LECTURE 2: DATA (PRE-)PROCESSING

Dr. Dhaval Patel CSE, IIT-Roorkee

• • • •

- □ In Previous Class,
 - We discuss various type of Data with examples

- In this Class,
 - We focus on Data pre-processing "an important milestone of the Data Mining Process"

Data analysis pipeline

Mining is not the only step in the analysis process

- Preprocessing: real data is noisy, incomplete and inconsistent.
 Data cleaning is required to make sense of the data
 - Techniques: Sampling, Dimensionality Reduction, Feature Selection.

 Post-Processing: Make the data actionable and useful to the user: Statistical analysis of importance & Visualization.

Data Preprocessing

- Attribute Values
- Attribute Transformation
 - Normalization (Standardization)
 - Aggregation
 - Discretization
- Sampling
- Dimensionality Reduction
- Feature subset selection
- Distance/Similarity Calculation
- Visualization

Attribute Values

Data is described using attribute values

Attribute Values

- Attribute values are numbers or symbols assigned to an attribute
- Distinction between attributes and attribute values
 - Same attribute can be mapped to different attribute values
 - Example: height can be measured in feet or meters
 - Different attributes can be mapped to the same set of values
 - Example: Attribute values for ID and age are integers
 - But properties of attribute values can be different
 - ID has no limit but age has a maximum and minimum value

Types of Attributes

- There are different types of attributes
 - Nominal
 - Examples: ID numbers, eye color, zip codes
 - Ordinal
 - Examples: rankings (e.g., taste of potato chips on a scale from 1-10), grades, height in {tall, medium, short}
 - Interval
 - Examples: calendar dates
 - Ratio
 - Examples: length, time, counts

Types of Attributes

Attribute Level	Transformation	Comments	
Nominal	Any permutation of values	If all employee ID numbers were reassigned, would it make any difference?	
Ordinal	An order preserving change of values, i.e., new_value = f(old_value) where f is a monotonic function.	An attribute encompassing the notion of good, better best can be represented equally well by the values	
Interval	<pre>new_value = a * old_value + b where a and b are constants</pre>	Calendar dates can be converted – financial vs. Gregorian etc.	
Ratio	new_value = a * old_value	Length can be measured in meters or feet.	

Discrete and Continuous Attributes

Discrete Attribute

- Has only a finite or countable infinite set of values
- Examples: zip codes, counts, or the set of words in a collection of documents
- Often represented as integer variables.

Continuous Attribute

- Has real numbers as attribute values
- Examples: temperature, height, or weight.
- Practically, real values can only be measured and represented using a finite number of digits.

Data Quality

Data has attribute values

Then,

How good our Data w.r.t. these attribute values?

Data Quality

- Examples of data quality problems:
 - Noise and outliers
 - Missing values
 - Duplicate data

A mistake or a millionaire?

Missing values

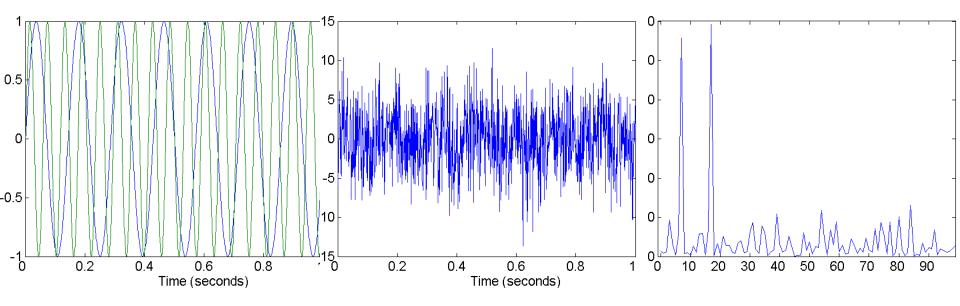

Inconsistent duplicate entries

Tid	Refund	Marital Status	Taxable Income	Cheat	
1	Yes	Single	125K	No	
2	No	Married	100K	No	
3	No	Single	70K	No	
4	Yes	Married	120K	No	
5	No	Divorced	10000K	Yes	
6	No	NULL	60K	No	
7	Yes	Divorced	220K	NULL	
8	No	Single	85K	Yes	
9	No	Married	90K	No	
9	No	Single	90K	No	

Data Quality: Noise

Two Sine Waves

- Noise refers to modification of original values
 - Examples: distortion of a person's voice when talking on

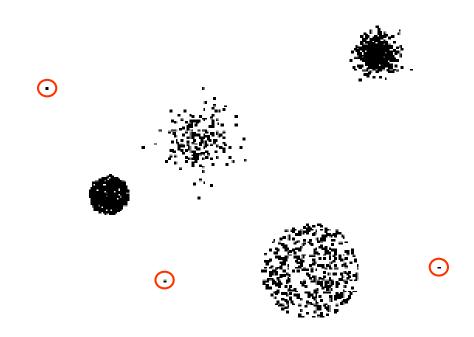

Two Sine Waves + Noise

Frequency Plot (FFT)

Data Quality: Outliers

 Outliers are data objects with characteristics that are considerably different than most of the other data objects in the data set

Data Quality: Missing Values

- Reasons for missing values
 - Information is not collected
 (e.g., people decline to give their age and weight)
 - Attributes may not be applicable to all cases (e.g., annual income is not applicable to children)
- Handling missing values
 - Eliminate Data Objects
 - Estimate Missing Values
 - Ignore the Missing Value During Analysis
 - Replace with all possible values (weighted by their probabilities)

Data Quality: Duplicate Data

- Data set may include data objects that are duplicates, or almost duplicates of one another
 - Major issue when merging data from heterogeous sources
- Examples:
 - Same person with multiple email addresses
- Data cleaning
 - Process of dealing with duplicate data issues

Data Quality: Handle Noise(Binning)

- Binning
 - sort data and partition into (equi-depth) bins
 - smooth by bin means, bin median, bin boundaries, etc.
- Regression
 - smooth by fitting a regression function
- Clustering
 - detect and remove outliers
- Combined computer and human inspection
 - detect suspicious values automatically and check by human

Data Quality: Handle Noise(Binning)

- Equal-width binning
 - Divides the range into N intervals of equal size
 - Width of intervals:
 - Simple
 - Outliers may dominate result
- Equal-depth binning
 - Divides the range into N intervals,
 each containing approximately same number of records
 - Skewed data is also handled well

Simple Methods: Binning

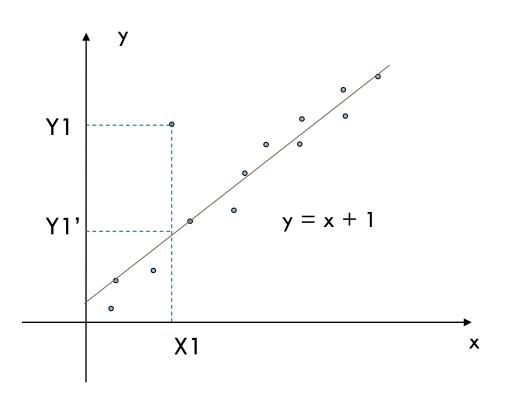

Data Quality: Handle Noise(Binning)

