SAFETY AND EFFICACY OF CO-ADMINISTERED DIETHYLCARBAMZINE, ALBENDAZOLE AND IVERMECTION DURING MASS DRUG ADMINISTRATION FOR LYMPHATIC FILARIASIS IN HAITI

Christine Dubray[1], Anita D. Sircar[1], Madsen Beau de Rochars[2], Joshua Bogus[3], Abdel N. Direny[4], Jean R. Ernest[5], Carl R. Fayette[5], Katiuscia O'Brian[6], Guy E. Pavilus[5], Daniel F. Sabin[5], Ryan E. Wiegand[1], Gary J. Weil[7], Jean F. Lemoine[8]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]University of Florida, Gainesville, FL, United States, [3]Washington University in St. Louis, St. Louis, MO, United States, [4]RTI International, Washington, DC, United States, [5]IMA World Health, Port-au-Prince, Haiti, [6]Washington University in St. Louis, St. Louis, MO, United States, [7]Washington University in St, Louis, St. Louis, MO, United States, [8]Ministry of Public Health and Population, Port-au-Prince, Haiti

Efficacy studies have shown that a single co-administered dose of diethylcarbamazine (DEC), albendazole (ALB) and ivermectin (IVM) is more effective eliminating *Wuchereria bancrofti* microfilariae (Mf) from the blood than DEC and ALB, which is currently used for mass drug administration (MDA). In Haiti, 23 communes still require MDA to eliminate lymphatic filariasis (LF) as a public health problem. In a clinical trial, we compared the safety and efficacy of a single dose of IVM (200 µg/kg) + DEC (6 mg/kg) + ALB (400 mg) vs. a single dose of DEC (6 mg/kg) +ALB (400 mg) administered to participants ≥ 5 years of age during an MDA in Haiti. Ten localities were randomized into two treatment arms. Participants were monitored for adverse events (AE), parasite antigenemia, and Mf. Antigen positive participants were tested for Mf and included a year later in an efficacy study. Overall, 3007 participants were included in the 3-drug arm and 3009 in the 2-drug arm. Fewer participants in the 3-drug arm (10.6%, 321/3007) experienced at least one AE compared to the 2-drug arm (16.3%, 491/3009, p<0.001). In both arms, most AEs were mild and consisted of headaches, dizziness and abdominal pain. Three participants included in the 2-drug arm developed serious AE that resolved within 48 hours. Before treatment, 8.0% (240/3006) of the participants in the 3-drug arm and 11.5% (346/3005, p<0.001) in the 2-drug arm were antigen positive. Of those, 17.6% (42/239) in the 3-drug arm and 21.5% (73/340, p=0.25) in the 2-drug arm were Mf positive. One year after treatment, 5.5% of the participants initially Mf positive in the 3-drug arm were still microfilaremic compared to 23.7% (p=0.02) in the 2-drug arm. Antigenemia persisted in 79.1% (159/201) of the participants tested in the 3-drug compared to 76.4% (217/291, p=0.24 in the 2-drug arm. In conclusion, the 3-drug therapy was more effective in eliminating Mf from the blood and fewer AEs were reported in the 3-drug arm than in the 2-drug arm during the study in Haiti. Effective MDA coverage with 3-drug therapy could accelerate the elimination of LF as a public health problem in the 23 communes still requiring MDA in Haiti.

FIRST COHORT STUDY TO INVESTIGATE THE ASSOCIATION BETWEEN ONCHOCERCIASIS AND EPILEPSY PROVIDES STRONG EVIDENCE FOR A CAUSAL RELATIONSHIP

Cédric B. Chesnais[1], Hugues C. Nana-Djeunga[2], Alfred K. Njamnshi[3], Anne-Cécile Zoung-Kanyi Bissek[4], Joseph Kamgno[5], Robert Colebunders[6], Michel Boussinesq[1]

[1]UMI 233 IRD – U1175 INSERM - Université de Montpellier, Montpellier, France, [2]Centre for Research on Filariasis and other Tropical Diseases, Yaoundé, Cameroon, [3]Neurology Department, Central Hospital/Faculty of Medicine & Biomedical Sciences, The University of Yaoundé I, FMBS-UYI, Yaoundé, Cameroon; Brain Research Africa Initiative, BRAIN, Yaoundé, Cameroon, [4]Dermatology Department, Chantal Biya Mother-Child Center/Ministry of Public Health/FMBS-UYI, Yaoundé, Cameroon, [5]Centre for Research on Filariasis and other Tropical Diseases; Public Health Department, Faculty of Medicine and Biomedical Sciences, University of Yaoundé I, Yaoundé, Cameroon, [6]Global Health Institute, University of Antwerp, Antwerp, Belgium

Previous meta-analyses on the relationship between onchocerciasis and epilepsy suggested that the two conditions are closely associated both at community and individual level. To tackle criticisms about the fact that these studies were cross-sectional, and that confounding factors might explain the relationship, we conducted a prospective cohort study to assess the incidence of epilepsy according to the initial *Onchocerca volvulus* microfilarial density (*Ov*-MFD). The study was conducted in the Mbam valley (Cameroon) where *Ov* MFD was measured in 1991-1993 in children by examination of skin snips. In 2017, seven villages with variable initial community microfilarial loads (CMFL) were revisited to gather information on the 858 children aged 5-10 years who had been examined in these communities in 1991-1993. Information on the occurrence of epilepsy between the initial parasitological survey and 2017 was collected from the subjects themselves or from their relatives, using a standardized "5-questions" questionnaire. Data on the history of epilepsy could be obtained from 85.2% of the 858 targeted subjects. In 2017, the overall incidence rate of epilepsy in the cohort subjects was 350 per 100,000 persons-years. Multivariable analyses taking into account age, sex, initial individual *Ov*-MFD, and initial CMFL in the village of residence, were performed. Using the individuals who had no *Ov* microfilariae (mf) in their skin in 1991-1993 as the reference group, the relative risks of having developed an epilepsy were 7.07, 11.26, 12.90, 20.00, 22.58, and 28.50 in subjects with initial *Ov*-MFD of 1-5, 6-20, 21-50, 51-100, 101-200, and >200 mf/skin snip, respectively. Individual *Ov* MFD at childhood was found to be strongly associated with the risk of developing subsequently epilepsy. This study adds a temporal dimension and demonstrates a dose-response effect supporting a causal relationship between onchocerciasis and epilepsy.

3

THE BURDEN OF SKIN DISEASE AND EYE DISEASE DUE TO ONCHOCERCIASIS IN AFRICA FOR 2015 AND 2025

Natalie V. Vinkeles Melchers[1], Wilma A. Stolk[1], Jan H. Remme[2], Michele E. Murdoch[3], Belén Pedrique[4], Roel Bakker[1], Sake J. de Vlas[1], Luc E. Coffeng[1]

[1]Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands, [2]120 rue des Campanules, Ornex, France, [3]Department of Dermatology, Watford General Hospital, Watford, Hertfordshire, United Kingdom, [4]Drugs for Neglected Diseases initiative (DNDi), Geneva, Switzerland

Onchocerciasis is now targeted for elimination through ivermectin mass drug treatment (MDA), after long-term morbidity control by the African Programme for Onchocerciasis Control (APOC: 1995-2015). Here we assess how this affected the prevalence and associated disease burden for 2015 and will affect that for 2025. We used the expanded disease framework within the individual-based mathematical model ONCHOSIM to estimate the prevalence of various onchocerciasis-associated clinical manifestations, focusing on onchocercal skin disease (OSD: severe itch, reactive skin disease (RSD), hanging groin, atrophy, and depigmentation) and onchocercal ocular disease (OOD: visual impairment, blindness). The model was quantified by reproducing pre-control associations between prevalence of disease and infection and age patterns. The distribution of pre-control mean mf prevalence per APOC administrative area ("project") was extracted from a published pixel-level onchocerciasis infection map. We simulated trends in prevalence of manifestations for various mf prevalences in 157 projects, accounting for project-level treatment history. Numbers of cases and disability-adjusted life years (DALYs) lost due to onchocerciasis were then calculated for each clinical manifestation per APOC project, each time point, and stratified by age, sex, and endemicity. The total number of cases with any type of OSD was estimated to be approximately 3,110,000 for 2015 (335,900 DALYs), and 370,500 for 2025 (40,000 DALYs). The total number of cases with vision loss was estimated to be approximately 234,700 for 2015 (18,500 DALYs), and 51,700 for 2025 (2,900 DALYs). Out of all OSD cases in 2025, 15% from a

chronic disease, and 85% from an acute clinical manifestation (i.e. severe itch, RSD). By 2025, vision loss remains mainly a problem for savanna areas (96% of all vision loss). By 2025, most of the onchocerciasis burden is expected to be in areas of DRC and Nigeria (39% of total DALYs). These areas might benefit most from alternative strategies or more efficient targeting of patient-based treatments, given the limited human and financial resources available.

4

LYMPHATIC FILARIASIS ELIMINATION IN AMERICAN SAMOA - HOUSEHOLD CLUSTERING OF SEROPOSITIVE PERSONS AND IMPLICATIONS FOR SURVEILLANCE STRATEGIES

Colleen L. Lau[1], Meru Sheel[1], Sarah Sheridan[1], Katherine Gass[2], Kimberly Y. Won[3], Saipale Fuimaono[4], Patricia M. Graves[5]

[1]Research School of Population Health, The Australian National University, Canberra, Australia, [2]Neglected Tropical Diseases Support Center, The Task Force for Global Health, Decatur, GA, United States, [3]Centers for Disease Control and Prevention, Division of Parasitic Diseases and Malaria, Atlanta, GA, United States, [4]American Samoa Department of Health, Pago Pago, American Samoa, [5]College of Public Health, Medical and Veterinary Sciences, James Cook University, Cairns, Australia

Under the Global Programme to Eliminate Lymphatic Filariasis, American Samoa made significant progress toward interrupting transmission of lymphatic filariasis (LF) by conducting seven rounds of mass drug administration (MDA) from 2000-2006, and passing WHO recommended Transmission Assessment Surveys (TAS) of Grade 1 & 2 school children in 2011 & 2015. As antigen (Ag) prevalence drops to very low levels at the end stages of elimination efforts, detection of residual infected persons and/or *Foci* of ongoing transmission becomes increasingly challenging. WHO has therefore highlighted the need for cost-effective and innovative post-MDA surveillance strategies for identifying residual infections and high-risk groups. In 2016, we conducted a TAS of Grade 1 & 2 (mostly 6-7 year old) school children in American Samoa, in parallel with a cluster survey of community members aged ≥8 years in 30 villages. To determine if household members of Ag-positive school children were a high-risk group, and therefore a potential focus for targeted surveillance, we compared Ag prevelance in household members aged ≥8 years with results from the community survey. The Alere Filariasis Test Strip™ was used to detect circulating filarial Ag. Of 1143 school children and 2507 participants in the community survey, 9 (0.8%, 95% CI 0.4-1.5%) and 102 (4.1%, 95% CI 3.3-4.9%) were Ag-positive, respectively. Of the 65 eligible household members, 58 (89%) were tested and 12 (20.7%, 95% CI 11.2-33.4%) were Ag-positive; Ag-positive household members were identified in 5 (55.6%) of the 9 households. Our findings indicate that household members of Ag-positive school children have a significantly higher Ag prevalence than the general community (chi^2 test, $p<0.001$) and should be considered for targeted surveillance. Considering the significant household-level clustering and the highly focal nature of LF transmission, future studies should explore the utility of snowball sampling of household members and near neighbours of Ag-positive persons, including those identified through opportunistic surveillance strategies such screening programs at work sites or health clinics.

