## Chapter 16: Acid-Base Equilibria

## Part One: Pure Solutions of Weak Acids, Bases (water plus a single electrolyte solute)

A. Weak Monoprotic Acids. (Section 16.1)

1. Solution of Acetic Acid:

$$
\mathrm{HAc}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O} \stackrel{\mathrm{~K}_{\mathrm{c}}}{\rightleftharpoons}\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]+\left[\mathrm{Ac}^{-}\right]
$$

$$
\begin{aligned}
& \mathrm{K}_{\mathrm{c}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{Ac}^{-}\right]}{\left[\mathrm{H}_{2} \mathrm{O}\right][\mathrm{HAc}]} \text {, but since }\left[\mathrm{H}_{2} \mathrm{O}\right] \text { always }=55.5 \mathrm{M} \\
& \mathrm{~K}_{\mathrm{c}}\left[\mathrm{H}_{2} \mathrm{O}\right]=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{Ac}^{-}\right]}{[\mathrm{HAc}]}, \quad \text { set } \mathrm{K}_{\mathrm{c}}\left[\mathrm{H}_{2} \mathrm{O}\right] \equiv \mathrm{K}_{\mathrm{a}} \\
& \mathrm{~K}_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{Ac}^{-}\right]}{[\mathrm{HAc}]} \quad \mathrm{K}_{\mathrm{a}}=\text { acid ionization constant } \\
& \mathrm{pK} \mathrm{~K}_{\mathrm{a}}=-\log \mathrm{K}_{\mathrm{a}} \\
& \mathrm{pK}_{\mathrm{a}} \uparrow \text { strength } \downarrow
\end{aligned}
$$

## 3. Calculation of equilibrium concentrations from $\mathrm{K}_{\mathrm{a}}$ :

What is the pH of a 2.0 M aqueous solution of acetic acid?

$$
\mathrm{HAc}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{Ac}^{-}
$$

initial
change
at equilib
$\mathrm{K}_{\mathrm{a}}=\frac{\mathrm{x}^{2}}{2.0-\mathrm{x}}=1.8 \times 10^{-5}$
Could solve the quadratic equation, but there is a simplifying approximation that is very accurate:
$2.0-x \approx 2.0$, since $x \ll 2.0 \mathrm{M}$
$\frac{x^{2}}{2.0} \approx 1.8 \times 10^{-5}$ so $\mathrm{x}^{2} \approx 3.6 \times 10^{-5}$ so $\mathrm{x} \approx \sqrt{3.6 \times 10^{-5}}=0.0060 \mathrm{M}$
$\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\mathrm{x}=0.0060 \mathrm{M}$
$\mathrm{pH}=-\log \left(6.0 \times 10^{-3}\right)=02.2$
Check your approximation:
Is $\quad 2.0-\mathrm{x} \approx 2.0$

$$
x \ll 2.0 \text { and } 0.006 \ll 2.0 \text { yes!! }
$$

4. General formula:
pure solution of weak monoprotic acid $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\sqrt{\mathrm{C}_{\mathrm{A}} \mathrm{K}_{\mathrm{a}}}$
where $\mathrm{C}_{\mathrm{A}}=$ formal concentration of the weak acid
5. Example: Calculate pH of $1.0 \mathrm{M} \mathrm{HF}(a q)$.

$$
\mathrm{HF}(a q)+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{F}^{-}
$$

initial
at equilib
1.0 M
$0 \quad 0$
$1.0-\mathrm{x}$
x
$K_{a}=\frac{x^{2}}{1.0-x}=7.2 \times 10^{-4}$
Assume x << 1.0

$$
\begin{aligned}
& \frac{x^{2}}{1.0}=7.2 \times 10^{-4} \\
& x=\sqrt{7.2 \times 10^{-4}}=2.68 \times 10^{-2}=0.0268 \mathrm{M}
\end{aligned}
$$

Now, is $\mathrm{x} \ll 1.0 \mathrm{M}$ ?
0.0268 << 1.00 borderline!

Could do a successive approximation:

$$
\begin{aligned}
& \frac{x^{2}}{1.0-0.0268}=7.2 \times 10^{-4}, \text { where } 0.0268 \text { is trial solution } \\
& \frac{x^{2}}{0.9732}=7.2 \times 10^{-4} \\
& x^{2}=7.01 \times 10^{-4} \\
& x=\sqrt{7.01 \times 10^{-4}}=0.0265 \mathrm{M} \text { (not much change, really unnecessary) }
\end{aligned}
$$

$$
\begin{aligned}
& {\left[\mathrm{F}^{-}\right]=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\mathrm{x}=0.0265 \mathrm{M}} \\
& \mathrm{pH}=1.58
\end{aligned}
$$

6. Percent ionization calculation of weak acid:
$\%$ ionization $=\frac{[\mathrm{HAc}]_{\text {ionized }}}{[\mathrm{HAc}]_{\text {total }}} \times 100 \%$
$\%$ ionization $=\frac{\left[\mathrm{Ac}^{-}\right]}{[\mathrm{HAc}]+\left[\mathrm{Ac}^{-}\right]} \times 100 \%$

Figure 16.3
7. Example: Calculate $\%$ ionization in a 2.0 M solution of $\mathrm{HCN}(a q)$.

$$
\begin{aligned}
& \mathrm{HCN}(a q)+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{CN}^{-} \\
& \text {initial } \\
& \text { at equilib } \\
& \frac{\mathrm{x}^{2}}{2.0-\mathrm{x}}=4.0 \times 10^{-10} \\
& \frac{x^{2}}{2.0} \approx 4.0 \times 10^{-10} \\
& \mathrm{x}^{2}=8.0 \times 10^{-10} \\
& \mathrm{x}=2.8 \times 10^{-5}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{CN}^{-}\right] \\
& \% \text { ioniz }=\frac{2.8 \times 10^{-5} M}{2.0 \mathrm{M}} \times 100 \% \\
& =1.4 \times 10^{-3} \%=0.0014 \% \text { (very small percent) } \\
& \mathrm{pH}=-\log \left(2.8 \times 10^{-5}\right)=4.55
\end{aligned}
$$

