**EE2403      SPECIAL ELECTRICAL MACHINES****AIM**

To expose the students to the construction, principle of operation and performance of special electrical machines as an extension to the study of basic electrical machines.

**OBJECTIVES**

To impart knowledge on

- i. Construction, principle of operation and performance of synchronous reluctance motors.
- ii. Construction, principle of operation, control and performance of stepping motors.
- iii. Construction, principle of operation, control and performance of switched reluctance motors.
- iv. Construction, principle of operation, control and performance of permanent magnet brushless D.C. motors.
- v. Construction, principle of operation and performance of permanent magnet synchronous motors.

**UNIT I SYNCHRONOUS RELUCTANCE MOTORS      9**

Constructional features – Types – Axial and Radial flux motors – Operating principles – Variable Reluctance and Hybrid Motors – SYNREL Motors – Voltage and Torque Equations – Phasor diagram - Characteristics.

**UNIT II STEPPING MOTORS      9**

Constructional features – Principle of operation – Variable reluctance motor – Hybrid motor – Single and multi stack configurations – Torque equations – Modes of excitations – Characteristics – Drive circuits – Microprocessor control of stepping motors – Closed loop control.

**UNIT III SWITCHED RELUCTANCE MOTORS      9**

Constructional features – Rotary and Linear SRMs – Principle of operation – Torque production – Steady state performance prediction – Analytical method – Power Converters and their controllers – Methods of Rotor position sensing – Sensor less operation – Closed loop control of SRM - Characteristics.

**UNIT IV PERMANENT MAGNET BRUSHLESS D.C. MOTORS      9**

Permanent Magnet materials – Magnetic Characteristics – Permeance coefficient – Principle of operation – Types – Magnetic circuit analysis – EMF and torque equations – Commutation – Power controllers – Motor characteristics and control.

**UNIT V PERMANENT MAGNET SYNCHRONOUS MOTORS      9**

Principle of operation – Ideal PMSM – EMF and Torque equations – Armature reaction MMF – Synchronous Reactance – Sine wave motor with practical windings - Phasor diagram – Torque/speed characteristics – Power controllers – Converter Volt-ampere requirements.

## UNIT I

### SYNCHRONOUS RELUCTANCE MOTORS

#### 1.1 CONSTRUCTION OF SYNCHRONOUS RELUCTANCE MOTOR

The structure of reluctance motor is same as that of salient pole synchronous machine as shown in fig. The rotor does not have any field winding. The stator has three phase symmetrical winding, which creates sinusoidal rotating magnetic field in the air gap, and the reluctance torque is developed because the induced magnetic field in the rotor has a tendency to cause the rotor to align with the stator field at a minimum reluctance position

Fig 1.1 Idealized Three Phase Four Pole Synchronous Machine (Salient Pole)

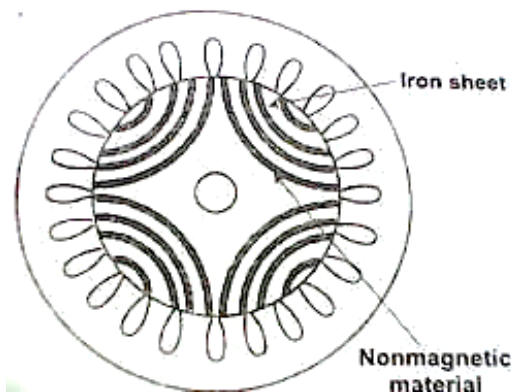

Fig 1.2 Cross Section of Synchronous Reluctance Motor.

The rotor of the modern reluctance machine is designed with iron laminations in the axial direction separated by non-magnetic material. The performance of the reluctance motor may approach that of induction machine. With high saliency ratio a power factor of 0.8 can be reached. The efficiency of a reluctance machine may be higher than an induction motor

because there is no rotor copper loss. Because of inherent simplicity, robustness of construction and low cost.

The synchronous reluctance motor has no synchronous starting torque and runs up from stand still by induction action. There is an auxiliary starting winding. This has increased the pull out torque, the power factor and the efficiency.

Synchronous reluctance motor is designed for high power applications. It can broadly be classified into

Axially laminated and

Radially laminated.

Fig.1.3 cross section of axially laminated

Reluctance motors can deliver very high power density at low cost, making them ideal for many applications. Disadvantages are high torque ripple (the difference between maximum and minimum torque during one revolution) when operated at low speed, and noise caused by torque ripple. Until the early twenty-first century their use was limited by the complexity of designing and controlling them. These challenges are being overcome by advances in the theory, by the use of sophisticated computer design tools, and by the use of low-cost embedded systems for control, typically based on microcontrollers using control algorithms and real-time computing to tailor drive waveforms according to rotor position and

current or voltage feedback. Before the development of large-scale integrated circuits the control electronics would have been prohibitively costly.

Fig 1.4 cross section of radially laminated

The stator consists of multiple projecting (salient) electromagnet poles, similar to a wound field brushed DC motor. The rotor consists of soft magnetic material, such as laminated silicon steel, which has multiple projections acting as salient magnetic poles through magnetic reluctance. The number of rotor poles is typically less than the number of stator poles, which minimizes torque ripple and prevents the poles from all aligning simultaneously—a position which cannot generate torque.

When a rotor pole is equidistant from the two adjacent stator poles, the rotor pole is said to be in the "fully unaligned position". This is the position of maximum magnetic reluctance for the rotor pole. In the "aligned position", two (or more) rotor poles are fully aligned with two (or more) stator poles, (which mean the rotor poles completely face the stator poles) and is a position of minimum reluctance.

When a stator pole is energized, the rotor torque is in the direction that will reduce reluctance. Thus the nearest rotor pole is pulled from the unaligned position into alignment with the stator field (a position of less reluctance). (This is the same effect used by a solenoid, or when picking up ferromagnetic metal with a magnet.) In order to sustain rotation, the stator field must rotate in advance of the rotor poles, thus constantly "pulling" the rotor along. Some motor variants will run on 3-phase AC power (see the synchronous reluctance variant below). Most modern designs are of the switched reluctance type, because electronic commutation gives significant control advantages for motor starting, speed control, and smooth operation (low torque ripple).

Dual-rotor layouts provide more torque at lower price per volume or per mass. The inductance of each phase winding in the motor will vary with position, because the reluctance also varies with position. This presents a control systems challenge.

### Applications

- ❖ Some washing machine designs.
- ❖ Control rod drive mechanisms of nuclear reactors.
- ❖ The *Dyson Digital Motor* used in some products produced by the Dyson company.

## 1.2 ROTOR DESIGN

### 1.2.1 Salient rotor (Segmental)

Salient rotor shape such that the quadrature air gap is much larger than the direct air gap. This yields reactively small  $L_d/L_q$  ratios in the range of 2.3.

Fig.1.5 Salient rotor

Salient rotor design is as shown. The low  $L_d/L_q$  ratios are largely the result of circulating flux in the pole faces of the rotor. However the ruggedness and simplicity of the rotor structure has encouraged for high speed applications.

### 1.2.2 Radially Laminated Rotor (Flux Barrier)

Another approach is to use laminations with flux barriers punched into the steel for a 4 pole machine. The flux barriers and the central hole of the lamination required for the shaft weaken the rotor structurally and thus make this approach a poor choice for high speed design.

Fig.1.6 Radially Laminated Rotor

### 1.2.3 Axially Laminated Rotor

Fig.1.7 Axially Laminated Rotor

Two pole phase axially laminated rotor with a  $L_d/L_q$  ratio of 20, the maximum efficiency is 94% has been reported in the literature. It is observed that torque ripple and iron losses are more axially laminated rotor than radially laminated rotor.

Another rotor design as shown in fig. The rotor consists of alternating layers of ferromagnetic and non-magnetic steel. If choose the thickness of the steel such that the pitch of the ferromagnetic rotor segments matched the slot pitch of the stator. The ferromagnetic rotor segments always see a

Fig 1.8 New rotor design

stator tooth pitch regardless of the angle of rotation of the rotor. This is done to maximize flux variations and hence iron losses in the rotor.

Special rotor laminations make it possible to produce the same number of reluctance path as there are magnetic poles in the stator. Synchronous speed is achieved as the poles lock in step with magnetic poles of the rotating stator field and cause the stator to run at the same speed as the rotating fields. The rotor is pressures with end rings similar to induction motor .Stator winding are similar to squirrel cage induction motor.

### 1.3 ROTOR CONSTRUCTION

Explosion bonding technique as shown in fig. Other joining techniques such as brazing roll bonding, or diffusion bonding may also appropriate for rotor construction.

First sheets of ferromagnetic and non-ferromagnetic steel are bonded. The bonded sheets are then cut into rectangular blocks which are machined into the desired rotor. The rotor shaft can also be machined out of the same block as the rotor.

Fig 1.9 Explosion bonding

The rotor joining technique known as explosion bonding. Explosion bonding uses explosive energy to force two or more metal sheets together at high pressures. Conventionally the high pressure causes several atomic layers on the surface of each sheet to behave as a fluid. The angle of collision between the two metals forces this fluid to jet outward. Effectively cleaning the metal surface, these ultra clean surfaces along with the high pressure forcing the metal plates together provide the necessary condition for solid phase welding.

Experimental tests on a stainless steel/mild steel bond indicate that the tensile and fatigue strengths of the bond are greater than those of either of the component materials due to the shock hardening which occurs during the process. The bond was also subjected to 10 cycles of temperature variation from 20° C - 70°C, with no significant reduction in tensile strength.

#### 1.4 WORKING OF SYNCHRONOUS RELUCTANCE MOTOR

In order to understand the working of synchronous reluctance motor, when a piece of magnetic material is located in a magnetic field, a force acts on the material tending to bring it into the denser portion of the field. The force tends to align the specimen of the material in such a way that the reluctance of the magnetic path that passes through the material will be minimum.

When supply is given to the stator winding, the revolving magnetic field will exert reluctance torque on the unsymmetrical rotor tending to align the salient pole axis of the rotor with the axis of the revolving magnetic field, because in this position, the reluctance of the magnetic path would be minimum. If the reluctance torque is sufficient to start the motor and its load, the rotor will pull into step with the revolving field and continue to run at the speed of the revolving field. Actually the motor starts as an induction motor and after it has reached its maximum speed as an induction motor, the reluctance torque pulls its rotor into step with the revolving field, motor now runs as synchronous motor by virtue of its saliency.

Reluctance motors have approximately one third the HP rating they would have as induction motors with cylindrical rotors. Although the ratio may be increased to one half by proper design of the field windings, power factor and efficiency are poorer than for the

equivalent induction motor. Reluctance motors are subject to cogging, since the locked rotor torque varies with the rotor position, but the effect may be minimized by skewing the rotor bars and by not having the number of poles.

Fig1.10 Rotor Position due to Revolving Magnetic Field

### 1.5 PRIMARY DESIGN CONSIDERATIONS

- ❖ High output power capability.
- ❖ Ability of the rotor to with stand high speeds.
- ❖ Negligible zero torque spinning losses.
- ❖ High reliability.
- ❖ High efficiency.
- ❖ Low cost.

#### (a) Power factor:

The maximum achievable power factor  $PF_{max}$  of a synchronous reluctance machine given as

$$PF_{max} = L_d/L_q - 1 / L_d/L_q + 1$$

Higher  $L_d/L_q$  ratio yield higher power factors, which corresponds to reduced  $I^2R$  losses and reduced volt ampere ratings of the inverter driving the machine.

#### (b) Copper loss and core loss:

$$\begin{aligned} \text{Copper loss} &= 3 I^2 R_s \\ &= 3V^2 R_s / (R_s^2 + \omega^2 L_d L_q)^2 \{ R_s^2 + R_s \omega (L_d - L_q) \sin 2\delta \} + \omega^2 [L_d^2 + L_q^2 / 2 - L_q^2 - L_d^2 / 2 \cos 2\delta] \end{aligned}$$

Where

$R_s$  – Stator resistance

$L_d, L_q$  - direct and quadrature inductance

$\delta$  - Torque Angle

$$\text{Core loss } P_{core}(R) = \frac{f}{400} \int k f i f b (v^2) dv$$

The core losses are calculated corresponding to the fundamental component of flux density in the stator iron core. There will also be significant core losses in the stator and rotor due to the winding and slot harmonics. The losses are difficult to estimate reliably.

## 1.6 TORQUE – SPEED CHARACTERISTICS

The torque speed characteristic of synchronous reluctance motor is shown in fig. The motor starts at anywhere from 300 to 400 percent of its full load torque (depending on the rotor position of the unsymmetrical rotor with respect to the field winding) as a two phase motor. As a result of the magnetic rotating field created by a starting and running winding displaced  $90^\circ$  in both space and time.

At about  $\frac{3}{4}$ th of the synchronous speed a centrifugal switch opens the starting winding and the motor continues to develop a single phase torque produced by its running winding only. As it approaches synchronous speed, the reluctance torque is sufficient to pull the rotor into synchronism with the pulsating single phase field. The motor operates at constant speed up to a little over 20% of its full load torque. If it is loaded beyond the value of pull out torque, it will continue to operate as a single phase induction motor up to 500% of its rated speed.

### Application Characteristics:

- ❖ Comparable power density but better efficiency than induction motor.
- ❖ Slightly lower power factor than induction motor.
- ❖ Slightly small field weakening range than induction motor.
- ❖ High cost than induction motor but lower than any type of PM motors.
- ❖ Need speed synchronization to inverter out frequency by rotor position sensor sensor less control.
- ❖ Sensor less control is much easier due to motor saliency.
- ❖ By adding squirrel cage induction motor to synchronous reluctance motor one obtains line starting reluctance motors.
- ❖ Line started reluctance motors can be parallel with open loop control if the load does not change suddenly.
- ❖ Other combinations are possible such as adding PM for improved performance

- ❖ Rotor design for best manufacturability is still being optimized especially for high speed applications.

### 1.7 PHASER DIAGRAM OF SYNCHRONOUS RELUCTANCE MOTOR

The synchronous reluctance machine is considered as a balanced three phase circuit, it is sufficient to draw the phasor diagram for only one phase. The basic voltage equation neglecting the effect of resistance is

Fig 1.12 Phasor Diagram of Synchronous Reluctance Motor

$$V = E - j I_{sd} X_{sd} - j I_{sq} X_{sq} \dots \dots \dots (1.1)$$

Where

V is the Supply Voltage

I<sub>s</sub> is the stator current

E is the excitation emf

δ is the load angle

φ is the phase angle

X<sub>sd</sub> and X<sub>sq</sub> are the synchronous reactance of direct and quadrature axis

I<sub>sd</sub> and I<sub>sq</sub> are the direct and quadrature axis current

$$I = I_{sd} + I_{sq} \dots \dots \dots (1.2)$$

I<sub>sd</sub> is in phase quadrtur with E and I<sub>sq</sub> is in phase with E.

$$V = E - j I_{sd} X_{sd} - j I_{sq} X_{sq}$$

From phasor diagram

$$V \cos \delta = E + I_{sd} + X_{sd} \dots \dots \dots (1.3)$$

$$I_{sd} = \frac{V \cos \delta - E}{X_{sd}}$$

$$I_{sq} X_{sq} = V \sin \delta$$

$$I_{sq} = \frac{V \sin \delta}{X_{sq}} \dots \dots \dots (1.4)$$

$$I_s \cos \phi = I_{sq} \cos \delta - I_{sd} \sin \delta \dots \dots \dots (1.5)$$

Where

$X_{sd}$  and  $X_{sq}$  are synchronous reactance of d and q axis.

Sub (3) and (4) in Equ (5)

$$I_s \cos \phi = \frac{E \sin \delta}{X_{sd}} + 2 \frac{X_{sd} - X_{sq}}{2 X_{sd} X_{sq}} \dots \dots \dots (1.6)$$

$$P = 3 V I_s \cos \phi \dots \dots \dots (1.7)$$

Sub equ (6) in equ (7)

$$P_m = 3 \left[ \frac{VE}{X_{sd}} \sin \delta + V^2 \frac{(X_{sd} - X_{sq})}{2 X_{sd} X_{sq}} \sin 2\delta \right]$$

$$P_m = T \omega_s$$

$$T = P_m / \omega_s$$

$$= \frac{3}{\omega_s} \left[ \frac{VE}{X_{sd}} \sin \delta + \frac{V^2 (X_{sd} - X_{sq})}{2 X_{sd} X_{sq}} \sin 2\delta \right] \dots \dots \dots (1.8)$$

Sub  $E = 0$

$$T = \frac{3}{\omega_s} V^2 \left[ \frac{X_{sd} - X_{sq}}{2 X_{sd} X_{sq}} \right] \sin 2\delta \dots \dots \dots (1.9)$$

Equation (9) is the torque equation of synchronous reluctance motor.

Fig 1.13 Torque Angle Characteristics of Salient Pole Machine

Plotting the equation (9) as shown in fig indicates that the stability limit is reached at  $\delta = \pm \pi / 4$

And by increasing  $\delta$  load angle torque also increases.

$$V^2 \left[ \frac{X_{sd} - X_{sq}}{2 X_{sd} X_{sq}} \right] \sin 2 \delta = \text{reluctance Power}$$

In synchronous reluctance motor, the excitation emf(E) is zero.

Fig 1.14 Phasor Diagram of Synchronous Reluctance Motor with E=0

## 1.8 ADVANTAGES AND DISADVANTAGES OF SYNCHRONOUS RELUCTANCE MOTOR

### Advantages

- ❖ There is no concern with demagnetization; hence synchronous reluctance machines are inherently more reliable than PM machines.
- ❖ There need not be any exciting field as torque is zero, thus eliminating electromagnetic spinning losses.
- ❖ Synchronous reluctance machine rotors can be constructed entirely from high strength, low cost materials.

### Disadvantages

- ❖ High cost than induction Motor.
- ❖ Need Speed synchronization to inverter output frequency by using rotor position sensor and sensor less control.
- ❖ Compared to induction motor it is slightly heavier and has low power factor.
- ❖ By increasing the saliency ratio  $L_{ds}/L_{qs}$ , the power factor can be improved.

## 1.9 APPLICATIONS OF SYNCHRONIZATION

- ❖ Metering Pumps.
- ❖ Auxiliary time Mechanism.
- ❖ Wrapping and folding Machines.
- ❖ Proportioning Devices on Pumps or conveyors.
- ❖ Synthetic fibre manufacturing equipment.
- ❖ Processing continuous sheet or film material.

## 1.10 VERNIER MOTORS

A Vernier motor is an unexcited (or reluctance Type) inductor synchronous motor. It is also named because it operates on the principle of a vernier. The peculiar feature of this kind of motor is that a small displacement of the rotor produces a large displacement of the axes of maximum and minimum permeance. When a rotating magnetic field is introduced in the air gap of the machine, rotor will rotate slowly and at a definite fraction of the speed of the rotating field.

This rotating field can be produced either by feeding poly phase current to the stator winding or by exciting the stator coil groups in sequence. AS the rotor speed steps down from the speed of the rotating field, the motor torque steps up. A vernier motor works as an electric gearing. This kind of motor is attractive in applications which require low speed and high torque and where mechanical gearing is undesirable.

### 1.10.1 Principle of operation

The stator of a vernier motor has slots and a distributed winding just like the stator of an ordinary poly phase induction motor. The rotor is a slotted iron core without winding. A 2 – pole machine with 12 stator slots and 10 rotor slots.

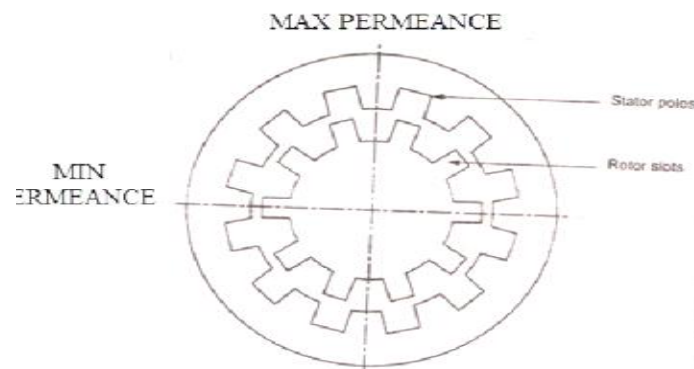

Fig 1.15 vernier motor

The stator and rotor teeth are facing each other in the vertical axis. The stator teeth are facing rotor slots in the horizontal axis. At this position therefore, the maximum permeance is along the vertical axis and the minimum permeance is along the horizontal axis. When the rotor is rotated one half of its slot pitch, the rotor slots will face stator teeth in the vertical axis. The rotor and stator teeth will face each other in the horizontal axis. The axis of maximum permeance is now horizontal and the axis of minimum permeance is now vertical. Thus the rotor movement of one –half rotor slot pitch results in a 90 degree displacement of the permeance axes.

Suppose that a magnetic field is rotating in the machine. Whenever the rotating field rotates 90 degrees, the rotor will rotate one half of its slot pitch. When the rotating field completes one revolution, the rotor will rotate through an angle corresponding to two rotor slot pitches.

### 1.10.2 Air – Gap permeance Distribution

The fluxes in the air gap are assumed all in the radial direction. The permeance of air space between stator and rotor at any location is inversely proportional to the radial length of air space at that location. The stator and rotor slot depth are much larger in comparison with air gap length, the permeance of airspace can be considered as zero, where stator tooth surface is facing rotor tooth surface. The width of rectangular blocks is the widths of overlap between the stator and the rotor teeth. These widths of overlap vary linearly from a maximum and back to a minimum. The area of overlap is reduced a constant amount for each successive stator tooth until a minimum is reached.

The permeance distribution curve is not convenient to use because it cannot be represented by simple mathematical function. When the rotor rotates, this permeance wave rotates at a much faster speed. Five times the rotor speed for the machine. The axes at which maximum and minimum permeance occur are the direct and quadrature axes respectively of the vernier motor.

Fig 1.16 (a) Air gap Permeance Distribution of Motor (b) Equivalent Permeance Distribution

### 1.10.3 Design of Vernier Motor

In a poly phase reluctance motor the rotor has the same number of poles as the stator mmf wave. Similarly in a vernier motor the air gap permeance wave should have the same number of poles as the stator mmf wave. The number of stator and rotor slots has the following relation

$$N_1 = N_2 \pm P$$

Where

$N_1$  – Number of Stator Slots

$N_2$  – Number of Rotor Slots

$P$  – Number of poles of the rotating magnetic field.

When the rotor rotates through an angle corresponding to one rotor slot pitch, the permeance wave rotates through an angle corresponding to one pole pitch. The pole pitch of the permeance wave is the same as the pole pitch of the stator mmf wave, because they have the same number of poles. Also in a reluctance machine, the speed of the permeance wave is the speed of rotating mmf.

Therefore,

$$\frac{\text{Rotor speed}}{\text{rotating field speed}} = \frac{\text{Rotor Slot Pitch}}{\text{MMF pole pitch}} = \frac{P}{N_2}$$

or

$$\text{Rotor Speed} = \frac{120 f}{N_2} \text{ rpm}$$

And

$$\text{Electric gear ratio} = \frac{N_2}{\pm(N_2 - N_1)}$$

The rotor speed is independent of the number of poles of the machine when the speed of rotating magnetic field is reduced by increasing the number of poles of the machine. It cannot be expected that the speed of the rotor be reduced proportionately because when  $P$  is increased the difference between  $N_2$  and  $N_1$  should also be increased, and the electric gear ratio is reduced in the inverse proportion. Thus the rotor speed is not affected by the number of poles but depends on the number of rotor slots.

The main step in design is to calculate the direct and quadrature axes reactance's  $X_d$  and  $X_q$ .

$$X_d = X_1 + X_{ad}$$

$$X_q = X_1 + X_{aq}$$

Where  $X_1$  is the stator leakage reactance and  $X_{ad}$  and  $X_{aq}$  are the direct and quadrature axes reactance of armature reaction.  $X_{ad}$  is the ratio of the fundamental component of reactive armature voltage, produced by the mutual flux due to the fundamental direct axis component of armature current, Similarly  $X_{aq}$  is the ratio of the fundamental component of reactive armature voltage produced by the mutual flux due to the fundamental quadrature axis component of the armature current, to its component under steady state conditions and at rated frequency.

### Glossary

1. Synchronous reluctance motor -- It is similar to the salient pole synchronous machine except that the rotor does not have any field winding.
2. Reluctance torque -- The tendency of the salient poles to align themselves in the minimum reluctance position.
3. Vernier Motor -- It is unexcited reluctance type synchronous motor. The peculiar feature of this motor is that a small displacement of the rotor produces a large displacement of the axis of maximum and minimum permeance.
4. Flux Barrier -- It is another approach is to use laminations. The lamination required for the shaft weaken the rotor .It is used for low speed design.
5. Axial air gap motor -- It is another approach is to use laminations. The torque ripple and iron losses are more in axially laminated rotor than dially laminated.
6. Explosion bonding -- First sheets of ferromagnetic and nonmagnetic steel are bonded .The bonded sheets are then cut into rectangular blocks which are the machined into the desired rotor.
7. Salient rotor -- Salient rotor shape such that the quadrature air gap is much larger than the direct air gap. It is used for high speed application.
8. Torque Twisting or turning moment of force.
9. Demagnetize To disrupt the regular pattern of aligned magnetic domains, which eliminates a material's attraction.
10. Magnetic Field A force of attraction that surrounds magnets and current-carrying conductors.
11. Magnetic Induction The use of magnets to cause voltage in a conductor. Magnetic induction occurs whenever a conductor passes through magnetic lines of flux.
12. Reluctance A material's resistance to becoming magnetized.
13. Residual Magnetism The attractive force that exists in an object or substance after it has been removed from a magnetic field.
14. Pole One of two ends of the axis of a sphere. Poles also refer to the opposite ends of a magnet.
15. Rotational Axis The center line on which a ball or sphere turns or

rotates. The earth has a rotational axis.

16. Saturation

A magnetic state in which the attractive strength of a magnet has reached its peak.

17. Magnetized

To be made magnetic or made to attract other metals.

18. Conductor

A material or element that allows free movement of electrons and therefore allows easy flow of electricity. Most conductors are metals.

**UNIT - II****STEPPING MOTOR****2.1 INTRODUCTION**

It is an electrodynamic and electromagnetic equipment.

These motors are also referred to as step motors or stepping motors.

On account of its unusual construction, operation and characteristics it is difficult to define a stepper motor. Definition given in British Standard specification (BSS) is

A stepper motor is brushless dc motor whose rotor rotates in discrete angular displacements when its stator windings are energized in a programmed manner. Rotation occurs because of magnetic interaction between rotor poles and poles of the sequentially energized winding. The rotor has no electrical windings, but has salient and magnetic/or magnetized poles.

The stepper motor is a digital actuator whose input is in the form of digital signals and whose output is in the form of discrete angular rotation. The angular rotation is dependent on the number of input pulses the motor is suitable for controlling the position by controlling the number of input pulses. Thus they are identically suited for open position and speed control.

**Applications:**

- ❖ Printers
- ❖ Graph plotters
- ❖ Tape driver
- ❖ Disk Drives
- ❖ Machine Tools
- ❖ X-Y Recorders
- ❖ Robotics space Vehicle
- ❖ IC Fabrication and Electric Watches

**2.2 CLASSIFICATION OF STEPPER MOTORS**

As construction is concerned stepper motors may be divided into two major groups.

1. Without Permanent Magnet (PM)
  - (a) Single Stack
  - (b) Multi Stack
2. With Permanent Magnet
  - (a) Claw Pole Motor
  - (b) Hybrid Motors

## 2.3 SINGLE STACK VARIABLE RELUCTANCE STEPPER MOTOR

### 2.3.1 Construction:

The VR stepper motor characterized by the fact there is no permanent magnet either on the rotor or the stator. The construction of a 3-phase VR stepper motor with 6 poles on the stator and 4-pole on the rotor as shown.

Fig 2.1 Single Stack Variable Reluctance Stepper Motor

The Stator is made up of silicon steel stampings with inward projected even or odd number of poles or teeth. Each and every stator poles carries a field coil an exciting coil. In case of even number of poles the exciting coils of opposite poles are connected in series. The two coils are connected such that their MMF gets added .the combination of two coils is known as phase winding.

The rotor is also made up of silicon steel stampings with outward projected poles and it does not have any electrical windings. The number of rotor poles should be different from that of stators in order to have self-starting capability and bi direction. The width of rotor teeth should be same as stator teeth. Solid silicon steel rotors are extensively employed. Both the stator and rotor materials must have lowering a high magnetic flux to pass through them even if a low magneto motive force is applied.

### 2.3.2 Electrical Connection

Electrical connection of VR stepper as shown fig. Coil A and A' are connected in series to form a phase winding. This phase winding is connected to a DC source with the help of semiconductor switch S1. Similarly B and B' and C and C' are connected to the same source through semiconductor switches S2 and S3 respectively. The motor has 3 –phases a, b and c.

- ❖ a phase consist of A and A' Coils
- ❖ b phase consist of B and B' Coils
- ❖ c phase consist of C and C' Coils

### 2.3.3 Principle of Operation

It works on the principle of variable reluctance. The principle of operation of VR stepper motor explained by referring fig.

