Executive Summary

This report is intended to verify the compliance of the Hauptman-Woodward Medical Research Institute with ASHRAE Standard 62.1-2004, using the prescribed Ventilation Rate Calculation Procedure. The Hauptman Woodward Institute is a 3 story, 73,000 square foot building consisting of office and collaborating space, as well as a biomedical research lab with supporting instrument and experiment spaces. Located between these two distinct areas is a grand atrium and lobby which serves as a gathering space and a bridge between the offices and laboratory spaces.

The Hauptman-Woodward Institute has 3 primary air systems which serve the building. Two rooftop units supply approximately 42,500 cfm of mixed air to the south and west portions of the building, and two air-handling units located in the roof penthouse provide 58,000 cfm of 100% outside air to the laboratory and supporting spaces. A fourth air handling unit, providing 3,000 cfm of makeup air to the penthouse, was not analyzed in this report.

The ventilation distribution effectiveness for each zone was required in order to complete the ventilation rate procedure. According to Table 6-2 of ASHRAE Standard 62.1-2004, the assumed ventilation distribution effectiveness (Ez) for the Hauptman-Woodward Institute was 0.8, based upon warm air which is supplied and returned through ceiling diffusers.

ASHRAE Standard 62.1-2004 was followed to determine the minimum required amount of outdoor air each system much supply. It was found that for each rooftop unit, the sum of the zone outdoor airflow (SVoz) was less than the design outdoor air intake airflow (Vot). According to the design schedules, the minimum outdoor air was sufficient to comply with Standard 62.1. In addition, the air handling units that supply the laboratory space provide 100% outdoor, thus provide a significantly greater amount of required outside air than is required to the laboratory. It is therefore in compliance with Standard 62.1.

Assumptions

1. The majority of the spaces at the Hauptman-Woodward Medical Research Institute fell into the occupancy categories listed in Table 6-1 of the Standard. For those that did not directly fall into one of those categories, the following assumptions were made:

A. All spaces in the laboratory research area, including Instrument Rooms, Fume Hoods, Equipment Rooms, Chromatography, etc were treated as "Education – Science Laboratories".

B. Vestibules, elevator lobbies, pass throughs, and other areas associated with corridor spaces were treated as corridors.

C. IT Server Rooms were treated as "Educational – Computer Labs".

2. All design occupancies used for the spaces are determined from the supplied architectural drawings by counting the number of chairs in each space. For spaces without furniture, the design condition was determined by the occupant density in Table 6.1 of ASHRAE Standard 62.1-2004.

3. Diversity of 1.0 is assumed as this is the most conservative value for required outdoor air.

4. ASHRAE Standard 62.1-2004 assumes that the outdoor air intake is sufficiently far away from the exhausted air of the building to ensure that outdoor air supply is not recirculated exhausted air.

5. It is assumed that when less then 100% outdoor is supplied that the outdoor air is evenly mixed with the recirculated return air.

6. Appendix A is used to determine System Ventilation Efficiency when the max Zp exceeds 0.55.

Description of Air Systems

The Hauptman-Woodward Medical Research Institute has 3 air systems in which this report will focus on. This section will describe the systems and what parts of the building they support. In general, the spaces that will be looked at in this report consist of offices, conference areas, library and computer lab spaces, and finally, laboratory and supporting spaces. The 4 Air Handling Units that serve these three systems supply approximately 102,475 CFM to the building, of which 68,600 CFM is outdoor air. For the duration of this report, the three systems which will be described will be referred to as System 1, System 2, and System 3. These systems will each be explained below.

System 1 is a recirculating air system that serves the western offices and supporting spaces on Floors 1-3 of the building. The air-handling unit that coincides with this system is RTU-1, which is located on the roof of the building. In addition to office space, RTU-1 serves conference rooms, server rooms, the institute's library, lunch room and finally, shipping and receiving areas. The unit supplies a total of 14,175 CFM to the building, of which 3,500 CFM is recirculated.

System 2 is also a recirculating air system that serves the south office spaces on floors 1-3 of the building as well as the three story atrium. The air handling unit that coincides with this system is RTU-2, which is located next to RTU-1 on the roof of the building. The unit supplies a total of 28,300 CFM to the building, of which 7,075 CFM is recirculated to the space.