RIVER BLINDNESS IN TOGO: PERFORMANCE OF THE OV-16 RAPID DIAGNOSTIC TEST AND THE ELISA IN PREVIOUSLY HYPERENDEMIC *FOCI*

Eugene W. Liu[1], Paul Cantey[1], Koffi Padjoudoum[2], Telou Gado[2], Joseph Rubagumya[1], Rachel Bronzan[3], Michel G. Datagni[4], Nicholas Ayebazibwe[5], Danaya Bethea[1], Guillherme Ogawa[1], Vitaliano Cama[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Togo Onchocerciasis Control Program (PNLO), Kara, Togo, [3]Health and Development International, Newburyport, MA, United States, [4]Health and Development International, Lome, Togo, [5]African Field Epidemiology Network, Kampala, Uganda

Decisions to stop mass drug administration (MDA) to eliminate onchocerciasis are based on evidence of interruption of parasite transmission, such as absence of antibody to Ov-16 in children. In 2014, a rapid diagnostic test (RDT), became commercially available that can be performed in the field using blood from a finger prick and can provide real-time results, compared to the currently accepted enzyme-linked immunosorbent assay (ELISA). Here we compare performance of the RDT to ELISA in two previously hyperendemic districts in Togo that underwent >20 years of MDA. In each selected village in Kozah and Yoto districts, we randomly sampled households. For each household, we selected 1 individual from ≤5, 6-10, 11-15, 16-20, and ≥21 year-old age groups, with a goal of obtaining 200 individuals per age group in each district. All participants provided blood specimens tested for Ov16 antibody by RDT (SD Bioline) and ELISA (CDC protocol). We adjusted seroprevalence estimates with sampling weights accounting for non-response and numbers of individuals by age group per household. We enrolled 1015 participants in Kozah and 980 in Yoto. The adjusted proportion of seropositive participants i n the youngest three age groups (0-15 years old) ranged from 0-1% by RDT and 0-7% by ELISA in Kozah and 0-2% by RDT and 0-3% by ELISA in Yoto. In the two oldest age groups, respective proportions were 1% and 9% by RDT, 4% and 28% by ELISA in Kozah; 5% and 9% by RDT, 7% and 22% by ELISA in Yoto. The overall adjusted proportion positive was 3.0% (95% confidence interval [CI] 0.7-5.3%) by RDT and 10.5% (95% CI 6.8-14.2%) by ELISA in Kozah and 4.8% (95% CI 2.0-7.7%) by RDT and 11.1% (95% CI 7.1-15.2%) by ELISA in Yoto. Thus, RDT sensitivity ranged from 28.6% to 43.2% in various age groups. We observed lower estimated seroprevalence using RDTs compared to ELISA, suggesting that the RDT may under-detect the number of individuals with exposure to Onchocerca volvulus in low prevalence settings. Negative results by RDT would need to be confirmed by ELISA or sample sizes would need to be substantially increased to compensate for the low sensitivity in these settings.

6

DETECTION OF LYMPHATIC FILARIASIS ELIMINATION THRESHOLDS IN PAPUA NEW GUINEA

Daniel J. Tisch[1], Brooke Mancuso[1], Estee Cramer[1], Nellie Sunuku[2], Samson Satofan[2], Philip Lus[2], Kazura W. James[1], Christopher L. King[1], Peter A. Zimmerman[1]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]PNG Institute for Medical Research, Maprik, Papua New Guinea

This study was designed to evaluate human markers of lymphatic filariasis infection and transmission in 14 communities in East Sepik Province of Papua New Guinea during a period when transmission was expected to cease. The site had received 5 rounds of mass drug administration (MDA) in the 1990's, vector control with insecticidal bednets from 2008 to present, and renewed MDA starting in 2015. This study collected finger prick blood samples between 10pm and 2am before and after annual MDA from 2015 to 2018. Samples were processed for microscopy to detect circulating microfilaria (MF) and serological assays. The site was characterized by western communities with historically higher entomological indicators of transmission and eastern communities with lower transmission (and mathematically predicted to achieve transmission cessation). MF prevalence decreased from 18.0% to 8.1% and 2.0% after one and two MDAs in western communities and from 1.4% to 0.8% and 0.4% in the eastern communities. Among the 56 MF-positive individuals followed longitudinally, 22 and 48 converted to MF-negative after one MDA and two MDAs, and only one individual followed longitudinally converted to MF positive after receiving MDA. An additional 10 MF-positive individuals were detected in annual surveys following the start of community-wide MDA. Only one sentinel-age child (<10 years of age) remained MF positive after two MDAS. However, antigen prevalence detected by Filarial Test Strips (FTS) remained high across the study site with 40.6% FTS positive in western communities and 7.4% positive in

eastern communities. Furthermore, 63.4% and 26.9 % of the FTs positive individuals exhibited moderate (>1+) and 26.9%high antigenemia (3+) on the semi-quantitative value of FTS result. These results suggest that elimination targets based on epidemiological criteria of MDA success (< 1% microfilaremia or < 2% antigenemia) have not yet been met across this study site. Additional serological assays (BM14, WB123, and Og4C3) are currently being processed to decipher markers of exposure and infection across these subpopulations before and during this MDA program.

7

TIME FOR DIAGNOSTIC TOOLS THAT ACCURATELY DETECT *ONCHOCERCA VOLVULUS* IN ONCHOCERCIASIS ELIMINATION PROGRAMS IS NOW

Moses Katabarwa[1], Peace Habomugisha[2], Annet Khainza[2], Edson Byamukama[2], David Oguttu[2], Christine Nahabwe[2], Monica Ngabirano[2], Paul Akampurira[2], Christopher Katongole[2], Edridah Tukahebwa[2], Lauri Hudson-Davis[3], Thomas Unnasch[4], Frank Richards[1]

[1]The Carter Center, Atlanta, GA, United States, [2]The Carter Center, Kampala, Uganda, [3]The Carter Center, Atlanta, Uganda, [4]Department of Global Health, College of Public Health, University of South Florida, Tampa, FL, United States

Simulium fly dissections is still being used as a method of determining infection and infective rates of *Onchocerca volvulus*. However, these same *Simulium* vectors are likely to be infected with other domestic or wild animals *Onchocerca* species such as *O. ochengi or O. ochengi 'Siisa'* type in cattle, and *O. ramachandrini* in Warthogs as demonstrated by Unnasch (2017) in a study in northern Uganda. Dissections can therefore lead to overestimation of *O. volvulus* in *Simulium* flies. For this reason, entomological assessment in the 2016 WHO guidelines for verification of onchocerciasis elimination require the use of specific O-150 polymerized chain reaction (PCR) tests for *O. volvulus*. The national onchocerciasis elimination program in Uganda used *Simulium* dissections in parallel with PCR in Kiryandongo District, Uganda. This gave us an opportunity to compare those results, together with and OV16 ELISA data from the same areas. A total of 830 *Simulium* flies from two fly collection sites along the River Nile were collected. Dissection results showed a parous rate of 45% (374), and an infection rate among the parous flies of 7 % (infective rate, 6%) indicating a very high transmission rate of onchocerciasis. However, PCR (20 pools, 200 flies) was negative (upper bound of the 95% CI 1.9/2000 flies carrying L3). Dry blood spots (DBS) from 3,302 young children analyzed with OV 16 were also negative. We concluded that the positive results from dissected flies were likely of *Onchocerca* species associated with domestic or wild animals. In the current elimination era, it is imperative to apply diagnostic tools that accurately detect *Onchocerca volvulus*. This calls for endemic countries to establish means for serological and PCR testing for accurate verification of onchocerciasis elimination.

8

SPECIFIC GUT MICROBIAL PROFILES ARE ASSOCIATED WITH ROBUST IMMUNE RESPONSES TO KILLED, WHOLE-CELL CHOLERA VACCINE

Ana A. Weil[1], Taufiq R. Bhuiyan[2], Meti D. Debela[1], Fahima Chowdhury[2], Ashraful Khan[2], Edward T. Ryan[1], Regina C. LaRocque[1], Jason B. Harris[1], Firdausi Qadri[2]

[1]Massachusetts General Hospital, Boston, MA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Killed, whole-cell cholera vaccines elicit immune responses of variable amplitude and kinetics. Limited data suggests that the gut microbiome may explain variation to mucosal vaccine responses. To evaluate for this interaction in an endemic area, we used 16S rRNA sequencing of stool and serum vibriocidal titers to examine the gut microbiome and immune responses to vaccination at day 0, 7, 17 and 44 in adult vaccine recipients in Dhaka, Bangladesh. Vibriocidal titer magnitude and kinetics were used to classify participants. Gut microbial diversity and bacterial phylogenetic groups were not significantly changed after vaccination. Within 17 days of vaccination, 86/89 (96%) adults developed a 4-fold rise in vibriocidal titer. The speed to seroconversion (fourfold increase in vibriocidal titer by day 3 after vaccination) was correlated to individuals with greater bacteria from the genus Prevotella (multivariate analysis using linear models, q value 0.04). The gut microbiome of participants with higher peak vibriocidal titers was characterized by increased Prevotella (3% vs <0.1% of the total microbiome, p<0.001 unpaired t test, linear discriminant analysis score >3.5), particularly the species *Prevotella copri* (p<0.001, unpaired t test, linear discriminant analysis score >3.5). In animal models, lipopolysaccharide from mucosally derived Prevotella species have been found to increase vaccination-associated antigen-specific antibody titers and influence antigen specific CD4 T cell clonal expansion. The biological interaction between mucosal vaccines and the gut microbiota, and potential modulation of immune responses, warrants further study.

9

LONG-TERM EFFECTIVENESS OF KILLED BIVALENT WHOLE CELL ORAL CHOLERA VACCINE IN HAITI - FOUR YEAR DATA

Molly Franke[1], Ralph Ternier[2], J Gregory Jerome[2], Wilfredo Matias[3], Jason B. Harris[4], **Louise C. Ivers**[4]

[1]Harvard Medical School, Boston, MA, United States, [2]Zanmi Lasante, Port-au-Prince, Haiti, [3]Brigham and Women's Hospital, Boston, MA, United States, [4]Massachusetts General Hospital, Boston, MA, United States

The two long-term efficacy trials of vaccination with a killed oral cholera vaccine (OCV) reported conflicting results. In addition, no study of long-term protection following killed OCV has been conducted outside of the historically cholera-endemic areas of South Asia. Gavi, the vaccine alliance has evaluated the investment case for OCV based on a need to revaccinate after two years. We examined the duration of protection of the standard two-dose regimen and a single-dose regimen up to four years following vaccination with OCV in Haiti. In the setting of two-dose vaccination campaigns with a killed bivalent whole cell (BivWC) OCV, we conducted a case-control study from October 2012 through November 2016. Cholera cases had a positive stool culture and were recruited from cholera treatment centers. Community controls were matched to cases by age group, time, and neighborhood. We conducted adjusted matched regression analyses to calculate vaccine effectiveness and examine heterogeneity in effectiveness over time. In analyses including 178 cases and 706 controls, we found no evidence that two-dose effectiveness decreased during follow-up. In adjusted analyses, the average cumulative four-year effectiveness for two doses was 76% [95% CI: 59% to 86%]. In contrast, single-dose effectiveness decreased over time in a log-linear fashion, with a predicted vaccine effectiveness of 79% at the end of 12 months [95% CI: 43% to 93%], which declined to zero before the end of the second year. In a setting of epidemic and newly endemic cholera, we found consistent, lasting protection with two doses of BivWC OCV up to four years post-vaccination, supporting its critical role in a comprehensive public health response to cholera, and suggesting that vaccine investment analyses should longer duration of protection in cost-effectiveness analyses.

10

PROJECTING THE HEALTH IMPACT AND COST-EFFECTIVENESS OF ORAL CHOLERA VACCINE INTRODUCTION IN AFRICA

Elizabeth C. Lee[1], Andrew S. Azman[1], Joshua Kaminsky[1], Sean M. Moore[2], Heather McKay[1], Justin Lessler[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]University of Notre Dame, Notre Dame, IN, United States

The World Health Organization's Global Task Force on Cholera Control (GTFCC) declared a commitment to reduce worldwide cholera deaths by 90% by 2030. The proposed Global Roadmap presents a multi-sectoral

strategy for intervening in cholera transmission hotspots with water sanitation and hygiene (WaSH), improvements to infrastructure and surveillance, community engagement, and routine mass oral cholera vaccine (OCV) campaigns. Building upon previously published high-resolution maps of cholera incidence, we projected the potential impact and cost-effectiveness of multiple OCV vaccination campaign targeting strategies in 43 countries in sub-Saharan Africa from 2018-2030. Realistic strategies targeted high incidence districts every three years with estimates of global vaccine availability based on forecasts from manufacturers and recent trends; best- and worst-case targeting strategies (targeting high incidence 20x20 km grid cells and no targeting, respectively) were also performed to demonstrate the upper and lower limits of impact. We then estimated the averted cases, deaths, disability-adjusted life-years, and cost-effectiveness of each strategy using phenomenological models that account for the direct and indirect vaccine effects and population projections over time. Sensitivity analyses for baseline cholera incidence projections, vaccine effectiveness and waning immunity, and frequency of campaigns in a given location were used to identify the factors most important for health impact. In models with 23-58 million vaccines available annually, we found that an untargeted strategy performed barely better than a model without vaccination. On the other hand, strategies targeting high incidence districts may avert 344,000-366,000 cholera cases from 2018-2030, representing 25-43% of the impact of the optimal, yet impractical, best-case targeting strategy. Averting a single cholera case with this strategy required 650-750 individuals to be fully vaccinated. Our findings may inform policy characterizing the health impact and cost-effectiveness of cholera interventions in advance of implementation.

