Current \& voltage phases in pure R, C, and L circuits Current is the same everywhere in a single branch (including phase) Phases of voltages in elements are referenced to the current phasor

- Apply sinusoidal voltage $\mathcal{E}(\mathrm{t})=\mathcal{E}_{\mathrm{m}} \operatorname{Cos}\left(\omega_{\mathrm{D}} \mathrm{t}\right)$
- For pure R, L, or C loads, phase angles are $0,+\pi / 2,-\pi / 2$
- Reactance" means ratio of peak voltage to peak current (generalized resistances).

$V_{R}$ \& $i_{R}$ in phase Resistance

$$
V_{\text {max }} / i_{R} \equiv \mathbf{R}
$$

$\mathrm{V}_{\mathrm{c}}$ lags $\mathrm{i}_{\mathrm{c}}$ by $\pi / 2$ Capacitive Reactance $\mathrm{V}_{\text {max }} / \mathrm{i}_{\mathrm{c}} \equiv \mathrm{X}_{\mathrm{c}}=1 / \omega_{\mathrm{D}} \mathrm{C}$

$\mathrm{V}_{\mathrm{L}}$ leads $\mathrm{i}_{\mathrm{L}}$ by $\pi / 2$ Inductive Reactance

$$
V_{\max } / \mathrm{i}_{\mathrm{L}} \equiv \mathrm{X}_{\mathrm{L}}=\omega_{\mathrm{D}} \mathrm{~L}
$$

Voltage phasor leads current phasor

Copyright R. Janow - Fall 2013

## The impedance is the ratio of peak EMF to peak current

$$
\overrightarrow{\mathbf{Z}} \equiv \frac{\overrightarrow{\mathcal{E}}_{\mathrm{m}}}{\mathbf{i}} \text { peak applied voltage } \quad[\mathbf{Z}]=\mathbf{o h m s}
$$

Magnitude of $\mathcal{E}_{\mathrm{m}}: \varepsilon_{\mathrm{m}}^{2}=\mathrm{V}_{\mathrm{R}}^{2}+\left(\mathrm{V}_{\mathrm{L}}-\mathrm{V}_{\mathrm{C}}\right)^{\mathbf{2}}$
Reactances: $\quad X_{L}=\omega_{D} L \quad X_{C}=\frac{1}{\omega_{D} C}$

$$
\begin{gathered}
X_{L} \equiv V_{L} / i_{L} \quad X_{C} \equiv V_{c} / i_{C} \quad R \equiv V_{R} / i_{R} \\
i_{m}=i_{R, \text { max }}=i_{L, \text { max }}=i_{C, \text { max }}
\end{gathered}
$$

If $X_{L}<X_{C}$, the source voltage phasor lags the current phasor, $X<0$, and $\phi$ is a negative angle between 0 and $-90^{\circ}$.

For series LRC circuit, divide $\mathcal{E}_{\mathrm{m}}$ by peak current

Magnitude of Z :

$$
Z \equiv\left[R^{2}+\left(X_{L}-X_{C}\right)^{2}\right]^{1 / 2}
$$

Phase angle $\Phi$ :

$$
\tan (\Phi) \equiv \frac{\mathrm{V}_{\mathrm{L}}-\mathrm{V}_{\mathrm{C}}}{\mathrm{~V}_{\mathrm{R}}}=\frac{\mathrm{X}_{\mathrm{L}}-\mathrm{X}_{\mathrm{C}}}{\mathrm{R}}
$$

Applies to a single branch with L, C, R
see diagram
$\Phi$ measures the power absorbed by the circuit: $\mathbf{P} \propto \overrightarrow{\mathcal{E}}_{\mathrm{m}} \circ \overrightarrow{\mathrm{i}}_{\mathrm{m}}=\mathcal{E}_{\mathrm{m}} \overrightarrow{\mathrm{i}}_{\mathrm{m}} \cos (\Phi)$
$\cdot R \sim 0 \rightarrow$ tiny losses, no power absorbed $\rightarrow \underline{i}_{\underline{m}}$ normal to $\underline{\varepsilon}_{m} \rightarrow \Phi \sim+/-\pi / 2$

- $X_{L}=X_{C} \rightarrow i_{m}$ parallel to $\mathcal{E}_{m} \rightarrow \Phi=0 \rightarrow Z=R \rightarrow$ maximum current (resonance) ${ }_{\| 2013}$

