APPENDIX F

DATA OBTAINED FROM PREVIOUS SITE INVESTIGATIONS

(SECTION 6.0 OF NUS WORK PLAN  
PREVIOUSLY SUBMITTED IN NOVEMBER 1983)

AR100667

## 6.0 ENVIRONMENTAL CONCENTRATIONS

(red)

6.1 Air

An air sampling program was conducted at the site on November 16 and 17, 1982 by the Environmental Response Team (ERT) from EPA Region III. Ten onsite locations and two background locations were sampled using calibrated portable air pumps with different capturing media for various chemical groups. These media were analyzed for total organics, organic solvents, aromatic amines, inorganic acids, PCBs, and metal particulates. No airborne vapor/gas contaminants were present above the detection limits.

Air samples were collected in the crawl spaces of houses adjacent to the landfill using similar collection equipment as the onsite air survey. Grab samples were collected and analyzed using a Photovac 10A10 portable gas chromatograph (GC). The samples that gave a response were sampled with the pumping system for a longer period of time. Table 6-1 presents the analytical results, which indicate that some form of hydrocarbons were present in all samples. Since there were compounds present at or slightly above the GC's detection limit, but not in sufficient concentration to be identified on a GC/MS, all compounds detected in a sample were totalled and reported as total hydrocarbons (as if it were toluene). The offsite sampling did not show the presence of compounds in sufficient concentrations to be identified on a GC/MS with the exception of carbon tetrachloride in one sample (<20 µg) in a 600 mg charcoal tube (ERT, 1983b).

6.2 Soil

Table 6-2 lists the locations and descriptions of soil samples collected at or near the site by various agencies. PADER collected three soil samples from on site and four samples from adjacent, offsite property. ERT collected soil samples from 23 locations on site, some of which were sampled at various depths. ERT sampling locations are shown on Figure 6-1. The analytical results are presented in Tables 6-3, 6-4, 6-5, and 6-6.

Sources: PADEP, October 26, 1982; ERT, April 1983.

Of the three onsite samples collected by PADER, SMCO1 and SMCO2 were analyzed for metals and were leached using the RCRA extraction procedure and analyzed. SMCO2 was also analyzed for other inorganic compounds. SMCO3 was analyzed for oil and PCB. SMCO1 and SMCO2 contained metals at various concentrations. SMCO3 contained 12 µg/kg of PCB (as Aroclor 1248) and 35,712 mg/kg of oil.

The samples that PADER collected off site (SMC 27 through SMC 30) were analyzed by GC/MS for priority pollutant organics. No acid extractables, volatiles, PCBs, or pesticides were detected in the four samples. All four samples contained numerous base/neutral extractables. The concentrations ranged from <1 µg/kg for acenaphthylene to 680 µg/kg for di-n-butyl phthalate.

Samples SMCO4 through SMCO8, collected by ERT, had water extracts from them analyzed using the Microtox System. The Microtox is intended for use in determining the acute toxicity of aqueous samples. The system uses a special strain of bioluminescent bacteria. A photomultiplier tube measures the relative light output of these organisms before and after exposure to serial dilutions of a sample. Toxicity is indicated by a percent decrease in light output. The results from duplicate samples are averaged to calculate a normalized percent light decrease (NPLD) corresponding to each dilution. Marginal toxicity is sometimes indicated by an increase in light output due to biostimulation of the bacteria (ERT, 1983b). The results of the Microtox System analysis are shown in Table 6-7.

Samples SMCO9 through SMC26, collected by ERT, were analyzed for organic priority pollutants. Base/neutral extractable compounds were detected in SMCO9 and SMC20 through SMC26. Volatile organics were detected in SMC13, SMC16, SMC17, and SMC26. PCB was detected in SMC21, SMC23, and SMC26. The volatile organics appeared to penetrate further into the ground and to accumulate in the saturated zone, in contrast to the base/neutral extractable compounds.

Especially evident were 1,2-trans-dichloroethylene and trichloroethylene, which appeared in deeper soils while absent from the surface soils. The base/neutral extractable compounds were generally confined to the top foot of soil.

6.3 Groundwater

(red)

Table 6-8 lists the locations of groundwater samples collected by various agencies. PADER collected 14 groundwater samples at or near the Millcreek Site, ERT and TAT collected 12 onsite groundwater samples, and a Technical Advisory Team (TAT) collected 3 groundwater samples off the site. Analytical results are presented in Tables 6-9, 6-10 and 6-11.

Millcreek Township had installed 5 monitoring wells on its portion of the site. Nine additional wells were installed around the site for the ERT investigation. Three public drinking water wells (Yoder Wells) and two private wells were also sampled.

PADER sampled the township monitoring wells in July 1982. These samples (GWMC01, GWMC03, GWMC04, GWMC08, and GWMC09) were analyzed for all priority pollutants and other inorganic parameters. Some metals and volatile organics were detected in the five wells at varying concentrations. PADER resampled two of the wells (GWMC04 and GWMC07) in January 1983. Metals and volatile organics were detected again, in addition to low concentrations (23 ug/l) of isophorone and bis(2-ethylhexyl)phthalate, base/neutral extractables, in GWMC04.

PADER sampled all five township monitoring wells (GWMC26 through GWMC30) in April 1983 and analyzed them for gross alpha and gross beta radioactivity. The very low levels measured were below drinking water standards and do not indicate a radioactivity hazard.

ERT and TAT sampled three of the five wells installed by the township and the nine additional onsite wells (No. 6-14) in December 1982. These samples (GWMC02, GWMC06, and GWMC10 through GWMC19) were analyzed for metals, volatile organics, and polynuclear aromatic hydrocarbons (PAH's). No PAH's were detected. Volatile organics were detected in GWMC02, GWMC06, and GWMC11 through GWMC16. Metals were detected in every sample.

TAT sampled the Yoder public drinking water supply wells in February 1983. These samples (GWMC20 through GWMC22) were analyzed for priority pollutant organic

compounds and some metals. Barium was detected in all the samples. Mercury was detected near the detection limit in GWMC21. No organics were detected in GWMC20. Trichlorofluoromethane was detected in GWMC21 at a concentration between 1 ug/l and 10 ug/l. 1,1,1-Trichloroethane was estimated at a concentration of 0.2 ug/l in GWMC22.

PADER sampled private wells owned by Knost (GWMC23) in December 1982 and Kraschneske (GWMC24) in July 1982. The Kraschneske well (GWMC25) was sampled by Erie County in November 1980. GWMC23 was analyzed for inorganics and priority pollutants. No organics were detected. GWMC24 was analyzed for organic priority pollutants; the results were negative. GWMC25 was analyzed only for inorganics.

#### 6.4 Surface Waters

Table 6-12 lists locations where surface water and sediment samples were collected by various agencies. PADER collected six surface water samples at or near the site. The EPA collected two surface water samples on site, while Ecology and Environment, Inc. (E & E) collected two sediment samples. The ERT and TAT collected four surface water samples. The Erie County Health Department (ECHD) collected six samples from Marshalls Run and one sample from the swamp. The analytical results from all samplings are presented in Table 6-13 through 6-16.