11

IMPACT OF CD4 T CELL RESPONSES ON CLINICAL OUTCOME IN A HUMAN CHALLENGE MODEL OF *VIBRIO CHOLERAE*

Monica A. McArthur, Mark E. Rudolph, Wilbur H. Chen, Marcelo B. Sztein

University of Maryland-Baltimore, Baltimore, MD, United States

Vibrio cholerae (*V. cholerae*) is the causative agent of cholera and remains a significant public health threat resulting in an estimated 1.3 to 4 million cases of diarrhea and greater than 100,000 deaths annually. Furthermore, cholera can occur in large, explosive outbreaks and pandemics resulting in considerable strain on health systems. Although there are vaccines licensed to combat cholera, including Vaxchora in the US, there remains limited information regarding the immunological mechanisms by which they confer protection. Due to the non-invasive nature of this pathogen, antibodies are presumed to be a major determinant of protection. However, the T cell responses that are associated with providing B cell "help" and inducing long-term humoral responses have not been explored. Using peripheral blood mononuclear cells (PBMC) from volunteers immunized with Vaxchora and/or challenged with wild-type *V. cholerae*, we have investigated the potential role of CD4 T cells, in particular circulating T follicular helper cells (cT_{fh}), in clinical outcome. We identified the presence of activated cT_{fh} (expressing the activation molecule CD154 and/or producing IL-2) with gut-homing potential (expressing integrin $\alpha4\beta7$) prior to immunization. Moreover, higher percentages of *V. cholerae*-responsive cT_{fh} with gut-homing potential prior to immunization were associated with lower cumulative stool output following challenge. We further demonstrate that volunteers who did not develop moderate-to-severe cholera diarrhea had significantly higher production of IL-2 by both gut-homing cT_{fh} and CD4 T effector memory cells (T_{EM}) prior to challenge. In conclusion, these results indicate a likely role for cT_{fh}, particularly those with gut-homing potential, in the induction of protection against moderate-to-severe cholera diarrhea.

12

HUMANS RECOVERING FROM CHOLERA IN BANGLADESH DEVELOP ANTIBODIES AGAINST THE O-SPECIFIC POLYSACCHARIDE (OSP) OF *VIBRIO CHOLERAE* O1 THAT INHIBIT *V. CHOLERAE* MOTILITY: A POSSIBLE MECHANISM OF PROTECTION AGAINST CHOLERA

RC Charles[1], M. Kelly[1], JM Tam[1], A. Akter[2], M. Hossain[2], K. Islam[2], F. Chowdhury[2], Ai Khan[2], DT Leung[3], A. Weil[1], RC LaRocque[1], Tr Bhuiyan[2], A. Rahman[2], LM Mayo-Smith[1], J. Vyas[1], M. Waldor[4], P. Kovak[5], P. Xu[5], SB Calderwood[1], RC Kauffman[6], J. Wrammert[6], F. Qadri[2], JB Harris[1], **Edward T. Ryan**[1]

[1]Massachusetts General Hospital - Harvard University, Boston, MA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]University of Utah, Salt Lake City, UT, United States, [4]Harvard Medical School, Boston, MA, United States, [5]NIDDK, LBC, National Institutes of Health, Bethesda, MD, United States, [6]Emory Vaccine Center, Emory University School of Medicine, Atlanta, GA, United States

The mechanism of protection against cholera afforded by previous illness or vaccination is currently unknown. We have recently shown that antibody responses targeting the O-specific polysaccharide (OSP) of *V. cholerae* correlate highly with protection against cholera. *V. cholerae* is a motile bacterium that has a single polar flagellum, and motility of *V. cholerae* highly correlates with virulence. The *V. cholerae* flagellum is sheathed and therefore covered by OSP. We hypothesize that protection against cholera may be mediated by anti-OSP antibodies that inhibit *V. cholerae* motility. To address this, we purified IgG, IgA, and IgM fractions from 10 humans recovering from cholera in Bangladesh. We also analyzed human monoclonal anti-OSP antibodies recovered from plasmablasts of patients with cholera. We characterized these fractions and antibodies for anti-OSP, vibriocidal, and agglutinating activity. Using high-speed video microscopy, we showed that at subagglutinating and agglutinating antibody concentrations that these antibodies impede *V. cholerae* motility, that this effect is blocked by adsorbing convalescent sera with purified OSP, and that Fab fragments of these antibodies did not affect *V. cholerae* motility, suggesting a requirement for antibody mediated crosslinking in antimotility action. Using *in vivo* competitive index studies in mice and a motile rough *V. cholerae* mutant lacking OSP, as well as a non-motile *V. cholerae* mutant expressing OSP, we showed that antibodies impeded survival of *V. cholerae in vivo*, and that this impact was OSP- and motility-dependent. These results are the first to show that humans recovering from cholera develop an antibody response that blocks *V. cholerae* motility. Since *V. cholerae* motility is required for virulence, our results strongly suggest a mechanism of protection against cholera.

EPIDEMIOLOGY OF CHOLERA IN ZANZIBAR: IMPLICATIONS FOR THE ZANZIBAR CHOLERA CONTROL AND ELIMINATION PLAN

Qifang Bi[1], Fadhil M. Abdalla[2], Salma Masauni[2], Rita Reyburn[3], Marko Msambazi[4], Carole Deglise[5], Lorenz von Seidlein[6], Jacqueline Deen[7], Mohamed Saleh Jiddawi[2], David Olson[8], Justin Lessler[1], Grace Saguti[9], Iriya Nemes[9], Jamala Adam Taib[2], Ghirmay Redae Andemichael[10], Andrew S. Azman[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Zanzibar Ministry of Health, Zanzibar, United Republic of Tanzania, [3]Pneumococcal Research, Murdoch Children's Research Institute, Melbourne, Australia, [4]UNICEF, Zanzibar, United Republic of Tanzania, [5]Médecins Sans Frontières, Geneva, Switzerland, [6]Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [7]Institute of Child Health and Human Development, National Institutes of Health, University of the Philippines, Manila, Philippines, [8]World Health Organization, Geneva, Switzerland, [9]World

Health Organization, Dar es Salaam, United Republic of Tanzania, [10]World Health Organization, Zanzibar, United Republic of Tanzania

Zanzibar is a semi-autonomous region of the United Republic of Tanzania consisting of two main islands, Unguja and Pemba. Frequent cholera epidemics pose a major threat to Zanzibar's economic development since at least 1978 and have repeatedly disrupted local public health services. To inform a multi-sectoral cholera elimination plan currently under development, we summarize the epidemiology of cholera in Zanzibar from 1997 to 2017 using detailed epidemiologic, environmental, and social data. From 1997 to 2017, 11,921 suspected cholera cases were reported across 87% of Zanzibar's shehias representing an average incidence rate of 4.4 per 10,000/year. The geographic distribution of cases across outbreaks was highly variable although a number of high-burden areas were identified. We found that on both islands, relative risk of cholera infection in a single outbreak was poorly correlated with the average relative risk across all other outbreaks (0.13 in Unguja and 0.18 in Pemba), making it difficult to target cholera control activities on the neighborhood level. If shehias are sequentially targeted based on historic cumulative incidence, targeting just 4.7% (IQR 1.6-10.5 in hold-out analyses) of Pemba's population living in 4 (IQR 2-11) shehias with an ideal cholera prevention package could avert 50% of future cases. However, 20.8% (IQR 15.5-24.6) of Unguja's population coming from 36 (IQR 20-36) shehias would need to be perfectly targeted in order to avert 50% of future cases on the island. Using flexible regression models, we found that outbreaks were highly seasonal, providing a clear window for annual preparedness activities. The risk of reporting cases at the start of two rainy periods in May and December was 2.6 times (95% CI 1.6-4.1) and 1.8 times (95% CI 1.1-3.0) higher than the mean risk throughout the year. Rainfall in the previous seven days had a significant positive relationship with daily reproductive number on both islands.

14

BIOMARKERS OF ENVIRONMENTAL ENTEROPATHY ASSOCIATE WITH IMMUNOGENICITY OF THE BIVALENT ORAL CHOLERA VACCINE IN HAITIAN CHILDREN

Brie W. Falkard[1], Kerling Israel[2], Richelle Charles[1], Molly Franke[3], Jason Harris[1], Louise Ivers[1]

[1]Massachusetts General Hospital, Boston, MA, United States, [2]Zanmi Lasante, Hôpital St Nicholas, St Marc, Haiti, [3]Harvard Medical School, Boston, MA, United States

Environmental enteropathy (EE) is a condition that is prevalent among children in low-income countries with chronic exposure to intestinal pathogens due to poor sanitation and water security. The disorder refers to inflammation and structural changes of the gut, leading to intestinal permeability and lack of nutrient absorption. The presence of EE in children associates with lower immunogenicity of the oral polio and rotavirus vaccines. Currently, a lack of interventions and non-invasive diagnostic tests limits our understanding and treatment of this condition. To determine whether there is an association between EE and immunogenicity of the bivalent whole cell oral cholera vaccine ((BivWC)), Shanchol, we examined a cohort of 98 Haitian children who received two doses of BivWC 14 days apart. We measured plasma antibody responses to cholera antigens at baseline and 7 days after each dose. We measured the following EE markers at baseline (Day 0): plasma C-reactive protein (CRP), alpha-1-acid glycoprotein (AGP), ferritin, soluble CD14 (sCD14), intestinal fatty acid binding protein (I-FABP) and endotoxin-core antibody (EndoCAb). Through a multivariate linear regression analysis, we identified associations between vibriocidal antibody titer after vaccination to markers of EE. Age and blood-type O were included in the model as possible confounders. There was no collinearity between the EE markers. We found significant associations between markers for EE to vibriocidal fold change after vaccination; Vibriocidal Inaba D21-AGP (P=0.002); Vibriocidal Ogawa D21- AGP (P=0.04); Vibriocidal Ogawa D21- CD14 (P=0.04); Vibriocidal Ogawa D21- Ferritin (P=0.03). Our findings suggest that EE impacts the immunogenicity of the BivWC oral cholera vaccine.

15

ENDOTOXIN AT THE MATERNAL-FETAL INTERFACE IS ASSOCIATED WITH ELEVATED EXPRESSION OF TISSUE INHIBITOR OF METALLOPROTEINASES

Emily A. McDonald[1], Zorimel Vargas[1], Palmera I. Baltazar[2], Remigio Olveda[2], Luz P. Acosta[2], Veronica Tallo[2], Jonathan D. Kurtis[3], Jennifer F. Friedman[1]

[1]Rhode Island Hospital, Providence, RI, United States, [2]Research Institute of Tropical Medicine and Hygiene, Manila, Philippines, [3]Brown University, Providence, RI, United States

Tightly regulated invasion of trophoblast cells into maternal decidua is essential for normal placentation in humans. We have previously shown trophoblasts to be responsive to schistosome egg antigen, demonstrating increased cytokine production and decreased invasion rates. We have also demonstrated that schistosomiasis is associated with elevated endotoxin at the maternal-fetal interface (MFI). We hypothesized that expression of proteins involved in extracellular matrix remodeling, namely tissue inhibitor of metalloproteinases (TIMPs) may be reduced at the MFI when complicated by schistosomiasis. Herein, we utilized samples from pregnant women who participated in a trial designed to evaluate the safety of praziquantel treatment during pregnancy. All women were positive for *S. japonicum* at enrollment and randomized to receive praziquantel or placebo. We examined levels of endotoxin, cytokines and TIMPs in blood from the MFI taken immediately following placental bed biopsy. Neither praziquantel nor infection with soil transmitted helminths (*A. lumbricoides*, *T. trichiura*, hookworm) impacted expression of TIMPs in blood from the MFI. High endotoxin expression was associated with elevated TIMP-1 and TIMP-3 at the MFI ($P<0.01$), after controlling for gestational and maternal age. Pro-inflammatory cytokine production (e.g. IL-1, IFNγ, IL-8, TNFα) was also correlated with elevated TIMP levels at the MFI ($P<0.02$). Further, TIMP-1, -2 and -3 levels were lower in mothers with iron deficiency anemia ($P<0.01$), in keeping with studies that have demonstrated increased trophoblast invasion among anemic women. In summary, an expression pattern of heightened TIMPs, observed in the context of elevated endotoxin and/or pro-inflammatory cytokines, suggests decreased invasion at the MFI, and may help explain the observed association between placental endotoxin and small-for-gestational-age newborns we have previously demonstrated in this cohort. These data provide a candidate mechanism by which chronic inflammation at the MFI may impact the invasion characteristics of trophoblasts and thus the establishment of a healthy placenta.

