

Vickers®

Vane Motors

MHT Vane Motors

High Torque, Low Speed
Single Torque, Multi-Torque

Introduction

Vickers MHT vane motors are the efficient, economical answer to a wide range of power needs. These high-quality motors are the ideal choice when:

- the combination of high torque and low speed is required
- a high power-to-weight/size ratio is required
- hazardous conditions or other design factors make it desirable that the electrical prime power source be located some distance away from the machinery driving motor.

Applications

MHT motors can be used in a wide variety of industrial and mobile applications, for example:

- Continuous casting machines
- Straightener drives
- Wheel rim rolling machines
- Forging manipulators
- Winding machine drives
- Sheet line accumulator systems
- Pre-plasticizer drives
- Machine tool spindle drives
- Coil winders
- Conveyors
- Feeder screws
- Rolling mill screwdown drives
- Drilling, boring machines
- Crushers

Features and Benefits

- Available in shaft-type or shaftless. Shaftless MHT motors can simplify installations, since the driven machine's splined shaft can be driven directly by the motor. Shaft-to-shaft couplings are thereby eliminated.
- MHT motors provide variable power throughout their entire pressure and speed range, and perform smoothly and efficiently in either direction of rotation.
- Shaftless MHT motors permit cooling water to be run through a hollow driving shaft, for example, driving plastic injection molding and extruder screws.
- Long operating life
- Stepless, infinitely variable speed control.
- Quick shaft reversing by reversing fluid flow.

Standard Motors

Vickers standard MHT motors are ideal for rotary power applications requiring high torque at low speed. They provide variable power throughout their entire pressure and speed range, and perform efficiently and smoothly in either direction of rotation.

Because these motors can eliminate the need for gear boxes or other external speed reducing devices, they offer the added advantage of compactness.

Multi-Torque Series

The Vickers multi-torque MHT motor is similar to the standard MHT motor in application and performance benefits, with one major difference – the design of the multi-torque motor permits choosing a number of different speed and torque combinations for any given flow and pressure.

For example, under conditions where maximum torque is not required, top motor speed can be achieved using the partial torque circuit shown. Conversely, maximum torque could also be achieved at less than maximum motor speed, using the full torque circuit shown.

This versatility permits substantial savings in pump size and costs for many applications without sacrificing necessary torque or speed characteristics.

- MHT multi-torque motors offer the ability to change the torque-to-speed ratios without requiring gear shifting mechanisms.

Installation Data

Mounting Information

This information points out areas of the motor where specific information is referenced. Refer to the respective "Installation Dimensions."

- The motor housing will accept no axial loading except at the following diameter bolt circles.

MHT Model	Bolt circle mm (inch)
32	203,2 (8.00)
50	250,8 (9.875)
70 90 70/35/35 90/45/45	266,7 (10.50)
130 150 130/75/75 150/75/75	298,5 (11.75)
190 220 250 380 440 500 750 1000 190/95/95 220/125/95 250/125/125 380/190/190 440/250/190 500/250/250 750/375/375 690/375/315 1000/500/500	342,9 (13.50)

- Mounting surface must be flat within 0.025 (0.001 in.) and perpendicular to the axis within 0.025 (0.001) TIR.
- The splined rotor will not accept any shaft translation, (sliding axially through spline).
- If the shaft must absorb axial forces, preloading will be required to prevent any translation. Consult your Vickers representative.

- If the application requires the mounting face to be sealed, an area has been provided for use with the following O-rings:

MHT Model	Vickers part number	I.D. O-ring mm (inch)
32	154112	158,34 (6.234)
50	192412	196,9 (7.75)
70 90 70/35/35 90/45/45	154120	215,9 (8.50)
130 150 130/75/75 150/75/75	199829	234,95 (9.25)
190 220 250 380 440 500 750 1000 190/95/95 220/125/95 250/125/125 380/190/190 440/250/190 500/250/250 750/375/375 690/375/315 1000/500/500	199838	279,4 (11.00)

- Motors may be supplied with the threads drilled out of the mounting surface body for through mounting with standard studs or screws, if required. Torque as shown in the following table:

Thru studs are not included. –S13 threads drilled from shaft end body; –S18 from head end body.

