

LabVIEW Developer Education Day

Everything You Ever Wanted To Know About Functional Global Variables

Nancy Hollenback

Field Architect

Agenda

- What is a functional global variable (FGV)?
- Does the FGV prevent race conditions?
- Is the FGV better than the global variable?
- Which use cases are a good fit for FGVs
- Is there a better way? (DVRs)

Why Do We Need Functional Global Variables?

- A large application usually has many processes executing concurrently
- Processes need to share data or send and receive messages.

Inter Process Communication

- Store Data
- Stream Data

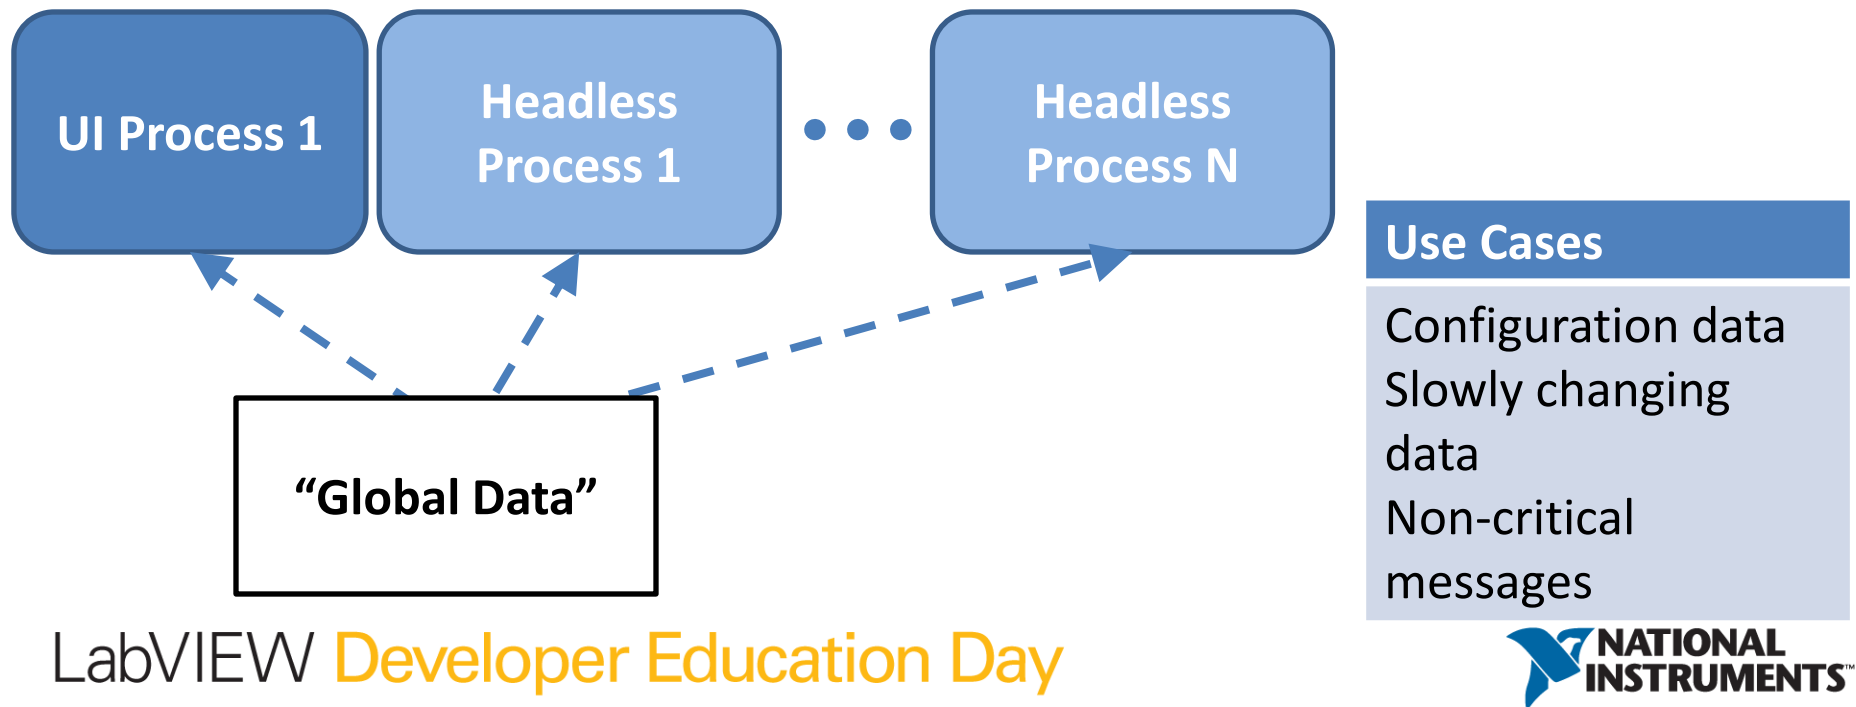

Typically straightforward use cases with limited implementation options

- Send Message

Many more variations, permutations, and design considerations

Store Data

- Data is stored and made “globally” accessible
- Storage mechanism holds only the current value
- Other code modules access the data as needed
- The potential for race conditions must be considered