Example: Sorted price values 4, 8, 9, 15, 21, 21, 24, 25, 26, 28, 29, 34

- * Partition into three (equi-depth) bins
 - Bin 1: 4, 8, 9, 15
 - Bin 2: 21, 21, 24, 25
 - Bin 3: 26, 28, 29, 34
- * Smoothing by bin means
 - Bin 1: 9, 9, 9, 9
 - Bin 2: 23, 23, 23, 23
 - Bin 3: 29, 29, 29, 29
- Smoothing by bin boundaries
 - Bin 1: 4, 4, 4, 15
 - Bin 2: 21, 21, 25, 25
 - Bin 3: 26, 26, 26, 34

Data Quality: Handle Noise(Regression)

- Replace noisy or missing values by predicted values
- Requires model of attribute dependencies (maybe wrong!)
- Can be used for data smoothing or for handling missing data

Data Quality

There are many more noise handling techniques

> Imputation

Data Transformation

Data has an attribute values

Then,

Can we compare these attribute values?

For Example: Compare following two records

- (1) (5.9 ft, 50 Kg)
- (2) (4.6 ft, 55 Kg)

Vs.

- (3) (5.9 ft, 50 Kg)
- (4) (5.6 ft, 56 Kg)

We need Data Transformation to makes different dimension(attribute) records comparable ...

Data Transformation Techniques

- Normalization: scaled to fall within a small, specified range.
 - min-max normalization
 - z-score normalization
 - normalization by decimal scaling

- Centralization:
 - Based on fitting a distribution to the data
 - Distance function between distributions
 - KL Distance
 - Mean Centering

Data Transformation: Normalization

min-max normalization

$$v' = \frac{v - min}{max - min} (new _max - new _min) + new _min$$

z-score normalization

$$v' = \frac{v - mean}{stand _dev}$$

normalization by decimal scaling

$$v' = \frac{v}{10^{j}}$$
 Where j is the smallest integer such that Max(|v'|)<1

Example: Data Transformation

- Assume, min and max value for height and weight.
- Now, apply Min-Max normalization to both attributes as given follow

```
(1) (5.9 ft, 50 Kg)
(2) (4.6 ft, 55 Kg)
Vs.
(3) (5.9 ft, 50 Kg)
(4) (5.6 ft, 56 Kg)
```

- Compare your results...

Data Transformation: Aggregation

 Combining two or more attributes (or objects) into a single attribute (or object)

- Purpose
 - Data reduction
 - Reduce the number of attributes or objects
 - Change of scale
 - Cities aggregated into regions, states, countries, etc
 - More "stable" data
 - Aggregated data tends to have less variability

Data Transformation: Discretization

- Motivation for Discretization
 - Some data mining algorithms only accept categorical attributes

May improve understandability of patterns

Data Transformation: Discretization

□ Task

- Reduce the number of values for a given continuous attribute by partitioning the range of the attribute into intervals
- Interval labels replace actual attribute values

□ Methods

- Binning (as explained earlier)
- Cluster analysis (will be discussed later)
- Entropy-based Discretization (Supervised)

Simple Discretization Methods: Binning

- Equal-width (distance) partitioning:
 - $lue{}$ Divides the range into N intervals of equal size: uniform grid
 - if A and B are the lowest and highest values of the attribute, the width of intervals will be: W = (B A)/N.
 - The most straightforward, but outliers may dominate presentation
 - Skewed data is not handled well.

- Equal-depth (frequency) partitioning:
 - Divides the range into N intervals, each containing approximately same number of samples
 - Good data scaling
 - Managing categorical attributes can be tricky.

Information/Entropy

□ Given probabilitites p_1 , p_2 , .., p_s whose sum is 1, *Entropy* is defined as:

$$H(p_1, p_2, ..., p_s) = \sum_{i=1}^{s} (p_i log(1/p_i))$$

- Entropy measures the amount of randomness or surprise or uncertainty.
- Only takes into account non-zero probabilities

Entropy-Based Discretization

Given a set of samples S, if S is partitioned into two intervals
 S1 and S2 using boundary T, the entropy after partitioning is

$$E(S,T) = \frac{|S_1|}{|S|} Ent(S_1) + \frac{|S_2|}{|S|} Ent(S_2)$$

- The boundary that minimizes the entropy function over all possible boundaries is selected as a binary discretization.
- The process is recursively applied to partitions obtained until some stopping criterion is met, e.g.,

$$Ent(S) - E(T,S) > \delta$$

 Experiments show that it may reduce data size and improve classification accuracy

Data Sampling

Data may be **Big**

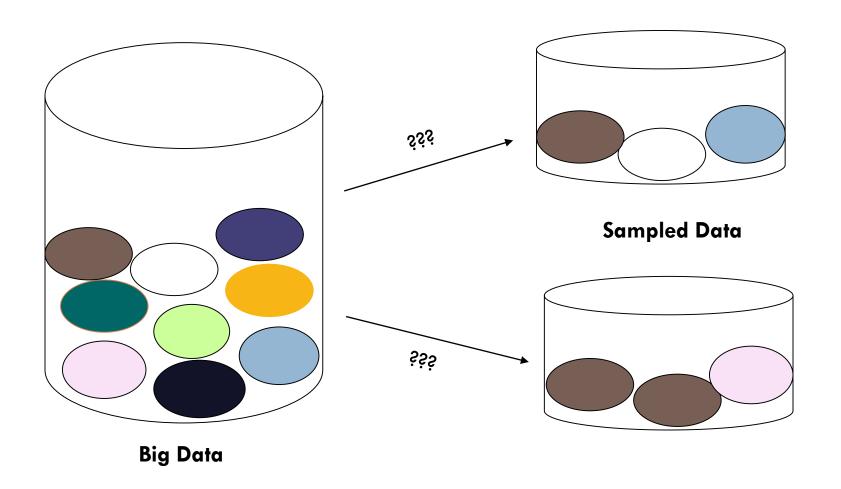

Then,

Can we make is it **Small** by selecting some part of it?

Data Sampling can do this...

"Sampling is the main technique employed for data selection."

Data Sampling

Data Sampling

- Statisticians sample because obtaining the entire set of data of interest is too expensive or time consuming.
 - Example: What is the average height of a person in loanning?
 - We cannot measure the height of everybody
- Sampling is used in <u>data mining</u> because processing the entire set of data of interest is too expensive or time consuming.
 - Example: We have 1M documents. What fraction has at least 100 words in common?
 - Computing number of common words for all pairs requires 10[^]12 comparisons

Data Sampling ...

- The <u>key principle</u> for effective sampling is the following:
 - Using a sample will work almost as well as using the entire data sets, if the sample is representative
 - A sample is representative if it has approximately the same property (of interest) as the original set of data
 - Otherwise we say that the sample introduces some bias
 - What happens if we take a sample from the university campus to compute the average height of a person at loanning?