MHT Model	Torque Nm (lb. ft.)
32	122 ± 6 (90 ± 5)
50	169 ± 6 (125 ± 5)
70	
90	
70/35/35 90/45/45

500/250/250	
750/375/375	
690/375/315	
1000/500/500	

- Conventional mounting is with six bolts through back of mounting plate, maximum length into motor and torque. Refer to the following table:

MHT model	Maximum length into motor mm (inch)	Torque Nm (lb. ft.)
32	44,45 (1.75)	81–95, (60–70)
50	44,45 (1.75)	81–95, (60–70)
70 90 70/35/35 90/45/45	31,75 (1.25)	81–95, (60–70)
70 90	44,45 (1.75)	81–95, (60–70)
130 150 130/75/75 150/75/75	38,1 (1.50)	81–95, (60–70)
190 220 250 380 440 500 750 1000 190/95/95 220/125/95 250/125/125 380/190/190 440/250/190 500/250/250 750/375/375 690/375/315 1000/500/500	38,1 (1.50)	81–95, (60–70)

- Motor mounting orientation is unrestricted as to port location and mounting face. The shaft may protrude from either body.
- Pilot must be a non-binding slip fit and must not exceed 5,84 mm (0.230) inch maximum into motor.

Suggested shaft seal size is according to the following table:

MHT model	Shaft seal size mm (inch)
50	64,26 (2.53)
70/35/35 90/45/45	69,85 (2.75)
130 150 130/75/75 150/75/75	79,5 (3.13)
190 220 250 380 440 500 750 1000 190/95/95 220/125/95 250/125/125 380/190/190 440/250/190 500/250/250 750/375/375 690/375/315 1000/500/500	104,78 (4.125)

Circuit

- Circuit design should protect the motor from pressure surges and cavitation.

CAUTION: CASE FLOW SHOULD BE UNRESTRICTED AND CHECKED TO ENSURE 1,89 lpm (0.05 USgpm) MINIMUM.

Case flow may be increased by applying back pressure to the motor return port. Operating the motor at a minimum pressure of 35 bar (500 psi) applied at the inlet port will provide the required case flow.

Thermal shocks in excess of 10° C (50° F) are not recommended. When the motor is cold or the oil is hot, start and stop motor until temperatures are equal.

Intermittent (15 minutes or less) unloaded running is permitted after a proper start and warm-up to 400 rpm, provided the minimum case flow is minimum case flow is maintained.

Shaft Information

- Shaft spline must slip fit into rotor.
- When disassembling or installing a shaft, there must be no binding or axial force applied.
- Shaft design must provide spline grease retention. The spline is not lubricated by system fluid. Customer shaft needs no shaft seal surface for system fluid retention.

- With a shaftless assembly, the customer will provide its own bearings and center the rotor with .004 TIR concentricity to the pilot diameters.
- The shaft spline should be packed with fibrous wheel-bearing grease at six month intervals, or sooner if operation is at high temperature. A standard 1/8 NPT grease fitting may be installed (not supplied) at the end of the shaft for this purpose.

A cover may be made to seal off shaftless models. The cover has a provision for a 1/8 NPT grease fitting. Use with O-ring 154094 and snap ring 380104 or equivalent.

If the installation uses no bearings in the motor, spline grease retention may be obtained by using a shaft seal adapter mounted in the bearing bore with an O-ring and snap ring.

Application Data

Start-Up Procedure

CAUTION: Failure to follow proper start-up procedures may damage the motor and system. Avoid dry shocks and thermal starts to prevent damage to the system or motor.

When an MHT motor is initially started, caution should be taken to ensure complete internal lubrication. The following will help ensure proper internal lubrication at start-up.

- Fill the unit with oil.
- Start split rise motors in full displacement.
- Set the speed control at 10 rpm or less.
- Jog the motor.
- Check for and maintain case drain flow while operating motor.
- Increase speed in low increments with load 35–69 bar (500–1000 psi) preferred.
- Warm the hydraulic system and the motor simultaneously.