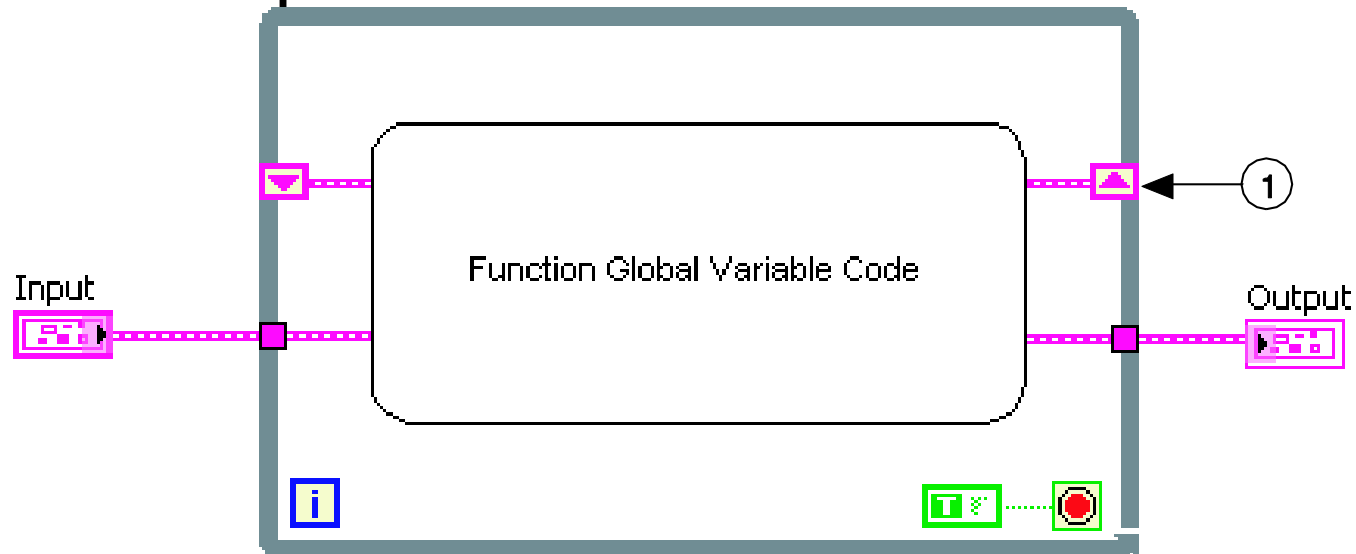

Functional Global Variables – Benefits

- Provide *global access to data* while also providing a framework to avoid potential race conditions.
- *Encapsulate data* so that debugging and maintenance is easier
- Facilitate the creation of *reusable modules* which simplifies writing and maintenance of code
- Program becomes more *readable*.

Functional Global Variable - Review

- The general form of a functional global variable includes an uninitialized shift register (1) with a single iteration For or While Loop

Functional Global Variables

- A functional global variable usually has an **action** input parameter that specifies which task the VI performs
- The VI uses an uninitialized shift register in a While Loop to hold the result of the operation

Best Practices for Documentation

- The action/method control should be a type defined enum.
- Make “get” the default action/method.
- Consider making the action/method required.
- Include this in the label.
- Wire to the top connector

Functional Global Variables – History

- (LV2 Style Global, Action Engine, VIGlobals, USRs, Components)
 - Global data storage mechanism prior to the introduction of the global variable in LabVIEW 3
 - Foundational programming technique that has been in extensive use in the LabVIEW community

Note: The behavior of an uninitialized shift register was not defined in LabVIEW 1.0

Replacing Global Variables with FGVs

- This is a common initial use case.

Main – Using a Global

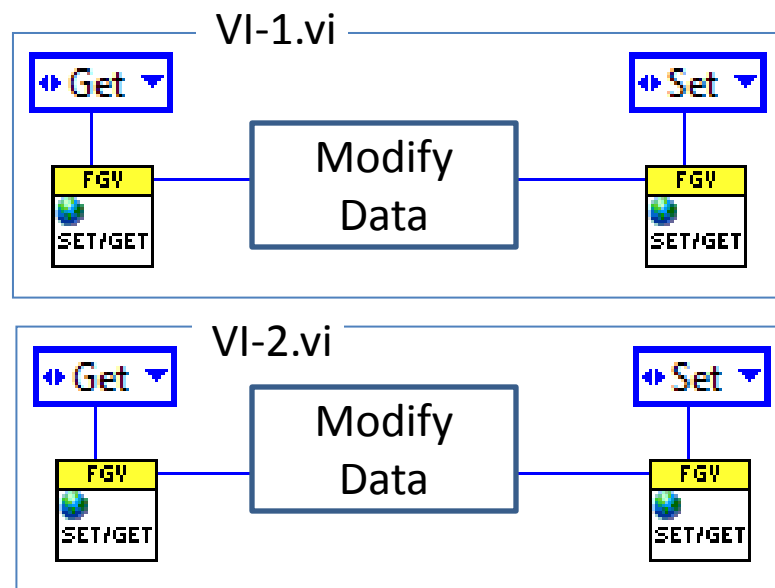

DEMO

Main – Using a Simple Set-Get FGV

DEMO

Do FGVs Eliminate Race Conditions?

- What if the FGV includes only set and get methods?

What happens when 2 VIs call the get and both modify the data before either has called the set?

Race Condition with a Set-Get Functional Global Variable

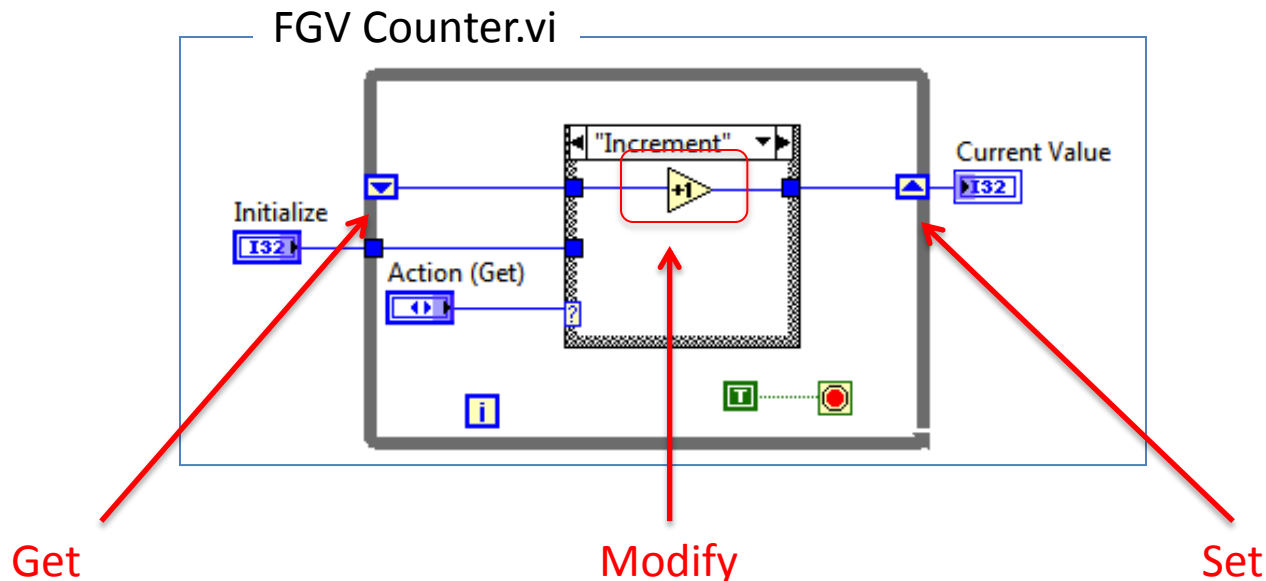

DEMO

Use FGVs to Protect Critical Sections of Code

- Identify a critical section of code, such as the modification of a counter value or a timer value.
- Identify the actions that modify the data (increment, decrement)
- Encapsulate the entire get/modify/set steps in the FGV

This is commonly called an Action Engine. It is a special type of FGV.