The onsite pond was sampled once by PADER (SWMC01) and once by EPA (SWMC02). SWMC01 was analyzed for inorganics and priority pollutants while SWMC02 was analyzed for priority pollutants. Small quantities of various metals were detected in both samples. Trace quantities of organics were detected in both samples.

The drainage ditch (SWMC03) north of the site was sampled by ERT and TAT and analyzed for metals, volatile organics, and polynuclear aromatic hydrocarbons (PAHs). All of the PAHs tested for were base/neutral extractable compounds. No volatiles or PAHs were detected, but some metals were.

AR100689

(red)

The drainage ditch (SWMC04) separating the Halmi and Riehl properties was sampled once by PADER and analyzed for inorganics and priority pollutants. Phenol (1.4 ug/l) and pentachlorophenol (0.3 ug/l) were detected along with metals and other inorganics.

Water from the south swamp was sampled once by EPA (SWMC05), once by ECHD (SWMC07), and once by ERT and TAT (SWMC08). The swamp sediment was sampled once by E & E (SWMC06). SWMC05 and 06 were analyzed for priority pollutants. SWMC08 was analyzed for metals, volatile organics, and PAHs. SWMC07 was analyzed for pH, oil, and metals. Metals were detected in all samples. SWMC06 contained phenol (220 ug/kg) and tetrachloroethylene (5 ug/kg). No volatiles or PAHs were detected in SWMC08. No organics were detected in SWMC05.

PADER collected two water samples from Marshalls Run, one upstream (SWMC10) and one downstream (SWMC11) of the Millcreek Township portion of the site. E & E collected a stream sediment sample from Marshalls Run (SWMC09). The aqueous samples were analyzed for organic priority pollutants. Diethyl phthalate (0.5 ug/l) was detected in SWMC10. SWMC09 was analyzed for priority pollutants. No volatiles were detected. Numerous metals and base/neutral extractables were detected along with lesser numbers of PCB, pesticides, and phenol.

Marshalls Run, upstream of the site, was sampled once by PADER (SWMC12) and once by ERT and TAT (SWMC13). Both samples were analyzed for priority pollutants while more inorganics were analyzed for in SWMC12. Some metals and volatile organics were detected in both samples.

Marshalls Run, downstream of the site, was sampled once by PADER (SWMC14), once by ECHD (SWMC16), and once by ERT and TAT (SWMC15). SWMC14 was analyzed for priority pollutants; SWMC15 for metals, volatiles, and PAHs; and SWMC16 for inorganics and metals. Various metals were detected in all samples. Volatile organics were detected in SWMC14.

AR100690

The Erie County Health Department conducted a study of Marshalls Run (red) the source to Lake Erie. Macroinvertebrates were collected in addition to water samples at five locations (SWMC 17 to 21). Samples were analyzed for inorganics and metals.

#### 6.5 Biota

The Erie County Health Department conducted a stream survey of Marshalls Run in June 1982. The survey involved water sample collection along with macroinvertebrate collection. From this survey, the department concluded that the stream exhibits a depressed macroinvertebrate population, and that the presence of contaminants in the stream has contributed to this depressed state. It also recommended that a more comprehensive study be conducted (Wellington, 1982).

## SURFACE SOIL SAMPLE RATIONALE

**ORIGINAL**

<u>Sample</u>	<u>Rationale</u>
SO-001	Near Small Willow Clump S.W. of Central Mound where dumping observed by PANDER Personnel
SO-002	Dark Stained area south of drum stage area
SO-003	Stream bed for drainageway adjacent to W. 17th St. near baseball fields where drums were observed earlier in the year
SO-004	Stream bed of the north wet weather drainage ditch behind W. 13th St.
SO-005	Barren area in woods behind W 13th St. contains car battery pile and old railroad-ties
SO-006	Pile of rubble (looks like coal waste) behind well 19A 2-3CY
SO-007	Barren furnace dust pile in center of site
SO-008	Near Pallet pile where PANDER reported possible bulk dumping
SO-009	Barren sandy soil adjacent to Well 14
SO-010	On Sitter property by pile of 5 slag drums
SO-011	Barren area within a grassy area near slag drums
SO-012	Stained soil on Halmi property near swamp
SO-013	Stained soil on Sitter property near front end loader
SO-014	Stained soil in Drum Stage Area
SO-015	Stained Soil near gas well on Halmi property
SO-016	In area of alleged bulk dumping or drum burial near dead twisted tree SW of central mound
SO-017	500 ft. North of SO-016
SO-018	In former open pit area behind homes on W. 14th St.

(red) DRAFT

SURFACE SOIL SAMPLE RATIONALE  
PAGE TWO

<u>Sample</u>	<u>Rationale</u>
SO-019	In barren fill adjacent to swamp
SO-020	In barren fill adjacent to swamp behind dead, twisted tree
SO-021	In area suspected of bulk dumping SE of central mound near 3 drums
SO-022	In pond area at outflow to intermit pond
SO-023	By wreckage of Green Ford Pinto - Area of suspected Bulk Dumping
SO-024	Stained soil near access road
SO-025	On dike between ponds
SO-026	1326 Harper Drive Hetrick in area flooded by Marshall's Run - Shallow Soil
SO-027	Same as SO-026 but deep soil to collect potential contamination by GW Discharge
SO-028	1413 Honeywood LN - Groeger - area downgradient of site - wet throughout year - Shallow Soil
SO-029	Same as 028 but deep soil
SO-030	3227 W. 13th St. - Churchill - Back by stream bed of we weather drainage ditch - downgradient and within flooding of ditch
SO-031	Same as SO-030 but deep
SO-032	3071 W. 12th St. - Mazza - In garden, wet spot throughout the year - elevated OVA readings
SO-033	Same as SO-032 but deep - downgradient
SO-034	Shallow Soil - Background - Frontier Park
SO-035	Deep Soil - Background - Frontier Park
SO-036	Shallow Garden Sample - Al Nobbs Transmission

## SURFACE WATER/SEDIMENT SAMPLE RATIONALE

<u>Samples</u>	<u>Location/Rationale</u>
SW-01/SD-01	Marshall's Run upstream of outflow from culvert beneath the railroad tracks
SW-02/SD-02	SW-02-Dry sediment taken at Marshall's Run converge with northern wet weather drainage ditch
SW-03/SD-03	Downstream Marshall's Run - North of West 12th Street. Appeared to be collection of road drainage.
SW-04/SD-04	West Branch of Marshall's Run - Downstream
SW-05/SD-05	Onsite Pond
SW-06/SD-06	In swamp near SO-19
SW-07/SD-07	In swap near Sittler Property
SW-08/SD-08	In lowland marshy area near the end of Marshall's Road. SW-08-Dry
SW-09/SD-09	In lowland marshy area between the Riehl and the Halmi property near MW-14. SW-09-Dry
SW-010/SD-010	West Branch of Marshall's Run upstream near baseball fields
SW-010A/SD-010A	Duplicates of SW-010 and SD-010

