

# Getting Started in Fixed/Random Effects Models using R

(ver. 0.1-*Draft*)

Oscar Torres-Reyna

*Data Consultant*  
*otorres@princeton.edu*

Fall 2010

Panel data (also known as longitudinal or cross-sectional time-series data) is a dataset in which the behavior of entities are observed across time.

These entities could be states, companies, individuals, countries, etc.

Panel data looks like this

country	year	Y	X1	X2	X3
1	2000	6.0	7.8	5.8	1.3
1	2001	4.6	0.6	7.9	7.8
1	2002	9.4	2.1	5.4	1.1
2	2000	9.1	1.3	6.7	4.1
2	2001	8.3	0.9	6.6	5.0
2	2002	0.6	9.8	0.4	7.2
3	2000	9.1	0.2	2.6	6.4
3	2001	4.8	5.9	3.2	6.4
3	2002	9.1	5.2	6.9	2.1

For a brief introduction on the theory behind panel data analysis please see the following document:  
<http://dss.princeton.edu/training/Panel101.pdf>

The contents of this document rely heavily on the document:  
“Panel Data Econometrics in R: the plm package” <http://cran.r-project.org/web/packages/plm/vignettes/plm.pdf> and notes from the ICPSR’s Summer Program in Quantitative Methods of Social Research (summer 2010)

# Exploring panel data

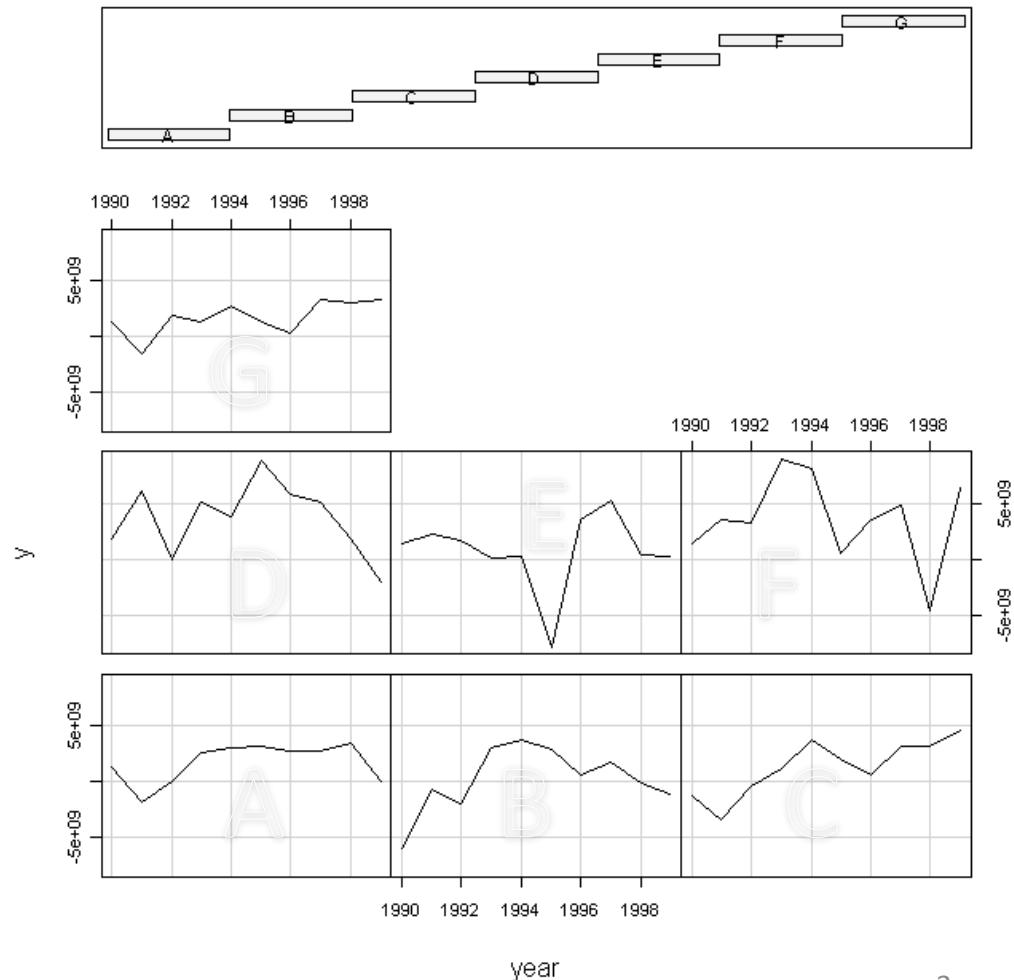

```
library(foreign)
Panel <- read.dta("http://dss.princeton.edu/training/Panel101.dta")
coplot(y ~ year|country, type="l", data=Panel)      # Lines
coplot(y ~ year|country, type="b", data=Panel)      # Points and lines
```