System 3 is a 100% outdoor-air system that serves the laboratory space within the complex. The system is comprised of two air-handlers, herein named AHU-1 and AHU-2. These units are connected via supply and return plenums and together, provide the necessary supply air to handle 100% of the anticipated load. Located in this space are the primary research labs, as well as supporting space including growth labs, equipment and instrument rooms, fume hoods, etc. Each unit supplies 29,000 CFM outdoor air, for a total of 58,000 CFM to the space.

Procedure

The procedure used for determining the outdoor air intake flow (Vot) for each airhandling unit follows the steps outlined in section 6.2 of ASHRAE 62.1- 2004. Below, each step describes the necessary equations and variables to complete the procedure. Refer to the Assumptions section for any necessary assumptions related to this procedure.

Step 1:

For each space, find the values for the zone floor areas (**A**_z) In addition, determine the zone population (**P**_z). Each of these values can be determined from the building architectural plans. Zone population was determined by counting the number of chairs for each space. In the instance that no occupancy density is provided, Table 6-1 in the standard provides default values to calculate zone population.

Step 2:

Calculate Breathing Zone Outdoor Airflow (Vbz):

$$V_{bz} = R_p * P_z + R_a * A_z$$

Where: Az = Zone floor area Pz = Zone population Rp = Outdoor airflow rate required per person Ra = Outdoor airflow rate required per unit area

Values for the outdoor airflow rate required per unit area (R_a) and the outdoor airflow rate required per person (R_p) can be determined from Table 6-1.

Step 3:

Determine the Zone Air Distribution Effectiveness (Ez) from Table 6-2, based on the design of the air distribution of the building.

Step 4:

Determine the Zone Outdoor Airflow (Voz) based on the following:

$$V_{oz} = V_{bz} / E_z$$

Step 5:

Determine the Zone Primary Outdoor Air Fraction (Z_p) for each zone in the system:

$$Z_p = V_{oz} / V_{pz}$$

Where: V_{pz}= Zone primary airflow

Step 6:

Determine System Ventilation Efficiency (E_v) by consulting Table 6-3 or Appendix A in the standard. If the efficiency is less than or equal to 0.55, Table 6-3 should be used. If the efficiency is more than 0.55, then the procedure described in Appendix A should be used. For the Hauptman-Woodward Medical Research Institute, each method will be used since both cases will occur. See Step 7 below for the procedure and equations used from ASHRAE Standard 62.1-2004 – Appendix A. *If the System Ventilation Efficiency* (E_v) *can be determined from table 6-3, proceed to Step 8.*

Step 7:

ASHRAE Standard 62.1-2004 Appendix A: The information and equations prescribed in this step are used to calculate the value for the system ventilation efficiency when E_v is greater than 0.55 and Table 6-3 cannot be used.

A. Calculate the ratio of the system population to the sum of the zone populations. This is called the Diversity Factor (D).

$$D = P_s / (\Sigma_{all \ zones} P_z)$$

Where: P_s = System population

Since the System Population is the sum of each zone, the diversity factor is 1.

B. Calculate the Uncorrected Outdoor Air Intake (Vou):

$$V_{ou} = D^* \Sigma R_p * P_z + \Sigma R_a * A_z$$

C. Calculate the System Primary Airflow (**V**_{Ps}). The sum of the zone primary airflows is the total supply air from the AHU to all the spaces it serves.

$$V_{ps} = \Sigma V_{pz}$$

D. Calculate the Average Outdoor Air Fraction (X_s):

$$X_s = V_{ou} / V_{ps}$$

E. Calculate the Discharge Outdoor Air Fraction (Zd):

$$Z_d = V_{oz} / V_{dz}$$

For VAV systems, the zone discharge airflow (Vdz) is equal to the amount of supply air to the space.