#### (a).Mode 1 : One phase ON or full step operation

In this mode of operation of stepper motor only one phase is energized at any time. If current is applied to the coils of phase 'a' (or) phase 'a' is excited, the reluctance torque causes the rotor to run until aligns with the axis of phase a. The axis of rotor poles 1 and 3 are in alignment with the axis of stator poles 'A' and 'A''. Then angle  $\theta = 0^\circ$  the magnetic reluctance is minimized and this state provides a rest or equilibrium position to the rotor and rotor cannot move until phase 'a' is energized.

Next phase b is energized by turning on the semiconductor switch S2 and phase 'a' is de-energized by turning off S1. Then the rotor poles 1 and 3 and 2 and 4 experience torques in opposite direction. When the rotor and stator teeth are out of alignment in the excited phase the magnetic reluctance is large. The torque experienced by 1 and 3 are in clockwise direction and that of 2 and 4 is in counter clockwise direction. The latter is more than the former. As a result the rotor makes an angular displacement of  $30^\circ$  in counterclockwise direction so that B and B' and 2 and 4 in alignment. The phases are excited in sequence a, b and c the rotor turns with a step of  $30^\circ$  in counter clockwise direction. The direction of rotation can be reversed by reversing the switching sequence in which are energized and is independent of the direction of currents through the phase winding.

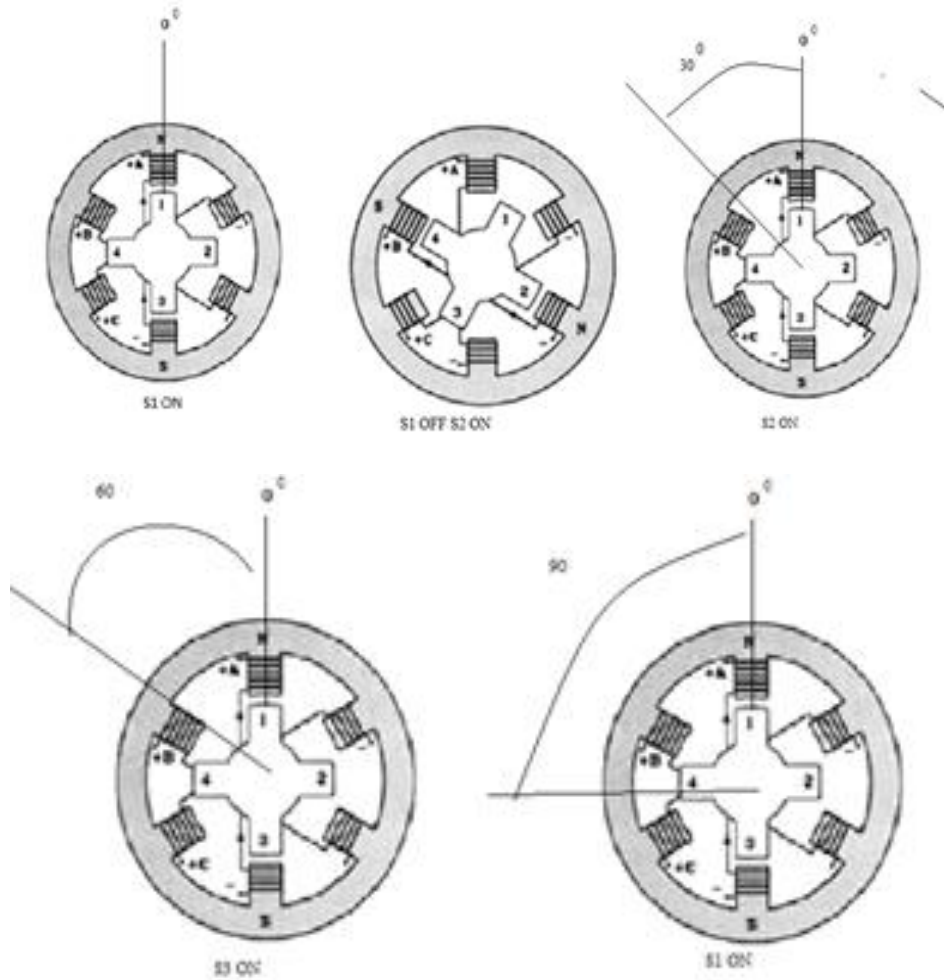

Fig 2.3 step motions as switching sequence process in a three phase VR motor

The truth table for mode I operation in counter and clockwise directions are given in the table

| -  | *  | -  | 330      |
| *  | -  | -  | 360      |

**(b).Mode II: Two Phase on Mode**

In this mode two stator phases are excited simultaneously. When phases a and b are energized together, the rotor experiences torque from both phases and comes to rest in a point mid-way between the two adjacent full step position. If the phases b and c are excited, the rotor occupies a position such that angle between AA' axis of stator and 1-3 axis of rotor is equal to  $45^\circ$ . To reverse the direction of rotation switching sequence is changed a and b, a and c etc. The main advantage of this type of operation is that torque developed by the stepper motor is more than that due to single phase ON mode of operation.

The truth table for mode II operation in counter clockwise and clockwise directions is given in a table

**Mode III: Half step Mode**

In this type of mode of operation one phase is ON for some duration and two phases are ON during some other duration. The step angle can be reduced from  $30^\circ$  to  $15^\circ$  by exciting phase sequence a, a+b, b, b+c, c etc. The technique of shifting excitation from one phase to another from a to b with an intermediate step of a+b is known as half step and is used to realize smaller steps continuous half stepping produces smoother shaft rotation.

The truth table for mode III operation in counter and clockwise directions are given in the table

## 2.4 MICRO STEPPING CONTROL OF STEPPING MOTOR

Stepping motor is a digital actuator which moves in steps of  $\theta_s$  in response to input pulses. such incremental motion results in the following limitations of the stepper motor

### Limited resolution

As  $\theta_s$  is the smallest angle through which the stepper motor can move, this has an effect on position accuracy of incremental servo system employing stepper motors because the stepper motor cannot position the load to an accuracy finer than  $\theta_s$ .

### Mid frequency Resonance

A phenomenon in which the motor torque suddenly drops to a low value at certain pulse frequencies as in fig

Fig 2.4 Mid frequency Resonance

A new principle known as micro stepping control has been developed with a view of overcoming the above limitation. It enables the stepping motor to move through a tiny micro step of size  $\Delta \theta_s \ll \theta_s$  full step angle is response to input pulses.

### 2.4.1 Principle of micro stepping

Assume a two phase stepper motor operating in 'one phase ON' sequence. Assume also that only B2 winding is On and carrying current  $I_{B2} = I_R$ , the rated phase current. All the other winding are OFF. In this state the stator magnetic field is along the positive real axis as show in fig (a). Naturally the rotor will also as be in  $\theta = 0^\circ$  position.

When the next input pulse comes, B2 is switched OFF while A1 is switched ON. In this condition  $I_{A1} = I_R$  while all the phase current are zero. As a result the stator magnetic field rotates through  $90^\circ$  in counter clockwise direction as show in fig (a).

The rotor follows suit by rotating through  $90^\circ$  in the process of aligning itself with stator magnetic field. Thus with a conventional controller the stator magnetic field rotates through  $90^\circ$  when a new input pulse is received causing the rotor to rotate full step.

However in micro stepping we want the stator magnetic field to rote through a small angle  $\theta_s \ll 90^\circ$  in respect to input pulse. This is achieved by modulating the current through B2 and A1 winding as show in fig (b) such that

$$I_{A1} = I_R \sin \theta$$

$$I_{B1} = I_R \cos \theta$$

Then the resulting stator magnetic field will be at an angle  $\theta^\circ$  with respect to the positive real axis. consequently the rotor will rotate through an angle  $\theta_s \ll 90^\circ$ .

This method of modulating current through stator winding so as to obtain rotation of stator magnetic field through a small angle  $\theta^\circ$

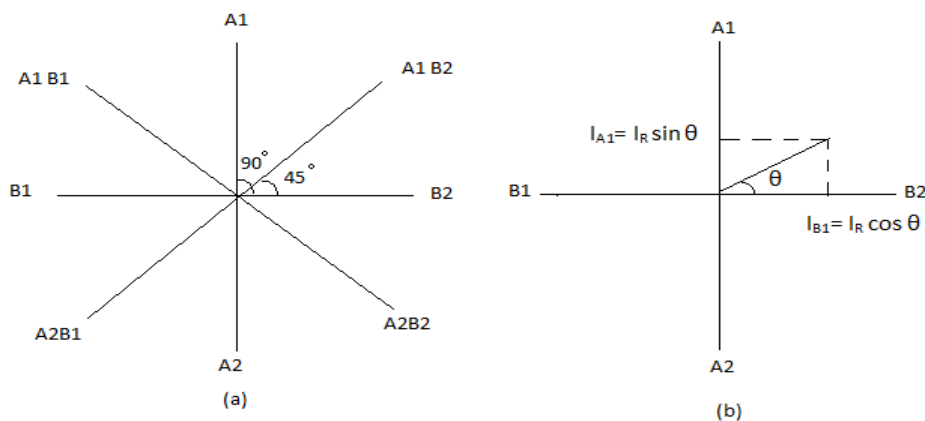

Fig 2.5 Principle of micro stepping

## 2.5. MULTISTACK VARIABLE RELUCTANCE STEPPER MOTOR

These are used to obtain smaller step sizes, typically in the range of  $2^\circ$  to  $15^\circ$ . Although three stacks are common a multistack motor may employ as many as seven stacks. This type is also known as the cascade type. A cutaway view of a three stack motor is shown in fig. 2.6.

Fig. 2.6: Construction of multi-stack VR motor.

A multistack (or m-stack) variable reluctance stepper motor can be considered to be made up of 'm' identical single stack variable reluctance motors with their rotors mounted on a single shaft. The stators and rotors have the same number of poles (or teeth) and therefore same pole (tooth) pitch. For a m0stack motor, the stator poles (or teeth) in all m stacks are aligned, but the rotor poles (teeth) are displaced by  $1/m$  of the pole pitch angle from one another. All the stator pole windings in a given stack are excited simultaneously and, therefore the stator winding of each stack forms one phase. Thus the motor has the same number of phases as number of stacks.

Fig. 2.7: Cross-section of a 3-stack, VR stepper motor parallel to the shaft.

Figure 2.7 shows the cross section of a three stack (3-phase) motor parallel to the shaft. In each stack, stator and rotors have 12 poles (teeth). For a 12 pole rotor, pole pitch is  $30^\circ$  and therefore, the rotor poles (teeth) are displaced from each other by  $1/3$ rd of the pole pitch or  $10^\circ$ . The stator teeth in each stack are aligned. When the phase winding A is excited rotor teeth of stack A are aligned with the stator teeth as shown in fig. 2.8.

When phase A is de-energized and phase B is excited the rotor teeth of stack B are aligned with stator teeth. The new alignment is made by the rotor movement of  $10^\circ$  in the anticlockwise direction. Thus the motor moves one step (equal to  $\frac{1}{2}$  pole pitch) due to change of excitation from stack A to stack B

Next phase B is de-energized and phase C is excited. The rotor moves by another step  $\frac{1}{3}$ rd of pole pitch in the anticlockwise direction. Another change of excitation from stack C to stack A will once more align the stator and rotor teeth in stack A. however during this process (A  $\rightarrow$  B  $\rightarrow$  C  $\rightarrow$  A) the rotor has moved one rotor tooth pitch.

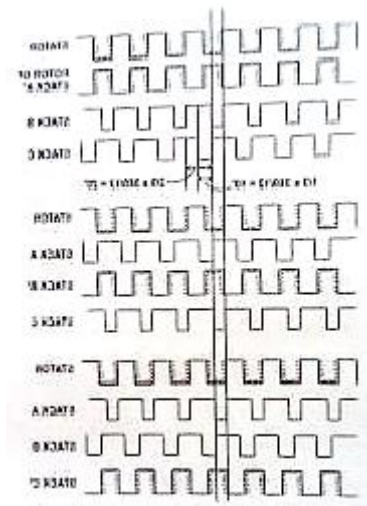

Fig. 2.8: Position of stator & rotor teeth of 3 stack VR motor

Let  $N_r$  be the number of rotor teeth and 'm' the number of stacks or phases, then

Tooth pitch  $T_p = 360/N_r$  ..... (2.1)

Step Angle  $\alpha = 360^\circ/mN_r$  ..... (2.2)

**2.6. Hybrid stepper motor**

**Principle of operation**

Most widely used hybrid motor is the two phase type as shown in fig2.11. This model has four poles and operates on one phase on excitation.

Fig2.9 cross-section of a two phase hybrid motor

The coil in pole 1 and that in pole 3 are connected in series consisting of phase A, and pole 2 and 4 are for phase B. Fig 2.12 shows the process of rotor journey as the winding currents are switched in one phase ON excitation.

Fig2.10 one-phase on operation of a two-phase hybrid motor.

The poles of phase A are excited the teeth of pole 1 attract some of the rotors north poles, while the teeth of pole 3 align with rotor's south poles. Current is then switched to phase B, The rotor will travel a quarter tooth pitch so that tooth alignment takes place in 2 and 4.

Next current is switched back to phase A but in opposite polarity to before, the rotor will make another quarter tooth journey. The tooth alignment occurs in opposite magnetic polarity to state 1. When current is switched to phase B in opposite polarity (4) Occurs as a result of quarter tooth pitch journey.

The structures of two phase motor considered in fig.2.11 will not produce force in a symmetrical manner with respect to the axis. The motor having 8 poles in the stator shown in fig2.13 considered as the structure in which torque is generated at a symmetrical position on the surface.

Fig2.11 Two-phase hybrid motor with 8 stator poles.

## 2.7 CLAW TOOTH PM MOTOR

This is another type of stepping motor. This is also known as can-stack Stepping motor, as the stator of this motor consists of a sort of metal can. Teeth are punched out of a circular metal sheet and the circle is then drawn into a bell shape. The teeth are then drawn inside to form claw teeth. A Stack of the stator is formed by joining two bell shaped casings so that the teeth of both of them are intermeshed and the toroid coil is contained within them

This type of motor shown in fig 2.14 is usually of two stacks. Since the rotor has magnetic poles that are axially aligned and is common for both stator stacks, the stator tooth pitches are misaligned by a quarter pitches between the two stacks.

Fig. 2.12 Cutaway diagram of a claw-tooth PM motor

The sequence of excitation is shown in fig. when phase A is excited, the rotor moves by the tension of magnetic lines (state 1).state 2 is the equilibrium position with phase A excited. Next if current is switched to phase B , the rotor will be driven further in the same direction, because the stator teeth in stack B are misaligned by a quarter tooth pitch to the left

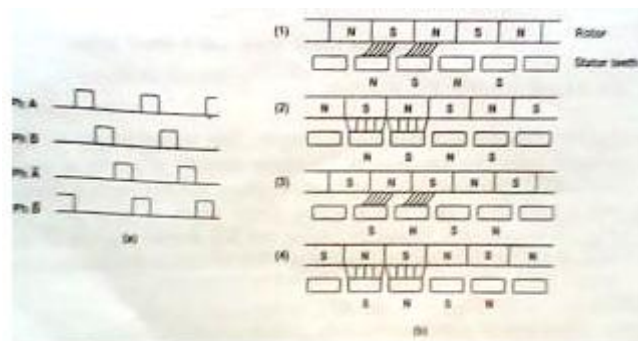

Fig. 2.13 Current waveform supplied to a claw-tooth PM motor

with respect to the teeth in stack A. State 3 shows the result due to this excitation. To advance the rotor further to the left and place in the next state (4), phase B is de-energized and phase A is excited. Next, current will be switched to phase B.

The claw tooth motor has low manufacturing cost through it cannot realize a very small step angle.

## 2.8. SINGLE PHASE STEPPING MOTOR

These are motors which are designed to be operated from single phase supply. They are widely use in watches and clocks, timers and counters. Present single phase stepping motors use one or more (two) permanent magnets, because permanent magnets are quite necessary to raise the ratio of torque to input power in a miniature motor.

The two requirements of single phase stepping motor are

To detent the motor at a particular position when the coil is not excited.

To rotate the motor at desired direction by switching the magnetic polarity of only one coil.

### 2.8.1 CONSTRUCTION

It is a permanent magnet type stepper motor with two poles. Rotor is a circular type of permanent magnet as shown in figure 2.27. Stator is made of silicon steel stampings with two salient poles. Stator carries a coil which is connected to a pulsed supply. The air gap is specially designed so that specific reluctance at different radial axes are different. Minimum values occur at one tip of the poles. Under normal conditions the rotor occupies any one of the detent positions shown in fig 2.28(a) or as in (b) to minimum reluctance position. Two positions shown in figures 2.28(a) & (b) are the detent positions of the rotor of the stepper motor.

Fig. 2.14 A single-phase stepping motor

Fig. 2.15 Detent positions and coil polarity to rotate motor.

### 2.8.2. PRINCIPLE OF OPERATION

When the coil is given an electric positive pulse, pole A in position 1 as shown in figure. 2.28(a) it experiences a torque in clockwise direction and finally attains a steady state as in fig 2.28(b). Then pulse given to the coil is zero. After a lapse of a second, from the start of the pulse, a negative pulse is given to the coil which makes the pole A as south and pole B as north. Rotor experiences another torque in figure 2.28(a). By repeating the cycle the rotor rotates continuously in step. It is not possible to develop torque in counter clockwise direction by altering pulses.

### 2.9. THEORY OF TORQUE PREDICTION

According to Faraday's laws of electromagnetic induction

Flux linkages  $\lambda=N\phi$  ..... (2.3)

$\lambda=Li$  ..... (2.4)

Flux linkages can be varied by

Varying flux  $\phi$

Varying the current ‘i’ of an electromagnet (i.e) equivalent of varying the mmf

Varying the reluctance  $L = \frac{N^2}{S}$

By varying reluctance

mmf =  $N\phi$  ..... (2.5)

Reluctance =  $\frac{1}{A\mu}$  .....(2.6)

Flux =  $\frac{Ni}{S}$  ..... (2.7)

Flux linkages  $\lambda = \frac{N.Ni}{S} = \frac{N^2}{S}$  ..... (2.8)

Inductance  $L = \frac{\text{flux linkages}}{\text{Ampere}}$  ..... (2.9)

$L = \frac{N^2i}{Si}$  ..... (2.10)

$L = \frac{N^2}{S}$  .....(2.11)

If the reluctance of magnetic circuit can be varied, inductance L and the flux linkages  $\lambda$  can also be varied.

Consider a magnetic circuit as shown in fig. 2.29.

Fig. 2.16 Magnetic circuit

The stator consists magnetic core with two pole arrangement. Stator core carries a coil. Rotor is also made up of ferrous material. The motor core is similar to a salient pole machine. Let the angle between the axis of stator pole and rotor pole be  $\theta$ . let the angular displacement be illustrated using fig. 2.29 (a, b and c).

**Case 1:  $\theta = 0$** 

As shown in fig. 2.29 (a) the air gap between the stator and rotor is very very small. Thereby the reluctance of the magnetic path is least. Due to minimum reluctance, the inductance of the circuit is minimum. Let it be  $L_{\max}$

**Case 2 :  $\theta = 45^\circ$** 

As shown in fig. 2.29(b) in this only a portion of rotor poles cover the stator poles. Therefore reluctance of the magnetic path is more than that of case 1. due to which the inductance becomes less than  $L_{\max}$ .

**Case 3:  $\theta = 90^\circ$** 

As shown in fig. 2.29(c) the air gap between the stator poles has maximum value. Thereby reluctance has a value yielding minimum inductance. Let it be  $L_{\min}$ .

Variation in inductance with respect to the angle between the stator and rotor poles is shown in fig. 2.30.

Fig. 2.17 Variation in induction w.r to  $\theta$ .

**Derivation for reluctance torque**

As per faradays law of electromagnetic induction an emf induced in an electric circuit when there exists a change in flux linkages.

$$\text{emf induced } e = - \frac{\partial y}{\partial t}$$

$$\text{Where } \lambda = N\Phi \text{ or } \lambda = Li \quad \dots\dots\dots (2.12)$$

$$\text{Therefore } e = - \frac{d}{dt} [Li] \quad \dots\dots\dots (2.13)$$

$$= - L \frac{\partial i}{\partial t} - i \frac{\partial L}{\partial t} \quad \dots\dots\dots (2.14(a))$$

$$= - L \frac{\partial i}{\partial t} - i \frac{\partial L}{\partial \theta} \times \frac{\partial \theta}{\partial t} \quad \dots\dots\dots (2.14(b))$$

$$= - L \frac{\partial i}{\partial t} - i \omega \frac{\partial L}{\partial \theta} \quad \dots\dots\dots (2.14(c))$$

$$\text{Magnitude of } e = L \frac{di}{dt} + \omega i \frac{\partial L}{\partial \theta} \quad \dots\dots\dots (2.15)$$

If the direction of current  $I$  is opposite to that of  $e$ , then the electric power is transferred from the source to the inductor. On the other hand, if the direction of current  $I$  is same as that of  $e$ , then the source gets the electrical power from the inductor.

On the basis of magnetic circuit/field theory it is known that the stored energy in a magnetic field.

$$W_e = \frac{1}{2} Li^2 \quad \dots\dots\dots (2.16)$$

The rate of change of energy transfer due to variation in stored energy or power due to variation in stored energy.

$$\frac{dW_e}{dt} = \frac{1}{2} L \cdot 2i \frac{di}{dt} + \frac{1}{2} i^2 \frac{\partial L}{\partial t} \quad \dots\dots\dots (2.17)$$

Mechanical power developed/consumed = power received from the electrical source – power due to change in stored energy in the inductor

Power received from the electrical source =  $e_i$

$$\therefore e_i = i L \frac{di}{dt} + \omega i^2 \frac{\partial L}{\partial \theta} \quad \dots\dots\dots (2.18)$$

Power due to change in stored energy

$$= Li \frac{di}{dt} + \frac{1}{2} \omega i^2 \frac{\partial L}{\partial \theta} \quad \dots\dots\dots (2.19)$$

Mechanical power developed

$$= i L \frac{di}{dt} + \omega i^2 \frac{\partial L}{\partial \theta} + Li \frac{di}{dt} + \frac{1}{2} \omega i^2 \frac{\partial L}{\partial \theta} \quad \dots\dots\dots (2.20)$$

Mechanical power developed

$$P_m = \frac{1}{2} \omega i^2 \frac{\partial L}{\partial \theta} \quad \dots\dots\dots (2.21)$$

$$P_m = \frac{2\pi NT}{60} \quad \dots\dots\dots (2.22)$$

$$P_m = \omega T \quad \dots\dots\dots (2.23)$$

Where  $\omega = \frac{2\pi N}{60}$

$$\text{Therefore reluctance torque } T = \frac{P_m}{\omega} \quad \dots\dots\dots (2.24)$$

$$\text{Reluctance torque } T = \frac{1}{2} i^2 \frac{\partial L}{\partial \theta} \quad \dots\dots\dots (2.25)$$

**Note:**

\* Torque corresponds to monitoring when  $\frac{\partial L}{\partial \theta}$  is +ve.

\* Torque corresponds to generating when  $\frac{\partial L}{\partial \theta}$  is -ve.

\* Torque is proportional to  $i_2^2$  : Therefore it does not depend upon the direction of the current.

## 2.10 TERMINOLOGIES USED IN STEPPER MOTOR

1. Step motor
2. Resolution
3. Stepping rate
4. Hold position
5. Detent position
6. Stepping error
7. Position Error

### 1. Step angle ( $\theta_s$ or $\beta$ )

It is the angular displacement of rotor of a stepper motor for every pulse of excitation given to the stator winding of the motor. It is determined by the number of teeth on the rotor and stator, as well as the number of steps in the energisation sequence. It is given by

$$\Theta_s = \beta = \frac{360}{mN_r}$$

Where

$m$  = Number of phases ( $m$  and  $q$ )

$N_r$ - number of teeth on rotor.

Also,  $\Theta_s = ((N_s \sim N_r) / (N_s \cdot N_r)) * 360$

### 2. Resolution

It is the number of steps per revolution. It is denoted as  $S$  or  $Z$ . It is given by

$$Z = 360 / (\Theta_s)$$

For variable reluctance motor  $Z = (q N_r)$  or  $(m N_r)$

For PM motor and hybrid motor  $Z = 2q N_r$

Also,  $Z = (N_s \cdot N_r) / (N_s \sim N_r)$

Where  $N_s$ -number of teeth/poles on stator.

### 3. Stepping Rate

The number of steps per second is known as stepping rate or stepping frequency.

### 4. Hold Position

It corresponds to the rest position when the stepper motor is excited or energized (this corresponds to align position of VR motor)

### 5. Detent Position

It corresponds to rest position of the motor when it is not excited.

### 6. Stepping Error

Actual step angle is slightly different from the theoretical step angle. This is mainly due to tolerances in the manufacture of stepper motor and the properties of the magnetic and other materials used.

The error in the step angle is expressed as a percentage of the theoretical step angle.

$$\% \text{error} = ((\text{step angle} - \text{theoretical step angle}) / \text{theoretical step angle}) * 100$$

Percentage error is restricted to  $\pm 5\%$ . In some cases it is restricted to  $\pm 2\%$ . The cumulative error between the actual angular displacement and theoretical angular displacement is expressed as a percentage of theoretical angular displacement. It is usually considered for one complete cycle.

### 7. Positional Error

The maximum range of cumulative percentage of error taken over a complete rotation of stepper motor is referred to as positional accuracy as shown in fig below.

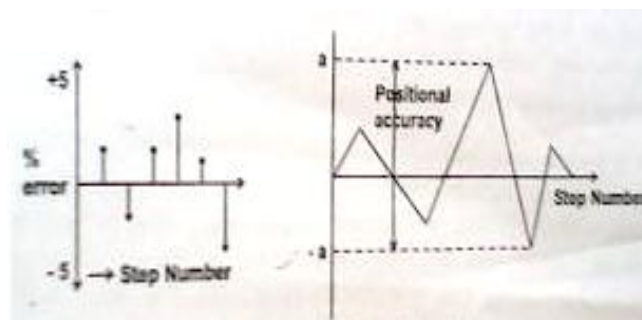

Fig. 2.18 Positional Accuracy

## 2.11. CHARACTERISTICS OF STEPPER MOTOR

Stepper motor characteristics are divided into two groups

- ❖ Static characteristics
- ❖ Dynamic characteristics

### 2.11.1. Static characteristics

It is divided into two characteristics.

(i) Torque Angle curve

(ii) Torque current curve

#### (i) Torque-Angle curve

Torque angle curve of a step motor is shown in fig.2.32. it is seen that the Torque increases almost sinusoid ally, with angle  $\Theta$  from equilibrium.

Fig. 2.19 Torque Angle

#### Holding Torque (T<sub>H</sub>)

It is the maximum load torque which the energized stepper motor can withstand without slipping from equilibrium position. If the holding torque is exceeded, the motor suddenly slips from the present equilibrium position and goes to the static equilibrium position.

#### Detent torque (T<sub>D</sub>):

It is the maximum load torque which the un-energized stepper motor can withstand slipping. Detent torque is due to magnetism, and is therefore available only in permanent magnet and hybrid stepper motor. It is about 5-10 % of holding torque.

#### Torque current curve

A typical torque curve for a stepper motor is shown in fig.2.34. It is seen the curve is initially linear but later on its slope progressively decreases as the magnetic circuit of the motor saturates.

Fig.2.20 Torque-current Curve

### Torque constant (Kt)

Torque constant of the stepper is defined as the initial slope of the torque-current (T-I) curve of the stepper motor. It is also known as torque sensitivity. Its units N-m/A, kg-cm/A or OZ-in/A

### 2.11.2. Dynamic characteristics

A stepper motor is said to be operated in synchronism when there exist strictly one to one correspondence between number of pulses applied and the number of steps through which the motor has actually moved. There are two modes of operation.

#### Start-Stop mode

Also called as pull in curve or single stepping mode.

#### Slewing mode

In start –stop mode the stepper motor always operate in synchronism and the motor can be started and stopped without using synchronism. In slewing mode the motor will be in synchronism, but it cannot be started or stopped without losing synchronism. To operate the motor in slewing mode first the motor is to be started in start stop mode and then to slewing mode. Similarly to stop the motor operating in slewing mode, first the motor is to be brought to the start stop mode and then stop.

#### Start Stop mode

Start stop mode of operation of stepper motor is shown in fig.2.35 (a). In this second pulse is given to the stepper motor only after the rotor attained a steady or rest position due to first pulse. The region of start-stop mode of operation depends on the operation depends on the torque developed and the stepping rate or stepping frequency of stepper motor.

Fig. 2.21 Modes of operation

pulse is given to the stepper motor only after the rotor attained a steady or rest position due to first pulse. The region of start-stop mode of operation depends on the operation depends on the torque developed and the stepping rate or stepping frequency of stepper motor.