# Bars at top indicates corresponding graph (i.e. countries)

from left to right starting on the bottom row

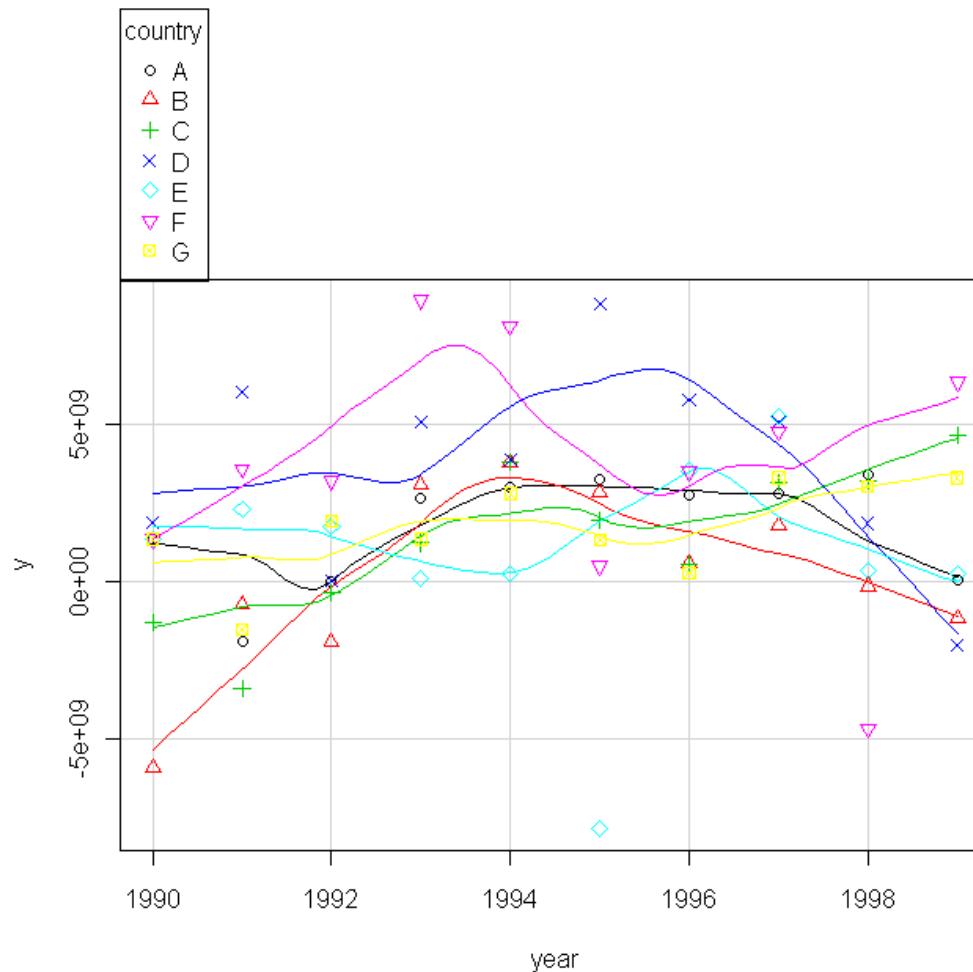

(Muenchen/Hilbe:355)

Given: country

# Exploring panel data

```
library(foreign)
Panel <- read.dta("http://dss.princeton.edu/training/Panel101.dta")
library(car)
scatterplot(y~year|country, boxplots=FALSE, smooth=TRUE, reg.line=FALSE, data=Panel)
```

# **FIXED-EFFECTS MODEL**

*(Covariance Model, Within Estimator,  
Individual Dummy Variable Model, Least  
Squares Dummy Variable Model)*

