

# Chemistry Unit: Chemical Bonding (chapter 7 and 8) Notes

## Topic-1: review

1. Valence electrons
2. Lewis dot structures
3. Electronegativity
4. Cations and Anions
5. Octet Rule

## Topic-2: Chemical Bonds

1. Ionic Bonds
2. Covalent bonds
3. Metallic bonds

## Topic-3: Inter-molecular Chemical Bonds

1. Van der Waalls attractions
2. Hydrogen bonds
3. Dipole-dipole bond

## Topic-1: Review:

### 1. Valence electrons:

- The electrons in the outermost \_\_\_\_\_ of an atom
- Valence** electrons are \_\_\_\_\_ or \_\_\_\_\_ during chemical reactions
- The \_\_\_\_\_ of valence electrons are directly responsible for the **chemical properties** and **reactivity of elements**
- Periodic-Table-Groups** are based on \_\_\_\_\_ electron numbers

### 2. Electron (Lewis) dot structures:

Lewis dot structures are \_\_\_\_\_ that show \_\_\_\_\_ electrons of atoms.

Table-1: Lewis dot structures of atoms:

	Atomic number	Element	Electron configuration	# of Valence Electrons	Electron dot diagram
<b>Period-1</b>	1	H	<u><math>1s^1</math></u>	1	$\cdot$ H
Energy level: $n=1$	2	He	<u><math>1s^2</math></u>	2	
Sub-levels: s	3	Li	$1s^2$ <u><math>2s^1</math></u>	1	
<b>Period-2</b>	4	Be			
Energy level: $n=2$	5	B			
Sub-levels: s, p	6	C			
	7	N			
	8	O			
	9	F			
	10	Ne			
<b>Period-3</b>	11	Na			
Energy level: $n=3$	12	Mg			
Sub-levels: s, p, d					

### 3. Electronegativity

- Electronegativity occurs when a one atom that \_\_\_\_\_ electrons with another is more attracted to these electrons due to its higher electron \_\_\_\_\_.
- Fluorine (F) is the \_\_\_\_\_ electronegative element on the periodic table. Followed by O, then N and Cl.
- In general, the electronegativity of an element \_\_\_\_\_ as one goes up a group and left to right across a period.
- Note that Noble gases (group 8A) are not electronegative)

Example: In group 7A: Electronegativity \_\_\_\_\_ in the order: I < Br < Cl < F.

In period 2: Li has the lowest and \_\_\_\_\_ has the highest electronegativity

**Table-2: Number of valence electrons in Noble gasses (group 8A):**

Atomic number	Symbol of noble gas	Electron configuration (underline the valence shell Orbitals)	Number of Valence electrons
10	Ne		
	Ar		
36			
	Xe		
86			

All noble gases have 8 valence electrons as their highest Principal Energy Level-SUB LEVELS (\_\_\_\_ and \_\_\_\_ ) are completely filled with electrons. This is the reason for the Non-reactivity and stability of noble gases.

### 4. Cations and anions (oxidation numbers):

Group 1A – 4A atoms tend to form \_\_\_\_\_ by giving electrons to complete octet

Group 4A-7A Tend to form \_\_\_\_\_ taking electrons to complete octet

Electron donors				Electron takers											
Oxidation number:	+1	+3	+4 -4	-3			0								
1A				8A											
1	H						2	He							
		2A		3A	4A	5A	6A	7A							
3	Li	4	Be	5	B	6	C	7	N	8	O	9	F	10	Ne
11	Na	12	Mg	13	Al	14	Si	15	P	16	S	17	Cl	18	Ar
19	K	20	Ca	21	Ga	22	Ge	23	As	24	Se	25	Br	26	Kr

 d-block has been omitted

### 5. Octet-Rule:

Atoms are always trying to get \_\_\_\_\_ electrons in their outer shell (principal energy level) to be like the \_\_\_\_\_ noble gas in the periodic table. This is because, having 8 electrons in outer shell is energetically very \_\_\_\_\_ for all atoms (except \_\_\_\_ and \_\_\_\_).

