| <i>ParzenCauchy</i> (x[, bandwidth, df_adjust, ...]) | Parzen's Cauchy kernel covariance estimation. |
| <i>ParzenGeometric</i> (x[, bandwidth, df_adjust, ...]) | Parzen's Geometric kernel covariance estimation. |
| <i>ParzenRiesz</i> (x[, bandwidth, df_adjust, ...]) | Parzen-Reisz kernel covariance estimation. |
| <i>QuadraticSpectral</i> (x[, bandwidth, df_adjust, ...]) | Quadratic-Spectral (Andrews') kernel covariance estimation. |
| <i>TukeyHamming</i> (x[, bandwidth, df_adjust, ...]) | Tukey-Hamming kernel covariance estimation. |
| <i>TukeyHanning</i> (x[, bandwidth, df_adjust, ...]) | Tukey-Hanning kernel covariance estimation. |
| <i>TukeyParzen</i> (x[, bandwidth, df_adjust, ...]) | Tukey-Parzen kernel covariance estimation. |

6.1.1 arch.covariance.kernel.Andrews

class arch.covariance.kernel.**Andrews**(x, bandwidth=None, df_adjust=0, center=True, weights=None, force_int=False)

Alternative name of the QuadraticSpectral covariance estimator.

See also:

QuadraticSpectral

Attributes

bandwidth

The bandwidth used by the covariance estimator.

bandwidth_scale

The power used in optimal bandwidth calculation.

centered

Flag indicating whether the data are centered (demeaned).

cov

The estimated covariances.

force_int

Flag indicating whether the bandwidth is restricted to be an integer.

kernel_const

The constant used in optimal bandwidth calculation.

kernel_weights

Weights used in covariance calculation.

name

The covariance estimator's name.

opt_bandwidth

Estimate optimal bandwidth.

rate

The optimal rate used in bandwidth selection.

Methods

Properties

| | |
|------------------------|---|
| <i>bandwidth</i> | The bandwidth used by the covariance estimator. |
| <i>bandwidth_scale</i> | The power used in optimal bandwidth calculation. |
| <i>centered</i> | Flag indicating whether the data are centered (de-meanned). |
| <i>cov</i> | The estimated covariances. |
| <i>force_int</i> | Flag indicating whether the bandwidth is restricted to be an integer. |
| <i>kernel_const</i> | The constant used in optimal bandwidth calculation. |
| <i>kernel_weights</i> | Weights used in covariance calculation. |
| <i>name</i> | The covariance estimator's name. |
| <i>opt_bandwidth</i> | Estimate optimal bandwidth. |
| <i>rate</i> | The optimal rate used in bandwidth selection. |

arch.covariance.kernel.Andrews.bandwidth

property Andrews.**bandwidth**: float

The bandwidth used by the covariance estimator.

Returns

float

The user-provided or estimated optimal bandwidth.

Return type

float

arch.covariance.kernel.Andrews.bandwidth_scale**property** Andrews.bandwidth_scale

The power used in optimal bandwidth calculation.

Returns**float**

The power value used in the optimal bandwidth calculation.

arch.covariance.kernel.Andrews.centered**property** Andrews.centered: **bool**

Flag indicating whether the data are centered (demeaned).

Returns**bool**

A flag indicating whether the estimator is centered.

Return type**bool****arch.covariance.kernel.Andrews.cov****property** Andrews.cov: *CovarianceEstimate*

The estimated covariances.

Returns*CovarianceEstimate*

Covariance estimate instance containing 4 estimates:

- long_run
- short_run
- one_sided
- one_sided_strict

See also:*CovarianceEstimate***arch.covariance.kernel.Andrews.force_int****property** Andrews.force_int: **bool**

Flag indicating whether the bandwidth is restricted to be an integer.

Return type**bool**

arch.covariance.kernel.Andrews.kernel_const**property** Andrews.**kernel_const**

The constant used in optimal bandwidth calculation.

Returns**float**

The constant value used in the optimal bandwidth calculation.

arch.covariance.kernel.Andrews.kernel_weights**property** Andrews.**kernel_weights**: **ndarray**

Weights used in covariance calculation.

Returns**ndarray**

The weight vector including 1 in position 0.

arch.covariance.kernel.Andrews.name**property** Andrews.**name**: **str**

The covariance estimator's name.

Returns**str**

The covariance estimator's name.

Return type**str****arch.covariance.kernel.Andrews.opt_bandwidth****property** Andrews.**opt_bandwidth**: **float**

Estimate optimal bandwidth.

Returns**float**

The estimated optimal bandwidth.

Notes

Computed as

$$\hat{b}_T = c_k [\hat{\alpha}(q) T]^{\frac{1}{2q+1}}$$

where c_k is a kernel-dependent constant, T is the sample size, q determines the optimal bandwidth rate for the kernel.

arch.covariance.kernel.Andrews.rate

property Andrews.rate

The optimal rate used in bandwidth selection.

Controls the number of lags used in the variance estimate that determines the estimate of the optimal bandwidth.

Returns

float

The rate used in bandwidth selection.

6.1.2 arch.covariance.kernel.Bartlett

class arch.covariance.kernel.**Bartlett**(*x*, *bandwidth=None*, *df_adjust=0*, *center=True*, *weights=None*, *force_int=False*)

Bartlett's (Newey-West) kernel covariance estimation.

Parameters

x

[numpy:array_like] The data to use in covariance estimation.

bandwidth

[float, default None] The kernel's bandwidth. If None, optimal bandwidth is estimated.

df_adjust

[int, default 0] Degrees of freedom to remove when adjusting the covariance. Uses the number of observations in x minus df_adjust when dividing inner-products.

center

[bool, default True] A flag indicating whether x should be demeaned before estimating the covariance.

weights

[numpy:array_like, default None] An array of weights used to combine when estimating optimal bandwidth. If not provided, a vector of 1s is used. Must have nvar elements.

force_int

[bool, default False] Force bandwidth to be an integer.

Notes

The kernel weights are computed using

$$w = \begin{cases} 1 - |z| & z \leq 1 \\ 0 & z > 1 \end{cases}$$

where $z = \frac{h}{H}$, $h = 0, 1, \dots, H$ where H is the bandwidth.

Attributes

bandwidth

The bandwidth used by the covariance estimator.

bandwidth_scale

The power used in optimal bandwidth calculation.

centered

Flag indicating whether the data are centered (demeaned).

cov

The estimated covariances.

force_int

Flag indicating whether the bandwidth is restricted to be an integer.

kernel_const

The constant used in optimal bandwidth calculation.

kernel_weights

Weights used in covariance calculation.

name

The covariance estimator's name.

opt_bandwidth

Estimate optimal bandwidth.

rate

The optimal rate used in bandwidth selection.

Methods

Properties

| | |
|------------------------|---|
| <i>bandwidth</i> | The bandwidth used by the covariance estimator. |
| <i>bandwidth_scale</i> | The power used in optimal bandwidth calculation. |
| <i>centered</i> | Flag indicating whether the data are centered (demeaned). |
| <i>cov</i> | The estimated covariances. |
| <i>force_int</i> | Flag indicating whether the bandwidth is restricted to be an integer. |
| <i>kernel_const</i> | The constant used in optimal bandwidth calculation. |
| <i>kernel_weights</i> | Weights used in covariance calculation. |
| <i>name</i> | The covariance estimator's name. |
| <i>opt_bandwidth</i> | Estimate optimal bandwidth. |
| <i>rate</i> | The optimal rate used in bandwidth selection. |

arch.covariance.kernel.Bartlett.bandwidth

property `Bartlett.bandwidth`: **float**

The bandwidth used by the covariance estimator.

Returns

float

The user-provided or estimated optimal bandwidth.

Return type

float

arch.covariance.kernel.Bartlett.bandwidth_scale**property** `Bartlett.bandwidth_scale`

The power used in optimal bandwidth calculation.

Returns**float**

The power value used in the optimal bandwidth calculation.

arch.covariance.kernel.Bartlett.centered**property** `Bartlett.centered`: **bool**

Flag indicating whether the data are centered (demeaned).

Returns**bool**

A flag indicating whether the estimator is centered.

Return type**bool****arch.covariance.kernel.Bartlett.cov****property** `Bartlett.cov`: *CovarianceEstimate*

The estimated covariances.

Returns*CovarianceEstimate*

Covariance estimate instance containing 4 estimates:

- `long_run`
- `short_run`
- `one_sided`
- `one_sided_strict`

See also:*CovarianceEstimate***arch.covariance.kernel.Bartlett.force_int****property** `Bartlett.force_int`: **bool**

Flag indicating whether the bandwidth is restricted to be an integer.

Return type**bool**

arch.covariance.kernel.Bartlett.kernel_const**property** Bartlett.**kernel_const**

The constant used in optimal bandwidth calculation.

Returns**float**

The constant value used in the optimal bandwidth calculation.

arch.covariance.kernel.Bartlett.kernel_weights**property** Bartlett.**kernel_weights**: **ndarray**

Weights used in covariance calculation.

Returns**ndarray**

The weight vector including 1 in position 0.

arch.covariance.kernel.Bartlett.name**property** Bartlett.**name**: **str**

The covariance estimator's name.

Returns**str**

The covariance estimator's name.

Return type**str****arch.covariance.kernel.Bartlett.opt_bandwidth****property** Bartlett.**opt_bandwidth**: **float**

Estimate optimal bandwidth.

Returns**float**

The estimated optimal bandwidth.

