

"There was no water and too much sand..."

- **Nofa Hamid,** sheep herder from Addami village in Syria (NPR 2010)

In the drought-stricken village of Addami in northern Syria, villagers such as Nofa Hamid have abandoned their once-fertile lands that have turned to dust in search of work in cities. The massive displacement of 'water refugees' is happening region-wide in response to increasing water scarcity and climate change. Nofa Hamid, who has been tending sheep for almost 50 years said the summer had been 'crazy' and that the sand was 'everywhere'. Sheep herders and farmers who depend on their livestock and farmlands are being forced to seek other livelihoods - many find temporary jobs in urban areas; however, the future for many sheep herders like Nofa Hamid is uncertain given the increased temperatures and significant reductions in annual average rainfall expected in the Arab region as a result of climate change. The effects of water scarcity and displacement of peoples to cities ranges greatly from unchecked sprawl, lack of basic services, increasing food insecurity, and pollution. The environment is also affected by reduced biodiversity and exacerbated soil erosion, which increases desertification. The degradation of the landscape has far reaching consequences, both social and environmental.

Just as oil largely defined the past century for the Arab region, water scarcity and desertification will likely define this century. The drought conditions in the village of Addami and the migrations of people forced to seek other livelihoods, have become commonplace in the Arab region; these conditions will worsen with increases in population, and in some cases, by conflict. Chapter 2 of this atlas describes water availability and supply as a transboundary issue, which highlights the potential for coordination and collaboration among water-sharing countries, but also emphasizes the potential for conflict over an increasingly scarce natural resource. In response, the Arab League nations are investing substantial effort and funds into developing alternative water supplies, adopting water conservation measures, and planting more water efficient crops to mitigate growing water scarcity problems. Some countries are going to extraordinary lengths to increase water supplies, such as the case with Morocco's cloud seeding program in the Central High Atlas Mountains, where silver iodide is used as a seeding agent to increase the precipitation efficiency of cold clouds to produce snowfall and augment the snowmelt runoff in the summer, when the water is needed most. Other Arab countries are implementing extensive wastewater recycling programs and the Arab region boasts some of the largest desalination plants in the world.

With almost 40 per cent of the global population projected by 2015 to be living in countries where it is difficult or impossible to meet basic water needs, and over half of the Arab countries expected to experience severe water scarcity by 2050, these innovative methods are key to ensuring future water supplies. As the UN Committee on Economic, Social and Cultural Rights commented: 'Water is fundamental for life and health. The human right to water is indispensable for leading a healthy life in human dignity. It is a pre-requisite to the realization of all other human rights'. Efficient water management and coordinated approaches to managing increasingly scarce natural resources in the Arab region are fundamental to ensuring a secure future for the people of this region.

ABOUT REMOTE SENSING IMAGES

he field of Remote Sensing has grown considerably since its infancy in the early 1970s when the initial earth-observing satellite of the Landsat program was launched. The Landsat program, jointly managed by NASA and the U.S. Geological Survey, has collected and archived images of the Earth's surface for nearly 40 years. This valuable historical record provides a unique opportunity for identifying and documenting environmental change anywhere on the planet. This atlas relies heavily, although not completely, on the images provided by the Landsat Program to depict environmental change in the Arab region. Since the initial earth-observing satellite of the Landsat Program was launched in the 1970s several new satellites with improved sensors (EO-1, OrbView, IKONOS etc.) collected data at higher resolutions and with an ability to capture different portions of electromagnetic radiation (e.g. radio waves, microwaves, visible light, infrared). The improved imagery from non-Landsat satellites proved invaluable in documenting change in the Arab region. Additionally, this atlas benefited from declassified satellite data, such as the images from the CORONA program, which allowed for documenting change in the Arab region from as early as the 1960s.

Satellites, like Landsat, use "multispectral" sensors to collect reflected electromagnetic energy from the visible range (400 to 700 nanometers), as well as wavelengths that the human eye cannot see (700 to 2 350 nanometers), and thermal energy to create images of the Earth. Multi-spectral sensors divide electromagnetic radiation into a small number of "bands" or ranges of wavelength. For example Landsat-7 collects electromagnetic radiation in eight different bands or ranges of wavelength (see table). Each of these ranges of "light" can tell us something different about the Earth's surface.

Creating usable and understandable images from multi-spectral sensors entails combining three or more of the available bands and displaying them as one of the three colours of standard monitor displays: red, green and blue. Often this yields an image that is not intuitive for the non-specialist to interpret (see the image at left, below). By selecting certain bands and adjusting the distribution of brightness - the overall brightness and the contrast - a more intuitive looking image can be achieved (see the image at right, below). The images in this atlas have been adjusted so that non-expert readers can interpret these images easily.

The specific sensors and the band combinations used in Chapter Three can be found in the references at the end of the chapter.

In general, images are displayed so that live vegetation shows as various shades of green. Coniferous forests are generally darker shades of green, as are mangroves. Broadleaf forests are typically depicted as a slightly brighter shade of green. Agricultural fields with actively growing crops are shown as an even brighter shade of green; however this is dependent on the crop and its state of growth. The patterns of brightness are often important clues as to the nature of the vegetation. Senescent or inactive vegetation generally appears as shades of grey and brown.

Water bodies are often blue to black in appearance; however when sediment is present or the water is shallow it will appear lighter, even taking on a pink caste. Areas of bare ground will show as bright, usually almost white, while urban areas and roads generally appear as a shade of pale purple. Clouds, when they cannot be avoided, will appear as bright white.

As mentioned above, data from other sensors, such as ASTER¹ and MODIS², as well as the high resolution commercial sensors QuickBird³ and IKONOS⁴, were used in the production of this atlas. Readers will note the number of black and white images in the atlas, which were collected by the declassified satellite CORONA⁵. Corona was the United States first photo reconnaissance satellite system, operating from August 1960 until May 1972. The program was declassified in February 1995.

Landsat-7 ETM+Bands					
Band	Spectral Range (nm)	Description			
1	450 to 515 nm	blue-green light			
2	525 to 605 nm	green light			
3	630 to 690 nm	red light			
4	775 to 900 nm	near-infrared radiation			
5	1 550 to 1 750 nm	mid-infrared radiation			
6	10 400 to 12 500 nm	thermal-infrared radiation			
7	2 090 to 2 350 nm	mid-infrared radiation			
8	520 to 900 nm	pan-chromatic			

Both of these images are from the same ASTER remote sensing image taken over Baghdad, Iraq in August of 2009. On the left, image bands are shown as red, green and blue, with the contrast and brightness determined by

1 ASTER (The Advanced Spaceborne Thermal Emission and Reflection Radiometer) is a sensor aboard the TERRA satellite is a joint effort between National Aeronautics and Space Administration (NASA) and Japan's Earth Remote Sensing Data Analysis Center (ERSDAC).
2 MODIS (Moderate Resolution Imaging Spectroradiometer) is a sensor carried on NASA's TERRA and ACIA catallites.

the default settings of a standard Geographic Information System software program. On the right, bands are displayed as red, green and blue and the colour balance, contrast and brightness have been adjusted.

- 3 QuickBird is a high resolution commercial multispectral sensor aboard the QuickBird satellite, operated by DigitalGlobe.
- 4 IKONOS is a high resolution commercial multispectral sensor aboard GeoEye's IKONOS satellite.
- 5 Corona is a U.S. photographic surveillance satellite flown from the 1960s through the 1970s.