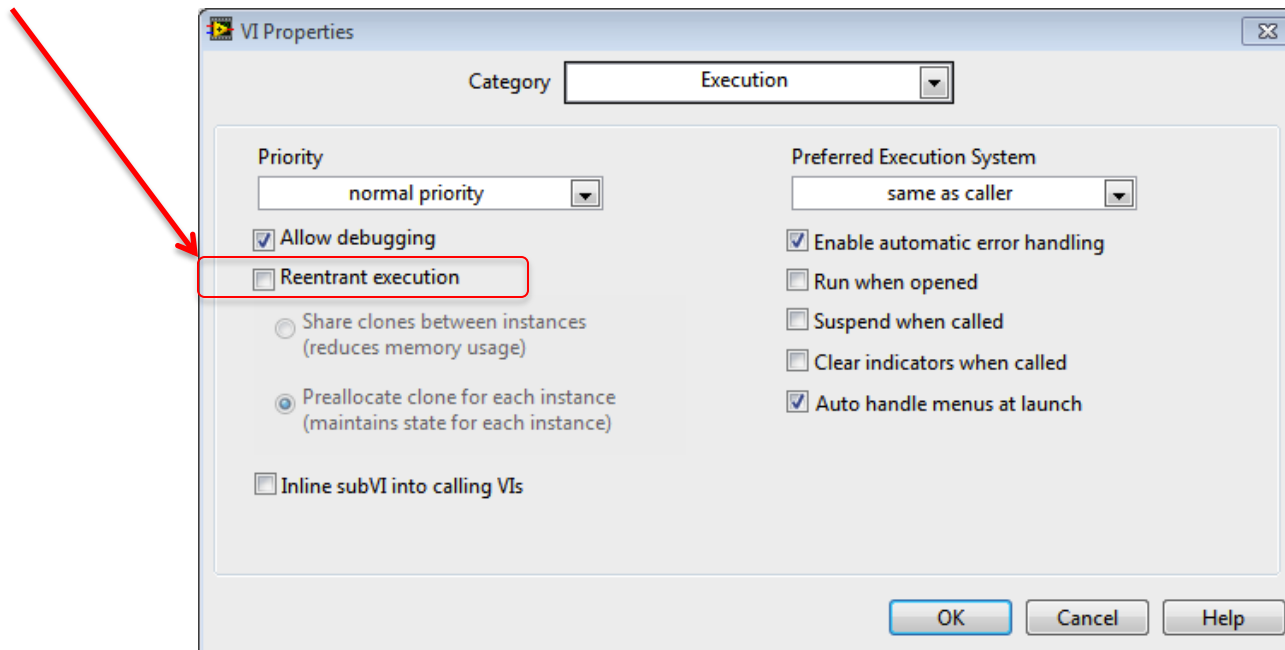

FGV – Action Engine Protects Critical Sections of Code

- This action engine wraps the “get/modify/set” around the critical section of code.

Sidebar: Execution Properties – Non Reentrant Execution

- VIs are non reentrant by default
- The LabVIEW execution system will not run multiple calls to the same SubVI simultaneously

Sidebar: Reentrant vs. Non-Reentrant

- Non reentrancy is required for FGVs
- Reentrancy allows one subVI to be called simultaneously from different places.
 - To allow a subVI to be called in parallel
 - To allow a subVI instance to maintain its own state

State (or the data that resides in the uninitialized shift register) is maintained between all instances of the FGV