Notes

Computed as

$$\hat{b}_T = c_k [\hat{\alpha}(q) T]^{\frac{1}{2q+1}}$$

where c_k is a kernel-dependent constant, T is the sample size, q determines the optimal bandwidth rate for the kernel.

arch.covariance.kernel.Bartlett.rate**property** `Bartlett.rate`

The optimal rate used in bandwidth selection.

Controls the number of lags used in the variance estimate that determines the estimate of the optimal bandwidth.

Returns

float

The rate used in bandwidth selection.

6.1.3 arch.covariance.kernel.Gallant

class `arch.covariance.kernel.Gallant`(*x*, *bandwidth=None*, *df_adjust=0*, *center=True*, *weights=None*, *force_int=False*)

Alternative name for Parzen covariance estimator.

See also:

[*Parzen*](#)

Attributes

bandwidth

The bandwidth used by the covariance estimator.

bandwidth_scale

The power used in optimal bandwidth calculation.

centered

Flag indicating whether the data are centered (demeaned).

cov

The estimated covariances.

force_int

Flag indicating whether the bandwidth is restricted to be an integer.

kernel_const

The constant used in optimal bandwidth calculation.

kernel_weights

Weights used in covariance calculation.

name

The covariance estimator's name.

opt_bandwidth

Estimate optimal bandwidth.

rate

The optimal rate used in bandwidth selection.

Methods

Properties

| | |
|------------------------|---|
| <i>bandwidth</i> | The bandwidth used by the covariance estimator. |
| <i>bandwidth_scale</i> | The power used in optimal bandwidth calculation. |
| <i>centered</i> | Flag indicating whether the data are centered (de-meanned). |
| <i>cov</i> | The estimated covariances. |
| <i>force_int</i> | Flag indicating whether the bandwidth is restricted to be an integer. |
| <i>kernel_const</i> | The constant used in optimal bandwidth calculation. |
| <i>kernel_weights</i> | Weights used in covariance calculation. |
| <i>name</i> | The covariance estimator's name. |
| <i>opt_bandwidth</i> | Estimate optimal bandwidth. |
| <i>rate</i> | The optimal rate used in bandwidth selection. |

arch.covariance.kernel.Gallant.bandwidth

property `Gallant.bandwidth`: `float`

The bandwidth used by the covariance estimator.

Returns

`float`

The user-provided or estimated optimal bandwidth.

Return type

`float`

arch.covariance.kernel.Gallant.bandwidth_scale

property `Gallant.bandwidth_scale`

The power used in optimal bandwidth calculation.

Returns

`float`

The power value used in the optimal bandwidth calculation.

arch.covariance.kernel.Gallant.centered

property `Gallant.centered`: `bool`

Flag indicating whether the data are centered (demeaned).

Returns

`bool`

A flag indicating whether the estimator is centered.

Return type

`bool`

arch.covariance.kernel.Gallant.cov

property `Gallant.cov`: `CovarianceEstimate`

The estimated covariances.

Returns

`CovarianceEstimate`

Covariance estimate instance containing 4 estimates:

- `long_run`
- `short_run`
- `one_sided`
- `one_sided_strict`

See also:

`CovarianceEstimate`

arch.covariance.kernel.Gallant.force_int

property `Gallant.force_int`: `bool`

Flag indicating whether the bandwidth is restricted to be an integer.

Return type

`bool`

arch.covariance.kernel.Gallant.kernel_const

property `Gallant.kernel_const`

The constant used in optimal bandwidth calculation.

Returns

`float`

The constant value used in the optimal bandwidth calculation.

arch.covariance.kernel.Gallant.kernel_weights**property** `Gallant.kernel_weights`: `ndarray`

Weights used in covariance calculation.

Returns`ndarray`

The weight vector including 1 in position 0.

arch.covariance.kernel.Gallant.name**property** `Gallant.name`: `str`

The covariance estimator's name.

Returns`str`

The covariance estimator's name.

Return type`str`**arch.covariance.kernel.Gallant.opt_bandwidth****property** `Gallant.opt_bandwidth`: `float`

Estimate optimal bandwidth.

Returns`float`

The estimated optimal bandwidth.

Notes

Computed as

$$\hat{b}_T = c_k [\hat{\alpha}(q) T]^{\frac{1}{2q+1}}$$

where c_k is a kernel-dependent constant, T is the sample size, q determines the optimal bandwidth rate for the kernel.

arch.covariance.kernel.Gallant.rate**property** `Gallant.rate`

The optimal rate used in bandwidth selection.

Controls the number of lags used in the variance estimate that determines the estimate of the optimal bandwidth.

Returns`float`

The rate used in bandwidth selection.

6.1.4 arch.covariance.kernel.NeweyWest

`class arch.covariance.kernel.NeweyWest(x, bandwidth=None, df_adjust=0, center=True, weights=None, force_int=False)`

Alternative name for Bartlett covariance estimator.

See also:

Bartlett

Attributes

bandwidth

The bandwidth used by the covariance estimator.

bandwidth_scale

The power used in optimal bandwidth calculation.

centered

Flag indicating whether the data are centered (demeaned).

cov

The estimated covariances.

force_int

Flag indicating whether the bandwidth is restricted to be an integer.

kernel_const

The constant used in optimal bandwidth calculation.

kernel_weights

Weights used in covariance calculation.

name

The covariance estimator's name.

opt_bandwidth

Estimate optimal bandwidth.

rate

The optimal rate used in bandwidth selection.

arch.covariance.kernel.NeweyWest.bandwidth

property NeweyWest.**bandwidth**: **float**

The bandwidth used by the covariance estimator.

Returns

float

The user-provided or estimated optimal bandwidth.

Return type

float

arch.covariance.kernel.NeweyWest.bandwidth_scale

property NeweyWest.**bandwidth_scale**

The power used in optimal bandwidth calculation.

Returns

float

The power value used in the optimal bandwidth calculation.

arch.covariance.kernel.NeweyWest.centered

property NeweyWest.**centered**: **bool**

Flag indicating whether the data are centered (demeaned).

Returns

bool

A flag indicating whether the estimator is centered.

Return type

bool

arch.covariance.kernel.NeweyWest.cov**property** `NeweyWest.cov`: *CovarianceEstimate*

The estimated covariances.

Returns*CovarianceEstimate*

Covariance estimate instance containing 4 estimates:

- `long_run`
- `short_run`
- `one_sided`
- `one_sided_strict`

See also:*CovarianceEstimate***arch.covariance.kernel.NeweyWest.force_int****property** `NeweyWest.force_int`: `bool`

Flag indicating whether the bandwidth is restricted to be an integer.

Return type`bool`**arch.covariance.kernel.NeweyWest.kernel_const****property** `NeweyWest.kernel_const`

The constant used in optimal bandwidth calculation.

Returns`float`

The constant value used in the optimal bandwidth calculation.

arch.covariance.kernel.NeweyWest.kernel_weights**property** `NeweyWest.kernel_weights`: `ndarray`

Weights used in covariance calculation.

Returns`ndarray`

The weight vector including 1 in position 0.

arch.covariance.kernel.NeweyWest.name

property `NeweyWest.name`: `str`

The covariance estimator's name.

Returns

`str`

The covariance estimator's name.

Return type

`str`

arch.covariance.kernel.NeweyWest.opt_bandwidth

property `NeweyWest.opt_bandwidth`: `float`

Estimate optimal bandwidth.

Returns

`float`

The estimated optimal bandwidth.

Notes

Computed as

$$\hat{b}_T = c_k [\hat{\alpha}(q) T]^{\frac{1}{2q+1}}$$

where c_k is a kernel-dependent constant, T is the sample size, q determines the optimal bandwidth rate for the kernel.

arch.covariance.kernel.NeweyWest.rate

property `NeweyWest.rate`

The optimal rate used in bandwidth selection.

Controls the number of lags used in the variance estimate that determines the estimate of the optimal bandwidth.

Returns

`float`

The rate used in bandwidth selection.

6.1.5 arch.covariance.kernel.Parzen

class `arch.covariance.kernel.Parzen`(*x*, *bandwidth=None*, *df_adjust=0*, *center=True*, *weights=None*, *force_int=False*)

Parzen's kernel covariance estimation.

Parameters

x

[numpy:array_like] The data to use in covariance estimation.

bandwidth

[float, default None] The kernel's bandwidth. If None, optimal bandwidth is estimated.

df_adjust

[int, default 0] Degrees of freedom to remove when adjusting the covariance. Uses the number of observations in x minus df_adjust when dividing inner-products.

center

[bool, default True] A flag indicating whether x should be demeaned before estimating the covariance.

weights

[numpy:array_like, default None] An array of weights used to combine when estimating optimal bandwidth. If not provided, a vector of 1s is used. Must have nvar elements.

force_int

[bool, default False] Force bandwidth to be an integer.

Notes

The kernel weights are computed using

$$w = \begin{cases} 1 - 6z^2(1 - z) & z \leq \frac{1}{2} \\ 2(1 - z)^3 & \frac{1}{2} < z \leq 1 \\ 0 & z > 1 \end{cases}$$

where $z = \frac{h}{H}$, $h = 0, 1, \dots, H$ where H is the bandwidth.

Attributes***bandwidth***

The bandwidth used by the covariance estimator.

bandwidth_scale

The power used in optimal bandwidth calculation.

centered

Flag indicating whether the data are centered (demeaned).

cov

The estimated covariances.

force_int

Flag indicating whether the bandwidth is restricted to be an integer.

kernel_const

The constant used in optimal bandwidth calculation.

kernel_weights

Weights used in covariance calculation.

name

The covariance estimator's name.

opt_bandwidth

Estimate optimal bandwidth.

rate

The optimal rate used in bandwidth selection.

