

Session 2:
Introduction to Epidemiology
and Genetic Epidemiology

ep·i·de·mi·ol·o·gy

/,epə,dēmē'äləjē/

noun

the branch of medicine that deals with the incidence, distribution, and possible control of diseases and other factors relating to health.

Cohort vs. case-control studies

Nature Reviews | Genetics

Estimated incidence rates in cohorts

Disease incidence per 100,000 per year (%)	Disease examples	Number of incident cases in 5 years for different cohort sizes		
		200,000	500,000	1,000,000
10 (0.01)	Parkinson disease, schizophrenia	91	228	457
50 (0.05)	Colorectal cancer, renal failure	456	1,141	2,282
100 (0.10)	Breast cancer, hip fracture	912	2,279	4,559
200 (0.20)	Diabetes, stroke, heart failure	1,820	4,550	9,100
500 (0.50)	Myocardial infarction, all cancers	4,524	11,309	22,618
3,000 (3.00)	Cataracts, hypertension	25,858	64,644	129,289

Estimated numbers of incident cases available after 5 years of follow-up across the entire age range in the US population are shown, assuming an attrition rate of 3% per year. Data are taken from the Incidence and Prevalence Database.

Manolio. *Nature Reviews Genetics* 2006

Compared to cohorts, case-control studies are cheap, fast and powerful

However, case-control studies suffer from several drawbacks:

the need to identify appropriate controls

they are more sensitive to recall bias

Association and Causality

- An exposure and outcome are associated if there is a differential distribution:
 - The prevalence of exposure differs between cases and controls.
 - An exposure is causal for the outcome if the presence (or absence) of the exposure directly or indirectly influences whether the outcome occurs.

"I wish they didn't turn on that seatbelt sign so much! Every time they do, it gets bumpy."

Sources of bias in epidemiology

- **Selection Bias**
 - Arises when cases and controls are coming from different source populations (e.g., pediatric cases, adult controls)
- **Survival bias**
 - When cases are recruited some time after they were diagnosed. Might lead to a milder form of disease. This is especially true for aggressive/fatal disease (e.g., pancreatic cancer, heart attack)
- **Diagnostic bias**
 - If the investigator determining the outcome knows whether the person was exposed or not to the risk factor under study (e.g., if the radiologist knows that a potential pulmonary disease patient smokes, they may look more carefully at the x-ray).
- **Recall bias**
 - Accuracy and completeness of exposures, life-style behaviors,... (e.g., cases might be more motivated to complete a questionnaire accurately).

Confounding

- A confounder is often defined as a factor that is:
 - ① A risk factor for the disease
 - ② Associated with the exposure
 - ③ Not a direct result of the exposure
- Confounding can lead to false positive findings.

BREAKOUT ACTIVITY

Confounding example: Birth order and Down syndrome

1. Can you think of a factor that would confound the observed association?
2. How can you use data on your proposed confounding factor to reassess the association between birth order and Down Syndrome?
3. Can you think of potential confounders in genetic epidemiology?

Genetic Epidemiology

***Genetic epidemiology** is the study of the role of **genetic** factors in determining health and disease in families and in populations, and the interplay of such **genetic** factors with environmental factors.*

Ed was unlucky enough to find the needle in the haystack!

'Fat' gene found by scientists

Mark Henderson, Science Editor

A gene that contributes to obesity has been identified for the first time, promising to explain why some people easily put on weight while others with similar lifestyles stay slim.

Loren Capelli

MY MOTHER fought cancer for almost a decade and died at 56. She held out long enough to meet the first of her grandchildren and to hold them in her arms. But my other children will never have the chance to know her and experience how loving and gracious she was.

We often speak of “Mommy’s mommy,” and I find myself trying to explain the illness that took her away from us. They have asked if the same could happen to me. I have always told them not to worry, but the truth is I carry a “faulty” gene, BRCA1, which sharply increases my risk of developing breast cancer and ovarian cancer.

NATIONAL CANCER INSTITUTE CHANCES OF DEVELOPING BREAST CANCER BY AGE 70

Specific inherited mutations in the BRCA1 and BRCA2 genes increase the risk of breast and ovarian cancers. Testing for these mutations is usually recommended in women without breast cancer only when the person's individual or family history suggests the possible presence of a harmful mutation in BRCA1 or BRCA2. Testing is often recommended in younger women newly diagnosed with breast cancer because it can influence treatment decisions and have implications for their family members.

