[Home](#)

[Schedule](#)

[Past talks](#)

[People](#)

We are a group of people interested in the intersection of computer science and economics (and the social sciences more broadly) and the impact of this interplay on decisions in information technology and digital business. This includes applying techniques from computer science and optimization to economics -- for example, using computation to design market clearing mechanisms and to implement efficient allocation and pricing in them -- as well as applying techniques from economics to computer science -- for example, designing incentives for users of networked computer systems and social networks.

Contacts

For organizational questions about the seminar series, please contact [Dima Korzhyk](#). For other matters, please approach the relevant faculty contact(s): [Atila Abdulkadiroglu](#) (Econ), [Vincent Conitzer](#) (CS), [Rachel Kranton](#) (Econ), [Ben Lee](#) (ECE), [Kamesh Munagala](#) (CS), [Sasa Pekec](#) (Fuqua). [Pam Spencer](#) helps with catering and arranging the speakers' travel.

Mailing List

Please subscribe to the [cs-econ mailing list](#) if you are at Duke (or in the vicinity) and interested in the seminar series. The list will be used for talk announcements.

<http://econ.cs.duke.edu>

Master's of Science in Economics and Computation (MSEC)

The MSEC degree is a joint master's program of the Departments of Economics and **Computer Science**. The joint field of economics and computation has recently emerged from two converging intellectual needs, which has created the opportunity for a truly interdisciplinary program.

The MSEC program is the outcome of exciting developments across the two fields:

- Computer science is becoming increasingly important for economists addressing complex questions on large repositories of data;
- The explosion of computer uses in all areas of life has made it necessary for computer scientists to understand the economics of computing systems; and,
- Computer scientists may now also analyze informational and financial transactions between people, businesses, governments, and electronic agents in economic terms.

"Macroeconomic problems are almost always analytically intractable and therefore require a computer to solve ... Having a background in computer science made it much easier to learn (computational) methods, as well as apply cutting-edge advances in technology to economic problems."

David Klemish
MSEM

"Tech giants such as Google, Microsoft, Yahoo, and Facebook are in many ways ahead of academia in getting computer scientists and economists to work together, and interest in these topics extends well beyond this group of companies. With this Master's program, Duke is at the forefront of catching up with industry in breaking down boundaries."

Vince Conitzer
Department of Computer Science

Application Deadline

For Fall 2014: February 15, 2014

Charles Becker, MSEC Program Director

The image shows a screenshot of the Duke University Economics website. At the top, the logo for Duke University Economics is displayed, with "Duke" in blue and "Economics" in orange. Below the logo is a navigation menu with six items: "About", "Undergraduate", "Master's Program", "Ph.D. Program", "Research", and "Centers & Initia". The "Master's Program" item is highlighted. Below the navigation menu is a breadcrumb trail: "Home / Master's Program / Master's of Science in Economics and Computation".

What is Economics?

- “Economics is the social science that describes the factors that determine the production, distribution and consumption of goods and services.” [[Wikipedia, Jan. 2016](#)]
- Some key concepts:
 - Economic **agents** or **players** (individuals, households, firms, ...)
 - Agents’ current **endowments** of goods, money, skills, ...
 - Possible **outcomes** ((re)allocations of resources, tasks, ...)
 - Agents’ **preferences** or **utility functions** over outcomes
 - Agents’ **beliefs** (over other agents’ utility functions, endowments, production possibilities, ...)
 - Agents’ possible **decisions/actions**
 - **Mechanism** that maps decisions/actions to outcomes

An economic picture

$$v(\text{server}) = 200$$

\$ 800

$$v(\text{television}) = 100$$

$$v(\text{laptop}) = 400$$

\$ 600

$$v(\text{laptop}) = 200$$

$$v(\text{server}, \text{television}) = 400$$

\$ 200

After trade (a more efficient outcome)

$$v(\text{server}) = 200$$

\$ 1100

... but how do we
get here?
Auctions?
Exchanges?
Unstructured trade?

$$v(\text{television}) = 100$$

$$v(\text{laptop}) = 400$$

\$ 400

$$v(\text{laptop}) = 200$$

$$v(\text{server} + \text{television}) = 400$$

\$ 100

Some distinctions in economics

- **Descriptive vs. normative** economics
 - Descriptive:
 - seeks only to describe real-world economic phenomena
 - does not care if this is in any sense the “right” outcome
 - Normative:
 - studies how people “should” behave, what the “right” or “best” outcome is
- **Microeconomics vs. macroeconomics**
 - Microeconomics: analyzes decisions at the level of individual agents
 - deciding which goods to produce/consume, setting prices, ...
 - “bottom-up” approach
 - Macroeconomics: analyzes “the sum” of economic activity
 - interest rates, inflation, growth, unemployment, government spending, taxation, ...
 - “big picture”

What is Computer Science?