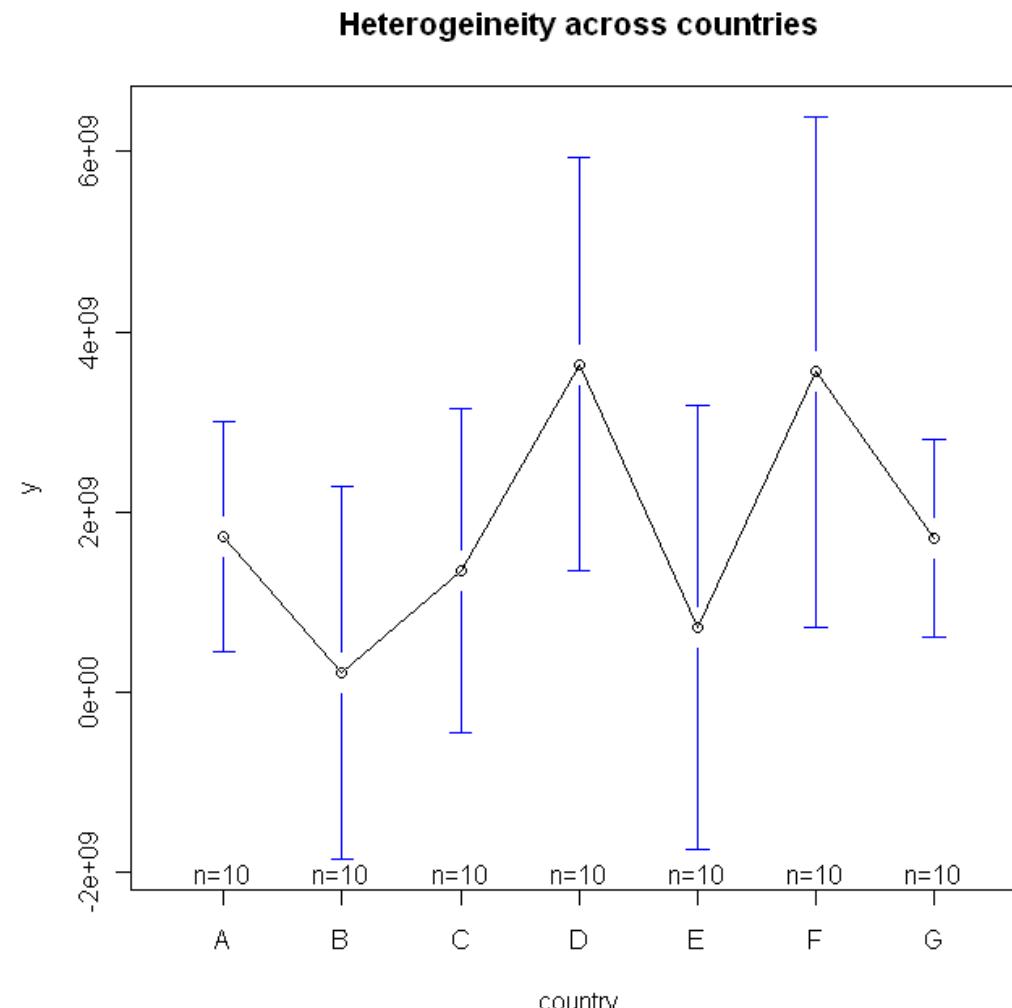

# Fixed effects: Heterogeneity across countries (or entities)

```
library(foreign)
Panel <- read.dta("http://dss.princeton.edu/training/Panel101.dta")
library(gplots)
plotmeans(y ~ country, main="Heterogeneity across countries", data=Panel)

# plotmeans draw a 95%
confidence interval
around the means

detach("package:gplots")

# Remove package 'gplots'
from the workspace
```