## Table 31.1 Circuit Elements with Alternating Current

| Circuit Element | Amplitude Relationship | Circuit Quantity | Phase of $\boldsymbol{v}$ |
| :--- | :--- | :--- | :--- |
| Resistor | $V_{R}=I R$ | $R$ | In phase with $i$ |
| Inductor | $V_{L}=I X_{L}$ | $X_{L}=\omega L$ | Leads $i$ by $90^{\circ}$ |
| Capacitor | $V_{C}=I X_{C}$ | $X_{C}=1 / \omega C$ | Lags $i$ by $90^{\circ}$ |

## Example 1: Analyzing a series RLC circuit

A series RLC circuit has $R=425 \Omega, L=1.25 \mathrm{H}, \mathrm{C}=3.50 \mu \mathrm{~F}$.
It is connected to an AC source with $f=60.0 \mathrm{~Hz}$ and $\varepsilon_{\mathrm{m}}=150 \mathrm{~V}$.
(A) Determine the impedance of the circuit.
(B) Find the amplitude of the current (peak value).
(C) Find the phase angle between the current and voltage.
(D) Find the instantaneous current across the RLC circuit.
(E) Find the peak and instantaneous voltages across each circuit element.

## Series LCR circuit driven by an external AC voltage

Apply EMF:

$$
\mathcal{E}(t)=\mathcal{E}_{\mathrm{m}} \operatorname{Cos}\left(\omega_{\mathrm{D}} \mathrm{t}\right) \quad \omega_{\mathrm{D}} \text { is the driving frequency }
$$

The current $i(t)$ is the same everywhere in the circuit $i(\mathrm{t})=\mathcal{E}_{\mathrm{m}} \operatorname{Cos}\left(\omega_{\mathrm{D}}^{\mathrm{t}}+\Phi\right)$

- Same frequency dependance as $\mathcal{E}(\mathrm{t})$ but...
- Current leads or lags $\mathcal{E}(\mathrm{t})$ by a constant phase angle $\Phi$
- Same phase for the current in $\mathcal{E}, \mathrm{R}, \mathrm{L}, \& \mathrm{C}$

Phasors all rotate CCW at frequency $\omega_{D}$

- Lengths of phasors are the peak values (amplitudes)
- The " $y$ " components are the measured values.

Plot voltages in components with phases
relative to current phasor $i_{m}$ :

- $V_{R}$ has same phase as $i_{m} \quad V_{R}=i_{m} R$
- $\mathrm{V}_{\mathrm{C}}$ lags $\mathrm{i}_{\mathrm{m}}$ by $\pi / 2 \quad \mathrm{~V}_{\mathrm{C}}=\mathrm{i}_{\mathrm{m}} \mathrm{X}_{\mathrm{c}}$
- $\mathbf{V}_{\mathrm{L}}$ leads $\mathrm{i}_{\mathrm{m}}$ by $\pi / \mathbf{2} \quad \mathrm{V}_{\mathrm{L}}=\mathrm{i}_{\mathrm{m}} \mathbf{X}_{\mathrm{L}}$

Kirchoff Loop rule for potentials (measured along y)

$$
\vec{\varepsilon}(t)-\vec{V}_{R}(t)-\vec{V}_{L}(t)-\vec{V}_{C}(t)=\mathbf{0}
$$

$$
\begin{aligned}
& \overrightarrow{\mathcal{E}}_{\mathrm{m}}=\overrightarrow{\mathrm{V}}_{\mathrm{R}}+\left(\overrightarrow{\mathrm{V}}_{\mathrm{L}}+\overrightarrow{\mathrm{V}}_{\mathrm{C}}\right) \quad \overrightarrow{\mathrm{V}}_{\mathrm{C}} \text { lags } \overrightarrow{\mathrm{V}}_{\mathrm{L}} \text { by } 180^{0} \\
& \text { along } \mathrm{i}_{\mathrm{m}}{ }^{\text {" }} \text { " perpendicular to } \mathrm{i}_{\mathrm{m}}
\end{aligned}
$$

## Example 1: Analyzing a series RLC circuit

A series RLC circuit has $R=425 \Omega$, $L=1.25 H, C=3.50 \mu \mathrm{~F}$.

