

LIGHTING GLOBAL

Solar Home System Kit

Quality Assurance Protocols

Version 1

2016 April 1

CONTENTS

1	Scope	14
2	Normative references	15
3	Definitions	16
4	System limits	20
4.1	System description	20
4.1.1	Components	20
4.1.2	Component categories	20
4.1.3	Lighting parts definitions	21
4.1.4	Appliance definitions	22
4.1.5	Additional system elements	23
4.2	System measurements and observations	23
4.2.1	General	23
4.2.2	Product design, manufacture, and marketing aspects	23
4.2.3	Product durability and workmanship aspects	26
4.2.4	Lighting durability aspects	30
4.2.5	Battery performance aspects	30
4.2.6	Battery-charging circuit efficiency	31
4.2.7	Solar module aspects	31
4.2.8	Electrical characteristics	32
4.2.9	Performance aspects	33
4.2.10	Light output aspects	35
4.2.11	Self-certification aspects	35
5	Product specification	36
5.1	General	36
5.2	Applications	37
5.3	Quality assurance principles	37
5.3.1	General	37
5.4	Product specification framework description	37
5.4.1	General	37
5.4.2	Product specification template	38
5.4.3	Tolerances	41
5.4.4	Quality standards criteria	42
5.4.5	Warranty requirements criteria	47
6	Quality test method	48
6.1	General	48
6.2	Applications	48
6.3	Sampling requirements	49
6.4	Laboratory requirements	49
6.5	Testing requirements	49
6.6	Recommended tests programme	52
6.6.1	General	52
6.6.2	Test preparation	54
6.6.3	Batch A tests	54
6.6.4	Batch B tests	55

6.6.5	Batch C tests	55
6.6.6	Batch D / spares -- potentially destructive tests	56
6.6.7	Report preparation.....	56
6.7	Reporting	57
7	Market check method	57
7.1	General.....	57
7.2	Applications	57
7.3	Sampling requirements	58
7.4	Laboratory requirements	58
7.5	Testing requirements	58
7.6	Recommended tests programme.....	59
7.7	Report requirements	59
8	Initial screening method.....	59
8.1	General.....	59
8.2	Applications	59
8.3	Sampling requirements	59
8.4	Laboratory requirements	60
8.5	Testing requirements	60
8.6	Recommended tests programme.....	63
8.7	Reporting	63
9	Standardized specification sheets.....	63
9.1	General.....	63
9.2	Applications	64
9.2.1	General	64
9.2.2	Guidance	64
9.2.3	Framework for SSS guidelines document.....	64
Annex A (informative) Recommended quality standards for off-grid lighting market support programme qualification		69
A.1	Scope	69
A.2	Test requirements	69
A.3	Product category requirements	69
A.4	Quality standards.....	69
A.5	Warranty and end-user support requirements.....	72
Annex B (informative) Recommended SSS guidelines.....		73
B.1	Scope	73
B.2	Qualification standards	73
B.3	Test result requirements	73
B.3.1	Original testing	73
B.3.2	Retesting and updates	73
B.4	Style and format	74
B.5	Reporting precision	74
B.6	Results verification	74
B.7	Section descriptions.....	75
B.7.1	General	75
B.7.2	Header / overall performance	75
B.7.3	General information	76
B.7.4	Performance Details	77
B.7.5	Light output	77

B.7.6	Special features.....	77
B.7.7	Durability.....	78
B.7.8	Solar module details.....	78
B.7.9	Battery details.....	79
B.7.10	Marks and certifications.....	79
B.7.11	SSS information.....	80
B.8	Example sheet.....	80
Annex C (normative)	Manufacturer self-reported information.....	81
C.1	Background.....	81
C.2	Outcomes.....	81
C.3	Solicited information.....	81
C.3.1	Confidential information (not released publicly).....	81
C.3.2	Public information (may be released publicly).....	82
C.4	Reporting.....	83
Annex D (normative)	Product sampling.....	85
D.1	Background.....	85
D.2	Test outcomes.....	85
D.3	Related tests.....	85
D.4	Procedure.....	85
D.4.1	Retail sampling.....	85
D.4.2	Warehouse sampling.....	86
D.5	Reporting.....	87
Annex E (normative)	Visual screening.....	88
E.1	Background.....	88
E.2	Test outcomes.....	88
E.3	Related tests.....	88
E.4	Procedure.....	88
E.4.1	Properties, features, and information.....	88
E.4.2	Specifications.....	93
E.4.3	Functionality and internal inspection.....	95
E.5	Reporting.....	97
Annex F (normative)	Sample preparation.....	102
F.1	Background.....	102
F.2	Test outcomes.....	102
F.3	Related tests.....	102
F.4	Procedure.....	102
F.4.1	General.....	102
F.4.2	Equipment requirements.....	102
F.4.3	Test prerequisites.....	103
F.4.4	Procedure.....	103
F.4.5	Calculations.....	105
F.5	Reporting.....	105
Annex G (normative)	Power supply setup procedure.....	106
G.1	Background.....	106
G.2	Test outcomes.....	106
G.3	Related tests.....	106
G.4	Equipment requirements.....	106

G.5	Setup procedure for photometric measurements and lumen maintenance tests	106
G.5.1	Test setup	106
G.5.2	DC voltage and current levels	107
G.5.3	Stabilization period	108
G.5.4	4-wire power supply measurements	108
G.5.5	Electromagnetic interference	108
G.5.6	Troubleshooting.....	109
G.6	Reporting	109
Annex H (normative)	Photovoltaic module I-V characteristics test	111
H.1	Background	111
H.2	Test outcomes	111
H.3	Related tests	112
H.4	Procedure	112
H.4.1	Testing using IEC 61215 or IEC 61646	112
H.4.2	Test programme using a solar simulator	113
H.4.3	Outdoor photovoltaic module I-V characteristics test.....	113
H.5	Reporting	118
Annex I (normative)	Battery test.....	120
I.1	Background	120
I.2	Test outcomes	120
I.3	Related tests	120
I.4	Procedure	120
I.4.1	General	120
I.4.2	Lead-acid battery test	121
I.4.3	Nickel-metal hydride battery test.....	124
I.4.4	Lithium-ion battery test	125
I.4.5	Lithium iron phosphate battery test	126
I.5	Reporting	127
Annex J (informative)	Battery testing recommended practices	128
J.1	Background	128
J.2	Deep discharge protection specifications by battery type	128
J.3	Overcharge protection specifications by battery type	129
Annex K (normative)	Charge controller behaviour test	130
K.1	Background	130
K.2	Test outcomes	130
K.3	Related tests	131
K.4	Procedure	131
K.4.1	Active deep discharge protection test	131
K.4.2	Active overcharge protection test.....	133
K.4.3	Passive deep discharge protection test.....	137
K.4.4	Passive overcharge protection test	138
K.4.5	Standby loss measurement.....	140
K.5	Reporting	141
Annex L (normative)	Full-battery run time test.....	143
L.1	Background	143
L.2	Test outcomes	143
L.3	Related tests	144

L.4	Equipment requirements	144
L.5	Test prerequisites	144
L.6	Apparatus	144
L.7	Procedure	145
L.8	Calculations	146
L.9	Reporting	148
Annex M (informative)	Full discharge preparation	149
M.1	Background	149
M.2	Test outcomes	149
M.3	Related tests	149
M.4	Procedure	149
M.4.1	General	149
M.4.2	Equipment requirements	149
M.4.3	Test prerequisites	149
M.4.4	Procedure	150
M.4.5	Calculations	151
M.5	Reporting	151
Annex N (normative)	Solar Charge Test	152
N.1	Background	152
N.2	Test outcomes	152
N.3	Related tests	152
N.4	Procedure	153
N.4.1	General	153
N.4.2	Test method using a resistor network	153
N.4.3	Test method using a solar array simulator (SAS)	157
N.4.4	Calculations	159
N.5	Reporting	164
Annex O (normative)	Protection Tests	167
O.1	Background	167
O.2	Test outcomes	167
O.3	Related tests	167
O.4	Procedure	167
O.4.1	Miswiring protection test	167
O.4.2	Output overload protection test	170
O.4.3	PV overvoltage protection test	173
O.5	Reporting	177
Annex P (normative)	Assessment of DC Ports	180
P.1	Background	180
P.2	Test outcomes	180
P.3	Related tests	181
P.4	Procedure	182
P.4.1	Preparation	182
P.4.2	Measurement of steady-state port characteristics	182
P.4.3	Dynamic measurement	188
P.4.4	Summary calculations	194
P.4.5	Pass/fail tests for functionality and truth in advertising	194
P.5	Reporting	195

Annex Q (normative) Appliance tests	197
Q.1 Background	197
Q.2 Appliance testing requirements	197
Q.3 Test outcomes	199
Q.4 Related tests	199
Q.5 Power consumption test.....	199
Q.5.1 General	199
Q.5.2 Test procedure for LED or CFL lighting appliances without internal batteries	200
Q.5.3 Test procedure for television sets without internal batteries	200
Q.5.4 Test procedure for radios without internal batteries.....	201
Q.5.5 Test procedure for fans, motor-driven appliances, and other appliances without internal batteries.....	202
Q.5.6 Test procedure for appliances with internal batteries	203
Q.6 Charging efficiency test	205
Q.6.1 General	205
Q.6.2 Equipment requirements.....	205
Q.6.3 Test prerequisites	205
Q.6.4 Procedure.....	205
Q.6.5 Calculations.....	205
Q.7 Appliance operating voltage range test	206
Q.7.1 General	206
Q.7.2 Equipment requirements.....	206
Q.7.3 Test prerequisites	206
Q.7.4 Simultaneous testing for multiple SHS kits and applicability of previous test results.....	207
Q.7.5 Procedure for lighting appliances without batteries that have been tested according to the input voltage range test of IEC 62257-12-1	207
Q.7.6 Procedure for appliances without an internal battery.....	209
Q.7.7 Procedure for appliances with an internal battery.....	210
Q.8 Appliance full-battery run time test procedure with deep discharge protection measurement.....	211
Q.8.1 General	211
Q.8.2 Equipment requirements.....	211
Q.8.3 Test prerequisites	212
Q.8.4 Apparatus.....	212
Q.9 Reporting.....	215
Annex R (normative) Energy service calculations.....	217
R.1 Background	217
R.2 Test outcomes	218
R.3 Related tests	220
R.4 Procedure	220
R.4.1 Full-battery run time energy service calculations	220
R.4.2 Solar run time energy service calculations.....	227
R.5 Reporting.....	241
Annex S (normative) Battery durability test	243
S.1 Background	243
S.2 Test outcomes	243
S.3 Related tests	243
S.4 Procedure	243

S.4.1	Durability storage test for valve-regulated lead-acid batteries	243
S.4.2	Durability storage test for flooded lead-acid batteries	244
S.4.3	Durability storage test for nickel-metal hydride batteries	245
S.4.4	Durability storage test for lithium-ion batteries	246
S.4.5	Durability storage test for lithium iron phosphate batteries	247
S.5	Reporting	247
Annex T (normative)	Lumen maintenance test	249
T.1	Background	249
T.2	Test outcomes	249
T.3	Related tests	250
T.4	Procedure	250
T.4.1	General	250
T.4.2	Full screening	250
T.4.3	Initial screening (500 hour test)	255
T.5	Calculations	255
T.6	Alternate method for testing lumen maintenance using IESNA LM80-08.....	255
T.6.1	Background	255
T.6.2	Test prerequisites	256
T.6.3	Procedure.....	256
T.6.4	DUT preparation and LED thermocouple attachment guidelines.....	256
T.6.5	Calculations.....	257
T.7	Reporting	257
Annex U (normative)	Light output test.....	259
U.1	Background	259
U.2	Test outcomes	259
U.3	Related tests	259
U.4	Luminous flux measurement techniques.....	259
U.4.1	General	259
U.4.2	Luminous flux calculation for lighting appliances that have been tested according to IEC 62257-12-1	260
U.4.3	Luminous flux measurements with an integrating sphere or goniophotometer.....	261
U.4.4	Luminous flux measurements using the multi-plane method.....	261
U.5	Correlated colour temperature (CCT) measurement	263
U.6	Colour rendering index (CRI) measurement	263
U.7	Reporting	263
Annex V (normative)	Light distribution test.....	265
V.1	Background	265
V.2	Test outcomes	265
V.3	Related tests	265
V.4	Substitution of results from IEC 62257-12-1	265
V.5	Approved test methods	266
V.5.1	General	266
V.5.2	Goniophotometer	268
V.5.3	Multi-plane method	268
V.5.4	Turntable method	271
V.6	Reporting	273
Annex W (normative)	Mechanical durability test.....	276

W.1	Background	276
W.2	Test outcomes	276
W.3	Related tests	277
W.4	Procedures	278
W.4.1	Drop test	278
W.4.2	Switch and connector test.....	280
W.4.3	Gooseneck/Moving parts test.....	281
W.4.4	Strain relief test	282
W.5	Reporting	283
Annex X (normative)	Physical and water ingress protection test.....	285
X.1	Background	285
X.2	Test outcomes	285
X.3	Related tests	286
X.4	Procedure	286
X.4.1	General	286
X.4.2	IP testing at a laboratory that has been accredited to test according to IEC 60529	287
X.4.3	Simplified IP inspection for ingress of solid foreign objects	287
X.4.4	Simplified IP preliminary inspection for ingress of water with harmful effects	288
X.5	Reporting	291
Annex Y (normative)	Level of water protection	292
Y.1	Background	292
Y.2	Test outcomes	292
Y.3	Related tests	293
Y.4	Laboratory requirements	293
Y.5	Procedure	293
Y.5.1	General	293
Y.5.2	Level of water protection for enclosure only.....	293
Y.5.3	Level of water protection from technical aspects.....	294
Y.5.4	Overall level of water protection	296
Y.6	Reporting	297
Annex Z (informative)	Reserved.....	299
Annex AA (informative)	Reserved	300
Annex BB (normative)	Equipment requirements	301
Annex CC	Generic appliances	312
CC.1	Background	312
CC.2	Test Outcomes	312
CC.3	Related Tests	312
CC.4	Equipment Requirements.....	312
CC.5	Procedures	312
CC.5.1	Constructing generic appliances	312
CC.5.2	Appliance reference values.....	314
CC.6	Reporting	315

1 Scope

This set of test methods apply to SHS kits with the following characteristics:

- All components required to provide basic energy services are packaged as a kit, including at a minimum
 - Solar module(s)
 - Power control unit(s) including battery charge control
 - A battery/batteries
 - Cables, switches, wiring, connectors and protective devices sufficient to connect the solar module(s), power control unit(s) and battery/batteries
 - Loads (optional), such as lighting, load adapter cables (e.g., for mobile phones), and appliances (television, radio, fan, etc.) .
- The battery and PV nominal system voltage is less than 24 V.
- The peak power rating of the kit is less than or equal to 240 W.
- Kits are plug-and-play: no design expertise is required to choose appropriate system components and no technicians or electricians are necessary to successfully install and operate the system. All electrical connections can be made without the use of tools. Installation and operation instructions are presented using language and graphics that can be understood by the typical consumer.

This technical specification presents a quality assurance framework that includes product specifications (a framework for interpreting test results), test methods, and standardized specification sheets (templates for communicating test results).

The intended users of this technical specification are listed below. In some clauses and subclauses of this technical specification, a description of the application of the subclause contents is offered to help provide context for each type of user.

- **Market support programmes** are programmes that support the off-grid lighting market with financing, consumer education, awareness, and other services. Market support programmes often use quality assurance to qualify for access to services like
 - greenhouse gas reduction certifications or other incentives,
 - access to financing (trade or consumer finance),
 - use of a buyer seal and certification (government or non-governmental institutional backing, consumer or “business to business” seals),
 - participation in a public product information database (e.g., standardized specification sheets),
 - access to a business network or trade group,
 - business support and development services,
 - access to market intelligence, and
 - participation in consumer awareness campaigns.
- **Manufacturers and distributors** need to verify the quality and performance of products from different batches and potential business partners. Manufacturers and distributors often use quality assurance plans or requirements to

- support quality control processes at a manufacturing plant or upon receipt of goods from a contract manufacturer, and
- choose products to distribute.
- **Bulk procurement programmes** facilitate or place large orders for devices from a distributor or manufacturer. Bulk procurement programmes may use quality assurance to
 - provide devices to a particular, relatively small group of end-users whose needs are understood (e.g., project developers and implementers for an electrification project may include quality assurance requirements in the GS of an electrification project (see the IEC TS 62257-3)), and
 - organize a subsidy, buy-down, or giveaway programme that will serve a broad set of users.
- **Trade regulators** are typically government policymakers and officials who craft and implement trade and tax policy. Regulators may use quality assurance requirements to
 - qualify for exemption from tax or duties, and
 - establish requirements for customs.

This technical specification establishes the framework for creating a product specification which serves as a basis for evaluating quality for a particular context. Product specifications include minimum requirements for quality standards and warranty requirements. Products are compared to specifications based on test results and other information about the product. The product specification framework is flexible and can accommodate the goals of diverse organizations and institutions. The tests and inspections are designed to be widely applicable across different markets, countries, and regions.

Standardized specification sheets are also defined that can be used to communicate the test results. Combined with a set of product specifications, the information in the standardized specification sheet can inform the use of a quality and/or performance label.

3 Definitions

For the purposes of this document, the following terms and definitions apply.

3.1

illuminance

illuminance of an elementary surface

symbol E

the luminous flux received by an elementary surface divided by the area of this surface

Note 1 to entry: In the SI system of units illuminance is expressed in lux (lx) or lumens per square metre (lm/m²).

[SOURCE: IEC 60050-723:1997-03, 723-08-30]

3.2

capacity

capacity of a cell or a battery

electric charge which a cell or battery can deliver under specified discharge conditions

Note 1 to entry: The SI unit for electric charge, or quantity of electricity, is the coulomb (1 C = 1 A·s) but in practice, capacity is usually expressed in ampere hours (Ah).

[SOURCE: IEC 60050-482:2004-04, 482-03-14]

¹ To be published.

3.3
device under test
DUT

particular sample that is being measured or observed

3.4
life
life of a lamp

total time for which a lamp has been operated before it becomes useless, or is considered to be so according to specified criteria

Note 1 to entry: Lamp life is usually expressed in hours.

[SOURCE: IEC 60050-845:1987, 845-07-61]

3.5
lux

SI unit of illuminance: illuminance produced on a surface of area 1 square metre by a luminous flux of 1 lumen uniformly distributed over that surface

[SOURCE: IEC 60050-845:1987, 845-01-52]

3.6
full width half maximum
FWHM

range of a variable over which a given characteristic is greater than 50 % of its maximum value

Note 1 to entry: FWHM may be applied to characteristics such as radiation patterns, spectral linewidths, etc. and the variable may be wavelength, spatial or angular properties, etc., as appropriate.

[SOURCE: IEC 60050-731:1991-10, 731-01-57]

3.7
ampere
symbol A

SI unit of electric current, equal to the direct current which, if maintained constant in two straight parallel conductors of infinite length, of circular cross-section with negligible area, and placed 1 metre apart in vacuum, would produce between these conductors a force per length equal to 2×10^{-7} N/m

Note 1 to entry: CGPM definition is as follows: "The ampere is that constant current which, if maintained in two straight parallel conductors of infinite length, of negligible circular cross-section, and placed 1 metre apart in vacuum, would produce between these conductors a force equal to 2×10^{-7} newton per metre of length."

[SOURCE: IEC 60050-112:2010-01, 112-02-07]

3.8
multimeter

multirange multifunction measuring instrument intended to measure voltage, current and sometimes other electrical quantities such as resistance

[SOURCE: IEC 60050-312:2001-07, 312-02-24]

3.9
ammeter

instrument intended to measure the value of a current

[SOURCE: IEC 60050-313:2001-07, 313-01-01]

3.10
voltmeter

instrument intended to measure the value of a voltage

[SOURCE: IEC 60050-313:2001-07, 313-01-03]

3.11

illuminance meter

instrument for measuring illuminance

[SOURCE: IEC 60050-845:1987, 845-05-16]

3.12

photometer

instrument for measuring light

[SOURCE: IEC 60050-845:1987, 845-05-15]

3.13

pyranometer

instrument for measuring incident global (direct-beam and diffuse) solar radiation

3.14

integrating sphere

hollow sphere whose internal surface is a diffuse reflector, as non-selective as possible, used to determine the total luminous flux (lumen output) of a lighting device

Note 1 to entry: An integrating sphere is used frequently with a radiometer or photometer.

[SOURCE: IEC 60050-845: date, 845-05-24]

3.15

goniophotometer

photometer for measuring the directional light distribution characteristics of sources, luminaires, media or surfaces

[SOURCE: IEC 60050-845: date, 845-05-22]

3.16

power supply

electric energy converter which draws electric energy from a source and supplies it in a specified form to a load

[SOURCE: IEC 60050-151:2001-07, 151-13-76]

3.17

overvoltage protection

protection intended to operate when the power system voltage is in excess of a predetermined value

[SOURCE: IEC 60050-448:1995-12, 448-14-32]

3.18

ingress protection class

ingress protection rating

IP class

IP rating

degree of protection provided by enclosures for electrical equipment against penetration by foreign bodies and dust / water

3.19

portable

products or subsystems are portable when two or more of the main components (energy source, energy storage, and light source) are connected in a way that makes the product or subsystem easy for an individual to carry

3.20

fixed

products or subsystems are fixed when the main components (energy source, energy storage, and light source) are designed for permanent or semi-permanent mounting and use in place

3.21

separate

products are separate when no solar module is present or the solar module is connected to other components via a long enough cable that the solar module could collect energy outdoors while the other product components remain indoors

3.22

integrated

products are integrated when the solar module is integrated into the same casing as the other components or the solar module is connected to other components via a cable that is too short to allow the solar module to collect energy outdoors while the other product components remain indoors

3.23

metadata

information that relates a test result to a specific sample and provides context about the result (e.g., specific test method used)

3.24

light emitting diode

LED

solid state device embodying a p-n junction, emitting optical radiation when excited by an electric current

[SOURCE: IEC 60050-845:1987, 845-04-40]

3.25

low-voltage disconnect

LVD

battery voltage at which the load terminals of the charge controller are switched off to prevent the battery from over discharging

[SOURCE: IEC 62509:2010-12]

3.26

standby loss

quantity of electricity (electric charge), expressed as a fraction of the total battery capacity, drawn from a product's battery with the product switched off over a specific length of time

3.27

compact fluorescent lamp

CFL

discharge lamp of the low pressure mercury type in which most of the light is emitted by one or several layers of phosphors excited by the ultraviolet radiation from the discharge, typically self-ballasted with a tube that is wound in a spiral or arched shape to make it "compact" as opposed to linear fluorescent lamps

3.28

standard operating voltage

standardized voltage corresponding to a typical battery operating point during discharge

3.29

typical port voltage

voltage present at a port with at a standardized typical load and battery operating voltage

3.30

coefficient of variation

ratio of the standard deviation to the mean

3.31

appliance

device which performs a specific function providing service to an end user, such as a light, radio, or television set

3.32

Sound pressure level meter

SPL meter

A meter for measuring sound pressure level

4 System limits

4.1 System description

4.1.1 Components

An SHS kit typically comprises:

- The following main components:
 - Solar module(s)
 - Power control unit(s) including battery charge control
 - Battery/batteries
 - Loads (optional), such as appliances (lighting, television, radio, fan, etc.), and load adapter cables (e.g., for mobile phones).
- The enclosure(s) and other components:
 - **casing or several casings** (including some translucent parts in many cases),
 - **circuits** (battery charge and discharge controller, regulated voltage and current sources),
 - **wiring** to connect the circuits to each other and the main components,
 - **fasteners** to secure components in the casings,
 - **switches** for light control/selection,
 - cables and connectors,
 - protective devices,
 - **status indicators** / user feedback,
 - **accessories** (mobile phone charging or other appliance interface, radio, fan, TV, etc.)
 - **hardware** for mounting

4.1.2 Component categories

Components of SHS kits can be placed into one of four categories based on the arrangement of components. It is important to categorize them because they have different inherent utility to the user and will encounter different environmental conditions based on their design.

Different quality standards may apply to different categories.

Each SHS kit may contain components from multiple categories. Appliances included with the kit may also be categorized according to this same system.

The first word in each category name refers to the portability of the system.

- *Fixed* components are designed for permanent or semi-permanent mounting and use in place. In addition to many large battery packs and installed light points, certain appliances, such as TVs, are typically considered to be fixed.

- *Portable* components are inherently portable and generally contain an internal energy source. For example, an SHS kit may include a portable light with a battery that can be charged from the main system battery.

Fixed components are further classified based on the expected use location:

- a) **Fixed indoor** components are not inherently portable and are used indoors. If a fixed indoor component is connected to a component that is intended to be used outdoors (such as a PV module), the cable connecting the two components shall be sufficiently long to place the outdoor component outdoors in an appropriate location while the indoor component remains indoors. Otherwise, the *fixed outdoor* category shall apply.
- b) **Fixed outdoor** components are not inherently portable and are intended to be used outdoors, or are connected to components intended to be used outdoors by a cable of insufficient length to allow the component in question to be placed indoors. *Fixed outdoor* components may contain integrated PV modules; however, PV modules without additional components form their own category.
- c) Portable components are further classified by the presence or absence of an integrated solar module:
- d) **Portable separate** components are portable, with a battery and load permanently or temporarily joined. If the component must be connected to a *fixed outdoor* or *portable integrated* component or a *PV module*, the cable connecting the two components shall be sufficiently long to place the outdoor component outdoors in an appropriate location while the indoor component remains indoors; otherwise, the *portable integrated* category shall apply.
- e) **Portable integrated** components are portable and are charged with a solar module that is integrated in the casing or is otherwise designed so that the whole component shall be left outdoors to charge via the solar module. This includes portable components that must be connected to *fixed outdoor* or *portable integrated* components, or a *PV module*, by a cable of insufficient length to allow the component in question to be placed indoors. *Portable integrated* components may contain PV modules; however, PV modules without additional components form their own category.

PV modules may be subjected to different standards for durability (including physical and water ingress protection), and are therefore considered a separate category:

- f) **PV modules** include one or more PV cells surrounded by encapsulating or laminating materials with a transparent glass or plastic covering, plus a junction box mounted on the back of the module for electrical connections. A PV module may be surrounded by a frame, typically of metal or plastic, and may include mounting brackets or other hardware. This category applies only to PV modules; assemblies containing one or more PV modules plus additional electrical or electronic components, such as circuit boards or batteries, shall be considered *fixed outdoor* components.

4.1.3 Lighting parts definitions

The portion of the solar home system kit which provides lighting may also be divided into several subsystems, as defined below. The subsystems are nested beginning with the smallest subsystem and working down to complete kits.

- a) Light source(s): individual LED, CFL, or other light emitting components
- b) Array(s): single or grouped light sources that can be controlled independently from other arrays
- c) Light point(s) or lighting appliance(s): house one or more arrays and can be moved with respect to other light points, if there are more than one
- d) Lighting unit(s): stand-alone parts of the kit, each with an independent battery that powers one or more light points. Note: it is appropriate to categorize each light unit (as described in 4.1.2) separately, since the arrangement of battery and light point(s) may be different in different light units.
- e) Solar home system kit: the overall package of integrated components, including one or several lighting units and potentially other loads or appliances.

Figure 4.1 below illustrates how a hypothetical lighting kit can be subdivided and categorized. The levels of division are labelled with letters, corresponding to the descriptions above. There are six light sources (A) in this kit divided among four arrays (B). Two of the three light points (C) have one array; the third light point (in the middle—C2) has two arrays. Note that one of the arrays—the one with three light sources—is turned off and the other is on. There are two light units (D). The light unit on the left (D1) may be categorized as portable separate; the other light unit (D2) may be categorized as fixed separate (fixed indoors). Both units are included in a single solar home system kit (E). Note that although only lights are illustrated below, other appliances may be included in the solar home system kit.

Figure 4.1 – Division of a lighting kit into subsystems—illustrative example

4.1.4 Appliance definitions

SHS kits typically include or advertise compatibility with one or more appliances (3.31), such as lights, radios, mobile phones. Two categories of appliances are addressed by this quality assurance protocol:

- **Included appliances** are packaged with and sold as part of the SHS kit, so their performance (e.g., power consumption) can be measured directly by the test laboratory.
- **Advertised appliances** are not included in the kit but are mentioned in the accompanying advertising material, such as the product packaging or the manufacturer’s website. This advertising can be a simple statement that the appliance can be used with the kit or an estimate of the run time or service provided by the appliance with a full battery or after a day of solar charging. This quality assurance protocol provides methods for evaluating these claims even though the appliances are not provided to the test laboratory.

In addition, appliances can be categorized by how they are connected to the other components of the SHS kit:

- **External appliances** can be powered or charged from the SHS kit by plugging a cable into a port, and can be disconnected when not in use.

- **Built-in appliances** are integrated into another component of the SHS kit so that they are not intended to be removed by the end user. These appliances include built-in radios and lights. The following are also considered built-in appliances for the purposes of this quality assurance protocol:
 - appliances (such as light points) connected to the kit by a permanently attached cable that is not intended to be removed by the end user
 - appliances (such as light points) that can be removed, but that depend on a circuit or assembly internal to another part of the SHS kit for their functionality. For example, a light point where some or all of the driver or ballast circuit is internal to the main control box of the kit is considered a built-in appliance.

In some cases, an appliance can be considered both “built-in” and “external.” For example, a product could have external lights that can be plugged into specially designated ports with brightness controls or into general-purpose appliance ports. Such appliances should generally be treated as built-in appliances, not external appliances, for testing.

Removable appliances can be further divided into appliances with and without internal batteries. Different test methods for power consumption and voltage compatibility apply to these two categories.

4.1.5 Additional system elements

In addition to technical elements, a system may also include:

- **packaging** with information about the product,
- user’s manual(s),
- various **advertising** for the product across media: print, radio, television, internet, and others, and/or
- **warranty** support from the manufacturer.
- hardware for mounting the PV module or outdoor components

4.2 System measurements and observations

4.2.1 General

Subclause 4.2 describes aspects of an off-grid lighting product that may be measured and/or observed to ascertain its quality and performance. The aspects are grouped into categories, and each aspect begins with a description of its relevance. The aspects may be measured and/or observed using test procedures, which are generally classified as “A” or “B.” Class A test procedures will generally result in measurements that are more accurate or less subjective than class B procedures, but class A procedures are also generally more costly to implement. The appropriateness of class A or class B procedures depends on the particular aspect and context of the testing. The description of each aspect concludes with a description of the result from the test procedure, the units, and an example result. In some cases, multiple pieces of information are grouped in a single aspect for clarity and concision.

4.2.2 Product design, manufacture, and marketing aspects

4.2.2.1 Arrangement of components

The arrangement of components is a critical aspect to observe because it determines the product category. Different arrangements will offer different utility to the end-user.

- a) Class A test procedure(s): Annex E: visual screening
- b) Class B test procedure(s): n/a
- c) Result: qualitative description of each separate electronic enclosure and what is housed in or mounted on each.
- d) Units: qualitative description
- e) Example: Enclosure A contains the battery and charge controller. Enclosure B is a remote lighting point with ambient, omnidirectional LEDs mounted on the outside; it is connected to enclosure A with a 5 m cable. A solar module with a 6 m cable for connection powers enclosure A.

4.2.2.2 Charging system information

This notes all the available options for charging the device. The key items to note are whether the device can be charged by “central” charging (e.g., via electric grid connection or at a central charging station), “independent” charging (e.g., via an included photovoltaic or electromechanical generator), or both. The available charging options can help determine the utility of the device for users.

- a) Class A test procedure(s): Annex E: visual screening
- b) Class B test procedure(s): Annex C: manufacturer self-reported information
- c) Result: for each charging option,
 - 1) Charger type
 - 2) Central or independent
- d) Units: qualitative type
- e) Example: Two charging options. 1) Independent solar charging via the included module; 2) central grid charging via an auxiliary input designed for use with mobile phone chargers (not included).

4.2.2.3 Lighting system information

This describes the types of light sources used in the product and their arrangement. This is important for understanding the general product design.

- a) Class A test procedure(s): Annex E: visual screening
- b) Class B test procedure(s): Annex C: manufacturer self-reported information
- c) Result: qualitative description of the type, number, and arrangement of light sources.
- d) Units: qualitative description
- e) Example: See 4.1.3.

4.2.2.4 Energy storage system information

This describes the type and number of energy storage systems included in the product.

- a) Class A test procedure(s): Annex E: visual screening
- b) Class B test procedure(s): Annex C: manufacturer self-reported information
- c) Result: the type and number of batteries in the system
- d) Units: qualitative description
- e) Example: Unit A has a 12 V VRLA battery with a capacity rating of 40 Ah.

4.2.2.5 Battery easy replaceability

This is an assessment of whether a low-skill technician can easily replace the battery with only a screwdriver (i.e., no soldering). It is important for considering the relevance of battery replacement information.

- a) Class A test procedure(s): Annex E: visual screening
- b) Class B test procedure(s): n/a
- c) Result: a yes or no result on whether it is “easy” to replace the battery
- d) Units: yes/no
- e) Example: Yes, battery is easily replaceable.

4.2.2.6 Battery general aspects

Those aspects of the battery(-ies) that are important for understanding selection of replacement batteries.

- a) Class A test procedure(s): Annex E: visual screening

- b) Class B test procedure(s): Annex C: manufacturer self-reported information or reference component rating
- c) Result (for each battery present):
 - 1) Battery chemistry
 - 2) Nominal voltage
 - 3) Package type
 - 4) Package size
 - 5) Connection type
- d) Units: qualitative type
- e) Example: A sealed lead-acid 12 V prismatic package, 80 mm x 80 mm x 120 mm, wire lead connections.

4.2.2.7 Packaging and user's manual information

Information about the packaging, user's manual, and other consumer-facing information helps establish a baseline for comparing measured values in truth-in-advertising assessments. It may also be important to document if certain programmes require particular information to be included in the manual, such as instructions for end-of-life disposal, particularly for batteries and other potentially hazardous components.

- a) Class A test procedure(s): Annex E: visual screening
- b) Class B test procedure(s): n/a
- c) Result: there are five types of result
 - 1) Photographic documentation of the packaging and manual (or digital copies of the original proofs)
 - 2) Notes on the type of manual and which languages are included
 - 3) Description of the method or pathway for replacing components, including the battery
 - 4) Specifications of components that may require replacement (fuses, batteries, PV)
 - 5) Instructions for PV and product installation and operation
- d) Units: qualitative type and photographs
- e) Example: [Photographs attached to test reports], "the user's manual is a single-sheet included in the package and includes pictograms with explanations in Hindi, English, French, and Swahili."

4.2.2.8 Warranty information

The terms and duration of warranty coverage provided to end-users are important factors for engendering confidence in stand-alone off-grid lighting and trying to prevent early failure. In practice, servicing warranties is highly variable depending on the structure of supply and service chains.

- a) Class A test procedure(s): Annex E: visual screening
- b) Class B test procedure(s): Annex C: manufacturer self-reported information
- c) Result: detailed warranty terms and a "concise" version that highlights the key points of coverage and duration.
- d) Units: qualitative type
- e) Example: [Detailed warranty terms are documented in scanned attachments to test report], Coverage is against manufacturing defects or under normal use conditions. The product in general is covered for 24 months from the time of purchase; the PV module is warranted for 5 years.

4.2.2.9 Auxiliary outlets, ports and adapters information

This notes all the auxiliary outlets and ports present on the product. The inclusion of USB ports, outlets or mobile phone adapters may be important purchasing factors for a consumer.

- a) Class A test procedure(s): Annex E: visual screening
- b) Class B test procedure(s): Annex C: manufacturer self-reported information
- c) Result: list of included auxiliary outlets, ports and adapters.
- d) Units: qualitative type
- e) Example: The product includes two 12 V cigar-lighter style ports and 3 USB ports.

4.2.2.10 Appliances information

This notes all the appliances included with the product and all appliances the product is advertised to support. Some products may include fans, radios or TVs as part of a kit. Others may state that they support certain appliances or make claims as to how long it can power certain appliances.

- a) Class A test procedure(s): Annex E: visual screening
- b) Class B test procedure(s): Annex C: manufacturer self-reported information
- c) Result: list of included appliances and list of claims related to supporting appliances.
- d) Units: qualitative type
- e) Example: The product includes a fan and states that it can “power a TV for 6 hours per day on a full battery”.

4.2.2.11 Other visual screening results

This incorporates various other important results obtained from visual screening (Annex E), including, but not limited to, component dimensions, component masses, the number of light output settings, and provided specifications.

- a) Class A test procedure(s): Annex E: visual screening
- b) Class B test procedure(s): Annex C: manufacturer self-reported information
- c) Result: various results including qualitative descriptions and quantitative measurements.
- d) Units: qualitative descriptions and quantitative measurements
- e) Example (for one result): The product’s lamp unit and control/battery enclosure have masses of 0,5 kg and 5 kg, respectively.

4.2.3 Product durability and workmanship aspects

4.2.3.1 Water protection – enclosure

This provides a description of the product enclosure’s ability to keep out water in terms of IP class. For components intended to be used and/or charged outside, water protection is important for product function as well as user safety.

- a) Class A test procedure(s): Annex X: Physical and water ingress protection test according to IEC 60529 or using the alternative methods if the alternative method results are unequivocal.
- b) Class B test procedure(s): Annex X: Physical and water ingress protection test
- c) Result: pass or fail for IP class (second digit) and a description of degree of water protection provided by enclosure
- d) Units: pass or fail and qualitative description
- e) Example: The portable lamp included with the product passes IP x3. The lamp’s enclosure contains tight fitting components, all of which have gaskets to prevent water intrusion. The battery, charge controller and TV are all fixed indoor components that do not require water ingress protection.

4.2.3.2 Water protection – circuit protection and drainage

This provides a description of any drainage means incorporated into a product and/or circuit board protection methods used in the product. The incorporation of drainage or circuit board protection is crucial for products intended to be portable or used outdoors that have enclosures providing little to no water intrusion protection.

- a) Class A test procedure(s): Annex E: visual screening combined with Annex C: manufacturer self-reported information
- b) Class B test procedure(s): Annex C: manufacturer self-reported information
- c) Result: qualitative description of drainage or circuit protection methods used.
- d) Units: qualitative description
- e) Example: The product has a conformal coating on its circuit board as well as drainage holes in the base of the enclosure to allow drainage of collected water.

4.2.3.3 Water protection - overall

This combines the protection afforded by the enclosure, circuit protection, and consumer labelling to assess the overall protection from water exposure.

- a) Class A test procedure(s): Annex Y: level of water protection
- b) Class B test procedure(s): n/a
- c) Result: descriptive assessment of exposure protection by enclosure only, technical means, and overall system. The assessment categories are “no protection,” “occasional rain,” “frequent rain,” “permanent rooftop installation for PV modules,” and “permanent outdoor exposure.”
- d) Units: qualitative type
- e) Example: Enclosure only: no protection. Technical means: occasional rain. Overall: occasional rain

4.2.3.4 Water protection – solar module

This provides a description of an *external* solar module’s ability to keep out water in terms of IP class (if the solar module is integrated into the product enclosure, then 4.2.3.1 already covers the solar module). Solar modules need to be left outside to collect solar energy; therefore, water protection is important for solar module function as well as user safety.

- a) Class A test procedure(s): Annex X: Physical and water ingress protection test according to IEC 60529 or using the alternative methods if the alternative method results are unequivocal.
- b) Class B test procedure(s): Annex X: Physical and water ingress protection test
- c) Result: pass or fail for IP class (second digit) and a description of degree of water protection
- d) Units: pass or fail and qualitative description
- e) Example: The product’s solar module passes IPx4; the solar module is well-sealed, providing an adequate level of protection against water ingress.

4.2.3.5 Physical ingress protection

This provides a description of the degree of protection from the intrusion of foreign objects a component’s enclosure provides in terms of IP class. Physical ingress protection is important for user safety as well as product functionality.

- a) Class A test procedure(s): Annex X: Physical and water ingress protection test according to IEC 60529 or using the alternative methods if the alternative method results are unequivocal.
- b) Class B test procedure(s): Annex X: Physical and water ingress protection test
- c) Result: pass or fail for IP class (first digit) and description of degree of physical ingress protection.
- d) Units: pass or fail and qualitative description
- e) Example: The portable components pass IP 4x; the product enclosure’s components fit together snugly without gaps, so that only tiny particulate matter (e.g., dust) could intrude. The fixed indoor components pass IP 2x.

4.2.3.6 Physical ingress protection – solar module

This provides a description of an *external* solar module's ability to prevent the intrusion of foreign objects in terms of IP class (if the solar module is integrated into the product enclosure, then 4.2.3.5 already covers the solar module). Solar modules need to be left outside to collect solar energy; therefore, physical ingress protection is important for solar module function as well as user safety.

- a) Class A test procedure(s): Annex X: Physical and water ingress protection test according to IEC 60529 or using the alternative methods if the alternative method results are unequivocal.
- b) Class B test procedure(s): Annex X: Physical and water ingress protection test
- c) Result: pass or fail for IP class (first digit) and description of degree of physical ingress protection
- d) Units: pass or fail and qualitative description

Example: The product's solar module is estimated to pass IP 3x.

4.2.3.7 Drop resistance

This provides an evaluation of a component's robustness and ability to withstand being dropped. Drop resistance is important for product functionality and user safety and satisfaction in portable components.

- a) Class A test procedure(s): Annex W: mechanical durability test
- b) Class B test procedure(s): n/a
- c) Result: pass or fail for functionality, damage, and the presence of user safety hazards.
- d) Units: a pass or fail result on whether the DUT functions, incurred damage, and presented a safety hazard to the user.

Example: When dropped, the portable lamp included with the product stopped working and its glass LED cover shattered, presenting a safety hazard to the user. Functional: Fail, Damage: Fail, Safety hazard: Fail.

4.2.3.8 Gooseneck and Moving Part durability

This provides an evaluation of a product's gooseneck or other moving part's robustness and ability to withstand being torqued through its expected range of motion. Gooseneck and moving part durability is important for product functionality and user safety and satisfaction.

- a) Class A test procedure(s): Annex W: mechanical durability test
- b) Class B test procedure(s): n/a
- c) Result: a pass or fail for functionality, damage, and the presence of user safety hazards.
- d) Units: a pass or fail result on whether the DUT functions, incurred damage, and presented a safety hazard to the user.

Example: After the gooseneck/moving parts test, the LEDs worked properly but there was visible damage (a cracked housing) that did not pose a hazard. Functional: pass. Damage: fail. Safety: pass.

4.2.3.9 Connector durability

This provides an evaluation of a product's connectors' robustness and ability to withstand plug cycling. Connector durability is important for product functionality and user safety and satisfaction.

- a) Class A test procedure(s): Annex W: mechanical durability test
- b) Class B test procedure(s): n/a
- c) Result: a pass or fail for functionality, damage, and the presence of user safety hazards.

- d) Units: a pass or fail result on whether the DUT functions, incurred damage, and presented a safety hazard to the user.

Example: After 400 cycles in the connector test, the PV module's barrel plug socket detached from the charge controller enclosure, rendering the PV module connector unusable. Functional: fail. Damage: fail. Safety: pass.

4.2.3.10 Switch durability

This provides an evaluation of a product's switches' robustness and ability to withstand switch cycling. Switch durability is important for product functionality and user safety and satisfaction.

- a) Class A test procedure(s): Annex W: mechanical durability test
b) Class B test procedure(s): n/a
c) Result: a pass or fail for functionality, damage, and the presence of user safety hazards.
d) Units: a pass or fail result on whether the DUT functions, incurred damage, and presented a safety hazard to the user.

Example: After 600 cycles in the switch test, the DUT's light switch stopped turning on the DUT. Functional: fail. Damage: fail. Safety: pass.

4.2.3.11 Strain relief durability

This provides an evaluation of a product's strain reliefs' robustness and ability to withstand being pulled. Strain relief durability is important for product functionality and user safety and satisfaction.

- a) Class A test procedure(s): Annex W: mechanical durability test
b) Class B test procedure(s): n/a
c) Result: a pass or fail for functionality, damage, and the presence of user safety hazards.
d) Units: a pass or fail result on whether the DUT functions, incurred damage, and presented a safety hazard to the user.

Example: The DUT's strain reliefs all withstood the strain relief test without incurring any damage. Functional: pass. Damage: pass. Safety: pass.

4.2.3.12 Wiring quality

This provides a qualitative evaluation of a product's wiring quality, including (but not limited to) neatness and connection quality.

- a) Class A test procedure(s): Annex E: visual screening
b) Class B test procedure(s): n/a
c) Result: a qualitative description of wiring quality.
d) Units: qualitative description and number of failures with respect to key indicators.

Example: The DUT's wires are neatly arranged (i.e., not tangled or wrapped around one another) and the solder joints are of good quality. No bad joints, pinched wires, or other poor wiring indicators.

4.2.3.13 Battery protection strategy

This provides a quantitative evaluation of a product's battery discharge-recharge protection strategy / algorithm, which is important for battery longevity as well as user safety.

- a) Class A test procedure(s): Annex K: charge controller behaviour test or Annex Q: Appliance tests
b) Class B test procedure(s): Annex C: manufacturer self-reported information
c) Result: deep discharge and overcharge protection voltages.
d) Units: quantitative description

Example: The DUT has a deep discharge protection voltage of 1,92 V/cell and an overvoltage protection voltage of 2,4 V/cell.

4.2.4 Lighting durability aspects

4.2.4.1 500 hour lumen maintenance

This is a measure of the amount of light degradation after 500 h of operation at a constant voltage, which can provide valuable insight into the quality of the LEDs and/or the DUT's circuitry.

- a) Class A test procedure(s): Annex T: lumen maintenance test
- b) Class B test procedure(s): n/a
- c) Result: percentage of lumen output maintained after 500 h of constant operation.
- d) Units: percentage (%)
- e) Example: The DUT maintained 96 % of its original lumen output after 500 h of operation.

4.2.4.2 2 000 hour lumen maintenance

This is a measure of the amount of light degradation after 1 000 h and 2 000 h of operation at a constant voltage, which can provide valuable insight into the quality of the LEDs and/or the DUT's circuitry.

- a) Class A test procedure(s): Annex T: lumen maintenance test
- b) Class B test procedure(s): n/a
- c) Result: percentage of lumen output maintained after 1 000 h and 2 000 h of constant operation.
- d) Units: percentage (%)
- e) Example: The DUT maintained 96 % and 93 % of its original lumen output after 1 000 h and 2 000 h of operation, respectively.

4.2.4.3 Fluorescent light durability

These are additional checks of durability for fluorescent lights that account for their unique characteristics.

- a) Class A test procedure(s): IEC 62257-12-1
- b) Class B test procedure(s): n/a
- c) Result: a pass or fail for cycling test in IEC 62257-12-1
- d) Units: pass or fail
- e) Example: The DUT passed the cycling test in IEC 62257-12-1

4.2.5 Battery performance aspects

4.2.5.1 Battery capacity

This is a measure of the quantity of electricity (electric charge), usually expressed in ampere-hours (Ah), which a fully charged battery can deliver under specified conditions, which affects the run time of products.

- a) Class A test procedure(s): Annex I: battery test (all chemistries), 7.3.2 of IEC 61951-2:2011 for nickel-metal hydride batteries, or 7.3.1 of IEC 61960:2011 for lithium-based batteries.
- b) Class B test procedure(s): Annex C: manufacturer self-reported information or reference component rating
- c) Result: capacity of the battery at a particular discharge rate.
- d) Units: ampere-hours (Ah) at a discharge rate expressed as the fraction of the battery capacity that is used each hour (I_t A)
- e) Example: 3,5 Ah at 0,2 I_t A

4.2.5.2 Battery round-trip energy efficiency

This is a measure of how efficient the DUT's battery is at storing energy to deliver for later use.

- a) Class A test procedure(s): Annex I: battery test
- b) Class B test procedure(s): n/a
- c) Result: storage efficiency of the battery pack.
- d) Units: percentage (%)
- e) Example: 95 %

4.2.5.3 Battery storage durability

These are measures of battery capacity degradation from cycling and storing, which can indicate batteries that may degrade prematurely under typical use.

- a) Class A test procedure(s): Annex S: battery durability test
- b) Class B test procedure(s): n/a
- c) Result: percent capacity loss from storing.
- d) Units: percentage (%)
- e) Example: The battery's capacity loss from storage is 90 %.

4.2.5.4 Battery nominal voltage

This is important for matching to the other components and determines, along with the battery ampere-hour capacity, the energy capacity of the battery. It depends on the battery chemistry (what materials are used to store energy) and the number of electrochemical cells that are in series.

- a) Class A test procedure(s): Annex E: visual screening
- b) Class B test procedure(s): Annex C: manufacturer self-reported information or reference component rating
- c) Result: nominal voltage of the battery pack.
- d) Units: voltage (V)
- e) Example: 3,6 V

4.2.6 Battery-charging circuit efficiency

The battery-charging circuit efficiency, or generator-to-battery charging efficiency, is a measure of how efficient the DUT electronics are at feeding generated energy into the battery.

- a) Class A test procedure(s): IEC 62509:2010, 5.3.2
- b) Class B test procedure(s): Annex N: solar charge test, Annex Q: Appliance tests
- c) Result: battery-charging circuit efficiency.
- d) Units: percentage (%)
- e) Example: 90 %
- f)

4.2.7 Solar module aspects

4.2.7.1 Solar I-V curve parameters

These are the key parameters describing solar module performance at standard test conditions ("STC"—AM 1,5, 25 °C cell temperature, 1 000 W/m² irradiance) and typical module operating temperature ("TMOT"—AM 1,5, 50 °C cell temperature, 1 000 W/m² irradiance).

- a) Class A test procedure(s): IEC 60904-1
- b) Class B test procedure(s): Annex H: photovoltaic module I-V characteristics test

- c) Result (for both STC and TMOT, unless otherwise noted):
 - 1) Open circuit voltage (V_{oc})
 - 2) Short circuit current (I_{sc})
 - 3) Maximum power voltage (V_{mpp})
 - 4) Maximum power current (I_{mpp})
 - 5) Peak power (P_{mpp})
 - 6) Voltage temperature coefficient (at STC only)
- d) Units: volts (V), amperes (A), watts (W), per degree Celsius ($1/^{\circ}\text{C}$)
- e) Example, STC values: $V_{oc} = 7,5 \text{ V}$, $I_{sc} = 0,55 \text{ A}$, $V_{mpp} = 5,8 \text{ V}$, $I_{mpp} = 0,50 \text{ A}$, and $P_{mpp} = 2,9 \text{ W}$. The module's voltage temperature coefficient is $-0,004 \text{ } 2/^{\circ}\text{C}$.

4.2.7.2 Cable length

The length of solar module cable and cables connected to fixed outdoor components are important because it is one aspect that determines the product category; a minimum length is typically specified for products to “qualify” as having separate PV modules to ensure that a user can place the solar module, or other component, outdoors while the other components remain indoors. This has implications for the degree of water protection in quality standards.

- a) Class A test procedure(s): Annex E: visual screening
- b) Class B test procedure(s): n/a
- c) Result: There are two main outputs: 1) the length of a solar module cable that is useful for separating the solar module from the enclosure that contains the battery being charged and 2) the length of the cable between any fixed outdoor component and any other component.
- d) Units: metres (m)
- e) Example: 5.5 m

4.2.8 Electrical characteristics

4.2.8.1 Appliance voltage compatibility

This provides an assessment of whether an included appliance can safely and properly operate over the entire set of operating conditions of the DUT, including discharging with a deeply discharged battery and charging with a nearly full battery.

- a) Class A test procedure(s): Annex P: assessment of DC ports or Annex Q: appliance tests
- b) Class B test procedure(s): n/a
- c) Result: pass or fail for functionality, damage, and safety
- d) Units: pass/fail; qualitative description
- e) Example: The DUT remained functional after the test and no damage or safety hazard was present.

4.2.8.2 Power consumption

The power consumed by an appliance or lighting appliance is an important metric for use in off-grid applications in which the supply of energy is limited. The power consumption must be measured in order to calculate the runtime for the solar home system kit.

- a) Class A test procedure(s): Annex Q: appliance tests
- b) Class B test procedure(s): n/a
- c) Result: DC power
- d) Units: watts (W)
- e) Example: 1,50 W

4.2.8.3 Circuit and overload protection

This provides an assessment of the system's PV overvoltage protection, output overload protection, and safeguards against miswiring.

- a) Class A test procedure(s): Annex O: protection tests
- b) Class B test procedure(s): Annex C: manufacturer self-reported information
- c) Result: a pass or fail result on whether the unit had adequate protection, functioned, or showed damage, fault indications or safety hazards after tests. Tables with quantitative and qualitative results of the voltage range and miswiring protection tests.
- d) Units: volts (V), pass or fail results on whether the unit had adequate protection, functioned, or showed damage, fault indications or safety hazards after test.
- e) Example: The DUT uses appropriately sized fuses to provide adequate circuit protection. Spare fuses are included and the fuse size is noted on the product casing.

4.2.8.4 DC ports

This provides an assessment of the system's DC ports.

- a) Class A test procedure(s): Annex P: assessment of DC ports
- b) Class B test procedure(s): n/a
- c) Result: minimum, typical, and maximum port voltages, tables and plots of voltage, current, power and efficiency of each port
- d) Units: volts (V), amperes (A), watts (W), percentage (%)
- e) Example: n/a

4.2.9 Performance aspects

4.2.9.1 General

Energy availability, component run times and light output are key elements of performance for solar home systems. Some of the aspects listed below will be different for different light settings and appliance combinations.

4.2.9.2 Daily energy service

The daily energy service is the duration of service provided to end-users after one day of solar charging and depends on the system-level performance for a particular setting. The standard solar charging day is defined as an incident solar resource of 5 kWh/m². This is an important metric because it is an estimate of the day-to-day services users can expect in ideal charging conditions. The daily energy service depends on the system-level performance for a particular light setting and combination of appliances.

- a) Class A test procedure(s): Annex L: full-battery run time test, Annex N: solar charge test, Annex Q: appliance tests, Annex R: energy service calculations
- b) Class B test Standards(s): n/a
- c) Result: Watt-hours per day of energy available after a battery is charged from empty for one standard solar day (defined above).
- d) Units: Watt-hours (Wh)
- e) Example: 600 Wh/day

4.2.9.3 Solar-day lighting run time

The solar-day run time is the duration of service provided to end-users from one day of solar charging and depends on the system-level performance for a particular setting. The standard solar charging day is defined as an incident solar resource of 5 kWh/m². This is an important metric because it is an estimate of the day-to-day services users can expect in ideal charging conditions. It is important to note that variations in available solar energy (due to climate, weather, or user behaviour) will result in commensurate differences in actual run time from solar charging.

- a) Class A test procedure(s): Annex L: full-battery run time test, Annex N: solar charge test, Annex R: energy service calculations
- b) Class B test procedure(s): n/a
- c) Result: hours of operation to 70 % of the initial brightness after the battery is charged from empty for one standard solar day (defined above).
- d) Units: hours (h)
- e) Example: 4,5 h

4.2.9.4 Solar-day appliance run time

The solar-day run time is the duration of service provided to end-users from one day of solar charging and depends on the system-level performance for a particular setting. The standard solar charging day is defined as an incident solar resource of 5 kWh/m². This is an important metric because it is an estimate of the day-to-day services users can expect in ideal charging conditions. It is important to note that variations in available solar energy (due to climate, weather, or user behaviour) will result in commensurate differences in actual run time from solar charging.

- a) Class A test procedure(s): Annex L: full-battery run time test, Annex N: solar charge test, Annex Q: appliance tests, Annex R: energy service calculations
- b) Class B test procedure(s): n/a
- c) Result: hours of operation after the battery is charged from empty for one standard solar day (defined above).
- d) Units: hours (h)
- e) Example: 4,5 h

4.2.9.5 Lighting full-battery run time

The full-battery run time is the duration of service provided to end-users from a fully charged battery and depends on the system-level performance for a particular setting. This is an important metric because it is an estimate of the services that can be provided by the product's battery.

- a) Class A test procedure(s): Annex L: full-battery run time test, Annex R: energy service calculations
- b) Class B test Standards(s): n/a
- c) Result: hours of operation to 70 % of the initial brightness after the battery is fully charged.
- d) Units: hours (h)
- e) Example: 10 h

4.2.9.6 Appliance full-battery run time

The appliance full-battery run time is the duration of service provided to end-users from a fully charged appliance battery, such as a lantern, radio, fan or TV with an internal battery. This is an important metric because it is an estimate of the services that can be provided by the appliance once it receives full charge from the main system.

- f) Class A test procedure(s): Annex L: Full-battery run time test or Annex Q: Appliance tests (measurement according to Q.8)
- g) Class B test Standards(s): Annex Q: Appliance tests (calculation according to Q.5.6.5)
- h) Result: hours of operation to the run time end point after the battery is fully charged.
- i) Units: hours (h)
- j) Example: 10 h

4.2.10 Light output aspects

4.2.10.1 Luminous flux output

Luminous flux output is the light output of a DUT when it is operated at the standard operating voltage or when an individual lighting appliance is measured at the typical port voltage. This is a key metric that compares the overall light output of DUTs.

- a) Class A test procedure(s): CIE 084, CIE 127, IESNA LM-78-07, or IESNA LM-79-08
- b) Class B test procedure(s): Annex U: light output test
- c) Result: average luminous flux.
- d) Units: lumens (lm)
- e) Example: 400 lm

4.2.10.2 Full width half maximum (FWHM) angles

The full width half maximum angle is a metric used to understand the light distribution of a DUT and is the total included angle for which the illumination is greater than or equal to half the illumination at the brightest point in the plane.

- a) Class A test procedure(s): CIE 084, CIE 127, IESNA LM-79-08
- b) Class B test procedure(s): Annex V: light distribution test
- c) Result: vertical and horizontal FWHM angles.
- d) Units: degrees (°)
- e) Example: The DUT's horizontal and vertical FWHM angles are both 65°.

4.2.10.3 Average light distribution characteristics

A light distribution is the illuminance "map" of a DUT. This metric is useful for determining the utility with respect to task lighting. Light distribution of each lighting appliance is measured when the DUT is operated at the standard operating voltage or the lighting appliances is operated at the typical port voltage.

- a) Class A test procedure(s): CIE 084, CIE 127, IESNA LM-79-08
- b) Class B test procedure(s): Annex V: light distribution test
- c) Result: constant-voltage usable area at a specified distance.
- d) Units: square metres (m²) and lux (lx)
- e) Example: The DUT's usable area at a distance of 0,75 m is 0,76 m² and the DUT's work surface illuminance is 100 lux.

4.2.10.4 Colour characteristics

The colour characteristics of light determine how accurately the light renders colours (CRI) and the colour of the light expressed as a temperature in kelvin.

- a) Class A test procedure(s): Annex U: light output test
- b) Class B test procedure(s): n/a
- c) Result: CRI value and colour temperature
- d) Units: CRI is unitless and the colour temperature is in kelvin (K)
- e) Example: The CRI is 80 and the colour temperature is 7 000 K.

4.2.11 Self-certification aspects

4.2.11.1 Product and manufacturer information

Manufacturer-reported product and manufacturer information is important for tracking purposes as well as for ensuring the test lab has up-to-date product information.

- a) Class A test procedure(s): Annex C: manufacturer self-reported information
- b) Class B test procedure(s): n/a

c) Result: various qualitative and quantitative information

d) Units: qualitative and quantitative

Example: The product's free-on-board price is 30 \$USD, it is sold in Kenya and India, etc.

4.2.11.2 Warranty coverage

Warranty coverage goes beyond the terms of a warranty and provides detail on coverage in a particular location. It is typically only provided in cases where it is necessary to verify coverage in a particular town or region.

a) Class A test procedure(s): Annex C: manufacturer self-reported information

b) Class B test procedure(s): n/a

c) Result: qualitative description

d) Units: qualitative description

e) Example: The support in [region name] is provided by a small network of technicians who have been trained to repair products by [manufacturer or distributor name]. For repairs that are beyond the scope of their capabilities, replacement products are provided. The consumers in [region name] can access warranty service by dialling a phone number that is on a sticker placed on the original packaging.

4.2.11.3 Third-party marks and certifications

Third-party marks and certifications (e.g., UL) can be an important aspect in the eyes of consumers and investors, alike.

a) Class A test procedure(s): Annex C: manufacturer self-reported information

b) Class B test procedure(s): n/a

c) Result: qualitative marks and certifications

d) Units: qualitative type

e) Example: ISO 9001-certified.

5 Product specification

5.1 General

Quality standards and warranty requirements are used to interpret the measurements and observations made about a product. Together they form a product specification.

- **Quality standards** set a minimum level of durability and protect buyers and users from false advertising claims.
- **Warranty requirements** set a minimum level of user protection from early failure.

Each criterion in a specification refers to a particular aspect of the product, as listed in 4.2, and requires a minimum level of quality, service, or performance.

The standards and requirements should be appropriate for the goals of the organization or individual who is using them as a framework for quality assurance and should consider the following factors:

- Availability of products on the market with the necessary quality and performance.
- Ability of buyers to pay for the products.

- Diversity of end-user needs.
- Tolerance for manufacturing variation.

Clause 5 describes the framework for standards and requirements in general and offers insights on the best practices for creating a product specification. It includes a template product specification followed by guidance on completing each section. Annex A presents an example specification for off-grid lighting market support programme qualification.

5.2 Applications

Product specifications that include some combination of quality standards and warranty requirements can support a broad range of quality assurance needs. Table 1 below lists examples of how they are applied depending on the type of quality assurance framework.

Table 1 – Applications of product specifications

Type of QA framework	Example(s) of applying Clause 5
General market support	Use quality standards and general warranty requirements to qualify for institutional market support. Use quality standards to qualify for “verified product” programmes. Use quality standards and other requirements to qualify for investment or financing.
Manufacturing / distribution	For manufacturers: incorporate quality standards from market support programmes or distributors in the design and production QC processes. For distributors: set minimum quality standards and warranty requirements for products to identify suppliers.
Bulk procurement	Set minimum quality standards and warranty requirements for products to qualify in a request for offers. If the project is in a specific location, the warranty requirements may also include specific levels of service in that particular area.
Trade regulation	Set minimum quality standards for tax exemption or customs.

5.3 Quality assurance principles

5.3.1 General

The framework for considering quality standards and warranty requirements presented in this Technical Specification is designed to support broad types of programmes and institutions in the off-grid lighting market. The following key principles guide the framework:

- Balance quality and affordability for price-sensitive buyers—it does not matter how well products perform if the target users cannot afford them.
- Encourage innovation and technological diversity. Wherever possible, be open-ended in the technical approaches that are allowed.
- Empower buyers to choose the right product for their needs and budget by focusing product specifications and communication on outcomes for end-users.
- Use low-cost, rigorous, targeted tests to match the general affordability requirements for the market and accommodate both incremental and innovative changes to product design. The tests should be feasible for use by a broad set of potential users.
- Focus quality standards on elements of a product that are difficult for typical buyers to assess themselves, like truth in advertising and durability.
- Focus warranty requirements on providing a baseline of support.

5.4 Product specification framework description

5.4.1 General

Subclause 5.4 describes a framework for creating product specification documents for off-grid lighting. First, a blank specification (5.4.2) is provided that lists all the pieces that may be specified. Next, 5.4.3 describes guidelines for setting tolerances in a product specification. Finally, the main sections in a specification are described in more detail with notes and guidance (5.4.4, 5.4.5).

An example product specification for general market support programmes is in Annex A.

A product specification has six parts:

- a) Scope:** defines the applicability and use of the quality standards
- b) Test requirements:** defines requirements for test result validity
- c) Product category requirements:** unambiguously defines the categories that may be referenced later
- d) Quality standards:** lists quality-related aspects and minimum or required results for each aspect with a tolerance; may be subdivided by product category
- e) Warranty requirements:** lists requirements for minimum levels of warranty support

5.4.2 Product specification template

5.4.2.1 General

Subclause 5.4.2 is a blank, rough template for setting quality standards and warranty requirements to support the goals of a programme or institution. Note that in many applications certain criteria or entire categories of criteria may not apply and should be removed. Text in *italics* is intended for replacement and describes what should go in each space.

5.4.2.2 Scope

Describe the intended use of the product specification. Describe the contents in general and provide guidance on how to use the document.

5.4.2.3 Test requirements

Specify the level of testing that is required. Typically this is Quality Test Method (QTM) testing (see clause 6).

Describe which tests and standards apply to each appliance type included in a kit. Describe if any external test results (such as test results from other IEC standards) could be used in place of results from this Technical Specification.

Describe any product sampling requirements for qualification testing.

Specify the number of light output settings required to be measured for products with multiple settings. Typically, at least one set of test results should fully characterize the performance on the highest light output setting.

5.4.2.4 Product category requirements

Describe which product categories (see 4.1.2) are covered / allowed.

Describe any other requirements or eligibility criteria for products that are categorical (e.g., shall be solar charged, shall be plug-and-play, shall be low-voltage, batteries shall be replaceable).

Qualification as a “separate” PV module requires meeting the criteria listed below (Table 2).

Table 2 – Qualification as separate PV module

Criterion	Aspect(s)	Required value
PV module cable length	4.2.7.2 Cable length	<i>Define the length in metres that is required for qualification as a separate PV module.</i>

5.4.2.5 Quality standards

The product shall meet each of the criteria listed in the truth-in-advertising (Table 3), safety and durability (Table 4), and end-user support (Table 5) tables.

Table 3 – Truth-in-advertising tolerance

Truth-in-advertising criterion	Aspect(s) considered in assessment	Requirement
System performance tolerance – numeric ratings	4.2.9 Performance aspects 4.2.10 Light output aspects Others, if applicable	<i>Define the tolerance for deviation from ratings.</i>
System components tolerance – numeric ratings	4.2.5 Battery performance aspects 4.2.7 Solar module aspects 4.2.8.1 Appliance voltage compatibility 4.2.8.2 Power consumption 4.2.8.4 DC ports Others, if applicable	<i>Define the tolerance for deviation from ratings.</i>
Other numeric ratings tolerance	Multiple	<i>Define the tolerance for deviation from ratings.</i>
Overall truth-in-advertising statement	Multiple	<i>Include an overall description of the requirements for truth in advertising that may not be covered by the requirements above.</i>

Table 4 – Safety and durability standards (1 of 2)

Safety or durability criterion	Aspect(s) considered in assessment	Product category (form factor and/or technology)	Requirement
Level of water exposure protection (overall, technical, or enclosure-only)	4.2.3.1 Water protection – enclosure 4.2.3.2 Water protection – circuit protection and drainage 4.2.3.3 Water protection - overall 4.2.3.4 Water protection – solar module 4.2.11.1 Product and manufacturer information 4.2.2.7 Packaging and user's manual information	Category 1	<i>Define level of protection in terms of water protection integrated assessment: No protection, occasional rain, frequent rain, or permanent outdoor exposure.</i>
		Category 2...	<i>Define level of protection in terms of water protection integrated assessment.</i>
Physical ingress protection	4.2.3.5 Physical ingress protection 4.2.3.6 Physical ingress protection – solar module	Category 1	<i>Define level of protection in terms of IP class.</i>
		Category 2...	<i>Define level of protection in terms of IP class.</i>
Mechanical durability – drop test	4.2.3.7 Drop resistance	Category 1	<i>Define type of drop test (2 drops or 6 drops per sample). Define maximum number of failures out of the number that are tested for damage, functionality, and safety.</i>
		Category 2...	<i>Define type of drop test (2 drops or 6 drops per sample). Define maximum number of failures out of the number that are tested for damage, functionality, and safety.</i>
Mechanical durability – goosenecks	4.2.3.8 Gooseneck and Moving Part durability	Products with goosenecks/moving parts	<i>Define maximum number of failures out of the number that are tested for damage, functionality, and safety.</i>
Mechanical durability – connectors	4.2.3.9 Connector durability	Products with connectors	<i>Define maximum number of failures out of the number that are tested for damage, functionality, and safety.</i>

Table 4 – Safety and durability standards (2 of 2)

Safety or durability criterion	Aspect(s) considered in assessment	Product category (form factor and/or technology)	Requirement
Mechanical durability – switches	4.2.3.10 Switch durability	All products	<i>Define maximum number of failures out of the number that are tested for damage, functionality, and safety.</i>
Mechanical durability – strain relief	4.2.3.11 Strain relief durability	Products with connectors	<i>Define maximum number of failures out of the number that are tested for damage, functionality, and safety.</i>
Workmanship	4.2.3.12 Wiring quality	All products	<i>Define maximum number of samples with bad solder joints, poor wiring, etc. out of the number that are tested.</i>
Battery durability	4.2.3.13 Battery protection strategy 4.2.5.3 Battery storage durability 4.2.11.1 Product and manufacturer information 4.2.11.3 Third-party marks and certifications	All products	<i>Define a minimum level of battery protection that will protect the product's battery and the user. Define maximum capacity loss following battery durability test.</i>
Lumen maintenance	4.2.4.2 2 000 hour lumen maintenance	All products	<i>Define maximum number of samples that may fail specified lumen maintenance criteria out of the number that are tested.</i>
Fluorescent light durability	4.2.4.3 Fluorescent light durability	Products with fluorescent lights	<i>Define maximum number of failures out of the number that are tested.</i>
AC-DC Charger Safety	4.2.11.1 Product and manufacturer information 4.2.11.3 Third-party marks and certifications	Products with AC-DC chargers included	<i>Define acceptable safety approval marks and certifications for AC-DC chargers.</i>
Hazardous Substances Ban	4.2.2.4 Energy storage system information 4.2.2.6 Battery general aspects 4.2.11.1 Product and manufacturer information	All products	<i>Define allowable battery chemistries.</i>
Cable Specifications	4.2.11.1 Product and manufacturer information 4.2.11.3 Third-party marks and certifications	All products	<i>Define acceptable approval marks and certifications for outdoor cables</i>
Circuit and Overload Protection, PV Overvoltage Protection, and Miswiring Protection	4.2.8.3 Circuit and overload protection	All products	<i>Define maximum number of failures and number of samples to be tested</i>

Table 5 – End-user support standards

Truth-in-advertising criterion	Aspect(s) considered in assessment	Requirement
Information on product design, utilization, and care	4.2.2.7 Packaging and user's manual information	<i>Define if there are requirements for consumer-facing information on packaging or in a user's manual, such as end-of-life disposal instructions, specifications of replaceable components, and instructions for product installation and maintenance.</i>
Other	4.2.2.11 Other visual	<i>Define other product requirements that support end-users to</i>

	screening results	<i>maintain the quality of the product.</i>
--	-------------------	---

5.4.2.6 Warranty requirements

The product shall meet each of the end-user support requirements listed in Table 6.

Table 6 – End-user support requirements

Support type	Aspect(s)	Requirement
Maintenance and warranty terms	4.2.2.8 Warranty information	<i>Define minimum warranty requirements (length, components covered, etc.)</i>
Service capabilities	4.2.11.2 Warranty coverage	<i>Define “on the ground” requirements for warranty service (typically only for projects in a specific location)</i>

5.4.3 Tolerances

Tolerances are an allowable deviation from the target value for a particular criterion in a product specification and are part of the product specification. In the case of truth in advertising the target value is what is advertised. Durability tests and other pass/fail criteria also have a target—passing the test.

Tolerances should be set carefully, considering how the measured or observed values from a test (with a limited number of samples) characterize the true quality or performance aspects of every product in the market. The sample size, expected manufacturing tolerance, and testing uncertainty should each be considered.

There are trade-offs between protecting buyers/end-users and suppliers from “false positive” and “false negative” results, respectively. Tighter tolerance tends to protect buyers/end-users better from poor quality or performance products but will also result in a higher number of good quality or performance products being excluded based on non-representative sampling or test results. The dynamic is reversed for looser tolerances.

The type of tolerance depends on the aspect being specified:

- a) Qualitative: aspects that are descriptive (e.g., type of light source) do not typically have a tolerance.
- b) Numeric: aspects that are described with a measured value (e.g., battery capacity) should have a tolerance defined in terms of percent deviation of the average DUT measurement from a particular value. Often it is allowable for the test result to deviate in one “direction” but not the other. For instance, it is allowable to over-perform on the run time but not underperform. There may also be a tolerance defined for the variance in results of the DUT.

In general, the percent deviation from a target value is calculated using the following formula:

$$D = \frac{x_{\text{target}} - x_{\text{meas}}}{x_{\text{target}}} \times 100\%$$

where:

D is the percent deviation in a numeric value;

x_{target} is the target value;

x_{meas} is a measured value or the average of the measured values for each sample.

- c) Boolean: aspects that are described in terms of “pass/fail” (e.g., drop test) should have a tolerance defined in terms of the number of allowable failures out of a set number of trials or tests. Note that the statistical power of Boolean results for predicting population pass/fail rates is not very high with small sample sizes. The implication is that it is not possible to accurately predict population failure rates for a particular aspect from a small

sample size, and it is often appropriate to allow some small but reasonable failure rate to avoid false negative results.

5.4.4 Quality standards criteria

5.4.4.1 General

Subclause 5.4.4 describes the quality standards aspects and give guidance on how to implement a quality standard.

There are several categories of quality criteria listed below. For each category, it is important for a set of quality standards to specify:

- Which aspects are referenced by the criteria.
- What level of failure or minimum quality level is acceptable for each aspect.
- Which product categories are subject to each criterion if there are differences across categories.

5.4.4.2 Truth in advertising

The goal of a truth-in-advertising standard (see Table 7) is to protect buyers and end-users from false advertising claims. It is particularly important to ensure that the description of advertised values corresponds with test results in cases where buyers (anywhere in the supply chain) will make product purchasing decisions based partly or solely on advertising and packaging or where users have expectations set by them.

In practice it is ideal to check **any** advertised quality or performance statements against the test results, keeping in mind that often the framing or messaging for advertised statements is different from test conditions and that there is always inherent uncertainty in the test result. In cases where the advertised values will not be directly comparable to test results, care should be taken to avoid wrongly identifying false advertising while maintaining vigilance for buyers.

For aspects that are described with numeric information, a tolerance should be defined for truth in advertising.

For aspects that are described with qualitative or Boolean information, judgement is required to discern if the test results match advertised values.

Table 7 – Truth-in-advertising criteria for quality standards

Truth-in-advertising criterion	Aspect(s) considered in assessment	Standard specification	Remarks
System performance tolerance – numeric ratings	4.2.9 Performance aspects 4.2.10 Light output aspects Others, if applicable	The tolerance between the rated performance and measured performance.	These are key aspects for end-user experiences with the product, but also tend to have test results with higher uncertainty due to a combination of intrinsic manufacturing variation and test uncertainty due to the system-level nature of the aspects.
System components tolerance – numeric ratings	4.2.5 Battery performance aspects 4.2.7 Solar module aspects 4.2.8.1 Appliance voltage compatibility 4.2.8.2 Power consumption 4.2.8.4 DC ports Others, if applicable	The tolerance between the rated performance and measured performance.	These aspects, while important, have less impact on the overall user experience in general. They are more important for identifying replacement parts.
Other numeric ratings tolerance	Multiple	The tolerance between the rated performance and measured performance.	n/a
Overall truth-in-advertising statement	Multiple	Describe the general policy for interpreting truth-in-advertising requirements. Suggested statement: “All advertised features must be functional. Any description of the product that appears on the packaging, inside the package and in any other medium (internet, etc.) should be truthful and accurate. No statements should mislead buyers or end users about the features or utility of the product. Any user interfaces (charge indicators, SOC estimates, etc.) must be accurate.”	It is important to lay out a broad expectation of truth in advertising and to interpret it on a case-by-case basis.

Table 8 includes notes with guidance on aspects that are often part of a truth-in-advertising check because they are commonly advertised.