Methods

Properties

| | |
|------------------------|---|
| <i>bandwidth</i> | The bandwidth used by the covariance estimator. |
| <i>bandwidth_scale</i> | The power used in optimal bandwidth calculation. |
| <i>centered</i> | Flag indicating whether the data are centered (de-meanned). |
| <i>cov</i> | The estimated covariances. |
| <i>force_int</i> | Flag indicating whether the bandwidth is restricted to be an integer. |
| <i>kernel_const</i> | The constant used in optimal bandwidth calculation. |
| <i>kernel_weights</i> | Weights used in covariance calculation. |
| <i>name</i> | The covariance estimator's name. |
| <i>opt_bandwidth</i> | Estimate optimal bandwidth. |
| <i>rate</i> | The optimal rate used in bandwidth selection. |

arch.covariance.kernel.Parzen.bandwidth

property Parzen.bandwidth: float

The bandwidth used by the covariance estimator.

Returns

float

The user-provided or estimated optimal bandwidth.

Return type

float

arch.covariance.kernel.Parzen.bandwidth_scale

property Parzen.bandwidth_scale

The power used in optimal bandwidth calculation.

Returns

float

The power value used in the optimal bandwidth calculation.

arch.covariance.kernel.Parzen.centered

property Parzen.centered: `bool`

Flag indicating whether the data are centered (demeaned).

Returns

`bool`

A flag indicating whether the estimator is centered.

Return type

`bool`

arch.covariance.kernel.Parzen.cov

property Parzen.cov: *CovarianceEstimate*

The estimated covariances.

Returns

CovarianceEstimate

Covariance estimate instance containing 4 estimates:

- long_run
- short_run
- one_sided
- one_sided_strict

See also:

CovarianceEstimate

arch.covariance.kernel.Parzen.force_int

property Parzen.force_int: `bool`

Flag indicating whether the bandwidth is restricted to be an integer.

Return type

`bool`

arch.covariance.kernel.Parzen.kernel_const

property Parzen.kernel_const

The constant used in optimal bandwidth calculation.

Returns

`float`

The constant value used in the optimal bandwidth calculation.

arch.covariance.kernel.Parzen.kernel_weights**property** Parzen.kernel_weights: ndarray

Weights used in covariance calculation.

Returns

ndarray

The weight vector including 1 in position 0.

arch.covariance.kernel.Parzen.name**property** Parzen.name: str

The covariance estimator's name.

Returns

str

The covariance estimator's name.

Return type

str

arch.covariance.kernel.Parzen.opt_bandwidth**property** Parzen.opt_bandwidth: float

Estimate optimal bandwidth.

Returns

float

The estimated optimal bandwidth.

Notes

Computed as

$$\hat{b}_T = c_k [\hat{\alpha}(q) T]^{\frac{1}{2q+1}}$$

where c_k is a kernel-dependent constant, T is the sample size, q determines the optimal bandwidth rate for the kernel.

arch.covariance.kernel.Parzen.rate**property** Parzen.rate

The optimal rate used in bandwidth selection.

Controls the number of lags used in the variance estimate that determines the estimate of the optimal bandwidth.

Returns

float

The rate used in bandwidth selection.

6.1.6 arch.covariance.kernel.ParzenCauchy

```
class arch.covariance.kernel.ParzenCauchy(x, bandwidth=None, df_adjust=0, center=True,
                                          weights=None, force_int=False)
```

Parzen's Cauchy kernel covariance estimation.

Parameters

- x**
[numpy:array_like] The data to use in covariance estimation.
- bandwidth**
[float, default None] The kernel's bandwidth. If None, optimal bandwidth is estimated.
- df_adjust**
[int, default 0] Degrees of freedom to remove when adjusting the covariance. Uses the number of observations in x minus df_adjust when dividing inner-products.
- center**
[bool, default True] A flag indicating whether x should be demeaned before estimating the covariance.
- weights**
[numpy:array_like, default None] An array of weights used to combine when estimating optimal bandwidth. If not provided, a vector of 1s is used. Must have nvar elements.
- force_int**
[bool, default False] Force bandwidth to be an integer.

Notes

The kernel weights are computed using

$$w = \begin{cases} \frac{1}{1+z^2} & z \leq 1 \\ 0 & z > 1 \end{cases}$$

where $z = \frac{h}{H}$, $h = 0, 1, \dots, H$ where H is the bandwidth.

Attributes

- bandwidth**
The bandwidth used by the covariance estimator.
- bandwidth_scale**
The power used in optimal bandwidth calculation.
- centered**
Flag indicating whether the data are centered (demeaned).
- cov**
The estimated covariances.
- force_int**
Flag indicating whether the bandwidth is restricted to be an integer.
- kernel_const**
The constant used in optimal bandwidth calculation.
- kernel_weights**
Weights used in covariance calculation.

name

The covariance estimator's name.

opt_bandwidth

Estimate optimal bandwidth.

rate

The optimal rate used in bandwidth selection.

Methods

Properties

| | |
|------------------------|---|
| <i>bandwidth</i> | The bandwidth used by the covariance estimator. |
| <i>bandwidth_scale</i> | The power used in optimal bandwidth calculation. |
| <i>centered</i> | Flag indicating whether the data are centered (de-meanned). |

| <i>force_int</i> | Flag indicating whether the bandwidth is restricted to be an integer. |
| <i>kernel_const</i> | The constant used in optimal bandwidth calculation. |
| <i>kernel_weights</i> | Weights used in covariance calculation. |
| <i>name</i> | The covariance estimator's name. |
| <i>opt_bandwidth</i> | Estimate optimal bandwidth. |
| <i>rate</i> | The optimal rate used in bandwidth selection. |

arch.covariance.kernel.ParzenCauchy.bandwidth

property ParzenCauchy.**bandwidth**: **float**

The bandwidth used by the covariance estimator.

Returns

float

The user-provided or estimated optimal bandwidth.

Return type

float

arch.covariance.kernel.ParzenCauchy.bandwidth_scale

property ParzenCauchy.**bandwidth_scale**

The power used in optimal bandwidth calculation.

Returns

float

The power value used in the optimal bandwidth calculation.

arch.covariance.kernel.ParzenCauchy.centered**property** ParzenCauchy.**centered**: **bool**

Flag indicating whether the data are centered (demeaned).

Returns**bool**

A flag indicating whether the estimator is centered.

Return type**bool****arch.covariance.kernel.ParzenCauchy.cov****property** ParzenCauchy.**cov**: *CovarianceEstimate*

The estimated covariances.

Returns*CovarianceEstimate*

Covariance estimate instance containing 4 estimates:

- long_run
- short_run
- one_sided
- one_sided_strict

See also:*CovarianceEstimate***arch.covariance.kernel.ParzenCauchy.force_int****property** ParzenCauchy.**force_int**: **bool**

Flag indicating whether the bandwidth is restricted to be an integer.

Return type**bool****arch.covariance.kernel.ParzenCauchy.kernel_const****property** ParzenCauchy.**kernel_const**

The constant used in optimal bandwidth calculation.

Returns**float**

The constant value used in the optimal bandwidth calculation.

arch.covariance.kernel.ParzenCauchy.kernel_weights**property** ParzenCauchy.**kernel_weights**: **ndarray**

Weights used in covariance calculation.

Returns**ndarray**

The weight vector including 1 in position 0.

arch.covariance.kernel.ParzenCauchy.name**property** ParzenCauchy.**name**: **str**

The covariance estimator's name.

Returns**str**

The covariance estimator's name.

Return type**str****arch.covariance.kernel.ParzenCauchy.opt_bandwidth****property** ParzenCauchy.**opt_bandwidth**: **float**

Estimate optimal bandwidth.

Returns**float**

The estimated optimal bandwidth.

Notes

Computed as

$$\hat{b}_T = c_k [\hat{\alpha}(q) T]^{\frac{1}{2q+1}}$$

where c_k is a kernel-dependent constant, T is the sample size, q determines the optimal bandwidth rate for the kernel.

arch.covariance.kernel.ParzenCauchy.rate**property** ParzenCauchy.**rate**

The optimal rate used in bandwidth selection.

Controls the number of lags used in the variance estimate that determines the estimate of the optimal bandwidth.

Returns**float**

The rate used in bandwidth selection.

6.1.7 arch.covariance.kernel.ParzenGeometric

```
class arch.covariance.kernel.ParzenGeometric(x, bandwidth=None, df_adjust=0, center=True,
                                             weights=None, force_int=False)
```

Parzen's Geometric kernel covariance estimation.

Parameters

- x**
[numpy:array_like] The data to use in covariance estimation.
- bandwidth**
[float, default None] The kernel's bandwidth. If None, optimal bandwidth is estimated.
- df_adjust**
[int, default 0] Degrees of freedom to remove when adjusting the covariance. Uses the number of observations in x minus df_adjust when dividing inner-products.
- center**
[bool, default True] A flag indicating whether x should be demeaned before estimating the covariance.
- weights**
[numpy:array_like, default None] An array of weights used to combine when estimating optimal bandwidth. If not provided, a vector of 1s is used. Must have nvar elements.
- force_int**
[bool, default False] Force bandwidth to be an integer.