**Table-3: atoms and their desired noble gas electron configuration based on OCTET-RULE**

Element	Number of valence electrons	Desired noble gas electron configuration based on OCTET-RULE:
Na		
Mg		
C		
N		
Cl		

## Topic-2: Bonds that Occur Between Atoms (Ionic, Metallic and Covalent Bonds)

### 1. Ionic Bonds:

- Ions with \_\_\_\_\_ **charges** are **mutually attracted** to each other.
- Attractions between oppositely charged ions are called \_\_\_\_\_ **attractions**.
- Ionic bonds** are electrostatic attractions that occur between ions with opposite charge.
- Ionic bonds always occur between \_\_\_\_\_ ions (cations) and **metal** ions (anions).
- All ionic compounds are \_\_\_\_\_ because their **total \_\_\_\_\_ and total negative charges add up to zero**.
- Ionic compounds arrange in a \_\_\_\_\_ called a \_\_\_\_\_ (like a lattice pie!)
- The energy needed to break this lattice is called \_\_\_\_\_.
- When the lattice is broken, the ions will become atoms with zero charge and the ionic bonds will be broken.

#### Properties of ionic compounds

- Form **crystalline solids** at room temperature
- Generally have **high \_\_\_\_\_ points**
- When dissolved in water, can **conduct \_\_\_\_\_** and form \_\_\_\_\_.

#### Questions:

- What is an electric current? \_\_\_\_\_
- Why do ionic compounds conduct electricity? \_\_\_\_\_

#### Lewis dot structure for NaCl:

#### Ex: Write the **net ionic equation** for the formation of $\text{Na}^{+}$ and $\text{Cl}^{-}$ ions:

- Na is in group 1A = donate the valence electron  $1e^{-}$
- Cl is in Group 7A = accept this valence  $1e^{-}$
- So, when Na and Cl atoms form a chemical bond, Na will donate an electron to Cl.
- Na donates 1** electron and become an  **$\text{Na}^{+}$  ion** and Cl will **accept 1** electron and become a  **$\text{Cl}^{-}$  ion**

#### Crisscross-method of predicting ionic compound formulas:

- Step-1:** Write the name of the atoms side by side: \_\_\_\_\_
- Step-2:** Find out the number of valence electrons for each atom and the Charges made when they ionize (become ions). Ex: +2 or -1 etc. Write the Charge above the atoms (super-scrips): \_\_\_\_\_
- Step-3:** Now swap the charges as shown by the arrows: \_\_\_\_\_
- Step-4:** Then write the swapped ionic-charges as coefficient in front of the Ion: \_\_\_\_\_

Note: Ones are not shown when writing formulas: \_\_\_\_\_

**This means, one Cl-ion combines with 3 Al-ions in the ionic compound. This will become clear to you once you draw the Lewis dot structures of the atoms and the compound.**

- **Step-5:** Now draw the combined electron dot structure for the compound and determine how many of each ion is found in a unit of the compound.

- *Note: Since each Cl atom needs only \_\_\_\_ electron and Al atoms has \_\_\_\_ valence electrons to donate, \_\_\_\_ Cl ions will come bine with a single Al atom to take its \_\_\_\_ valence electrons and complete their octets!*

Name \_\_\_\_\_ Class period: \_\_\_\_ score: \_\_\_\_/100 (submissions after 1-28-19 will NOT be graded)

## Chemical Bonding Homework-1 (assigned: 1-11-2019): Due date 1-14-19

**FYI: Electron Filling Order: 1s, 2s 2p, 3s 3p, 4s 3d 4p, 5s 4d 5p, 6s 4f 5d 6p ,7s 4f 6d 7p**

- What are valence electrons? \_\_\_\_\_
- If you need to find the valence electrons of an element in the periodic table which would you use? The group number, atomic number, atomic mass, period number (circle the correct answers)
- What is a Lewis dot structure? \_\_\_\_\_
- Draw the electron dot structures of the following atoms:
 

a) Calcium	d) Carbon
b) Iodine	e) Oxygen
c) Rubidium	f) chlorine
- Explain the octet rule: \_\_\_\_\_
- True or false? Metallic atoms tend to lose electrons and form cations while non-metal ions tend to gain electrons and become anions.
- Explain why anions have a negative charge: \_\_\_\_\_
- Write the electron configuration of the following metal atoms and Circle the electrons LOST when these metals form cations:

Element Symbol	Total electrons	Electron configuration	Orbital box diagram
Mg			
Al			
K			

9. Match the correct noble gas or ion with the electron configurations below using arrows:

- |              |   |
|--------------|---|
| 1) Ar        | a. $1s^2$                                       |
| 2) $Ca^{2+}$ |   |
| 3) $Cl^-$    | b. $1s^2 2s^2 2p^6$                             |
| 4) $Li^+$    |   |
| 5) $Se^{2-}$ | c. $1s^2 2s^2 2p^6 3s^2 3p^6$                   |
| 6) He        |   |
| 7) Ne        | d. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6$ |

10. Draw the orbital box diagrams of the following:

- 1) Ar
- 2)  $Cl^-$
- 3)  $Li^+$
- 4) He
- 5)  $Al^{3+}$

11. What is an ionic bond: \_\_\_\_\_

12. What are the properties of ionic compounds?

13. Predict the formulas of the ionic compounds formed by the atoms below:

- 1) Na and Cl \_\_\_\_\_
- 2) Na and S \_\_\_\_\_
- 3) Na and P \_\_\_\_\_
- 4) Na and C \_\_\_\_\_
- 5) Mg and Cl \_\_\_\_\_
- 6) Mg and S \_\_\_\_\_
- 7) Mg and P \_\_\_\_\_
- 8) Mg and C \_\_\_\_\_
- 9) Al and Cl \_\_\_\_\_

- 10) Al and S \_\_\_\_\_
- 11) Al and P \_\_\_\_\_
- 12) Al and C \_\_\_\_\_
- 13) C and Cl \_\_\_\_\_
- 14) C and S \_\_\_\_\_
- 15) C and P \_\_\_\_\_
- 16) Mg and C \_\_\_\_\_
- 17) Potassium and Oxygen: \_\_\_\_\_
- 18) Magnesium and Nitrogen: \_\_\_\_\_

Periodic Table of the Elements																		18 VIIIA 8A

## 2. Metallic Bonds

**What is a metallic bond?** The attraction between metal cations and the surrounding sea of delocalized valence electrons is called metallic bond.

### Physical Properties of Metals:

- Metals form \_\_\_\_\_ cubic, rigid crystals
- Metals are good \_\_\_\_\_ conductors as they have readily mobile electrons to produce a current
- The \_\_\_\_\_ -electron mobility is also why metals are \_\_\_\_\_ (hammered into shapes) and \_\_\_\_\_ (stretched into wires).

### Metal Alloys:

What is a metal Alloy? \_\_\_\_\_

#### **Metal alloys can be of two types:**

- Substitution alloy** = another metal atom of \_\_\_\_\_ is substituted in the space of a former metal atom (made up of 2 or more metals)
- Interstitial alloy:** made up of metal atoms and another \_\_\_\_\_ metal or non-metal atom that is in the \_\_\_\_\_ metal atoms.

Examples of alloys:

1. \_\_\_\_\_: Cu + Tin + Al /Mn /Zn sterling silver,
2. Cast iron: Fe + \_\_\_\_\_ + Si
3. Steel: Fe + \_\_\_\_\_

Q: Why is steel stronger than cast iron? Explain your answer

## 3. Covalent Bonds [co-valent = shared- valence]

**What is a covalent bond?** Covalent bonds are \_\_\_\_\_ bonds formed when atoms \_\_\_\_\_ electrons. All compounds that make molecules are formed by \_\_\_\_\_ bonding of the atoms within.

- In covalent bonds, electrons are usually shared between 2 or more \_\_\_\_\_ atoms so that each can obtain the noble gas electron configuration.
- There can be single, double or triple covalent bonds between two atoms
- Based on the \_\_\_\_\_ values of each atom in a covalent bond, the resulting molecule may have a dipole (polarity) based on negative and positive charged regions of the same molecule. [Polarity is explained with the symbol 'delta' = \_\_\_\_\_ or \_\_\_\_\_]
- Covalent bonds and ionic bonds exist in a \_\_\_\_\_ (continuum) going from zero to extreme electronegativity.

