## Potential Energy of a system of charges

Potential Energy PE (scalar):
$\Delta P E=-$ Work done by the Electric
field

$$
\Delta P E=-W=-F d=-q E d
$$

$\quad($ units $=J)$

Work done by the E-field (to move the +q closer to the negative plate) REDUCES the P.E. of the system

If a positive charge is moved AGAINST an E-field (which points from + to -), the charge-field system gains Pot. Energy. If a negative charge is moved against an E-field, the system loses potential energy

## Electric Potential Difference, $\Delta \mathrm{V}$

$\Delta V=V_{B}-V_{A}=\Delta P E / q$
Units: Joule/Coulomb $=$ VOLT
Scalar quantity

Relation between $\Delta \mathrm{V}$ and E :
$\Delta V=E d$
$E$ has units of $V / m=N / C$
( $\mathrm{V} / \mathrm{m}=\mathrm{J} / \mathrm{Cm}=\mathrm{Nm} / \mathrm{Cm}=\mathrm{N} / \mathrm{C}$ )

## Potential vs. Potential Energy

POTENTIAL: Property of space due to charges; depends only on location

Positive charges will accelerate towards regions of low potential.

POTENTIAL ENERGY: due to the interaction between the charge and the electric field

## Example of Potential Difference

A parallel plate capacitor has a constant electric field of $500 \mathrm{~N} / \mathrm{C}$; the plates are separated by a distance of 2 cm . Find the potential difference between the two plates.

> E-field is uniform, so we can use $\Delta V=E d=(500 \mathrm{~V} / \mathrm{m})(0.02 \mathrm{~m})=10 \mathrm{~V}$

Remember: potential difference $\Delta V$ does not depend on the presence of any test charge in the E-field!

## Example of Potential Difference

Now that we've found the potential difference $\Delta \mathrm{V}$, let's take a molecular ion, $\mathrm{CO}_{2}{ }^{+}$(mass $=7.3 \times 10^{-26} \mathrm{~kg}$ ), and release it from rest at the anode (positive plate). What's the ion's final velocity when it reaches the cathode (negative plate)?

Solution: Use conservation of energy: $\Delta \mathrm{PE}=\Delta \mathrm{KE}$

$$
\begin{aligned}
& \Delta \mathrm{PE}=\Delta \mathrm{Vq} \\
& \Delta \mathrm{KE}=1 / 2 \mathrm{~m} \mathrm{v}_{\text {final }}{ }^{2}-1 / 2 \mathrm{~m}_{\text {initi }^{2}}{ }^{2} \\
& \Delta \mathrm{Vq}=1 / 2 \mathrm{mv}_{\text {final }}{ }^{2} \\
& \mathrm{v}_{\text {final }}{ }^{2}=2 \Delta \mathrm{Vq} / \mathrm{m}=(2)(10 \mathrm{~V})\left(1.6 \times 10^{-19} \mathrm{C}\right) / 7.3 \times 10^{-26} \mathrm{~kg} \\
& \mathrm{~V}_{\text {final }}=6.6 \times 10^{3} \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

## Thunderstorms:

From ground to cloud base:
$\Delta V=10^{8} \mathrm{~V}, \quad \mathrm{E} \sim 10^{4-5} \mathrm{~V} / \mathrm{m}$
Lightning: $E=3 \times 10^{6} \mathrm{~V} / \mathrm{m}$ is
electric field strength at which air becomes ionized enough to act as a conductor.