B. Polyprotic Acids. (Section 16.2)

1. Consider $\mathrm{H}_{3} \mathrm{PO}_{4}$ : Have three simultaneous equilibria!!

$$
\begin{aligned}
& \mathrm{H}_{3} \mathrm{PO}_{4}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{H}_{2} \mathrm{PO}_{4}^{-} \\
& \mathrm{K}_{1}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{H}_{2} \mathrm{PO}_{4}^{-}\right]}{\left[\mathrm{H}_{3} \mathrm{PO}_{4}\right]}=7.5 \times 10^{-3} \\
& \mathrm{H}_{2} \mathrm{PO}_{4}^{-}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \\
& \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{HPO}_{4}^{2-} \\
& \mathrm{K}_{2}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{HPO}_{4}^{2-}\right]}{\left[\mathrm{H}_{2} \mathrm{PO}_{4}^{-}\right]}=6.2 \times 10^{-8} \\
& \mathrm{HPO}_{4}^{2-}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \\
& \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{PO}_{4}^{3-} \\
& \mathrm{K}_{3}=\frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{PO}_{4}^{3-}\right]}{\left[\mathrm{HPO}_{4}^{2-}\right]}=3.6 \times 10^{-13}
\end{aligned}
$$

2. Simplifying factor: $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$present at equilibrium will be almost totally due to first step of ionization.
3. Calculate the conc. of all species present in $2.00 M \mathrm{H}_{3} \mathrm{PO}_{4}$.
a. First ionization:

$$
\mathrm{H}_{3} \mathrm{PO}_{4}+\mathrm{H}_{2} \mathrm{O} \stackrel{\mathrm{~K}_{1}}{\rightleftharpoons} \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{H}_{2} \mathrm{PO}_{4}^{-}
$$

$\begin{array}{cccc}\text { at equilib. } 2.00-\mathrm{x} & \mathrm{x} & \mathrm{x}\end{array}$
$\mathrm{K}_{1}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}\right]}{\left[\mathrm{H}_{3} \mathrm{PO}_{4}\right]}=\frac{\mathrm{x}^{2}}{2.00-\mathrm{x}}$
$\mathrm{x} \approx \sqrt{2.00 \mathrm{~K}_{1}}=\sqrt{2.00 \times 7.5 \times 10^{-3}}=0.122 \mathrm{M}$
$\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{H}_{2} \mathrm{PO}_{4}^{-}\right]=0.122 \mathrm{M}$
$\mathrm{pH}=-\log (.122)=0.912$
b. Second ionization:

$$
\begin{gathered}
\mathrm{H}_{2} \mathrm{PO}_{4}^{-}+\mathrm{H}_{2} \mathrm{O} \stackrel{\mathrm{~K}_{2}}{\rightleftharpoons} \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{HPO}_{4}^{2-} \\
0.122-\mathrm{y} \\
0.122+\mathrm{y} \quad \mathrm{y} \\
\mathrm{~K}_{2}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{HPO}_{4}^{2-}\right]}{\left[\mathrm{H}_{2} \mathrm{PO}_{4}^{-}\right]}=\frac{(0.122+\mathrm{y}) \mathrm{y}}{0.122-\mathrm{y}}
\end{gathered}
$$

Assume y << 0.122 M
$\mathrm{K}_{2}=6.2 \times 10^{-8} \approx \frac{0.122}{0.122} \mathrm{y}$
$y=6.2 \times 10^{-8}=K_{2}$
OR:
$\left[\mathrm{HPO}_{4}{ }^{2-}\right]=\mathrm{K}_{2}=6.2 \times 10^{-8}$

General rule: anion produced by second ionization $=\mathrm{K}_{2}$
Second ionization produces additional $6.2 \times 10^{-8} \mathrm{M}$ of $\mathrm{H}_{3} \mathrm{O}^{+}$, which is negligible.
Still $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=0.122 \mathrm{M}$ (from first ionization)
c. Third ionization:

$$
\mathrm{HPO}_{4}^{2-}+\mathrm{H}_{2} \mathrm{O} \stackrel{\mathrm{~K}_{3}}{\rightleftharpoons} \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{PO}_{4}^{3-}
$$

$$
6.2 \times 10^{-8} M-\mathrm{z} \quad 0.122+\mathrm{z} \quad \mathrm{z}
$$

$\mathrm{K}_{3}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{PO}_{4}{ }^{3-}\right]}{\left[\mathrm{HPO}_{4}{ }^{2-}\right]}=\frac{(0.122+\mathrm{z}) \mathrm{z}}{6.2 \times 10^{-8}-\mathrm{z}}$
Assume $\mathrm{z} \ll 6.2 \times 10^{-8} \mathrm{M}$
$\mathrm{K}_{3}=3.6 \times 10^{-13}=\frac{0.122 \mathrm{z}}{6.2 \times 10^{-8}}$
$\mathrm{z}=1.83 \times 10^{-19} \mathrm{M}$
$\left[\mathrm{PO}_{4}{ }^{3-}\right]=1.83 \times 10^{-19} \mathrm{M}$
General rule: $\left[\mathrm{PO}_{4}{ }^{3-}\right]=\mathrm{K}_{3} \mathrm{~K}_{2} /\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\mathrm{K}_{3} \mathrm{~K}_{2} / \sqrt{\mathrm{C}_{\mathrm{A}} \mathrm{K}_{1}}$
(where $\mathrm{C}_{\mathrm{A}}$ is formal conc. of polyprotic acid 2.00 M )
4. Summary - for pure solution of:
a. Weak monoprotic acid:

$$
\left[\mathrm{H}^{+}\right] \approx \sqrt{\mathrm{C}_{\mathrm{A}} \mathrm{~K}_{\mathrm{a}}}
$$

b. Weak diprotic acid (weak at both stages):

$$
\begin{aligned}
& {\left[\mathrm{H}^{+}\right]=\sqrt{\mathrm{C}_{\mathrm{A}} \mathrm{~K}_{1}}} \\
& {\left[\mathrm{HA}^{-}\right]=\text {same }} \\
& {\left[\mathrm{A}^{-}\right]=\mathrm{K}_{2}}
\end{aligned}
$$

c. Weak triprotic acid:

$$
\begin{aligned}
& {\left[\mathrm{H}^{+}\right]=\sqrt{\mathrm{C}_{\mathrm{A}} \mathrm{~K}_{1}}} \\
& {\left[\mathrm{H}_{2} \mathrm{~A}^{-}\right]=\text {same }} \\
& {\left[\mathrm{HA}^{2-}\right]=\mathrm{K}_{2}} \\
& {\left[\mathrm{~A}^{3-}\right]=\mathrm{K}_{3} \mathrm{~K}_{2} /\left[\mathrm{H}^{+}\right]}
\end{aligned}
$$