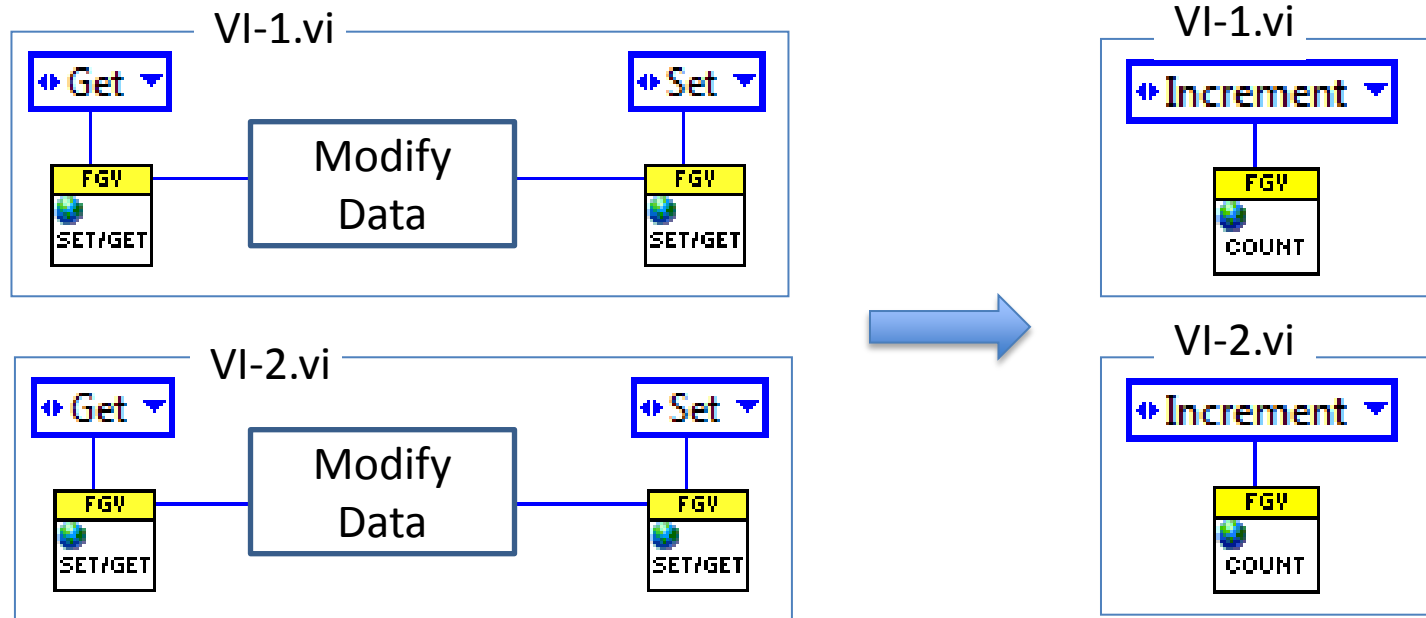

Non Reentrant VIs Block Other Calls

- These two VIs are non reentrant by default
- They cannot run simultaneously
- One will run until completion and block the other from running until completed.

Action Engines Protect Critical Sections!

The FGV will block other instance from running until it has completed execution. Therefore, encapsulating the entire action prevents the potential race condition.

*Avoid Race Conditions!!! Fully encapsulate the
get/modify/set.*

Action Engine FGV

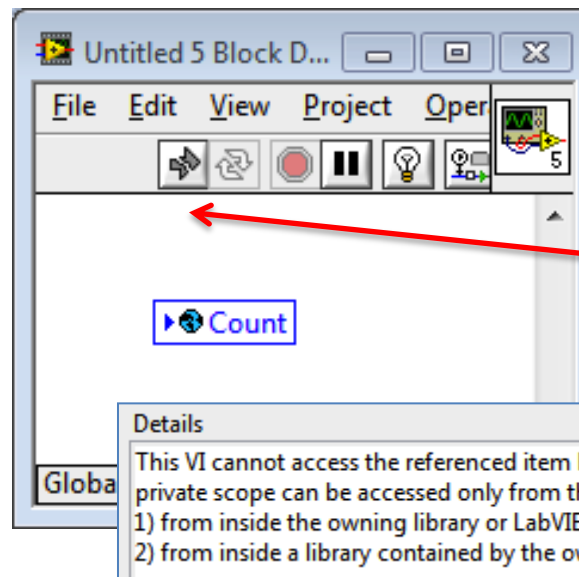

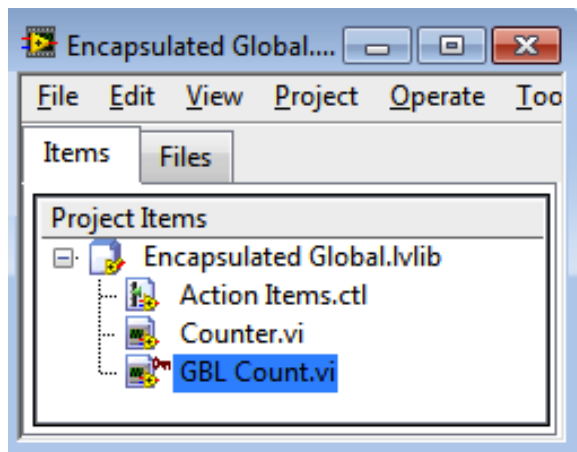

DEMO

Globals vs FGVs

- Globals are significantly faster.
- FGVs allow for extra code to check for valid data.

Encapsulated Global

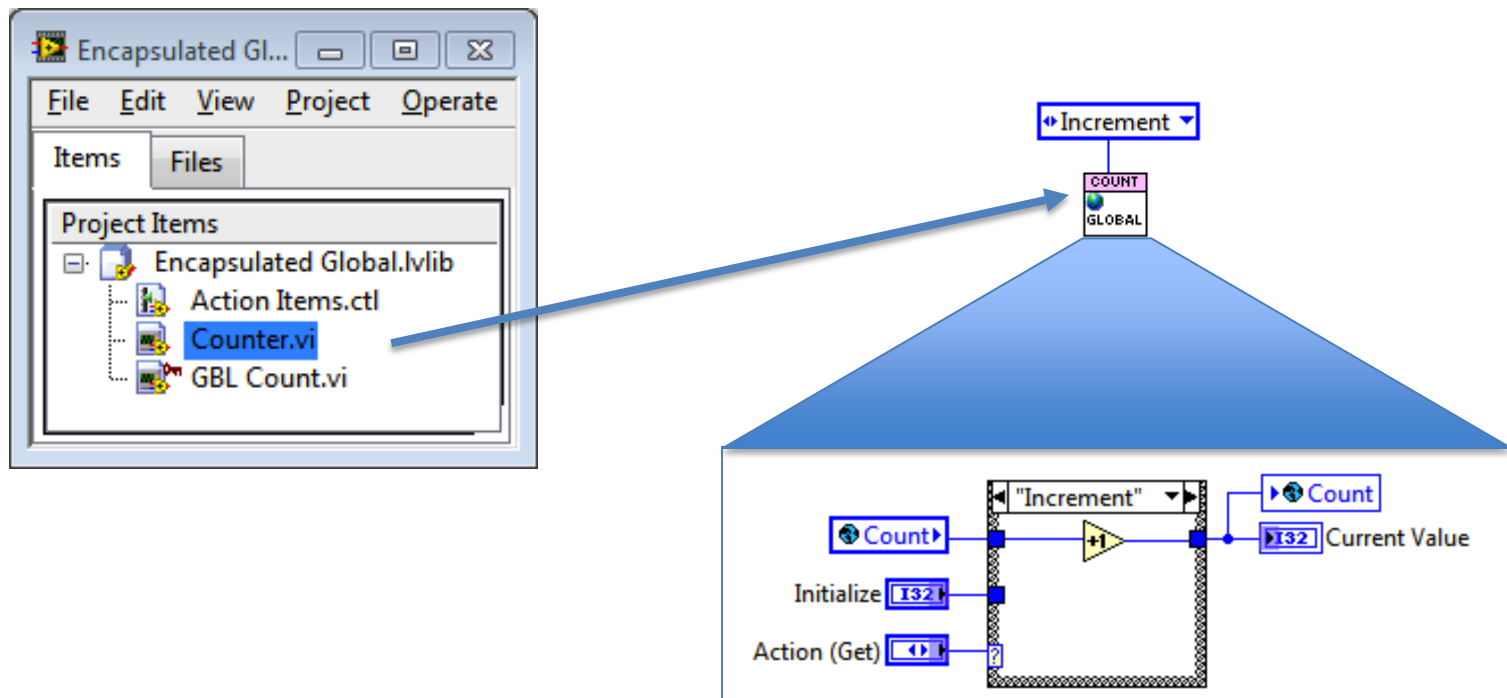

- Create a global variable
- Add it to a project library and set access scope to private

Private VIs
cannot be
used outside
the .lvlib

Encapsulated Global

- Create the VI in the lvlib, that will act on the privately scoped global variable.