Fair weather: $\mathrm{E} \sim 10^{2} \mathrm{~V} / \mathrm{m}$

## Example for Potential Difference:

 BATTERIES: the potential difference across terminals is kept at a constant value, e.g., 9 volts

## 16.2: $V$ and $P E$ due to point charges

Recall that $\quad \vec{E}=\frac{k_{c} q}{r^{2}} \quad$ for a single point charge.

$$
\text { Potential } V=\frac{k_{c} q}{r}
$$

$V$ is defined such that $V=0$ at $r=\infty$

Dimensional arguments: For a constant field, $\mathrm{V}=\mathrm{Ed}$
For a point charge, V has units of $\mathrm{E} \times$ distance

## P.E. of two point charges

Define $\mathrm{V}_{21}$ as the potential due to the presence of charge $q_{2}$ at the location of charge $\mathrm{q}_{1}$.

$$
V_{21}=\frac{k_{c} q_{2}}{r}
$$

$$
\begin{aligned}
& P E=q_{1} V_{21}=q_{2} V_{12} \\
& P E=0 \quad \text { at } \quad r=\infty
\end{aligned}
$$

## P.E. of two point charges

Define $\mathrm{V}_{21}$ as the potential due to the presence of charge $\mathrm{q}_{2}$ at the location of charge $\mathrm{q}_{1}$.

$$
\begin{aligned}
V_{21}=\frac{k_{c} q_{2}}{r} & r \\
& P E=q_{1} V_{21}=q_{2} V_{12} \\
& P E=0 \quad \text { at } \quad r=\infty
\end{aligned}
$$

Reminder: V \& PE are scalar (not vector) quantities
Point charge $q_{1}$ :

$$
\vec{E}=k_{e} q_{1} / r^{2}
$$

Point charge $q_{1}$ :
$V=k_{e} q_{1} / r$
$(=\vec{E} r)$
Point charge $q_{1}$, introduce $q_{2}: \mathrm{PE}=k_{e} q_{1} q_{2} / r \quad\left(=V q_{2}\right)$
Point charge $q_{1}$, introduce $q_{2}: \overrightarrow{F_{E}}=k_{e} q_{1} q_{2} / r^{2}$
$\left(=\vec{E} q_{2}\right)$

Note:
When two LIKE charges are close together, the potential energy is positive (the higher the PE, the more likely the system is to come apart)
When two UNLIKE charges are close together, the potential energy is negative (the lower the PE, the more stable the system is)

## V \& PE of atoms in a crystal lattice

In a crystal of salt ( $\mathrm{Na}^{+} \& \mathrm{Cl}^{-}$) the distance between the ions is 0.24 nm . Find the potential due to $\mathrm{Cl}^{-}$at the position of the $\mathrm{Na}^{+}$ion. Find the electrostatic energy of the $\mathrm{Na}^{+}$due to the interaction with $\mathrm{Cl}^{-}$.

## V \& PE of atoms in a crystal lattice

In a crystal of salt $\left(\mathrm{Na}^{+} \& \mathrm{Cl}^{-}\right)$the distance between the ions is 0.24 nm . Find the potential due to $\mathrm{Cl}^{-}$at the position of the $\mathrm{Na}^{+}$ion. Find the electrostatic energy of the $\mathrm{Na}^{+}$due to the interaction with $\mathrm{Cl}^{-}$.

$V=k_{e} q / r=9 \times 10^{9} \mathrm{Nm}^{2} / \mathrm{C}^{2}\left(-1.6 \times 10^{-19} \mathrm{C}\right) /\left(0.24 \times 10^{-9} \mathrm{~m}\right)=-6.0 \mathrm{~V}$
$P E=q V=\left(1.6 \times 10^{-19} \mathrm{C}\right)(-6.0 \mathrm{~V})=-9.6 \times 10^{-19} \mathrm{~J}$
ELECTRON VOLT (convenient unit for atomic physics) $1 \mathrm{eV}=1.6 \times 10^{-19} \mathrm{~J}$

So $\mathrm{PE}=-6.0 \mathrm{eV}$ (energy in eV is $\mathrm{V} \times$ the charge in units of $e$ )

## V for a distribution of charges

Potential is a scalar: Total V at point A dur to other charges $=V_{1 A}+V_{2 A}+V_{3 A}+\ldots$
Two charges of $+q$ each are placed at corners of an equilateral triangle, with sides of 10 cm . If the electric field due to each charge at point A is $100 \mathrm{~V} / \mathrm{m}$, find the total potential at A .