- “Computer science is the scientific and practical approach to computation and its applications. [...] A computer scientist specializes in the theory of computation and the design of computational systems.” [\[Wikipedia, Jan. 2016\]](#)
- A **computational problem** is given by a function f mapping inputs to outputs
 - For integer x , let $f(x) = 0$ if x is prime, 1 otherwise
 - For an initial allocation of resources x , let $f(x)$ be the (re)allocation that maximizes the sum of utilities
- An **algorithm** is a fully specified procedure for computing f
 - E.g., sieve of Eratosthenes
 - A **correct algorithm** always returns the **right** answer
 - An **efficient algorithm** returns the answer **fast**
- Computer science is also concerned with building **larger artifacts** out of these building blocks (e.g., personal computers, spreadsheets, the Internet, the Web, search engines, artificial intelligence, ...)

Resource allocation as a computational problem

input

$v(\text{server, monitor}) = \400

$v(\text{laptop}) = \$600$

\$ 800

$v(\text{server, monitor}) = \500

$v(\text{laptop}) = \$400$

\$ 400

output

\$ 750

\$ 450

Here, gains from trade (\$300) are divided evenly (not essential)

Economic mechanisms

“true” input

$$v(\text{server, printer}) = \$400$$
$$v(\text{laptop}) = \$600$$

agent 1's
bidding
algorithm

agents' bids

$$v(\text{server, printer}) = \$500$$
$$v(\text{laptop}) = \$501$$

exchange
mechanism
(algorithm)

result

\$ 800

$$v(\text{server, printer}) = \$500$$
$$v(\text{laptop}) = \$400$$

\$ 400

agent 2's
bidding
algorithm

$$v(\text{server, printer}) = \$451$$
$$v(\text{laptop}) = \$450$$

\$ 400

*Exchange mechanism designer
does not have direct access to
agents' private information*

*Agents will selfishly respond to
incentives*

What is **game theory**?

- “Game theory is "the study of mathematical models of conflict and cooperation between intelligent rational decision-makers. Game theory is mainly used in economics, political science, and psychology, as well as logic, computer science, biology and Poker (Texas No Limit Hold'em).”
[Wikipedia, Jan. 2016]

What is **game theory**...

- Game theory studies settings where multiple parties (**agents**) each have
 - different preferences (utility functions),
 - different actions that they can take
- Each agent's utility (potentially) depends on all agents' actions
 - What is optimal for one agent depends on what other agents do
 - Very circular!
- Game theory studies how agents can rationally form **beliefs** over what other agents will do, and (hence) how agents should **act**
 - Useful for acting as well as predicting behavior of others

Penalty kick example

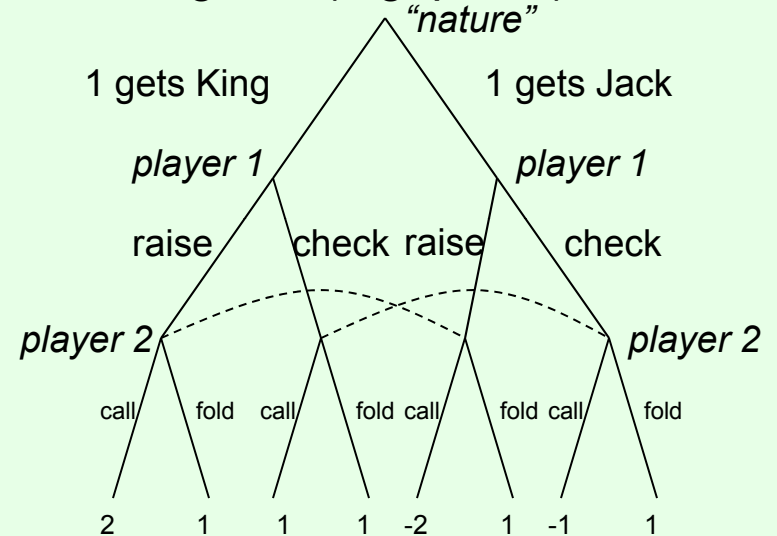

Game playing & AI

perfect information games:
no uncertainty about the state of the game (e.g. tic-tac-toe, chess, Go)