Notes

The kernel weights are computed using

$$w = \begin{cases} \frac{1}{1+z} & z \leq 1 \\ 0 & z > 1 \end{cases}$$

where $z = \frac{h}{H}$, $h = 0, 1, \dots, H$ where H is the bandwidth.

Attributes

- bandwidth**
The bandwidth used by the covariance estimator.
- bandwidth_scale**
The power used in optimal bandwidth calculation.
- centered**
Flag indicating whether the data are centered (demeaned).
- cov**
The estimated covariances.
- force_int**
Flag indicating whether the bandwidth is restricted to be an integer.
- kernel_const**
The constant used in optimal bandwidth calculation.
- kernel_weights**
Weights used in covariance calculation.

name

The covariance estimator's name.

opt_bandwidth

Estimate optimal bandwidth.

rate

The optimal rate used in bandwidth selection.

arch.covariance.kernel.ParzenGeometric.bandwidth

property ParzenGeometric.**bandwidth**: **float**

The bandwidth used by the covariance estimator.

Returns

float

The user-provided or estimated optimal bandwidth.

Return type

float

arch.covariance.kernel.ParzenGeometric.bandwidth_scale

property ParzenGeometric.**bandwidth_scale**

The power used in optimal bandwidth calculation.

Returns

float

The power value used in the optimal bandwidth calculation.

arch.covariance.kernel.ParzenGeometric.centered**property** `ParzenGeometric.centered`: `bool`

Flag indicating whether the data are centered (demeaned).

Returns`bool`

A flag indicating whether the estimator is centered.

Return type`bool`**arch.covariance.kernel.ParzenGeometric.cov****property** `ParzenGeometric.cov`: *CovarianceEstimate*

The estimated covariances.

Returns*CovarianceEstimate*

Covariance estimate instance containing 4 estimates:

- `long_run`
- `short_run`
- `one_sided`
- `one_sided_strict`

See also:*CovarianceEstimate***arch.covariance.kernel.ParzenGeometric.force_int****property** `ParzenGeometric.force_int`: `bool`

Flag indicating whether the bandwidth is restricted to be an integer.

Return type`bool`**arch.covariance.kernel.ParzenGeometric.kernel_const****property** `ParzenGeometric.kernel_const`

The constant used in optimal bandwidth calculation.

Returns`float`

The constant value used in the optimal bandwidth calculation.

arch.covariance.kernel.ParzenGeometric.kernel_weights**property** ParzenGeometric.kernel_weights: ndarray

Weights used in covariance calculation.

Returns

ndarray

The weight vector including 1 in position 0.

arch.covariance.kernel.ParzenGeometric.name**property** ParzenGeometric.name: str

The covariance estimator's name.

Returns

str

The covariance estimator's name.

Return type

str

arch.covariance.kernel.ParzenGeometric.opt_bandwidth**property** ParzenGeometric.opt_bandwidth: float

Estimate optimal bandwidth.

Returns

float

The estimated optimal bandwidth.

Notes

Computed as

$$\hat{b}_T = c_k [\hat{\alpha}(q) T]^{\frac{1}{2q+1}}$$

where c_k is a kernel-dependent constant, T is the sample size, q determines the optimal bandwidth rate for the kernel.

arch.covariance.kernel.ParzenGeometric.rate**property** ParzenGeometric.rate

The optimal rate used in bandwidth selection.

Controls the number of lags used in the variance estimate that determines the estimate of the optimal bandwidth.

Returns

float

The rate used in bandwidth selection.

6.1.8 arch.covariance.kernel.ParzenRiesz

class arch.covariance.kernel.ParzenRiesz(*x*, *bandwidth=None*, *df_adjust=0*, *center=True*, *weights=None*, *force_int=False*)

Parzen-Reisz kernel covariance estimation.

Parameters

- x**
[numpy:array_like] The data to use in covariance estimation.
- bandwidth**
[float, default None] The kernel's bandwidth. If None, optimal bandwidth is estimated.
- df_adjust**
[int, default 0] Degrees of freedom to remove when adjusting the covariance. Uses the number of observations in x minus df_adjust when dividing inner-products.
- center**
[bool, default True] A flag indicating whether x should be demeaned before estimating the covariance.
- weights**
[numpy:array_like, default None] An array of weights used to combine when estimating optimal bandwidth. If not provided, a vector of 1s is used. Must have nvar elements.
- force_int**
[bool, default False] Force bandwidth to be an integer.

Notes

The kernel weights are computed using

$$w = \begin{cases} 1 - z^2 & z \leq 1 \\ 0 & z > 1 \end{cases}$$

where $z = \frac{h}{H}$, $h = 0, 1, \dots, H$ where H is the bandwidth.

Attributes

- bandwidth**
The bandwidth used by the covariance estimator.
- bandwidth_scale**
The power used in optimal bandwidth calculation.
- centered**
Flag indicating whether the data are centered (demeaned).
- cov**
The estimated covariances.
- force_int**
Flag indicating whether the bandwidth is restricted to be an integer.
- kernel_const**
The constant used in optimal bandwidth calculation.
- kernel_weights**
Weights used in covariance calculation.

name

The covariance estimator's name.

opt_bandwidth

Estimate optimal bandwidth.

rate

The optimal rate used in bandwidth selection.

Methods

| <i>name</i> | The covariance estimator's name. |
| <i>opt_bandwidth</i> | Estimate optimal bandwidth. |
| <i>rate</i> | The optimal rate used in bandwidth selection. |

arch.covariance.kernel.ParzenRiesz.bandwidth

property ParzenRiesz.**bandwidth**: **float**

The bandwidth used by the covariance estimator.

Returns

float

The user-provided or estimated optimal bandwidth.

Return type

float

arch.covariance.kernel.ParzenRiesz.bandwidth_scale

property ParzenRiesz.**bandwidth_scale**

The power used in optimal bandwidth calculation.

Returns

float

The power value used in the optimal bandwidth calculation.

arch.covariance.kernel.ParzenRiesz.centered**property** ParzenRiesz.**centered**: **bool**

Flag indicating whether the data are centered (demeaned).

Returns**bool**

A flag indicating whether the estimator is centered.

Return type**bool****arch.covariance.kernel.ParzenRiesz.cov****property** ParzenRiesz.**cov**: *CovarianceEstimate*

The estimated covariances.

Returns*CovarianceEstimate*

Covariance estimate instance containing 4 estimates:

- long_run
- short_run
- one_sided
- one_sided_strict

See also:*CovarianceEstimate***arch.covariance.kernel.ParzenRiesz.force_int****property** ParzenRiesz.**force_int**: **bool**

Flag indicating whether the bandwidth is restricted to be an integer.

Return type**bool****arch.covariance.kernel.ParzenRiesz.kernel_const****property** ParzenRiesz.**kernel_const**

The constant used in optimal bandwidth calculation.

Returns**float**

The constant value used in the optimal bandwidth calculation.

arch.covariance.kernel.ParzenRiesz.kernel_weights**property** ParzenRiesz.**kernel_weights**: ndarray

Weights used in covariance calculation.

Returns

ndarray

The weight vector including 1 in position 0.

arch.covariance.kernel.ParzenRiesz.name**property** ParzenRiesz.**name**: str

The covariance estimator's name.

Returns

str

The covariance estimator's name.

Return type

str

arch.covariance.kernel.ParzenRiesz.opt_bandwidth**property** ParzenRiesz.**opt_bandwidth**: float

Estimate optimal bandwidth.

Returns

float

The estimated optimal bandwidth.

Notes

Computed as

$$\hat{b}_T = c_k [\hat{\alpha}(q) T]^{\frac{1}{2q+1}}$$

where c_k is a kernel-dependent constant, T is the sample size, q determines the optimal bandwidth rate for the kernel.

arch.covariance.kernel.ParzenRiesz.rate**property** ParzenRiesz.**rate**

The optimal rate used in bandwidth selection.

Controls the number of lags used in the variance estimate that determines the estimate of the optimal bandwidth.

Returns

float

The rate used in bandwidth selection.

6.1.9 arch.covariance.kernel.QuadraticSpectral

```
class arch.covariance.kernel.QuadraticSpectral(x, bandwidth=None, df_adjust=0, center=True,
                                              weights=None, force_int=False)
```

Quadratic-Spectral (Andrews') kernel covariance estimation.

Parameters

- x**
[numpy:array_like] The data to use in covariance estimation.
- bandwidth**
[float, default None] The kernel's bandwidth. If None, optimal bandwidth is estimated.
- df_adjust**
[int, default 0] Degrees of freedom to remove when adjusting the covariance. Uses the number of observations in x minus df_adjust when dividing inner-products.
- center**
[bool, default True] A flag indicating whether x should be demeaned before estimating the covariance.
- weights**
[numpy:array_like, default None] An array of weights used to combine when estimating optimal bandwidth. If not provided, a vector of 1s is used. Must have nvar elements.
- force_int**
[bool, default False] Force bandwidth to be an integer.

Notes

The kernel weights are computed using

$$w = \begin{cases} 1 & z = 0 \\ \frac{3}{x^2} \left(\frac{\sin x}{x} - \cos x \right), & x = \frac{6\pi z}{5} \quad z > 0 \end{cases}$$

where $z = \frac{h}{H}$, $h = 0, 1, \dots, H$ where H is the bandwidth.

