

## DMOS driver for three-phase brushless DC motor

### Features

- Operating supply voltage from 8 to 52 V
- 2.8 A output peak current (1.4 A RMS)
- $R_{DS(on)}$  0.73  $\Omega$  typ. value @  $T_J = 25\text{ }^\circ\text{C}$
- Integrated fast free wheeling diodes
- Operating frequency up to 100 kHz
- Non dissipative overcurrent detection and protection
- Cross conduction protection
- Diagnostic output
- Uncommitted comparator
- Thermal shutdown
- Under voltage lockout

### Application

- BLDC motor driving
- Sinusoidal / 6-steps driving
- Field oriented control driving system

### Description

The L6230 is a DMOS fully integrated three-phase motor driver with overcurrent protection, optimized for FOC application thanks to the independent current senses.

Realized in BCDmultipower technology, the device combines isolated DMOS Power Transistors with CMOS and bipolar circuits on the same chip.

An uncommitted comparator with open-drain output is available.

Available in PowerSO36 and VFQFPN-32 5x5 packages the L6230 features a non dissipative overcurrent protection on the high side power MOSFETs and thermal shutdown.

1. Mounted on a multi-layer FR4 PCB with a dissipating copper surface on the top side of 6 cm<sup>2</sup> (with a thickness of 35 μm).
2. Mounted on a multi-layer FR4 PCB with a dissipating copper surface on the top side of 6 cm<sup>2</sup> (with a thickness of 35 μm), 16 via holes and a ground layer.
3. Mounted on a multi-layer FR4 PCB without any heat-sinking surface on the board.
4. Mounted on a double-layer FR4 PCB with a dissipating copper surface of 0.5 cm<sup>2</sup> on the top side plus 6 cm<sup>2</sup> ground layer connected through 18 via holes (9 below the IC).

### 3 Pin connection

Figure 2. Pin connection PowerSO36 (top view)

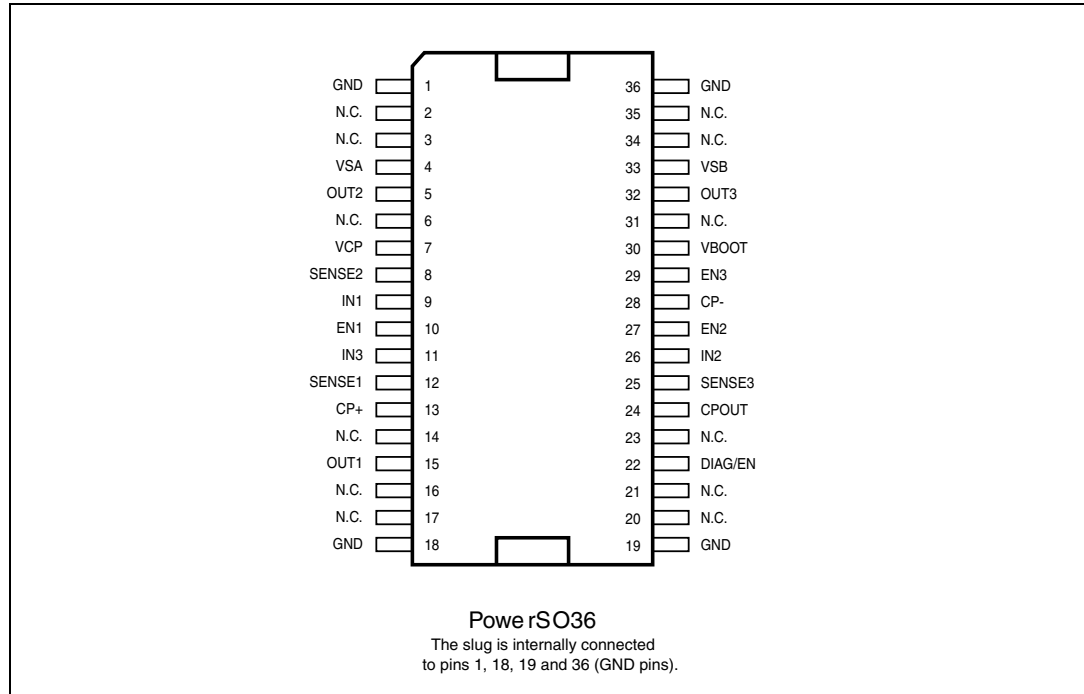

Figure 3. Pin connection VFQFPN32 (top view)

*Note:* The pins 2 to 8 are connected to die PAD.  
The die PAD must be connected to GND pin.