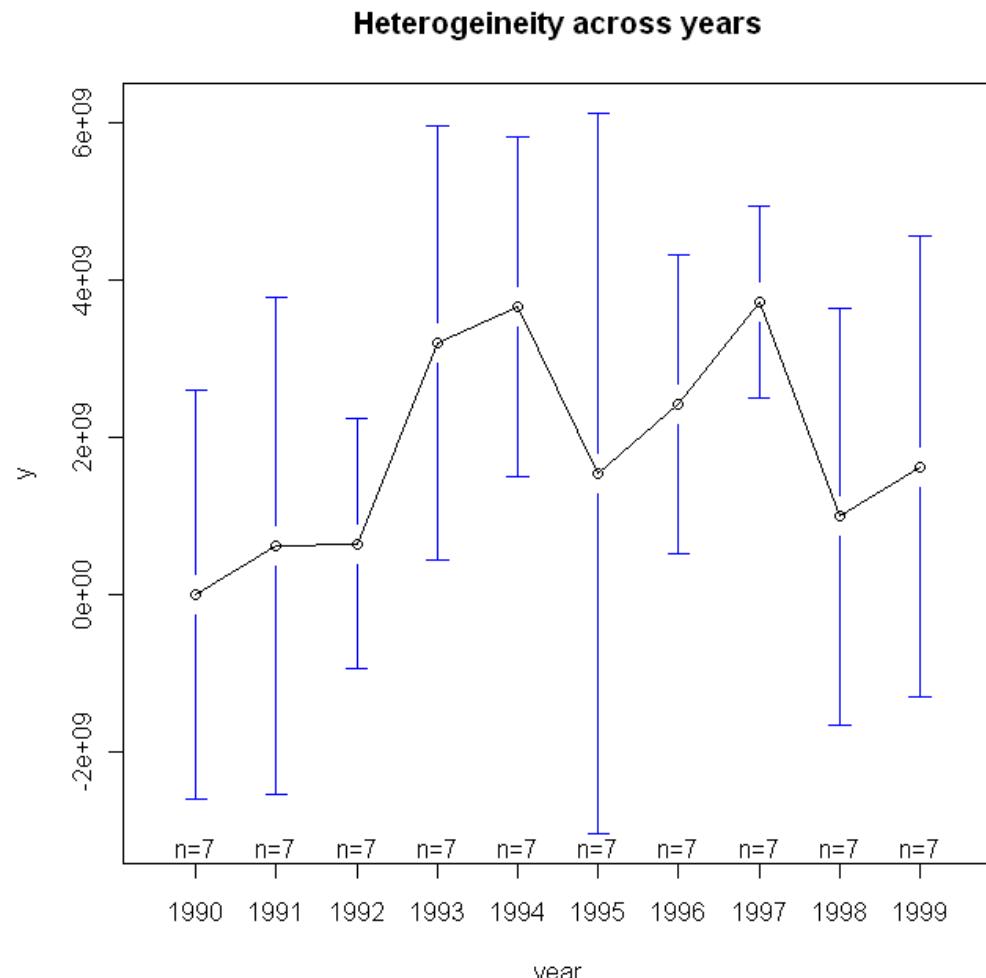

# Fixed effects: Heterogeneity across years

```
library(foreign)
Panel <- read.dta("http://dss.princeton.edu/training/Panell01.dta")
library(gplots)
plotmeans(y ~ year, main="Heterogeneity across years", data=Panel)

# plotmeans draw a 95%
confidence interval
around the means

detach("package:gplots")

# Remove package 'gplots'
from the workspace
```

# OLS regression

```
> library(foreign)
> Panel <- read.dta("http://dss.princeton.edu/training/Panel101.dta")
> ols <- lm(y ~ x1, data=Panel)
> summary(ols)
```

```
Call:
lm(formula = y ~ x1, data = Panel)

Residuals:
    Min      1Q  Median      3Q     Max 
-9.546e+09 -1.578e+09  1.554e+08  1.422e+09  7.183e+09 

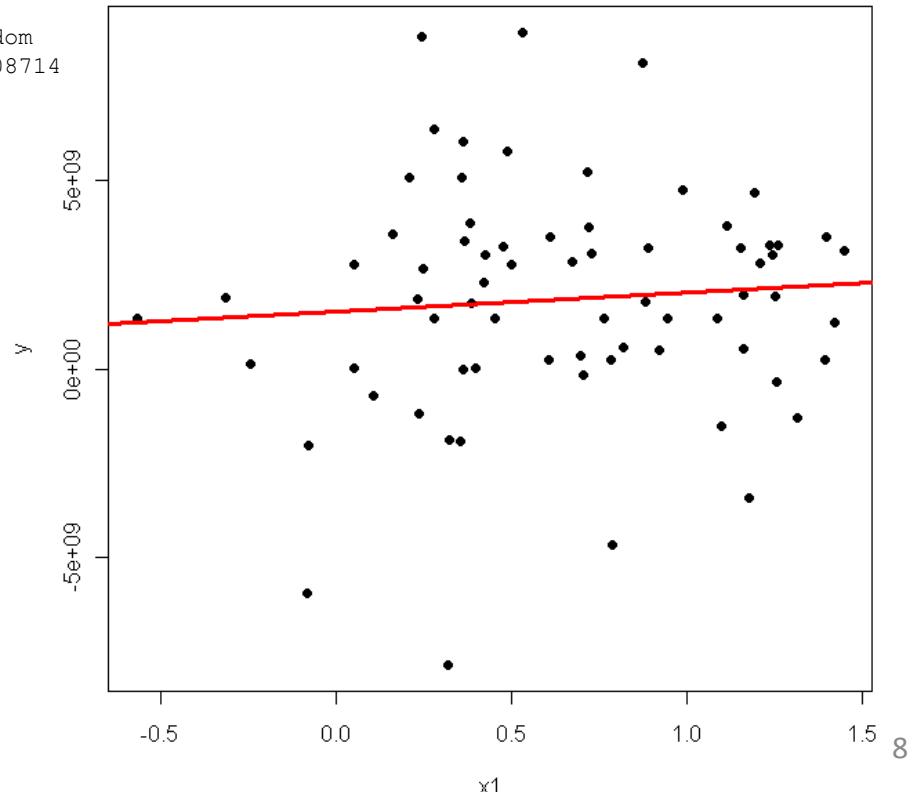

Coefficients:
            Estimate Std. Error t value Pr(>|t|)    
(Intercept) 1.524e+09  6.211e+08   2.454   0.0167 *  
x1          4.950e+08  7.789e+08   0.636   0.5272    
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

