31. "Like dissolves like" refers to the fact that polar and ionic substances dissolve better in polar solvents than in non-polar solvents. Non-polar solutes dissolve better in non-polar solvents.
b) Water is a polar solvent because of the electronegativity difference between hydrogen and oxygen. The electrons in the OH bonds are unequally shared. As well, the water molecule is not symmetrical. The oxygen has a slightly negative charge, and the hydrogen's have a slightly positive charge. The presence of these two "poles" results in an overall polar molecule.
c) Water is referred to as the universal solvent because it is able to dissolve a large number and variety of solutes.

51. Three major flaws are given below:

- According to the Arrhenius definition, an $\mathrm{H}^{+}$dissociates and is responsible for the acidic properties of a solution. In the Brønsted-Lowry theory, protons do not exist alone in aqueous solution but as hydrated ions called hydronium ions, $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$. This is thought to be closer to the reality of the reactions.
- The Arrhenius definition cannot explain the basic properties of ammonia. Nor can it explain the fact that some other substances, such as salts that contain carbonate ions, also have basic properties. These are important bases, even though they do not have hydroxide. The Brønsted-Lowry definition of a base as a proton acceptor explains the basic properties of these compounds.
- The Arrhenius definition is limited to acid and base reactions in a single solvent, water. The Brönsted-Lowry definition still requires an acid to have a dissociable proton. However, any negative ion that has the ability to accept a proton (not just $\mathrm{OH}^{-}$) can be a Brønsted-Lowry base.

$x=12.3 \mathrm{~mol}$
$V=\frac{n R T}{P}=\frac{12.3 \mathrm{~mol} \times 8.314 \frac{\mathrm{kPa} \cdot \mathrm{L}}{\mathrm{mol} \cdot \mathrm{K}} \times 307 \mathrm{~K}}{93.3 \mathrm{kPa}}=336 \mathrm{~L}$
70. First find the number of moles of both reactants. Use $n=m / M$ to find the number of moles of FeS. Use $P V=n R T$ to find the number of moles of $\mathrm{O}_{2}$. Use the mole ratio to determine the limiting reactant. Then use the mole ratio to find the number of moles of $\mathrm{Fe}_{2} \mathrm{O}_{3}$. Use $n=m / M$ to find the mass of $\mathrm{Fe}_{2} \mathrm{O}_{3}$.
Moles $\mathrm{FeS}_{2}: n=\frac{m}{M}=\frac{25.2 \mathrm{~g}}{119.99 \mathrm{~g} / \mathrm{mol}}=0.210 \mathrm{~mol}$
Moles $\mathrm{O}_{2}: n \frac{P V}{R T}=\frac{100 \mathrm{kPa} \times 5.50 \mathrm{~L}}{293 \mathrm{~K} \times 8.314 \frac{\mathrm{kPa} \cdot \mathrm{L}}{\mathrm{mol} \cdot \mathrm{K}}}=0.226 \mathrm{~mol}$
Mole ratio: $\frac{4 \mathrm{~mol} \mathrm{FeS}_{2}}{11 \mathrm{~mol} \mathrm{O}_{2}}=\frac{0.210 \mathrm{~mol}}{x}$
$x=0.578 \mathrm{~mol}$ of $\mathrm{O}_{2}$
Only 0.226 mol of $\mathrm{O}_{2}$ are available, however. Since there is not enough $\mathrm{O}_{2}$ available, oxygen gas is the limiting reactant.

Mole ratio: $\frac{11 \mathrm{~mol} \mathrm{O}_{2}}{2 \mathrm{~mol} \mathrm{Fe}_{2} \mathrm{O}_{3}}=\frac{0.226 \mathrm{~mol}}{x}$
$x=0.0411 \mathrm{~mol}$
$m=n \times M=0.0411 \mathrm{~mol} \times 159.70 \mathrm{~g} / \mathrm{mol}=6.56 \mathrm{~g}$