Attributes

- bandwidth**
The bandwidth used by the covariance estimator.
- bandwidth_scale**
The power used in optimal bandwidth calculation.
- centered**
Flag indicating whether the data are centered (demeaned).
- cov**
The estimated covariances.
- force_int**
Flag indicating whether the bandwidth is restricted to be an integer.
- kernel_const**
The constant used in optimal bandwidth calculation.
- kernel_weights**
Weights used in covariance calculation.

name

The covariance estimator's name.

opt_bandwidth

Estimate optimal bandwidth.

rate

The optimal rate used in bandwidth selection.

Methods

Properties

| <i>name</i> | The covariance estimator's name. |
| <i>opt_bandwidth</i> | Estimate optimal bandwidth. |
| <i>rate</i> | The optimal rate used in bandwidth selection. |

arch.covariance.kernel.QuadraticSpectral.bandwidth

property QuadraticSpectral.**bandwidth**: **float**

The bandwidth used by the covariance estimator.

Returns

float

The user-provided or estimated optimal bandwidth.

Return type

float

arch.covariance.kernel.QuadraticSpectral.bandwidth_scale

property QuadraticSpectral.**bandwidth_scale**

The power used in optimal bandwidth calculation.

Returns

float

The power value used in the optimal bandwidth calculation.

arch.covariance.kernel.QuadraticSpectral.centered**property** QuadraticSpectral.**centered**: **bool**

Flag indicating whether the data are centered (demeaned).

Returns**bool**

A flag indicating whether the estimator is centered.

Return type**bool****arch.covariance.kernel.QuadraticSpectral.cov****property** QuadraticSpectral.**cov**: *CovarianceEstimate*

The estimated covariances.

Returns*CovarianceEstimate*

Covariance estimate instance containing 4 estimates:

- long_run
- short_run
- one_sided
- one_sided_strict

See also:*CovarianceEstimate***arch.covariance.kernel.QuadraticSpectral.force_int****property** QuadraticSpectral.**force_int**: **bool**

Flag indicating whether the bandwidth is restricted to be an integer.

Return type**bool****arch.covariance.kernel.QuadraticSpectral.kernel_const****property** QuadraticSpectral.**kernel_const**

The constant used in optimal bandwidth calculation.

Returns**float**

The constant value used in the optimal bandwidth calculation.

arch.covariance.kernel.QuadraticSpectral.kernel_weights**property** QuadraticSpectral.**kernel_weights**: ndarray

Weights used in covariance calculation.

Returns

ndarray

The weight vector including 1 in position 0.

arch.covariance.kernel.QuadraticSpectral.name**property** QuadraticSpectral.**name**: str

The covariance estimator's name.

Returns

str

The covariance estimator's name.

Return type

str

arch.covariance.kernel.QuadraticSpectral.opt_bandwidth**property** QuadraticSpectral.**opt_bandwidth**: float

Estimate optimal bandwidth.

Returns

float

The estimated optimal bandwidth.

Notes

Computed as

$$\hat{b}_T = c_k [\hat{\alpha}(q) T]^{\frac{1}{2q+1}}$$

where c_k is a kernel-dependent constant, T is the sample size, q determines the optimal bandwidth rate for the kernel.

arch.covariance.kernel.QuadraticSpectral.rate**property** QuadraticSpectral.**rate**

The optimal rate used in bandwidth selection.

Controls the number of lags used in the variance estimate that determines the estimate of the optimal bandwidth.

Returns

float

The rate used in bandwidth selection.

6.1.10 arch.covariance.kernel.TukeyHamming

class arch.covariance.kernel.TukeyHamming(*x*, *bandwidth=None*, *df_adjust=0*, *center=True*,
weights=None, *force_int=False*)

Tukey-Hamming kernel covariance estimation.

Parameters

- x**
[numpy:array_like] The data to use in covariance estimation.
- bandwidth**
[float, default None] The kernel's bandwidth. If None, optimal bandwidth is estimated.
- df_adjust**
[int, default 0] Degrees of freedom to remove when adjusting the covariance. Uses the number of observations in x minus df_adjust when dividing inner-products.
- center**
[bool, default True] A flag indicating whether x should be demeaned before estimating the covariance.
- weights**
[numpy:array_like, default None] An array of weights used to combine when estimating optimal bandwidth. If not provided, a vector of 1s is used. Must have nvar elements.
- force_int**
[bool, default False] Force bandwidth to be an integer.

Notes

The kernel weights are computed using

$$w = \begin{cases} 0.54 + 0.46 \cos \pi z & z \leq 1 \\ 0 & z > 1 \end{cases}$$

where $z = \frac{h}{H}$, $h = 0, 1, \dots, H$ where H is the bandwidth.

Attributes

- bandwidth**
The bandwidth used by the covariance estimator.
- bandwidth_scale**
The power used in optimal bandwidth calculation.
- centered**
Flag indicating whether the data are centered (demeaned).
- cov**
The estimated covariances.
- force_int**
Flag indicating whether the bandwidth is restricted to be an integer.
- kernel_const**
The constant used in optimal bandwidth calculation.
- kernel_weights**
Weights used in covariance calculation.

name

The covariance estimator's name.

opt_bandwidth

Estimate optimal bandwidth.

rate

The optimal rate used in bandwidth selection.

Methods

Properties

| <i>kernel_const</i> | The constant used in optimal bandwidth calculation. |
| <i>kernel_weights</i> | Weights used in covariance calculation. |
| <i>name</i> | The covariance estimator's name. |
| <i>opt_bandwidth</i> | Estimate optimal bandwidth. |
| <i>rate</i> | The optimal rate used in bandwidth selection. |

arch.covariance.kernel.TukeyHamming.bandwidth

property `TukeyHamming.bandwidth`: **float**

The bandwidth used by the covariance estimator.

Returns

float

The user-provided or estimated optimal bandwidth.

Return type

float

arch.covariance.kernel.TukeyHamming.bandwidth_scale

property `TukeyHamming.bandwidth_scale`

The power used in optimal bandwidth calculation.

Returns

float

The power value used in the optimal bandwidth calculation.

arch.covariance.kernel.TukeyHamming.centered**property** `TukeyHamming.centered`: `bool`

Flag indicating whether the data are centered (demeaned).

Returns`bool`

A flag indicating whether the estimator is centered.

Return type`bool`**arch.covariance.kernel.TukeyHamming.cov****property** `TukeyHamming.cov`: *CovarianceEstimate*

The estimated covariances.

Returns*CovarianceEstimate*

Covariance estimate instance containing 4 estimates:

- `long_run`
- `short_run`
- `one_sided`
- `one_sided_strict`

See also:*CovarianceEstimate***arch.covariance.kernel.TukeyHamming.force_int****property** `TukeyHamming.force_int`: `bool`

Flag indicating whether the bandwidth is restricted to be an integer.

Return type`bool`**arch.covariance.kernel.TukeyHamming.kernel_const****property** `TukeyHamming.kernel_const`

The constant used in optimal bandwidth calculation.

Returns`float`

The constant value used in the optimal bandwidth calculation.

arch.covariance.kernel.TukeyHamming.kernel_weights**property** TukeyHamming.kernel_weights: ndarray

Weights used in covariance calculation.

Returns

ndarray

The weight vector including 1 in position 0.

arch.covariance.kernel.TukeyHamming.name**property** TukeyHamming.name: str

The covariance estimator's name.

Returns

str

The covariance estimator's name.

Return type

str

arch.covariance.kernel.TukeyHamming.opt_bandwidth**property** TukeyHamming.opt_bandwidth: float

Estimate optimal bandwidth.

Returns

float

The estimated optimal bandwidth.

Notes

Computed as

$$\hat{b}_T = c_k [\hat{\alpha}(q) T]^{\frac{1}{2q+1}}$$

where c_k is a kernel-dependent constant, T is the sample size, q determines the optimal bandwidth rate for the kernel.

arch.covariance.kernel.TukeyHamming.rate**property** TukeyHamming.rate

The optimal rate used in bandwidth selection.

Controls the number of lags used in the variance estimate that determines the estimate of the optimal bandwidth.

Returns

float

The rate used in bandwidth selection.

6.1.11 arch.covariance.kernel.TukeyHanning

class arch.covariance.kernel.TukeyHanning(*x*, *bandwidth=None*, *df_adjust=0*, *center=True*,
weights=None, *force_int=False*)

Tukey-Hanning kernel covariance estimation.

Parameters

- x**
[numpy:array_like] The data to use in covariance estimation.
- bandwidth**
[float, default None] The kernel's bandwidth. If None, optimal bandwidth is estimated.
- df_adjust**
[int, default 0] Degrees of freedom to remove when adjusting the covariance. Uses the number of observations in x minus df_adjust when dividing inner-products.
- center**
[bool, default True] A flag indicating whether x should be demeaned before estimating the covariance.
- weights**
[numpy:array_like, default None] An array of weights used to combine when estimating optimal bandwidth. If not provided, a vector of 1s is used. Must have nvar elements.
- force_int**
[bool, default False] Force bandwidth to be an integer.

Notes

The kernel weights are computed using

$$w = \begin{cases} \frac{1}{2} + \frac{1}{2} \cos \pi z & z \leq 1 \\ 0 & z > 1 \end{cases}$$

where $z = \frac{h}{H}$, $h = 0, 1, \dots, H$ where H is the bandwidth.

Attributes

- bandwidth**
The bandwidth used by the covariance estimator.
- bandwidth_scale**
The power used in optimal bandwidth calculation.
- centered**
Flag indicating whether the data are centered (demeaned).
- cov**
The estimated covariances.
- force_int**
Flag indicating whether the bandwidth is restricted to be an integer.
- kernel_const**
The constant used in optimal bandwidth calculation.
- kernel_weights**
Weights used in covariance calculation.

name

The covariance estimator's name.

opt_bandwidth

Estimate optimal bandwidth.

rate

The optimal rate used in bandwidth selection.