(A) Determine the impedance of the circuit.

$$
\text { Angular frequency: } \quad \omega_{D}=2 \pi f=2 \pi(60.0) \mathrm{Hz}=377 \mathrm{~s}^{-1}
$$

Resistance:

$$
R=425 \Omega
$$

Inductive reactance:

$$
X_{L}=\omega_{D} L=\left(377 \mathrm{~s}^{-1}\right)(1.25 H)=471 \Omega
$$

Capacitive reactance:

$$
X_{C}=1 / \omega_{D} C=1 /\left(377 \mathrm{~s}^{-1}\right)\left(3.50 \times 10^{-6} F\right)=758 \Omega
$$

$$
Z=\sqrt{R^{2}+\left(X_{L}-X_{C}\right)^{2}}=\sqrt{(425 \Omega)^{2}+(471 \Omega-758 \Omega)^{2}}=513 \Omega
$$

(B) Find the peak current amplitude:

$$
I_{m}=\frac{\varepsilon_{m}}{Z}=\frac{150 \mathrm{~V}}{513 \Omega}=0.293 \mathrm{~A}
$$

(C) Find the phase angle between the current and voltage.

$$
\begin{aligned}
& X_{C}>X_{L}(\text { Capacitive }) \quad \begin{array}{l}
\text { Current vector } I_{m} \text { leads the Voltage } \mathcal{E}_{m} \\
\text { Phase angle should be negative }
\end{array} \\
& \phi=\tan ^{-1}\left(\frac{X_{L}-X_{C}}{R}\right)=\tan ^{-1}\left(\frac{471 \Omega-758 \Omega}{425 \Omega}\right)=-34.0^{\circ}=-0.593 \text { rad. }
\end{aligned}
$$

## Example 1: analyzing a series RLC circuit - continued

A series RLC circuit has $R=425 \Omega$, $\mathrm{L}=1.25 \mathrm{H}, \mathrm{C}=3.50 \mu \mathrm{~F}$. It is connected to an AC source with $f=60.0 \mathrm{~Hz}$ and $\varepsilon_{\mathrm{m}}=\mathbf{1 5 0} \mathrm{V}$.
(D) Find the instantaneous current across the RLC circuit.

$$
I_{m} \cos (\omega t+\varphi)=0.292 \cos (377 t-0.593 \mathrm{rad})
$$

(E) Find the peak and instantaneous voltages across each circuit element.

$$
\begin{aligned}
& \left.\mathbf{V}_{\mathbf{R}, \mathbf{m}}=\mathrm{I}_{\mathbf{m}} \mathbf{R}=\mathbf{( 0 . 2 9 2} \mathbf{A}\right)(\mathbf{4 2 5} \boldsymbol{\Omega})=\mathbf{1 2 4} \mathrm{V} \\
& v_{R}(t)=V_{R} \cos (\omega t+\varphi)=124 \cos (377 t-\underline{0.593} \mathrm{rad}) \\
& \mathbf{V}_{\mathrm{L}, \mathrm{~m}}=\mathrm{I}_{\mathrm{m}} \mathrm{X}_{\mathrm{L}}=(\mathbf{0} .292 \mathrm{~A})(\mathbf{4 7 1} \Omega)=\mathbf{1 3 8} \mathrm{V} \\
& v_{L}(t)=V_{L} \cos (\omega t+\varphi+\pi / 2)=124 \cos (377 t-0.593 \mathrm{rad}+\pi / 2) \\
& \mathbf{V}_{\mathbf{C}, \mathrm{m}}=\mathrm{I}_{\mathrm{m}} \mathbf{X}_{\mathbf{C}}=\mathbf{( 0 . 2 9 3 A ) ( 7 5 8 \Omega} \mathbf{)}=\mathbf{2 2 2} \mathrm{V} \\
& V_{R} \text { in phase with } I_{m} \\
& V_{R} \text { leads } \mathcal{E}_{m} \text { by }|\Phi| \\
& V_{L} \text { leads } V_{R} \text { by } 90^{\circ} \\
& \mathrm{V}_{C} \text { lags } \mathrm{V}_{\mathrm{R}} \text { by } 90^{\circ} \\
& v_{C}(t)=V_{C} \cos (\omega t+\varphi-\pi / 2)=222 \cos (377 t-0.593 \mathrm{rad}+\pi / 2)
\end{aligned}
$$

Note that: $\quad \mathrm{V}_{\mathrm{R}}+\mathrm{V}_{\mathrm{L}}+\mathrm{V}_{\mathrm{C}}=\mathbf{4 8 3 V} \neq 150 \mathrm{~V}=\mathcal{E}_{\mathrm{m}} \quad$ Why not?
Voltages add with proper phases: $\mathcal{E}_{\mathrm{m}}=\left(\mathrm{V}_{\mathrm{R}}^{2}+\left[\mathrm{V}_{\mathrm{L}}-\mathrm{V}_{\mathrm{C}}\right]^{2}\right)^{1 / 2}=150 \mathrm{~V}_{\text {:013 }}$

## Example 2: Resonance in a series LCR Circuit:

$$
\mathrm{R}=3000 \Omega \quad \mathrm{~L}=0.33 \mathrm{H} \quad \mathrm{C}=0.10 \mathrm{mF} \quad \mathcal{E}_{\mathrm{m}}=100 \mathrm{~V} .
$$