## V for a distribution of charges

Potential is a scalar: Total V at point A dur to other charges $=\mathrm{V}_{1 \mathrm{~A}}+\mathrm{V}_{2 \mathrm{~A}}+\mathrm{V}_{3 \mathrm{~A}}+\ldots$
Two charges of $+q$ each are placed at corners of an equilateral triangle, with sides of 10 cm . If the electric field due to each charge at point A is $100 \mathrm{~V} / \mathrm{m}$, find the total potential at A .

$$
\begin{aligned}
& \vec{E}=k_{e} q / r^{2} \text { generated by each charge } \\
& V \text { due to each: } k_{e} q / r=E r= \\
& (100 \mathrm{~V} / \mathrm{m})(0.10 \mathrm{~m})=10 \mathrm{~V} \\
& V_{\text {total }}=V_{1 A}+V_{2 A}=10 \mathrm{~V}+10 \mathrm{~V}=20 \mathrm{~V}
\end{aligned}
$$

## Total Energy of a charge distribution

Suppose you have two charges, each +q, held fixed a distance d apart. When released, they'll want to fly away from each other and head out to infinity.

$$
\begin{aligned}
& P E_{\text {init }}=\frac{k_{c} q_{1} q_{2}}{d}(\text { positive value }) \\
& P E_{\text {final }}=\frac{k_{c} q_{1} q_{2}}{\infty} \\
& \text { Note: } P E_{\text {init }}=\text { high } ; P E_{\text {final }}=\text { zero. } \\
& \Delta P E=P E_{\text {final }}-P E_{\text {init }}=\text { negative } \\
& \text { Work }=-\Delta P E=\text { positive: }
\end{aligned}
$$

(this is work done BY the E-fields to separate the charges)
Total energy of system = amount of work needed to assemble the system

## Total Energy of a charge distribution

Now let's do the opposite situation: We will bring in two charges, each of $+1 q$, from $r=\infty$ to $r=d$. How much work will be required (by us) to overcome the repelling E-fields?

$$
\Delta P E=P E_{f i n a l}-P E_{\text {init }}=\frac{k_{c} q_{1} q_{2}}{d}-\frac{k_{c} q_{1} q_{2}}{\not \partial 6} 0
$$

(work done by E-field $=-\Delta P E$ is negative because the E-fields made "negative progress" in trying to separate the charges)

Total energy of system= amount of work needed (by us) to assemble the system = amount of energy stored in a chemical bond, for instance

## Total energy of a charge distribution

Suppose you wish to bring in THREE protons, from infinity to the corners of an equilateral triangle with sides having length 1 nm . How much work is required (by us) to accomplish this?

## Total energy of a charge distribution

Suppose you wish to bring in THREE protons, from infinity to the corners of an equilateral triangle with sides having length 1 nm . How much work is required (by us) to accomplish this?

How many interactions? 3

## Total energy of a charge distribution

Suppose you wish to bring in THREE protons, from infinity to the corners of an equilateral triangle with sides having length 1 nm . How much work is required (by us) to accomplish this?

How many interactions? 3

$$
P E=P E_{12}+P E_{13}+P E_{23}=3\left(k_{e} q_{1} q_{2} / r\right)=3 k_{e} q^{2} / r
$$

## Total energy of a charge distribution

Suppose you wish to bring in THREE protons, from infinity to the corners of an equilateral triangle with sides having length 1 nm . How much work is required (by us) to accomplish this?