Methods

Properties

| | |
|------------------------|---|
| <i>bandwidth</i> | The bandwidth used by the covariance estimator. |
| <i>bandwidth_scale</i> | The power used in optimal bandwidth calculation. |
| <i>centered</i> | Flag indicating whether the data are centered (de-meanned). |
| <i>cov</i> | The estimated covariances. |
| <i>force_int</i> | Flag indicating whether the bandwidth is restricted to be an integer. |
| <i>kernel_const</i> | The constant used in optimal bandwidth calculation. |
| <i>kernel_weights</i> | Weights used in covariance calculation. |
| <i>name</i> | The covariance estimator's name. |
| <i>opt_bandwidth</i> | Estimate optimal bandwidth. |
| <i>rate</i> | The optimal rate used in bandwidth selection. |

arch.covariance.kernel.TukeyHanning.bandwidth

property `TukeyHanning.bandwidth`: `float`

The bandwidth used by the covariance estimator.

Returns

`float`

The user-provided or estimated optimal bandwidth.

Return type

`float`

arch.covariance.kernel.TukeyHanning.bandwidth_scale

property `TukeyHanning.bandwidth_scale`

The power used in optimal bandwidth calculation.

Returns

`float`

The power value used in the optimal bandwidth calculation.

arch.covariance.kernel.TukeyHanning.centered**property** `TukeyHanning.centered`: `bool`

Flag indicating whether the data are centered (demeaned).

Returns`bool`

A flag indicating whether the estimator is centered.

Return type`bool`**arch.covariance.kernel.TukeyHanning.cov****property** `TukeyHanning.cov`: *CovarianceEstimate*

The estimated covariances.

Returns*CovarianceEstimate*

Covariance estimate instance containing 4 estimates:

- `long_run`
- `short_run`
- `one_sided`
- `one_sided_strict`

See also:*CovarianceEstimate***arch.covariance.kernel.TukeyHanning.force_int****property** `TukeyHanning.force_int`: `bool`

Flag indicating whether the bandwidth is restricted to be an integer.

Return type`bool`**arch.covariance.kernel.TukeyHanning.kernel_const****property** `TukeyHanning.kernel_const`

The constant used in optimal bandwidth calculation.

Returns`float`

The constant value used in the optimal bandwidth calculation.

arch.covariance.kernel.TukeyHanning.kernel_weights**property** TukeyHanning.kernel_weights: ndarray

Weights used in covariance calculation.

Returns

ndarray

The weight vector including 1 in position 0.

arch.covariance.kernel.TukeyHanning.name**property** TukeyHanning.name: str

The covariance estimator's name.

Returns

str

The covariance estimator's name.

Return type

str

arch.covariance.kernel.TukeyHanning.opt_bandwidth**property** TukeyHanning.opt_bandwidth: float

Estimate optimal bandwidth.

Returns

float

The estimated optimal bandwidth.

Notes

Computed as

$$\hat{b}_T = c_k [\hat{\alpha}(q) T]^{\frac{1}{2q+1}}$$

where c_k is a kernel-dependent constant, T is the sample size, q determines the optimal bandwidth rate for the kernel.

arch.covariance.kernel.TukeyHanning.rate**property** TukeyHanning.rate

The optimal rate used in bandwidth selection.

Controls the number of lags used in the variance estimate that determines the estimate of the optimal bandwidth.

Returns

float

The rate used in bandwidth selection.

6.1.12 arch.covariance.kernel.TukeyParzen

class `arch.covariance.kernel.TukeyParzen`(*x*, *bandwidth=None*, *df_adjust=0*, *center=True*, *weights=None*, *force_int=False*)

Tukey-Parzen kernel covariance estimation.

Parameters

- x**
[numpy:array_like] The data to use in covariance estimation.
- bandwidth**
[float, default None] The kernel's bandwidth. If None, optimal bandwidth is estimated.
- df_adjust**
[int, default 0] Degrees of freedom to remove when adjusting the covariance. Uses the number of observations in x minus df_adjust when dividing inner-products.
- center**
[bool, default True] A flag indicating whether x should be demeaned before estimating the covariance.
- weights**
[numpy:array_like, default None] An array of weights used to combine when estimating optimal bandwidth. If not provided, a vector of 1s is used. Must have nvar elements.
- force_int**
[bool, default False] Force bandwidth to be an integer.

Notes

The kernel weights are computed using

$$w = \begin{cases} 0.436 + 0.564 \cos \pi z & z \leq 1 \\ 0 & z > 1 \end{cases}$$

where $z = \frac{h}{H}$, $h = 0, 1, \dots, H$ where H is the bandwidth.

Attributes

- bandwidth**
The bandwidth used by the covariance estimator.
- bandwidth_scale**
The power used in optimal bandwidth calculation.
- centered**
Flag indicating whether the data are centered (demeaned).
- cov**
The estimated covariances.
- force_int**
Flag indicating whether the bandwidth is restricted to be an integer.
- kernel_const**
The constant used in optimal bandwidth calculation.
- kernel_weights**
Weights used in covariance calculation.

name

The covariance estimator's name.

opt_bandwidth

Estimate optimal bandwidth.

rate

The optimal rate used in bandwidth selection.

Methods

Properties

| | |
|------------------------|---|
| <i>bandwidth</i> | The bandwidth used by the covariance estimator. |
| <i>bandwidth_scale</i> | The power used in optimal bandwidth calculation. |
| <i>centered</i> | Flag indicating whether the data are centered (de-meanned). |
| <i>cov</i> | The estimated covariances. |
| <i>force_int</i> | Flag indicating whether the bandwidth is restricted to be an integer. |
| <i>kernel_const</i> | The constant used in optimal bandwidth calculation. |
| <i>kernel_weights</i> | Weights used in covariance calculation. |
| <i>name</i> | The covariance estimator's name. |
| <i>opt_bandwidth</i> | Estimate optimal bandwidth. |
| <i>rate</i> | The optimal rate used in bandwidth selection. |

arch.covariance.kernel.TukeyParzen.bandwidth

property `TukeyParzen.bandwidth`: **float**

The bandwidth used by the covariance estimator.

Returns

float

The user-provided or estimated optimal bandwidth.

Return type

float

arch.covariance.kernel.TukeyParzen.bandwidth_scale

property `TukeyParzen.bandwidth_scale`

The power used in optimal bandwidth calculation.

Returns

float

The power value used in the optimal bandwidth calculation.

arch.covariance.kernel.TukeyParzen.centered**property** `TukeyParzen.centered`: `bool`

Flag indicating whether the data are centered (demeaned).

Returns`bool`

A flag indicating whether the estimator is centered.

Return type`bool`**arch.covariance.kernel.TukeyParzen.cov****property** `TukeyParzen.cov`: *CovarianceEstimate*

The estimated covariances.

Returns*CovarianceEstimate*

Covariance estimate instance containing 4 estimates:

- `long_run`
- `short_run`
- `one_sided`
- `one_sided_strict`

See also:*CovarianceEstimate***arch.covariance.kernel.TukeyParzen.force_int****property** `TukeyParzen.force_int`: `bool`

Flag indicating whether the bandwidth is restricted to be an integer.

Return type`bool`**arch.covariance.kernel.TukeyParzen.kernel_const****property** `TukeyParzen.kernel_const`

The constant used in optimal bandwidth calculation.

Returns`float`

The constant value used in the optimal bandwidth calculation.

arch.covariance.kernel.TukeyParzen.kernel_weights**property** TukeyParzen.**kernel_weights**: ndarray

Weights used in covariance calculation.

Returns

ndarray

The weight vector including 1 in position 0.

arch.covariance.kernel.TukeyParzen.name**property** TukeyParzen.**name**: str

The covariance estimator's name.

Returns

str

The covariance estimator's name.

Return type

str

arch.covariance.kernel.TukeyParzen.opt_bandwidth**property** TukeyParzen.**opt_bandwidth**: float

Estimate optimal bandwidth.

Returns

float

The estimated optimal bandwidth.

Notes

Computed as

$$\hat{b}_T = c_k [\hat{\alpha}(q) T]^{\frac{1}{2q+1}}$$

where c_k is a kernel-dependent constant, T is the sample size, q determines the optimal bandwidth rate for the kernel.

arch.covariance.kernel.TukeyParzen.rate**property** TukeyParzen.**rate**

The optimal rate used in bandwidth selection.

Controls the number of lags used in the variance estimate that determines the estimate of the optimal bandwidth.

Returns

float

The rate used in bandwidth selection.

6.2 Results

| | |
|---|---|
| <code>CovarianceEstimate</code> (short_run, one_sided_strict) | Covariance estimate using a long-run covariance estimator |
|---|---|

6.2.1 arch.covariance.kernel.CovarianceEstimate

```
class arch.covariance.kernel.CovarianceEstimate(short_run, one_sided_strict, columns=None,
                                                long_run=None, one_sided=None)
```

Covariance estimate using a long-run covariance estimator

Parameters

short_run

[ndarray] The short-run covariance estimate.

one_sided_strict

[ndarray] The one-sided strict covariance estimate.

columns

[{None, list[str]}] Column labels to use if covariance estimates are returned as DataFrames.

long_run

[ndarray, default None] The long-run covariance estimate. If not provided, computed from short_run and one_sided_strict.

one_sided_strict

[ndarray, default None] The one-sided-strict covariance estimate. If not provided, computed from short_run and one_sided_strict.