Find $Z$ and $\Phi$ for $f_{D}=200 \mathrm{Hertz}, \mathrm{f}_{\mathrm{D}}=876 \mathrm{~Hz}$, \& $\mathrm{f}_{\mathrm{D}}=2000 \mathrm{~Hz}$

$\begin{gathered}\text { Why should } f_{D} \text { make } \\ \text { a difference? }\end{gathered} X_{L}=\omega_{D} L \quad X_{C}=\frac{1}{\omega_{D} C} \quad I_{m} \equiv \frac{\mathcal{E}_{m}}{Z}$

$$
\mathrm{Z} \equiv\left[\mathrm{R}^{2}+\left(\mathrm{X}_{\mathrm{L}}-\mathrm{X}_{\mathrm{C}}\right)^{2}\right]^{1 / 2}
$$

$$
\Phi=\tan ^{-1}\left(\frac{\mathrm{X}_{\mathrm{L}}-\mathrm{X}_{\mathrm{C}}}{\mathrm{R}}\right)
$$

| Frequency f | Resistance R | $\begin{gathered} \text { Reactance } \\ \mathbf{X}_{\mathrm{C}} \end{gathered}$ | $\begin{gathered} \text { Reactance } \\ \text { X }_{L} \end{gathered}$ | $\begin{gathered} \text { Impedance } \\ \mathbf{Z} \end{gathered}$ | Phase Angle $\Phi$ | Circuit <br> Behavior |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 200 Hz | $3000 \Omega$ | 7957 ת | $415 \Omega$ | $8118 \Omega$ | - $68.3^{\circ}$ | Capacitive $\mathcal{E}_{\mathrm{m}} \text { lags } \mathrm{I}_{\mathrm{m}}$ |
| 876 Hz | $3000 \Omega$ | 1817 ת | 1817 ת | $3000 \Omega$ <br> Resonance | 0 | Resistive Max current |
| 2000 Hz | $3000 \Omega$ | $796 \Omega$ | 4147 ת | 4498 ת | +48.0 ${ }^{\circ}$ | Inductive $\mathcal{E}_{\mathrm{m}} \text { leads } \mathrm{I}_{\mathrm{m}}$ |

$X_{C}>X_{L}$

$\mathrm{X}_{\mathrm{C}}=\mathrm{X}_{\mathrm{L}}$

$\mathrm{X}_{\mathrm{L}}>\mathrm{X}_{\mathrm{C}}$

## Resonance

Vary $\omega_{D}$ : At resonance maximum current flows \& impedance is minimized
$X_{C}=X_{L}$ when $\omega_{D}=1 / \sqrt{L C} \equiv \omega_{\text {res }} \quad \Rightarrow Z=R, \quad I_{m}=\mathcal{E}_{M} / R, \quad \Phi=0$
width of resonance (selectivity, "Q") depends on R. Large $R \rightarrow$ less selectivity, smaller current at peak

## Power in AC Circuits

- Resistors always dissipate power, but the instantaneous rate varies as $\mathrm{i}^{2}(\mathrm{t}) \mathrm{R}$
- No power is lost in pure capacitors and pure inductors in an AC circuit
- In a capacitor, during one-half of a cycle energy is stored and during the other half the energy is returned to the circuit
- In an inductor, the source does work against the back emf of the inductor and energy is stored in the inductor. When the current in the circuit begins to decrease, the energy is returned to the circuit

## Instantaneous and RMS (average) power

 $\begin{aligned} & \text { instantaneous power } \\ & \text { consumed by circuit }\end{aligned} \equiv P_{\text {inst }}=i^{2}(t) R=I_{m}^{2} R \sin ^{2}(\omega t-\Phi)$- Power is dissipated in R, not in L or C
- $\operatorname{Sin}^{2}(x)$ is always positive, so $P_{\text {inst }}$ is always positive. But, it is not constant.
- Pattern for power repeats every $\pi$ radians (T/2)

The RMS power, current, voltage are useful, DC-like quantities

$$
\mathbf{P}_{\mathrm{av}} \equiv \text { averageof } \mathrm{P}_{\mathrm{inst}} \text { over a whole cycle }(\omega \mathbf{T}=2 \pi)
$$

Integrate

$$
\left.P_{a v}=I_{m}^{2} R \frac{1}{T} \int_{0}^{T} \sin ^{2}(\omega t-\Phi) d t=\frac{1}{2} I_{m}^{2} R \quad \text { (the integral }=1 / 2\right)
$$

$\mathrm{P}_{\mathrm{av}}$ is an "RMS" quantity:

- "Root Mean Square"
- Square a quantity (positive)
- Average over a whole cycle
- Compute square root.
- In practice, divide peak value by sqrt(2) for $I_{m}$ or $\mathcal{E}_{\mathrm{m}}$ since $\sin ^{2}(x)$ appears

$$
P_{r m s} \equiv P_{a v}=I_{r m s}^{2} R
$$

$\mathcal{E}_{\mathrm{rms}} \equiv \frac{\mathcal{E}_{\mathrm{m}}}{\sqrt{2}} \quad \mathrm{I}_{\mathrm{rms}} \equiv \frac{\mathrm{I}_{\mathrm{m}}}{\sqrt{2}} \quad \mathrm{I}_{\mathrm{rms}}=\frac{\mathcal{E}_{\mathrm{rms}}}{\mathrm{Z}}$

Household power example: 120 volts RMS $\leftrightarrow 170$ volts peak

## Power factor for AC Circuits

The PHASE ANGLE $\Phi$ determines the average RMS power actually absorbed by the RMS current and applied voltage in the circuit.

Result (proven below):

$$
\begin{aligned}
P_{\mathrm{av}} \equiv \mathrm{P}_{\mathrm{rms}}=\overrightarrow{\mathcal{E}}_{\mathrm{rms}} \circ \overrightarrow{\mathbf{I}}_{\mathrm{rms}}=\mathcal{E}_{\mathrm{rms}} \mathrm{rms}_{\mathrm{rm}} \cos (\Phi) \\
\cos (\Phi) \equiv \mathrm{R} / \mathrm{Z} \text { is the "power factor" }
\end{aligned}
$$

Proof: start with instantaneous power (not very useful, shift $\cos (x)$ by pi/2):

$$
P_{\text {inst }}(t)=\mathcal{C}(t) I(t)=\mathcal{E}_{\mathrm{m}} I_{\mathrm{m}} \sin \left(\omega_{\mathrm{D}} \mathrm{t}\right) \sin \left(\omega_{\mathrm{D}} \mathrm{t}-\Phi\right)
$$

Average it over one full cycle:

$$
\mathbf{P}_{\mathrm{av}} \equiv \frac{1}{\tau} \int_{0}^{\tau} \mathrm{P}_{\mathrm{inst}}(\mathrm{t}) \mathrm{dt}=\mathcal{E}_{\mathrm{m}} \mathrm{I}_{\mathrm{m}} \frac{1}{\tau} \int_{0}^{\tau} \sin \left(\omega_{\mathrm{D}} \mathrm{t}\right) \sin \left(\omega_{\mathrm{D}} \mathrm{t}-\Phi\right) \mathrm{dt}
$$

Note trig identities:

$$
\begin{aligned}
& \sin \left(\omega_{D} t \pm \Phi\right)=\sin \left(\omega_{D} t\right) \cos (\Phi) \pm \cos \left(\omega_{D} t\right) \sin (\Phi) \\
& \sin \left(\omega_{D} t\right) \cos \left(\omega_{D} t\right)=\frac{1}{2} \sin \left(2 \omega_{D} t\right)
\end{aligned}
$$

## Power factor for AC Circuits - continued

Substitute trig identities:

$$
P_{\mathrm{av}}=\mathcal{E}_{\mathrm{m}} \mathrm{I}_{\mathrm{m}} \cos (\Phi) \frac{1}{\tau} \int_{0}^{\tau} \sin ^{2}\left(\omega_{\mathrm{D}} \mathrm{t}\right) \mathrm{dt}-\mathcal{E}_{\mathrm{m}} \mathrm{I}_{\mathrm{m}} \sin (\Phi) \frac{1}{2 \tau} \int_{0}^{\tau} \sin \left(2 \omega_{\mathrm{D}} \mathrm{t}\right)
$$

Over a full period:

$$
\omega_{D} \tau=2 \pi \quad \frac{1}{\tau} \int_{0}^{\tau} \sin ^{2}\left(\omega_{D} t\right) d t=\frac{1}{2} \quad \frac{1}{2 \tau} \int_{0}^{\tau} \sin \left(2 \omega_{D} t\right)=0
$$