Using Performance Curves

The curves are typical for conventional MHT 150 motors. Factors are also provided for using the curves for multi-torque motors. Examples of both follow:

Full Displacement (150 mode)

Required: 130 rpm, 3796 Nm (2800 lb. ft.) torque using MHT 150-R1-30 motor and 180 SUS oil.

- Determine the operating pressure: Draw coordinated from the 3796 (2800 lb. ft.) point on the left vertical axis to connect to the 130 rpm speed on the horizontal axis at point "A." The operating differential pressure is 145 bar (2100 psi). Be sure to work between the pressure lines.
- Determine the input flow required: The point obtained from step one must be extended to the top of the curve by an imaginary new curve to obtain the 273 l/min (72 USgpm) flow.

Partial Displacement (130, 75 or 55 mode)

Required: 215 rpm, 1627 Nm (1200 lb. ft.) torque, using the reduced

displacement 75 mode of an MHT130/75/55 or MHT 150/75/75 motor with 180 SUS oil.

- Determine the operating pressure: Since the 75 mode will produce only 0.49 of the torque of the 150 mode, the operating differential pressure must be based on 1200 divided by 0.49. The torque factor shown below for this mode, or 3322 Nm (2450 lb. ft.) torque. This "new" torque figure is used to find the operating differential pressure from the curves. Again, connect the torque and speed coordinates to locate point "B." The operating differential pressure based on 3322 Nm (2450 lb. ft.) torque and 215 rpm speed is 124 bar (1800 psi) to produce 1627 Nm (1200 lb.ft.) in this mode.
- Determine the input flow required. Since the 75 mode displacement is 51% of the full displacement 150 mode, the input flow obtained from the curves for point "B" must be multiplied by .51 to obtain the input flow required. Extend an

imaginary curve to the top of the graph to read 427 l/min (113 USgpm). The actual flow required 113 x .51, or 220 l/min (58 USgpm)

Partial Displacement Factors

For use with split-rise, multi-torque motors as described in example 2 above.

Model Mode	Flow Factor	Torque Factor
150	1.00	1.00
130	.86	.86
75	.51	.49
55	.37	.36

Drain flow at 138 bar (2000 psi) may be as much as 8 l/min (2 USgpm) on some motors

NOTE: Due to manufacturing and viscosity variations, flow and torque values may vary from the typical data shown.

Typical performance in 180 SSU fluid @ 138 bar (2000) Δ psi

MHT-150

Using Performance Curves

The curves are typical for conventional MHT 250 motors. Factors are provided for using the curves for multi-torque motors. Examples of both follow:

Full displacement (250 mode)

Required: 110 rpm, 5085 Nm (3750 lb. ft.) torque using MHT 250-R1-30 motor and 180 SUS oil

1. Determine the operating pressure: Draw coordinated from the 5085 (3750 lb. ft.) point on the left vertical axis to connect to the 110 rpm speed on the horizontal axis at point "A." The operating differential pressure is 110 bar (1600 psi). Be sure to work between the pressure lines.
2. Determine the input flow required: The point obtained from step one must be extended to the top of the curve by an imaginary new curve to obtain the 356 l/min (94 USgpm) flow.

Partial Displacement (220, 190 or 125 modes)

Required: 160 rpm, 2373 Nm (1750 lb. ft.) torque, using the reduced

displacement 125 mode of an MHT250/125/125 or MHT 220/125/95 motor with 180 SUS oil

1. Determine the operating pressure: Since the 125 mode will produce only 0.48 of the torque of the 250 mode, the operating differential pressure must be based on 1750 divided by 0.48. The torque factor shown below for this mode, or 4943 Nm (3645 lb. ft.) torque. This "new" torque figure is used to find the operating differential pressure from the curves. Again, connect the torque and speed coordinates to locate point "B." The operating differential pressure based on 4943 Nm (3645 lb. ft.) torque and 160 rpm speed is 108 bar (1560 psi) to produce 2372 Nm (1750 lb. ft.) in this mode.
2. Determine the input flow required. Since the 125 mode displacement is 51% of the full displacement 250 mode, the input flow obtained from the curves for point "B" must be multiplied by .51 to obtain the input flow required. Extend an

imaginary curve to the top of the graph to read 511 l/min (135 USgpm). The actual flow required 135 x .51, or 260,7 l/min (68,9 USgpm)

Partial Displacement Factors

For use with split-rise, multi-torque motors as described in example 2 above.