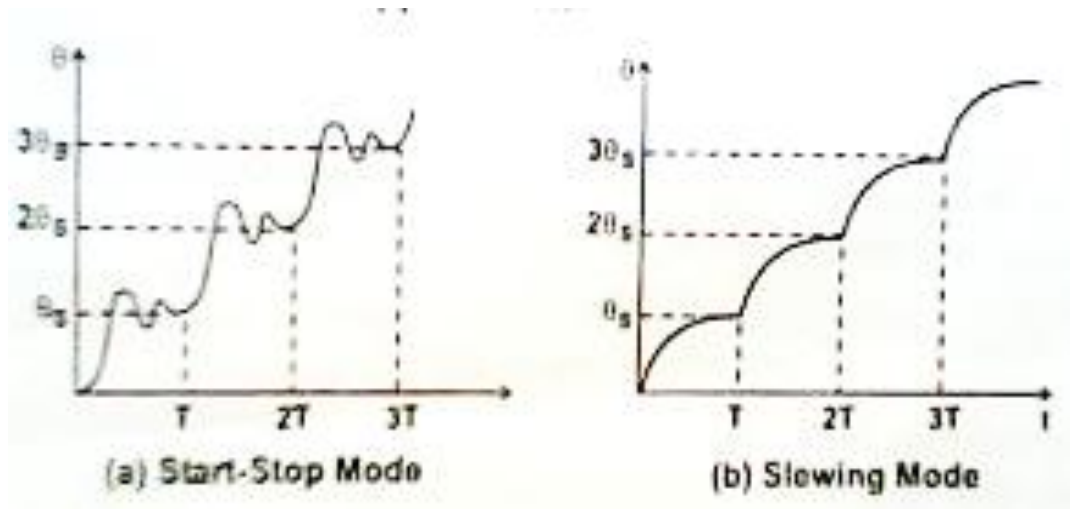

Fig. 2.21 Modes of operation

## 2.12. TORQUE-SPEED CHARACTERISTICS

Torque developed by the stepper motor and stepping rate characteristics for both modes of operation are shown in fig.2.36. the curve ABC represents the "pull in" characteristics and the curve ADE represents the "pull-out" characteristics.

Fig. 2.22 Torque-Speed Characteristics

The area OABCO represents the region for start stop mode of operation. At any operating point in the region the motor can start and stop without losing synchronism. The area ABCEDA refers to the region for slewing mode of operation. At any operating point without losing synchronism to attain an operating point in the slewing mode at first the motor is to operate at a point in the start-stop mode and then stepping rate is increased to operate in slewing mode, similarly while switching off it is essential to operate the motor from slewing mode to start-stop mode before it is stopped.

**Pull in torque**

It is the maximum torque developed by the stepper motor for a given stepping rate in the start-stop mode of operation without losing synchronism. In the fig.2.36 LM represents the pull in torque (i.e.)TPI corresponding to the stepping rate F (i.e.) OL.

**Pull out torque**

It is the maximum torque developed by the stepper motor for a given stepping rate in the slewing mode without losing synchronism. In fig.2.36 LN represents the pull in torque (i.e.) TPO corresponding to F (i.e.) OL.

**Pull in range**

It is the maximum stepping rate at which the stepper motor can operate in start-stop mode developing a specific torque (without losing synchronism).In fig. 2.36 PIT represents pull in range for a torque of T (i.e.) OP. This range is also known as response range of stepping rate for the given torque T.

**Pull out range**

It is the maximum stepping rate at which the stepper motor can operate in slewing mode developing a specified torque without losing synchronism. In fig.2.36 PIPO represents the pull out range for a torque of T. The range PIPO is known slewing range.

**Pull in rate (FPI)**

It is the maximum stepping rate at which the stepper motor will start or stop without losing synchronism against a given load torque T.

**Pull out rate (FPO)**

It is the maximum stepping rate at which the stepper motor will slew, without missing steps, against load torque T.

**Synchronism**

This term means one to one correspondence between the number of pulses applied to the stepper motor and the number of steps through which the motor has actually moved.

**Mid frequency resonance**

The phenomenon at which the motor torque drops to a low value at certain input pulse frequencies.

**2.13 FIGURES OF MERIT (FM'S)**

Figures of merit (FM'S) are performance indices which give quantitative information on certain aspects of performance and design of actuators such as stepper motors. DC or AC servomotors etc.

**1. Electrical Time constant (Te)**

$$T_e = L_m / R_m \quad \dots\dots\dots (2.26)$$

where  $L_m$ -Inductance of motor winding

$R_m$ -resistance of motor.

$T_e$  governs the rate at which current rises when the motor winding is turned on. It also determines how quickly the current decays when the winding is turned off.

In motion control, the speed of response is of importance. Hence electrical time constant  $T_e$  must be minimized.

$T_e$  dependent upon inductance and resistance of the motor winding. Inductance is determined by magnetic circuit. (i.e.) magnet iron volume as well as volume of copper used in the motor design. Once these have been designed, neither reducing conductor size nor increasing the number of turns will reduce  $T_e$ . Otherwise magnetic circuit itself has to be redesigned.

**2. Motor time constant (Tm)**

$$T_m = J / (K_e \cdot K_t R_m) = J R_m / K_e \quad \dots\dots\dots (2.27)$$

$J$ -moment of inertia of motor (kg-m<sup>2</sup>)

$R_m$ -resistance of the motor winding ( $\Omega$ )

$K_e$ -back emf constant (volt s/ rad)

$K_t$ - torque constant (Nm/A)

Motor back emf and torque constants are determined by magnetic circuit and phase winding design. Winding resistance also from winding design. Moment of inertia is determined by mechanical design.

In this way motor time constant  $T_m$  combines all the three aspects of motor design viz, magnetic circuit, electrical circuit and mechanical design. Achieving a low  $T_m$  requires excellence in motor design. As a thumb rule the ratio of  $T_e/T_m \approx 0.1$

Initial Acceleration ( $a_0$ ):

$$A_0 = T/J \text{ (rad/S}^2\text{)}$$

Where  $T$ -rated torque (N-M)

$J$ -moment of inertia (kg-m<sup>2</sup>)

$a_0$  gives a quantitative idea of how fast the motor accelerates to its final velocity or position. Maximization of  $a_0$  calls for good magnetic circuit design to produce high torque in conjunction with good mechanical design to minimize rotor inertia. The moment of inertia of the load coupled to motor also determines  $a_0$ .

**Motor Constant (km)**

$$k_m = T / \sqrt{\omega}$$

where T- rated motor torque

$\omega$  -rated power(w) of the motor

$$k_m = \sqrt{K_t K_e / R_m}$$

This shows that maximizing  $k_m$  causes minimizing R, maximizing  $K_e$  and  $K_t$ . Maximizing  $K_e$  and  $K_t$ . Call for optimization of magnetic circuit design, decreasing electrical time constant  $T_e$  which is undesirable. A trade off between electrical and magnetic circuit design is necessary to achieve a good  $k_m$ .

Power rate (dP/dt):

$$\text{Power rate is } (dP/dt) = (d/dt)(T \cdot (d\theta/dt)) = T \cdot (d^2\theta/dt^2) = T \cdot (T/J) = (T^2/J) \quad \dots(2.28)$$

Now  $T = K_t I$  so

**2.14 DRIVE SYSTEM AND CONTROL CIRCUITRY FOR STEPPER MOTOR****2.14.1 DRIVE SYSTEM**

The stepper motor is a digital device that needs binary (digital) signals for its operation. Depending on the stator construction two or more phases have to be sequentially switched using a master clock pulse input. The clock frequency determines the stepping rate, and hence the speed of the motor. The control circuit generating the sequence is called a translator or logic sequencer.

Fig. 2.23 Block Diagram of the drive system of a stepping motor.

The fig 2.38 shows the block diagram of a typical control circuit for a stepper motor. It consists of a logic sequencer, power driver and essential protective circuits for current and voltage limiting. This control circuit enables the stepper motor to be run at a desired speed in either direction. The power driver is essentially a current amplifier, since the sequence generator can supply only logic but not any power. The controller structure for VR or hybrid types of stepper motor

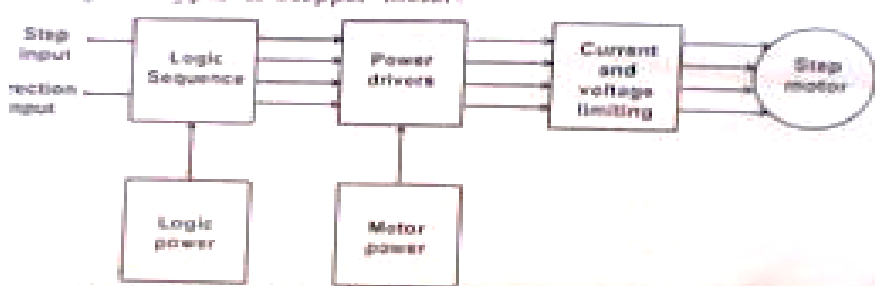

Fig. 2.24 Block diagram of a typical step motor control

**2.14.2 LOGIC SEQUENCER**

The logic sequencer is a logic circuit which control the excitation of the winding sequentially, responding to step command pulses. A logic sequencer is usually composed of a shifter register and logic gates such as NANDs, NORs etc. But one can assemble a logic sequencer for a particular purpose by a proper combination of JK flip flop, IC chips and logic gate chips.

Two simple types of sequencer build with only two JK-FFs are shown in fig 2.39 for unidirectional case. Truth tables for logic sequencer also given for both the directions.

TABLE 2.7 Logic Sequencer

|                  | R | 1 | 2 | 3 | 4 | 5 | 6 | .... |
|------------------|---|---|---|---|---|---|---|------|
| Ph A,Q1          | 0 | 1 | 1 | 0 | 0 | 1 | 1 | .... |
| Ph B,Q2          | 0 | 0 | 1 | 1 | 0 | 0 | 1 | .... |
| Ph $\bar{A}$ ,Q1 | 1 | 0 | 0 | 1 | 1 | 0 | 0 | .... |
| Ph $\bar{B}$ ,Q2 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | ...  |

|                  | R | 1 | 2 | 3 | 4 | 5 | 6 | .... |
|------------------|---|---|---|---|---|---|---|------|
| Ph A,Q1          | 0 | 0 | 1 | 1 | 0 | 0 | 1 | .... |
| Ph B,Q2          | 0 | 1 | 1 | 0 | 0 | 1 | 1 | .... |
| Ph $\bar{A}$ ,Q1 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | .... |
| Ph $\bar{B}$ ,Q2 | 1 | 0 | 0 | 1 | 1 | 0 | 0 | .... |

Fig.2.25 A unidirectional logic sequencer for two phase on operation of a two phase hybrid motor

The corresponding between the output terminals of the sequencer and the phase windings to be controlled is as follows.

Q1-----Ph A

$\bar{Q1}$ -----Ph  $\bar{A}$

Q2-----Ph B

$\bar{Q2}$ -----Ph  $\bar{B}$

If Q1 is on the H level the winding Ph A is excited and if Q1 is on L level, Ph A is not excited.

To reserve the rotational direction, the connection of the sequencer must be interchanged. The direction switching circuits shown in fig 2.40 may be used for this purpose. The essential functions being in the combination of three NAND gates or two AND gates and a NOR gate.

### 2.14.3. Power Driver Circuit

The number of logic signals discussed above is equal to the number of phases and the power circuitry is identical for all phases. Fig. 2.44(a) shows the simplest possible circuit of one phase consisting of a Darlington pair current amplifier and associated protection circuits. The switching waveform shown in fig. 2.44(c) is the typical R-L response with an exponential rise followed by decay at the end of the pulses.

In view of the inductive switching operation, certain protective elements are introduced in the driver circuit. These are the inverter gate 7408, the forward biased diode D1 and the freewheeling diode D. The inverter IC provides some sort of isolation between the logic circuit and the power driver.

There are some problems with this simple power circuit. They can be understood by considering each phase winding as a R-L circuit shown in fig. 2.44(b) subject to repetitive switching. On application of a positive step voltage, the current rises exponentially as

$$i(t) = I(1 - e^{-t/\tau}) \dots \dots (2.29)$$

Where  $I = V/R$  – rated current and

$\tau = L/R$  winding time constant.

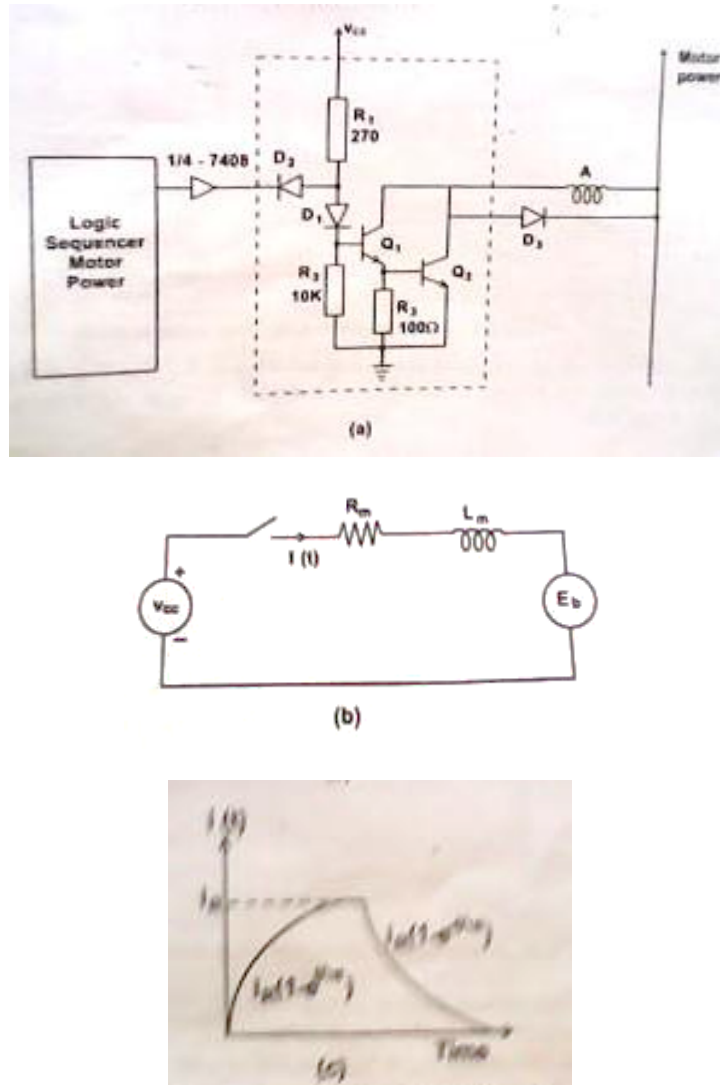

Fig. 2.26 Power Driver Stage of Stepper Motor Controller

In practice, the time constant  $\tau$  limits the rise and fall of current in the winding. At low stepping rate the current rises to the rated value in each ON interval and falls to zero value in each OFF interval. However as the switching rate increases, the current is not able to rise to the steady state, nor fall down to zero value with in the on/off time intervals set by the pulse waveform. This in effect, smoothens the winding current reducing the swing as shown in fig. 2.45. As a result the torque developed by the motor gets reduced considerably and for higher frequencies, the motor just ‘vibrates’ or oscillates within one step of the current mechanical position.

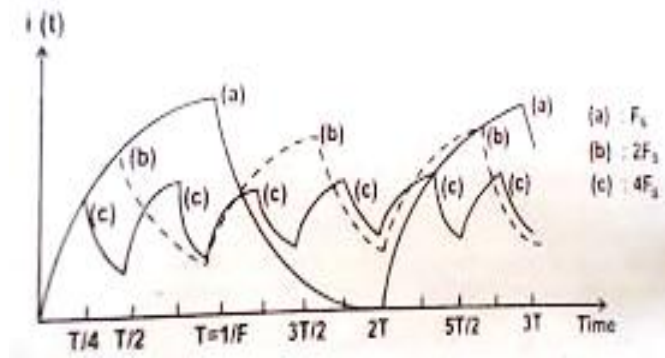

Fig. 2.27 Effect of increasing Stepping Rate on Current Swing

In order to overcome these problems and to make improvement of current build up several methods of drive circuits have been developed.

For example when a transistor is turned on to excite a phase, the power supply must overcome effect of winding inductances has tendency to oppose the current built up. As switching frequency increases the position that the buildup time takes up within the switching cycle becomes large and it results in decreased torque and slow response.

**2.14.4 Improvement of current buildup/special driver circuit**

**(a) Resistance drive (L/R drive)**

Here the initial slope of the current waveform is made higher by adding external resistance in each winding and applying a higher voltage proportionally. While this increases the rate of rise of the current, the maximum value remains unchanged as shown in fig. 2.46.

Fig. 2.28 L/R drive

The circuit time constant is now reduced and the motor is able to develop normal torque even at high frequencies. The disadvantage of this method is

Flow of current through external resistance causes  $I^2R$  losses and heating. This denotes wastage of power as far as the motor is concerned.

In order to reach the same steady state current  $I_R$  as before, the voltage required

To be applied is much higher than before. Hence this approach is suitable for small instrument stepper motor with current ratings around 100 mA, and heating is not a major problem.

**(b) Dual voltage driver (or) Bi-level driver**

To reduce the power dissipation in the driver and increase the performance of a stepping motor, a dual-voltage driver is used. The scheme for one phase is shown in fig. 2.47.

When a step command pulse is given to the sequencer, a high level signal will be put out from one of the output terminal to excite a phase winding. On this signal both  $T_r 1$  and  $T_r 2$  are turned on, and the higher voltage  $E_H$  will be applied to the winding. The diode  $D_1$  is now reverse biased to isolate the lower voltage supply. The current build up quickly due to the higher voltage  $E_H$ . The time constant of the monostable multivibrator is selected so that transistor  $T_r 1$  is turned off when the winding current exceeds the rated current by a little. After the higher

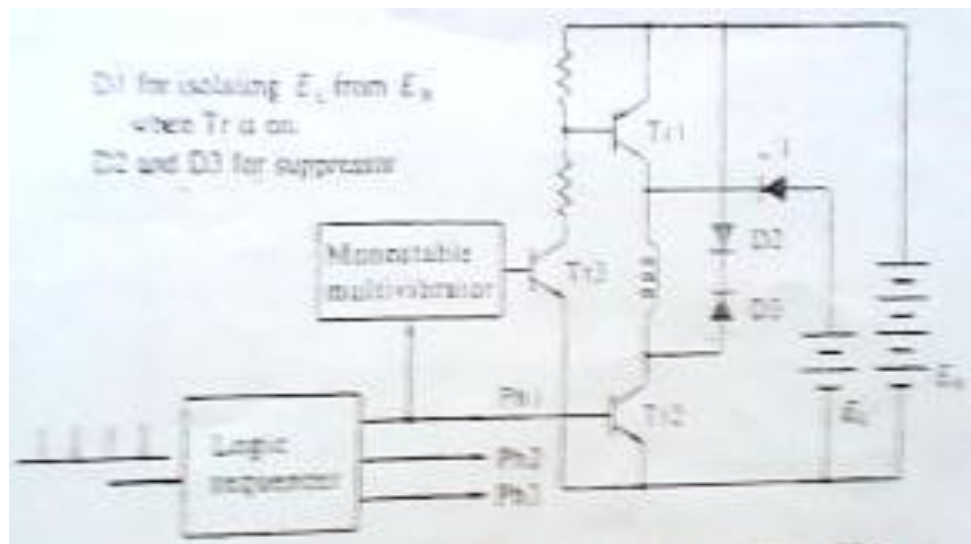

Fig. 2.29 Improvement of current buildup by dual voltage drive

Voltage source is cut off the diode is forward biased and the winding current is supplied from the lower voltage supply. A typical current wave form is shown in fig. 2.48.

Fig. 2.30 Voltage and current wave form in dual voltage driver

When the dual voltage method is employed for the two phase on drive of a two phase hybrid motor, the circuit scheme will be such as that shown in fig.2.49. Two transistors  $T_r 1$  &  $T_r 2$  and two diodes  $D_1$  and  $D_2$  are used for switching the higher voltage. In dual voltage

scheme as the stepping rate is increased, the high voltage is turned on for a greater percentage of time.

Fig. 2.31 A dual-voltage driver for the two-phase-on drive of a two phase hybrid motor

This drive is good and energy efficient. However it is more complex as it requires two regulated power supplies EH& EL end two power transistor switches Tr1 & Tr2 and complex switching logic. Hence it is not very popular.

**(c)Chopper drive**

Here a higher voltage 5 to 10 times the related value is applied to the phase winding as shown in fig.2.50(a) and the current is allowed to raise very fast. As soon as the current reaches about 2 to 5% above the rated current, the voltage is cut off ,allowing the current to decrease exponentially. Again as the current reaches some 2 to 5% below the rated value, the voltage is applied again. The process is repeated some 5-6 times within the ON period before the phase is switched off. During this period the current oscillates about the rated value as shown in fig. A minor modification is to chop the applied dc voltage at a high frequency of around 1khz, with the desired duty cycle so as to obtain the average on-state current equal to the rated value.

Fig. 2.32 Chopper drive

The chopper drive is particularly suitable for high torque stepper motors. It is energy efficient like the bi-level drive but the control circuit is simpler.

#### (d) Problems with driver circuits

A winding on a stepping motor is inductive and appears as a combination of inductance and resistance in series. In addition, as a motor revolves a counter emf is produced in the winding. The equivalent circuit to a winding is hence, such as that shown for designing a power driver one must take into account necessary factors and behavior of this kind of circuit. Firstly the worst case conditions of the stepping motor, power transistors, and supply voltage must be considered. The motor parameters vary due to manufacturing tolerance and operating conditions. Since stepping motors are designed to deliver the highest power from the smallest size, the case temperature can be as high as about 100°C and the winding resistance therefore increases by 20 to 25 per cent.

#### Suppressor circuits

These circuits are needed to ensure fast decay of current through the winding when it is turned off. When the transistor in the above fig is turned off a high voltage builds up to  $Ldi/dt$  and this voltage may damage the transistor. There are several methods of suppressing this spike voltage and protecting the transistor as shown in the following.

#### (a) Diode suppressor

If a diode is put in parallel with the winding in the polarity as shown in fig. a circulating current will flow after the transistor is turned off, and the current will decay with time. In this scheme, no big change in current appears at turn off, and the collector potential is the supply potential  $E$  plus the forward potential of the diode. This method is very simple but a drawback is that the circulating current lasts for a considerable length of time and it produces a braking torque.

Fig. 2.33 Diode suppressor

#### (b) Diode-Resistor suppressor

A resistor is connected in series with the diode as shown in fig to damp quickly the circulating current. The voltage  $V_{CE}$  applied to the collector at turn-off in this scheme is

$$V_{CE} = E + I R_S + V_D$$

Where  $E$  = supply potential

$I =$  Current before turning off

$R_s =$  resistance of suppressor resistor

$V_D =$  forward potential of diode

Fig. 2.34 Diode-resistor suppressor

A high resistance  $R_S$  is required to achieve a quick current decay, but this also results in a higher collector potential  $V_{CE}$ , thus a transistor with a high maximum voltage rating is necessary.

**(a) Zener diode suppressor**

In this zener diode are often used to connect in series with the ordinary diode as shown in fig. Compared with preceding two cases zener diode which provides negative bias causes the current to decay more quickly after turn off. In addition to this, it is a merit of this method that the potential applied to the collector is the supply potential plus the zener potential, independent of the current. This makes the determination of the rating of the maximum collector potential easy. However zeners are signal diodes, rather than power diodes. Their power dissipation is limited to 5w. Consequently, this suppressor can be used for very small instrument stepper motors of typical size 8 to 11.

Comparison of effects of various suppressor schemes of various suppressor schemes

Fig. 2.35 Zener diode

Fig. 2.36 Comparison of effects

**(d) Condenser suppressor**

This scheme is often employed for bifilar-wound hybrid motor. An explanation is given for the given for the circuit shown in fig:

Fig. 2.37 Condenser suppressor

A condenser is put between ph A and ph A $\bar{}$  and between ph B and ph B $\bar{}$ . These condensers serve two fold purposes.

1. When a transistor is turned off, the condenser connected to it via a diode absorbs the decaying current from the winding to protect the transistor.

Let us see the situation just after the Tr 1 is turned off in the one phase on mode. Either Tr 2 or Tr 4 will turn on, but Tr 3 will still be in the turned off state. Since the winding of ph A & ph A $\bar{}$  are wound in the bifilar fashion, a transient current will circulate in loop. If Tr 3 is turned on when the transient current becomes zero and the charge stored in the condenser becomes maximum, a positive current can easily flow through phase A winding. By this resonance mechanism, currents are used efficiently in this scheme. This feature remains in the two phase on mode too. The condenser suppressor is suited to drives in which stepping rate is limited in a narrow range.

2. Another utility of condensers is as an electrical damper, a method of damping rotor oscillations is to provide a mechanism to convert kinetic energy to joule heating. If a rotor having a permanent magnet oscillates, an alternating emf is generated in the winding. However if a current path is not provided or a high resistance is connected, no current will be caused by this emf. When the condenser is connected between phases an oscillatory current will flow in the closed loop and joule heat is generated in the windings, which means that the condenser works as an electrical damper.

**2.15. LINEAR AND NON LINEAR ANALYSIS**

The linear and nonlinear analysis of the motor performance with respect to the torque produced by the rotor of the motor is explained.

Let

$T_m$  be the motor torque produced by the rotor in Nm

$J$  be the inertia of the rotor and load combination in  $\text{kgm}^2$

$\omega$  be the angular velocity of the rotor

$D$  be the damping coefficient or viscous frictional coefficient

$T_f$  be the frictional load torque independent of the speed

$\theta_s$  be the step angle in radians

$F$  be the stepping rate in steps/sec or pps

Frictional load torque  $T_f = K \theta$

According to rotor dynamics

$$T_m = -J \frac{d\omega}{dt} + D\omega + T_f \quad \dots\dots\dots (2.30)$$

Also  $\theta_s = \theta = \omega t = \text{step angle}$

$$\omega = \theta_s / t = f \theta_s \quad \dots\dots\dots (2.31)$$

$$\text{where } f = 1/t \quad \dots\dots\dots (2.32)$$

By putting  $\omega = f \theta_s$

$$T_m = J \frac{d}{dt}(f \theta_s) + D(f \theta_s) + T_f \quad \dots\dots\dots (2.33)$$

$\theta_s = 360/mNr$  is fixed for a particular type of motor

So  $\theta_s$  can be considered as constant

$$\text{Therefore } T_m = J \theta_s \frac{d}{dt}(f) + D \theta_s (f) + T_f \quad \dots\dots\dots (2.34)$$

In equation 2.47 if viscous friction constant is neglected the equation will be a linear equation, the corresponding acceleration will be nonlinear and the equation will be nonlinear which given rise to nonlinear analysis.

Linear acceleration on linear analysis

If the damping coefficient is neglected  $D=0$

The expression for motor torque becomes

$$T_m = -J \frac{d\omega}{dt} + T_f \quad \dots\dots\dots (2.35)$$

$$T_m - T_f = J \frac{d\omega}{dt}$$

$$(T_m - T_f) / J = \frac{d\omega}{dt}$$

$$d\omega = ((T_m - T_f) / J) dt \quad \dots\dots\dots (2.36)$$

Integrating

$$\omega = ((T_m - T_f)/J)dt + \omega_1$$

..... (2.37)

Where

$\omega_1$  = Integration constant

Mathematically  $\omega_1$  is the constant of integration but it indicates the initial angular velocity of the motor before the occurrence of acceleration.

Therefore  $\omega = \theta s f$  and  $\omega_1 = \theta s f_1$

Substituting  $\omega$  and  $\omega_1$  in equation 2.50

$$((T_m - T_f)/J)t + \theta s f_1 = \theta s f \quad \dots\dots\dots(2.38)$$

Dividing throughout by  $\theta s$  we get

$$((T_m - T_f)/J \theta s)t + f_1 = f$$

Therefore stepping rate  $f = ((T_m - T_f)/J \theta s)t + f_1 \quad \dots\dots\dots(2.39)$

And  $T_f = K \theta$

Figure 2.38 shows the linear acceleration from  $\omega_1$  to  $\omega_2$

Nonlinear (exponential) acceleration on Nonlinear analysis

Considering the torque produced by the motor

$$T_m = j\theta s \frac{df}{dt} + D\theta s f + T_f \quad \dots\dots(2.40)$$

$$(T_m - T_f) = j\theta s \frac{df}{dt} + D\theta s f$$

Dividing throughout by  $j\theta s$  We get

$$(\frac{df}{dt}) + (D/J)f - (T_m - T_f / j \theta s) = 0$$

(or)  $(\frac{df}{dt}) + (D/J)f = (T_m - T_f / j \theta s) \quad \dots (2.41)$

The above eqn. 2.54 is of the form

$(\frac{dy}{dx}) + py = Q$  Which have the solution of

$$y e^{\int p dx} = \int Q e^{\int p dx} + C \quad \dots\dots\dots(2.42)$$

Here  $y=f$ ;  $x=t$ ;  $p=(D/j)$  and  $Q=(T_m-T_f)/j\theta_s = \text{constant}$

$$f e^{D/J dt} = [(T_m - T_f)/j\theta_s] e^{D/J dt} + C \quad \dots\dots\dots(2.43)$$

$$f e^{D/J t} = [(T_m - T_f)/j\theta_s] e^{D/J t} + C \quad \dots\dots\dots(2.44)$$

$$f e^{D/J t} = (T_m - T_f)/j\theta_s (e^{D/J t} / (D/J)) + C \quad \dots\dots\dots(2.45)$$

where  $C$  is the integration constant

To find  $C$  substituting initial condition at  $t=0$ ;  $f=f(0)=f_1$   $f_1 e^{0} = (T_m - T_f)/j\theta_s (1/(D/J)) + C$  .....(2.46)

$$f_1 = (T_m - T_f)/j\theta_s (J/D) + C$$

.....(2.47)

$$f_1 = (T_m - T_f)/D\theta_s + C$$

.....(2.48)

$$C = f_1 - (T_m - T_f)/D\theta_s$$

.....(2.49)

Substituting eqn. (2.62) in eqn. (2.58)

$$f e^{(D/J)t} = (T_m - T_f)/j\theta_s (J/D) e^{(D/J)t} + (f_1 - (T_m - T_f)/D\theta_s) e^{(D/J)t} \quad \dots\dots\dots(2.50)$$

$$f e^{(D/J)t} = (T_m - T_f)/D\theta_s e^{(D/J)t} + (f_1 - (T_m - T_f)/D\theta_s) e^{(D/J)t} \quad \dots\dots\dots(2.51)$$

Dividing throughout by  $e^{(D/J)t}$  we get

$$F = (T_m - T_f)/D\theta_s + (f_1 - (T_m - T_f)/D\theta_s) e^{-D/j t} \quad \dots\dots\dots(2.52)$$

Stepping frequency  $f = (T_m - T_f)/D\theta_s + (f_1 - (T_m - T_f)/D\theta_s) e^{-D/j t}$

The above equation is a nonlinear exponential equation which gives rise to nonlinear acceleration of the rotor of the motor.