16

INTRODUCING *SCHISTOSOMA MANSONI* AMP-ACTIVATED PROTEIN KINASE (AMPK): DEVELOPMENTAL REGULATION, ACTIVITY, AND ROLE IN SCHISTOSOME ENERGY METABOLISM

Kasandra S. Hunter

Uniformed Services University, North Bethesda, MD, United States

Schistosomes are obligate parasites and auxotrophic for many critical biomolecules, such as such as fatty acids and cholesterol, which must be acquired from the host in order to sustain parasite growth and development. Furthermore, schistosome development requires other signals from the host, as parasite growth and reproductive capacity are significantly attenuated in certain lines of gene-targeted mice. We previously showed that impaired growth and reproduction of *Schistosoma mansoni* in immunodeficient mice correlated with reduced expression and activity of the parasite cAMP-dependent protein kinase (PKA), a cellular protein involved in metabolic regulation. As schistosomes use a combination of glycolysis, fatty acid oxidation and oxidative phosphorylation to meet their bioenergetic needs and support the daily production of hundreds of eggs, we hypothesized that schistosomes from immunodeficient mice might also exhibit alterations in signaling

pathways and enzymes that more directly regulate energy metabolism. First, we show that adult schistosomes express an AMP-activated protein kinase (AMPK), a heterotrimeric enzyme that is central to regulating energy metabolism in other eukaryotes. Second, we provide evidence that expression of the catalytic alpha subunit is developmentally regulated during the parasite's life cycle. While there is evidence of AMPK in all developmental stages, our data indicate that transcription of the AMPK alpha gene is shut off in cercariae and is re-initiated once inside the mammalian host. Third, we show that schistosome AMPK activity is sensitive to changes in the worm's environment, suggesting a mechanism by which schistosome metabolism may be responsive to host factors. Finally, we provide evidence that AMPK expression is attenuated in parasites isolated from immunodeficient mice, suggesting the host exerts significant influence over the regulation of schistosome energy metabolism. Elucidating how schistosome energy metabolism is regulated and how host factors influence parasite energy metabolism may reveal opportunities to disrupt transmission of these important pathogens.

TARGETING THE REDOX NETWORK FOR DRUG DISCOVERY FOR SCHISTOSOMIASIS

David L. Williams

Rush University Medical Center, Chicago, IL, United States

Praziquantel is the only drug available for schistosomiasis treatment. The FAD/NAD linked enzyme thioredoxin glutathione reductase (TGR) is central to the redox network of these worms and has been determined to be essential and druggable. We have screened >500,000 small molecules for TGR inhibition and have identified >10,000 actives. Progress to identify potential lead compounds in these actives will be discussed. 3D structures of small molecules in complex with TGR has identified an allosteric binding site for inhibitor development. Compounds binding this site perturb the catalytic mechanism. Related FAD/NAD linked reductases, targets for malaria, trypanosomiasis, leishmaniasis, and cancer drug development, have similar catalytic mechanisms and binding pockets. The topology/charge distribution in this binding site is not highly conserved, suggesting ways to develop enzyme-specific inhibitors for drug development for many diseases in addition to schistosomiasis.

18

USING A GLYCAN MICROARRAY TO IDENTIFY DOMINANT ANTI-GLYCAN IGE RESPONSES IN GHANAIAN SCHOOL-CHILDREN LIVING IN A HELMINTH-ENDEMIC AREA

Abena S. Amoah[1], Elias K. Asuming-Brempong[2], Benedicta B. Obeng[1], Serge A. Versteeg[3], Irene A. Larbi[2], Yvonne Aryeetey[2], Thomas A. Platts-Mills[4], Adriano Mari[5], Katarzyna Brzezicka[6], Ben Gyan[2], Mohamed Mutocheluh[7], Daniel A. Boakye[2], Niels-Christian Reichardt[6], Ronald van Ree[3], Cornelis H. Hokke[1], Angela van Diepen[1], Maria Yazdanbakhsh[1]

[1]Leiden University Medical Center, Leiden, Netherlands, [2]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [3]Academic Medical Center, Amsterdam, Netherlands, [4]University of Virginia, Charlottesville, VA, United States, [5]Associated Centers for Molecular Allergology, Rome, Italy, [6]CIC biomaGUNE, San Sebastián, Spain, [7]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

In helminth-endemic areas, elevated levels of cross-reactive IgE to environmental and food allergens are often observed that do not translate into allergy symptoms. In Ghanaian children, this cross-reactivity has been shown to be associated with *Schistosoma haematobium* infection and dominated by elevated levels of IgE against the sugar structures on glycoproteins known as cross-reactive carbohydrate determinants. The aim of the current study was to characterize the specific carbohydrate motifs involved in this IgE recognition in Ghanaian children using a synthetic glycan microarray. The target population was schoolchildren living in rural and urban areas with different socioeconomic status (SES). Sera from children attending a rural school (n=20), an urban low SES school (n=20) and an urban high SES school (n=20) were used to assess IgE responses against 128 synthetic N-glycans and short oligosaccharides by microarray. The highest levels of IgE to glycan structures were observed among rural children followed by urban low SES and urban high SES children. Analysis of specific N-glycan entities showed that IgE responses were predominantly directed to structures with a core α-1,3-fucose motif alone and to a lesser extent, to those with core xylose only. *S. haematobium* infection was mainly observed in urban low SES subjects and was significantly associated with elevated IgE to structures with core xylose. Glycan microarray technology represents a novel approach to characterize IgE responses to carbohydrate motifs that could complement existing *in vitro* immunoassay technologies and clinical evaluation.

19

UROGENITAL SCHISTOSOMIASIS IS ASSOCIATED WITH WIDESPREAD IMPACTS ON THE ADOLESCENT INTESTINAL MICROBIOME

Olumide Ajibola[1], Aislinn D. Rowan[2], Clement O. Ogedengbe[3], Mari B. Mshelia[1], Damien J. Cabral[2], Anthonius A. Eze[3], Peter Belenky[2]

[1]Federal University Birnin Kebbi, Kebbi, Nigeria, [2]Brown University, Providence, RI, United States, [3]University of Nigeria Enugu Campus, Enugu, Nigeria

Urogenital schistosomiasis is a neglected parasitic disease endemic to Nigeria, affecting millions across Africa. Given previous work indicating that helminth infection can impact immune responses and even the composition of the intestinal microbiome, we examined the impacts of infection with *Schistosoma haematobium* on the gut microbiome of adolescents in Kebbi State in Nigeria. We sequenced the hypervariable V4 region of the 16S rRNA gene of the faecal microbiome of infected and uninfected participants, and analyzed whether there were diversity or taxonomical differences in the microbial community composition. While the overall richness and evenness of the infected individuals was similar to controls, we detected an increased number of observed taxa, decreased phylogenetic diversity, and differential beta diversity in infected individuals resulting from decreased prevalence of Firmicutes and increased prevalence of Proteobacteria. More specifically, we detected a number of changes in taxa reminiscent of changes seen in inflammatory bowel disease in adolescents infected with *S. haematobium*, including increases in members of Bacteroides, Veillonellaceae, Pasteurellaceae, and Desulfovibrio and decreases in Clostridiales; these changes were confirmed using qPCR. Functional potential analysis also revealed an enrichment in urease producers, which past studies have linked to dysbiosis and inflammation.Overall, our analysis indicates that *S. haematobium* infection state is associated with widespread perturbations in the gut microbiota.

BETA GLUCAN, IRI-1677, MODULATES TH2 INDUCED PATHOLOGY, INFLAMMATION AND FIBROSIS IN A MURINE MODEL OF SCHISTOSOMIASIS

Robert W. Thompson[1], Erik Karmele[1], Richard L. Gieseck III[1], Myra Patchen[2], Steve Smith[2], Sandra Oland[1], Alessandra Ricciardi[1], Pedro Gazzinelli-Guimaraes[1], Kevin Hart[1], Thomas A. Wynn[1], Thomas B. Nutman[1]

[1]National Institutes of Health/National Institute of Allergy and Infectious Diseases/LPD, Bethesda, MD, United States, [2]ImmunoResearch, Eagan, MN, United States

Beta glucans are Pathogen Associated Molecular Pattern, or PAMP, molecules that trigger a coordinated immune response to pathogens. They can induce a variety of responses, including the ability to shift an overstimulated Th2 immune response to a Th1 response. Because Schistosoma mansoni (Sm) infection in mice is associated with a Th2-dominated inflammatory response that drives liver pathology (and fibrosis)

we examined the effects of a purified yeast beta 1,3/1,6 glucan, IRI-1677, for its modulatory effects on pathology, inflammation, and concomitant fibrosis in murine Sm infection. C57BL/6 mice were infected with (Sm) cercariae. Five weeks after infection, mice were treated with biweekly doses of IRI-1677 for a total of 4 weeks and then sacrificed. IRI-1677, in a dose dependent manner, was able to dramatically suppress the expression of genes (assessed by Nanostring) in the liver that target IL-13 (a key cytokine regulating fibrosis in murine schistosomiasis). In particular, IRI-1677 -treated Sm-infected mice were able to down regulate IL-13Ra2, Fizz 1 and Col6a1 while upregulating Th1/Th17-associated cytokines compared to IRI-1677-untreated Sm-infected mice. The IRI-1677-induced changes in cytokines in Sm-infected mice were paralleled by alterations in the makeup of liver tissue inflammation with the beta glucan driving neutrophil and inflammatory monocyte infiltration compared to the eosinophil and M2-macrophage rich environment seen in untreated Sm-infected mice. Gross pathology was also markedly different between IRI-1677-treated and -untreated Sm-infected mice. We are currently assessing markers (tissue hydroxyproline) of fibrosis, inflammation and pathology to understand whether balancing the effect of chronic robust TH2 responses in this parasite model with IRI-1677 administration can be used to limit the pathologic consequences of infection with Sm.

21

THE INTERLEUKIN-4 INDUCING PRINCIPLE FROM *SCHISTOSOMA MANSONI* EGGS (IPSE) EXACERBATES UTI-INDUCED PAIN AND SUPPRESSES ANTI-MICROBIAL PEPTIDE PRODUCTION

Evaristus C. Mbanefo[1], Luke Pennington[2], Kristina Lapira[3], Theodore Jardetzky[2], Franco Falcone[4], Michael Hsieh[1]

[1]Biomedical Research Institute, Rockville, MD, United States, [2]Department of Structural Biology, Stanford University School of Medicine, Stanford, CA, United States, [3]University of California, San Diego, CA, United States, [4]Division of Molecular Therapeutics and Formulation, School of Pharmacy, University of Nottingham, Nottingham, United Kingdom

Numerous parasitic infections can increase susceptibility to bacterial co-infections. This appears to be true for urogenital schistosomiasis and bacterial urinary tract co-infections (UTI). In a 2014 Infection and Immunity paper, we reported that this co-infection is immunologically facilitated by *Schistosoma haematobium* eggs triggering interleukin-4 (IL-4) production, which in turn ablates NKT cell activation-associated bacteria clearance. We sought to determine how *S. haematobium* eggs induce this IL-4-dependent response. The interleukin-4 inducing principle from *Schistosoma mansoni* eggs (IPSE) is one of the most abundant schistosome egg-secreted proteins, and is a molecule that binds to IgE on the surface of basophils and mast cells to trigger IL-4 release. IPSE is also able to translocate into host nuclei using a nuclear localization sequence (NLS) to modulate host gene transcription. We hypothesized that IPSE is the factor responsible for the ability of *S. haematobium* eggs to worsen UTI pathogenesis. Mice were intravenously administered a single 25ug dose of recombinant *S. haematobium*-derived IPSE, an NLS mutant of IPSE or PBS and 24 hours later challenged with the uropathogenic *E. coli* strain UTI89 by urethral catheterization. We verified that a single intravenous dose of IPSE induced IL-4 production by basophils. Unexpectedly, we did not observe significant differences in urine bacterial CFU. Even more surprisingly, IPSE worsened UTI-induced pain. The NLS mutant induced even worse outcomes. Moreover, IPSE administration resulted in significant reduction in the expression of anti-microbial peptides. Our data show that IPSE may play a major role in *S. haematobium* induced UTI exacerbation, albeit in an unexpected fashion. These findings also indicate that IPSE either works in concert with other IL-4-inducing factors to increase susceptibility of *S. haematobium*-infected hosts to bacterial co-infection, or does not play a role in these co-infections.

22

EVIDENCE CONSISTENT WITH SCHOOL BASED TRANSMISSION OF *TAENIA SOLIUM* CYSTICERCOSIS IN PRIMARY SCHOOLS, SOUTHWEST CHINA

John Openshaw[1], Carole Chedid[2], Alexis Medina[1], Stephen A. Felt[1], Tiaoying Li[3], Zhou Huan[4], Scott Rozelle[1], Stephen P. Luby[1]

[1]Stanford University, Stanford, CA, United States, [2]Ecole Normale Supérieure de Lyon, Lyon, France, [3]Sichuan Centers for Disease Control and Prevention, Chengdu, China, [4]West China School of Public Health, Chengdu, China

Cysticercosis is caused by larval forms of the pig tapeworm, *Taenia solium*, invading human tissue. The disease is spread person-to-person via a fecal oral route from tapeworm carriers shedding eggs in their feces. We characterized exposure and the relationship of infection to social networks in primary school children in southwest China. We surveyed 3,038 students across 27 schools in southwest China, drawing blood for *T. solium* cysticercosis IgG antibody testing by ELISA. We collected social network data in one school study site (362 children), speciating tapeworms in taeniasis cases and detailing social networks by having students identify peers sharing their same classroom, dorm, and dining table as well as frequent playmates and children with whom they frequently shared food. 6% of children (180/2867) had serologic evidence of cysticercosis IgG antibodies, the proportion of seropositive children in different schools ranged from 0% to 22%. 11% (283/2606) of children reported having worms or worm segments in their feces, with a range of 0% to 28% in different schools. In the social network study, 4% of the school population had *T. solium* GI carriage (16/362), with the highest prevalence found in 9 year olds (3rd, graders, 15%, 6/39) and 8 year olds (2nd graders, 8%, 3/38). 22% (9/41) of seropositive children had identifiable school based close contacts with tapeworm carriers consistent with school based transmission. Students attending schools with a higher proportion of self-reported taeniasis were more likely to have serologic evidence of cysticercosis antibodies ($p = 0.017$; odds of seropositivity increases 1.13 [95% CI 1.01 - 1.25] with a 5% increase in school prevalence). Social connections between infectious tapeworm carriers and students with cysticercosis antibodies as well as the association between seropositivity and the proportion of children with taeniasis suggests potential transmission of cysticercosis within schools. School based interventions including improving school hygiene measures as well as school based treatment of taeniasis carriers may play a role in decreasing disease burden in school-aged children.