Table 8 – Remarks on common truth-in-advertising aspects

Aspect(s)	Remarks
4.2.9.2 Daily energy service	Depends on the desired services / appliances
4.2.9.5 Lighting full-battery run time	Depends on the setting.
4.2.9.3 Solar-day lighting run time	Depends on the setting and often depends on the assumptions about solar resource, which may be location-dependent.
4.2.10.1 Luminous flux output	The light output of a DUT when it is operated at the standard operating voltage or when an individual lighting appliance is measured at the typical port voltage.
4.2.2.4 Energy storage system information 4.2.2.6 Battery general aspects 4.2.5 Battery performance aspects 4.2.2.5 Battery easy replaceability	Package type, nominal voltage, capacity are all important for understanding if spares will be available; the replaceability determines if it is easy to service.
4.2.10.3 Average light distribution characteristics	Peak illuminance at a specified distance is often advertised in lieu of luminous flux. It is important to carefully adjust the test result to match the distance specified in the advertised value using known light propagation relationships (“inverse square law”).
4.2.7 Solar module aspects	Peak power capacity and type are often listed.
4.2.2.9 Auxiliary outlets, ports and adapters information 4.2.2.10 Appliances information	The presence of functional auxiliary features (e.g., a mobile phone charger or USB power source) and available appliances (e.g., fan, radio, or television) may be very important to some end-users.
4.2.3.1 Water protection – enclosure 4.2.3.2 Water protection – circuit protection and drainage	Ensure that there is no information that misleads consumers about the level of protection afforded them by the combination of the enclosure and other water protection systems.
4.2.4.2 2 000 hour lumen maintenance	Lifetime is often given for much longer durations (e.g., 20 000 h). These may be compared to the 2 000 h lifetime to ensure the claim is possible.

5.4.4.3 Safety and durability

5.4.4.3.1 General

Safety and durability criteria protect the user from harm and the product from early failure during typical use. It is important to balance the safety and durability requirements with cost implications and reasonable expectations of consumer care, or the safety and durability criteria risk being over-prescribed. It is helpful to consider the expected minimum product lifetime when determining durability-related criteria.

For pass/fail tests, tolerances for failure rates should be specified (see Table 9).

Table 9 – Safety and durability criteria for quality standards (1 of 2)

Safety or durability criterion	Aspect(s) considered in assessment	Standard specification	Remarks
Level of water exposure protection (overall, technical, or enclosure-only)	4.2.3.1 Water protection – enclosure 4.2.3.2 Water protection – circuit protection and drainage 4.2.3.3 Water protection - overall 4.2.3.4 Water protection – solar module 4.2.11.1 Product and manufacturer information 4.2.2.7 Packaging and user’s manual information	The required level of water protection (see list below) and which aspects may contribute to protection. Levels of water protection: No protection Occasional rain Frequent rain Permanent outdoor exposure Permanent exposure in context of rooftop installation for PV modules	The degree of protection should include consideration of product category and expected exposure. Specify the aspects that may contribute to the level of water exposure protection by choosing an overall, technical, or enclosure-only criterion.
Physical ingress protection	4.2.3.5 Physical ingress protection 4.2.3.6 Physical ingress protection – solar module	The required level of physical ingress protection in terms of the minimum IP Class.	Degree of protection should include consideration of product category and expected exposure. Also, consider how connectors will be incorporated. Most external power connectors are not protected above IP2x.
Mechanical durability – drop test	4.2.3.7 Drop resistance	The required success rates in the drop test for functionality and safety (two success rates).	Failure allowance should consider Boolean nature of results and consider product category (i.e., fixed products are unlikely to be dropped compared to portable products, and TVs may not be expected to be dropped).
Mechanical durability – goosenecks and moving parts	4.2.3.8 Gooseneck and Moving Part durability	The required success rates in the gooseneck and moving parts durability test for functionality and safety (two success rates).	Only applies to products with goosenecks or moving parts.
Mechanical durability – connectors	4.2.3.9 Connector durability	The required success rates in the connector test for functionality and safety (two success rates).	Failure allowance should consider Boolean nature of results.
Mechanical durability – switches	4.2.3.10 Switch durability	The required success rates in the switch test for functionality and safety (two success rates).	Failure allowance should consider Boolean nature of results.
Mechanical durability – strain relief	4.2.3.11 Strain relief durability	The required success rates in the switch test for functionality and safety (two success rates).	Failure allowance should consider Boolean nature of results.
Workmanship	4.2.3.12 Wiring quality	The required success rate for each aspect of the wiring quality inspection.	Failure allowance should consider the prevalence of each fault type.

Table 9 – Safety and durability criteria for quality standards (2 of 2)

Safety or durability criterion	Aspect(s) considered in assessment	Standard specification	Remarks
Battery durability	4.2.3.13 Battery protection strategy 4.2.5.3 Battery storage durability 4.2.11.1 Product and manufacturer information 4.2.11.3 Third-party marks and	The guidelines for determining if batteries are well protected from early failure and if users are protected from potential harm due to battery failure.	Be careful not to over-prescribe the requirements, since there are a wide range of battery protection strategies that may provide satisfactory results—particularly for emerging chemistries.
Lumen maintenance	4.2.4.2 2 000 hour lumen maintenance	The minimum average level of lumen maintenance after 2 000 h and the required success rate on a sample-to-sample basis.	Consider the expected rate of use and desired product lifetime.
Fluorescent light durability	4.2.4.3 Fluorescent light durability	The required success rate for each sample in additional tests for fluorescent light durability.	Failure allowance should consider Boolean nature of results.
AC-DC Charger Safety	4.2.11.1 Product and manufacturer information 4.2.11.3 Third-party marks and certifications	The guidelines for determining if AC-DC chargers have acceptable safety approval marks and certifications.	Self-certification marks may not be meaningful if no market oversight exists.
Hazardous Substances Ban	4.2.2.4 Energy storage system information 4.2.2.6 Battery general aspects 4.2.11.1 Product and manufacturer information	The guidelines for determining allowable battery chemistries.	A hazardous substance ban could apply to product components beyond the battery, though monitoring and enforcement may be difficult in most markets.
Cable Specifications	4.2.11.1 Product and manufacturer information 4.2.11.3 Third-party marks and certifications	The guidelines for determining if outdoor cables have acceptable safety approval marks and certifications.	Self-certification marks may not be meaningful if no market oversight exists.
Circuit and Overload Protection, PV Overvoltage Protection, and Miswiring Protection	4.2.8.3 Circuit and overload protection	The required success rate and number of samples required for each protection test.	Failure allowance should consider Boolean nature of results, while sample number should consider the that each test is destructive.

5.4.4.3.2 Water exposure protection considerations

The specifying organization should consider several factors when establishing water exposure protection requirements for solar lighting products. The product category (as outlined in 4.1.2) is primarily responsible for determining these requirements, as some products are more likely than others to be exposed to water based on the product design. Cost is also a consideration, as products designed to be resistant to higher levels of water exposure are often more expensive because of the additional manufacturing costs associated with sealing the enclosure or internal circuit elements.

Table 10 describes how various levels of water protection are determined based on a combination of laboratory test results, product design and manufacturing information, and consumer information. The levels of protection are:

- No protection
- Occasional rain
- Frequent rain
- Permanent outdoor exposure
- Permanent exposure in context of rooftop installation for PV modules

The results of an assessment will include several “types” of water protection level. A quality standard will need to specify which type is applicable. The types are:

- Overall protection: water protection by all the potential sources, including user behaviour
- Technical protection: protection from all product design and manufacturing aspects
- Enclosure-only protection: protection from the enclosure only

Table 10 – Recommended level of water protection by product category

Product category	Recommended level of water protection	Remarks
Fixed separate (indoor)	No protection	Products intended for indoor use are unlikely to be exposed to water and do not require water protection.
Portable separate	Occasional rain	Portable products may experience occasional water exposure in service and should have some degree of water protection.
Portable integrated	Frequent rain	Portable integrated products are likely to be exposed to water when left outside to solar charge and should have good water exposure protection.
Fixed integrated (outdoor)	Permanent outdoor exposure	Outdoor products are certain to be exposed to rain and should have a high degree of water exposure protection.
Separate PV module	Permanent rooftop installation for PV modules	Separate PV modules are certain to be exposed to rain and any sensitive electronics should have a high degree of water exposure protection.

5.4.4.4 End-user support

End-user support criteria describe the information (labelling, instructions, and built-in indicators) that enables end-users to maintain and fully realize the potential of a device (Table 11).

Table 11 – End-user support criteria for quality standards

End user support criterion	Aspect(s) considered in assessment	Standard specification	Remarks
Information on product design, utilization, and care	4.2.2.7 Packaging and user's manual information	Requirements for end-user information.	Define if there are requirements for consumer-facing information on packaging or in a user's manual. In some cases, a specific piece of information may have implications for the required level of quality in another criterion (e.g., advising the user to protect the device from exposure to water on the packaging or in the user's manual may warrant a reduction in the requirements for water protection defined by 4.2.3.1 and 4.2.3.2)
Other	4.2.2.11 Other visual screening results	Requirements for particular aspects of the visual screening.	Define if there are requirements for other aspects of end-user support (e.g., indicator lights). As with requirements for consumer-facing information, these requirements should be added with care to avoid over-prescribing.

5.4.5 Warranty requirements criteria

Warranty requirements are generally narrow in scope, focusing on the minimum duration and coverage for product warranties. In situations where there is a specific need for service in a

particular location, service capabilities may be added to the warranty requirements. Table 12 lists criteria that are included in a warranty standard.

Table 12 – Criteria for warranty standards

End user support criterion	Aspect(s) considered in assessment	Standard specification	Remarks
Maintenance and warranty terms	4.2.2.8 Warranty information	Minimum warranty duration and coverage.	Define the minimum warranty terms with consideration for the implications on availability of service and reasonable expectations for guaranteed lifetime.
Service capabilities	4.2.11.2 Warranty coverage	Minimum availability of service to end-users in a particular location	These requirements are very specific to “local” projects typically.

6 Quality test method

6.1 General

The Quality Test Method (QTM) is a rigorous set of tests with a relatively large sample size that uses randomly procured samples. It is the most stringent set of tests in this technical specification and is appropriate for:

- Qualification for market support programmes
- Generating information for third-party verified specification sheets

6.2 Applications

QTM tests can support a broad range of quality assurance needs where rigorous, unbiased test results are required. Table 13 lists examples of how they are applied depending on the type of quality assurance framework:

Table 13 – Applications of product specifications

Type of QA framework	Example(s) of applying Clause 6
General market support	Require QTM results for qualifying for market support. Accept QTM results from any accredited laboratory. Use QTM results to produce standardized specification sheets.
Manufacturing / distribution	Use QTM results to assess the full production / supply chain. Require QTM results for assessing potential business partners. Accept QTM results from any accredited laboratory.
Bulk procurement	Require QTM results for assessing potential suppliers. Accept QTM results from any accredited laboratory.
Trade regulation	Require QTM results for qualifying for tax exemption. Accept QTM results from any accredited laboratory.

6.3 Sampling requirements

The product samples should be selected and shipped to the test lab according to the random sampling guidelines outlined in Annex D.

The recommended number of samples to procure for QTM testing is 16: four each for two parallel batches and four destructive tests plus four spares.

To minimize the in-kind cost of products and shipping costs, an alternative to sampling 16 complete kits is to sample the following numbers of individual components, along with the packaging for the kit. The recommended numbers of samples of each individual component to procure for QTM testing are as follows:

- PV module: 9
- PV mounting material, if applicable: 1
- Control box with battery: 12
- Battery only: 4 (if cell balancing or protection is included in the control box, 4 additional control boxes should be sampled as well)
- Included lighting appliances: 13 of each type
- Included non-lighting appliances (or lighting appliances that are not required to undergo the lighting tests): 9 of each type
- Included lighting appliance with its own battery: 13 of each type

These recommendations assume that 4 spares are sufficient to conduct the potentially destructive tests, such as the drop test, miswiring test, output overvoltage protection, PV overvoltage protection, and switches/connectors test. If additional samples are required, they may be procured during the testing process.

6.4 Laboratory requirements

The test laboratory should be properly trained to undertake the test methods described below and accredited by an international or national standards body (e.g., ILAC using ISO 17025). The measurement equipment should be calibrated against reference instruments annually, or as directed by the equipment manufacturer or laboratory accreditation organization.

6.5 Testing requirements

Each of the aspects listed in Table 14 should be measured where they are applicable to a product. It is not necessary that each aspect be measured on each sample under test, but it is important to note in the test results which samples were the source of each result in an unambiguous way. A general description of the test method family for each aspect is listed for informative purposes only. In Table 14, the designation “all products” indicates that the aspect should be measured for all types of products, including sub-components or appliances, unless otherwise indicated. The product specification may define categories of lighting appliances that need not be subjected to the lighting tests, as noted below.

For products with multiple settings, at least one set of test results should fully characterize the performance on the highest light output setting. Additional settings may be measured at the discretion of the test laboratory to verify advertising statements from the manufacturer when other light settings are advertised, or as required in the product specification.

Table 14 – QTM testing requirements (1 of 3)

Aspect	Reference	Applicability	Sample size	Test classes	Test method family
Product design, manufacture, and marketing aspects	4.2.2				
Arrangement of components	4.2.2.1	All products	1	A	Visual screening
Charging system information	4.2.2.2	All products	1	A	Visual screening
Lighting system information	4.2.2.3	All products	1	A	Visual screening
Energy storage system information	4.2.2.4	All products	1	A	Visual screening
Battery easy replaceability	4.2.2.5	All products	1	A	Visual screening
Battery general aspects	4.2.2.6	All products	1	A	Visual screening
Packaging and user's manual information	4.2.2.7	All products	1	A	Visual screening
Warranty information	4.2.2.8	All products	1	A	Visual screening
Auxiliary features information	4.2.2.9	All products	1	A	Visual screening
Appliances information	4.2.2.10	All products	1	A	Visual screening
Other visual screening results	4.2.2.11	All products	1	A	Visual screening
Product durability and workmanship aspects	4.2.3				
Water protection – enclosure and PV module	4.2.3.1 4.2.3.4	All products	1	A,B	IP class assessment
Water protection – circuit protection and drainage	4.2.3.2	At the request of the testing client	1	A	n/a
Water protection - overall	4.2.3.3	All products	1	A	IP class assessment
Physical ingress protection	4.2.3.5 4.2.3.6	All products	1	A,B	IP class assessment
Drop resistance	4.2.3.7	Portable components, excluding TVs and other specified appliances that are not typically expected to meet durability standards	4	A,B	Durability
Gooseneck and moving parts durability	4.2.3.8	Products with a gooseneck or moving parts	4	A	Durability
Connector durability	4.2.3.9	All products	4	A	Durability
Switch durability	4.2.3.10	All products	4	A	Durability
Strain relief durability	4.2.3.11	All products	4	A	Durability
Wiring quality	4.2.3.12	All products	4	A	Visual screening

Table 14 – QTM testing requirements (2 of 3)

Aspect	Reference	Applicability	Sample size	Test classes	Test method family
Battery protection strategy	4.2.3.13	All products	4	A	Charge controller testing
Lighting durability aspects	4.2.4				
2 000 hour lumen maintenance	4.2.4.2	All products required to undergo lighting tests	4	A	Lumen maintenance
Fluorescent light durability	4.2.4.3	Products with fluorescent light required to undergo lighting tests	4	A	Extra tests for fluorescent lights
Battery performance aspects	4.2.5				
Battery capacity	4.2.5.1	All products and appliances with internal batteries	4	A	Battery tests
Battery round-trip energy efficiency	4.2.5.2	All products and appliances with internal batteries	4	A	Battery tests

6.6 Recommended tests programme

6.6.1 General

The following programme, illustrated in Figure 6.1, is one strategy to accomplish all the tests in a timely manner.

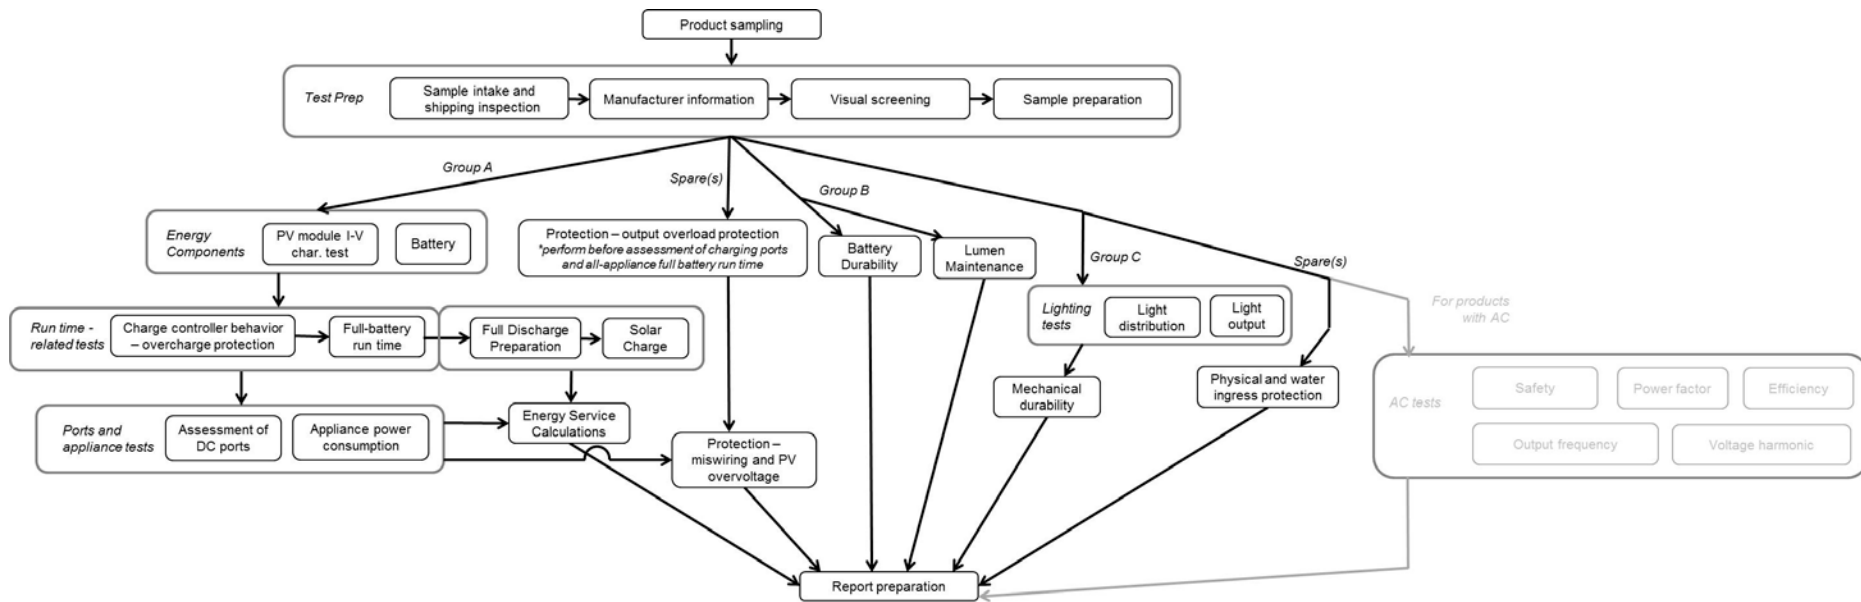

Figure 6.1 – Recommended sequence of testing for QTM

6.6.2 Test preparation

6.6.2.1 General

The initial intake steps involve ensuring the samples are intact, preparing them for further tests, and requesting self-certification information from the manufacturer.

6.6.2.2 Test sample intake and shipping inspection

The samples should all be inspected for shipping damage, unambiguously labelled for identification during the testing process, and placed into batches.

6.6.2.3 Manufacturer self-reported information

If it has not already been done, the manufacturer (or their proxy) should be contacted to ask for self-certification information that is outlined in Annex C and to inform them the test samples were received.

6.6.2.4 Visual screening

The visual screening should be done before any other tests and before the samples are altered to prepare them for other tests. The visual screening procedure is presented in Annex E.

6.6.2.5 Sample preparation

After the visual screening, prepare the samples for further testing by partially disassembly to provide easy access to various components. Sample preparation procedures are presented in Annex F. All samples, except for spares, shall be prepared.

6.6.3 Batch A tests

6.6.3.1 General

Batch A undergoes the set of tests to assess the DUT's energy service aspects.

6.6.3.2 Energy component tests

6.6.3.2.1 General

Energy component tests can generally be done independently of each other on an ad-hoc basis. The recommendation is to complete them before running system-level tests, or complete them opportunistically as is appropriate.

6.6.3.2.2 Battery test

The battery tests (in particular capacity measurements) should be done before any system-level run time tests to ensure the batteries are “refreshed” from any time they spent in storage before testing. The battery test procedure is presented in Annex I.

6.6.3.2.3 Photovoltaic module I-V characteristics test

Since outdoor solar module testing is subject to the availability of a clear “solar window” they are often the most “opportunistic” of the tests in the programme. The photovoltaic module I-V characteristics test procedure is presented in Annex H.

For amorphous solar modules, it is important to begin sun soaking the modules immediately after they are received since at least 30 days of outdoor exposure are needed before the tests commence.

6.6.3.3 Run time tests

6.6.3.3.1 General

The full-battery run time test should be carried out prior to the additional run time related tests. The additional run time related tests require using measured values during the test to determine the specified run time.

6.6.3.3.2 Full-battery run time

It is often convenient to do the full-battery run time test directly after the battery capacity measurements. Cycle the batteries (as is done in the battery capacity measurements) and fully charge them before this test. The full-battery run time test procedure is presented in Annex L.

6.6.3.4 Charge controller behaviour test

The deep-discharge protection charge controller measurement may be incorporated into the full-battery run time. The overcharge protection charge controller measurement requires independent testing. The charge controller behaviour test procedure is presented in Annex K.

6.6.3.5 Full discharge preparation

A full discharge must be conducted to prepare the sample for the solar charge test. Procedures for a full discharge are presented in Annex M.

6.6.3.6 Solar charge test

Solar charging efficiency testing shall be commenced after the sample is fully discharged according to the full discharge preparation in Annex M. The solar charge efficiency value is used to determine the solar run time. The solar charge test procedure is presented in Annex N.

6.6.3.7 Energy Service Calculations

The energy service calculations described in Annex R are used to estimate the system-level run time at a given utility level (e.g., lumens of light, or volume of radio play). The calculations use values from the battery test (Annex I), the solar charge test (Annex N), the assessment of DC ports (Annex P), generic appliances (Annex CC), Appliance tests (Annex Q), and full-battery run time test (Annex L). All of these tests must be conducted prior to finalizing the energy service calculations.

6.6.4 Batch B tests

6.6.4.1 General

Batch B undergoes long-term lumen maintenance testing in parallel with Batch A testing.

6.6.4.2 Lumen maintenance test

The batch B samples shall not have undergone any other testing prior to lumen maintenance testing. This test is long-term and is carried out in parallel with those tests undergone by batch A samples. The lumen maintenance test procedure is presented in Annex T.

6.6.4.3 Battery durability test

While the lighting appliances of the batch B samples are connected to power supplies for the lumen maintenance test, the batteries of the batch B samples are tested for durability during storage according to the test procedure in Annex S. This test is also long-term and is carried out in parallel with the tests undergone by batch A samples.

6.6.5 Batch C tests

6.6.5.1 General

Batch C undergoes light output and distribution testing. The potentially destructive mechanical durability tests may be conducted following the lighting tests or may be conducted on unaltered spare samples or minimally altered samples from batch A or B.

6.6.5.2 Light output test

The light output test is not strictly on components, but of a system including a driver, light source, and optical components. However, the system may be treated as a single component if it is separable from the other main components while maintaining the same electrical and thermal characteristics that are present when the product is fully assembled. The light output test procedure should be done after the full-battery run time test and is presented in Annex U.

6.6.5.3 Light distribution test

Like the light output test, the light distribution test is not strictly on components, but of a system including a driver, light source, and optical components. However, the system may be treated as a single component if it is separable from the other main components while maintaining the same electrical and thermal characteristics that are present when the product is fully assembled. The light distribution test procedure should be done after the full-battery run time test and is presented in Annex V.

6.6.5.4 Mechanical durability test

It is preferable to do durability testing (switches, connectors, gooseneck/moving parts, and drop test) on the “spare” samples that have not been altered for testing. However, it is often infeasible to accomplish this if the unadulterated spares are required for other tests and in the best case there will be four unadulterated spares out of the original 16. In this case, the “least modified” samples from Batch A, B or C should be used. The mechanical durability test procedure is presented in Annex W.

6.6.6 Batch D / spares -- potentially destructive tests

6.6.6.1 General

The following tests are all potentially destructive and are to be conducted using a sample size of 1, rather than the sample size of 4 required for other tests.

6.6.6.2 Physical and water ingress protection test

Physical and water ingress protection shall be assessed on samples that have the least amount of impact or adulteration from the testing process. Unused spares should be the preferred samples for this assessment. The physical and water ingress protection test procedure is presented in Annex X. It is also possible for product to be assessed for water protection with the level of water protection procedure, which is presented in Annex Y.

6.6.6.3 Circuit protection tests

6.6.6.3.1 Output overload protection test

This test assesses whether the DUT is protected against excessive load or short circuits applied to the appliance receptacles and is described in Annex O. The test is not dependent on any other tests, but is required to be conducted prior to the assessment of DC ports in Annex P. The test is potentially destructive and should be conducted on either samples that have finished testing in batches B or C, or spare samples that are not required for any other tests.

6.6.6.3.2 Miswiring protection test

This test assesses whether the DUT is protected against improper wiring. The test is not dependent on any other tests, but is potentially destructive and should be conducted on either samples that have finished testing in batches A, B or C, or spare samples that are not required for any other tests. Note there are several situations described in Annex O in which this test is not required to be conducted.

6.6.6.3.3 PV overvoltage protection test

The PV overvoltage protection test assesses whether the DUT can withstand a PV overvoltage condition when the battery is disconnected. This test is conducted on only one sample and must be conducted after performing the photovoltaic module I-V performance test (Annex H). The test is potentially destructive and may be conducted on either samples that have finished testing in batches A, B or C, or spare samples. Note there are several situations described in Annex O in which this test is not required to be conducted.

6.6.7 Report preparation

After testing is complete and the results are validated, a report is generated and checked for accuracy before submission to the client.

6.7 Reporting

The report for QTM testing should support any activities that depend on the information from QTM testing.

At a minimum the report should include the following elements:

- a) Informative cover page.
- a) Summary page(s)
- b) Detailed test reports that include results for the aspects described in 6.5 that were measured at the primary test lab. Required results are listed at the end of each annex.
- c) Detailed test reports for tests performed at other labs (e.g., ingress protection test results done at a specialty IP test lab).
- d) Annexes that include supplementary images and/or other supporting information.
- e) Annexes that indicate manufacturer-provided information and self-certification evidence (e.g., certificates of compliance).

7 Market check method

7.1 General

The Market Check Method (MCM) is a flexible set of tests that is designed for market monitoring and enforcement. The MCM may comprise all the QTM tests, or a targeted subset of the QTM tests. The tests are designed for use in the following situations:

- when a program wants to monitor the on-going quality and performance of previously tested products
- when there is suspicion that products on the market are substandard compared to those that were originally tested for programme qualification or the production of a standardized specification sheet
- when a product is partially updated and an update is required for a standardized specification sheet

MCM testing may be implemented as a two-stage process. In the first stage, which is referred to as Primary Check Testing, the Initial Screening Method (ISM) described in Clause 8 is used with a sample size between two to four. If results from these tests meet or exceed performance from prior QTM testing, no further action is required. However, if the results indicate possible deficiencies relative to the Minimum Quality Standards and/or prior QTM test results, additional testing may be used to confirm the problem. This subsequent testing, which is referred to as Secondary Check Testing, will focus only on the aspects of the product that appeared to have deficiencies according to the Primary Check Testing results. The required sample size and allowable test classes for Secondary Check Testing using the MCM should be the same as those required for QTM testing of the same aspect (see 6.5).

Alternatively, if a product is partially updated or only suspected to be substandard in particular aspects, a program may choose to forego the first stage of Primary Check Testing and conduct targeted Secondary Check Testing on only those aspects.

7.2 Applications

MCM tests may have a narrower focus than QTM results—they can be targeted for determining if a deviation has occurred from previous QTM results for particular aspects. Table 15 lists examples of how MCM tests are applied depending on the type of quality assurance framework:

Table 15 – Applications of MCM results

Type of QA framework	Example(s) of applying MCM testing
General market support	Use MCM results for market monitoring and enforcement. Use MCM results to update standardized specification sheets. Use MCM results to renew QTM test results.
Manufacturing / distribution	Use MCM results for market monitoring.
Bulk procurement	N/A
Trade regulation	Use MCM results for market monitoring and enforcement.

7.3 Sampling requirements

The test samples should be randomly procured from retail outlets in the market according to procedures in Annex D. In select cases it may be appropriate to accept samples randomly sampled from a manufacturer’s warehouse according to procedures in Annex D.

Enough samples should be provided or selected so it is possible to complete the tests in a timely manner and account for unforeseen needs of additional samples.

The recommended number of samples for Primary Check Testing is eight: two per batch plus two spares. The recommended number of samples for Secondary Check Testing will depend on the aspects under test, but may be up to 16: four per batch plus adequate spares.

To minimize the in-kind cost of products and shipping costs, an alternative to sampling 8 complete kits is to sample the following numbers of individual components, along with the packaging for the kit. The recommended numbers of samples of each individual component to procure for QTM testing are as follows:

- PV module: 5
- PV mounting material, if applicable: 1
- Control box with battery: 6
- Battery only: 2 (if cell balancing or protection is included in the control box, 4 additional control boxes should be sampled as well)
- Included lighting appliances: 5 of each type
- Included non-lighting appliances (or lighting appliances that are not required to undergo the lighting tests): 5 of each type
- Included lighting appliance with its own battery: 7 of each type

These recommendations assume that 2 spares are sufficient to conduct the potentially destructive tests, such as the drop test, miswiring test, output overvoltage protection, PV overvoltage protection, and switches/connectors test. If additional samples are required, they may be procured during the testing process.

7.4 Laboratory requirements

The test laboratory should be properly trained to undertake the test methods described below and accredited by an international or national standards body (e.g., ILAC using ISO 17025). The measurement equipment should be calibrated against reference instruments annually, or as directed by the equipment manufacturer or laboratory accreditation organization.

7.5 Testing requirements

Most of the specific test requirements for MCM tests will depend on the aspects that are being tested.

The particular test plan for MCM testing is case-dependent and up to the judgement of the organization or institution who initiates the testing. The following recommendations should be kept in mind when creating MCM test plans:

- Always include a visual screening test to uncover any unexpected changes to the product; be ready to augment the original test plan pending the visual screening results.
- Consider system-level impacts of component changes.

7.6 Recommended tests programme

See 6.6.

7.7 Report requirements

The report for MCM testing should support any activities that depend on the information from MCM testing.

At a minimum the report should include the following elements:

- Informative cover page.
- Table of contents.
- Summary page(s)
- Detailed test reports that include results for the aspects described in 7.5.
- Annexes that include images and other supporting information.
- Annexes that indicate manufacturer-provided information and self-certification evidence (e.g., certificates of compliance).

8 Initial screening method

8.1 General

The Initial Screening Method (ISM) is appropriate for preliminary testing and providing quick feedback on product design and performance in absolute terms.

8.2 Applications

ISM tests should be used for obtaining quick, preliminary results to help inform subsequent rounds of testing that confirm the preliminary results. Table 16 lists examples of how they are applied depending on the type of quality assurance framework:

Table 16 – Applications of product specifications

Type of QA framework	Example(s) of applying Clause 8
General market support	Use ISM results to filter potential organizations / products for targeted support, followed up by QTM testing for those with promise. Use ISM results to trigger MCM testing when there is suspicion of a change in the quality or performance of products in the market.
Manufacturing / distribution	Use ISM results for batch-to-batch monitoring of production runs of shipments.
Bulk procurement	Use ISM results for batch-to-batch monitoring shipments.
Trade regulation	Use ISM results to make preliminary decisions, followed up with QTM testing to confirm results.

8.3 Sampling requirements

The test samples may be provided directly by a manufacturer (or their proxy) or may be randomly procured from the market according to procedures in Annex D.

Enough samples should be provided or selected so it is possible to complete the tests in a timely manner and account for unforeseen needs of additional samples.

The recommended number of samples for ISM testing is four: one each for three parallel batches and one spare. It may be necessary to obtain additional spares if the product fails more than one of the potentially destructive tests.

To minimize the in-kind cost of products and shipping costs, an alternative to sampling 4 complete kits is to sample the following numbers of individual components, along with the packaging for the kit. The recommended numbers of samples of each individual component to procure for QTM testing are as follows:

- PV module: 3
- PV mounting material, if applicable: 1
- Control box with battery: 3
- Battery only: 1 (if cell balancing or protection is included in the control box, 1 additional control box should be sampled as well)
- Included lighting appliances: 3 of each type
- Included non-lighting appliances (or lighting appliances that are not required to undergo the lighting tests): 3 of each type
- Included lighting appliance with its own battery: 4 of each type

These recommendations assume that 1 spare is sufficient to conduct the potentially destructive tests, such as the drop test, miswiring test, output overvoltage protection, PV overvoltage protection, and switches/connectors test. If additional samples are required, they may be procured during the testing process.

8.4 Laboratory requirements

The test laboratory should be properly trained to undertake the test methods described below. The measurement equipment should be calibrated against reference instruments annually, or as directed by the equipment manufacturer.

8.5 Testing requirements

Each of the aspects listed in Table 17 should be measured where they are applicable to a product. It is not necessary that each aspect be measured on each sample under test, but it is important to note in the test results which samples were the source of each result in an unambiguous way. A general description of the test method family for each aspect is listed for informative purposes only. In Table 17, the designation “all products” indicates that the aspect should be measured for all types of products, including sub-components or appliances, unless otherwise indicated. The product specification may define categories of lighting appliances that need not be subjected to the lighting tests, as noted below.

For products with multiple settings, at least one set of test results should fully characterize the performance on the highest light output setting. Additional settings may be measured at the discretion of the test laboratory to verify advertising statements from the manufacturer when other light settings are advertised, or as required in the product specification..

Table 17 – ISM testing requirements (1 of 3)

Aspect	Reference	Applicability	Sample size	Test classes allowed	Test method family
Product design, manufacture, and marketing aspects	4.2.2				
Arrangement of components	4.2.2.1	All products	1	A	Visual screening
Charging system information	4.2.2.2	All products	1	A	Visual screening
Lighting system information	4.2.2.3	All products	1	A	Visual screening
Energy storage system information	4.2.2.4	All products	1	A	Visual screening
Battery easy replaceability	4.2.2.5	All products	1	A	Visual screening
Battery general aspects	4.2.2.6	All products	1	A	Visual screening
Packaging and user's manual information	4.2.2.7	All products	1	A	Visual screening
Warranty information	4.2.2.8	All products	1	A	Visual screening
Auxiliary features information	4.2.2.9	All products	1	A	Visual screening
Appliances information	4.2.2.10	All products	1	A	Visual screening
Other visual screening results	4.2.2.11	All products	1	A	Visual screening
Product durability and workmanship aspects	4.2.3				
Water protection – enclosure and PV module	4.2.3.1 4.2.3.4	All products	1	A,B	IP class assessment
Water protection – circuit protection and drainage	4.2.3.2	At the request of the testing client	0	A	n/a
Water protection - overall	4.2.3.3	All products	1	A	IP class assessment
Physical ingress protection – enclosure and PV module	4.2.3.5 4.2.3.6	All products	1	A,B	IP class assessment
Drop resistance	4.2.3.7	Portable components, excluding TVs or other specified appliances that are not typically expected to meet durability standards	1	A,B	Durability
Gooseneck and moving part durability	4.2.3.8	Products with a gooseneck or moving parts	1	A	Durability
Connector durability	4.2.3.9	All products	1	A	Durability
Switch durability	4.2.3.10	All products	1	A	Durability
Strain relief durability	4.2.3.11	All products	1	A	Durability
Wiring quality	4.2.3.12	All products	1	A	Visual screening
Battery protection strategy	4.2.3.13	All products	1	A	Charge controller testing
Lighting durability aspects	4.2.4				

Table 18 – ISM testing requirements (2 of 3)

Aspect	Reference	Applicability	Sample size	Test classes allowed	Test method family
500 hour lumen maintenance	4.2.4.1	All products required to undergo lighting tests	1	A	Lumen maintenance
Battery performance aspects	4.2.5				
Battery capacity	4.2.5.1	All products	1	A	Battery tests
Battery round-trip energy efficiency	4.2.5.2	All products	1	A	Battery tests
Battery storage durability	4.2.5.3	All products required to undergo lighting tests	1	A	Battery tests
Battery voltage	4.2.5.4	All products	1	A	Battery tests
Solar module aspects	4.2.6				
Solar I-V curve parameters	4.2.6.1	All products	1	A, B	Solar module tests
Solar module cable length	4.2.6.2	All products	1	A	Visual screening
Electrical characteristics	4.2.8				
Appliance voltage compatibility	4.2.8.1	All products with appliances	1	A	DC ports, Appliance tests
Power consumption	4.2.8.2	All products with appliances	1	A	Appliance power
Circuit and overload protection	4.2.8.3	All products; not required for appliances	1	A	Protection Tests
PV overvoltage protection	4.2.8.3	All products; not required for appliances	1	A	Protection test
Miswiring protection	4.2.8.3	All products; not required for appliances	1	A	Protection test
DC ports	4.2.8.4	All products; not required for appliances	1	A	DC ports
Performance aspects	4.2.9				
Daily energy service	4.2.9.2	All products	1	A	Energy Service Calculations
Solar-day lighting run time	4.2.9.3	All products	1	A	Energy Service Calculations
Solar-day appliance run time	4.2.9.4	All products	1	A	Energy Service Calculations
Lighting full-battery run time	4.2.9.5	All products	1	A	Energy Service Calculations
Light output aspects	4.2.10				
Luminous flux output	4.2.10.1	All products required to undergo lighting tests	1	A	Luminous flux

Table 19 – ISM testing requirements (3 of 3)

Full width half maximum (FWHM) angles	4.2.10.2	All products required to undergo lighting tests	1	A	Light distribution
Average light distribution characteristics	4.2.10.3	All products required to undergo lighting tests	1	A	Light distribution
Colour characteristics	4.2.10.4	Optional	1	A,B	Luminous flux
Circuit efficiency aspects					
Battery-charging circuit efficiency	4.2.6	Optional	1	A	Circuit efficiency
DC port efficiency	4.2.8.4	All products; not required for appliances	1	A	DC Ports
Self-certification aspects					
4.2.11					
Product and manufacturer information	4.2.11.1	All products	1	A	Self-reported
Warranty coverage	4.2.11.2	All products	1	A	Self-reported
Third-party marks and certifications	4.2.11.3	Optional	1	A	Self-reported

8.6 Recommended tests programme

See 6.6.

8.7 Reporting

The report for ISM testing should support any activities that depend on the information from ISM testing.

At a minimum the report should include the following elements:

- a) Informative cover page.
- b) Table of contents.
- c) Summary page(s)
- d) Detailed test reports that include results for the aspects described in 8.5.
- e) Annexes that include images and other supporting information.
- f) Annexes that indicate manufacturer-provided information and self-certification evidence (e.g., certificates of compliance).

9 Standardized specification sheets

9.1 General

Standardized Specification Sheets (SSS) are a way to communicate quality assurance information to the market. They include key information for potential buyers of off-grid lighting products. The information in SSS is based on standardized test results from QTM testing.

9.2 Applications

9.2.1 General

SSS requirements are useful to understand for the broad market, since they are typically the primary way to communicate and share QTM test results. Table 19 lists examples of how they are applied depending on the type of quality assurance framework:

Table 20 – Applications of product specifications

Type of QA framework	Example(s) of applying Clause 9
General market support	Administer a SSS third-party verification programme.
Manufacturing / distribution	Use SSS to advertise products.
Bulk procurement	Use SSS from third-party verified sources to screen potential products for purchase.
Trade regulation	Use SSS from third-party verified sources to screen applicants for import / tax programmes.

9.2.2 Guidance

A SSS guidelines document should provide a framework for providing clear information to buyers to enable fair comparisons to be made between different products. In general, the following are best practices for designing an SSS programme:

- Focus on specifications for system level performance (as opposed to component performance) wherever possible.
- Keep the required element list as short as possible for simplicity and clarity while still providing key information to the target buyers for the SSS programme.
- Reach out to the people who use SSS to make decisions and ask their opinion on them.
- Use graphics to convey key points.

9.2.3 Framework for SSS guidelines document

9.2.3.1 General

The key elements of a guidelines document for an SSS programme are:

- **Qualification requirements**, that is, the quality standards that shall be met to use the SSS.
- **Test result requirements**, including the type of testing required and requirements for updating the results in the SSS.
- **Style and format requirements** to ensure easy comparison of information across SSS.
- **Reporting precision** that guides the level of rounding that is allowed from measured test results.
- **Results verification** mechanisms to reduce the incidence of counterfeit SSS.
- **Required elements** that shall be in every SSS.
- **Optional elements** that may be included at the discretion of the manufacturer or their proxy.
- **An example** of the style, format, and contents in a fully implemented SSS.

An example framework document is included in Annex B.

9.2.3.2 Qualification standards

This defines if there are qualification criteria for participating in the SSS programme and generally references a product specification (see clause 5).

9.2.3.3 Test result requirements

9.2.3.3.1 General

Details on the test result requirements for information presented in the SSS. The details should be specific about the requirements both when SSS are originally made and when they are updated.

9.2.3.3.2 Original testing

Typically, QTM test results are used as the basis for the original SSS of a particular product. In some cases the results may come from other sources. It is important to specify how long results are valid before retesting is required.

9.2.3.3.3 Retesting and updates

This section of the guidelines document describes the test requirements for several situations:

- Full retesting after the original results have expired
- Partial retesting when the product is updated and the tolerance for changes in the specification that triggers retesting
- Partial retesting when a market check indicates there are discrepancies between the SSS and products available in the market

9.2.3.4 Style and format

The style and format of SSS is generally uniform across all the SSS in a particular programme to make them useful for buyers or other stakeholders who rely on them as an information resource.

Style and formatting guidelines should generally specify the following:

- Character font and size
- Use of colour
- General guidelines for language and style

The style and format guidelines are typically supplemented by an example SSS.

9.2.3.5 Reporting precision

Reporting precision guidelines describe the process to round quantitative test results so the information in each element of the SSS reflects the degree of significance for test results and is easy to read. For example, an average measurement of 52,3 lumens across several samples might be rounded to 50 lumens for placement on the SSS.

The guidelines should define three rounding rules for each SSS element that is covered:

- a) Maximum precision of reporting: The highest number of significant figures allowed in the display on the SSS.
- b) Minimum precision of reporting: The fewest number of significant figures allowed in the display on the SSS.
- c) Maximum adjustment before additional rounding: If an element is going to be displayed with fewer significant figures than specified in 9.2.3.5 (b), the maximum percentage a measured value may be adjusted up or down before additional rounding. Typically this is a very low number (e.g., 5 %).
- d) Allowable direction for additional rounding: If an element is going to be displayed with fewer significant figures than specified in 9.2.3.5 (b), this specifies the allowable direction for additional rounding. Often this is the direction towards “worse” performance or quality.

Table 20 lists several elements that might be included in a SSS and provides recommended rounding rules for each. A similar table should be included in SSS guidelines documents.

Table 21 – Recommended precision requirements for metrics on a continuous scale

Metric	Maximum precision of reporting	Minimum precision of reporting	Maximum adjustment before rounding	Allowable direction for additional rounding	Example(s)
Run time	2 s.f.*	1 s.f.	5 %	Down	4,33 h → 4,3 h or 4 h 36,6 h → 37 h or 30 h
Light output (lm)	2 s.f.	1 s.f.	5 %	Down	19,2 lm → 19 lm or 20 lm
Colour rendering (CRI) (R _a)	2 s.f.	2 s.f.	n/a	n/a	83,2 → 83
Colour temperature (CCT) (K)	2 s.f.	2 s.f.	n/a	n/a	4 678 K → 4 700 K
Light distribution (FWHM)	2 s.f.	2 s.f.	n/a	n/a	87°→87° 178°→180°
Battery capacity (Ah)	2 s.f.	2 s.f.	n/a	n/a	1,432 Ah → 1,4 Ah or 1,0 Ah
Other information	2 s.f.	1 s.f.	5 %	Varies	n/a
* s.f. = “significant figures”					

9.2.3.6 Results verification

Describe any features of the SSS that will facilitate verification of the contents. This may be via an online check, holograms, or any other security feature.

9.2.3.7 Section descriptions

Each section in the SSS should include a heading name and list the required and optional elements in the section. Each element should include a description of which aspects from the test results are referred to and a note on how to format the information. If graphics are used, a general format should be defined.

9.2.3.8 Example sheet

An illustrative example standardized specification sheet is provided below (Figure 9.1 and Figure 9.2).

Sunshine SHS

Lamp Manufacturer, Inc.

Results based on test procedures detailed in Solar Home System Test Method, Ed. 1.0

Verify online:

www.example.org/products/sunshine-lamp

Valid Until: July 2018

Available Daily Electrical Energy (Wh/day)

85

Lumens

1,700

Meets Quality Standards

Mobile Charging

Pay-As-You-Go Option Available

2 Light Points

2 5-volt USB Ports

4 12-volt Ports

Warranty Information

A 3-year warranty covering manufacturing defects in the system and a 2-year warranty for the battery.

Performance Details

Appliance**	Description	Included/Advertised	Run Time After a Typical Day of Solar Charging*		
			Used Alone***	Used In Combination****	Run Time Units
Main lighting	2 light points on totaling 1700 lumens	included	10	6.5	hours
Torch	25 lumens	included	9.0	8.2	hours
Television	16" TV	advertised	15	3.2	hours
Fan	table fan	advertised	18	4.4	hours
Radio	portable radio	advertised	30	2.3	hours
Mobile	2.6 Wh battery	advertised	10	1.2	number of full charges
Advertised lighting	3 light points on: night light, disco light and tube light	advertised	12	--	hours
Available daily electrical energy***** (Wh/day)			85		
Performance Measure			Brightness Setting: Two lights on		
Lighting full battery run time***** (hours)			15		
Total light output (lumens)			1700		
Work surface illuminance of a single lamp***** (lux)			110		

* A typical day of solar charging assumes 5 kWh/m²/day

**Only included appliances were tested. Run times for other appliances come from manufacturer power ratings or standard estimates.

*** Without any other loads used during the run time

**** Based on an example use profile with all of the advertised appliances listed above used in combination

***** Lighting full battery run time estimates do not account for mobile phone charging or other auxiliary loads; the run time is defined as the time until the output is 70% of the initial, stabilized output.

***** The work surface illuminance is the brightness over two A4 sheets of paper with the brightest light at a distance of 0.75 m.

Figure 9.1 — First portion of example SSS

Lighting Details	
Lamp type	LED
Description of light points	Two 400 lumen lamps
Colour characteristics	CRI 79 CCT "Cool" (5000-7000 K)
Distribution type	Wide
Lumen maintenance	>99% of the original output remains after 2,000 hours of run time
Special Features	
Mobile charging and appliances	USB and 12 V ports available to charge devices and power
Durability	
Overall durability and workmanship	Pass
Durability tests passed	Drop test (applies to torch), switch and connector cycling, strain relief test, physical ingress protection, protection from occasional rain (applies to torch)
Solar Details	
PV module type	Polycrystalline silicon
PV maximum power	30 watts
Battery Details	
Battery replaceability	Easily replaceable with common tools
Battery chemistry	Lithium iron phosphate
Battery package type	4x 1865 package
Battery capacity	12 Ah
Battery nominal voltage	13 V
Appropriate battery protection circuit	Pass
Marks and Certifications	
Factory certification	ISO 9001:2008
Product Details	
Manufacturer name	Lamp Manufacturer, Inc.
Product name	Sunshine SHS
Product model / ID number	sl-002
Contact information	sunny-info@sunshine.com
Website	www.sunshine.com/sunshine-lamp
SSS Information	
Specs sheet expiration date	July 2018
Quality Standards Framework Version	2016
Revision	2016.07

Figure 9.2 — Last (second) portion of example SSS

Annex A (informative)

Recommended quality standards for off-grid lighting market support programme qualification

A.1 Scope

These quality standards and warranty requirements are appropriate for qualification for market support programmes that support energy access for broad sets of end-users with low to middle incomes who are off-grid in the developing world.

The target end-users are typically cash-poor and will be expected to purchase qualifying products outright, under financing terms, or through pay-as-you-go (PAYG) mechanisms.

Meeting only the quality standards and warranty requirements provides access to basic programme services and incentives.

The aim of these quality standards is to protect end-users from early failure and ensure that advertised information is valid. The warranty requirements provide a baseline of support.

NOTE This product specification is meant to be an informative example, with a structure and set of standards based on experience in a particular context. It is expected that programmes that reference this quality assurance protocol will tailor a product specification to meet their needs.

A.2 Test requirements

Initial qualification under these standards requires QTM test results (Clause 6). On-going qualification is subject to successful market checks according to the market check method (Clause 7). Renewal testing, equivalent to a Primary Market Check Test, is required after two years.

A.3 Product category requirements

This document applies to solar home system products where all components are packaged as a kit. The kits shall be plug-and-play, with no design expertise required to choose appropriate system components and no technicians or electricians necessary to safely and successfully install and operate the system. Only DC systems, outputs and loads are covered. The system voltage shall be less than 50 V and the peak power rating of the kit shall not exceed 100 W. Batteries shall be field replaceable.

Components within the kit may be fixed separate (indoor), portable separate, portable integrated, and fixed integrated (outdoor).

Qualification as a “separate” PV module requires meeting the criteria listed in Table A.1:

Table A.1 – Qualification as separate PV module

Criterion	Aspect(s)	Required value
PV module cable length	4.2.7.2 Cable length	≥ 3 m to qualify as a “separate” PV module with 10 % tolerance

A.4 Quality standards

The product shall meet each of the criteria listed in Table A.2 and Table A.3 to meet the quality standards.

Table A.2 – Truth-in-advertising tolerance

Truth-in-advertising criterion	Aspect(s) considered in assessment	Requirement
System performance tolerance – numeric ratings	4.2.9 Performance aspects 4.2.10 Light output aspects Others, if applicable	≤ 15 % deviation from ratings (always ok if actual performance is better than advertised).
System components tolerance – numeric ratings	4.2.5 Battery performance aspects 4.2.7 Solar module aspects 4.2.8.1 Appliance voltage compatibility 4.2.8.2 Power consumption 4.2.8.4 DC ports Others, if applicable	≤ 15 % deviation from ratings (always ok if actual performance is better than advertised).
Other numeric ratings tolerance	Multiple	≤ 15 % deviation from ratings (always ok if actual performance is better than advertised).
Overall truth-in-advertising statement	Multiple	Any description of the product that appears on the packaging, inside the package, and in any other media should be truthful and accurate. No statements should mislead buyers or end users about the features or utility of the product.

Table A.3 – Safety and durability standards (1 of 2)

Safety or durability criterion	Aspect(s) considered in assessment	Component category	Requirement
Overall water exposure protection	4.2.3.1 Water protection – enclosure	Fixed separate (indoor)	No protection required.
	4.2.3.2 Water protection – circuit protection and drainage	Portable separate	Protection from occasional exposure to rain.
	4.2.3.3 Water protection - overall	Portable integrated	Protection from frequent exposure to rain.
	4.2.3.4 Water protection – solar module	Fixed integrated (outdoor)	Protection from permanent outdoor exposure.
	4.2.11.1 Product and manufacturer information 4.2.2.7 Packaging and user's manual information	External PV modules	Modified IPx4 or circuit protection.
Physical ingress protection	4.2.3.5 Physical ingress protection	All except below	Minimum of IP 2x protection.
	4.2.3.6 Physical ingress protection – solar module	Fixed integrated (outdoor)	Minimum of IP 5x protection.
		External PV modules	Minimum of IP3x protection.
Mechanical durability – drop test	4.2.3.7 Drop resistance	Fixed separate (indoor) and fixed integrated (outdoor)	No protection required
		Portable lighting components and appliance	Full drop test required (6 drops per sample). Maximum failure rate for functionality is 0/4; none result in safety hazards.
		Portable non-lighting appliances (excluding portable televisions)	Modified appliance drop test required (2 drops per sample). Maximum failure rate for functionality is 1/4; none result in safety hazards.
Mechanical	4.2.3.8 Gooseneck and	Any with gooseneck	Maximum failure rate for

durability – goosenecks and moving parts	Moving Part durability	or moving parts	functionality is 0/4; none result in safety hazards.
--	------------------------	-----------------	--

Table A.3 – Safety and durability standards (2 of 2)

Safety or durability criterion	Aspect(s) considered in assessment	Product category	Requirement
Mechanical durability – connectors	4.2.3.9 Connector durability	All products	Maximum failure rate for functionality is 0/4; none result in safety hazards.
Mechanical durability – switches	4.2.3.10 Switch durability	All products	Maximum failure rate for functionality is 0/4; none result in safety hazards.
Mechanical durability – strain relief	4.2.3.11 Strain relief durability	All products	Maximum failure rate for functionality is 0/4; none result in safety hazards.
Workmanship	4.2.3.12 Wiring quality	All products	Maximum prevalence of bad solder joints is 0/4 samples; maximum prevalence of poor wiring is 0/4 samples; maximum prevalence of overall workmanship failure is 0/4.
Battery durability	4.2.3.13 Battery protection strategy 4.2.5.3 Battery storage durability 4.2.11.1 Product and manufacturer information 4.2.11.3 Third-party marks and certifications	All products; not required for non-lighting appliances	An appropriate battery protection strategy is used that will protect batteries from early failure and end-users from harm. Lithium batteries must additionally carry UN 38.3 certification and be protected with a cell balancing circuit. The average capacity loss from storage of 4 samples shall not exceed 25% and only one sample may have a capacity loss greater than 35% following the battery durability storage test
Lumen maintenance	4.2.4.2 2 000 hour lumen maintenance	All products	L_{90} time is greater than 2 000 h for the average sample. No more than 1/4 samples fails (defined as being below L_{85} at 2 000 h). OR L_{95} time is greater than 1 000 h for all 4/4 samples.
Fluorescent light durability	4.2.4.3 Fluorescent light durability	Products with fluorescent lights	Maximum failure rate for functionality is 0/4.
AC-DC charger safety	4.2.2 Product design, manufacture, and marketing aspects 4.2.11.3 Third-party marks and certifications	Products that include an AC-DC grid charger	Any included AC-DC charger carries approval from a recognized consumer electronics safety regulator, such as UL or similar.
Hazardous Substances Ban	4.2.2.4 Energy storage system information 4.2.2.6 Battery general aspects 4.2.11.1 Product and manufacturer information	All products	No battery may contain cadmium or mercury at levels greater than trace amounts.
Cable Specifications	4.2.11.1 Product and manufacturer information 4.2.11.3 Third-party marks and certifications	All products	Any included outdoor cable shall be outdoor rated and UV-resistant.
Circuit and Overload Protection, PV	4.2.8.3 Circuit and overload protection	All products; not required for appliances	Maximum failure rate for functionality is 0/1 for each test.

Overvoltage Protection, and Miswiring Protection			
--	--	--	--

A.5 Warranty and end-user support requirements

The product shall meet each of the criteria listed in Table A.4 to meet the warranty requirements.

Table A.4 – End-user support requirements

Support type	Aspect(s)	Requirement
Information on product design, utilization, and care	4.2.2.7 Packaging and user's manual information	For products that include charging ports, user manual shall present instructions for installation, use and troubleshooting of the system. Installation instructions shall include appropriate placement and installation of the PV module. A description of the method or pathway for replacing components, including the battery, as well as specifications of components that may require replacement (fuses, batteries, PV) shall be included. Installation and operation instructions should be presented using language and graphics that can be understood by the typical consumer.
Maintenance and warranty terms	4.2.2.8 Warranty information 4.2.11.2 Warranty coverage	End-users are provided at least three years of warranty coverage from the point of purchase; it should cover manufacturing defects that impede operation under normal use and protection from early component failure, including at least two years coverage on the battery.

Annex B (informative)

Recommended SSS guidelines

B.1 Scope

These guidelines apply to creating SSS for market support programmes. The goal of the SSS is to provide clear, verifiable, and accurate information on quality and performance to potential buyers, with a focus on distributors and bulk purchasing agents.

B.2 Qualification standards

To qualify for the SSS programme, a product shall meet the quality standards and warranty requirements listed in Annex A.

B.3 Test result requirements

B.3.1 Original testing

QTM test results, obtained in accordance with Clause 6, are required for initial SSS qualification and creation.

B.3.2 Retesting and updates

Table B.1 lists the requirements for retesting to update SSS.

Table B.1 – Requirements for retesting to update SSS

Trigger for testing	Scope of testing	Test requirements	Remarks
Two years since previous QTM or MCM testing	Any element on SSS	QTM (Clause 6) MCM (Clause 7)	--
Product update with changes in performance aspects lower than $\pm 10\%$	None required	Self-declaration allowed	Performance aspects include light output and run time aspects.
Product update with changes in performance aspects greater than $\pm 10\%$	Elements that are different	Aspects related to element that is changing tested according to MCM (Clause 7) using randomly procured samples	--
Product update with changes in quality or durability aspects	Elements that are updated	Aspects related to element that is changing tested according to MCM (Clause 7) using randomly procured samples	Quality aspects include water protection, lumen maintenance, drop test, etc.
Product update with new, non-lighting features	Elements that are new	Aspects related to element that is changing tested according to MCM (Clause 7) using manufacturer-provided samples	--
A programme-initiated market check test (in accordance with MCM (Clause 7) indicates an improvement in quality or performance)	None required	Accept new results	--
A programme-initiated market check test in accordance with MCM (Clause 7) indicates a decline in quality or performance	Any element that is shown to decline	Aspects related to element that is changing tested according to MCM (Clause 7) using randomly procured samples	This essentially means that there is a chance to prove that programme-initiated market check results were an anomaly in cases where they indicate a reduction in quality or performance.

B.4 Style and format

Following are the style guidelines for SSS:

- a) Dominant colours: black and white.
- b) Secondary colours should be consistent and harmonized (e.g., on graphs); the base colour may be from the product packaging or corporate branding from the product marketer.
- c) Product images: colour image on a white background.
- d) Font: Helvetica; 12 pt for most text, 16 pt for product name on headline, 10 pt for notes and graphics.
- e) Language: English (optional to create translations in other languages).
- f) Style: Write in a way that is clear and understandable by a broad set of potential readers.

B.5 Reporting precision

The qualitative parts of the specification sheet (warranty, manufacturer name, lighting type, etc.) should always be accurate and updated.

Quantitative parts of the specification sheet that are reported on a continuous scale may be rounded for ease of interpretation. The rounded specification shall be reported so that it meets the precision guidelines presented in Table B.2. The guidelines are in terms of significant figures of reporting (s.f.). If one is rounding to the maximum precision, the rounding should be according to standard conventions ($\geq 0,5$ rounds to 1; $< 0,5$ rounds to 0). Alternatively, if the minimum precision requirements are lower than the maximum, one may round further (to fewer significant figures than the maximum) but any further rounding shall be in the “Allowable direction” as defined in the table, starting from the original measured value plus or minus the percentage adjustment that is allowed before additional rounding (i.e. the standard rounding convention does not apply in that case).

Table B.2 – Recommended precision requirements for metrics on a continuous scale

Metric	Maximum precision of reporting	Minimum precision of reporting	Maximum adjustment before rounding	Allowable direction for additional rounding	Example(s)
Run time (h)	2 s.f.	1 s.f.	5 %	Down	4,33 h → 4,3 h or 4 h 36,6 h → 37 h or 30 h
Light output (lm)	2 s.f.	1 s.f.	5 %	Down	19,2 lm → 19 lm or 20 lm
Colour rendering (CRI) (R_a)	2 s.f.	2 s.f.	n/a	n/a	83,2 → 83
Colour temperature (CCT) (K)	2 s.f.	2 s.f.	n/a	n/a	4 678 K → 4 700 K
Light distribution (FWHM)	2 s.f.	2 s.f.	n/a	n/a	87° → 87° 178° → 180°
Battery capacity (Ah)	2 s.f.	1 s.f.	n/a	n/a	1,432 Ah → 1,4 Ah or 1,0 Ah
Other information	2 s.f.	1 s.f.	5 %	Varies	n/a
NOTE s.f. = “significant figures”					

B.6 Results verification

Each SSS includes a unique internet URL that is directed towards a web page that is managed by [programme name]. If one goes to the web page, it is possible to download a verified copy of the SSS to ensure the veracity and validity of SSS.

B.7 Section descriptions

B.7.1 General

Subclauses B.7.2 through B.7.11 should be included in the SSS. Each section should begin with a grey bar with the section name in bold, black type. The elements in each section should be black type on a white background with thin grey lines separating the elements.

B.7.2 Header / overall performance

B.7.2.1 General

This SSS section includes the name of the product in the header area and a link to verify the SSS. The header elements are white text on a black background.

Below that is a description of the overall performance—brightness and run time—for up to two settings. For each of the settings listed, the lumen output and hours of run time should be described using plain language phrasing. The run time should be “on a full battery charge” for AC charged or central charging model products, “after one day of solar charging” for solar-charged products and “after XX minutes/hours of cranking” for electromechanically-charged products.

Next to the key performance indicator description is a “thumbnail” image of the product, only including items that are included in the package.

In this SSS section, only the content is displayed (the element names are not indicated). Table B.3 lists all of the elements that should be included in the header area.

Table B.3 – Elements in the header / overall performance SSS section

Element	Display type	Optional or required	Aspect(s) involved / origin of information	Remarks
Product name	Text	Required	4.2.11.1 Product and manufacturer information	The product name should be “complete” enough to differentiate it from other similar products in the same manufacturing line. Example: Sunshine Lamp
Verification link	Text	Required	Generated by SSS programme website developer	This unique link should point to a webpage where the original, up-to-date SSS is available for verification. Example: www.example.org/sss/sunshine-lamp
Expiration date	Text	Required	From QTM report	Indicate a date two years after the completion of the QTM test report that is the foundation for the SSS.
Results summary statement	Text	Required	4.2.8 Electrical characteristics 4.2.9 Performance aspects 4.2.9.3 Solar-day lighting run time 4.2.10.1 Luminous flux output	This is text that describes the run time and light output from the product, synthesized as a daily energy service number. See details on calculation in B.7.4. Example: 240 Wh/day
Thumbnail image	Image	Required	Provided directly by manufacturer or from 4.2.2.11 Other visual screening results.	The image should show the product against a white background.
Graphical summary	Graphic	Required	4.2.8 Electrical characteristics 4.2.9 Performance aspects 4.2.10.1 Luminous flux output 4.2.10.3 Average light distribution characteristics	This is a graphical summary of the daily energy service and brightness as described in the Results Summary Statement. It also includes an iconographic summary of features, and quality standards.

B.7.2.2 Graphical summary instructions:

The graphical summary should include two elements:

- Graph(s) showing the daily energy service and light output for the brightest setting
- Icons indicating successful passing or presence of features:
 - Overall workmanship pass
 - Number of ports and port types
 - Mobile charging feature
 - Number of light points
 - Meeting quality standard for a particular program
 - Optional pay-as-you-go (PAYG) feature

B.7.3 General information

Table B.4 lists the elements in the general information SSS section.

Table B.4 – Elements in the general information SSS section

Element	Display type	Optional or required	Aspect(s) involved / origin of information	Remarks
Manufacturer	Text	Required	4.2.11.1 Product and manufacturer information	The name of the manufacturer or “official” marketing firm for the product. Example: Sirius Lighting Corporation
Product name	Text	Required	4.2.11.1 Product and manufacturer information	The product name should be “complete” enough to differentiate it from other similar products in the same manufacturing line. Example: Sunshine Lamp
Model number	Text	Required	4.2.11.1 Product and manufacturer information	Often more detailed than the product name; may include version number.
Contact	Text	Required	4.2.11.1 Product and manufacturer information	An email or phone contact at the manufacturer
Website	Text	Optional	4.2.11.1 Product and manufacturer information	A URL for the manufacturer web page.
Warranty	Text	Required	4.2.2.8 Warranty information 4.2.11.2 Warranty coverage	A short (≤ 200 character) description of the warranty coverage that highlights the duration of coverage; this should match with the detailed information provided to consumers and documented in 4.2.2.8 Warranty information.

B.7.4 Performance Details

Table B.5 lists the elements in the performance details SSS section.

Table B.5 – Elements in the performance details section

Element	Display type	Optional or required	Aspect(s) involved / origin of information	Remarks
Lighting full-battery run time	Text	Required	4.2.9.5 Lighting full-battery run time	Specify a full-battery run time for each setting included in any other part of the SSS.
Run time per day of solar charging	Text	Required for solar products	4.2.9.3 Solar-day lighting run time	Specify a solar run time for each setting included in any other part of the SSS.
Light output	Text	Required	4.2.10.1 Luminous flux output	Include for each setting
Task surface brightness	Text	Optional	4.2.10.3 Average light distribution characteristics	Include for each setting
Daily energy service	Text	Required	Synthesis of other elements in performance details in 4.2.9.2 Daily energy service	The units are watt-hours/day (WH/day)

B.7.5 Light output

Table B.6 lists the elements in the light output SSS section.

Table B.6 – Elements in the light output SSS section

Element	Display type	Optional or required	Aspect(s) involved / origin of information	Remarks
Lamp type	Text	Required	4.2.2.3 Lighting system information	Include number and type of light sources.
Colour Characteristics	Text	Required	4.2.10.4 Colour characteristics	Include for highest setting; use "slider" graphics to display
Distribution category	Text	Required	4.2.10.2 Full width half maximum (FWHM) angles	Place in category based on FWHM angle: Narrow (<15°), Wide (15°-270°), Omni (>270°)
Lumen Maintenance	Text	Required	4.2.4.2 2 000 hour lumen maintenance	Indicate fraction of original light output remaining at 2 000 hours of operation.

B.7.6 Special features

Table B.7 lists the elements in the special features SSS section.

Table B.7 – Elements in the special features SSS section

Element	Display type	Optional or required	Aspect(s) involved / origin of information	Remarks
Mobile Charging	Text	Optional	4.2.2.9 Auxiliary outlets, ports and adapters information	Specify if a mobile charging feature is available
Other features	Text	Optional	4.2.2.9 Auxiliary outlets, ports and adapters information	Specify other features, such as housing material.

B.7.7 Durability

Table B.8 lists the elements in the durability SSS section.

Table B.8 – Elements in the durability SSS section

Element	Display type	Optional or required	Aspect(s) involved / origin of information	Remarks
Overall durability and workmanship	Text	Required	Multiple	Indicate pass or fail
Water protection	Text	Required	Water exposure protection as defined in Annex X: physical and water ingress protection test or Annex Y: Level of water protection	Specify the overall level of water protection and the elements of the product that contribute to the level of protection (enclosure, product design, user information)
Physical ingress protection	Text	Required	4.2.3.5 Physical ingress protection	Indicate pass or fail
Drop test	Text	Required	4.2.3.7 Drop resistance	Indicate pass or fail for damage, functionality, and safety.
Switches, connectors, strain relief, and goosenecks	Text	Required	4.2.3.8 Gooseneck and Moving Part durability 4.2.3.9 Connector durability 4.2.3.10 Switch durability 4.2.3.11 Strain relief durability	Indicate pass or fail for damage, functionality, and safety.

B.7.8 Solar module details

Table B.9 lists the elements in the solar module details SSS section.

Table B.9 – Elements in the solar module details SSS section

Element	Display type	Optional or required	Aspect(s) involved / origin of information	Remarks
PV module type	Text	Optional	4.2.2.2 Charging system information	Indicate PV chemistry (e.g., mono-Si)
PV maximum power	Text	Optional	4.2.7.1 Solar I-V curve parameters	Specify the PV power at standard test conditions (STC)

B.7.9 Battery details

Table B.10 lists the elements in the battery details SSS section.

Table B.10 – Elements in the battery details SSS section

Element	Display type	Optional or required	Aspect(s) involved / origin of information	Remarks
Battery replaceability	Text	Required	4.2.2.5 Battery easy replaceability	Either “easily replaceable” or “requires specialized technician”
Battery chemistry	Text	Required	4.2.2.4 Energy storage system information	Indicate chemistry
Battery package type	Text	Required if battery is easily replaceable, otherwise optional	4.2.2.6 Battery general aspects	Indicate the battery package type and/or size
Battery capacity	Text	Required	4.2.5.1 Battery capacity	Indicate battery capacity from battery test (Annex I)
Battery nominal voltage	Text	Required if battery is easily replaceable, otherwise optional	4.2.2.6 Battery general aspects 4.2.5.4 Battery nominal voltage	Indicate the nominal voltage
Appropriate battery protection strategy	Text	Optional	4.2.3.13 Battery protection strategy	Indicate “pass” if battery protection is appropriate (this is required to use SSS)

B.7.10 Marks and certifications

Table B.11 lists the elements in the marks and certifications SSS section.

Table B.11 – Elements in the marks and certifications SSS section

Element	Display type	Optional or required	Aspect(s) involved / origin of information	Remarks
Factory certification	Text	Optional	4.2.11.3 Third-party marks and certifications	ISO 900x, etc.
LED / CFL certification	Text	Optional	4.2.11.3 Third-party marks and certifications	UV-free LEDs, etc.
Safety certification	Text	Optional	4.2.11.3 Third-party marks and certifications	UL, etc.
Durability certification	Text	Optional	4.2.11.3 Third-party marks and certifications	UV-resistant plastics used, etc.
Other certifications	Text	Optional	4.2.11.3 Third-party marks and certifications	Allowed if they pertain to the particular product and are relevant (e.g., CE, RoHS).

B.7.11 SSS information

Table B.12 lists the elements in the SSS information section.

Table B.12 – Elements in the SSS information section

Element	Display type	Optional or required	Aspect(s) involved / origin of information	Remarks
Expiration date	Text	Required	From QTM report	Indicate a date two years after the completion of the QTM test report that is the foundation for the SSS.
Revision	Text	Required	n/a	Indicate an internal SSS revision tracking number.

B.8 Example sheet

An example standardized specification sheet is provided in Figure 9.1 and Figure 9.2.

Annex C (normative)

Manufacturer self-reported information

C.1 Background

Having proper manufacturer information is important for communication throughout the testing process as well as for understanding key product information and any certifications the manufacturer's lab or product may have. To this end, there are three categories of self-reported information: manufacturer information, product information, and manufacturer self-certification regarding either the manufacturing lab or product.

C.2 Outcomes

The manufacturer self-reported information outcomes are listed in Table C.1.

Table C.1 – Manufacturer self-reported information outcomes

Metric	Reporting units	Related aspects	Remarks
Manufacturer information	Varied	4.2.11.1 Product and manufacturer information	Record all provided manufacturer information
Product information	Varied	4.2.11.1 Product and manufacturer information	Record all provided product information
Self-certification information	Varied	4.2.11.3 Third-party marks and certifications	Record all manufacturer or product certifications

C.3 Solicited information

At a minimum, the information contained in C.3.1 and C.3.2 should be solicited from the manufacturer.

C.3.1 Confidential information (not released publicly)

C.3.1.1 Manufacturer information

The following confidential manufacturer information should be solicited:

- a) Manufacturer company physical address.
- b) Contact person name.
- c) Contact person position at company (i.e., job title).
- d) Contact telephone number.
- e) Contact fax number.
- f) Contact e-mail address.

C.3.1.2 Product information

The following confidential product information should be solicited:

- a) Markets in which the product is for sale (e.g., Kenya, India, China, etc.).
- b) Free on board (FOB) product price for at least 1 000 units (\$).
- c) Typical product shipping point of origin.
- d) Product driver type (e.g., resistor, pulse-width modulation, etc.).
- e) Battery charge control methods (i.e., deep discharge protection and/or overcharge protection).

- f) Description of battery charge control methods.
- g) Battery information sheet from battery manufacturer, preferably showing acceptable deep discharge protection and overcharge protection cut-offs at a minimum.

C.3.2 Public information (may be released publicly)

C.3.2.1 Manufacturer information

The following public manufacturer information should be solicited:

- a) Manufacturer company name.
- b) Manufacturer company physical address.
- c) Contact person name.
- d) Contact person position at company (i.e., job title).
- e) Contact telephone number.
- f) Contact fax number.
- g) Contact e-mail address.
- h) Manufacturer company website.

C.3.2.2 Product information

The following public product information should be solicited:

- a) Product name.
- b) Product model number.
- c) All product lighting technologies used (e.g., fluorescent tube, LED, etc.). If the product uses LEDs, are the LEDs high-power or low-power?
- d) Battery chemistry (VRLA, NiMH, etc.).
- e) Battery package type.
- f) Battery nominal voltage (V).
- g) Battery capacity (Ah).
- h) All product charging system types (e.g., solar module, AC power, dynamo, etc.):
 - 1) If the product has AC power charging, is an adapter included?
 - 2) If the product has solar charging, what active material is used in the PV module (e.g., mono-Si, poly-Si, CIS, etc.)?
- i) All included product features (e.g., mobile phone charging, radio, etc.).
- j) All optional product features (e.g., mobile phone charging, radio, etc.).
- k) Description of product warranty terms, including duration.
- l) Confirmation of AC-DC charger approval from a recognized consumer electronics safety regulator, such as UL (if product includes an AC-DC charger).
- m) Manufacturer statement regarding the adequate sizing of external current carrying conductors used in the product.

C.3.2.3 Manufacturer certifications

These certifications should be accompanied with supporting documentation, such as copies of the original certifications, letters from an appropriate organization, or self-certification.

- a) All manufacturer company certifications and markings (e.g., ISO 9000, UL, CE, etc.).
- b) All product certifications and markings (e.g., UV-resistant plastic, UV-free LEDs, high-temperature batteries, etc.).
- c) All component-level certifications and markings (e.g., IEC 62133 for battery safety, etc.)

C.4 Reporting

Report the following in the product manufacturer self-reported information report.

- Metadata
 - Report name
 - Product manufacturer
 - Product name
 - Product model number
 - Name of test laboratory
 - Approving person
 - Date of report approval
- Confidential information
 - Manufacturer company physical address
 - Contact person name
 - Contact person position at company
 - Contact telephone number
 - Contact fax number
 - Contact e-mail
 - Product markets
 - Product FOB price (\$)
 - Product shipping point of origin
 - Product driver type
 - Product charge control methods and description
- Public information
 - Manufacturer company name
 - Manufacturer company physical address
 - Contact person name
 - Contact person position at company
 - Contact telephone number
 - Contact fax number
 - Contact e-mail
 - Manufacturer company website
 - Product name
 - Product model number
 - Product lighting technologies
 - Product battery chemistry
 - Product battery package type

Annex D (normative)

Product sampling

D.1 Background

Proper product sampling is the first step in the testing process, and it is critical to maintaining the test method's fairness and credibility.

D.2 Test outcomes

The product sampling outcomes are listed in Table D.1.

Table D.1 – Product sampling outcomes

Metric	Reporting units	Related aspects	Remarks
Sample type	Retail/warehouse	n/a	--
Sample procurement agency	Agency name	n/a	The third-party agency that procures the samples
Sample procurement agent	Name	n/a	The name of the person who procures the samples
Sample procurement date	Date	n/a	--
Sample procurement address(es)	Address(es)	n/a	--
Sample shipping date	Date	n/a	The date the samples are shipped to the test lab(s) from the third-party sampling agency
Test lab(s)	Test lab name(s)	n/a	--
Test lab address(es)	Address(es)	n/a	--
Sample delivery date(s)	Date(s)	n/a	The date the samples are received by the test lab(s)

D.3 Related tests

Testing is predicated upon the product samples already being procured, shipped, and received at the test lab(s).

D.4 Procedure

D.4.1 Retail sampling

D.4.1.1 General

For retail sampling, third-party agents will procure product samples from a variety of retail outlets in the market.

D.4.1.2 Equipment requirements

No equipment is required for retail sampling.

D.4.1.3 Test prerequisites

Samples shall be procured from a geographically diverse set of retail outlets. Retail outlets include both vendors or retail shops where end users may directly purchase products, and local or regional distributors.

D.4.1.4 Apparatus

No apparatus is required for retail sampling.

D.4.1.5 Procedure

These steps shall be followed:

- a) The third party sampling agency identifies a specified number of retail outlets in the market from various geographic locations.
- b) The sampling agency selects a subset of the retail outlets to procure samples from, ensuring that the subset of retail outlets is geographically diverse (e.g., each retail outlet is in a different city and/or country than the rest of the subset).
- c) The sampling agency procures the product samples from the various retail outlets, ensuring that no more than 40 % of the overall number of procured samples comes from any single retail outlet.
- d) The date, locations, sampling agent, and number of samples procured from each location should be documented by the sampling agency.
- e) The sampling agency ships the products to one or more test labs and reports the shipment tracking number(s), when available.
- f) Once received at the test lab(s), the date(s) of reception, test lab name(s), and test lab location(s) should be documented.

D.4.1.6 Calculations

There are no calculations for retail sampling.

D.4.2 Warehouse sampling

D.4.2.1 General

For warehouse sampling, third-party agents will procure samples from a warehouse, distributorship, factory, or other bulk storage location.