Types of Sampling

- Simple Random Sampling
 - There is an equal probability of selecting any particular item
- Sampling without replacement
 - As each item is selected, it is removed from the population
- Sampling with replacement
 - Objects are not removed from the population as they are selected for the sample.
 - In sampling with replacement, the same object can be picked up more than once
- Stratified sampling
 - Split the data into several partitions; then draw random samples from each partition

Types of Sampling

- Simple Random Sampling
 - There is an equal probability of selecting any particular item
- Sampling without replacement
 - As each item is selected, it is removed from the population
- Sampling with replacement
 - Objects are not removed from the population as they are selected for the sample.
 - In sampling with replacement, the same object can be picked up more than once. This makes analytical computation of probabilities easier
 - E.g., we have 100 people, 51 are women P(W) = 0.51, 49 men P(M) = 0.49. If I pick two persons what is the probability P(W,W) that both are women?
 - Sampling with replacement: $P(W,W) = 0.51^2$
 - Sampling without replacement: P(W,W) = 51/100 * 50/99

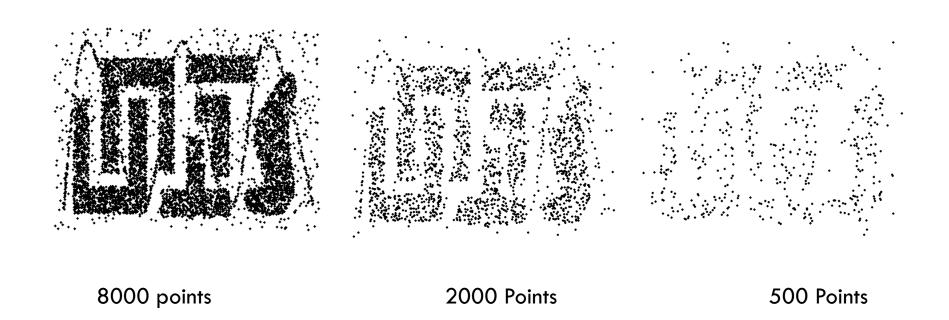

Types of Sampling

- Stratified sampling
 - Split the data into several groups; then draw random samples from each group.
 - Ensures that both groups are represented.
 - Example 1. I want to understand the differences between legitimate and fraudulent credit card transactions. 0.1% of transactions are fraudulent. What happens if I select 1000 transactions at random?
 - I get 1 fraudulent transaction (in expectation). Not enough to draw any conclusions. Solution: sample 1000 legitimate and 1000 fraudulent transactions

Probability Reminder: If an event has probability p of happening and I do N trials, the expected number of times the event occurs is pN

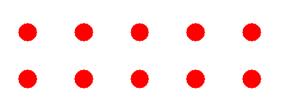

- Example 2. I want to answer the question: Do web pages that are linked have on average more words in common than those that are not? I have 1M pages, and 1M links, what happens if I select 10K pairs of pages at random?
 - Most likely I will not get any links. Solution: sample 10K random pairs, and 10K links

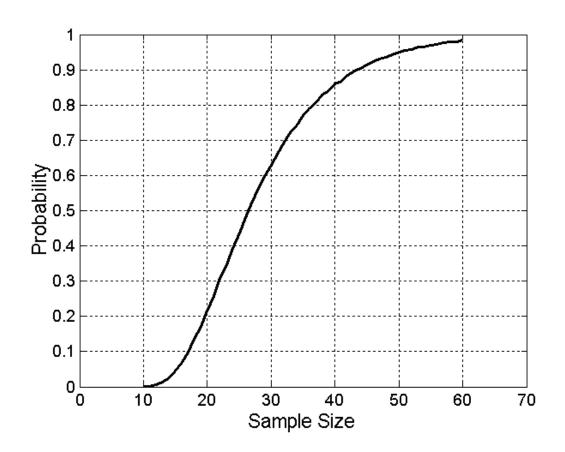

Sample Size

Sample Size

□ What sample size is necessary to get at least one object from each of 10 groups.

A data mining challenge

- You have N integers and you want to sample one integer uniformly at random. How do you do that?
- The integers are coming in a stream: you do not know the size of the stream in advance, and there is not enough memory to store the stream in memory. You can only keep a constant amount of integers in memory
- □ How do you sample?
 - Hint: if the stream ends after reading n integers the last integer in the stream should have probability 1/n to be selected.
- Reservoir Sampling:
 - Standard interview question for many companies

Reservoir Sampling

```
array R[k]; //
result integer i, j;
// fill the reservoir array
for each i in 1 to k do
     R[i] := S[i]
done;
for each i in k+1 to length(S) do
     j := random(1, i);
     if j \le k then
       R[i] := S[i]
     fi done
```

Reservoir Sampling

- Algorithm: With probability 1/n select the n-th item of the stream and replace the previous choice.
- Claim: Every item has probability 1/N to be selected after N items have been read.
- Proof
 - What is the probability of the n-the item to be selected?
 - $\frac{1}{n}$
 - What is the probability of the n-th items to survive for N-n rounds?
 - $\left(1-\frac{1}{n+1}\right)\left(1-\frac{1}{n+2}\right)\cdots\left(1-\frac{1}{N}\right)$

Reservoir sampling

Do you know "Fisher-Yates shuffle"

- S is an array with n number, a is also an array of size
- □ $a[0] \leftarrow S[0]$ for i from 1 to n - 1 do $r \leftarrow random (0 .. i)$ $a[i] \leftarrow a[r]$ $a[r] \leftarrow S[i]$

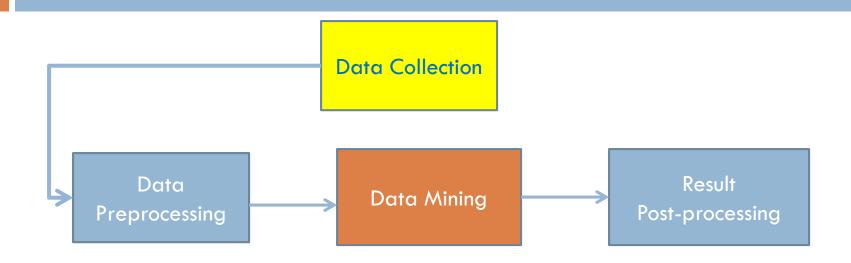

A (detailed) data preprocessing example

Suppose we want to mine the comments/reviews of people on <u>Yelp</u> and <u>Foursquare</u>.

Example: Data Collection

- Today there is an abundance of data online
 - Facebook, Twitter, Wikipedia, Web, etc...
- We can extract interesting information from this data, but first we need to collect it
 - Customized crawlers, use of public APIs
 - Additional cleaning/processing to parse out the useful parts
 - Respect of crawling etiquette

Example: Mining Task

- Collect all reviews for the top-10 most reviewed restaurants in NY in Yelp
 - (thanks to Sahishnu)

- Find few terms that best describe the restaurants.
- Algorithm?