$\therefore \mathbf{P}_{\mathrm{av}}=\mathcal{E}_{\mathrm{m}} \mathrm{I}_{\mathrm{m}}\left\{\frac{\cos (\Phi)}{2}-0\right\}$
Recall: RMS values $=$ Peak values divided by sqrt(2)
$\therefore \mathrm{P}_{\mathrm{av}} \equiv \mathrm{P}_{\mathrm{rms}}=\mathcal{E}_{\mathrm{rms}} \mathrm{I}_{\mathrm{rms}} \operatorname{Cos}(\Phi)$
Also note: $\quad \therefore \mathcal{E}_{\mathrm{rms}}=\mathrm{I}_{\mathrm{rms}} \mathbf{Z}$ and $\quad \mathbf{R}=\mathbf{Z} \cos (\Phi)$
Alternate form: $\quad P_{r m s}=I_{r m s}^{2} Z \cos (\Phi)=I_{r m s}^{2} R$
If $\mathrm{R}=0$ (pure LC circuit) $\Phi \rightarrow+/-\pi / 2$ and $P_{a v}=P_{r m s}=0$

## Example 2 continued with RMS quantities:

$$
\mathrm{R}=3000 \Omega \quad \mathrm{~L}=0.33 \mathrm{H} \quad \mathrm{C}=0.10 \mathrm{mF} \quad \mathcal{E}_{\mathrm{m}}=100 \mathrm{~V} .
$$

$$
f_{D}=200 \mathrm{~Hz}
$$

Find $\mathcal{E}_{\mathrm{rms}}: \quad \mathcal{E}_{\mathrm{rms}}=\mathcal{E}_{\mathrm{m}} / \sqrt{2}=71 \mathrm{~V}$.
Find $I_{\text {rms }}$ at $200 \mathrm{~Hz}: \quad Z=8118 \Omega$ as before

$$
\mathrm{I}_{\mathrm{rms}}=\mathcal{\varepsilon}_{\mathrm{rms}} / Z=71 \mathrm{~V} / 8118 \Omega=8.75 \mathrm{~mA} .
$$

Find the power factor:

$$
\cos (\Phi)=R / Z=\frac{3000}{8118}=0.369
$$

Recall: do not use arc-cos to find $\Phi$

Find the phase angle $\Phi$ :

$$
\Phi=\tan ^{-1}\left[\frac{X_{L}-X_{C}}{R}\right]=-68^{\circ} \text { as before }
$$

Find the average power:

$$
\mathrm{P}_{\mathrm{av}}=\mathcal{E}_{\mathrm{rms}} \mathrm{I}_{\mathrm{rms}} \cos (\Phi)=71 \times 8.75 \times 10^{-3} \times 0.369=0.23 \text { Watts }
$$

or

$$
P_{\mathrm{av}}=I_{\mathrm{rms}}^{2} R=\left(8.75 \times 10^{-3}\right)^{2} \times 3000=0.23 \text { Watts }
$$

## Example 3 - LCR circuit analysis using RMS values

A 240 V (RMS), 60 Hz voltage source is applied to a series LCR circuit consisting of a $50-$ ohm resistor, a 0.5 H inductor and a $20 \mu \mathrm{~F}$ capacitor. $\omega_{\mathrm{D}}=2 \pi \mathrm{f}=6.28 \times 60=377 \mathrm{rad} / \mathrm{s}$

Find the capacitive reactance of the circuit: $X_{C} \equiv 1 / \omega_{D} C=1 /\left(377 \times 2 \times 10^{-5}\right)=133 \Omega$
Find the inductive reactance of the circuit: $\quad X_{L} \equiv \omega_{D} L=377 x .5=188.5 \Omega$
The impedance of the circuit is: $\quad Z \equiv\left[R^{2}+\left(X_{L}-X_{C}\right)^{2}\right]^{1 / 2}=74.7 \Omega$
The phase angle for the circuit is: $\quad \tan (\Phi)=\frac{X_{L}-X_{C}}{R} \Rightarrow \Phi=48.0^{\circ}, \cos (\Phi)=0.669$
$\Phi$ is positive since $X_{L}>X_{C}$ (inductive)
The RMS current in the circuit is: $\quad \mathrm{I}_{\mathrm{rms}}=\frac{\mathcal{E}_{\mathrm{rms}}}{\mathrm{Z}}=\frac{240}{74.7}=3.2 \mathrm{~A}$.
The average power consumed in this circuit is:

$$
P_{\mathrm{rms}}=I_{\mathrm{rms}}^{2} R=(3.2)^{2} \times 50=516 \mathrm{~W} . \quad \text { or } P_{\mathrm{rms}}=\mathcal{E}_{\mathrm{rms}} I_{\mathrm{rms}} \cos (\Phi) \text { where } \cos (\Phi)=R / Z
$$

If the inductance could be changed to maximize the current through the circuit, what would the new inductance L' be? Current is a maximumat RESONANCE.

$$
\omega_{D}=377=\frac{1}{\sqrt{L C}} \Rightarrow L^{\prime}=\frac{1}{\omega_{D}^{2} C}=\frac{1}{377^{2} \times 2 \times 10^{-5}}=0.352 \mathrm{H}
$$