Consider locking and password protecting the .lvlib

Encapsulated Global

DEMO

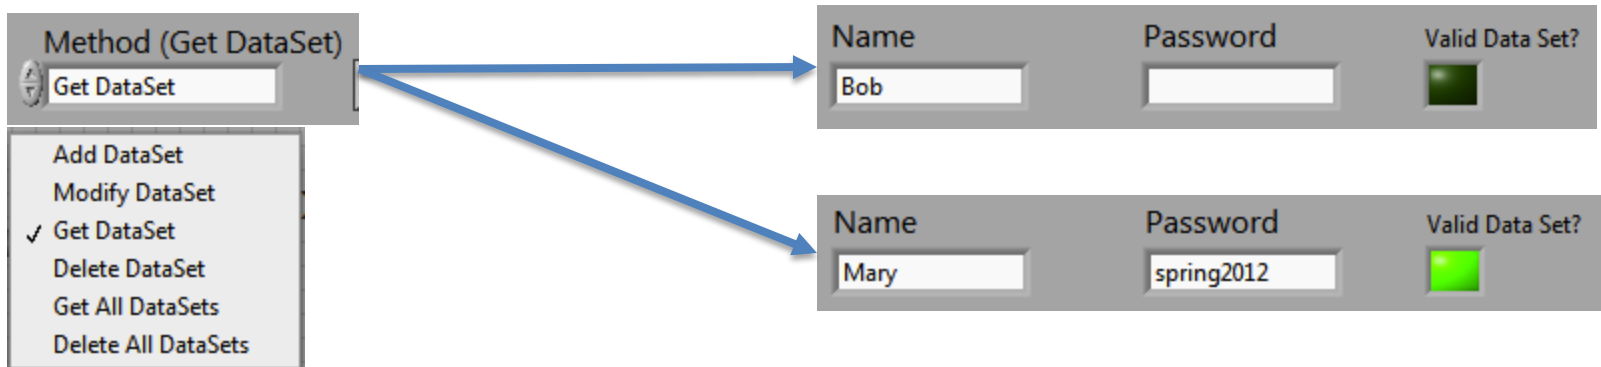

Reusable components with FGVs

- Recall that FGVs encapsulate the data and functionality and as such are a good design pattern for building reusable components
- Consider using a FGV as a look-up table.

Name	Password
John	66ford90
Mary	spring2012

*Array of names has corresponding array
of values or datasets*

Name Value Look Up Table

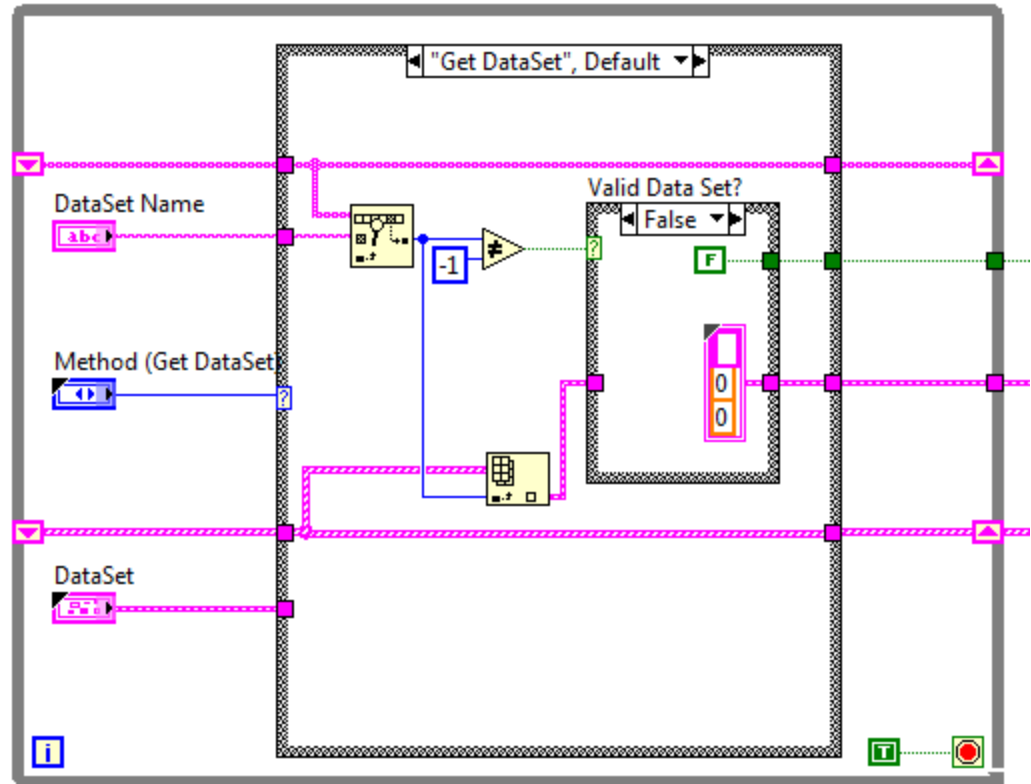

- Define the data type of the value that is associated with the name.
- Modify the method to include all actions to perform related to adding, getting, and deleting items from the list.
- Add code to ensure whether data is valid

FGV – Resource Storage

Design pattern for a key-value look up table.