TEST PIT LOCATION RATIONALE

<u>Test Pit</u>	<u>Location/Rationale</u>
TP-1	Near wreckage of Green Ford Pinto - reported area of bulk dumping
TP-2	East side of foundry sand mound reported area of burial/bulk dumping
TP-3	Same as TP-2
TP-4	Same as TP-2 and TP-3
TP-4A	In an effort to delineate the areal extent of a high OVA reading layer TP-4A and 5 were excavated
TP-5	See TP-4A
TP-6	Near area previously excavated by ERT to locate a drum
TP-7	In lowland oily area previously found to contain PCB
TP-8	8 and 8A were in the area west of the mound reported to have drums buried
TP-9	Same as TP-8
TP-10	Near small willow clump where PADER personnel noted bulk dumping

DRAFT

TEST PIT LOCATION RATIONALE  
PAGE TWO

<u>Test Pit</u>	<u>Location/Rationale</u>
TP-10A	Continued excavation in area reportedly containing buried drums
TP-11	Same as TP-10A
TP-12, 13, and 14	In area of dead twisted tree - bulk or buried dumping reporting in the area
TP-15	In wooden pallet area report to have bulk dumping
TP-16	Excavation exploraton of the Halmi property
TP-17	Excavation in the area of the gas well explosion and stained soil area

Soil samples taken from test pits either represented saturated samples, samples exhibiting elevated OVA reading, samples from near buried drums or in some cases actual drum contents (solids).

Additional Information:

pH (Standard Units) 6.0  
Oil and Grease 660 990

Notes:

- 1 Values in parentheses adjacent to contaminant names are instrument detection limits.
- 2 Values in brackets are correction factors. Multiplication of the correction factor and the given instrument detection limit will yield the method detection limits for each fraction of each sample. Correction factor accounts for necessary dilutions and percent moisture.
- 3 B Lab qualifier indicating compound was detected in reagent blank.
- 4 J Lab qualifier indicating value is an approximation.
- 5 K Lab qualifier indicating compound detected below method detection limit.
- 6 R Rejected during data validation process, detection limits did not satisfy requirements of contract.
- 7 RI Rejected during data validation because of reagent blank contamination.

Notes: Subsurface soils (SS) are samples of cuttings taken with a split-spoon sampler.  
 The location shown at the top is the monitoring well and the depth over which a composite sample was taken.  
 K - Actual value, within limitations of this method, is less than the actual value given  
 C - Value corrected for blank concentration  
 Values in parenthesis are the instrument detection limits for a given compound.  
 Values in brackets are correction factors which account for dilution of samples; multiplication of the instrument detection limit by the appropriate correction factor, for that fraction will yield the method detection limit for a given compound of a given sample  
 (1) - Rejected during data validation process because of reagent blank contamination  
 (2) - Rejected during data validation process, matrix spike recoveries below contract specifications.

PCB DETECTION LIMITS

Detection limit of 1 microgram of PCB's per section of the sample.

AR100751

INORGANIC ACIDS DETECTION LIMITS

(red)

All samples were checked for the presence of six acids: HF, HCL, HBr, HNO<sub>3</sub>, H<sub>2</sub>SO<sub>4</sub>, and H<sub>3</sub>PO<sub>4</sub>.

The detection limit for acids: 20 micrograms with the exception of hydrochloric acid and hydrofluoric acid, which is 3 micrograms.

The following is a summary of the Thermal desorption/field GC done on-site.

DATE	STATION	MEDIA	VOLUME	ANALYSES	Results	
					Total # Peaks	Total Conc. **
11/16/82	5	Tenax	9.26 L	Total Vapors Gases	1 peak	BDL

ANALYSES	CONTAMINANT	CONCENTRATIONS
Organics***	1. Milligrams of total hydrocarbon per cubic meter of air	0.49 mg/m <sup>3</sup>
	2. Parts of total hydrocarbon as Toluene per million parts of air	0.13 ppm

\* BDL = below detection limits

\*\* = total concentrations = time weighted average (TWA) as methane

\*\*\* Since one or more very small peaks were observed between the standard organics in NIOSH Method P&CAM 127 by a GC, the extractions were then analyzed by a GC/MS. With the exception of the organic sample from 1326 Harpes, the GC/MS analysis did not reveal any additional information. The GC/MS analysis of the organic sample from station 1326 Harpes revealed the presence of carbon tetrachloride, however, the concentration was below the detection limit.

#### CONCLUSION:

On-site samples: While the November 16th & 17th air sampling did not reveal the presence of airborne vapor/gas contaminants approaching the PEL's or TLV's, it should not be interpreted to mean that the air was free of potential hazardous contaminants. Since a large portion of the site was not covered by vegetation, potential for exposure to hazardous particulates must be taken into consideration and evaluated against the surface soil samples and personnel job functions. In addition, potential personnel exposure to hazardous gases/vapors must be evaluated since temperature during the sampling periods ranged from 20°F to 49°F and the only positive air sample was a 150 mg carbon tube which was placed inside of a clean black metal pan face down into the soil which was not covered with vegetation.

#### OFF-SITE OBSERVATIONS

Since there were peaks at or slightly above the GC's detection limit, but not in sufficient concentration to be identified on a GC/MS, I requested the contract lab to total all peaks in a sample and report it as total hydrocarbons (as if it were Toluene). Again, the ambient temperatures must be kept in mind since they ranged from 20°F to 49°F. The only organic identified was Carbon Tetrachloride. While the results are relatively low and do not approach PEL's or TLV's, it should not be interpreted to mean that the air was free of potential hazardous contaminants. It was recommended that a public health official review this data.

AR100754

SAFETY PLAN

Based on the on-site air analyses and site conditions, Level C (red) protection appears to have been the appropriate level of protection for most of the site activities conducted during ERT activities. Once the surface soil samples are analyzed and data available, it may be appropriate to extend the support and contamination reduction areas further into the contaminated area as well designate some portions of the contamination zone as Level D.