23

INTRODUCING CYSTIAGENT: AN AGENT-BASED MODEL TO SIMULATE *TAENIA SOLIUM* TRANSMISSION IN PERU

Ian W. Pray[1], Wayne Wakeland[2], William Pan[3], William E. Lambert[1], Robert H. Gilman[4], Armando E. Gonzalez[5], Cesar M. Gavidia[5], Hector H. Garcia[6], Seth E. O'Neal[1], for the Cysticercosis Working Group in Peru[6]

[1]School of Public Health, Oregon Health and Science University and Portland State University, Portland, OR, United States, [2]Systems Science Program, Portland State University, Portland, OR, United States, [3]Global Health Institute, Duke University, Durham, NC, United States, [4]Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [5]School of Veterinary Medicine, Universidad Nacional Mayor de San Marcos, Lima, Peru, [6]Department of Microbiology, Universidad Peruana Cayetano Heredia, Lima, Peru

Persistent endemic transmission of the pork tapeworm, *Taenia solium*, causes widespread neurological disease (neurocysticercosis) and a significant economic burden on low-income rural populations across Latin America, Asia and Africa. The past 20 years have seen important advances in the development of effective control interventions against *T. solium*, including mass anti-helminthic treatment, pig vaccination, and geographically targeted ring interventions. Despite this progress,

few strategies have been systematically evaluated, and there is a critical lack of evidence on which to base recommendation for control in different geographic settings. To address this evidence gap, we introduce CystiAgent, an agent-based model designed to simulate *T. solium* transmission. CystiAgent can be used to compare the effectiveness of available control strategies in a variety of endemic settings, and prioritize those most likely to be successful for evaluation in prospective studies. While previous transmission models for *T. solium* have been developed, CystiAgent is the first spatially-explicit model, and therefore the first with the ability to model clustered transmission patterns while accounting for risk heterogeneities caused by open human defecation, pig roaming, and travel patterns. It is also the first model to be validated with data collected from prospective control and elimination interventions. This presentation includes visual demonstration of CystiAgent operation and output, and provides validation results using prospective intervention data from two large multi-year studies (Cysticercosis Elimination Project and Optimizing Ring Strategy) that span 10 unique interventions and 40 villages (pop. ~20,000) in northern Peru. Validation results include the accuracy of model-predicted reductions in the prevalence of taeniasis and porcine cysticercosis, and sensitivity analyses demonstrating parameter uncertainty and opportunities for future model improvements. This oral presentation represents a unique opportunity to share a much-anticipated tool with the cysticercosis research community.

24

EVALUATING POTENTIAL FOR AN UNADDRESSED URBAN RESERVOIR OF *TAENIA SOLIUM* TAENIASIS IN PERU

Lauralee J. Fernandez[1], Ricardo Gamboa[2], Percy Vilchez[2], Ian Pray[3], Michelle Beam[3], Brian Garvey[3], Angela Spencer[1], Claudio Muro[2], Luz Maria Moyano[2], Hector H. Garcia[2], Seth E. O'Neal[1], for the Cysticerocsis Working Group in Peru[2]

[1]Oregon Health & Science University and Portland State University School of Public Health, Portland, OR, United States, [2]Center for Global Health Tumbes, Universidad Peruana Cayetano Heredia, Tumbes, Peru, [3]Oregon Health & Science University, Portland, OR, United States

Neurocysticercosis is a leading cause of adult onset epilepsy. In 2012, the causative parasite, *Taenia solium*, was eliminated from 107 rural villages in the region of Tumbes, Peru. Urban centers were not included in the elimination project given that the conditions for established transmission (free ranging pigs and open human defecation) are uncommon in these settings. However, a recent study found active transmission of the parasite in two of the villages that had been previously cleared. These villages experience both frequent travel and commerce with the nearby city of Zarumilla, as well as immigration from other rural regions outside the elimination zone. The objective of this study was to determine the prevalence of taeniasis in the urban center of Zarumilla, and to explore the plausibility of an urban reservoir of taeniasis as a potential threat for reintroduction of *T. solium* into the elimination area. We conducted random cluster sampling at the block level within the city limits of Zarumilla (population ~ 20,000). Participants were asked about the frequency, duration and sites of travel to rural areas. They were also offered oral niclosamide as presumptive treatment for tapeworms, and were asked to provide a stool sample for diagnosis of taeniasis using coproantigen ELISA. 636/ 1113 (67%) of households approached had one or more participants. A total of 2340 residents provided survey data, of which 2061(88 %) accepted treatment, and 1621 (69%) provided a stool sample. Four participants (0.25% [95%CI: 0.08, 0.64]) were diagnosed with taeniasis; all had traveled to a nearby rural community and three reported having defecated outside while there. While it is possible that urban taeniasis carriers could have contributed to reintroduction of *T. solium* to the rural elimination area, the low prevalence of urban taeniasis compared to the typical prevalence of 1-2% in rural areas, suggests that other sources are more likely. Alternative sources for reintroduction such as rural-rural migration and persistent parasite eggs in the environment should be considered.

25

RELATIONSHIP BETWEEN PLASMA LEVELS OF ALBENDAZOLE SULFOXIDE AND ANTIPARASITIC EFFICACY IN THE TREATMENT OF NEUROCYSTICERCOSIS

Gianfranco Arroyo[1], Andres G. Lescano[1], Javier A. Bustos[1], Isidro Gonzales[2], Herbert Saavedra[2], Javier E. Pretell[3], Armando E. Gonzalez[4], Robert H. Gilman[5], Hector H. Garcia[1]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Instituto Nacional de Ciencias Neurologicas, Lima, Peru, [3]Hospital Alberto Sabogal, Callao, Peru, [4]Universidad Nacional Mayor de San Marcos, Lima, Peru, [5]Johns Hopkins University, Baltimore, MD, United States

The efficacy of albendazole therapy to destroy brain cysticercosis cysts is incomplete. Plasma levels of albendazole sulfoxide (ABZSO), the active metabolite of albendazole, are extremely variable among patients. We assessed whether high plasma ABZSO levels during albendazole therapy are associated with increased antiparasitic efficacy. Plasma ABZSO levels were measured at treatment day 7 in 118 patients with intraparenchymal neurocysticercosis enrolled in a trial of antiparasitic efficacy. Drug levels were analyzed in regard to the likelihood of complete cyst clearance in the patient, and the proportion of baseline cysts that resolved by therapy (evaluated by brain MRI 6 months after treatment). A trend towards high cure rates in patients with increasing quartiles of ABZSO levels was observed (40%, 48%, 50%, and 60% for Q_1 [≤245 ng/ml], Q_2 [>245 to ≤385 ng/ml], Q_3 [>385 to ≤650 ng/ml], and Q_4 [>650 ng/ml] respectively; *P*-value = 0.059). A similar trend was also observed for the proportion of resolved cysts with increasing quartiles of ABZSO levels (46%, 60%, 58%, and 77% for Q_1, Q_2, Q_3, and Q_4 respectively; *P*-value = 0.093). In patients with ≥3 baseline brain cysts, the regression models adjusted by praziquantel co-administration, and the type of anti-epileptic drug used showed higher cure rates and proportion of resolved cysts when comparing ABZSO levels in the 4th versus the 1st quartile (risk ratio = 3.17 [95% CI: 1.12-8.99] for cure rates, and risk ratio = 2.0 [95% CI: 1.03-3.93] for the proportion of resolved cysts); in patients with 1-2 baseline cysts not effect between ABZSO levels and antiparasitic efficacy was observed. There is a direct relationship betwen increasing levels of ABZSO in plasma and treatment efficacy, although the strength of the association is mild to moderate, and other factors including baseline brain cyst burden, and antiparasitic drug scheme may also impact in treatment efficacy.

26

DESIGN AND VALIDATION OF A SENSITIVE LOOP-MEDIATED ISOTHERMAL AMPLIFICATION, LAMP ASSAY, TARGETED *T. SOLIUM COX 1* GENE TO IMPROVE THE DIAGNOSTIC OF NEUROCYSTICERCOSIS USING CEREBROSPINAL FLUID

Anjanirina Rahantamalala[1], Julien Razafimahefa[2], Oria Davidson[1], Prisca Ramandanirainy[1], Siddharta Mahanty[3], Mahenina Rakotondrazaka[1], Rado Lalaina Rakotoarison[1], Nônô Randrianasolo[1], Francesca Bisio[4], Frédérique Randrianirina[5], Alain Djacoba Tehindrazanarivelo[2], Ronan Jambou[6], Inès Vigan-Womas[1]

[1]Immunology of Infectious Diseases Unit, Institut Pasteur de Madagascar, Antananarivo, Madagascar, [2]Neurology Department of Befelatanana Hospital, Antananarivo, Madagascar, [3]Laboratory of Parasitic Diseases, National Institutes of Health, Bethesda, MD, United States, [4]Centre Hospitalier de Référence Régionale Monja Jaona, Ambovombe Androy, Madagascar, [5]Centre of Clinical Biology, Institut Pasteur de Madagascar, Antananarivo, Madagascar, [6]Institut Pasteur de Cote d'Ivoire, Abidjan, Côte D'Ivoire

Taenia solium neurocysticercosis (NCC) is a common cause of epileptic seizures and other neurological morbidity in several low-income countries including Madagascar. The neuroimaging diagnosis remains challenging and expensive especially for the population living in remote areas. Here we describe a sensitive and affordable NCC molecular diagnosis test based on LAMP method using cerebrospinal fluid (CSF). Patients presenting epileptic

seizures and/or unusual progressive headache, with neuroimaging lesions, recruited at the Neurology Department of Befelatanana Hospital were included in this study. In-depth CT-Scan analysis was used as reference test to ascertain the NCC diagnosis. LAMP-NCC technique detecting *T. solium* cytochrome C oxydase subunit 1 gene was first validated on 7 patients with confirmed NCC (presence of scolex in CT-Scan) and 4 patients with negative NCC. Immunoblot test (EITB) using purified *T. solium* metacestode glycoproteins were realized on blood and CSF. The LAMP-NCC presented a detection limit of 2.5pg using DNA extracted from *T. solium* metacestodes and showed no amplification with *T. saginata*, *T. asiatica* and *Loa loa* DNA. Using CT-Scan as reference method, the sensibility of LAMP-NCC on CSFs without any DNA extraction step is higher compared to the immunoblot (70% vs 40%) when the specificity for both tests was similar (80%). The validation of the LAMP-NCC is on-going on a biobank of CSFs samples from patients with confirmed NCC diagnosis or with other neurological pathologies. The encouraging preliminary results obtained indicates that LAMP-NCC is a promising molecular Point-Of-Care tool to strengthen the NCC diagnosis in Madagascar.

ALVEOLAR ECHINOCOCCOSIS IN GERMANY, 1992-2017: PREVALENCE, SURVEILLANCE AND SPATIAL AUTOCORRELATION

Julian Schmidberger, Beate Grüner, Wolfgang Kratzer, Tilmann Gräter

University Hospital Ulm, Ulm, Germany

Alveolar echinococcosis (AE) caused by the parasite *Echinococcus multilocularis* is a rare disease in Germany. The aim of this analysis was the detection of high risk areas and the determination of prevalence of AE in Germany. EpiInfo ™ was used for cartographic representation and visualization of the penetration position. The Moran's I geoanalysis by clusters and risk areas was performed with GeoDa™. SAS Version 9.2 was used for statistical analysis. The analysis of the AE cases (N=566) revealed a concentration of diseases in Baden-Württemberg and Bavaria. Analysis based on Moran's I gave a positive spatial autocorrelation for Germany (I=0.215887, Z=33,1461, p<0.001). The prevalence for Germany in the period 1992-2017 resulted in 0.69 cases per 100,000 inhabitants. For Baden-Württemberg, the estimated prevalence was 2.42 cases and in Bavaria 1.64 cases per 100,000 inhabitants. The analysis on spatial autocorrelation and possible risk areas shows the direct neighborhood of "high-high" risk areas in the southeastern regions of Baden-Württemberg (I=0.203845, Z=11,6582, p<0.001) and in the southwestern part of Bavaria (I=0.153844, Z=11,4593, p<0.001). Striking are clusters of illnesses in the area of the Swabian Alb uplands, the Alps and the foothills of the Alps. By informing the population in high risk areas, AE cases can possibly be prevented or diagnosed at an early stage.