```
Residual standard error: 3.028e+09 on 68 degrees of freedom
Multiple R-squared: 0.005905, Adjusted R-squared: -0.008714 
F-statistic: 0.4039 on 1 and 68 DF, p-value: 0.5272
```

```
> yhat <- ols$fitted
```

```
> plot(Panel$x1, Panel$y, pch=19, xlab="x1", ylab="y")
> abline(lm(Panel$y~Panel$x1), lwd=3, col="red")
```

Regular OLS regression does  
not consider heterogeneity  
across groups or time

## Fixed effects using Least squares dummy variable model

```
> library(foreign)
>Panel <- read.dta("http://dss.princeton.edu/training/Panel101.dta")

> fixed.dum <- lm(y ~ x1 + factor(country) - 1, data=Panel)
> summary(fixed.dum)

Call:
lm(formula = y ~ x1 + factor(country) - 1, data = Panel)

Residuals:
    Min      1Q  Median      3Q     Max 
-8.634e+09 -9.697e+08  5.405e+08  1.386e+09  5.612e+09 

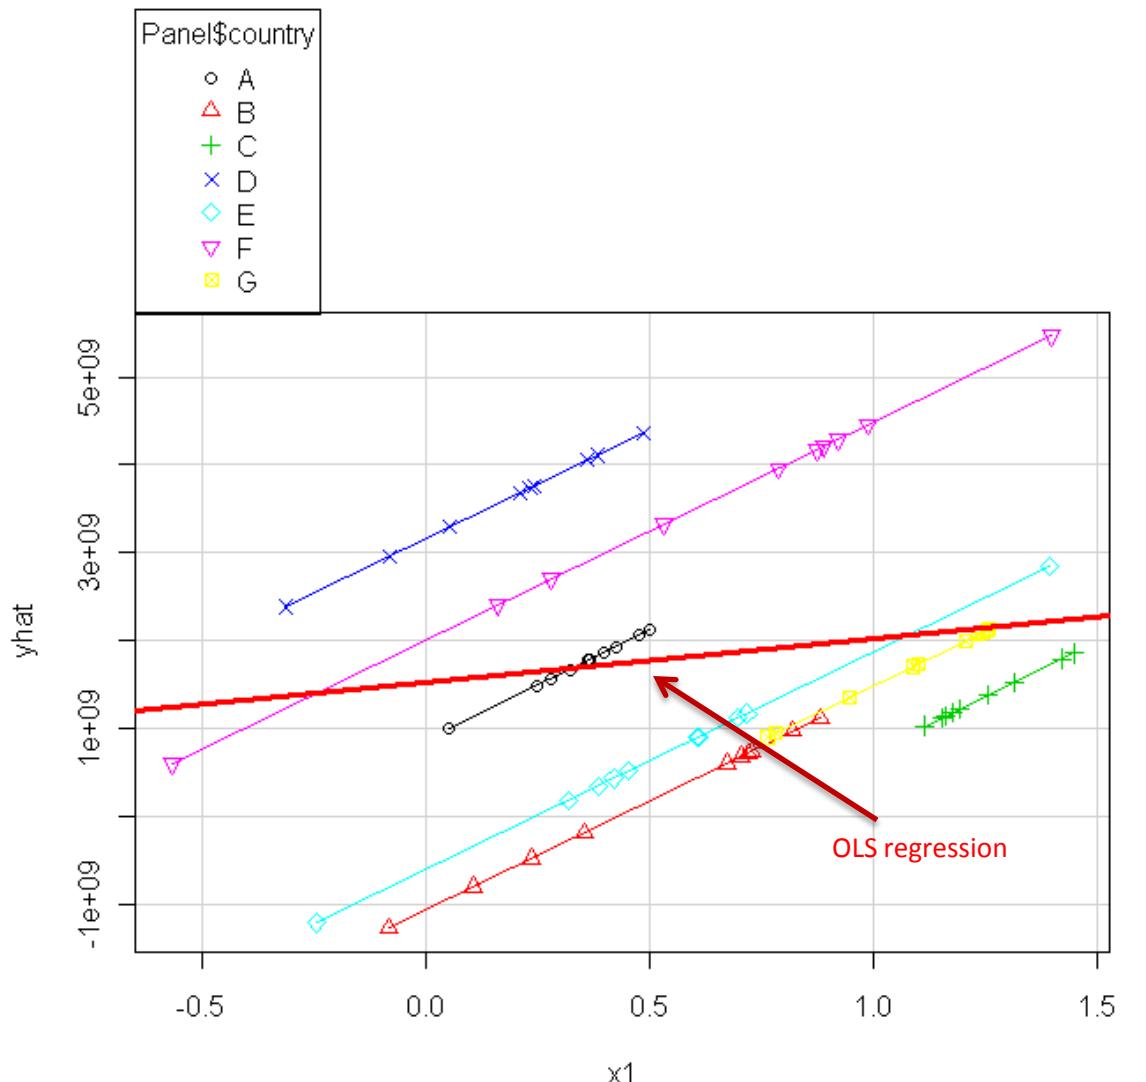

Coefficients:
            Estimate Std. Error t value Pr(>|t|)    
x1          2.476e+09  1.107e+09  2.237 0.02889 *  
factor(country)A 8.805e+08  9.618e+08  0.916 0.36347

factor(country)C -1.723e+09  1.632e+09 -1.056 0.29508  
factor(country)D  3.163e+09  9.095e+08  3.478 0.00093 *** 
factor(country)E -6.026e+08  1.064e+09 -0.566 0.57329  
factor(country)F  2.011e+09  1.123e+09  1.791 0.07821 .  
factor(country)G -9.847e+08  1.493e+09 -0.660 0.51190  
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 2.796e+09 on 62 degrees of freedom
Multiple R-squared:  0.4402,    Adjusted R-squared:  0.368 
F-statistic: 6.095 on 8 and 62 DF,  p-value: 8.892e-06
```

For the theory behind fixed effects, please see <http://dss.princeton.edu/training/Panel101.pdf>

# Least squares dummy variable model

```
> yhat <- fixed.dum$fitted  
> library(car)  
> scatterplot(yhat~Panel$x1|Panel$country, boxplots=FALSE, xlab="x1", ylab="yhat", smooth=FALSE)  