Example: Data

- I heard so many good things about this place so I was pretty juiced to try it. I'm from Cali and I heard Shake Shack is comparable to IN-N-OUT and I gotta say, Shake Shake wins hands down. Surprisingly, the line was short and we waited about 10 MIN. to order. I ordered a regular cheeseburger, fries and a black/white shake. So yummerz. I love the location too! It's in the middle of the city and the view is breathtaking. Definitely one of my favorite places to eat in NYC.
- I'm from California and I must say, Shake Shack is better than IN-N-OUT, all day, err'day.
- Would I pay \$15+ for a burger here? No. But for the price point they are asking for, this is a definite bang for your buck (though for some, the opportunity cost of waiting in line might outweigh the cost savings) Thankfully, I came in before the lunch swarm descended and I ordered a shake shack (the special burger with the patty + fried cheese & portabella topping) and a coffee milk shake. The beef patty was very juicy and snugly packed within a soft potato roll. On the downside, I could do without the fried portabella-thingy, as the crispy taste conflicted with the juicy, tender burger. How does shake shack compare with in-and-out or 5-guys? I say a very close tie, and I think it comes down to personal affliations. On the shake side, true to its name, the shake was well churned and very thick and luscious. The coffee flavor added a tangy taste and complemented the vanilla shake well. Situated in an open space in NYC, the open air sitting allows you to munch on your burger while watching people zoom by around the city. It's an oddly calming experience, or perhaps it was the food coma I was slowly falling into. Great place with food at a great price.

Example: First cut

- Do simple processing to "normalize" the data (remove punctuation, make into lower case, clear white spaces, other?)
- Break into words, keep the most popular words

Example: IDF

- Important words are the ones that are unique to the document (differentiating) compared to the rest of the collection
 - All reviews use the word "like". This is not interesting
 - We want the words that characterize the specific restaurant
- Document Frequency DF(w): fraction of documents that contain word w.
 - DF(w) D(w): num of docs that contain word w D: total number of documents
- \Box Inverse Document Frequency IDF(w):

$$IDF(w) = \log\left(\frac{1}{DF(w)}\right)$$

- \square Maximum when unique to one document : $IDF(w) = \log(D)$
- \square Minimum when the word is common to all documents: IDF(w) = 0

Example: TF-IDF

- The words that are best for describing a document are the ones that are important for the document, but also unique to the document.
- TF(w,d): term frequency of word w in document d
 - Number of times that the word appears in the document
 - Natural measure of importance of the word for the document
- □ IDF(w): inverse document frequency
 - Natural measure of the uniqueness of the word w
- \Box TF-IDF(w,d) = TF(w,d) \times IDF(w)

Example: Third cut

Ordered by TF-IDF

Example: Third cut

- TF-IDF takes care of stop words as well
- We do not need to remove the stop words since they will get IDF(w) = 0

Example: Decisions, decisions...

- When mining real data you often need to make some
 - What data should we collect? How much? For how long?
 - Should we throw out some data that does not seem to be useful?

An actual review

- Too frequent data (stop words), too infrequent (errors?), erroneous data, missing data, outliers
- How should we weight the different pieces of data?
- Most decisions are application dependent. Some information may be lost but we can usually live with it (most of the times)
- Dealing with real data is hard...

Dimensionality Reduction

Each record has many attributes

useful, useless or correlated

Then,

Can we select some small subset of attributes?

Dimensionality Reduction can do this....

Dimensionality Reduction

■ Mhy is

- When dimensionality increases, data becomes increasingly sparse in the space that it occupies
- Curse of Dimensionality: Definitions of density and distance between points, which is critical for clustering and outlier detection, become less meaningful

Objectives:

- Avoid curse of dimensionality
- Reduce amount of time and memory required by data mining algorithms
- Observation: Certain Dimensions are correlated

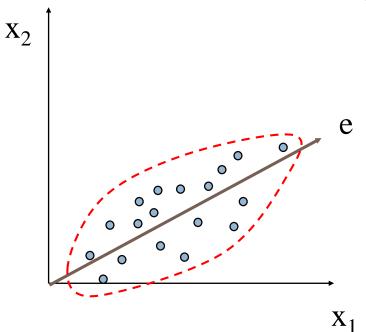

Dimensionality Reduction

- Allow data to be more easily visualized
- May help to eliminate irrelevant features or reduce noise

- Techniques
 - Principle Component Analysis or Singular Value Decomposition
 - (Mapping Data to New Space): Wavelet Transform
 - Others: supervised and non-linear techniques

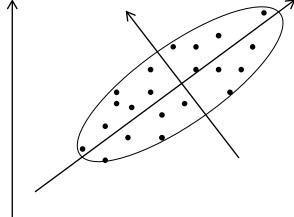

Principal Components Analysis: Intuition

- Goal is to find a projection that captures the largest amount of variation in data
- □ Find the eigenvectors of the covariance matrix
- The eigenvectors define the new space

Principal Component Analysis (PCA)

- Eigen Vectors show the direction of axes of a fitted ellipsoid
- Eigen Values show the significance of the corresponding axis
- □ The larger the Eigen value, the more separation
 - between mapped data
- For high dimensional data,
 only few of Eigen values
 are significant

PCA: Principle Component Analysis

PCA (Principle Component Analysis) is defined as an orthogonal linear transformation that transforms the data to a new coordinate system such that the greatest variance comes to lie on the first coordinate, the second greatest variance on the second coordinate and so on.

PCA: Principle Component

 Each Coordinate in Principle Component Analysis is called Principle Component.

$$C_i = b_{i1}(x_1) + b_{i2}(x_2) + ... + b_{in}(x_n)$$

where, C_i is the ith principle component, b_{ij} is the regression coefficient for observed variable j for the principle component i and x_i are the variables/dimensions.

PCA: Overview

- Variance and Covariance
- Eigenvector and Eigenvalue
- Principle Component Analysis
- Application of PCA in Image Processing

PCA: Variance and Covariance (1/2)

- The variance is a measure of how far a set of numbers is spread out.
- □ The equation of variance is

$$\operatorname{var}(x) = \frac{\sum_{i=1}^{n} \left(x_i - x\right) \left(x_i - x\right)}{n-1}$$

PCA: Variance and Covariance (2/2)

- Covariance is a measure of how much two random variables change together.
- □ The equation of variance is

$$cov(x, y) = \frac{\sum_{i=1}^{n} (x_i - \bar{x})(y_i - \bar{y})}{n-1}$$

PCA: Covariance Matrix

 Covariance Matrix is a n*n matrix where each element can be define as

$$M_{ij} = \text{cov}(i, j)$$

A covariance matrix over 2 dimensional dataset is

$$M = \begin{bmatrix} cov(x, x) & cov(x, y) \\ cov(y, x) & cov(y, y) \end{bmatrix}$$

PCA: Eigenvector

The eigenvectors of a square matrix A are the nonzero vectors x such that, after being multiplied by the matrix, remain parallel to the original vector.