Model Mode	Flow Factor	Torque Factor
250	1.00	1.00
220	.88	.84
190	.76	.71
125	.51	.46
95	.39	.36

Drain flow at 138 bar (2000 psi) may be as much as 8 l/min (2 USgpm) on some motors

NOTE: Due to manufacturing and viscosity variations, flow and torque values may vary from the typical data shown.

Typical performance in 180 SSU fluid @ 138 bar (2000) Δ psi

MHT-250

Using Performance Curves

The curves are typical for conventional MHT 500 motors. Factors are provided for using the curves for multi-torque motors. Examples of both follow:

Full displacement (500 mode)

Required: 90 rpm, 9830 Nm (7250 lb. ft.) torque using MHT 500-R1-30 motor and 180 SUS oil

1. Determine the operating pressure: Draw coordinated from the 9830 (7250 lb. ft.) point on the left vertical axis to connect to the 90 rpm speed on the horizontal axis at point "A." The operating differential pressure is 108 bar (1565 psi). Be sure to work between the pressure lines.
2. Determine the input flow required: The point obtained from step one must be extended to the top of the curve by an imaginary new curve to obtain the 582 l/min (154 USgpm) flow.

Partial Displacement (250 or 190 modes)

Required: 150 rpm, 3000 lb. ft. torque, using the reduced displacement 250

mode of an MHT 500/250/250 motor with 180 SUS oil

1. Determine the operating pressure: Since the 250 mode will produce only 0.48 of the torque of the 500 mode, the operating differential pressure must be based on 3000 divided by 0.48. The torque factor shown below for this mode, or 8475 Nm (6250 lb. ft.) torque. This "new" torque figure is used to find the operating differential pressure from the curves. Again, connect the torque and speed coordinates to locate point "B." The operating differential pressure based on 8475 Nm (6250 lb. ft.) torque and 150 rpm speed is 97 bar (1400 psi) to produce 4068 Nm (3000 Lb. Ft.) in this mode.
2. Determine the input flow required: Since the 250 mode displacement is 48% of the full displacement 500 mode, the input flow obtained from the curves for point "B" must be multiplied by .48 to obtain the gpm input flow required. Extend an

imaginary curve to the top of the graph to read 973 l/min (257 USgpm). The actual flow required is 257 x .48, or 469 l/min (124 USgpm).

Partial Displacement Factors

For use with split-rise, multi-torque motors as described in example 2 above.

Model	Flow Factor	Torque Factor
440	.88	.84
380	.76	.71
250	.48	.46
190	.36	.36

Drain flow at 138 bar (2000 psi) may be as much as 8 l/min (2 USgpm) on some motors

Fluid Information

Fluid Cleanliness

Proper fluid condition is essential for long and satisfactory life of hydraulic components and systems. Hydraulic fluid must have the correct balance of cleanliness, materials, and additives for protection against wear of components, elevated viscosity, and inclusion of air.

Essential information on the correct methods for treating hydraulic fluid is included in Vickers publication 561 "Vickers Guide to Systemic Contamination Control" available from your local Vickers distributor or by

contacting Vickers, Incorporated. Recommendations on filtration and the selection of products to control fluid condition are included in 561.

Recommended cleanliness levels, using petroleum oil under common conditions, are based on the highest fluid pressure levels in the system and are coded in the chart below. Fluids other than petroleum, severe service cycles, or temperature extremes are cause for adjustment of these cleanliness codes. See Vickers publication 561 for exact details.

Vickers products, as any components, will operate with apparent satisfaction in fluids with higher cleanliness codes than those described. Other manufacturers will often recommend levels above those specified. Experience has shown, however, that life of any hydraulic component is shortened in fluids with higher cleanliness codes than those listed below. These codes have been proven to provide a long, trouble-free service life for the products shown, regardless of the manufacturer.

Product	System Pressure Level bar (psi)		
	<70 (<1000)	70-210 (1000-3000)	210+ (3000+)