> abline(lm(Panel$y~Panel$x1), lwd=3, col="red")
```

# Comparing OLS vs LSDV model

Each component of the factor variable (country) is absorbing the effects particular to each country. Predictor  $x_1$  was not significant in the OLS model, once controlling for differences across countries,  $x_1$  became significant in the OLS\_DUM (i.e. LSDV model).

```
> library(apsrtable)
> apsrtable(ols,fixed.dum, model.names = c("OLS", "OLS_DUM")) # Displays a table in Latex form
```

```
\begin{table}[!ht]

> fixed <- plm(y ~ x1, data=Panel, index=c("country", "year"), model="within")
> summary(fixed)
```

Oneway (individual) effect Within Model

Predictor variable(s)

Fixed effects option

Call:

```
plm(formula = y ~ x1, data = Panel, model = "within", index = c("country",
  "year"))
```

Balanced Panel: n=7, T=10, N=70

n = # of groups/panels, T = # years, N = total # of observations

Residuals :

Min.	1st Qu.	Median	Mean	3rd Qu.	Max.
-8.63e+09	-9.70e+08	5.40e+08	1.81e-10	1.39e+09	5.61e+09

Coefficients :

	Estimate	Std. Error	t-value	Pr(> t )
x1	2475617827	1106675594	2.237	0.02889 *

---

Signif. codes: 0 '\*\*\*\*' 0.001 '\*\*\*' 0.01 '\*\*' 0.05 '\*' 0.1 '.' 1

Total Sum of Squares: 5.2364e+20

Residual Sum of Squares: 4.8454e+20

R-Squared : 0.074684

Adj. R-Squared : 0.066148

F-statistic: 5.00411 on 1 and 62 DF, p-value: 0.028892

$\text{Pr}(>|t|)$ = Two-tail p-values test the hypothesis that each coefficient is different from 0. To reject this, the p-value has to be lower than 0.05 (95%, you could choose also an alpha of 0.10), if this is the case then you can say that the variable has a significant influence on your dependent variable (y)

The coeff of x1 indicates how much Y changes overtime, on average per country, when X increases by one unit.