28

PERFORMANCE OF A POINT-OF-CARE RAPID DIAGNOSTIC TEST FOR THE SERODIAGNOSIS OF CYSTIC ECHINOCOCCOSIS IN AN ENDEMIC SETTING: A FIELD STUDY IN PERÙ

Tommaso Manciulli[1], Raffaella Lissandrin[1], Raul Enriquez Laurente[2], Ambra Vola[3], Francesca Tamarozzi[4], Annalisa De Silvestri[5], Carmine Tinelli[5], Saul Santivanez[2], Enrico Brunetti[1], Mara Mariconti[1]

[1]Department of Clinical, Surgical, Diagnostic and Pediatric Sciences, Pavia, Italy, [2]Instituto Peruano de Parasitología Clinica y Experimental, Lima, Peru, [3]Unit of Infectious and Tropical Diseases, IRCCS San Matteo Hospital Foundation, Pavia, Italy, [4]Center for Tropical diseases, Sacro Cuore-Don Calabria Hospital, Negrar, Italy, [5]Unit of Clinical Epidemiology and Biometry, IRCCS San Matteo Hospital Foundation, Pavia, Italy

Cystic Echinococcosis (CE) is a zoonosis caused by the infection with the larval stage of the dog tapeworm *Echinococcus granulosus*. 1.2 million people are estimated to be infected worldwide. Peruvian highlands are endemic for CE. Ultrasound (US) is the gold standard for the diagnosis of abdominal CE, while serology has a complementary role. However, in rural endemic areas, expertise in US is often scant and conventional serology is unavailable. We studied the performance of a commercial Rapid Diagnostic Test (RDT) (VIRapid HYDATIDOSIS - Vircell, Spain) for the serodiagnosis of CE during an US-based screening in 3 districts in the central Peruvian highlands. Of the 546 volunteers scanned by abdominal US (227 in Ondores, 213 in Corpacancha and 106 in Tomas), 37 (6.7%; 95%CI 4.8-9.2%) had CE cysts. The highest prevalence was observed in Corpacancha (13,6%). A history of surgery for CE was reported by 6% of the subjects. We found 68 cysts: 28 (41%) were active (CE1, CE2, CE3b), 8 (12%) transitional (CE3a) and 32 (47%) inactive (CE4, CE5). Blood samples were taken on the same day of US examination from 34 patients with CE cysts, 23 patients with a history of CE surgery and 57 US-negative controls matched for age and sex. Sensitivity and specificity were calculated using individuals with CE as cases and individuals with negative US exam (including those reporting past surgery for CE) as controls. RDT results were positive for 25 individuals with abdominal CE (73,5%), 8 subjects with no visible abdominal CE (14%), and 9 individuals with a history of surgery for CE (39%). Sensitivity and specificity were 73.5% and 78.8% (75% and 84.5% when subjects reporting past surgery for CE were excluded from the analysis). Although a proportion of positive serology results in subjects with negative US may be due to lung CE until proven otherwise (a chest X-ray examination is planned for these subjects), our initial findings show that the RDT we tested has a low specificity when used on field samples from an endemic area.

PHOSPHOETHANOLAMINE-N-METHYLTRANSFERASE IS A POTENTIAL BIOMARKER FOR THE DIAGNOSIS OF *PLASMODIUM KNOWLESI*, *P. FALCIPARUM* AND *P. VIVAX* MALARIA

Robert G. Krause, Dean J. Goldring

University of KwaZulu-Natal Pietermaritzburg, Pietermaritzburg, South Africa

Plasmodium knowlesi is recognised as the main cause of human malaria in Southeast Asia. *P. knowlesi* is primarily diagnosed by PCR as it is difficult to diagnose by microscopy. Prompt diagnosis and treatment of *P. knowlesi* infections is required as this species can rapidly cause severe disease. There are currently no biomarkers for antibody based rapid diagnostic tests (RDT) to detect a *P. knowlesi* infection. We aimed to identify a protein biomarker with potential for the diagnosis of *P. knowlesi*, *P. falciparum* and *P. vivax* malaria. Phosphoethanolamine-N-methyltransferase (PMT), a protein involved in malaria lipid biosynthesis and not expressed in humans was selected. Peptides on the surface of PMT that were either common (*P*LENNQYTDEGVKC) or unique to *P. knowlesi* (*Pk*LYPTDEYNSLKDC), *P. falciparum* (*Pf*CEVEHKYLHENKE) and *P. vivax* (*Pv*VYSIKEYNSLKDC) PMT were selected. Polyclonal antibodies against all of the peptides and recombinant *P. knowlesi*, *P. falciparum* and *P. vivax* PMT proteins, were raised in chickens and affinity purified. The antibodies against each recombinant PMT protein and the common PMT epitope (*P*LENNQYTDEGVKC) each detected all three recombinant proteins. Antibodies raised against unique peptides selectively detected the parent protein in western blots and in spiked blood lysates. The antibodies detected a 29 kDa protein in a *P. falciparum* culture lysate. PMT, like the pan-specific malaria LDH biomarker used in RDTs is soluble, present at similar concentrations to LDH, is essential to parasite survival and represents a promising antimalarial drug target. Unlike LDH, PMT is not present in the human proteome. PMT has the potential as a biomarker for malaria and in particular to detect *P. knowlesi* parasites.

30

A NOVEL QUANTITATIVE SUSPENSION ARRAY TOOL FOR HIGH SENSITIVE QUANTIFICATION OF HRP2 AND PLDH IN BLOOD FROM *PLASMODIUM FALCIPARUM* AND *P. VIVAX*-INFECTED PATIENTS IN PERU AND NIGERIA

Sandra Incardona[1], Xavier Martiañez Vendrell[2], Stefano Ongarello[1], Aurélien Macé[1], Freddy Alava[3], Dionicia Gamboa[3], Uche Igbasi[4], Alfons Jimenez[2], Oladosu Oladipo[4], Wellington Oyibo[4], Katherine Torres[3], Ifeoma Udenze[4], Iveth J. Gonzalez[1], Cassandra Kelly[1], Bill Rodriguez[1], Alfredo Mayor[2]

[1]FIND, Geneva, Switzerland, [2]Barcelona Institute for Global Health (ISGlobal), Barcelona Centre for International Health Research (CRESIB), Hospital Clinic - Universitat de Barcelona, Barcelona, Spain, [3]Laboratorios de Investigación y Desarollo, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru, [4]ANDI Centre of Excellence for Malaria Diagnosis, College of Medicine, University of Lagos, Lagos, Nigeria

Quantification of protein antigens is increasingly important for the assessment of ultrasensitive diagnostic tools for infectious diseases. We developed a quantitative suspension array technology (qSAT) for multiplexed quantification of HRP2 and pLDH malaria antigens in patient blood samples, and assessed its performance as part of a malaria RDT evaluation study in 4489 patients in Peru and Nigeria. Patient samples underwent on-site and off-site reference testing (with malaria RDTs, microscopy, real-time PCR, and sequencing for *Plasmodium* species determination). qSAT testing was performed on samples positive for *P. falciparum* (845/4489, 18.8%) and *P. vivax* (892/4489, 19.9%) by real-time PCR and sequencing. Analysis of HRP2 detection was conducted on Nigerian samples only because of *hrp2* gene deletions known to be prevalent in Peru. The limit of quantification of the qSAT was 7.2 pg/mL for HRP2 and 47.8 pg/mL for pfLDH. Preliminary results on 791 *P. falciparum* samples showed that the qSAT assay could detect and quantify HRP2 and pfLDH antigens in 49.0% (123/251) and 36.2% (147/406) of samples, respectively, which were PCR-positive but negative by microscopy and RDT, confirming its increased sensitivity over microscopy and RDT. When the qSAT is used as the reference method, the sensitivity and specificity of the HRP2 test line of the SD Bioline Malaria Ag Pf/Pan (Alere, USA) used in Nigeria was 70.3% [CI95%: 66.1-74.6%] and 87.2% [CI95%: 81.8-92.6%], respectively, while the panLDH test line of the Carestart Pf/PAN (pLDH) Antigen test (Access Bio, USA) used in Peru was 85.3% sensitive [CI95%: 79.7-90.1%] and 96.6% specific [CI95%: 91.9-100.0%]. This compares closely to PCR as a reference method, and confirms that this new qSAT assay can successfully be used as a reference test for detection and quantification of HRP2 and pLDH in *P. falciparum* and *P. vivax* samples. Preliminary and first-of-its-kind data also show good quantification of pLDH in *P. vivax* samples, which is extremely important given concerted efforts by the global health community to improve the sensitivity of *P. vivax* diagnostics to support elimination of all malaria species.

31

SCREENING FOR *PFHRP2/3*-DELETED *PLASMODIUM FALCIPARUM*, NON-FALCIPARUM, AND LOW-DENSITY MALARIA INFECTIONS USING A MULTIPLEX ANTIGEN ASSAY

Eric Rogier[1], Camelia Herman[1], Sophie Allen[1], Rafael Dimbu[2], Filomeno Fortes[2], Dragan Ljolje[1], Naomi Lucchi[1], Sean C. Murphy[3], Nahum T. Smith[3], Kurtis R. Cruz[3], Annette M. Seilie[3], Eric S. Halsey[1], Mateusz M. Plucinski[1], Venkatachalam Udhayakumar[1], Michael Aidoo[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]National Malaria Control Program, Ministry of Health, Luanda, Angola, [3]Department of Laboratory Medicine, University of Washington, Seattle, WA, United States

Detection of *Plasmodium* antigens from human malaria parasites has broad applications for diagnostics, surveillance, and laboratory research. A bead-based multiplex assay was developed to simultaneously detect the pan-*Plasmodium* aldolase (pAldo), pan-*Plasmodium* lactate dehydrogenase (pLDH), and *P. falciparum* histidine rich protein 2 (PfHRP2) antigens. The multiplex assay was validated against recombinant antigens and 239 mono-species malaria infections. Limit of detection for the antigens in human blood samples was determined for pAldo at 128pg/mL, Pf-pLDH at 4,425pg/mL, Pv-pLDH at 4,435pg/mL, PfHRP2(A) at 6.7pg/mL, PfHRP2(B) at 8.8pg/mL, and PfHRP2(C) at 15.8pg/mL. Samples from Angolan patients attending outpatient clinics (n=1267) were assayed, and the most common antigen profiles were PfHRP2+/pAldo+/pLDH+ (167, 36%), PfHRP2+/pAldo-/pLDH- (163, 35%), and PfHRP2+/pAldo+/pLDH- (130, 28%) with the number of detected antigens being predictive of qRT-PCR positivity and parasite density as well as patient febrile status. Of the 466 (36.8%) Angolan samples positive for any antigens, eight had either no or very low levels of PfHRP2, but were positive for pan-*Plasmodium* antigens. Molecular analysis confirmed three were *P. ovale* infections, and two represented *P. falciparum* parasites lacking *Pfhrp2* and/or *Pfhrp3*. The findings suggest HRP2-based rapid diagnostic tests are still an appropriate tool for confirmation of *P. falciparum* diagnosis in Angola. High-throughput multiplex antigen detection can inexpensively screen for low density *P. falciparum*, non-falciparum, and *Pfhrp2/3*-deleted malaria parasites to provide population-level antigen estimates and identify specimens requiring further molecular characterization.

32

CAN MEDICAL-DETECTION DOGS IDENTIFY PEOPLE WITH MALARIA PARASITES?

Steve W. Lindsay[1], Margaret Pinder[1], Chelci Squires[2], Mark Doggett[3], Benjamin J. Kasstan[1], Kate Hampshire[1], Balla Kandeh[4], Sarah Dewhirst[2], James G. Logan[5], Umberto D'Alessandro[6], Claire Guest[3]

[1]Durham University, Durham City, United Kingdom, [2]ARCTEC, London School of Hygiene & Tropical Medicine, United Kingdom, [3]Medical Detection Dogs, Milton Keynes, United Kingdom, [4]National Malaria Control Programme, Banjul, Gambia, [5]Department of Disease Control, London School of Hygiene & Tropical Medicine, United Kingdom, [6]MRC Unit The Gambia at London School of Hygiene & Tropical Medicine, Fajara, Gambia

The task of malaria elimination would be simpler if a non-invasive method was available for detecting infected individuals in populations where the parasite prevalence is low; infected individuals could then be treated with antimalarials. Dogs have a highly developed sense of smell and may be able to detect volatiles released from people carrying malaria parasites. We carried out a pilot study to determine whether trained dogs could detect malaria infections in Gambian children aged 5-13 years old. Samples of skin odour were collected from 600 school children. Samples from malaria-infected children and uninfected children were used to train medical-detection dogs in the UK. After four months of training a double-blinded study was undertaken to assess the diagnostic accuracy of the dogs. To assess the reaction of local people to medical-detection dogs, a well-disciplined dog with a 'medical-detection dog' coat was introduced to residents of a Gambian village. Focus group discussions assessed the benefits and challenges of using medical-detection dogs for malaria surveillance in Gambian villages. The results of this study will be reported at the meeting. If successful, this diagnostic approach could be used for mass screening of malaria cases at ports of entry.