D.4.2.2 Equipment requirements

No equipment is required for warehouse sampling.

D.4.2.3 Test prerequisites

The sampling location should be the main bulk storage location in the region, and there shall be enough products available that the procured samples account for no more than 8 % of the total product stock. Furthermore, the sampling agent shall be able to sample from the bulk storage location's entire stock.

D.4.2.4 Apparatus

No apparatus is required for warehouse sampling.

D.4.2.5 Procedure

These steps shall be followed:

- a) At least 24 h before the sampling takes place, the sampling agency shall make contact (via email or telephone) with representatives at the sampling location to provide proper notice and ensure that the number of samples procured will not exceed 8 % of the sampling location's total product stock.
- b) The sampling agency randomly procures the product samples from the entire bulk storage location's stock (i.e., the entire product stock shall be available to sample from).
- c) The date, location, sampling agent, and number of samples procured should be documented by the sampling agency.
- d) The sampling agency ships the products to one or more test labs and reports the shipment tracking number(s), when available.

- e) Once received at the test lab(s), the date(s) of reception, test lab name(s), and test lab location(s) should be documented.

D.4.2.6 Calculations

There are no calculations for warehouse sampling.

D.5 Reporting

Report the following in the product sampling test report.

- Metadata
 - Report name
 - Procedure(s) used
 - Product manufacturer
 - Product name
 - Product model number
 - Name of test laboratory
 - Approving person
 - Date of report approval
- Sampling instructions
- Sampling and shipping information
 - Name of sampling agency
 - Name(s) of sampling agent(s)
 - Sampling location name(s), address(es), and description(s)
 - Number of samples procured (at each location)
 - Name of shipping agency
 - Shipment tracking number(s)
 - Date samples are shipped to test lab(s)
 - Date samples are received at test lab(s)

Annex E (normative)

Visual screening

E.1 Background

The visual screening process covers DUT specifications, properties (such as external DUT measurements), functionality, observations, and internal/external construction quality.

The DUT's components, materials, and utilities are categorized and, in some cases, evaluated. This test provides a thorough qualitative and quantitative assessment of the DUT as received from the manufacturer and serves to uniquely identify a DUT. The DUT's operation out of the packaging is documented before any modifications are made for subsequent tests.

E.2 Test outcomes

The test outcomes of the visual screening process are listed in Table E.1.

Table E.1 – Visual screening test outcomes

Metric	Reporting units	Related aspects	Remarks
DUT specifications	Varied	4.2.2 Product design, manufacture, and marketing aspects	Record all provided specifications
DUT information	Varied	4.2.2 Product design, manufacture, and marketing aspects 4.2.11.1 Product and manufacturer information	Record dimensions and qualitative descriptors
Internal DUT inspection	Varied	4.2.3 Product durability and workmanship aspects	Describe/document wiring and electronics fixtures
Internal DUT inspection	Number of defects	4.2.3 Product durability and workmanship aspects	Record the number of soldering and/or electronics quality defects

E.3 Related tests

Annex E is not related to any of the other annexes.

E.4 Procedure

E.4.1 Properties, features, and information

E.4.1.1 General

Relevant DUT information, such as external DUT measurements and observations, are recorded to capture the DUT's characteristics. Sufficient comments should be provided to thoroughly describe the DUT's characteristics. This part of the procedure may be completed on a single sample.

E.4.1.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Callipers and/or ruler
- Balance (scale)
- Bright task light with good colour rendering
- Camera

E.4.1.3 Test prerequisites

The DUT should be new, unaltered, and in its original packaging. Read the DUT's box and documentation for instructions on using the DUT. Consult the manufacturer for missing information pertaining to the required observations.

E.4.1.4 Apparatus

The DUT may be positioned under a bright task light in the examination, if necessary.

E.4.1.5 Procedure

All photographs or scans of packaging, documents (e.g., user's manual and warranty card), and labels shall be in colour and of sufficient quality that all text is legible (unless illegible in the original document) and all diagrams, icons, and other images are clearly reproduced. All photographs of DUT components shall be in colour and of sufficient quality that all relevant text is legible (unless illegible on the item being photographed) and all relevant icons and images are clearly reproduced. These steps shall be followed.

a) Provide the following:

- 1) Note the date that the samples were received.
- 2) Note the method of sample procurement.
- 3) Note any identification code for the inspected sample(s) for properties, features, and information.
- 4) Note all available manufacturer contact information (e.g., name, address, phone number, email, website, etc.)
- 5) Note all available designer contact information (e.g., name, address, phone number, e-mail address, and website).
- 6) Photograph or scan all sides of the DUT's retail box and describe the box's quality, if available.
- 7) Note if a user's manual is included with the DUT. If so, report the type of manual it is (e.g. booklet, sheet, etc.), report the language(s) in which it is written, and photograph or scan each page.
- 8) Note and describe any labelling of hazards (e.g., related to inverters or high DC output).
- 9) If a warranty is available for the DUT, record the warranty duration, in months, describe the terms and conditions, and photograph or scan the warranty material. Note if there are separate warranty durations for the battery and included appliances.
- 10) Photograph or scan any other documents included with the DUT.
- 11) Note and describe any instructions for proper disposal of the battery and/or product.
- 12) Note and describe any instructions for replacement of the battery.
- 13) Note and describe any instructions for obtaining service or replacement parts in case of a problem with the product. Note and describe any instructions for ensuring the PV module is not shaded.
- 14) Note and describe any instructions on how to connect the PV module to the product's main unit for charging.
- 15) Note and describe any instructions on facing the PV module surface towards the sun.
- 16) Note and describe any required pre-use instructions during installation (e.g. charging the battery fully, inserting a supplied fuse, etc.).

- 17) Note and describe any instructions on how to make required permanent connections during installation.
 - 18) Note and describe any instructions on how to connect advertised appliances.
 - 19) Note and describe any instructions on the battery's state of charge.
 - 20) Note and describe any specifications for product components that may require replacement (e.g. fuses, lights, PV module, batteries, etc.).
 - 21) Note and describe any instructions on keeping the PV module surface clean.
 - 22) Note and describe any instructions to not ding the PV module from the backside.
 - 23) Note and describe any instructions to not carry the PV module by its cable.
 - 24) Note and describe any instructions on preventing the PV module from cracking during handling.
 - 25) Note and describe any instructions to keep the product away from fire.
 - 26) Note and describe any instructions on how to install the product securely.
 - 27) Note and describe any instructions on the product's graphical display, if a display is included.
 - 28) Note and describe any instructions to not drop the product.
 - 29) Note and describe any instructions to not cut or heat the product's cables.
 - 30) Note and describe any instructions to avoid keeping the battery at a low state of charge for long periods of time.
 - 31) Note and describe any instructions on replacing product components that may require replacement (e.g. fuses, lights, PV, batteries, etc.).
 - 32) Note and describe any instructions to fully charge the batteries before long-term storage of the product.
- b) Provide the following (in the specified units) without disassembling the DUT:
- 1) List each individual component group along with a description and a list of the items included in each group. Do not include the photovoltaic module in this section.
 - 2) Measure the DUT's mass, in grams (g), as it would typically be used in a lighting application (not including any external solar modules or mobile phone charging connectors) and indicate the specific components included in mass measurement.
 - 3) Measure any included appliances' mass, in grams (g).
 - 4) Measure the length, width, and height, in centimetres (cm), of the DUT, lamp unit(s) and any additional included appliances, components or interconnected parts, separately. Do not include dimensions of an external PV module or any mobile phone charging accessories.
- c) Observe the following (consult the documentation for any explanations; see 4.1.3 for details on the terminology used in the following steps):
- 1) Measure and describe the length, in metres (m), of any cables connecting the control box to the batteries, the control box to the lamp units or the control box to any included appliances.
 - 2) Note if any cables will be predominantly used outdoors. Note if certification documentation has been provided for these cables indicating they are suitable for outdoor use.
 - 3) Note the DUT's total number of unique lighting units, indicate the technology used in each (LED, fluorescent, incandescent, etc.), and provide a description and photographs of each.
 - 4) Note the number of light points in each lighting unit.
 - 5) Note the number of arrays contained in each light point (e.g., a group of LEDs that function as a single unit is an array). For example: If a lamp unit contains 10 LEDs and

5 LEDs illuminate for one DUT setting, and all 10 LEDs illuminate for the DUT's only other setting, this lamp unit contains two arrays (5-LED and 10-LED).

- 6) Note the number of independent light sources (i.e., the total number of LEDs or other bulb types) in each array.
- 7) Determine the number of DUT light output settings. Use the setting descriptions provided by the DUT's literature. If no setting descriptions are provided, use appropriate descriptions (e.g., high, medium, low, 1 high-power LED, 3 low-power LEDs, etc.).
- 8) Describe the configuration of the main lighting unit. The main lighting unit shall be the main control unit (if applicable) or the brightest lighting unit (if no main control unit is included).
- 9) Note any built-in appliances, as defined in 4.1.4, including lights with some or all of their driver or ballast circuits internal to another component of the kit. Lights with any of the following properties should be examined to determine whether they should be treated as a built-in appliance:
 - The light has multiple brightness settings that are selected using a control on the main unit;
 - The light is to be connected to a port which cannot be used for any other appliance (according to labels and/or user documentation);
 - Internal inspection of the light point (E.4.3) reveals no electronic components on the PCB except the light sources (e.g., LEDs) themselves.
 - The behaviour of the port (e.g., as observed in the assessment of DC ports, Annex P), is consistent with the output of an LED driver circuit (e.g., a constant-current power supply), or a time-varying voltage waveform (e.g., PWM) is observed.
- 10) Describe and photograph the arrangement of lamp units, included appliances, battery(-ies), and energy source(s) in terms of housing/cases.

EXAMPLE There are two housings. In the main housing there is a battery with a gooseneck lamp protruding from the housing. The other housing is a remote lamp unit with no battery; it is connected to the main housing with a 4 m cable that has an inline switch. The PV module is external and connects to the main housing with a cable.

- 11) Describe the materials that compose the DUT's lamp units, battery housing, charge controller housing, included appliances, and/or any other housings (e.g., plastic, metal, glass, or other).
 - 12) Note if the DUT and included appliances have any indicators (e.g., charge indicators) and, if so, include descriptions of indication meanings and photographs of the indicators.
 - 13) Note and photograph any other features present on or included with the DUT and included appliances (e.g., handles, mounting brackets, stands, etc.).
 - 14) Note if the DUT has a radio or mobile phone charging capabilities. If so, photograph the connectors.
 - 15) Describe and photograph any other included appliances, accessories or connectors not yet documented (excluding DC ports and connectors associated with the DUT's PV module).
 - 16) Indicate if the DUT provides central (e.g., grid, central station, etc.) or independent (e.g., electromechanical, solar PV, etc.) charging and the specific charging means and describe the robustness of each included charging mechanism.
 - 17) If a grid charger is included, note if it carries any recognized safety marks, such as the CE mark. Note the source and nature of the safety marks and be sure to photograph any labels provided on the grid charger.
 - 18) Note each component's primary form factor (fixed indoor, fixed outdoor, portable separate, portable integrated, or other) and also note any secondary form factors.
 - 19) Note the DUT's expected use(s) (e.g., ambient, torch, task, etc.).
- d) Provide any general comments regarding the DUT's properties, features, and/or information. Measure and observe the following (in the provided units) for the DUT's PV module:

- 1) Measure the mass (g) of the PV module.
 - 2) Measure the PV module's overall length and width, in centimetres (cm), including the frame.
 - 3) Measure the active solar material's overall area, in square centimetres (cm²).
 - 4) Note if the PV module is external or integrated into the DUT's housing.
 - 5) Measure the PV module's cable length, in metres (m), in the case of external PV modules.
 - 6) Note the PV module's solar material (e.g., poly-Si, mono-Si, CIS, amorphous, etc.).
 - 7) Note the PV module's encasing (e.g., lamination, glass, epoxy, etc.). Carefully inspect each PV module under an illumination of not less than 1 000 lux and note any of the following visual defect conditions:
 - cracked, bent, misaligned or torn external surfaces;
 - broken cells;
 - cracked cells;
 - faulty interconnections or joints;
 - cells touching one another or the frame;
 - failure of adhesive bonds;
 - bubbles or delaminations forming a continuous path between a cell and the edge of the module;
 - tacky surfaces of plastic materials;
 - faulty terminations, exposed live electrical parts;
 - any other conditions which may affect performance;
 - (*for thin film PV modules*) voids in, and visible corrosion of any of the thin film layers of the active circuit.
 - 8) Make note of and photograph the nature and position of any visual defects, cracks, bubbles or delaminations, etc. which may worsen and adversely affect the module performance.
 - 9) Photograph both sides of the PV module.
 - 10) Note whether any appliances can turn on while the DUT is charging.
 - 11) Describe the robustness of the PV module.
 - 12) Describe the quality of workmanship in the PV module's junction box, if present.
 - 13) Note any additional information about the PV module (e.g., number of individual cells).
- e) Provide the following information regarding the DUT's DC ports:
- 1) Number of distinct port types.
 - 2) For each port type:
 - i) Brief description of the port (e.g., "USB port 1")
 - ii) Receptacle type (e.g., USB 2 type A, barrel jack, cigarette lighter jack, etc.)
 - iii) Number of identical ports of this type
 - iv) Nominal port voltage, determined from any of the following sources:
 - Manufacturer-supplied information
 - User documentation and labelling
 - If the port is a standardized or conventional connector, the applicable standards and/or conventions
 - Measurement of the open-circuit voltage and the voltage under load.
 - v) Rated maximum port current, if any, determined from any of the following sources:

- Manufacturer-supplied information
 - User documentation and labelling
 - Markings on any DUT components, such as a fuse or circuit breaker, if it can be determined that the component limits the current for the port
- vi) Whether the port is intended or expected to be used for charging mobile phones (e.g., based on labelling, documentation, or provided adapters)
- vii) Photograph of the port
- f) Note any other general visual screening comments not applicable to any other section

E.4.2 Specifications

E.4.2.1 General

All relevant DUT specifications are recorded for later comparison in testing results. This part of the procedure may be completed on a single sample.

E.4.2.2 Equipment requirements

No equipment is required for this part of the visual screening procedure.

E.4.2.3 Test prerequisites

The DUT should be new, unaltered, and in its original packaging. Read the DUT's box and documentation for instructions on using the DUT. Consult the manufacturer for missing information pertaining to the required observations.

E.4.2.4 Apparatus

No apparatus is required for this part of the visual screening procedure.

E.4.2.5 Procedure

Examine the DUT's packaging, user's manual, product website, and components for battery, lamp, charge controller, included appliances and PV module specifications. While obtaining the specifications, the DUT should not be opened or otherwise tampered with in any way. The internal inspection of E.4.3 may reveal more product specifications, which should be included with the specifications from E.4.2 and noted accordingly.

- a) When provided, note the following specifications (in the specified units of measurement), indicate and photograph the source(s) of each, and comment on any specification discrepancies. Indicate if the specification is not provided but can be ascertained by observation (e.g., battery chemistry and battery nominal voltage):
- 1) Battery chemistry (VRLA, NiMH, Li-ion, LiFePO₄, or specify other)
 - 2) Rated battery capacity, in ampere hours (Ah)
 - 3) Battery nominal voltage, in volts (V)
 - 4) Lamp type (LED, compact fluorescent, linear fluorescent, incandescent, or specify other)
 - 5) Lamp driver (constant voltage source, constant current source, pulse width modulation, resistor, or specify other)
 - 6) Charge controller present (yes/no)
 - 7) Charge controller deep discharge protection voltage, in volts (V)
 - 8) Charge controller overcharge protection voltage, in volts (V)
 - 9) PV module maximum power point power (P_{mpp}), in watts (W)
 - 10) PV module open circuit voltage (V_{oc}), in volts (V)
 - 11) PV module short circuit current (I_{sc}), in amperes (A)
 - 12) PV module maximum power point voltage (V_{mpp}), in volts (V)
 - 13) PV module maximum power point current (I_{mpp}), in amperes (A)

- 14) Daily energy service, in watt-hours (Wh/day)
- b) For each advertised appliance, provide its advertised name along with the following information:
- 1) The advertised name of the appliance
 - 2) Whether it was included with the SHS kit (yes/no)
 - 3) Whether or not it is a lighting unit (yes/no)
 - 4) The name of each setting, a description of each setting, and the total number of settings
 - 5) Appliance input voltage range (V)
 - 6) Appliance maximum power usage (W)
 - 7) Appliance average power usage (W)
 - 8) Appliance standby power usage (W)
 - 9) Where available, note basic television specifications – the screen size (inch), TV technology (LCD, LED, plasma or CRT), antenna type, built-in DVD player, AC power adapter included and built-in FM tuner/radio capabilities.
 - 10) Where available, basic fan specifications – the fan diameter in millimetres (mm), speed settings, type of stand and ceiling mounting.
 - 11) Where available, note for any included radio specifications – the radio bands, built-in MP3 player, battery chemistry, battery capacity in ampere hours (Ah), nominal battery voltage in volts (V) and battery runtime specified.
 - 12) Where available, note for any included portable video player specifications – the screen size (inch), DVD player, AC power adapter included, USB inputs, memory card slots, built-in FM tuner/radio capabilities, built-in MP3 player, battery chemistry, battery capacity in ampere hours (Ah), nominal battery voltage in volts (V) and battery run time specified.
 - 13) Where available, note for any included refrigerator specifications – the refrigerator capacity in litres (L), the freezer capacity in litres (L), the energy use per day in watt-hours per day (Wh/day) and the temperature the energy use is specified for in degrees Celsius (°C).
 - 14) Where available, note for any other included appliances any relevant specifications on their use.
- c) When provided, record the following run time specifications, in hours (h), indicate and photograph the source(s) of each, and comment on any discrepancies:
- 1) Note the number of hours of operation on a full battery charge for all appliance settings (full-battery run time) and all appliance uses specified.
 - 2) Note the number of hours of operation on a battery charge from a day of solar charging for all lamp appliance settings (daily solar run time) and all appliance uses specified.
 - 3) Note and describe any specified run times that do not fit into the previous two categories.
 - 4) Note any additional claims regarding charging of mobile phones or other devices, including the number of devices, types of devices, energy availability or hours of charging, etc.
- d) Where available, note any light output specifications, in lumens (lm), indicate and photograph the source(s) of each, the corresponding lamp setting(s), and comment on any discrepancies.
- e) Note any general comments related to specifications and discrepancies in specifications, if any.

E.4.3 Functionality and internal inspection

E.4.3.1 General

An internal inspection is performed to assess the electronics and soldering workmanship. The DUT and included appliances may fail the inspection if poor internal workmanship inhibits the DUT and included appliances from properly functioning. This part of the procedure should be completed for at least four of the samples being tested.

E.4.3.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Bright task light with good colour rendering
- Miscellaneous hand tools (screwdrivers, wrenches, etc.) to disassemble DUT
- Camera to document DUT characteristics with particular attention to potential points of failure (e.g., cold solder joints)
- DC voltmeter or multimeter for conducting basic electronic integrity and functionality tests
- Optional: DC current clamp meter

E.4.3.3 Test prerequisites

The DUT and included appliances should be new, unaltered, and in original packaging. Read the retail box and documentation for instructions on using the DUT and included appliances. Consult the manufacturer for missing information pertaining to the required observations. If the DUT or appliance instructions require them to be fully charged prior to operation, do so prior to conducting this test.

E.4.3.4 Apparatus

The DUT and included appliances should be positioned under a bright task light for examination.

E.4.3.5 Procedure

All photographs of DUT components shall be in colour and of sufficient quality that all relevant text is legible (unless illegible on the item being photographed) and all relevant icons and images are clearly reproduced. These steps shall be followed:

- a) Check the functionality of the DUT and included appliances before disassembling. If a proper charging cable and/or appliances is not included in the DUT's kit, the proper charging cable and/or appropriate appliance shall be obtained by the test laboratory to check for functionality.
 - 1) Do the DUT and included appliances work as described with provided documentation?
 - 2) Do the DUT and included appliances charge as described with provided documentation? Be sure that any included grid charger properly functions. To ensure that the DUT is receiving a charge, the current going into the battery can be measured with a DC current clamp meter. The DUT's charging indicator may turn on incorrectly when no current enters the DUT's battery.
 - 3) For functions that require additional components for testing that are not included with the DUT kit (e.g. mobile phone charging), obtain the appropriate appliance and/or charging cable. Does the DUT's advertised charging work as described with provided documentation?
 - 4) Do all of the DUT and included appliances' switches and connectors function as they should?
 - 5) Comment on any notable characteristics of the DUT's light output (e.g., glare, colour, inconsistency between samples).
 - 6) Comment on any notable characteristics of the functionality of the DUT's included appliances.

- 7) Comment on the proper functioning of the DUT's indicator lights (such as a charging indicator) and/or informative displays (such as a display showing the battery's state of charge), if applicable.
 - 8) Comment on any faulty operation and provide photographs, if necessary.
 - 9) A DUT is considered to no longer function if any of the following functions fail to work with the battery at the appropriate state of charge:
 - one or more included appliance will not turn on;
 - any of the light sources, arrays and light points will not turn on;
 - the product will not charge via solar, and/or grid, and/or mechanical, as applicable;
 - battery is unsafe (leaked fluid, inflated, etc.).
- b) Inspect the DUT and included appliances for potential hazards or safety issues, such as:
- bare conductors;
 - sharp points and edges that can cut someone (including exposed screws and fasteners with sharp points and edges);
 - plugs that may exceed ampacity ratings if improperly used;
 - electrical situations that could lead to a fire;
- Make note of and photograph any potential hazards or safety issues identified.
- c) Disassemble the DUT and included appliances so the following internal observations may be made:
- 1) Inspect the electronic components' quality and workmanship. Document the workmanship with comments and photographs. Record the number of observations of each deficiency listed below for each sample examined:
 - soldering: note any poor solder joints, such as cold joints or joints with insufficient or excess solder;
 - wiring: note any poor wiring, such as a badly pinched wire;
 - fixture: note any poor securing of internal components, such as poor gluing that is likely to fail;
 - battery:
 - note any battery-related deficiency, such as inflated batteries, fluid leakage, or corrosion of battery terminals;
 - note if the battery is adequately fastened, such as with screw mounts;
 - safety: note anything that could result in a safety concern, such as a potential for shorting the product's battery if two bare wires near each other could touch. If lithium batteries are inflated or fluid is present, these batteries are dangerous and shall not be used for any additional tests. Dispose of the batteries properly;
 - functionality: functional deficiencies include an indicator light or display failing to work, a non-functional accessory (such as extension cable), and an extra port not functioning. Functional deficiencies are not severe enough to result in the product no longer functioning according to E.4.3.5 a) 9) , above.
 - 2) Determine the product's total deficiencies score. Sum the number of deficiencies observed between the examined samples for soldering, wiring, fixture, and battery. Sum and triple the number of deficiencies observed between the examined samples for safety and functionality. Add these two sums together – this is the total deficiencies score.
- NOTE The workmanship quality may be reassessed upon completion of the DUT's testing, as samples may discontinue to function under normal use during a later test.
- 3) Indicate whether the DUT and included appliances use cable strain reliefs and, if so, which cables have strain reliefs. Document with photographs.

- 4) Indicate methods used to secure parts inside the DUT and included appliances (e.g., screws, glue, tape, clamps/straps, or other) and document with photographs.
- 5) Indicate methods used for securing wire and cable connections (e.g. solder, harness, terminal junction, etc.) and document with photographs.
- 6) Note if the DUT and included appliances have an easily replaceable battery and/or printed circuit board (PCB). The battery and PCB are easily replaceable if they can be interchanged without any tools other than screwdriver(s) (i.e., no soldering or splicing) that are used only for the removal and replacement of screws (i.e., no prying). If the battery and/or PCB can be replaced in this manner, it is considered “field replaceable.” Note if any instructions are included for replacing the battery and/or PCB.
- 7) Some batteries utilize safety and/or cell balancing circuitry on the DUT’s PCB. By this arrangement, the battery requires intelligence from the DUT’s PCB for proper charging and/or discharging. Note if the DUT’s battery utilizes a safety/cell balancing circuit on the DUT’s PCB. This arrangement can be observed as additional wire connections between the battery and the PCB. Document with photographs. Consult the manufacturer if uncertain.
- 8) Examine the internal components, especially the batteries, and note any specifications that were not apparent in E.4.2.5.
- 9) Determine and note the workmanship quality using the following guidelines:
 - good: no deficiencies were observed with the samples examined, and all samples being tested continued to function throughout normal use during testing without any hazards or safety issues;
 - fair: deficiencies score of one to five observed per four samples examined, and all of the samples being tested continued to function throughout normal use during testing without any hazards or safety issues;
 - poor: one or more samples being tested discontinued to function throughout normal use during testing or developed one or more hazards or safety issues, or a deficiencies score greater than five observed per four samples examined.
- 10) Provide any additional overall internal screening comments as necessary.

Note if the batteries contain any internal circuitry. This type of circuitry typically consists of a small PCB located beneath a plastic jacket encasing the battery. Document with photographs. NOTE Additional wire connections between the battery and the PCB can have other functions as well; for example temperature sensing. Voltage measurements of the additional wires may be helpful in assessing their function; voltages on wires added for cell monitoring and/or balancing will be multiples of the cell voltage.

E.5 Reporting

Report the following in the visual screening test report.

- Metadata
 - Report name
 - Procedure(s) used
 - DUT manufacturer
 - DUT name
 - DUT model number
 - Name of test laboratory
 - Approving person
 - Date of report approval
- Manufacturer contact information (e.g., website, email address, phone number, etc.)
- Retail box description, if available
- User’s manual information
 - Included with DUT (yes/no)
 - Type (e.g., booklet, pamphlet, sheet, etc.)

- Language
- Comments
- Proper disposal instructions information, if available
- Battery replacement instructions, if available
- Hazard labelling, if available
- Warranty information, if available
 - Length (months)
 - Description of terms and conditions
- Complete DUT information (e.g., battery unit, lamp units, control unit, appliances, etc.)
 - Mass (g)
 - List of components included in mass measurement
- DUT cable information
 - Length of all cables except those used to connect PV modules (m)
 - Cable to be used outdoors (yes/no)
 - Certification documents provided for cables to be used outdoors (yes/no)
 - Description of all cables except those used to connect PV modules
- DUT component information
 - Length of each component (cm)
 - Width of each component (cm)
 - Height of each component (cm)
 - Number of each component included with DUT
 - Description of each component
- DUT lamp unit technology information
 - Type of each unique lamp unit variety (e.g., LED, CFL, incandescent, etc.)
 - Number of light points in each unique lamp unit variety
 - Number of arrays in each unique lamp unit variety
 - Description of each unique lamp unit variety's technology use
- Description of DUT arrangement in expected typical use
- DUT setting information
 - Name of all individual light output settings
 - Description of each individual light output setting
- DUT and included appliances materials information
 - List of all materials used to construct each DUT component (e.g., glass, balsa wood, plastic, etc.)
 - Description of all DUT component construction materials
- DUT and included appliances indicators information
 - List of all indicators present on each DUT component (e.g., battery charge indicators)
 - Description of all DUT component indicators
- DUT and included appliances features information
 - List of all features present on each DUT component (e.g., handles, mounting brackets, stand, etc.)
 - Description of all DUT component features

- DUT accessories and appliances information
 - Radio included (yes/no)
 - Mobile phone charging capability (yes/no)
 - Descriptions of included appliances
 - Descriptions of other included DUT accessories and connectors
- DUT charging mechanism information
 - Grid charging supported (yes/no)
 - Solar charging supported (yes/no)
 - Description of each included charging mechanism
- DUT charging mechanism safety information
 - Grid charger included (yes/no)
 - Grid charger approved by recognized consumer electronics safety regulator (yes/no)
 - Description of grid charger safety marks and/or language
- DUT port information
 - Number of distinct port types
 - Description of each port type
 - Receptacle type for each port type
 - Number of identical ports of each type
 - Nominal port voltage for each port type and source of information stating nominal voltage
 - Rated maximum port current for each port type and source of information stating maximum port current
 - Whether each port type is intended or expected to be used for charging mobile phones
- DUT PV module information
 - Mass of each PV module (g)
 - Length of each PV module (cm)
 - Width of each PV module (cm)
 - Active area of each PV module (cm²)
 - Form of each PV module (external or integrated)
 - Cable length of each PV module (m)
 - Active solar material of each PV module (e.g., mono-Si, amorphous, CIS, etc.)
 - Encasing of each PV module (e.g., lamination, glass, etc.)
 - Presence of any visual defects (yes/no)
 - Description of any PV module visual defect conditions
 - Description of the robustness of each PV module
 - Description of PV module junction box workmanship
 - Other PV module information
- DUT form factor and use information
 - DUT's primary form factor (e.g., fixed indoor, fixed outdoor, etc.)
 - DUT's secondary form factor(s)
 - DUT's expected use(s) (e.g., ambient, torch, task, etc.)
- Overall comments based on the visual inspection
- Provided DUT specification information, if available

- Battery chemistry and source of information
- Rated battery capacity (Ah) and source of information
- Battery nominal voltage (V) and source of information
- Lamp type(s) and source of information
- Lamp driver and source of information
- Presence of charge controller (yes/no) and source of information
- Charge controller deep discharge protection voltage (V) and source of information
- Charge controller overcharge protection voltage (V) and source of information
- PV module P_{mpp} (W) and source of information
- PV module V_{oc} (V) and source of information
- PV module I_{sc} (A) and source of information
- PV module V_{mpp} (V) and source of information
- PV module I_{mpp} (A) and source of information
- Description of any provided DUT specification discrepancies
- Provided appliance specification information, if available
- Description of any provided appliance specification discrepancies
- Provided DUT run time information, if available
 - Full-battery run time (h) for each setting and source of information
 - Daily solar run time (h) for each setting and source of information
 - Claims regarding mobile phone or other device charging abilities
 - Other run time (h) for each setting and source of information
- Description of any provided run time discrepancies
- Provided light output (lm) for each setting and source of information
- Description of any light output discrepancies
- DUT and appliances function out of box (yes/no)
- All switches and connectors function for each DUT sample and appliances with comments as necessary (yes/no)
- Description of any potential hazards or safety issues
- Description of cable strain relief methods used and for which connections, if applicable
- Number of poor solder joints and workmanship deficiencies for each DUT sample and appliances with comments as necessary
- Total deficiencies score
- Workmanship quality (good/fair/poor) and comments on the workmanship quality
- Means (e.g., screws, glue, tape, etc.) used to secure parts in each DUT component (e.g., lamp unit(s), charge controller, PV module(s), appliance, etc.)
- General fixture of parts comments
- Means (e.g., solder, wiring harness, terminal junctions, etc.) of securing wire and cable in each DUT component (e.g., lamp unit(s), charge controller, PV module(s), appliance, etc.)
- Comments on overall layout and securing of wires and cables
- Easily replaceable battery and PCB for the DUT and appliances (yes/no)
- Comments on ease of battery and/or PCB replacement
- Type of battery connectors

- Presence of battery replacement guide (yes/no)
- Sufficient information for proper disposal of batteries (yes/no)
- Overall description of internal workmanship
- Figures
 - Properties, features, and information photographs
 - Specifications photographs
 - Functionality and internal inspection photographs

Annex F (normative)

Sample preparation

F.1 Background

The product shall be prepared before starting the tests. The preparation includes configuring the product to allow connection with a laboratory power supply, as well as taking measurements. For DUTs with multi-cell lithium battery packs, the preparation also includes charging the product.

F.2 Test outcomes

There are no sample preparation outcomes.

F.3 Related tests

The sample preparation procedures shall be performed on all DUTs prior to conducting the, battery test (Annex I), charge controller behaviour test (Annex K), full-battery run time test (Annex L), solar charge test (Annex N), protection tests (Annex O), assessment of DC ports (Annex P), appliance tests (Annex Q), battery durability test (Annex S), lumen maintenance test (Annex T), light output test (Annex U), and light distribution test (Annex V).

F.4 Procedure

F.4.1 General

The DUT is configured in order to make measurements of current and voltage during selected tests, charge the DUT's battery via a battery analyser, and simulate a specified battery voltage during selected tests with a laboratory power supply. In some cases this will mean selecting and attaching the correct plug and receptacle components. In other cases the DUT may need to be modified, by cutting wires and/or drilling holes, to allow electrical connections. When possible, the testing laboratory shall use all cables and connectors that are provided with the DUT and shall configure the system according to product instructions and in a way consistent with the normal use of the product. Any modifications shall be kept to a minimum. Additional configuration information can also be found in Annex G and Figure G.1.

F.4.2 Equipment requirements

The following equipment and supplies, or their equivalent, are required. Equipment and supplies shall meet the requirements in Table BB.2.

- Plugs and receptacles (e.g., pin-and-socket connectors) that connect to the DUT electrical ports to allow the use of a laboratory power supply and battery analyser with the DUT appliances
- Insulated copper wire. The conductor size shall be 0,75 mm² or thicker; for many products it is necessary to use thicker wire to avoid introducing excessive voltage drop. The required conductor size depends on the wire length, the maximum current, and the sensitivity of the product to voltage drop; in all cases, the wire size shall be sufficient to avoid significantly affecting the behaviour of the DUT. Recommended minimum wire sizes are given in Table F.1. It is recommended to use four different colours.
- Wire cutters
- Wire strippers
- Soldering iron and solder
- Heat-shrink tubing and heat gun
- Screwdrivers and/or other appropriate tools for opening the DUT

- Optional for DUTs with multi-cell lithium battery packs: DC power supply
- Optional: DC current clamp meter
- May be required depending on the DUT: a power drill with an appropriately sized drill bit to make a hole in the DUT's enclosure to fit four extension wires

Table F.1 – Recommended minimum conductor sizes

Expected maximum current (A)	Minimum wire thickness (mm ²)	Minimum wire thickness (American Wire Gauge)
≤ 2,0	0,75	--
≤ 2,2	0,82	18
≤ 3,5	1,31	16
≤ 4,0	1,50	--
≤ 5,5	2,08	14
≤ 6,7	2,50	--
≤ 8,8	3,31	12
≤ 10,7	4,00	--
≤ 14,0	5,26	10

F.4.3 Test prerequisites

The DUT's visual screening shall be completed prior to performing the sample preparation procedures.

F.4.4 Procedure

These steps shall be followed:

- For DUTs with multi-cell lithium battery packs, fully charge the product using the DUTs charging circuitry to ensure the DUT has been given the opportunity to balance the cells of its battery pack. Use one of the two options:
 - With the DUT configured for charging (e.g. solar module connected to main unit), face the DUT's solar module towards the sun until the DUT reaches a full charge. Be sure to protect the DUT from water ingress.
 - For locations with minimal sun, charge the DUT using a power supply. Set the power supply to the DUT's rated maximum power-point voltage and current. For DUTs with separate solar modules, use a severed PV connector to deliver the power to the DUT's PV socket. For DUTs with integrated solar modules, open the DUT to access and sever the leads between the solar module and electronics to deliver the power through the DUT's electronics. If the DUT's maximum power-point voltage and current values are not rated, contact the DUT manufacturer to obtain the values.

To determine when the DUT is fully charged, the lab may use the DUT's instructions or check that current no longer enters the DUT's battery pack with a current clamp meter when the solar module is exposed to sun or power supply is providing power.

- Identify the DUT's system components and appliances and determine the method of electrical connections between system components
- Modify the DUT to electrically isolate the battery from the DUT electronics. This will allow the battery to be tested and will also allow the DUT electronics and ports to be powered from a laboratory power supply.
 - With wire cutters, cut the positive and negative wires individually where the DUT's battery connects with the rest of the DUT circuit. To avoid a short circuit, which could result in personal injury, fire, or explosion, do not cut the wires simultaneously. In some cases, additional wires are attached between the DUT's battery and circuit for battery temperature monitoring and/or cell balancing—do not cut these wires. Some

batteries have two wires connected to each battery terminal—keep the wires attached to each terminal together and treat them as one wire end for the remainder of the procedure. Occasionally, multiple batteries or battery cells are connected through the PCB (or other electronics external to the battery). When isolating these batteries, ensure that the cells are connected in an equivalent manner to how they were originally connected through the PCB.

- 2) Extend the four wire ends (two connected to the battery terminals, two connected to the DUT's PCB or other electronics) by soldering on additional wires. Make the wire extensions long enough to be extended approximately 6 cm outside the DUT's enclosure. To avoid electric shock, keep the battery positive and negative extensions separated. Cover the wire connections with heat-shrink tubing once soldered. To minimize voltage drop, the conductor size of the extension wires added in this step shall be $\geq 0,75 \text{ mm}^2$ (see recommendations in Table G.1) and equal to or larger than the existing DUT battery supply wires. Wire extensions shall be kept as short as possible. The laboratory shall monitor the behaviour of the DUT to ensure that modifications do not significantly change the DUT's performance. Changes in performance can include changes to the DUT's power consumption, output, or any other function that is substantially different than the function of the unaltered sample.

NOTE In the American Wire Gauge (AWG) system, 18 AWG ($0,823 \text{ mm}^2$) is the smallest conductor size meeting this requirement.

- 3) Close the DUT such that the wires may extend outside the DUT's enclosure without being pinched.
 - Some products are designed with openings in their enclosures such that the wires may fit through these openings without physically changing the DUT's enclosure.
 - Some products do not have openings for wire extensions to fit through, in which case a hole shall be drilled into the side of the DUT's enclosure. A drill bit with a diameter slightly greater than the combined diameter of all four extension wires should be used. Choose a location on the DUT's enclosure to minimize the extension wire length and minimize changes to the DUT's enclosure. Be sure that the extension wires do not interfere with the DUT's light output.
- 4) Optionally, attach connectors (e.g., pin-and-socket connectors) to the ends of the extension wires for easy use during testing. Attach the battery positive and negative extension wires in one half of the connector pair and the DUT power supply lead wires in the other half of the connector pair. If no connectors are used, be sure to keep the battery positive and negative extensions separate when bare to avoid short-circuiting the battery. Covering the ends of the wires with electrical tape is one method to keep the extensions separate.

The charge controller behaviour test (Annex K), full-battery run time test (Annex L), and solar charge test (Annex N) impose limits on the total series resistance of the measurement apparatus. To meet these requirements, the use of connectors, soldered connections, or screw terminals is recommended.

- 5) To ensure the DUT still works after it has been rewired, connect the wire pairs (with connectors or electrical tape) so the original, unaltered circuit is replicated and turn the DUT on. If the DUT does not turn on, check that the wires are connected correctly and that the solder joints connecting wires are good. Some products require having their PV modules attached with light shining on the PV module to get the product to turn on; afterwards the PV module may be removed and the product will continue working until its circuit is broken again.
- d) (optional) In some situations the test lab may supply a regulated voltage from a power supply directly to an appliance plug or wire end instead of supplying power to the DUT power control unit. In order to use this method, the port that supplies power to the appliance must be a voltage regulated port (constant voltage). Built-in appliances as defined in 4.1.4 cannot be tested by this procedure since they do not have plugs or wire ends. If the test lab is uncertain about the voltage regulation of the port, do not use this procedure and instead use b) above.

- 1) Identify the positive and negative terminals or leads on the DUT's plug and receptacle connectors. This can be done by checking DUT instructions or by measuring the voltage polarities on the connector terminals with the DUT turned ON.
- 2) Configure plug and receptacle components to mate with the DUT system components and allow the use of a laboratory power supply (to power the appliances) and a battery analyser (to test the battery(-ies)). In cases where suitable plug and receptacles cannot be found, it may be necessary to modify the DUT by cutting off connectors and/or opening DUT enclosures and proceeding with the DUT modifications outlined above. When possible, use the cables and connector components that are provided with the DUT and intended for normal operation.

F.4.5 Calculations

No calculations are required with the sample preparation procedures.

F.5 Reporting

No reporting is required with the sample preparation procedures.

Annex G (normative)

Power supply setup procedure

G.1 Background

Several of the test procedures replace the battery with an external laboratory (bench) power supply to provide electrical power to the DUT for the duration of the test. Annex G specifies the power supply equipment requirements and setup procedure for these tests.

G.2 Test outcomes

The test outcome of the power supply setup procedure is listed in Table G.1.

Table G.1 – Power supply setup test outcome

Metric	Reporting units	Related aspects	Remarks
Standard operating voltage	volts	n/a	Used when a typical battery voltage during discharge is needed.

G.3 Related tests

Annex G is related to the light output test (Annex T), the lumen maintenance test (Annex T), the solar charge test (Annex N), the charge controller behaviour test (Annex K), the light distribution test (Annex V), and the assessment of DC ports test (Annex P). In some unusual cases (battery types other than lead-acid, NiMH, lithium iron phosphate, or other lithium-ion), it may be necessary to perform the battery test (Annex I) in order to determine the standard operating voltage in G.5.2.

G.4 Equipment requirements

The DC power supply shall be capable of delivering a stable, accurate DC input to the DUT. The power supply should have a voltage readout resolution of at least 0,01 V and a current readout resolution of at least 0,001 A. The voltage applied to the DUT should be regulated to within $\pm 0,2$ % during photometric measurements, charge controller tests, and solar charging tests and ± 3 % for the duration of lumen maintenance tests. Equipment shall meet the requirements in Table BB.2.

Some test configurations may use power supplies without voltage and current readouts capable of measuring voltage and current values. For example, a single power supply may be used to run concurrent lifetime tests on multiple DUT's (the DUT's are run in parallel from a single DC voltage rail). For these configurations, voltage measurements may be made at each DUT input using a voltmeter or multimeter and current measurements may be made using a voltage drop measurement on a series shunt resistor using Ohm's Law.

G.5 Setup procedure for photometric measurements and lumen maintenance tests

G.5.1 Test setup

These steps shall be followed:

- a) The power supply and DUT are configured according to Figure G.1.
- b) The voltage level is set according to G.5.2 and measured according to G.5.4.

- c) The DUT is powered on and allowed to stabilize for ≥ 20 min according to G.5.3.
- d) Tests are performed on the DUT.
- e) During testing, monitor the DUT for erratic behaviour that could indicate a problem with the test setup. This may include light output flickering, voltage and current instability, and difficulty in device start-up.

Key

- 1 DC power supply
- 2 DC power supply lead wires (+ voltage sense wires for light output test)
- 3 Power control unit with battery
- 4 Power supply attachment and voltage sense location for appliances that connect to a power control unit using external power cables (Note: battery is electrically isolated from DUT electronics; see F.4.4.)
- 5 Power supply attachment and voltage sense location for appliance with internal battery (Note: battery is electrically isolated from DUT electronics; see F.4.4.)

Figure G.1 – Power supply and 4-wire test configuration

G.5.2 DC voltage and current levels

The constant DC voltage level for testing a product sample is based on the test requirements and battery characteristics.

When supplying power with a laboratory power supply to the DUT power control unit the **standard operating voltage** (Table G.2) is used. This simulates the DUT's battery voltage.

When supplying power with a laboratory power supply directly to an appliance the **typical port voltage** as determined in P.4.4 is used. This simulates the DUT's port voltage for that appliance.

The standard operating voltage depends on the type, configuration, and number of cells of the battery pack. This is typically provided by the manufacturer but may be determined by testing the discharge profile (Annex I) and inspecting the battery.

The standard operating voltages for several battery chemistries are listed in Table G.2. For unknown or new types of batteries, it is possible to estimate a standard operating voltage using the average voltage during the final discharge cycle in the battery capacity test (Annex L).

Table G.2 – Standard operating voltages per cell for several common battery types

Battery Type	Standard operating voltage per cell (V/cell)
Lead-acid (valve-regulated or flooded)	2,05
NiMH	1,25
Lithium iron phosphate	3,2
Other lithium-ion	3,7
Other battery chemistry	Use a typical discharge voltage as determined from manufacturer-provided battery specifications or the battery test (Annex I).

During testing, some DUTs do not start up at the desired voltage and require an input slightly greater than the standard operating voltage. In this case, incrementally increase the power supply voltage by 0,05 V until the DUT is operational at the desired light setting. After start up, reduce the voltage back to the desired battery voltage and allow the DUT to stabilize. If the DUT will not remain on when the voltage is reduced, repeat this step and run the DUT as close to the desired battery voltage as possible, making note of the issue.

The current level of a DUT powered with an external power supply should be at or near the average current level measured in the full-battery run time test for the desired setting (see Annex L). Variations greater than 5 % can indicate a problem with the power supply setup and should be noted in the test report.

G.5.3 Stabilization period

A DUT shall be allowed to stabilize (warm up) before light output measurements are made. There are two approved stabilization procedures:

- a) The DUT is powered on and allowed to stabilize for 20 min.
- b) The DUT is powered on and is considered stable when three consecutive output measurements, taken 15 min apart, have a variation of $\leq 0,5 \%$ (IES LM-79-08).

In order to facilitate testing of multiple samples, 20 min is specified as the minimum stabilization time and is adequate for most products. Longer times may be necessary for DUT's with large heat sinks or high-powered LEDs. Voltage, current, and light output for a DUT should be monitored to determine if 20 min is an adequate stabilization time. If a longer stabilization time is necessary, the IES LM-79-08 procedure may be used to determine the stabilization time for a single DUT sample, and this time may then be used to test additional DUT samples of the same type.

G.5.4 4-wire power supply measurements

Current carrying lead wires used to provide power to the DUT appliances should be appropriately sized and as short as possible, and shall be separate from the wires used to measure the voltage (Figure G.1). This is typically referred to as a 4-wire test measurement, and eliminates the voltage drop associated with the resistance of the test leads because very little electric current is carried in the voltage sensing wires. Many power supplies are equipped to handle this measurement automatically (also known as remote sensing), although test personnel may make corrections by adjusting the sense voltage manually.

G.5.5 Electromagnetic interference

Electromagnetic interference (EMI) generated by the DUT or the test environment can interfere with voltage and current measurements. This can occur from switching power supplies found in some electronic devices and is exacerbated by using long lead wires from the power supply to the DUT. Problems with EMI will typically cause input voltage and current instability, and can result in performance variations in the DUT.

When supplying power to the DUT power control unit with a DC power supply, input capacitors shall be placed at the DUT input connections, between supply positive and negative leads, as close to the device as possible. Wires connecting the capacitors to the DUT should be at least 0,82 mm². The capacitors should be ceramic chip or tantalum types and have 1 µF, 10 µF, and 100 µF values. These three capacitor values, used in parallel, will effectively mitigate most EMI problems.

G.5.6 Troubleshooting

If the DUT will not turn on after replacing its battery with a power supply, try the following steps, in order. If the DUT turns off or drops to a lower light output setting after a period of time, try the following steps starting with step b). If possible, consult the product manufacturer to ensure that any troubleshooting steps taken will not damage the product.

- a) Follow the above guidelines in G.5.1 for replacing the DUT's battery with a power supply. If the product is solar-charged, plug in the DUT's solar module into its charging socket (plugging is not required for integrated DUTs) and shine a bright light very close to the solar module. The DUT's on/off switch may also need to be cycled. After the light turns on, the solar module may be removed.
- b) Follow the above guidelines in G.5.1 for replacing the DUT's battery with a power supply. Use an additional power supply to provide a voltage-controlled input to the DUT's solar module socket (for products with external solar modules) at the solar module's maximum power point voltage (V_{mpp}) and maximum power point (I_{mpp}). (The product manufacturer may need to provide the appropriate voltage and current values.) The connector from the DUT's solar module shall be cut, stripped, and used to supply the simulated solar power to the DUT's solar module socket. For products with integrated solar modules, the wires connecting the solar module to the PCB shall be cut, and the wire leads still connected to the PCB shall be stripped. The voltage-controlled input shall be supplied to these leads. The voltage-controlled input to the DUT's solar module socket (or solar PCB leads for products with integrated solar modules) may need to be supplied for the duration of the test.
- c) Instead of replacing the DUT's battery with a power supply, leave the battery connected within the DUT. Connect a "jumper" between the DUT's battery and electronics so that the battery voltage and current can be measured during the test. Also use an additional power supply to provide a voltage-controlled input to the DUT's solar module socket at the solar module's maximum power point voltage (V_{mpp}) and maximum power point current (I_{mpp}). (The product manufacturer may need to provide the appropriate voltage and current values.) The connector from the DUT's solar module shall be cut, stripped, and used to supply the simulated solar power to the DUT's solar module socket. For products with integrated solar modules, the wires connecting the solar module to the PCB shall be cut, and the wire leads still connected to the PCB shall be stripped. The voltage-controlled input shall be supplied to these leads. The voltage-controlled input to the DUT's solar module socket (or solar PCB leads for products with integrated solar modules) may need to be supplied for the duration of the test.
- d) If the product has a cell balancing or protection circuit that is external to the battery (i.e., on a PCB external to the battery), as determined during visual screening (E.4.3.5), that was disconnected between the battery and PCB, then incorporate resistors between each of the DUT's battery cell voltage inputs to provide the required voltages and allow the product to turn on. If possible, communicate with the product manufacturer to determine the proper resistor sizing, or if an alternative option is more appropriate. If cell balancing wires extend from the battery, these wires may be used to solder on the resistors. Only proceed with this option if safe, at the tester's discretion. The test lab shall ensure that the current drawn by the resistors does not result in an error of more than 1 % in any current measurement. In some cases, more complex circuitry may be necessary to supply stable voltages to the DUT under all operating conditions.

G.6 Reporting

The voltage and current for tests using an external power supply shall be reported according to Table G.3.

Table G.3 – Voltage and current reporting requirements

Reported value	Remarks
Standard operating voltage	Determined from Table G.2
DC voltage	Regulated to within $\pm 0,2$ % during photometric measurements and ± 3 % for the duration of lifetime tests
DC current	Measured using the power supply readout or series shunt resistor. Readout resolution should be $\leq 0,001$ A

Annex H (normative)

Photovoltaic module I-V characteristics test

H.1 Background

The purpose of the photovoltaic (PV) module I-V characteristics test is to validate the DUT manufacturer's PV module data (if available) and determine the PV module's I-V characteristic curve under standard test conditions (STC) and typical module operating temperatures (TMOT).

Solar home system units are often powered by PV modules having a power range from approximately 10 watts (W) to 100 W and above.²⁾ When selecting a measurement instrument, it is important to ensure that it is able to make accurate measurements of modules in the desired size range.

The PV module may be measured with a solar simulator in accordance with IEC 60904-1:2006 and corrected for TMOT with IEC 60891:2009. This is the preferred technique for characterizing PV modules and laboratories with access to a solar simulator should use this procedure.

The test may also be performed with an instrument that is designed to make outdoor performance measurements of solar modules.

H.2 Test outcomes

The test outcomes of the photovoltaic module I-V characteristics test are listed in Table H.1.

²⁾ This is the nominal power a PV module shows under standard test conditions (STC). Since being at STC is extremely rare in practice, the achieved power is usually lower.

Table H.1 – Photovoltaic module I-V characteristics test outcomes

Metric	Reporting units	Related aspects	Remarks
Short-circuit current (I_{sc}) at STC	Amperes (A)	4.2.7.1 Solar I-V curve parameters	Report at STC
Open-circuit voltage (V_{oc}) at STC	Volts (V)	4.2.7.1 Solar I-V curve parameters	Report at STC
Maximum power point power (P_{mpp}) at STC	Watts (W)	4.2.7.1 Solar I-V curve parameters	Report at STC
Maximum power point current (I_{mpp}) at STC	Amperes (A)	4.2.7.1 Solar I-V curve parameters	Report at STC
Maximum power point voltage (V_{mpp}) at STC	Volts (V)	4.2.7.1 Solar I-V curve parameters	Report at STC
Short-circuit current ($I_{sc, TMOT}$) at TMOT	Amperes (A)	4.2.7.1 Solar I-V curve parameters	Report at TMOT
Open-circuit voltage ($V_{oc, TMOT}$) at TMOT	Volts (V)	4.2.7.1 Solar I-V curve parameters	Report at TMOT
Maximum power point power ($P_{mpp, TMOT}$) at TMOT	Watts (W)	4.2.7.1 Solar I-V curve parameters	Report at TMOT

Temperature coefficient	Per degree Celsius ($1/^\circ\text{C}$)	4.2.7.1 Solar I-V curve parameters	Based on temperature variation in V_{oc} .
STC I-V Curve dataset	Volts (V), Amperes (A)	4.2.7.1 Solar I-V curve parameters	Delimited dataset

H.3 Related tests

Annex H should be completed before the solar charge test (Annex N).

H.4 Procedure

H.4.1 Testing using IEC 61215 or IEC 61646

The I-V characteristics of the DUT's PV module may be determined using the "Performance at STC and NOCT" test of IEC 61215 (for crystalline silicon modules), or IEC 61646 (for thin-film modules). Test results provided by the manufacturer of the DUT may be accepted if the tests were performed at a laboratory accredited to perform the tests by a recognized accrediting organization (e.g., ILAC) and if the test results include full datasets for the I-V curves.

If the module's nominal operating cell temperature (NOCT), as determined in IEC 61215, 10.5, or IEC 61646, 10.5, is within the range $50\text{ }^\circ\text{C} \pm 5\text{ }^\circ\text{C}$, the performance at TMOT may be assumed to be identical to the performance at NOCT. Otherwise, the I-V curve at TMOT ($50\text{ }^\circ\text{C}$ cell temperature, solar irradiance of $1\ 000\ \text{W}/\text{m}^2$, and air mass 1,5) shall be calculated from the performance at STC and NOCT using any of the correction procedures in IEC 60891:2009.

NOTE Correction procedure 3 (IEC 60891:2009, 3.4) is recommended as it requires no additional measurements other than the two I-V curves.

H.4.2 Test programme using a solar simulator

H.4.2.1 Test prerequisites

If the PV module is amorphous silicon or otherwise may be subject to degradation (e.g., because it is thin film or of unknown technology), it shall sun-soak for 30 days prior to performing this test.

H.4.2.2 I-V curve measurements

Use the procedure defined in IEC 60904-1:2006, with the following modifications:

- The spectral mismatch correction described in IEC 60904-1:2006, Clause 3 a), may be omitted if the reference device is a PV cell or module made using the same cell technology or using optical filtration to achieve a spectral response typical of the cell technology of the DUT. For example, a monocrystalline PV cell with KG5 glass window may be used with an amorphous silicon DUT.
- For measurements in steady-state simulated sunlight, the irradiance sensor of IEC 60904-1:2006, 4.2 d), may be omitted.
- For temperature measurements, a single thermocouple, meeting the accuracy requirements of H.4.3.1 and positioned directly behind a cell near the centre of the module, may be used. If the back of the module is inaccessible, the front-mounted thermocouple procedure detailed in the outdoor test procedure (H.4.3.4.3) shall be used for the indoor test.
- If the PV module charges the DUT via a cable extended from the PV module's junction box, measure the I-V curve from the end of the cable that plugs into the DUT for charging by cutting the connector from the end of the PV module cable, leaving as much of the cable connected to the PV module as possible, and strip the wire ends. However, if the PV module's performance deviates from the advertised values by more than the truth-in-advertising tolerance specified in the product specification, the I-V curve test may be repeated measuring the I-V curve from the PV module's junction box (before the PV module's charging cable). The results from the original test shall be used as input for the solar charge test both sets of results shall be reported for the photovoltaic module I-V characteristics test.

H.4.2.3 I-V curve adjustment for STC and TMOT

The I-V curve measured in H.4.2.2 shall be adjusted to STC (25 °C cell temperature, solar irradiance of 1 000 W/m², and air mass 1,5) and TMOT (50 °C cell temperature, solar irradiance of 1 000 W/m², and air mass 1,5) using either of the following two procedures, ensuring that all voltage measurements are taken with the same device and all temperature measurements are taken with the same device:

Procedure 1: Use any of the correction procedures defined in IEC 60891:2009. For temperature coefficient measurements, a single thermocouple, meeting the accuracy requirements of Annex BB and positioned directly behind a cell near the centre of the module, may be used. If the back of the module is inaccessible, the front-mounted thermocouple procedure detailed in the outdoor test procedure (H.4.3.4.3) shall be used.

NOTE Correction procedure 3 (IEC 60891:2009, 3.4) allows temperature correction using two I-V curves at different temperatures. If no irradiance correction is needed, this method is likely to be the simplest for a low-cost test.

Procedure 2: Measure the temperature coefficient of voltage ($T_{c,voc}$) using the procedure defined in H.4.3, under either natural or simulated sunlight, then use the calculations in H.4.3.4.4 to adjust the curve to STC and TMOT.

H.4.3 Outdoor photovoltaic module I-V characteristics test

The PV module is tested outdoors to obtain its characteristic I-V curve, from which the maximum power (P_{mpp}), open-circuit voltage (V_{oc}), and short-circuit current (I_{sc}) may be determined.

H.4.3.1 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Outdoor I-V curve analyser. The analyser may include an integrated pyranometer, provided it is fast-response (i.e., silicon PV-based pyranometer).
- Fast-response (i.e., silicon PV-based) pyranometer
- Voltmeter or multimeter
- Surface-mounted thermocouple(s) and a thermocouple reader

H.4.3.2 Test prerequisites

The following prerequisites shall be met:

- Constant atmospheric conditions (i.e., a clear, sunny day with no clouds)
- Incident solar radiation between 850 W/m² and 1 150 W/m² and an ambient temperature between 15 °C and 35 °C
- Air mass less than or equal to 2
- If the PV module is amorphous silicon or otherwise may be subject to degradation (e.g., because it is thin film or of unknown technology), it shall sun-soak for 30 days prior to performing this test

H.4.3.3 Apparatus

There should be an appropriate stand to hold the PV module and pyranometer in the same plane, directly normal to the sun. The PV module should be placed as close as possible to the pyranometer to ensure that each device “sees” the same sky view. A sighting tube with bracket may be used to ensure the stand is directly normal to the sun (Figure H.1).

Key

- 1 Pyranometer
- 2 Board or other flat surface
- 3 Bracket
- 4 Sighting tube
- θ 90°

Figure H.1 – PV module I-V curve testing rack

H.4.3.4 Procedure

H.4.3.4.1 General

Determine the appropriate thermocouple mounting technique based on PV panel configuration. If the PV module is separate from the lighting product or can be easily removed without damaging the active PV material and the back of the PV module is accessible, use the back-mounted thermocouple procedure (H.4.3.4.2). Otherwise, use the front-mounted thermocouple procedure (H.4.3.4.3).

Procedure 1 of H.4.2.3 may be used as an alternative means to adjust the I-V curve to STC and TMOT (as opposed to using the methods provided below in H.4.3.4.2 and H.4.3.4.3). This would involve taking I-V curve measurements at two different module temperatures, rather than only taking I-V curve measurements when the module has reached thermal equilibrium after warming under natural sunlight. When using Procedure 1 of H.4.2.3, it is permitted to use step a) in H.4.3.4.4 to adjust all measured curves to an irradiance value of 1 000 W/m².

H.4.3.4.2 Back-mounted thermocouple

These steps shall be followed:

a) Before the PV module is exposed to sunlight, do the following:

- 1) If the PV module charges the DUT via a cable extended from the PV module's junction box, measure the I-V curve from the end of the cable that plugs into the DUT for charging by cutting the connector from the end of the PV module cable, leaving as much of the cable connected to the PV module as possible, and strip the wire ends.

If the PV module's I-V curve results show that the PV module's performance deviates from the advertised values by more than the truth-in-advertising tolerance specified in the product specification, the I-V curve test may be repeated measuring the I-V curve from the PV module's junction box (before the PV module's charging cable). The

results from the original test shall be used as input for the solar charge test both sets of results shall be reported for the photovoltaic module I-V characteristics test.

- 2) Connect a voltage meter or multimeter (DC voltage range) to the PV module.
 - 3) Fix the thermocouple to the back of the PV module directly behind a cell near the centre of the active area and affix insulating material (e.g., foil-backed foam tape) over the thermocouple.
- b) Expose the PV module to direct normal sunlight and immediately measure and record the open-circuit voltage ($V_{oc,1}$) and the PV module temperature (T_1).
 - c) Leave the PV module in direct normal sunlight until thermal equilibrium is reached (i.e., the PV module temperature is not changing by more than 1 °C/min).
 - d) Connect the PV module to the I-V curve analyser per the I-V curve analyser's manufacturer's instructions.
 - e) Execute the I-V measurement per the I-V curve analyser's manufacturer's instructions and record the PV module temperature (T) and incident solar radiation.
 - f) After the I-V curve measurement, measure and record the PV module temperature again (T_2) using the same instrument that was used in step a).
 - g) Measure and record the PV module's open-circuit voltage at T_2 ($V_{oc,2}$) using the same instrument that was used in step a).

H.4.3.4.3 Front-mounted thermocouple

These steps shall be followed:

- a) Before the PV module is exposed to sunlight, do the following:
 - 1) If the PV module charges the DUT via a cable extended from the PV module's junction box, measure the I-V curve from the end of the cable that plugs into the DUT for charging by cutting the connector from the end of the PV module cable, leaving as much of the cable connected to the PV module as possible, and strip the wire ends.

If the PV module's I-V curve results show that the PV module's performance deviates from the advertised values by more than the truth-in-advertising tolerance specified in the product specification, the I-V curve test may be repeated measuring the I-V curve from the PV module's junction box (before the PV module's charging cable). The results from the original test shall be used as input for the solar charge test both sets of results shall be reported for the photovoltaic module I-V characteristics test.
 - 2) Connect a voltage meter or multimeter (DC voltage range) to the PV module.
 - 3) Fix the thermocouple to the front of the PV module directly over a cell in the centre of the active area and affix insulating material (e.g., foil-backed foam tape) over the thermocouple.
- b) Expose the PV module to direct normal sunlight and immediately measure and record the PV module temperature (T_1), then quickly remove the thermocouple and insulating material from the front of the PV module, and measure and record the open-circuit voltage ($V_{oc,1}$).
- c) After measuring ($V_{oc,1}$), again fix the thermocouple to the front of the PV module directly over a cell in the centre of the active area in the same location as before and affix insulating material (e.g., foil-backed foam tape) over the thermocouple.
- d) Leave the PV module in direct normal sunlight until thermal equilibrium is reached (i.e., the PV module temperature is not changing by more than 1 °C/min).
- e) Connect the PV module to the I-V curve analyser per the I-V curve analyser's manufacturer's instructions.
- f) Remove the thermocouple.
- g) Measure and record the PV module's open-circuit voltage at T_2 ($V_{oc,2}$) using the same instrument that was used in step a).

- h) Immediately after obtaining $V_{oc,2}$, affix the thermocouple and insulating material to the front of the PV module (i.e., the same place as in step (a)) and measure and record the temperature of the PV module (T_2 & T) using the same instrument that was used in step a).
- i) Immediately execute the I-V measurement per the I-V curve analyser's manufacturer's instructions.

H.4.3.4.4 Calculations

The following calculations shall be made, unless temperature adjustments are being performed using Procedure 1 of H.4.2.3. If Procedure 1 of H.4.2.3 is being used, the current measurements may be converted to 1 000 W/m² using step a).

- a) Convert all of the current measurements to STC using the following formula:

$$I = I_m \cdot \frac{1\,000\text{ W/m}^2}{G}$$

where

I is the PV module's current at STC, in amperes (A);

I_m is the PV module's measured current, in amperes (A);

G is the measured incident solar radiation during the I-V curve measurement, in watts per square metre (W/m²).

- b) Determine the temperature coefficient for the voltage ($T_{c,voc}$) using the following formula:

$$T_{c,voc} = \frac{(V_{oc,1} - V_{oc,2}) / V_{oc,2}}{T_1 - T_2}$$

where

$T_{c,voc}$ is the PV module's temperature coefficient for the voltage, per degree Celsius (1/°C);

$V_{oc,1}$ is the PV module's open-circuit voltage immediately after exposure to sunlight, in volts (V);

$V_{oc,2}$ is the PV module's open-circuit voltage after the I-V measurement is taken, in volts (V);

T_1 is the PV module's temperature immediately before exposure to sunlight, in degrees Celsius (°C);

T_2 is the PV module's temperature after the I-V curve measurement is taken, in degrees Celsius (°C).

- c) Convert all of the voltage measurements to STC using the following formula:

$$V = V_m \cdot \left[1 + T_{c,voc} \cdot (T_{stc} - T) \right]$$

where

V is the PV module's voltage at STC, in volts (V);

V_m is the PV module's measured voltage, in volts (V);

$T_{c,voc}$ is the PV module's temperature coefficient for the voltage, per degree Celsius (1/°C);

T_{stc} is the temperature at STC, 25 °C;

T is the PV module's temperature during the I-V curve measurement, in degrees Celsius (°C).

- d) The PV module's short-circuit current at STC (I_{sc}) is the current corresponding to 0 V on the STC-adjusted I-V curve.

- e) The PV module's open-circuit voltage at STC (V_{oc}) is the voltage corresponding to 0 A on the STC-adjusted I-V curve.
- f) Determine the PV module's measured maximum power point power at STC (P_{mpp}) using the following formula:

$$P_{mpp} = \max(I \cdot V)$$

where

P_{mpp} is the PV module's measured maximum power point power at STC, in watts (W);

I is the PV module's current at STC, in amperes (A);

V is the PV module's voltage at STC, in volts (V).

- g) The PV module's maximum power point current at STC (I_{mpp}) is the current corresponding to P_{mpp} on the STC-adjusted I-V curve.
- h) The PV module's maximum power point voltage at STC (V_{mpp}) is the voltage corresponding to P_{mpp} on the STC-adjusted I-V curve.
- i) Repeat steps c) through h) for TMOT in place of STC, where TMOT is defined as 50 °C.

H.5 Reporting

Report the following in the photovoltaic module I-V characteristics test report.

- Metadata
 - Report name
 - Procedure(s) used
 - Lighting product manufacturer
 - Lighting product name
 - Lighting product model number
 - Name of test laboratory
 - Description of location of test
 - Approving person
 - Date of report approval
- Results for tested PV module aspects for samples 1 through n
 - Short-circuit current at STC (A)
 - Open-circuit voltage at STC (V)
 - Maximum power point power at STC (W)
 - Maximum power point current at STC (A)
 - Maximum power point voltage at STC (V)
 - Short-circuit current at TMOT (A)
 - Open-circuit voltage at TMOT (V)
 - Maximum power point power at TMOT (W)
 - Maximum power point current at TMOT (A)
 - Maximum power point voltage at TMOT (V)
 - Temperature coefficient for voltage (1/°C)
- Average of n sample results for each PV module aspect tested
- Coefficient of variation of n sample results for each PV module aspect tested (%)

- PV module's rating for aspects tested, if available
- Deviation of the average result from the PV module's rating for each aspect tested, if available (%)
- Comments
 - Individual comments, as necessary, for samples 1 through n
 - Overall comments, as necessary, for collective set of samples 1 through n
- Figures
 - Single plot showing the I-V and power-voltage curves for every PV module sample
- Datasets
 - Comma-delimited or tabular dataset listing current (A) and voltage (V) adjusted to STC across the full measured I-V curve

Annex I (normative)

Battery test

I.1 Background

The battery test is used to determine a DUT's actual battery capacity and round-trip energy efficiency. This information is useful to determine if a battery is mislabelled or damaged. During the test the battery is connected to a battery analyser, which performs charge-discharge cycles on the battery. The last charge-discharge cycle data from the battery test is analysed to determine the actual battery capacity and battery round-trip energy efficiency.

I.2 Test outcomes

The test outcomes of the battery test are listed in Table I.1.

Table I.1 – Battery test outcomes

Metric	Reporting units	Related aspects	Note
Battery capacity (C_b)	Ampere-hours (Ah) at a specific discharge current	4.2.5.1 Battery capacity	--
Battery round trip energy efficiency (η_b)	Percentage (%)	4.2.5.2 Battery round-trip energy efficiency	At least two complete charge-discharge cycles are required for the calculation

I.3 Related tests

The battery test results are inputs to the full-discharge preparation procedure (Annex M), the solar charge test (Annex N), the battery durability test (Annex S), and the energy service calculations (Annex R).

I.4 Procedure

I.4.1 General

Table I.2 contains battery testing information specific to the four common types (i.e., chemistries) of batteries. This information is pertinent to I.4.2.4, I.4.3.4, I.4.4.4, and I.4.5.4.

New or improved battery technologies could emerge for which Table I.2 does not contain information. The test lab should sufficiently research the new or improved battery technology to determine appropriate recommended battery practices for that new or improved battery technology. Communication directly with the supplier of the DUT's battery is recommended. For example, if the battery under test is a lithium battery but is not the lithium ion (3,7 V nominal voltage) or lithium iron phosphate chemistry, alternative charging and discharging rates and end-of-cycle voltage parameters should be obtained, preferably from the battery supplier.

Table I.2 – Recommended battery testing specifications according to battery chemistry

Battery type	Charging				Discharging	
	Charge rate (I _t A)	Maximum charge voltage (V/cell) ^a	End-of-charge / topping charge rate (I _t A)	End-of-charge time with constant voltage (h) ^b	Discharge rate (I _t A)	End-of-discharge voltage (V/cell)
Lead-acid	0,1	2,40	0,05	10	0,1	1,80
Lithium-ion	0,2	4,20	0,05	1	0,2	3,00
Lithium iron phosphate	0,2	3,60	0,01	1	0,2	2,50
Battery type	Charging			Discharging		
	Charge rate (I _t A)	Overcharge (charge factor)	Partial charge duration (h) ^c	Discharge rate (I _t A)	End-of-discharge voltage (V/cell)	
Nickel-metal hydride	0,1	1,6	9	0,2	1,00	
<p>^a For safety, never exceed the battery supplier's specified maximum allowable voltage.</p> <p>^b After a battery is charged to a specified voltage, it may be topped off using the recommended end-of-charge/ topping charge rate, or alternatively the battery may be topped off by supplying a constant voltage (the maximum charge voltage) over the recommended end-of-charge time.</p> <p>^c This value is used for measuring the battery efficiency only.</p>						

I.4.2 Lead-acid battery test

I.4.2.1 General

The DUT's lead-acid battery is cycled on a battery analyser and the data from the final charge-discharge cycle is used to determine the DUT's actual battery capacity and storage efficiency.

If cell balancing or battery protection circuitry is external to the battery, the usable capacity of the battery may differ when measured without the DUT's circuitry included. In cases where the test results are disputed for this reason, the battery capacity may also be evaluated by disassembling the battery pack and performing the test on a single cell (or parallel cellblock). The positions of the cells or cellblocks to test should be selected randomly in a way that maximizes coverage. The capacity of the entire pack may be assumed to be equal to the capacity of the selected cell or parallel cellblock. If the battery under test is to be used for further testing, all cells of the battery shall be returned to a balanced state of charge prior to further testing, e.g. by fully discharging or charging the cells under test to match the rest of the battery pack's state of charge.

I.4.2.2 Equipment requirements

A battery analyser meeting the requirements in Table BB.2 is required.

A DC power supply is needed in some cases, depending on the battery tested and the battery analyser in use. A hydrometer is needed in some cases for flooded lead-acid batteries.

I.4.2.3 Test prerequisites

The battery may be taken out of the DUT for this test, if desired. The DUT shall have been prepared as described in Annex F. The test shall be carried out at 20 °C ± 5 °C.

If the DUT is a flooded lead-acid battery that was shipped dry, add acid according to the following directions:

- a) Fill the battery with battery acid. The correct volume and density shall be determined from either the manufacturer-supplied information or the battery packaging. If the values from these two sources conflict, consult the manufacturer.
- b) Measure the voltage and density immediately after filling the battery, and again 30 minutes after filling.
- c) If after 30 minutes, the voltage is greater than 2,0 V/cell, continue with the battery test procedure (I.4.2.4)
- d) If after 30 minutes the voltage is less than 2,0 V/cell, the density has dropped, and the battery temperature has increased, then the negative electrode (Pb) is likely oxidized. If the negative electrode is oxidized, the oxidation must be removed by overcharging as follows:
 - Conduct a 24 h IU charge (a constant current charge followed by a float charge held at a constant voltage with a total duration of 24 h). A charge rate of 0,1 It A (calculated using the battery's rated capacity) shall be used for the I phase and a voltage of 2,45 V shall be used for the U phase. The relatively high voltage and duration of this charge may cause the battery to produce hydrogen and oxygen, a combustible gas mixture. Conduct this procedure outdoors or in a well-ventilated room.

If after 30 minutes, the battery voltage is less than 2,0 V/cell, but the density has not dropped or the temperature has not risen, the battery may have defects that cannot be addressed by overcharging. Attempt the overcharging procedure, but note that the battery conditions indicate possible defects.

I.4.2.4 Procedure

Perform the capacity test from IEC 61427-1:2013, 8.1 (which references IEC 61056-1), with the following modifications:

- Perform a minimum of five charge-discharge cycles to ensure that the battery is sufficiently exercised prior to determining capacity and to ensure that enough data are available to calculate round-trip energy efficiency. Use the final charge-discharge cycle to calculate the battery's actual capacity and round-trip energy efficiency.
- Carry out the test at 20 °C ± 5 K
- The battery shall be kept at open circuit for 1 h to 24 h after charging before starting each discharge. (It is not necessary to wait 5 h as required by IEC 60156-1.)
- Equipment need not meet the accuracy requirements of IEC 61427-1:2013 or IEC 61056-1, provided that it meets the requirements of Table BB.2.
- Record the current at an interval of 1 min or less.

If the battery contains internal circuitry (refer to E.4.3.5) and either the battery analyser will not start the test or the tester decides that the results from the test are unexpected or faulty in some way, the test may be repeated with the battery analyser connected on the battery side of the internal circuitry, if the test laboratory determines that it is safe to do so.

If the battery will be stored after undergoing this test, charge the battery using the charge information in Table I.2 and disconnect the battery from the DUT. Charge the battery every six months, or every three months if stored at a temperature greater than 30 °C.

If the battery analyser does not recognize the battery upon starting any of the above steps, the battery voltage could have dropped below the battery analyser's minimum threshold. If this is the case, a power supply shall be used to charge the battery in accordance with IEC 61427-1:2013 before the DUT's battery capacity is determined.

I.4.2.5 Calculations

Perform the following calculations:

- a) Determine the total energy input into the DUT's battery during the final charge cycle (E_c) using the following formula:

$$E_c = \sum (V_c \cdot I_c \cdot \Delta t)$$

where

E_c is the energy entering the battery during the charge cycle, in watt-hours (Wh);

V_c is the voltage recorded during the charge cycle, in volts (V);

I_c is the current recorded during the charge cycle, in amperes (A);

Δt is the time interval between measurements, in hours (h).

- b) Determine the total energy output from the DUT's battery during the final discharge cycle using the following formula:

$$E_d = \sum (V_d \times I_d \times \Delta t)$$

where

E_d is the battery's energy output during the discharge cycle, in watt-hours (Wh);

V_d is the voltage recorded during the discharge cycle, in volts (V);

I_d is the current recorded during the discharge cycle, in amperes (A);

Δt is the time interval between measurements, in hours (h).

- c) Determine the DUT's battery capacity with data from the final discharge cycle using the following formula:

$$C_b = \sum (I_d \cdot \Delta t)$$

where

C_b is the measured battery capacity, in ampere-hours (Ah);

I_d is the current recorded during the discharge cycle, in amperes (A);

Δt is the time interval between measurements, in hours (h).

- d) Correct the capacity to the reference temperature of 25 °C using the following formula (from IEC 60896-21), with λ set to 0,006 K⁻¹:

$$C_a = C / (1 + \lambda(T - 25 \text{ °C}))$$

where

C_a is the actual battery capacity, in ampere-hours (Ah);

C is the measured battery capacity, in amperes (A);

λ is 0,006 K⁻¹.

T is the battery temperature at the start of the final discharge cycle, in degrees Celsius (°C).

- e) Determine the DUT's battery round-trip energy using the following formula:

$$\eta_b = \frac{E_d}{E_c}$$

where

η_b is the battery's round-trip energy efficiency;

E_d is the battery's energy output during the final discharge cycle, in watt-hours (Wh);

E_c is the energy input to the battery during the final charge cycle, in watt-hours (Wh).

Report the actual capacity (i.e., the value that has been corrected to 25 °C).

I.4.3 Nickel-metal hydride battery test

I.4.3.1 General

The DUT's nickel-metal hydride battery is cycled on a battery analyser and the data from the final charge-discharge cycle is used to determine the DUT's actual battery capacity and battery round-trip energy efficiency.