## APPENDIX K

## GROUNDWATER EXTRACTION AND TREATMENT

K.1 Groundwater Extraction and Treatment

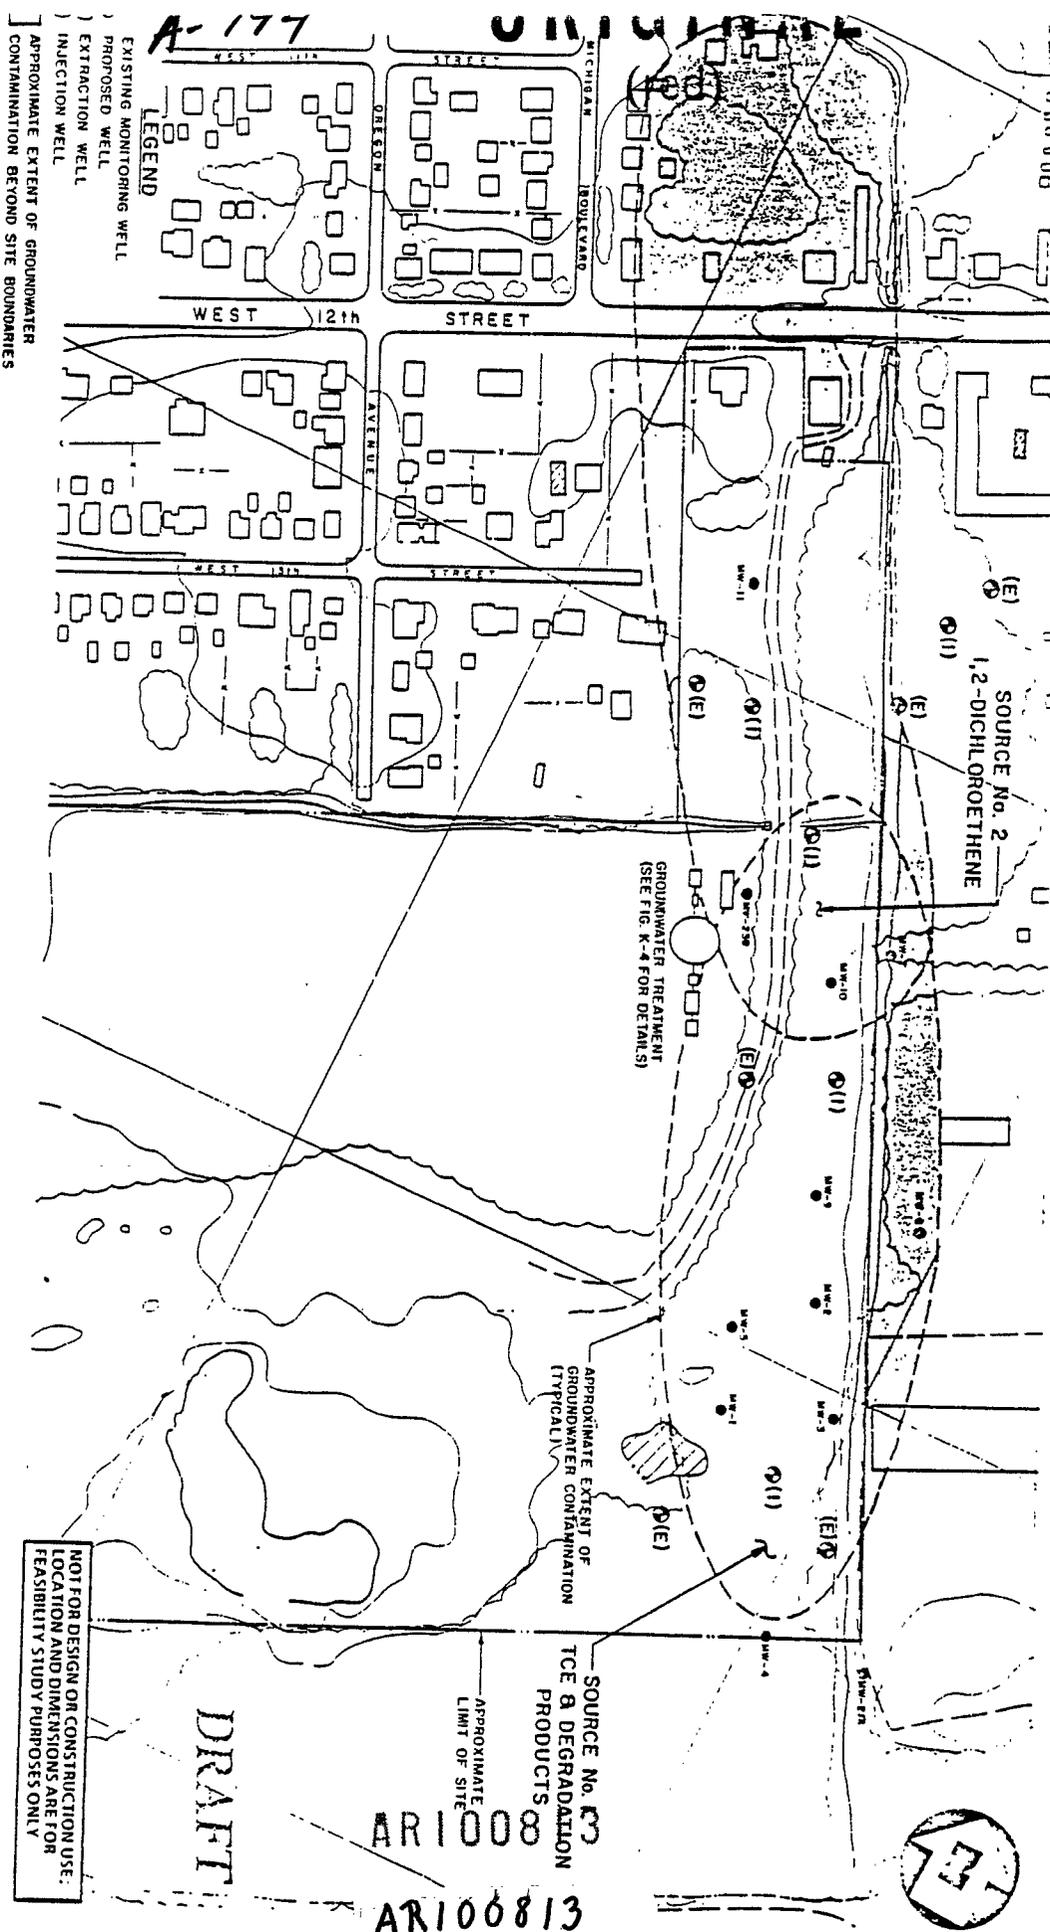

Data gathered during the Remedial Investigation at the Millcreek Site indicate that on and offsite contamination of groundwater has occurred. Control of this contaminated groundwater may be accomplished by pumping the water to the surface and treating the recovered liquids for release or reinjection. Groundwater extraction and treatment will achieve the following objectives:

- Control of flow or influences of plume flow.
- Prevent further contaminant migration off site. (See Figure K-1 for current plume.)
- Control of toxic groundwater contaminants using treatment system specific to the quality desired.
- Protection of nearby surface waters by retarding the rate at which groundwater recharges Marshall's Run.

A series of extraction and injection wells can be used to lift groundwater to the surface, where it can be treated using physical, chemical, or biological methods. Treated effluent may either be released to an offsite POTW for further treatment, released to Marshall's Run, or injected into the aquifer from which it was pumped.

Careful monitoring of pumped groundwater is necessary to assure that the plume is extracted to the surface in an effective manner. In particular, the impact of reinjection must be determined early to make certain that the plume is not diverted away from the recovery wells. The groundwater collection and treatment system designed for Millcreek will be described in detail in the following sections.

AR100812

**ORIGINAL** DRAFT  
(red)**K2 Groundwater Recovery System****K2.1 General**

The groundwater extraction system was designed to recover the contaminated groundwater from the sand, silt, and gravel aquifer beneath the Millcreek Site. Aquifer characteristics were reported in the RI Report prepared by NUS Corporation.

The groundwater extraction system was designed with the assistance of BESTWELLS, a computer optimization model designed by In-Situ, Inc. The model determines the optimum number and location of wells to achieve a targeted drawdown. Injection wells purge the low-flow velocity regions between wells so that stagnant contamination could be removed.

