Barry Hanslit

Summary

Barry Hanslit acquired the 8,893 acres (3,599 ha) that compose the nine Big Ledge claims as part of a larger package of claims in the early spring of 2006. The claims were purchased by Kazuki Nohdomi in the spring of 2012. The Big Ledge claims are located within portions of National Topographic System (NTS) 1:50,000-scale map sheets 82L/08, 82L/09, 82K/05 and 82K/12 in the Slocan Mining District of British Columbia, approximately 60 km south of Revelstoke and 31 km northwest of Nakusp.

Exploration has been performed within the property area since 1892. During which time, numerous geological, geochemical and geophysical surveys were conducted. Additionally, exploration has resulted in four adits, trenching and over 10,000 m of drilling. The most recent work on the property was conducted by Teck Corp. between 1991 and 1993, including widely spaced soil and magnetometer surveys, trenching and diamond drilling. Regional mapping by the GSC reveals the Big Ledge to be primarily underlain by rocks of the Thor-Odin gneiss dome of the Proterozoic Monashee Complex and metamorphic rocks of the Proterozoic to Paleozoic Kootenay Assemblage. These rocks are schist and gneiss, calcareous quartzite, calc-silicate gneiss, marble and amphibolite. On the property, rocks are folded into a series of east-west trending, open to tight folds, inclined to the south, overturned to the north and plunging variably to the east and west. The Big Ledge horizon is 30m of a mineralized quartzite unit in the core of a fold which is likely a tight antiform, inclined to the south and overturned to the north.

Between June 6 and 10, 2012, one 500 foot hole was drilled on the property. The logging road access has been significantly degraded and transport into the site was difficult. No mineralization was intersected.

Further drilling at the extremities of the known mineralization is recommended and follow up on the anomalies identified in the 2010 ground geophysical surveys. This deposit is highly prospective and to facilitate more extensive in-depth programs on this property, a joint-venture partner should be sought out.

1.0 INTRODUCTION

Barry Hanslit acquired the 8,893 acres (3,599 ha) that compose the nine Big Ledge claims as part of a larger package of claims in the early spring of 2006. The claims were purchased by Kazuki Nodhomi in the spring of 2012 and he is currently the owner/operator on the claims. The Big Ledge claims are located within portions of National Topographic System (NTS) 1:50,000-scale map sheets 82L/08, 82L/09, 82K/05 and 82K/12 in the Slocan Mining District of British Columbia, approximately 60 km south of Revelstoke and 31 km northwest of Nakusp (Figure 1 and 2).

Exploration has been performed within the property area since 1892. During this time, numerous geological, geochemical and geophysical surveys were conducted. Additionally, exploration has resulted in four adits, trenching and over 10,000 m of drilling. The most recent work on the property was conducted by Teck Corp. between 1991 and 1993, including widely spaced soil and magnetometer surveys, trenching and diamond drilling. Minor diamond drilling and rock sampling was carried out by Barry Hanslit in 2006 revealing weakly anomalous rock samples (Hanslit, 2007). Regional mapping by the GSC reveals the Big Ledge to be primarily underlain by rocks of the Thor-Odin gneiss dome of the Proterozoic Monashee Complex and metamorphic rocks of the Proterozoic to Paleozoic Kootenay Assemblage. These rocks are schist and gneiss, calcareous quartzite, calc-silicate gneiss, marble and amphibolite. On the property, rocks are folded into a series of east-west trending, open to tight folds, inclined to the south, overturned to the north and plunging variably to the east and west. The Big Ledge horizon is 30m of a mineralized quartzite unit in the core of a fold which is likely a tight antiform, inclined to the south and overturned to the north (Figure 3).

In June of 2012, diamond drilling was conducted on the Big Ledge by Barry Hanslit on behalf of Kazuki Nodhomi. This report documents that work, and also provides a description of claims, location, access, physiography and other relevant information. A discussion of the deposit mineralogy follows a description of regional and property scale geology.

 Assessment Report

2.0 DESCRIPTION OF LANDHOLDINGS

2.1 Location and Mineral Claims

The Big Ledge Property comprises 9 mineral claims (8,893 acres) bordered to the north by Big Ledge Creek and to the south by Vanstone Creek. The claims stretch approximately 13.5 kilometers from Upper Arrow Lake towards the border of Monashee Park in British Columbia. The property is located 60 km south of Revelstoke and 31 km northwest of Nakusp within National Topographic System (NTS) 1:50,000-scale map sheets 82 L/08,82L/09,82 K/05 and 82K/12 (Figure 2). The mineral claims were staked by Barry Hanslit in the early spring of 2006 as shown in Appendix I. Work on the property was conducted by Barry Hanslit. Additional claim information is provided in Appendix I.