**Table 5. Pin description**

Pin	Type	Function
VBOOT	Power supply	Bootstrap voltage needed for driving the upper power MOSFETs.
VCP	Output	Charge pump oscillator output.
DIAG-EN	Logic output/input	Double function: chip Enable as input and Overcurrent/Over-temperature indication as output. LOW logic level switches OFF all Power MOSFETs, putting the power stages in high impedance status. An internal open drain transistor pulls to GND the pin when an overcurrent on one of the High Side MOSFETs is detected or during Thermal Protection.
IN1	Logic input	Logic input half bridge 1.
EN1	Logic input	Enable input half bridge 1.
IN2	Logic input	Logic input half bridge 2.
EN2	Logic input	Enable input half bridge 2.
IN3	Logic input	Logic input half bridge 3.
EN3	Logic input	Enable input half bridge 3.
CP-	Analog input	Inverting input of internal comparator.
CP+	Analog input	Non-Inverting input of internal comparator.
CPOUT	Output	Open-drain output of internal comparator.
SENSE3		Half bridge 3 source pin. This pin must be connected to power ground through a sensing power resistor.
OUT3	Power output	Output half bridge 3.
VSB	Power supply	Half bridge 3 power supply voltage. it must be connected to the supply voltage together with pin VSA.
SENSE2		Half bridge 2 source pin. This pin must be connected to power ground through a sensing power resistor.
OUT2	Power output	Output half bridge 2.
SENSE1		Half bridge 1 source pin. This pin must be connected to power ground through a sensing power resistor.
OUT1	Power output	Output half bridge 1.
VSA	Power supply	Half bridge 1 and half bridge 2 power supply voltage. It must be connected to the supply voltage together with pin VSB.
GND	Ground	Ground terminal.

## 4 Electrical characteristics

( $V_S = 48\text{ V}$ ,  $T_A = 25\text{ °C}$ , unless otherwise specified)

**Table 6. Electrical characteristics**

Figure 5. Overcurrent detection timing definition

## 5 Circuit description

### 5.1 Power stages and charge pump

The L6230 integrates a three-phase bridge, which consists of 6 power MOSFETs connected as shown on the block diagram (see [Figure 1](#)), each power MOS has an  $R_{DS(ON)} = 0.73 \Omega$  (typical value @ 25 °C) with intrinsic fast freewheeling diode. Cross conduction protection is implemented by using a dead time ( $t_{DT} = 1 \mu s$  typical value) set by internal timing circuit between the turn off and turn on of two power MOSFETs in one leg of a bridge.

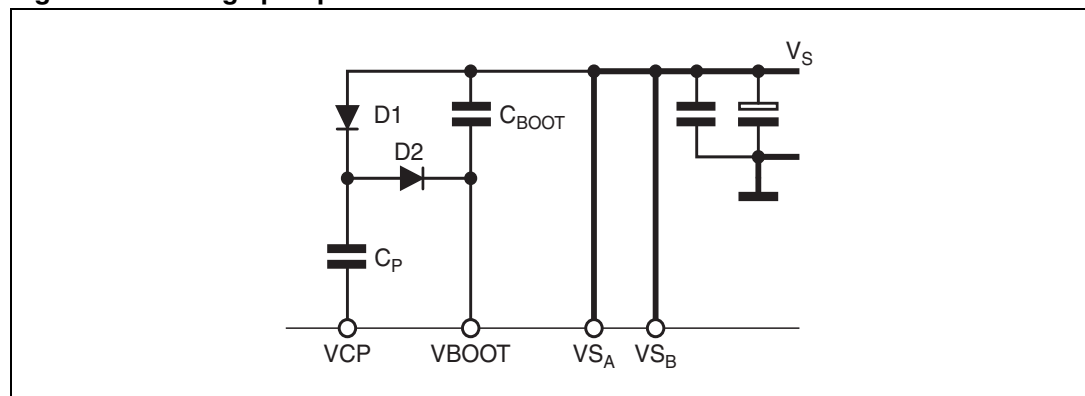

Pins  $VS_A$  and  $VS_B$  must be connected together to the supply voltage ( $V_S$ ).