F. Calculate the System Ventilation Efficiency (Ev):

$$E_{vz} = 1 + X_s - Z_d$$
$$E_v = minimum (E_{vz})$$

Step 8:

Calculate the Occupant Diversity (**D**). The diversity factor is the ratio of the system populations to the sum of the zone populations.

$$D = P_s / (\Sigma_{all \ zones} P_z)$$

Where: P_s = System population

Step 9:

Calculate the Uncorrected Outdoor Air Intake (Vou). The uncorrected outdoor air intake is adjusted for diversity.

$$V_{ou} = D^* \Sigma R_p * P_z + \Sigma R_a * A_z$$

Step 10:

Determine the Design Outdoor Air Intake Flow (Vot):

 $V_{ot} = V_{ou} / E_v$

Calculations

Following the procedure outlined in the previous section, the design outdoor air intake flow (V_{ot}) will be calculated in this section. For all equations and variables used in the calculation, refer back to the Procedure section.

It was observed after computing the primary outdoor air fractions (\mathbf{Z}_P) that System 1 had a primary outdoor air fraction greater than 0.55. Since this was the case, the system efficiency (\mathbf{E}_v) was calculated from Appendix A. For System 2, the zone primary outdoor air fraction was greater than 0.55; therefore the system efficiency was calculated from Table 6-3. Since the procedure using Appendix A requires one extra step of calculations, System 1 will be shown to demonstrate the procedure listed in the previous section.

As shown in the appendices, the critical zone for System 1 was the Computer/Visual lab (Room 221) located on the west side of the building. The lab has an area of 270 square feet and has a supply of 300cfm. To calculate the design outdoor air intake flow (V_{0t}) for System 1, the following steps were used, as outlined in the procedure:

Step 1: A_z = 270 square feet P_z = 10 people

Step 2:

 $R_{p} = 10 \text{ cfm/person}$ $R_{a} = 0.12 \text{ cfm/square foot}$ $A_{z} = 270 \text{ square feet}$ $P_{z} = 10 \text{ people}$ $V_{bz} = R_{p}*P_{z}+R_{a}*A_{z} = (10 \text{ cfm/person})*(6 \text{ people}) + (0.12 \text{ cfm/square foot})*(270 \text{ square feet})$ $V_{bz} = 92.4 \text{ cfm}$

Step 3:

 $E_z = 0.8$ (from Table 6-2, for ceiling supply of warm air 15°F or more above space temperature and ceiling return)

Step 4:

 $V_{oz} = V_{bz} / E_z = 92.4 \text{ cfm} / 0.8$ $V_{oz} = 116 \text{ cfm}$

Step 5:

 $Z_p = V_{oz} / V_{pz} = 116 \text{ cfm} / 150 \text{ cfm}$ $Z_p = 0.77$ Max. $Z_p = 0.77$

Step 6:

Must follow Appendix A procedure to find $E_{v, \text{ since }} Z_p = 0.77 > 0.55$

Step 7A:

 $D = P_s / (\Sigma_{all \ zones} P_z)$ where: $P_s = \Sigma_{all \ zones} P_z$ D = 1.0

Step 7B:

 $V_{ou} = D^* \Sigma R_p * P_z + \Sigma R_a * A_z = (1.0)^* \Sigma R_p * P_z + \Sigma R_a * A_z$ $V_{ou} = \Sigma V_{oz}$ $V_{ou} = 2,504 \text{ cfm}$

Step 7C:

 $V_{ps} = \Sigma V_{pz}$ $V_{ps} = 7,430 \text{ cfm}$

Step 7D:

 $X_s = V_{ou} / V_{ps} = 2,504 \text{ cfm} / 7,430 \text{ cfm}$ $X_s = 0.34$

Step 7E:

 $Z_d = V_{oz} / V_{dz} = 116 \text{ cfm} / 300 \text{ cfm}$ $Z_d = 1.26$

Step 7F: $E_{vz} = 1 + X_s - Z_d = 1 + 0.34 - 0.39$ $E_{vz} = 0.95$

Step 7G:

 $E_v = minimum (E_{vz})$ $E_v = minimum (0.95) = 0.95$ Step 8:

 $D = P_s / (\Sigma_{all \ zones} P_z) \qquad (where \ P_s = \Sigma_{all \ zones} P_z)$ D = 1.0

Step 9:

 $V_{ou} = D^* \Sigma R_p * P_z + \Sigma R_a * A_z = (1.0)^* \Sigma R_p * P_z + \Sigma R_a * A_z$ $V_{ou} = \Sigma V_{oz}$ $V_{ou} = 2,504 \text{ cfm}$