2.2 Access

The Big Ledge property is located approximately 60 kilometers south of Revelstoke and 31 km northwest of Nakusp. The property can be accessed by logging roads in the summer months south of Revelstoke on Highway 23 to the Shelter Bay logging roads, then traveling 18km south to the Limekiln spur road, and finally an additional 3.1km to Odin road.

2.3 Physiography, Flora and Fauna

The property lies west of Upper Arrow Lake and east along the Monashee Mountain Range. Elevations on the property range from 2,200 meters in the west to roughly 500 meters on Upper Arrow Lake. The property is vegetated in a mixture of fir and cedar with open underbrush at lower elevations, and sub-alpine spruce forests at higher elevations (Evans, 1993). Outcrop is rare to the east of the property and more abundant (averaging 80%) in the west. Ungulates such as elk, moose and deer winter along Upper Arrow Lake. Other wildlife in the region includes black and grizzly bears. In addition, trout occupy some of the lakes and rivers.

2.4 Property History

The Big Ledge Property has been the focus of exploration since 1892, when the deposit was originally staked as a gossan. By 1925, 210 metres of underground work in 4 adits had been completed on the Bonanza, Sunshine, Skyline and Adventurer claims. In 1927, 16 holes were drilled on the property (BCGS, 2007). Consolidated Mining and Smelting Company of Canada Ltd. (Cominco) combined a large portion of the deposit in 1947 and by 1953 they drilled 6,100 metres on the property. In 1960, the ground was re-staked as the BL group. From 1964 to 1966, approximately 3,960 metres of drilling, geological mapping and geochemical and magnetometer surveys were carried out.

Since that time numerous other companies have explored within the area around the Big Ledge. In 1977, Metallgesellschaft and Cyprus Anvil Mining Corp.

mapped the geology. Esperanza Explorations completed geotechnical, geophysical and geochemical surveys between 1980 and 1981. Geochemical and geological surveys were carried out in the vicinity of the Big Ledge by Noranda in 1988 and 1989. Between 1991 and 1993, Teck Corp. mapped the property, conducted widely spaced soil and magnetometer surveys, trenched and performed diamond drilling (Evans, 1993). Between 2006 and 2009, Barry Hanslit drilled on the property and did not intersect mineralized horizons (Hanslit, 2007; 2008; 2009; 2010; 2012). Rock sampling in 2006 resulted in several weakly anomalous samples (Hanslit, 2007). A ground magnetic survey was carried out in 2010 and identified some scattered magnetic anomalies (Hanslit, 2011).

3.0 GEOLOGY

3.1 Regional Geology

This area has been mapped in 1977, 1979 and 1985 by the GSC and is primarily underlain by rocks of the Thor-Odin gneiss dome of the Proterozoic Monashee Complex and metamorphic rocks of the Proterozoic to Paleozoic Kootenay Assemblage. The Thor-Odin is one of a series of gneiss domes spaced approximately 80 kilometres apart on the eastern edge of the Shuswap Complex. The Shuswap metamorphic rocks are part of the Proterozoic-Mesozoic amphibolite grade complex intruded by Eocene granodiorites and pegmatites (Evans, 1993; BCGS, 2007).

A central core zone in the Thor-Odin dome consists of gneissic and migmatitic rocks. This zone is surrounded by a heterogeneous assemblage of metasedimentary rocks of the Mantling zone and Fringe zone, the latter containing abundant pegmatite and lineated quartz monzonite. The Supracrustal zone, consisting of quartzite, marble, phyllite, schist and metavolcanic rocks, forms a cover to the gneisses (BCGS, 2007).

The Big Ledge deposit is located south of the Core zone in an east-west trending succession of metasedimentary rocks of the Mantling zone. The rusty weathering succession consists of a heterogeneous mixture of schist and gneiss, calcareous quartzite, calcsilicate gneiss, marble and amphibolite. The structure is dominated by a series of east-west trending, open to tight folds. These are inclined to the south, overturned to the north and plunge variably to the east and west. The mineralized horizon is within the core of a tight antiform, inclined to the south and overturned to the north. (BCGS, 2007)

Diamond Drilling Assessment Report		

3.2 Property Geology

The property geology shown in Figure 4, based on the data from BCGS online geology map, shows that the majority of the property is underlain by Proterozoic to Lower Paleozoic Monashee Complex comprised of calc-silicates, paragneiss and quartz-quartz arenite. Calc-silicate metamorphic rocks underlying the main body of the claims are faulted through the center of the claims. To the north, paragneiss is thrust over a thin layer of quartzite and quartz arenite. Along the northern border of claim 527425, separated by a thrust fault is Early Proterozoic orthogneiss. South of the main body of calcsilicates is paragneiss. Lying in an arc through claims 527374, 527436 and 527431 is Late Paleocene to Early Eocene granite and alkali feldspar granite intrusive rocks.