$$\begin{bmatrix} 2 & 1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 3 \\ -3 \end{bmatrix} = \begin{bmatrix} 3 \\ -3 \end{bmatrix}$$

PCA: Eigenvalue

For each Eigenvector, the corresponding **Eigenvalue** is the factor by which the eigenvector is scaled when multiplied by the matrix.

$$\begin{bmatrix} 2 & 1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 3 \\ -3 \end{bmatrix} = 1 \bullet \begin{bmatrix} 3 \\ -3 \end{bmatrix}$$

PCA: Eigenvector and Eigenvalue (1/2)

□ The vector x is an eigenvector of the matrix A with eigenvalue λ (lambda) if the following equation holds:

$$Ax = \lambda x$$

$$or, Ax - \lambda x = 0$$

$$or, (A - \lambda I)x = 0$$

PCA: Eigenvector and Eigenvalue (2/2)

Calculating Eigenvalues

$$|A - \lambda I| = 0$$

Calculating Eigenvector

$$(A - \lambda I)x = 0$$

PCA: Eigenvector and Principle Component

- It turns out that the Eigenvectors of covariance matrix of the data set are the principle components of the data set.
- □ Eigenvector with the highest eigenvalue is first principle component and with the 2nd highest eigenvalue is the second principle component and so on.

PCA: Steps to find Principle Components

- Adjust the dataset to zero mean dataset.
- Find the Covariance Matrix M
- Calculate the normalized Eigenvectors and Eigenvalues of M
- Sort the Eigenvectors according to Eigenvalues from highest to lowest
- 5. Form the Feature vector F using the transpose of Eigenvectors.
- 6. Multiply the transposed dataset with F

PCA: Example

AdjustedDataSet = OriginalDataSet - Mean

Applying the PCs to transform data

Using all PCs

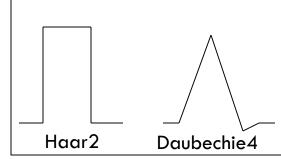

Using only 2 PCs

What Is Wavelet Transform?

- Decomposes a signal into different frequency subbands
 - Applicable to n-dimensional signals
- Data are transformed to preserve relative distance between objects at different levels of resolution
- Allow natural clusters to become more distinguishable
- Used for image compression

Wavelet Transformation

- Discrete wavelet transform (DWT) for linear signal processing, multi-resolution analysis
- Compressed approximation: store only a small fraction of the strongest of the wavelet coefficients
- Similar to discrete Fourier transform (DFT), but better lossy compression, localized in space

Method:

- Length, L, must be an integer power of 2 (padding with 0's, when necessary)
- Each transform has 2 functions: smoothing, difference
- Applies to pairs of data, resulting in two set of data of length L/2
- Applies two functions recursively, until reaches the desired length

Wavelet Decomposition

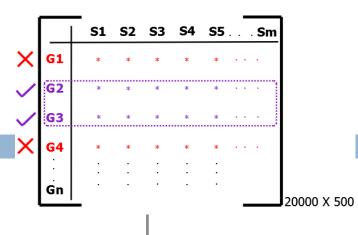

- Wavelets: A math tool for space-efficient hierarchical decomposition of functions
- □ S = [2, 2, 0, 2, 3, 5, 4, 4] can be transformed to $S_{\wedge} = [2^3/_4, -1^1/_4, 1/_2, 0, 0, -1, -1, 0]$
- Compression: many small detail coefficients can be replaced by 0's, and only the significant coefficients are retained

Resolution	Averages	Detail Coefficients
8	[2, 2, 0, 2, 3, 5, 4, 4]	
4	[2,1,4,4]	[0,-1,-1,0]
2	$[1\frac{1}{2}, 4]$	$[\frac{1}{2}, 0]$
1	$[ilde{2}rac{3}{4}]$	$[-1\frac{1}{4}]$

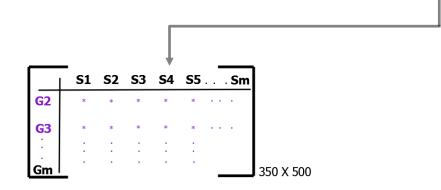

Feature Subset Selection

- Another way to reduce dimensionality of data
- Redundant features
 - duplicate much or all of the information contained in one or more other attributes
 - Example: purchase price of a product and the amount of sales tax paid
- Irrelevant features
 - contain no information that is useful for the data mining task at hand
 - Example: students' ID is often irrelevant to the task of predicting students' GPA

1-2 Opening.... For ... M.Tech.
Dissertation in the Area of Feature Subset Selection

Feature Subset Selection from High Dimensional Biological Data

Abhinna Agarwal M.Tech.(CSE)

Guided by

Dr. Dhaval Patel

Outline.....

So far, our Trajectory on Data Preprocessing is as follow:

- 1. Data has attributes and their values
 - Noise, Quality, Inconsistent, Incomplete, ...
- 2. Data has many records
 - Data Sampling
- 3. Data has many attributes/dimensions
 - Feature Selections or Dimensionality Reduction
- 4. Can you guess What is next?

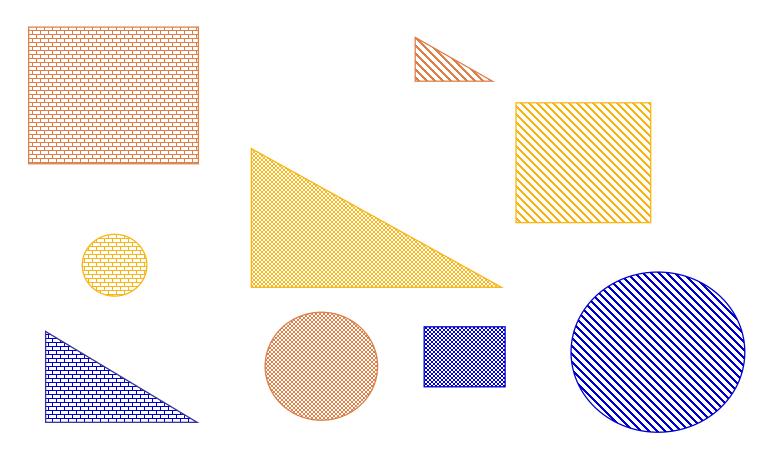

Distance/Similarity

Data has many records

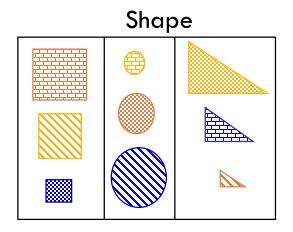

Then,

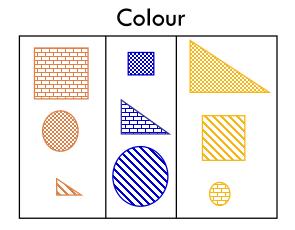

Can we find **similar records**?

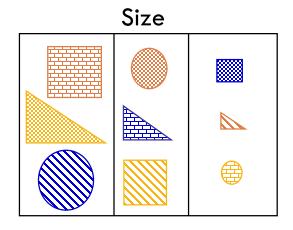

<u>Distance and Similarity</u> are commonly used....