- Array of names has a one-to-one correspondence to the array of data sets
- Does not protect against race conditions
- Allows for the qualification of valid data

FGV Password Storage

DEMO

Resource Storage FGVs

- Build drop-in reusable components.
- Provide protection and validation of data.
- Susceptible to race conditions.
- Can be used to store:
 - References (User Events, DVRs, etc)
 - Information about devices
 - Paths for data storage
 - Operator information
 - Anything that requires a name-value lookup

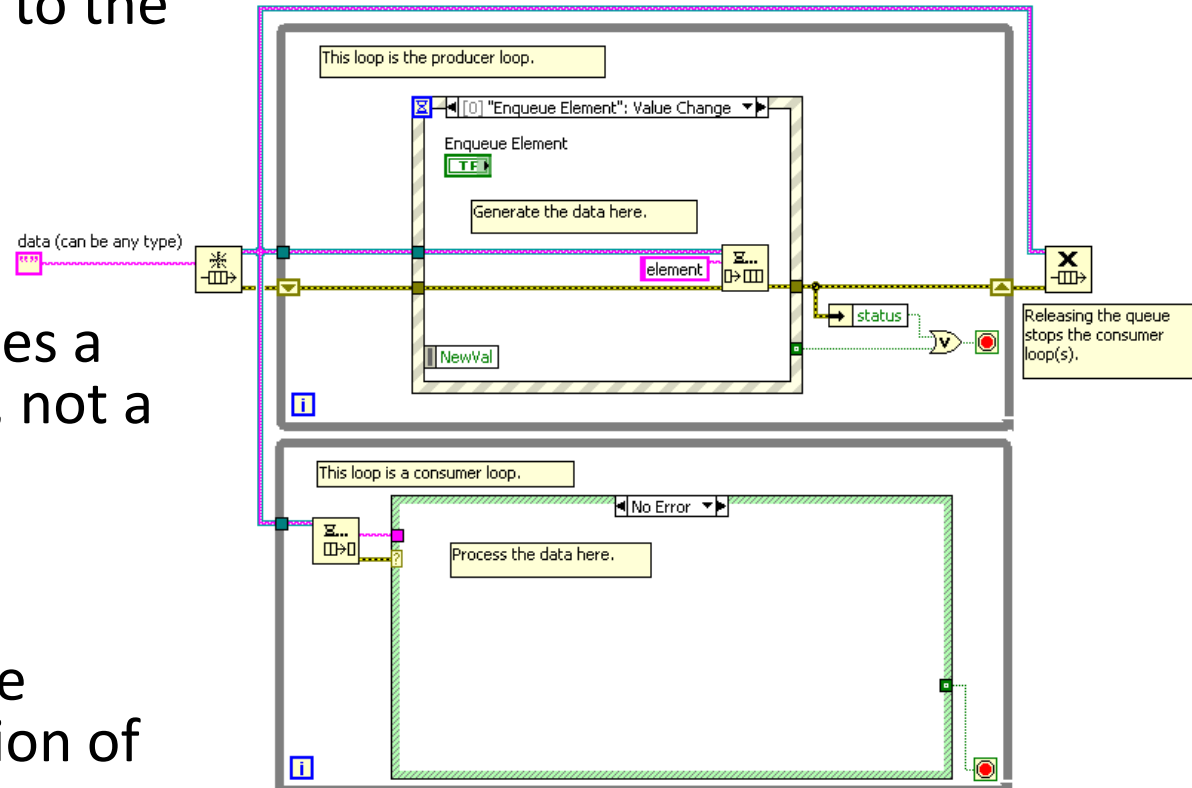

What if You Need Multiple Counters...

- Reentrant functional global?
- Array manipulation of the functional global data?
- Perhaps there is a better way...

Review of Queues and References

- Reference is a pointer to the data
- The wire contains the reference, not the data.
- Forking the wire creates a copy of the reference, not a copy of the data
- Access data through methods (VIs)
- Developer controls the creation and destruction of the data

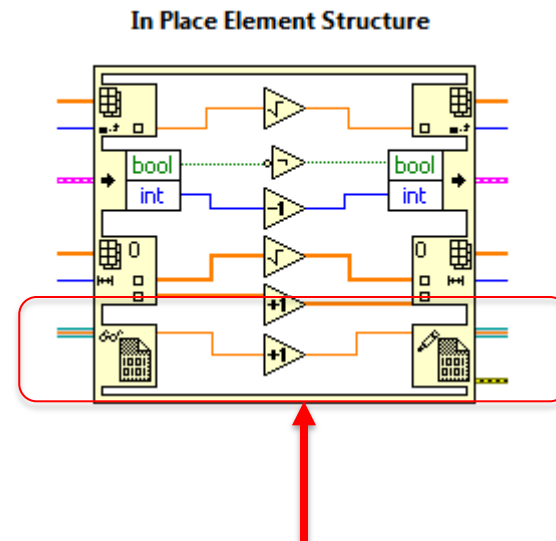

What is the Data Value Reference (DVR)?

- This is a simple way to wrap a reference around any type of data.