The nickel-metal hydride battery test procedure refers to the overcharge charging method, whereby the battery is charged at constant current for a fixed duration given by the following formula:

$$T_c = OC \times \frac{C_b}{I_c}$$

where

T_c is the duration of the charge cycle, in hours (h);

OC is the overcharge (charge factor) value given in Table I.2;

C_b is the measured or rated battery capacity, in ampere-hours (Ah);

I_c is the charge current, in amperes (A);

If cell balancing or battery protection circuitry is external to the battery, the usable capacity of the battery may differ when measured without the DUT's circuitry included. In cases where the test results are disputed for this reason, the battery capacity may also be evaluated by disassembling the battery pack and performing the test on a single cell (or set of cells connected in parallel). The cell or parallel grouping of cells should be selected at random for each DUT. The capacity of the entire pack may be assumed to be equal to the capacity of the selected cell or parallel grouping of cells. If the battery under test is to be used for further testing, care should be taken to return all cells of the battery to a balanced state of charge prior to further testing, e.g. by fully discharging or charging the cells under test to match the rest of the battery pack's state of charge.

I.4.3.2 Equipment requirements

A battery analyser meeting the requirements in Table BB.2 is required.

I.4.3.3 Test prerequisites

The battery may be taken out of the DUT for this test, if desired. The DUT shall have been prepared as described in Annex F. The test shall be carried out at 20 °C ± 5 °C. As specified in IEC 61951-2:2011, the test shall be carried out at a relative humidity of 65 % ± 20 %.

I.4.3.4 Procedure

Perform the capacity test from IEC 61951-2:2011, 7.2, with the following modifications:

- Perform a minimum of five charge-discharge cycles to ensure that the battery is sufficiently exercised prior to determining capacity and to ensure that enough data are available to calculate round-trip energy efficiency. Use the final charge-discharge cycle to calculate the battery's actual capacity and round-trip energy efficiency.
- Record the current at an interval of 1 min or less.

If the battery contains internal circuitry (refer to E.4.3.5) and either the battery analyser will not start the test or the tester decides that the results from the test are unexpected or faulty in some way, the test may be repeated with the battery analyser connected on the battery side of the internal circuitry, if the test laboratory determines that it is safe to do so.

- f) If the battery analyser does not recognize the battery upon starting any of the above steps, the battery output may have dropped to 0 V. If this is the case, a constant-current charge

as specified in Table I.2 of Annex I from a power supply may be required to bring the battery out of a 0 V state of charge before the DUT's battery capacity is determined.

- g) Nickel-based batteries need not be charged prior to storage; however, batteries should be disconnected from the DUT prior to long-term storage to avoid polarity reversal. It may be convenient to end the battery test with a charge to allow for further testing.

I.4.3.5 Calculations

Perform the calculations listed in I.4.2.5.

I.4.4 Lithium-ion battery test

I.4.4.1 General

The DUT's lithium-ion battery is cycled on a battery analyser and the data from the final charge-discharge cycle is used to determine the DUT's actual battery capacity and battery round-trip energy efficiency.

I.4.4.2 Equipment requirements

A battery analyser meeting the requirements in Table BB.2 is required.

For battery packs containing more than one cell in series, a protection circuit that monitors the voltage of each cell (or each set of cells connected in parallel) shall be used during charging, if this functionality is not incorporated into the battery pack. This functionality may be built into the battery analyser or may be a separate piece of equipment. The voltage of each individual cell (or each set of cells connected in parallel) should not be allowed to exceed the maximum battery testing voltage given in Table J.2 unless manufacturer-provided battery specifications indicate that such operation can be performed safely. The temperature of each individual cell should not be allowed to exceed 45 °C. Care should be taken that any voltage drop introduced by the protection circuit (e.g., relay contact resistance) does not affect the results.

The use of a battery protection circuit other than the one incorporated into the DUT may affect the usable capacity of the battery. Additionally, if cell balancing circuitry is external to the battery, the usable capacity of the battery may differ when measured without the cell balancing circuitry included. In cases where the test results are disputed for this reason, the battery capacity may also be evaluated by disassembling the battery pack and performing the test on a single cell (or set of cells connected in parallel). The cell or parallel grouping of cells should be selected at random for each DUT. The capacity of the entire pack may be assumed to be equal to the capacity of the selected cell or parallel grouping of cells. If the battery under test is to be used for further testing, care should be taken to return all cells of the battery to a balanced state of charge prior to further testing, e.g. by fully discharging or charging the cells under test to match the rest of the battery pack's state of charge.

I.4.4.3 Test prerequisites

The battery may be taken out of the DUT for this test, if desired. The DUT shall have been prepared as described in Annex F. The test shall be carried out at 20 °C ± 5 °C. As specified in IEC 61960-2:2011, the test shall be carried out in still air. Batteries with multiple cells (or parallel cellblocks) in series shall be prepared according to F.4.4 a).

I.4.4.4 Procedure

Perform the capacity test from IEC 61960-2:2011, 7.1 and 7.2, with the following modifications:

- Perform a minimum of five charge-discharge cycles to ensure that the battery is sufficiently exercised prior to determining capacity and to ensure that enough data are available to calculate round-trip energy efficiency. Use the final charge-discharge cycle to calculate the battery's actual capacity and round-trip energy efficiency.
- Charge and discharge the battery using the information in Table I.2—calculated using the battery's rated capacity.
- Record the current at an interval of 1 min or less.

If the battery contains internal circuitry (refer to E.4.3.5) and either the battery analyser will not start the test or the tester decides that the results from the test are unexpected or faulty in some way, the test may be repeated with the battery analyser connected on the battery side of the internal circuitry, if the test laboratory determines that it is safe to do so.

If the battery will be stored after undergoing this test, charge the battery using the charge rate specified in Table I.2 for 2.5 h (i.e., store at 50 % state of charge) and disconnect the battery from the DUT.

If the battery analyser does not recognize the battery upon starting any of the above steps, the battery may have been disconnected by its internal protection circuit. In this case, the voltage at the battery terminals will be zero, which can prevent the battery analyser from recognizing the battery. In this situation, a current-limited constant-voltage charge, at a current no higher than that specified in Table I.2 of Annex I from a power supply may be required to re-enable the battery before the DUT's battery capacity is determined. If the cell voltage has decreased below 2,5 V for lithium iron phosphate or 3,0 V for other lithium-ion, perform the charge at 0,1 I_t A. The voltage shall not exceed the value given in Table I.2. It is recommended to set the power supply to the lowest possible voltage that will allow the battery analyser to recognize the battery and complete the charge cycle. If the battery is suspected to be damaged, it should not be charged using this method. It may be necessary to bypass the battery's internal protection circuit to perform this step; in this case, the cell voltage should be measured prior to charging the battery to ensure that it has not dropped below the minimum battery testing voltage given in Table J.1. If the battery voltage has dropped below the minimum battery testing voltage, charging the battery can be unsafe; the test laboratory should discontinue the test if in the tester's discretion it would be unsafe to continue.

I.4.4.5 Calculations

Perform the calculations listed in I.4.2.5.

I.4.5 Lithium iron phosphate battery test

I.4.5.1 General

The DUT's lithium iron phosphate battery is cycled on a battery analyser and the data from the final charge-discharge cycle is used to determine the DUT's actual battery capacity and battery round-trip energy efficiency.

I.4.5.2 Equipment requirements

A battery analyser meeting the requirements in Table BB.2 is required.

For battery packs containing more than one cell in series, a protection circuit that monitors the voltage of each cell (or each set of cells connected in parallel) shall be used during charging, if this functionality is not incorporated into the battery pack. This functionality may be built into the battery analyser or may be a separate piece of equipment. The voltage of each individual cell (or each set of cells connected in parallel) should not be allowed to exceed the maximum battery testing voltage given in Table J.2 unless manufacturer-provided battery specifications indicate that such operation can be performed safely. The temperature of each individual cell should not be allowed to exceed 45 °C. Care should be taken that any voltage drop introduced by the protection circuit (e.g., relay contact resistance) does not affect the results.

The use of a battery protection circuit other than the one incorporated into the DUT may affect the usable capacity of the battery. Additionally, if cell balancing circuitry is external to the battery, the usable capacity of the battery may differ when measured without the cell balancing circuitry included. In cases where the test results are disputed for this reason, the battery capacity may also be evaluated by disassembling the battery pack and performing the test on a single cell (or set of cells connected in parallel). The cell or parallel grouping of cells should be selected at random for each DUT. The capacity of the entire pack may be assumed to be equal to the capacity of the selected cell or parallel grouping of cells. If the battery under test is to be used for further testing, care should be taken to return all cells of the battery to a balanced state of charge prior to further testing, e.g. by fully discharging or charging the cells under test to match the rest of the battery pack's state of charge.

I.4.5.3 Test prerequisites

The battery may be taken out of the DUT for this test, if desired. The DUT shall have been prepared as described in Annex F. The test shall be carried out at $20\text{ °C} \pm 5\text{ °C}$. As specified in IEC 61960-2:2011, the test shall be carried out in still air. Batteries with multiple cells (or parallel cellblocks) in series shall be prepared according to F.4.4 a).

I.4.5.4 Procedure

Follow the procedure in I.4.4.4.

I.4.5.5 Calculations

Perform the calculations listed in I.4.2.5.

I.5 Reporting

Report the following in the battery test report.

- Metadata
 - Report name
 - Procedure(s) used
 - DUT manufacturer
 - DUT name
 - DUT model number
 - Name of test laboratory
 - Approving person
 - Date of report approval
- Results for tested DUT aspects for samples 1 through n
 - Battery capacity (Ah) at a discharge current ($0, x I_t$ A)
 - Battery round-trip energy efficiency (%)
- Average of n sample results for each DUT aspect tested
- Coefficient of variation of n sample results for each DUT aspect tested (%)
- DUT's rating for aspects tested, if available
- Deviation of the average result from the DUT's rating for each aspect tested, if available (%)
- Comments
 - Individual comments, as necessary, for samples 1 through n
 - Overall comments, as necessary, for collective set of samples 1 through n

Annex J (informative)

Battery testing recommended practices

J.1 Background

Several tests in this quality assurance protocol involve charging or discharging a battery:

- During the charge controller behaviour test (Annex K), the DUT's battery is either charged or discharged to determine if the DUT has appropriate deep discharge protection and overcharge protection.
- During the solar charge test (Annex N), the DUT's battery is charged.
- During the full-battery run time test (Annex L), the DUT's battery is discharged.

In some cases, it is not known whether the DUT provides sufficient protection to avoid damage to the battery or test apparatus or injury to test laboratory personnel. Annex J provides recommended charging and discharging practices to prevent damage to the DUT and ensure safety of test personnel.

A variety of battery chemistry types are used in products meeting the scope of this quality assurance protocol, potentially including types that were not in common use at the date of publication. The information in Table J.1 and Table J.2 is intended to prevent damage to the DUT and test apparatus and ensure safety of test personnel for most common battery types. When possible, battery specifications should be obtained from the battery manufacturer to evaluate whether the protection strategy used by the DUT is appropriate for the specific battery used.

J.2 Deep discharge protection specifications by battery type

Table J.1 contains recommended battery deep discharge protection voltages and minimum battery voltages for five common types (i.e., chemistries) of batteries. If the product or battery manufacturer has not provided an appropriate deep discharge protection voltage cutoff design value for the battery in the manufacturer self-reported information (Annex C), the information in Table J.1 may be used when determining if the DUT has appropriate deep discharge protection.

Table J.1 contains two voltage values for each battery type. The “recommended deep discharge protection voltage” is the recommended setpoint for the DUT's deep discharge protection (low voltage disconnect). The tolerance given is intended to account for measurement uncertainty both in the DUT and in the laboratory apparatus. The “minimum battery testing voltage” is intended to ensure laboratory personnel safety and prevent immediate, permanent damage to the battery. The test laboratory should immediately stop charging a battery if the battery voltage reaches the minimum testing voltage.

If the DUT does not have appropriate deep discharge protection, the DUT's battery can be damaged during the full-battery run time and the charge controller behaviour tests. As an option, the tester may incorporate a low-voltage disconnect device that will stop a DUT's discharge when the DUT's battery reaches the minimum battery testing voltage specified in Table J.1.

Table J.1 – Recommended battery deep discharge protection voltage specifications according to battery chemistry

Battery type	Deep discharge protection voltage (V/cell)			Minimum battery testing voltage (V/cell)
	Recommended	Minimum	Maximum	
Flooded lead-acid	≥ 1,87	1,82	--	none
Valve-regulated lead-acid	≥ 1,87	1,82	--	none
Lithium-ion	≥ 3,00	2,95	--	2,50
Lithium iron	≥ 2,50	2,45	--	2,00
Nickel-metal hydride	= 1,00	0,95 ^a	1,10 ^b	0,80 ^a

^a These lower limits for NiMH batteries only apply to batteries with multiple cells in series. There is no personnel safety risk from discharging batteries below this limit, but there is a risk of polarity reversal, which can cause irreversible damage to the battery. There is no lower voltage limit for single-cell NiMH batteries.

^b The intent of this upper limit is to prevent reversible capacity loss due to voltage depression (“memory effect”) resulting from partial discharge.

J.3 Overcharge protection specifications by battery type

Table J.2 contains recommended battery overcharge protection voltages and maximum battery voltages and cell temperatures specific to five common types (i.e., chemistries) of batteries. If the product or battery manufacturer has not provided an appropriate overcharge protection voltage cutoff or maximum cell temperature design value for the battery in the manufacturer self-reported information (Annex C), the information in Table J.2 may be used when determining if the DUT has appropriate overcharge protection. The maximum cell temperature should not be exceeded at any time when the battery is being charged.

Table J.2 contains two voltage values for each battery type. The “recommended overcharge protection voltage” is the recommended setpoint for the DUT’s overcharge protection (overvoltage protection). The tolerance given is intended to account for measurement uncertainty both in the DUT and in the laboratory apparatus. The “maximum battery testing voltage” is intended to ensure laboratory personnel safety and prevent immediate, permanent damage to the battery. The test laboratory should immediately stop charging a battery if the battery voltage reaches the maximum testing voltage.

Table J.2 – Recommended battery overcharge protection voltage and temperature specifications according to battery chemistry

Battery type	Overcharge protection voltage (V/cell)			Maximum battery testing voltage (V/cell)	Maximum charging temperature (°C)
	Recommended	Minimum	Maximum		
Flooded lead-acid	= 2,40	2,35	2,50	2,60	45
Valve-regulated lead-acid	= 2,40	2,35	2,45	2,60	45
Lithium-ion	≤ 4,20	--	4,25	4,26	45
Lithium iron	≤ 3,65	--	3,70	3,85	45
Nickel-metal hydride	≤ 1,45	--	1,50	1,51	60

Annex K (normative)

Charge controller behaviour test

K.1 Background

Deep discharge and overcharge protection is important for user safety and battery longevity. Charge control is most critical for products with lead-acid, Li-ion, and LiFePO₄ batteries.

The charge controller behaviour test contains five methods to examine a DUT's charge controller. Every DUT shall be tested with the active **deep discharge** method, where the DUT is discharged until its appliance(s) no longer function, the DUT's battery voltage drops below its recommended deep discharge voltage threshold, or a sufficiently long period passes with minimal appliance function. Every DUT shall also be tested with the **active overcharge protection** method, where the DUT is charged until reaching its overvoltage protection (OVP) voltage or appropriately exceeding its recommended OVP voltage threshold. For DUTs that have no active deep discharge protection and no ports for powering appliances, the **passive deep discharge** protection method shall be used, where the DUT's battery voltage is examined for safety during a long-term discharge. For DUTs with NiMH batteries that have no active overcharge protection, the **passive overcharge protection** method shall be used, where the DUT's long-term charging current is examined for safety.

Every DUT shall also be examined for **standby losses**. A DUT's electronics can draw substantial amounts of energy from the DUT's batteries while the DUT is not in use, and this standby loss can lead to shorter run times or problems when storing the DUT for long periods of time.

The choice of test methods and assessment of the appropriateness of charge control should include input from the battery manufacturer and/or system integrator about the approach to charge control and the design values for cut-off or other control algorithms. The best practice for testing is to establish what the design algorithm and setpoints are and measure for those using the appropriate methods. The assessment of whether charge control is present and appropriate may then be based on the combination of two factors: the appropriateness of the design values and whether the design was accurately realized as shown during the tests.

K.2 Test outcomes

The test outcomes of the charge controller behaviour test are listed in Table K.1.

Table K.1 – Charge controller behaviour test outcomes

Metric	Reporting units	Related aspects	Remarks
Active deep discharge protection	Yes/no	4.2.3.13 Battery protection strategy	--
Deep discharge protection voltage	Volts (V)	4.2.3.13 Battery protection strategy	Measured only if the DUT has active deep discharge protection
Active overcharge protection	Yes/no	4.2.3.13 Battery protection strategy	--
Overcharge protection voltage	Volts (V)	4.2.3.13 Battery protection strategy	Measured only if the DUT has active overcharge protection
Passive deep discharge protection	Yes/no	4.2.3.13 Battery protection strategy	--
Passive deep discharge protection battery voltage	Volts per cell (V/cell)	4.2.3.13 Battery protection strategy	Required only if tested for passive deep discharge protection, DUT must not have any ports for powering appliances
Passive overcharge protection	Yes/no	4.2.3.13 Battery protection strategy	Measured only for NiMH batteries with no active overcharge protection
Passive overcharge protection continuous charging current	Amperes (A)	4.2.3.13 Battery protection strategy	Required only if tested for passive overcharge protection
Standby loss current	Amperes (A)	4.2.3.13 Battery protection strategy	Current that is drawn from a product's battery when the product is switched off when at 50% state of charge

K.3 Related tests

The results of the active deep discharge protection test (K.4.1) may be substituted with results of the full-battery run time test combined with deep discharge protection measurement (Annex L), if only lighting appliances are advertised for use with the DUT.

The results of the passive deep discharge protection test (K.4.3) may be substituted with results of the full-battery run time test combined with deep discharge protection measurement (Annex L), if only lighting appliances are advertised for use with the DUT.

Annex K shall be performed after the photovoltaic module IV characteristics test (Annex M) for solar-charged products because the active overcharge protection test (K.4.2) requires the DUT's maximum power point current (I_{mpp}) and the passive overcharge protection test (K.4.3) requires the DUT's entire I-V curve data set.

The DUT's full battery run time from the full-battery run time test procedure (Annex L) is required to set the DUT's battery to the proper state of charge during the standby loss test.

K.4 Procedure

K.4.1 Active deep discharge protection test

K.4.1.1 General

The DUT is set in a safe location with all its advertised appliances plugged in and switched on to run while recording its battery voltage and current over the duration of its discharge. The DUT is discharged until its battery voltage reaches the DUT's low-voltage disconnect (LVD) voltage or until the battery voltage falls well below its recommended deep discharge voltage threshold (e.g., the low-voltage disconnect device's set point).

K.4.1.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC voltmeter or multimeter
- Voltage data logger
- Current data logger (e.g. voltage data logger with a current transducer)
- Low-voltage disconnect device that will stop a DUT's discharge when the DUT's battery reaches a specified voltage (recommended)

The total series resistance added by the test apparatus and all measurement equipment shall be no more than 60 m Ω . This value includes the resistance of the wires and connectors, if any, added in the sample preparation procedure (F.4.4).

K.4.1.3 Test prerequisites

The DUT shall be either fully charged at the start of the test or charged enough to provide at least 20 min of service before reaching its deep discharge protection voltage or reaching sufficiently below the recommended deep discharge protection voltage threshold for the DUT's battery chemistry (see Table J.1 for recommended thresholds).

If the DUT's battery needs to be charged, charge the DUT's battery according to the procedures in the battery test annex (Annex I) or by using one of the two procedures according to the DUT's battery chemistry:

- If the DUT's battery is of NiMH then use the procedures in the battery test (Annex I).
- If the DUT's battery is of any other chemistry, then use the procedures in the active overcharge protection test (K.4.2). If the DUT's solar module has not yet been tested, then set up the apparatus according to Figure K.1 and set the current limit to the rated maximum power point current at STC, I_{mpp} .

K.4.1.4 Apparatus

The DUT shall be set in a secure location such that its parameters may be monitored and/or data-logged.

If necessary, a low-voltage disconnect device may be used that monitors the battery voltage and can cut the battery circuit if the voltage drops below a predetermined level.

K.4.1.5 Procedure

These steps shall be followed:

- a) If it is unclear if the DUT has deep discharge protection for its battery, the tester may prepare the low-voltage disconnect device so that it stops the DUT's discharge if the DUT's battery reaches the minimum battery testing voltage specified in Annex J.
- b) Set and secure the DUT in a safe location to prevent interference and plug in all the appliances that the DUT can power. Use appliances provided with the DUT when possible. If an appliance is not provided with the DUT (i.e., the DUT's packaging advertises that it can power a radio, but a radio is not provided with the DUT), then use the appropriate generic appliance(s), as defined in Annex CC, to simulate its power consumption. If any of the appliances used include a battery, fully discharge the appliances' batteries according to the full discharge preparation procedures in Annex M.
- c) Prepare the voltage data loggers to measure voltage across the DUT's battery terminals at intervals of 1 min or less. Prepare the current data loggers to measure the current exiting the DUT's battery at the negative battery terminal at intervals of 1 min or less. If it is unclear if the DUT has deep discharge protection for its battery, the tester may prepare the low-voltage disconnect device so that it stops the DUT's discharge if the DUT's battery reaches the minimum battery testing voltage specified in Annex J.

In case of pulse-width modulation (PWM) controllers, aliasing effects (beat effects) may occur due to un-synchronised PWM frequency and sampling frequency of the current logger. This may lead to "chaotic" measurements which are difficult to interpret. In this

case, the test may be conducted using a power meter with accuracy equivalent to that of the multimeters.

- d) Switch all appliances on in their highest settings (i.e., lights in their brightest setting, fan in its fastest speed, etc.) and start the measurements.
- e) The test shall be continued until all the appliances no longer function, the battery voltage falls below the value set on the optional low-voltage disconnect device, or the DUT continues to remain on for 24 h after the current drawn from the DUT's battery is 70% of the current draw measured 20 minutes after the start of the test. If the DUT's low-voltage disconnect device stops the DUT's discharge during the test, record that the battery voltage reached the minimum battery testing voltage and that no deep discharge voltage was observed.
- f) If the battery contains internal circuitry (refer to E.4.3.5) and the measured deep discharge protection voltage is outside of the targets specified by the manufacturer (C.3.1.2) or the DUT's battery voltage falls below the recommended deep discharge protection voltage specified in Annex J, the test may be repeated with the voltage data logger connected on the battery side of the internal circuitry, if the test laboratory determines that it is safe to do so.
- g) If the low-voltage disconnect device stops the DUT's discharge during the test, record that the battery voltage reached the minimum battery testing voltage and that no active deep discharge voltage was observed.

K.4.1.6 Calculations

Perform the following steps:

- a) Analyse the time-series current and voltage data to determine if the DUT has deep discharge protection incorporated into its charge controller and determine the deep discharge protection voltage. If the DUT has active deep discharge protection, one of two behaviours can be observed: (1) an abrupt drop will occur in the DUT's light output (or other appliance operation) and current will quickly decrease to 0 A, or (2) a relatively quick drop will occur in the DUT's light output (or other appliance operation) and current will ultimately decrease to 0 A. In either case, the minimum battery voltage recorded up to the time at which the DUT's battery current reaches zero is the deep discharge protection voltage.
- b) Report whether the deep discharge protection is internal to the battery. Typically, if the deep discharge protection circuit is external to the battery, the battery voltage will remain constant or increase after the deep discharge protection circuit disconnects the battery. If the deep discharge protection is internal to the battery pack, the voltage will drop to zero once the deep discharge protection voltage is reached. (In the latter case, ensure that the reported deep discharge protection voltage occurred before the internal protection circuit isolated the battery. If the battery voltage drops quickly, this can be difficult to determine.)
- c) Report if appropriate deep discharge protection was observed in the DUT.
- d) If the DUT has appropriate deep discharge protection, report the DUT's deep discharge protection voltage, in volts (V).

K.4.2 Active overcharge protection test

K.4.2.1 General

The DUT is charged until its battery voltage reaches the DUT's OVP voltage or the overcharge protection disconnect device's set point, or if the battery's temperature exceeds a safe value (refer to Table J.2).

K.4.2.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC power supply or solar array simulator
- DC voltmeter or multimeter
- DC ammeter or multimeter
- Voltage data logger (optional)

- Current data logger (e.g. voltage data logger with a current transducer) (optional)
- Series resistor or series and parallel resistors (or variable resistors) for simulating PV input (when using a DC power supply as opposed to a solar array simulator)
- Surface-mounted thermocouple(s) and a thermocouple reader (optional)
- Overcharge disconnect device that will stop a DUT's discharge when the DUT's battery reaches a specified voltage (if necessary)

The total series resistance added by the test apparatus and all measurement equipment shall be no more than 60 mΩ. This value includes the resistance of the wires and connectors, if any, added in the sample preparation procedure (F.4.4).

K.4.2.3 Test prerequisites

The DUT shall be either fully discharged at the start of the test or discharged enough to accept at least 20 min of charging before reaching its overcharge protection voltage or the overcharge disconnect device's cut-off, which may be selected based on information in Table J.2 if the overcharge voltage set point is not supplied by the manufacturer.

K.4.2.4 Apparatus

The DUT shall be set in a secure location such that its parameters may be monitored and/or data-logged. If the DUT has a solar-charging option, the DUT is charged via the PV module socket from a DC power supply with a series resistor in place (Figure K.1). An alternative is to charge the DUT via the PV module socket from a DC power supply with a series resistor and parallel resistor in place (Figure N.1), or using a solar array simulator.

^a Set current limiting with the maximum power point current at STC, I_{mpp} , from the photovoltaic module I-V characteristics test (Annex M).

Figure K.1 – Schematic of the DC power supply-DUT connection using a series protection resistor

K.4.2.5 Procedure

These steps shall be followed if the DUT has a solar charging option:

- a) If the setup includes the parallel resistor (Figure N.1), adjust the current limiting value of the DC power supply to the current setpoint at TMOT, $I_{sim,1000}$, calculated in the solar

charge test (Annex N). Also adjust the voltage of the DC power supply, V_{ps} , to the voltage setpoint, V_{sim} , calculated in the solar charge test (Annex N). Also set the series resistance, R_s , and the parallel resistance, R_p , to the values calculated in the solar charge test (Annex N). Skip steps b) through f) and proceed to step g).

- b) If the setup uses a solar array simulator, configure the solar array simulator as for the solar charge test (Annex N) to simulate the I-V curve at an irradiance of 1000 W/m². Skip steps c) through f) and proceed to step g)
- c) If the setup includes a series resistor only (Figure K.1), adjust the current limiting value of the DC power supply to the PV module's maximum power point current at TMOT, $I_{mpp, TMOT}$ (refer to the results of the photovoltaic module I-V characteristics test (Annex M)).
- d) Due to voltage drops from the PV module's blocking diode, cable losses, and the series resistor, set the power supply output voltage, V_{ps} , using the following formula:

$$V_{ps} = 1,25 \cdot V_{b,max}$$

where

V_{ps} is the DC power supply output voltage, in volts (V);

$V_{b,max}$ is the DUT's battery's maximum charge voltage, in volts (V), which may be obtained from the battery testing recommended practices annex (Annex J).

- e) Connect the PV module socket of the DUT to the DC power supply in series with a protection resistor. In cases where the DUT has an integrated PV module, connect the positive and negative wires from the DUT that were attached to the PV module to the DC power supply in series with a protection resistor. (This protection resistor is only needed in cases where a "shunt regulator" is built in; however, as a schematic of the DUT's electronics is usually not provided, this resistor should be used in all cases for safety reasons). The voltage drop in the series resistor should be between 10 % and 15 % of the voltage setting of the DC power supply (V_{ps}); therefore, size the resistor based on the following formula:

$$\frac{0,1 \cdot V_{ps}}{I_{mpp, TMOT}} \leq R_s \leq \frac{0,15 \cdot V_{ps}}{I_{mpp, TMOT}}$$

where

V_{ps} is the DC power supply output voltage, in volts (V);

$I_{mpp, TMOT}$ is the PV module's maximum power point current at TMOT, in amperes (A), obtained from the photovoltaic module I-V characteristics test (Annex M);

R_s is the resistance of the series resistor, in ohms (Ω).

- f) Ensure the series resistor's power dissipation rating is greater than or equal to the value given by the following formula:

$$P_{rs} = I_{mpp, TMOT}^2 \cdot R_s$$

where

P_{rs} is the series resistor's minimum required power dissipation, in watts (W);

$I_{mpp, TMOT}$ is the PV module's maximum power point current at TMOT, in amperes (A), obtained from the photovoltaic module I-V characteristics test (Annex M);

R_s is the resistance of the series resistor, in ohms (Ω).

- g) If it is unknown whether the DUT has an overcharge protection disconnect, integrate the overcharge protection disconnect device into the setup. The overcharge protection device shall disconnect if battery voltage rises above safety limits that are determined by the laboratory. In some cases, the DUT's charge controller will be designed with an OVP battery voltage that is greater than the overcharge protection device's cut-off; therefore,

the tester has the discretion to allow the battery voltage to proceed above the recommended OVP voltage threshold if deemed safe and necessary. **For Li-ion batteries, the battery voltage shall not exceed the maximum safe value specified by the battery supplier, or 4,26 V/cell if no supplier-provided information is available; otherwise there is a risk of explosion.** Optionally, monitor the DUT's battery temperature to ensure that it does not exceed a safe value (refer to Table J.2). If temperature monitoring is used, lithium-based batteries shall not be allowed to exceed 45 °C unless higher temperatures are allowed by the battery manufacturer.

- h) Charge the DUT while continuously monitoring the DUT's battery terminal voltage and current at the negative battery terminal. The battery voltage and current shall be collected at intervals less than or equal to 1 min.

In case of pulse-width modulation (PWM) controllers, aliasing effects (beat effects) may occur due to unsynchronised PWM frequency and sampling frequency of the current logger. This may lead to "chaotic" measurements which are difficult to interpret. In this case, the test may be conducted using a power meter with accuracy equivalent to that of the multimeters.

- i) If the DUT automatically stops accepting charge, the highest voltage measured during the test is the DUT's overcharge protection voltage. For some DUTs, the current will not stop completely, but will begin tapering off when the DUT's battery voltage reaches its overcharge protection voltage. Continue monitoring until the DUT's battery voltage is no longer rising.
- j) If the battery contains internal circuitry (refer to E.4.3.5) and the measured overcharge protection voltage is outside of the targets specified by the manufacturer (C.3.1.2) or the DUT's battery voltage exceeds the recommended overcharge protection voltage specified in Annex J, the test may be repeated with the voltage data logger connected on the battery side of the internal circuitry, if the test laboratory determines that it is safe to do so.
- k) If the battery terminal voltage reaches the overcharge protection cut-off device's voltage threshold, no active overcharge protection is incorporated into the DUT's charge controller.
- l) If in the case of a NiMH battery the battery voltage levels off or begins to decrease before reaching the recommended overcharge protection voltage, but the current does not go to zero, no active overcharge protection is detected.

These steps shall be followed if the DUT does not have a solar charging option:

- m) If it is unknown whether the DUT has an overcharge protection disconnect, integrate the overcharge protection disconnect device into the setup. The overcharge protection device shall disconnect if battery voltage rises above safety limits that are determined by the laboratory. In some cases, the DUT's charge controller will be designed with an OVP battery voltage that is greater than the overcharge protection device's cutoff; therefore, the tester has the discretion to allow the battery voltage to proceed above the recommended OVP voltage threshold if deemed safe and necessary. **For Li-ion batteries, the battery voltage shall not exceed the maximum safe value specified by the battery supplier, or 4,26 V/cell if no supplier-provided information is available; otherwise there is a risk of explosion.** Optionally, monitor the DUT's battery temperature to ensure that it does not exceed a safe value (refer to Table J.2). If temperature monitoring is used, lithium-based batteries shall not be allowed to exceed 45 °C unless higher temperatures are allowed by the battery manufacturer.
- n) If the product has a grid-charging option, plug the AC power adapter supplied with the DUT into an outlet with AC voltage that is suitable for the DUT's supplied AC power adapter.
- o) If the product does not have a grid-charging option, but has an electromechanical charging option, crank-charge the DUT continuously at approximately 120 rpm or use a power supply to source current that is equal to the charging current generated at 120 rpm.
- p) Charge the DUT while continuously monitoring the DUT's battery terminal voltage and current at the negative battery terminal. The battery voltage and current shall be collected at intervals less than or equal to 1 min.

- q) If the DUT automatically stops accepting charge, the DUT has active overcharge protection, and the highest voltage measured during the test is the DUT's overcharge protection voltage. For some DUTs, the current will not stop completely, but will begin tapering off when the DUT's battery voltage reaches its overcharge protection voltage.
- r) If the battery contains internal circuitry (refer to E.4.3.5) and the measured overcharge protection voltage is outside of the targets specified by the manufacturer (C.3.1.2) or the DUT's battery voltage exceeds the recommended overcharge protection voltage specified in Annex J, the test may be repeated with the voltage data logger connected on the battery side of the internal circuitry, if the test laboratory determines that it is safe to do so.
- s) If the battery terminal voltage sufficiently exceeds the predetermined overvoltage limit, no active overcharge protection is incorporated into the DUT's charge controller.

K.4.2.6 Calculations

There are no calculations for the active overcharge protection test.

K.4.3 Passive deep discharge protection test

K.4.3.1 General

The DUT is set in a safe location with all its advertised appliances plugged in and switched on to run while recording its battery voltage and current over the duration of its discharge. The DUT is discharged until 24 hours after the current drawn from the DUT's battery is 70% of the current draw measured 20 minutes after the start of the test, or until the battery voltage falls well below its recommended deep discharge voltage threshold (e.g., the low-voltage disconnect device's set point).

This method is only performed on DUTs that show no active deep discharge protection and no ports for powering appliances.

K.4.3.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC voltmeter or multimeter
- Voltage data logger (recommended)
- Ammeter or current data logger (e.g. voltage data logger with a current transducer) (optional)
- Low-voltage disconnect device that will stop a DUT's discharge when the DUT's battery reaches a specified voltage (recommended)

The total series resistance added by the test apparatus and all measurement equipment shall be no more than 60 m Ω . This value includes the resistance of the wires and connectors, if any, added in the sample preparation procedure (F.4.4).

K.4.3.3 Test prerequisites

The DUT shall have undergone the active deep discharge protection test. For DUTs with NiMH batteries, the battery voltage shall have just passed its recommended deep discharge protection voltage (Table J.1) when discharging. For DUTs with other battery chemistries, the battery shall be in the same state of charge as when the DUT reaches L_{70} (70 % of its initial light output during the full-battery run time test).

K.4.3.4 Apparatus

The DUT shall be placed in a secure location where it can discharge for 24 h.

If necessary, a low-voltage disconnect device may be used that monitors the battery voltage and can cut the battery circuit if the voltage drops below a predetermined level.

K.4.3.5 Procedure

These steps shall be followed:

- a) Specify the accepted 24 h passive deep discharge battery protection voltage. This voltage may be selected based on information from Table J.1, if it is not supplied with the DUT or battery manufacturer.
- b) If it is unclear if the DUT has deep discharge protection for its battery, the tester may prepare the low-voltage disconnect device so that it stops the DUT's discharge if the DUT's battery reaches the minimum battery testing voltage specified in Annex JJ.
- c) Set and secure the DUT in a safe location to prevent interference and plug in all the included appliances that the DUT can power. Turn on the DUT and discharge the battery for 24 h. The DUT service(s) shall be on in highest setting(s) (i.e., lights in their brightest setting, fan in its fastest speed). Continuously monitor the DUT's battery terminal voltage and optionally monitor the DUT's battery current at the negative battery terminal. The battery voltage and optional current shall be collected at intervals less than or equal to 1 min.

In case of pulse-width modulation (PWM) controllers, aliasing effects (beat effects) can occur due to unsynchronised PWM frequency and sampling frequency of the current logger. This can lead to "chaotic" measurements which are difficult to interpret. In this case, the test may be conducted using a power meter with accuracy equivalent to that of the multimeters.

- d) The minimum battery voltage observed over 24 h is the DUT's passive deep discharge battery protection voltage.
- e) If the battery contains internal circuitry (refer to E.4.3.5) and the measured deep discharge protection voltage is outside of the targets specified by the manufacturer (C.3.1.2) or the DUT's battery voltage falls below the recommended deep discharge protection voltage specified in Annex J, the test may be repeated with the voltage data logger connected on the battery side of the internal circuitry, if the test laboratory determines that it is safe to do so.
- f) If the low-voltage disconnect device stops the DUT's discharge during the test, record that the battery voltage reached the minimum battery testing voltage and that no passive deep discharge voltage was observed.

K.4.3.6 Calculations

There are no calculations for the passive deep discharge protection test.

K.4.4 Passive overcharge protection test

K.4.4.1 General

This method is only performed on DUTs with NiMH batteries that show no active overcharge protection.

In some cases, the DUT's PV module's short circuit current alone proves that the DUT has passive overcharge protection; otherwise, the DUT is overcharged and the charging current is observed to determine if the DUT has passive overcharge protection. If the product does not have a solar-charging option, the DUT shall be charged via its provided grid charger or charged via its electromechanical charging process. This method is only performed on DUTs with NiMH batteries that show no active overcharge protection.

K.4.4.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC power supply or solar array simulator
- DC ammeter or multimeter
- Voltage data logger (optional)
- Current data logger (e.g., voltage data logger with a current transducer) (optional)
- Series resistor or series and parallel resistors (or variable resistors) for simulating PV input (when using a DC power supply as opposed to a solar array simulator)

- Surface-mounted thermocouple(s) and a thermocouple reader with a precision less than 2 °C (optional)

The total series resistance added by the test apparatus and all measurement equipment shall be no more than 60 mΩ. This value includes the resistance of the wires and connectors, if any, added in the sample preparation procedure (F.4.4).

K.4.4.3 Test prerequisites

The DUT shall have undergone the active overcharge protection test, such that its battery voltage has just passed its recommended overcharge protection voltage (Table J.2) when charging or, if the battery voltage does not reach the recommended overcharge protection voltage, the battery has reached the maximum voltage observed during the active overcharge protection test (i.e., the battery voltage has levelled off or peaked and begun to decrease).

K.4.4.4 Apparatus

The DUT shall be set in a secure location such that its parameters can be monitored and/or data-logged. If the DUT has a solar-charging option, the DUT is charged via the PV module socket from a DC power supply using a series resistor or series and parallel resistor identical to those used in the active overcharge protection test (K.4.2.4).

K.4.4.5 Procedure

These steps shall be followed if the DUT has a solar charging option and the product's battery-charging circuit does not include a DC-DC converter (see N.4.4, step (n)):

- a) Determine the accepted passive overcharge protection continuous battery charging current. A passive overcharge protection continuous battery charging current of less than or equal to $0,2 I_t$ A is recommended for NiMH batteries.
- b) Compare the PV module's short-circuit current at STC (I_{sc}) to the passive overcharge protection continuous battery charging current (I_{sc} may be obtained from the photovoltaic module I-V characteristics test (Annex M)). If I_{sc} is the smaller of the two, the DUT has passive overcharge protection and no further testing is necessary.
- c) Convert the PV module's STC I-V pairs from the photovoltaic module I-V characteristics test (Annex H) to typical module operating temperature (TMOT), where TMOT is defined as 50 °C cell temperature and solar irradiance of 1000 W/m². Refer to H.4.3.4.4 of Annex H for conversion formulas.
- d) Plot the TMOT I-V curve.
- e) If the passive overcharge protection test follows the active overcharge protection test using a parallel resistor (Figure N.1), use the same current limiting and voltage values and resistor values that were used in the active overcharge protection test (K.4.2.5).
- f) If the passive overcharge protection test follows the active overcharge protection test using a solar array simulator, use the same solar array simulator configuration that was used in the active overcharge protection test (K.4.2.5).
- g) If the passive overcharge protection test follows the active overcharge protection test with a series resistor only (Figure K.1), set the current limiting and voltage values of the DC power supply to the PV module's maximum power point current at TMOT, $I_{mpp, TMOT}$ and $V_{oc, TMOT}$ (refer to the results of the photovoltaic module I-V characteristics test (Annex H)), respectively. Use the same series resistor value as was used in the active overcharge protection test (K.4.2.5).
- h) Connect the DC power supply via the resistor(s) and the product's entire PV cable to the DUT's PV module input socket. Let charge for 5 min. After the 5 min period is complete, determine the voltage drop, V_{drop} , between the power supply's output and the DUT's battery terminals. If the DUT is has an integrated PV module, connect the DC power supply to the ends of the internal leads where the PV module connects to the DUT's circuitry. Optionally, monitor the DUT's battery temperature to ensure that it does not exceed a safe value (refer to Table J.2). If temperature monitoring is used, lithium-based batteries shall not be allowed to exceed 45 °C unless higher temperatures are allowed by the battery manufacturer.

- i) Add V_{drop} to the battery end of the charge voltage, V_{charge} , which is determined by multiplying the number of battery cells by the recommended overcharge protection voltage for NiMH batteries (Table J.2). This is the total charge voltage, V_{max} .
- j) Plot a vertical line at V_{max} on the TMOT I-V curve (see part (d)) that extends from the voltage axis to the I-V curve.
- k) Plot a horizontal line that intersects the TMOT I-V curve at the same point V_{max} does and extends to the current axis. The current where the horizontal line intersects the current axis is the charging current.
- l) If the charging current is less than or equal to $0,2 I_t$ A, the DUT has passive overcharge protection.
- m) These steps shall be followed if the DUT does not have a solar charging option or if the DUT utilizes a DC-DC converter:
- n) Determine the DUT's accepted passive overcharge protection continuous battery charging current. A passive overcharge protection continuous battery charging current of less than or equal to $0,2 I_t$ A is recommended for DUTs with NiMH batteries.
- o) Compare the passive overcharge protection continuous battery-charging current to the average charging current observed over the final 5 minutes from when carrying out the active overcharge protection procedure (S.4.2). If the average charging current is the smaller of the two, the DUT has passive overcharge protection.

K.4.4.6 Calculations

There are no calculations for the passive overcharge protection test.

K.4.5 Standby loss measurement

K.4.5.1 General

This measurement quantifies the standby loss of a DUT when not in use. If the standby loss is substantial, it may affect the use of the DUT. The DUT shall be configured to best simulate how it would be left in the home while not in use.

K.4.5.2 Equipment requirements

An ammeter (data-logging functionality is optional) and a timer. Equipment shall meet the requirements in Table BB.2.

K.4.5.3 Test prerequisites

Set the DUT's battery to a 50% state of charge. If the DUT's battery needs to be charged, charge the DUT's battery according to the procedures in the battery test annex (Annex I) or by using one of the two procedures according to the DUT's battery chemistry:

- If the DUT's battery is of NiMH chemistry, then use the procedures in the battery test (Annex I).
- If the DUT's battery is of any other chemistry, then use the procedures in the active overcharge protection test (K.4.2). If the DUT's solar module has not yet been tested, then set up the apparatus according to Figure K.1 and set the current limit to the rated maximum power point current at STC, I_{mpp} .

After the battery is fully charged, turn the DUT on its brightest setting. Stop the discharge once the discharge duration equals 50% of the DUT's full-battery run time $\pm 25\%$ (between 25% and 75% of the DUT's full-battery run time).

K.4.5.4 Apparatus

The DUT shall be set in a secure location such that its battery's current draw can be recorded for 15 min.

K.4.5.5 Procedure

These steps shall be followed:

- a) Configure the DUT to simulate how it would be left in the home while not in use. Connect all the included appliances to the product that can be turned off with an on/off switch. For example, it is unlikely that a user unplugs a light point that has an on/off switch every time he or she wants to turn off the light; it is more likely that the user will turn off the light point via its switch. If the DUT does not have enough ports to connect all the included appliances that have on/off switches, connect the appliances that are estimated to maximize the standby loss. In addition, turn on/off system power switches on. For example, if the DUT's control box has a system on/off switch that connects the DUT's battery to the rest of the system, keep the switch in the on position. It is unlikely that a user will turn the system's power switch off when the system is not in use.
- b) For DUTs with a solar module, connect the DUT's solar module and prevent light from reaching the PV material (e.g. cover the solar module with an opaque dark cloth or turn the module upside down so that its PV material is facing downwards over an opaque surface).
- c) Break the DUT's circuit at the battery's negative terminal, connect the current meter in series, and ensure that all power buttons and switches on the DUT are turned off.
- d) Wait 5 min to allow the DUT to stabilize. Then, over a 10 minute period, record (or data-log) the current draw at the battery's negative terminal at intervals less than or equal to 1 min.
- e) Report the average battery current draw over the 10 min data-collection period.

K.4.5.6 Calculations

There are no calculations for the standby loss measurement.

K.5 Reporting

Report the following in the charge controller behaviour test report:

- Metadata
 - Report name
 - Procedure(s) used
 - DUT manufacturer
 - DUT name
 - DUT model number
 - Name of test laboratory
 - Approving person
 - Date of report approval
- Results for tested DUT aspects for samples 1 through n
 - Presence of active deep discharge protection (yes/no)
 - Active deep discharge protection voltage, if applicable (V)
 - Presence of active overcharge protection (yes/no)
 - Active overcharge protection voltage, if applicable (V)
 - Presence of passive deep discharge protection (yes/no)
 - Passive deep discharge protection voltage, if applicable (V)
 - Presence of passive overcharge protection (yes/no)
 - Passive overcharge protection continuous charging current (A)
 - Standby loss current (A)
- Average of n sample results for each DUT aspect tested
- Coefficient of variation of n sample results for each DUT aspect tested (%)
- DUT's rating for aspects tested, if available

- Deviation of the average result from the DUT's rating for each aspect tested, if available (%)
- Comments
 - Individual comments, as necessary, for samples 1 through n
 - Overall comments, as necessary, for collective set of samples 1 through n. In particular, include an assessment of the appropriateness of the charge control strategy given the information available.
- Figures
 - Plot of the PV module's new, realistic-temperature I-V curve with lines indicating the presence of passive overcharge protection, if applicable

Annex L (normative)

Full-battery run time test

L.1 Background

The full-battery run time captures one of the key system-performance metrics from a user's perspective. It combines the relationship between battery capacity, circuit efficiency, and appliance power consumption under realistic operating conditions.

A solar home system may power several appliances, some of which may have variable power settings. Full battery run time depends on which appliances are running and at what power settings. The full-battery run time test described here involves completing one full-battery run time configuration. Calculations to estimate additional full-battery run time configurations may be performed according to the energy service calculations (Annex R).

The full-battery run time configuration involves operating all of the DUT's lighting appliances, and only the lighting appliances, in their brightest setting, with a fully charged battery, until the light output has decreased to some pre-defined minimum value (70 % in this case).

$$\Phi_{v,rel} = \Phi_v(t) / \Phi_v(t_i)$$

where

$\Phi_{v,rel}$ is the DUT's relative luminous flux, expressed in lumens (lm);

$\Phi_v(t)$ is the DUT's luminous flux, expressed in lumens (lm), corresponding to 70 % of the DUT's initial luminous flux;

$\Phi_v(t_i)$ is the DUT's initial luminous flux, expressed in lumens (lm).

The full-battery run time for this configuration is defined as when $\Phi_{v,rel}$ reaches 70 % of the initial luminous flux $\Phi_v(t_i)$.³⁾ To ensure that the DUT is measured in its thermal balance and with stabilized battery voltage (after initial voltage drop), the initial luminous flux is measured 20 min into the DUT's discharge.

For DUTs that include additional appliances with internal batteries, such as fans, TVs, mobile phones, and radios, a second full-battery run time test may need to be carried out according to the appliance full-battery run time procedures (Q.8).

L.2 Test outcomes

The test outcomes of the full-battery run time test are listed in Table L.1.

³⁾ This limit was chosen since a decrease of more than 30 % is clearly visible for human eyes according to the Alliance for Solid-State Illumination Systems and Technologies (ASSIST).

Table L.1 – Full-battery run time test outcomes

Metric	Reporting units	Related aspects	Remarks
Lighting full-battery run time, to L_{70}	Hours (h)	4.2.9.5 Lighting full-battery run time	Run time to 70 % of initial light output with only the lighting appliance(s) on in their brightest setting
Average power over the L_{70} run time	Watts (W)	n/a	Average power draw over the run time while light output is over 70 % of initial light output with only the lighting appliance(s) on in their brightest setting
Energy removed from the battery over the L_{70} run time	Watt-hours (Wh)	n/a	Total energy removed over the run time while light output is over 70 % of initial light output with only lighting appliances on in their brightest setting
Active deep discharge protection	Yes/no	4.2.3.13 Battery protection strategy	
Deep discharge protection voltage	Volts (V)	4.2.3.13 Battery protection strategy	

L.3 Related tests

Annex L is related to the charge controller behaviour test (Annex K), and the daily energy service calculations (Annex R).

L.4 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Integrating sphere, or other approved measurement cavity
- Data-logging illuminance meter
- Battery analyser
- Voltage data logger
- Current data logger (e.g. voltage data logger and current transducer)
- Low-voltage disconnect device that will stop a DUT's discharge when the DUT's battery reaches a specified voltage (recommended)

The total series resistance added by the test apparatus and all measurement equipment shall be no more than 60 mΩ. This value includes the resistance of the wires and connectors, if any, added in the sample preparation procedure (F.4.4).

L.5 Test prerequisites

Cycle the DUT's battery according to the procedures in the battery test annex (Annex I) and the information in the battery testing recommended practices annex (Annex J).

L.6 Apparatus

The full-battery run time test requires an accurate measurement of relative light output over time. In practice, this means using an integrating sphere or a fixed-geometry measurement cavity to measure the illuminance level⁴⁾ under constant conditions. Three approved

4) A measurement of illuminance in a fixed geometry (such as a dark room or isolated box) is always directly proportional in a linear fashion to the luminous flux of a lamp. Therefore, fixed-geometry measurements of illuminance may be used in place of luminous flux measurements for this test, which relies on relative light output to indicate the end of a discharge cycle.

measurement cavities are listed below in order of preference.⁵⁾ The lighting measurement is taken indirectly (reflected) in the first two types, while it is taken directly in the last type.

- Integrating sphere
- A self-built photometer box with a baffled measurement of illuminance on a port (i.e., an “integrating cube” as shown in Figure L.1).
- A darkened room or cabinet with direct illuminance measurement under fixed geometry.

Figure L.1 – Interior view of photometer box with suspended light

L.7 Procedure

Before measurement, fully charge the battery using one of the two procedures according to the DUT's battery chemistry:

- If the DUT's battery is of NiMH chemistry, then use the procedures in the battery test (Annex I).
- If the DUT's battery is of any other chemistry, then use the procedures in the active overcharge protection test (K.4.2). If the DUT's solar module has not yet been tested, then set up the apparatus according to Figure K.1 and set the current limit to the rated maximum power point current at STC, I_{mpp} .

The run time test may be started between 1 h and 24 h after the DUT has finished receiving its full charge. Use the following procedure:

- a) Set and secure the DUT inside the test cavity such that it is stable and cannot be jostled. When using an integrating sphere or photometer box measurement cavity, position the DUT so that only reflected light reaches the detector. This can be accomplished by pointing the light point(s) away from the detector or by using baffles to shield the detector from direct light. Position the direction of light directly towards the illuminance meter for a darkened room/cabinet or tube measurement cavity. In either case, it is extremely important that the DUT and apparatus do not move during the test.
- b) Prepare the voltage data logger to measure voltage across the DUT's battery terminals at intervals of 1 min or less. Prepare the current data logger to measure the current exiting the DUT's battery at the negative battery terminal at intervals of 1 min or less. If it is unclear if the DUT has deep discharge protection for its battery, the tester may prepare the low-voltage disconnect device so that it stops the DUT's discharge if the DUT's battery reaches the minimum battery testing voltage specified in Annex J.

⁵⁾ Any of these cavities can result in identical estimates for full-battery run time. The preference order is related to the degree of operator care required to maintain a fixed geometry in each, with a preference for cavities whose relative measurement is less sensitive to small changes in the system (e.g., from accidentally bumping into the cavity during a test).

- c) Some DUTs that use coulomb counting or similar methods for estimating state of charge will not correctly detect the battery state of charge when a discharge is started immediately after the battery is disconnected. This may result in the DUT turning off or reducing brightness prematurely during the full-battery run time test. When testing such DUTs, appropriate steps shall be taken, prior to starting the discharge, to reset the DUT's battery gauge. For example, in some products, charging the product for a few minutes via the PV input using a solar array simulator or power supply configured as described in K.4.2.5 will reset the battery gauge. The test laboratory should consult with the manufacturer of the DUT to determine an appropriate reset procedure. After the reset procedure, the battery shall not be disconnected from the DUT prior to starting the discharge in step c).

In case of pulse-width modulation (PWM) controllers, aliasing effects (beat effects) may occur due to un-synchronised PWM frequency and sampling frequency of the current logger. This may lead to “chaotic” measurements which are difficult to interpret. In this case, the test may be conducted using a power meter with accuracy equivalent to that of the multimeters.

- d) The lighting appliances are switched on at the correct brightness setting and the measurement is started. Light output (luminous flux for the integrating sphere; illuminance for other measurement devices) should be recorded every minute, at a minimum.
- e) The initial light output is measured after 20 min (t_i). This defines the point at which relative light output (RLO) is 100 %. In the case where the DUT's light output cascades in steps while it discharges and the DUT's light output steps down to a dimmer setting prior to having been on for 20 minutes, t_i is the latest time before the DUT steps down from the initial setting.
- f) If it is necessary to measure the deep discharge protection voltage, continue the test until the a low-voltage disconnect is observed with the DUT, or 24 hours after the RLO is 70 % of the initial value at t_i (i.e., the light output is 70 % of the value at t_i). Otherwise, continue the test until an RLO reaches 10 %.
- g) If the battery contains internal circuitry (refer to E.4.3.5) and the measured deep discharge protection voltage is outside of the targets specified by the manufacturer (C.3.1.2) or the DUT's battery falls below the recommended deep discharge protection voltage specified in Annex J, the test may be repeated with the voltage data logger connected on the battery side of the internal circuitry, if the test laboratory determines that it is safe to disassemble the battery.

L.8 Calculations

Analyse the time-series light output data to estimate the L_{70} run time, the average relative light output, and the operating characteristics (voltage and current) that correspond to the average relative light output. Analyse the time-series current and voltage data to estimate the average power over the L_{70} run time and the total energy removed from the battery over the L_{70} run time.

- a) The end of the L_{70} discharge period is reached when the RLO is 70 % of the initial value at t_i (i.e., the light output is 70 %). The result shall be noted, expressed in hours (h).
- b) If an integrating sphere was utilized, use the luminous flux averaged over the L_{70} run time.
- c) The recorded data should be presented in a graph such as the one shown in Figure L.2 for each brightness level (Figure L.2 shows only the result of one brightness level). The graph should include the full discharge, beginning at 0 min, and may include RLO values greater than 100 %. If more than one brightness level was tested, prepare a separate graph for each test.

Key

t Time (min)

φ Relative light output (%), which is directly proportional to the luminous flux output

- 1 20 min from point DUT is turned on
- 2 t_i , time when RLO is defined as 100 %
- 3 L_{70} reached (RLO is 70 %)
- 4 t_{70} , time when RLO is 70 %

Figure L.2 – Plot of example results from the full-battery run time test

d) Determine the average power over the L_{70} run time ($P_{b,i}$) using the following formula:

$$P_{b,i} = \frac{\sum(I_{b,i} \cdot V_{b,i})}{n}$$

where

$P_{b,i}$ is the average power exiting the battery over the L_{70} run time, in watts (W);

$I_{b,i}$ is the current exiting the battery over the L_{70} run time, in amperes (A);

$V_{b,i}$ is the voltage exiting the battery over the L_{70} run time, in volts (V);

n is the total number of current and voltage measurements over the L_{70} run time (unit less)

e) Determine the energy removed from the battery over the L_{70} run time ($E_{b,i}$) using the following formula:

$$E_{b,i} = \sum(I_{b,i} \cdot V_{b,i} \cdot t_i)$$

where

$E_{b,i}$ is the energy exiting the battery over the L_{70} run time, in watt-hours (Wh);

$I_{b,i}$ is the current exiting the battery over the L_{70} run time, in amperes (A);

$V_{b,i}$ is the voltage exiting the battery over the L_{70} run time, in volts (V);

t_i is the duration of time associated with each current and voltage point over the L_{70} run time, in hours (h)

- f) Determine if the DUT has deep discharge protection incorporated into its charge controller and determine the deep discharge protection voltage. If the DUT has active deep discharge protection, one of two behaviours can be observed: (1) an abrupt drop will occur in the DUT's light output and current will quickly decrease to 0 A; or (2) a relatively quick drop will occur in the DUT's light output and current will ultimately decrease to 0 A. In either case, the minimum battery voltage recorded up to the time at which the DUT's battery current reaches zero is the deep discharge protection voltage.
- g) Report whether the deep discharge protection is internal to the battery. Typically, if the deep discharge protection circuit is external to the battery, the battery voltage will remain constant or increase after the deep discharge protection circuit disconnects the battery. If the deep discharge protection is internal to the battery pack, the voltage will drop to zero once the deep discharge protection voltage is reached. (In the latter case, ensure that the reported deep discharge protection voltage occurred before the internal protection circuit isolated the battery. If the battery voltage drops quickly, this can be difficult to determine.)
- h) Report if appropriate deep discharge protection was observed in the DUT.
- i) If the DUT has appropriate deep discharge protection, report the DUT's deep discharge protection voltage, in volts (V).

L.9 Reporting

Report the following in the full-battery run time test report:

- Metadata
 - Report name
 - Procedure(s) used
 - DUT manufacturer
 - DUT name
 - DUT model number
 - DUT setting
 - Name of test laboratory
 - Approving person
 - Date of report approval
 - Results for tested DUT aspects for samples 1 through n
 - Lighting full-battery run time to L_{70} (h)
 - Average power over the lighting full-battery run time to L_{70} (W)
 - Energy removed from the battery over the lighting full-battery run time to L_{70} (Wh)
 - Presence of appropriate deep discharge protection, if applicable (yes/no)
 - Appropriate deep discharge protection voltage, if applicable (V)
 - Average of n sample results for each DUT aspect tested
 - Coefficient of variation of n sample results for each DUT aspect tested (%)
 - DUT's rating for aspects tested, if available
 - Deviation of the average result from the DUT's rating for each aspect tested, if available (%)
 - Comments
 - Individual comments, as necessary, for samples 1 through n
 - Overall comments, as necessary, for collective set of samples 1 through n
 - Figures
 - Plot showing the luminous flux (lm) against the run time (min), as in Figure L.2

Annex M (informative)

Full discharge preparation

M.1 Background

Prior to starting the solar charge test (Annex N), a DUT shall be fully discharged. When performing the full-battery run time with deep discharge protection measurement procedures (Annex L), a DUT is considered fully discharged when it reaches its L_{70} . The initial light output is the light output reading taken at minute 20 of the DUT's full-battery run time.

The solar charge test (Annex N) uses a specified charge cycle and the DUT's initial state of charge will influence the DUT's performance during the charge. It is important that the DUT be set to a prescribed state of charge to simulate a full discharge prior to commencing the solar charge test so the results are repeatable and comparable across products.

M.2 Test outcomes

There are no full discharge preparation procedures outcomes.

M.3 Related tests

The full discharge preparation procedures shall be performed on all DUTs prior to conducting the solar charge test (Annex N).

M.4 Procedure

M.4.1 General

Each DUT is fully discharged prior to starting the solar charge test.

M.4.2 Equipment requirements

One of the following three pieces of equipment is required for the full discharge preparation. Equipment shall meet the requirements in Table BB.2.

- Battery analyser
- Programmable electronic load, with timer function, meeting the accuracy requirement for battery analysers in Table BB.2.
- Timer disconnect device consisting of a digital timer and a relay that can break the connection between the DUT's circuit and its battery (e.g., an AC digital timer combined with an AC-actuated mechanical relay).

M.4.3 Test prerequisites

Before measurement, fully charge the battery using one of the following two procedures according to the DUT's battery chemistry:

- If the DUT's battery is of NiMH chemistry, then use the procedures in the battery test (Annex I).
- If the DUT's battery is of any other chemistry, then use the procedures in the active overcharge protection test (K.4.2). If the DUT's solar module has not yet been tested, then set up the apparatus according to Figure K.1 and set the current limit to the rated maximum power point current at STC, I_{mpp} .

Any following steps may be started between 1 h and 24 h after the DUT has finished receiving its full charge.

M.4.4 Procedure

M.4.4.1 General

Products generally have one of five types of discharge curves:

- 1) A constant light output with a sharp turn-off when the product reaches its low-voltage disconnect (LVD) such that the light output does not drop below L_{70} prior to turning off
- 2) A relatively constant light output that begins to decrease in light output just prior to experiencing a sharp turn-off when the product reaches its LVD such that the light output does drop below the L_{70} prior to turning off
- 3) A cascade of constant light outputs such that the product steps down in its light setting during its discharge, often reaching an LVD after providing some light in its lowest setting
- 4) A gradually decreasing light output as the product discharges, reaching an LVD after reaching L_{70}
- 5) A gradually decreasing light output as the product discharges with no LVD

If the product discharges as type 1), proceed with the procedure using the product's low-voltage disconnect (M.4.4.2). If the product discharges as type 2), 3), 4), or 5), proceed with M.4.4.3 if using a battery analyser or electronic load, or M.4.4.4 if using a timer disconnect device..

For products that use coulomb counting or similar methods for estimating state of charge, for which special preparation was required during the full-battery run time test in L.7 c), ensure that the same preparation is carried out prior to starting the discharge, if the battery has been disconnected from the DUT at any time after the product was fully charged according to M.4.3 or if otherwise required by the product's design.

M.4.4.2 Procedure using the product's low-voltage disconnect

These steps shall be followed:

- a) Set the DUT in a secure location.
- b) Turn the DUT's lighting on in the setting that it will be tested in for the selected run time test.
- c) Allow the DUT to discharge uninterrupted until its LVD automatically turns it off.
- d) After the DUT finishes discharging, wait at least 1 h but no longer than 24 h prior to commencing the selected run time test.

M.4.4.3 Procedure using a battery analyser or electronic load

These steps shall be followed:

- a) Calculate the average discharge current measured from the DUT's battery during its full-battery run time test (Annex L) until it reached L_{70} in the particular setting that it will be tested in for the selected run time test.
- b) Use the battery analyser or electronic load to discharge the DUT at the average discharge current calculated in step a) for a duration equal to the full-battery run time to L_{70} , measured in Annex L, for the particular setting in which it will be tested for the selected run time test.
- c) After the DUT finishes, wait at least 1 h but no longer than 24 h prior to commencing the selected run time test.

M.4.4.4 Procedure using a timer disconnect device

These steps shall be followed:

- a) Program the timer for a duration equal to the full-battery run time to L_{70} , measured in Annex L, for the particular setting in which the DUT will be tested for the selected run time test.

- b) Connect the DUT to the timer device such that the timer device relay will disconnect the DUT circuit from the battery upon reaching the programmed discharge time. Turn the DUT on in the setting to be tested for the selected run time test.
- c) After the DUT finishes discharging, wait at least 1 h but no longer than 24 h prior to commencing the selected run time test.

M.4.5 Calculations

No calculations are required with the full discharge preparation procedures.

M.5 Reporting

No reporting is required with the full discharge preparation procedures.

Annex N (normative)

Solar Charge Test

N.1 Background

The solar charge test provides estimates for two key sources of energy loss during solar charging: suboptimal operation of the solar module (“solar operation efficiency”) and losses from the DUT’s internal electronic circuits that charge the battery(-ies) (“battery-charging circuit efficiency”). Along with the battery round-trip energy efficiency (Annex I), these values are used in the daily energy service calculations (Annex R).

A power supply along with two resistors is used to simulate a solar module and charge a DUT’s battery(-ies). The voltage operating point during the test combined with the solar I-V curve is used to calculate the solar operating efficiency. Measurements of energy input to the DUT solar charging port and DUT battery(-ies) are used to estimate the battery-charging circuit efficiency.

If the DUT is a kit that has multiple independent units (each with their own battery pack) that can be charged simultaneously by a single solar module, the test should be done with all the independent units connected at once. This will require additional measurements of battery current and voltage for each battery. The independent units may be lighting units or non-lighting units.

N.2 Test outcomes

The test outcomes of the solar charge test are listed in Table N.1.

Table N.1 – Solar charge test outcome

Metric	Reporting units	Related aspects	Note
Solar operation efficiency (η_{sol-op})	Percentage	4.2.7 Solar module aspects	This is representative of the efficiency with respect to optimal operation of the PV module (where optimal operation is at the maximum power point).
Battery-charging circuit efficiency (η_{bcc})	Percentage	4.2.6	This is a lump figure for the whole lighting kit and is not disaggregated by lighting unit.
The maximum amount of energy available at the PV socket over the solar charge ($E_{max,sim}$)	Watt-hours (Wh)	n/a	
Average charging voltage	Volts (V)	n/a	This value is used in the assessment of DC ports (Annex P) when a typical charging voltage is needed.
Solar charging system characteristics	n/a	n/a	This describes key features of the solar charging circuit

N.3 Related tests

The solar charge test is related to the battery test (Annex I), the photovoltaic module I-V characteristics test (Annex M), full-battery run time test (Annex L) and the energy service calculations (Annex R).

N.4 Procedure

N.4.1 General

In this test, the DUT is charged using an apparatus to simulate the PV module during a typical day of solar charging. The PV simulation may be performed using a resistor network and programmable laboratory power supply or a solar array simulator meeting the requirements of Table BB.2. The voltage and current at the DUT's PV input and battery(-ies) are recorded at one-minute or shorter intervals.

N.4.2 Test method using a resistor network

N.4.2.1 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Programmable power supply with constant-voltage and constant-current modes and ability to automatically step through a timed program
- Voltage data loggers (one for the DUT's PV input and one for each of the DUT's batteries)
- Current data loggers (e.g. voltage data logger and current transducer) (one for the DUT's PV input and one for each of the DUT's batteries)

NOTE Most DUTs have only one battery.

- Series and parallel resistors (or variable resistors) for simulating PV input
- Variable resistor for measuring the I-V curve from the PV simulator (optional)
- Resistance meter or multimeter
- Surface-mounted thermocouple(s) and a thermocouple reader or other suitable surface-mounted temperature measurement devices (optional)
- Overcharge disconnect device that will stop a DUT's discharge when the DUT's battery reaches a specified voltage (if necessary)

The series resistance added by the test apparatus and all measurement equipment between the PV-simulating apparatus and the DUT's PV input, and the series resistance added between the DUT and the battery, shall each be no more than 90 mΩ. This value includes the resistance of the wires and connectors, if any, added in the sample preparation procedure (F.4.4).

N.4.2.2 Test prerequisites

The DUT's battery should be at a state of charge that corresponds to the "end of discharge," which may be accomplished using procedures in Annex M. Additionally, this test shall be performed after completion of the PV module I-V characteristics measurements (Annex H), since the I-V curve information from the PV module during that test are needed to set up the inputs to the power supply for the electronics efficiency test. The results from the battery test (Annex I) and full-battery run time test (Annex L) are required for the calculations.

Special charging features that do not operate during a normal charge cycle, such as equalization or boost charging, shall not be enabled during this test, unless it is not possible to disable these features. Lights and appliances not containing batteries shall be disconnected and any built-in appliances shall be turned off.

In some cases an SHS kit can contain multiple components with batteries that can charge from the PV module. In this case, the test is conducted with all batteries connected except those batteries that can be charged from another battery in the system (i.e., batteries that can be charged at night). For example, if a system contains two battery units that connect to a single PV module via a splitter cable, both battery units would be connected for this test. However, a radio, torch, or portable lamp that contains a battery and charges via a USB port would not be connected.

N.4.2.3 Apparatus

The apparatus for the solar charge test is shown schematically in Figure N.1.

Key

- 1 PV simulation circuit
- 2 Laboratory power supply
- 3 Series and parallel resistors (or variable resistors)
- 4 PV simulation circuit output (measure current and voltage here during simulated solar charging)
- 5 Connection cable from PV simulation circuit to lighting unit
- 6 Lighting product battery (measure current and voltage here during simulated solar charging)
- 7 [optional] Additional lighting units with separate batteries that are included in the kit
- 8 [optional] Additional lighting unit battery(-ies) (measure current and voltage here during simulated solar charging)

Figure N.1 – Schematic of the power supply and DUT connection for the solar charge test

N.4.2.4 Procedure

Preparation for the test:

- a) Use the TMOT I-V curve (from Annex H) to find appropriate resistor values and power supply set points to simulate the PV module operating at TMOT during the charging cycle. A computer spreadsheet or program should be used for this step.
 - The spreadsheet or program is used to estimate the response curve of the PV simulator circuit over the range of voltages that corresponds to the I-V curve.
 - The input variables to the spreadsheet shall be the following:
 - Series resistance
 - Parallel resistance
 - Voltage setpoint
 - Current setpoints corresponding to each level of simulated solar radiation (SSR) listed in Table N.2
 - The circuit simulation shall be based on Ohm's law.
 - The spreadsheet or program shall estimate the TMOT current at evenly spaced voltage points by linearly interpolating between points on the measured I-V curve.
 - The spreadsheet or program shall scale the interpolated I-V curve for each level of simulated solar radiation listed in Table N.2 by multiplying the interpolated current values by the ratio of the desired solar radiation level to 1 000 W/m²:

$$I_{pv}(V) = I_{interp}(V) \cdot \frac{G}{1\,000\text{ W/m}^2}$$

where

$I_{pv}(V)$ is the scaled, interpolated current at each solar radiation level i and voltage V , in amperes (A);

$I_{interp}(V)$ is the interpolated current at TMOT and $1\,000\text{ W/m}^2$ at voltage V , in amperes (A);

G is the simulated solar radiation, in watts per square metre (W/m^2).

- The spreadsheet or program shall use a non-linear minimization technique to minimize the weighted sum of the squared residuals between the scaled, interpolated TMOT I-V curve values and the simulated I-V curve of the PV simulator by altering the input variables. To give preference for close agreement near the maximum power point, the SSR at each point shall be weighted by the product of the duration of each solar radiation step (from Table N.2) and the power in the scaled TMOT curve:

$$\text{weighted SSR} = \sum_G \left(\Delta t_G \cdot \sum_V I_{pv,G}(V) \cdot V \cdot (I_{fit,G}(V) - I_{pv,G}(V))^2 \right)$$

where

G is the simulated solar radiation, in watts per square metre (W/m^2);

Δt_G is the duration corresponding to each solar radiation level i , in hours (h);

V is the voltage at each point in the interpolated I-V curve, in volts (V);

$I_{pv,G}(V)$ is the scaled, interpolated current at solar radiation level G and voltage V , in amperes (A);

$I_{fit,G}(V)$ is the fitted simulated current at solar radiation level G and voltage V , in amperes (A);

- The outcomes of the spreadsheet or program are the best fit input variables:
 - Series resistance (R_s)
 - Parallel resistance (R_p)
 - Voltage setpoint (V_{sim})
 - Current setpoints ($I_{sim,1000}$, $I_{sim,900}$, $I_{sim,700}$, $I_{sim,500}$, $I_{sim,300}$)
- b) Build a PV simulator circuit as in Figure N.1 using fixed or variable resistors with appropriate power ratings wired in parallel and series with the power supply. Use a resistance meter or multimeter to verify that the actual resistance values meet the accuracy requirement in Table BB.2.
- c) For each simulated solar radiation level, check that the simulated I-V curve is a reasonable approximation of the true curve by calculating the deviation ratio between the simulated and scaled, interpolated TMOT I-V curves. The deviation ratio is defined as the simulated current divided by the scaled, interpolated TMOT current at each voltage point. For this calculation, use the true values of the input variables rounded to the precision of the test equipment. In the example below (Figure N.2), the deviation ratio is close to unity (between 0,95 and 1,05, or less than 5 % error) in the key parts of the I-V curve (at and to the left of the maximum power point).

Key

I is current with units of amperes on the primary vertical axis

V is voltage with units of volts on the horizontal axis

D is the deviation ratio (unitless) on the secondary vertical axis

1 is the measured “true” I-V curve, plotted on the primary axis

2 is the I-V curve from the PV simulator ($I_{\text{fit},G}(V)$), plotted on the primary axis

3 is the deviation ratio as a function of voltage, plotted on the secondary axis

Figure N.2 – Example “true” and simulated I-V curves plotted with the deviation ratio

- d) (optional step) Experimentally verify the calculated deviation for the 1 000 W/m² I-V curve, using the following procedure. Alternatively, the I-V curve analyser specified in Annex H may be used to trace the I-V curve of the simulated solar module.
- 1) Connect data-logging current and voltage sensors to the PV simulator output. Set the sensors to log data at very short intervals, 1 s or less.
 - 2) Simulate a PV module at TMOT and 1 000 W/m². Set the power supply current and voltage setpoints to $I_{\text{sim},1000}$ and V_{sim} .
 - 3) Measure an I-V curve for the PV simulator. Connect a variable resistor between the positive and negative terminals of the PV simulator and slowly sweep from high to low resistance and back.
 - 4) Disconnect the resistor and stop the data collection.
 - 5) Check to ensure the quality of the I-V curve data; cross check with the original (target) I-V curve to ensure the PV simulator is reasonably close, particularly in the region with voltages slightly below the maximum power point. Figure N.2 shows an example comparison. The true I-V curve (line 1) is compared to the simulated I-V curve (line 2).
- e) Set up the prepared DUT (see requirements in N.4.2.2) and PV simulator circuit with current and voltage sensors, ensuring the PV simulator circuit is connected such that it replaces only the part of the PV module assembly included in the I-V curve (i.e., the PV simulator circuit is connected at the same point the I-V curve data were measured). Set the data-logging interval to 1 minute or less. Record the following quantities:

- Current entering the DUT’s battery(-ies), in amperes (A).
- Voltage across the DUT’s battery(-ies), in volts (V).
- Current provided by the PV simulator circuit, in amperes (A).
- Voltage across the PV simulator circuit output, in volts (V).

If the DUT is a kit that has multiple independent units (each with their own battery pack) that can be charged simultaneously by a single solar module, the current and voltage shall be measured for each independent unit’s battery(-ies) during the test.

- f) Program the power supply to simulate a “standard solar day” of charging using the steps indicated below (Table N.2). To facilitate identification of solar radiation levels during data analysis, short pauses at 0 volts may be inserted between steps.

Table N.2 – Simulated solar day power supply settings

Step duration	Simulated solar radiation	Current setpoint	Voltage setpoint
0,5 h	300 W/m ²	$I_{sim,300}$	V_{sim}
0,5 h	500 W/m ²	$I_{sim,500}$	V_{sim}
1 h	700 W/m ²	$I_{sim,700}$	V_{sim}
1 h	900 W/m ²	$I_{sim,900}$	V_{sim}
1 h	1000 W/m ²	$I_{sim,1000}$	V_{sim}
1 h	900 W/m ²	$I_{sim,900}$	V_{sim}
1 h	700 W/m ²	$I_{sim,700}$	V_{sim}
0,5 h	500 W/m ²	$I_{sim,500}$	V_{sim}
0,5 h	300 W/m ²	$I_{sim,300}$	V_{sim}

- g) The DUT’s battery voltage shall be continuously monitored such that the battery voltage shall not exceed a safety limit, either relying on the internal charge controller or based on the judgement of the laboratory. If necessary, integrate the overcharge protection disconnect device into the setup. The overcharge protection device shall disconnect if battery voltage rises above safety limits that are determined by the laboratory. Refer to the battery recommended testing practices (Annex J) for recommended maximum battery testing voltage values (refer to Table J.2). Optionally, monitor the DUT’s battery temperature to ensure that it does not exceed Table J.2. If temperature monitoring is used, lithium-based batteries shall not be allowed to exceed 45 °C unless higher temperatures are allowed by the battery manufacturer. If the charge cycle is stopped by an overcharge or overtemperature protection device added by the test laboratory, the test results shall be considered invalid.
- h) Check the connections and setpoints, then begin data logging and start the simulated charging cycle. Caution: Do not disconnect the product after having started the simulated charging cycle. The electronics of some DUTs may be damaged if their batteries are disconnected while voltage is applied to the PV input.
- i) After the 7 h charging cycle is complete, stop the power supply, stop the data logging, disconnect the product from the PV simulator, and verify that the current and voltage data are valid with a quick check.

N.4.3 Test method using a solar array simulator (SAS)

N.4.3.1 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Solar array simulator meeting the accuracy requirement specified in Table BB.2, including footnote a.
- Voltage data loggers (one for the DUT’s PV input and one for each of the DUT’s batteries)

- Current data loggers (e.g. voltage data logger and current transducer) (one for the DUT's PV input and one for each battery)

NOTE Most DUTs have only one battery.