5. Strong polyprotic acid $\mathrm{H}_{2} \mathrm{SO}_{4}$ :

$$
\begin{aligned}
& \mathrm{H}_{2} \mathrm{SO}_{4}+\mathrm{H}_{2} \mathrm{O} \stackrel{\mathrm{~K}_{1} \gg 1}{\rightleftharpoons} \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{HSO}_{4}^{2-} \\
& \mathrm{HSO}_{4}^{-}+\mathrm{H}_{2} \mathrm{O} \stackrel{\mathrm{~K}_{2}=1.2 \times 10^{-2}}{\rightleftharpoons} \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{SO}_{4}^{2-}
\end{aligned}
$$

Suppose we have $2.00 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$.
a. First ionization goes completely:

$$
\begin{aligned}
& {\left[\mathrm{H}_{2} \mathrm{SO}_{4}\right]=0} \\
& {\left[\mathrm{HSO}_{4}^{-}\right]=2.00 \mathrm{M}} \\
& {\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=2.00 \mathrm{M}}
\end{aligned}
$$

b. Second ionization is weak:

$$
\begin{aligned}
& \mathrm{HSO}_{4}^{-}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \\
& 2.00-\mathrm{x} \\
& 2 . \mathrm{O}^{+}+\mathrm{SO}_{4}^{2-} \\
& 2.00+\mathrm{x} \quad \mathrm{x} \\
& \mathrm{~K}_{2}=1.2 \times 10^{-2}=\frac{(2.00+\mathrm{x}) \mathrm{x}}{2.00-\mathrm{x}}
\end{aligned}
$$

Try x $\ll 2.00$ approx.

$$
\begin{aligned}
& 1.2 \times 10^{-2} \approx \frac{2.00 \mathrm{x}}{2.00} \\
& \mathrm{x}=1.2 \times 10^{-2}=0.012 \mathrm{M}
\end{aligned}
$$

$\left[\mathrm{SO}_{4}{ }^{2-}\right]=0.012 \mathrm{M}=\mathrm{K}_{2}$

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=2.00 \mathrm{M}+0.012 \mathrm{M} \approx 2.012 \mathrm{M}
$$

$$
\left[\mathrm{HSO}_{4}^{-}\right]=2.00-0.012 \approx 1.99 \mathrm{M}
$$

C. Weak Monoprotic Bases. (Section 16.3)

1. Calculate conc. of species present and pH of 0.10 M aqueous $\mathrm{NH}_{3}$.

$$
\begin{aligned}
& \mathrm{NH}_{3}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{NH}_{4}^{+}+\mathrm{OH}^{-} \\
& \mathrm{K}_{\mathrm{b}}=\frac{\left[\mathrm{NH}_{4}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{NH}_{3}\right]}=1.8 \times 10^{-} \\
& \frac{\mathrm{x}^{2}}{0.10-\mathrm{x}}=1.8 \times 10^{-5} \\
& \mathrm{x}^{2}=1.8 \times 10^{-6} \\
& {\left[\mathrm{NH}_{4}^{+}\right]=\left[\mathrm{OH}^{-}\right]=\mathrm{x}=1.34 \times 10^{-3} \mathrm{M}} \\
& {\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\frac{\mathrm{K}_{\mathrm{w}}}{\left[\mathrm{OH}^{-}\right]}=\frac{1.0 \times 10^{-14}}{1.34 \times 10^{-3}}} \\
& {\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=7.45 \times 10^{-12} \mathrm{M}} \\
& \mathrm{pH}=-\log \left(7.45 \times 10^{-12}\right)=11.1
\end{aligned}
$$

2. General formula:
pure aqueous of weak base $\left[\mathrm{OH}^{-}\right]=\sqrt{\mathrm{C}_{\mathrm{B}} \mathrm{K}_{\mathrm{b}}}$
where $C_{B}=$ formal concentration of the base

## Part Two: Acidity and Basicity of Salts in Aqueous Solution

A. Salts from Neutralizing Strong Base with Strong Acid. (Section 16.4)

1. Cations from strong soluble bases:
e.g., $\mathrm{Na}^{+}, \mathrm{K}^{+}, \mathrm{Ca}^{2+}, \mathrm{Sr}^{2+} \ldots$ (these ions have no effect on pH )
2. Anions from strong acids:
e.g., $\mathrm{Cl}^{-}, \mathrm{Br}^{-}, \mathrm{I}^{-}, \mathrm{ClO}_{4}^{-} \ldots \quad$ (no effect on pH )
3. These salts produce neutral solutions.
a. The anion is the conjugate base of a strong acid so are very weak bases.
B. Salts from Neutralizing Strong Bases with Weak Acids. (Section 16.4)
4. Again, cations are $\mathrm{Na}^{+}, \mathrm{K}^{+} \ldots$
5. Anions from weak acids:
e.g., $\mathrm{Ac}^{-}, \mathrm{NO}_{2}{ }^{-}, \mathrm{CN}^{-}, \mathrm{OCl}^{-} \ldots$
6. These conjugate bases of weak acids WILL affect pH by following reactions called hydrolysis (or solvolysis) reactions:

$$
\mathrm{NaAc} \rightarrow \mathrm{Na}^{+}(a q)+\mathrm{Ac}^{-}(a q) \quad \text { salt ionizes }
$$