33

CELL FREE DNA AS A MARKER OF CEREBRAL MALARIA

Iset M. Vera[1], Anne Kessler[2], McKenze Moss[3], Li-Min Ting[1], Visopo Harawa[4], Wilson Mandala[5], Stephen Rogerson[6], Karl Seydel[7], Kami Kim[1]

[1]University of South Florida, Tampa, FL, United States, [2]Albert Einstein College of Medicine, Bronx, NY, United States, [3]Xavier University, New Orleans, LA, United States, [4]Malawi Liverpool Wellcome Trust, Blantyre, Malawi, [5]Malawi University of Science and Technology, Thylo, Malawi, [6]University of Melbourne, Melbourne, Australia, [7]Michigan State University, Lansing, MI, United States

Cerebral malaria (CM) is a life-threatening manifestation of *Plasmodium falciparum* infection that disproportionately affects young children living in sub-Saharan African. Pediatric CM is characterized by parasitemia and coma, but additional tests are required to identify those most at risk for an adverse or fatal outcome. Retinal funduscopy, to identify malarial retinopathy (Ret+CM), and quantification of histidine rich protein 2 (Pfhrp2), a surrogate measure of total parasite biomass, assist in identifying pediatric CM cases at highest clinical risk, but are not widely available. Recent work identified cell free parasite DNA concentration in the plasma as a correlate of disease severity in children with malaria. Host neutrophils and circulating neutrophil extracellular traps, comprised of host DNA, are reported to be activated in malaria. Thus, we hypothesized that total plasma cell free DNA (host & parasite) may also correlate with CM classification. Here, we assayed the plasma of Malawian children ages 1-12 years with uncomplicated malaria (UM) (n=37) or CM (total n=61; Ret-CM n=15; Ret+CM n=46), without extraction or enrichment steps, for total cell free DNA (cfDNA) level using the Qubit 2.0 Fluorometer, a compact benchtop analyzer with high sensitivity and reproducibility. Total cfDNA in the plasma distinguishes children with UM or Ret-CM from children with Ret+CM (UM ROC: 0.85, p<0.0001; Ret-CM ROC: 0.69, p=0.03). Amongst Ret+CM cases, cfDNA differentiates fatal cases (n=7) from children with resolution of coma and clinical disease (n=39) (ROC: 0.87, p=0.02). The ability to distinguish case classifications by total cfDNA level paralleled that of Pfhrp2, and both measures were superior in distinguishing cases relative to cell free parasite DNA levels only. Current studies are underway to determine the relative contributions of host vs parasite DNA to cfDNA. As expected, plasma cfDNA level declined by 30 days post-infection. The simple methodology and high assay sensitivity suggest that Qubit plasma cfDNA quantification may be useful in identifying CM cases in field settings where resources and trained staff are highly limited.

34

AI SCOPE - OPEN SOURCE AUTOMATED MICROSCOPY USING MACHINE LEARNING FOR MALARIA DIAGNOSIS

Eduardo Peire Paredes[1], Laura Moro[1], Ramón Perez Tanoira[2], Jakub Cieslik[3], Wiebe Wagemans[1], Raminderpal Singh[4], Ernesto Salazar Sanchez[5], Maria J. Pons[6], **Antonio M. Quispe**[7]

[1]Ai Scope, Barcelona, Spain, [2]Servicio de Enfermedades Infecciosas, IIS-Fundacion Jiménez Díaz, Madrid, Spain, [3]Wrocław University of Science and Technology, Wrocław, Poland, [4]Dept of Electrical Engineering, Newcastle University, Newcastle, United Kingdom, [5]Facultad de medicina de la Universidad Nacional de la Amazonia Peruana, Loreto, Peru, [6]Universidad Científica del Sur, Lima, Peru, [7]Johns Hopkins Bloomberg School of Public Health, Lima, Peru

Access to accurate microscopy diagnosis still represents a cornerstone for delivering treatment for many global killers. Currently, machine learning reached a point where deep learning scripts (convolutional neural networks) can help to improve the accuracy of microscopy diagnosis by recognizing pathogens automatically, quickly and accurately, even with low image resolution. The study aim was to develop an open source automated microscope and assess its diagnostic accuracy for falciparum malaria. The Ai Scope was developed as an automated, low cost (under 50$), portable, user-friendly and multiplatform, do-it-yourself microscope. It was designed to allow to plug in any of the standard smartphones. The scripts were developed using deep learning frameworks TensorFlow (for the first models) and MXNet (latest version). Also, it allows further applications such as real-time surveillance, big data analytics, and telemedicine. The mobile app connects via Bluetooth to the microscope motors for slides focusing and mapping. To train the *Plasmodium falciparum* malaria deep learning script we used a total of 1,317 images from Giemsa-stained thick blood smears. Of these, we obtained 5,492 images from infected erythrocytes with ring-stage trophozoites and 5,492 images from nearby uninfected erythrocytes as controls. We randomly extracted 70% from each subset to train the neural network during 150 epochs using technics of data augmentation such as rotations and symmetries. We used the remaining 30% to assess its diagnostic accuracy of the algorithm. Compared to controls, the Ai scope correctly classified 98.2% of the positive images, with an estimated sensitivity of 97.2-98.6% (95% CI), a specificity of 97.7-98.9%, a positive predictive value of 97.6-98.9%, a negative predictive value of 97.3-98.6%, and a ROC area of 97.7-98.9%. To sum up, the Ai Scope showed promising results by diagnosing ring-stage trophozoites accurately from falciparum malaria under laboratory conditions. Further improvements will allow the Ai Scope to offer the diagnosis of other infectious diseases such as tuberculosis and diarrhea caused by intestinal parasites.

35

ASSESSMENT OF ULTRASENSITIVE DIAGNOSTICS FOR ASYMPTOMATIC MALARIA IN A HIGH TRANSMISSION AREA OF ETHIOPIA

Seble G. Demissie[1], Sindew Mekasha Feleke[2], Adugna Abera[2], Abu Naser Mohon[3], Lemu Golassa[1], Dylan R. Pillai[3]

[1]Addis Ababa University, Addis Ababa, Ethiopia, [2]Ethiopian Public Health Institute, Addis Ababa, Ethiopia, [3]University of Calgary, Calgary, AB, Canada

To accomplish malaria elimination, it is necessary to address the asymptomatic reservoir which contributes to perennial transmission. Microscopy and rapid diagnostic tests (RDT) are feasible, but they have a relatively high limit of detection. Hrp2/3 gene deletions may also contribute to false negative RDT results. Molecular methods such as polymerase chain reaction (PCR) are highly sensitive but remain too complex. There is an urgent need for ultrasensitive diagnostics able to identify low-level infections and parasites with Hrp2/3 deletions at the community level. We performed a community-based, cross-sectional study in Gambella, Ethiopia at four kebeles in the district of Abobo between November 2017 and March 2018. Individuals were screened to determine baseline medical information and epidemiological data. If afebrile, blood was collected by venipuncture in EDTA blood tubes. Two RDTs (SD Bioline PfHrp2/PfLDH and Carestart PfHrp2/PvLDH) were performed on site. Ultra-sensitive RDT (Alere PfHrp2) was also performed from stored blood samples. Dried blood spots (DBS) were collected on site and hemoglobin measured using HemoCue® HB 201+ strips. DBS was evaluated by ultrasensitive loop mediated isothermal amplification (usLAMP) and real-time PCR (RT-PCR). We collected 940 blood samples from afebrile community members. The majority were female (526, 56%), adult (676, 72%), living in rural areas (800, 85.1%) and farmers (545, 58%). Blood testing revealed that 225 (23.9%) were anemic. The prevalence of *P. falciparum* malaria among the subjects studied was 4.3% (40), 2.64% (25) and 8.1% (76) as detected by Carestart PfHrp2, SD Bioline PfHrp2/PfLDH and ultrasensitive Alere PfHrp2 RDTs, respectively. Preliminary results with usLAMP suggest 10 out 46 (21.7%) are positive for malaria. Our data demonstrate that the ultrasensitive RDT targeting PfHrp2 can detect between 1.9 to 3.1 times more cases of *P. falciparum* malaria than traditional RDTs, whereas usLAMP can detect 5.0 to 8.2 fold higher asymptomatic individuals in this high transmission setting. Current efforts are focused on completing usLAMP and RT-PCR on all specimens.

36

META-ANALYSIS OF *ANOPHELES GAMBIAE* POPULATIONS FROM ACROSS AFRICA IDENTIFIES POTENT NEW PYRETHROID RESISTANT MECHANISMS

Victoria A. Ingham, G Lycett, Simon Wagstaff, A Anthousi, Hilary Ranson

Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Vector control represents the single largest contributor to the reduction in human malaria cases since the year 2000 with pyrethroid treated bednets estimated to be responsible for nearly two thirds of the malaria cases averted. Resistance to pyrethroid insecticides is now widespread in African malaria vectors and there is increasing evidence that this is reducing the efficacy of bednets. In order to understand more about the causes and consequences of pyrethroid resistance for malaria control, we searched all available transcriptomic data on insecticide resistant populations across Africa to identify the major resistance mechanisms. Previous approaches for selecting potential resistance mechanisms have largely focused on *a priori* candidates such as those associated with insecticide detoxification. By integrating 31 geographically disparate datasets, representing collections over 5 years (2009-2014) and three species of the *Anopheles gambiae* complex, and using gene silencing to confirm the association between transcriptomics profiles and resistance phenotype we have: (a) Confirmed the association between over expression of a small subset of cytochrome P450s and pyrethroid resistance; (b) Identified novel gene families representing potent resistance mechanisms across much of Africa; (c) Identified potential transcriptional regulators of insecticide resistance; and (d) Employed correlation networks to identify putatively co-regulated transcripts and hence, elucidate transcript function. A public access, easy to use ShinyR web-based application (IR-TEx), has been developed to facilitate integration of future data on insecticide resistance and to enable the geographic distribution of resistance genes to be visualised.

37

SEXUAL SELECTION AS A POSSIBLE DRIVER OF CUTICULAR INSECTICIDE RESISTANCE IN *ANOPHELES GAMBIAE* POPULATIONS FROM WEST AFRICA

Kelsey L. Adams[1], William R. Shaw[1], Abdoulaye Niang[2], Simon Sawadogo[2], Jennifer Wang[3], Adam South[1], Maurice Itoe[1], Kristine Werling[1], Hilary Ranson[4], Abdoulaye Diabaté[2], Flaminia Catteruccia[1]

[1]Harvard University, Boston, MA, United States, [2]Insitut de Recherche en Sciences de la Santé, Bobodioulasso, Burkina Faso, [3]Harvard University, Cambridge, MA, United States, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Insecticide resistance is now widespread across Africa and threatens progress in vector control efforts against *Anopheles* mosquitoes, the vectors of malaria. Several mechanisms are known to convey insecticide resistance, including target site mutations, metabolic resistance, behavioural changes, and cuticular resistance. Cuticular resistance is characterized by a thickening of the cuticle, including an increase in the quantity of Cuticular hydrocarbons (CHCs) present in the epicuticle. Cuticular resistance has been only recently described in *Anopheles* mosquitoes, and the extent of its contributions to resistance in natural populations is not yet understood. We therefore investigate the presence of cuticular resistance in natural populations of *Anopheles* mosquitoes in Burkina Faso. Additionally, we hypothesize that an increase in CHC production may play overlapping roles with mate selection, given known roles of CHCs in mating behavior of other *Dipterans*. To address these questions, we exposed mosquitoes derived from natural breeding sites in Burkina Faso to permethrin, using time to knock-down to classify individuals into groups of high, medium, and low permethrin resistance. We measured quantities of CHCs in these mosquitoes using hexane extraction of hydrocarbon compounds followed by Gas Chromatography Mass Spectrometry. We demonstrate for the first time, to our knowledge, that higher quantities of CHCs are correlated with higher levels of insecticide resistance in natural *Anopheles* populations. We further investigate the association of CHCs with mating success by comparing CHCs of males caught in copula from natural mating swarms with CHCs of males who were not mated during the time of the swarm. We find higher levels of CHCs in mated males compared to their unmated counterparts, indicating that increased CHC production is associated with mating success, as well as insecticide resistance. This provides evidence for a sexual selection mechanism for cuticular resistance, which could greatly affect the dynamics of spread of insecticide resistance by increasing the selective pressure on resistance traits.