- Optimal play: value of each node = value of optimal child for current player (**backward induction**, minimax)
- For chess and Go, tree is too large
 - Use other techniques (heuristics, limited-depth search, alpha-beta, ...)
- Top computer programs (arguably) better than humans in chess, not yet in Go

imperfect information games: uncertainty about the state of the game (e.g. poker)

- Player 2 **cannot distinguish** nodes connected by dotted lines
 - Backward induction fails; need more sophisticated game-theoretic techniques for optimal play
- Small poker variants can be solved optimally
- Humans still better than top computer programs at full-scale poker (at least most versions)
- Top computer (heads-up) poker players are based on techniques for game theory

Real-world security applications

Milind Tambe's TEAMCORE group (USC)

Airport security

- Where should checkpoints, canine units, etc. be deployed?
- Deployed at LAX and another US airport, being evaluated for deployment at all US airports

Federal Air Marshals

- Which flights get a FAM?

US Coast Guard

- Which patrol routes should be followed?
- Deployed in Boston Harbor

Questions and problems in (computational) game theory

- How should we **represent** games (=strategic settings)?
 - Standard game-theoretic representations not always concise enough
- What does it mean to **solve** a game?
 - **Solution concepts** from game theory, e.g., Nash equilibrium
- How **computationally hard** is it to solve games?
 - Can we solve them approximately?
- Is there a role for **(machine) learning** in games?
- What types of **modeling problems** do we face when addressing real-world games?
 - E.g., applications in security
- ...

What is **social choice**?

- “Social choice theory or social choice is a theoretical framework for analysis of combining individual opinions, preferences, interests, or welfares to reach a collective decision or social welfare in some sense.” [[Wikipedia, Jan. 2016](#)]
- I.e., making decisions based on the preferences of multiple agents
- Largely, but not exclusively, focused on **voting**

Voting over outcomes

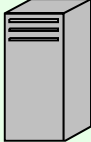

voting rule
(mechanism)
determines winner
based on votes

- Can vote over other things too
 - Where to go for dinner tonight, other joint plans, ...
- Many different rules exist for selecting the winner

Combinatorial auctions

Simultaneously for sale:  ,  , 

bid 1

$$v(\text{server rack} \text{ cabinet}) = \$500$$

bid 2

$$v(\text{laptop} \text{ cabinet}) = \$700$$

bid 3

$$v(\text{laptop}) = \$300$$

used in truckload transportation, industrial procurement, radio spectrum allocation, ...