Then: $\quad \mathrm{Ac}^{-}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{HAc}+\mathrm{OH}^{-}$
4. These salts produce basic solutions. If $A c^{-}$is a base, what is its $K_{b}$ ?
$\mathrm{K}_{\mathrm{b}}=\frac{\mathrm{K}_{\mathrm{w}}}{\mathrm{K}_{\mathrm{a}}(\text { of } \mathrm{HAc})}$

## OR:

$\mathrm{K}_{\mathrm{w}}=\mathrm{K}_{\mathrm{a}} \mathrm{K}_{\mathrm{b}} \quad$ a,b are conj acid/base pair
5. Problem: What is pH of 1.0 NaAc solution?

$$
\begin{aligned}
& \mathrm{NaAc} \longrightarrow \mathrm{Na}^{+}+\mathrm{Ac}^{-} \\
& \mathrm{Ac}^{-}+\mathrm{H}_{2} \mathrm{O} \stackrel{\mathrm{~K}_{\mathrm{b}} \text { of } \mathrm{Ac}^{-}}{\rightleftharpoons} \mathrm{HAc}+\mathrm{OH}^{-} \\
& \text {1.0-X X X } \\
& \mathrm{K}_{\mathrm{b}}=\frac{[\mathrm{HAc}]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{Ac}^{-}\right]}=\frac{\mathrm{K}_{\mathrm{w}}}{\mathrm{~K}_{\mathrm{a}}(\text { of } \mathrm{HAc})} \\
& \frac{\mathrm{x}^{2}}{1.0-\mathrm{x}}=\frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}}=5.55 \times 10^{-10} \\
& x \approx \sqrt{1.0 \times 5.55 \times 10^{-10}} ; \quad x=2.36 \times 10^{-5} M
\end{aligned}
$$

$\left[\mathrm{OH}^{-}\right]=2.36 \times 10^{-5} \mathrm{M}$

$$
\left[\mathrm{H}^{+}\right]=\frac{\mathrm{K}_{\mathrm{w}}}{\left[\mathrm{OH}^{-}\right]}=\frac{1.0 \times 10^{-14}}{2.36 \times 10^{-5}}=4.24 \times 10^{-10} \mathrm{M}
$$

$\mathrm{pH}=9.37$ (basic); Therefore, $\mathrm{Ac}^{-}$acts as weak base.
6. Problem: What is pH of 0.20 M NaCN ? $\mathrm{K}_{\mathrm{a}}$ for HCN is $4.0 \times 10^{-10}$ ?

NaCN is salt containing conj base $\mathrm{CN}^{-}$of weak acid HCN .

$$
\begin{aligned}
& \mathrm{K}_{\mathrm{b}}\left(\mathrm{CN}^{-}\right)=\frac{\mathrm{K}_{\mathrm{w}}}{\mathrm{~K}_{\mathrm{a}}(\mathrm{of} \mathrm{HCN})}=\frac{1.0 \times 10^{-14}}{4.0 \times 10^{-10}}=0.25 \times 10^{-4} \\
& \left.\mathrm{CN}^{-}+\mathrm{H}_{2} \mathrm{O} \stackrel{\mathrm{~K}_{\mathrm{b}}(\mathrm{CN}}{ } \mathrm{CN}^{-}\right) \\
& \mathrm{HCN}+\mathrm{OH}^{-} \\
& 0.20-\mathrm{x} \\
& \mathrm{x} \quad \mathrm{x} \\
& \mathrm{~K}_{\mathrm{b}}\left(\mathrm{CN}^{-}\right)=\frac{[\mathrm{HCN}]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{CN}^{-}\right]}
\end{aligned}
$$

$$
\begin{aligned}
& 0.25 \times 10^{-4}=\frac{\mathrm{x}^{2}}{0.20-\mathrm{x}} \\
& \mathrm{x} \approx \sqrt{0.20 \times 0.25 \times 10^{-4}} \\
& \mathrm{x}=2.24 \times 10^{-3} \mathrm{M}=\left[\mathrm{OH}^{-}\right]=[\mathrm{HCN}] \\
& \mathrm{pOH}= 2.65 ; \mathrm{pH}=11.3 \quad \text { quite alkaline! }!
\end{aligned}
$$

Since HCN is such a weak acid, $\mathrm{CN}^{-}$makes a good base, though still a weak base.
C. Salts from Neutralizing Weak Base with Strong Acid. (Section 16.4)

1. Cations are conj acids of that weak base: e.g., $\mathrm{NH}_{4}^{+}$
2. Anions: e.g., $\mathrm{Cl}^{-}, \mathrm{Br}^{-}, \mathrm{I}^{-} . \ldots$
3. These salts will produce acid solutions.
4. If $\mathrm{NH}_{4}{ }^{+}$is an acid, what is its $\mathrm{K}_{\mathrm{a}}$ ?

$$
\mathrm{K}_{\mathrm{a}}\left(\mathrm{NH}_{4}^{+}\right)=\frac{\mathrm{K}_{\mathrm{w}}}{\mathrm{~K}_{\mathrm{b}}\left(\mathrm{NH}_{3}\right)}=\frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}}=5.55 \times 10^{-10}
$$

5. What is the pH of $0.100 \mathrm{M} \mathrm{H}_{4} \mathrm{Cl}$ solution?

$$
\mathrm{NH}_{4} \mathrm{Cl} \longrightarrow \mathrm{NH}_{4}^{+}+\mathrm{Cl}^{-}
$$