Using N-channel power MOS for the upper transistors in the bridge requires a gate drive voltage above the power supply voltage. The bootstrapped supply ( $V_{BOOT}$ ) is obtained through an internal oscillator and few external components to realize a charge pump circuit as shown in [Figure 6](#). The oscillator output (pin VCP) is a square wave at 600 kHz (typically) with 10 V amplitude. Recommended values/part numbers for the charge pump circuit are shown in [Table 7](#).

**Table 7. Charge pump external component values**

Component	Value
$C_{BOOT}$	220 nF
$C_P$	10 nF
D1	1N4148
D2	1N4148

**Figure 6. Charge pump circuit**

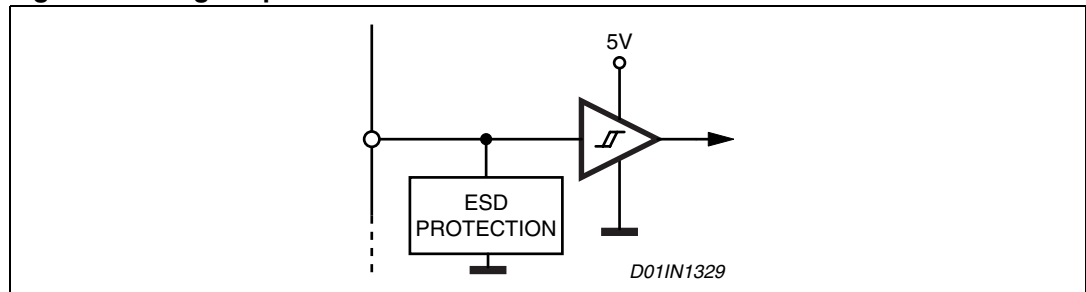

## 5.2 Logic inputs

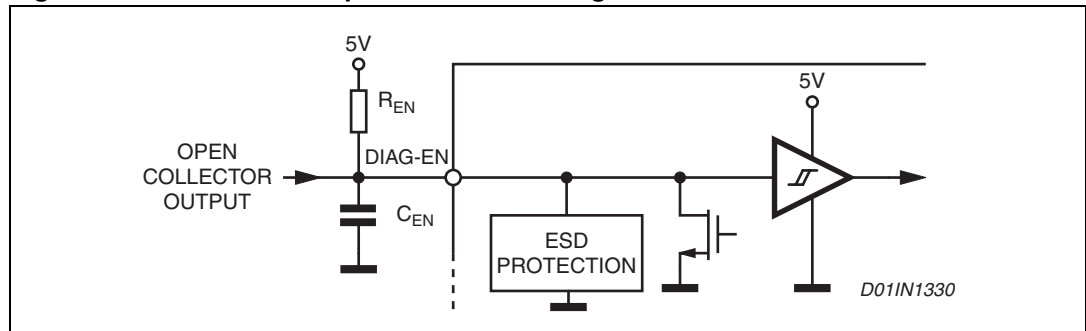

Pins INx and ENx are TTL/CMOS and microcontroller compatible logic inputs. The internal structure is shown in [Figure 7](#). Typical value for turn-on and turn-off thresholds are respectively  $V_{th(ON)} = 1.8\text{ V}$  and  $V_{th(OFF)} = 1.3\text{ V}$ .