Kidney exchange

Problems in computational social choice

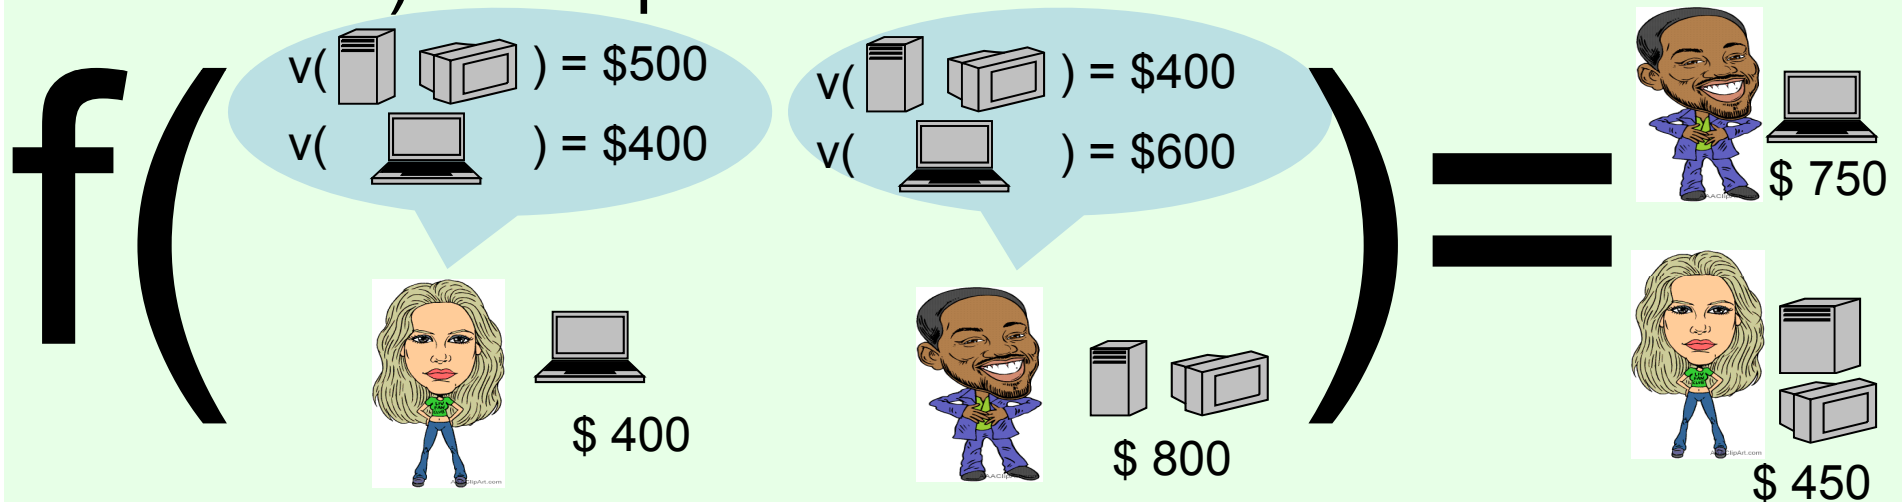

- **Winner determination** problem
 - For some voting rules, determining the winner is NP-hard
 - In a combinatorial auction, deciding which bids win is (in general) an NP-hard problem
- **Preference elicitation** (communication) problem
 - Can be impractical to communicate all of one's preferences (e.g., valuation for every bundle)
- **Mechanism design** problem
 - How do we get the bidders to behave so that we get good outcomes?
- These problems **interact** in nontrivial ways
 - E.g. limited computational or communication capacity can limit mechanism design options
 - ... but can perhaps also be used in a positive way

What is **mechanism design**?

- “Mechanism design is a field in economics and game theory that takes an engineering approach to designing economic mechanisms or incentives, toward desired objectives, in strategic settings, where players act rationally. [...] Two distinguishing features of [mechanism design] are:
 - that a game “designer” chooses the game structure rather than inheriting one
 - that the designer is interested in the game’s outcome
- [\[Wikipedia, Jan. 2016\]](#)

Mechanism design...

- **Mechanism** = rules of auction, exchange, ...
- A **function** that takes **reported preferences** (bids) as input, and produces **outcome** (allocation, payments to be made) as output

- The **entire function** f is **one** mechanism
- E.g., the mechanism from before: find allocation that maximizes (reported) utilities, distribute (reported) gains evenly
- Other mechanisms choose different allocations, payments

Example: (single-item) auctions

- **Sealed-bid** auction: every bidder submits bid in a sealed envelope
- **First-price** sealed-bid auction: highest bid wins, pays amount of own bid
- **Second-price** sealed-bid auction: highest bid wins, pays amount of second-highest bid

Which auction generates more revenue?

- Each bid depends on
 - bidder's **true valuation** for the item (utility = valuation - payment),
 - bidder's **beliefs** over what others will bid (\rightarrow game theory),
 - and... the **auction mechanism** used
- In a first-price auction, it does not make sense to bid your true valuation
 - Even if you win, your utility will be 0...
- In a second-price auction, (we will see later that) it always makes sense to bid your true valuation

Are there other auctions that perform better? How do we know when we have found the best one?

Mechanism design...

- Mechanism = game
- → we can use game theory to predict what will happen under a mechanism
 - if agents act strategically
- When is a mechanism “good”?
 - Should it result in outcomes that are good for the **reported** preferences, or for the **true** preferences?
 - Should agents ever end up **lying** about their preferences (in the game-theoretic solution)?
 - Should it always **generate the best allocation**?
 - Should agents ever **burn money**?(!?)
- Can we solve for the optimal mechanism?