Then:

$$
\begin{aligned}
& \mathrm{NH}_{4}^{+}+\mathrm{H}_{2} \mathrm{O} \stackrel{\mathrm{Ka}_{3}\left(\mathrm{NH}_{4}^{+}\right)}{\rightleftharpoons} \mathrm{NH}_{3}+\mathrm{H}_{3} \mathrm{O}^{+} \\
& 0.100-\mathrm{x} \\
& \mathrm{~K}_{\mathrm{a}}=\frac{\left[\mathrm{NH}_{3}\right]\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}{\left[\mathrm{NH}_{4}^{+}\right]} \\
& 5.55 \times 10^{-10}=\frac{\mathrm{x}^{2}}{0.100-\mathrm{x}}
\end{aligned}
$$

$$
\begin{gathered}
x \approx \sqrt{0.100 \times 5.55 \times 10^{-10}} \\
x=7.45 \times 10^{-6} \mathrm{M} \\
{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=7.45 \times 10^{-6} \mathrm{M}} \\
\mathrm{pH}=5.13 \text { slightly acidic }
\end{gathered}
$$

D. Salts from Neutralizing Weak Acid and Weak Base. (Section 16.4)

1. Cation is slightly acidic:
$\mathrm{NH}_{4}^{+}$
2. Anion is slightly basic:
$\mathrm{Ac}^{-}, \mathrm{OCl}^{-} .$.
3. Produces $\approx$ neutral solutions if:

$$
\mathrm{K}_{\mathrm{a}}(\text { parent acid }) \approx \mathrm{K}_{\mathrm{b}}(\text { parent base })
$$

4. Example: $\mathrm{NH}_{4} \mathrm{Ac}$ (ammonium acetate)

$$
\mathrm{K}_{\mathrm{a}}\left(\mathrm{NH}_{4}^{+}\right)=\frac{\mathrm{K}_{\mathrm{w}}}{\mathrm{~K}_{\mathrm{a}}\left(\mathrm{NH}_{3}\right)}=\frac{10^{-14}}{1.8 \times 10^{-5}}=5.6 \times 10^{-10}
$$

parent base is $\mathrm{NH}_{3}$

$$
\mathrm{K}_{\mathrm{b}}\left(\mathrm{Ac}^{-}\right)=\frac{\mathrm{K}_{\mathrm{w}}}{\mathrm{~K}_{\mathrm{a}}(\mathrm{HAc})}=\frac{10^{-14}}{1.8 \times 10^{-5}}=5.6 \times 10^{-10}
$$

parent acid is $H A c$
Neutral solution!

## Part Three: Solutions With More Than One Electrolyte

A. The Common Ion Effect. (Section 16.5)

1. Common-ion effect: the shift in an ionic equilibrium caused by the addition of another solute that provides an ion that takes part in the equilibrium.
2. Example: Solution of weak acid plus soluble salt containing its conjugate base.
3. Problem: A solution is prepared which is 1.0 M HAc and 0.50 M NaAc . What is its pH ?

$$
\begin{aligned}
\mathrm{NaAc}(a q) \longrightarrow & \mathrm{Na}^{+}(a q)+\mathrm{Ac}^{-} \\
& 0.50 \mathrm{M} \quad 0.50 \mathrm{M} \\
\mathrm{HAc}(a q)+ & \mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{Ac}^{-}
\end{aligned}
$$

X
$0.50+\mathrm{x}$
$\mathrm{K}_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{Ac}^{-}\right]}{[\mathrm{HAc}]}$
$1.8 \times 10^{-5}=\frac{\mathrm{x}(0.50+\mathrm{x})}{1.0-\mathrm{x}}$
Make assumption that $1.0-x \approx 1.0$ and $0.50+x \approx 0.5$
$1.8 \times 10^{-5}=\frac{\mathrm{x}(0.50)}{1.0}$
$\mathrm{x}=3.6 \times 10^{-5} \mathrm{M}$
$\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=3.6 \times 10^{-5} \mathrm{M}$
$\left[\mathrm{Ac}^{-}\right]=0.50+\mathrm{x} \approx 0.50 \mathrm{M}$
[HAc] $=1.0-\mathrm{x} \approx 1.00 \mathrm{M}$
$\mathrm{pH}=-\log \left(3.6 \times 10^{-5}\right)=4.44$
4. What would the pH of pure 1.0 M HAc have been?

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\sqrt{1.0 \times 1.8 \times 10^{-5}}=4.24 \times 10^{-3} \mathrm{M}
$$

$\mathrm{pH}=2.37$ (more acidic!)
5. Adding the conjugate base $\mathrm{Ac}^{-}$in the form of the salt NaAc raised pH by 2 points, making solution less acidic.
6. Common ion effect means effect of having $\mathrm{Ac}^{-}$ions from two different sources:

- HAc
- NaAc
(two electrolytes have $\mathrm{Ac}^{-}$in common)

7. Solution of weak base plus soluble salt containing its conjugate acid.
8. Example: A solution which is $0.20 \mathrm{M} \mathrm{NH}_{3}(a q)$ and $0.30 \mathrm{MH}_{4} \mathrm{Cl}(a q)$. What is its pH ?

$$
\begin{array}{ll}
\mathrm{NH}_{4} \mathrm{Cl}(a q) \longrightarrow & \mathrm{NH}_{4}^{+}(a q)+\mathrm{Cl}^{-} \\
& 0.30 \mathrm{M} \\
& \\
\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O} \stackrel{\mathrm{~K}_{\mathrm{t}}}{\rightleftharpoons} \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-} \\
& \\
0.20 \mathrm{M} & 0.30 \mathrm{M} \\
0.20-\mathrm{x} & 0.30+\mathrm{x}
\end{array}
$$

initial at equilib

$$
\begin{aligned}
& \mathrm{K}_{\mathrm{b}}=\frac{\left[\mathrm{NH}_{4}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{NH}_{3}\right]}=1.8 \times 10^{-5} \\
& \quad \frac{\mathrm{x}(0.30+\mathrm{x})}{0.20-\mathrm{x}}=1.8 \times 10^{-5} \\
& \frac{0.30 \mathrm{x}}{0.20} \approx 1.8 \times 10^{-5} \\
& \mathrm{x}=1.2 \times 10^{-5} \mathrm{M} \\
& {\left[\mathrm{OH}^{-}\right]=1.2 \times 10^{-5} \mathrm{M}}
\end{aligned}
$$