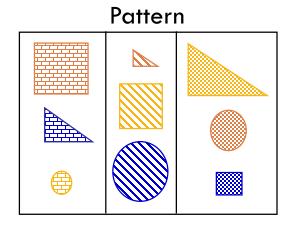

What is similar?

Similarity and Dissimilarity

- Similarity
 - Numerical measure of how alike two data objects are.
 - Is higher when objects are more alike.
 - Often falls in the range [0,1]
- Dissimilarity
 - Numerical measure of how different are two data objects
 - Lower when objects are more alike
 - Minimum dissimilarity is often 0
 - Upper limit varies
- Proximity refers to a similarity or dissimilarity

Euclidean Distance

Euclidean Distance

$$dist = \sqrt{\sum_{k=1}^{n} (p_k - q_k)^2}$$

Where n is the number of dimensions (attributes) and p_k and q_k are, respectively, the k^{th} attributes (components) or data objects p and q.

Standardization is necessary, if scales differ.

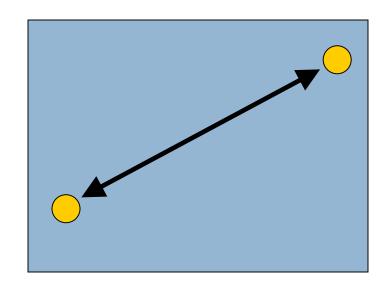

Euclidean Distance (Metric)

Euclidean distance:

Point 1 is: $(x_1, x_2, ..., x_n)$

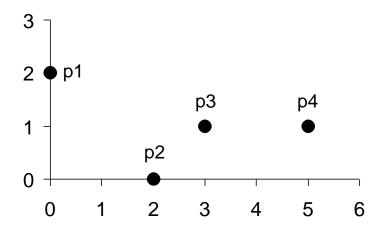

Point 2 is: $(y_1, y_2, ..., y_n)$

Euclidean distance is:

$$\sqrt{(y_1-x_1)^2+(y_2-x_2)^2+...+(y_n-x_n)^2}$$

Euclidean Distance

point	X	y
p1	0	2
p2	2	0
р3	3	1
p4	5	1

	p1	p2	р3	p4
p1	0	2.828	3.162	5.099
p2	2.828	0	1.414	3.162
р3	3.162	1.414	0	2
p4	5.099	3.162	2	0

Distance Matrix

Minkowski Distance

 Minkowski Distance is a generalization of Euclidean Distance

$$dist = \left(\sum_{k=1}^{n} |p_k - q_k|^r\right)^{\frac{1}{r}}$$

Where r is a parameter, n is the number of dimensions (attributes) and p_k and q_k are, respectively, the kth attributes (components) or data objects p and q.

Minkowski Distance: Examples

- r = 1. City block (Manhattan, taxicab, L_1 norm) distance.
 - A common example of this is the Hamming distance, which is just the number of bits that are different between two binary vectors
- r = 2. Euclidean distance
- $r \to \infty$. "supremum" (L_{max} norm, L_{∞} norm) distance.
 - □ This is the maximum difference between any component of the vectors
 - **Example:** L_infinity of (1, 0, 2) and (6, 0, 3) = ??
 - \square Do not confuse r with n, i.e., all these distances are defined for all numbers of dimensions.

Manhattan Distance

Manhattan distance (aka city-block distance)

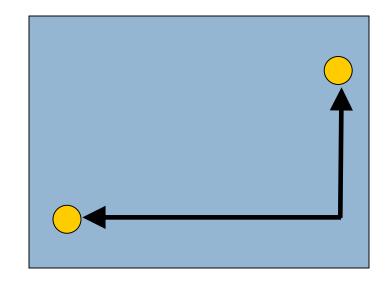

Point 1 is:

$$(x_1, x_2, ..., x_n)$$

Point 2 is:

$$(y_1, y_2, ..., y_n)$$

Manhattan distance is:

$$|y_1 - x_1| + |y_2 - x_2| + ... + |y_n - x_n|$$

(in case you don't know: |X| is the absolute value of x.)

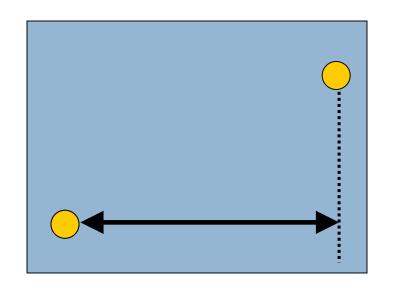

Chebychev Distance

Chebychev distance

Point 1 is: $(x_1, x_2, ..., x_n)$

Point 2 is: $(y_1, y_2, ..., y_n)$

Chebychev distance is:

$$\max\{|y_1-x_1|,|y_2-x_2|,...,|y_n-x_n|\}$$

L1-L2-... Distances

point	X	y
p1	0	2
p2	2	0
р3	3	1
p4	5	1

L1	p1	p2	р3	p4
p1	0	4	4	6
p2	4	0	2	4
р3	4	2	0	2
p4	6	4	2	0

L2	p1	p2	р3	p 4
p1	0	2.828	3.162	5.099
p2	2.828	0	1.414	3.162
р3	3.162	1.414	0	2
p4	5.099	3.162	2	0

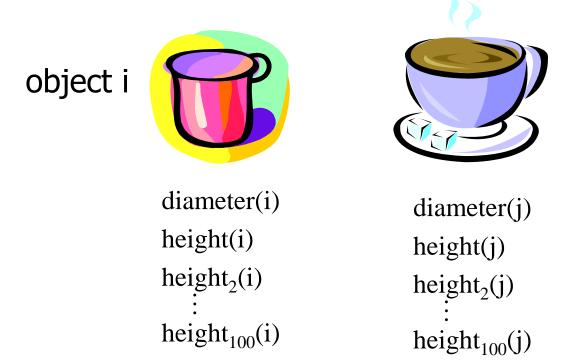

L_{∞}	p1	p2	р3	p4
p1	0	2	3	5
p2	2	0	1	3
р3	3	1	0	2
p4	5	3	2	0

Distance Matrix

Additive Distances

- Each variable contributes independently to the measure of distance.
- May not always be appropriate... e.g., think of nearest neighbor classifier

object j

Dependence among Variables

- Covariance and correlation measure linear dependence (distance between variables, not objects)
- Assume we have two variables or attributes X and Y and n objects taking on values x(1), ..., x(n) and y(1), ..., y(n). The sample covariance of X and Y is:

$$Cov(X,Y) = \frac{1}{n} \sum_{i=1}^{n} (x(i) - \bar{x})(y(i) - \bar{y})$$

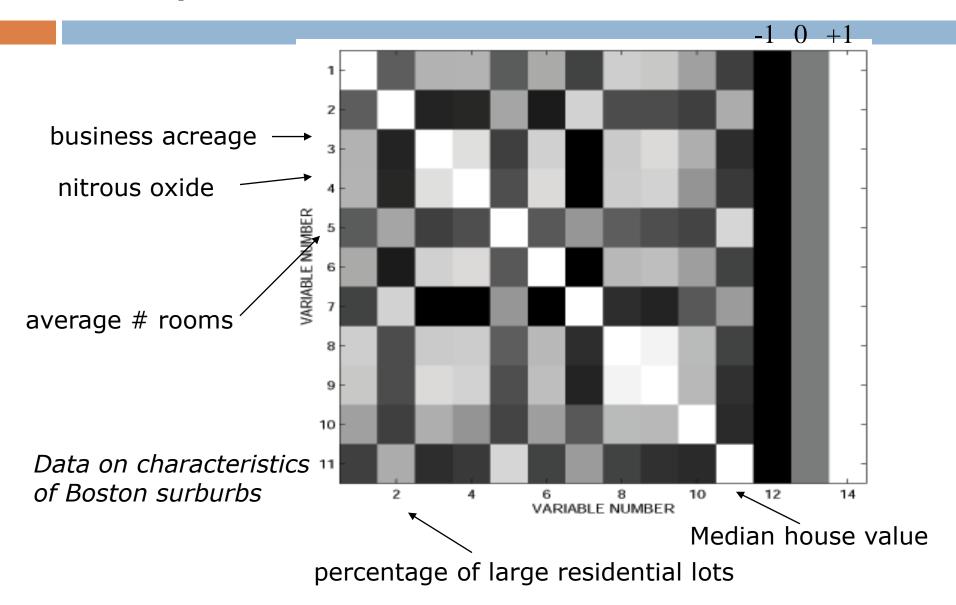

- □ The covariance is a measure of how X and Y vary together.
 - \blacksquare it will be large and positive if large values of X are associated with large values of Y, and small X \Longrightarrow small Y

Correlation coefficient

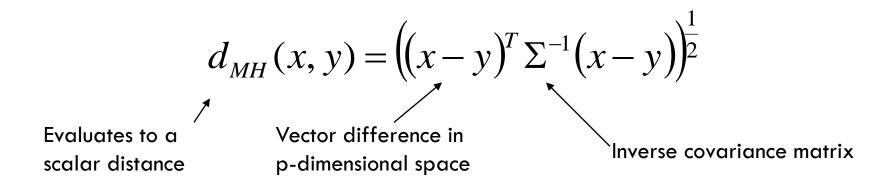

- Covariance depends on ranges of X and Y
- Standardize by dividing by standard deviation
- Linear correlation coefficient is defined as:

$$\rho(X,Y) = \frac{\sum_{i=1}^{n} (x(i) - \overline{x})(y(i) - \overline{y})}{\left(\sum_{i=1}^{n} (x(i) - \overline{x})^{2} \sum_{i=1}^{n} (y(i) - \overline{y})^{2}\right)^{\frac{1}{2}}}$$

Sample Correlation Matrix

Mahalanobis distance (between objects)

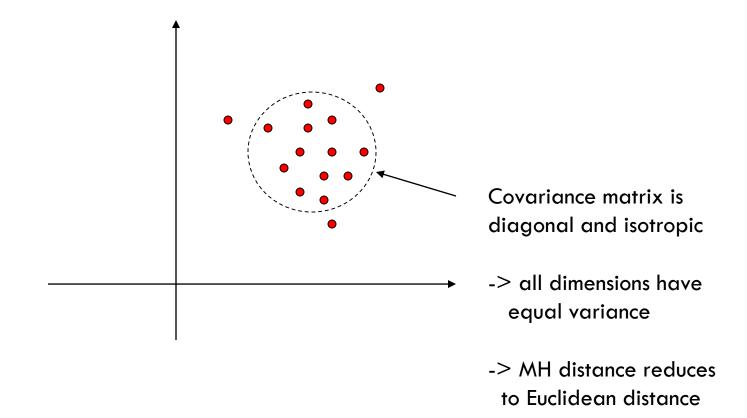

- 1. It automatically accounts for the scaling of the coordinate axes
- 2. It corrects for correlation between the different features

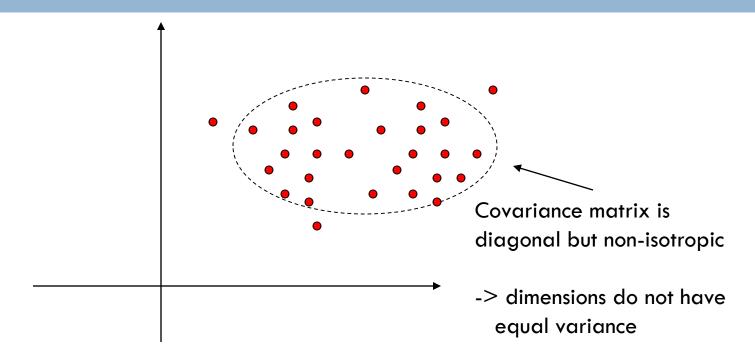

Cost:

- 1. The covariance matrices can be hard to determine accurately
- 2. The memory and time requirements grow quadratically, $O(p^2)$, rather than linearly with the number of features.

Example 1 of Mahalonobis distance

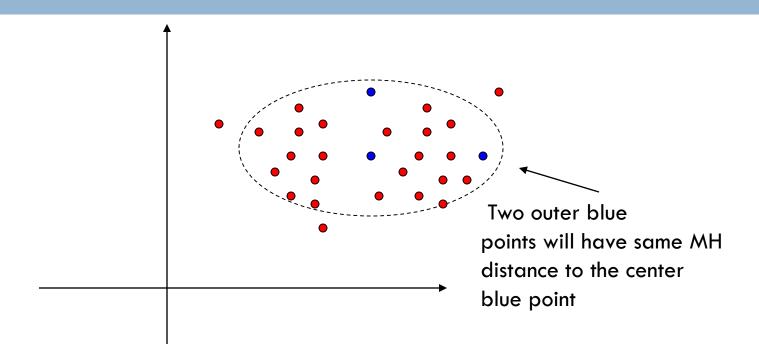

Example 2 of Mahalonobis distance

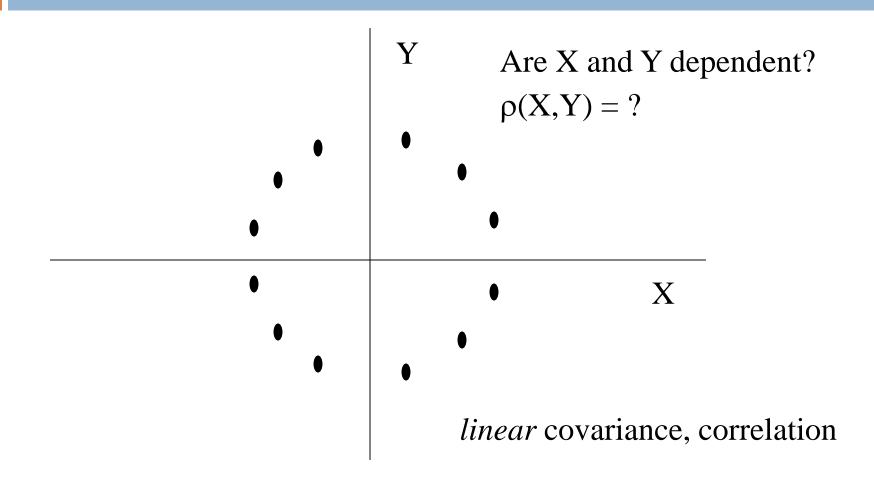

- -> MH distance reduces to weighted Euclidean distance with weights
 - = inverse variance