Property-scale mapping by Teck Corp. revealed the property to consist of approximately 60% biotite-sillimanite schists interbedded with quartzites and amphibolites as well as the occasional marble unit. The Fawn Lake assemblage strikes east-west to north-south with generally moderate to shallow dip to the south or east. No evidence of “tops” was found. Through a portion of 527436 are large sill-like bodies of pegmatite and Ladybird intrusives, which have conformably flooded into the amphibolites and biotite schists. Ladybird intrusives comprise less than 10% of the property. Scattered throughout the claims are small Tertiary lamprophyre dykes exhibiting little to no metamorphism. Several styles of folding are evident on property and outcrop scale. Compositional layering is very close to being parallel to bedding with isoclinal folds common along the axial plane. Limited lineation measurements indicate a shallow westerly plunge. There may be several stages of folding along this orientation related to the peak of metamorphism. Later broad, one to fifty meter scale, folds can be seen along Upper Arrow Lake. Faulting along the foliation is common with no true sense of offset. Late stage faults are apparent along north-south trends such as Pingston Creek with a left lateral offset.

Detailed geologic mapping by Teck Corp. resulted in more detailed rocks descriptions of lithologies within the property area. These have been provided below, they are not listed in any stratigraphic order.

0 km 0.5 1 2

SHUSWAP ROCKS (Proterozoic - Mesozoic)

- 1a) Massive Amphibolite - Amphibole dominated medium- to coarse-grained groundmass with lesser amounts of biotite and plagioclase. Commonly contains varying amounts of almandine garnet (<2 cm in size) in layered amphibolites.
- 1b) Amphibolite with Calc-silicate Laminations - The same amphibolite unit as 1a with alternating bands of quartzite and diopside-tremolite-actinolite. Laminations are generally on a one centimeter scale or less.
- 1c) Amphibolite with Biotite Schist - A mixture of medium-grained amphibolites containing an equal amount of micas (biotite and muscovite), commonly contains sillimanite aggregates.
- 2) Biotite Schist – Well-laminated biotite with lesser muscovite-bearing schists that may contain quartzite laminations and occasionally 0.5 cm almandine garnets. The surface is strongly gossanous due to high iron content and trace amounts of disseminated pyrite and pyrrhotite are present.
- 3) Biotite Gneiss – The matrix is dominated by finely laminated, medium-grained white-grey quartzite with 20 to 30% biotite schist laminations varying in thickness from 0.5-10 cm.
- 4a) Quartzite – Medium-grained quartzite in beds 10 to 20 cm in thickness with preferential weathering of certain beds due to change in grain size and carbonate content. Color varies from white to buff to grey. Minor rutile, biotite and muscovite grains are present.
- 4b) Quartzite with Flake Graphite - Dull grey colored fine-grained quartzite with trace to 20% disseminated flake graphite grains. Typically contains two to 10% disseminated pyrite and pyrrhotite with trace amounts of disseminated sphalerite.
- 4c) Quartzite with Calc-silicate Laminations – Medium-grained quartzite is light green color with diopside in the matrix. There are occasional laminations of calc-silicates consisting of diopside, tremolite and actinolite. Calc-silicates contain minor grains of rutile, muscovite and biotite.
- 5a) Marble - Marble units normally appear as grey massive weathered units grading to dark grey with increasing graphite component. Calcite grains are 1 to 3mm and bedding is usually apparent with graphitic beds or minor calc-silicate laminations. Occasionally flake graphite disseminations are present within the marble.
- 5b) Calc-silicates +/- Marble - These rocks are a pale green with beds and preferentially eroded pods of marble. The calc-silicates consist of impure quartzites containing diopside, amphibole and biotite with minor rutile and muscovite.

JURASSIC ROCKS (above Columbia and Okanogan Faults)

- 6a) Argillite - Graphitic argillite and phyllite with strong slaty cleavage. Bedding is preserved with interbedded greywackes common.
- 6b) Mafic Volcanics - Pervasive chlorite alteration in various mafic volcanic units with a strong schistosity developed. Remnant textures include laminated tuffs, vesicular flow and lapilli tuff.