```
> fixef(fixed) # Display the fixed effects (constants for each country)
```

A	B	C	D	E	F
880542404	-1057858363	-1722810755	3162826897	-602622000	2010731793
G					
-984717493					

```
> pFtest(fixed, ols) # Testing for fixed effects, null: OLS better than fixed
```

F test for individual effects

```
data: y ~ x1
F = 2.9655, df1 = 6, df2 = 62, p-value = 0.01307
alternative hypothesis: significant effects
```

If this number is < 0.05 then your model is ok. This is a test (F) to see whether all the coefficients in the model are different than zero.

If the p-value is < 0.05 then the fixed effects model is a better choice

# **RANDOM-EFFECTS MODEL**

*(Random Intercept, Partial Pooling Model)*

# Random effects (using plm)

```
> random <- plm(y ~ x1, data=Panel, index=c("country", "year"), model="random")
> summary(random)
```

Oneway (individual) effect Random Effect Model  
 (Swamy-Arora's transformation)

Call:

```
plm(formula = y ~ x1, data = Panel, model = "random", index = c("country",
    "year"))
```

Balanced Panel: n=7, T=10, N=70

Effects:

	var	std.dev	share
idiosyncratic	7.815e+18	2.796e+09	0.873
individual	1.133e+18	1.065e+09	0.127
theta:	0.3611		

Interpretation of the coefficients is tricky since they include both the within-entity and between-entity effects. In the case of TSCS data represents the average effect of X over Y when X changes across time and between countries by one unit.

Outcome variable

Random effects (using plm)

Predictor variable(s)

Panel setting

Random effects option

n = # of groups/panels, T = # years, N = total # of observations

Residuals :

Min.	1st Qu.	Median	Mean	3rd Qu.	Max.

$Pr(>|t|)$ =Two-tail p-values test the hypothesis that each coefficient is different from 0. To reject this, the p-value has to be lower than 0.05 (95%, you could choose also an alpha of 0.10), if this is the case then you can say that the variable has a significant influence on your dependent variable (y)

Total Sum of Squares: 5.6595e+20

Residual Sum of Squares: 5.5048e+20

R-Squared : 0.02733

Adj. R-Squared : 0.026549

F-statistic: 1.91065 on 1 and 68 DF, p-value: 0.17141

If this number is < 0.05 then your model is ok. This is a test (F) to see whether all the coefficients in the model are different than zero.

# Setting as panel data (an alternative way to run the above model

```
Panel.set <- plm.data(Panel, index = c("country", "year"))
```

```
# Random effects using panel setting (same output as above)
```

```
random.set <- plm(y ~ x1, data = Panel.set, model="random")
summary(random.set)
```

***FIXED OR RANDOM?***

To decide between fixed or random effects you can run a Hausman test where the null hypothesis is that the preferred model is random effects vs. the alternative the fixed effects (see Green, 2008, chapter 9). It basically tests whether the unique errors ( $u_i$ ) are correlated with the regressors, the null hypothesis is they are not.

Run a fixed effects model and save the estimates, then run a random model and save the estimates, then perform the test. If the p-value is significant (for example <0.05) then use fixed effects, if not use random effects.

```
> phtest(fixed, random)
```

Hausman Test

```
data: y ~ x1  
chisq = 3.674, df = 1, p-value = 0.05527  
alternative hypothesis: one model is inconsistent
```

If this number is < 0.05 then use fixed effects

# *OTHER TESTS/ DIAGNOSTICS*

# Testing for time-fixed effects

```
> library(plm)
> fixed <- plm(y ~ x1, data=Panel, index=c("country", "year"),
model="within")
> fixed.time <- plm(y ~ x1 + factor(year), data=Panel, index=c("country",
"year"), model="within")
> summary(fixed.time)
Oneway (individual) effect Within Model

Call:

> # Breusch-Pagan Lagrange Multiplier for random effects. Null is no panel effect (i.e. OLS better).

> plmtest(pool, type=c("bp"))

Lagrange Multiplier Test - (Breusch-Pagan)

data: y ~ x1
chisq = 2.6692, df = 1, p-value = 0.1023
alternative hypothesis: significant effects
```

The LM test helps you decide between a random effects regression and a simple OLS regression.

The null hypothesis in the LM test is that variances across entities is zero. This is, no significant difference across units (i.e. no panel effect). (<http://dss.princeton.edu/training/Panel101.pdf>)

Here we failed to reject the null and conclude that random effects is not appropriate. This is, no evidence of significant differences across countries, therefore you can run a simple OLS regression.

## Testing for cross-sectional dependence/contemporaneous correlation: using Breusch-Pagan LM test of independence and Pasaran CD test

According to Baltagi, cross-sectional dependence is a problem in macro panels with long time series. This is not much of a problem in micro panels (few years and large number of cases).

The null hypothesis in the B-P/LM and Pasaran CD tests of independence is that residuals across entities are not correlated. B-P/LM and Pasaran CD (cross-sectional dependence) tests are used to test whether the residuals are correlated across entities\*. Cross-sectional dependence can lead to bias in tests results (also called contemporaneous correlation).