- Surface-mounted thermocouple(s) and a thermocouple reader or other suitable surface-mounted temperature measurement devices (optional)
- Overcharge disconnect device that will stop a DUT's discharge when the DUT's battery reaches a specified voltage (if necessary)

If the solar array simulator includes data-logging functionality, this functionality may be used instead of the voltage and current data loggers at the PV input, provided the accuracy and resolution requirements for data loggers (Table BB.2) are met.

N.4.3.2 Test prerequisites

The test prerequisites are identical to those for the test method using a resistor network (N.4.2.2).

N.4.3.3 Apparatus

The apparatus is identical to that for the test method using a resistor network (N.4.2.3), except the PV simulator circuit (item 1 in Figure N.1) is replaced with a solar array simulator.

N.4.3.4 Procedure

These steps shall be followed:

- a) Configure the solar array simulator to simulate the DUT's I-V curve at TMOT.
- b) If the solar array simulator does not meet the accuracy requirement described in Table BB.2 according to the manufacturer's specifications, measure the simulator's I-V curve and verify that the simulated current is within the tolerance specified in Table BB.2 for all applicable voltage values. If the measured current is not within the specified tolerance, the solar array simulator shall not be used for this DUT. If the solar array simulator meets the accuracy requirement described in Table BB.2 according to the manufacturer's specifications, this step is optional.
- c) Set up the prepared DUT (see requirements in N.4.3.2) and PV simulator circuit with current and voltage sensors, ensuring the PV simulator circuit is connected such that it replaces only the part of the PV module assembly included in the I-V curve (i.e., the PV simulator circuit is connected at the same point the I-V curve data were measured). Set the data-logging interval to 1 minute or less. Record the following quantities:
 - Current entering the DUT's battery(s), in amperes (A).
 - Voltage across the DUT's battery(s), in volts (V).
 - Current provided by the PV simulator circuit, in amperes (A).
 - Voltage across the PV simulator circuit output, in volts (V).

If the DUT is a kit that has multiple independent units (each with their own battery pack) that can be charged simultaneously by a single solar module, the current and voltage must be measured for each independent unit's battery(-ies) during the test.

- d) Program the solar array simulator to simulate a "standard solar day" of charging using the steps indicated in Table N.2. To facilitate identification of solar radiation levels during data analysis, short pauses at 0 volts may be inserted between steps. Adjust the curve to the reduced solar radiation levels by adjusting the current only, according to the following formula:

$$I_{SAS} = I_{TMOT} \cdot \frac{G_{sim}}{G_{TMOT}}$$

where

I_{SAS} is the current at each point on the simulated I-V curve, in amperes (A);

I_{TMOT} is the current at each point on the measured I-V curve, adjusted to TMOT, in amperes (A);

G_{sim} is the simulated solar radiation from Table N.2, in watts per square metre (W/m^2).

G_{TMOT} is the solar radiation at TMOT ($1000 \text{ W}/\text{m}^2$)

- e) The DUT's battery voltage shall be continuously monitored such that the battery voltage shall not exceed a safety limit, either relying on the internal charge controller or based on the judgement of the laboratory. If necessary, integrate the overcharge protection disconnect device into the setup. The overcharge protection device shall disconnect if the battery voltage rises above safety limits that are determined by the laboratory. Refer to the battery recommended testing practices (Annex J) for recommended maximum battery testing voltage values (refer to Table J.2). Optionally, monitor the DUT's battery temperature to ensure that it does not exceed a safe value (refer to Table J.2). If temperature monitoring is used, lithium-based batteries shall not be allowed to exceed $45 \text{ }^\circ\text{C}$ unless higher temperatures are allowed by the battery manufacturer. If the charge cycle is stopped by an overcharge or overtemperature protection device added by the test laboratory, the test results shall be considered invalid.
- f) Check the connections and setpoints, then begin data logging and start the simulated charging cycle. Caution: Do not disconnect the battery after having started the simulated charging cycle. The electronics of some DUTs may be damaged if their batteries are disconnected while voltage is applied to the PV input.
- g) After the 7 h charging cycle is complete, stop the power supply, stop the data logging, disconnect the battery from the PV simulator, and verify that the current and voltage data are valid with a quick check.

N.4.4 Calculations

The following calculations shall be made:

NOTE In the following procedure, "PV simulator" refers to the resistor network or solar array simulator, whichever is applicable to the test method used.

- a) Determine the maximum power available from the PV simulator ($P_{\text{max,sim},G}$) at each simulated solar radiation level G , using the following formula:

$$P_{\text{max,sim},G} = \max_V (I_{\text{pvsim},G}(V) \times V)$$

where

$P_{\text{max,sim},G}$ is the maximum power available from the PV simulator at simulated solar radiation level G , in watts(W);

V is the voltage at each point in the interpolated I-V curve, in volts (V);

$I_{\text{pvsim},G}(V)$ is the simulated current at solar radiation level G and voltage V , in amperes (A). If a resistor network is used, this is the fitted current $I_{\text{fit},G}(V)$ calculated in step (a) of N.4.2.4, as a function of voltage. If a solar array simulator is used, this is the I-V curve programmed into the solar array simulator, as a function of voltage.

NOTE Regardless of the test method used, this quantity is the power at the maximum power point of the simulated I-V curve. This quantity is calculated from the DUT's I-V curve, not from the measurements performed for this test.

- b) For each measurement at time t , identify the maximum power available from the PV simulator ($P_{\text{max,sim}}(t)$). This is the maximum available power $P_{\text{max,sim},G}$ at the solar radiation level $G(t)$ corresponding to time t .
- c) For each measurement at time t , compute the power supplied by the PV simulator ($P_{\text{pvsim}}(t)$) using the following formula:

$$P_{\text{pvsim}}(t) = I_{\text{pvsim}}(t) \cdot V_{\text{pvsim}}(t)$$

where

$P_{\text{pvsim}}(t)$ is the power supplied by the PV simulator at time t , in watts (W);

$I_{\text{pvsim}}(t)$ is the current supplied by the PV simulator at time t , in amperes (A);

$V_{\text{pvsim}}(t)$ is the voltage supplied by the PV simulator at time t , in volts (V).

- d) For each measurement at time t and each battery i , compute the power delivered to the battery ($P_{\text{b},i}(t)$) using the following formula:

$$P_{\text{b},i}(t) = I_{\text{b},i}(t) \cdot V_{\text{b},i}(t)$$

where

$P_{\text{b},i}(t)$ is the power supplied by the PV simulator at time t , in watts (W);

$I_{\text{b},i}(t)$ is the current supplied by the PV simulator at time t , in amperes (A);

$V_{\text{b},i}(t)$ is the voltage across battery i at time t , in volts (V).

- e) If the charge controller terminates the battery charge during the test (for example, if the battery is full), the battery-charging circuit efficiency and solar operation efficiency shall be calculated based on the current and voltage data prior to charge termination. To identify the charge termination time and detect if the event has occurred, the following procedure shall be used:

- 1) For each battery i , identify the battery-specific charge termination time ($t_{\text{end},i}$) by plotting the current into the battery vs. time and identifying the time at which the current drops to zero or becomes negative. If the current does not drop to zero, but there is a clear change in the charging regime as the battery approaches a full charge, the tester may use his or her discretion in determining whether charging has stopped. If the current drops to zero due to a full battery, but then increases (for example, if the battery voltage drops below the overcharge protection voltage and charging resumes), the earliest cut-off time should be used. In any case, the tester may use his or her discretion to determine the most accurate charge termination time. See Figure N.3 below for examples.

An automated method, such as a spreadsheet or computer program, may be used to identify a possible value for the charge termination time, provided the result obtained by such a method is checked for correctness by examining the plot of the current vs. time. The tester should also check that the current dropped to zero due to the behaviour of the DUT, not due to a data collection error, loose connection, or other fault in the test apparatus or DUT.

Due to noise or measurement error, the current may be observed to drop to a low but nonzero value rather than to zero. For this step, the current should be considered to have dropped to zero if it drops to a value that is indistinguishable from zero due to the uncertainty in the current measurement.

If pauses were inserted between solar radiation steps to facilitate identification of solar radiation levels, some DUTs may restart charging after a pause, even if charging had previously stopped. In this case, the charge termination time should be the first time that charging stopped, before the pause.

In case of pulse-width modulation (PWM) controllers, aliasing effects (beat effects) may occur due to un-synchronised PWM frequency and sampling frequency of the current logger. This may lead to “chaotic” measurements which are difficult to interpret. In this case, the test may be conducted using a power meter with accuracy equivalent to that of the multimeters.

Key

X is time with units of hours on the horizontal axis
 Y is current or voltage in arbitrary units on the vertical axis

- 1 is the current into the battery, in arbitrary units
- 2 is the battery voltage, in arbitrary units
- 3 indicates the charge termination time

NOTE 1 The thick dashed line indicates the correct charge termination time for each battery. The battery voltage is also plotted for reference.

NOTE 2 Plotting the battery voltage may be helpful in determining whether the charge has terminated due to the behaviour of the DUT's charge controller or due to a fault in the apparatus or DUT. Usually, the battery voltage will reach a local maximum at the charge termination time and then remain constant or decrease after charging stops.

Figure N.3 – Example plots of current vs. time for four different DUT batteries.

- 2) Determine the overall data analysis end time (t_{end}) as the largest value of $t_{end,i}$ for all batteries:

$$t_{end} = \max_i(t_{end,i})$$

where

t_{end} is the overall data analysis end time, in hours (h);

$t_{end,i}$ is the battery-specific data analysis end time for battery i , in hours (h).

For the remaining calculation steps, all energy totals ($E_{pv\text{sim}}$, $E_{max,\text{sim}}$, and $E_{b,i}$) shall be calculated using only the values for times less than t_{end} .

- f) Determine the energy supplied by the PV simulator ($E_{pv\text{sim}}$) using the following formula:

$$E_{pv\text{sim}} = \sum_{t=0}^{t_{end}} (P_{pv\text{sim}}(t) \cdot \Delta t)$$

where

E_{pvsim} is the energy supplied by the PV simulator, in watt-hours (Wh);

t is the elapsed time, in hours (h);

t_{end} is the overall data analysis end time, in hours (h);

$P_{pvsim}(t)$ is the power supplied by the PV simulator at time t , in watts (W);

Δt is the duration of time associated with each measurement, in hours (h).

- g) Calculate the maximum available simulated PV energy ($E_{max,sim}$) using the following formula:

$$E_{max,sim} = \sum_{t=0}^{t_{end}} (P_{max,sim}(t) \cdot \Delta t)$$

where

$E_{max,sim}$ is the maximum available simulated PV energy, in watt-hours (Wh);

t is the elapsed time, in hours (h);

t_{end} is the overall data analysis end time, in hours (h);

$P_{max,sim}(t)$ is the maximum power available from the PV simulator at time t , in watts (W);

Δt is the duration of time associated with each measurement, in hours (h).

- h) Determine the energy delivered to each battery ($E_{b,i}$) using the following formula:

$$E_{b,i} = \sum_{t=0}^{t_{end}} (P_{b,i}(t) \cdot \Delta t)$$

where

$E_{b,i}$ is the energy delivered to battery i , in watt-hours (Wh);

t is the elapsed time, in hours (h);

t_{end} is the overall data analysis end time, in hours (h);

$P_{b,i}(t)$ is the power delivered to battery i at time t , in watts (W);

Δt is the duration of time associated with each measurement, in hours (h).

- i) Determine the energy allocation ratio for each battery using the following formula:

$$\alpha_i = \frac{E_{b,i}}{\sum_i E_{b,i}}$$

where

α_i is the energy allocation ratio for battery i , a unitless ratio;

$E_{b,i}$ is the energy delivered to battery i , in watt-hours (Wh).

- j) Determine the battery-charging circuit efficiency (η_{bcc}) using the following formula:

$$\eta_{bcc} = \frac{\sum E_{b,i}}{E_{pvsim}}$$

where

η_{bcc} is the battery-charging circuit efficiency as a fraction, from the battery test (Annex I);

$E_{b,i}$ is the energy delivered to battery i , in watt-hours (Wh), from the full-battery run time test (Annex L);

E_{pvsim} is the energy supplied by the PV simulator, in watt-hours (Wh).

- k) Estimate the solar operation efficiency (η_{sol-op}) using the following formula:

$$\eta_{sol-op} = \frac{E_{pvsim}}{E_{max,sim}}$$

where

η_{sol-op} is the solar operation efficiency as a fraction;

$E_{max,sim}$ is the maximum available simulated PV energy, in watt-hours (Wh);

E_{pvsim} is the energy supplied by the PV simulator, in watt-hours (Wh).

- l) For each time t , calculate the instantaneous battery-charging circuit efficiency ($\eta_{bcc}(t)$) using the following formula:

$$\eta_{bcc}(t) = \frac{\sum P_{b,i}(t)}{P_{pvsim}(t)}$$

where

$\eta_{bcc}(t)$ is the instantaneous battery-charging circuit efficiency at time t as a fraction;

$P_{b,i}(t)$ is the power delivered to battery i at time t , in watts (W);

$P_{pvsim}(t)$ is the power supplied by the PV simulator at time t , in watts (W).

- m) For each time t , calculate the instantaneous solar operation efficiency ($\eta_{sol-op}(t)$) using the following formula:

$$\eta_{sol-op}(t) = \frac{P_{pvsim}(t)}{P_{max,sim}(t)}$$

where

$\eta_{sol-op}(t)$ is the instantaneous solar operation efficiency at time t as a fraction;

$P_{pvsim}(t)$ is the power supplied by the PV simulator at time t , in watts (W);

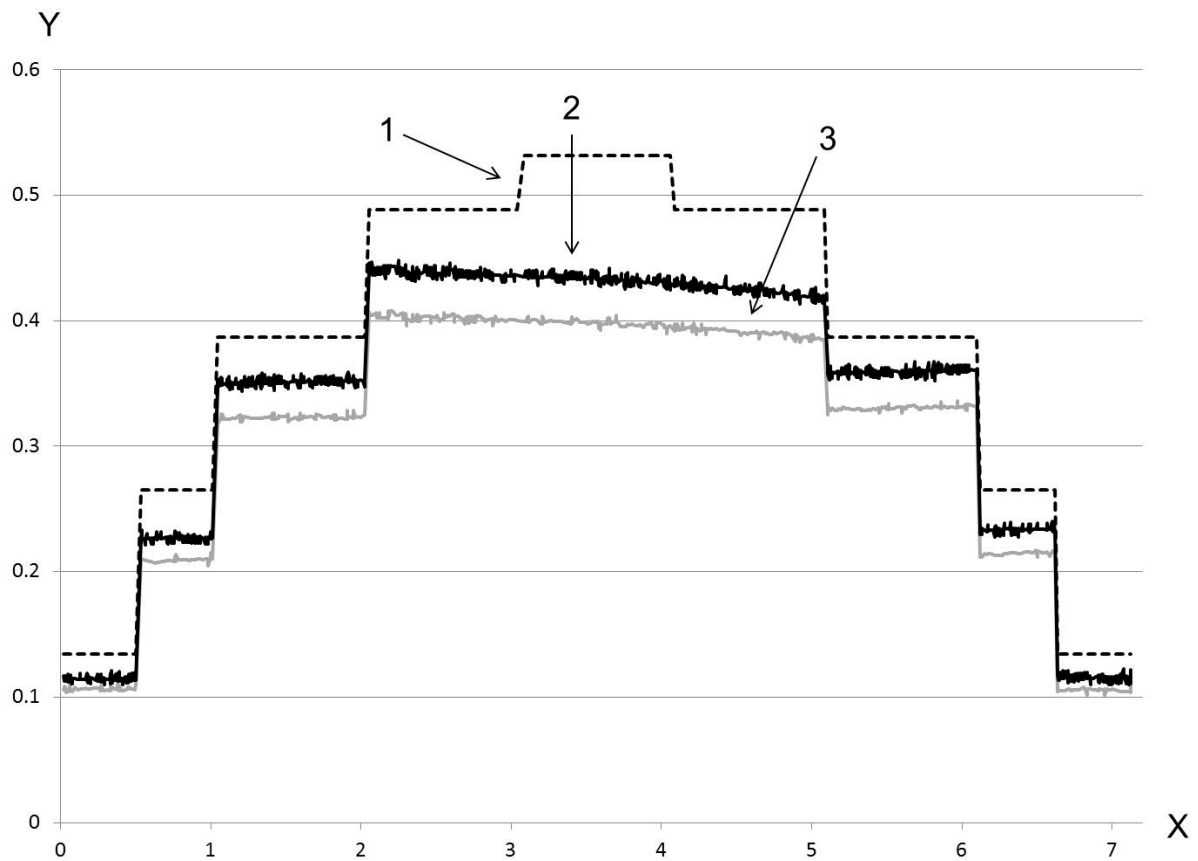

$P_{max,sim}(t)$ is the maximum power available from the PV simulator at time t , in watts (W);

- n) Based on the test data, identify if the following characteristics are present in the circuit between the solar module and the battery:
- DC-DC converter: if present, the sum of the current entering all batteries does not equal the current delivered from the PV simulator.
 - Constant current with voltage drop: if present, the sum of the current entering all batteries equals the current delivered from the PV simulator throughout the test. Use the relationship between current and voltage drop to approximate the resistance and/or diode characteristics of the circuit. The voltage drop as a function of current in this case will be equal to a constant term (diode) plus a linear term (resistor).
- o) For each battery i , calculate the average voltage from the start of the test to $t_{end,i}$. This is the **average charging voltage**.

N.5 Reporting

Report the following in the electronics efficiency test:

- Metadata
 - Report name
 - Procedure(s) used
 - DUT manufacturer
 - DUT name
 - DUT model number
 - Name of test laboratory
 - Approving person
 - Date of report approval
- Results for tested DUT aspects for samples 1 through n
 - Battery-charging circuit efficiency (%)
 - Solar operation efficiency (%)
 - Average charging voltage for each battery (V)
- Average of n sample results for tested DUT aspects
- Coefficient of variation of n sample results for tested DUT aspects
- Solar charging circuit characteristics
- Comments
 - Individual comments, as necessary, for samples 1 through n
 - Overall comments, as necessary, for collective set of samples 1 through n
- Figures
 - Plot showing the solar charging cycle for each sample in time series over the 7-hour charging period including the maximum power available from the PV simulator ($P_{\max, \text{sim}}(t)$), actual power supplied by the PV simulator ($P_{\text{pvsim}}(t)$), and power delivered to the batteries ($P_{\text{b},i}(t)$) (see Figure N.4 for an example plot). (This may be plotted as the sum over all batteries or separately for each battery.) In a separate plot or on a secondary axis show the instantaneous solar operation efficiency and instantaneous battery-charging circuit efficiency in time series (see Figure N.5 for an example plot).

Key

X is time with units of hours on the horizontal axis

Y is power with units of watts on the vertical axis

1 is the maximum power available from the PV simulator ($P_{\max, \text{sim}}(t)$), in watts

2 is the actual power supplied by the PV simulator ($P_{\text{pvsim}}(t)$), in watts

3 is the power delivered to the batteries ($P_{b,i}(t)$), in watts

Figure N.4 – Example time series plot of the solar charging cycle showing the maximum power available from the PV simulator, actual power supplied by the PV simulator, and power delivered to the batteries.

Key

X is time with units of hours on the horizontal axis

Y is efficiency as a percent on the vertical axis

1 is the instantaneous battery-charging circuit efficiency ($\eta_{\text{bcc}}(t)$), as a percent

2 is the instantaneous solar operation efficiency ($\eta_{\text{sol-op}}(t)$), as a percent

Figure N.5 – Example time series plot of the solar charging cycle showing the instantaneous battery-charging circuit efficiency and solar operation efficiency.

Annex O (normative)

Protection Tests

O.1 Background

Annex O contains test methods to assess the robustness of the solar home system kit to faults, including incorrect wiring and a disconnected battery. To meet the requirements of these tests, the product must withstand the fault condition without being damaged or presenting a safety hazard.

O.2 Test outcomes

The test outcomes of the protection tests are listed in Table S.1.

Table O.1 – Protection test outcomes

Metric	Reporting Units	Related aspects	Remarks
Presence of sufficient PV overvoltage protection	pass/fail	4.2.8.3 Circuit and overload protection	Overall pass/fail result for entire DUT
PV overvoltage protection test damage	Yes/no, description	4.2.8.3 Circuit and overload protection	One result for every port or built-in appliance
PV overvoltage protection test safety hazard	Yes/no, description	4.2.8.3 Circuit and overload protection	One result for every port or built-in appliance
PV overvoltage protection test receptacle allowable voltage limit	Voltage (V)	4.2.8.3 Circuit and overload protection	One result for every port
PV overvoltage protection test receptacle voltage	Voltage (V)	4.2.8.3 Circuit and overload protection	One result for every port
PV overvoltage protection test fault indication	Yes/no, description	4.2.8.3 Circuit and overload protection	Single result for entire DUT
Presence of sufficient miswiring protection	pass/fail	4.2.8.3 Circuit and overload protection	Overall pass/fail result for entire DUT
Miswiring protection test damage	Yes/no, description	4.2.8.3 Circuit and overload protection	One result for every tested configuration
Miswiring protection test safety hazard	Yes/no, description	4.2.8.3 Circuit and overload protection	One result for every tested configuration
Miswiring protection test fault indication	Yes/no, description	4.2.8.3 Circuit and overload protection	One result for every tested configuration

O.3 Related tests

The protection tests use results from the photovoltaic module I-V performance test (Annex H). The maximum sustained current calculated in the output overload protection test (O.4.2) is used in the assessment of DC ports (Annex P).

O.4 Procedure

O.4.1 Miswiring protection test

O.4.1.1 General

This test assesses whether the DUT is protected against improper wiring and system component connections. In many cases it is infeasible to test every possible combination of incorrect connections, so this procedure attempts to identify and test configurations that are likely to occur during installation, operation, and routine maintenance.

O.4.1.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC power supply
- Battery simulator (optional), which, if used, shall be one of the following:
 - The battery simulator circuit defined in IEC 62509:2010, Figure 1, with parameters from IEC 62509:2010, 5.1.6.2.
 - A two- or four-quadrant (bipolar) power supply or power amplifier.

The use of a battery simulator can provide more stable and controllable operating conditions, resulting in more repeatable results, but the use of the DUT's battery is permitted as a low-cost option.

O.4.1.3 Test prerequisites

The visual screening (Annex E) and photovoltaic module I-V performance test (Annex H) shall be performed before performing the miswiring protection test.

If a battery simulator is not used, the DUT's battery shall be partially charged so that the battery will accept charge from the PV input and supply power to the ports and any built-in appliances for the duration of the test. (That is, neither the deep discharge protection limit nor the overcharge protection limit shall be reached during the test. If one of these limits is reached during the test, the battery may be charged or discharged as needed and the test continued.)

O.4.1.4 Procedure

Perform the following steps:

- a) Identify the connectors subject to the miswiring protection test. A connector shall be tested if both of the following are true:
 - The connector is accessible to the user or installer during normal installation, operation, and routine maintenance. (A compartment or enclosure is considered “accessible” if it can be opened without the use of any tools, or if it is opened at any time during the normal processes of installation, operation, or routine maintenance.)
 - The connector can be inserted, assembled, or mated incorrectly (for example, backwards) without excessive force or modification, and/or the connector can be inserted into or mated with a receptacle or connector other than those with which it is intended to be used.
 - Examples of situations requiring testing:
 - The PV module and lighting appliances have the same type of plug, so one can be inserted into the socket intended for the other.
 - The battery, mounted in a user-accessible enclosure (as defined above), is connected to the charge controller using quick-disconnect lugs, and the positive and negative leads are physically interchangeable.
 - Examples of situations *not* requiring testing:
 - The battery is connected to the DUT's electronics within an enclosure that is not intended to be accessed by the user or installer. In this case, the battery connector does not require testing.
 - The kit includes several different appliances with USB plugs and four USB sockets intended for connecting appliances. Although a given appliance could be connected to any of the four sockets, this would not be an incorrect connection, so it does not require testing.
 - The kit includes a non-polarized connector that is designed to function correctly when connected in either direction. (For example, a non-polarized AC plug or a plug with a symmetrical arrangement of contacts.)
- b) Identify each incorrect configuration to be tested, using the following rules:
 - In these rules, a *pair* is defined as a positive and negative lead from the same circuit.

- The following configurations shall be tested:
 - The conductors making up a single pair are swapped (e.g., the battery is connected in reverse polarity).
 - A single connector or pair of conductors is matched with the wrong mating connector, and all other connections are made correctly (e.g., the PV module is connected to an appliance receptacle).
 - Two connectors or pairs of conductors are swapped (e.g., the battery is connected to the PV input and the PV module is connected to the battery input).
 - A single connector is inserted in the wrong orientation (e.g., the battery connector is inserted backwards)
 - Combinations of the above situations (e.g., both battery and PV module are connected in reverse polarity) need not be tested.
 - If multiple connectors are functionally identical, only one connector is required to be tested. For example, if the DUT includes four identical sockets for connecting appliances, and a PV connector that fits in the appliance sockets, the PV connector shall be tested in one of the four appliance sockets. Testing of the other three sockets is optional.
 - All required configurations shall be tested prior to testing any optional configurations, since the test may be destructive.
 - In addition to the configurations tested above, the test laboratory should test any additional configurations if, in the tester's judgment, the configuration is likely to occur during installation, use, or routine maintenance.
 - If the testing laboratory determines that a configuration will result in a safety hazard to property or personnel, the laboratory should not test that configuration. If this is a required configuration, the DUT fails the test. (For example, if reversing a connector would result in a short-circuit path across the battery with no overcurrent protection, the configuration should not be tested.)
 - It is not necessary to test configurations in which excessive force or modifications to the DUT would be required to make connections, provided that no electrical contact occurs unless excessive force is applied or modifications are performed. (For example, if the battery and PV module use connectors of different sizes or shapes, a configuration in which these connectors are swapped need not be tested.) “Excessive force” is defined as sufficient force to physically damage the DUT in a way that would be apparent to a typical user. If a connector can be forced into a socket without causing obvious damage, even if non-obvious damage (e.g., bent pins or contacts) occurs, this configuration shall be tested.
- c) If a PV module input is required for the wiring configuration under test, use a DC power supply set to the maximum power voltage (V_{mpp}) and maximum power point current (I_{mpp}) of the PV module at typical module operating temperature (TMOT). Prior to testing, connect the power supply to the PV input and verify that the DUT charges correctly.
- d) For each incorrect wiring configuration identified in b), perform the following steps:
- 3) Configure the DUT according to the incorrect wiring configuration under test. (If necessary for safety, disconnect the battery and/or PV input before making wiring configuration changes.)
 - 4) Reconnect and turn on the power supply simulating the PV module.
 - 5) Allow the DUT to remain connected for 20 min, unless a safety hazard develops (e.g., smoke or a burning smell). The DUT is not required to function correctly while configured incorrectly.
 - 6) If the DUT provides an indication of the fault condition (for example, a warning light, error code, or audible alarm), note the type of indication.
 - 7) Restore the DUT to the correct wiring configuration. (If necessary for safety, disconnect the battery and/or PV input before making wiring configuration changes.)

- 8) If a safety hazard develops, disconnect the battery and PV input from the DUT and discontinue the test.
- 9) Test the functionality of the DUT. If the DUT no longer functions:
 - i) If the problem can be identified and repaired by following instructions in the user documentation (e.g., replacing a blown fuse or resetting a tripped circuit breaker), using no tools except a screwdriver used to remove and insert screws, without creating a safety hazard, repair the fault. Only spare parts included with DUT (or their equivalent, in case the supply of included spare parts is exhausted due to testing multiple configurations) may be used. (For example, if a fuse is blown, and the manufacturer did not supply replacement fuses, the DUT fails the test.) If the DUT is functional after the repair, and the repair can be conducted without exposing the person conducting the repair to a safety hazard, the DUT does not fail the test.
 - ii) If the problem can be easily identified and repaired by the test laboratory, but requires steps not documented in the user documentation, tools other than a screwdriver used to remove and insert screws, or spare parts not included with the DUT, the DUT fails the test. However, the test laboratory may, at its discretion, repair the fault and continue the test. (For example, if a replacement fuse is required, the test laboratory may replace the fuse, continue the test, and state in the report that the DUT failed the test, but would have passed the test had spare fuses been included).
 - iii) In the test report, describe any repairs made.
- 10) Record whether the DUT remains functional at the end of the test, whether any damage occurred, and whether any user safety hazard is present. Describe any failures and take photographs of any visible damage or safety hazards.

The DUT passes the miswiring protection test if it remains functional after the final incorrect configuration is tested and no safety hazards developed during the test. The DUT is not required to function normally during the test, although any abnormal operation should be noted in the test report. The DUT is not required to provide indication of the fault condition (for example, a warning light, error code, or audible alarm), but any such indication should be noted and described.

O.4.2 Output overload protection test

O.4.2.1 General

This test assesses whether the DUT is protected against excessive load or short circuits applied to the appliance ports.

NOTE This test can be conducted using the same apparatus as the assessment of DC ports (Annex P).

O.4.2.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC power supply
- Two DC ammeters or multimeters
- Two DC voltmeters or multimeters
- Electronic load or fixed and variable resistors as described below

In some cases it may be necessary to use multiple laboratory power supplies in parallel to achieve the required current. Unless otherwise specified by the power supply manufacturer, a diode should be used at the output of each power supply to prevent backfeeding. If the power supplies do not include current-sharing functionality, set one power supply to constant-voltage mode to control the voltage and set the remaining power supplies to constant-current mode with a voltage limit not exceeding the battery's overcharge protection voltage threshold, as determined in the charge controller behaviour test (Annex K).

If the optional battery simulator specified in O.4.3.2 can supply sufficient current and meet the voltage regulation requirements for the DC power supply in Table BB.2, it may be used

instead of the DC power supply, allowing Procedure A of the PV overvoltage protection test (O.4.3.4) to be performed concurrently; see O.4.3.4 for details.

The currents required in this test can exceed the maximum range of many multimeters. In this case, a current transducer or current sense resistor and voltmeter may be used instead of an ammeter or multimeter. The voltage should be measured at the DUT to compensate for the voltage drop across the ammeter or current sense resistor.

In this test, a variable load is applied to each port. This variable load may be an electronic load or fixed and variable resistors. The load should be capable of sinking 125 % of the rated current for the port (see O.4.2.4 a) at the nominal port voltage. (Since port voltage usually drops under load, and the maximum sustained current determined by this test can be less than 125 % of the rated current, it is sometimes possible to use a load with lower limits if care is taken not to exceed the limits during the test.)

If an electronic load is used, and the electronic load contains current and voltage measurement functionality that meets the requirements for DC ammeters and voltmeters in Table BB.2 after accounting for any voltage drop between the port and the load, this functionality may be used instead of an ammeter and/or voltmeter at the port.

It may be necessary to galvanically isolate the electronic load from the power supply to avoid altering the behaviour of the DUT.

O.4.2.3 Test prerequisites

The visual screening (Annex E), the charge controller behaviour test (Annex K), and photovoltaic module I-V performance test (Annex H) shall be performed before performing the output overload protection test.

O.4.2.4 Procedure

Perform the following steps for each port under test. If the DUT has multiple identical ports, it is only necessary to test one port from each set of identical ports. In the following procedure, the term “overload protection device” refers to a fuse, circuit breaker, PTC device, other overcurrent protection device, thermal fuse, thermal switch, or other thermal protection device).

- a) Determine the maximum testing current for each port, using the following rules:
 - 1) If the manufacturer supplied a maximum current rating or overcurrent protection limit for the port, the maximum testing current is 125 % of the manufacturer-provided value. If more than one value was given by the manufacturer (for example, a nominal current value and an overcurrent protection limit), use the largest value.
 - 2) If a current rating or overcurrent protection limit for the port is given in the user documentation or product packaging or marked on the product or on an internal component (such as a fuse or circuit breaker), the maximum testing current is 125% of the value given in the documentation or marked on the product or component.
 - 3) If no rating was given and no markings can be found, calculate the highest power consumption that could be achieved using a combination of the included and advertised appliances that can be powered simultaneously using the port and all identical ports, plus any splitters or similar components that are included or advertised for use with the port. Use Table CC.1 to determine the power consumption of appliances that are not included in the kit. Divide the total power consumption by the nominal port voltage (E.4.1.5) and multiply by 1,25 to calculate the maximum testing current.
 - 4) For USB or 5 V mobile-phone charging receptacles, the maximum testing current shall not be less than 1,875 A.
- b) Use a laboratory power supply to power the DUT power control unit according to Annex G. Set the power supply to the DUT standard operating voltage (on a per-cell basis) as described in Annex G, clause G.5.2. Measure the voltage as close to the DUT as possible and adjust the power supply to compensate for voltage drop in the wires, ammeter, and paralleling diodes if used.

- c) Turn on the power supply and verify that the DUT is functional.
- d) Connect an adjustable load to the port under test. The load should have current and power ratings sufficient to achieve the maximum testing current at the port's output voltage.
- e) Adjust the load in order to find the largest current, less than or equal to the maximum testing current, that does not result in the trigger of an overload protection device after 20 minutes of operation. This is the **maximum sustained current**. It is only necessary to test multiples of 5% of the maximum testing current. The test laboratory may use any algorithm to identify the maximum sustained current, including:

- Starting at a low value and slowly increasing the current until the overload protection device is triggered. This method may be preferable if the overload protection device is a fuse that needs to be replaced after each operation, or if the overload protection device requires a long cool-down period to reset.
- Starting at a high value and slowly decreasing the current until the overload protection device does not trigger. This method may give faster results but may result in excessive operation of the overload protection device or may damage the DUT.
- Performing a binary search, as follows:

- 1) Define I_L to be equal to zero and I_H to be equal to the maximum testing current.
- 2) Calculate the test current I_{test} , as follows:

$$I_{\text{test}} = \frac{I_L + I_H}{2}$$

- 3) Round the value of I_{test} to the nearest multiple of 5% of the maximum current.
 - 4) Apply a current of I_{test} for 20 minutes.
 - 5) If an overcurrent protection device operates, set I_H equal to I_{test} . Otherwise, set I_L equal to I_{test} .
 - 6) If the difference between I_H and I_L is less than 5% of the maximum current, stop the procedure. Otherwise, go to step 2.
- Using a combination of these methods. For example, one or two steps of a binary search could be performed to get a coarse estimate of the maximum sustained current, followed by a slow ramp-up to find the precise value without excessive operation of the overload protection device.

For some types of overload protection, it may be necessary to allow the DUT to cool before repeating the test. When possible, the test laboratory should avoid unnecessary operation of the overload protection device, especially if the type of device is not known.

- f) If an overload protection device operates, record the type of overload protection device, the tools required to reset it, and whether the user documentation (including the user's manual and any labels on the product) contains sufficient instructions to carry out the procedure. If the overload protection device is a fuse that must be replaced, record whether the kit includes spare fuses.
- g) If no overload protection device operates when the device is operated at the maximum testing current for 20 minutes, no overload protection is detected and the maximum sustained current cannot be determined. The test laboratory may consult with the DUT manufacturer to determine whether a higher value for the maximum sustained current should be used; if so, the test should be repeated.
- h) If the port driver circuitry limits the current such that even when the load resistance is decreased, the current remains below the maximum testing current, the maximum sustained current is the maximum current measured during the test.
- i) Note the functionality of the DUT after operating at the maximum sustained current for 20 minutes. Be sure to remove the variable load prior to checking the DUT's functionality.
- j) Record the following:

- 1) Record whether an overload protection device operated during the test.
- 2) Record whether the DUT remains functional after the test is completed. Describe any abnormal operation during or after the test. (If abnormal operation occurred during the test, note whether the behaviour returned to normal when the overload condition was removed.)
- 3) Record whether the DUT was damaged during the test. Describe and photograph any damage.
- 4) Record whether any safety hazards developed during the test. Describe and document with photographs where applicable.
- 5) If the DUT provides indication of the overload condition (for example, a warning light, error code, or audible alarm), describe the indication.
- 6) Record whether the DUT provides adequate protection against PV overvoltage, if applicable.

The DUT is considered to have adequate output overload protection if all of the following are true:

- The maximum sustained current is less than or equal to the maximum testing current.
- The DUT remains functional after the test. (The DUT is not required to operate normally while the overload condition exists, but must return to normal operation after the overload is removed.)
- No damage occurred and no safety hazards developed when the DUT was operated at the maximum sustained current for 20 minutes.

O.4.3 PV overvoltage protection test

O.4.3.1 General

The open-circuit voltage of a PV module can be significantly higher than the normal operating voltage of the system when a battery is connected. If not properly regulated, this has the potential to cause damage if applied to system components. Additionally, if a port voltage exceeds a certain value above the nominal voltage for that port, appliances connected to that port may be damaged. This voltage limit is defined here as the **allowable port voltage limit**.

The PV overvoltage protection test assesses whether the DUT:

- can withstand a PV overvoltage condition;
- provides sufficient protection to appliances if the system battery is disconnected; and
- provides a mechanism for alerting the user to the fault condition.

The PV overvoltage protection test includes two procedures. The purpose of Procedure A (O.4.3.4) is to determine whether an overcurrent protection device can isolate the battery from the system and result in an overvoltage condition at one or more ports. The purpose of Procedure B (O.4.3.5) is to determine whether such an overvoltage condition occurs when the battery is manually removed from the system.

Procedure A shall be conducted if *both* of the following are true:

- The battery cannot be isolated from the system by the user or installing technician without opening an enclosure that is not intended to be opened during installation, operation, or maintenance.
- The battery is connected to the system in such a way that it is unlikely to become disconnected during shipping, installation, or normal operation and maintenance. The battery may be replaceable by a technician using ordinary tools, as long as the connector or other means of disconnecting the battery is not accessible to the user during ordinary use.

If either of the above conditions is not true, Procedure B shall be conducted.

Generally, these conditions are met if the battery is enclosed in a part of the product enclosure that is screwed or glued closed so that tools are required to open it, provided that

the battery is adequately fixed in place and all connections are secure. Procedure B is expected to be used primarily in cases where the battery is external to the system or can be removed without the use of tools. (Exception: if the battery is enclosed but the enclosure is opened during installation, operation, or routine maintenance, by following instructions provided by the manufacturer to the user, Procedure A should be used.)

O.4.3.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC power supply
- DC voltmeter or multimeter
- Resistor(s) selected to draw a current of $0,1 \text{ mA} \pm 10 \%$ at the nominal port voltage for each port

NOTE For voltages of 5 V, 6 V, and 12 V, this requirement can be met using standard resistor values of 51 k Ω , 62 k Ω , and 120 k Ω , respectively, with 5 % tolerance.

If Procedure A (O.4.3.4) is to be used, the following additional equipment, meeting the requirements in Table BB.2, is required:

- Electronic load or fixed and variable resistors as described in O.4.2.2
- (optional) Battery simulator, as described in O.4.1.2

If used, the battery simulator shall have sufficient current capacity to trigger the overload protection identified in the output overload protection test (O.4.2).

O.4.3.3 Test prerequisites

The visual screening (Annex E) and photovoltaic module I-V performance test (Annex H) shall be performed before performing the PV overvoltage protection test. For Procedure A (O.4.3.4), the output overload protection test (O.4.2) is also a prerequisite; it is likely to be most convenient to perform Procedure A immediately after performing the output overload protection test.

For Procedure A (O.4.3.4), unless a battery simulator is used, the battery shall be at a state of charge sufficient to trigger the overload protection identified in the output overload protection test (O.4.2). If no overcurrent protection was detected for any port in O.4.2, this test cannot be performed.

O.4.3.4 Procedure A

This procedure is for products that *meet* both of the conditions in O.4.3.1. If either condition is not met, Procedure B (O.4.3.5) shall be performed instead.

If the battery simulator used for this test can sink and source sufficient current while maintaining a regulated voltage, the test may be performed concurrently with the output overload protection test (O.4.2) by performing these steps after O.4.2 f), while the overload protection device is in the tripped state.

- a) Determine the allowable port voltage limit for each port, using the following procedure:
 - 1) If the nominal voltage of the port (from E.4.1.5) is listed in Table O.2, use the allowable port voltage limit from Table O.2.
 - 2) If the nominal voltage of the receptacle is not listed in Table O.2, determine an appropriate voltage limit using any available information about the loads intended or expected to be connected to the receptacle, taking into account any existing conventions or standards as well as any markings on or documentation provided with the product.

Table O.2 –Allowable port voltage limit by nominal voltage

Nominal port voltage (V)	Allowable port voltage limit (V)
5	5,50
6	7,90
12	15,8

- b) Calculate the maximum open-circuit voltage of the PV module using the following formula:

$$V_{oc,max} = 2 \cdot V_{oc,STC} - V_{oc,TMOT}$$

where

$V_{oc,max}$ is the maximum open-circuit voltage for the PV overvoltage protection test, in volts (V);

$V_{oc,STC}$ is the measured open-circuit voltage at STC, in volts (V);

$V_{oc,TMOT}$ is the measured open-circuit voltage at TMOT, in volts (V).

NOTE This is an estimate of the open-circuit voltage at 0 °C.

- c) Disconnect all removable appliances from the DUT.
- d) If using a battery simulator, connect the simulator in place of the DUT's battery and set the output voltage to the standard operating voltage, as defined in G.5.2. (Omit this step if performing the test concurrently with O.4.2.)
- e) Apply a load to one port of the DUT sufficient to activate (trip) the overcurrent protection for that port identified in the output overload protection test. The exact value of the load current is not critical for this test as long as it activates the overcurrent protection. Alternatively, if the overload protection device that operated in the output overload protection test can be manually activated (e.g., by turning off a circuit breaker or removing a fuse), this may be done instead of activating the overload protection device by applying an excess current.
- f) Connect a DC power supply to the PV input connector of the DUT.
- g) Apply a voltage equal to the maximum open-circuit voltage calculated in step b). Set the current limit to the short-circuit current of the PV module measured at STC.
- h) Disconnect the load from the port.
- i) Perform the following steps for one port from each set of identical ports of the DUT:
- 1) Select a resistor to draw 0,1 mA from the port at the nominal port voltage. (See O.4.3.2.)
 - 2) Connect the resistor to the port.
 - 3) Perform any actions necessary to enable the port. (For example, if a DC socket is controlled by a switch, turn the switch on.)
 - 4) Measure and record the voltage at the port.
- j) Turn on any power switches for any built-in appliances, as identified in E.4.1.5 c) 9).
- k) Allow the built-in appliances to remain turned on with the power supply applied for 20 min, regardless of whether the appliance functions, unless a safety hazard develops (e.g., smoke or a burning smell). Record any abnormal operation.
- l) Reset the overcurrent protection device.
- m) Test the functionality of the DUT. If the DUT no longer functions, perform the following steps:
- 1) If the problem can be identified and repaired by following instructions in the user documentation (e.g., replacing a blown fuse or resetting a tripped circuit breaker), using no tools except a screwdriver used to remove and insert screws, without creating a safety hazard, repair the fault. Only spare parts included with the DUT (or their equivalent, in case the supply of included spare parts is exhausted due to testing

multiple configurations) may be used. (For example, if a fuse is blown, and the manufacturer did not supply replacement fuses, the DUT fails the test.) If the DUT is functional after the repair, and the repair can be conducted without exposing the person conducting the repair to a safety hazard, the DUT does not fail the test.

- 2) If the problem can be easily identified and repaired by the test laboratory, but requires steps not documented in the user documentation, tools other than a screwdriver used to remove and insert screws, or spare parts not included with the DUT, the DUT fails the test. However, the test laboratory may, at its discretion, repair the fault and continue the test.
- 3) In the test report, describe any repairs made.
- n) Record whether the DUT remains functional at the end of the test, whether any damage occurred, and whether any user safety hazard is present. Describe any failures and take photographs of any visible damage or safety hazards.
- o) If the DUT has multiple port types, repeat steps e) through n) with the load connected to one port of each type. (Exception: if two port types are protected by the same overcurrent protection device, the test need not be repeated with the load applied to both port types. This exception only applies if the test lab can determine with certainty the overcurrent protection device that operates in each case.) Note that this procedure can result in multiple voltage values for each port type; at a minimum, report the highest voltage measured at each port.
- p) The DUT is considered to have sufficient protection from PV overvoltage if all of the following are true:
 - All features of the DUT, including built-in appliances, remain functional at the end of the test.
 - No safety hazard developed during or after the test.
 - The highest voltage measured at each port did not exceed the allowable voltage limit calculated in step a) above.

If the overload protection test failed to detect any overload protection for any port, this procedure cannot be performed. This should be considered a passing result for this test, since it is not possible for an overcurrent protection device to disconnect the battery from the circuit in this situation. (However, the DUT would fail the output overload protection test.)

O.4.3.5 Procedure B

This procedure is for products that *do not* meet both of the conditions in O.4.3.1. If both conditions are met, Procedure A (O.4.3.4) shall be performed instead.

Perform the following steps:

- a) Calculate the allowable port voltage limit according to O.4.3.4 a).
- b) Calculate the maximum open-circuit voltage of the PV module according to O.4.3.4 b).
- c) Disconnect all removable appliances from the DUT.
- d) Disconnect the battery from the DUT.
- e) Connect a DC power supply to the PV input connector of the DUT.
- f) Apply a voltage equal to the maximum open-circuit voltage calculated in step b). Set the current limit to the short-circuit current of the PV module measured at STC.
- g) If the DUT provides an indication of the fault condition (for example, a warning light, error code, or audible alarm), note the type of indication.
- h) Perform the following steps for one port from each set of identical ports of the DUT:
 - 1) Select a resistor to draw 0,1 mA from the port at the nominal port voltage. (See O.4.3.2.)
 - 2) Connect the resistor to the port.

- 3) Perform any actions necessary to enable the port. (For example, if a DC socket is controlled by a switch, turn the switch on.)
- 4) Measure and record the voltage at the port.
- i) Turn on any power switches for any built-in appliances, as identified in E.4.1.5 c) 9).
- j) Allow the built-in appliances to remain turned on with the power supply applied for 20 min, regardless of whether the appliance functions, unless a safety hazard develops (e.g., smoke or a burning smell). Record any abnormal operation.
- k) Turn off the power supply.
- l) Reconnect the battery to the DUT.
- m) Test the functionality of the DUT. If the DUT no longer functions, perform the following steps:
 - 1) If the problem can be identified and repaired by following instructions in the user documentation (e.g., replacing a blown fuse or resetting a tripped circuit breaker), using no tools except a screwdriver used to remove and insert screws, without creating a safety hazard, repair the fault. Only spare parts included with DUT (or their equivalent, in case the supply of included spare parts is exhausted due to testing multiple configurations) may be used. (For example, if a fuse is blown, and the manufacturer did not supply replacement fuses, the DUT fails the test.) If the DUT is functional after the repair, and the repair can be conducted without exposing the person conducting the repair to a safety hazard, the DUT does not fail the test.
 - 2) If the problem can be easily identified and repaired by the test laboratory, but requires steps not documented in the user documentation, tools other than a screwdriver used to remove and insert screws, or spare parts not included with the DUT, the DUT fails the test. However, the test laboratory may, at its discretion, repair the fault and continue the test.
 - 3) In the test report, describe any repairs made.
- n) Record whether the DUT remains functional at the end of the test, whether any damage occurred, and whether any user safety hazard is present. Describe any failures and take photographs of any visible damage or safety hazards.
- o) The DUT is considered to have sufficient protection from PV overvoltage if all of the following are true:
 - All features of the DUT, including built-in appliances, remain functional at the end of the test.
 - No safety hazard developed during or after the test.
 - The voltage measured at each port did not exceed the allowable voltage limit calculated in step a) above.

The DUT is not required to function normally during the test, although any abnormal operation should be noted in the test report. The DUT is not required to provide indication of the fault condition (for example, a warning light, error code, or audible alarm), but any such indication should be noted and described.

O.5 Reporting

Report the following in the protection test report:

- Metadata
 - Report name
 - Procedure(s) used
 - DUT manufacturer
 - DUT name
 - DUT model number
 - DUT setting

- DUT orientation
- Test room temperature (°C)
- Name of test laboratory
- Approving person
- Date of report approval
- Results for tested DUT aspects for samples 1 through n
 - Presence of sufficient protection against miswiring (pass/fail)
 - Functionality after PV overvoltage protection test (yes/no)
 - Damage present after miswiring protection test (pass/fail)
 - User safety hazard present after miswiring protection test (pass/fail)
 - Fault indication for miswiring (yes/no, description)
 - Repairs needed after miswiring protection test (yes/no, description)
 - Presence of sufficient protection against output overload (pass/fail)
 - Functionality after output overload protection test (yes/no)
 - Damage present after output overload protection test (yes/no)
 - User safety hazard present after miswiring protection test (yes/no)
 - Fault indication for output overload (yes/no, description)
 - Repairs needed after output overload protection test (yes/no, description)
 - Presence of sufficient PV overvoltage protection (pass/fail)
 - Functionality after PV overvoltage protection test (yes/no)
 - Damage present after PV overvoltage protection test (yes/no)
 - User safety hazard present after PV overvoltage protection test (yes/no)
 - Fault indication for PV overvoltage (yes/no, description)
- Tables
 - Table of results from miswiring protection test including configuration description, description of fault indication, damage, safety hazard, functionality, and overall pass/fail result after test for each configuration (see Table O.3 for an example).
- Table of nominal voltage, voltage limit, measured voltage, functionality, and pass/fail result during PV overvoltage test for each port and built-in appliance (see Table O.4 for an example).Comments
 - Individual comments, as necessary, for samples 1 through n
 - Overall comments, as necessary, for collective set of samples 1 through n

Table O.3 – Example table of miswiring protection test results

Configuration	Sample ID	Fault indication	Damage?	Safety hazard?	Functional ?	Pass/fail	Remarks
PV reverse polarity	1	Warning light	No	No	Yes	Pass	PV fuse replaced with included spare.
	2	Warning light	No	No	Yes	Pass	PV fuse replaced with included spare.
	3	Warning light	No	No	Yes	Pass	PV fuse replaced with included spare.
	4	Warning light	No	No	Yes	Pass	PV fuse replaced with included spare.
Battery reverse polarity	1	Warning light	Yes	Yes	N/A	Fail	Control box emitted smoke. Test was discontinued.
	2	Warning light	No	No	Yes	Pass	
	3	Warning light	No	No	Yes	Pass	
	4	Warning light	No	No	Yes	Pass	
PV/battery plugs swapped	1	--	--	--	--	--	Test not performed due to prior failure.
	2	None	No	Yes	No	Fail	
	3	None	No	Yes	No	Fail	
	4	None	No	Yes	No	Fail	

Table O.4 – Example table of PV overvoltage test results

Receptacle	Nominal voltage (V)	Voltage limit (V)	Sample ID	Measured voltage (V)	Functional after test?	Pass/fail
USB port	5	5,50	1	5,09	Yes	Pass
			2	5,08	Yes	Pass
			3	5,19	Yes	Pass
			4	5,36	Yes	Fail
Cigarette lighter port	12	15,8	1	21,3	Yes	Fail
			2	21,3	Yes	Fail
			3	21,7	Yes	Fail
			4	20,9	Yes	Fail
5 mm barrel plug	12	15,8	1	21,4	Yes	Fail
			2	21,4	Yes	Fail
			3	21,5	Yes	Fail
			4	21,0	Yes	Fail
Built-in light	--	--	1	--	Yes	Pass
			2	--	No	Fail
			3	--	Yes	Pass
			4	--	Yes	Pass

Annex P (normative)

Assessment of DC Ports

P.1 Background

DC ports (also called receptacles or outlets) are a key component of a solar home system kit; the specifications of the DC ports determine what appliances can be powered by the kit. Annex P contains test procedures to determine the following properties of DC ports:

- The output voltage range and current-voltage relationship over a variety of operating conditions;
- The efficiency of the path from the DUT's battery to the port; and
- The ability of included appliances to function at the voltage supplied by the port over a variety of operating conditions.

Universal Serial Bus (USB), a standard defined by the USB Implementers Forum, is a common port format for charging mobile phones and other portable devices, as well as providing power to small electronic appliances. Annex P contains additional procedures to evaluate the performance of USB ports, including undershoot and overshoot during step increases and decreases in current, to ensure that these ports can safely power mobile phones and other portable devices. These test methods are derived from the *USB Battery Charging Specification*, revision 1.2, and the *USB Battery Charging 1.2 Compliance Plan*, revision 1.0, published by the USB Implementers Forum.

P.2 Test outcomes

The test outcomes of the DC ports assessment are listed in Table P.1.

Table P.1 – DC ports assessment outcomes.

Metric	Reporting Units	Related aspects	Remarks
Minimum port voltage for each port	Volts (V)	4.2.8.4 DC ports	One value for each port
Typical port voltage for each port	Volts (V)	4.2.8.4 DC ports	One value for each port
Maximum port voltage for each port	Volts (V)	4.2.8.4 DC ports	One value for each port
Plots of output voltage vs. output current, and associated data, for each port and each simulated battery voltage	Volts (V), amperes (A)	4.2.8.4 DC ports	Four plots for each tested port, and associated tabular data.
Plots of output voltage vs. output power, and associated data, for each port and each simulated battery voltage	Volts (V), watts (W)	4.2.8.4 DC ports	Four plots for each tested port, and associated tabular data
Plots of battery-to-port efficiency vs. output current, and associated data, for each port and each simulated battery voltage	Percentage, amperes (A)	4.2.8.4 DC ports	Four plots for each tested port, and associated tabular data
Plots of battery-to-port efficiency vs. output power, and associated data, for each port and each simulated battery voltage	Percentage, watts (W)	4.2.8.4 DC ports	Four plots for each tested port, and associated tabular data
Power consumption values for each built-in appliance for each simulated battery voltage	Watts (W)	4.2.8.4 DC ports	Three values for each built-in appliance
Functionality of each appliance for each simulated battery voltage	Yes/no	4.2.8.1 Appliance voltage compatibility	Three values for each tested appliance
Tables of peak overshoot voltages, minimum undershoot voltages, and undershoot times for each port and each voltage tested.	Volts (V), milliseconds (ms)	4.2.8.4 DC ports	Three tables for each port, showing values for each current transition.
Maximum power for each port	Watts (W)	4.2.8.4 DC ports	One value for each port
Pass/fail for functionality for each port	Yes/no	4.2.8.4 DC ports	One value for each port
Pass/fail for truth in advertising for each port	Yes/no	4.2.8.4 DC ports	One value for each port
Data line resistance for each USB port	Ohms (Ω)	4.2.8.4 DC ports	One value for each USB port
D+ voltage for each USB port	Volts (V)	4.2.8.4 DC ports	One value for each applicable USB port
D- voltage for each USB port	Volts (V)	4.2.8.4 DC ports	One value for each applicable USB port

P.3 Related tests

The tests in Annex P use some of the same equipment as the protection tests (Annex O), particularly the output overload protection test (O.4.2), which is a prerequisite. Test laboratories may wish to perform the DC ports tests immediately after the protection tests to

take advantage of equipment commonalities. However, since the protection tests are potentially destructive, they are generally not performed on the same samples.

Several other tests, including the visual screening (Annex E), the charge controller behaviour test (Annex K), the solar charge test (Annex N), and the full-battery run time test (Annex L), are used to derive operating parameters for the ports tests.

The efficiencies measured in Annex P are used in the energy service calculations (Annex R).

The **typical port voltage** is used when a power supply is configured to directly power an appliance (Annex G).

P.4 Procedure

P.4.1 Preparation

Perform the following steps:

- a) Identify the ports to be tested using this procedure. All ports capable of supplying power, including mobile-phone charging ports, shall be tested, except that if the DUT has multiple identical ports only one port need be tested from each group of identical ports. Ports shall only be considered identical if they have identical driver circuitry and identical voltage and current limits.
- b) If multiple samples of the product are being tested, the selected port from each group shall rotate between samples. (For example, if six samples of a product with three USB ports are to be tested, port 1 shall be tested on samples 1 and 4, port 2 on samples 2 and 5, and port 3 on samples 3 and 6.)
- c) If a port has multiple selectable voltage settings, each setting shall be considered a separate “port” for the purposes of testing.
- d) Identify the maximum current for each port, using the following procedure:
 - 1) Use the maximum sustained current, measured in the output overload protection test (O.4.2).
 - 2) If, during the output overload protection test, damage or a safety hazard was noted when a current less than or equal to the maximum sustained current was applied to the port, the maximum current for this test is the highest possible current that does not result in damage or a safety hazard.
- e) Identify any special procedures required to enable the output on each port. For example, some USB ports may require an attached device to be enumerated and negotiate to receive power in excess of a certain limit. If any such requirements exist, it may be necessary to consult with the manufacturer of the DUT to develop a plan to successfully test the port.
- f) Determine whether the port should be treated as a USB port for the purposes of this test. A port shall be considered a USB port if any of the following is true:
 - The port accepts a standard USB connector.
 - The DUT includes an adapter that allows a USB connector to be connected to the port.
 - The port is intended or expected to be used for charging mobile phones with a nominal input voltage of 5 V DC.

P.4.2 Measurement of steady-state port characteristics

P.4.2.1 General

This test measures the relationship of output voltage and steady-state battery-to-port efficiency to load current at four simulated battery voltages:

- a) The standard operating voltage defined in Annex G, corresponding to typical operation during discharge;

- b) The deep discharge protection voltage measured during the full-battery run time test (Annex L) or charge controller behaviour test (K.4.1), corresponding to operation in a deeply discharged state;
- c) The average charging voltage measured during the solar charge test (Annex N), corresponding to typical operation during solar charging;
- d) A voltage corresponding to operation during solar charging with a nearly full battery.

This test also assesses the ability of built-in and removable appliances to function normally and without damage at the voltage levels supplied by the product's ports under these usage conditions, and measures the power consumption of built-in appliances. These tests are carried out in P.4.2.5 f) through h). The number of appliance samples used in steps P.4.2.5 g) and P.4.2.5 h) should be the same as the number of samples required for the appliance operating voltage range test. This may be different from the sample size for the assessment of DC ports. If the product specification requires a sample size greater than one, each combination of kit sample and appliance sample shall be tested. Developers of product specifications should consider the added cost of testing multiple combinations of kit and appliance when determining the required sample size for the appliance operating voltage range test.

EXAMPLE 1 The product specification requires a sample size of 1 for the appliance operating voltage range test and a sample size of 4 for the assessment of DC ports. The product includes a main unit and a fan without internal battery. Step P.4.2.5 g) would be carried out 16 times: once for each voltage level and each main unit sample, using the same fan sample for each test.

EXAMPLE 2 The product specification requires a sample size of 4 for both the appliance operating voltage range test and the assessment of DC ports; the other product details are the same as in Example 1. Step P.4.2.5 g) would be carried out 64 times: once for each combination of voltage level, main unit sample, and fan sample.

The laboratory may choose to perform the appliance operating voltage test (Q.7) instead of steps P.4.2.5 g) and P.4.2.5 h) for some or all appliances included with the kit. The use of the appliance operating voltage test can be advantageous in the following circumstances:

- One or more appliances are used with more than one SHS kit product under test. In some circumstances, described in Q.7.4, the results from a single test may be used for multiple products with identical appliances.
- One or more lighting appliances without batteries have been previously tested according to the input voltage range test of IEC 62257-12-1.
- The laboratory testing the appliances does not possess samples of the full SHS kit.
- The product specification requires a sample size greater than 1 for the appliance operating voltage range test.

P.4.2.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC power supply with sufficient output current to achieve the maximum current identified in P.4.1 d)
- Two DC ammeters or multimeters
- Two DC voltmeters or multimeters
- Electronic load or variable and fixed resistors with specifications calculated in P.4.2.5.

In some cases it may be necessary to use multiple laboratory power supplies in parallel to achieve the required current. Unless otherwise specified by the power supply manufacturer, a diode should be used at the output of each power supply to prevent backfeeding. If the power supplies do not include current-sharing functionality, set one power supply to constant-voltage mode to control the voltage and set the remaining power supplies to constant-current mode with a voltage limit not exceeding the battery's overcharge protection voltage threshold, as measured in the charge controller behaviour test (Annex K).

The currents required in this test can exceed the maximum range of many multimeters. In this case, a current transducer or current sense resistor and voltmeter may be used instead of an ammeter or multimeter. The voltage should be measured at the DUT to compensate for the voltage drop across the ammeter or current sense resistor.

If an electronic load is used, and the electronic load contains current and voltage measurement functionality that meets the requirements for DC ammeters and voltmeters in Table BB.2 after accounting for any voltage drop between the port and the load, this functionality may be used instead of an ammeter and/or voltmeter at the port.

The electronic load may need to be galvanically isolated from the power supply to avoid altering the behaviour of the DUT.

P.4.2.3 Test prerequisites

The output overload protection test (O.4.2), charge controller behaviour test (Annex K), and solar charge test (Annex N) shall be performed prior to the measurement of steady-state port characteristics. In addition, if the deep discharge protection voltage is measured during the full-battery run time test (Annex L), this test shall be performed prior to the measurement of steady-state port characteristics.

P.4.2.4 Apparatus

Example apparatus for the measurement of port characteristics during discharge is shown schematically in Figure P.1.

Key

- 1 DC Power supply (sink/source).
- 2 DC-DC converter from the battery voltage to output voltage.
- 3 Standardized DC port (e.g. 12 V)
- 4 Data pins configuration (D+ and D- are shorted with max. resistance 200Ω for dedicated charging port type). The configuration might be different depending on its capability to charge particular a mobile phone.
- 5 Standard USB Female port.
- 6 Cable with DC adapter and USB cable with shield and drain wire connected to the ground.
- 7 Load with a fixed resistor to prevent short circuit and variable resistors.
- 8 Voltage and current measurements using DC multimeters and shunt resistors.

Figure P.1 – Schematic of the DUT with DC port and USB port and variable resistors connected for the measurement of steady-state port characteristics.

P.4.2.5 Procedure

Perform the following steps:

- a) Build the test configuration as in Figure P.1.
- b) Prepare the DUT sample according to Annex F.
- c) Use a laboratory power supply to power the DUT power control unit according to Annex G. Set the power supply to the DUT **standard operating voltage** as described in Annex G.
- d) Measure the current and voltage at the battery with no loads applied. Any power switches that do not control individual loads shall be turned on. (For example, if the DUT has a master power switch, turn it on.)
- e) For each port under test, perform the following steps:
 - 1) Measure the open-circuit voltage of the receptacle (with no load).
 - 2) Calculate the safety resistor value, R_{safety} , corresponding to a current of 100% of the maximum current for the port (P.4.1 d)) at the nominal port voltage (from E.4.1.5):

$$R_{\text{safety}} = \frac{V_{\text{nom,port}}}{I_{\text{max,port}}}$$

where

R_{safety} is the safety resistor value, in ohms (Ω);

$V_{\text{nom,port}}$ is the nominal voltage of the port (from E.4.1.5), in volts (V);

$I_{\text{max,port}}$ is the maximum current for the port, in amperes (A).

The safety resistor should have a power rating sufficient to allow the maximum voltage of the port to be applied:

$$P_{\text{Rsafety}} \geq \frac{V_{\text{max,port}}^2}{R_{\text{safety}}}$$

where

P_{Rsafety} is the maximum power rating of the safety resistor, in watts (W);

$V_{\text{max,port}}$ is the maximum expected voltage of the port, in volts (V);

R_{safety} is the safety resistor value, in ohms (Ω).

- 3) Calculate the value of the variable resistor R_{variable} . The full scale resistance of the variable resistor in series with the fixed resistor R_{safety} should result in a current of no more than 10% of the maximum current for the port (P.4.1 d)) at the nominal port voltage (E.4.1.5):

$$R_{\text{variable}} \geq \frac{V_{\text{nom,port}}}{0.1 \cdot I_{\text{max,port}}} - R_{\text{safety}}$$

where

R_{variable} is the variable resistor value, in ohms (Ω);

$V_{\text{nom,port}}$ is the nominal voltage of the port (from E.4.1.5), in volts (V);

$I_{\text{max,port}}$ is the maximum current for the port, in amperes (A);

R_{safety} is the safety resistor value, in ohms (Ω).

The variable resistor should have a maximum current rating sufficient to allow the maximum current of the port to be applied and a resolution sufficient to achieve the required current values (20%, 40%, 60%, 80%, and 100% of the maximum sustained current) to within 5 %.

NOTE: Variable resistors are generally rated by their manufacturers according to the maximum power dissipation of the full resistance element. If a maximum current rating is not given by the component manufacturer, the minimum allowable power rating can be calculated based on the full-scale resistance:

$$P_{R\text{variable}} \geq I_{\text{max,port}}^2 \cdot R_{\text{variable}}$$

where

$P_{R\text{variable}}$ is the maximum power rating of the variable resistor, in watts (W);

$I_{\text{max,port}}$ is the maximum current for the port, in amperes (A);

R_{variable} is the variable resistor value, in ohms (Ω).

An electronic load or other programmable load device may be used instead of a resistor. The current and voltage measurement functionality may be incorporated into the load device provided it meets the accuracy requirements of Table BB.2.

- 4) Connect the safety and variable resistors, in series, to the output of the port.
 - 5) Allow the voltage to stabilize.
 - 6) Using a DC ammeter and voltmeter, or two multimeters, record the current and voltage at the port. Simultaneously, measure and record the voltage and current at the battery input terminals.
 - 7) Repeat steps 1-5 with total resistance values corresponding to 20%, 40%, 60%, 80%, and 100% of the maximum sustained current (within 5 %).
 - 8) Perform any additional measurements necessary to verify compliance with the product specification, if applicable.
 - 9) Disconnect the test load from the port.
- f) Perform the following procedure for each built-in appliance, if any. A light with the driver circuitry incorporated into the control box or main DUT housing is considered a built-in appliance, even if the light itself may be unplugged; see E.4.1.5 c) 9) for details.
- 1) Identify the appliance settings to be measured by referring to the procedure in Q.5 that pertains to the type of appliance under test.
 - 2) Turn on the built-in appliance. Record whether the appliance functions correctly.
 - 3) If testing at the standard operating voltage, perform the following steps:
 - i) Allow the appliance to stabilize for at least 5 minutes.
 - ii) Measure and record the current and voltage at the battery.
 - 4) If the appliance has multiple settings, repeat steps 2) and 3) for each setting to be tested.
- g) Perform the following procedure for each included appliance, without an internal battery, intended to be connected to the port under test, other than built-in appliances, which were tested in step f). This step may be omitted for appliances that will undergo the appliance operating voltage range test (Q.7). Repeat the step for all appliance samples as described in P.4.2.1.
- 1) Connect the appliance to the port. If the appliance can be turned off, leave the appliance connected to the port but turned off for at least five minutes.
 - 2) Turn on the appliance and allow it to operate for at least five minutes. Record whether the appliance functions correctly. If the appliance has multiple settings or operating modes, operate the appliance for five minutes in a setting or operating mode with high expected power consumption and five minutes in a setting or operating mode with low expected power consumption. For example, for a fan, the use the highest and lowest speeds.
 - 3) Disconnect the appliance.
- h) Perform the following procedure for each appliance with an internal battery, intended to be connected to the port under test, other than built-in appliances, which were tested in step

- f). This step may be omitted for appliances that will undergo the appliance operating voltage range test (Q.7). Repeat the step for all appliance samples as described in P.4.2.1.
- 1) Fully discharge the appliance's battery.
 - 2) Connect the appliance to the port and leave it connected for at least five minutes. Determine whether the appliance charges by observing the port current as well as any charging indicators on the appliance. Record whether the appliance charges.
 - 3) Fully charge the appliance's battery. (Alternatively, use a different sample of the appliance with a fully charged battery.)
 - 4) Connect the appliance to the port and leave it connected for at least five minutes. (In some cases, an appliance may briefly charge when connected even though the battery was fully charged. In this case, allow the appliance to stop charging (e.g., wait until the current drops to zero or to a low value) before starting the five-minute waiting period.)
 - 5) Disconnect the appliance from the port.
 - 6) Check the appliance for functionality. Note any damage or abnormal operation.
- i) Change the power supply voltage (simulated battery voltage) to the deep discharge protection voltage measured during the full-battery run time test (Annex L) or charge controller behaviour test (K.4.1), then repeat steps d) through h). (If the DUT will not turn on or will not stay on at the selected voltage, increase the voltage in 0,05 V increments until the DUT turns on, then decrease the voltage in 0,05 V increments to the lowest value for which the DUT remains on.)
 - j) Change the power supply voltage (simulated battery voltage) to the maximum battery voltage measured during the active overcharge protection test (K.4.2), or, if the active overcharge protection test need not be performed for the DUT, the maximum battery voltage observed during the solar charge test (Annex N). Repeat steps d) through h) at this voltage. (If the DUT will not turn on or stay on at the selected voltage, decrease the voltage in 0,05 V increments to the lowest value for which the DUT remains on.)
 - k) (optional) Change the power supply voltage (simulated battery voltage) to the average charging voltage measured during the solar charge test (Annex N). Repeat steps d) through f) at this voltage (steps g) and h) need not be repeated).

P.4.2.6 Calculations

Perform the following calculations for each simulated battery voltage measured in P.4.2.

- a) For each operating point tested, calculate the battery input power and port output power by multiplying the current and voltage values.
- b) For each battery voltage setting, calculate the idle power, P_{idle} , by multiplying the current and voltage measured at the battery with no load applied.
- c) For each battery voltage setting, port, and load current, calculate the battery-to-port efficiency using the following formula:

$$\eta_{batt-port} = \min\left(1, \frac{P_{port}}{P_{batt} - P_{idle}}\right) \cdot 100\%$$

where

$\eta_{batt-port}$ is the battery-to-port efficiency, as a percentage (%);

P_{port} is the port output power, in watts (W);

P_{batt} is the power supplied to the DUT by the simulated battery, in watts (W);

P_{idle} is the idle power, in watts (W).

- d) For each battery voltage setting and each setting of each built-in appliance, calculate the power consumption using the following formula:

$$P_{app} = P_{batt,app} - P_{idle}$$

where

P_{app} is the appliance power consumption, in watts (W);

$P_{batt,app}$ is the power supplied to the DUT by the simulated battery when the appliance is in use, in volts (V);

P_{idle} is the idle power, in watts (W).

e) For each port and each battery voltage setting, plot the following:

- 1) Output voltage vs. output current.
- 2) Output voltage vs. output power (P_{port}).
- 3) Battery-to-port efficiency ($\eta_{batt-port}$) vs. output current.
- 4) Battery-to-port efficiency ($\eta_{batt-port}$) vs. output power (P_{port}).

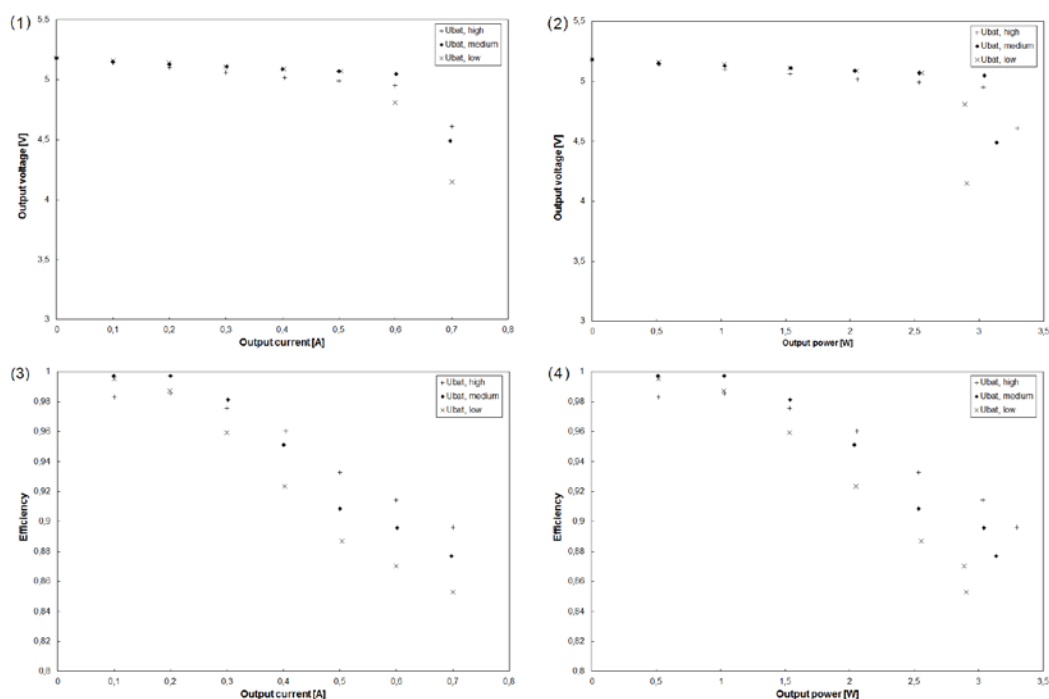

Figure P.2 – Example of the plots of port characteristics

P.4.3 Dynamic measurement

P.4.3.1 General

In this test, the dynamic performance of the DC port is evaluated. The DC port is loaded with a variable pulsed load that represents the typical dynamic load (i.e. mobile charging, LED driver). The voltage and current transients are analysed by recording the data acquisition device (e.g. oscilloscope). Two different input voltages (high and low battery operational voltage) are performed to evaluate the capability of the port to cope with the dynamic load at different levels of states of charge. The performance of the ports in simultaneous operation is also evaluated under droop test.

This test is largely based on the DCP Overshoot and Undershoot Voltage Test from the *USB Battery Charging 1.2 Compliance Plan*, revision 1.0, published by the USB Implementers Forum.

This test may be omitted for all ports that are not USB ports as defined in P.4.1.

P.4.3.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Electronic load capable of generating a stepped current waveform as defined in Table P.2, with a minimum step duration of 20 ms and three or four distinct current levels (including zero), depending on whether optional tests are performed. Many commercially available electronic loads meet this requirement; alternatively, the load may be constructed using fixed and/or variable power resistors (see P.4.2.5 for calculations) and/or power MOSFETs or similar switching devices.
- DC power supply.
- Digital storage oscilloscope or data-logging device capable of recording voltage and current at a rate of at least 1 000 samples per second. This functionality may be incorporated into the electronic load.
- Current transducer or current sense resistor, if needed, to allow current to be recorded by the oscilloscope or data-logging device. This functionality may be incorporated into the electronic load. (For example, some electronic loads provide an analogue current monitor output.)

In some cases, the oscilloscope or data-logging device may need to be galvanically isolated from the power supply and load to avoid altering the behaviour of the DUT. Any isolation device shall have sufficient bandwidth to provide an accurate measurement of the voltage transients.

The voltage drop between the power supply and the DUT's battery input terminals shall be minimized; components such as ammeters and diodes (required or permitted in P.4.2) shall not be included between the power supply and the DUT for the dynamic port measurement.

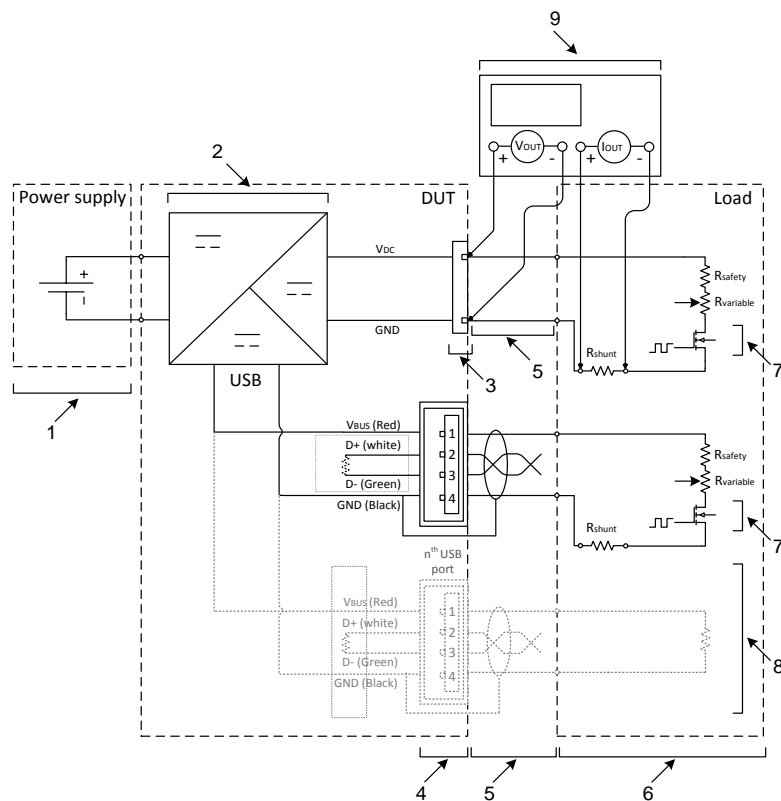

NOTE Since this test is only required for USB ports, in most cases, a lower power supply current will be needed than in the steady-state measurement (P.4.2), and multiple power supplies in parallel will not be required.