BESTWELLS is a steady-state, analytical model with the following built-in assumptions:

- The aquifer is of uniform thickness.
- The aquifer is infinite in extent.
- The properties of the aquifer are homogeneous and constant.
- All wells are fully screened and 100 percent efficient.
- The pumping rate of the well remains constant during the lifetime of the project; i.e., the pumping rate of the well represents the average pumping rate for the given pumping period.
- The groundwater head is constant at the boundary of the project area.

AR100814

Since site conditions at Millcreek can be characterized by the model assumption, BESTWELLS is a useful tool in estimating the location and production rate of the proposed groundwater extraction system.

## K.2.2 System Operation

The groundwater extraction system was designed based on the following input data obtained during the Remedial Investigation:

- Well diameter - 4 inches
- Maximum available drawdown - 15 feet
- Pumping duration - 6 months
- Aquifer type - unconfined
- Existing water table elevation - 708.1 feet above MSL
- Hydraulic conductivity - 17.8 gpd/ft<sup>2</sup>
- Specific yield - 0.15
- Target drawdown - 15 feet
- Physical boundary of well field - see Figure K-1
- Location of contaminated plume - see Figure K-1
- Thickness of contaminated plume - 15 feet
- Plume volume - 1.7 x 10<sup>6</sup> cubic feet.

The purpose of applying BESTWELLS is to determine the optimum number and location of wells to recover the contaminant plume. In other words, the model is used to design a well field to lower the water table 15 feet below current elevation. Twelve existing wells were used in the well field design to lower construction costs. Additionally, the sand, silt, and gravel media in the aquifer must be flushed at least once during the pumping period.

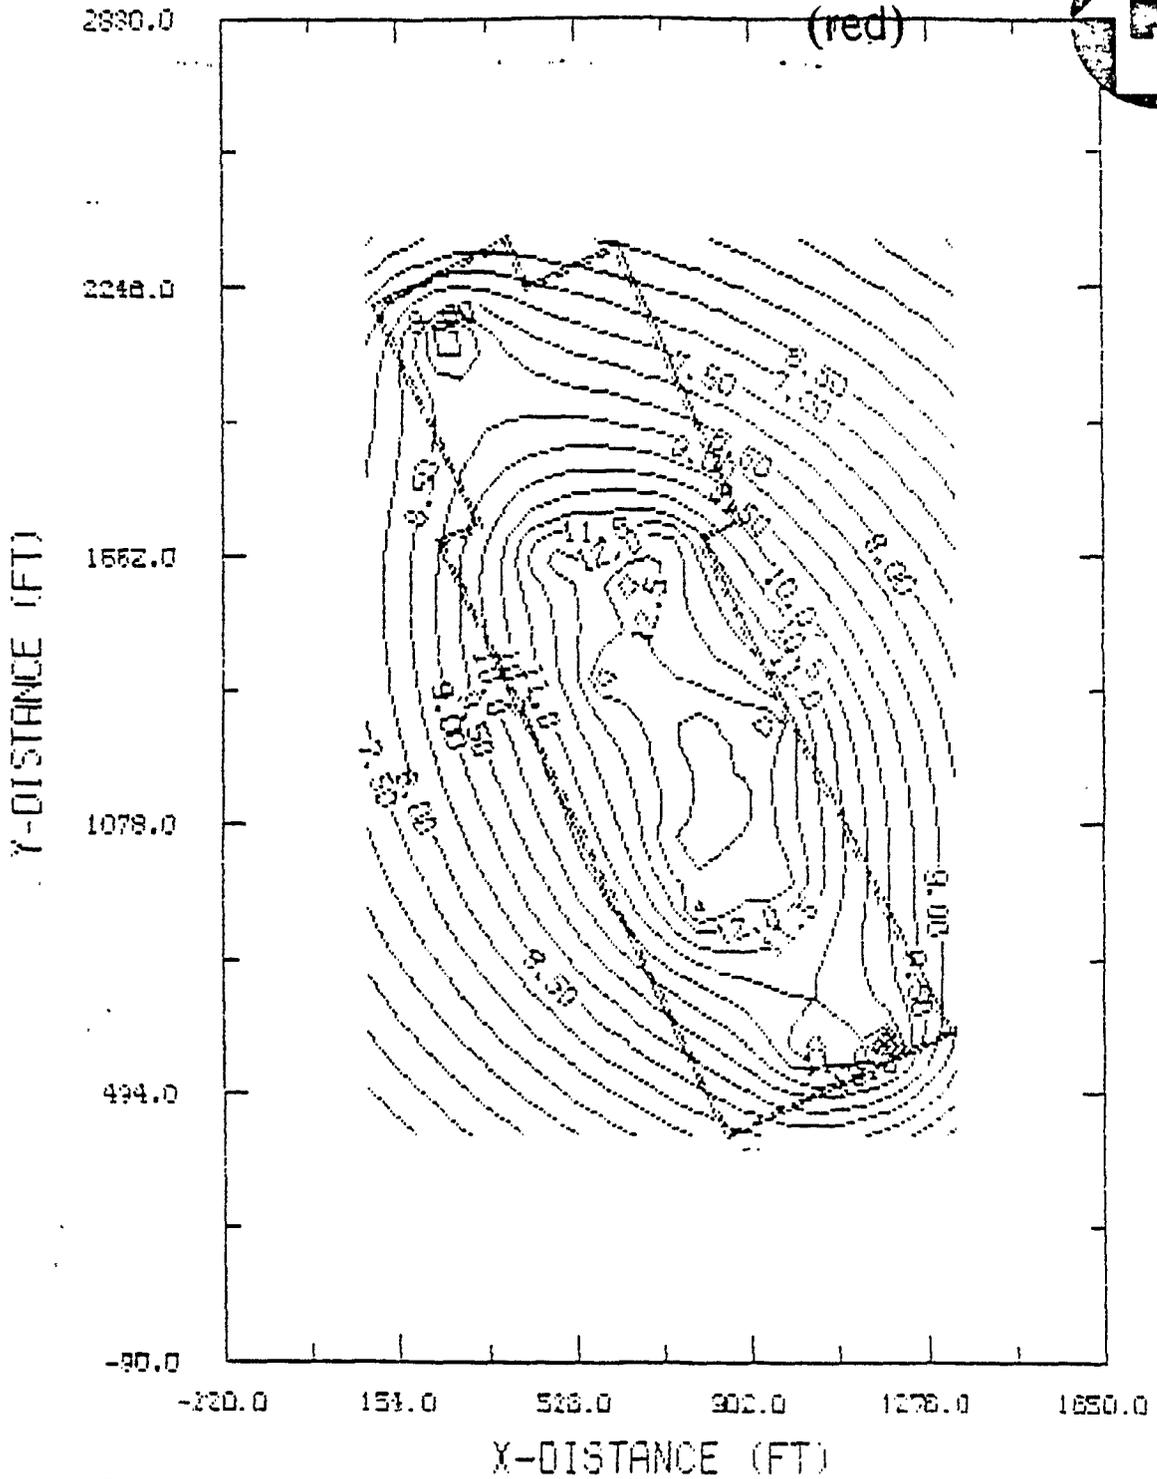

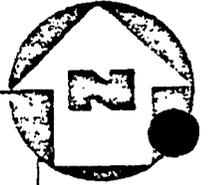

## K.2.3 Model Output

The model indicates that using 12 existing and 6 new wells, at an associated pumping rate of 500 gpm, will lower the water table by 12 feet (see Figure K-2).