## 2.16 APPLICATION OF STEPPER MOTOR:

The main application of stepper motor may be divided into the following groups.

1. Instrumentation applications.
2. Computer peripherals & Office equipment's.
3. Numerical control of machine tools and robotics.
4. Applications in semiconductor technology.
5. Space vehicles and satellites.

6. Electro medical and
7. Miscellaneous applications.

### **1. Instrumentation application:**

This involve low torque applications such as  
Quartz watches.  
Synchronized clocks.  
Camera shutter operations.

### **2. Stepper motor application in computer peripherals:**

This involve medium torque, high performance and high volume application such as  
Dot matrix and line printers.  
Graph plotters.  
Floppy disk drives  
Digital X-Y plotters.  
Magnetic tape drives.  
Paper tape drives.

### **3. Application is office equipment:**

Electronic typewriters.  
Copiers  
Facsimile machines.

### **4. Machine tool applications:**

This involve high torque application such as  
Numerical control system for milling machine  
X-Y tables and index table.  
Home use and industrial sewing machines.

### **5. Application in semiconductor technology:**

Stepper motors used in high vacuum.  
Goniometer-An instrument used to determine crystalline structure.

Electron beam micro fabricator.

6. Stepper motor used in space vehicles and satellites.

7. Robotics.

**8. Electro medical applications:**

This involve high torque applications such as

X-ray machines.

Radiation therapy units.

Ultra sound scanner.

**9. Miscellaneous applications:**

Nuclear reactors.

Heavy industry applications.

Automatic focusing mechanism in camera

**Glossary**

1. Stepper motor -- Stepper motor is a brushless DC motor whose rotor rotates in discrete displacements when its stator windings are energized in a programmer manner. The rotor has no winding, magnets or case winding.
2. Full step operation -- Single phase on mode is the one in which at time only one phase winding is energized.
3. Step Angle -- It is the angular displacement of the rotor of the stepper motor for every pulse of excitation given to the stator windings of the motor
4. Resolution -- It is number of steps per revolution.
5. Stepping rate/frequency -- The number of steps per second
6. Hold Position -- It is corresponds to the rest position when the stepper motor is excited or energized.
7. Stepping Error -- Actual step angle is slightly different from the theoretical step angle.
8. Positional Error -- The maximum range of cumulative percentage of error taken over a complete rotation of stepper motor.
9. Holding torque -- It is the maximum load torque which the energized stepper motor can withstand slipping from equilibrium position.
10. Detent torque -- It is the maximum load torque which the un-energized stepper motor can withstand without slipping.
11. Static stiffness -- The ability of the actuator to resist disturbing torques and forces and thereby to maintain position.
12. Band width -- It is a measure of the frequencies up to which the actuator or servo system can respond.
13. Synchronism -- It is the one to one correspondence between the numbers of pulses applied to the stepper motor and the number of steps through which the motor has actually moved.
14. Half step operation -- It is alternate one phase on and two phase on mode operation. Here the rotor rotates through half of the full step angle.
15. Slewing -- Steeper may operate at high stepping rates, 25,000 steps per second.

## UNIT III

### SWITCHED RELUCTANCE MOTOR

#### 3.1 INTRODUCTION

Switched reluctance motor (SRM) is electromagnetic and electrodynamic equipment which converts the electrical energy into mechanical energy. The electromagnetic torque is produced on variable reluctance principle. SRM makes use of

- ❖ Power semiconductor switching circuitry and
- ❖ Rotor position sensor.

SRM is singly excited and doubly salient electrical motor. This means that it has salient poles on both the rotor and the stator but the only one member carries winding. The rotor has no winding, magnets and cage winding but it is built from a stack of salient pole laminations.

- ❖ Its construction is simple and robust
- ❖ It requires less maintenance
- ❖ Its overall efficiency is better
- ❖ It is flexible control driving motor as motoring mode generating mode of operations of the machine can be easily achieved,

In the light of above it is a competitive motor variable speed dc motor and variable speed 3 – phase cage induction motor.

#### 3.2 CONSTRUCTION AND OPERATION OF SRM

##### 3.2.1 Construction of SRM

Construction details of switched reluctance motor with six stator poles and four rotor poles can be explained by referring to figure 3.1

The stator is made up of silicon steel stampings with inward projected poles. The number of poles. The number of poles of the stator can be either an even number or an odd number. Most of the motors available have even number of stator poles (6 or 8). All these poles carry field coils. The field coils of opposite poles are connected in series such that their mmf's are additive and they are called phase windings. Individual coil or a group of coils constitute phase windings. Each of the phase windings are connected to the terminal of the motor. These terminals are suitably connected to the output terminals of a power semiconductor switching circuitry, whose input is a d.c. supply.

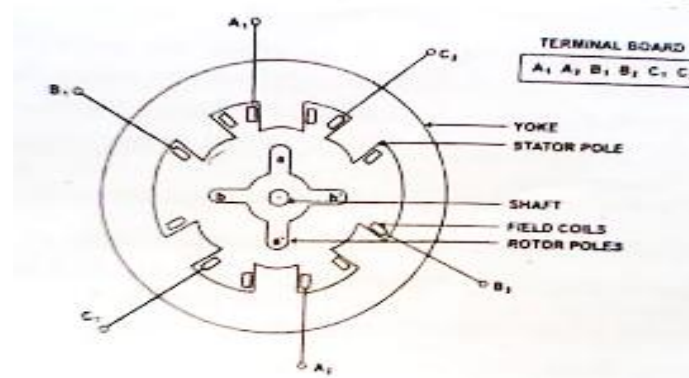

Fig 3.1 Cross sectional view of SRM

The rotor is also made up of silicon steel stampings with outward projected poles. Number of poles of rotor is different from the number of poles of the stator. In most of the available motors the number of poles of the rotor is 4 or 6 depending upon the number of stator poles 6 or 8.

The rotor shaft carries a position sensor. The turning ON and turning OFF operation of the various devices of the power semiconductor circuitry are influenced by the signals obtained from the rotor position sensor.

### 3.2.2 Block Diagram Of SRM

Fig. 3.2 shows the block diagram of SRM. Dc supply is given to the power semiconductor switching circuitry which is connected to various phase windings of SRM. Rotor position sensor which is mounted on the shaft of SRM, provides signals to the controller about the position of the rotor with reference to reference axis. Controller collects this information and also the reference speed signal and suitably turns ON and OFF the concerned power semiconductor device to the dc supply. The current signal is also fed back to the controller to limit the current within permissible limits.

Fig. 3.2 Block Diagram Of SRM

### 3.2.3. Principle of operation

Fig. 3.3 represents the physical location of the axis stator poles and rotor poles of a 6/4 SRM.

To start with stator pole axis AA' and rotor pole axis aa' are in alignment as shown in fig. 3.3(a). They are in the minimum reluctance position so far as phase windings is concerned. Then  $dL_a/d\theta=0$ . At this position inductance of B windings is neither maximum nor minimum. There exists  $dL_b/d\theta$  and  $dL_c/d\theta$ .

Fig. 3.3 Physical location of the axis of stator and rotor poles of 6/4 SRM

Now if B phase is energized then the rotor develops a torque because of variable reluctance and existences of variation in inductance. The torque developed is equal to  $(1/2)i_B^2(dL_B/d\theta)$ . This direction is such that BB' and bb' try to get aligned. If this torque is more than the opposing load torque and frictional torque the rotor starts rotating. When the shaft occupies the position such that BB' and bb' are in alignment (i.e.,  $\theta=30^\circ$ ), no torque is developed as in this position  $dL_B/d\theta=0$ . [Vide fig. 3.3(b)]

Now phase winding B is switched off and phase winding C is turned on to DC supply. Then the rotor experiences a torque as  $(dL_C/d\theta)$  exists. The rotor continues to rotate. When the rotor rotates further  $30^\circ$ , the torque developed due to winding C is zero [vide fig. 3.3(c)] Then the phase winding C is switched off and phase winding A is energized. Then rotor experiences a torque and rotates further step  $30^\circ$ . This is a continuous and cyclic process. Thus the rotor starts. It is a self-starting motor.

As the speed increases, the load torque requirement also changes. When the average developed torque is more than the load torque the rotor accelerates. When the torques balance the rotor attains dynamic equilibrium position. Thus the motor attains a steady speed. At this steady state condition power drawn from the mains is equal to the time rate of change of stored energy in magnetic circuit and the mechanical power developed.

When the load torque is increased, the speed of the motor tends to fall, so that the power balance is maintained. If the speed is to be develop at the same value, the develop

torque is to be increased by increasing the current. Thus more power is drawn from the mains. Vice-versa takes place when the load is reduced. Thus electrical to mechanical power conversion takes place.

### 3.3. POWER SEMICONDUCTOR SWITCHING CIRCUITS FOR SRM (POWER CONTROLLERS)

The selection of controller (converter) depends upon the application. One of the main aspects of the research in SRM drives has been the converter design. The main objectives of the design of the converter are performance of the drive and cost of the drive.

The power semiconductor switching circuits used are

1. Two power semiconductor switching devices per phase and two diodes.
2.  $(n+1)$  power semiconductor switching devices  $(n+1)$  diodes.
3. Phase winding using bifilar wires.
4. Split-link circuit used with even-phase number.
5. C-dump circuit.

#### 3.3.1 Two Power Semiconductor Switching Devices per phase and two diodes

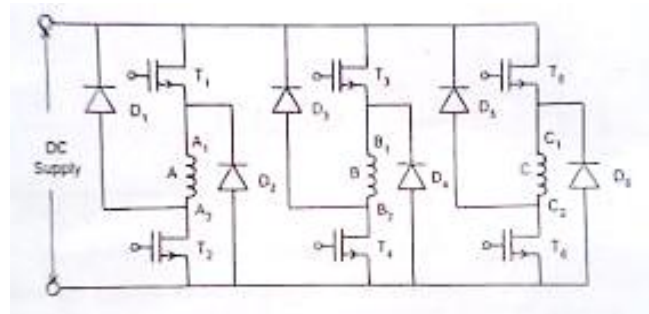

Fig. 3.4 Two Power Semiconductor switching devices and two diodes.

As shown in fig 3.4 phase winding A is connected to the dc supply through power semiconductor devices  $T_1$  and  $T_2$ . Depending upon the rotor position, when the phase winding A is to be energized the devices  $T_1$  and  $T_2$  are turned ON. When the phase winding is to be disconnected from the supply (this instant is also dependent on the position of the shaft) the devices  $T_1$  and  $T_2$  are turned off. The stored energy in the phase winding A tends to maintain the current in the same direction. This current passes from the winding through  $D_1$  and  $D_2$  to the supply. Thus the stored energy is fed back to the mains.

Similarly phase winding B & C are also switched on to the supply and switched off from the supply in a cyclic manner. This circuit requires 2 power switching devices and 2 diodes for each phase winding. For high speed operation it is required to see that the stored energy can be fed back to the mains within the available period.

Usually the upper devices  $T_1$ ,  $T_3$  and  $T_5$  are turned on and off from the signals obtained from the rotor position sensor. The duration of conduction or angle of conduction  $\theta$  can be controlled by using suitable control circuitry. The lower devices  $T_2$ ,  $T_4$ ,  $T_6$  are controlled from signals obtained by chopping frequency signal. The current in the phase winding is the result of logical AND ing of the rotor position sensor and chopping frequency. As a result it is possible to vary the effective phase current from a very low value to a high value. For varying the following methods are available.

1. By varying the duty cycle of the chopper.
2. By varying the conduction angle of the devices.

### Merits

- ❖ Control of each phase is completely independent of the other phase.
- ❖ The converter is able to free wheel during the chopping period at low speeds which helps to reduce the reduce the switching frequency and thus the switching losses of the converter.
- ❖ The energy from the off going phase is feedback to the source, which results in utilization of energy

### Demerits

- ❖ Higher number of switches required in each phase, which makes the converter expensive and also used for low voltage applications.

### 3.3.2 (n+1) power switching devices and (n+1) diodes

Fig. 3.5 (n+1) power switching devices and (n+1) diodes

This circuit makes use of less number of power switching devices and diodes as shown in fig 3.5. When the (SCRs) switching devices  $T$  and  $T_1$  are turned on phase winding A is energized from the dc supply. When these devices are turned off the stored energy in the phase winding is fed back to the mains through diodes D and D1. When devices  $T$  and  $T_2$  are

turned on the phase winding B is energized .When they are turned off ,the stored energy in B phase winding C is switched on and off from the mains. The cycle gets repeated.

This circuit makes use of  $(n+1)$  power switching devices and  $(n+1)$  diodes where  $n$  is equal to the number of phases.

### Merits

- ❖ The converter uses low number of switching devices, which reduces the cost of the converter.
- ❖ The converter is able to freewheel during the chopping, thus reducing the switching frequency and losses.
- ❖ Voltage rating of all the switching devices and the diodes are  $V_{dc}$ , which is relatively low.
- ❖ The energy for the off going phase is transferred back into the source, which results in useful utilization of the energy and also improves the efficiency.

### Demerits

- ❖ Disability to magnetize a phase while the off going phase is still demagnetizing which results in higher torque ripple during commutation.
- ❖ At higher speeds of the off going phase cannot be de-energized fast enough because the common switch “T” keeps turnings on intermediately, disabling forced demagnetization.
- ❖ The common switch conducts for all the phases and thus has higher switching stress.

### 3.3.3Phase winding using bifilar wires

Each phase winding has two exactly similar phase windings as shown in fig 3.6.For this bifilar wires are used .Each phase consists of two identical windings and are magnetically coupled when one of them are excited.

In stepper motor, the purpose of bifilar winding is for bipolar excitation with a reduced number of switching elements.

Fig 3.6 Phase winding using bifilar wires

When  $T_1$  is turned on the dc current passes through the phase winding A. when the devices  $T_1$  is turned off the stored energy in the magnetic field is fed back to the dc source through the winding A' and  $D_1$  to the supply.

The three devices operate in a sequential way depending upon the signals obtained from the rotor position sensor and the chopping signals for PWM technique obtained from the controller.

### Merits

- ❖ The converter uses lower number of switching devices thus reducing the cost on the converter.
- ❖ The converter allows fast demagnetization of phases during commutation.

### Demerits

- ❖ Bifilar winding suffers from double number of connections.
- ❖ A poor utilization of copper.
- ❖ Freewheeling is not possible during chopping as the phases have  $-V_{dc}$ . this causes of higher ripples in current and torque during chopping.
- ❖ The imperfection in the coupling between the two winding causes voltage spikes during turn off.
- ❖ The copper loss associated with the auxiliary winding is unacceptable high for many applications.

### 3.3.4 Split – link circuit used with even phase number

Fig. 3.7 split link circuit used with even phase number

The circuit shown in fig.3.7 is used in a range of highly efficient drives (from 4-80kw).

The main power supply is split into two halves using split capacitors. During conduction, energy is supplied to the phases by one half the power supply. During commutation period, the phases demagnetize into other half of the power supply.

When switch T1 is turned on, phase winding 1 is energized by capacitor c1. When switch T2 is turned off, the stored energy in the phase winding 1 is fed back to the capacitor c2 through diode D4.

When T4 is turned on by capacitor C2 and phase winding 4 is energized. When switch T4 is turned off, stored energy in the winding 4 is feedback to the capacitor C1 through diode D1. The similar operation takes place in the remaining winding also.

### Merits

- ❖ It requires lower number of switching devices.
- ❖ Faster demagnetization of phases during commutation.

### Demerits

- ❖ During chopping, freewheeling is not possible as the phaser have the voltage  $V_{dc}/2$ . This causes higher switching frequency and more losses.
- ❖ This is not feasible for low voltage application.
- ❖ The converter is fewer faults tolerant as fault in any phase will unbalance the other phase that is connected to it.

### 3.3.5 C-Dump circuit

In the C dump circuit shown in fig. 3.8. the device count is reduced to 'n' plus one additional devices to bleed the stored energy from the dump capacitor C back to supply via the step down chopper circuit. The mean capacitor voltage is maintained well above the supply to permit rapid defluxing after commutation.

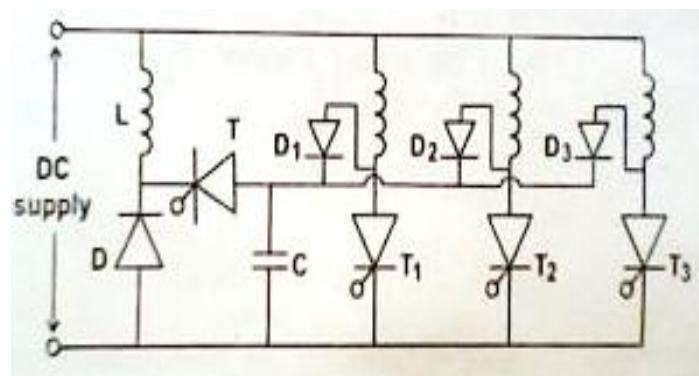

Fig. 3.8 C dump circuit

A control failure in the energy-recovery circuit would result in the rapid build-up of charge on the capacitor and if protective measures were not taken the entire converter could fail from over voltage.

### Demerits

- ❖ Dump capacitor voltage is maintained “2 Vdc” to allow fast demagnetization. But use of a capacitor and an inductor in the dump circuit and also the voltage rating of other devices is twice the bus voltage

- ❖ Monitoring of the dump capacitor voltage ‘C’ and control of dump switch T makes the converter very complicated and also the converter does not allow freewheeling.

### 3.4 VOLTAGE AND TORQUE EQUATIONS OF SRM

#### 3.4.1 Basic voltage equation of SRM

From fig. 3.9

$$V=iR+\frac{d\lambda}{dt} \dots\dots\dots (3.1)$$

Fig. 3.9 Basic R-L circuit of SRM.

where  $\lambda$  is a function of  $\theta$  and L

$$\frac{d\lambda}{dt} = \frac{d}{dt} i + \frac{di}{dt} \theta \dots\dots\dots(3.2)$$

$$V=iR+\frac{d(Li)}{dt} \dots\dots\dots(3.3)$$

$$=iR+L\frac{d}{dt} + i\frac{dL}{dt}$$

$$=iR+L\frac{di}{dt} + i\frac{dL}{d} \times \frac{d}{dt}$$

$$V=iR+L\frac{di}{dt} + i\omega\frac{dL}{d} \dots\dots\dots(3.4)$$

where  $iR$  □ ohmic drop

$L\frac{di}{dt}$  □ Emf due to incremental inductance

$i\omega\frac{dL}{d}$  □ self induced emf e or self emf

$$V=iR+L\frac{di}{dt} + e \dots\dots\dots(3.5)$$

Self-induced emf e is proportional to current speed and rate of change of inductance with rotor angle.

If flat topped current is assumed  $L\frac{di}{dt} = 0$  on the other hand if the inductance is constant, self emf is zero. So the first term  $L\frac{di}{dt}$  absorbs all the applied voltage.

$$Vi=i^2R+L\frac{di}{dt} + i^2\omega\frac{dL}{d} \dots\dots\dots(3.6)$$

Energy stored in the magnetic circuit  $= \frac{1}{2} Li^2$

Rate of change of energy stored

in the magnetic circuit  $= \frac{d}{dt} \left[ \frac{1}{2} Li^2 \right]$  .....(3.7)

$$\begin{aligned} &= \frac{1}{2} L \cdot 2i \frac{di}{dt} + \frac{1}{2} i^2 \frac{dL}{dt} \\ &= Li \frac{di}{dt} + \frac{1}{2} i^2 \frac{dL}{dt} \times \frac{d}{dt} \end{aligned}$$

$$\frac{dW_{mag}}{dt} = Li \frac{di}{dt} + \frac{1}{2} i^2 \omega \frac{dL}{d} \quad \dots\dots\dots(3.8)$$

Mechanical energy transferred = electrical energy input  $\square i^2 R$   $\square$  rate of change of energy stored in the magnetic circuit.

$$\begin{aligned} \text{Mechanical energy transferred} &= Vi \square i^2 R \square \frac{dW_{mag}}{dt} \\ &= i^2 R + Li \frac{di}{dt} + i^2 \omega \frac{dL}{d} \square i^2 R \square Li \frac{di}{dt} \square \frac{1}{2} i^2 \omega \frac{dL}{d} \end{aligned}$$

$$P_m = \frac{1}{2} i^2 \omega \frac{dL}{d} \quad \dots\dots\dots(3.9)$$

$$P_m = \omega T \quad \dots\dots\dots(3.10)$$

$$\therefore \text{Torque } T = \frac{1}{2} i^2 \frac{dL}{d} \quad \dots\dots\dots(3.11)$$

### 3.5 CONTROL CIRCUITS FOR SRM

For motoring operation the pulses of phase current must coincide with a period of accuracy inductance. The timing and dwell (i.e.) period of conductance of the current pulse determine the torque, the efficiency and other parameters. With fixed firing angles, there is a monotonic relationship exist between average torque and rms phase current but generally it is not linear. This may present some complications in feedback-controlled systems. Although it is possible to achieve 'near servo-quality' dynamic performance, particularly in respects of speed range torque/inertia and reversing capability.

More complex controls are required for higher power drives, particularly where a wide speed range is required at constant power, and microprocessor controls are used. As high-speed operation, the peak current is limited by the self-emf of the phase winding. A smooth current waveform is obtained with a peak/rms ratio similar to that of a half sinewave.

At low speed, the self-emf of the winding is small and the current must be limited by chopping or PWM of the applied voltage.

Two types of control circuits used are:

1. Hysteresis type to maintain constant current
2. Voltage pulse width modulation control (or) duty cycle control.

### 3.6 HYSTERISIS TYPE CURRENT REGULATION

As by this control circuit current is maintained more or less constant like “hysteresis” throughout the conduction period in each phase it is known as hysteresis type control. Fig 3.10 (a) shows the current waveform controlled by the hysteresis type current regulator. The schematic arrangement of the control circuit is shown in fig 3.10 (b).

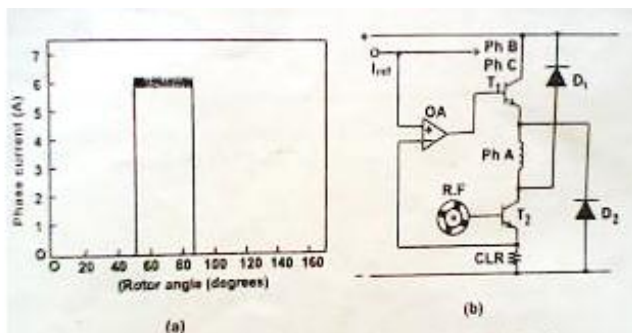

Fig 3.10 (a) Chopped current wave form, (b) Hysteresis type current regulator

#### Principle of operation

As shown in fig. 3.10(b) the transducer (a tachogenerator) is connected from the rotor and then the output signal from the transducer is given as a feedback signal at the base of transistor T<sub>2</sub>. From the emitter of transistor T<sub>2</sub>, the portion of the feedback signal (current) is fed at the input of the operational amplifier (O.A.). There it is compared with the reference current and correspondingly after amplification the feedback signal is given at the base of transistor T<sub>1</sub>. This signal in combination with collector current will flow from the emitter of transistor T<sub>1</sub> through A phase winding of the machine. Thus the current through A phase winding can be controlled depending on the requirement. CLR is the resistance for limiting the current as per the design.

As the current reference increase the torque increases. At low currents the torque is roughly proportional to current squared but at higher current it becomes more nearly linear. At very high currents, saturation decreases the torque per ampere again. This type of control produces a constant-torque type of characteristics.

With loads whose torque increases monotonically with speed, such as fans and blowers, speed adjustment is possible without tachometer feedback but general feedback is needed to provide accurate speed control. In some cases the pulse train from the soft position sensor may be used for speed feedback, but only at relative high speeds.

As low speeds, a larger number of pulses per revolution are necessary and this can be generated by an optical encoder or resolver for alternatively by phase-locking a high

frequency oscillator to the pulses of the commutation sensor. System with resolver-feedback or high-resolution optical encoders can work right down to zero speed.

The “hysteresis type” current regulator may require current transducers of wide bandwidth, but the SR drive has the advantage that they can be grounded at one end with the other connected to the negative terminal of the lower phase leg switch. The sensors used are shunts or hall-effect sensors or sensefets with in build current sensing.

### 3.7 VOLTAGE PWM TYPE CURRENT REGULATION

The schematic arrangement of PWM type control circuit is shown in fig. 3.11

#### Principle of operation

Through transducer (tachogenerator) the mechanical signal (speed) is converted into electrical signal (current), which is fed from at the base of transistor T2. This base current combining with collector current flows the emitter of transistor T2 through CLR to the

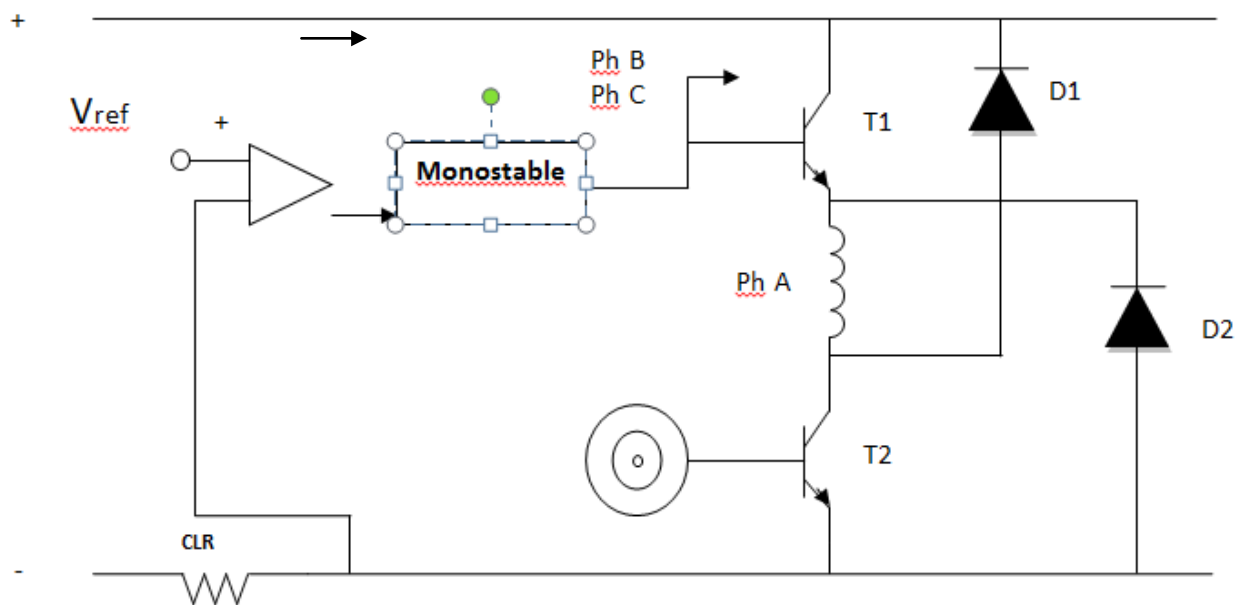

Fig.3.11 Voltage PWM type current regulator

CLR -Current limiting resistor

R.F-Rotor feed back

OA -Operational Amplifier

T1T2-Switching transistor

D1 D2-Diodes to return stored energy

negative of the supply. Based on the feedback signal, the voltage at phase A changes. This feedback voltage is given as one input to the operational amplifier where it is compared with the reference voltage, correspondingly the difference is amplified and fed to the mono stable circuit. This circuit modulates the pulse width of the incoming signal based on the requirement and the modulated signal is given at the base of T1. This signal combines with collector current of T1 and flows through phase A as modulated current based on the

requirement. Thus the current is regulated or controlled using pulse width modulation and rotor feedback.