Liede et al. BCRT 2018

Estimated total number of people tested by consumer genetic companies*

* Direct-to-consumer genetic testing uses DNA samples, such as saliva, to track a person's ancestry; find family members; disclose a limited array of possible health risks; or brief someone on their personal preferences, like a taste for cilantro or wine.

March 6, 2018

Authorization allows 23andMe to report on BRCA1- and BRCA2-related genetic risk for breast, ovarian and prostate cancer

Why do we want to study how our genome is involved in disease?

“Association does not imply causation”

HDL (“Good”) Cholesterol and Myocardial Infarction (MI)

- **↑** HDL -> **↓** MI risk

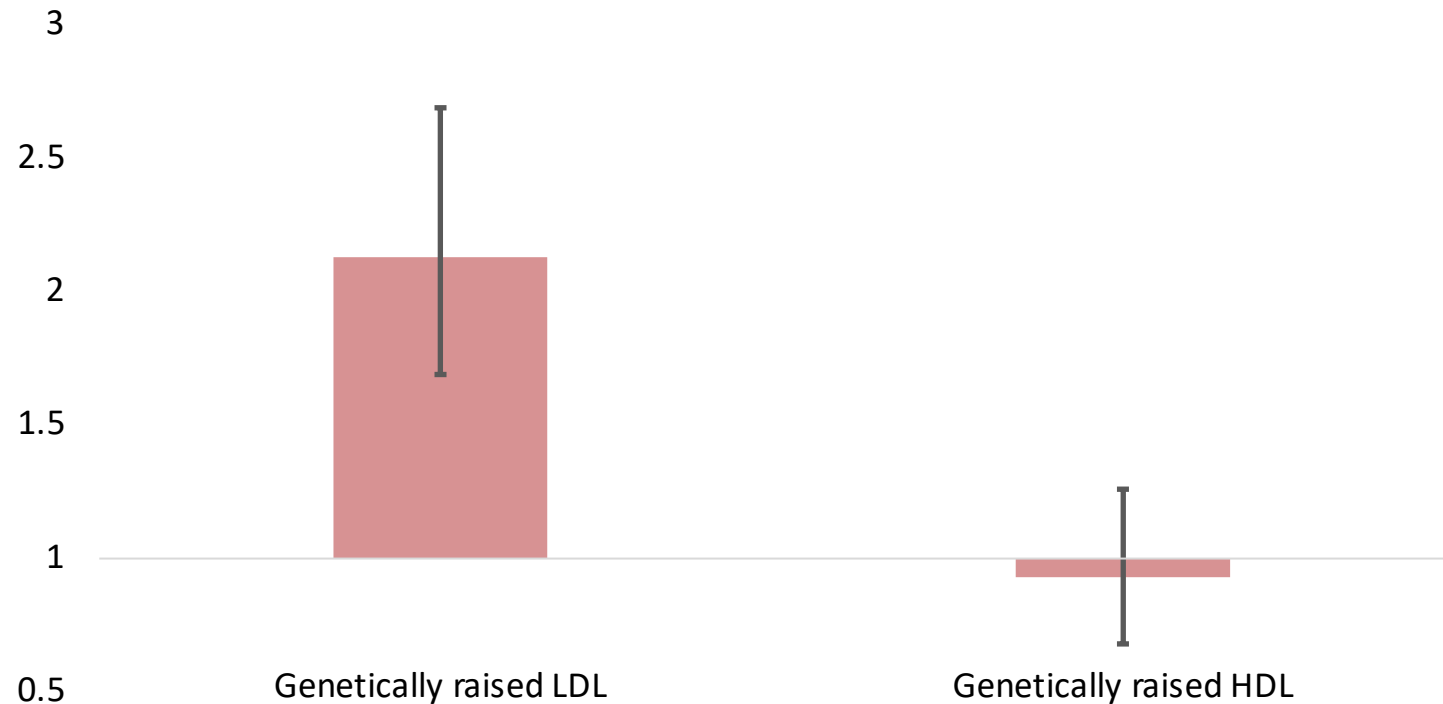

Increasing HDL concentrations
might help decrease
cardiovascular disease risk.

People who carry gene variants that increase HDL do not have a lower risk of MI

Since HDL is correlated with exercise, weight loss, diet (nuts, fish) it is likely that these lower your risk for MI rather than HDL itself