Notes

If Γ_0 is the short-run covariance and Λ_1 is the one-sided strict covariance, then the long-run covariance is defined

$$\Omega = \Gamma_0 + \Lambda_1 + \Lambda_1'$$

and the one-sided covariance is

$$\Lambda_0 = \Gamma_0 + \Lambda_1.$$

Attributes

long_run

The long-run covariance estimate.

one_sided

The one-sided covariance estimate.

one_sided_strict

The one-sided strict covariance estimate.

short_run

The short-run covariance estimate.

Methods

Properties

| | |
|-------------------------|---|
| <i>long_run</i> | The long-run covariance estimate. |
| <i>one_sided</i> | The one-sided covariance estimate. |
| <i>one_sided_strict</i> | The one-sided strict covariance estimate. |
| <i>short_run</i> | The short-run covariance estimate. |

`arch.covariance.kernel.CovarianceEstimate.long_run`

property `CovarianceEstimate.long_run`: `numpy.ndarray` | `pandas.core.frame.DataFrame`
The long-run covariance estimate.

`arch.covariance.kernel.CovarianceEstimate.one_sided`

property `CovarianceEstimate.one_sided`: `numpy.ndarray` | `pandas.core.frame.DataFrame`
The one-sided covariance estimate.

`arch.covariance.kernel.CovarianceEstimate.one_sided_strict`

property `CovarianceEstimate.one_sided_strict`: `numpy.ndarray` | `pandas.core.frame.DataFrame`
The one-sided strict covariance estimate.

`arch.covariance.kernel.CovarianceEstimate.short_run`

property `CovarianceEstimate.short_run`: `numpy.ndarray` | `pandas.core.frame.DataFrame`
The short-run covariance estimate.

API REFERENCE

This page lists contains a list of the essential end-user API functions and classes.

7.1 Volatility Modeling

7.1.1 High-level

| | |
|--|--|
| <code>arch_model(y[, x, mean, lags, vol, p, o, q, ...])</code> | Initialization of common ARCH model specifications |
|--|--|

7.1.2 Mean Specification

| | |
|---|---|
| <code>ConstantMean(y, hold_back, volatility, ...)</code> | Constant mean model estimation and simulation. |
| <code>ZeroMean(y, hold_back, volatility, ...)</code> | Model with zero conditional mean estimation and simulation |
| <code>HARX(y, x, lags, constant, use_rotated, ...)</code> | Heterogeneous Autoregression (HAR), with optional exogenous regressors, model estimation and simulation |
| <code>ARX(y, x, lags, constant, hold_back, ...)</code> | Autoregressive model with optional exogenous regressors estimation and simulation |
| <code>LS(y, x, constant, hold_back, volatility, ...)</code> | Least squares model estimation and simulation |

7.1.3 Volatility Process Specification

| | |
|---|--|
| <code>GARCH([p, o, q, power])</code> | GARCH and related model estimation |
| <code>EGARCH([p, o, q])</code> | EGARCH model estimation |
| <code>HARCH([lags])</code> | Heterogeneous ARCH process |
| <code>FIGARCH([p, q, power, truncation])</code> | FIGARCH model |
| <code>MIDASHyperbolic([m, asym])</code> | MIDAS Hyperbolic ARCH process |
| <code>EWMAVariance([lam])</code> | Exponentially Weighted Moving-Average (RiskMetrics) Variance process |
| <code>RiskMetrics2006([tau0, tau1, kmax, rho])</code> | RiskMetrics 2006 Variance process |
| <code>ConstantVariance()</code> | Constant volatility process |
| <code>FixedVariance(variance[, unit_scale])</code> | Fixed volatility process |

7.1.4 Shock Distributions

| | |
|--|---|
| <i>Normal</i> ([random_state, seed]) | Standard normal distribution for use with ARCH models |
| <i>StudentsT</i> ([random_state, seed]) | Standardized Student's distribution for use with ARCH models |
| <i>SkewStudent</i> ([random_state, seed]) | Standardized Skewed Student's distribution for use with ARCH models |
| <i>GeneralizedError</i> ([random_state, seed]) | Generalized Error distribution for use with ARCH models |

7.2 Unit Root Testing

| | |
|--|---|
| <i>ADF</i> (y[, lags, trend, max_lags, method, ...]) | Augmented Dickey-Fuller unit root test |
| <i>DFGLS</i> (y[, lags, trend, max_lags, method, ...]) | Elliott, Rothenberg and Stock's ([1]) GLS detrended Dickey-Fuller |
| <i>PhillipsPerron</i> (y[, lags, trend, test_type]) | Phillips-Perron unit root test |
| <i>ZivotAndrews</i> (y[, lags, trend, trim, ...]) | Zivot-Andrews structural-break unit-root test |
| <i>VarianceRatio</i> (y[, lags, trend, debiased, ...]) | Variance Ratio test of a random walk. |
| <i>KPSS</i> (y[, lags, trend]) | Kwiatkowski, Phillips, Schmidt and Shin (KPSS) stationarity test |

7.3 Cointegration Testing

| | |
|---|---|
| <i>engle_granger</i> (y, x[, trend, lags, max_lags, ...]) | Test for cointegration within a set of time series. |
| <i>phillips_ouliaris</i> (y, x[, trend, test_type, ...]) | Test for cointegration within a set of time series. |

7.4 Cointegrating Relationship Estimation

| | |
|---|---|
| <i>CanonicalCointegratingReg</i> (y, x[, trend, x_trend]) | Canonical Cointegrating Regression cointegrating vector estimation. |
| <i>DynamicOLS</i> (y, x[, trend, lags, leads, ...]) | Dynamic OLS (DOLS) cointegrating vector estimation |
| <i>FullyModifiedOLS</i> (y, x[, trend, x_trend]) | Fully Modified OLS cointegrating vector estimation. |

7.5 Bootstraps

| | |
|--|---|
| <i>IIDBootstrap</i> (*args[, random_state, seed]) | Bootstrap using uniform resampling |
| <i>IndependentSamplesBootstrap</i> (*args[, ...]) | Bootstrap where each input is independently resampled |
| <i>StationaryBootstrap</i> (block_size, *args[, ...]) | Politis and Romano (1994) bootstrap with expon distributed block sizes |
| <i>CircularBlockBootstrap</i> (block_size, *args[, ...]) | Bootstrap using blocks of the same length with end-to-start wrap around |
| <i>MovingBlockBootstrap</i> (block_size, *args[, ...]) | Bootstrap using blocks of the same length without wrap around |

7.5.1 Block-length Selection

| | |
|---------------------------------|---|
| <i>optimal_block_length</i> (x) | Estimate optimal window length for time-series bootstraps |
|---------------------------------|---|

7.6 Testing with Multiple-Comparison

| | |
|---|--|
| <i>SPA</i> (benchmark, models[, block_size, reps, ...]) | Test of Superior Predictive Ability (SPA) of White and Hansen. |
| <i>MCS</i> (losses, size[, reps, block_size, ...]) | Model Confidence Set (MCS) of Hansen, Lunde and Naason. |
| <i>StepM</i> (benchmark, models[, size, block_size, ...]) | StepM multiple comparison procedure of Romano and Wolf. |

7.7 Long-run Covariance (HAC) Estimation

| | |
|---|---|
| <i>Bartlett</i> (x[, bandwidth, df_adjust, center, ...]) | Bartlett's (Newey-West) kernel covariance estimation. |
| <i>Parzen</i> (x[, bandwidth, df_adjust, center, ...]) | Parzen's kernel covariance estimation. |
| <i>ParzenCauchy</i> (x[, bandwidth, df_adjust, ...]) | Parzen's Cauchy kernel covariance estimation. |
| <i>ParzenGeometric</i> (x[, bandwidth, df_adjust, ...]) | Parzen's Geometric kernel covariance estimation. |

CHANGE LOGS

8.1 Version 5

8.1.1 Release 5.3

- Fixed a bug in `arch_model()` where `power` was not passed to the `FIGARCH` constructor (GH572).
- Fixed a bug that affected downstream projects due to an overly specific assert (GH569).

8.1.2 Release 5.2

- Fixed a bug in `std_resid()` that would raise an exception when the data used to construct the model with a NumPy array (GH565).
- Fixed a bug in `forecast()` and related `forecast` methods when producing multi-step forecasts using simulation with exogenous variables (GH551).

8.1.3 Release 5.1

Unit Root

- Improved automatic lag length selection in `DFGLS` by using OLS rather than GLS detrended data when selecting the lag length. This problem was studied by Perron, P., & Qu, Z. (2007).

8.1.4 Release 5.0

Unit Root

- All unit root tests are now immutable, and so properties such as `trend` cannot be set after the test is created.

Bootstrap

- Added seed keyword argument to all bootstraps (e.g., *IIDBootstrap* and *StationaryBootstrap*) that allows a NumPy `numpy.random.Generator` to be used. The seed keyword argument also accepts legacy `numpy.random.RandomState` instances and integers. If an integer is passed, the random number generator is constructed by calling `numpy.random.default_rng()`. The seed keyword argument replaces the `random_state` keyword argument.
- The `random_state()` property has also been deprecated in favor of `generator()`.
- The `get_state()` and `set_state()` methods have been replaced by the `state()` property.