P.4.3.3 Test prerequisites

The test prerequisites are identical to those for the measurement of steady-state port characteristics (P.4.2).

P.4.3.4 Apparatus

Example apparatus for the dynamic port measurement is shown schematically in Figure P.3.

Key

- 1 DC Power supply (sink/source).
- 2 DC-DC converter from the battery voltage to output voltage.
- 3 Standardized DC port (e.g. 12 V).
- 4 Standard USB Female port.
- 5 Cable with DC adapter and USB cable with shield and drain wire connected to the ground.
- 6 Pulse load with a fixed resistor to prevent short circuit and variable resistors.
- 7 Electronic switch controlled by pulse generator.
8. Additional USB port
9. Oscilloscope

Figure P.3 – Schematic of the DUT with DC port and USB port and variable resistors connected for the dynamic measurement.

P.4.3.5 Procedure

The following steps shall be followed to evaluate the transient response of the port:

- a) Build the test configuration illustrated in Figure P.3 with variable pulsed load specified in P.4.3.2.
- b) Use a laboratory power supply to power the DUT power control unit according to Annex G. Set the power supply to the DUT standard operating voltage as described in Annex G.
- c) Connect the voltage and current data acquisition device at the output of the DC port. Set the logging interval or sampling rate to at least 1 ms or 1 000 samples per second.
- d) Perform either of the following procedures to conduct the test. Procedure 1 can be performed using low-cost equipment, while Procedure 2 can be simpler to perform if a suitable electronic load is used. The currents shall be accurate to within 5 %.

Procedure 1:

- 1) Configure the pulsed load to alternate between the two current levels shown in the first row of Table P.2 with a frequency of no more than 5 Hz and duty cycle of 50 %.

- 2) Record the voltage and current for at least 100 ms after the current transitions indicated in Table P.2.
- 3) Repeat 1) and 2) for the remaining current pairs in Table P.2. Omit row 4 if not required by the product specification or if the maximum sustained current from O.4.2 is less than or equal to 0,5 A.

Procedure 2:

- 1) Configure the pulsed load with a stepped current waveform similar to that illustrated in Figure P.4 in order to capture all current transitions required in Table P.2. Omit row 4 if not required by the product specification or if the maximum current from P.4.1 d) is less than or equal to 0,5 A. The duration of each step shall be no less than 100 ms.
 - 2) Record the voltage and current for at least 100 ms after the current transitions indicated in Table P.2.
- e) Change the power supply voltage to the deep discharge protection voltage measured during the full-battery run time test (Annex L) or charge controller behaviour test (K.4.1), then repeat step d). (If the DUT will not turn on or will not stay on at the selected voltage, increase the voltage in 0,05 V increments until the DUT turns on, then decrease the voltage in 0,05 V increments to the lowest value for which the DUT remains on.) Omit this step if the voltage would be greater than or equal to the standard operating voltage.
- f) Change the power supply voltage to the maximum voltage measured during the active overcharge protection test (K.4.2), or the solar charge test (Annex N) if the active overcharge protection test need not be performed for the DUT, then repeat step d). (If the DUT will not turn on or stay on at the selected voltage, decrease the voltage in 0,05 V increments to the lowest value for which the DUT remains on.) Omit this step if the voltage would be less than or equal to the standard operating voltage.

Table P.2 – Current pairs for dynamic test

Row number	Current 1 (A)	Current 2 (A)	Current transitions to record
1	0,0	0,1	rising edge
2	0,1	0,5	rising edge
3	0,0	0,5	rising and falling edges
4 (optional)	0,0	Maximum current from P.4.1 d)	rising and falling edges

NOTE This step waveform is based on the DCP Overshoot and Undershoot Voltage Test from the *USB Battery Charging 1.2 Compliance Plan*, revision 1.0, published by the USB Implementers Forum.

Key

1 Current, in amperes (A)

2 Time, in milliseconds (ms)

I_{max} maximum current for the port, from P.4.1 d)

Figure P.4 – Illustration of stepped current waveform for Procedure 2

P.4.3.6 Calculations

For each port and each voltage setting measured, at each current transition, measure and record the following quantities:

- Minimum undershoot voltage, defined as the minimum voltage reached during a transient drop in voltage (Figure P.5);
- Undershoot time, defined as the duration of the transient drop in voltage below 4,75 V (Figure P.5);
- Peak overshoot voltage, defined as the maximum voltage amplitude of the transient change of the output voltage that exceeds the steady state value (Figure P.6).

Key

- V Port voltage, in volts (V)
- I Port current, in amperes (A)
- t Elapsed time, in milliseconds (ms)
- 1 Minimum undershoot voltage (2,64 V)
- 2 Undershoot time (1,07 ms)

Figure P.5 – Example time series plot of voltage and current showing a step increase in current and the resulting voltage undershoot

Key

- V Port voltage, in volts (V)
- I Port current, in amperes (A)
- t Elapsed time, in milliseconds (ms)
- 1 Peak overshoot voltage (6,71 V)

Figure P.6 – Example time series plot of voltage and current showing a step decrease in current and the resulting voltage overshoot

P.4.4 Summary calculations

For each port, perform the following calculations:

- a) Calculate the minimum port voltage and maximum port voltage ($V_{\min, \text{port}}$ and $V_{\max, \text{port}}$) over the entire range of conditions (battery voltage and load) in P.4.2. Also report the power supply voltage (simulated battery voltage) and port current under which each voltage value was measured.
- b) Calculate the maximum port output power over the entire range of conditions in P.4.2.

EXAMPLE For port 1, the minimum port voltage was 4.86 V, measured with a simulated battery voltage of 3.07 V/cell and load 3.3 Ω ; the maximum port voltage was 5.10 V, measured with a simulated battery voltage of 4.20 V/cell and no load (open circuit).

- c) Calculate the **typical port voltage** ($V_{\text{typ, port}}$) using the following procedure:

- 1) Identify the typical load current for the port. The typical port current is the lesser of 0,5 A and the maximum current from P.4.1 d).

NOTE This definition takes into account that USB ports are permitted by the Battery Charging Specification, revision 1.2, published by the USB Implementers Forum, to operate within a wide voltage range for currents between 0,5 A and 1,5 A.

- 2) Identify the output voltage at the typical load, determined in 1), under the conditions specified in P.4.2 steps a) through c) (e.g., when the DUT's battery input is driven at the standard operating voltage); interpolate between measurements if no measurement was performed at the required load. This is the typical port voltage ($V_{\text{typ, port}}$).

P.4.5 Pass/fail tests for functionality and truth in advertising

Perform the following steps:

- a) Assess each port's functionality using the following steps:
 - 1) If the manufacturer specifies minimum and/or maximum voltage values for the port, use the data from P.4.2 to assess whether the output voltage remains within the manufacturer-specified range.
 - 2) Assess compliance with any other requirements defined in the product specification.
- b) Assess truth in advertising using the following steps:
 - 1) If the manufacturer advertises a current or power value or range for one or more ports, use the data from P.4.2 to determine whether the advertised value or range is accurate. If minimum and/or maximum values are given, compare the advertised values to the minimum and/or maximum values from P.4.4. If a nominal, typical, or average value is given, determine whether the nominal value is within the range of the minimum and maximum values from P.4.4.
 - 2) If the manufacturer advertises that one or more ports can be used to charge or power appliances (e.g., mobile phone, radio, refrigerator, fan, etc.) other than those included in the kit, use the procedure in CC.5 step a) to determine the power consumption of the appliance. Compare this value with the maximum power calculated in P.4.4. If the generic appliance power consumption from CC.5 is greater than the maximum power output of the port from P.4.4, the port's capabilities are not accurately advertised.

EXAMPLE If the manufacturer claims that the 12 V port can power a small television, but the maximum port output power is 5 W, then the port's capabilities are not accurately advertised because according to Table CC.1 a small television consumes 10 W.

- 3) For USB ports, perform the following steps:
 - i) With the DUT powered at the standard operating voltage, measure the voltages on the data lines (D+ and D-) relative to the ground line. Also record the port voltage at the time this measurement is made. (See Figure P.7 for a schematic diagram of a typical USB charging port; Figure P.8 shows the pin configuration of a type A receptacle.)
 - ii) If no voltage is present on the data lines, measure the resistance between the data lines. (Use caution as applying a voltage to an ohmmeter may damage the instrument.)

Figure P.7 – Typical configuration of USB port for special charger.

Key

- 1 VBUS (+5V); usually red wire
- 2 D-; usually white wire
- 3 D+; usually green wire
- 4 GND; usually black wire

Figure P.8 – Pin configuration of type A receptacle.

P.5 Reporting

Report the following in the input voltage range test report:

- Metadata
 - Report name
 - Procedure(s) used
 - DUT manufacturer
 - DUT name
 - DUT model number
 - DUT setting
 - DUT orientation
 - Test room temperature (°C)
 - Name of test laboratory
 - Approving person
 - Date of report approval
- Plots
 - Four plots of port voltage vs. output current for each port.
 - Four plots of port voltage vs. output power for each port.
 - Four plots of battery-to-port efficiency vs. output current for each port.
 - Four plots of battery-to-port efficiency vs. output power for each port.
 - One plot of voltage and current vs. time for each port during dynamic test.

NOTE Multiple characteristic curves may be plotted on the same plot, as long as the results are clearly readable. For example, results from multiple ports for the same operating conditions (e.g., discharging, 14.8 V) may be

combined into a single plot; multiple scenarios for the same port may be combined into a single plot; or multiple quantities (voltage and efficiency) may be plotted on the same plot.

- Tables

- Four tables for each port showing the relationship between output current and output voltage.
- Four tables for each port showing the relationship between output power and output voltage.
- Six tables for each port showing the relationship between output current and battery-to-port efficiency.
- Four tables for each port showing the relationship between output power and battery-to-port efficiency.
- Table of power consumption values and functionality for each tested appliance.
- Table of pass/fail functionality and truth in advertising values for each port.
- Table of minimum, typical, and maximum voltages and maximum power for each port.
- Three tables of peak overshoot voltage, peak undershoot voltage, and undershoot time.
- Table of data line voltages and resistances for each USB port.

NOTE Multiple tables sharing the same set of row or column headings may be combined into a single table.

- Comments

- Individual comments, as necessary, for samples 1 through n
- Overall comments, as necessary, for collective set of samples 1 through n

Annex Q (normative)

Appliance tests

Q.1 Background

Annex Q applies to any appliances included or advertised for use with SHS kits. Appliances to be tested include light points, fans, televisions, radios, refrigerators, and other similar devices. If more than one identical appliance is included with the DUT kit, only one of each identical appliance should be tested to represent a single sample.

Annex Q contains four test methods: an appliance power consumption test (Q.5), a charging efficiency test (Q.6), an operating voltage range test (Q.7), and an appliance full-battery run time test (Q.8). The charging efficiency test (Q.6) and appliance full-battery run time test (Q.8) are only applicable to appliances with internal batteries. The operating voltage range test (Q.7) is applicable to appliances with and without internal batteries, but is necessary only for appliances that were not tested with the SHS kit in P.4.2.5 (for example, new appliances that a manufacturer wishes to test for use with an SHS kit that has already been tested).

Some included appliances are portable, have internal batteries, and/or provide light. Specific tests for these appliances are outlined in Q.2.

Built-in appliances, such as integrated radios or light points with a driver or ballast that is included as part of the battery box, shall be identified in the visual screening (E.4.1.5 c) 9)) and the power consumption and voltage range shall be tested according to methods described in the assessment of DC ports (Annex P).

Q.2 Appliance testing requirements

Appliances shall be evaluated for specific outcomes according to the appliance category as described below:

- All appliances shall undergo the switch and connector test (W.4.2), the gooseneck/moving parts test (W.4.3), the strain relief test (W.4.4), and physical ingress protection test (X.4.3), as applicable.
- Portable appliances shall also undergo the appliance drop test (W.4.1), as applicable (for example, a television is not expected to pass a drop test and other non-lighting appliances are subject to a modified drop test), and level of water protection assessment (Annex Y).
- Appliances with an internal battery shall undergo the battery test (Annex I), deep discharge protection test (K.4.1), overcharge protection test (K.4.2 and/or K.4.3), and charging efficiency test (Q.6). The appliance's full-battery run time shall be determined using one of the following two methods:
 - The appliance full-battery run time test (Q.8) may be performed.
 - The measured appliance's battery energy (Wh) may be determined using the battery test (Annex I) current-voltage pairs from the battery's final discharge curve. The measured appliance's power consumption may be determined using the procedures in Q.5.6. The estimated appliance full-battery run time may then be calculated according to Q.5.6.5. If the full-battery run time estimated by the laboratory using the measured appliance's battery energy (Wh) and power consumption deviates from the advertised value by more than the truth-in-advertising tolerance specified in the product specification, then the manufacturer's full-battery run time rating shall be used in energy service calculations (Annex R), otherwise the run time estimated by the laboratory shall be used. If the estimated value is disputed, the appliance full-battery run time test (Q.8) may be performed.
- Appliances without an internal battery shall undergo the power consumption tests (Q.5).

- Lighting appliances (appliances that are required by the product specification to undergo the lighting tests) shall undergo the light output test (Annex U), lumen maintenance (Annex T), and light distribution test (Annex V).
- Appliances shall undergo the appliance operating voltage range test (Q.7) unless they have been or will be tested in the assessment of DC ports (Annex P), as described in P.4.2.1.

Table Q.1 – Appliance testing requirements

Metric(s)	Test annex	Non-lighting appliances with an internal battery	Non-lighting appliances without an internal battery	Lighting appliances with an internal battery	Lighting appliances without an internal battery
Switch and connector	Annex W	Yes	Yes	Yes	Yes
Gooseneck/moving parts	Annex W	Yes	Yes	Yes	Yes
Strain relief	Annex W	Yes	Yes	Yes	Yes
Drop test	Annex W	Maybe ^a , see above	No	Yes ^a	No
Physical ingress protection	Annex X	Yes	Yes	Yes	Yes
Level of water protection	Annex Y	Yes ^a	No	Yes ^a	No
Battery capacity	Annex I	Yes	No	Yes	No
Deep discharge protection	Annex K	Yes	No	Yes	No
Overcharge protection	Annex K	Yes	No	Yes	No
Charging efficiency	Annex Q	Yes	No	Yes	No
Full-battery run time	Annex L	Maybe, see above	No	Maybe, see above	Likely tested during Lighting FBRT
Power consumption	Annex Q	Maybe, see above	Yes	Maybe, see above	Yes
Luminous flux	Annex U	No	No	Yes	Yes
Lumen maintenance	Annex T	No	No	Yes	Yes
Light distribution	Annex V	No	No	Yes	Yes
Operating voltage range	Annex P or Annex Q	Yes	Yes	Yes	Yes
^a if portable					

Q.3 Test outcomes

The appliance tests outcomes are listed in Table Q.2.

Table Q.2 – Appliance test outcomes

Metric	Reporting units	Related aspects	Remarks
Power consumption table	Volts (V), Amperes (A), Watts (W), Yes/no	4.2.8.1 Power consumption	A table with 4 columns and multiple rows, including the column headings for each appliance on each measured setting.
Charging efficiency	Percentage	4.2.6	One value for each appliance with an internal battery.
Estimated full-battery run time	Hours (h)	4.2.9.2 Daily energy service	One value for each appliance with an internal battery.
Functionality of each appliance for each simulated battery voltage	Yes/no	4.2.8.1 Appliance voltage compatibility	One yes/no value for appliance functionality under each set of test conditions, and a description of any damage or abnormal operation.
Appliance full-battery run time	Hours (h)	4.2.9.6 Appliance full-battery run time	Dependent on appliance type
Average power over the run time	Watts (W)	n/a	Average power draw over the appliance's run time
Energy removed from the battery over the run time	Watt-hours (Wh)	n/a	Total energy removed over the run time
Active deep discharge protection	Yes/no	4.2.3.13 Battery protection strategy	
Deep discharge protection voltage	Volts (V)	4.2.3.13 Battery protection strategy	
Passive deep discharge protection	Yes/no	4.2.3.13 Battery protection strategy	
Passive discharge protection voltage	Volts (V)	4.2.3.13 Battery protection strategy	

Q.4 Related tests

The power consumption test uses inputs from the visual screening (Annex E) and the assessment of DC ports (Annex P). The measurements of power consumption, appliance full-battery run time, and charging efficiency are used in the energy service calculations (Annex R).

Q.5 Power consumption test

Q.5.1 General

The appliance is tested for power consumption using one of the procedures below:

- LED or CFL light points are tested according to Q.5.2;
- Television sets are tested according to Q.5.3;
- Radios are tested according to Q.5.4;
- All other appliances without internal batteries are tested according to Q.5.5.

Q.5.2 Test procedure for LED or CFL lighting appliances without internal batteries

Q.5.2.1 General

The DUT's included LED or CFL lighting appliances with no internal battery (light points) are tested for power consumption. If the lighting appliance has an internal battery, follow the procedures in Q.5.6. If the lighting appliance has been tested according to the power consumption test of IEC 62257-12-1 at all required settings, and the test was conducted at a voltage within 1 % of the typical port voltage for a port that could be used to power the appliance, the power value from the IEC 62257-12-1 test may be used and this procedure need not be performed.

Q.5.2.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC power supply
- DC ammeter and voltmeter, or two multimeters

Q.5.2.3 Test prerequisites

At the start of the test the light point samples shall be minimally altered and fully functional. Samples should be prepared according to Annex F.

Q.5.2.4 Procedure

- a) Identify the DUT's typical port voltages for any ports that could be used to power the light point, using the values calculated in P.4.4.
- b) Identify the light point settings to be measured. Each of the light point settings should be measured. If the light point has continuous settings, choose the maximum, minimum, and median settings.
- c) Prior to measuring, connect the appliance to a power supply. Turn the light point on, set it to one of the settings to be measured and stabilize the light point according to G.5.3 at the typical port voltage.
- d) After stabilization is complete, using a DC ammeter and voltmeter, or two multimeters, record the current and voltage at the light point (where the wire leads are connected to the light point as shown in Figure G.1). (The current and voltage measurement may be read from the power supply, provided it meets the accuracy requirements of Table BB.2, after accounting for voltage drop in the wires between the power supply and the light point.)
- e) For each additional setting to be measured, set the light point to the setting being measured and allow it to stabilize for 5 minutes. Then repeat step d) for the setting being measured.

Q.5.2.5 Calculations

Calculate the DC power consumption for each setting by multiplying the current and voltage measured at the typical port voltage for each setting.

Q.5.3 Test procedure for television sets without internal batteries

Q.5.3.1 General

The DUT's included television set's On (operation) mode power consumption shall be measured as per IEC 62087-3:2015, 6.4, using the dynamic broadcast-content video signal provided in IEC 62087-2:2015, 4.1.3. If the television set has an internal battery, follow the procedures in Q.5.6.

Q.5.3.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC power supply
- Power measurement instrument meeting the requirements of IEC 62087-1:2015, 5.1.5

- Audio/video signal generation equipment meeting the requirements of IEC 62087-2:2015, 6.1, 6.2 and 6.3
- Dynamic broadcast-content video signal media provided in IEC 62087-2:2015, 4.1.3
- Illuminance measuring instrument meeting the requirements of IEC 62087-1:2015, 5.1.8, if the television set is tested with automatic brightness control enabled

Q.5.3.3 Test prerequisites

At the start of the test the television set samples shall be minimally altered and fully functional. Samples should be prepared according to Annex F.

Q.5.3.4 Procedure

Perform the following steps:

- a) Identify the DUT's typical port voltages for any ports that could be used to power the television set, using the values calculated in P.4.4.
- b) Prior to measuring, connect the television set to a power supply set at the typical port voltage for one of the ports identified in step a).
- c) Configure the television set as specified in IEC 62087-3:2015, 6.3.10.
- d) Stabilize the television set as specified in IEC 62087-3:2015, 6.4.2.
- e) Measure the television set's On (operation) mode power consumption using the dynamic broadcast-content video signal as specified in IEC 62087-3:2015, 6.4.5.3.

For television sets with an automatic brightness control feature enabled by default, the product specification should specify whether the testing should be done with automatic brightness control enabled or disabled.

Q.5.3.5 Calculations

Calculate the average power consumed over the full, ten minute duration of the dynamic broadcast-content video signal as per IEC 62087-3:2015, Clause A.4.

Q.5.4 Test procedure for radios without internal batteries

Q.5.4.1 General

The DUT's included radio without an internal battery is tested for power consumption. If the radio has an internal battery, follow the procedures in Q.5.6.

Q.5.4.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC power supply
- Power measurement instrument meeting the requirements of IEC 62087-1:2015, 5.1.5
- Class 2 sound pressure level (SPL) meter, specified in IEC 61672-1, with A-weighting, specified in IEC 60268-1
- Sine wave audio signal media provided in IEC 62087-2:2015, 4.3.1
- Computer or hardware device able to play the sine wave signal
- A RF/FM transmitter able to receive the sine wave signal played from the computer or hardware device output

Q.5.4.3 Test prerequisites

At the start of the test the radio samples shall be minimally altered and fully functional. Samples should be prepared according to Annex F.

Q.5.4.4 Procedure

Perform the measurement procedure from IEC 62087-6:2015, Clause 6, with the following modifications:

- a) Identify the DUT's typical port voltages for any ports that could be used to power the radio, using the values calculated in P.4.4.
- b) Connect the radio to a power supply set at the typical port voltage.
- c) The On mode of the radio shall be measured according to the steps below. The Off mode, Partial On mode, Idle mode or auto power down shall not be measured.
- d) The radio shall be set up as per IEC 62087-6:2015, 6.2.3, in an environment that approximates an anechoic environment in which a radius of at least 1 m around the SPL meter and 1 m around the radio is clear of objects in order to minimize sound reflection.
- e) Generate the sine wave audio signal using a computer or hardware device and output this to the RF/FM transmitter. The On mode measurement shall only be performed using the computer or hardware device and RF/FM transmitter providing the audio signal. Playing the audio signal directly on the radio through a memory card or other means shall not be used in substitution.
- f) Adjust the output volume from the computer or hardware device and the FM transmitter to approximately 50 %.
- g) Set the radio to its On mode and tune the radio to clearly receive the audio signal from the FM transmitter.
- h) Adjust the audio volume of the radio as per IEC 62087-6:2015, 5.11. If the radio cannot output a volume providing a SPL of 60 dB measured at 1 m from the radio loudspeaker, increase the volume of the computer or hardware device and the RF/FM transmitter to achieve the SPL of 60 dB. If the SPL of 60 dB cannot be achieved, then run the test with the volumes of the radio, computer or hardware device and RF/FM transmitters at their maximum possible level. Note the maximum SPL achieved in the report.
- i) Stabilize the radio by playing the audio signal for 5 minutes.
- j) Measure the On-play mode of the radio for at least 2 minutes as per IEC 62087-6:2015, 6.3.3.1.

Q.5.4.5 Calculations

Calculate the average power consumed over the period the radio plays the sine wave audio signal in On mode.

Q.5.5 Test procedure for fans, motor-driven appliances, and other appliances without internal batteries

Q.5.5.1 General

The DUT's included fan, motor-driven appliance, or other appliances are tested for power consumption. If the appliance has an internal battery, follow the procedures in Q.5.6.

Q.5.5.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC power supply
- DC ammeter and voltmeter, or two multimeters

Q.5.5.3 Test prerequisites

At the start of the test the appliance samples shall be minimally altered and fully functional. Fans shall be tested in still air. Samples should be prepared according to Annex F.

Q.5.5.4 Procedure

- a) Identify the DUT's typical port voltages for any ports that could be used to power the appliance, using the values calculated in P.4.4.
- b) Identify the appliance settings to be measured. Each of the appliance settings should be measured. If the appliance has continuous settings, choose the maximum, minimum and median setting.

- c) Prior to measuring, connect the appliance to a power supply set to the typical port voltage. Turn the appliance on set it to one of the settings to be measured.
- d) Adjust the power supply so that the voltage at the appliance (where the wire leads are connected to the appliance as shown in Figure G.1) is the typical port voltage.
- e) Allow the appliance to stabilize for 30 minutes.
- f) After stabilization is complete, using a DC ammeter and voltmeter, or two multimeters, record the current and voltage at the appliance (where the wire leads are connected to the appliance as shown in Figure G.1). (The current and voltage measurement may be read from the power supply provided it meets the accuracy requirements of Table BB.2 after taking into account the voltage drop in the wires connecting the power supply to the appliance.)
- g) For each additional setting to be measured, set the appliance to the setting being measured and allow it to stabilize for 30 minutes. Then repeat step f) for the setting being measured.

Q.5.6 Test procedure for appliances with internal batteries

Q.5.6.1 General

The DUT's included appliance with an internal battery is tested for power consumption.

Q.5.6.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC power supply
- For radios and television sets:
 - Power measurement instrument meeting the requirements of IEC 62087-1:2015, 5.1.5
 - Audio/video signal generation equipment meeting the requirements of IEC 62087-2:2015, 6.1, 6.2 and 6.3
- For television sets:
 - Dynamic broadcast-content video signal media provided in IEC 62087-2:2015, 4.1.3
 - Illuminance measuring instrument meeting the requirements of IEC 62087-1:2015, 5.1.8, if the television set is tested with automatic brightness control enabled
- For radios:
 - Class 2 sound pressure level meter, specified in IEC 61672-1, with A-weighting, specified in IEC 60268-1
 - Computer or hardware device able to play the sine wave signal
 - A RF/FM transmitter able to receive the sine wave signal played from the computer or hardware device output
- For other appliances, DC ammeter and voltmeter, or two multimeters

Q.5.6.3 Test prerequisites

At the start of the test the appliance samples shall be minimally altered and fully functional. Fans shall be tested in still air. Samples should be prepared according to Annex F.

Q.5.6.4 Procedure

- a) Replace the appliance's battery with a power supply providing power at the standard operating voltage (on a per-cell basis) as defined in G.5.2.
- b) If the appliance is a lighting appliance, perform the following steps:
 - 1) Identify the light point settings to be measured. Each of the light point settings should be measured. If the light point has continuous settings, choose the maximum, minimum, and median settings.
 - 2) Turn the light point on, set it to one of the settings to be measured and stabilize the light point according to G.5.3 at the typical port voltage.

- 3) After stabilization is complete, using a DC ammeter and voltmeter, or two multimeters, record the current and voltage draw of the lighting appliance from its power source (where the power supply wire leads are connected to the appliance's electronics). (The current and voltage measurement may be read from the power supply provided it meets the accuracy requirements of Table BB.2 after taking into account the voltage drop in the wires connecting the power supply to the appliance.)
 - 4) For each additional setting to be measured, set the light point to the setting being measured and allow it to stabilize for 5 minutes. Then repeat step 3) for the setting being measured.
- c) If the appliance is a television set, follow step c) in Q.5.3.4.
- d) If the appliance is a radio, perform the steps in Q.5.4.4, omitting steps a) and b).
- e) If the appliance is a fan, is motor-driven, or other, perform the following steps:
- 1) Identify the appliance settings to be measured. Each of the appliance settings should be measured. If the appliance has continuous settings, choose the maximum, minimum and median setting.
 - 2) Turn the appliance on set it to one of the settings to be measured.
 - 3) Allow the appliance to stabilize for 30 minutes.
 - 4) After stabilization is complete, using a DC ammeter and voltmeter, or two multimeters, record the current and voltage at the appliance where the power supply wire leads are connected to the appliance's electronics). (The current and voltage measurement may be read from the power supply provided it meets the accuracy requirements of Table BB.2 after taking into account the voltage drop in the wires connecting the power supply to the appliance.)
 - 5) For each additional setting to be measured, set the appliance to the setting being measured and allow it to stabilize for 30 minutes. Then repeat step 4) for the setting being measured.

Q.5.6.5 Calculations

For television sets, follow the calculations in Q.5.3.5. For radios, follow the calculations in Q.5.4.5. For all other appliances, calculate the DC power consumption for each setting by multiplying the current and voltage measured at the typical port voltage for each setting.

Calculate an estimate of the appliance's full battery run time using the following formula:

$$t_{\text{efbri}} = \frac{\sum (V_d \cdot I_d \cdot \Delta t)}{P_{\text{app}}}$$

where

t_{efbri} is the estimated full-battery run time of the appliance, in hours (h);

V_d is the voltage recorded during the final discharge cycle during the appliance battery capacity test, in volts (V);

I_d is the current recorded during the final discharge cycle during the appliance battery capacity test, in amperes (A);

Δt is the time interval between measurements during the appliance battery capacity test, in hours (h);

P_{app} is the DC power consumption measured for the appliance (W);

Q.6 Charging efficiency test

Q.6.1 General

The charging efficiency is measured for all the DUT's included appliances with an internal battery.

Q.6.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC power supply
- DC ammeter and voltmeter, or two multimeters
- Battery simulator (optional), which, if used, shall be one of the following:
 - The battery simulator circuit defined in IEC 62509:2010, Figure 1, with parameters from IEC 62509:2010, 5.1.6.2.
 - A or two- or four-quadrant (bipolar) power supply or power amplifier (which may be a commercially available battery simulator).
 - An electronic load

The use of a battery simulator can provide more stable and controllable operating conditions, resulting in more repeatable results, but the use of the appliance's battery is permitted as a low-cost option. If an electronic load is used, it may be necessary to use a DC power supply set to constant-current mode connected in parallel with the load to provide a voltage at the battery terminals when the appliance is not attempting to charge the battery.

Q.6.3 Test prerequisites

At the start of the test the appliance batteries should be at a 50% state of charge. Samples should be prepared according to Annex F.

Q.6.4 Procedure

- a) Identify the DUT's typical port voltage for the port that is used to power the appliance with an internal battery, using the values calculated in P.4.4.
- b) Prior to measuring, connect the appliance to a power supply with its charging cable. Do *not* turn the appliance on.
- c) Adjust the power supply so that the voltage at the appliance (where the wire leads are connected to the appliance as shown in Figure G.1) is the typical port voltage. Record if the appliance is properly charging, i.e. charging function.
- d) Allow the appliance to stabilize for 5 minutes.
- e) After stabilization is complete, using a DC ammeter and voltmeter, or two multimeters, record the current and voltage at the appliance's plug (where the wire leads are connected to the appliance as shown in Figure G.1), while simultaneously using an additional DC ammeter and voltmeter, or two multimeters, to record the current and voltage at the leads of the appliance's battery. (The current and voltage measurement *at the appliance's plug* may be read from the power supply provided it meets the accuracy requirements of Table BB.2 after taking into account the voltage drop in the wires connecting the power supply to the appliance.)
- f) Repeat steps a) through e) for all appliances with batteries that are included in the DUT's kit.

Q.6.5 Calculations

Calculate the charging efficiency for each of the DUT's appliances with an internal battery using the following formula:

$$\eta_{ac} = \frac{V_{ab} \cdot I_{ab}}{V_{ap} \cdot I_{ap}}$$

where

- η_{ac} is the appliance's charging efficiency as a fraction;
- V_{ab} is the voltage measured across the appliance's battery (V);
- I_{ab} is the current measured entering the appliance's battery (A);
- V_{ap} is the voltage measured across the appliance's port (V);
- I_{ap} is the current measured entering the appliance's port (A).

Q.7 Appliance operating voltage range test

Q.7.1 General

This procedure assesses whether the appliance operates normally and without damage at the operating voltages that it would experience when powered by the SHS kit under test. This procedure shall be performed on all appliances that were not subject to the test procedure in P.4.2.5. If the appliance was tested with the SHS kit in P.4.2.5, this procedure is not necessary.

This procedure is primarily intended to enable testing of additional appliances for SHS kits that have already been tested, in cases where the test laboratory does not possess samples of the SHS kit components required for the test in P.4.2.5, for example in cases where a manufacturer wishes to include a new appliance in an existing SHS kit that has already been tested according to this quality assurance protocol. While the test may be performed by a laboratory that does not possess samples of the full kit, the results are only applicable to the full kit under test, except as specified in Q.7.4, since the results used are dependent on the port performance data for that particular kit.

Q.7.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC power supply
- DC ammeter and voltmeter, or two multimeters
- Procedure for appliances without internal batteries

Q.7.3 Test prerequisites

The measurement of steady-state port performance (P.4.2) and summary calculations (P.4.4), in the assessment of DC ports (Annex P), and the appliance power consumption test (Q.5) are prerequisites for the appliance operating voltage test.

The required values from the assessment of DC ports shall aggregated over all tested samples, as follows:

- For the typical port voltage, use the average of the typical port voltages of all tested samples for the port selected. If the appliance can be used with multiple port types, use the average for all ports with which the appliance can be used.
- For the minimum and maximum voltages calculated in Q.7.5 b) 2), Q.7.5 c) 1), Q.7.6 a) 2), Q.7.6 b) 1), and Q.7.7 f), use the minimum and maximum over all samples for the port selected. If the appliance can be used with multiple port types, use the minimum and maximum over all ports with which the appliance can be used.

For appliances with internal batteries, it is necessary to determine the discharge endpoint for the appliance full-battery run time test (Q.8) prior to performing the appliance operating voltage range test. To expedite the test, fully charged and/or discharged appliance samples may be prepared in advance, using either of the following methods:

- Twice the required number of samples may be used, with half of the samples fully charged and half fully discharged before the procedure;

- The required samples may be prepared by charging half and discharging half. After the test is completed on these samples, the fully discharged samples are fully charged and the fully charged samples are discharged, and then the test is repeated.

Q.7.4 Simultaneous testing for multiple SHS kits and applicability of previous test results

This test may be performed using aggregated data from multiple SHS kit products, using the aggregation rules defined in Q.7.3 (i.e., the average typical port voltage and minimum and maximum voltage values over all kits are used.) Combining tests in this way can reduce testing costs significantly, but can result in a failing result in some cases where separate testing for each kit would have resulted in passing results for some kits and failing results for others. In such a situation the laboratory should repeat the test, performing separate tests for each kit, unless otherwise agreed with the testing client in advance.

If an appliance has undergone the operating voltage range test for a different SHS kit, the previous results may be used if the minimum and maximum voltages for the new SHS kit, calculated in Q.7.5 b) 2), Q.7.5 c) 1), Q.7.6 a) 2), Q.7.6 b) 1), and Q.7.7 f) as applicable, are fully included in the corresponding voltage ranges from the previous testing (i.e., the new minimum voltage in each step is less than or equal to the minimum voltage from previous testing and the new maximum voltage in each step is greater than or equal to the maximum voltage from previous testing).

In anticipation of future products, the testing client may specify minimum and maximum voltages to be used in this test, provided that the minimum voltage is less than or equal to those determined in the test procedure, and the maximum voltage is greater than or equal to those determined in the test procedure. If any maximum voltage calculated in the procedure is greater than the manufacturer-specified maximum voltage, or any minimum voltage is less than the manufacturer-specified minimum voltage, the calculated voltages shall be used instead of the manufacturer-specified voltages.

Q.7.5 Procedure for lighting appliances without batteries that have been tested according to the input voltage range test of IEC 62257-12-1

For lighting appliances without batteries that have been tested according to the input voltage range test of IEC 62257-12-1, the following procedure may be performed. Alternatively, the procedure in Q.7.6 may be used. For all test results reported in this procedure, indicate whether the result is based on measurement of the DUT or the IEC 62257-12-1 test results.

- a) If the maximum allowable voltage from the input voltage range test of IEC 62257-12-1 is greater than or equal to the maximum port voltage identified in P.4.4, or if the appliance does not have an on/off switch and cannot otherwise be turned off while connected to a port, record that the appliance is adequately protected when turned off, then skip step b).

NOTE Steps a) and b) are performed because components of the appliance can be exposed to the port voltage even though the appliance is turned off, and the port voltage can be higher in this case than when the appliance is turned on and drawing current.

- b) If the maximum allowable voltage from the input voltage range test of IEC 62257-12-1 is less than the maximum port voltage identified in P.4.4, *and* the appliance has an on/off switch or can otherwise be turned off while connected to a port, perform the following steps:
 - 1) Turn off the appliance. Measure the power or current consumption of the appliance at the typical port voltage. (If multiple samples underwent the assessment of DC ports, use the average value of the typical port voltage over all tested samples. If the appliance can be used with multiple port types, use the average over all ports with which the appliance can be used.)
 - 2) From the plots of port voltage vs. power or port voltage vs. current generated in P.4.2.6, and corresponding data, identify the maximum value of port voltage, over all simulated battery voltages and all tested samples, corresponding to the current or power measured in 1). If necessary, linearly interpolate between adjacent measurements. Figure Q.1 illustrates the calculation procedure. If the appliance can be used with multiple ports, use the highest value over all ports with which the appliance can be used.

- 3) If the maximum allowable voltage from the input voltage range test of IEC 62257-12-1 is greater than or equal to the voltage identified in 2), record that the appliance is adequately protected when turned off, then skip step 4) and proceed with step c).
 - 4) If the maximum allowable voltage from the input voltage range test of IEC 62257-12-1 is less than the voltage identified in 2), perform Q.7.6 a) 3) through 6) using the voltage identified in 2).
- c) Perform the following steps for each appliance setting measured in Q.5:
- 1) From the plots of port voltage vs. power generated in P.4.2.6, and corresponding data, identify the minimum and maximum values of port voltage, over all simulated battery voltages and all tested samples, corresponding to the power value measured in Q.5. If necessary, linearly interpolate between adjacent measurements. Figure Q.1 illustrates the calculation procedure. If the appliance can be used with multiple ports, use the minimum and maximum values over all ports with which the appliance can be used.
 - 2) If the IEC 62257-12-1 test results show that the appliance was functional at a voltage less than or equal to the minimum voltage identified in 1), record that the appliance is functional at that voltage. Otherwise, perform Q.7.6 b) 2) and 3).
 - 3) If the IEC 62257-12-1 test results show that the appliance was functional at a voltage greater than or equal to the maximum voltage identified in 1), record that the appliance is functional at that voltage, then skip steps 4) and 5).
 - 4) If the maximum allowable voltage from the input voltage range test of IEC 62257-12-1 is greater than the maximum voltage identified in 1) and no safety hazard was identified, but the IEC 62257-12-1 test results indicate that the appliance was *not* functional at the voltage identified in 1), record that the appliance is not functional at that voltage but that no damage or safety hazard occurs, then skip step 5).
 - 5) If the maximum allowable voltage from the input voltage range test of IEC 62257-12-1 is less than the maximum voltage identified in 1) *or* if it is not possible to determine from the IEC 62257-12-1 results whether the appliance was functional at the voltage identified in 1), perform Q.7.6 b) 4) through 6).

Key

P Port output power, in watts

V Port voltage, in volts

1 Plot of voltage vs. power at the overcharge protection voltage (P.4.2.5 j))

2 Plot of voltage vs. power at the average charging voltage (P.4.2.5 k))

3 Plot of voltage vs. power at the standard operating voltage (P.4.2.5 a) through e))

4 Plot of voltage vs. power at the deep discharge protection voltage (P.4.2.5 i))

5 Appliance power measured in Q.5

6 Minimum value of port voltage over all simulated battery voltages

7 Maximum value of port voltage over all simulated battery voltages

NOTE 1 The minimum port voltage will typically, but not always, occur when the product is powered at the deep discharge protection voltage, and the maximum port voltage will typically, but not always, occur when the product is powered at the overcharge protection voltage.

NOTE 2 The minimum and maximum values of the port voltage shown here are not to be confused with the minimum port voltage and maximum port voltage defined in P.4.4. The voltages defined in P.4.4 are not used in the appliance operating voltage range test because they are not reflective of the operating conditions when a specific appliance is connected to the port.

NOTE 3 The data for one sample is shown in this plot. If multiple samples underwent the assessment of DC ports, the minimum and maximum values are calculated using the data for all samples, not separately for each sample.

Figure Q.1 – Illustration of calculation of minimum and maximum values of port voltage for the appliance operating voltage range test

Q.7.6 Procedure for appliances without an internal battery

Perform the following steps:

- a) If the appliance has an on/off switch or can otherwise be turned off while connected to a port, perform the following steps:

NOTE This step is performed because components of the appliance can be exposed to the port voltage even though the appliance is turned off, and the port voltage can be higher in this case than when the appliance is turned on and drawing current.

- 1) Turn off the appliance. Measure the power or current consumption of the appliance at the typical port voltage. (If multiple samples underwent the assessment of DC ports, use the average value of the typical port voltage over all tested samples. If the appliance can be used with multiple port types, use the average over all ports with which the appliance can be used.)

- 2) From the plots of port voltage vs. power or port voltage vs. current generated in P.4.2.6, and corresponding data, identify the maximum value of port voltage, over all simulated battery voltages and all tested samples, corresponding to the current or power consumption of the appliance when turned off, as measured in 1). If necessary, linearly interpolate between adjacent measurements. Figure Q.1 illustrates the calculation procedure. If the appliance can be used with multiple ports, use the highest value over all ports with which the appliance can be used.
 - 3) Without turning the appliance on, apply a voltage to the appliance equal to the value identified in 2).
 - 4) Wait five minutes.
 - 5) Return the voltage at the appliance to the typical port voltage.
 - 6) Record whether the appliance functions correctly; note any damage or abnormal operation.
- b) Perform the following steps for each appliance setting measured in Q.5:
- 1) From the plots of port voltage vs. power generated in P.4.2.6, and corresponding data, identify the minimum and maximum values of port voltage, over all simulated battery voltages and all tested samples, corresponding to the power consumption of the appliance as measured in Q.5. If necessary, linearly interpolate between adjacent measurements. Figure Q.1 illustrates the calculation procedure. If the appliance can be used with multiple ports, use the minimum and maximum values over all ports with which the appliance can be used.
 - 2) Apply a voltage to the appliance equal to the minimum voltage identified in 1).
 - 3) Turn on the appliance and allow it to operate at the setting under test for at least five minutes. Record whether the appliance functions correctly; note any damage or abnormal operation.
 - 4) Set the voltage at the appliance to the maximum voltage identified in 1).
 - 5) Allow the appliance to operate at the setting under test for at least five minutes. Record whether the appliance functions correctly; note any damage or abnormal operation.
 - 6) If the appliance does not function correctly, return the voltage at the appliance to the typical port voltage and again test the appliance for functionality.

Q.7.7 Procedure for appliances with an internal battery

Perform the following steps:

- a) Identify the typical port voltage of the port or ports with which the appliance can be used. (If multiple samples underwent the assessment of DC ports, use the average value of the typical port voltage over all tested samples. If the appliance can be used with multiple port types, use the average over all ports with which the appliance can be used.)
- b) Fully discharge the appliance's battery to the discharge endpoint defined in the appliance full battery run time test (Q.8).
- c) Using a DC power supply, apply a voltage to the appliance equal to the typical port voltage identified in a).
- d) Allow the appliance to stabilize for 5 min.
- e) Measure the power or current after the 5 min stabilization period has elapsed.
- f) From the plots of port voltage vs. power or port voltage vs. port current generated in P.4.2.6, and corresponding data, identify the minimum and maximum values of port voltage, over all simulated battery voltages and all tested samples, corresponding to the appliance power or current measured in e). If necessary, linearly interpolate between adjacent measurements. Figure Q.1 illustrates the calculation procedure. If the appliance can be used with multiple ports, use the minimum and maximum values over all ports with which the appliance can be used.
- g) Apply a voltage to the appliance equal to the minimum voltage identified in f).

- h) Determine whether the appliance charges by observing the port current as well as any charging indicators on the appliance. Record whether the appliance charges.
- i) Apply a voltage to the appliance equal to the maximum voltage identified in f).
- j) Determine whether the appliance charges by observing the port current as well as any charging indicators on the appliance. Record whether the appliance charges.
- k) If the appliance does not charge or exhibits abnormal behaviour in j), decrease the voltage at the appliance to the typical port voltage and again check whether the appliance charges.
- l) Fully charge the appliance's battery. (Alternatively, use a different sample of the appliance with a fully charged battery.)
- m) Using a DC power supply, apply a voltage to the appliance equal to the typical port voltage identified in a).
- n) Allow the appliance to stabilize for at least five minutes. (In some cases, an appliance may begin charging when connected even though the battery was previously fully charged. In this case, allow the appliance to stop charging (i.e., wait until the current drops to zero or stabilizes at a low value) before starting the five-minute waiting period. Note that some appliances can indicate a full charge even though the battery is still charging.)
- o) Repeat steps e) through k) with the fully charged appliance. If the appliance starts charging when the voltage is changed, start the 5 min timer after the appliance stops charging, as in n).
- p) Disconnect the appliance from the port.
- q) Check the appliance for functionality. Note any damage or abnormal operation.

The order of testing the fully charged and fully discharged appliance may be reversed at the discretion of the laboratory.

Q.8 Appliance full-battery run time test procedure with deep discharge protection measurement

Q.8.1 General

The appliance is set in a safe location while the appliance battery current and voltage are recorded while it discharges from a full state of charge. This procedure is only performed on non-lighting appliances with an internal battery. The full-battery run time for any included lighting appliance with an internal battery may be determined using the full-battery run time test (Annex L).

Q.8.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Battery analyser
- Voltage data logger
- Current data logger (e.g. voltage data logger and current transducer)
- Low-voltage disconnect device that will stop a DUT's discharge when the DUT's battery reaches a specified voltage (recommended)
- For testing radios:
 - Class 2 sound pressure level meter, specified in IEC 61672-1, with A-weighting, specified in IEC 60268-1
 - Computer or hardware device able to play the sine wave signal
 - A RF/FM transmitter able to receive the sine wave signal played from the computer or hardware device output
- For testing fans, an anemometer
- DC power supply
- DC ammeter and voltmeter, or two multimeters

The total series resistance added by the test apparatus and all measurement equipment shall be no more than 60 mΩ. This value includes the resistance of the wires and connectors, if any, added in the sample preparation procedure (F.4.4).

Q.8.3 Test prerequisites

Cycle the DUT's battery according to the procedures in the battery test annex (Annex I) and the information in the battery testing recommended practices annex (Annex J).

Q.8.4 Apparatus

The required apparatus depends on the type of appliance being tested. The most common appliances that may include an internal battery are radios and fans. The apparatus for other appliance types shall be decided between the manufacturer and the test laboratory.

If the appliance is a radio, set up an environment as per IEC 62087-6:2015, 6.2.3, that approximates an anechoic environment in which a radius of at least 1 m around the SPL meter and 1 m around the radio is clear of objects in order to minimize sound reflection. If the appliance is a fan, an enclosure that is at least 3 m³ with no detectable airflow is required.

Q.8.4.1 Procedure

- a) Determine the power draw corresponding to the appliance's full-battery run time end point. The appliance's full-battery run time end point is dependent on the appliance type.
 - If the appliance is a radio, set it to receive the sine wave audio signal from the RF/FM transmitter and output a volume of 40 dB at 1 m from the radio loudspeaker.
 - If the appliance is a fan, replace the battery with a power supply and adjust the power supply until the fan's air velocity measures 0 m/s. The anemometer shall be placed at a distance of 0.5 m in front of the centre of the fan's blades.
 - If the DUT is a different appliance type, the method to determine the DUT's full-battery run time end point shall be decided between the manufacturer and the test laboratory.
- b) Replace the appliance battery with a laboratory power supply set to the appliance battery's standard operating voltage (Annex G). Measure the appliance battery voltage and current draw according dependent on the appliance type.
 - If the appliance is a radio, follow Q.5.4.4 steps h) and i).
 - If the DUT is a different appliance type, follow Q.5.5.4 steps e) and f).
- c) Calculate the appliance's battery power draw corresponding to the specified full-battery run time end point.
- d) Before measurement, fully charge the appliance battery using one of the following two procedures according to the appliance's battery chemistry:
 - If the appliance battery is NiMH , then the procedures in the battery test (Annex I) may be used.
 - If the appliance battery is any chemistry, then charge the appliance via its charging cable using a laboratory power supply set to the typical port voltage of a port to which the appliance can be connected (P.4.4).

The run time test may be started between 1 h and 24 h after the DUT has finished receiving its full charge. Use the following procedure:

- e) Set and secure the appliance inside the appropriate test cavity such that it is stable and cannot be jostled.
- f) Prepare the voltage data logger to measure voltage across the appliance's battery terminals at intervals of 1 min or less. Prepare the current data logger to measure the current exiting the appliance battery at the negative battery terminal at intervals of 1 min or less. If it is unclear if the appliance has deep discharge protection for its battery, the tester may prepare the low-voltage disconnect device so that it stops the appliance's

discharge if the appliance battery reaches the minimum battery testing voltage specified in Annex J.

- g) Some appliances that use coulomb counting or similar methods for estimating state of charge will not correctly detect the battery state of charge when a discharge is started immediately after the battery is disconnected. This may result in the appliance turning off or reducing brightness prematurely during the full-battery run time test. When testing such appliances, appropriate steps shall be taken, prior to starting the discharge, to reset the appliance's battery gauge. For example, in some products, charging the product for a few minutes via the charging input using its typical charging source or power supply configured to provide the DUT's typical port voltage (P.4.4) will reset the battery gauge. The test laboratory should consult with the manufacturer of the DUT to determine an appropriate reset procedure. After the reset procedure, the battery shall not be disconnected from the appliance prior to starting the discharge in step c).

In case of pulse-width modulation (PWM) controllers, aliasing effects (beat effects) can occur due to un-synchronised PWM frequency and sampling frequency of the current logger. This can lead to "chaotic" measurements which are difficult to interpret. In this case, the test may be conducted using a power meter with accuracy equivalent to that of the multimeters.

- h) Set up the appliance and switch it ON at the setting specified below to begin the appliance's full-battery run time test.
- If the appliance is a radio, set it to receive the sine wave audio signal from the RF/FM transmitter and output a volume of 60 dB at 1 m from the radio loudspeaker. If the radio cannot output a volume providing a SPL of 60 dB measured at 1 m from the radio loudspeaker, increase the volume of the computer or hardware device and the RF/FM transmitter to achieve the SPL of 60 dB. If the SPL of 60 dB cannot be achieved, then run the test with the volumes of the radio, computer or hardware device and RF/FM transmitters at their maximum possible level. Note the maximum SPL achieved in the report.
 - If the appliance is a fan, set the fan to provide its maximum airflow. The anemometer shall be placed at a distance of 0.5 m in front of the centre of the fan's blades.
 - If the appliance is a different appliance type, the setting shall be decided between the manufacturer and the test laboratory.
- i) Measure the appliance battery voltage and current at intervals of 1 min or less.
- j) The appliance's full-battery run time end point is dependent on the appliance type. The appliance's battery power draw corresponds to the specified full-battery run time end point.
- If the appliance is a radio, the full-battery run time is the duration of the appliance's discharge from the start of the test to when the measured radio volume reaches 40 dB. Use the appliance battery power draw corresponding to the specified full-battery run time end point, determined in step b) above, to determine when the measured radio volume reaches 40 dB.
 - If the appliance is a fan, the full-battery run time is the duration of the DUT's discharge from the start of the test to when the fan's air velocity reaches 0 m/s. Use the time at which the appliance's battery power draw corresponds to the specified full-battery run time end point, determined in step b) above, to determine when the measured fan air velocity reaches 0 m/s.
 - If the appliance is a different appliance type, the end point for the appliance's full-battery run time shall be decided between the manufacturer and the test laboratory. Use the time at which the appliance's battery power draw corresponding to the specified full-battery run time end point, determined in step b) above, to determine when the different appliance type reaches its full-battery run time end point
- k) The test should be continued until the a low-voltage disconnect is observed with the appliance, or 24 hours after reaching the appliance's full-battery run time endpoint.
- l) If the battery contains internal circuitry (refer to E.4.3.5) and the measured deep discharge protection voltage is outside of the targets specified by the manufacturer (C.3.1.2) or the appliance's battery falls below the recommended deep discharge protection voltage

specified in Annex J, the test may be repeated with the voltage data logger connected on the battery side of the internal circuitry, if the test laboratory determines that it is safe to do so.

Q.8.4.2 Calculations

Analyse the time-series service data to estimate the appliance’s full battery run time. Analyse the time-series current and voltage data to estimate the average power over the run time and the total energy removed from the battery over the run time.

- a) The end of the discharge period is reached according to the appliance type:
 - If the appliance is a radio, the full-battery run time is the duration of the appliance’s discharge from the start of the test to when the measured radio volume reaches 40 dB.
 - If the appliance is a fan, the full-battery run time is the duration of the appliance’s discharge from the start of the test to when the fan’s air velocity reaches 0 m/s.
 - If the appliance is a different appliance type, the end point for the DUT’s full-battery run time shall be decided between the manufacturer and the test laboratory.
- b) The result shall be noted, expressed in hours (h).
- c) The recorded data should be presented in a graph such as the one shown in Figure L.2. The graph should include the full discharge, beginning at 0 min.

Key

- t Time (min)
 ϕ Relative light output (%), which is directly proportional to the luminous flux output

- 1 20 min from point DUT is turned on
- 2 t_i , time when RLO is defined as 100 %
- 3 L_{70} reached (RLO is 70 %)
- 4 t_{70} , time when RLO is 70 %

Figure Q.2 – Plot of example results from the full-battery run time test

- d) Determine the average power over the full-battery run time ($P_{b,i}$) using the following formula:

$$P_{b,i} = \frac{\sum (I_{b,i} \cdot V_{b,i})}{n}$$

where

$P_{b,i}$ is the average power exiting the battery over the run time, in watts (W);

$I_{b,i}$ is the current exiting the battery over the run time, in amperes (A);

$V_{b,i}$ is the voltage exiting the battery over the run time, in volts (V);

n is the total number of current and voltage measurements over the run time (unitless)

- e) Determine the energy removed from the battery over the run time ($E_{b,i}$) using the following formula:

$$E_{b,i} = \sum_i (I_{b,i} \cdot V_{b,i} \cdot t_i)$$

where

$E_{b,i}$ is the energy exiting the battery over the run time, in watt-hours (Wh);

$I_{b,i}$ is the current exiting the battery over the run time, in amperes (A);

$V_{b,i}$ is the voltage exiting the battery over the run time, in volts (V);

t_i is the duration of time associated with each current and voltage point over the run time, in hours (h)

- f) Determine if the appliance has deep discharge protection incorporated into its charge controller and report the deep discharge protection voltage. If the appliance has active deep discharge protection, one of two behaviours can be observed: (1) an abrupt drop will occur in the appliance's service and current will quickly decrease to 0 A, or (2) a relatively quick drop will occur in the appliance's service and current will ultimately decrease to 0 A. In either case, the minimum battery voltage recorded up to the time at which the appliance's battery current reaches zero is the deep discharge protection voltage.
- g) Report whether the deep discharge protection is internal to the battery. Typically, if the deep discharge protection circuit is external to the battery, the battery voltage will remain constant or increase after the deep discharge protection circuit disconnects the battery. If the deep discharge protection is internal to the battery pack, the voltage will drop to zero once the deep discharge protection voltage is reached. (In the latter case, ensure that the reported deep discharge protection voltage occurred before the internal protection circuit isolated the battery. If the battery voltage drops quickly, this can be difficult to determine.)
- h) If the DUT does not have active deep discharge protection, determine if the appliance has passive deep discharge protection. If the DUT has passive deep discharge protection, a gradual decrease will occur in the DUT's service and current will gradually decrease to a relatively low value. If the DUT's battery voltage is greater than or equal to the identified deep discharge protection voltage (see J.2) threshold 24 hours after it reaches its run time, then the product has appropriate passive deep discharge protection. Report if passive deep discharge protection was observed in the DUT.
- i) If the DUT has passive deep discharge protection, report the DUT's passive deep discharge protection voltage at 24 h, in volts (V). The battery voltage typically continues to decrease during the 24 hours after the DUT reaches its run time. Determine the passive deep discharge protection voltage by identifying the battery voltage 24 hours after the DUT reaches its run time.
- j) Report if appropriate deep discharge protection was observed in the DUT.
- k) If the DUT has appropriate deep discharge protection, report the DUT's deep discharge protection voltage, in volts (V).

Q.9 Reporting

Report the following in the appliance test report:

- Metadata

- Report name
- Procedure(s) used
- DUT manufacturer
- DUT name
- DUT model number
- Test room temperature (°C)
- Name of test laboratory
- Approving person
- Date of report approval
- Appliances tested
- Appliance settings tested
- Results for tested appliances' aspects for samples 1 through n
- Comments
- Figures
 - Plot showing the service against the run time (min), as in Figure L.2
- Tables
 - Table of typical port voltage, measured voltage, measured current, power, and, whether the appliance is functional for each sample of each appliance on each setting (see Table Q.3 for an example).
 - Comments
 - Individual comments, as necessary, for samples 1 through n
 - Overall comments, as necessary, for collective set of samples 1 through n

Table Q.3 – Example table of nominal operating voltage, measured voltage, measured current, and calculated power.

Appliance	Setting	Sample #	Typical Port Voltage (V DC)	Measured Voltage (V DC)	Measured Current (A DC)	Power (W DC)	Functionality (Yes/no)	Remarks
Light 1	High	1	12,3	12,32	0,27	3,3	Yes	
Fan	High	1	12,3	12,32	,67	8,25	Yes	
TV	Standard	1	12,3	12,32	1,21	14,9	Yes	

Annex R (normative)

Energy service calculations

R.1 Background

Annex R describes methods for synthesizing test results to estimate the energy service capabilities for an SHS kit. The range of energy services encapsulate a utility level (e.g., lumens of light, or volume of radio play) and a duration or run time. Run times are often advertised for one or two initial battery states – with a fully charged battery and after a typical day's solar charge. As systems get more complex and can power a diverse range of loads, the number of permutations in potential service level combinations grows exponentially. The methods described here include estimates for

- a) appliances used individually in each setting (all other appliances off), and
- b) specified combinations of appliances used together in specific settings.

The full-battery run time test (Annex L) directly measures the run time with only the lighting appliance(s) (on the brightest settings) connected. This approach estimates one but not all possible full-battery run time settings or appliance combinations. Combining this estimate with supporting information about the system, Annex R describes estimates for

- a) each appliance's full-battery run time used individually in each setting,
- b) full-battery run times for appliances combined under an example usage profile specified by the test method, and
- c) full-battery run times for appliances combined under an advertised usage (only captured if a run time combination is advertised).

The three scenarios of interest aim to cover all possible methods of advertising the DUT's full-battery run time as well as an example usage profile if no appropriate usage combination is advertised. If the DUT has only one lighting appliance and no additional appliance options, then run times described in scenarios b) and c) above cannot be estimated.

Another core output from this method is a set of similar run times describing the way the DUT can utilize a typical day's solar charge, referred to as the DUT's solar run times. The procedures in Annex R estimate the DUT's solar run times based on efficiency values determined in the solar charge test (Annex N) for the following:

- a) Each appliance's solar run time used individually in each setting,
- b) Solar run times for appliances combined under an example usage profile specified by the test method, and
- c) Solar run times for appliances combined under an advertised usage (only captured if a run time combination is advertised).

A third core output of this method is an estimate of the daily energy available to appliances after a standard solar day. This estimate is presented in Wh/day and is intended to offer a standard metric with which to compare the energy available from different SHS kits.

Estimates for the energy service are based on a conceptual model of off-grid power systems summarized in Figure R.1. The energy pathways outlined here are the framework for estimating available service from a fully charged battery or daily patterns of solar charging and utilization.

Key

- 1 Energy available from solar charging
- 2 Power control electronics
- 3 Energy for charging the battery
- 4 Energy discharge from the battery
- 5 Energy utilized by port 1 by one or more appliances (e.g., light point(s))
- 6 Energy utilized by port 2 by one or more appliances (e.g. mobile phone(s))
- 7 Energy utilized by other port(s) by one or more appliances
- 8 Bounding box for energy transformation, storage, and control elements

Figure R.1 – Conceptual energy flow diagram for energy service estimates

R.2 Test outcomes

The test outcomes of the daily energy service calculations are listed in Table R.1.

Table R.1 – Energy service calculations outcomes

Metric	Reporting Units	Related aspects	Remarks
Estimated full-battery run time(s) for each appliance under advertised usage	Hours (h)	n/a	Estimated full-battery run time for all advertised appliances under advertised usage with a fully charged battery. Multiple outcomes may be found – one for each specified appliance on each independent setting.
Estimated full-battery run time(s) for each appliance under an example usage profile	Hours (h)	n/a	Estimated full-battery run time for all advertised appliances under an example usage profile with a fully charged battery. Multiple outcomes will be found – one for each specified load on each independent setting.
Estimated full-battery run time(s) for each appliances under individual usage	Hours (h)	n/a	Estimated full-battery run time for all advertised appliances under individual usage with a fully charged battery. Multiple outcomes will be found – one for each specified load on each independent setting.
Estimated full-battery run time fraction of a full charge an advertised mobile phone receives	Percentage (%)	n/a	Only determined for DUT's that advertise charging a mobile phone. Estimates shall be determined under advertised usage (if advertised), typical usage, and individual usage.
Daily energy available to appliances after a standard solar day	Energy (Wh)	4.2.9.2 Daily energy service	The amount of energy available to the product's appliances after charging over a standard solar day. Multiple outcomes will be found – one assuming typical load usage and another assuming the load usage advertised with the product.
Daily energy service for all specified loads under advertised usage after a standard solar day	Hours (h)	4.2.9.2 Daily energy service	Calculated for the use of all specified loads over a day based on advertised usage. Multiple outcomes may be found if multiple combinations are advertised.
Daily energy service for all specified loads under an example usage profile after a standard solar day	Hours (h)	4.2.9.3 Solar-day lighting run time 4.2.9.4 Solar-day appliance run time	Calculated for the use of all specified loads over a day based on an example usage profile. Multiple outcomes will be found – one for each specified load on each independent setting.
Daily energy service for all specified loads under individual usage after a standard solar day	Hours (h)	4.2.9.3 Solar-day lighting run time 4.2.9.4 Solar-day appliance run time	Calculated for the use of only one specified load over a day. Multiple outcomes will be found – one for each specified load on each independent setting.
Estimated solar run time fraction of a full charge an advertised mobile phone receives	Percentage (%)	4.2.9.4 Solar-day appliance run time	Only determined for DUT's that advertise charging a mobile phone. Estimates shall be determined under advertised usage (if advertised), the example usage profile, and individual usage.

R.3 Related tests

The daily energy service calculation is related to the battery test (Annex I), the solar charge test (Annex N), the assessment of DC ports (Annex P), generic appliances (Annex CC), appliance tests (Annex Q), and full-battery run time test (Annex L).

R.4 Procedure

R.4.1 Full-battery run time energy service calculations

R.4.1.1 General

Full-battery run time estimates are made for each appliance used individually, appliances used in an advertised combination, and appliances used in an example usage combination.

R.4.1.2 Equipment requirements

No equipment is required for Annex R since it only consists of calculations.

R.4.1.3 Test prerequisites

This calculation shall be performed after completion of the assessment of DC ports (Annex P), the battery test (Annex I), generic appliances (Annex CC), appliance tests (Annex Q), and the full-battery run time test (Annex L).

R.4.1.4 Procedure

A number of input values from other test methods are required to determine the DUT's full-battery run time estimates. First identify which input values are needed for which run time estimates.

- a) Identify the required input values specified in Table R.2.

Table R.2 – Required inputs to estimate the full-battery run time(s)

Test method	Annex	Required input
Full-battery run time	Annex L	Full-battery energy from battery (Wh) Average power (W)
Battery test	Annex I	Battery efficiency for each appliance with a battery that is included with the product (%) Required for appliances with an internal battery that the appliance full-battery run time test is not conducted on: Energy required for a full charge for each included appliance with an internal battery (Wh) [Determined using the current-voltage pairs from the battery's final discharge curve during the battery test.]
Charge controller behavior	Annex K	Standby loss current draw (A)
Appliance tests	Annex Q	Power consumption measurements at typical port voltage for each appliance included with the product (W) Charging efficiency for each included appliance with an internal battery that is included with the product (%) Full-battery run time for each included appliance with an internal battery that is included with the product (h)
Generic appliances	Annex CC	Power consumption values for each appliance that is advertised but not included with the product (W) Energy required for a full charge for each appliance with an internal battery that is advertised by not included with the product (Wh) Charging efficiency for each appliance with an internal battery that is advertised, but not included with the product (%) Estimated battery efficiency for each appliance with a battery that is advertised by not included with the product (%)
Assessment of DC ports	Annex P	Plots of battery-to-port efficiency vs. output power for each appliance (%) Power consumption values for each built-in appliance for each tested scenario (W) ^a

^a Only required for built-in appliances as defined in 4.1.4.

- b) Use the following set of guidelines below to determine the power consumption value(s) to use for each type of appliance without an internal battery.
- For built-in appliances, use the power consumption value for the built-in appliance, calculated in the assessment of DC ports methods (Annex P), or the average power from the full-battery run time test (Annex L). For built-in light points, the value from the full-battery run time test is generally more representative of typical use and should be used when available; however, the value from Annex P may be used, for example to estimate lighting service for settings or configurations not tested in the full-battery run time test.
 - For included, removable appliances, use the power consumption measurement(s) from the appliance tests (Annex Q).
 - For non-included, advertised appliances, reference the generic appliances annex (Annex CC).
- c) Use the following set of guidelines below to determine the charging efficiency value(s) and battery efficiency value(s) to use for each type of appliance with an internal battery.

Charging efficiency:

- For included appliances, use the charging efficiency measurement(s) from the appliance tests (Annex Q).

NOTE The calculations assume that even if an appliance with an internal battery can be powered by its charging cable when no battery is inserted into the appliance, the appliance will always be used when not plugged into the main unit via its charging cable.

- For non-included, advertised appliances, reference the generic appliances annex (CC.5.2).

Battery efficiency:

- For included appliances, use the battery efficiency measurement(s) from the battery test (Annex I).
- For non-included, advertised appliances, reference the generic appliances annex (CC.5.2).

- d) The total energy available from the main unit's battery (E_b) is determined by subtracting the estimated standby energy loss (E_{sb}) from the energy removed from the battery during the full-battery run time test (E_{MBfbrt}) in Annex L.

Determine the estimated standby energy loss (E_{sb}) for the system by multiplying the standby loss current measured in K.4.5 (I_{sb}), the standard operating voltage determined in Annex G (V_{so}), and the estimated daily standby time (t_{sb}):

$$E_{sb} = I_{sb} \cdot V_{so} \cdot t_{sb}$$

where

E_{sb} is the estimated daily energy loss due to standby power loss (Wh);

I_{sb} is the measured standby power current draw, in amperes (A);

V_{so} is the standard operating voltage, in volts (V);

t_{sb} is the estimated daily standby time, defined as 15 hours (h). The estimated daily standby time assumes the unit will be charging for 7 hours each day.

The total energy available (E_b) is then:

$$E_b = E_{MBfbrt} - E_{sb}$$

where

E_b is the energy available to power appliances from the main unit's battery (Wh);

E_{MBfbrt} is the energy removed from the main battery during the full battery run time test (Wh);

E_{sb} is the estimated daily energy loss due to standby power loss (Wh);

- e) If the DUT includes any appliances with an internal battery, obtain the appliance's full-battery run time and the energy consumed from the appliance's battery during its full-battery run time. The total energy consumed from the appliance's battery may be determined using the full-battery run time test (Annex L or Annex Q). The appliance's full-battery run time provided by the manufacturer may instead be used if the manufacturer's rating satisfies the requirement specified in Q.2, in which case the energy removed from the appliances' batteries during the battery test (Annex I) may be used as the energy consumed by the appliance's battery during its full-battery run time.
- f) For each included or advertised removable appliance, calculate the battery-to-appliance (also referred to as battery-to-port) efficiency using the following steps:
- 1) Identify the port(s) with which the appliance is likely to be used. If the appliance is likely to be used with multiple ports, perform the following steps for each port and then select the one with the highest battery-to-appliance efficiency. For advertised appliances that are not included with the DUT kit, use the port most likely to be used with an appliance of that type; the following guidance may be used to make the determination:
 - If the packaging, user documentation, or manufacturer-supplied information depicts the connections between the DUT and the advertised appliances or states which ports are to be used, use the port shown or stated in the documentation.
 - If the nominal voltage of the appliance or its plug form factor is stated or shown in the documentation or manufacturer-supplied information (e.g., "12 V TV" or "USB radio"), use the corresponding port.
 - If a specific model of appliance is advertised, and the specifications for that model are available, use the appliance specifications to determine the correct port.
 - In the absence of other guidance, battery-powered appliances (including mobile phones, smartphones, or tablets) may be assumed to be powered by USB or 5 V ports, when available, and appliances without batteries may be assumed to be powered by ports of other voltages (e.g., 12 V).
 - 2) Using data collected in the measurement of steady-state port characteristics (P.4.2) with the simulated battery voltage set to the standard operating voltage, linearly interpolate between measured values of battery-to-appliance efficiency vs. port power to calculate the battery-to-appliance efficiency at the power level determined in step b) above. For the purposes of interpolation, the battery-to-appliance efficiency at zero power may be assumed to be 100 %. If the power consumption determined in b) is greater than the highest value measured in P.4.2, use the battery-to-appliance efficiency corresponding to the highest measured power value (do not extrapolate).

NOTE To simplify the calculation procedure, this interpolation can be automated using a spreadsheet or computer program.

NOTE The battery-to-appliance efficiency for any built-in appliance is 100%.

- g) An example usage profile is shown in Table R.3 for possible advertised appliances. This profile is used to determine relative proportions of energy for the DUT's appliances.

Table R.3 – Example usage profile for an SHS

Appliance	Typical use per standard solar day
Light (brightest setting)	4 h
Fan	5 h
Mobile phone	1 charge ^a
Radio	3 h

TV	2 h
^a Assume the energy required to fully charge a representative basic/feature mobile phone according to Table CC.2.	

Follow steps g) through n) to determine each advertised appliance's full-battery run time used individually in each setting. Advertised appliances are appliances that the DUT is advertised to power; their run times are not necessarily advertised nor are they necessarily included with the DUT.

- h) Identify the power consumption by each appliance without an internal battery referencing step b) above.
- i) Identify the charging efficiency and battery efficiency for each appliance with an internal battery referencing step c) above.
- j) Identify the energy available from the main unit's battery to each appliance used individually referencing step d) above.
- k) Identify the energy required from each appliance with an internal battery to provide the appliance's full-battery run time, and identify the appliance full-battery run time for each appliance with an internal battery, referencing step e) above.
- l) Identify the battery-to-appliance efficiency value for each appliance referencing step f) above.
- m) Determine the maximum run time (t_1) of each appliance *without* an internal battery when used individually using the power consumption (P_a) for the appliance, determined in step h), energy consumption from the DUT's main battery by the appliance (E_b), determined in step j), and the appropriate battery-to-appliance efficiency (η_{b-a}), determined in step l). Use the following formula:

$$t_1 = \frac{E_b \cdot \eta_{b-a}}{P_a}$$

where

- t_1 is the duration of time the appliance can be used individually, in hours (h);
- E_b is the energy available from the DUT's main battery, in watt-hours (Wh);
- P_a is the average power consumed by the appliance, in watts (W);
- η_{b-a} is the battery-to-appliance efficiency as a fraction.

- n) Determine the maximum run time (t_1) of each appliance with an internal battery, *except* mobile phones and tablets, when used individually using the charging efficiency (η_{ac}) and battery efficiency (η_{b_app}) for the appliance, determined in step i), energy consumption from the DUT's main battery by the appliance (E_b), determined in step j), the appropriate battery-to-appliance efficiency (η_{b-a}), determined in step l), the appliance's full-battery run time and the energy consumed by the appliance's battery determined in step k). Use the following formula:

$$t_1 = \frac{E_b \cdot \eta_{ac} \cdot \eta_{b-a} \cdot \eta_{ab} \cdot t_{fbrt}}{E_{fbrt}}$$

where

- t_1 is the duration of time the appliance can be used individually, in hours (h);
- E_b is the energy available from the DUT's main battery, in watt-hours (Wh);
- η_{ac} is the charging efficiency of the appliance as a fraction;
- η_{b-a} is the battery-to-appliance efficiency as a fraction;

- η_{ab} is the battery efficiency of the appliance battery as a fraction;
- t_{fbrt} is the full-battery run time of the appliance, in hours (h);
- E_{fbrt} is the energy consumed from the appliance's battery during the appliance's full-battery run time, in watt-hours (Wh).

- o) If a mobile phone or tablet is one of the DUT's advertised appliances, determine the fraction of full battery charges for that appliance when used individually. Unless smartphone or tablet charging capability is specifically mentioned, use the specifications for a basic/feature mobile phone as defined in CC.5.2.

$$f_I = \frac{E_I \cdot \eta_{ac} \cdot \eta_{b-a}}{E_{ab}}$$

where

- f_I is the fraction of a full charge that a mobile phone receives when used individually;
- E_I is the energy available from the DUT's main battery when using the appliance individually, in watt-hours (Wh);
- η_{ac} is the charging efficiency of the appliance as a fraction;
- η_{b-a} is the battery-to-appliance efficiency as a fraction;
- t_{fbrt} is the full-battery run time of the appliance, in hours (h);
- E_{ab} is the energy required to fully charge a representative mobile phone or tablet battery, in watt-hours (Wh); specified in Table CC.2.

Follow steps p) through y) to determine the full-battery run times for the advertised appliances under the example usage profile. Typical usage for appliances is based on how a customer expects to use the appliances of an SHS kit. Table R.3 provides an example usage profile for possible appliances in an SHS kit and can be used to determine each appliance's relative proportion of energy allocation.

- p) Identify the power consumption by each appliance without an internal battery referencing step b) above.
- q) Identify the charging efficiency and battery efficiency for each appliance with an internal battery referencing step c) above.
- r) Identify the energy available from the main unit's battery to each appliance used individually referencing step d) above.
- s) Identify the energy required from each appliance with an internal battery to provide the appliance's full-battery run time, and identify the appliance full-battery run time for each appliance with an internal battery, referencing step e) above.
- t) Identify the battery-to-appliance efficiency value for each appliance referencing step f) above.
- u) Determine the necessary energy from the DUT's main battery (E_{ar}) for each appliance *without* a battery, sufficient to provide the target usage values per appliance (t_r) according to the example usage profile in Table R.3. For each appliance, use the appropriate power consumption (P_a) determined in step p), and the appropriate battery-to-appliance efficiency (η_{b-a}) determined in step t) to find energy demand:

$$E_{ar} = \frac{P_a \cdot t_r}{\eta_{b-a}}$$

where

- E_{ar} is the energy demand from the DUT's main battery to power the appliance over the specified use period, in watt-hours (Wh);
- P_a is the average power consumed by the appliance, in watts (W);
- t_r is the target duration of time the appliance is in use, in hours (h);
- η_{b-a} is the battery-to-appliance efficiency as a fraction.

- v) Determine the necessary energy from the DUT's main battery (E_{ar}) for each appliance with a battery *except* mobile phones or tablets, sufficient to provide the target usage values per appliance (t_r) according to the example usage profile in Table R.3. For each appliance, use the charging efficiency (η_{ac}) and battery efficiency (η_{ab}) for the appliance, determined in step q), the appropriate battery-to-appliance efficiency (η_{b-a}), determined in step t), the appliance's full-battery run time, and the energy consumed by the appliance's battery determined in step s) to find energy demand:

$$E_{ar} = \frac{t_r \cdot E_{fbrt}}{\eta_{b-a} \cdot \eta_{ac} \cdot \eta_{ab}}$$

where

- E_{ar} is the energy demand from the DUT's main battery to power the appliance over the specified use period, in watt-hours (Wh);
- t_r is the target duration of time the appliance is in use, in hours (h);
- t_{fbrt} is the full-battery run time of the appliance, in hours (h);
- η_{b-a} is the battery-to-appliance efficiency as a fraction;
- η_{ac} is the charging efficiency of the appliance as a fraction;
- η_{ab} is the battery efficiency of the appliance battery as a fraction.