```
> fixed <- plm(y ~ x1, data=Panel, index=c("country", "year"), model="within")  
  
> pcdtest(fixed, test = c("lm"))
```

Breusch-Pagan LM test for cross-sectional dependence in panels

```
data: formula  
chisq = 28.9143, df = 21, p-value = 0.1161  
alternative hypothesis: cross-sectional dependence
```

No cross-sectional dependence

```
> pcdtest(fixed, test = c("cd"))
```

Pesaran CD test for cross-sectional dependence in panels

```
data: formula  
z = 1.1554, p-value = 0.2479  
alternative hypothesis: cross-sectional dependence
```

\*Source: Hoechle, Daniel, "Robust Standard Errors for Panel Regressions with Cross-Sectional Dependence",  
[http://fmwww.bc.edu/repec/bocode/x/xtscce\\_paper.pdf](http://fmwww.bc.edu/repec/bocode/x/xtscce_paper.pdf)

## Testing for serial correlation

Serial correlation tests apply to macro panels with long time series. Not a problem in micro panels (with very few years). The null is that there is not serial correlation.

```
> pbgttest(fixed)
Loading required package: lmtest

Breusch-Godfrey/Wooldridge test for serial correlation in panel models

data: y ~ x1
chisq = 14.1367, df = 10, p-value = 0.1668
alternative hypothesis: serial correlation in idiosyncratic errors
```

No serial correlation

The Dickey-Fuller test to check for stochastic trends. The null hypothesis is that the series has a unit root (i.e. non-stationary). If unit root is present you can take the first difference of the variable.

```
> Panel.set <- plm.data(Panel, index = c("country", "year"))

> library(tseries)

> adf.test(Panel.set$y, k=2)

Augmented Dickey-Fuller Test

data: Panel.set$y
Dickey-Fuller = -3.9051, Lag order = 2, p-value = 0.01910
alternative hypothesis: stationary
```

If p-value < 0.05 then no unit roots present.

# Testing for heteroskedasticity

The null hypothesis for the Breusch-Pagan test is homoskedasticity.

```
> library(lmtest)
> bptest(y ~ x1 + factor(country), data = Panel, studentize=F)

Breusch-Pagan test

data: y ~ x1 + factor(country)
BP = 14.6064, df = 7, p-value = 0.04139
```

Presence of heteroskedasticity

If heteroskedasticity is detected you can use robust covariance matrix to account for it. See the following pages.

# Controlling for heteroskedasticity: Robust covariance matrix estimation (Sandwich estimator)

The `--vcovHC`- function estimates three heteroskedasticity-consistent covariance estimators:

- "white1" - for general heteroskedasticity but no serial correlation. Recommended for random effects.
- "white2" - is "white1" restricted to a common variance within groups. Recommended for random effects.
- "arellano" - both heteroskedasticity and serial correlation. Recommended for fixed effects.

The following options apply\*:

- HC0 - heteroskedasticity consistent. The default.
- HC1, HC2, HC3 - Recommended for small samples. HC3 gives less weight to influential observations.
- HC4 - small samples with influential observations
- HAC - heteroskedasticity and autocorrelation consistent (type `?vcovHAC` for more details)

See the following pages for examples

# Controlling for heteroskedasticity: Random effects

```
> random <- plm(y ~ x1, data=Panel, index=c("country", "year"), model="random")

> coeftest(random)      # Original coefficients

t test of coefficients:

            Estimate Std. Error t value Pr(>|t|) 
(Intercept) 1037014284  790626206  1.3116  0.1941 
x1          1247001782  902145601  1.3823  0.1714 

> coeftest(random, vcovHC)      # Heteroskedasticity consistent coefficients

t test of coefficients:

            Estimate Std. Error t value Pr(>|t|) 
(Intercept) 1037014284  907983029  1.1421  0.2574 
x1          1247001782  828970247  1.5043  0.1371 

> coeftest(random, vcovHC(random, type = "HC3")) # Heteroskedasticity consistent coefficients, type 3

t test of coefficients:

            Estimate Std. Error t value Pr(>|t|) 
(Intercept) 1037014284  943438284  1.0992  0.2756 
x1          1247001782  867137585  1.4381  0.1550 

> # The following shows the HC standard errors of the coefficients

> t(sapply(c("HC0", "HC1", "HC2", "HC3", "HC4"), function(x) sqrt(diag(vcovHC(random, type = x)))))

            (Intercept)           x1
HC0      907983029 828970247
HC1      921238957 841072643
HC2      925403820 847733474
HC3      943438284 867137584
HC4      941376033 866024033

Standard errors given different types of HC.

```

```

> fixed <- plm(y ~ x1, data=Panel, index=c("country", "year"), model="within")

> coeftest(fixed)      # Original coefficients

t test of coefficients:

    Estimate Std. Error t value Pr(>|t|)