TERTIARY LADYBIRD LEUCOGRANITE SUITE

- 7a) Pegmatites – Coarse-grained dykes, sills and small plugs of pegmatites are common. Rock is dominated by 0.5-1 cm crystals of quartz, alkali feldspar and plagioclase with varying lesser amounts of biotite, muscovite and tourmaline.
- 7b) Ladybird Granites - Fine- to medium-grained stocks and plutons. Compositionally these rocks range from granite to quartz monzonite. Minerals consist of plagioclase, alkali feldspar and quartz with accessory muscovite, biotite and occasionally garnet.

EOCENE DYKES

- 8) Lamprophyre Dykes - Unaltered extremely mafic dykes with a dark brown fine-grained biotite, amphibole and mafic matrix with occasional vesicles and calcite filled amygdules.

3.3 Deposit Mineralogy

The Big Ledge contains showings of pyrrhotite, pyrite, sphalerite, galena, chalcopyrite and marcasite occurring along a layer known as the Ledge for a distance of over 10 kilometres. Indicated ore reserves are 6.5 million tonnes grading less than 6 per cent combined lead and zinc (CIM Bulletin Vol. 75, No. 840, page 119).

The Big Ledge is hosted in a quartzite package consisting of fine grained, dark graphitic-sericitic schist, dark quartz-rich schist, calc-silicate gneiss and minor siliceous marble layers. Pyrite and pyrrhotite are disseminated throughout these units resulting in a characteristic rusty weathering. Drilling indicates that there are at least four massive sulphide layers within the Big Ledge. It is not known if these are individual layers or fold repetitions of one or more layers. The massive sulphide layers consist of medium- to coarse-grained pyrrhotite or pyrite with varying amounts of dark sphalerite. This massive sulphide layer can be 5 to 75% of the sequence (Evans, 1993). Quartz-eyes are common in the massive sulphide layers and sphalerite is typically aligned parallel to layering in the adjacent schists (BCGS, 2007).

The Big Ledge averages 30 metres in thickness and is conformable to bedding. Pyrrhotite is the most abundant sulphide and pyrite, usually in nodular masses, is locally abundant. Sphalerite is erratically distributed with the

pyrrhotite. Galena is occasionally present in minor amounts along with the other sulphides, but the only notable concentrations are small occurrences in calcareous beds adjacent to the main mineralized sections. In general, the sulphides are coarse-grained and a small amount of the ore minerals are intergrown with pyrrhotite. Iron sulphides are usually accompanied by scattered graphite flakes.

A zone of heavier mineralization occurs in the upper portion of the rock series. This zone ranges from 0.61 to 6 metres in thickness and is conformable with bedding, but the sulphides are erratically distributed in irregular massive and disseminated bodies. There is a large amount of granitic and pegmatitic material in this zone. Sphalerite appears to be most abundant in disseminated sulphide sections, but small irregular high-grade patches occur with both the massive and disseminated sulphides (BCGS, 2007). While the thickness of this horizon is unusually large in many respects it could be considered a typical Shuswap style Zn-Pb-Ag system. Alteration is essentially absent supporting a possible syngenetic origin for this system such as in a sedimentary exhalative Zn-Pb system.

4.0 2012 EXPLORATION PROGRAM

4.1 Introduction

Diamond drilling was completed on the property in the summer of 2012 by Barry Hanslit on behalf of Kazuki Nodhomi. Costs associated with the program and personnel are listed in Appendix II and III respectively. The details and results of the program will be discussed in the subsequent section, and drill logs can be found in Appendix IV.

4.2 2012 Diamond Drilling

Drilling took place from the existing logging roads located at UTM NAD 83, 11U 428387E, 5590678N oriented at 0° azimuth and 45° dip and was fully reclaimed upon completion (Figure 5). Drill cuttings were left to dry out and hauled off-site. Core was logged on-site by Barry Hanslit and stored on-site with the Teck Corp. core at 11U 428098E, 5591260N. Drilling was accomplished with the help of Steven Bachen using a Model A5 drill from Zinex Mining Corp. drilling NQ core. The road into the site was seriously degraded and the drill and equipment had to be broken down and hauled in by truck. This added an extra day to the mobilization. Casing was difficult as expected and a total depth of 500 feet was drilled. Magnetic susceptibility readings were taken on the core using a KT-10 magnetometer on the core setting. An average of 5-6 readings were taken for each rock unit. Work was completed between June 6 and 10, 2012.