- w) If a mobile phone or tablet is one of the DUT's advertised appliances, determine necessary energy from the DUT's main battery (E_{ar}) for the mobile phone or tablet, sufficient to provide the target usage values per appliance (f_r) according to the example usage profile in Table R.3. Unless smartphone or tablet charging capability is specifically mentioned, use the specifications for a basic/feature mobile phone as defined in CC.5.2.

$$E_{ar} = \frac{f_r \cdot E_{ab}}{\eta_{b-a} \cdot \eta_{ac}}$$

where

- E_{ar} is the energy demand from the DUT's main battery to power the appliance over the specified use period, in watt-hours (Wh);
- f_r is the target fraction of a full charge that a mobile phone receives when used individually;
- E_{ab} is the energy required to fully charge a representative mobile phone or tablet battery, in watt-hours (Wh); specified in Table CC.2;
- η_{b-a} is the battery-to-appliance efficiency as a fraction;
- η_{ac} is the charging efficiency of the appliance as a fraction.

- x) Determine the actual energy available from the DUT's battery to each appliance (E_a), either taking away or adding to the service of each appliance in proportion. The expected energy available from the battery (E_b) is parsed to each appliance's energy allocation based on the following formula:

$$E_a = E_b \cdot \frac{E_{ar}}{\sum_i E_{ar,i}}$$

where

E_a is the actual expected energy consumption used by the appliance during the full-battery run time, in watt-hours (Wh);

E_b is energy available from the battery during the full-battery run time, in watt-hours (Wh);

E_{ar} is the energy consumption by an appliance over the specified target use period, in watt-hours (Wh);

$\sum E_{ar,i}$ is the total energy consumption from all the appliances in the set over their specified use periods, in watt-hours (Wh).

- y) Determine the actual duration of each appliance's service (as appropriate) using the actual energy provided from the DUT's battery to each appliance (E_a).

Use the following formula for appliances *without* an included battery:

$$t_a = \frac{E_a \cdot \eta_{b-a}}{P_a}$$

where

t_a is the actual duration of time the appliance is available for use under the specified scenario for allocating energy to a set of appliances, in hours (h);

E_a is the actual energy consumption for the appliance during the full-battery run time, in watt-hours (Wh);

P_a is the power entering the appliance, in watts (W);

η_{b-a} is the battery-to-appliance efficiency as a fraction.

Use the following formula for appliances with an included battery *except* mobile phones or tablets:

$$t_a = \frac{E_a \cdot \eta_{b-a} \cdot \eta_{ac} \cdot \eta_{ab} \cdot t_{fbrt}}{E_{fbrt}}$$

where

t_a is the actual duration of time the appliance is available for use under the specified scenario for allocating energy to a set of appliances, in hours (h);

E_a is the actual energy consumption for the appliance during the full-battery run time, in watt-hours (Wh);

η_{b-a} is the battery-to-appliance efficiency as a fraction;

η_{ac} is the charging efficiency of the appliance as a fraction;

η_{ab} is the battery efficiency of the appliance battery as a fraction;

t_{fbrt} is the full-battery run time of the appliance, in hours (h);

E_{fbrt} is the energy consumed from the appliance's battery during the appliance's full-battery run time, in watt-hours (Wh).

Use the following formula for mobile phone or tablet appliances. Unless smartphone or tablet charging capability is specifically mentioned, use the specifications for a basic/feature mobile phone as defined in CC.5.2.

$$f_a = \frac{E_{ab} \cdot \eta_{ac} \cdot \eta_{b-a}}{E_{ab}}$$

where

- f_a is the fraction of a full charge that a mobile phone receives under the specified scenario for allocating energy to a set of appliances;
- E_{ab} is the actual energy consumption for the appliance during the full-battery run time, in watt-hours (Wh);
- η_{ac} is the charging efficiency of the appliance as a fraction;
- η_{b-a} is the battery-to-appliance efficiency as a fraction;
- t_{fbrt} is the full-battery run time of the appliance, in hours (h);
- E_{ab} is the energy required to fully charge a representative mobile phone or tablet battery, in watt-hours (Wh); specified in Table CC.2.

Repeat steps p) through y) to determine the full-battery run times for the advertised appliances combined under any advertised usage profiles or other important sets to characterize. For example, if the DUT advertises that it can power multiple appliances for specific durations with a fully charged battery, the specific durations for the specified appliances shall be used as the usage values per appliance (t_r and f_r) in steps u) through w) *instead* of referencing the example usage profile from Table R.3. All other values used will be identical to those used for the full-battery run times for the advertised appliances under the example usage profile. If the DUT does not advertise usages for multiple appliances with a fully charged battery, then this metric cannot be determined.

R.4.2 Solar run time energy service calculations

R.4.2.1 General

Solar run time estimates are made for individual appliances and sets of multiple appliances. The assumptions about energy allocation and priorities mirrors those in the full-battery run time estimates. The daily energy service available over a standard solar day is determined by adding information about the solar charging circuit.

R.4.2.2 Equipment requirements

No equipment is required for Annex R since it only consists of calculations.

R.4.2.3 Test prerequisites

This calculation shall be performed after completion of the solar charge test (Annex N), the assessment of DC ports (Annex P), appliance tests (Annex Q), the battery test (Annex I), and the full-battery run time test (Annex L).

R.4.2.4 Procedure

A number of input values from other test methods are required to determine the DUT's solar run time estimates. First identify which input values are needed for which run time estimates.

- a) Identify the required input values specified in Table R.4.

Table R.4 – Required inputs to estimate the solar run time

Test method	Annex	Required input
Full-battery run time	Annex L	Full-battery run time energy from battery (Wh) Average power (W)
Battery test	Annex I	Battery efficiency of the main battery (%) Battery efficiency for each appliance with a battery that is included

		with the product (%) Required for appliances with an internal battery that the appliance full-battery run time test is not conducted on: Energy required for a full charge for each appliance with a battery that is included with the product (Wh) [Determined using the current-voltage pairs from the battery's final discharge curve during the battery test.]
Charge controller behavior	Annex K	Standby loss current draw (A)
Appliance tests	Annex Q	Power consumption measurements for each appliance included with the product (W) Charging efficiency for each appliance with an internal battery that is included with the product (%) Full-battery run time for each appliance with an internal battery that is included with the product (h)
Generic appliances	Annex CC	Power consumption measurements for each appliance that is advertised but not included with the product (W) Energy required for a full charge for each appliance with a battery that is advertised by not included with the product (Wh) Charging efficiency for each appliance with an internal battery that is advertised, but not included with the product (%) Estimated battery efficiency for each appliance with an internal battery that is advertised by not included with the product (%)
Assessment of DC ports	Annex P	Plots of battery-to-port efficiency vs. output power for each appliance (%) Power consumption values for each built-in appliance for each tested scenario (W) ^a
Solar charge	Annex N	Energy delivered to the DUT's PV socket per day, $E_{PV,sim}$ (Wh) Generator-to-battery efficiency (%)
^a Only required for built-in appliances as defined in 4.1.4.		

- b) Identify the power consumption by each appliance without an internal battery referencing R.4.1.4 step b) above.
- c) Identify the charging efficiency and battery efficiency for each appliance with an internal battery referencing R.4.1.4 step c) above. Also, identify the estimated standby energy loss (E_{sb}) for the system referencing R.4.1.4 step d) above.
- d) An example usage profile is shown in Table R.3 for possible advertised appliances. This profile is used to determine relative proportions of energy for the DUT's appliances.
- e) The DUT's appliances may be used either while the DUT is solar charging or while it is not solar charging. This balance in appliance use has implications that derive the technical capabilities of the system to simultaneously power daytime loads and charge the battery sufficient for night-time operation. The percentage of day/night use in Table R.5 present an example case for usage.

Table R.5 – Example case for appliance usage when solar charging

Appliance	Percentage use when not solar charging (night)	Percentage use when solar charging (day)
Light (specified setting)	100%	0%
Fan	75%	25%
Mobile	50%	50%
Radio	75%	25%
TV	75%	25%
Other	75%	25%

- f) Follow the instructions in R.4.1.4, step f), to determine the battery-to-port charging efficiency for each appliance.

Follow steps g) through w) to determine the solar run times for the advertised appliances under an example usage profile. Table R.3 provides an example usage profile for possible appliances in an SHS and can be used to determine each appliance's relative proportion of energy allocation. Only appliances included in the example usage profile shall be included. If main lighting is included, no additional non-included, advertised lighting shall be added in the product's example use profile. Likewise, if an SHS is advertised to power multiple appliances of the same type, use those that are included with the kit in the calculation; if none are included with the kit, choose the one that will require the most energy (e.g. large television over small television).

- g) Identify the power consumption by each appliance without an internal battery referencing step b) above.
- h) Identify the charging efficiency and battery efficiency of each appliance with an internal battery referencing step c) above. Also referencing step c) above, identify the estimated standby energy loss (E_{sb}) for the system.
- i) Identify the battery-to-port efficiency value for each appliance referencing step f) above.
- j) Determine the PV-to-port efficiency values for each appliance used individually as the product between the system's generator-to-battery efficiency determined in the solar charge test (Annex N) and the appliance's battery-to-port efficiency, referencing step i) above.

$$\eta_{g-a} = \eta_{g-b} \cdot \eta_{b-a}$$

where

- η_{g-a} is the PV-to-port efficiency as a fraction;
- η_{g-b} is the generator-to-battery efficiency as a fraction;
- η_{b-a} is the battery-to-port efficiency as a fraction.

Equations assessing night-time usage will additionally include the battery efficiency of the main battery. Identify the battery efficiency of the main battery (η_b) determined during the battery test in Annex I.

- k) Use the percentages in Table R.5 above to determine what time of the day the advertised appliances are used. It is assumed that any daytime use will occur while the DUT is solar charging.
- l) Determine the necessary energy from the energy delivered to the DUT's PV socket for each appliance without an internal battery for both day and night usage ($E_{ar,day}$ and $E_{ar,night}$), sufficient to provide the target usage values per appliance (t_r) according to the example usage profile in Table R.3 and use percentages in Table R.5. For each appliance, use the appropriate power consumption (P_a), determined in step g), and the PV-to-port efficiency (η_{g-a}), determined in step j), to find energy demand during the day:

$$E_{ar,day} = \frac{P_a \cdot t_{r,day}}{\eta_{g-a}}$$

where

- $E_{ar,day}$ is the energy demand from the DUT's main battery to power the appliance over the specified use period when the DUT is solar charging, in watt-hours (Wh);
- P_a is the average power consumed by the appliance, in watts (W);

- $t_{r,day}$ is the target duration of time the appliance is in use during the day, in hours (h);
- η_{g-a} is the PV-to-port efficiency as a fraction.

$$E_{ar,night} = \frac{P_a \cdot t_{r,night}}{\eta_{g-a} \cdot \eta_b}$$

where

- $E_{ar,night}$ is the energy demand from the DUT's main battery to power the appliance over the specified use period when the DUT is not solar charging, in watt-hours (Wh);
- P_a is the average power consumed by the appliance, in watts (W);
- $t_{r,night}$ is the target duration of time the appliance is in use during the night, in hours (h);
- η_{g-a} is the PV-to-port efficiency as a fraction;
- η_b is the battery efficiency of the main battery as a fraction.

- m) Determine the necessary energy from the energy delivered to the DUT's PV socket for each appliance with an internal battery for both day and night usage ($E_{ar,day}$ and $E_{ar,night}$) *except* mobile phones or tablets, sufficient to provide the target usage values per appliance (t_r) according to the example usage profile in Table R.3 and use percentages in Table R.5. For each appliance, use the appropriate charging efficiency (η_{ac}), determined in step h), the PV-to-port efficiency (η_{g-a}), determined in step j), and the battery efficiency of the appliance battery (η_{ab}) to find energy demand during the day:

$$E_{ar,day} = \frac{\frac{t_{r,day}}{t_{fbrt}} \cdot E_{fbrt}}{\eta_{g-a} \cdot \eta_{ac} \cdot \eta_{ab}}$$

where

- $E_{ar,day}$ is the energy demand from the DUT's main battery to power the appliance over the specified use period when the DUT is solar charging, in watt-hours (Wh);
- $t_{r,day}$ is the target duration of time the appliance is in use during the day, in hours (h);
- t_{fbrt} is the full-battery run time of the appliance, in hours (h);
- E_{fbrt} is the energy consumed from the appliance's battery during the appliance's full-battery run time, in watt-hours (Wh);
- η_{g-a} is the PV-to-port efficiency as a fraction;
- η_{ac} is the charging efficiency of the appliance as a fraction;
- η_{ab} is the battery efficiency of the appliance as a fraction.

$$E_{ar,night} = \frac{\frac{t_{r,night}}{t_{fbrt}} \cdot E_{fbrt}}{\eta_{g-a} \cdot \eta_{ac} \cdot \eta_{ab} \cdot \eta_b}$$

where

$E_{ar,night}$	is the energy demand from the DUT's main battery to power the appliance over the specified use period when the DUT is not solar charging, in watt-hours (Wh);
$t_{r,night}$	is the target duration of time the appliance is in use during the night, in hours (h);
t_{fbrt}	is the full-battery run time of the appliance, in hours (h);
E_{fbrt}	is the energy consumed from the appliance's battery during the appliance's full-battery run time, in watt-hours (Wh);
η_{g-a}	is the PV-to-port efficiency as a fraction;
η_{ac}	is the charging efficiency of the appliance as a fraction;
η_{ab}	is the battery efficiency of the appliance as a fraction;
η_b	is the battery efficiency of the main battery as a fraction.

- n) If a mobile phone or tablet is one of the DUT's advertised appliances, determine necessary energy from the DUT's main battery for both day and night usage ($E_{ar,day}$ and $E_{ar,night}$) for the mobile phone or tablet, sufficient to provide the target usage values per appliance (f_r) according to the example usage profile in Table R.3. Unless smartphone or tablet charging capability is specifically mentioned, use the specifications for a basic/feature mobile phone as defined in CC.5.2.

$$E_{ar,day} = \frac{f_{r,day} \cdot E_{ab}}{\eta_{g-a} \cdot \eta_{ac}}$$

where

$E_{ar,day}$	is the energy demand from the DUT's main battery to power the appliance over the specified use period when the DUT is solar charging, in watt-hours (Wh);
$f_{r,day}$	is the target fraction of a full charge that a mobile phone or tablet receives when the DUT is solar charging;
E_{ab}	is the energy required to fully charge a representative mobile phone or tablet battery, in watt-hours (Wh); specified in Table CC.2;
η_{g-a}	is the PV-to-port efficiency as a fraction;
η_{ac}	is the charging efficiency of the appliance as a fraction.

$$E_{ar,night} = \frac{f_{r,night} \cdot E_{ab}}{\eta_{g-a} \cdot \eta_{ac} \cdot \eta_b}$$

where

$E_{ar,night}$	is the energy demand from the DUT's main battery to power the appliance over the specified use period when the DUT is not solar charging, in watt-hours (Wh);
$f_{r,night}$	is the target fraction of a full charge that a mobile phone or tablet receives when the DUT is not solar charging;
E_{ab}	is the energy required to fully charge a representative mobile phone or tablet battery, in watt-hours (Wh); specified in Table CC.2;
η_{g-a}	is the PV-to-port efficiency as a fraction;
η_{ac}	is the charging efficiency of the appliance as a fraction;
η_b	is the battery efficiency of the main battery as a fraction.

- o) Determine the maximum possible energy available from the DUT's PV socket to each appliance for day usage (E_{a,day^*}), by either taking away or adding to the service of each appliance in proportion. The expected energy available from the DUT's PV socket over a standard solar day ($E_{PV,sim}$), less the daily energy loss due to standby power draw (E_{sb}) adjusted to the PV socket location, is parsed to each appliance's energy allocation based on the following formula:

$$E_{a,day^*} = \left(E_{PV,sim} - \left(\frac{E_{sb}}{\eta_b \cdot \eta_{g-b}} \right) \right) \cdot \frac{E_{ar,day}}{\sum_i E_{ar,i}}$$

where

- E_{a,day^*} is the maximum energy used by the appliance during the day over when the DUT is solar charging, not considering the a maximum daytime use (i.e. 8 h), in watt-hours (Wh);
- $E_{PV,sim}$ is energy available from the DUT's PV socket during a standard solar day, in watt-hours (Wh);
- E_{sb} is the estimated daily energy loss due to standby power draw (Wh);
- η_b is the battery efficiency of the main battery as a fraction ;
- η_{g-b} is the generator-to-battery efficiency as a fraction;
- $E_{ar,day}$ is the energy consumption by an appliance during day use over the specified target use period, in watt-hours (Wh);
- $\sum E_{ar,i}$ is the total energy consumption from all the appliances (during both day and night usage) in the set over their specified use periods, in watt-hours (Wh).

NOTE The sum of the calculated energy available to the daytime appliance(s) calculated above can exceed the maximum energy that the DUT's battery can supply during the daytime hours when solar charging, hence the asterisked E_{a,day^*} .

- p) Determine the duration of service for each appliance without an internal battery (as appropriate) using the energy used by the appliance during day use not considering the maximum daytime usage (E_{a,day^*}), determined in step o), the appropriate power consumption (P_a), determined in step g), and the appropriate PV-to-port efficiency (η_{g-a}), determined in step j). This duration considers that a maximum daytime use of 8 h. Use the following formula for appliances without batteries:

$$t_{a,day} = \min \left(\frac{E_{a,day^*} \cdot \eta_{g-a}}{P_a}, 8 \text{ h} \right)$$

where

- $t_{a,day}$ is the actual duration of time the appliance is available for use under the specified scenario for allocating energy to a set of appliances in day usage, in hours (h). It is assumed that no appliance can provide service for more than 8 hours during daytime use;
- E_{a,day^*} is the maximum energy used by the appliance during the day usage over when the DUT is solar charging, not considering the a maximum daytime use (i.e. 8 h), in watt-hours (Wh);
- P_a is the power entering the appliance, in watts (W);
- η_{g-a} is the PV-to-port efficiency, as a fraction.

- q) Determine the duration of service for each appliance with an internal battery, *except* mobile phones or tablets, using the energy used by the appliance during day use not considering the maximum daytime usage (E_{a,day^*}), determined in step o), the appropriate charging efficiency (η_{ac}), determined in step h), the appropriate PV-to-port efficiency (η_{g-a}), determined in step j), and the battery efficiency of the appliance battery (η_{ab}). This duration considers that a maximum daytime use of 8 h. Use the following formula for appliances without batteries:

$$t_{a,day} = \min\left(\frac{E_{a,day^*} \cdot \eta_{g-a} \cdot \eta_{ac} \cdot \eta_{ab} \cdot t_{fbrt}}{E_{fbrt}}, 8 \text{ h}\right)$$

where

- $t_{a,day}$ is the actual duration of time the appliance is available for use under the specified scenario for allocating energy to a set of appliances in day usage, in hours (h). It is assumed that no appliance can provide service for more than 8 hours during daytime use;
- E_{a,day^*} is the maximum energy used by the appliance over when the DUT is solar charging, not considering the a maximum daytime use (i.e. 8 h), in watt-hours (Wh);
- η_{ac} is the charging efficiency of the appliance as a fraction;
- η_{g-a} is the PV-to-port efficiency as a fraction;
- t_{fbrt} is the full-battery run time of the appliance, in hours (h);
- E_{fbrt} is the energy consumed from the appliance's battery during the appliance's full-battery run time, in watt-hours (Wh);
- η_{ab} is the battery efficiency of the appliance as a fraction.

- r) Determine the *actual* energy used from the DUT's PV socket by each appliance without an internal battery for day usage ($E_{a,day}$), to provide the actual daytime usage values per appliance ($t_{a,day}$), determined to step p). For each appliance, use the appropriate power consumption (P_a), determined in step g), and the PV-to-port efficiency (η_{g-a}), determined in step j), to find the actual energy usage:

$$E_{a,day} = \frac{P_a \cdot t_{a,day}}{\eta_{g-a}}$$

where

- $E_{a,day}$ is the actual energy used to power the appliance over when the DUT is solar charging, considering the a maximum daytime use (i.e. 8 h), in watt-hours (Wh);
- P_a is the average power consumed by the appliance, in watts (W);
- $t_{a,day}$ is the actual duration of time the appliance is in use during the day, in hours (h);
- η_{g-a} is the PV-to-port efficiency as a fraction.

- s) Determine the *actual* energy from the DUT's PV socket for each appliance with an internal battery for day usage ($E_{a,day}$) *except* mobile phones or tablets, to provide the actual daytime usage values per appliance ($t_{a,day}$), determined to step p). For each appliance, use the appropriate charging efficiency (η_{ac}), determined in step h), the PV-to-port efficiency (η_{g-a}), determined in step j), and the battery efficiency of the appliance battery (η_{ab}) to find energy demand:

$$E_{a,\text{day}} = \frac{\frac{t_{a,\text{day}}}{t_{\text{fbrt}}} \cdot E_{\text{fbrt}}}{\eta_{g-a} \cdot \eta_{ac} \cdot \eta_{ab}}$$

where

- $E_{a,\text{day}}$ is the actual energy used to power the appliance over when the DUT is solar charging, considering the a maximum daytime use (i.e. 8 h), in watt-hours (Wh);
- $t_{a,\text{day}}$ is the actual duration of time the appliance is in use during the day, in hours (h);
- t_{fbrt} is the full-battery run time of the appliance, in hours (h);
- E_{fbrt} is the energy consumed from the appliance's battery during the appliance's full-battery run time, in watt-hours (Wh);
- η_{g-a} is the PV-to-port efficiency as a fraction;
- η_{ac} is the charging efficiency of the appliance as a fraction;
- η_{ab} is the battery efficiency of the appliance as a fraction.

- t) If a mobile phone or tablet is one of the DUT's advertised appliances, determine the actual energy from the DUT's PV socket for daytime use ($E_{a,\text{day}}$) of the mobile phone or tablet. Because there is no use constraint on how many mobile phones or tablets can be fully charged from the system, the actual energy used to charge the appliance is equal to the maximum.

$$E_{a,\text{day}} = E_{a,\text{day}^*}$$

where

- $E_{a,\text{day}}$ is the actual energy used to power the appliance over when the DUT is solar charging, in watt-hours (Wh);
- E_{a,day^*} is the maximum energy used by the appliance over when the DUT is solar charging, in watt-hours (Wh).

- u) Determine the maximum possible energy available from the DUT's PV socket to each appliance for night usage (E_{a,night^*}), by either taking away or adding to the service of each appliance in proportion, as well as adding any energy not used during the daytime due to the maximum usage constraint (i.e. 8 h). The expected energy available from the DUT's PV socket over a standard solar day ($E_{\text{PV},\text{sim}}$), less the daily energy loss due to standby power draw (E_{sb}) adjusted to the PV socket location, is parsed to each appliance's energy allocation based on the following formula:

$$E_{a,\text{night}^*} = \left(E_{\text{PV},\text{sim}} - \left(\frac{E_{\text{sb}}}{\eta_b \cdot \eta_{g-b}} \right) \cdot \frac{E_{\text{ar},\text{night}}}{\sum_i E_{\text{ar},i}} \right) + (E_{a,\text{day}^*} - E_{a,\text{day}})$$

where

- E_{a,night^*} is the energy used by the appliance during night use after a standard solar day of charging, not considering the DUT's battery capacity, in watt-hours (Wh);
- $E_{\text{PV},\text{sim}}$ is energy available at the DUT's PV socket after a standard solar day, in watt-hours (Wh);
- E_{sb} is the estimated daily energy loss due to standby power draw (Wh);

η_b	is the battery efficiency of the main battery as a fraction ;
η_{g-b}	is the generator-to-battery efficiency as a fraction;
$E_{ar,night}$	is the energy consumption by an appliance during night use over the specified target use period, in watt-hours (Wh);
$\sum E_{ar,i}$	is the total energy consumption from all the appliances (during both day and night usage) in the set over their specified use periods, in watt-hours (Wh).
E_{a,day^*}	is the energy used by the appliance during the day usage after a standard solar day of charging, not considering the a maximum daytime use (i.e. 8 h), in watt-hours (Wh);
$E_{a,day}$	is the actual energy used by the DUT's main battery to power the appliance over when the DUT is solar charging, considering the a maximum daytime use (i.e. 8 h), in watt-hours (Wh).

NOTE The sum of the calculated energy available to the night-time appliance(s) calculated above can exceed the maximum energy that the DUT's battery can supply during the night when not solar charging, hence the asterisked $E_{a,night^*}$.

- v) Check that the sum of the energy consumption values for the appliances during night use calculated in the above step do not exceed the amount of energy that the DUT's battery can possibly supply when fully charged. Use the formula below to determine the actual energy available to the appliances during night use:

$$E_{a,night,total} = \min \left(\sum_i E_{a,night^*,i}, \frac{E_{FBRT}}{\eta_{g-b} \cdot \eta_b} \right)$$

where

$E_{a,night,total}$	is the sum of the actual energy consumption used by the appliance during the solar run time during night-time usage, in watt-hours (Wh);
$\sum E_{a,night^*,i}$	is the total energy consumption used by the appliances during the solar run time during night-time usage, not considering the DUT's battery capacity, in watt-hours (Wh);
E_{FBRT}	is the energy consumed from the main unit's battery during the lighting full-battery run time, in watt-hours (Wh).
η_b	is the battery efficiency of the main battery as a fraction ;
η_{g-b}	is the generator-to-battery efficiency as a fraction.

- w) Use the following formula to determine the *actual* night-time energy usage ($E_{a,night}$) by either taking away or adding to the service of each appliance used at night in proportion:

$$E_{a,night} = E_{a,night,total} \cdot \frac{E_{a,night^*}}{\sum_i E_{a,night^*,i}}$$

where

$E_{a,night}$	is the <i>actual</i> energy consumption by an appliance over the specified target use period, in watt-hours (Wh);
$E_{a,night,total}$	is the sum of the actual energy consumption used by the appliance during the solar run time during night-time usage, in watt-hours (Wh);

- $E_{a,night^*}$ is the energy consumption used by the appliance during the solar run time during night-time usage, not considering the DUT's battery capacity, in watt-hours (Wh);
- $\sum E_{a,night^*,i}$ is the total energy consumption from all the appliances (during only night usage), not considering the DUT's battery capacity, in the set over their specified use periods, in watt-hours (Wh)

- x) Determine the actual duration of service for each appliance without an internal battery (as appropriate) using the actual energy provided from the DUT's PV socket to each appliance during night usage ($E_{a,night}$), determined in step w), the appropriate power consumption (P_a), determined in step g), and the appropriate PV-to-port efficiency (η_{g-a}), determined in step j), and the battery efficiency of the main battery (η_b). Use the following formula for appliances without batteries:

$$t_{a,night} = \frac{E_{a,night} \cdot \eta_{g-a} \cdot \eta_b}{P_a}$$

where

- $t_{a,night}$ is the actual duration of time the appliance is available for use under the specified scenario for allocating energy to a set of appliances in night usage, in hours (h);
- $E_{a,night}$ is the actual energy consumption by the appliance during its night use after a standard solar day of charging, in watt-hours (Wh);
- P_a is the power delivered to the appliance, in watts (W);
- η_{g-a} is the PV-to-port efficiency, as a fraction;
- η_b is the battery efficiency of the main battery as a fraction.

- y) Determine the actual duration of service for each appliance with an internal battery *except* mobile phones or tablets (as appropriate) using the actual energy provided from the DUT's PV socket to each appliance during night usage ($E_{a,night}$), determined in step w), the appropriate charging efficiency (η_{ac}), determined in step h), the appropriate PV-to-port efficiency (η_{g-a}), determined in step j), and the battery efficiency of the appliance battery (η_{ab}). Use the following formula for appliances without batteries:

$$t_{a,night} = \frac{E_{a,night} \cdot \eta_{g-a} \cdot \eta_{ac} \cdot \eta_{ab} \cdot \eta_b \cdot t_{fbrt}}{E_{fbrt}}$$

where

- $t_{a,night}$ is the actual duration of time the appliance is available for use under the specified scenario for allocating energy to a set of appliances in night usage, in hours (h);
- $E_{a,night}$ is the actual energy consumption by the appliance during its night use after a standard solar day of charging, in watt-hours (Wh);
- η_{ac} is the charging efficiency of the appliance as a fraction;
- η_{g-a} is the PV-to-port efficiency as a fraction;
- t_{fbrt} is the full-battery run time of the appliance, in hours (h);
- E_{fbrt} is the energy consumed from the appliance's battery during the appliance's full-battery run time, in watt-hours (Wh);
- η_{ab} is the battery efficiency of the appliance as a fraction;

η_b is the battery efficiency of the main battery as a fraction.

- z) If a mobile phone or tablet is one of the DUT's advertised appliances, determine the actual fraction of charge for both day and night usage ($f_{a,\text{day}}$ and $f_{a,\text{night}}$) for the mobile phone or tablet. Unless smartphone or tablet charging capability is specifically mentioned, use the specifications for a basic/feature mobile phone as defined in CC.5.2.

$$f_{a,\text{day}} = \frac{E_{a,\text{day}} \cdot \eta_{g-a} \cdot \eta_{ac}}{E_{ab}}$$

where

$f_{a,\text{day}}$ is the actual fraction of charge the mobile phone or tablet receives for use under the specified scenario for allocating energy to a set of appliances in day usage as a fraction;

$E_{a,\text{day}}$ is the actual energy consumption by the appliance during its day use after a standard solar day of charging, in watt-hours (Wh);

η_{ac} is the charging efficiency of the appliance as a fraction;

η_{g-a} is the PV-to-port efficiency as a fraction;

E_{ab} is the energy required to fully charge a representative mobile phone or tablet battery, in watt-hours (Wh); specified in Table CC.2.

$$f_{a,\text{night}} = \frac{E_{a,\text{night}} \cdot \eta_{g-a} \cdot \eta_{ac} \cdot \eta_b}{E_{ab}}$$

where

$f_{a,\text{night}}$ is the actual fraction of charge the mobile phone or tablet receives for use under the specified scenario for allocating energy to a set of appliances in night usage as a fraction;

$E_{a,\text{night}}$ is the actual energy consumption by the appliance during its night use after a standard solar day of charging, in watt-hours (Wh);

η_{ac} is the charging efficiency of the appliance as a fraction;

η_{g-a} is the PV-to-port efficiency as a fraction;

E_{ab} is the energy required to fully charge a representative mobile phone or tablet battery, in watt-hours (Wh); specified in Table CC.2;

η_b is the battery efficiency of the main battery as a fraction.

- aa) Determine the total actual duration of each appliance's service, *except* mobile phones or tablets (as appropriate), using the actual duration of each appliance during both day and night usage together, using the following formula:

$$t_a = t_{a,\text{day}} + t_{a,\text{night}}$$

where

t_a is the actual duration of time the appliance is available for use under the specified scenario for allocating energy to a set of appliances in both day and night usage, in hours (h);

$t_{a,\text{day}}$ is the actual duration of time the appliance is available for use under the specified scenario for allocating energy to a set of appliances in day usage, in hours (h);

$t_{a,night}$ is the actual duration of time the appliance is available for use under the specified scenario for allocating energy to a set of appliances in night usage, in hours (h).

- bb) If a mobile phone or tablet is one of the DUT's advertised appliances, determine the total fraction of charge that can be powered after a standard solar day using the following formula. Unless smartphone or tablet charging capability is specifically mentioned, use the specifications for a basic/feature mobile phone as defined in CC.5.2.

$$f_a = f_{a,day} + f_{a,night}$$

where

f_a is the total actual fraction of charge the mobile phone or table receives for use under the specified scenario for allocating energy to a set of appliances usage as a fraction;

$f_{a,day}$ is the actual fraction of charge the mobile phone or table receives for use under the specified scenario for allocating energy to a set of appliances in day usage as a fraction;

$f_{a,night}$ is the actual fraction of charge the mobile phone or table receives for use under the specified scenario for allocating energy to a set of appliances in night usage as a fraction;

- cc) Determine the total energy at the appliance ports per solar day that the DUT can supply based on the example usage profile using the formulas below. First, the energy consumption values determined thus far at the PV socket must be converted to energy consumption values at the appliance port using the appropriate efficiencies.

For appliances without an internal battery:

$$E_{ag} = (E_{a,day} \cdot \eta_{g-a}) + (E_{a,night} \cdot \eta_{g-a} \cdot \eta_b)$$

where

E_{ag} is the energy consumption used by the appliance during the solar run time at the appliance port during both day and night usage, in watt-hours (Wh);

$E_{a,day}$ is the actual energy used by the DUT's main battery to power the appliance over when the DUT is solar charging at the PV socket, in watt-hours (Wh);

$E_{a,night}$ is the actual energy consumption by an appliance over the specified target use period at the PV socket, in watt-hours (Wh);

η_{g-a} is the PV-to-port efficiency as a fraction;

η_b is the battery efficiency of the main battery as a fraction.

For appliances with an internal battery:

$$E_{ag} = (E_{a,day} \cdot \eta_{g-a} \cdot \eta_{ac}) + (E_{a,night} \cdot \eta_{g-a} \cdot \eta_{ac} \cdot \eta_b)$$

where

E_{ag} is the energy consumption used by the appliance during the solar run time at the appliance port during both day and night usage, in watt-hours (Wh);

$E_{a,day}$ is the actual energy used by the DUT's main battery to power the appliance over when the DUT is solar charging at the PV socket, in watt-hours (Wh);

$E_{a,night}$ is the *actual* energy consumption by an appliance over the specified target use period at the PV socket, in watt-hours (Wh);

- η_{g-a} is the PV-to-port efficiency as a fraction;
 η_{ac} is the charging efficiency of the appliance as a fraction;
 η_b is the battery efficiency of the main battery as a fraction.

$$E_{ag,total} = \sum_i E_{ag,i}$$

where

- $E_{ag,total}$ is the sum of the actual energy consumption used by the appliance during the solar run time at the appliance port during both day and night usage, in watt-hours (Wh);
 $\sum E_{ag,i}$ is the total energy consumption from all the appliances at the appliance port, in the set, in watt-hours (Wh);

- dd) Repeat steps g) through cc) to determine the solar run times for the advertised appliances combined under an advertised usage or other important sets to characterize. For example, if the DUT advertises that it can power multiple appliances for specific durations after a day's solar charge, the specific durations for the specified appliances shall be used as the usage values per appliance ($t_{r,day}$, $t_{r,night}$, $f_{r,day}$, and, $f_{r,night}$) in steps l) through n). All other input values used will be identical to those used for the solar run times for the advertised appliances under the example usage profile. If the DUT does not advertise usages for multiple appliances after a day's solar charge, then this metric cannot be determined.
- ee) Determine each advertised appliance's solar run time when used individually in each setting. First repeat steps g) through n), then follow step ff) below, then repeat steps p) through t), then follow steps gg) and hh) below, and finally repeat steps x) through bb) to determine the solar run times for the advertised appliances when used individually. For example, if the DUT advertises that it can power an appliance for specific durations after a day's solar charge, the specific duration for the specified appliance shall be used as the usage values per appliance ($t_{r,day}$, $t_{r,night}$, $f_{r,day}$, and, $f_{r,night}$) in steps l) through n). All other input values used will be identical to those used for the solar run times for the advertised appliances under the example usage profile.
- ff) Determine the maximum possible energy available from the DUT's PV socket to the individually-used appliance for day usage ($E_{a,day*}$), by either taking away or adding to the service of each appliance in proportion. The expected energy available from the DUT's PV socket over a standard solar day ($E_{PV,sim}$), less the daily energy loss due to standby power draw (E_{sb}), is parsed to each appliance's energy allocation based on the following formula:

$$E_{a,day*} = \left(E_{PV,sim} - \frac{E_{sb}}{\eta_b \cdot \eta_{g-b}} \right) \cdot \frac{E_{ar,day}}{E_{ar,day} + E_{ar,night}}$$

where

- $E_{a,day*}$ is the energy used by the appliance during the day usage after a standard solar day of charging, not considering the a maximum daytime use (i.e. 8 h), in watt-hours (Wh);
 $E_{PV,sim}$ is the energy available from the DUT's PV socket during a standard solar day, in watt-hours (Wh);
 E_{sb} is the estimated daily energy loss due to standby power draw (Wh);
 η_b is the battery efficiency of the main battery as a fraction ;
 η_{g-b} is the generator-to-battery efficiency as a fraction;

$E_{ar,day}$ is the energy consumption by an appliance during day use over the specified target use period, in watt-hours (Wh);

$E_{ar,night}$ is the energy consumption by an appliance during night use over the specified target use period, in watt-hours (Wh).

NOTE The sum of the calculated energy available to the daytime appliance(s) calculated above can exceed the maximum energy that the DUT's battery can supply during the daytime hours when solar charging, hence the asterisked E_{a,day^*} .

gg) Determine the maximum possible energy available from the DUT's PV socket to the individually-used appliance for night usage ($E_{a,night^*}$), by either taking away or adding to the service of each appliance in proportion, as well as adding any energy not used during the daytime due to the maximum usage constraint (i.e. 8 h). The expected energy available from the DUT's PV socket over a standard solar day ($E_{PV,sim}$), less the daily energy loss due to standby power draw (E_{sb}), is parsed to each appliance's energy allocation based on the following formula:

$$E_{a,night^*} = \left(E_{PV,sim} - \frac{E_{sb}}{\eta_b \cdot \eta_{g-b}} \right) \cdot \frac{E_{ar,night}}{E_{ar,day} + E_{ar,night}} + (E_{a,day^*} - E_{a,day})$$

where

$E_{a,night^*}$ is the expected energy consumption used by the appliance during the solar run time during night-time usage, not considering the DUT's battery capacity, in watt-hours (Wh);

$E_{PV,sim}$ is the energy available from the DUT's PV socket during a standard solar day, in watt-hours (Wh);

E_{sb} is the estimated daily energy loss due to standby power draw (Wh);

η_b is the battery efficiency of the main battery as a fraction ;

η_{g-b} is the generator-to-battery efficiency as a fraction;

$E_{ar,night}$ is the energy consumption by an appliance during night use over the specified target use period, in watt-hours (Wh);

$E_{ar,day}$ is the energy consumption by an appliance during day use over the specified target use period, in watt-hours (Wh);

E_{a,day^*} is the maximum energy used by the appliance over when the DUT is solar charging, not considering the a maximum daytime use (i.e. 8 h), in watt-hours (Wh);

$E_{a,day}$ is the actual energy used to power the appliance over when the DUT is solar charging, considering the a maximum daytime use (i.e. 8 h), in watt-hours (Wh).

NOTE The sum of the calculated energy available to the night time appliance calculated above may exceed the maximum energy that the DUT's battery can supply during the night when not solar charging, hence the asterisked $E_{a,night^*}$.

hh) Check that the energy consumption value for the appliance during night use calculated in the above step does not exceed the amount of energy that the DUT's battery can possibly supply. Use the formula below to determine the actual energy available to the appliance during night use:

$$E_{a,night} = \min \left(E_{a,night^*}, \frac{E_{FBRT}}{\eta_{g-b} \cdot \eta_b} \right)$$

where

$E_{a,night}$	is the actual energy consumption used by the appliance during the solar run time during night-time usage, in watt-hours (Wh);
$E_{a,night^*}$	is the energy consumption used by the appliance during the solar run time during night-time usage, not considering the DUT's battery capacity, in watt-hours (Wh);
$E_{a,FBRT}$	is the energy consumed from the main unit's battery during the lighting full-battery run time, in watt-hours (Wh);
η_b	is the battery efficiency of the main battery as a fraction ;
η_{g-b}	is the generator-to-battery efficiency as a fraction.

R.5 Reporting

Report the following in the energy service calculations test report:

- Metadata
 - Report name
 - Procedure(s) used
 - DUT manufacturer
 - DUT name
 - DUT model number
 - DUT setting
 - Name of test laboratory
 - Approving person
 - Date of report approval
- Results for tested DUT aspects for samples 1 through n
 - Estimated full-battery run time(s) for each appliances under advertised usage (h)
 - Estimated full-battery run time(s) for each appliances under an example usage profile (h)
 - Estimated full-battery run time(s) for each appliances under individual usage (h)
 - Estimated full-battery run time fraction of a full charge for an advertised mobile phone (basic/feature) receives (%)
 - Estimated full-battery run time fraction of a full charge for an advertised smartphone receives (%)
 - Daily energy available to appliances after a standard solar day (Wh)
 - Daily energy service for all specified loads under advertised usage after a standard solar day (h)
 - Daily energy service for all specified loads under an example usage profile after a standard solar day (h)
 - Daily energy service for all specified loads under individual usage after a standard solar day (h)
 - Estimated solar run time fraction of a full charge for an advertised mobile phone (basic/feature) receives
 - Estimated solar run time fraction of a full charge for an advertised smartphone receives
- Average of n sample results for each DUT aspect tested
- Coefficient of variation of n sample results for each DUT aspect tested (%)
- DUT's rating for aspects tested, if available

- Deviation of the average result from the DUT's rating for each aspect tested, if available (%)
- Comments
 - Individual comments, as necessary, for samples 1 through n
 - Overall comments, as necessary, for collective set of samples 1 through n

Annex S (normative)

Battery durability test

S.1 Background

The battery durability test aims to identify batteries unsuitable for the application in solar home system kits. The procedures are related to storage of solar home system kits.

In general terms, the storage procedures use methods to accelerate the ageing mechanisms occurring during storage. This method enables the identification of batteries which age prematurely and are therefore unsuitable for use in solar home system kits.

S.2 Test outcomes

The test outcomes of the battery durability test are listed in Table S.1.

Table S.1 – Battery durability test outcomes

Metric	Reporting Units	Related aspects	Remarks
Capacity loss from storing (δC)	Percentage (%)	4.2.5.3 Battery	

S.3 Related tests

The battery durability test is related to the battery test (Annex I).

The storage test was derived from the following documents: PVRS 5A, VW 75073, AS 4086, (Flooded lead-acid); PVRS 5A, DIN EN 43539-5, (Sealed lead-acid); DIN EN 43539-15, IEC 61951-2, (NiMH); IEC 61960 (Lithium-ion)

S.4 Procedure

S.4.1 Durability storage test for valve-regulated lead-acid batteries

S.4.1.1 General

The DUT's valve-regulated lead-acid battery is stored for 360 hours connected to a resistance corresponding to a current of $2 I_t$ A, which causes a deep discharge.

S.4.1.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Battery analyser
- Wire cutters
- Wire strippers
- Soldering iron and solder
- Heat-shrink tubing and heat gun, or electrical tape
- Resistor with resistance corresponding to a current of $2 I_t$ A \pm 10 % and a power rating that is greater than the maximum power dissipated during the test, as specified in IEC 61056-1:2012, 7.9.2.

S.4.1.3 Test prerequisites

The DUT's battery shall be recently received and fully charged. The battery capacity shall have been determined using the lead-acid battery test (I.4.2). The product shall have been cycled no more than two times and shall have been stored for no more than 1 week since undergoing the battery capacity test. The battery shall be removed from the DUT.

S.4.1.4 Procedure

Perform the charge acceptance after the deep discharge test from IEC 61056-1:2012, 7.9, with the following modifications:

- The requirements of IEC 61056-1:2012, 7.9.1 need not be met;
- Capacity before and after storage shall be measured using the method defined in I.4.2;
- The battery shall be stored at an ambient temperature of 20 °C ± 5 K or 25 °C ± 5 K.

S.4.1.5 Calculations

Determine the capacity loss using following formula:

$$\delta C = \left(1 - \frac{C_A}{C_B} \right) \times 100\%$$

where

δC is the percent capacity loss experienced by the battery after the 30 days storage (%);

C_A is the battery capacity measured after the storage, in ampere-hours (Ah);

C_B is the battery capacity measured before the storage, in ampere-hours (Ah).

S.4.2 Durability storage test for flooded lead-acid batteries

S.4.2.1 General

The DUT's flooded lead-acid battery is stored for 30 days connected to a resistance corresponding to a current of 0,01 I_t A, which causes a deep discharge.

S.4.2.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Battery analyser
- Wire cutters
- Wire strippers
- Soldering iron and solder
- Heat-shrink tubing and heat gun, or electrical tape
- Resistors with resistance corresponding to a current of 0,1 I_t A and 0,01 I_t A, and a power rating that is greater than the maximum power dissipated during the test. The tolerance of the resistor itself shall be at least 5 %; a 20 % range within the calculated resistance value of the resistor is adequate.

S.4.2.3 Test prerequisites

The DUT's battery shall be recently received and fully charged. If testing a flooded lead-acid battery that was shipped dry, the battery shall have been filled with battery acid according to instructions in Annex I.

The battery capacity shall have been determined using the lead-acid battery test (Annex I). The product shall have been cycled no more than two times and shall have been stored for no more than 1 week since undergoing the battery capacity test. The battery shall be removed from the DUT. The storage test shall be carried out at 30 °C ± 5 °C.

S.4.2.4 Procedure

The following steps shall be followed, starting with a fully charged battery:

- a) Discharge the battery at a rate of 0,1 I_t A until a voltage of 1,8 V/cell is reached. The value of I_t shall be determined using the battery capacity measured in the battery test (Annex I).

- b) Connect across the battery terminals a resistor with resistance and power rating calculated using the following formulas, respectively:

$$R = \frac{V_{\text{nom}}}{0,01 \times I_t}$$

where

R is the resistance corresponding to a current of $0,01 I_t$ A, in ohms (Ω);

V_{nom} is the battery's nominal voltage, in volts (V);

I_t is the current corresponding to a 1 h discharge, in amperes (A).

$$P \geq \frac{(V_{\text{initial}})^2}{R}$$

where

P is the resistor's power rating, in watts (W);

V_{initial} is the battery voltage when the resistor is first connected, in volts (V);

R is the resistance of the selected resistor, in ohms (Ω);

- c) Store the battery for 30 days at $30 \text{ }^\circ\text{C} \pm 5 \text{ }^\circ\text{C}$.
d) Determine the DUT's battery capacity according to the lead-acid battery test (I.4.2).

S.4.2.5 Calculations

Determine the capacity loss using following formula:

$$\delta C = \left(1 - \frac{C_A}{C_B}\right) \times 100\%$$

where

δC is the percent capacity loss experienced by the battery after the 30 days storage (%);

C_A is the battery capacity measured after the storage, in ampere-hours (Ah);

C_B is the battery capacity measured before the storage, in ampere-hours (Ah).

S.4.3 Durability storage test for nickel-metal hydride batteries

S.4.3.1 General

The DUT's nickel-metal hydride battery is stored for 30 days at $60 \text{ }^\circ\text{C} \pm 5 \text{ }^\circ\text{C}$ connected to a resistance corresponding to a current of $0,2 I_t$ A, which causes a deep discharge in the battery.

S.4.3.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Battery analyser
- Wire cutters
- Wire strippers
- Soldering iron and solder
- Heat-shrink tubing and heat gun, or electrical tape
- Oven, environmental chamber, or other apparatus capable of maintaining temperature in the required range
- Resistor with resistance corresponding to a current of $0,2 I_t$ A and a power rating that is greater than the maximum power dissipated during the test. The tolerance of the resistor

itself shall be at least 5 %; a 20 % range within the calculated resistance value of the resistor is adequate.

S.4.3.3 Test prerequisites

The battery shall be recently received and fully charged. The battery capacity shall have been determined using the nickel-metal hydride battery test (Annex I). The product shall have been cycled no more than two times and shall have been stored for no more than 1 week since undergoing the battery capacity test. The battery shall be taken out of the DUT. The storage test shall be carried out at $60\text{ °C} \pm 5\text{ °C}$.

S.4.3.4 Procedure

The following steps shall be followed, starting with a fully charged battery:

- a) Discharge the battery at a rate of $0,2 I_t$ A until a voltage of 1,0 V/cell is reached. The value of I_t shall be determined using the battery capacity measured in the battery test (Annex I).
- b) Connect across the battery terminals a resistor with resistance and power rating determined using the formulas listed in S.4.1.4, step b).
- c) Store the battery for 30 days at $60\text{ °C} \pm 5\text{ °C}$.
- d) Determine the DUT's battery capacity according to the nickel-metal hydride battery test (I.4.3).

S.4.3.5 Calculations

The calculations required for the storage test for nickel-metal hydride batteries are identical to those for valve-regulated lead-acid batteries (S.4.1.5).

S.4.4 Durability storage test for lithium-ion batteries

S.4.4.1 General

The DUT's lithium-ion battery is stored for 30 days at $60\text{ °C} \pm 5\text{ °C}$ at a state of charge of 50 %.

S.4.4.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Battery analyser
- Oven, environmental chamber, or other apparatus capable of maintaining temperature in the required range.

S.4.4.3 Test prerequisites

The battery shall be recently received and fully charged. The battery capacity shall have been determined using the lithium-ion battery test (Annex I). The product shall have been cycled no more than two times and shall have been stored for no more than 1 week since undergoing the battery capacity test. The battery shall be taken out of the DUT. The storage shall be carried out at $60\text{ °C} \pm 5\text{ °C}$.

S.4.4.4 Procedure

The following steps shall be followed, starting with a fully charged battery:

- a) Discharge the battery at a rate of $0,2 I_t$ A for 2 h and 30 min. The battery is then at a state-of-charge of 50 %. The value of I_t shall be determined using the battery capacity measured in the battery test (Annex I).
- b) Store the battery for 30 days at $60\text{ °C} \pm 5\text{ °C}$.
- c) If the battery has multiple cells (or parallel cellblocks) in series, charge according to F.4.4 a).
- d) Determine the DUT's battery capacity according to the lithium-ion battery test (I.4.4).

S.4.4.5 Calculations

The calculations required for the storage test for lithium-ion batteries are identical to those for valve-regulated lead-acid batteries (S.4.1.5).

S.4.5 Durability storage test for lithium iron phosphate batteries

S.4.5.1 General

S.4.5.2 The DUT's lithium iron phosphate battery is stored for 30 days at 60 °C ± 5 °C at a state of charge of 50 %. Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Battery analyser
- Oven, environmental chamber, or other apparatus capable of maintaining temperature in the required range.

S.4.5.3 Test prerequisites

The battery shall be recently received and fully charged before undertaking the procedure. The battery capacity shall have been determined using the lithium iron phosphate battery test (Annex I). The battery shall be taken out of the DUT. The product shall have been cycled no more than two times and shall have been stored for no more than 1 week since the undergoing the battery capacity test. The storage shall be carried out at 60 °C ± 5 °C.

S.4.5.4 Procedure

The following steps shall be followed, starting with a fully charged battery:

- a) Discharge the battery at a rate of 0,2 I_t A for 2,5 h. The battery is then at a state of charge of 50 %. The value of I_t shall be determined using the battery capacity measured in the battery test.
- b) Store the battery for 30 days at 60 °C ± 5 °C.
- c) If the battery has multiple cells (or parallel cellblocks) in series, charge according to F.4.4 a).
- d) Determine the DUT's battery capacity according to the lithium iron phosphate battery test (I.4.5).

S.4.5.5 Calculations

The calculations required for the storage test for lithium-ion batteries are identical to those for lead-acid batteries (S.4.1.5).

S.5 Reporting

Report the following in the battery test report:

- Metadata:
 - Report name
 - Procedure(s) used
 - DUT manufacturer
 - DUT name
 - DUT model number
 - Battery manufacturer, if available
 - Battery name, if available
 - Battery model number, if available
 - Name of test laboratory
 - Approving person
 - Date of report approval

- Results for tested DUT aspects for samples 1 through n:
 - Capacity loss from storing (%)
- Average of n sample results for each DUT aspect tested
- Coefficient of variation of n sample results for each DUT aspect tested (%)
- DUT's rating for aspects tested, if available
- Deviation of the average result from the DUT's rating for each aspect tested, if available (%)
- Comments:
 - Individual and overall comments, as necessary

Annex T (normative)

Lumen maintenance test

T.1 Background

An important performance metric for LED lights is consistent luminous flux over the product's lifetime. The lifetime of LEDs is strongly influenced by electrical operating conditions and thermal management. Further criteria which can accelerate degradation include the quality of the phosphor used in white LEDs, component level chip design and LED packaging materials and processes, and the environmental stability of secondary optical components in the product housing. Assuming that an overall lifetime of 5 years and a daily burn time (DBT) of 4 h are achieved, this results in a total operation time of 7 300 h.

Examination of the lumen maintenance of LED light sources and products is performed in a long-term test of either the individual LED components or the entire LED product. LED components are sometimes tested by the LED manufacturer for a minimum of 6000 hours under IESNA LM80-08. Because of time constraints, however, it is generally not practical to measure a complete LED lighting product over its entire expected lifespan. The test methods described in this module take two different approaches to estimating lumen maintenance.

The first approach monitors a DUT's light output over a fixed period of operation in order to identify and flag products that are found to suffer significant lumen depreciation. An initial screening method is described which monitors light output for 500 h (approximately 3 weeks) as well as a longer term evaluation in which light output is monitored for 2 000 h (approximately 12 weeks).

Several of the tests used to evaluate solar LED products are relatively short-term, thus allowing a single test sample to be used on several different tests. Because the lumen maintenance test requires a sample to be dedicated for such a long period of time (up to 12 weeks), test samples should be dedicated to this test until the test is completed. In cases where the battery is not required to conduct the lumen maintenance test, the DUT's battery can be used for other testing (e.g., battery durability testing).

An alternate method for estimating lumen maintenance uses an IESNA LM80-08 (LM80) test report from the manufacturer of the LED component. The temperature of the LED(s) in the DUT are measured and compared to the LM80 data for the component LED(s) and an estimate is reported. The initial screening method monitoring light output for 500 hours is still performed, but no further lumen maintenance tests are required. This method therefore represents a faster assessment of a product's lumen maintenance performance.

T.2 Test outcomes

The lumen maintenance test outcomes are listed in Table T.1.

Table T.1 – Lumen maintenance test outcomes

Metric	Reporting units	Related aspects	Remarks
Lumen maintenance at 2 000 h	%	4.2.4.2 2 000 hour lumen maintenance	The percentage of initial light output (time = 0 h) that the product generates at the end of the test (time = 2 000 h)
Lumen maintenance at 1 000 h	%	4.2.4.2 2 000 hour lumen maintenance	The percentage of initial light output (time = 0 h) that the product generates at the mid-point of the test (time = 1 000 h); this may be used as a provisional result at the discretion of stakeholders.
Lumen maintenance at 500 h	%	4.2.4.1 500 hour lumen maintenance	The percentage of initial light output (time = 0 h, after the initial 20-min warm-up period) that the product generates at the end of the test

			(time = 500 h)
--	--	--	----------------

T.3 Related tests

Annex T is not related to any of the other annexes.

For lighting appliances without batteries, the lumen maintenance test of IEC 62257-12-1 may be used in place of Annex T.

T.4 Procedure

T.4.1 General

Two tests are described in T.4: a full lumen maintenance characterization in which DUTs are tested for 2 000 h and a quick screening test in which DUTs are tested for 500 h.

Similar to the full-battery run time test (Annex L), the lumen maintenance test requires an accurate measurement of relative light output over time. Measurements shall be taken in a conditioned space such that the air temperature is $24\text{ °C} \pm 3\text{ °C}$. During the duration of the test (2 000 h or 500 h), the DUTs shall be placed in a position similar to how they would normally be used (e.g. hanging lights should be hanging, etc.). There are four approved methods for making these measurements:

- Photometer tube method (T.4.2.1)
- Fixed geometry method (T.4.2.2)
- Photometer box method (T.4.2.3)
- Integrating sphere method (T.4.2.4)

T.4.2 Full screening

T.4.2.1 Photometer tube method

T.4.2.1.1 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Photometer tube test apparatus that includes an illuminance meter (described below)
- DC power supply
- DC voltmeter or multimeter

T.4.2.1.2 Test prerequisites

The DUT shall have been prepared as described in Annex F.

T.4.2.1.3 Apparatus

The photometer tube is a self-made device (made from low-cost materials that are readily available in developing countries) for taking measurements of relative luminous flux. A basic rendering of a photometer tube is included in Figure T.1.

Key

- 1 Tube
- 2 Open end
- 3 Photometer
- 4 End cap
- 5 Photometer sensor

Figure T.1 – Schematic of a photometer tube

The recommended tube for this application is made of cardboard, often available free of cost from fabric or paper rolls. PVC pipe is also relatively inexpensive and appropriate for use as a photometer tube. The tube inside diameter should be between 5 cm and 7 cm. The tube should be at least 50 cm in length.

An end cap is fit snugly to one end of the tube. The end cap holds the illuminance meter sensor in a fixed position at the end of the tube and restricts stray light from entering. Due to material cost and ease of manufacture, wood is the recommended material for the end cap.

No reflective coating is necessary on the internal surface of the photometer tube.

T.4.2.1.4 Procedure

These steps shall be followed:

- a) Supply power to the lighting appliance according to U.4.1.
- b) Light from the DUT is directed into the open end of the photometer tube.

The DUT and the photometer are both fixed to the photometer tube for the duration of the test. It is recognized that laboratories testing a large number of samples may not be able to dedicate a photometer to each sample that they are testing during the duration of the lumen maintenance test. Thus, an apparatus may be used in which the DUT or the photometer is installed just prior to the making measurements and then removed afterwards.

If such a method is utilized, great care shall be made to ensure that the photometer and the DUT are placed in precisely the same geometric arrangement for each measurement, as even slight variation in placement can generate significant measurement errors. Also, if a photometer is installed and removed from an apparatus, it is important that the same photometer is used for all measurements (i.e., do not measure some readings with meter A, and subsequent readings with meter B). Using photometers with “max” functions can facilitate replication of the original geometry (i.e., if the original reading is at the peak of the light distribution it is possible, and permitted, to search for the peak using a max function).

For DUTs with multiple identical lighting appliances, it is only necessary to measure one of each type of identical lighting appliance; therefore, it is not necessary for all the product’s lighting appliances to be running during the duration of the test. For example, if a DUT includes three different types of lighting appliances (e.g. a tube light, four ambient light points, and two more focused light points), then three of the seven lighting appliances would be measured during testing – one of each lighting appliance type.

- c) Care shall be taken to ensure that the DUT is secured to the photometer tube such that exactly the same alignment is maintained for each measurement. Care shall also be taken when securing the DUT to the photometer tube that the DUT does not have its thermal environment altered significantly. If airflow around the DUT is significantly reduced due to the connection to the photometer tube (i.e., if the entire DUT is placed inside the tube), the test results could show a lower lumen maintenance rate than would actually result from normal use.
- d) Refer to Table T.2 for the minimum frequency at which the relative illuminance of the DUT, ambient temperature, DUT voltage, and current are measured and recorded. The voltage measurement shall be made as close to the DUT as possible.
- e) (optional) A data logger or a lux meter with a data-logging function may be used to record the illuminance every hour.

Table T.2 – Lumen maintenance test minimum frequency of measurement for full screening test

Measurement number	Time interval (h)	Cumulative time (h)
1	0,33 (20 min)	0
2	24	24
3	48	72
4	48	120
5	48	168
6	48	216
7	168	384
8	168	552
9	168	720
10	168	888
(optional)	112	1000
11	168	1056
12	168	1224
13	168	1392
14	168	1560
15	168	1728
16	168	1896
17	104	2000

T.4.2.1.5 Calculations

See T.5.

T.4.2.2 Fixed geometry method

T.4.2.2.1 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- DC power supply
- DC voltmeter or multimeter
- Illuminance meter

T.4.2.2.2 Test prerequisites

The DUT shall have been prepared as described in Annex F.

T.4.2.2.3 Apparatus

The apparatus for the method is simply any dedicated space in which the DUT and the photometer are secured so they do not move relative to one another during testing and so no outside light is received. This could be a dedicated area in a “dark room” in which the light sensor and DUT are secured, or other similar setup.

T.4.2.2.4 Procedure

These steps shall be followed:

- f) Supply power to the lighting appliance according to U.4.1 The DUT and the photometer are both placed in a fixed locations relative to one another for the duration of the test. Care shall be taken to ensure that the DUT and the photometer are secured such that exactly the same alignment is maintained for each measurement. Care shall also be taken such that no stray light (i.e., ambient light, light from other test samples, etc.) is able to reach the light sensor.

For DUTs with multiple identical lighting appliances, it is only necessary to measure one of each type of identical lighting appliance; therefore, it is not necessary for all the product's lighting appliances to be running during the duration of the test. For example, if a DUT includes three different types of lighting appliances (e.g. a tube light, four ambient light points, and two more focused light points), then three of the seven lighting appliances would be measured during testing – one of each lighting appliance type.

The test lab shall determine the best way to test multiple lighting appliances. In some cases, it is possible to test all of the lighting appliances together (for example, the lighting appliances are small and can be placed and tested together inside the test enclosure). In other cases, the lighting appliances should be tested individually (for example, one lighting appliance is placed inside the test enclosure and the others are powered on but left outside the enclosure during the test).

- g) Refer to Table T.2 for the minimum frequency at which the relative illuminance of the DUT, ambient temperature, DUT voltage, and current are measured and recorded. The voltage measurement shall be made as close to the DUT as possible.
- h) A data logger or a lux meter with a data-logging function may be used to record the illuminance every hour.

T.4.2.2.5 Calculations

See T.5.

T.4.2.3 Photometer box method

T.4.2.3.1 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Photometer box that includes an illuminance meter
- DC power supply
- DC voltmeter or multimeter

T.4.2.3.2 Test prerequisites

The DUT shall have been prepared as described in Annex F.

T.4.2.3.3 Apparatus

The apparatus for the method is a photometer box, as described in the full-battery run time test (Annex L).

T.4.2.3.4 Procedure

These steps shall be followed:

- a) Supply power to the lighting appliance according to Annex U.4.1.
- b) The relative illuminance is measured using the photometer box.

- c) The location of the DUT in the photometer box shall be accurately noted to ensure exact replication of alignment and orientation for each measurement. A printed photograph of the DUT placement within the box is a useful reference (Figure T.1). Alignment marks may also be used to ensure repeatability.

For DUTs with multiple identical lighting appliances, it is only necessary to measure one of each type of identical lighting appliance; therefore, it is not necessary for all the product's lighting appliances to be running during the duration of the test. For example, if a DUT includes three different types of lighting appliances (e.g. a tube light, four ambient light points, and two more focused light points), then three of the seven lighting appliances would be measured during testing – one of each lighting appliance type.

The test lab shall determine the best way to test multiple lighting appliances. In some cases, it is possible to test all of the lighting appliances together (for example, the lighting appliances are small and can be placed and tested together inside the test enclosure). In other cases, the lighting appliances should be tested individually (for example, one lighting appliance is placed inside the test enclosure and the others are powered on but left outside the enclosure during the test).

- d) For the following measurements, the DUT shall be placed in the photometer box with exactly the same alignment and orientation.
- e) Refer to Table T.2 for the minimum frequency at which the relative illuminance of the DUT, ambient temperature, DUT voltage, and current are measured and recorded. The voltage measurement shall be made as close to the DUT as possible.
- f) In the case that the DUT remains in the box throughout the duration of the test, a data logger or a lux meter with a data-logging function may be used to record the illuminance every hour.

T.4.2.3.5 Calculations

See T.5.

T.4.2.4 Integrating sphere method

T.4.2.4.1 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Integrating sphere
- DC voltmeter or multimeter
- DC ammeter

T.4.2.4.2 Test prerequisites

The DUT shall have been prepared as described in Annex F.

T.4.2.4.3 Apparatus

Integrating sphere

T.4.2.4.4 Procedure

These steps shall be followed:

- a) Supply power to the lighting appliance according to Annex U.4.1.
- b) The luminous flux is measured using an integrating sphere system.

For DUTs with multiple identical lighting appliances, it is only necessary to measure one of each type of identical lighting appliances; therefore, not all the product's lighting appliance need to be running during the duration of the test. For example, if a DUT includes three different types of lighting appliances (e.g. a tube light, four ambient light points, and two more focused light points), then three of the seven lighting appliances would be measured during testing – one of each lighting appliance type.

The test lab shall determine the best way to test multiple lighting appliances. In some cases, it is possible to test all of the lighting appliances together (for example, the lighting

appliances are small and can be placed and tested together inside an integrating sphere). In other cases, the lighting appliances should be tested individually (for example, one lighting appliance is placed inside an integrating sphere and the others are powered on but left outside the sphere during the test).

- c) Refer to Table T.2 for the minimum frequency at which the luminous flux of the DUT, ambient temperature, DUT voltage, and current are measured and recorded. The voltage measurement shall be made as close to the DUT as possible.

T.4.2.4.5 Calculations

See T.5.

T.4.3 Initial screening (500 hour test)

The lumen maintenance initial screening test is identical to the full screening test with the exception of the test duration, which is reduced from 2 000 h to 500 h. All four of the methods described above for the full screening test (photometer tube, fixed geometry, photometer box, and integrating sphere) may be used for the initial screening test. Table T.3 shall be used for minimum testing duration.

Table T.3 – Lumen maintenance test minimum frequency of measurement for Initial screening test

Measurement number	Time interval (h)	Cumulative time (h)
1	0,33 (20 min)	0
2	24	24
3	48	72
4	48	120
5	48	168
6	48	216
7	168	384
8	116	500

T.5 Calculations

Lumen maintenance is calculated by dividing the final light output reading by the initial light output reading. Lumen maintenance is always reported along with the test duration.

If the light output of the DUT ever drops below 90 % of the initial reading, then operating hours at which this occurs should be reported as L_{90} . For example, if the initial reading was 1 000 lx, and readings dropped to 900 lx after 720 h, then $L_{90} = 720$ h.

If the light output of the DUT at the end of the 2 000 hour test has not dropped below 90 % of the initial reading, the L_{90} result will then be $L_{90} > 2\ 000$ h.

T.6 Alternate method for testing lumen maintenance using IESNA LM80-08

T.6.1 Background

The lumen maintenance of an LED or LED array contained in a lighting product can be estimated by measuring the LED case temperature(s) (T_C). This measurement is compared to IESNA LM80-08 data (minimum 6000 hours) from the LED manufacturer to estimate the DUT's lumen maintenance at 2000 hours.

The LED case temperature (T_C) measurement location, also sometimes referred to as the LED temperature measurement point (TMP), is established by the LED manufacture. T_C is related to the temperature of the LED die and is measured by attaching a thermocouple as close to the LED component as possible on a printed circuit board pad adjacent to the LED. This measurement location may be one of the LED lead pads or may be a separate, electrically neutral pad on the printed circuit board configured as a heat sink for the LED. The

LED manufacturer will have information on the correct TMP for the LED that was used during the LM80-08 tests. The DUT manufacturer must provide a TMP for the LEDs in the product that matches the T_C measurement location used for the LM80 tests. This is often done by using the same printed circuit board pad configuration that was used for the LM80 tests in the design of the DUT.

This LED temperature procedure tests the instantaneous LED temperature during normal operation to make an LED lumen maintenance assessment. It does not test longer duration operation of the LED or LED drive circuitry. To assess the ability of the DUT electronics to drive the LED(s) over a longer time period, a 500 hour initial screening test shall also be performed as described in T.4.3.

T.6.2 Test prerequisites

This test may not be performed unless *all* of the following criteria are met:

- The DUT manufacturer has supplied the DUT LED component specification(s), including the complete component number and the LED specification document from the LED manufacturer.
- The DUT manufacturer has supplied IESNA LM80-08 (LM80) test data for the LED(s) used in the lighting product. LM80 testing is typically done by the LED manufacturer. The laboratory performing the LM80 test shall be accredited to do this type of testing.
- The DUT manufacturer has supplied an LED RMS drive current measurement at the product's highest light setting.
- The LM80 test data includes an LED case temperature (T_C) and LED drive current higher than the DUT's LED case temperature and drive current.
- The DUT is designed in such a way as to allow temperature measurement of the LED T_C as specified by the LED manufacturer.
- The DUT manufacturer has provided instructions and diagrams showing the appropriate attachment point for thermocouples used during the test.

T.6.3 Procedure

Perform the following procedure:

- a) Review documentation supplied by the DUT manufacturer to confirm that the DUT qualifies for testing under this section.
- b) Prepare the DUT for LED testing as outlined in section T.6.4 below.
- c) Attach thermocouples to one or more LED(s) as outlined in section T.6.4 below.
- d) Reassemble the product and orient in its normal operating position. The DUT shall be operated in a $25\text{ °C} \pm 2\text{ °C}$ still air environment free from drafts, fans, and other air currents that could produce forced air convective currents and contribute to the cooling of the product.
- e) Supply power to the lighting appliance according to Annex U.4.1.
- f) Allow the product to thermally stabilize for a minimum of 1 hour. The LED case temperatures should be monitored to confirm thermal stabilization.
- g) Record the LED case temperature (T_C).
- h) Prepare the DUT for initial screening and perform a 500 hour test as described in T.4.3.

T.6.4 DUT preparation and LED thermocouple attachment guidelines

The LED(s) in the DUT must be accessed to allow the attachment of thermocouple wires. When opening the DUT optical housing to access the LED(s), care must be taken to preserve the normal operating environment. Holes drilled into compartments should be as small as possible and covered with tape to prevent additional air movement during operation. The T_C location of the LED(s) must be accessible to allow thermocouple attachment without disturbing the normal operation of the array.

Small gauge Type T thermocouples (wire diameter ≤ 0.13 mm) are recommended and can be readily soldered to copper circuit board pads. Other thermocouples are permitted but require the appropriate soldering flux and may be difficult to solder. The thermocouple attachment, including any additional solder or epoxy, shall be as small as possible to prevent an additional heat conduction pathway that could artificially contribute to the heat sinking of the LED component. LED(s) with large thermal pads or heat sinks may require preheating to facilitate soldering the thermocouple to the TMP or T_C measurement location.

A thermocouple may be attached to an LED's temperature measurement point by soldering or gluing using a thermally conductive adhesive/epoxy. The attachment method shall ensure adequate thermal contact between the thermocouple and the TMP. Thermocouple wire should be routed away from direct illumination by the LED(s) and/or should be shielded from direct light to prevent artificial heating of the wire. This can usually be accomplished with white tape or white heat-shrink tubing. Tape or tubing should not cover the LED in a way that could increase the self-heating of the LED component.

When testing a DUT with multiple LEDs in an LED array, the test lab shall attempt to identify the LED in the array that will experience the highest temperature in operation. In practice this is often an LED located in the centre of the array. Measurements on multiple LEDs in an array may be warranted to adequately identify the T_C value used for an LM80 assessment.

T.6.5 Calculations

The LM80 test report for the DUT LED will contain lumen maintenance data for LED temperature measurements at 55 °C, 85 °C, and one additional temperature chosen by the LED manufacturer. These measurements are performed for a minimum duration of 6000 hours and will therefore contain test data at 2000 hours.

The test lab shall compare the LM80 data and T_C to estimate the lumen maintenance of the product. The test lab shall use the nearest LM80 data point above the duration (>2000 hours), DUT T_C , and LED drive current. For example, if the DUT T_C is measured at 65°C, LM80 data at 85°C (or greater than 65°C when available) shall be used. If the DUT LED drive current is 65 mA, the LM80 data shall be at drive currents greater than 65 mA.

The test lab shall report the lumen maintenance of the DUT as the lumen maintenance measured by the nearest (higher conditions for T_C and drive current) LM80 test data as specified above.

T.7 Reporting

Report the following in the lumen maintenance test report:

- Metadata
 - Report name
 - Procedure(s) used
 - DUT manufacturer
 - DUT name
 - DUT model number
 - DUT setting
 - Test room temperature (°C)
 - Name of test laboratory
 - Approving person
 - Date of report approval
- Results for tested DUT aspects for samples 1 through n
 - Drive current (A)
 - Drive voltage (V)

- Stabilisation time (min)
- Lumen maintenance (note if at 500 h, 1 000 h, or 2 000 h) (%)
- L_{90} (the cumulative time at which the light output of the DUT first drops below 90 % of the initial reading) (h)
- Average of n sample results for each lumen maintenance and L_{90} DUT aspect tested
- Coefficient of variation of n sample results for each lumen maintenance and L_{90} DUT aspect tested (%)
- DUT's rating for lumen maintenance and L_{90} aspects tested, if available
- Deviation of the average result from the DUT's rating for each lumen maintenance and L_{90} aspect tested, if available (%)
- Comments
 - Individual comments, as necessary, for samples 1 through n
 - Overall comments, as necessary, for collective set of samples 1 through n
- Figures
 - Plot of lumen maintenance (see example in Figure T.2)
- Datasets
 - Table with all illuminance or flux, ambient temperature, DUT voltage, and current measurements

Key

- t Time (h)
- Y Relative luminous flux

Figure T.2 – Example lumen maintenance plot

Annex U (normative)

Light output test

U.1 Background

The light output of a lighting appliance is a key parameter as products that do not provide a sufficient amount of light have limited value.

Light output measurements (total luminous flux or lumen output) typically require the use of an integrating sphere or goniophotometer. An additional luminous flux measurement technique, referred to as the multi-plane method, involves conducting illuminance measurements on six planes that define a “box” around a test product and uses these measurements to calculate luminous flux. The multi-plane method is unique to IEC 62257 and quality assurance protocol and is described in U.4.4.

Laboratories may measure total luminous flux using an integrating sphere, goniophotometer, or the multi-plane method.

The light output of all lighting appliances to be tested shall be measured individually. If more than one identical lighting appliance is included with the DUT kit, more than one of each type of identical lighting appliances need not be measured. The product specification may define categories of lighting appliances that need not be subjected to the light output test.

U.2 Test outcomes

The test outcomes of the light output test are listed in Table U.1.

Table U.1 – Light output test outcomes

Metric	Reporting units	Related aspects	Remarks
Luminous flux	Lumens (lm)	4.2.10.1 Luminous flux output	Measured using a DC power supply, light sensor, and integrating sphere or goniophotometer (or using a multi-plane measurement).
Correlated colour temperature (CCT)	Kelvin (K)	4.2.10.4 Colour characteristics	Measured using equipment capable of characterizing spectral distribution
Colour rendering index (CRI)	0-100 (unitless)	4.2.10.4 Colour characteristics	Measured using equipment capable of characterizing spectral distribution

U.3 Related tests

The light output test is related to the light distribution test (Annex V).

The light output test allows several alternatives for determining light output. The multi-plane method described in U.4.4 and a goniophotometer may be used to generate information on the distribution of the device (needed for Annex V) as well as information on light output. When these methods are utilized, data may also be used by Annex V to calculate full width half maximum (FWHM) angles as described in V.5.3.6.

U.4 Luminous flux measurement techniques

U.4.1 General

The luminous flux of all of the lighting appliances supplied with the DUT shall be measured. If more than one identical appliance is included with the DUT kit, it is not required that more than one of each set of identical appliances be tested.

These steps shall be followed:

- a) Determine the method of supplying power to the lighting appliance(s). The appliance shall be connected either to a port on the DUT's power control unit (i.e., the component containing the battery that powers the lighting appliances) or directly to a laboratory power supply. See Annex G for additional information on selecting an appropriate method to power the lighting appliance.
- b) Prepare the test sample for lighting evaluation as described in Annex F. Set up a power supply to drive the DUT as described in Annex G. Measurements shall be taken in a conditioned space such that the air temperature is $24\text{ }^{\circ}\text{C} \pm 3\text{ }^{\circ}\text{C}$.
- c) When connecting a lighting appliance to a port on the DUT's power control unit use the **standard operating voltage** (Annex G) to supply power from a laboratory power supply to the power control unit. All of the lighting appliances in the DUT kit shall be connected, powered on, and set at their highest output setting, unless otherwise specified in the product specification or requested by the client. Additional settings may be tested at the laboratory's discretion.

When a DUT has multiple lights, these lighting appliances shall be tested individually (for example, one lighting appliance is placed inside an integrating sphere and the others are powered on but left outside the sphere during the test). Though all lighting appliances are connected and powered on during the test, for DUTs with multiple identical lighting appliances, it is not required that more than one of each type of identical lighting appliances be measured. For example, if a DUT includes three different types of lighting appliances (e.g. a tube light, four ambient light points, and two more focused light points), then three of the seven lighting appliances would be measured during testing – one of each lighting appliance type.

- d) When connecting a lighting appliance directly to a laboratory power supply, use the **typical port voltage** (P.4.4) for the port to which the appliance is normally connected. The DUT shall be powered on and set to the highest output setting. It is not required that more than one of each type of identical lighting appliance be measured.

All DUT luminous flux measurements will be performed with the DUT(s) set to the highest output setting, unless otherwise specified in the product specification or requested by the client. Additional settings may be tested at the laboratory's discretion.

- e) Allow the DUT to stabilize according to G.5.3.
- f) Record the voltage and current draw of the DUT at the DUT's input connector.
- g) When powering DUT lighting appliances with a product's power control unit, record the voltage and current at the power control unit's battery input connector.

U.4.2 Luminous flux calculation for lighting appliances that have been tested according to IEC 62257-12-1

If a lighting appliance without an internal battery has been tested according to the light output test method of IEC 62257-12-1, the light output test need not be repeated provided that the typical port voltage (P.4.4) is within the range of voltages at which relative light output was measured during the input voltage range test of IEC 62257-12-1.