How many interactions? 3

$$
P E=P E_{12}+P E_{13}+P E_{23}=3\left(k_{e} q_{1} q_{2} / r\right)=3 k_{e} q^{2} / r
$$

$$
\begin{aligned}
& \mathrm{PE}=\frac{3\left(9 \times 10^{9} \mathrm{Nm}^{2} / \mathrm{C}^{2}\right)\left(1.6 \times 10^{-19} \mathrm{C}\right)^{2}}{10^{-9} \mathrm{~m}} \\
& \mathrm{PE}=6.9 \times 10^{-19} \mathrm{~J} \\
& \quad\left(1 \mathrm{eV}=1.6 \times 10^{-19} \mathrm{~J}\right. \text {, so } \\
& \text { this } \mathrm{PE}=4.32 \mathrm{eV})
\end{aligned}
$$

## Total energy of a charge distribution

Suppose instead of 3 protons, you have 2 protons and 1 electron.
Now how much work would be required by us?
Note: pay attention to signs of each charge!

## Total energy of a charge distribution

Suppose instead of 3 protons, you have 2 protons and 1 electron.
Now how much work would be required by us?
Note: pay attention to signs of each charge!

## Total energy of a charge distribution

Suppose instead of 3 protons, you have 2 protons and 1 electron.
Now how much work would be required by us?
Note: pay attention to signs of each charge!

How many interactions? 3

$$
\begin{aligned}
& \mathrm{PE}=\mathrm{PE}_{12}+\mathrm{PE}_{13}+\mathrm{PE}_{23}=+\left(\mathrm{k}_{\mathrm{e}} \mathrm{q}^{2} / r\right)-\left(\mathrm{k}_{\mathrm{e}} \mathrm{q}^{2} / r\right)-\left(\mathrm{k}_{\mathrm{e}} \mathrm{q}^{2} / r\right) \\
& \mathrm{PE}=-\mathrm{k}_{\mathrm{e}} \mathrm{q}^{2} / r
\end{aligned}
$$

$$
\mathrm{PE}=\frac{-1\left(9 \times 10^{9} \mathrm{Nm}^{2} / \mathrm{C}^{2}\right)\left(1.6 \times 10^{-19} \mathrm{C}\right)^{2}}{10^{-9} \mathrm{~m}}
$$

$$
P E=-2.3 \times 10^{-19} \mathrm{~J}=-1.44 \mathrm{eV}
$$

Total P.E. is less than before (in fact, negative): distribution is MUCH more stable!

## Which is more stable?

That is, which has the lower total P.E.?
(closer to -infty $\rightarrow$ more stable)

## Which is more stable?

That is, which has the lower total P.E.?
(closer to -infty $\rightarrow$ more stable)

Total PE $=$ PE of each side + PE of each diagonal

## Which is more stable?

That is, which has the lower total P.E.?
(closer to -infty $\rightarrow$ more stable)

Total PE $=$ PE of each side + PE of each diagonal
$\mathrm{PE}_{\text {side }}=\mathrm{k}_{\mathrm{e}} \mathrm{q}_{1} \mathrm{q}_{2} / \mathrm{d}$ (pay attention to signs of charges!!!!!)
$P E_{\text {diagonal }}=k_{e} q_{1} q_{2} /(d \sqrt{2})$

## Which is more stable?

Define $P E E_{0}=k_{e} q^{2 / d}$
Sides: $\mathrm{PE}_{0} \quad+2 \quad-2$
Diag.: $\mathrm{PE}_{0} / \sqrt{2} \quad-2$
Total PE $\quad(-2 / \sqrt{2}) \mathrm{PE}_{0}=-1.41 \mathrm{PE}_{0} \quad(-4+2 / \sqrt{2}) \mathrm{PE}_{0}=-2.59 \mathrm{PE}_{0}$

Yes, this distribution is stable....
... but this one is
MORE stable!

## The Size of Atomic Nuclei

Ernest Rutherford et al.'s scattering experiments, 1911
Goal: Probe structure of atoms: How are the + and charges distributed, and what's their size?

Figure 1 The experimental arrangement used in Rutherford's laboratory to study the scattering of $\alpha$ particles by thin metal foils. The detector can be rotated to various scattering angles $\theta$.