A desirable future of both control methods is that the current wave form tends to retain the same shape over a wide speed range.

When the PWM duty cycle reaches 100%, the motor speed can be increased by increasing the conduction period. These increases eventually reach maximum values after which the torque becomes inversely proportional to speed squared but they can typically double the speed range at constant torque. The speed range over which constant power can be maintained is also quite wide and very high maximum speeds can be achieved, as in the synchronous reluctance motor and induction motor, because there is not the limitation imposed by fixed as in PM motors.

### 3.8 TORQUE-SPEED CHARACTERISTICS

Torque developed (i.e.) average torque developed but SRM depends upon the current wave form of SRM phase winding. Current waveform depends upon the conduction period and chopping details. It also depends upon the speed.

Consider a case that conduction angle  $\theta$  is constant and the chopper duty cycle is 1.(i.e.) it conducts continuously. For low speed operating condition, the current is assumed to be almost flat shaped. Therefore the developed torque is constant. For high speed operating condition, the current wave form gets changed and the average torque developed gets reduced.

Fig. 3.12(a) represents the speed torque characteristics of SRM for constant  $\theta$  and duty cycle. It is constant at low speeds and slightly droops as speed increases. For various other constant value of  $\theta$ , the family of curves for the same duty cycle is shown in fig.3.12.

Fig. 3.12 Torque speed characteristics at constant conduction angle  $\theta$  and duty cycle

Torque speed characteristics for fixed  $\theta$  and for various duty cycles are shown in fig. 3.12.  $\theta$  and duty cycle are varied by suitably operating the semiconductor devices.

### 3.8.1 Torque Speed Capability Curve

Maximum torque developed in a motor and the maximum power that can be transferred are usually restricted by the mechanical subsystem design parameters.

For given conduction angle the torque can be varied by varying the duty cycle of the chopper. However the maximum torque developed is restricted to definite value based on mechanical consideration.

Fig. 3.13 Torque speed characteristic of switched reluctance motor

AB in the fig.3.13 represents constant maximum torque region of operation.

At very low speeds, the torque / speed capability curve may deviate from the clock torque characteristics. If the chopping frequency is limited or if the bandwidth of the current regulator is limited, it is difficult to limit the current without the help of self emf of the motor and the current reference may have to be reduced.

If very low windage and core loss permit the chopper losses to be increased, so that with higher current a higher torque is obtained. Under intermittent condition of course very much higher torque can be obtained in any part of the speed range up to  $\omega_b$ .

The motor current limits the torque below base speed. The 'corner point' or base speed ' $\omega_b$ ' is the highest speed at which maximum current can be supplied at rated voltage with fixed firing angles. If these angles are still kept fixed, the maximum torque at rated voltage decreases with speed squared. But if the conduction angle is increased, (i.e.)  $\theta_{on}$  is decreased, there is a considerable speed range over which maximum current can be still be forced into the motor. This maintains the torque at a higher level to maintain constant power characteristic. But the core losses and windage losses increases with the speed. Thus the curve BC represents the maximum permissible torque at each speed without exceeding the

maximum permissible power transferred. This region is obtained by varying  $\theta_D$  to its maximum value  $\theta_{D \max}$ .  $\theta_D$  is dwell angle of the main switching devices in each phase. Point C corresponds to maximum permissible power; maximum permissible conduction angle  $\theta_{D \max}$  and duty cycle of the chopper is unity.

Curve CD represents  $T\omega^2$  constant. The conduction angle is kept maximum and duty cycle is maximum by maintaining  $T\omega^2$  constant. D corresponds to maximum  $\omega$  permissible. The region between the curve ABCD and X axis is the “permissible region of operation of SRM”.

### **3.9 DISTINCTION BETWEEN SWITCHED RELUCTANCE MOTOR AND THE VARIABLE RELUCTANCE STEPPER MOTOR**

The conduction angle for phase currents is controlled and synchronized with the rotor position, usually by means of a shaft position sensor.

Thus SR motor is exactly like a brushless dc motor. But the stepper motor is usually fed with a square-wave of phase current without rotor position feedback.

SR motor is designed for efficient power conversion at high speeds comparable with those of the PM brushless dc motor. The stepper motor is usually designed as a torque motor with a limited speed range. SR motor is more than a high-speed stepper motor. Its performance and low manufacturing cost make it a competitive motor to PM brushless dc system.

#### **3.9.1 Merits of SRM**

1. Construction is simple and robust, as there is no brush.
2. Rotor carries no windings, no slip rings and brush-less maintenance.
3. No permanent magnet, neither in the stator nor in the rotor.
4. Ventilating system is simpler as losses takes place mostly in stator.
5. Power semiconductor switching circuitry is simpler.
6. No shoot-through fault is likely to happen in power semiconductor circuits.
7. Torque developed does not depend upon the polarity of the current in the phase winding.
8. The operation of the machine can be easily changed from motoring mode to generating mode by varying the region of conduction.
9. It is impossible to have very high speeds.
10. Depending upon the requirement, the desired torque speed characteristics can be tailor made.
11. It is a self-starting machine.

12. Starting torque can be very high without excessive inrush currents.

### 3.9.2 Demerits of SRM

1. Stator phase winding should be capable of carrying the magnetizing current also, for setting up the flux in the air gap.
2. For high speed operations, the developed torque has undesirable ripples. As a result it develops undesirable acoustic losses (noise).
3. For high speeds, current waveform also has undesirable harmonics. To suppress this effect a large size capacitor is to be connected.
4. The air gap at the aligned axis should be very small while the air gap at the inter-polar axis should be very large. It is difficult to achieve. No standardized practice is available.
5. The size of the motor is comparable with the size of variable speed induction motor drive.
6. Number of power wires between power semiconductor circuitry and the motor and the number of control cables from one controller to the power semiconductor circuitry are more and all to be properly connected.
7. It requires a position sensor.

### 3.9.3 Application of SRM

1. Washing machines
2. Vacuum cleaners
3. Fans
4. Future automobile applications
5. Robotic control applications

### 3.10 SHAFT POSITION SENSING

- ❖ Commutation requirement of the SR motor is very similar to that of a PM brushless motor.
- ❖ The shaft position sensor and decoding logic are very similar and in some cases it is theoretically possible to use the same shaft position sensor and the same integrated circuit to decode the position signals and control PWM as well.
- ❖ The shaft position sensors have the disadvantage of the associated cost, space requirement and possible extra source of failure. Reliable methods are well established. In position sensors or speed sensors, resolvers or optical encoders may be used to perform all the functions of providing commutation signals, speed feedback and position feedback.

- ❖ Operation without position sensor is possible. But to have good starting and running performance with a wide range of load torque and inertias, sensor is necessary.
- ❖ When the SR motor is operated in the 'open-loop' mode like a stepper motor in the slewing range, the speed is fixed by the reference frequency in the controller as long as the motor maintains 'step integrity'. (i.e) stay in synchronism. Therefore like an asynchronous motor, the switched reluctance motor has truly constant speed characteristics.

This open-loop control suffers from two dis-advantages.

- (a) To ensure that synchronism is maintained even though the load torque may vary.
  - (b) To ensure reliable starting.
- ❖ Because of the large step angle and a lower torque/inertia ratio, the SR motor usually does not have reliable 'starting rate' of the stepper motor.
  - ❖ Also some form of inductance sensing or controlled current modulation (i.e) such as sine wave modulation may be necessary in the control at low speeds.

### 3.11 MICROPROCESSOR OR COMPUTER BASED CONTROL OF SRM DRIVE

Today in industrial places there is high demands on control accuracies, flexibility, ease of operation, repeatability of parameters for many drive applications. Nowadays switched reluctance motors are increasingly used in industries. To meet the above requirements, uses of microprocessor have become important.

Fig. 3.14 Microprocessor or computer based control of SRM

Fig. shows the block diagram of microprocessor based control of SRM drive. This control system consists of power semiconductor switching circuit, SRM with rotor position sensor and microprocessor system. In this system microprocessor acts as a controller for the switched reluctance motor and generate control pulses to the power semiconductor switching circuits.

The input DC supply is fed to the power semiconductor switching circuits. Different types of power semiconductor switching circuits are used for different application. Normally the circuits are inverter circuit configuration.

The power semiconductor devices are turned on and off by controller circuit. Here the controller circuit is microprocessor or computer based control system.

In the SRM drive shown in fig. 3.14, the rotor position sensor gives the information about the rotor with respect to the reference axis to the microprocessor or computer control. The controller also receives the status of current, flow through the phase winding and reference signal.

The microprocessor or computer compares the signals obtained from the RPS and reference and generate square pulses to the power semiconductor devices. This signal is fed to the inverter circuit. The phase winding of the SRM is energized depending upon the turning on and off of the power semiconductor switching circuit.

The microprocessor or computer controller can perform the following functions.

- a) Control the feedback loops.
- b) PWM or square wave signal generation to inverters.
- c) Optimal and adaptive control.
- d) Signal monitoring and warning.
- e) General sequencing control.
- f) Protection and fault overriding control.
- g) Data acquisition.

The superiority of microprocessor or computer control over the conventional hardware based control can be easily recognized for complex drive control system. The simplification of hardware saves control electronics cost and improves the system reliability. The digital control has inherently improves the noise immunity which is particularly important because of large power switching transients in the converters.

**Glossary**

1. Switched reluctance motor -- It is a doubly salient, singly excited motor. It has salient poles on both the rotor and the stator, but only one member carries Winding. The rotor has no winding, magnets or case winding.
2. Phase winding -- Stator poles carries field coils. The field coils of opposite poles are connected in series such that mmfs are additive.
3. Energy Ratio -- The ration between mechanical energy transformed to stored energy.
4. Bifilar wires -- Each phase winding has two exactly similar phase windings. It is used for bipolar excitation.
5. Demagnetization -- After conducting a magnetic particle inspection, it is usually necessary to demagnetize the component.
6. Chopping -- Cutting
7. Hysteresis -- input alternately increases and decreases, the output tends to form a loop
8. Microprocessor -- Microprocessor is a multipurpose, programmable, clock-driven, register based electronic device
9. Reluctance -- A material's resistance to becoming magnetized.
10. Microcontroller -- microcontroller is a Device that includes microprocessor, memory and I/O signal lines on a single chip, fabricated using VLSI technology
11. Electromagnetism -- A state of sameness. Objects that are in equilibrium are either completely still or moving at a consistent rate.
12. power semiconductor device -- A power semiconductor device is a semiconductor device used as switch or rectifier in power electronics; a switch-mode power supply is an example. Such a device is also called a power device or, when used in an integrated circuit, a power IC.
13. PWM -- A modulation technique that generates variable-width pulses to represent the amplitude of an analog input signal.

## UNIT IV

**PERMANENT MAGNET BRUSHLESS D.C. MOTORS****4.1 INTRODUCTION**

Conventional DC motors are highly efficient and their characteristics make them suitable for use as servomotors. However, their only drawbacks that they need a commutator and brushes which are subject to wear and require maintenance.

When the functions of commutator and brushes were implemented by solid state switches, maintenance free motors were realized. These motors are known as brushless DC motors. The function of magnets is the same in both brushless motor and the dc commutator motor. The motor obvious advantage of brushless configuration is the removal of brushes. Brush maintenance is no longer required, and many problems associated with brushes are removed.

An advantage of the brushless configuration in which the rotor inside the stator is that more cross sectional area is available for the power or armature winding. At the same time conduction of heat through the frame is providing greater specific torque. The efficiency is likely to be higher that of a commutator motor of equal size and the absence of brush friction help further in this regard.

**4.2 CONSTRUCTIONAL FEATURES OF BLPM MOTORS****4.2.1 Construction**

The stator of the BLPM dc motor is made up of silicon steel stampings with slots in its interior surface. These slots accommodate either a closed or opened distributed armature winding usually it is closed. This winding is to be wound for a specified number of poles. This winding is suitably connected to a dc supply through a power electronic switching circuitry (named as electronic commutator).

Fig 4.1 Arrangement of permanent magnet in the rotor

Rotor is made of forged steel. Rotor accommodates permanent magnet. Number of poles of the rotor is the same as that of the stator. The rotor shaft carries a rotor position sensor. This position sensor provides information about the position of the shaft at any instant to the controller which sends suitable signals to the electronic commutator.

### 4.2.2 Merits and Demerits

#### Merits

- ❖ There is no field winding. Therefore there is no field cu loss.
- ❖ The length of the motor is less as there is no mechanical commutator.
- ❖ Size of the motor becomes less.
- ❖ It is possible to have very high speeds.
- ❖ It is self-starting motor. Speed can be controlled.
- ❖ Motor can be operated in hazardous atmospheric condition.
- ❖ Efficiency is better.

#### Demerits

- ❖ Field cannot be controlled.
- ❖ Power rating is restricted because of the maximum available size of permanent magnets.
- ❖ A rotor position sensor is required.
- ❖ A power electronic switch circuitry is required.

### 4.2.3 Comparison of brushless dc motor relative to induction motor drives

- ❖ In the same frame, for same cooling, the brushless PM motor will have better efficiency and p.f and therefore greater output. The difference may be in the order of 20 – 50% which is higher.
- ❖ Power electronic converter required is similar in topology to the PWM inverters used in induction motor drives.
- ❖ In case of induction motor, operation in the weakening mode is easily achieved providing a constant power capability at high speed which is difficult in BLPM dc motor.
- ❖ PM excitation is viable only in smaller motors usually well below 20 kw also subject to speed constraints, In large motors PM excitation does not make sense due to weight and cost.

### 4.2.4 Commutator and brushes arrangement

Because of the heteropolar magnetic field in the air gap of dc machine the emf induced in the armature conductors is alternating in nature. This emf is available across brushes as unidirectional emf because of commutator and brushes arrangement.

The dc current passing through the brushes is so distributed in the armature winding that unidirectional torque is developed in armature conductor.

A dc current passing through the brushes because of commutator and brushes action, always sets up a mmf whose axis is in quadrature with the main field axis, irrespective of the speed of the armature.

### 4.2.5 Construction of Mechanical Commutator

#### Commutator Segment

Fig 4.2 Commutator Segment

Commutator is made up of specially shaped commutator segments made up of copper. These segments are separated by thin mica sheets (ie) Insulation of similar shape. The commutator segments are tapered such that when assembled they form a cylinder.

These segments are mechanically fixed to the shaft using V – shaped circular steel clamps, but are isolated electrically from the shaft using suitable insulation between the clamps and the segment.

Fig 4.3 connection of commutator segments to shaft

### 4.2.6 Mechanical Commutator and Brushes Arrangement

Fig 4.4 Mechanical Commutator and Brushes Arrangement

It represents a case with 2poles and 12 commutator segments.

To start with the brush X contacts with CSI and brush Y with 7.A dc supply is connected across the brushes X and Y. The dc current I passes through brush X,CSI,tapping 1,tapping 7and brush Y. There are two armature parallel paths between tapping's 1 and 7.the current passing through the armature winding aets up a magneto motive force whose axis is along the axes of tapping 7 and 1 of the brush axes Y and X.

Allow the armature to rotate by an angle in a counter clockwise direction. Then the brush X contacts CS2 and the tapping's a and the brush Y. Contact CS8 and tapping 8.The dc current passes through the tapping's 2 and 8 there are two parallel paths.

- (i) 2 – 3 – 4 – 5 – 6 – 7 – 8
- (ii) 2 – 1 – 12 – 11 – 10 – 9 – 8

Now the mmf set up by the armature winding is form tapping 8 to 2 along the brush axis YX Thus the armature mmf direction is always along the brush axis YX, even though the current distribution in the armature winding gets altered.

In a normal dc machine brushes are kept in the interpolar axis. Therefore, the axis of the armature mmf makes an angle  $90^\circ$ elec with the main field axis.

The function of commutator and brushes arrangement in a conventional dc machine is to set up an armature mmf always in quadrature with the main field mmf respectively of the speed of rotation of the rotor.

#### 4.2.7 Electronic commutator

The armature winding which is in the stator has 12 tapping's. each tapping is connected to the positive of the dc supply node and through 12 switches designated as S1 ,S2,....S12 and negative of the supply at node Y through switches S'1,S'2,.....S'12.

Fig 4.5 Electronic Commutator

When S1 and S'1 are closed the others are in open position, the dc supply is given to the tappings 1 and 7.there are two armature parallel path.

- (i) 1 – 2 – 3 – 4 – 5 – 6 – 7
- (ii) 1 – 12 – 11 – 10 – 9 – 8 – 7

They set up armature mmf along the axis 7 to 1.

After a small interval S1 and S'1 are kept open and S2 and S'2 are closed. Then dc current passes from tapping 2 to 8 sets up mmf in the direction 8 – 2.

Fig 4.6 switching circuit of electronics commutator

Thus by operating the switch in a sequential manner it is possible to get a revolving mmf in the air gap. The switches S1 to S12 and S'1 to S'12 can be replaced by power electronic switching devices such as SCR's MOSFET's IGBT's, power transistor etc.

When SCR's are used suitable commutating circuit should be included. Depending upon the type of forced commutated employed, each switch requires on or two SCRs and other commutating devices. As number of devices is increased, the circuit becomes cumbersome.

Fig 4.7 Delta Connected Stator Armature Winding

For normal electronic commutator, usually six switching devices are employed. Then the winding should have three tapping's. Therefore the winding can be connected either in star or in delta.

Fig 4.8 Star Connected Armature Winding

#### 4.2.8 Comparison between mechanical Commutator and brushes and Electronic Commutator

| S. No | Mechanical Commutator   | Electronic Commutator   |
|-------|---|---|
| 1.    | Commutator is made up of copper segment and mica insulation. Brushes are of carbon or graphite. | Power electronic switching device is used in the commutator. it requires a position sensor.   |
| 2.    | Commutator arrangements are located in the rotor.   | It is located in the stator.  |
| 3.    | Shaft position sensing is inherent in the arrangement   | Separate rotor position sensor is required.   |
| 4.    | Numbers of commutator segments are very high.   | Number of switching devices is limited to 6.  |
| 5.    | Highly reliable.  | Reliability is improved by specially designing the devices and protective circuits.           |
| 6.    | Difficult to control the voltage available across the tappings.                                 | The voltage available across armature tappings can be controlled by employing PWM techniques. |
| 7.    | Interpole windings are employed to have sparkles commutation.                                   | By suitable operating the switching devices, better performance can be achieved.              |

## 4.3 B – H LOOP AND DEMAGNETIZATION CHARACTERISTICS

### 4.3.1 Permanent Magnets Material

NdFeB – Neodymium – iron – boron has the highest energy product of all commercially available magnets at room temperature. It has high remanence and coercivity in the motor frame size for the same output compared with motors using ferrite magnets. But it is costlier. But both of the above stated magnets are sensitive to temperature and care should be taken for working temperature above  $100^\circ$ . For very high temperature applications, alnico or rare earth cobalt magnets must be used.

### 4.3.2 B – H Loop

It is used for understanding characteristics hysteresis loop as shown.

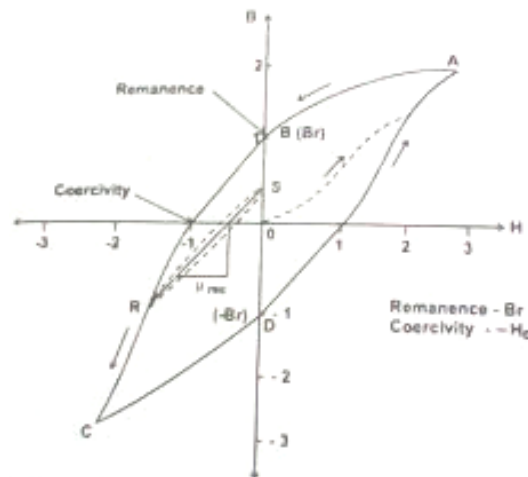

Fig 4.9 BH Hysteresis loop of hard permanent magnet material

X – axis – Magnetizing force or field intensity H.

Y – axis – Magnetic flux density B in the material.

- ❖ An un-magnetized sample has  $B = 0$  and  $H = 0$  and therefore starts out at the origin.

#### Curve OA

- ❖ If it is subjected to a magnetic field, magnetic fixture (an electromagnetic with shaped pole pieces to focus flux into the magnet), then B and H in the magnet follow the curve OA as the external ampere – turns are increased.

#### Curve AB

- ❖ If the external ampere – turns are switched off, the magnet relaxes along AB. The operating point (H, B) depends on the shape of the magnet and permanence of the surrounding magnetic circuit. If the magnet is surrounded by a highly permeable magnetic circuit, that is if it is kepted then its poles are effectively shorted together so that  $H = 0$  and then the flux density is the value at point remanence Br.

Permanence: Maximum flux density that can be retained by the magnet at a specified temperature after being magnetized to saturation.

### Curve BC

- ❖ External ampere turns applied in the opposite direction cause the magnets operating point to follow the curve from B through the second quadrant to C.

### Curve CD

- ❖ If the ampere – turns are switched off at c the magnet relaxes along CD.

It is now magnetized in the opposite direction and the maximum flux density it can retain when kepted is  $-B_r$ .

- ❖ To bring B to zero from negative remanence point D, the field  $+H_c$  must be applied.
- ❖ The entire loop is usually symmetrical and be measured using instruments such as hysteresis graph.

### 4.3.3 Soft PM

- ❖ Soft PM materials have Knee in the second quadrant such as Alnico.
- ❖ Alnico magnets have very high remanence and excellent mechanical and thermal properties. But they are limited in the demagnetizing field they can withstand.
- ❖ These soft PM are hard when compared with lamination steels the hysteresis loop of typical non oriented electrical steel is very narrow when compared with Alnico.

### 4.3.4 Demagnetization curve

Fig 4.10 Demagnetization curve

In the absence of externally applied ampere – turn, the magnets operating point is at the intersection of the demagnetization curve and the load line.

- ❖ The slope of the load line is the product of  $\mu_0$  and the permeance co efficient of the external circuit.

In a permanent magnet, the relationship between  $B$  and  $H$  is

$$B = \mu_0 H + J$$

$\mu_0 H$  – flux density that would exist if the magnet were removed and the magnetizing force remain at the value  $H$ .

$J$  – contribution of the magnet to the flux - density within its own volume.

- ❖ If the demagnetization curve is a straight line, and therefore its relative slope and there by the  $\mu_{rec}$  is unity, Then  $J$  is constant.

$J$  – Magnetization of the magnet, unit T tesla

- ❖ Hard magnets have  $\mu_{rec} \geq 1$ ,  $J$  decreases as the  $-H_c$  increases.
- ❖ The magnet can recover or recoil back to its original flux density as long as the magnetization is constant.
- ❖ The coercive force required to permanently demagnetize the magnet is called the intrinsic coercivity and it is  $H_{ci}$ .

#### 4.4 PRINCIPLE OF OPERATION OF BRUSHLESS PM DC MOTOR

##### Starting

When dc supply is switched on to the motor the armature winding draws a current. The current distribution within the stator armature winding depends upon rotor position and the devices turned on. An emf perpendicular to the permanent magnet field is set up. Then the armature conductors experience a force. The reactive force develops a torque in the rotor. If this torque is more than the opposing frictional and load torque the motor starts. It is a self-starting motor.

##### Demagnetization curve

As the motor picks up speed, there exists a relative angular velocity between the permanent magnet field and the armature conductors. AS per faradays law of electromagnetic induction, an emf is dynamically induced in the armature conductors. This back emf as per len's law opposes the cause armature current and is reduced. As a result the developed torque reduces. Finally the rotor will attain a steady speed when the developed torque is exactly equal to the opposing frictional load torque. Thus the motor attains a steady state condition.

##### Electromechanical transfer

When the load – torque is increased, the rotor speed tends to fall. As a result the back emf generated in the armature winding tends to get reduced. Then the current drawn from the mains is increased as the supply voltage remains constant. More torque is developed by the motor. The motor will attain a new dynamic equilibrium position when the developed torque is equal to the new torque. Then the power drawn from the mains  $V * I$  is equal to the mechanical power delivered  $\frac{2\pi NT}{60} = P_m = \omega T$  and the various losses in the motor and in the electronic switching circuitry.

## 4.5 CLASSIFICATION OF BLPM DC MOTOR

BLPM dc motors can be classified on the basis of the flux density distribution in the air gap of the motor. They are

- (a). BLPM Square wave dc motor [BLPM SQW DC Motor]
- (b). BLPM sinusoidal wave dc motor [BLPM SINE WAVE DC Motor]

### (a) BLPM Square wave motor

These are two types:  $180^\circ$  pole arc.

$120^\circ$  pole arc.

Air gap flux density distribution in  $180^\circ$  BLPM SQW motor as shown in fig.

Fig 4.11 Air gap flux density distribution in  $180^\circ$  BLPM SQW motor.

Air gap density distribution of BLPM DC SQW motor with  $120^\circ$  pole arc, as shown in fig.

Fig 4.12 Air gap flux density distribution in  $120^\circ$  BLPM SQW motor

### (b) BLPM Sine wave DC Motor

Air gap density distribution of BLPM dc sine wave motor as shown in fig.

Fig 4.13 Flux density distribution of BLPM DC sine wave motor

#### 4.6 EMF EQUATION OF BLPM SQW DC MOTORS

The basic torque emf equations of the brushless dc motor are quite simple and resemble those of the dc commutator motor.

The co-ordinate axis have been chosen so that the center of a north pole of the magnetic is aligned with the x-axis at  $\Theta = 0$ . the stator has 12 slots and a three phasing winding. Thus there are two slots per pole per phase.

❖ Consider a BLPM SQW DC MOTOR

Let 'p' be the number of poles (PM)

' $B_g$ ' be the flux density in the air gap in wb/m<sup>2</sup>.

$B_k$  is assumed to be constant over the entire pole pitch in the air gap ( $180^\circ$  pole arc)

'r' be the radius of the airgap in m.

'l' be the length of the armature in m.

' $T_c$ ' be the number of turns per coil.

' $\omega_m$ ' be the uniform angular velocity of the rotor in mechanical rad/sec.

$\omega_m = 2\pi N/60$  where N is the speed in rpm.

Flux density distribution in the air gap is as shown in fig 4.14. At  $t=0$  (it is assumed that the axis of the coil coincides with the axis of the permanent magnet at time  $t=0$ ).

Let at  $\omega_{mt}=0$ , the centre of N-pole magnet is aligned with x-axis.

At  $\omega_{mt}=0$ , x-axis is along PM axis.

Therefore flux enclosed by the coil is

$$\Phi_{\max} = B \times 2\pi r/p \times l \quad \dots\dots\dots(4.1)$$

$$= \text{flux/pole}$$

$$\Phi_{\max} = r l \int_0^\pi B(\theta) d\theta$$

$$= B_g r l [\theta]_0^\pi$$

$$= B_g r l [\pi]$$

At  $\omega_{mt}=0$ , the flux linkage of the coil is

$$\Lambda_{\max} = (B_g \times 2\pi r/p \times l) T_c \omega_b - T \quad \dots\dots\dots(4.2)$$

Fig 4.14 Magnetic Flux Density around the Air gap.

Fig 4.15 Motor Showing two Coils of One Phase.

Let the rotor rotating in ccw direction and when  $\omega_{mt} = \pi/2$ , the flux enclosed by the coil  $\Phi$ , Therefore  $\lambda = 0$ .

The flux linkages of the coil vary with  $\theta$  variation of the flux linkage is as shown above.

The flux linkages of the coil changes from  $B_g r l T c \pi / p$  at  $\omega_{mt} = 0$  (i.e)  $t = 0$  to  $\theta$  at  $t = \pi / p \omega_m$ .

Change of flux linkage of the coil (i.e)  $\Delta \lambda$  is

$$\Delta \lambda / \Delta t = \text{Final flux linkage} - \text{Initial flux linkage} / \text{time.}$$

$$= 0 - (2B_g r l T c \pi / p) / (\pi / p \omega_m)$$

$$= -(2B_g r l T c \omega_m) \dots \dots \dots (4.3)$$

The emf induced in the coil  $e_c = - d\lambda / dt$

$$e_c = 2B_g r l T c \omega_m \dots \dots \dots (4.4)$$

Distribution of  $e_c$  with respect to  $t$  is shown in fig 4.16

Fig 4.16 Emf waveform of coil 1

It is seen that the emf waveform is rectangular and it toggles between +  $e_c$  to -  $e_c$ . The period of the wave is  $2\pi/p\omega_m$  sec and magnitude of  $e_c$  is

$$e_c = 2B_g r l T c \omega_m \text{ volts} \dots\dots\dots(4.5)$$

Consider two coils a1A1 and a2A2 as shown in fig 5.15. Coil a2A2 is adjacent to a1A1 is displaced from a1A1 by an angle  $30^\circ$  (i.e.) slot angle  $Y$ .

The magnitude of emf induced in the coil a1A1

$$e_{c2} = B_g r l T c \omega_m \text{ volts} \dots\dots\dots(4.6)$$

The magnitude of emf induced in the coil a2A2

$$e_{c2} = B_g r l T c \omega_m \text{ volts} \dots\dots\dots(4.7)$$

Its emf waveform is also rectangular but displaced by the emf of waveform of coil  $e_{c1}$  by slot angle  $Y$ .