Volatility Modeling

- Added seed keyword argument to all distributions (e.g., *Normal* and *StudentsT*) that allows a NumPy `numpy.random.Generator` to be used. The seed keyword argument also accepts legacy `numpy.random.RandomState` instances and integers. If an integer is passed, the random number generator is constructed by calling `numpy.random.default_rng()`. The seed keyword argument replaces the `random_state` keyword argument.
- The `random_state()` property has also been deprecated in favor of `generator()`.
- Added *ARCHInMean* mean process supporting (G)ARCH-in-mean models.
- Extended *VolatilityProcess* with `volatility_updater()` that contains a *VolatilityUpdater* to allow *ARCHInMean* to be created from different volatility processes.

Setup

- Added support for using an environmental variable to disable C-extension compilation.
 - Linux and OSX: `export ARCH_NO_BINARY=1`
 - PowerShell: `$env:ARCH_NO_BINARY=1`
 - cmd: `set ARCH_NO_BINARY=1`

8.2 Version 4

8.2.1 Release 4.19

- Added the keyword argument `reindex` to `forecast()` that allows the returned forecasts to have minimal size when `reindex=False`. The default is `reindex=True` which preserved the current behavior. This will change in a future release. Using `reindex=True` often requires substantially more memory than when `reindex=False`. This is especially true when using simulation or bootstrap-based forecasting.
- The default value `reindex` can be changed by importing

```
from arch.__future__ import reindexing
```

- Fixed handling of exogenous regressors in `forecast()`. It is now possible to pass values for $E_t[X_{t+h}]$ using the `x` argument.

8.2.2 Release 4.18

- Improved `fit()` performance of ARCH models.
- Fixed a bug where `typing_extensions` was subtly introduced as a run-time dependency.

8.2.3 Release 4.17

- Fixed a bug that produced incorrect conditional volatility from EWMA models (GH458).

8.2.4 Release 4.16

- Added *APARCH* volatility process (GH443).
- Added support for Python 3.9 in `pyproject.toml` (GH438).
- Fixed a bug in model degree-of-freedom calculation (GH437).
- Improved HARX initialization (GH417).

8.2.5 Release 4.15

- This is a minor release with doc fixes and other small updates. The only notable feature is `regression()` which returns regression results from the model estimated as part of the test (GH395).

8.2.6 Release 4.14

- Added Kernel-based long-run variance estimation in `arch.covariance.kernel`. Examples include the *Bartlett* and the *Parzen* kernels. All estimators suppose automatic bandwidth selection.
- Improved exceptions in *ADF*, *KPSS*, *PhillipsPerron*, *VarianceRatio*, and *ZivotAndrews* when test specification is infeasible to the time series being too short or the required regression model having reduced rank (GH364).
- Fixed a bug when using “bca” confidence intervals with `extra_kwargs` (GH366).
- Added Phillips-Ouliaris (*phillips_ouliaris()*) cointegration tests (GH360).
- Added three methods to estimate cointegrating vectors: *CanonicalCointegratingReg*, *DynamicOLS*, and *FullyModifiedOLS* (GH356, GH359).
- Added the Engle-Granger (*engle_granger()*) cointegration test (GH354).
- Issue warnings when unit root tests are mutated. Will raise after 5.0 is released.
- Fixed a bug in `arch.univariate.SkewStudent` which did not use the user-provided *RandomState* when one was provided. This prevented reproducing simulated values (GH353).

8.2.7 Release 4.13

- Restored the vendored copy of `property_cached` for conda package building.

8.2.8 Release 4.12

- Added typing support to all classes, functions and methods (GH338, GH341, GH342, GH343, GH345, GH346).
- Fixed an issue that caused tests to fail on SciPy 1.4+ (GH339).
- Dropped support for Python 3.5 inline with NEP 29 (GH334).
- Added methods to compute moment and lower partial moments for standardized residuals. See, for example, `moment()` and `partial_moment()` (GH329).
- Fixed a bug that produced an `OverflowError` when a time series has no variance (GH331).

8.2.9 Release 4.11

- Added `std_resid()` (GH326).
- Error if inputs are not `ndarrays`, `DataFrames` or `Series` (GH315).
- Added a check that the covariance is non-zero when using “studentized” confidence intervals. If the function bootstrapped produces statistics with 0 variance, it is not possible to studentized (GH322).

8.2.10 Release 4.10

- Fixed a bug in `arch_lm_test` that assumed that the model data is contained in a pandas `Series`. (GH313).
- Fixed a bug that can affect use in certain environments that reload modules (GH317).

8.2.11 Release 4.9

- Removed support for Python 2.7.
- Added `auto_bandwidth()` to compute optimized bandwidth for a number of common kernel covariance estimators (GH303). This code was written by Michael Rabba.
- Added a parameter `rescale` to `arch_model()` that allows the estimator to rescale data if it may help parameter estimation. If `rescale=True`, then the data will be rescaled by a power of 10 (e.g., 10, 100, or 1000) to produce a series with a residual variance between 1 and 1000. The model is then estimated on the rescaled data. The scale is reported `scale()`. If `rescale=None`, a warning is produced if the data appear to be poorly scaled, but no change of scale is applied. If `rescale=False`, no scale change is applied and no warning is issued.
- Fixed a bug when using the BCA bootstrap method where the leave-one-out jackknife used the wrong centering variable (GH288).
- Added `optimization_result()` to simplify checking for convergence of the numerical optimizer (GH292).
- Added `random_state` argument to `forecast()` to allow a `RandomState` object to be passed in when forecasting when `method='bootstrap'`. This allows the repeatable forecast to be produced (GH290).
- Fixed a bug in `VarianceRatio` that used the wrong variance in nonrobust inference with overlapping samples (GH286).

8.2.12 Release 4.8.1

- Fixed a bug which prevented extension modules from being correctly imported.

8.2.13 Release 4.8

- Added Zivot-Andrews unit root test *ZivotAndrews*. This code was originally written by Jim Varanelli.
- Added data dependent lag length selection to the KPSS test, *KPSS*. This code was originally written by Jim Varanelli.
- Added *IndependentSamplesBootstrap* to perform bootstrap inference on statistics from independent samples that may have uneven length (GH260).
- Added *arch_lm_test()* to perform ARCH-LM tests on model residuals or standardized residuals (GH261).
- Fixed a bug in *ADF* when applying to very short time series (GH262).
- Added ability to set the *random_state* when initializing a bootstrap (GH259).

8.2.14 Release 4.7

- Added support for Fractionally Integrated GARCH (FIGARCH) in *FIGARCH*.
- Enable user to specify a specific value of the *backcast* in place of the automatically generated value.
- Fixed a big where parameter-less models were incorrectly reported as having constant variance (GH248).

8.2.15 Release 4.6

- Added support for MIDAS volatility processes using Hyperbolic weighting in *MidasHyperbolic* (GH233).

8.2.16 Release 4.5

- Added a parameter to forecast that allows a user-provided callable random generator to be used in place of the model random generator (GH225).
- Added a low memory automatic lag selection method that can be used with very large time-series.
- Improved performance of automatic lag selection in ADF and related tests.

8.2.17 Release 4.4

- Added named parameters to Dickey-Fuller regressions.
- Removed use of the module-level NumPy RandomState. All random number generators use separate RandomState instances.
- Fixed a bug that prevented 1-step forecasts with exogenous regressors.
- Added the Generalized Error Distribution for univariate ARCH models.
- Fixed a bug in MCS when using the max method that prevented all included models from being listed.

8.2.18 Release 4.3

- Added *FixedVariance* volatility process which allows pre-specified variances to be used with a mean model. This has been added to allow so-called zig-zag estimation where a mean model is estimated with a fixed variance, and then a variance model is estimated on the residuals using a *ZeroMean* variance process.

8.2.19 Release 4.2

- Fixed a bug that prevented `fix` from being used with a new model (GH156).
- Added `first_obs` and `last_obs` parameters to `fix` to mimic `fit`.
- Added ability to jointly estimate smoothing parameter in EWMA variance when fitting the model.
- Added ability to pass optimization options to ARCH model estimation (GH195).

8.3 Version 3

- Added forecast code for mean forecasting
- Added volatility hedgehog plot
- Added `fix` to arch models which allows for user specified parameters instead of estimated parameters.
- Added Hansen's Skew T distribution to distribution (Stanislav Khrapov)
- Updated IPython notebooks to latest IPython version
- Bug and typo fixes to IPython notebooks
- Changed MCS to give a pvalue of 1.0 to best model. Previously was NaN
- Removed `hold_back` and `last_obs` from model initialization and to `fit` method to simplify estimating a model over alternative samples (e.g., rolling window estimation)
- Redefined `hold_back` to only accept integers so that is simply defined the number of observations held back. This number is now held out of the sample irrespective of the value of `first_obs`.

8.4 Version 2

8.4.1 Version 2.2

- Added multiple comparison procedures
- Typographical and other small changes

8.4.2 Version 2.1

- Add unit root tests: * Augmented Dickey-Fuller * Dickey-Fuller GLS * Phillips-Perron * KPSS * Variance Ratio
- Removed deprecated locations for ARCH modeling functions

8.5 Version 1

8.5.1 Version 1.1

- Refactored to move the univariate routines to *arch.univariate* and added deprecation warnings in the old locations
- Enable *numba* jit compilation in the python recursions
- Added a bootstrap framework, which will be used in future versions. The bootstrap framework is general purpose and can be used via high-level functions such as *conf_int* or *cov*, or as a low level iterator using *bootstrap*

CITATION

This package should be cited using Zenodo. For example, for the 4.13 release,