K-5

However, to achieve complete recovery of groundwater contaminants, five recharge wells were added. These wells are located where the drawdown gradient was relatively flat. The injection rate for each recharge well is designed at 30 gpm. This injection rate is based on the average pumping rate of the 18 extraction wells. The total pumping rate of 18 extraction wells and five recharge wells is 585 gpm. Approximately 150 gpm will be treated and injected into the aquifer. The net discharge rate will be 435 gpm or 1 cfs.

The drawdown contours from the combined pumping and recharge system indicated the average drawdown is approximately identical to the 18 extraction well system (see Figure K-3). However, the stagnant areas between the extraction wells are significantly reduced by the mixing that is obtained through injection. Based on the production rate of 585 gpm obtained by the pumping and recharge system, the amount of water pumped during the 6-month period is  $2.0 \times 10^{-7} \text{ ft}^3$ , or 12 pore volumes.

During design of the groundwater recovery system, consideration was given to the Yoder Wells, located about 2,000 feet south of the site. The drawdown contours indicate that the cone of depression may extend to the Yoder Wells. The maximum induced drawdown is approximately 1 foot, attained at the end of the 6-month pumping period. This effect will be reduced by the natural recovery that occurs when pumping operations at the site cease. During normal rainfall times, the induced drawdown is not expected to have an effect on the Yoder Wells' capacity. However, there is a possibility that during dry conditions there may be some effect.

### K.3 Water Treatment

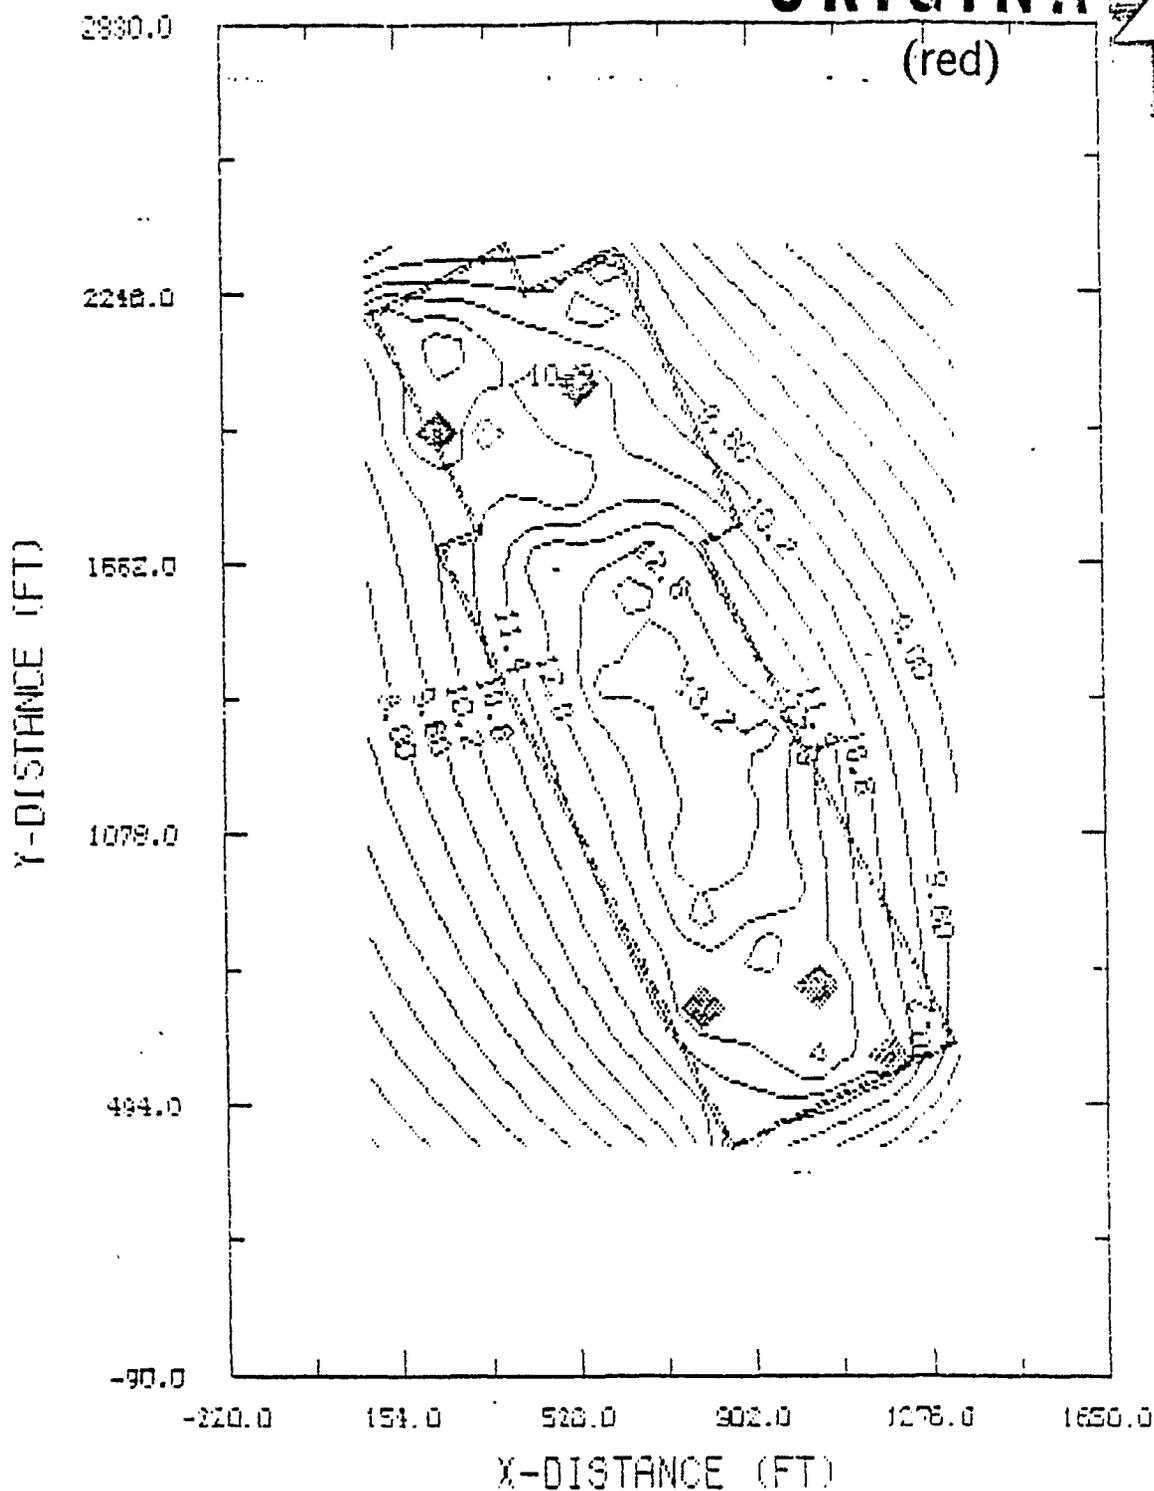

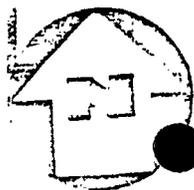

#### K.3.1 General

Retaining groundwater collection as a control technology leads automatically to considering appropriate methods of treatment and disposal. Because groundwater at the Millcreek Site contains volatile and nonvolatile organics and certain metals,

DRAFT

several different unit processes may have to be combined to effectively treat the water. Three basic categories of treatment for potential application are biological, chemical, and physical.