If the two coils are connected in series, the total phase voltage is the sum of the two separate coil voltages.

$$e_{c1} + e_{c2} = 2B_g r l T c \omega_m \dots\dots\dots(4.8)$$

Let  $n_c$  be the number of coils that are connected in series per phase  $n_c T_c = T_{ph}$  be the number of turns/phase.

$$e_{ph} = n_c [2B_g r l T c \omega_m] \dots\dots\dots(4.9)$$

$$e_{ph} = 2B_g r l T_{ph} \omega_m \text{ volts} \dots\dots\dots(4.10)$$

$e_{ph}$  = resultant emf when all  $n_c$  coils are connected in series.

The waveforms are as shown in fig 4.17

Fig 4.17 Emf waveform of phase a

The waveform of  $e_{ph}$  is stepped and its amplitude is  $2B_g r l T p h \omega_m$  volts.

At any instant 2-phase windings are connected in series across the supply terminals as shown in fig 4.18.

Fig.4.18 converter of brushless dc motor with star connected phase winding.

### Assumption

- Armature winding is Y connected.
- Electronic switches are so operated using rotor position sensor that the resultant emfs across the winding terminals is always = 2 eph.
- Amplitude of back emf generated in Y connected armature winding  $E = 2$  eph.

### 4.7 BASIC VOLTAGE EQUATION OF BLPMDM MOTOR

Let  $V$  be the dc supply voltage

$I$  be the armature current

$R_{ph}$  be the resistance per phase of the  $\lambda$  connected armature winding.

$V_{dd}$  be the voltage drop in the device (it is usually neglected)

$e_{ph}$  be the back emf generated per phase of Y connected armature winding .

$$V = 2 e_{ph} + 2IR_{ph} + 2V_{dd} \dots\dots\dots(4.11)$$

If  $V_{dd}$  is neglected

$$V = 2 e_{ph} + 2 I R_{ph}$$

$$I = \frac{V - 2 e_{ph}}{2R_{ph}}$$

$$I = \frac{V - E}{R} \dots\dots\dots(4.12)$$

**(a) Starting condition**

Speed is zero  $\omega_m = 0$

Supply voltage is  $V$

Since  $\omega_m=0$ ;  $e_{ph} = 0$

$$\text{Starting current } I_{stg} = \frac{V - 0}{2R_{ph}} = \frac{V}{2R_{ph}} = \frac{V}{R} \dots\dots\dots(4.13)$$

$R = 2 R_{ph}$  is Y connected

This current is also known as starting current.

**(b) NO load condition**

Current is very very small

Then  $V = 2 e_{ph} + 2 I R_{ph}$

$2I R_{ph}$  – negligible

$$V = 2 e_{pho} \dots\dots\dots(4.14)$$

$$= 2 [2 B_g r l \omega_{mo} T_{ph}]$$

$$= 4 [B_g r l \omega_{mo} T_{ph}]$$

$$V = k_e \omega_{mo} \dots\dots\dots(4.15)$$

$$\text{No load speed, } \omega_{mo} \cong \frac{V}{4 B_g r l T_{ph}} \dots\dots\dots(4.16)$$

$$= \frac{V}{k_e} \dots\dots\dots(4.17)$$

No load current  $I_o=0$

**(c) ON load condition:**

$$V = 2 e_{ph} + 2 I R_{ph}$$

$$= 4 B_g r l \omega_m t_{ph} + 2 I R_{ph} \dots\dots\dots(4.18)$$

On load current

$$I = \frac{V - 2 eph}{2Rph} = \frac{V - 4 Bgr l \omega_m tph}{2Rph} \dots\dots\dots(4.19)$$

$$= \frac{V - k_e \omega_m}{2 Rph} \dots\dots\dots(4.20)$$

$$I = \frac{V - k_e \omega_m}{2 Rph} \dots\dots\dots(4.21)$$

I vs  $\omega_m$  curve is shown in fig 4.19

Fig.4.19 I Vs.  $\omega_m$  Curve

**4.8 TORQUE EQUATION OF BLPM SQUARE WAVE MOTOR**

Power input = VI  
 = [ 2 eph + 2 I Rph + 2 Vdd ] I .....(4.22)

VI = [ 2 eph + 2 I Rph + 2 Vdd ] I .....(4.23)

VI = electrical power input

2 eph I = power converted as mechanical

2 I<sup>2</sup> Rph = power loss in the armature winding

2 Vdd I = power loss in the device

Mechanical power developed = 2 eph I .....(4.24)

eph = 2(2BgrlTph $\omega_m$ )I

eph = 4BgrlTph $\omega_m$  .....(4.25)

Mechanical power = (2 $\pi$ N/60)T .....(4.26)

=  $\omega_m$ T .....(4.27)

Where N = Speed in rpm

T = Torque in N-m

$\omega_m$  = Speed in rad/sec

Therefore T = 4BgrlTphI .....(4.28)

= KtI .....(4.29)

Where Kt = 4BgrlTph = Ke .....(4.30)

**(a) Case1: Starting Torque**

$\omega_m = 0$

Istg = (V/2Rph) .....(4.31)

Tstg = 4BgrlTph(V/2Rph) .....(4.32)

Tstg = Kt(V/2Rph) .....(4.33)

Starting torque or stalling torque depends upon V.

To vary the starting torque the supply voltage is to be varied.

**(b) Case 2: On load condition**

$$T = K_t I \dots\dots\dots(4.34)$$

$$= 4 B_g r l T_{ph} I$$

$$I = (V - 2e_{ph}) / (2R_{ph}) \dots\dots\dots (4.35)$$

$$2e_{ph} = V - 2I R_{ph}$$

$$4 B_g r l T_{ph} \omega_m = V - 2I R_{ph} \dots\dots\dots (4.36)$$

$$K_e \omega_m = V - 2I R_{ph}$$

$$\omega_m = (V - 2I R_{ph}) / K_e \dots\dots\dots (4.37)$$

$$\omega_{m0} = V / K_e \dots\dots\dots(4.38)$$

$$\omega_m / \omega_{m0} = ((V - 2I R_{ph}) / K_e) (V / K_e)$$

$$= (V - 2I R_{ph}) / V$$

$$\omega_m / \omega_{m0} = 1 - ((V - 2I R_{ph}) / V) \dots\dots\dots (4.39)$$

$$I / (T_{stg}) = (K_t I) / (K_t I_{stg})$$

$$= I \cdot (2R_{ph} / V)$$

$$T / T_{stg} = 2I R_{ph} / V \dots\dots\dots (4.40)$$

Substituting eqn. 5.40 in eqn. 5.39

$$\omega_m / \omega_{m0} = 1 - (T / T_{stg}) \dots\dots\dots (4.41)$$

$$\omega_m / \omega_{m0} = 1 - (I - I_{stg}) \dots\dots\dots (4.42)$$

**4.9 TORQUE- SPEED CHARACTERISTICS OF BLPM SQM DC MOTOR**

Let the supply voltage V be constant. A family of torque speed characteristics for various constant supply voltages is as shown in figure 4.20

Fig 4.20 T- $\omega_m$  curve for various supply voltages

### Permissible region of operation in T- $\omega_m$ plane

Torque speed characteristics of BLPM square wave motor is shown in fig.4.21. The constraints are

1. The continues current should not exceed the permissible current limit  $I_n$  (i.e) Torques should not exceed  $K_t I_n$ .
2. The maximum permissible supply voltage =  $V_n$ .
3. The speed should not exceed  $\omega_{mn}$ .

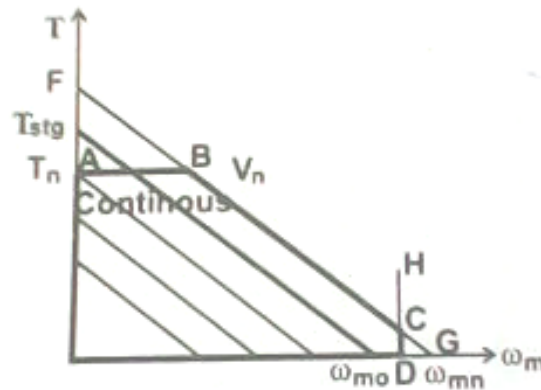

Fig. 4.21 Torque-speed characteristics

#### Line AB

Parallel to X-axis represents maximum permissible torque line which corresponds to maximum permissible current  $I_n$ .

#### Line FG

It represents T- $\omega_m$  characteristics corresponding to the maximum permissible  $V_n$ . B and C are points in Fig. B is the point of intersection between AB and FG.

#### Line DH

It represents constant maximum permissible speed line (i.e)  $\omega_{mn}$  is constant. DH intersects FG and x axis at D.

The area OABCD is the permissible region of operation. To obtain a particular point P corresponding to given load-torque and speed condition the only way to operate the motor at P is by suitably adjusting the supply voltage fed to the motor.

Fig.4.22 Torque speed characteristics of ideal brushless DC motor

- ❖ If the phase resistance is small as it should be in an efficient design, then the characteristics are similar to that of a shunt dc motor. The speed is essentially controlled by the voltage  $V$  and may be changed by changing the supply voltage. Then the current drawn just to drive the torque at its speed.
- ❖ As the load torque is increased, the speed drops and the drop is directly proportional to the phase resistance and the torque.
- ❖ The voltage is usually controlled by chopping or PWM. This gives rise to a family of torque speed characteristics as shown in fig. 4.22. The boundaries of continuous and intermittent limits are shown.

Continuous limit - determined by the heat transfer and temperature rise.

Intermittent limit – determined by the maximum ratings of semiconductor devices in circuit.

In practice the torque speed characteristics deviates from the ideal form because of the effects of inductance and other parasitic influences.

Also the speed range can be extended by increasing the dwell of conduction period relative to the rotor position.

#### 4.10 COMMUTATION IN MOTORS WITH 120° AND 180° MAGNET ARC

BLPM dc motor with 180° magnet arcs and 120° square wave phase currents are shown in fig. 4.23 and 4.24.

Fig.4.23 BLDC motor with 180° magnet arc and 120° square wave phase currents

Fig.4.24 BLDC motor with 120° magnet arcs and 180° square wave phase currents

In Fig. 4.26 the rotor magnet poles are shaded to distinguish north and south. The phase belts are shaded as complete 60° sector of the stator bore. There are two slots in each of these phase belts. The current in these two slots are identical and conductors in them are in series

Fig.4.25 Flux density around air gap

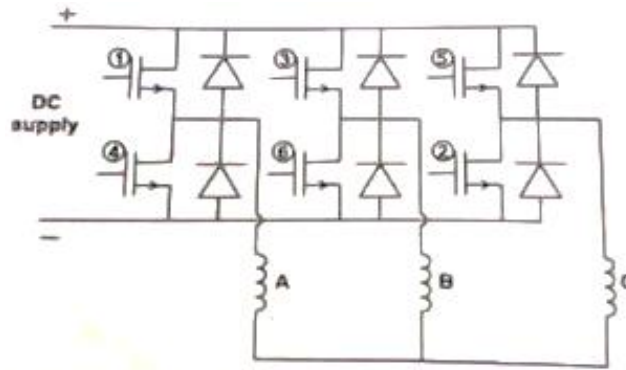

Fig.4.26 Converter of brushless DC motor for star connected phase winding

Between the rotor ring and the stationary belt ring in fig. 4.26 there is a third ring called the "mmf ring". This represents the mmf distribution of the stator currents at a particular instant.

- ❖ At the instant shown  $\omega t=0$ , phase A is conducting positive current and phase C is conducting negative current. The resulting mmf distribution has the same shading as the N and S rotor poles to indicate the generation of torque,
- ❖ Where the mmf distribution has like shading, positive torque is produced. Where mmf and flux shading are unlike, negative torque is produced. Where one is zero, no torque is produced. The total torque is the integral of the contributions from around the entire air gap periphery.

The rotor is rotating in the clockwise direction. After  $60^\circ$  of rotation, the rotor poles start to 'uncover' the C phase belts and the torque contribution of phase C starts to decrease linearly.

During this period, the magnet poles, have been 'covering' the B phase belts. Now if the negative current is commutated from C to B exactly at then point  $60^\circ$ , then the torque will be unaffected and will continue constant for a further  $60^\circ$ . After  $120^\circ$ , positive current must be commutated from A to C.

Commutation tables for three-phase brushless dc motors.

**TABLE 4.1 180° Magnet-Star Winding. 120° Square wave phase Currents**

| Rotor Position | A  | B  | C  | au(1) | aL(4) | bu(3) | bL(6) | cu(5) | cL(2) |
|----------------|----|----|----|-------|-------|-------|-------|-------|-------|
| 0 – 60         | +1 | 0  | -1 | 1     | 0     | 0     | 0     | 0     | 1     |
| 60 – 120       | +1 | -1 | 0  | 1     | 0     | 0     | 1     | 0     | 0     |
| 120 – 180      | 0  | -1 | +1 | 0     | 0     | 0     | 1     | 1     | 0     |
| 180 – 240      | -1 | 0  | +1 | 0     | 1     | 0     | 0     | 1     | 0     |
| 240 – 300      | -1 | +1 | 0  | 0     | 1     | 1     | 0     | 0     | 0     |

|              |   |    |   |   |   |   |   |   |   |
|--------------|---|----|---|---|---|---|---|---|---|
| 300 -<br>360 | 0 | +1 | 1 | 0 | 0 | 1 | 0 | 0 | 1 |
|--------------|---|----|---|---|---|---|---|---|---|

- ❖ The production of smooth, ripple free torque depends on the fact the magnet pole arc exceeds the mmf arc by  $60^\circ$ .
- ❖ Here only  $2/3$  of the magnet and  $2/3$  of the stator conductors are active at any instant

Fig. 4.27 phase current waveforms of BLDC motor with  $180^\circ$  pole arc.

In a practical motor the magnet flux-density distribution cannot be perfectly rectangular as shown in fig.4.27. for a highly coercive magnets and full  $180^\circ$  magnet arcs there is a transition section of the order of  $10-20^\circ$  in width. This is due to fringing effect. Likewise on the stator side, the mmf distribution is not rectangular but have a stepped wave form as shown in fig.4.28 that reflects the slotting.

Fig 4.28 Air Gap Flux Density on Open Circuit

To some extent these effects cancel each other so that satisfactory results are obtained with a magnet arc as short as  $150^\circ$ , and two slots per pole per phase.

But there is always dip in the torque in the neighborhood of the commutation angles. This torque dip occurs every  $60^\circ$  elec degrees, giving rise to a torque ripple component with a fundamental frequency equal to  $6P$  times the rotation frequency where  $P$  is the number of pole pairs. The magnitude and width of the torque dip depends on the time taken to commutate the phase current.

Phase current waveforms corresponding to high speed and low speed operations are as shown in fig. 4.29 (a & b)

(a) High speed, full voltage. Note the dip caused by commutation of other 2 phases,  
 (b) Low speed with current controlled by chopping.

Fig.4.29 Phase current wave forms.

- ❖ The back emf is of equal value in the incoming phase and is in such a direction as to oppose the current build up.
- ❖ While the flux distribution of the magnet rotates in a continuous fashion, the mmf distribution of the stator remains stationary for 60° and then jumps to a position 60° ahead.

Similar analysis is made with a motor having 120° pole arc magnets with delta connected armature winding.

**Table 4.2 120° Magnet Delta Winding, 180° Square Wave Phase Currents.**

| Rotor Position | A  | B  | C  | ab u | ab L | bc u | bc L | ca u | ca L |
|----------------|----|----|----|------|------|------|------|------|------|
|                |    |    |    | (1)  | (4)  | (3)  | (6)  | (5)  | (2)  |
| 0 – 60         | +1 | +1 | -1 | 0    | 0    | 1    | 0    | 0    | 1    |
| 60 – 120       | +1 | -1 | -1 | 1    | 0    | 0    | 0    | 0    | 1    |
| 120 – 180      | +1 | -1 | +1 | 1    | 0    | 0    | 1    | 0    | 0    |
| 180 – 240      | -1 | -1 | +1 | 0    | 0    | 0    | 1    | 1    | 0    |
| 240 – 300      | -1 | +1 | +1 | 0    | 1    | 0    | 0    | 1    | 0    |
| 300 - 360      | -1 | +1 | 1  | 0    | 1    | 1    | 0    | 0    | 0    |

Fig.4.30 phase currents wave forms of BLDC motor with 120° pole arc

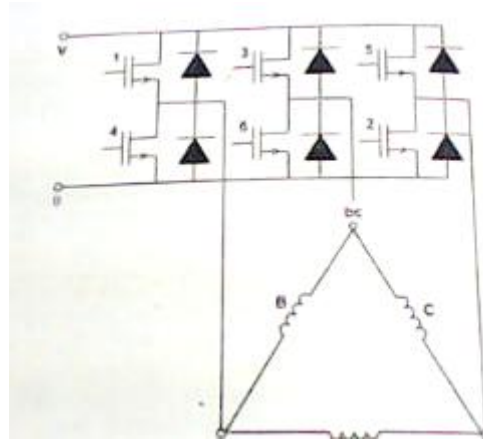

Fig 4.31 converter of brushless dc motor for delta connected phase winding

- ❖ C phase belt remains covered by the magnet poles. While the coverage of A phase belt increases thereby decreasing that of B phase belt.
- ❖ Since all the conductors are varying same current the increasing torque contribution of phase A is balancing by the decreasing contribution of phase B. Therefore, the total torque remains constant.
- ❖ Similarly there is a linear increase in the back emf of A and equal and opposite decrease in the back emf in phase B, Therefore the back emf at the terminals remains constant.
- ❖ Line current divides equally between two paths  
One-phase C Second-phase A & B series.

This balance is not perfect in practice because of the resistance and inductance of the windings. But the current balance should be maintained, otherwise circulating current may produce excessive torque ripple and additional losses.

When compared with  $180^\circ$  pole arc machine.

- ❖ For the same ampere-conductors per slot and for the same peak flux density, the  $120^\circ$  pole arc machine has 1.5 times copper losses, but produces the same torque.
- ❖ Also the ampere-conductors per slot would have to be reduced because the duty cycle is 1.0 instead of  $2/3$ .

### Merits

- ❖ For the same magnet flux density the total flux is only  $2/3$  of that of  $180^\circ$  pole arc motor, so that only  $2/3$  of the stator yoke thickness is required. If the stator outside diameter is kept the same, the slots can be made deeper so that the loss of ampere conductors can be at least partially covered. Consequently the efficiency of the motor may not be very much less than that of  $180^\circ$  pole arc machine.
- ❖ In this machine also, the effects of fringing flux, slotting and commutation overlap combine to produce torque ripple.
- ❖ Only emf and torque are discussed. The concept of hanging flux-linkage and energy balance can also be used to analyze the operation.

**4.11 MAGNETIC CIRCUIT ANALYSIS ON OPEN CIRCUIT**

Cross section of a 2 pole brushless dc motor having high energy rare earth magnets on the rotor and the demagnetization curve are as shown in fig 4.32 (a & b)

(a) Motor cross section and flux pattern

(b) magnet demagnetization curve

Fig 4.32 magnetic circuit analysis of BLDC motor

First step to analyze a magnetic circuit is to identify the main flux paths and the reluctance or permeances assigned to them.

The equivalent magnetic circuit is shown in fig 4.33. only half of the equivalent circuit is shown & the lower half is the mirror image of the upper half about the horizontal axis, which is at equipotential. This assumption is true only if the two halves are balanced. If not the horizontal axis might still be an equipotential but the fluxes and the magnetic potentials in the two halves would be different and there could be residual flux in the axial direction .along the shaft. The axial flux is undesirable because it can induce current to flow in the bearing.

Fig .4.33 magnetic equivalent circuit.

The steel cores of the stator and rotor shaft are assumed to be infinitely permeable.

Each magnet is represented by a 'Norton' equivalent circuit consisting of a flux generator in parallel with an internal leakage permeance  $p_{mo}$ .

$$\phi_r = B_r A_m \quad \dots\dots(4.43)$$

$$p_{mo} = \mu_0 \mu_{rec} A_m / l_m \quad \dots\dots(4.44)$$

where  $A_m$  – pole area the magnet

$l_m$  – length of the magnet in the direction of magnetization (in this case its radial thickness)

$B_r$ - remanent flux density

$\mu_{rec}$ - relative recoil permeability (the slope of the demagnetization curve)

In this case the outer pole area is larger than the inner pole area but to keep the analysis simple average pole area is considered.

with a magnet arc of  $120^\circ$

$$A_m = \frac{2}{3} \pi [r_1 - g - l_m/2] l \quad \dots\dots\dots(4.45)$$

$r_1$ - radius of the rotor

$g$ - air gap length

most of the magnet flux crosses the air gap via the air gap reluctance  $R_g$

$$R_g = g' / \mu_0 A_g \quad \dots\dots\dots(4.46)$$

$g'$ - equivalent air gap length allowing for slotting.

the slotting can be taken into account by means of Carter's coefficient, which case,

$$g' = K_c g \quad \dots\dots\dots(4.47)$$

$A_g$ - air gap area through which the flux passes as it crosses the gap. The precise boundary of this area is uncertain because of fringing both at the edges of the magnet and at the ends of the rotor. An approximate allowance for fringing can be made by adding ' $g$ ' at each of the four boundaries, giving

$$A_g = \left[ \frac{2}{3} \pi (r_1 - g/2) + 2g \right] (1 + 2g) \quad \dots\dots(4.48)$$

- ❖ the remaining permeance in the magnetic circuit is the rotor leakage permeance  $p_{rl}$ , which represents the paths of the magnet flux components that fail to cross the air gap. This can be conveniently included in a modified magnet internal permeance by writing

$$p_m = p_{mo} + p_{rl} \quad \dots\dots\dots(4.49(a))$$

$$p_m = p_{mo} (1 + p_{rl}) \quad \dots\dots(4.49(b))$$

$p_{rl}$ -normalized rotor leakage permeance

## 4.12 A controller for BLPM SQW DC Motor

### 4.12.1 Power Circuit

Power Circuit of BLPM DC motor is as shown fig consists of six power semiconductor switching device connected in bridge configuration across a DC supply. A suitable shunt resistance is connected in series to get the current feedback. Feedback diodes are connected across the device. The armature winding is assumed to be star connected. Rotor has a rotor position sensor and a tachogenerator is coupled to the shaft to get feedback signal.

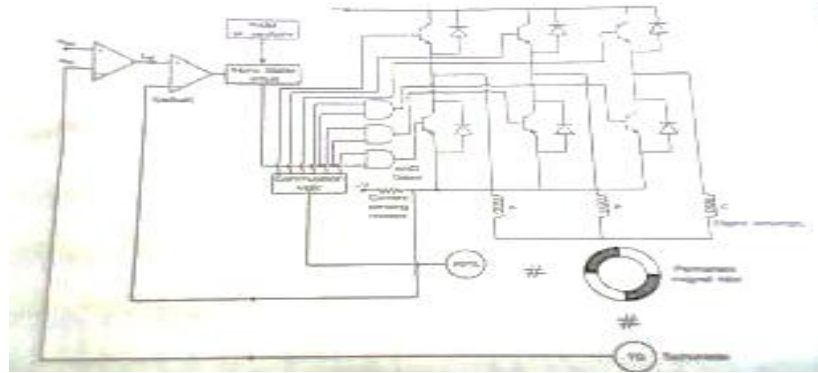

Fig 4.34 structure of controller for brushless PM DC Motor

#### 4.12.2 Control circuit

The control circuits consist of a commutation logic unit. Which get the information about the rotor shaft position and decides which switching devices are to be turned on and which devices are to be turned off. This provides six output signals out of which three are used as the base drive for the upper leg devices. The other three output signal are logically AND with the high frequency pulses and the resultant signals are used to drive the lower leg devices.

A comparator compares the tachogenerator output with reference speed and the output signal is considered as the reference current signal for the current comparator which compare the reference current with the actual current and the error signal output is fed to the monostable multivibrator which is excited by high frequency pulses. The duty cycle of the output of monostable is controlled by error signal. This output signal influences the conduction period and duty cycle of lower leg devices.

#### Rotor Position sensors for BLPM motor

It converts the information of rotor shaft position into suitable electrical signal. This signal is utilized to switch ON and OFF the various semiconductor devices of electric switching and commutation circuitry of BLPM motor.

Two popular rotor sensors are

Optical Position Sensor.

Hall Effect Position Sensor.

##### (a) Optical position sensor

This makes use of six photo transistors. This device is turned into ON state when light rays fall on the devices. Otherwise the device is in OFF state the schematic representation is shown in fig.

Fig 4.35 Optical position sensor

The phototransistors are fixed at the end shield cover such that they are mutually displaced by 60 degree electrical by a suitable light source. The shaft carries a circular disc which rotates along the shaft. The disc prevents the light ray falling on the devices. Suitable slot are punched in the disc such turned into on state suitably turns the main switching devices of electronic commutation circuitry into on state.

As the shaft rotates, the devices of electronic commutation which are turned into ON are successively changed.

**(b) Hall effect position sensor**

Consider a small pellet of n-type semiconducting material as shown in fig 4.36.

Fig 4.36 Hall Effect

A current  $i_c$  is allowed to pass from the surface ABCD to the surface EFGH. Let the surface ABEF be subjected to a North pole magnetic field of flux density  $B$  tesla. As per Fleming left hand rule, the positive charge in the pellet get concentrated near surface ADHE and negative charges near the surface BCFG. Since n-type material has free negative charges, there electrons gets concentrated near the surface BCGF. This charge in distribution makes the surface ADHE more positive than the surface BCFG. This potential known as Hall emf or emf due to Hall Effect.

It has been experimentally shown that emf due to hall effect is  $V_H$  is given by

$$V_H = R_H(i_c / d) \text{ volts}$$

Where  $i_c$  current through the pellet in amps

B- Flux density in tesla

d- Thickness of the pellet in m.

$R_H$  – Constant which depends upon the physical dimensions or physical properties of the pellet.

If the polarity of B is changed from North Pole to South Pole the polarity of the emf due to Hall Effect also get changed.

#### 4.12.3 Hall Effect Position Sensor

Hall effect position sensor can be advantageously used in a BLPM motor. Consider a 2 pole BLPM motor with two winding  $w_1$  and  $w_2$  as shown in fig.

Fig 4.37 2 pole BLPM motor

When  $w_1$  carries a current on closing  $S_1$  it set up a North Pole flux in the air gap. Similarly when  $S_2$  is closed  $w_2$  is energized and sets up a North Pole flux.  $w_1$  and  $w_2$  are located in the stator such that their axes are 180 degree apart. A Hall Effect position sensor is kept in an axis of the winding.

When Hall Effect position sensor is influenced by North Pole flux the hall emf is made to operate the switch  $S_1$ . Then  $w_1$  sets up North Pole flux. The rotor experiences a torque and South Pole of the rotor tends to align with the axis of  $w_1$ . because of inertia. it overshoot the rotor hence rotates in clockwise direction. Now HEPS is under the influence of S pole flux of the rotor. Then the polarity of hall emf gets changed. This make the switch  $S_1$  in off state and  $S_2$  is closed. Now  $w_2$  sets up N pole flux in the air gap, the rotor rotates in clockwise direction. So that the s pole gets aligned with  $w_2$  axis. Then this process continuous. The rotor rotates continuously.

#### 4.13 Types of BLPM motor

BLPM motor is classified on the basis of number of phase windings and the number of pulses given to the devices during each cycle.

### 4.13.1 One phase winding one pulse BLPM motor

The stator has one phase winding as shown in fig4.38.

It is connected to the supply through a power semiconductor switch. When the rotor position sensor is influenced by say n pole flux, the stator operates and the rotor developed a torque. When the RPS is under the influence of S pole, the transistor is in off state. The rotor gets torque whenever the rotor position is under the influence of n pole.

Fig. 4.38 one phase one pulse BLPM motor.

The current and torque are approximated as sinusoidally varying as shown in fig. 4.39.

Fig.4.39 Current and torque waveform

#### Advantage

- ❖ One transistor and one position sensor is sufficient.
- ❖ Inertia should be such that the rotor rotates continuously.
- ❖ Utilization of transistor and winding are less than 50%.

### 4.13.2 One phase two pulse BLPM motor

Stator has only one winding. It is connected to DC three wire supply through two semiconductor devices as shown in fig. 4.40.

Fig. 4.40 One phase two pulse BLPM motor

There is only one position sensor. When the position sensor is under the N-pole influence,  $T_1$  is in on-state and  $T_2$  is in off-state. When it is under the influence of S-pole,  $T_2$  is on and  $T_1$  is off.

Fig. 4.41 Torque waveform

In the first case, the winding carries current from A to B and when  $T_2$  is on, the winding carries current from B to A. The polarity of the flux setup by the winding gets alerted depending upon the position of the rotor. This provides the unidirectional torque as shown in fig. 4.41.

### Advantages

- ❖ Winding utilization is better.
- ❖ Torque developed is more uniform.

### Demerit

- ❖ Transistor utilization is less
- ❖ The current needs a 3-wire dc supply.

### 4.13.3 Two phase winding and two pulse BLPM motor

Stator has two phase windings which are displaced by  $180^\circ$  electrical. Electrical connections are as shown in fig. 4.42. It makes use of two semiconductor switches.

Fig. 4.42 two phase winding and two pulse motor

Fig. 4.43 torque waveform

Performance of this type is similar to one phase 2 pulse BLPM motor. Torque waveform are as shown in fig. 4.43. However it requires two independent phase windings.

