- Question Answering Overview
- Personalized Question Answering
- Business Analysis use case
- Personalized Question Answering Framework
- Conclusion and Future work

- Originated in the 1960s as natural language front ends to databases [1]
- Remains an active research area
- 2 main categories: Open-Domain & Domain-specific QA

- QA track at Text Retrieval Conference TREC [2]
- Pre-defined, large newswire text corpus as knowledge base
- World Wide Web as an auxiliary source of information
- No domain specific knowledge

- Database as knowledge base
- Domain ontologies as knowledge base
- Text collection as knowledge base

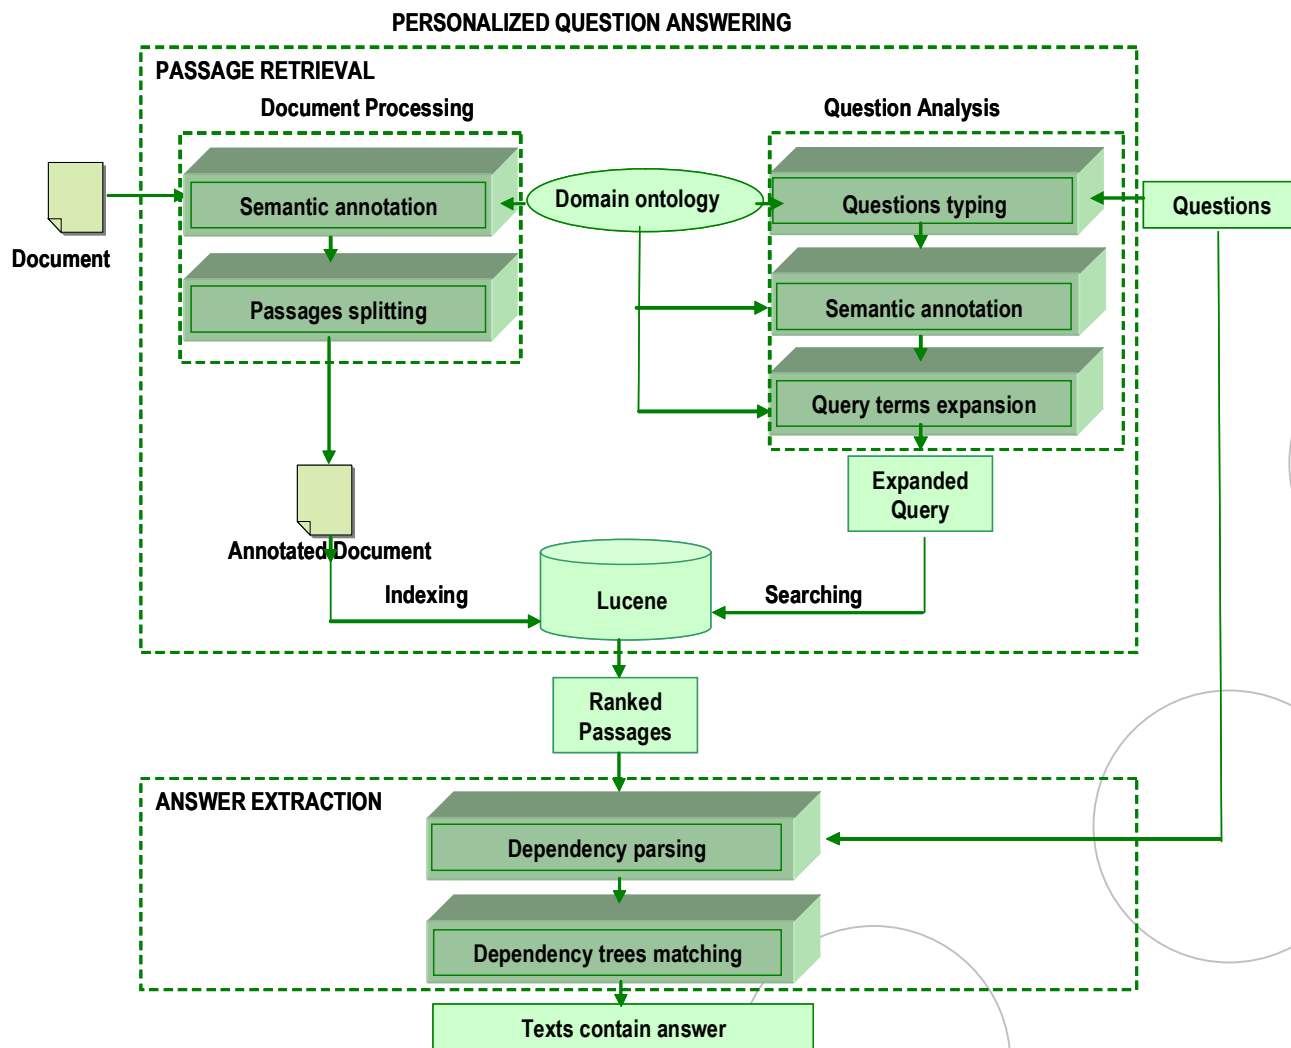

- Inadequate consideration of dynamic authoritative source of information
- Inadequate consideration of contextual information
- Ambiguity due to the complex writing style of documents