How much RMS current would flow in that case?

$$
\text { At resonance } Z=R \Rightarrow I_{\mathrm{rms}}=\frac{\mathcal{C}_{\mathrm{rms}}}{R}=\frac{240 \mathrm{~V}}{50 \Omega}=4.8 \mathrm{~A} .
$$

Copyright R. Janow - Fall 2013

## Transformers

Devices used to change AC voltages. They have:

- Primary
- Secondary
- Power ratings

Primary $\uparrow$ Secondary
iron core

## Transformers

Assume zero internal resistances, EMFs $\mathcal{E}_{\mathrm{p}}, \mathcal{E}_{\mathrm{s}}=$ terminal voltages $\mathrm{V}_{\mathrm{p}}, \mathrm{V}_{\mathrm{s}}$ Faradays Law for primary and secondary:

$$
V_{p}=-N_{p} \frac{d \Phi_{B}}{d t} \quad V_{s}=-N_{s} \frac{d \Phi_{B}}{d t}
$$

The same flux $\Phi_{\mathrm{B}}$ cuts each turn in both primary and secondary windings of an ideal transformer (counting self- and mutual-induction)

$$
\frac{\text { induced voltage }}{\text { turn }} \equiv \frac{d \Phi_{\mathrm{B}}}{d t}=\frac{V_{p}}{N_{p}}=\frac{V_{\mathrm{s}}}{N_{\mathrm{s}}}
$$

$$
\therefore \mathbf{V}_{\mathbf{s}}=\frac{\mathbf{N}_{\mathbf{s}}}{\mathbf{N}_{\mathrm{p}}} \mathbf{V}_{\mathrm{p}} \left\lvert\, \begin{aligned}
& \begin{array}{l}
\text { Turns ratio fixes } \\
\text { the step up or step } \\
\text { down voltage ratio }
\end{array}
\end{aligned}\right.
$$

$\mathrm{V}_{\mathrm{p}}, \mathrm{V}_{\mathrm{s}}$ are instantaneous (time varying) but can also be regarded as RMS averages, as can be the power and current.

## Ideal Transformer

- zero resistance in coils
- no hysteresis losses in iron core
- all field lines are inside core

Assume no losses: energy and power are conserved

$$
P_{s}=V_{s} I_{s}=\text { conserved }=P_{p}=V_{p} I_{p}
$$

$$
\therefore \frac{\mathbf{I}_{\mathrm{p}}}{\mathbf{I}_{\mathbf{s}}}=\frac{\mathbf{N}_{\mathbf{s}}}{\mathbf{N}_{\mathrm{p}}}
$$

Copyright R. Janow - Fall 2013

Example: A dimmer for lights using a variable inductance $\mathrm{f}=60 \mathrm{~Hz} \quad \omega=377 \mathrm{rad} / \mathrm{sec}$
Without Inductor:
$P_{\text {rms }}=\mathcal{E}_{\text {rms }}^{2} / R=18$ Watts, $\Phi=0$

a) What value of the inductance would dim the lights to 5 Watts?

Recall: $\mathrm{P}_{\mathrm{rms}}=\mathrm{I}_{\mathrm{rms}}^{2} \mathrm{R} \quad \mathrm{I}_{\mathrm{rms}}=\frac{\mathcal{E}_{\mathrm{rms}}}{\mathrm{Z}}=\frac{\mathcal{E}_{\mathrm{rms}}}{\mathrm{R}} \cos (\Phi)$

$$
\therefore \mathrm{P}_{\mathrm{rms}}=\frac{\mathcal{E}_{\mathrm{rms}}^{2}}{\mathrm{R}} \cos ^{2}(\Phi)
$$

5 Watts = 18 Watts $x \cos ^{2}(\Phi)$

$$
\begin{aligned}
& \cos (\Phi)=0.527=\cos \left(58.2^{\circ}\right) \\
& \Phi=58.2^{\circ}=\tan ^{-1}\left[X_{L} / R\right] \\
& X_{L}=R \tan (\Phi)=50 \tan \left(58.2^{\circ}\right)=80.6 \Omega=2 \pi f L
\end{aligned}
$$

$$
\therefore L=80.6 / 377=214 \mathrm{mH}
$$

b) What is the change in the RMS current?