	0 meters 5 10 20

4.3 2012 Diamond Drilling Results

The hole was oriented north (0 azimuth) with a 45° dip and was 500 feet (approximately 152m) in depth. The drill hole was located in a logging road pull-out at approximately 3,150 feet in elevation did not intersect any mineralization. The overburden was deep (9.5 m) and full of boulders. As in previous years the main rock types intersected were garnet-bearing biotite schist with marble and quartzite interbeds. The concentration and size of the garnets within the biotite schist unit are larger at depth in the hole. Quartzite (in marble/quartzite units) and quartz veining (in biotite schist) are more dominant at depth with interbeds becoming wider and more common. No mineralization was intersected. Magnetic susceptibility readings on all units are close to zero. The schist units ranged from 0 to 1 SI, with quartzite beds registering 0.001 SI (recorded as zero in the drill logs). A cross-section of the drill hole is provided in figure 6.

4.0 CONCLUSIONS AND RECOMMENDATIONS

Diamond drilling on the property for the season was designed to hold the property while pursuing joint-venture opportunities that will be able to perform more detailed exploration. The core was logged superficially and not in enough detail to clearly identify the sequence of rocks and how they relate to the Big Ledge horizon. Drilling did not encounter mineralization and future drill work should be focused on expanding the known resource, or pursuing anomalies detected in the ground geophysical work. Future prospecting and further ground magnetic surveys should be performed with the focus outside the known area of mineralization to identify other possible zones of interest.

The Big Ledge is a highly prospective deposit that has a long history of exploration and deserves further work. A more extensive, in-depth program should be pursued with a joint-venture partner.

Appendix II

Project Cost Schedule

Statement of Expenditures (1 page)

The expenditures on the Big Ledge (\$18,100) were generated during the diamond drilling program between June 6 and 10, 2012. The costs are summarized as the drilling costs (\$15,000.00) and personnel costs (\$3,100.00).

Drilling costs were \$30.00 per foot for 500 feet of drilling this cost includes equipment rental, parts and consumables such as drill muds. Personnel on the project include those in the field and the office. Man-days are shown for the drilling component (8 man days) as well as for report and field preparation (1.25 man days). Camp costs are not shown as personal camp gear was used on the project.

Appendix II

Big Ledge 2012 Drilling Project Cost Schedule

Drilling Costs

include equipment rental, drilling parts and consumables

	Cost per foot	Total feet	
Zinex Mining Corp.	\$30.00	500	\$15,000.00
Subtotal Drilling Costs			\$15,000.00

Personnel Costs

Activity	Person	Day Rate	Days	Total
Field Preparation				
	Barry Hanslit	\$400.00	0.5	\$200.00
In the Field				
	Barry Hanslit	\$400.00	4	\$1,600.00
	Steve Bachen	\$250.00	4	\$1,000.00
Report Preparation				
	Barry Hanslit	\$400.00	0.25	\$100.00
	Janet Miller	\$400.00	0.5	\$200.00
Subtotal Personnel Costs				\$3,100.00

Grand Total \$18,100.00

Appendix III

List of Project Personnel

List of Project Personnel

The following personnel were involved in the acquisition, processing, interpretation, and presentation of data relating to work performed on the Big Ledge, BC. Duties were performed at various times between June 6, 2012 and June 10, 2012. Contact addresses can be obtained through Barry Hanslit at:

Appendix V
Certificate of Authors

CERTIFICATE OF AUTHORS

I, Janet L. P. Miller, of Whistler, British Columbia, Canada do hereby certify that:

1. I was an employee of Strongbow Exploration Inc. formerly Navigator Exploration Corp., 800-625 Howe St., Vancouver, British Columbia, Canada from 2000 to 2005.
2. I graduated from the University of British Columbia (2004) with a BSc in Honours Geology with a minor in Biology.
3. I have been employed continuously in geology during the summer terms of my education with a focus in diamond exploration.
4. I have been active in the field aspects of diamond and base metal exploration for four years (2002-2005) in the Northwest Territories and Nunavut, including project management, planning and implementation, as well as detailed mapping of surficial deposits, sampling, prospecting, and ground truthing geophysical anomalies on various properties.
5. I have been involved in data compilation, and analysis for diamond and base/precious metal exploration from 2000-2006 under the supervision of a registered professional geologist, and have been involved in a number of aspects of projects in the Northwest Territories, British Columbia, and Nunavut.