$\left[\mathrm{NH}_{4}^{+}\right] \approx 0.30 \mathrm{M}$
$\left[\mathrm{NH}_{3}\right] \approx 0.20 \mathrm{M}$
$\mathrm{pH}=? ? \quad\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\frac{\mathrm{K}_{\mathrm{w}}}{\left[\mathrm{OH}^{-}\right]}=\frac{1.0 \times 10^{-14}}{1.2 \times 10^{-5}}=8.33 \times 10^{-10} \mathrm{M}$
$\mathrm{pH}=9.08$
B. Buffer Solutions. (Section 16.6)

1. The two previous examples were, in reality, buffer solutions.
2. Buffer solutions are those which resist changes in pH when other acids or bases are added.
3. Prepare by mixing solution of:
a. weak acid and its salt in comparable amounts.
example - HF and NaF (acidic buffer)

OR:
b. weak base and its salt in comparable amounts.

$$
\text { example - } \mathrm{NH}_{3} \text { and } \mathrm{NH}_{4} \mathrm{Cl} \text { (basic buffer) }
$$

4. Calculating the pH of an acidic buffer:

$$
\begin{aligned}
& \frac{\left[\mathrm{H}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}=\mathrm{K}_{\mathrm{a}} \\
& {\left[\mathrm{H}^{+}\right]=\mathrm{K}_{\mathrm{a}} \frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}} \\
& {\left[\mathrm{H}^{+}\right]=\mathrm{K}_{\mathrm{a}} \frac{[\mathrm{acid}]}{[\text { salt }]}} \\
& -\log \left[\mathrm{H}^{+}\right]=-\log \mathrm{K}_{\mathrm{a}}-\log \frac{[\text { acid }]}{[\text { salt }]} \\
& \mathrm{pH}=\mathrm{pK}_{\mathrm{a}}-\log \left(\frac{[\text { acid }]}{[\text { salt }]}\right)
\end{aligned}
$$

Henderson-Hasselbach Equation:
$\mathrm{pH}=\mathrm{pK}_{\mathrm{a}}+\log \left(\frac{[\text { salt }]}{[\text { acid }]}\right)$
5. Use it: A buffer solution is $1.0 M \mathrm{HF}$ and 0.5 M NaF . What is pH ? $\mathrm{K}_{\mathrm{a}}$ of HF is $7.2 \times$ $10^{-4}$.

$$
\begin{aligned}
& {[\text { acid }]=1.0 \mathrm{M} \quad[\text { salt }]=0.5 \mathrm{M}} \\
& \begin{aligned}
\mathrm{pH} & =\mathrm{pK}_{\mathrm{a}}+\log \left(\frac{[\text { salt }]}{[\text { acid }]}\right) \\
& =-\log \left(7.2 \times 10^{-4}\right)+\log (0.5 / 1.0) \\
& =3.143+(-.301) \\
\mathrm{pH} & =2.842
\end{aligned}
\end{aligned}
$$

6. Special important case: When [acid] $=[$ salt $]$.

$$
\begin{aligned}
& \mathrm{pH}=\mathrm{pK}_{\mathrm{a}}+\log (1) \\
& \mathrm{pH}=\mathrm{pK}_{\mathrm{a}}
\end{aligned}
$$

Therefore, the $\mathrm{pK}_{\mathrm{a}}$ of an acid tells us approximately the pH of its buffer solution.
7. For basic buffers:
$\mathrm{pOH}=\mathrm{pK}_{\mathrm{b}}+\log \left(\frac{[\text { salt }]}{[\text { base }]}\right)$
C. Buffering Action.

1. Now let's demonstrate the buffering action:
a. Prepare 500 mL of buffer solution which is 1.00 M acetic acid and 1.00 M sodium acetate. Calculate pH .

$$
\begin{aligned}
& \mathrm{HAc}+\mathrm{H}_{2} \mathrm{O} \stackrel{\mathrm{Ka}_{\mathrm{a}}}{\rightleftharpoons} \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{Ac}^{-} \\
& {[\text {acid }]=[\text { salt }], \text { so: }} \\
& \mathrm{pH}=\mathrm{pK}_{\mathrm{a}}=-\log \left(1.8 \times 10^{-5}\right)=4.74
\end{aligned}
$$

b. Add 1.00 gram of NaOH to this buffer solution. What is new pH ?

$$
\frac{1.00 \mathrm{~g}}{40.0 \mathrm{~g} / \mathrm{mol}}=0.025 \mathrm{~mol} ; \quad \frac{0.025 \mathrm{~mol}}{0.500 \mathrm{~L}}=0.050 \mathrm{M}
$$

c. Instead suppose we had added $2.50 \mathrm{~g} \mathrm{HClO}_{4}$. What is new pH ?

$$
\frac{2.50 \mathrm{~g}}{100.4 \mathrm{~g} / \mathrm{mol}}=0.0250 \mathrm{~mol} ; \quad \frac{.0250 \mathrm{~mol}}{500 \mathrm{~L}}=0.0500 \mathrm{M}
$$

$$
\begin{aligned}
& \text { Now: } \begin{array}{l}
{[\text { acid }]=1.00 M+0.0500=1.05 \mathrm{M}} \\
\\
{[\text { salt }]=1.00 M-0.0500=0.95 \mathrm{M}}
\end{array} \\
& \mathrm{pH}=4.74+\log \left(\frac{0.95}{1.05}\right)=4.74-0.0434 \\
& \text { new } \mathrm{pH}=4.70 \quad \text { - hardly changed at all again!! }
\end{aligned}
$$