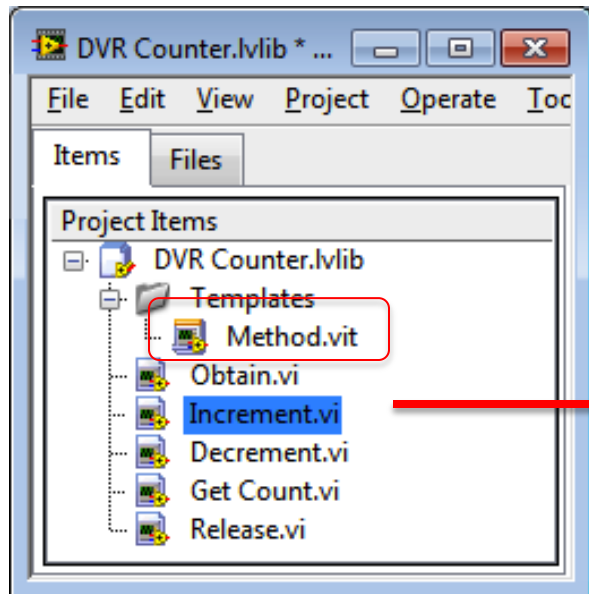

Create & Destroy

Modify

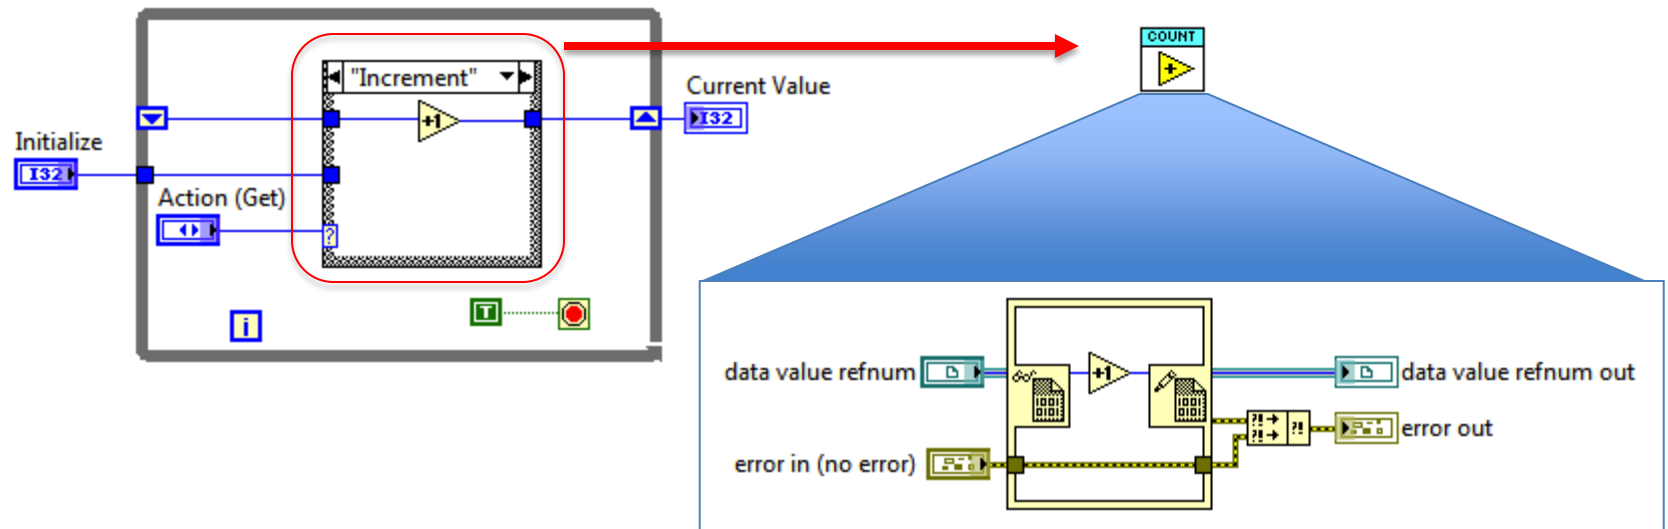

Data Value Reference (DVR) Library

- Create a constructor and destructor.
- Create a template for the methods.
- Create a method for each case that will modify the data.

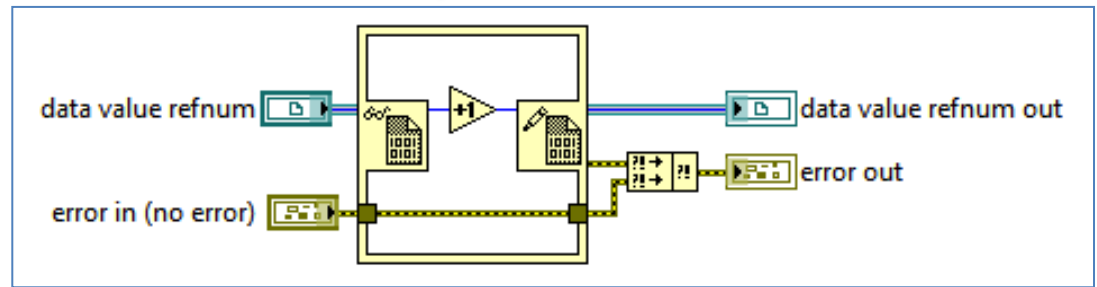

Creating a DVR from an FGV

- If you already have an FGV, you can easily transform it into the more flexible DVR library.
- Create the constructor and destructor.
- Create a method (VI) for each case that was in the FGV.

Data Value Reference (DVR) - Library

- Reference acts as a pointer to the data
- Create unlimited instances
- Easily expand the library

Using a DVR Library

DEMO

DVR Library Design Issues

- Easily add new methods (VIs) to the library as needed.
- Create a library that has a similar look and feel to native APIs (Queues, Notifiers, Semaphores)
- Identify the owner of the library who will update and maintain the library.
- Anyone with Core 1 & Core 2 understanding can use the DVR library.

Add a Method to the DVR Library

DEMO

What Else Do I need to Know?