#### Merit

- ❖ Better torque waveform.

#### Demerit

- ❖ Their utilization is only 50% which is less.
- ❖ Cabling with rotor position sensor should be made proper.

#### 4.13.4 Three phase winding and three pulse BLPM motor

The stator has  $3\Phi$  windings as shown in fig. 4.44. Whose areas are displaced by  $120^\circ$ elec. apart. Each phase windings is controlled by a semiconductor switch which is operated depending upon the position of the rotor. Three position sensors are required for this purpose.

Fig. 4.44 3 phase, 3 pulse BLPM motor.

#### 4.13.5 Three phase six pulse BLPM motor

Most commonly used. It has 3 phase windings and six switching devices as shown in fig. 4.45.

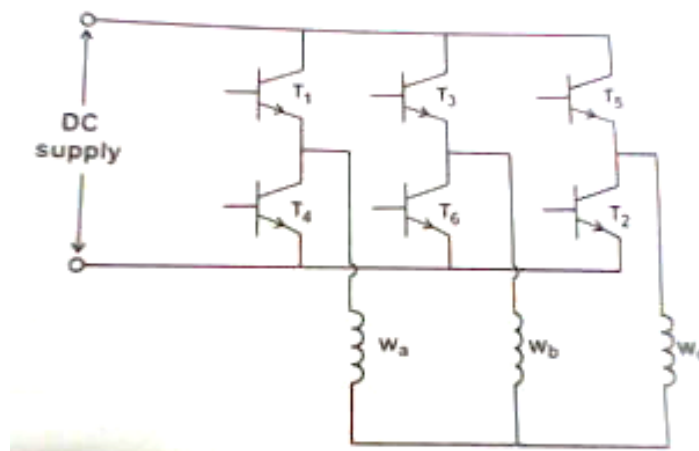

Fig. 4.45 3-phase six pulse BLPM motor.

## Glossary

1. Brushless PM D.C.Motor -- It is similar to salient pole D.C.Motor except that there is no field winding on rotor and is provided by PM. It reduces losses. Complexity in construction is reduced.
2. Magnetic Remanence -- The magnetic flux density which persists in magnetic materials even though the magnetizing forces are completely removed.
3. Coercivity Forces -- The demagnetizing force which is necessary to neutralize completely the magnetism in an electromagnet after the magnetizing force becomes zero.
4. Position Sensors -- The position sensors detect the position of rotating magnets and send logic codes to commutation decoder.
5. Energy Product -- The absolute value of product of flux density and field intensity at each point along the demagnetization curve is called energy product.
6. Electronic Commutator -- It is to transfer the current to the armature. Power semiconductors are used as switching devices. Armature has three tappings, which can be connected either in star or in delta.
7. Commutator -- A commutator is a rotary electrical switch in certain types of electric motors or electrical generators.
8. Friction -- A force that resists motion between two objects that are in contact with each other. Smoother surfaces exhibit less friction, while rougher surfaces exhibit more friction.
9. Magnet -- A device or object that attracts iron and produces a magnetic field.
10. Magnitude -- The measurement of the amount of an applied force.
11. Rotary Speed -- A measure of circular motion found by counting the number of revolutions that occur in a specific amount of time.

13. Atmospheric Hazard -- A confined space hazard that is present in the environment. Atmospheric hazards are categorized as flammable, toxic, irritant, and asphyxiating.
14. Remanence The ability of a material to retain magnetization, equal to the magnetic flux density of the material after the removal of the magnetizing field Also called: retentivity
15. Permeance, In general, is the degree to which a material admits a flow of matter or energy.

## UNIT-5

### PERMANENT MAGNET SYNCHRONOUS MOTOR

#### 5.1 INTRODUCTION

A permanent magnet synchronous motor is also called as brushless permanent magnet sine wave motor. A sine wave motor has a

1. Sinusoidal or quasi-sinusoidal distribution of magnetic flux in the air gap.
2. Sinusoidal or quasi-sinusoidal current wave forms.
3. Quasi-sinusoidal distribution of stator conductors (i.e.) short-pitched and distributed or concentric stator windings.

The quasi sinusoidal distribution of magnetic flux around the air gap is achieved by tapering the magnet thickness at the pole edges and by using a shorter magnet pole arc typically 120°.

The quasi sinusoidal current wave forms are achieved through the use of PWM inverters and this may be current regulated to produce the best possible approximation to a pure sine wave. The use of short pitched distributed or concentric winding is exactly the same as in ac motors.

#### 5.2 CONSTRUCTION AND PRINCIPLE OF OPERATION

Permanent magnet synchronous machines generally have same operating and performance characteristics as synchronous machines. A permanent magnet machine can have a configuration almost identical to that of the conventional synchronous machines with absence of slip rings and a field winding.

##### Construction

Fig. 5.1 shows a cross section of simple permanent magnet synchronous machines. It consists of the stationary member of the machine called stator. Stator laminations for axial air gap machines are often formed by winding continuous strips of soft steel. Various parts of the laminations are the teeth slots which contain the armature windings. Yoke completes the magnetic path. Lamination thickness depends upon the frequency of the armature source voltage and cost.

Armature windings are generally double layer (two coil side per slot) and lap wound. Individual coils are connected together to form phasor groups. Phasor groups are connected together in series/parallel combinations to form star, delta, two phase (or) single windings.

AC windings are generally short pitched to reduce harmonic voltage generated in the windings.

Coils, phase groups and phases must be insulated from each other in the end-turn regions and the required dielectric strength of the insulation will depend upon the voltage ratings of the machines.

Fig. 5.1 structure of the stator and rotor

In a permanent magnet machines the air gap serves an role in that its length largely determines the operating point of the permanent magnet in the no-load operating condition of the machines. Also longer air gaps reduce machines windage losses.

The permanent magnets form the poles equivalent to the wound field pole of conventional synchronous machines. Permanent magnet poles are inherently “salient” and there is no equivalent to the cylindrical rotor pole configurations used in many conventional synchronous machines.

Many permanent magnet synchronous machines may be cylindrical or “smooth rotor” physically but electrically the magnet is still equivalent to a salient pole structure. Some of the PMSM rotors have the permanent magnets directly facing the air gap as in fig. 5.2.

Rotor yoke is the magnetic portion of the rotor to provide a return path for the permanent magnets and also provide structural support. The yoke is often a part of the pole structure

Fig. 5.2 PMSM rotor

Damper winding is the typical cage arrangement of conducting bars, similar to induction motor rotor bars and to damper bars used on many other types of synchronous machines. It is not essential for all permanent magnet synchronous machines applications, but is found in most machines used in power applications.

The main purpose is to dampen the oscillations about synchronous speed, but the bars are also used to start synchronous motors in many applications.

The design and assembly of damper bars in permanent magnet machines are similar to the other types of synchronous machines.

Synchronous machines are classified according to their rotor configuration. There are four general types of rotors in permanent magnet synchronous machines. They are

1. Peripheral rotor
2. Interior rotor
3. Claw pole or lundell rotor.
4. Transverse rotor.

❖ **Peripheral rotor**

The permanent magnets are located on the rotor periphery and permanent magnet flux is radial.

❖ **Interior rotor**

The permanent magnets are located on the interior of the rotor and flux is generally radial.

❖ **Claw pole or Lund ell**

The permanent magnets are generally disc shaped and magnetized axially. Long soft iron extensions emanate axially from periphery of the discs like claws or Lund ell poles. There is set of equally spaced claws on each disc which alternate with each other forming alternate north and south poles.

❖ **Transverse rotor**

In this type the permanent magnets are generally between soft iron poles and the permanent magnet flux is circumferential. In this soft iron poles act as damper bars. Magnetically this configuration is similar to a reluctance machine rotor, since the permeability of the permanent magnet is very low, almost the same as that of a non-magnetic material. Therefore, reluctance torque as well as torque resulting from the permanent magnet flux is developed.

Thus BLPM sine waves (SNW) motor is construction wise the same as that of BLPM square wave (SQW) motor. The armature winding and the shape of the permanent magnet are so designed that flux density distribution of the air gap is sinusoidal(i.e.) .The magnetic field setup by the permanent magnet in the air gap is sinusoidal

### 5.3 EMF EQUATION OF BLPM SINE WAVE MOTOR

#### 5.3.1 Flux density distribution

Flux density can be expressed as  $B = B_m \sin \theta$  or  $B_m \cos p\theta$  or  $B_m \sin(p\theta + \alpha)$  or  $B_m \cos(p\theta + \alpha)$ ,  $2p = p$ , (i.e)  $p$ -no of pole pairs depending upon the position of the reference axis as shown in fig.6.3

Fig 5.3 flux density distribution

Consider a full pitched single turn armature coil as shown in fig 5.4. Let the rotor be revolving with a uniform angular velocity of  $\omega_m$  mech.rad/sec.

At time  $t = 0$ , let the axis of the single turn coil be along the polar axis.

Fig 5.4 full pitched single turn armature coil

Consider a small strip of  $d\theta$  mech.radians at a position  $\theta$  from the reference.

Flux density at the strip  $B = B_m \sin p\theta$

Incremental flux in the strip  $d\phi = B \times \text{area swept by the conductor}$

$d\phi = B_m \sin p\theta \times l r d\theta$

$B l r d\theta$  weber

Where

$L$  – Length of the armature in m

$r$  – Radius of the armature

$d\phi = B_m \sin p\theta \times l r d\theta$

$= B_m l r \sin p\theta \times d\theta$

Flux enclosed by the coil after lapses of  $t$  sec is

$$\Phi = \int_0^{\omega m + \frac{\pi}{p}} B^{\wedge} l r \sin P \theta d \theta \quad \dots\dots\dots(5.1)$$

$$\Phi = (2 B \square l r / p) \cos p \theta \omega_{mt}$$

### 5.3.2. EMF Equation of an ideal BLPM sine wave motor

As per faradays law of electromagnetic induction, emf induction in the single turn coil.

$$e = -N d \Phi / dt$$

$$\begin{aligned} & -d\Phi / dt \quad \text{as } N=1 \\ & = - d\Phi / dt \quad ((2 B \square l r / p) \cos p \theta \omega_{mt}) \\ & = (2 B \square l r / p) p \omega_m \sin p \omega_{mt} \end{aligned}$$

$$e = 2 B \square l r \omega_m \sin p \omega_{mt} \quad \dots\dots\dots(5.2)$$

let the armature winding be such that all turns of the phase are concentrated full pitched and located with respect to pole axis in the same manner.

Let  $T_{ph}$  be the number of turns connected in series per phase. Then the algebraic addition of the emfs of the individual turns gives the emf induced per phase as all the emf are equal and in phase.

$$\begin{aligned} e_{ph} &= (2 B \square l r \omega_m \sin p \omega_{mt}) T_{ph} \quad \dots\dots\dots(5.3) \\ &= 2 B \square l r \omega_m T_{ph} \sin p \omega_{mt} \end{aligned}$$

$$= \check{E}_{ph} \sin p \omega_{mt} \quad \text{where } p \omega_{mt} = \omega_e \text{ angular frequency in rad/sec}$$

$$= \check{E}_{ph} \sin \omega_{et}$$

$$\check{E}_{ph} = 2 B \square l r \omega_m T_{ph} \omega_m \quad \dots\dots\dots(5.4)$$

$$\check{E}_{ph} = \text{rms value of the phase emf}$$

$$= \check{E}_{ph} / \sqrt{2}$$

$$= \sqrt{2} B \square l r \omega_m T_{ph} \omega_m$$

$$\omega_m = \omega_e / p$$

$\Phi_m$  – sinusoidal distributed flux / pole

$$\Phi = B_{av} \tau l \quad \dots\dots\dots(5.5)$$

$$= B_{av} X (2\pi r / 2p) X l$$

Average value of flux density for sinewave  $=2/\pi$

$$= (2/\pi) B_m$$

$$\Phi_m = (2/\pi) B_m \times (\pi r / P) \cdot l$$

$$\Phi_m = (2 B_m r l / P)$$

$$B_m r l = (P \Phi_m / 2) \quad \dots\dots\dots(5.6)$$

$$E_{ph} = \sqrt{2} B_m l r \omega_m T_{ph} \text{ volt}$$

Sub equ

$$E_{ph} = \sqrt{2} (P \Phi_m / 2) \omega_m T_{ph}$$

$$= \sqrt{2} (P \Phi_m / 2) (\omega/p) T_{ph}$$

$$= \sqrt{2} (P \Phi_m / 2) (2\pi f/p) T_{ph}$$

$$E_{ph} = 4.44 f \Phi_m T_{ph} \text{ Volt} \quad \dots\dots\dots(5.7)$$

### 5.3.3 EMF equation of practical BLPM sine wave motor

In a practical BLPM sine wave motor at the time of design it is taken care to have the flux density is sinusoidal distributed and rotor rotates with uniform angular velocity. However armature winding consists of short chorted coils properly distributed over a set of slot.

These aspect reduce the magnitude of  $E_{ph}$  of an ideal winding by a factor  $K_{w1}$  which is known as the winding factor the fundamental component of flux.

$$K_{w1} = K_{s1} K_{p1} K_{b1} \quad \dots\dots\dots(5.8)$$

$K_{s1}$  =slew factor

$$K_{s1} = (\sin \sigma/2) / (\sigma/2)$$

$$K_{s1} = 1 \text{ (slightly less than 1)}$$

$\sigma$  – Skew angle in elec. Radians.

$K_{p1}$  = pitch factor (or) short chording factor

$$= \sin m\pi/2 \text{ or } \cos \rho/2$$

Where  $m$  = coil span/pole pitch

= fraction  $< 1$

$$\pi(1 - m) = \rho$$

[Coil span =  $\tau$

$$= \pi \text{ elec rad}$$

$$= \pi/\rho \text{ mech. Rad}]$$

$$K_{p1} = \sin \frac{m\pi}{2} \text{ or } \cos \frac{\rho}{2}$$

[ $m\pi$  is elec rad  $\frac{m\pi}{p}$  mech. Rad. ]

$K_{b1}$  = Distribution factor or width factor

$$K_{b1} = \frac{\sin q \frac{v}{2}}{q \sin \frac{v}{2}}$$

Where  $v$  = slot angle in elec. Radians

$$= \frac{2\pi\rho}{n_s}; n_s = \text{no. of slots (total)}$$

$q$  = slots/pole/phase for  $60^\circ$  phase spread

= slots/pair of poles/phase

$$K_{b1} < 1; K_{p1} < 1; K_{s1} < 1$$

Therefore  $K_{w1} = K_{p1} K_{b1} K_{s1} < 1$  (winding factor)

Thus rms value of the per phase emf is

$$E_{ph} = 4.44 f \phi_m T_{ph} K_{w1} \text{ volts.} \quad \dots\dots\dots(5.9)$$

## 5.4. TORQUE EQUATION OF BLPM SINE WAVE MOTOR

### 5.4.1. Ampere conductor density distribution

Let the fig. 5.5 shows the ampere conductor density distribution in the air gap due to the current carrying armature winding be sinusoidal distributed in the airgap space.

Fig. 5.5 Ampere conductor density distribution

$$A = A^{\wedge} \sin p \Theta$$

Where  $A$  = ampere conductor density

= ampere conductor/degree

Consider a strip of  $d\theta$  at an angle  $\theta$  from the reference axis.

$$\text{Ampere conductor in the strip } d\theta = A d\theta \quad \dots\dots\dots(5.10)$$

$$= A^{\wedge} \sin P \theta d\theta$$

$$\text{Ampere conductor per pole} = \int_0^{\pi} A^{\wedge} \sin P \theta d\theta \quad \dots\dots\dots(5.11)$$

$$= -A^{\wedge} \left[ \frac{\cos P \theta}{P} \right]$$

$$= -\frac{A^{\wedge}}{P} [\cos \pi - \cos 0]$$

$$= \frac{2 A^{\wedge}}{P}$$

Let  $T_{ph}$  be the number of full pitched turns per phase.

Let  $i$  be the current

$i T_{ph}$  be the total ampere turns which is assumed to be  $\theta$  sine distributed.

Total ampere conductors [sine distributed] =  $2i T_{ph}$

$$\text{Sine distributed ampere conductors/pole} = \frac{2i T_{ph}}{2P}$$

Equating eqn. 6.30 and eqn. 6.32

$$\frac{2 A^{\wedge}}{P} = \frac{2i T_{ph}}{2P}$$

$$\hat{A} = \frac{i T p h}{2} \dots\dots\dots(5.12)$$

**5.4.2. Torque equation of an ideal BLPM sine wave motor:**

Let the ampere conductor distribution of ideal BLPM sine wave motor be given by

$$A = \hat{A} \sin P \theta$$

Let the flux density distribution set up by the rotor permanent magnet be also sinusoidal.

Let the axis of armature ampere conductor distribution be displaced from the axis of the flux density distribution by an angle  $(\frac{\pi}{2} - \alpha)$  as shown in fig 5.6

$$[ B = \hat{B} \sin \left( P \theta + \left( \frac{\pi}{2} - \alpha \right) \right) \dots\dots\dots(5.13)$$

$$= \hat{B} \sin \left[ \frac{\pi}{2} - (P \theta - \alpha) \right]$$

$$= \hat{B} \cos (P \theta - \alpha)$$

$$B = \hat{B} \cos (P \theta - \alpha) \dots\dots\dots(5.14)$$

Fig. 5.6 Ampere conductor and flux density distribution.

Consider a small strip of width  $d \theta$  at an angle  $\theta$  from the reference axis.

Flux density at the strip  $B = \hat{B} \cos(p\theta - \alpha)$

Ampere conductors in the strip  $= A d\theta$

$$= \hat{A} \sin P\theta d\theta \dots\dots\dots(5.15)$$

Force experienced by the armature conductors in the strip  $d\theta = B I A d\theta$

$$dF = \hat{B} \cos(P\theta - \alpha) \cdot \hat{A} \sin P\theta \cdot d\theta$$

$$dF = A \hat{B} \hat{I} \sin P\theta \cos(P\theta - \alpha) d\theta.$$

Let 'r' be the radial distance of the conductors from the axis of the shaft.

Torque experienced by the ampere conductors of the strip =  $dF \cdot r$

$$dT = AB r l \sin P\theta \cos(P\theta - \alpha) D\theta \text{ N-m}$$

Torque experienced by the ampere conductors/pole  $T/\text{Pole} = \int_0^{\pi/p} dT$

$$T = \int_0^{\pi} A B r l \sin P\theta \cos(P\theta - \alpha) d\theta \quad \dots\dots\dots(5.16)$$

$$= A B r l / 2 \int_0^{\pi/p} (\sin P\theta + P\theta - \alpha + \sin \alpha) d\theta$$

$$= A B r l / 2 \left[ -\frac{\cos(2P\theta - \alpha)}{2p} + \theta \sin \alpha \right]$$

$$= A B r l / 2 \left[ -\frac{\cos \alpha}{2p} + \frac{\cos \alpha}{2p} + \frac{\pi}{p} \sin \alpha \right]$$

$$T = A B r l / 2 \cdot \frac{\pi}{p} \sin \alpha \text{ N-m} \quad \dots\dots\dots(5.17)$$

The total torque experienced by all the armature conductors

$$= 2P \times \text{torque/pole}$$

$$= 2P \times \frac{\pi}{p} \times \frac{ABrl}{2} \sin \alpha$$

$$T = \pi A B r l \sin \alpha \text{ N-m} \dots\dots\dots(5.18)$$

As the armature conductors are located in stator of the BLPM SNW motor, the rotor experiences an equal and opposite torque.

Torque experienced by the rotor

$$= \text{Torque developed by the rotor}$$

$$= -\pi A B r l \sin \alpha$$

$$= \pi A B r l \sin \beta \text{ where } \beta = -\alpha \quad \dots\dots\dots(5.19)$$

$\beta$  is known as power angle or torque angle.

$$T = \pi A B r l \sin \beta \text{ in an ideal motor.}$$

Consider the case of an armature winding which has three phases. Further the winding consists of short chorded coils and the coils of a phase group are distributed. The 3 phase armature

winding carries a balanced 3 phase ac current which are sinusoidally varying. The various phase windings are ph a, ph b and ph c.

The axis of phase winding are displaced by  $2\pi/3p$  mechanical radians or  $2\pi/3$  elec. Radians. The current in the winding are also balanced. An armature winding is said to be balanced if all the three phase winding are exactly identical in all respects but there axes are mutually displaced by  $2\pi/3p$  mech radians apart.

A three phase armature current is said to be balanced when the 3 phase currents are exactly equal but mutually displaced in phase by 120 degree.

Let

$$i_a = I_m \cos \omega t \quad (\text{i. e.}) \sqrt{2} I \cos \omega t \quad \dots\dots(5.20)$$

$$i_b = I_m \cos\left(\omega t - \frac{2\pi}{3}\right) = \sqrt{2} I \cos(\omega t - 2\pi/3) \quad \dots\dots(5.21)$$

$$i_c = I_m \cos\left(\omega t + \frac{2\pi}{3}\right) = \sqrt{2} I \cos(\omega t - 4\pi/3) \quad \dots\dots(5.22)$$

When the 3 phase ac current passes through the 3 phase balanced winding it sets up an armature mmf in the air gap.

Space distribution of the fundamental component of armature ampere conductors can be written as.

$$f_a = F_m \cos P \theta \quad \dots\dots(5.23)$$

$$f_b = F_m \cos [P \theta - 2\pi/3] \quad \dots\dots(5.24)$$

$$f_c = F_m \cos [P \theta - 4\pi/3] \quad \dots\dots(5.25)$$

#### 5.4.3 Torque developed in a practical BLPM SNW motor:

- ❖ Ampere turn distribution of a phase winding consisting of full pitched coil is rectangular of amplitude  $I T$  ph. But the fundamental component of this distribution is the fundamental component of this distribution is  $4/\pi I T$  ph.
- ❖ In a practical motor, the armature turns are short chorded and distributed. Further they may be accomodated in skewed slots. In such a case for getting fundamental component of ampere turns distribution the turns per phase is modified as  $K_w I T$  ph where  $K_w$  is winding factor which is equal to  $K_s I K_p I K_d I$

$K_s I =$  Skew factor

$$= \frac{\sin \sigma/2}{\sigma/2}; \quad \sigma = \text{skew angle in elec. rad.}$$

$$K_{p1} = \sin \frac{m\pi}{2}; m\pi = \text{coil span in elec. Rad}$$

$K_d$  = distribution factor

$$= \frac{\sin q \frac{v}{2}}{q \sin \frac{v}{2}} \quad v\text{-slot angle in electrical.rad, } q\text{-slot per pole for } 60\text{degree phase spread.}$$

Fundamental component of ampere turns per phase of a practical one

$$= 4/\pi I T_{ph} K_w1 \quad \dots\dots(5.26)$$

- ❖ when a balanced sinusoidally varying 3 phase ac current pass through a balanced 3 phase winding it can be shown that the total sinusoidally distributed ampere turns is equal to  $3/2.4/\pi I_{max} K_w1 T_{ph}$ .

$$= 4/\pi.3/2 \sqrt{2} I_{ph} K_w1 T_{ph} \quad \dots\dots(5.27)$$

- ❖ 4.The amplitude of the ampere conductor density distribution is shown is equal to the total sinusoidally distributed ampere turns divided by 2.

$$\text{Therefore } \bar{A} \text{ in a practical 3 phase motor} = \frac{4.3/2.\sqrt{2}}{2} I_{ph} K_w1 T_{ph}$$

Electromagnetic torque developed in a practical BLPL SNW motor

$$= \pi A B r l \sin \beta \quad \dots\dots(5.28)$$

$$= \pi \left[ 3 \sqrt{\frac{2}{\pi} I_{ph} K_w1 T_{ph}} \right] B r l \sin \beta$$

$$= 3(\sqrt{2}K_w1 T_{ph} B r l)I_{ph} \sin\beta$$

$$= 3 \frac{E_{ph}}{\omega m} I_{ph} \sin \beta \quad \dots\dots(5.29)$$

$$i_a T_{ph} = I_{max} \cos \omega t \cos \theta \quad \dots\dots(5.30)$$

$$i_b T_{ph} = I_{max} \cos \left( \omega t - \frac{2\pi}{3} \right) \cos \left( \theta - \frac{2\pi}{3} \right) \quad \dots\dots(5.31)$$

$$i_c T_{ph} = I_{max} \cos \left( \omega t - \frac{4\pi}{3} \right) \cos \left( \theta - \frac{4\pi}{3} \right) \quad \dots\dots(5.32)$$

$$i T_{ph} = i_a T_{ph} + i_b T_{ph} + i_c T_{ph} \quad \dots\dots(5.33)$$

$$= I_{max} \left( \frac{\cos(\omega t + \theta) + \cos(\omega t - \theta)}{2} \right) + I_{max} \left( \frac{\cos(\omega t + \theta - 4\pi/3) + \cos(\omega t - \theta)}{2} \right) + I_{max} \left( \frac{\cos(\omega t + \theta - 8\pi/3) + \cos(\omega t - \theta)}{2} \right)$$

$$\begin{aligned}
&= \frac{1}{2} I_{max} \cdot 3 \cos(\omega t - \theta) + \frac{1}{2} I_{max} [\cos(\omega t + \theta) \cos 240 + \sin(\omega t + \theta) \sin 240 + \cos(\omega t + \theta) \cos 480 + \sin(\omega t + \theta) \sin 480] \\
&= \frac{3}{2} I_{max} \cos(\omega t - \theta) + \frac{1}{2} I_{max} [\cos(\omega t + \theta) - \cos(\omega t + \theta) - 0.866 \sin(\omega t + \theta) - 0.5 \cos(\omega t + \theta) + 0.866 \sin(\omega t + \theta)] \\
&= \frac{3}{2} I_{max T_{ph}} \cos(\omega t - \theta) \quad \dots\dots\dots(5.34)
\end{aligned}$$

Properties of 'A' (Ampere conductor density);

- ❖ Ampere conductor density is sinusoidally distributed in space with amplitude  $\hat{A}$ . This distribution has 2p poles (i.e) same as the rotor permanent magnetic field.
- ❖ The ampere conductor distribution revolves in air gap with uniform angular velocity  $\omega_m$  rad/sec .or  $\omega_{elec}$ .rad/sec.(Ns rpm). This is the same speed as that of rotor magnetic field.
- ❖ The direction of rotation of armature ampere conductor distribution is same as that of rotor. This is achieved by suitably triggering the electronic circuit from the signals obtained from rotor position sensor.
- ❖ 4. The relative angular velocity between sine distributed permanent magnetic field and sine distributed armature ampere conductor density field is 0. Under such condition it has been shown an electromagnetic torque is developed whose magnitude is proportional to  $\sin \beta$ .

$\beta$ -torque angle or power angle.

Angle between the axes of the two fields is  $\pi/2 - \alpha$  and  $\beta = -\alpha$

Torque developed by the motor =  $3E_{ph}I_{ph}\sin\beta/\omega_m$  N-m

Where  $\omega_m$ -angular velocity in rad/sec.

$$\omega_m = 2\pi N_s / 60 \quad \text{where } N_s \text{ is in rpm}$$

$$T = 60 / 2\pi N_s (3E_{ph}I_{ph}\sin\beta)$$

$$= 3E_{ph}I_{ph}\sin\beta \text{ syn.watts.}$$

$$1 \text{ syn.watt} = 60 / 2\pi N_s \text{ N-m}$$

It is a machine dependent conversion factor

## 5.5 PHASOR DIAGRAM OF A BRUSHLESS PM SNW OR BLPB SYNCHRONOUS MOTOR:

Consider a BLPM SNW motor, the stator carries a balanced 3 $\phi$  winding. This winding is connected to a dc supply through an electronic commutator whose switching action is influenced by the signal obtained from the rotor position sensor.

Under steady state operating condition, the voltage available at the input terminals of the armature winding is assumed to be sinusoidally varying three phase balanced voltage. The electronic commutator acts as an ideal inverter whose frequency is influenced by the rotor speed. Under this condition a revolving magnetic field is set up in the air gap which is sinusoidally distributed in space, having a number of poles is equal to the rotor. It rotates in air gap in the same direction as that of rotor and a speed equal to the speed of the rotor.

Rotor carries a permanent magnet. Its flux density is sine distributed. It also revolves in the air gap with a particular speed.

It is assumed that the motor acts as a balanced 3 $\phi$  system. Therefore it is sufficient to draw the phasor diagram for only one phase. The armature winding circuit is influenced by the following emfs.

1.  $V$  - supply voltage per phase across each winding of the armature.

The magnitude of this voltage depends upon dc voltage and switching techniques adopted.

2.  $E_f$  - emf induced in the armature winding per phase due to sinusoidally varying permanent magnetic field flux.

$$\text{Magnitude of } E_f = 4.44 f \phi_m K_{w1} T_{ph} = I E_f I$$

As per Faraday's law of electromagnetic induction, this emf lags behind  $\phi_m$  - permanent magnet flux enclosed by armature phase winding by  $90^\circ$ .