2. For comparison, what if we added $2.50 \mathrm{~g} \mathrm{HClO}_{4}$ to 500 mL of simply 1.00 M HAc? (not a buffer solution)

$$
\mathrm{HAc}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{Ac}^{-}
$$

| before <br> $\mathrm{HClO}_{4}$ | 1.00 M | $1.8 \times 10^{-5}$ | $1.8 \times 10^{-5}$ |
| :--- | :---: | :---: | :---: |
| after <br> $\mathrm{HClO}_{4}$ | 1.00 | 0.0500 M | $\uparrow$ <br> no conjugate <br> base to react with |

$$
\left[\mathrm{H}^{+}\right]=.0500 \mathrm{M} ; \mathrm{pH}=1.30
$$

Almost all $\left[\mathrm{H}^{+}\right]$new comes from the strong acid, not weak.
3. Try a basic buffer:
a. Prepare 1.000 L of $0.500 \mathrm{M} \mathrm{NH}_{3}$ and 0.400 M NH 4 Cl . What is pH ? $\mathrm{K}_{\mathrm{b}}$ of $\mathrm{NH}_{3}$ is $1.8 \times 10^{-5}$.

$$
\mathrm{pOH}=\mathrm{pK}_{\mathrm{b}}+\log \left(\frac{[\text { salt }]}{[\text { base }]}\right)
$$

|  | $=4.74+\log \left(\frac{0.400}{0.500}\right)=4.74-0.0969$ |
| ---: | :--- |
| pOH | $=4.64$ so $\mathrm{pH}-14-\mathrm{pOH}=9.36$ |

b. Now add 2.0 g NaOH . What is new pH ?

| $\frac{2.0 \mathrm{~g}}{40.0 \mathrm{~g} / \mathrm{mol}}=0.050 \mathrm{~mol} \text { in } 1 \mathrm{~L}=0.050 \mathrm{M}$ |  |  |
| :---: | :---: | :---: |
| $\mathrm{NH}_{3}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{OH}^{-}+\mathrm{NH}_{4}^{+}$ |  |  |
| before$\mathrm{NaOH}$ | 0.500 M | $1.8 \times 10^{-5} \quad 0.400 \mathrm{M}$ |
|  |  | $\uparrow$ |
|  |  | OH - reacts with strongest acid present \& neutralizes part |
| after <br> NaOH | $0.500+.050 \mathrm{M}$ | 0.400-.050 M |
|  |  |  |

$$
\begin{aligned}
& \mathrm{pOH}=\mathrm{pK}_{\mathrm{b}}+\log \left(\frac{0.350}{0.550}\right) \\
& \mathrm{pOH}=4.54 \\
& \mathrm{pH}=14-4.54=9.45 \quad-\text { little change }
\end{aligned}
$$

## Part Four: Titration Curves

## A. Strong Acid/Strong Base Curve. (Section 16.7)

1. Titration curve is plot of pH versus volume of acid or base added.
2. Example: Start with 100.0 mL of 0.100 M HCl . Begin adding 0.100 M NaOH and plot pH .

Titration Data for 100.0 mL of 0.100 M HCl Versus NaOH

| mL of 0.100 M <br> NaOH Added | mmol NaOH Added | mmol Excess Acid or Base | pH |
| :---: | :---: | :---: | :---: |
| 0.0 | 0.00 | $10.0 \mathrm{H}_{3} \mathrm{O}^{+}$ | 1.00 |
| 20.0 | 2.00 | 8.0 | 1.18 |
| 50.0 | 5.00 | 5.0 | 1.48 |
| 90.0 | 9.00 | 1.0 | 2.28 |
| 99.0 | 9.90 | 0.10 | 3.30 |
| 99.5 | 9.95 | 0.05 | 3.60 |
| 100.0 | 10.00 | 0.00 (eq. pt.) | 7.00 |
| 100.5 | 10.05 | $0.05 \mathrm{OH}^{-}$ | 10.40 |
| 110.0 | 11.00 | 1.00 | 11.68 |
| 120.0 | 12.00 | 2.00 | 11.96 |

3. Plot:

4. Note: Curve is so vertical at equivalence point that mere drops of NaOH cause pH to change several units.
5. One desires entire indicator color change to be in this vertical region.
6. Thus, just a drop or two will produce complete color transition.
7. Look at the following table. What other indicators would work here?

## Range and Color Changes of Some Common Acid-Base Indicators

8. Problem: strong acid/strong base titration.

Titrate 200.0 mL of 0.500 M HBr with 0.400 M KOH .
a. What is pH at the start of the titration?

$$
\begin{aligned}
& \mathrm{pH} \text { of } 0.500 \mathrm{M} \mathrm{HBr} \\
& {\left[\mathrm{H}^{+}\right]=0.500 \mathrm{M}} \\
& \mathrm{pH}=-\log (0.500)=0.301
\end{aligned}
$$

b. What is pH after 50.0 mL of base added?

Start: $\quad 200.0 \mathrm{~mL} * 0.500 \mathrm{M} \mathrm{HBr}=100.0 \mathrm{mmol}$ acid
Add: $\quad 50.0 \mathrm{~mL}$ of $0.400 \mathrm{M} \mathrm{KOH}=20.0 \mathrm{mmol}$ base
$\mathrm{OH}^{-}$will neutralize an equivalent amount of acid, so will have left only 80.0 mmol acid.
$\left[\mathrm{H}^{+}\right]=80.0 \mathrm{mmol}$ acid $/ 250.0 \mathrm{~mL}$ tot $\mathrm{vol}=0.32 \mathrm{M}$
$\mathrm{pH}=-\log (0.32)=0.49$
B. Weak Acid/Strong Base Titration Curve. (Section 16.7)

1. Start with 100 mL solution of the acid 0.100 M HAc. Add 0.100 M solution dropwise.
2. Titration data:

Titration Data for 100.0 mL of $0.100 \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$ with 0.100 M NaOH

| $\begin{gathered} \mathrm{mL} 0.100 \mathrm{M} \\ \mathrm{NaOH} \text { Added } \end{gathered}$ |  | mmol Base Added | mmol Excess Acid or Base | pH |
| :---: | :---: | :---: | :---: | :---: |
| 0.0 mL |  | 0 | $10.0 \mathrm{CH}_{3} \mathrm{COOH}$ | 2.89 |
| 20.0 mL |  | 2.00 | 8.00 | 4.14 |
| 50.0 mL |  | 5.00 | 5.00 | 4.74 |
| 75.0 mL | buffered | 7.50 | 2.50 | 5.22 |
| 90.0 mL | region | 9.00 | 1.00 | 5.70 |
| 95.0 mL |  | 9.50 | 0.50 | 6.02 |
| 99.0 mL |  | 9.90 | 0.10 | 6.74 |
| 100.0 mL |  | 10.0 | 0 (equivalence point) | 8.72 |
| 101.0 mL |  | 10.1 | $0.10 \mathrm{OH}^{-}$ | 10.70 |
| 110.0 mL |  | 11.0 | 1.0 | 11.68 |
| 120.0 mL |  | 12.0 | 2.0 | 11.96 |