### Physical Properties of covalent molecules:

- Bond strength varies depending on type of bond and atoms involved in bonding
- Can be found in Solid, liquid or gas state depending on the compound
- Poor electrical conductors (as they do not have readily mobile electrons to produce a current)
- Can be colorless or have colors
- Low melting point and boiling point
- Do not conduct heat well

### Types of covalent bonds:

1. Single bonds [formed by sharing \_\_\_ electron-pair = \_\_\_ electrons between 2 atoms]
2. Double bonds [formed by sharing \_\_\_ electron-pairs = \_\_\_ electrons between 2 atoms]
3. Triple bonds [formed by sharing \_\_\_ electron-pair = \_\_\_ electrons between 2 atoms]

### Note:

- Each bond is represented as a straight \_\_\_\_\_. A single bond will have \_\_\_\_\_ line, double will have 2 lines and a triple bond will have \_\_\_\_\_ lines.
- \_\_\_\_\_ bonds are the strongest and single bonds are the weakest and \_\_\_\_\_ to break.
- Bond distance is shortest in triple bonds and longest in single bonds. See figure below:

**Sigma (Single) bond**

**Double bond**

**Triple bond**

Draw the Lewis dot structures of the following covalent compounds/molecules:

1. HCL

2. CO<sub>2</sub> (carbon dioxide)

3. N<sub>2</sub> (nitrogen gas)

4. H<sub>2</sub> (hydrogen gas)

5. O<sub>2</sub> oxygen gas

6. H<sub>2</sub>O (Water)

## Sale of valence electron sharing in covalent bonds:

### Polar covalent bonds

Ex: water molecule \_\_\_\_\_

- Oxygen is much more \_\_\_\_\_ than Hydrogen, so Oxygen pulls the shared electrons towards itself
- This greater electronegativity of oxygen compared to hydrogen in the covalent bonds of water molecules result in a \_\_\_\_\_ or polarity. The result is a shifting of the electron density towards Oxygen.
- H gets a small positive charge Delta + ( \_\_\_\_ ) and Oxygen gets a \_\_\_\_\_ charge ( \_\_\_\_ ) as electrons are less equally shared between O and H.

### Non-polar covalent bonds:

Ex: N<sub>2</sub>

- If a molecule is formed by the same kind of atom or atoms with similar electronegativity then the covalent bond is \_\_\_\_\_ (Ex: O<sub>2</sub>, N<sub>2</sub>, Cl<sub>2</sub>, O<sub>3</sub>, Br<sub>2</sub>)
- Carbon and \_\_\_\_\_ makes non polar covalent molecules such as hydrocarbons (CH<sub>4</sub>, C<sub>2</sub>H<sub>6</sub>, C<sub>3</sub>H<sub>8</sub> and so on.)

Draw C<sub>2</sub>H<sub>8</sub>

Co-ordinate Covalent bonds:

In typical covalent bond, each atom in the bond provides an electron for a single bond. But in coordinate covalent bonds this is not the case. Here, one atom contributes both of the shared electrons for one covalent bond.

Q: How are covalent compounds (molecules) different from ionic compounds?

### Electronegativity difference and Bond-Types:

## Periodic Table of Electronegativities

[illegible]

Calculate the electronegativity of

1. F: \_\_\_\_\_
2. H: \_\_\_\_\_
3. C: \_\_\_\_\_
4. H-F: \_\_\_\_\_
5. C-C: \_\_\_\_\_
6. C-H: \_\_\_\_\_

**Properties of chemical bonds:**

	Property	Meaning
1	Bond Length	Distance between the nuclei of _____ bonded atoms ( unit = picometers =pm)
2	Bond angle	Angles of any two bonds around an _____
3	Bond energy (bond dissociation energy)	Energy required to break a bond. ( unit = Kilo _____ per mole = KJ/mol)