Based upon review of the available treatment alternatives in Section 11.0, and upon consideration of the groundwater characteristics at the Millcreek Site, the most effective treatment sequence would include a process to reduce dissolved metals concentration (e.g., precipitation); a process to reduce volatile organics loadings (e.g., air stripping); and a process to reduce nonvolatile organics loadings (e.g., carbon absorption or biological treatment). Other treatment components (e.g., filtration, equalization, flocculation/sedimentation) may be required to achieve differing levels of effluent quality, but the basic components will be common to most treatment alternatives.

At most sites, treatment can be accomplished either on site, in specially constructed facilities tailored to specific site requirements, or off site, in an existing Publicly Owned Treatment Works (POTW). Even when offsite treatment is selected, a need for some degree of onsite pretreatment usually exists prior to release to the POTW.

### K3.2 System Design

The groundwater at the Millcreek Site must be treated for removal of volatile organics, dissolved metals, and nonvolatile organics. To ensure a thorough purging of low-flow velocity regions between existing wells, 6 additional wells will be installed to pump water to the surface, and 5 injection wells will be strategically located to inject treated water.

The use of injection wells ensures that the stagnant areas of the contaminated plume can be moved into positions where the groundwater can be lifted to the surface for treatment. The groundwater pumping and treatment system is based on pumping 585 gpm, treating this entire flow, injecting 150 gpm via the 5 injection wells, and releasing 435 gpm to Marshall's Run. During discussions with local

engineers regarding the capacity of Millcreek Township's sanitary sewer system, NUS learned that the proposed 400-450 gpm flow cannot be discharged to any nearby sewer. This 576,000 to 648,000 gpd flow rate is greater than the total system capacity that the Millcreek Township serves. The nearest sewers with sufficient total capacity are more than 2 miles away, in the city of Erie. Even here, existing sewer flows leave insufficient room for the Millcreek Site's discharge flows. The option to pretreat groundwaters for additional treatment off site in the POTW is not applicable.

The major contaminants identified in groundwater samples were volatile organics, especially 1,2-dichloroethene, and two dissolved metals, iron, and manganese. The relative absence of dissolved toxic metals indicates that they remain in subsurface soils and are not currently migrating into the groundwater. Low levels of other organics, such as phthalates and isophorone, were reported for single monitoring wells only. The groundwater treatment will be used to control of volatile organics. Iron and manganese, even though nontoxic and found at appreciable levels in background samples, will have to be reduced in concentrations before the groundwater can be released or injected into the aquifer. Their presence also would have adverse effects on the treatment components used to remove organics.

The sequence of treatment technologies to be used to remediate the Millcreek Site groundwater is as follows:

- Equalization to eliminate surges in raw groundwater quality.
- Precipitation of dissolved iron and manganese using lime or sodium hydroxide at a pH between 8.0 and 10.0.
- Flocculation/sedimentation of suspended matter in a sedimentation basin or tank. Polymer additions may be used to enhance settling.
- Air stripping of volatile organics, using pack-tower air strippers and counter-current flow.

AR100820

- Adsorption of trace metals, residual volatile organics, and other organics, using granular activated carbon columns.
- Separating the treated effluents into two discharge flows -- 150 gpm to aquifer recharge via 5 injection wells, and 435 gpm -- to direct discharge via Marshall's Run.

Variations on the basic treatment sequence proposed above are possible. For example, filtration could be substituted for the flocculation/sedimentation step prior to air stripping. Biological treatment processes could be considered instead of air stripping for removal of organics. However, in this latter case, air stripping has definite advantages over the three retained biological treatment processes (activated sludge, trickling filters, and rotating biological contactors). The biological processes are all more effective in controlling a wide range of organic contaminants, but the Millcreek Site groundwaters contain volatiles only. For this reason, air stripping, which only treat volatiles, is the more efficient unit process for organics control.

A simplified groundwater treatment system for use at Millcreek Site consists of an oxidation/volatilization basin, wherein dissolved iron and manganese may be oxidized by brisk mechanical agitation or air sparging. At the same time, volatile organic compounds will be driven off to the atmosphere. By using theoretical oxygen consumption rates, with dissolved oxygen in water as the primary oxidant, and theoretical half-life data for volatile organics under mixing conditions, it is possible to size the oxidation/volatilization with reasonable retention and mixing times. Aerated groundwaters would overflow to another onsite basin designed to provide enough retention time to settle out the ferric and manganic oxide flocs. Final effluents to Marshall's Run would still contain measurable, but safe, concentrations of the groundwater contaminants

This treatment sequence requires no chemical addition and less complicated treatment components than the air strippers and carbon adsorption systems proposed earlier. Similar systems are widely used to aerate and oxidize ferrous and

manganous compounds found in coal mine drainage. However, these latter systems usually include chemical addition to neutralize acids in the mine drainage, thus greatly accelerating the rate at which dissolved iron and manganese will precipitate.

Even though the simplified treatment approach appears to have advantages, there are a number of reasons why it should not be considered as an acceptable remedial alternative. First, and most serious, there is no provision for controlling the quantity of volatile organics that will be transferred from groundwater to the ambient atmosphere not only on site, but also in the residential areas immediately adjacent to the site in the prevailing downwind direction. On an average basis, the 3,540 to 4,715 µg/l of one volatile compound -- 1,2-dichloroethene -- represents a potential release of 26.4 to 35.1 pounds per day. The remaining volatile organics will contribute smaller shares to an average total volatile release rate of 28.3 to 36.0 pounds per day. Moreover, depending on which groundwater wells are being pumped at any given time, a potential maximum release of up to 216 pounds per day is possible. The proximity of residential housing to these releases ensures an immediate negative response to this practice, even though groundwater effluents would be of acceptable quality.

The amounts of iron and manganese to be treated are low enough that the projected conversion to ferric and manganic oxides is supportable, especially since mechanical aeration or air sparging will replace the dissolved oxygen consumed during this reaction. Reaction rates will vary with season, but the need for long control times to volatilize high concentrations of 1,2-dichloroethene, estimated to be 3 hours and 20 minutes, should permit oxidation of metals to proceed to completion. However, this long mixing time for a large volume of groundwater will require heavy-duty mechanical mixers or aerators, with an accompanying high energy cost. To allow at least 3 hours, 20 minutes of contact time, the basin volume has to be at least 124,000 gallons. This entire volume must be continuously agitated to provide adequate oxidation and volatilization. Much of the money saved in eliminating air-stripping and chemical addition will have to be spent in operating and maintaining the aeration system, typically a high maintenance item.