3. Let's calculate one of these points for practice. Calculate pH after adding 20.0 mL of NaOH solution.

Start: $\quad 100.0 \mathrm{~mL}$ of $0.100 \mathrm{M} \mathrm{HAc}=0.0100$ moles HAc
Add: $\quad 20.0 \mathrm{~mL}$ of $0.100 \mathrm{MaOH}=0.0020$ moles NaOH
Then: $\quad[\mathrm{HAc}]=\frac{0.0080 \mathrm{moles}}{120 \mathrm{~mL}}=0.0666 \mathrm{M}$

$$
\left[\mathrm{Ac}^{-}\right]=\frac{0.0020 \mathrm{moles}}{120 \mathrm{~mL}}=1.66 \times 10^{-2} \mathrm{M}
$$

$$
\mathrm{K}_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{Ac}^{-}\right]}{[\mathrm{HAc}]}
$$

$1.8 \times 10^{-5}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] 1.66 \times 10^{-2}}{0.0666}$
$\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=7.20 \times 10^{-5} \mathrm{M} \quad$ so $\quad \mathrm{pH}=4.14$
4. Plot:

5. Problem: Titrate 200.0 mL of 0.500 M KHP (weak acid, $\mathrm{K}_{\mathrm{a}}=1.0 \times 10^{-4}$ ) with 0.500 M NaOH .
a. What is the pH at the start of the tiration?

KHP is simply a weak acid, so treat as a pure solution of a weak monoprotic acid.

$$
\begin{aligned}
& {\left[\mathrm{H}^{+}\right] \approx \sqrt{\mathrm{C}_{\mathrm{A}} \mathrm{~K}_{\mathrm{a}}} \approx \sqrt{0.500 * 1.0 \times 10^{-4}}} \\
& {\left[\mathrm{H}^{+}\right]=0.00707 \mathrm{M}} \\
& \mathrm{pH}=2.15
\end{aligned}
$$

b. What is the pH after 50.0 mL of base has been added?

The base converts some of the weak acid to its conjugate base (salt), so you have a buffer solution.

Start: $\quad 200 \mathrm{~mL} * 0.500 \mathrm{M}=100 \mathrm{mmol}$ weak acid
Add: $\quad 50 \mathrm{~mL} * 0.500 \mathrm{M}=25 \mathrm{mmol} \mathrm{OH}^{-}$

Use buffer equation:

$$
\begin{aligned}
\mathrm{pH} & =\mathrm{pK}_{\mathrm{a}}+\log ([\text { salt }] /[\text { acid }]) \\
& =-\log \left(1.0 \times 10^{-4}\right)+\log (25 \mathrm{mmol} / 100-25 \mathrm{mmol}) \\
& =4-0.477=3.52
\end{aligned}
$$

C. Weak Acid with Weak Base Titration Curve.

1. Example: HAc with $\mathrm{NH}_{3}$.
2. Curve:

D. Titrate Weak Base with a Weak Acid:

Figure 16.14
E. How Acid/Base Indicators Work. (optional)

1. Indicator is a weak acid itself. Symbolize it HIn:

$$
\begin{array}{ll}
\quad \mathrm{HIn}+\mathrm{H}_{2} \mathrm{O} \stackrel{\mathrm{~K}_{\mathrm{a}}(\mathrm{in})}{\rightleftharpoons} & \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{In}^{-} \\
& \begin{array}{l}
\text { base form } \\
\text { of indicator } \\
\text { (color } 2)
\end{array} \\
\text { of indicator } & \begin{array}{l}
\text { indicator } 1)
\end{array}
\end{array}
$$

pH where it changes $\approx \mathrm{pK}_{\mathrm{a}}$ of HIn.
2. Example: Bromothymol blue $\mathrm{K}_{\mathrm{a}}(\mathrm{in})=7.9 \times 10^{-8} ; \mathrm{pK}_{\mathrm{a}}=7.1$

$$
\mathrm{HIn}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{In}^{--}
$$ yellow blue

Color depends on $\frac{\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]}$ ratio:
if $\frac{\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]} \geq 10$, then $\mathrm{In}^{-}$color observed blue $(\mathrm{pH} \geq 8)$
if $\frac{\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]} \leq 1 / 10$, then HIn color observed yellow $(\mathrm{pH} \leq 6)$
3. Since $\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]}=\mathrm{K}_{\mathrm{a}}(\mathrm{in})$

Ratio $\frac{\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]}=\frac{\mathrm{K}_{\mathrm{a}}(\mathrm{in})}{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}=$depends on $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$
4. Add acid to solution, causes shift ( $\leftarrow)$, more HIn present.
5. Add base to solution, causes shift $(\rightarrow)$, more In ${ }^{-}$present.
6. Midpoint of change is when:

$$
\frac{\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]}=1=\frac{\mathrm{K}_{\mathrm{a}}(\mathrm{in})}{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}
$$

Thus, when

$$
\begin{aligned}
& {\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\mathrm{K}_{\mathrm{a}}(\mathrm{in}), \text { or }} \\
& \mathrm{pH}=\mathrm{pK}_{\mathrm{a}}(\mathrm{in})
\end{aligned}
$$

(for Bromothymol blue $\mathrm{pK}_{\mathrm{a}}(\mathrm{in})=7.1$, i.e. neutral is midpoint)
7. Tables of indicators and their $\mathrm{pK}_{\mathrm{a}}$ are available.