Figure 3 The angle through which an $\alpha$ particle is scattered depends on how close its extended incident path lies to the nucleus of an atom. Large deflections result only from very close encounters.

Method: Fire positively charged alpha-particles (ionized He nuclei, $Z=2$ ) at a very thin metal ( $A u, Z=79$ ) foil Most passed through, but a few were deflected through large angles-- including up to $180^{\circ}$ ! (See Ch 28-29 of text)

Figure 1 The experimental arrangement used in Rutherford's laboratory to study the scattering of $\alpha$ particles by thin metal foils. The detector can be rotated to various scattering angles $\theta$.

Figure 3 The angle through which an $\alpha$ particle is scattered depends on how close its extended incident path lies to the nucleus of an atom. Large deflections result only from very close encounters.

An alpha particle $\left(\mathrm{He}^{2+}=2 \mathrm{p}+2 \mathrm{n}\right.$, total mass $=$ $4^{*} 1.67^{*} 10^{-27} \mathrm{~kg}$ ) is fired at $\mathrm{v}=1.0 \times 10^{7} \mathrm{~m} / \mathrm{s}$ and happens to be headed directly for the nucleus of a gold atom (79 p) at rest. How close does it get to the gold nucleus before the electric force brings it to a momentary stop and reverses its course? Neglect the recoil of the Au nucleus; neglect the Au atom's electrons.

## The Size of Atomic Nuclei

Initially, total energy $=$ K.E. of $\mathrm{He}^{+2}($ P.E. $=$ zero since $\mathrm{d}=\infty)$
At closest interaction, total energy $=$ P.E. $=k_{e} Q_{1} Q_{2} / d$
$d=k_{e} Q_{1} Q_{2} / K . E$.
K.E. $=1 / 2 \mathrm{~m}_{\text {не }} \mathrm{v}^{2}=1 / 2\left(4^{* 1} 1.67 \times 10^{-27} \mathrm{~kg}\right)\left(1 \times 10^{7} \mathrm{~m} / \mathrm{s}\right)^{2}=3.3 \times 10^{-13} \mathrm{~J}$
$\mathrm{d}=\left(9 \times 10^{9} \mathrm{Nm}^{2} / \mathrm{C}^{2}\right)(2)(79)\left(1.6 \times 10^{-19} \mathrm{C}\right)^{2} /\left(3.3 \times 10^{-13} \mathrm{~J}\right)=1.1 \times 10^{-13} \mathrm{~m}$
$=110 \mathrm{fm}$
Size of nucleus must be smaller than this -- VERY compact compared to size of atom ( $\sim 10^{-11} \mathrm{~m}$ )

110 fm is small by atomic standards, but not by nuclear standards

## Equipotential Surfaces

Surface at which all points have the same potential
Potential difference between any 2 points on the same equipotential surface is zero

Potential is a scalar, not a vector: so no arrows drawn

Note that E-field lines and equipotential surfaces are perpendicular

## Ex.: Surface of a Charged Conductor

Potential is same at all points on conductor's surface
E-field is $\perp$ to surface at all points

## Ex.: Surface of a Charged Conductor

Potential is same at all points on conductor's surface
E-field is $\perp$ to surface at all points
No net work required to move a charge along surface
$W=-\Delta P E$
$\Delta P E=q\left(V_{b}-V_{a}\right)$
If $\mathrm{V}_{\mathrm{a}}=\mathrm{V}_{\mathrm{b}}$, then $\mathrm{W}=0$ !

## Interior of a Charged Conductor

At all points inside a conductor, the potential is the same as at the surface

Reminder: E = 0 inside the conductor
$\Delta V=E d=0 d$

## A Dipole's Equipotential Surfaces

## 2 Oppositely-Charged Planes

Equipotential surfaces are parallel to the planes and $\perp$ to the E-field lines