Many uses of linear programming, mixed integer (linear) programming in this course

	Linear programming	Mixed integer linear programming
Game theory	<p>Dominated strategies</p> <p>Minimax strategies</p> <p>Correlated equilibrium</p> <p>Optimal mixed strategies to commit to</p>	<p>Nash equilibrium</p> <p>Optimal mixed strategies to commit to in more complex settings</p>
Social choice, expressive marketplaces	<p>Winner determination in auctions, exchanges, ... with partially acceptable bids</p>	<p>Winner determination in: auctions, exchanges, ... without partially acceptable bids; Kemeny, Slater, other voting rules; kidney exchange</p>
Mechanism design	<p>Automatically designing optimal mechanisms that use randomization</p>	<p>Automatically designing optimal mechanisms that do not use randomization</p>

Prediction markets

The screenshot shows the PredictIt website interface. The browser address bar displays the URL: <https://www.predictit.org/Contract/444/Will-Hillary-Clinton-win-the-2016-US-presidential-election#>. The PredictIt logo is in the top left, and navigation links for MARKETS, ANALYSIS, ABOUT, SIGN IN, and SIGN UP are in the top right. A search bar is also present.

The main content area features the title "Will Hillary Clinton win the 2016 U.S. presidential election?" and the latest price: "Latest Price: 44¢ ↑ 1¢". Below the title is a portrait of Hillary Clinton and two buttons: "Buy Yes" (green) and "Buy No" (red). The "Buy Yes" button includes the text "Click to match Offers starting at 45¢, or to make your own, lower Offer." The "Buy No" button includes the text "Click to match Offers starting at 56¢, or to make your own, lower Offer."

A disclaimer below the buttons reads: "If this prediction comes true, PredictIt will redeem all Yes shares at \$1. Shares in No will have zero value. If this prediction does not come true, PredictIt will redeem all No shares at \$1. Shares in Yes will have zero value."

Below the disclaimer are tabs for "Data", "Rules", and "Prices". The "Data" tab is active, showing a table with the following information:

Symbol:	CLINTON.USPREZ16
Market Type:	Linked
Start Date:	10/14/2014
End Date:	12/19/2016
Shares Traded:	470,751
Today's Volume:	1,370
Total Shares:	171,022
Today's Change:	+1¢ ↑

To the right of the table is a line chart showing the price history from 01/08/2016 to 01/14/2016. The chart has a y-axis from 0 to 100 and a blue line representing the price, which starts at approximately 55¢ and ends at 44¢. The chart includes tabs for "24 Hour", "7 Day", "30 Day", and "90 Day".

On the left side of the page, there are navigation links: "Most Predicted", "Closing Soon", "U.S. Elections", "U.S. Politics", and "World". A "Need Help?" button is located on the right side of the page.

Financial securities

- Tomorrow there must be one of   
- Agent 1 offers \$5 for a security that pays off \$10 if  or 
- Agent 2 offers \$8 for a security that pays off \$10 if  or 
- Agent 3 offers \$6 for a security that pays off \$10 if 
- Can we accept some of these at offers **at no risk?**

How to incentivize a weather forecaster

$$P(\text{☀}) = .5$$

$$P(\text{☁}) = .3$$

$$P(\text{⚡}) = .2$$

$$P(\text{☀}) = .8$$

$$P(\text{☁}) = .1$$

$$P(\text{⚡}) = .1$$

- Forecaster's bonus can depend on
 - Prediction
 - Actual weather on predicted day
- Reporting true beliefs should maximize expected bonus

Why should economists care about computer science?

- Finding efficient allocations of resources is a (typically hard) **computational problem**
 - Sometimes beyond current computational techniques
 - If so, unlikely that **any** market mechanism will produce the efficient allocation (even without incentives issues)
 - Market mechanisms must be designed **with computational limitations in mind**
 - New algorithms allow new market mechanisms

Why should economists care about computer science...

- **Agents** also face difficult computational problems in participating in the market
 - Especially acting in a game-theoretically optimal way is often **computationally hard**
 - Game-theoretic predictions **will not come true** if they cannot be computed
 - Sometimes bad (e.g., want agents to find right bundle to trade)
 - Sometimes good (e.g., do not want agents to manipulate system)

Why should computer scientists care about economics?

- Economics provides high-value computational problems
- Interesting technical twist: **no direct access to true input**, must incentivize agents to reveal true input
- Conversely: Computer systems are increasingly used by **multiple parties** with different preferences (e.g., Internet)
- Economic techniques must be used to
 - **predict** what will happen in such systems,
 - **design** the systems so that they will work well
- Game theory is relevant for **artificial intelligence**
 - E.g., computer poker