Example 2 of Mahalonobis distance

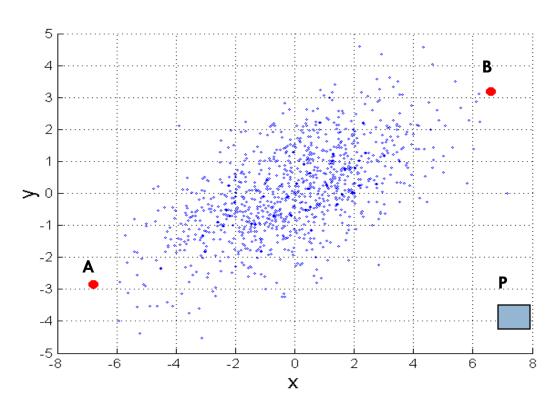

What about...

Mahalanobis Distance

mahalanobis
$$(p,q) = (p-q)\sum^{-1}(p-q)^T$$

 Σ is the covariance matrix of the input data X

$$\Sigma_{j,k} = \frac{1}{n-1} \sum_{i=1}^{n} (X_{ij} - \overline{X}_{j})(X_{ik} - \overline{X}_{k})$$

For red points, the Euclidean distance is 14.7, Mahalanobis distance is 6.

Mahalanobis Distance

Covariance Matrix:

$$\Sigma = \begin{bmatrix} 0.3 & 0.2 \\ 0.2 & 0.3 \end{bmatrix}$$

A: (0.5, 0.5)

B: (0, 1)

C: (1.5, 1.5)

Mahal(A,B) = 5

Mahal(A,C) = 4

Distances between Categorical Vectors

Proportion different

Point 1 is: $(x_1, x_2, ..., x_n)$

Point 2 is: $(y_1, y_2, ..., y_n)$

Proportion different is:

(red, male, big, hot)

(green, male, small, hot)

$$d = 0$$

for each field f
if $(y_f \neq x_f)$ then $d = d + 1$
proportion different is d / n

Distances between Categorical Vectors

Jaccard coefficient

Point 1 is a set: A

Point 2 is a set: B

Jaccard Coefficient is:

(bread, cheese, milk, nappies)

(batteries, cheese)

$$\frac{|A \cap B|}{|A \cup B|}$$

The number of things that appear in **both** (1 - cheese), divided by the total number of different things (5))

Using common sense

Data vectors are: (colour, manufacturer, top-speed)

e.g.: (red, ford, 180)

(yellow, toyota, 160) (silver, bugatti, 300)

What distance measure will you use?

Using common sense

Data vectors are: (colour, manufacturer, top-speed)

e.g.: (dark, ford, high)

(medium, toyota, high)

(light, bugatti, very-high)

What distance measure will you use?

Using common sense

With different types of fields, e.g.

```
p1 = (red, high, 0.5, UK, 12)

p2 = (blue, high, 0.6, France, 15)
```

You could simply define a distance measure for each field Individually, and add them up.

Similarly, you could divide the vectors into ordinal and numeric parts:

```
p1a = (red, high, UK) p1b = (0.5, 12)
p2a = (blue, high, France) p2b = (0.6, 15)
```

and say that dist(p1, p2) = dist(p1a,p2a)+d(p1b,p2b) using appropriate measures for the two kinds of vector.

Using common sense...

Suppose one field varies hugely (standard deviation is 100), and one field varies a tiny amount (standard deviation 0.001) – why is Euclidean distance a bad idea? What can you do?

What is the distance between these two?

"Star Trek: Voyager"

"Satr Trek: Voyagger"

Normalising fields individually is often a good idea – when a numerical field is normalised, that means you scale it so that the mean is 0 and the standard deviation is 1.

Edit distance is useful in many applications: see

http://www.merriampark.com/ld.htm

Cosine Similarity

□ If d_1 and d_2 are two document vectors, then $\cos(d_1,d_2) = (d_1 \bullet d_2) / ||d_1|| ||d_2||,$ where • indicates vector dot product and ||d|| is the length of vector d.

Example:

$$d_1 = 3205000200$$

 $d_2 = 1000000102$

$$d_1 \bullet d_2 = 3*1 + 2*0 + 0*0 + 5*0 + 0*0 + 0*0 + 0*0 + 2*1 + 0*0 + 0*2 = 5$$

$$||d_1|| = (3*3 + 2*2 + 0*0 + 5*5 + 0*0 + 0*0 + 0*0 + 2*2 + 0*0 + 0*0)^{0.5} = (42)^{0.5} = 6.481$$

$$||d_2|| = (1*1 + 0*0 + 0*0 + 0*0 + 0*0 + 0*0 + 1*1 + 0*0 + 2*2)^{0.5} = (6)^{0.5} = 2.245$$

$$\cos(d_1, d_2) = .3150, \, \text{distance} = 1 - \cos(d_1, d_2)$$

Nominal Variables

- A generalization of the binary variable in that it can take more than 2 states, e.g., red, yellow, blue, green
- Method 1: Simple matching
 - □ m: # of matches, p: total # of variables

$$d(i,j) = \frac{p-m}{p}$$

- Method 2: use a large number of binary variables
 - creating a new binary variable for each of the M nominal states

Ordinal Variables

- An ordinal variable can be discrete or continuous
- order is important, e.g., rank
- Can be treated like interval-scaled
 - Arr replacing x_{if} by their rank $r_{if} \in \{1,...,M_f\}$
 - \blacksquare map the range of each variable onto [0, 1] by replacing *i*-th object in the *f*-th variable by

$$z_{if} = \frac{r_{if} - 1}{M_f - 1}$$

compute the dissimilarity using methods for interval-scaled variables

Common Properties of a Distance

- Distances, such as the Euclidean distance, have some well known properties.
 - 1. $d(p, q) \ge 0$ for all p and q and d(p, q) = 0 only if p = q. (Positive definiteness)
 - 2. d(p, q) = d(q, p) for all p and q. (Symmetry)
 - 3. $d(p, r) \le d(p, q) + d(q, r)$ for all points p, q, and r. (Triangle Inequality)

where d(p, q) is the distance (dissimilarity) between points (data objects), p and q.

A distance that satisfies these properties is a metric

Common Properties of a Similarity

- Similarities, also have some well known properties.
 - s(p, q) = 1 (or maximum similarity) only if p = q.
 - s(p, q) = s(q, p) for all p and q. (Symmetry)

where s(p, q) is the similarity between points (data objects), p and q.