Step 10:

 $V_{ot} = V_{ou} / E_v = 2,504 \text{ cfm} / 0.95$ $V_{ot} = 2,635 \text{ cfm}$

Discussion

Comparison of Nominal Outside Air and Required Outside Air for Each System

System 1:

RTU-1 supplies mixed air to floors 1-3 of the west side of the building. Following the procedure of ASHRAE 62.1-2004, the required outside airflow to the space was determined to be 2,504 cfm, and the design outdoor air intake flow was 2,635 cfm. Since the design as verified by the mechanical schedules, the actual amount of outdoor air supplied to the space from the unit is 3,500cfm and the total air supply was 14,175 cfm. Since the actual value of outdoor air supplied to the unit is greater than the required outdoor air quantity, *RTU-1 is in compliance with ASHRAE Standard* 62.1-2004.

System 2:

RTU-2 supplies mixed air to floors 1-3 of the south side of the building, which is predominantly office space and includes the 3-story atrium. Following the procedure of ASHRAE 62.1-2004, the required outside airflow to the space was determined to be 3,530 cfm, and the design outdoor air intake flow was 5,885 cfm. As verified by the mechanical schedules, the actual amount of outdoor air supplied to the space from the unit is 7,075 cfm and the total air supply was 28,300 cfm. Since the actual value of outdoor air supplied to the unit is greater than the required outdoor air quantity, *RTU-2 is in compliance with ASHRAE Standard* 62.1-2004.

System 3:

AHU-1 and AHU-2 are ducted together in parallel, and combined provide 100% outside air to the laboratory space. Following the procedure of ASHRAE 62.1-2004, the required outside airflow for the space was determined to be 5,892 cfm. As verified by the mechanical schedules, the actual amount of outdoor air supplied to the unit is 58,000 cfm. Since the actual value of outdoor air supplied to the unit is greater than the required outdoor air quantity, *the system served by AHU-1 and AHU-2 is in compliance with ASHRAE Standard* 62.1-2004.

Ventilation Rate Procedure compared to Indoor Air Quality Procedure

Within ASHRAE Standard 62.1-2004, two different methods are described for determining required outdoor air requirements. The first method is the Ventilation Rate Procedure, which is a very straightforward means of finding the required outside air rates. Alternatively, the Indoor Air Quality Procedure is an alternate way to determine these requirements. The Indoor Air Quality Procedure is more of a performance-based design approach, in that it analyzes the concentration of contaminants in the space. Below, each method will be discussed and their major differences and applications will be compared.

Ventilation Rate Procedure

The method used in this report to determine the amount of required air at the Hauptman-Woodward Medical Research Institute is the Ventilation Rate Procedure. This procedure has a very straightforward approach in that it consists of a series of equations for find the rate of outside air intake to the building. If all floor areas, occupancies, and uses are known, this process can be followed very easily. The Standard lists in Table 6-1 of Standard 62.1-2004 general contaminant concentrations in various space designations, and provides design values based on floor areas and occupancy levels.

Indoor Air Quality Procedure

The Indoor Air Quality Procedure defines a number of contaminants as well as acceptable levels that are typical in different types of spaces. Using these constraints, the procedure is able to help one analyze the concentration of contaminants in the space and provides a target value for the concentration of each contaminant within each space. This procedure allows for adjustment by other measures to reduce the levels of contaminants in the system, by means of air cleaning devices or other contaminant removal systems. In addition, the selection of building materials that contain fewer impurities can also reduce the amount of contamination to the building.

<u>Comparison</u>

The Ventilation Rate Procedure and Indoor Air Quality Procedure both provide an accurate procedure to verify the amount of outside air required to a particular space; however the Ventilation Rate procedure presents an efficient way to determine the acceptable ventilation rate without the requirement of much information. For most practical purposes, the Indoor Air Quality Procedure is too in-depth and could provide difficulty if building information is not available. In addition the simplicity of the Ventilation rate procedure makes its use effective at any stage of the design process, most importantly in the schematic design phase when building materials may not be specified. The Indoor Air Quality Procedure would most likely be better suited to specialized spaces where the contaminant levels were crucial to the function of the building.