Pin DIAG-EN has identical input structure with the exception that the drain of the Overcurrent and thermal protection MOSFET is also connected to this pin. Due to this connection some care needs to be taken in driving this pin. The EN input may be driven in one of two configurations as shown in [Figure 8](#) or [Figure 9](#). If driven by an open drain (collector) structure, a pull-up resistor  $R_{EN}$  and a capacitor  $C_{EN}$  are connected as shown in [Figure 8](#). If the driver is a standard Push-Pull structure the resistor  $R_{EN}$  and the capacitor  $C_{EN}$  are connected as shown in [Figure 9](#). The resistor  $R_{EN}$  should be chosen in the range from 2.2 kΩ to 180 kΩ. Recommended values for  $R_{EN}$  and  $C_{EN}$  are respectively 10 kΩ and 5.6 nF. More information on selecting the values is found in the overcurrent protection section.

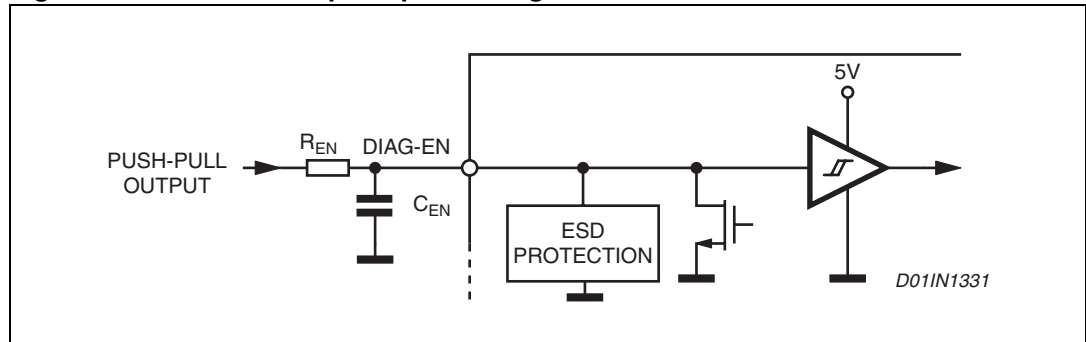

**Figure 7. Logic inputs internal structure**

**Figure 8. Pin DIAG-EN open collector driving**

**Figure 9. Pin DIAG-EN push-pull driving**

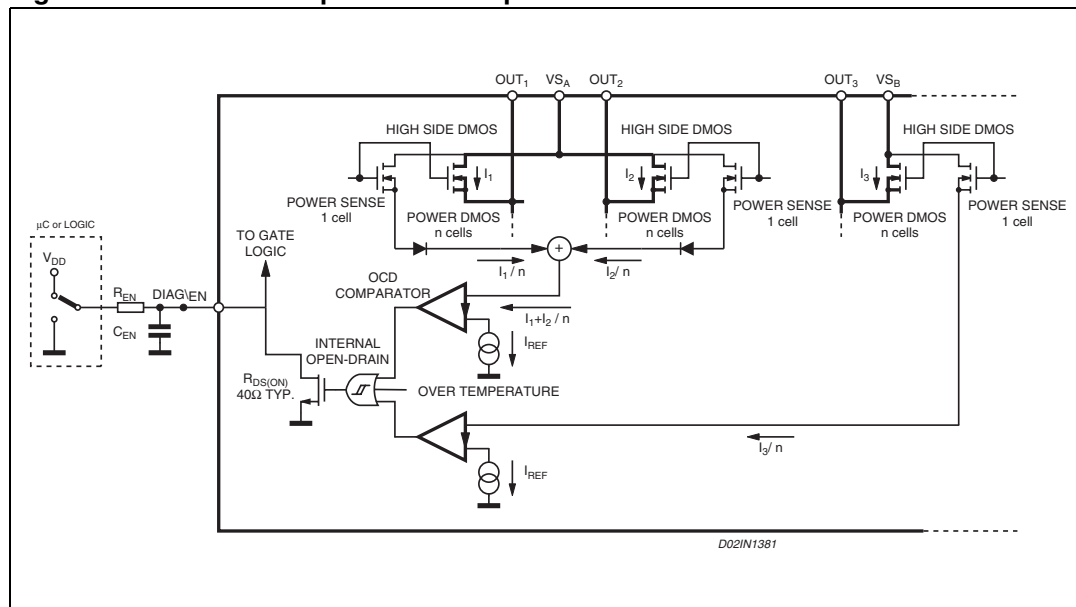

### 5.3 Non-dissipative overcurrent detection and protection

The L6230 integrates an overcurrent detection circuit (OCD) for full protection. This circuit provides output-to-output and output-to-ground short circuit protection as well. With this internal over current detection, the external current sense resistor normally used and its associated power dissipation are eliminated. *Figure 10* shows a simplified schematic for the overcurrent detection circuit.