The relative light output and luminous flux measurements shall have been made at the setting for which light output is to be calculated. (For example, the relative light output measured at the high setting shall not be used to calculate the light output at the medium setting.) The CRI and CCT values measured in the light output test of IEC 62257-12-1 may be used without correction even if the drive voltage was not equal to the typical port voltage.

To calculate light output for such a lighting appliance, use the following procedure:

- a) Calculate, using linear interpolation, the relative light output percentage at the typical port voltage (P.4.4) for the port to which the appliance is normally connected, using the relationship between voltage and relative light output measured in the input voltage range test of IEC 62257-12-1. (The relative light output at the standard operating voltage defined in IEC 62257-12-1 is always 100 %.)

NOTE The standard operating voltage from IEC 62257-12-1 is not necessarily the same as the standard operating voltage defined in G.5.2.

- b) Multiply the relative light output value calculated in a) by the luminous flux value measured in the light output test of IEC 62257-12-1.

U.4.3 Luminous flux measurements with an integrating sphere or goniophotometer

Refer to the following standard test methods for the measurement of luminous flux with an integrating sphere or goniophotometer:

- CIE084: The measurement of luminous flux
- CIE127: Measurement of LEDs
- IESNA LM-78-07: IESNA approved method for total luminous flux measurement of lamps using an integrating sphere photometer
- IESNA LM-79-08: Electrical and photometric measurement of solid state lighting products

U.4.4 Luminous flux measurements using the multi-plane method

U.4.4.1 General

1 lux is equal to 1 lumen per square metre. This relationship is used in this method to obtain total lumen output by determining the average illuminance (lux) on a 1 m² surface at six surfaces (left, right, front, back, top, and bottom) that completely encompass the lighting appliance and summing up the zonal lumen output from each of these six surfaces. This method is similar conceptually to the method by which lumen output is calculated by summing zonal lumen output for goniophotometric measurements.

When connecting a lighting appliance to a port on the DUT's power control unit use the **standard operating voltage** to supply power from a laboratory power supply to the power control unit. All of the lighting appliances in the DUT kit shall be connected, powered on, and set at the desired output setting. Only one lighting appliance can be tested at a time with this procedure. Other lighting appliances shall be covered or otherwise arranged so that no light from these appliances reaches the measurement plane.

Though all lighting appliances must be connected and powered on during the test, for DUTs with multiple identical lighting appliances, it is only necessary to measure one of each type of identical lighting appliance. For example, if a DUT includes three different types of lighting appliances (e.g. a tube light, four ambient light points, and two more focused light points), then three of the seven lighting appliances would be measured during testing – one of each lighting appliance type.

If instead connecting a lighting appliance directly to a laboratory power supply, use the **typical port voltage** (P.4.4) for the port to which the appliance is normally connected. The DUT shall be powered on and set to the desired output setting. It is only necessary to measure one of each type of identical lighting appliance.

U.4.4.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Illuminance meter
- Multi-plane test apparatus (described below)
- DC power supply
- DC voltmeter or multimeter
- DC ammeter

U.4.4.3 Test prerequisites

See general procedure (U.4.1).

U.4.4.4 Apparatus

The test requires a light distribution grid surface that can be used to position an illuminance meter on a 1 m² surface with 0,1 m spacing—an 11 × 11 grid with 121 points (Figure U.1). The 81 interior points each represent 100 cm² of surface area, the 36 edge points each represent 50 cm² of surface area, and the four corner points represent 25 cm² of surface area.

The light is fixed 0,5 m away from the centre of the grid surface (the 0,5 m is measured from the centre of the light source itself).

Figure U.1 – Conceptual schematic of the light output test setup, including the 11 × 11 grid, Cartesian coordinate axes for rotation reference, and the DUT

U.4.4.5 Procedure

In general, the lighting appliance shall be situated so the first surface that is measured is the one that contains the peak of the overall light distribution. Subsequently, the light is carefully rotated to capture the other five surface measurements. Three of the remaining five positions are achieved by rotating the lamp exactly 90° about the vertical (Z) axis between each measurement. The remaining two positions are achieved by rotating the light about the horizontal (X) axis (see Figure U.1). After every rotation, the centre point of the light source should be exactly 0,5 m from the illuminance meter's sensor when it is placed in the centre of the measurement plane. The DUT shall be mounted using a turntable (rotating platform) or a clamping system.

Be sure no stray light hits the photometer and no reflections from other surfaces in the room interfere with the readings. Installing a black curtain around the test setup and having the test operator wear all black are recommended.

These steps shall be followed:

- a) Arrange the room and prepare the lighting appliance(s), ensuring the stand can hold the lighting appliance steadily and enables precise rotation.
- b) Supply power to the DUT and allow the DUT to stabilize at the desired output setting according to U.4.1.
- c) Position the DUT such that the centre of its light source is 0,5 m away from the centre of the grid surface as shown in Figure U.1.
- d) The centre of the grid surface shall read the highest light output provided by the lighting appliance at a 0,5 m distance.
- e) Measure illuminance levels at every 0,1 m distance on the grid surface, with the illuminance meter co-planar to the measurement grid (not normal to the light source).

- f) Measure illuminance levels for the grid points that read a lux value greater than the resolution of the illuminance meter and greater than 0,2 % of the maximum lux reading from the first surface measured.
- g) Rotate the DUT 90° clockwise, repositioning the DUT, if necessary, such that the centre point of the light output is exactly 0,5 m from the illuminance meter's sensor. It is also permissible to rotate the measurement grid about the DUT. Repeat steps d) through g) for the two remaining side faces until reaching the DUT's initial position.
- h) Tilt the DUT 90° down (about the X axis) and reposition the DUT, if necessary, such that the centre point of the light output is exactly 0,5 m from the illuminance meter's sensor. It is also permissible to rotate the measurement grid about the DUT.
- i) Measure illuminance levels for the grid points that read a lux value greater than the resolution of the illuminance meter and greater than 0,2 % of the maximum lux reading from the first surface measured.
- j) Tilt the DUT 180° up (about the X axis) and reposition the DUT, if necessary, such that the centre point of the light output is exactly 0,5 m from the illuminance meter's sensor. It is also permissible to rotate the measurement grid about the DUT.
- k) Measure illuminance levels for the grid points that read a lux value greater than the resolution of the illuminance meter and greater than 0,2 % of the maximum lux reading from the first surface measured.
- l) Repeat steps a) through k) for additional lighting appliances supplied in the DUT kit. Configure the lighting appliances so that only one appliance is tested at a time.

U.4.4.6 Calculations

The illuminance data may be used to estimate the lighting appliance luminous flux output. The six measured sides have virtually enclosed the lighting appliance light output within a box. All the illuminance values over the virtual surfaces will be integrated to calculate an estimate for luminous flux.

- a) Estimate the luminous flux incident on the first measured surface.
 - 1) Multiply the illuminance values by the appropriate area each one represents (0,01 m² for interior points, 0,005 m² for edge points, and 0,0025 m² for corner points) to obtain the luminous flux (lm) represented by each illuminance measurement.
 - 2) Sum the illuminance measurements over the entire surface.
- b) Repeat step a) to calculate the luminous flux for the remaining five sides.
- c) Total the luminous flux estimates over all six sides to obtain an estimated constant-voltage luminous flux emitted from the lighting appliance.
- d) Sum all of the luminous flux estimates from each lighting appliance to produce a total luminous flux estimate for the DUT.

U.5 Correlated colour temperature (CCT) measurement

Measurement of correlated colour temperature shall be made in accordance with IEC 60081:1997, Annex D (which references CIE 15:2004).

U.6 Colour rendering index (CRI) measurement

Measurement of colour rendering index (R_a) shall be made in accordance to CIE 13.3 and CIE 177.

U.7 Reporting

Report the following in the light output test report:

- Metadata
 - Report name
 - Procedure(s) used

- DUT manufacturer
- DUT name
- DUT model number
- DUT setting
- Test room temperature (°C)
- Name of test laboratory
- Approving person
- Date of report approval
- Results for tested DUT aspects for samples 1 through n
 - Drive current into DUT's main unit (A)
 - Drive voltage at DUT's main unit (V)
 - Drive current(s) into DUT's lighting appliance(s) for non-integrated lighting appliances (A)
 - Drive voltage(s) at DUT's lighting appliance(s) for non-integrated lighting appliances (V)
 - Stabilisation time (min)
 - Total constant-voltage luminous flux (lm) for each non-identical lighting appliance
 - Total constant-voltage luminous flux (lm) for the DUT
 - Correlated colour temperature
 - Colour rendering index
- Average of n sample results for each DUT aspect tested
- Coefficient of variation of n sample results for each DUT aspect tested (%)
- DUT's rating for aspects tested, if available
- Deviation of the average result from the DUT's rating for each aspect tested, if available (%)
- Comments
 - Individual comments, as necessary, for samples 1 through n
 - Overall comments, as necessary, for collective set of samples 1 through n

Annex V (normative)

Light distribution test

V.1 Background

Luminous flux and light distribution are two primary metrics used to assess the performance of a lighting product. Measurements of luminous flux (the total amount of light emitted by a source) are appropriate for any type of light and are discussed in Annex U. Measurements of light distribution are also appropriate for any type of light, with particular relevance to the performance of task lights that have focused light outputs.

The light distribution of lighting appliances can vary greatly, ranging from very narrow-beam task lights to omnidirectional ambient lights. While there is no distribution that is necessarily “ideal,” some distributions are more appropriate for certain applications than others. Annex V is intended to characterize a product’s light distribution so purchasers can select products that are appropriate for the applications in which they are used.

The light distribution of all lighting appliances (those that are required by the product specification to undergo the lighting tests), supplied with the DUT shall be measured individually. If more than one identical appliance is included with the DUT kit, only one of each set of identical appliances shall be measured.

V.2 Test outcomes

The light distribution test outcomes are listed in Table V.1

Table V.1 – Light distribution test outcomes

Metric	Reporting units	Related aspects	Remarks
Vertical and horizontal full width half maximum (FWHM) angles	Degrees (°)	4.2.10.2 Full width half maximum (FWHM) angle 4.2.10.3 Average light distribution characteristics	--
Luminous flux	Lumens (lm)	4.2.10.1 Luminous flux output	Only obtained when using multi-plane (V.5.3) or goniophotometer (V.5.2) test methods

V.3 Related tests

The light distribution test is related to the light output test (Annex U) and the full-battery run time test (Annex L). Specifically, either the multi-plane method described in U.4.4 or the goniophotometer method described in U.4.3 may be used to gather all needed data to generate full width half maximum (FWHM) angles for lights.

V.4 Substitution of results from IEC 62257-12-1

For lighting appliances without internal batteries, the light distribution test of IEC 62257-12-1 may be used in place of the light distribution test in Annex V. Since the voltage supplied to the lighting appliance in IEC 62257-12-1 may be different from the typical port voltage (P.4.4), the results of the IEC 62257-12-1 light distribution test shall be adjusted as follows:

- Full width half maximum angles need not be adjusted.
- Luminous flux values shall be adjusted by multiplying by the relative light output percentage value determined in U.4.2 a).

V.5 Approved test methods

V.5.1 General

There are multiple approved methods. Each of the approved options and their associated apparatus are described in V.5.1. Table V.2 summarizes the test outcomes for each of the approved test methods.

Each method shall be completed on a sample size of one. If more than one identical lighting appliance is included with the DUT kit, only one of each type of identical lighting appliances should be tested. Also, if the DUT has multiple unique lighting appliances, each unique lighting appliance must be tested.

Table V.2 – Summary of testing options for characterizing lamp distributions

Test method	Test outcomes
Goniophotometer or multi-plane	<ul style="list-style-type: none"> • Vertical and horizontal FWHM angles • Luminous flux (see Annex T)
Turntable	<ul style="list-style-type: none"> • Vertical and horizontal FWHM angles

These steps shall be followed before performing the test by any method:

- a) Determine the “horizontal” and “vertical” planes for the purposes of the light distribution measurement, using the following guidelines. Describe the selected orientation in the test report. Photographs or diagrams may be useful in describing the product orientation, but are not required if the text description is unambiguous.
 - 1) These guidelines consider two types of light points: **omnidirectional** and **directed**. If the distribution of illuminance is measured on an imaginary sphere surrounding an omnidirectional product, the maximum illuminance will occur at the equator and local minima will occur at the poles. For a directional product, the maximum illuminance will occur at one pole and the minimum will occur at the other pole. Typical omnidirectional light points include lanterns and some bulbs; typical directed light points include torches and suspended task lights.
 - 2) For an **omnidirectional light point**, the horizontal plane is the plane of maximum illuminance, typically parallel to the ground, and the vertical plane is the plane perpendicular to the horizontal plane containing the point of maximum illuminance. In some cases there may be multiple possible choices of vertical plane, if the maximum illuminance value occurs at more than one point. In this case, the test laboratory should select one plane to measure.

Figure V.1 – Horizontal plane for determining FWHM angle and radial illuminance distribution, for an omnidirectional light point.

- 3) Some **directed light points** have identifiable top and bottom surfaces. For example, the bottom surface could be flat for desktop mounting and the power button could be located on the top of the light point. In this case, the vertical plane is the plane that contains the point of maximum illuminance and the centres of the top and bottom surfaces of the light point, and the horizontal plane is the plane perpendicular to the horizontal plane that contains the point of maximum illuminance.

Figure V.2 – Horizontal plane for determining FWHM angle and radial illuminance distribution, for a directed light point.

- 4) For light points with no identifiable top and bottom, the choice of horizontal and vertical planes may be arbitrary.
- 5) If the light point contains a two-dimensional array of light sources (e.g., LEDs) and multiple choices of horizontal and/or vertical planes are available following the above criteria, it is preferable to align the light point such that the intersections of the horizontal and vertical planes with the array plane are lines of symmetry of the array configuration, if possible. For example, if the product contains LEDs in a grid pattern, the grid lines should be parallel with the horizontal and vertical plane.
- 6) If the light point contains a three-dimensional array of light sources (e.g., LEDs) and multiple choices of horizontal and/or vertical planes are available following the above criteria, it is preferable to align the light point such that the horizontal and vertical planes are planes of symmetry of the array configuration, if possible. For example, if the light point contains four LED PCBs with outward-facing LEDs at 90° angles, the vertical plane could be chosen to pass through the centres of two of the LED PCBs.
- 7) In all cases, the intersection of the horizontal and vertical planes should contain the line segment that connects the centre of the light source with the point of maximum illuminance.
- 8) Sometimes, as in the case of LED bulbs, it may be difficult to determine whether a light point should be treated as omnidirectional prior to conducting the test. In some cases, it may be necessary to perform the test with multiple choices of horizontal and vertical planes. Generally, the radial distribution of illuminance in the vertical plane of an omnidirectional product will have two local maxima at or near 90° and 270°. If a light point is tested as directed but exhibits this characteristic, or if the horizontal and vertical FWHM angles are greater than 180°, the possibility should be considered that the light point should be tested as omnidirectional.

NOTE The terms “horizontal” and “vertical” are used for notational convenience; the horizontal and vertical planes for the purposes of light distribution may or may not be horizontal and vertical relative to the ground when the light point is in use or when the measurement is being performed. The orientation of the light point in the laboratory does not necessarily correspond to the product’s intended use.

b) Prepare the test sample for lighting evaluation as described in U.4.1.

V.5.2 Goniophotometer

A goniophotometer may be used to measure both the light distribution characteristics of a light source and also the total luminous flux. Operation of a goniophotometer is beyond the scope of this quality assurance protocol, and testing with a goniophotometer device should be conducted according to the following standard test methods, with the lighting appliance operated using a laboratory power supply as described in U.4.1:

- CIE084: The Measurement of Luminous Flux
- CIE127: Measurement of LEDs
- IESNA LM-79-08: Electrical and Photometric Measurement of Solid State Lighting Products

V.5.3 Multi-plane method

V.5.3.1 General

The multi-plane method, described in U.4.4, can be used to measure luminous flux and determine the full width half maximum angles for lights.

V.5.3.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Multi-plane test apparatus (described in U.4.4)
- DC power supply
- Illuminance meter
- DC voltmeter or multimeter

- DC ammeter

V.5.3.3 Test prerequisites

The product specification shall define the distance(s) at which the radial distribution of illuminance are to be determined and the minimum illuminance to be used in the usable area calculation. Distances shall be specified as the distance from the grid surface to the centre of the light point. The specified distance is 1 m unless the product specification states otherwise. The lighting appliance shall be prepared for lighting evaluation as described in Annex F. Before measurement, the battery of the DUT shall be replaced by a DC power supply. Prepare the test sample for lighting evaluation as described in U.4.1.

V.5.3.4 Apparatus

The multi-plane apparatus is described in U.4.4.

V.5.3.5 Procedure

The test procedures for determining the ambient light characterization are the same procedures as those used to determine total luminous flux and are described in U.4.4. This procedure needs only to be conducted once **per test sample** to gather all necessary information needed to calculate luminous flux (as detailed in Annex U) and FWHM angles.

V.5.3.6 Calculations

In order to generate polar plots of the distribution and to calculate FWHM angles, the data collected by the multi-plane method will need to be adjusted to estimate the illuminance on the inner surface of a virtual sphere centred on the DUT's light source. These calculations are only valid if the distance from the light source to the illuminance meter is at least five times the longest dimension of the emissive surface of the DUT. If this condition is not met, the polar plots shall be generated and FWHM angles determined using the goniophotometer (V.5.2) or turntable (V.5.4) method.

Use the following procedure to perform the correction:

- a) Correct the original, measured illuminance values ($E_{v,surf}$) for differences in measurement distance by adjusting each measured illuminance value to a constant distance from the DUT, using the following formula:

$$E_{v,d} = E_{v,surf} \frac{x^2 + z^2 + y_{surf}^2}{R^2}$$

where

$E_{v,d}$ is the illuminance adjusted to a constant distance from the light source, in lux (lx);

$E_{v,surf}$ is the measured illuminance on the grid surface, in lux (lx);

x is the horizontal position of the illuminance meter relative to the centre of the grid, in metres (m);

z is the vertical position of the illuminance meter relative to the centre of the grid, in metres (m);

y_{surf} is the distance between the centre of the grid surface and the DUT during the test (0,5 m), in metres (m);

R is the distance at which the radial distribution of illuminance is to be determined (see V.5.3.3), in metres (m).

NOTE 1 The coordinate axes are oriented according to Figure U.1, with the origin at the DUT's light source; that is, at the centre of the grid, $x = 0$, $z = 0$, and $y = y_{surf}$. The numerator of the fraction in the formula is the distance, in metres, from the illuminance meter to the DUT.

NOTE 2 Only those values that will be used in further calculations need to be corrected. Typically, this is the set of values lying in the horizontal and vertical planes, as described in steps (i) and (j) below.

- b) Next, correct for differences in measurement angle so that the illuminance values represent the illuminance on the inner surface of a sphere of radius R centred at the DUT's light source, using the following formula:

$$E_{v,sphere} = \frac{E_{v,d}}{\cos\theta} = E_{v,d} \frac{\sqrt{x^2 + z^2 + y_{surf}^2}}{R}$$

where

$E_{v,sphere}$ is the illuminance on the virtual sphere, in lux (lx);

$E_{v,surf}$ is the measured illuminance on the grid surface, in lux (lx);

θ is the angle between a line connecting the DUT and the illuminance meter and a line connecting the DUT and the centre of the grid;

x is the horizontal position of the illuminance meter relative to the centre of the grid, in metres (m);

z is the vertical position of the illuminance meter relative to the centre of the grid, in metres (m);

y_{surf} is the distance between the centre of the grid surface and the DUT during the test, in metres (m);

R is the distance at which the radial distribution of illuminance is to be determined (see V.5.3.3), in metres (m).

c) Calculate the horizontal FWHM angle using the following steps:

- 1) Identify the illuminance values on the virtual sphere ($E_{v,sphere}$) that lie on the horizontal plane (as defined in V.5.1; see Figure V.1 and Figure V.2) that intersects the centre of the brightest surface of the 1 m² grid. The point of maximum illuminance should fall on this plane.
- 2) For each illuminance value in the horizontal plane, calculate the angle between the Y axis (as defined in Figure U.1, with the origin of the coordinate system at the DUT) and the line connecting the DUT's light source and the location of the illuminance measurement. Tabulate the illuminance ($E_{v,sphere}$) as a function of angle.
- 3) Calculate the half-maximum illuminance ($E_{v,1/2}$), which is half of the maximum value of $E_{v,sphere}$ in the plane identified in step (1).
- 4) Linearly interpolate between adjacent illuminance values (as a function of angle) to identify the regions over which the illuminance $E_{v,sphere}$ is greater than $E_{v,1/2}$.
- 5) Calculate the FWHM angle as the angle subtended by the region where $E_{v,sphere}$ is greater than $E_{v,1/2}$. If there are multiple regions over which the illuminance is greater than or equal to $E_{v,1/2}$, and the sum of the angles subtended by all such regions is greater than 300°, then the FWHM angle is the *sum* of the angles subtended by all regions over which the illuminance is greater than or equal to $E_{v,1/2}$; otherwise, it is the *average* of the angles subtended by all regions over which the illuminance is greater than $E_{v,1/2}$. If there are no points for which the illuminance is less than $E_{v,1/2}$, the FWHM angle is 360°. See Figure V.3 for examples.

a) Suspended task light with FWHM = 119°

b) Omnidirectional ambient light with FWHM = 335°

Key

$E_{v,max}$ Maximum illuminance (lx)

$E_{v,1/2}$ Half-maximum illuminance (lx)

NOTE The half-maximum illuminance ($E_{v,1/2}$) is indicated by the dotted line. The illuminance exceeds $E_{v,1/2}$ in the shaded areas. The sum of the angles subtended by the shaded areas is the FWHM angle.

Figure V.3 – Radial illuminance distributions for two example DUTs, showing the calculation of the FWHM angle.

- d) To calculate the vertical FWHM angle, repeat the previous step using the vertical plane that intersects the centre of the brightest surface of the 1 m² grid, as defined in V.5.1. Report horizontal and vertical FWHM angles separately.
- e) Plot the radial distribution of illuminance in the horizontal and vertical planes (as defined in V.5.1) on two separate polar plots. See Figure V.5 for an example of a polar plot.

V.5.4 Turntable method

V.5.4.1 General

This test measures the radial distribution of illuminance at a constant distance from the lighting appliance. This method may be used to determine the FWHM angles.

V.5.4.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Turntable (see Figure V.4)
- DC power supply
- Illuminance meter
- DC voltmeter or multimeter

V.5.4.3 Test prerequisites

The product specification shall define the distance at which the radial distribution of illuminance is to be determined. The specified distance is 1 m unless the product specification states otherwise. The DUT shall be prepared for lighting evaluation as described in Annex U.4.1.

V.5.4.4 Apparatus

This test is performed using a turntable (see Figure V.4). The lighting appliance is placed on the turntable and illuminance is measured at the distance given in the product specification (from the centre of the DUT's light source to the illuminance meter sensor). Testing shall be done in a completely dark space, except for illumination provided by the lighting appliance. The test operator should wear all-black clothing if required to be near to the measurement surface. Ensure that the centre of the DUT's light source is at the same height as the illuminance meter during the test and that the illuminance meter is positioned at the point of maximum illuminance. If tilting the DUT to position the illuminance meter at the point of maximum illuminance would result in an inaccurate measurement of the FWHM angle and radial illuminance distribution (for example, if the DUT is an omnidirectional ambient light), the DUT or illuminance meter may be raised or lowered instead. As an alternative to a turntable, an apparatus in which the illuminance meter is rotated or positioned at points at a constant distance around a stationary DUT may be used.

Figure V.4 – Schematic of turntable setup, with the DUT shown.

V.5.4.5 Procedure

These steps shall be followed:

- a) Supply power to the lighting appliance using a DC power supply according to U.4.1. Secure the DUT to the turntable so that the measured illuminance values lie in the horizontal plane shown in Figure V.1 and Figure V.2, with the illuminance meter at the point of maximum illuminance. The distance from the centre of the DUT's light source to the illuminance meter should be equal to the distance at which the radial distribution of illuminance is to be measured (see V.5.4.3)
- b) Measure illuminance levels at least every 10° for the full 360° angle. However, measurements need not be taken for angles at which the illuminance value is known to be less than the resolution of the illuminance meter or less than 0,2 % of the illuminance at the brightest point. Further, if the FWHM angles are captured after measuring the illuminance levels over the brightest 180°, additional measurements need not be performed.
- c) Repeat the procedure with the lighting appliance oriented so that the measured illuminance values are in the vertical plane defined in V.5.1. A special apparatus is sometimes necessary to secure the lighting appliance in this orientation.

V.5.4.6 Calculations

The following calculations shall be made:

- a) Calculate the horizontal FWHM angle using the following steps:
 - 1) Calculate the half-maximum illuminance ($E_{v,1/2}$), which is half of the maximum illuminance value from the horizontal sweep.
 - 2) Identify the regions from the horizontal sweep over which the measured illuminance is greater than $E_{v,1/2}$. If the angular resolution of the measurements performed in V.5.4.5 is coarser than 2° , linearly interpolate between measurements (as a function of angle) to obtain finer resolution.
 - 3) Calculate the FWHM angle as the total angle subtended by the regions where the measured illuminance is greater than $E_{v,1/2}$. If there are multiple regions over which the illuminance is greater than or equal to $E_{v,1/2}$, and the sum of the angles subtended by all such regions is greater than 300° , then the FWHM angle is the *sum* of the angles subtended by all regions over which the illuminance is greater than or equal to $E_{v,1/2}$; otherwise, it is the *average* of the angles subtended by all regions over which the illuminance is greater than $E_{v,1/2}$. If there are no points for which the illuminance is less than $E_{v,1/2}$, the FWHM angle is 360° . See Figure V.3 for examples.
- b) To calculate the vertical FWHM angle, repeat the previous step using the measurements from the vertical sweep. Report horizontal and vertical FWHM angles separately.
- c) Plot the illuminance values over the “horizontal” and “vertical” sweeps as two separate polar plots. See Figure V.5 for an example of a polar plot.

V.6 Reporting

Report the following in the light distribution test report:

- Metadata
 - Report name
 - Procedure(s) used
 - DUT manufacturer
 - DUT name
 - DUT model number
 - DUT setting
 - Test room temperature ($^\circ\text{C}$)
 - Name of test laboratory
 - Approving person
 - Date of report approval
- Results for tested DUT aspects for samples 1 through n
 - Drive current into DUT’s main unit(A)
 - Drive voltage at DUT’s main unit (V)
 - Drive current(s) into DUT’s lighting appliance(s) for non-integrated lighting appliances (A)
 - Drive voltage(s) at DUT’s lighting appliance(s) for non-integrated lighting appliances (V)
 - Waiting time (min)
 - Vertical FWHM angle ($^\circ$)
 - Horizontal FWHM angle ($^\circ$)
- Average of n sample results for each DUT aspect tested
- Coefficient of variation of n sample results for each DUT aspect tested (%)
- Comments
 - Individual comments, as necessary, for samples 1 through n

- Overall comments, as necessary, for collective set of samples 1 through n
- Figures
 - Polar plots of the radial illuminance distribution (see Figure V.5 for an example)

Figure V.5 – Example of resulting polar plot of illuminance from the multi-plane or turntable method

Annex W (normative)

Mechanical durability test

W.1 Background

The mechanical durability test captures a DUT's robustness in withstanding the rigors of expected daily usage. The mechanical durability test includes the drop test, the switch and connector test, the gooseneck and moving parts test (if applicable), and the strain relief test (if applicable). This test should be conducted on all appliances included with the DUT, in addition to the primary components of the DUT.

During the drop test, the DUT is dropped from a height of 1 m onto a concrete surface. The number of times each sample is dropped depends on the type of component and number of samples required for testing. During the switch and connector test, each switch and/or connector of the DUT sample is cycled. The gooseneck and moving parts test is only conducted on DUT samples with goosenecks or moving parts, and it requires the gooseneck or other moving part of the DUT sample to be bent through its feasible range of usage. Switches, connectors, goosenecks and moving parts that are intended for regular use are cycled 1 000 times, while any of these mechanisms that are expected to be used primarily during installation are cycled only 100 times. (Product specifications may require additional cycles.) The strain relief test involves attaching a 2 kg weight onto any permanently attached cable ends (i.e., cable ends without connectors) for 60 s at three different strain angles. Throughout all four tests, the DUT sample is examined for functionality, damage, and the presence of user safety hazards.

W.2 Test outcomes

The test outcomes of the mechanical durability test are listed in Table W.1.

Table W.1 – Mechanical durability test outcomes

Metric	Reporting units	Related aspects	Remarks
Drop test sample functionality	Yes/no	4.2.3.7 Drop resistance	--
Drop test user safety hazard(s) present	Yes/no, description	4.2.3.7 Drop resistance	--

W.3 Related tests

Annex W is not related to any of the other annexes.

For lighting appliances without batteries, the mechanical durability tests of IEC 62257-12-1 may be used in place of Annex W.

W.4 Procedures

W.4.1 Drop test

W.4.1.1 General

The DUT sample is dropped from a height of 1 m onto a level concrete surface and examined for functionality, user safety hazards, and damage. The number of times each sample is dropped depends on the type of component and number of samples required for testing.

W.4.1.2 Equipment requirements

The camera is required.

W.4.1.3 Test prerequisites

At the start of the drop test the DUT samples shall be minimally altered (ideally unaltered), fully functional, and have sufficient charge to check for functionality throughout the test.

If the DUT samples have multiple units or components, determine an appropriate order to test the parts that need to undergo the drop test. Portable DUT samples or sample components (e.g., torches, lanterns, desktop lamps, etc.) shall be drop tested. DUT samples or sample parts that are portable but are expected to meet less rigorous durability standards (non-lighting appliances such as radios, razors, portable fans, etc.) should be drop tested under less rigorous criteria as outlined in the following sections.

DUT samples or sample parts that are intended to be stationary (e.g., separate control boxes, lamp units intended to be mounted, etc.) and PV modules do not need to be drop tested. Portable appliances that are not typically expected to meet the same durability standards, such as TVs, do not need to be drop tested.

This test is destructive. Do not carry out additional tests with the tested samples.

W.4.1.4 Apparatus

Choose an appropriate location to perform the drop test. The location should have a smooth, level concrete surface with ample space to avoid personal injury from a DUT projectile (e.g., glass and/or plastic shards). A height of 1 m shall be established from the ground to begin the drop.

W.4.1.5 Procedure

These steps shall be followed:

- a) Drop the DUT sample from a height of 1 m as indicated below:
 - 1) For testing portable lighting components:
 - i) Drop the DUT sample six times—once on each of the six “faces” of the product, taking care to drop the DUT sample on parts deemed mechanically weak (e.g., handles, loose parts, etc.). Using the three-dimensional system shown in Figure W.1, the DUT should be rotated after each drop as follows: The DUT sample is rotated by 90° along the x-axis following each of the first three drops, rotated by 90° along the y-axis from its initial drop orientation for the fifth drop, and rotated 180° along the y-axis from its fifth drop orientation for the sixth drop.

Figure W.1 – Three-dimensional Cartesian coordinate system for drop test reference

2) For testing non-lighting portable appliances (radios, razors, etc.):

ii) If the product specification requires testing four samples (such as for the SHS-QTM):

- Drop each DUT sample two times—once on each of two of the six “faces” of the product, taking care to drop the DUT sample on parts deemed mechanically weak (e.g., handles, loose parts, etc.). Rotate the angle of drop between samples so that after the third sample, all six sides have been tested once.
- The fourth DUT sample should be used for verification. If any of the first three DUTs sustained major damage during drop testing, the sides on which they were dropped should be re-tested with the fourth sample. If none of the first three DUTs sustained major damage, the fourth DUT sample may be dropped on two sides with parts deemed mechanically weak.

iii) If the product specification requires testing two samples (such as when conducting two concurrent ISM tests or an AVM test):

- Drop each DUT sample two times—once on each of two of the six “faces” of the product, taking care to drop the DUT sample on parts deemed mechanically weak (e.g., handles, loose parts, etc.). Rotate the angle of drop between samples so that after the second sample, four of the six sides are tested.

iv) If the product specification requires testing only one sample (such as for the ISM):

- Drop the DUT sample six times—once on each of the six “faces” of the product, taking care to drop the DUT sample on parts deemed mechanically weak (e.g., handles, loose parts, etc.).

NOTE: It is recommended to drop the non-lighting appliance sample six times during a one-sample test for informative purposes only. If the test is being used for other purposes, such as program entry or qualification for subsidies, it may be more appropriate to only consider the results from the first two drops.

NOTE: For radios, the antenna should not be extended.

b) After each of the drops, examine the DUT sample for functionality, the presence of user safety hazards (e.g., glass shards, short circuits, etc.), and damage and record the observations with descriptions and photographs. Superficial damage (minor scrapes or “popped off” components that can easily be put back in place) shall not be noted; only note damage that is permanent and non-superficial. Similarly, if only simple repairs are required to maintain the functionality of the product (a broken casing can be taped or a

component can easily be put back into place), then the sample shall still be considered functional.

W.4.1.6 Calculations

No calculations are made for the drop test.

W.4.2 Switch and connector test

W.4.2.1 General

Each DUT sample switch and/or connector intended for regular use is cycled 1 000 times (unless otherwise specified in the product specification) and examined for functionality, user safety hazards, and damage. Each DUT sample switch and/or connector that is expected to be used primarily during installation is cycled 100 times (unless otherwise specified in the product specification) and examined for functionality, user safety hazards, and damage.

The following examples may be used as guidelines to determine which category applies to each switch and/or connector.

- **Switches/connectors used primarily during installation:**
 - A safety disconnect switch or circuit breaker that is turned on during installation and only turned off for maintenance
 - Connectors dedicated to light points that are unlikely to be relocated after installation.
 - Connections between a light point and an extension cable
- **Switches/connectors intended for regular use:**
 - Connectors to be used in USB ports
 - Switches for light points or ports
 - Main power switches if unit is intended to be regularly turned off and on.

W.4.2.2 Equipment requirements

A camera is required.

W.4.2.3 Test prerequisites

At the start of the switch and connector test the DUT samples shall be fully functional and have sufficient charge to check for functionality throughout the test.

This test is destructive. Do not carry out additional tests with the tested samples, with the exception of the switch and connector test, the strain relief test, and the drop test (if the DUT samples are still functional after the switch and connector test).

W.4.2.4 Apparatus

No apparatus is required for the switch and connector test.

W.4.2.5 Procedure

These steps shall be followed:

- c) Cycle each of the DUT sample's unique switch(es) and/or connector(s) either 1 000 times or 100 times, or as specified in the product specification, depending on the expected use of the switch or connector. This test can be done manually or by using a mechanical device. A unique switch or connector is one that is not identical to any other switch or connector of the DUT. If the DUT has two or more identical switches or connectors, only one of those identical switches is considered unique and must be cycled. A cycle consists of actuating a switch through all possible positions or mechanical states or fully inserting and removing a connector; at the end of the cycle, the switch or connector should be in the same mechanical state as at the start of the cycle. For example:
 - For a slide, rocker, rotary, or toggle switch with three positions, a cycle could start in position 1 and cycle through positions 2, 3, 2, and back to 1;

- For a momentary pushbutton switch, a cycle consists of pressing and releasing the button once, even if the product changes state (e.g., brightness setting);
 - For a mechanically latching (push-on-push-off) switch, a cycle consists of pressing and releasing the button twice to return the switch to its initial mechanical state.
- a) If the DUT has at least two identical switches or connectors and more than one DUT is being tested (e.g., four DUTs are tested using the QTM), the selection of the unique switch or connector to be tested within the set of identical switches or connectors on any single DUT shall rotate between the identical switches or connectors (e.g., if a product has four identical barrel plug sockets and the product is undergoing QTM testing, each DUT should have a different barrel plug socket tested).
 - b) If damage is observed during the testing, record the observations with descriptions and photographs. Superficial damage (minor scrapes or “popped off” components that can easily be put back in place) shall not be noted; only note damage that is permanent and non-superficial.
 - c) Continue testing until the product fails to function, a user safety hazard develops (e.g., short circuit), or the targeted number of cycles are achieved. If potential damage cannot instantly be observed during testing (e.g., damage to a PV module or mobile phone connector), check for DUT sample functionality after every 100 cycles.

W.4.2.6 Calculations

No calculations are made for the switch and connector test.

W.4.3 Gooseneck/Moving parts test

W.4.3.1 General

If applicable, each DUT sample’s gooseneck or other moving part intended for regular use is bent 1 000 times (unless otherwise specified in the product specification) through its feasible range of usage. Each DUT sample’s gooseneck or other moving part that is expected to be used primarily during installation is bent 100 times (unless otherwise specified in the product specification) through its feasible range of usage.

The following examples may be used as guidelines to determine which category applies to each gooseneck or moving part.

- **Moving parts used primarily during installation:**
 - Parts that are not critical to the function of the product
 - Hinged joints adjusted only during installation
- **Moving parts intended for regular use:**
 - Hinges and goosenecks that include wires
 - Parts that are intended to be adjusted regularly
 - Radio dials and dials for dimming lights

W.4.3.2 Equipment requirements

A camera is required.

W.4.3.3 Test prerequisites

At the start of the gooseneck and moving parts test the DUT samples shall be fully functional and have sufficient charge to check for functionality throughout the test.

This test is destructive. Do not carry out additional tests with the tested samples, with the exception of other destructive tests (if the DUT samples are still functional after the gooseneck and moving parts test).

W.4.3.4 Apparatus

No apparatus is required for the gooseneck and moving parts test.

W.4.3.5 Procedure

These steps shall be followed:

- a) Bend the DUT sample's gooseneck or other moving part through its feasible range of usage either 1 000 times or 100 times, or as required by the product specification, depending on the expected use of the gooseneck or moving part. This can be done manually or by using a mechanical device.
- b) If damage is observed during the testing, record the observations with descriptions and photographs. Superficial damage (minor scrapes or "popped off" components that can easily be put back in place) shall not be noted; only note damage that is permanent and non-superficial.
- c) Continue testing until the product fails to function, a user safety hazard develops (e.g., short circuit), or the targeted number of bends is achieved.

W.4.3.6 Calculations

No calculations are made for the gooseneck/moving parts test.

W.4.4 Strain relief test

W.4.4.1 General

If applicable, each DUT samples' permanent cable ends (i.e., cable ends without connectors) are subjected to a 2 kg weight for 60 s at various strain angles.

PV modules that have been tested according to and met all requirements of the robustness of terminations test for type A (wire or flying lead) terminations (10.14) of IEC 61215 or IEC 61646, whichever is applicable, need not be tested using this procedure, provided that the junction box or cable entry has not been modified from the version that was tested. Test results provided by the manufacturer of the DUT may be accepted if the tests were performed at a laboratory accredited to perform the tests by a recognized accrediting organization (e.g., ILAC).

W.4.4.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Camera
- Clamp or other means of holding DUT components in place
- Calibrated 2 kg weight
- Protractor or other means of determining the strain angle
- Stopwatch

W.4.4.3 Test prerequisites

At the start of the strain relief test the DUT samples and their PV modules should be fully functional and the DUTs should have sufficient charge to check for functionality throughout the test.

This test is destructive. Do not carry out additional tests with the tested samples, with the exception of the switch and connector test, the drop test, and the gooseneck and moving parts test (if the DUT samples and PV modules are still functional after the strain relief test).

W.4.4.4 Apparatus

A clamp or other means of securely holding a 2 kg weight and the DUT and/or the DUT's PV module in place is required.

W.4.4.5 Procedure

These steps shall be followed:

- a) Determine which DUT cable ends are permanently attached (i.e., do not have a connector end) to the DUT and/or PV module.
- b) Clamp the DUT, DUT component, or PV module in place and attach the 2 kg weight to the cable so that the strain angle (γ) is 0° relative to the direction from which the cable protrudes from the DUT, DUT component, or PV module (see Figure W.2).

Key

γ Cable strain angle ($^\circ$)

Figure W.2 – Cable strain angle (γ) schematics for a PV module junction box (left) and a separate light point (right)

- d) Observe the DUT, DUT component, or PV module for 60 s. After 60 s, record the DUT's, DUT component's, or PV module's functionality, any physical damage, and the presence of safety hazards. Superficial damage (minor scrapes or "popped off" components that can easily be put back in place) should not be noted; only note damage that is permanent and non-superficial.
- e) Repeat steps b) and c) for strain angles of 45° and 90° .
- f) Repeat step b) through step d) for each permanently attached cable end found in step a).

W.4.4.6 Calculations

No calculations are made for the strain relief test.

W.5 Reporting

Report the following in the mechanical durability test report:

- Metadata
 - Report name
 - Procedure(s) used
 - DUT manufacturer
 - DUT name
 - DUT model number
 - Name of test laboratory
 - Approving person
 - Date of report approval
- Results for tested DUT aspects for samples 1 through n

- Drop Tests:
 - Functions after each drop (pass/fail)
 - No damage present after each drop (pass/fail)
 - No user safety hazard present after each drop (pass/fail)
- Switch / Connector Tests:
 - Cycles achieved for each switch and/or connector
 - Functions after test (pass/fail)
 - No damage present after test (pass/fail)
 - No user safety hazard present after test (pass/fail)
- Gooseneck/Moving Parts Test:
 - Cycles achieved for the gooseneck/moving part
 - Functions after test (pass/fail)
 - No damage present after test (pass/fail)
 - No user safety hazard present after test (pass/fail)
- Strain relief test:
 - Time achieved for each strain angle (s)
 - Functions after test (pass/fail)
 - No damage present after test (pass/fail)
 - No user safety hazard present after test (pass/fail)
- Comments
 - Individual comments, as necessary, for samples 1 through n for each test
 - Overall comments, as necessary, for collective set of samples 1 through n for each test
- Figures
 - Photographs of observed user safety hazards and/or DUT sample damage

Annex X (normative)

Physical and water ingress protection test

X.1 Background

Ingress protection (IP) testing determines the degrees of protection provided by the enclosures of a DUT's components. The IP rating uses two numerals to define the degrees of protection. The first numeral identifies the degree the DUT component has protection against solid foreign objects. The second numeral identifies the degree the DUT component has protection against ingress of water with harmful effects.

This test applies to any components of the DUT that contain electronics or electrical connections, including the primary components of the DUT, the PV module, and any appliances included with the DUT. Note that the test requirements for components may be specified based on the component category (Fixed Outdoor, Portable Integrated, Portable Separate, Fixed Indoor or PV Module) as described in 4.1.2. If more than one identical component or appliance is included with the DUT kit, only one of each set of identical appliances should be tested.

X.2 Test outcomes

The water exposure and physical ingress protection test outcomes are listed in Table X.1.

Table X.1 – Water exposure and physical ingress protection test outcomes

Metric	Reporting units	Related aspects	Remarks
IP2x	Pass/fail	4.2.3.5 Physical ingress protection	12,5 mm diameter probe
IP3x	Pass/fail	4.2.3.6 Physical ingress protection – solar module	2,5 mm diameter probe
IP5x	Pass/fail	4.2.3.5 Physical ingress protection 4.2.3.6 Physical ingress protection – solar module	No ingress of dust Must be tested by a laboratory that has been accredited to test according to IEC 60529. Laboratories shall use the procedure in IEC 60529; no simplified alternative is permitted.
IPx1	Pass/fail	4.2.3.1 Water protection – enclosure 4.2.3.2 Water protection – circuit protection and drainage	Vertically dripping water
IPx3	Pass/fail	4.2.3.1 Water protection – enclosure 4.2.3.2 Water protection – circuit protection and drainage	Direct sprays of water from within 60° of vertical
Modified IPx4	Pass/fail	4.2.3.4 Water protection – solar module	Splashes of water from any direction
IPx4	Pass/fail	4.2.3.1 Water protection – enclosure 4.2.3.2 Water protection – circuit protection and drainage	Splashes of water from any direction Shall be tested by a laboratory that has been accredited to test according to IEC 60529. Laboratories shall use the procedure in IEC 60529; no simplified alternative is permitted.
IPx5	Pass/fail	4.2.3.1 Water protection – enclosure 4.2.3.2 Water protection – circuit protection and drainage	Water projected in jets Must be tested by a laboratory that has been accredited to test according to IEC 60529. Laboratories shall use the procedure in IEC 60529; no simplified alternative is permitted.

X.3 Related tests

Annex X is related to the level of water protection annex (Annex Y).

For lighting appliances without batteries, the physical ingress and water protection test of IEC 62257-12-1 may be used in place of Annex X, provided that the IEC 62257-12-1 test method defines procedures for estimating or testing the IP classes for which testing is needed according to the product specification and/or the assessment of level of water protection (Annex Y).

X.4 Procedure

X.4.1 General

The IP class may be assessed by either sending samples of the DUT to a laboratory that has been accredited to test according to IEC 60529 or by estimating the IP class according to the methods below, except for in the case of testing for IPx4, IPx5 or IP5x by where the DUT component must be tested by a laboratory that has been accredited to test according to IEC 60529. When testing for IPx4, IPx5 or IP5x, laboratories shall use the procedure in IEC 60529; no simplified alternative is permitted.

X.4.2 IP testing at a laboratory that has been accredited to test according to IEC 60529

X.4.2.1 General

Samples are sent to a laboratory that has been accredited to test according to IEC 60529 to determine the passing or failing for the desired IP requirements.

X.4.2.2 Guidance on working with external IP testing laboratory

Many international IP testing laboratories will require two samples for testing. These should be samples that have not been altered in anyway.

This test is destructive. Do not perform any additional tests on the samples after testing.

For water ingress testing, specify to the laboratory that has been accredited to test according to IEC 60529 how the DUT component shall be oriented during testing. It shall be oriented in the way that the DUT component is most likely to be used.

NOTE The test used to assess solar modules for ingress of water with harmful effects is modified from the test described in IEC 60529. The modified IPX4 assessment for water ingress protection follows the same procedure to test for IPX4 as described in IEC 60529 with the exception of the angle of spray. IEC 60529 requires that the solar module be sprayed at angles $\pm 180^\circ$ from vertical, while the modified method described below requires that the solar module be sprayed at angles $\pm 90^\circ$ from vertical.

X.4.3 Simplified IP inspection for ingress of solid foreign objects

X.4.3.1 General

The DUT component is visually inspected for protection against ingress of solid foreign objects to determine the passing or failing for the desired IP requirement. This method may be performed to estimate IP ratings IP2x and IP3x.

X.4.3.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- 2,5 mm diameter rigid probe or 12,5 mm diameter rigid probe
- Camera

X.4.3.3 Test prerequisites

This test is destructive. Do not perform any additional tests on the sample after testing. The sample tested should have not been altered in anyway.

X.4.3.4 Apparatus

No apparatus is required for this test.

X.4.3.5 Procedure

X.4.3.5.1 Procedure for testing DUT component enclosures

- a) Before the measurement, be sure that the DUT component is properly functioning and that it is sufficiently charged to check for functionality during the test.
- b) If the DUT component requires passing IP2x, select the 12,5 mm probe. If the DUT requires passing IP3x, select the 2,5 mm probe.
- c) Explore the DUT component's entire surface to test for penetration with the selected probe.
- d) If the 12,5 mm probe can enter a part of the DUT component's enclosure *and touch* electronic components, electrical connections or circuits, with minimal force the DUT component is estimated to fail the IP2x assessment for ingress of solid foreign objects.
- e) If the 2,5 mm probe can enter a part of the DUT's enclosure *that contains* electronic components, electrical connections or circuits, with minimal force the DUT is estimated to fail the IP3x assessment.
- f) If the probe can enter an external jack, this is not considered a failure, unless it can enter the DUT component's enclosure through the external jack. Document any failures with photographs and text.

X.4.3.5.2 Procedure for testing a product's external solar module (if applicable)

PV modules that have been tested according to and meet all requirements of IEC 61215 or IEC 61646, whichever is applicable, need not be tested using this procedure. Test results provided by the manufacturer of the DUT may be accepted if the tests were performed at a laboratory accredited to perform the tests by a recognized accrediting organization (e.g., ILAC).

- a) Before the measurement, be sure that the solar module is properly functioning and that *the enclosure and/or junction box has never been opened previously*.
- b) To estimate IP3x, select the 2,5 mm probe.
- c) Explore the solar module's entire surface to test for penetration with the selected probe.
- d) If the probe can enter a part of the solar module's enclosure that contains electronic components, electrical connections or circuits, the solar module is estimated to fail the IP3x assessment for ingress of solid foreign objects. If the probe can enter an external jack, this is not considered a failure, unless it can enter the solar module's enclosure through the external jack. Document any failures with photographs and text.

NOTE Since the solar module junction box is not opened until the enclosure inspection steps below, it may not be possible to determine whether the DUT passes or fails this test until after the enclosure inspection steps are performed.

- e) Enclosure inspection: Open the junction box or PV enclosure of the solar module to determine if a circuit board or other sensitive electronics are present. (This may be destructive.) If no circuit boards or sensitive electronics are present or if the junction box or PV enclosure is completely potted with silicone or similar sealant, the solar module is estimated to pass for protection from water ingress and the tester does not need to assess the solar module for water ingress. (Note: simple screw terminals or a single diode, not soldered to a circuit board, are not considered "sensitive electronic components." Any printed circuit board is considered "sensitive.")
- f) If a circuit board or other sensitive electronic components are present within the junction box or PV enclosure, the water ingress test should be conducted on a new solar module sample that has not been opened.

X.4.3.6 Calculations

No calculations are made for the ingress of solid foreign objects IP test performed through visual inspection.

X.4.4 Simplified IP preliminary inspection for ingress of water with harmful effects

X.4.4.1 General

The DUT component is visually inspected for protection against ingress of water with harmful effects to determine if it is likely to pass or fail with respect to the desired IP requirement. This method may be performed to estimate IP ratings IPx1, IPx3 and a modified IPx4.

NOTE The test used to assess solar modules for ingress of water with harmful effects is modified from the test described in IEC 60529. The modified IPX4 assessment for water ingress protection follows the same procedure to test for IPX4 as described in IEC 60529 with the exception of the angle of spray. IEC 60529 requires that the solar module be sprayed at angles $\pm 180^\circ$ from vertical, while the modified method described below requires that the solar module be sprayed at angles $\pm 90^\circ$ from vertical.

X.4.4.2 Equipment requirements

The following equipment is required. Equipment shall meet the requirements in Table BB.2.

- Controlled water source
- Camera

X.4.4.3 Test prerequisites

This test is destructive. Do not perform any additional tests on the sample after testing. The sample tested should have not been altered in anyway.

X.4.4.4 Apparatus

No apparatus is required for this test.

X.4.4.5 Procedure

X.4.4.5.1 Procedure for testing DUT component enclosures

- a) Before the measurement, be sure that the DUT component is properly functioning and that it is sufficiently charged to check for functionality during the test.
- b) The DUT component should be oriented in the way that it is most likely to be used. Reference the product's packaging, user's manual, and/or website to determine the orientation in which the DUT is most likely to be used. Record the selected orientation.
- c) If the DUT component requires passing IPx1, sprinkle water from the controlled water source over the DUT component so that the water drops are vertical to the DUT component. The water flow rate should be close to 1 mm/min. Let the water drip over the DUT component for 10 min while rotating the DUT component at approximately 1 rpm about its vertical axis. The distance between the water source and DUT component should be approximately 0,2 m.
- d) If the DUT component requires passing IPx3, spray water from the controlled water source over the DUT component in all practical directions at an angle less than or equal to 60° from vertical. The water flow rate should be close to 10 l/min. Spray the water over the DUT component for approximately 1 min per square metre of enclosure surface area for a minimum of 5 minutes. The distance between the water source and the DUT component should be between 0,3 m and 0,5 m.
- e) After sprinkling or spraying water over the DUT component, dry the enclosure's exterior with a towel without moving the DUT component from its orientation during testing.
- f) Enclosure inspection: While keeping the component in the same orientation from testing, open the enclosure with the proper screwdriver(s) or other devices. If any water is found within any compartment holding electronic components inside the enclosure, the DUT component does not pass the required IP class for ingress of water with harmful effects. Document with photographs and text.

X.4.4.5.2 Procedure for testing a product's external solar module (if applicable)

PV modules that have been tested according to and meet all requirements of IEC 61215 or IEC 61646, whichever is applicable, need not be tested using this procedure. Test results provided by the manufacturer of the DUT may be accepted if the tests were performed at a laboratory accredited to perform the tests by a recognized accrediting organization (e.g., ILAC).

- a) Be sure that before the measurement, the junction box of another sample's external solar module has already been opened to determine if a circuit board or other sensitive electronics are present. (This may be destructive.) If no circuit boards or sensitive electronics are present or if the junction box is completely potted with silicone or similar sealant, the solar module passes for protection from water ingress with harmful effects and the tester does not need to further assess the solar module for water ingress.
- b) Before the measurement, be sure that the solar module is properly functioning and that *the enclosure and/or junction box has never been opened previously*.
- c) Place the solar module with the active PV area facing up on a smooth, solid, flat surface that is tilted at a 10° angle from the horizontal (Figure X.1). The solar module should be placed in the least favourable orientation on the surface. The placement is intended to resemble common rooftop installations and allow for the possibility that water would run behind the module. This will typically be accomplished by allowing the PV cord to rest under the frame as could occur when installed.

NOTE The least favourable orientation is typically the one in which the cable exits the junction box on the upslope side.

Key

- 1 Solar module cable
- 2 Solar module
- 3 Flat surface
- θ 10° incline

Figure X.1 – Side view of the apparatus for testing a DUT's external solar module for protection against water ingress

- d) Spray water from the controlled water source over the solar module in all practical directions (at angles up to 90° from vertical). The water flow rate should be close to 10 l/min. Spray the water over the solar module for approximately 1 min per square metre of enclosure surface area for a minimum of 5 minutes. The distance between the water source and the DUT should be between 0,3 m and 0,5 m.
- e) After spraying water over the solar module, dry the solar module's exterior on all sides with a towel without tilting the solar module.
- f) Open the junction box or the solar module's enclosure protecting its electronic components with the proper screwdriver(s) or other devices. (This may be destructive.)

NOTE Some external solar modules do not have a typical junction box; instead, the connections are within an enclosure around the module itself.

- g) After opening the solar module's junction box or enclosure, note if there are any unsealed penetrations around the solar module's frame through which water reaches the active material of the solar module.
- h) If no water is found inside the junction box, enclosures or any unsealed penetrations, the DUT's solar module is estimated to pass for modified IPx4 protection from water ingress with harmful effects.
- i) If any water is found on electronic components inside the junction box, enclosures or any unsealed penetrations, document with photographs and text. For the DUT to pass, electronic components and the active material of the PV module must be adequately protected according to the technical aspects outlined in Annex Y. Adequate protection is evaluated by an organization with expertise in product design, failure analysis, energy systems, and general engineering practices. This requirement cannot be met through labelling or consumer-facing documentation.

X.4.4.6 Calculations

No calculations are made for the ingress of water with harmful effects IP test performed through visual inspection.

X.5 Reporting

Report the following in the water exposure and physical ingress protection test report:

- Metadata
 - Report name
 - Procedure(s) used
 - DUT manufacturer
 - DUT name
 - DUT model number
 - Name of test laboratory
 - Approving person
 - Date of report approval
 - Component name
- Results for tested DUT aspects for samples 1 through n
 - IP rating for the ingress of solid foreign objects
 - IP rating for the ingress of water with harmful effects
 - Pass/fail for the IP rating for the ingress of solid foreign objects, if applicable
 - Pass/fail for the IP rating for the ingress of water with harmful effects, if applicable
- Comments
 - Individual comments, as necessary, for samples 1 through n
 - Overall comments, as necessary, for collective set of samples 1 through n
- Figures
 - Photographs to evidence the ingress of solid foreign objects or water, as necessary

Annex Y (normative)

Level of water protection

Y.1 Background

The enclosure of a solar lighting product can prevent water and solid foreign particles from coming in contact with internal electronic circuits, components, wires, and battery components (electronic components). The degree of protection provided by the enclosure is determined through Ingress Protection (IP) as outlined in Annex X. IP testing does not, however, assess the actual or potential damage caused to electronic components by water exposure.

Alternate means of protection exist for electronic components exposed to water. These alternate means may allow manufactures to reduce the cost of their product(s) to the consumer, thereby increasing consumer access to modern lighting technology. Annex Y outlines procedures for assessing overall water exposure protection based on IP test results combined with alternate protection means.

Annex Y does not attempt to characterize the damage caused by water exposure to sensitive electronic components. Rather, Annex Y provides a framework to assess the likelihood, during the service life of a product, that unprotected internal electronic components will be exposed to water that could negatively affect product operation.

Y.2 Test outcomes

The procedures in Annex Y may be used to establish a DUT component's water exposure protection level. The four levels are:

- a) **No protection** – The product has no water protection and could be damaged by any water exposure.
- b) **Occasional rain** – The product can be exposed to occasional light rain without damage.
- c) **Frequent rain** – The product can be exposed to frequent rain without damage.
- d) **Permanent rooftop installation for PV modules** – when installed on a roof, the product's solar module can be exposed to frequent heavy rain without damage.
- e) **Permanent outdoor exposure** – The product can be exposed to frequent heavy rain without damage.

The water exposure and physical ingress protection test outcomes are listed in Table Y.1.

Table Y.1 – Water exposure and physical ingress protection test outcomes

Metric	Reporting units	Related aspects	Remarks
Overall level of water protection	Qualitative (from list above)	4.2.3.1 Water protection – enclosure 4.2.3.2 Water protection – circuit protection and drainage 4.2.11.1 Product and manufacturer information 4.2.2.7 Packaging and user’s manual information	This is the level of water protection that is achieved when considering user instructions and labels in addition to the technical elements of the product.
Technical level of water protection	Qualitative (from list above)	4.2.3.1 Water protection – enclosure 4.2.3.2 Water protection – circuit protection and drainage 4.2.3.4 Water protection – solar module 4.2.11.1 Product and manufacturer information	This is the level of water protection provided by only the technical elements of the product—the enclosure, circuits, and other physical aspects.
Enclosure-only level of water protection	Qualitative (from list above)	4.2.3.1 Water protection – enclosure 4.2.3.4 Water protection – solar module	This only refers to the IP rating of the enclosure.

Y.3 Related tests

Annex Y is related to the water exposure and physical ingress protection test (Annex X) and visual screening (Annex E).

Y.4 Laboratory requirements

The assessments in Annex Y are typically done by an organization with broad experience in the off-grid lighting sector, including technical and field experience.

Assessments regarding the technical level of water protection should be completed by an organization with expertise in product design, failure analysis, energy systems, and general engineering practices.

Assessments of the overall level of water protection (incorporating consumer labelling information) should be completed by a committee with expertise in communication and end-user behaviour in the off-grid lighting market.

Y.5 Procedure

Y.5.1 General

The following procedures establish a product’s level of water protection. All of the procedures in Annex Y require an IP test result as specified in Annex X. Additional factors, such as product labelling or specific product design features, may also be considered when determining the level of water protection.

Y.5.2 Level of water protection for enclosure only

This procedure uses a product’s IP rating, and only its IP rating, to determine the level of water protection. No other tests are required. The level of water protection by IP rating is determined according to Table Y.2.

Table Y.2 – Enclosure-only level of water protection requirements

Enclosure level of water protection	IP rating requirement
No protection	IPx0
Occasional rain	IPx1
Frequent rain	IPx3
Permanent rooftop installation for PV modules	Modified IPx4
Permanent outdoor exposure	IPx5

NOTE The modified IPx4 assessment for water ingress protection follows the same procedure to test for IPx4 as described in IEC 60529 with the exception of the angle of spray. IEC 60529 requires that the DUT be sprayed at angles $\pm 180^\circ$ from vertical, while the modified method described below requires that the DUT be sprayed at angles $\pm 90^\circ$ from vertical.

Y.5.3 Level of water protection from technical aspects

Y.5.3.1 General

This procedure describes an assessment of the technical aspects of a product to establish the level of water protection that is achieved by a product from an engineering design standpoint. The aspects included in this holistic assessment are:

- The enclosure
- Circuit design and protection
- Internal draining
- Manufacturing processes
- Other innovative approaches

The overall product design shall be assessed on a case-by-case basis to determine the technical level of water protection. The assessment includes information from lab tests, field experience, and statements supplied by the manufacturer.

Products may be considered to have a technical level of water protection according to Table Y.3.

Table Y.3 – Technical level of water protection requirements

Technical level of water protection	Requirement
No protection	N/A
Occasional rain	Assessment indicates the enclosure and other technical aspects will protect from occasional rain, equivalent to IPx1 protection.
Frequent rain	Assessment indicates the enclosure and other technical aspects will protect from frequent rain, equivalent to IPx3 protection.
Permanent rooftop installation for PV modules	Assessment indicates the enclosure and other technical aspects will protect from permanent outdoor exposure in the context of a rooftop installation, equivalent to a modified IPx4 protection.
Permanent outdoor exposure	Assessment indicates the enclosure and other technical aspects will protect from permanent outdoor exposure, typically requiring an enclosure with at least IPx3 protection and additional circuit protection.

Y.5.3.2 Gathering product design information from lab testing

Results and observations from the following tests are relevant for this assessment:

- Annex X (physical and water ingress protection test)
- Annex E (visual screening)

Y.5.3.3 Gathering field and experiential information

Information from field trials and using samples of the product in a variety of environmental conditions may supplement other information and provide unique, targeted insights.

Y.5.3.4 Gathering product design information from the manufacturer

Y.5.3.4.1 General

The manufacturer is responsible for providing information about product design and manufacturing that is part of a water protection strategy.

Ask the manufacturer to provide product design data and explanations justifying a technical level of water protection. This data should include the following:

- a) Written descriptions of the product design elements and materials that will protect the circuit components from water exposure damage.
- b) Photographs or video clips showing the relevant design features.
- c) Specification sheets for materials used for protection.
- d) Written descriptions of protection for each circuit component in Y.5.3.4.2
- e) Written descriptions of relevant manufacturing processes employed for circuit component protection.
- f) Written descriptions of quality control processes relevant to circuit component protection.
- g) Descriptions of tests performed by the manufacturer to demonstrate protection of circuit components from damage caused by water exposure.

Y.5.3.4.2 Circuit design information

The relevant circuit components to provide information about include:

- a) Printed circuit boards
- b) Component solder joints
- c) Wire to board solder joints
- d) Wire to board connectors
- e) Wire to battery terminal solder joints
- f) Wire to battery terminal connectors
- g) LED components
- h) Switch components

Y.5.3.4.3 Manufacturing quality control information

The manufacturer should describe quality control processes that are in place to ensure consistent application of coatings, use of gaskets, etc.

Y.5.3.4.4 Water resistant coatings

Polymer coatings on printed circuit boards, wire solder joints, connectors, and electronic components have been shown to reduce or eliminate the negative effects of water exposure to live electronic circuit elements. In order to be effective, these coatings shall be properly applied to clean substrates in a quality controlled manufacturing process.

Y.5.3.4.5 Novel design approaches

Other means may be available to protect electronic components from water exposure damage. For example, the product may be designed to allow water to drain from the case and not collect on circuit components. These novel approaches shall be outlined and explained by the

manufacturer with supporting documentation justifying a level of water protection as outlined in Table Y.3.

Y.5.3.5 Assessment of technical level of water protection

The final assessment of the technical level of water protection should include information from each of the sources listed above.

The assessment details should include an evaluation of protection for critical components on a piece by piece basis. Reference should be provided where appropriate to the manufacturer supplied data. See Table Y.4 for an example product where the manufacturer is using conformal coatings and silicone sealants to protect internal circuit components:

Table Y.4 – Example detailed assessment supporting technical level of water protection

Circuit component	Method of protection	Manufacturer reference material	Remarks
Printed circuit boards	Conformal coating	Pcb_coating1.jpg	
Component solder joints	Conformal coating	Pcb_coating2.jpg	
Wire to board solder joints	None		Wire to board solder joints are not sealed or encapsulated
Wire to board connectors	N/A		None used
Wire to wire connectors	N/A		None used
Wire to battery terminal solder joints	Silicone encapsulant	Battery_coating1.jpg	
Wire to battery terminal connectors	N/A		None used
LED components	Case design	LED_lens1.jpg	Manufacturer statement
Switch components	None		Switch is not sealed

Y.5.4 Overall level of water protection

Y.5.4.1 General

The overall level of water protection assessment accounts for consumer labelling and instructions in combination with either the technical or enclosure-only level of water protection.

If appropriate consumer information is provided, the level of water protection is increased relative to the technical or enclosure-only findings.

This assessment cannot result in an increase to the permanent outdoor exposure level, since products that are permanently mounted outdoors are not protected from water by the end-user.

Table Y.5 lists the requirements for assessing the overall level of water protection.

Table Y.5 – Overall level of water protection requirements

Technical level of water protection OR Enclosure-only level of water protection	Overall level of water protection WITHOUT consumer labelling	Overall level of water protection WITH consumer labelling
No protection	Same	Occasional rain
Occasional rain	Same	Frequent rain
Frequent rain	Same	Same
Permanent rooftop installation for PV modules	Same	Same
Permanent outdoor exposure	Same	Same

Y.5.4.2 Assessing consumer labels and information

Y.5.4.2.1 General

Subclause Y.5.4.2 describes a framework for assessing consumer labels and instructions for appropriateness.

The overall requirement for consumer labels and instructions is that the communication strategy should be designed and implemented so that a typical user understands both the degree of protection from water for the product and what they should do to maintain the product in an instance of water exposure.

The factors to consider are:

- Language and literacy of expected end-users
- Prominence of information
- Clarity of presentation

Y.5.4.2.2 Gathering information on water protection messages

Information from visual screening (Annex E) and additional inspection of the packaging should be used to establish the messages to buyers and end-users concerning water protection.

Potential locations (not inclusive) of information:

- Labels and pictograms on packaging
- Instructions in the users manual
- Information on the warranty card
- Advertising and media

Y.6 Reporting

Report the following in the Equivalent IP water exposure protection report:

- Metadata
 - Name of test
 - Procedures used to qualify for level of water protection (IP rating, labelling and/or product design)
 - DUT manufacturer
 - DUT name
 - DUT model number
 - Name of test laboratory
 - Approving person
 - Date of report approval
 - DUT component
- Main findings:
 - Overall level of water protection
 - Technical level of water protection
 - Enclosure-only level of water protection
- Supporting information:
 - IP rating for enclosure
 - Description of other technical approaches (if applicable)
 - Suitability of consumer labelling for communicating level of technical water protection and steps to protect the product

- Manufacturer supplied data (include all manufacturer supplied data in the test report)
- Assessment of manufacturer supplied data
- Comments
 - Individual comments, as necessary, on the specific material provided by the manufacturer demonstrating an equivalent IP level protection
 - Overall comments, as necessary, for the collective set of materials provided by the manufacturer demonstrating an equivalent level of IP protection

Annex AA is reserved for future use.

Annex BB (normative)

Equipment requirements

Annex BB gives requirements and recommendations for the equipment needed for the test methods described in this Technical Specification (Table BB.2). Many pieces of equipment can be used for multiple tests; the right side of the table shows which test methods require each piece of equipment. The symbols used in these columns of Table BB.2 are defined in Table BB.1.

Table BB.1 — Symbols used in Test Method column of Table BB.2

Symbol	Meaning
No symbol	Equipment is not used for this test.
•	Equipment is required for this test regardless of the test laboratory class.
○	Equipment is optional for this test.
A	Equipment is required for this test for test laboratories of class A.
B	Equipment is a permitted alternative to the equipment labelled A for test laboratories of class B.

Table BB.2 – Specifications for all required test equipment (1 of 10)

Equipment	Recommendations	Requirements	Test Methods																				
			Visual screening	Sample preparation	Photovoltaic module IV characteristics test	Light output test	Light distribution test	Battery test	Full battery run time	Full discharge preparation	Solar charge test	Grid charge test	Mechanical charge test	Charge controller behaviour test	Protection tests	Assessment of DC ports	Appliance tests	Daily energy calculations	Lumen maintenance test	Physical and water ingress protection test	Mechanical durability test	Battery storage	
Computer	Depends on equipment that needs to be connected; typically, multiple RS-232 serial ports and USB ports are needed for test equipment I/O. Test equipment often requires Windows®.	Depends on equipment	•	•	•	•	•	•	•	•	•	•	•	•	•	•	•	•	•	•	•	•	•

Oven or environmental chamber	Large enough to fit up to four 100 Ah lead-acid batteries.	Able to maintain 60 °C ± 5 °C and 30 °C ± 5 °C																				•	•

^a Some commercial solar array simulators are designed for large modules and are not accurate at the low currents seen with smaller solar home system kits. For example, an SAS with a rated accuracy of ±(0,2 % + 20 mA) would not necessarily be appropriate to simulate a module with a maximum power point current of 300 mA. If the manufacturer-provided measurement uncertainty is insufficient to meet this requirement, the instrument may be used if the simulated I-V curve is measured to verify that the current values are within 5 % of the actual I-V curve at all points where the actual current is greater than half the maximum power point current. This test shall be performed each time the SAS is set up to test a new DUT.

Annex CC

Generic appliances

CC.1 Background

Solar Home System kits will often include ports intended to power appliances such as televisions, radios, fans, and other devices. Some kits include these appliances, which can then be used in Annex K for the **deep discharge protection** test. When a kit does not include these appliances but does include ports which are intended to power these types of loads, the testing laboratory shall use a generic appliance (also commonly referred to as a “dummy load”) to simulate these appliances during the charge controller behaviour test (Annex K).

The test laboratory shall construct generic appliances (dummy loads) with the ability to dissipate the required power. This can be achieved with the proper use of power resistors that have been configured to attach to the output ports of a DUT’s power control unit.

Values provided in Annex CC are also used as inputs in the energy service calculations (Annex R). The energy service calculations annex requires power or energy consumption values for appliances that are advertised but not included with the kit; therefore, performance values for generic appliances are used when not provided by the manufacturer.

CC.2 Test Outcomes

There are no test outcomes for the construction of generic appliances.

CC.3 Related Tests

The generic appliances constructed in Annex CC are used in the charge controller behaviour test (Annex K). Generic appliance values provided in Annex CC are used in the energy service calculations (Annex R) and may be used in the assessment of DC ports (Annex P) for evaluating truth in advertising.

CC.4 Equipment Requirements

The following equipment may be required. Equipment shall meet the requirements in Table BB.2.

- Appropriate connectors to connect to the DUT’s electrical ports to allow the use of a generic appliance constructed by the test laboratory
- Wire, wire cutters, and wire strippers
- Power resistors capable of providing the required resistance and power dissipation
- Heat sinks as required by the power resistor manufacturer
- Soldering iron and solder
- Heat-shrink tubing and heat gun
- Screwdrivers and/or other appropriate tools for constructing the generic appliance hardware

CC.5 Procedures

CC.5.1 Constructing generic appliances

The following procedure for constructing generic appliances may be used during the charge controller behaviour test (Annex K).

Perform the following steps to construct generic appliances to simulate any appliances advertised for use with, but not included with, the DUT:

- a) Determine the power (watts) of each required generic appliance without a battery from Table CC.1. If the advertised appliance’s power rating is provided by the manufacturer, and within 15% of the appliance’s power value in Table CC.1, then use the power rating provided by the manufacturer, else use the power value provided for that appliance in Table CC.1. If the size of the advertised television is not specified, assume the larger television. If the appliance is not

included in Table CC.1, use an appropriate value determined from sources including published literature, appliance data sheets, and the DUT’s user documentation and packaging. Note the power values used in the test report, as well as the source(s) of values not given in Table CC.1.

Table CC.1 – Power consumption chart for generic appliances

Type of appliance	Power (watts) for a generic appliance (dummy load)
Appliances without internal batteries	
Television – large	20
Television – small	10
Radio	5
Fan	3
Appliances with internal batteries (charging power)	
(Basic/feature) mobile phone	2,25
Smartphone	5
Tablet computer	10
Other appliance with internal battery	2,25

- b) Appliances with internal batteries are sometimes capable of charging at lower rates if high rates are not supported by the port. If the power value for an appliance with an internal battery from Table CC.1 exceeds the power output capability of the port, reduce the power value to the highest value supported by the port. Obtain this value from the plots generated in P.4.2.5 at the standard operating voltage. If it is necessary to construct a generic appliance before this test has been performed, the resistor value may be determined by trial and error.

NOTE 1 The most convenient “trial and error” method in many cases would be to perform the output overload protection test (O.4.2) while recording the port voltage in order to calculate power; this would enable the maximum port power to be determined without performing the entire assessment of DC ports procedure.

NOTE 2 There is no comparable adjustment for appliances without internal batteries as these appliances are generally not able to reduce their power consumption without also reducing the level of service provided.

- c) If needed, calculate the resistance of the required power resistor using the following formula:

$$R = \frac{V^2}{P}$$

where

R is the resistance in ohms (Ω);

V is the typical port voltage for that appliance, in volts (V), as determined in P.4.4;

P is the required power for the dummy load appliance, in watts (W).

- d) Obtain power resistors capable of providing the correct resistance and dissipating the required power. Configure a power resistor, or power resistor array, to be used as a generic appliance, subject to the following requirements and recommended practices:
- The generic appliance shall connect to the appropriate port used for that type of appliance.
 - It may be necessary to attach the resistors to heat sinks as specified by the resistor manufacturer. The test laboratory shall use its best judgement to determine the appropriate design and hardware for its generic appliances. In some cases, cooling fans may be required.
 - Use wire and connector hardware capable of handling the voltage and current of the generic appliance. The test laboratory may use, where appropriate, a port connector from another appliance included in the DUT kit by cutting off the connector on the appliance and attaching it to the generic appliance, or may use matching connectors purchased separately.

- Power resistors may be combined in series and/or parallel to achieve the required resistance. The final resistance for the generic appliance should be within 10 % of the calculated resistance from step b) above.
- Variable resistors (rheostats) or electronic loads capable of dissipating the required power may be used in place of fixed power resistors.

Variable resistors are generally rated by their manufacturers according to the maximum power dissipation of the full resistance element. If a maximum current rating is not given by the component manufacturer, the minimum allowable power rating can be calculated based on the full-scale resistance:

$$P_{R_{\text{variable}}} \geq I_{\text{max,port}}^2 \times R_{\text{variable}}$$

where

$P_{R_{\text{variable}}}$ is the maximum power rating of the variable resistor, in watts (W);

$I_{\text{max,port}}$ is the maximum current for the port, in amperes (A);

R_{variable} is the variable resistor full-scale value, in ohms (Ω).

CC.5.2 Appliance reference values

The following procedure may be used to determine appliance reference values for use in the energy service calculations (Annex R) for appliances that are advertised, but not included with the DUT kit. These values may also be used for evaluating truth in advertising regarding DC port performance (P.4.5).

- a) For appliances without an internal battery, determine power consumption by following CC.5.1 a) above.
- b) For appliances with an internal battery, assume an 80 % charging efficiency and a 90% battery efficiency. For calculating the battery-to-appliance efficiency.
- c) For generic appliances with internal batteries, determine the energy in watt-hours required to fully charge the battery from Table CC.2.
- d) For generic appliances that are not a mobile phone or tablet, determine the appliance's full-battery run time and energy removed during the appliance's full-battery run time using the following equations:

$$E_{\text{fbrt}} = E_{\text{ab}} \cdot \eta_{\text{ab}}$$

where

E_{fbrt} is the energy consumed from the appliance's battery during the appliance's full-battery run time, in watt-hours (Wh);

E_{ab} is the energy required to fully charge a representative mobile phone or tablet battery, in watt-hours (Wh); specified in Table CC.2;

η_{ab} is the appliance's battery efficiency.

$$t_{\text{fbrt}} = \frac{E_{\text{fbrt}}}{P_a}$$

where

t_{fbrt} is the full-battery run time of the appliance, in hours (h);

E_{fbrt} is the energy consumed from the appliance's battery during the appliance's full-battery run time, in watt-hours (Wh);

P_a is the average power consumed by the appliance, in watts (W), determined following CC.5.1 a) above.

Table CC.2 – Energy and power consumption for generic appliances with batteries

Type of appliance	Power (watts) for a generic appliance with a battery when in use	Energy (watt-hours) for a generic appliance with a battery
Television – large	20	TBD
Television – small	10	10
Radio	0,5	3,7
Fan	3	3
Torch	0,3	2
(Basic/feature) mobile phone	--	3,7
Smartphone	--	5,7
Tablet computer	--	15

CC.6 Reporting

In the test report, note the generic appliances constructed, the power and resistance values used, and the source of any power values not given in Table CC.1.