DRAFT

For the above reasons, the simplified system will not be included in the list of remedial alternatives under consideration. The uncontrolled release of volatiles to the atmosphere, while remediating the groundwater, will have adverse impacts on the atmosphere and create unfavorable public reaction to EPA's efforts. The treatment system illustrated in Figure K-4 addresses this problem by controlling volatile emissions by means of a confined air stripper with an activated carbon trap on the exhaust line.

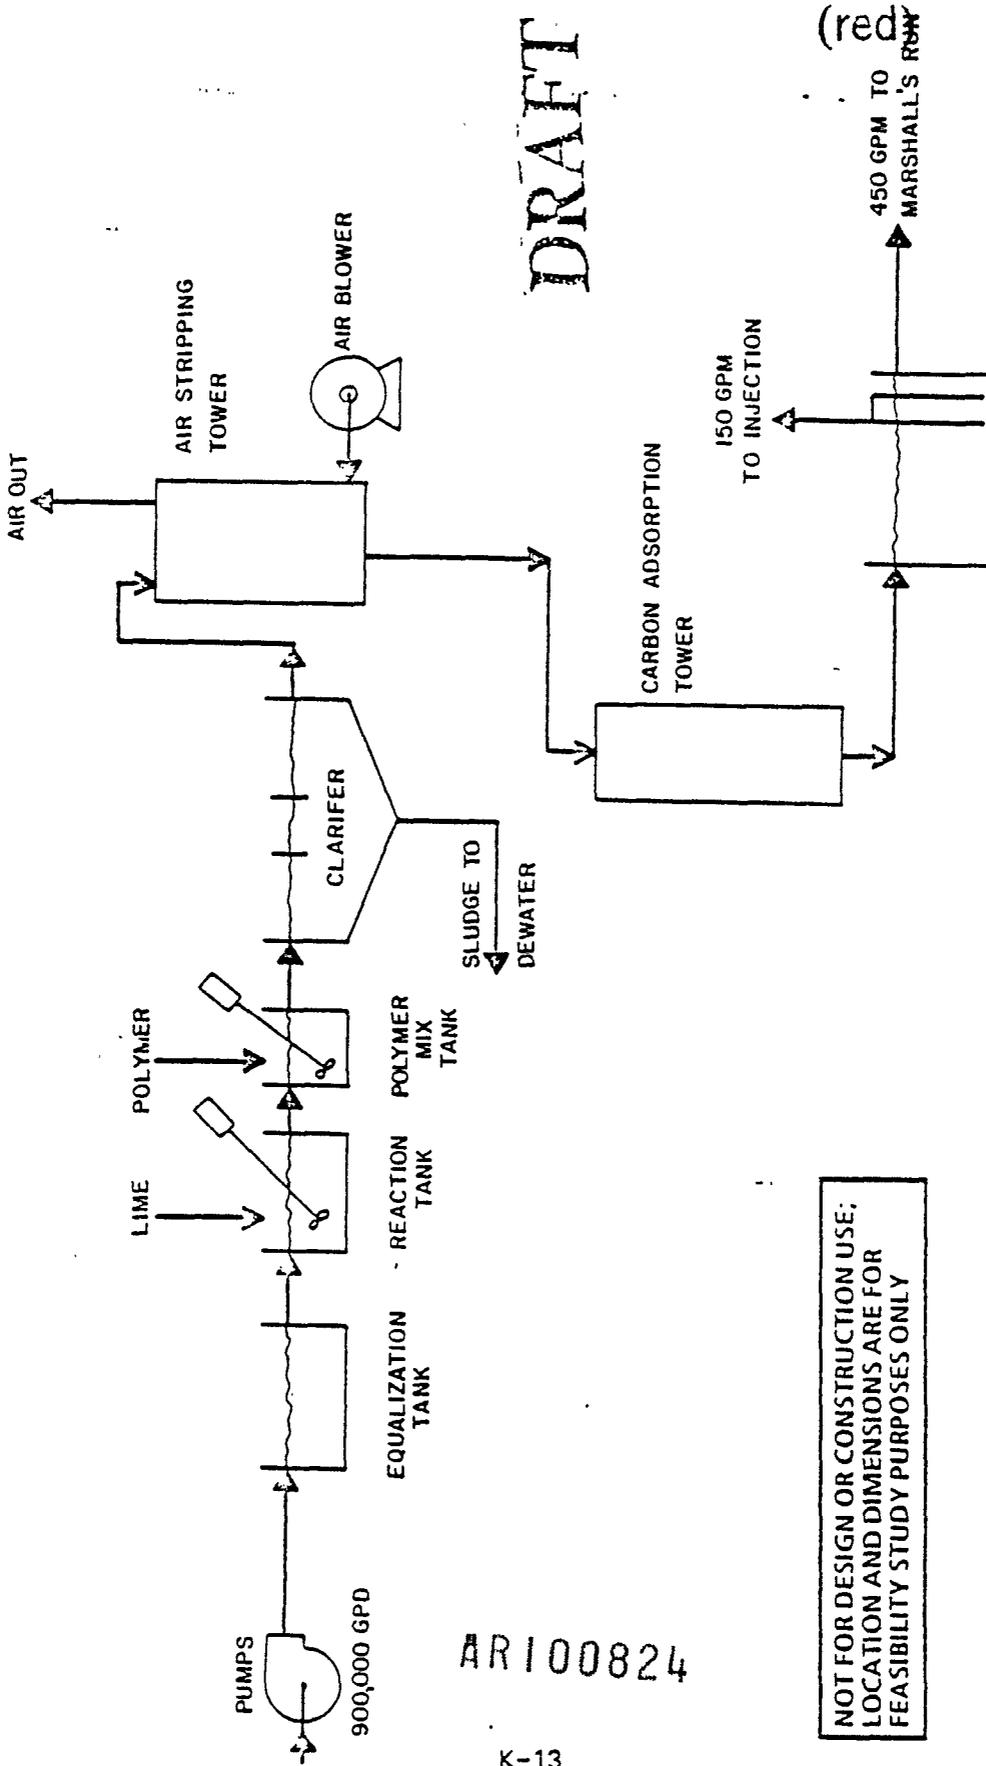

*Handwritten notes:*  
C  
10/1/82

The groundwater treatment system will be designated to accommodate a flow rate of 620 gpm. This allows for some excess capacity to account for minor variations in expected pumping rates, and to permit treatment of the existing pond waters and drainage from sludges and sediments in the same treatment plant. When these waters are brought into the system during the early days of remediation activities, other pumping rates may have to be adjusted to keep from grossly exceeding treatment plant capacity. To prevent overloading, Marshall's Run effluent release rates from the treatment plant should not exceed about 1 cfs (450 gpm). Since the 5 injection wells will each handle 30 gpm, 150 gpm of treatment plant effluent can be injected and 450 gpm discharged, giving a maximum total flow through treatment of 600 gpm. Refer to Figure K-4 for a diagram of the groundwater treatment system, and to Appendix M for details on costs.

Treatment duration is difficult to estimate at this time. Dewatering model studies indicate that groundwater volumes pumped over a 6-month period will provide sufficient flushing to replace the original plume volume 10 to 12 times. However, because of model limitations, costs are based on a more conservative pumping duration of 24 months.