Bond	Length	Energy
C – C	154	348
C = C	134	614
C $\equiv$ C	120	839
O – O	148	145
O = O	121	498

Compound	Bond	length (pm)	energy (kJ/mol)
H <sub>2</sub>	H – H	74	436
HF	F – H	92	565
H <sub>2</sub> O	O – H	96	464
NH <sub>3</sub>	N – H	101	389
CH <sub>4</sub>	C – H	109	414

**\*\*Bond length decreases when number of bonds increase**

**\*\*Bond Strength increases when number of bonds increase**

## Topic 3: INTER-MOLECULAR BONDS

### 1. Dipole-Dipole bonds (attractions)

When two polar molecules get near each other, the positive end ( $\delta^+$ ) of one attracts the negative ( $\delta^-$ ) end of the other. This attraction between the two dipoles is known as a dipole-dipole bond

Ex: HF

- Because F is very \_\_\_\_\_, it pulls the shared electrons towards it causing a partial negative charge. This leads to a partial positive charge on the side of H leading to a **dipole** (opposite charges) in the atom.
- Between HF molecules, the \_\_\_\_\_ **charged ends attract** as shown in thick arrows. These are called dipole-dipole attractions.

### 2. Hydrogen bonds:

**Hydrogen bonds:** formed between non-bonding electrons of O, N, F atoms of one molecule and \_\_\_\_\_ atoms of another molecule

Ex: Water molecules

### 3. Van der Waal's attractions

- Electrons in atoms are in constant motion, and there are brief periods of time in which they are slightly to one side of the molecule or the other. During this time, the molecule has a very slight, \_\_\_\_\_.
- If another, similar, temporary dipole exists in a \_\_\_\_\_ molecule, the **weak \_\_\_\_\_ attraction** causes the **two dipoles to persist for slightly longer** than they otherwise would, and the two molecules remain attracted for a short period of time. Such forces are called **van der Waal's forces**.
- **So, \_\_\_\_\_ compounds have these!**

## Topic 4: MOLECULAR GEOMETRY

### VSPR: Valence-Shell Electron Pair Repulsion theory:

Repulsion between \_\_\_\_\_ electron pairs cause molecular shapes to change so that valence electron pairs repel each other and want to stay as far apart as possible.

#### Two bonds

Bent triatomic

Linear triatomic

#### Three bonds

Pyramidal

Trigonal planar

#### Four bonds

Tetrahedral

Square planar

#### Five bonds

Trigonal  
bipyramidal

#### Six bonds

Octahedral

Example: Water molecule:

Repulsion between \_\_\_\_\_ electrons also effect 3D molecular shapes: Ex.  $\text{H}_2\text{O}$

In water, the two lone pair electron repulsion and the electron clouds of these electron pairs cause the molecule to have a \_\_\_\_\_ rather than a triatomic shape.

#### Repulsive force between unpaired electrons

Tetrahedral

**1-18-2019 (HW2) HOME WORK QUESTIONS Due date: 1-22-19 (will NOT be graded 2 weeks post due date)**

1. How are covalent compounds (molecules) different from Ionic compounds?
2. What is the molecular geometries of the following molecules?

a.  $\text{H}_2\text{O}$

b.  $\text{CO}_2$

c.  $\text{NH}_3$

3. Draw the Lewis dot structures of the following compounds:

Name	Chemical formula
Hydrogen peroxide	$\text{H}_2\text{O}_2$
Hydrochloric acid	$\text{HCl}$
Sulfur trioxide	$\text{SO}_3$
Hydrogen cyanide	$\text{HCN}$
Nitrous Oxide	$\text{N}_2\text{O}$
Nitrogen dioxide	$\text{NO}_2$
Ethane	$\text{C}_2\text{H}_2$

4. Explain why all molecules have van der Waals forces:

5. Consider the following molecule:

- a. What are the chemical bonds formed between atoms in the following molecule?

- b. Which types of the chemical bonds formed between these molecules? Draw the two molecules and indicate bonds with arrows
- c. What are chemical bonds formed between these molecules and H-Br molecules? Draw the two molecules and indicate bonds with arrows