- Store Data
- Stream Data

Typically straightforward use cases with limited implementation options

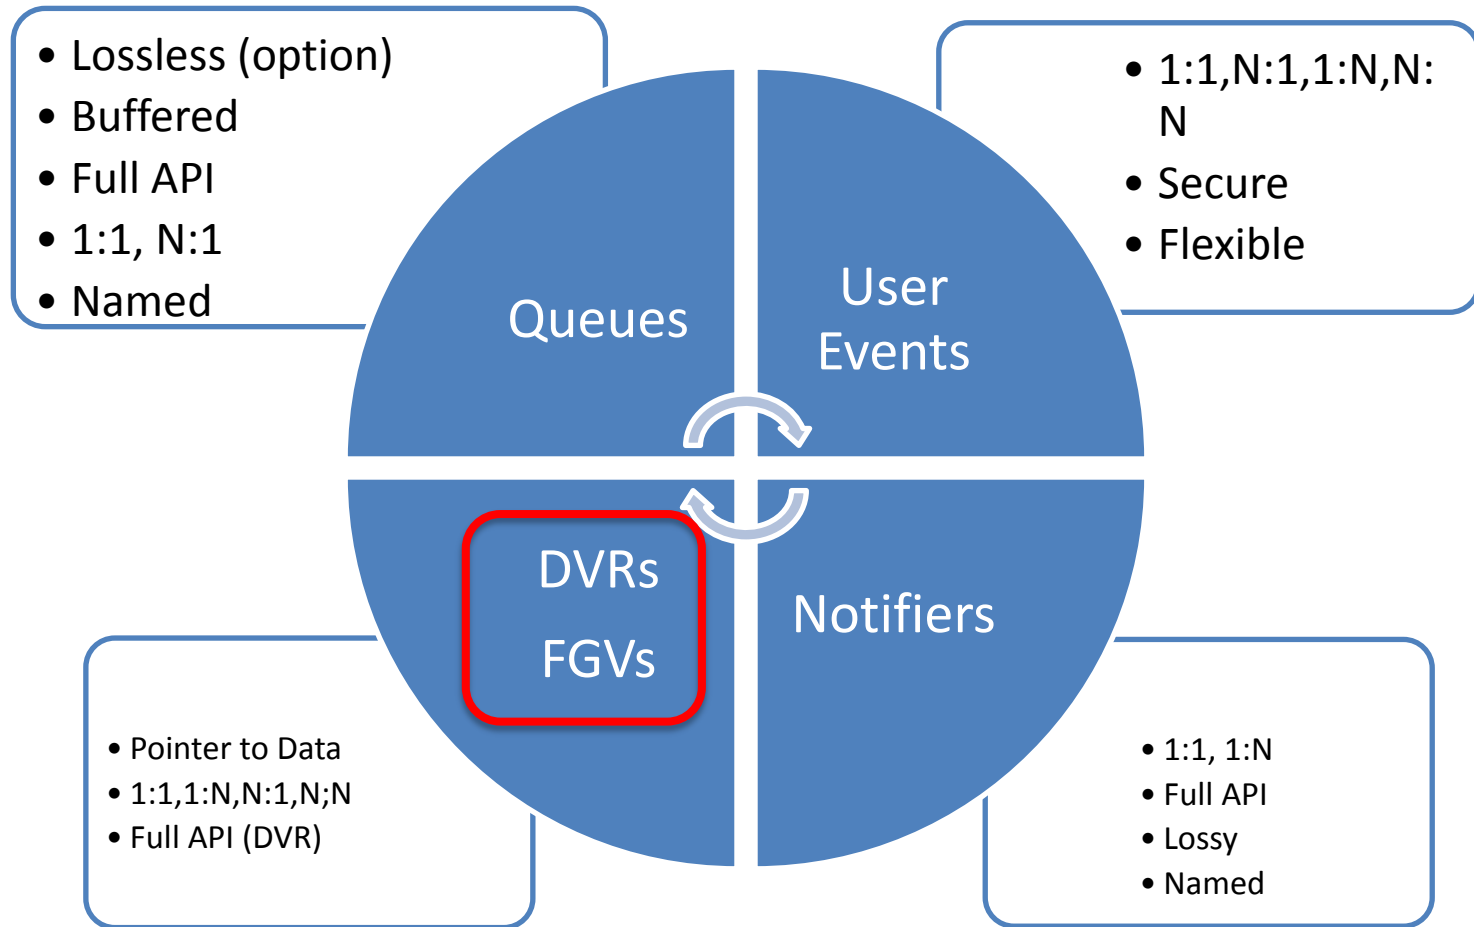

- Send Message

Many more variations, permutations, and design considerations

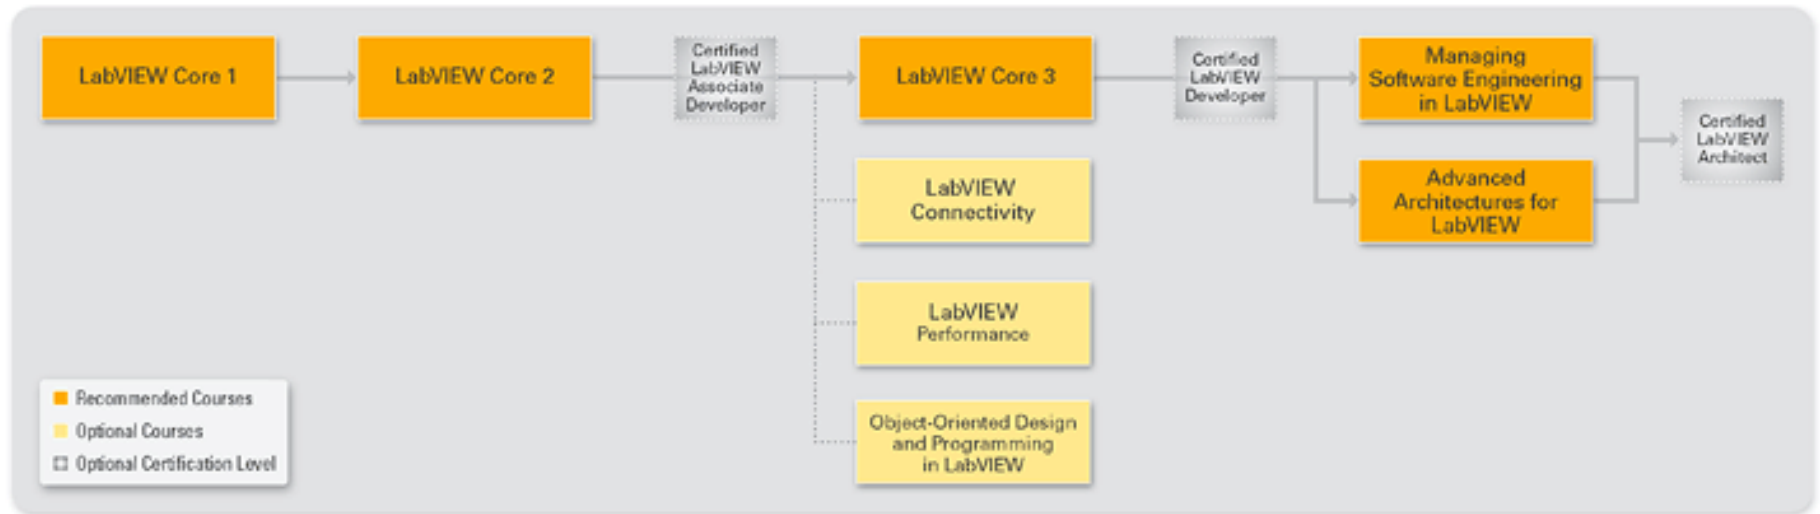

Various Inter-process Communication Methods

	Same target Same application instance	Same target, different application instances OR Different targets on network