- domain specific
- dynamic collection of unstructured texts written in rhetorical style as knowledge base
- able to handle various question types
- able to resolve implicit context within questions
- provides an answer-containing chunk of texts rather than the precise answer

- Enterprises perform customer analysis → identify new business opportunities
- Form 10-Q provides financial information and management statements
- Searching, identification & extraction of relevant information → a resource intensive activity
- Potential intuitive and timely solution: QA

Personalized Question Answering Framework

- Passage Retrieval
 - Document Processing
 - Semantic annotation

e.g. "CompanyX releases a new operating system."

→ "CompanyX **BIOntoCompany** releases a new operating system
BIOntoSoftware"

whereby *BIOntoCompany*, *BIOntoSoftware* are labels of ontological concepts <http://localhost/temp/BIOnto#Company>,
<http://localhost/temp/BIOnto#Software>

- Passage splitting & stop-words removal

- **Passage Retrieval**

- Document Indexing
- Question Analysis

- Questions typing: pattern-matching rules to map the question type to concepts in the domain ontology

e.g. (1) *"Which products did CompanyX release?"*

→ *"BIOntoProduct did CompanyX release?"*

(2) *"Are there any CompanyX's plans to release new products?"*

→ Treated as: *"What are CompanyX's plans to release new products?"*

- Semantic annotation
- Query terms expansion: based on sub-class relationships in the domain ontology & synonyms list

- Searching

- Answer Extraction

- Why is Answer Extraction necessary?

e.g. *"Which company acquired Compaq?"*

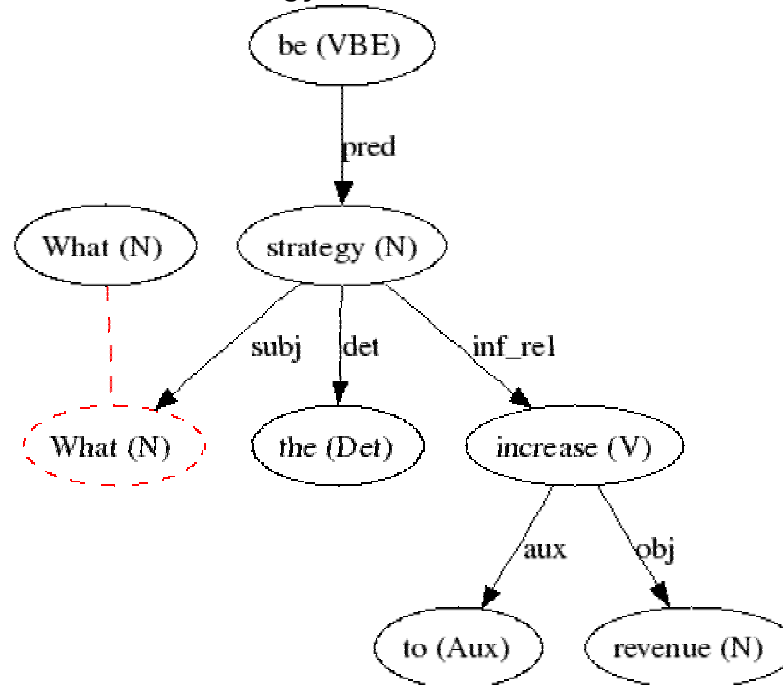

→ word overlap / term density ranking techniques cannot distinguish *"HP acquired Compaq"* from *"Compaq acquired HP"*

- Solution: take grammatical constraints / relations of question and candidate sentences into consideration
- MiniPar Dependency Parser generates dependency trees for words within a given sentence.

- Answer Extraction

- Example of dependency tree generated by Minipar visualization tool

“What is the strategy to increase revenue ?”

- Pitfall: strict relations matching suffers substantially from poor recall [3]

- Answer Extraction

- Potential solution: Approximate/Fuzzy relation matching proposed by Cui et al. [3]
- Mapping scores model between relation paths based on a variation of a Statistical Translation Model
- Application to Personalized Question Answering

- **Conclusion**

- Proposed design of Personalized Question Answering framework
- Business Analysis use case scenario
- The availability of domain semantics → potential improvement for recall in passage retrieval
- Approximate dependency matching between question-candidate answer pairs may yield higher precision for answer extraction without impacting on recall

- **Future work**

- Examining the possibility of using domain semantics in the Answer Extraction task
- Handling complex questions whose answers are not explicitly stated
- Evaluation scheme
- Integrate the QA system with the Analyst Workbench [4]