To implement the over current detection, a sensing element that delivers a small but precise fraction of the output current is implemented with each high side power MOS. Since this current is a small fraction of the output current there is very little additional power dissipation. This current is compared with an internal reference current  $I_{REF}$ . When the output current reaches the detection threshold (typically  $I_{SOVER} = 2.8\text{ A}$ ) the OCD comparator signals a fault condition. When a fault condition is detected, an internal open drain MOS with a pull down capability of 4 mA connected to pin DIAG is turned on.

The pin DIAG-EN can be used to signal the fault condition to a  $\mu\text{C}$  and to shut down the three-phase bridge simply by connecting the pin to an external R-C (see  $R_{EN}$ ,  $C_{EN}$ ).

**Figure 10. Overcurrent protection simplified schematic**

*Figure 11* shows the overcurrent detection operation. The disable time  $t_{DISABLE}$  before recovering normal operation can be easily programmed by means of the accurate thresholds of the logic inputs. It is affected whether by  $C_{EN}$  and  $R_{EN}$  values and its magnitude is reported in *Figure 12*. The delay time  $t_{DELAY}$  before turning off the bridge when an overcurrent has been detected depends only by  $C_{EN}$  value. Its magnitude is reported in *Figure 13*

$C_{EN}$  is also used for providing immunity to pin DIAG-EN against fast transient noises. Therefore the value of  $C_{EN}$  should be chosen as big as possible according to the maximum tolerable delay time and the  $R_{EN}$  value should be chosen according to the desired disable time.

The resistor  $R_{EN}$  should be chosen in the range from  $2.2\text{ k}\Omega$  to  $180\text{ k}\Omega$ . Recommended values for  $R_{EN}$  and  $C_{EN}$  are respectively  $100\text{ k}\Omega$  and  $5.6\text{ nF}$  that allow obtaining  $200\text{ }\mu\text{s}$  disable time.

Figure 11. Overcurrent protection waveforms

Figure 12.  $t_{DISABLE}$  versus  $C_{EN}$  and  $R_{EN}$

Figure 13.  $t_{DELAY}$  versus  $C_{EN}$

## 6 Application information

Some typical applications using L6230 are shown in this paragraph. A high quality ceramic capacitor ( $C_2$ ) in the range of 100 nF to 200 nF should be placed between the power pins  $VS_A$  and  $VS_B$  and ground near the L6230 to improve the high frequency filtering on the power supply and reduce high frequency transients generated by the switching. The capacitor ( $C_{EN}$ ) connected from the DIAG-EN input to ground sets the shut down time when an over current is detected (see overcurrent protection). The current sensing inputs ( $SENSE_X$ ) should be connected to the sensing resistors  $R_{SENSE}$  with a trace length as short as possible in the layout. The sense resistors should be non-inductive resistors to minimize the  $dl/dt$  transients across the resistors. To increase noise immunity, unused logic pins are best connected to 5 V (high logic level) or GND (low logic level) (see pin description). It is recommended to keep power ground and signal ground separated on PCB.

**Table 8. Component values for typical application**

Component	Value
$C_1$	100 $\mu$ F
$C_2$	100 nF
$C_{BOOT}$	220 nF
$C_{EN}$	5.6 nF
$C_P$	10 nF
$D_1$	1N4148
$D_2$	1N4148
$R_{EN}$	100 k $\Omega$

The examples reported describe some typical application to drive a 3-phase BLDC motor using L6230 device.