3.  $E_a$  - emf induced in the armature phase winding due to the flux  $\phi_a$  set up by resultant armature mmf  $\phi \propto I_a$

$$I E_a I = 4.44 f \phi_a K_{w1} T_{ph}$$

$$= 4.44 f (K_{Ia}) K_{w1} T_{ph}$$

$$I E_a I = I I_a X_a I \text{ where } X_a = 4.44 f K K_{w1} T_{ph}$$

This lags behind  $\phi_a$  by  $90^\circ$  or in other words  $E_a$  lags behind  $I_a$  by  $90^\circ$ .

$$\text{Therefore } E_a = -j X_a I_a$$

4.  $E_{al}$  - emf induced in the same armature winding due to armature leakage flux.

$$|E_{al}| = 4.44 f \phi_{al} K_{w1} T_{ph}$$

$\phi_{al}$  is the leakage flux and is directly proportional to  $I_a$ .

Therefore  $|E_{al}| = 4.44 f (K_{al} I_a K_{w1} T_{ph})$

$$|E_{al}| = I_a X_{al}$$

Where  $X_{al} = 4.44 f K_{al} K_{w1} T_{ph}$  in the leakage inductance.  $E_{al}$  lags behind  $\phi_{al}$

Or  $I_a$ , by  $90^\circ$

Therefore  $E_{al} = -j I_a X_{al}$

### **Voltage equation:**

The Basic voltage equation of the armature circuit is

$$V + \dot{E}_f + \dot{E}_{al} = I_a R_a \quad \dots\dots\dots(5.35)$$

Where  $R_a$  is the resistance per phase of the armature winding.

$$V + \dot{E}_f - j I_a X_a - j I_a X_{al} = I_a R_a$$

$$V + \dot{E}_f - j I_a (X_a + X_{al}) = I_a R_a$$

$$V + \dot{E}_f - j I_a X_s = I_a R_a \quad \dots\dots\dots(5.36)$$

Where  $X_s = X_a + X_{al}$

$X_s$  is known as synchronous reactance per phase or fictitious reactance.

$$V = (-E_f) + I_a (R_a + j X_s)$$

$$V = \dot{E}_q + I_a Z_s$$

Where  $Z_s$  is the synchronous impedance.

Let  $E_q$  be the reference phasor. Let it be represented by OA.

Let  $I$  be the current phasor. OB represents  $I$ .

$E_f$  be the emf induced in the armature winding by permanent magnet flux =  $-E_q$

OC represents  $E_f$

Fig 5.7 phasor diagram of BLPM sine wave motor

$\phi_{mf}$  be the mutual flux set up by the permanent magnet, but linked by the armature winding.

$E_f$  lags behind  $\phi_{mf} = \phi_d$

AF represents  $I_a R_a$

FG represents  $I_a X_s$ ; FG is perpendicular to I phasor

OG represents V

Angle between the I and  $\phi_{mf}$  is  $\beta$  the torque or power angle.

Power input =  $3VI$

$$= 3 (E_q + I_a R_a + j I X_s) \cdot I$$

$$= 3 E_q I_a + 3 I^2 R_a + 0 \quad \dots\dots\dots(5.37)$$

$3 E_q I$  – electromagnetic power transferred as mechanical power.

$3 I^2 R_a$  – copper losses.

$$\text{Mechanical power developed} = 3 E_q I \quad \dots\dots\dots(5.38)$$

$$= 3 E_q I \cos(90^\circ - \beta)$$

$$= 3 E_q I \sin \beta$$

$$= 3 E_f I \sin \beta \quad \dots\dots\dots(5.39)$$

The motor operates at  $N_s$  rpm or  $120f/2p$  rpm

Therefore electromagnetic torque developed =  $60/2\pi N_s \times 3 E_q I \sin \beta$

$$= P/\omega_m$$

$$= 3 E_q I \sin \beta / \omega_m \quad \dots\dots\dots(5.40)$$

The same phasor diagram can be redrawn as shown in fig with  $\phi_d$  or  $\phi_{fm}$  as the reference phasor.

Fig 5.8 Phasor Diagram of BLPM sine wave motor with  $\phi_d$  or  $\phi_{mf}$  as reference axis

Further the current I phasor is resolved into two components  $I_d$  and  $I_q$

$I_d$  set up mmf along the direct axis (or axis of the permanent magnet)

$I_q$  sets up mmf along quadrature axis (i.e) axis perpendicular to the axis of permanent magnet.

$$V = E_q + I R_a + j I X_s \tag{5.41}$$

$$I = I_d + j I_q \tag{5.42}$$

Therefore  $V = E_q + I_d r_a + I_q r_a + j I_d X_s + j I_q X_s$

V can be represented as a complex quantity.

$$V = (V_{rr} + j V_{IP})$$

From the above drawn phasor.

$$V = (I_d r_a - I_q X_s) + j (E_q + I_q r_a + I_d X_s)$$

I can also be represented as a complex quantity

$$I = I_d + j I_q$$

Power input =  $\text{Re}(3VI^*)$   $I^*$  - conjugate

$$= \text{Re}(3((I_d r_a - I_q X_s) + j (E_q + I_q r_a + I_d X_s)) ((I_d - j I_q)))$$

$$\begin{aligned}
\text{(i,e) power input} &= \operatorname{Re}(3(I_d^2 r_a - I_d I_q X_s) + (-j I_d I_q r_a + j I_q^2 X_s) + j(E_q I_d + I_q I_d r_a + I_d^2 X_s) \\
&+ (E_q I_q + I_q^2 r_a + I_d I_q X_s)) \\
&= 3(I_d^2 r_a - I_d I_q X_s) + 3(E_q I_q + I_q^2 r_a + I_d I_q X_s) \\
&= 3 E_q I_q + 3(I_d^2 + I_q^2) r_a \\
&= 3 E_q I_q + 3 I^2 r_a \quad \dots\dots\dots(5.43)
\end{aligned}$$

Electromagnetic power transferred =  $3 E_q I_q$

$$= 3 EI \sin \beta$$

Torque developed =  $60/2\pi N_s \cdot 3 EI \sin \beta$

Electromagnetic Torque developed =  $3 E_q I_q / \omega_m$  N-m

**Note:**

In case of salient pole rotors the electromagnetic torque developed from the electrical power.

From eqn. (5.43)

$$\begin{aligned}
\frac{p}{\omega_m} &= 3[I_d^2 r_a - I_d I_q X_s] + 3[E_q I_q + I_q^2 r_a + I_d I_q X_s] \\
&= 3[I_d^2 r_a - I_d I_q (X_d + X_q)] + 3[E_q I_q + I_q^2 r_a + I_d I_q (X_d + X_q)]
\end{aligned}$$

$$\begin{aligned}
\text{Power input} &= R_e 3[(I_d r_a - I_q X_s) + j(E_q + I_d X_s + I_q r_a)(I_d - j I_q)] \\
&= R_e 3\left[\left(I_d r_a - I_q (X_d + X_q)\right) + j(E_q + I_d (X_d + X_q) + I_q r_a)(I_d - j I_q)\right] \\
&= R_e 3[I_d^2 r_a - I_q (X_d + X_q) I_d + E_q I_q + I_d I_q (X_d + X_q) + I_q^2 r_a] \\
&= 3 E_q I_q + 3 I^2 R_a
\end{aligned}$$

Torque developed for a salient pole machine is given by

$$T = \frac{3p}{\omega_m} [E_q I_q + (X_d - X_q) I_d I_q] N - m$$

$\frac{3p}{\omega_m} E_q I_q$  = magnet alignment torque.

$\frac{3p}{\omega_m} (X_d - X_q) I_d I_q$  = reluctance torque.

In case of surface – magnet motors, the reluctance torque becomes zero.

$$\text{Therefore, torque developed} = \frac{3E_q I_q}{\omega_m} \text{N-m}$$

$$\text{Or} = \frac{3P}{\omega} E_q I_q \text{N-m}$$

At a given speed,  $E_q$  is fixed as it is proportional to speed. Then torque is proportional to q-axis current  $I_q$ .

The linear relationship between torque and current simplifies the controller design and makes the dynamic performance more regular and predictable. The same property is shared by the square wave motor and the permanent  $d_c$  commutator motor.

In the phasor diagram shown in fig. 5.10.

Fig 5.9 Phasor Diagram neglecting the effect of resistance

Neglecting the effect of resistance, the basic voltage equation of BLPMSNW motor

$$\text{(i.e.,)} \dot{V} = \dot{E}_q + jX_s \dot{I}$$

As the effect of resistance is neglected

$$\frac{\dot{V}}{jX_s} = \frac{\dot{E}_q}{jX_s} + \dot{I} \tag{5.44}$$

$$\dot{I} = \frac{\dot{V} - \dot{E}_q}{jX_s} \tag{5.45}$$

For a particular frequency of operation the phasor diagram can be drawn as shown in figure.

## 5.6. PERMISSIBLE TORQUE-SPEED CHARACTERISTICS

The torque-speed characteristics of BLPM sine wave motor is shown in fig. 5.10

Fig 5.10 torque-speed characteristics of BLPM sine wave (SNW) motor.

For a given  $V_c$  and  $I_c$  (i.e) maximum permissible voltage and maximum permissible current, maximum torque remains constant from a low frequency to  $f_o$  (i.e) corner frequency.

Any further increase in frequency decreases the maximum torque. At  $f=f_D$  (i.e.)  $f_{max}$  the torque Developed is zero. Shaded pole represents the permissible region of operation in torque speed characteristics.

### Effect of over speed

In the torque speed characteristics, if the speed is increased beyond the point D, there is a risk of over current because the back emf  $E_q$  continues to increase while the terminal voltage remains constant. The current is then almost a pure reactive current flowing from the motor back to the supply. There is a small q axis current and a small torque because of losses in the motor and in the converter. The power flow is thus reversed. This mode of operation is possible only if the motor 'over runs' the converter or is driven by an external load or prime mover.

In such a case the reactive current is limited only by the synchronous reactance. As the speed increase further, it approaches the short circuit current  $\frac{E_q}{X_s}$  which is many times larger than the normal current rating of the motor winding or the converter. This current may be sufficient to demagnetize the magnets particularly if their temperature is high. Current is rectified by the freewheeling diodes in the converter and there is a additional risk due to over voltage on the dc side of the converter, especially if a filter capacitor and ac line rectifiers are used to supply the dc. But this condition is unusual, even though in the system design the possibility should be assessed.

## Solution

An effective solution is to use an over speed relay to short circuit the 3 $\phi$  winding in a 3 $\phi$  resistor or a short circuit to produce a braking torque without actually releasing the converter.

### 5.7. VECTOR CONTROL OF BLPM SNW MOTOR

Electromagnetic torque in any electrical machine is developed due to the interaction of current carrying armature conductors with the air gap flux. Consider a two machine whose armature conductor currents and air gap flux are as shown in fig. 5.12. Here the flux is in quadrature with the armature mmf axis.

Fig. 5.11 Quadrature position of air gap flux and armature mmf axis.

Fig. 5.12 Non- Quadrature position of air gap flux and armature mmf axis.

Each and every armature conductor experiences a force which contributes the torque. The torque contributed by various armature conductors have the same direction even through their magnitude may vary. It is observed that the steady state and dynamic (behaviors) performance of a most of such an arrangement are better.

Consider a second case wherein the armature conductor current distribution and air gap flux distribution are as shown in fig. 6.26. In this case the angle between the axis of the air gap flux and the armature mmf axis is different from 90° elec.

In this case also each and every armature conductor experiences a force and contributes to the torque. But in this case the direction of the torque experienced by the conductors is not the same. Since conduction develops torque in one direction while the others develop in the opposite direction. As a result, the resultant torque gets reduced; consequently it is observed that both the steady state and dynamic performance of such a motor is poorer.

For a BLPM motor to have better steady state and dynamic performance, it is essential that the armature mmf axis and the axis of PM are to be in quadrature for all operating condition.

### 5.7.1. Principle of vector control

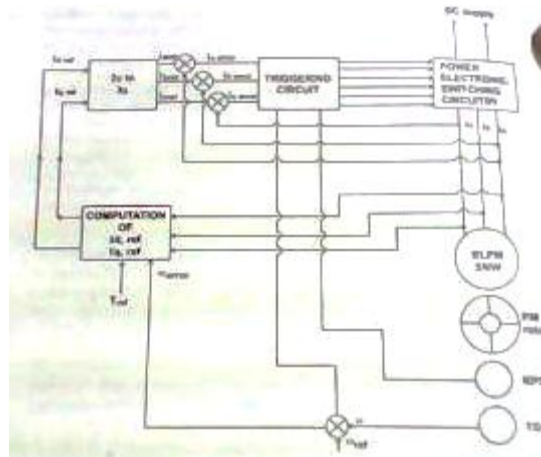

BLPM SNW motor is usually employed for variable speed applications. For this we keep  $V/f$  constant and vary  $V$  and  $f$  to get the desired speed and torque.

From the theory of BLPM SNW motor it is known that as the speed is varied from a very low value upto the corner frequency, the desired operating point of current is such that  $I_d=0$  and  $I$  is along the  $q$ -axis. Such a condition can be achieved by suitably controlling the voltage by PWM technique after adjusting the frequency to a desired value.

When the frequency is more than the corner frequency it is not possible to make  $I_d=0$ , due to the voltage constraints. In such a case a better operating point for current is obtained with minimum  $I_d$  value after satisfying the voltage constraints. Controlling BLPM SNW motor taking into consideration the above mentioned aspects is known as “vector Control” of BLPM SNW motor.

### 5.7.2. Schematic Diagram of Vector Control

The schematic block diagram of vector control is as shown in figure 5.13. Knowing the value of the desired torque and speed and also the parameters and the voltage to which the motor is subjected to, it is possible to complete the values of  $i_{d,ref}$  and  $i_{q,ref}$  for the desired dynamic and steady state performance.

RPS – Rotor position sensor, TG – Tachogenerator

Fig.5.13 Schematic diagram of vector control

The reference values of  $i_d$  and  $i_q$  are transformed into reference values of currents namely  $i_a,ref$ ,  $i_b,ref$  and  $i_c,ref$ . These currents are compared with the actual currents and the error values actuate the triggering circuitry which is also influenced by the rotor position sensor and speed. Thus the vector control of BLPM SNW motor is achieved.

## 5.8 SELF CONTROL OF PMSM

As the rotor speed changes the armature supply frequency is also change proportionally so that the armature field always moves (rotates) at the same speed as the rotor. The armature and rotor field move in synchronism for all operating points. Here accurate tracking of speed by frequency is realized with the help of rotor position sensor.

When the rotor makes certain predetermined angle with the axis of the armature phases the firing pulses to the converter feeding the motor is also change. The switches are fired at a frequency proportional to the motor speed. Thus the frequency of the voltage induced in the armature is proportional to the speed.

Self-control ensures that for all operating points the armature and rotor fields move exactly at the same speed. The torque angle is adjusted electronically hence there is an additional controllable parameter passing greater control of the motor behavior by changing the firing of the semi-conductor switches of an inverter.

The torque angle is said electronically hence the fundamental component of phase A needs  $\Phi/\beta$ , it lies along the direct axis that rotates at a synchronous speed. The switches must be triggered by phase A current component when  $\Phi$  axis is  $\beta$  electrical degrees behind the phase A axis. This is achieved by firing the switch when direct axis is  $\delta+\beta$  behind axis of A as show shown in fig.

Self-control is applicable to all variable frequency converters, the frequency being determined by machine.

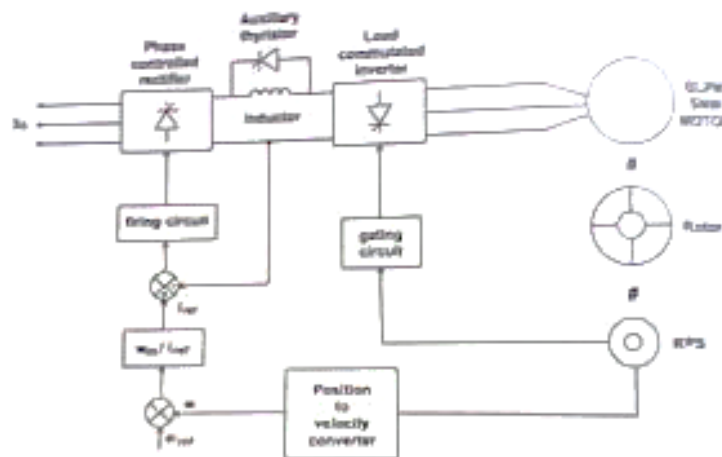

Fig 5.14 Schematic diagram of self-control

At high power levels the most common power converter configuration is the current fed DC link converter which is shown in fig. 5.14.

### 5.8.1 Inner current and outer speed loop

The phase controlled thyristor rectifier on the supply side of the DC link has the current regulating loop and operate as a control current source. The regulated DC current is delivered to the DC link inductor to the thyristor of load commutator inverter which supplies line current to the synchronous motor.

The inverter gating signals are under the control of shaft-position sensor giving a commutator less dc motor with armature current controlled. The thyristor of these inverters utilize load commutation because of the generated emf appearing at the armature. It is ensured by the over excitation of synchronous motor, so that it operates at leading power factor hence it reduces commutating circuitry, low losses and is applicable to power levels of several megawatts.

The shaft position is sensed by the position sensor. The shaft speed is obtained by converting the position information. This speed is compared with the reference speed signal which provides the speed error. This is the current reference signal for the linear current loop.

This reference current is compared with the sensed dc link current which provides control signals for the rectifier thyristor. The sensed shaft position is used as gating signal for inverter thyristor.

### 5.8.2 Commutation at low speed

Load commutation is ensured only at high speeds. Whereas at low speeds the emf generated is not sufficient for load commutation. The inverter can be commutated by supplying pulsating on and off dc link current. This technique produces large pulsating torque but this is not suitable for drives which require smooth torque at low speed.

The DC link current is pulsed by phase shifting the gate signal of the supply side converter from rectification to inversion and back again. When the current is zero the motor side converter is switched to a new conduction period and supply side converter is then turned on. Time required for the motor current to fall to zero can be significantly shortened by placing a shunt thyristor in parallel with a DC link inductor. When the current zero is needed the line side converter is phased back to inversion and the auxiliary thyristor is gated.

The DC link inductor is then short circuited and its current can supply freely without affecting the motor. When the line side converter is turned on the auxiliary thyristor is quickly blocked. This method of interruption of the motor current reduces the effect of pulsating torque.

### 5.8.3 Four Quadrant Operations

The drive characteristics are similar to those of a conventional DC motor drive. Motor speed can be increased to a certain base speed corresponding to the maximum voltage from the supply. Further, increase in speed is obtained by reducing the field current to give a field weakening region of operation.

Regenerative braking is accomplished by shifting the gate signal, so that machine side inverter acts as a rectifier and supply side rectifier as a inverter, hence the power is return to the ac utility network. The direction of rotation

Of the motor is also reversible by alternating the gate sequence of the motor side converter. Thus four quadrant operations are achieved, without additional circuitry.

## 5.9 MICROPROCESSOR BASED CONTROL OF PMSE

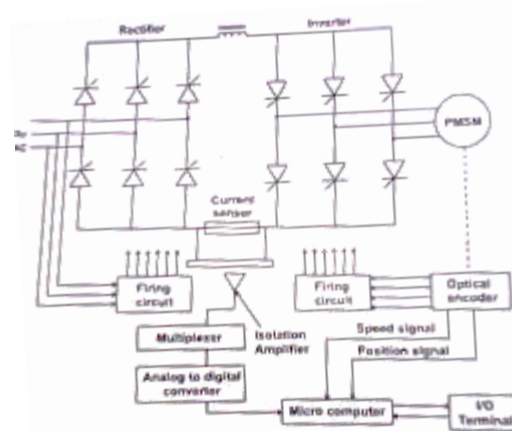

Fig.5.15 Microprocessor Based Control of PMSM

Fig 5.15 shows the block diagram of microprocessor based permanent magnet synchronous motor drive.

The advent of microprocessor has raised interest in digital control of power converter systems and electronics motor drives since the microprocessor provides a flexible and low cost alternative to the conventional method.

For permanent magnet synchronous motor drive systems, microprocessor control offers several interesting features principally improved performance and reliability, versatility of the controller, reduced components and reduced development and manufacturing cost. In the block diagram of the microprocessor controller PMSM shown in fig 5.15, the permanent magnet synchronous motor is fed from a current source d.c link converter system, which consists of a SCR inverter through rectifier and which is operated from three phase a.c supply lines, and its gating signals are provided by digitally controlled firing circuit.

The optical encoder which is composed of a coded disk attached to the motor shaft and four optical sensors, providing rotor speed and position signals. The inverter triggering pulses are synchronized to the rotor position reference signals with a delay angle determined by an 8-bit control input. The inverter SCR's are naturally commutated by the machines voltages during

normal conditions. The speed signals, which is a train of pulses of frequency, proportional to the motor speed, is fed to a programmable counter used for speed sensing.

The stator current is detected by current sensor and amplified by optically isolated amplifier. The output signals are multiplexed and converted to digital form by a high speed analog to digital converter.

The main functions of the microprocessor are monitoring and control of the system variables for the purpose of obtaining desired drive features. It can also perform various auxiliary tasks such as protection, diagnosis and display. In normal operation, commands are fetched from the input-output terminals, and system variables (the dc link current, the rotor position and speed) are sensed and fed to the CPU. After processing, the microprocessor issues control signal to the input rectifier, then the machine inverter, so as to provide the programmed drive characteristics.

### Glossary

1. Permanent Magnet Synchronous Motor -- It is also called as brushless permanent magnet sine wave motor. It has Sinusoidal magnetic flux in the air gap, Sinusoidal current wave forms, and Quasi-sinusoidal distribution stator windings.
2. Flux density -- The intensity of this flux
3. Vector Control -- Also called field-oriented control (FOC), isa variable frequency drive (VFD) control method which controls three-phase AC electric motor
4. Self-Control -- Self-control is the ability to control one's , behavior, and desires in order to obtain some reward.
5. Peripheral rotor -- The permanent magnets are located on the rotor periphery and permanent magnet flux is radial.
6. Interior rotor -- The permanent magnets are located on the interior of the rotor and flux is generally radial.
7. Resistivity -- Also known as specific resistance, the measure of a material's natural resistance to current flow. Resistivity is the opposite of conductivity, so it follows that good conductors have low resistivity per circular mil foot.
8. Specific Resistance -- Another term for resistivity. Every material has a set specific resistance per circular mil foot at a specific temperature.
9. Temperature Coefficient -- A ratio of increased conductor resistance per degree Celsius rise in temperature. Most metals increase in resistance as temperature increases, giving them a positive temperature coefficient.
10. Pole -- One of two ends of the axis of a sphere. Poles also refer to the opposite ends of a magnet.
11. Reluctance -- A material's resistance to becoming magnetized.
12. Residual Magnetism -- The attractive force that exists in an object or substance after it has been removed from a magnetic field.

**Question bank****UNIT I****SYNCHRONOUS RELUCTANCE MOTORS****PART – A**

1. What is synchronous reluctance motor?
2. What are the advantages and disadvantages of synchronous reluctance motor?
3. Mention some applications of synchronous reluctance motor.
4. Define synchronous reluctance.
5. Define reluctance torque.
6. Distinguish between axial and radial air gap motors with relevant figures.
7. Draw the steady state phasor diagram of synchronous reluctance motor.
8. List out the primary design considerations of synchronous reluctance motor.
9. State the advantages of synchronous reluctance motor over PM machines.
10. What are factors to be considered while designing a vernier motor?

**PART – B**

1. Explain the constructions and working principle of synchronous reluctance motor.
2. Explain in detail about classification of synchronous reluctance motor.
3. Draw the phasor diagram of synchronous reluctance motor.
4. Derive the torque equation of synchronous reluctance motor.
5. Draw and explain the characteristics of synchronous reluctance motor.
6. Explain in detail about vernier motor.

**UNIT - II****STEPPING MOTOR****PART – A**

1. What is stepper motor?
2. Define step angle.
3. Define slewing.

4. Sketch the diagram of a VR Stepper motor.
5. What are the different modes of excitation used in variable reluctance stepper motor?
6. Mention some applications of stepper motor?
7. Define resolution.
8. What are the advantages and disadvantages of stepper motor?
9. What is meant by micro stepping in stepper motor?
10. Differential between VR, PM and hybrid stepper motor?
11. Define holding torque.
12. Define detent torque.
13. Define pull-in torque and pull-out torque.
14. Draw the typical dynamic characteristics of a stepper motor
15. What is slew range?
16. What is synchronism in stepper motor?
17. Draw the block diagram of the drive system of a stepper motor.
18. What is the step angle of a four phase stepper motor with 12 stator teeth and 3 rotor teeth?
19. A single stack, 3-phase VR motor has a step angle of  $15^\circ$ . Find the number of its rotor and stator poles.

### **PART – B**

1. Explain the construction and various modes of excitation of VR stepper motor.
2. Explain the construction and various modes of excitation of PM stepper motor.
3. Explain the construction and working principle of Hybrid Stepper motor.
4. State and explain the static and dynamic characteristics of a stepper motor.
5. Explain in detail about different types of power drive circuits for stepper motor.
6. Explain the mechanism of torque production in VR stepper motor.
7. Draw any two drive circuits for stepper motor.

## **UNIT III**

# **SWITCHED RELUCTANCE MOTOR**

### **PART – A**

1. What is switched reluctance motor?
2. What are the essential differences between a stepper motor and SRM?
3. Mention any four advantages of switched reluctance motor.
4. Write about the disadvantages of SRM.
5. Mention some applications of SRM.
6. Draw the simple block diagram of SRM.
7. What are the different power controllers used for the control of SRM?
8. Why rotor position sensor is essential for the operation of SRM?
9. What is meant by energy ratio?
10. Draw the ' $\lambda - i$ ' curve for SRM.
11. What is phase winding?
12. What is the step angle of a 3, SRM having 12 stator poles 8 rotor poles, also calculate commutation frequency at each phase and speed of 6000 rpm?

#### **PART – B**

1. Explain the construction and working principle of switched reluctance motor.
2. Describe the various power controller circuits applicable to switched reluctance motor and explain the operation of any one scheme with suitable circuit diagram.
3. Draw a schematic diagram and explain the operation of a 'C' dump converter used for the control of SRM.
4. Derive the torque equation of SRM.
5. Draw and explain the general torque-speed characteristics of SRM and discuss the type of control strategy used for different regions of the curve. Sketch the typical phase current waveforms of low speed operation.
6. Describe the hysteresis type and PWM type current regulator for one phase of a SRM

## **UNIT IV**

# **PERMANENT MAGNET BRUSHLESS**

# **D.C. MOTORS**

#### **PART – A**

1. What are the advantages dc brushless dc motor drives?
2. What are the disadvantages dc brushless dc motor drives?
3. List out the various permanent magnet materials.
4. Draw the magnetic equivalent circuit of 2 pole permanent magnet brushless dc motor
5. Why a PMBLDC motor is called an electronically commutated motor?
6. Write the torque and emf equation of square wave brushless motor.
7. Mention some applications of PMBLDC motor.
8. What are the differences between the mechanical and electronic Commutator?
9. What are the difference between the conventional dc motor and PMBLDC motor?
10. What are the classifications of PMBLDC motor?
11. What are the two types of rotor position sensors?
12. What are the materials used for making Hall IC pallet?
13. A permanent magnet dc Commutator motor has a stall torque of 1 N-m with a stall current of 5A. Estimate it's no load speed in rpm when fed from a 28 V dc voltage supply.

### **PART – B**

1. Sketch the structure of controller for PMBLDC motor and explain the functions of various blocks.
2. Explain the closed loop control scheme of a permanent magnet brushless dc motor drive with a suitable schematic diagram.
3. Drive the expressions for the emf and torque of a PMBLDC motor.
4. Draw the diagram of electronic Commutator. Explain the operation of electronic Commutator.
5. Discuss the use of Hall sensors for position sensing in PMBLDC motor.
6. Sketch the torque-speed characteristics of a PMBLDC motor.

## **UNIT-5**

# PERMANENT MAGNET SYNCHRONOUS MOTOR

## PART – A

1. What is permanent magnet synchronous motor?
2. What are the advantages and disadvantages of PMSM?
3. What are the applications of PMSM?
4. What are the different types of PMSM?
5. Compare electromagnetic excitation with permanent magnet of PMSM.
6. Clearly explain the differences between the synchronous reluctance motor and PMSM.
7. What are the differences in the constructional features of PMBLDC motor and PMSM?
8. Write the emf equation of PMSM.
9. What is meant by self-control?
10. What is 'pulsed mode'?
11. What is load commutation?
12. A three phase, four pole, brushless PM rotor has 36 stator slots. Each phase winding is made up of three coils per pole with 20 turns per coil. The coil span is seven slots. If the fundamental component of magnet flux is 1.8 Mwb. Calculate the open circuit phase emf ( $E_g$ ) at 3000 rpm.

## PART – B

1. Explain the construction and operation of PMSM.
2. Explain the principle of operation of a sine wave PM synchronous machine in detail. Draw its phasor diagram and derive its torque equation.
3. Derive the emf equation of PMSM.
4. Write about Self-control of PMSM.
5. Derive the expressions for power input and torque of a PMSM. Explain how its torque speed characteristics are obtained.
6. Explain in detail the vector control of permanent magnet synchronous motor.