Without inductor: $\quad \mathrm{I}_{\mathrm{rms}}=\frac{\mathcal{E}_{\mathrm{rms}}}{\mathrm{Z}}=\frac{30 \mathrm{~V}}{50 \Omega}=0.6 \mathrm{~A} \quad \mathrm{P}_{\mathrm{rms}}=18 \mathrm{~W}$.
With inductor: $\quad \dot{I}_{\text {rms }}=\frac{\mathcal{E}_{r m s}}{R} \cos (\Phi)=0.6 \mathrm{~A} \times 0.527=0.316 \mathrm{~A} \quad \underset{\text { Copyright }}{P_{\text {R }} \text { Jansw }- \text { Fall } 2013}$.

## SUMMARY - AC CIRCUIT RELATIONS

Phasors and alternating current: An alternator or ac source produces an emf that varies sinusoidally with time. A sinusoidal voltage or current can be represented by a phasor, a vector that rotates counterclockwise with constant angular velocity $\omega$ equal to the angular frequency of the sinusoidal quantity. Its projection on the horizontal axis at any instant represents the instantaneous value of the quantity.

For a sinusoidal current, the rectified average and rms (root-mean-square) currents are proportional to the current amplitude $I$. Similarly, the rms value of a sinusoidal voltage is proportional to the voltage amplitude V. (See Example 31.1.)

$$
\begin{align*}
& I_{\mathrm{rav}}=\frac{2}{\pi} I=0.637 I  \tag{31.3}\\
& I_{\mathrm{rms}}=\frac{I}{\sqrt{2}}  \tag{31.4}\\
& V_{\mathrm{rms}}=\frac{V}{\sqrt{2}} \tag{31.5}
\end{align*}
$$

Voltage, current, and phase angle: In general, the instantaneous voltage between two points in an ac circuit is not in phase with the instantaneous current passing
$i=I \cos \omega t$
$v=V \cos (\omega t+\phi)$ through those points. The quantity $\phi$ is called the phase angle of the voltage relative to the current.

Resistance and reactance: The voltage across a resistor $R$ is in phase with the current. The voltage across an inductor $L$ leads the current by $90^{\circ}\left(\phi=+90^{\circ}\right)$, while the voltage across a capacitor $C$ lags the current by $90^{\circ}\left(\phi=-90^{\circ}\right)$. The voltage amplitude across each type of device is proportional to the current amplitude $I$. An inductor has inductive reactance $X_{L}=\omega L$, and a capacitor has capacitive reactance $X_{C}=1 / \omega C$. (See Examples 31.2 and 31.3.)

Impedance and the $L-R-C$ series circuit: In a general ac circuit, the voltage and current amplitudes are related by the circuit impedance $Z$. In an $L-R-C$ series circuit, the values of $L, R, C$, and the angular frequency $\omega$ determine the impedance and the phase angle $\phi$ of the voltage relative to the current. (See Examples 31.4 and 31.5.)

$$
\begin{align*}
& V=I Z  \tag{31.22}\\
& \begin{array}{l}
Z=\sqrt{R^{2}+\left(X_{L}-X_{C}\right)^{2}} \\
\quad=\sqrt{R^{2}+[\omega L-(1 / \omega C)]^{2}} \\
\tan \phi=\frac{\omega L-1 / \omega C}{R}
\end{array}
\end{align*}
$$

## Lecture 13/14 Chapter 31 - LCR and AC Circuits, Oscillations

Power in ac circuits: The average power input $P_{\mathrm{av}}$ to an ac circuit depends on the voltage and current amplitudes (or, equivalently, their rms values) and the phase angle $\phi$ of the voltage relative to the current. The quantity $\cos \phi$ is called the power factor. (See Examples 31.6 and 31.7.)

| $P_{\mathrm{av}}$ | $=\frac{1}{2} V I \cos \phi$ |
| ---: | :--- |
|  | $=V_{\mathrm{rms}} I_{\mathrm{rms}} \cos \phi$ |

Resonance in ac circuits: In an $L-R-C$ series circuit, the current becomes maximum and the impedance becomes minimum at an angular frequency called the resonance angular frequency. This phenomenon is called resonance. At resonance the voltage and current are in phase, and the impedance $Z$ is equal to the resistance $R$. (See Example 31.8.)
$\omega_{0}=\frac{1}{\sqrt{L C}}$
(31.32)

Transformers: A transformer is used to transform the voltage and current levels in an ac circuit. In an ideal transformer with no energy losses, if the primary winding has $N_{1}$ turns and the secondary winding has $N_{2}$ turns, the amplitudes (or rms values) of the two voltages are related by Eq. (31.35). The amplitudes (or rms values) of the primary and secondary voltages and currents are

$$
\begin{align*}
& \frac{V_{2}}{V_{1}}=\frac{N_{2}}{N_{1}}  \tag{31.35}\\
& V_{1} I_{1}=V_{2} I_{2} \tag{31.36}
\end{align*}
$$