In the first example is shown a field oriented control (FOC) system, with this method it is possible to provide smooth and precise motor control of BLDC motors.

A six-step driving method with current control is reported in the second example, the inputs sequence is generated by external controller and the L6230 comparator is used to obtain the information for the peak current control.

Finally, the third example shows how to implement a sensorless motor control system, the information on rotor position is achieved by BEMF zero-crossing detection.

### 6.1 Field oriented control driving method

In this configuration (see [Figure 14](#)) three sensing resistors are required, one for each channel. The sensing signals coming from the output power stage are conditioned by external operational amplifiers which provide the proper feedback signals to the AtoD converter and the system controller. According to the feedback signals the six input lines are generated by the controller.

Note that some filtering and level shifting RC networks should be added between the sense resistor and the correspondent op-amp input.

The uncommitted internal comparator with open-drain output is available.

**Figure 14. F.O.C. typical application**

## 6.2 Six-step driving method with current control

In this configuration only one sense resistor are needed, the three OUT pins are connected together to R<sub>SENSE</sub> (see [Figure 15](#)).

The non-inverting input comparator CP+ monitors the voltage drop across the external sense resistor connected between the source of the three lower power MOS transistors and ground.

As the current in the motor increases the voltage across the R<sub>SENSE</sub> increases proportionally. When the voltage drop across the sense resistor becomes greater than the reference voltage applied at inverting input CP- the comparator open-drain output is switched on pulling down the CPOUT pin.

This signal could be managed by controller to generate the proper input sequence for six-step driving method with current control and select what current decay method to implement.

When the sense voltage decrease below the CP- voltage, the open-drain is switched off and the voltage at CPOUT pin start to increase charging the capacitor C3.

The reference voltage at pin CP- will be set according to sense resistor value and the desired regulated current ( $V_{CP-} \cong R_{SENSE} \times I_{TARGET}$ ). A very simple way to obtain variable voltage is to low-pass filter a PWM output of a controller.

Figure 15. Six-step with current control typical application

### 6.3 Six-step driving method with BEMF zero crossing detection

The BEMF zero crossing information can be used to evaluate the rotor position; in this way no Hall effect sensors or encoder are needed.

In six-step driving mode one of the three phases is left in high impedance state.

Comparing the voltage of this phase with the center-tap voltage we can detect the BEMF zero-crossing.

In shown example (see [Figure 16](#)), the OUT1 phase voltage is monitored by the CP+; the center-tap voltage is obtained as combination of three phase voltages and monitored by the CP- pin. Only when the OUT1 is in high impedance, the CPOUT will perform a commutation each time a BEMF zero crossing is detected.

In this configuration one sense resistor is needed, the three OUT pins are connected together to  $R_{SENSE}$ .

Figure 16. Six-step with zero crossing detection typical application

## 6.4 Thermal management

In most applications the power dissipation in the IC is the main factor that sets the maximum current that can be delivered by the device in a safe operating condition. Therefore, it has to be taken into account very carefully. Besides the available space on the PCB, the right package should be chosen considering the power dissipation. Heat sinking can be achieved using copper on the PCB with proper area and thickness.

For instance, using a VFQFPN32L 5 x 5 package the typical  $R_{th(JA)}$  is about 42 °C/W when mounted on a double-layer FR4 PCB with a dissipating copper area of 0.5 cm<sup>2</sup> on the top side plus 6 cm<sup>2</sup> ground layer connected through 18 via holes (9 below the IC).

Otherwise, using a PowerSO package with copper slug soldered on a 1.5 mm copper thickness FR4 board with 6cm<sup>2</sup> dissipating footprint (copper thickness of 35 μm), the  $R_{th(jA)}$  is about 35°C/W.

Using a multi-layer board with vias to a ground plane, thermal impedance can be reduced down to 15°C/W.

## 7 Package mechanical data

In order to meet environmental requirements, ST offers these devices in different grades of ECOPACK® packages, depending on their level of environmental compliance. ECOPACK® specifications, grade definitions and product status are available at: [www.st.com](http://www.st.com). ECOPACK® is an ST trademark.