We describe the launch of an open, collaborative network, leveraging genome sequencing technologies to undertake coordinated surveillance of malaria vector populations. In Africa the network has two overarching goals. The first goal is to realise the use of genome sequencing as an operational tool for insecticide resistance management (IRM), providing information and tools to aid the design of optimal IRM strategies, and providing feedback on the impact of IRM implementations on vector

populations and their adaptive responses. The second goal is to accelerate the development of new vector control tools, particularly new insecticides, synergists, and gene drive systems, by providing comprehensive data on natural genetic variation, and by using genetic data to estimate key parameters needed to model vector population dynamics, particularly aestivation and migration behaviours. In Southeast Asia the goal is to survey the full taxonomic diversity of malaria vector species, and to identify and characterise the species and populations that are primarily responsible for malaria transmission in different geographical locations, especially transmission of parasites resistant to antimalarial drugs. Building on insights, technologies and best practices developed in the *Anopheles gambiae* 1000 Genomes Project, the Vector Observatory has been operating in a pilot phase since 2017, and has been establishing lab, data processing and analytical pipelines to accommodate whole genome sequencing of 10,000 mosquito specimens per year, as well as developing new sequencing technologies that can scale to larger sample sizes and be deployed to regional facilities. We give an overview of current projects and partnerships within the network, the datasets generated so far, the model for participation in the network, and the roadmap for future data generation and technology development. We illustrate the network with three case studies: (1) longitudinal sampling of *An. gambiae* complex populations in West Africa; (2) A broad geographical survey of African *An. funestus* populations; (3) A taxonomic survey of *Anopheles* species from Cambodia.

39

NOVEL SCREENING ASSAYS TO ACCELERATE THE PATH TO DELIVERY OF NEXT GENERATION VECTOR CONTROL TOOLS

Geraldine M. Foster[1], Amy Guy[1], Jay Hutchison[1], Annabel Murphy[1], Mischa Emery[1], Giorgio Praulins[1], Vitaly Voloshin[2], Christian Kröner[2], Agnes Matope[1], Jim Maas[1], David Towers[2], Hilary Ranson[1], Philip J. McCall[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]University of Warwick, Coventry, United Kingdom

The development of new vector control tools, both insecticides and methods for their delivery, is essential if the challenges of resistance and other threats to malaria control are to be met. Widespread resistance across insecticide classes and the lengthy screening pipeline for new chemistries mean that rapid, accurate and informative assays to supplement or replace existing evaluation methods are urgently needed. We are developing a suite of bioassays incorporating human bait, ranging in scale from bench top (*e.g.* simple wind tunnel, modified cone tests, thumb tests) to room scale (video tracking at whole LLINs), to explore and quantify detailed behavioral responses to vector control products. Early results using pyrethroid susceptible and resistant *An. gambiae* in various bench top assays showed that behavior at untreated netting and LLINs (PermaNet® 2.0, Olyset) was not altered by insecticide susceptibility status. Without access to bloodfeed, mosquitoes mainly rested on nets, with some 'bouncing' (multiple rapid brief contacts) and probing. When allowed to bloodfeed through nets, feeding duration was reduced significantly on LLINs compared to untreated nets, in both susceptible and resistant strains. A modified WHO cone test that video records responses to a host demonstrated that mildly repellent effects seen with some net treatments, are overridden by the presence of the host, whether or not feeding is permitted. Since resistant populations of *An. gambiae s.l.* are now the norm across Africa, we have been exploring impacts of insecticides beyond 24-hrs post-exposure, by examining possible sub-lethal impacts on longevity, reproductive output and re-feeding rates in 'resistant' strains (as defined by WHO tests). Data and video from this suite of assays allows characterization of a wide and complex range of behavioral responses and consequences of mosquito exposure to, and interaction with, vector control products and illustrate their potential to provide meaningful data far beyond what is currently possible using existing standard assays.

40

COPY NUMBER VARIATION AND INSECTICIDE RESISTANCE IN *ANOPHELES GAMBIAE*

Eric R. Lucas[1], Emily J. Rippon[1], Alistair Miles[2], Nicholas J. Harding[2], Mara K. Lawniczak[3], Dominic P. Kwiatkowski[3], David Weetman[1], Martin J. Donnelly[1], Ag1000G Consortium[3]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Big Data Institute, Oxford, United Kingdom, [3]Wellcome Trust Sanger Institute, Hinxton, United Kingdom

Metabolic resistance in the form of increased expression of detoxification genes underlies much of the insecticide resistance observed in mosquito populations, yet the causal genetic variants for these differences remain poorly characterised. Using data from the *Anopheles gambiae* 1000 Genomes project, we have described 44 duplications found in four major detoxification gene clusters (GSTU4-GSTE3, CYP9K1, CYP6M2-CYP6Z1 and CYP6AA1-CYP6P2), with 10 of the 11 independent duplications in the GSTU-GSTE cluster encompassing GSTE2 and 13 out of the 15 independent duplication in the CYP6AA-CYP6P cluster encompassing CYP6AA1. We designed molecular assays, based on the duplication breakpoints to test for the presence of duplications in a wide range of recently collected samples. We found that some of these duplications have risen sharply in frequency, suggesting a response to selection by insecticide pressure.

41

MUSCARINIC ACETYLCHOLINE RECEPTORS AS A TARGET FOR RESISTANCE-BREAKING INSECTICIDE DEVELOPMENT

Aaron D. Gross[1], Paul R. Carlier[1], Jeffrey R. Bloomquist[2]

[1]Virginia Polytechnic Institute and State University, Blacksburg, VA, United States, [2]University of Florida, Gainesville, FL, United States

Widespread insecticide resistance amongst insect pests establishes a need for new insecticides with unique modes of action. Insects are known to possess muscarinic acetylcholine receptors (mAChRs), and muscarinic agonists are effective insecticides, but suffer from high mammalian toxicity. Of the three types of mAChRs in insects (A, B, and C), type-B activation is thought to decrease levels of cAMP and is pharmacologically distinct, having little sensitivity to the classical mAChR antagonist, atropine. Recently, we've identified a novel pyrazole oxime (747) that is toxic to *An. gambiae* (WHO paper assay LC_{50} = 0.122 mg/mL), has low toxicity to mice (oral LD_{50} > 2,000 mg/kg), and shares some structural similarity to pilocarpine, a non-selective mAChR agonist. Pilocarpine and 747 also shared similar signs of intoxication in mosquitoes, which include lethargic movement and loss of flight behavior. Pilocarpine toxicity was antagonized by atropine injection, whereas 747 toxicity was not. Consequently, we hypothesized that 747 affects the insect mAChR-B receptor. Exposure of a larval *Drosophila melanogaster* CNS preparation to 10 µM 747 resulted in a biphasic effect on the CNS firing rate; a slight increase followed by a nearly complete inhibition of nerve discharge. Neither effect was blocked by atropine. Whereas, pilocarpine's (10 µM) biphasic effect on CNS nerve firing, with strong initial neuroexcitation, was sensitive to atropine.. In addition to the electrophysiology preparations, biochemical assays using cockroach nerve cord showed that 747 (10 µM) resulted in a significant decrease in the production of forskolin-stimulated cAMP, and this effect was insensitive to atropine (100 µM). The insect mAChR-B is an attractive target for mosquitocide development that warrants further investigation.

42

NOVEL MICROBIAL CANDIDATE MARKERS OF PYRETHROID RESISTANCE IN *ANOPHELES ALBIMANUS*, A MAJOR LATIN AMERICAN MALARIA VECTOR

Nsa Dada[1], Juan C. Lol[2], Ana C. Benedict[2], Francisco López[2], Mili Sheth[1], Norma Padilla[2], Audrey Lenhart[1]

[1]United States Centers for Diseases Control and Prevention, Atlanta, GA, United States, [2]Centro de Estudios en Salud, Universidad del Valle de Guatemala, Guatemala City, Guatemala

A deeper understanding of the biological mechanisms underlying insecticide resistance in malaria vectors is needed to mitigate its threat to vector control efforts. Our previous findings identified links between *Anopheles albimanus* microbiota and resistance to the organophosphate insecticide fenitrothion. We have now characterized the microbiota of *An. albimanus* with differing pyrethroid resistance profiles across four locations in Guatemala using 16S rRNA gene sequencing. We focused on identifying patterns of microbial composition across mosquitoes expressing susceptibility or resistance to alphacypermethrin, deltamethrin and permethrin, in both larvae and adults. F1 progeny of wild-caught mosquitoes from each location were reared separately under identical conditions, and characterized using the CDC bioassay as resistant (Res), susceptible (Sus) or unexposed to insecticide (Unexp). This resulted in 44 pools of late instar larvae and 45 pools of 2-5day old non-blood-fed virgin adult females - 3 mosquitoes/pool, 3 pools/category, with all insecticides tested in at least one location. Differential microbial compositions (p<0.05), mostly driven by type of insecticide (R2=0.51), were identified between Res, Sus and Unexp, for all three insecticides, in both larvae and adults, and across each location tested. With more than five-fold greater abundance in Res compared to any other category (p<0.05), *Klebsiella* (alphacypermethrin and deltamethrin), *Asaia* and *Pantoea* (permethrin) were identified as candidate markers associated with resistance in adults but not in larvae, suggesting the presence of transient microbiota in larvae. These results build upon our initial findings and identify candidate microbial markers of pyrethroid resistance in adult *An. albimanus* that are being functionally validated. The results also suggest a specificity of candidate microbial markers within the pyrethroid class of insecticides.

43

SPATIOTEMPORAL MODELLING OF PREVALENCE OF *PLASMODIUM FALCIPARUM* DRUG RESISTANCE MUTATIONS IN THE *DHPS* GENE ACROSS AFRICA, 1990 - 2015

Georgina S. Humphreys[1], Jennifer Flegg[2], Annemieke van Eijk[3]

[1]WorldWide Antimalarial Resistance Network, Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine, University of Oxford, UK, Oxford, United Kingdom, [2]School of Mathematics and Statistics, University of Melbourne, Melbourne, Australia, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Despite global efforts to control and prevent malaria, it remains one of the most important global public health issues. Large-scale prevention programmes include intermittent preventive treatment for pregnant women (IPTp) using sulfadoxine-pyrimethamine (SP), and Seasonal Malaria Chemoprevention (SMC) with monthly courses of amodiaquine plus SP to all children under 5 years in the high transmission season in areas of the Sahel sub-region of Africa. Molecular surveillance of mutations in the *pfdhps* gene can guide the assessment of the effectiveness of IPTp. This study updated previously developed geospatial maps displaying the published evidence of the prevalence of *dhps*540E, a marker associated with resistance to SP. To update these maps a systematic literature search was conducted to identify publications with data on *dhps*K540E genotype and/or haplotype combined with other alleles from *P. f* pre-treatment isolates, study year and geo-position in publications up to 2017. Data were extracted from the publications and entered into a standardised relational database. In total, we used 366 data points (42514 samples) collected between1978-2015 across 41 countries and 253 sites. The data was used in a Bayesian model based geostatistics approach to create predictive distributions of the prevalence of *dhps*K540E in Africa from 1990 to 2015. These predictive maps provide predicted resistance levels in places where no data are available and give insight on the spatial and temporal spread of resistance in a way that the data alone do not allow. The maps present the changing spatio-temporal prevalence patterns across Africa. Interestingly, despite SP use in IPTp and SMC, the prevalence of dhps540E is remarkably stable from 2010-2016. In East Africa, although SP has not been widely used as a treatment regimen for many years now we do not see a return to the wildtype population. There is reduced drug pressure on the parasite population but the prevalence of this resistance marker remains high, confirming other studies that suggest the mutation does not confer a high fitness cost for the parasite.

44

TRAVEL PATTERNS OF PATIENTS WITH MALARIA IN THE GREATER MEKONG SUBREGION AND NEIGHBORING COUNTRIES IN SOUTH ASIA

[1]Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [2]Wellcome Trust Sanger Institute, Hinxton, United Kingdom, [3]Chittagong Medical College, Chittagong, Bangladesh, [4]Dev Care Foundation, Dhaka, Bangladesh, [5]Harvard TH Chan School of Public Health, Harvard University, Boston, MA, United States

Malaria elimination is an important public health goal for countries in the Greater Mekong Subregion (GMS), Bangladesh and India. In the GMS, the reported number of malaria cases has declined by 74% and deaths by 91%. However, malaria hotspots persist in remote rural and forested areas close to border regions, with disproportionate representation of migrant and marginalized communities. Dihydroartemisinin-piperaquine resistance first noted in Cambodia has also been reported in Southern Vietnam. We hypothesize that dissemination of malaria and anti-malarial drug resistance could take place through migration. From August 2015, we have interviewed 4469 patients with malaria from over 150 study sites and obtained information on demographics and travel patterns (including travel to forests). These were combined with census and surveillance data from the national malaria control programmes. Dried blood spots were also collected to examine malaria parasite DNA. Of the 4469 patients collected so far, 48% of cases are from Bangladesh primarily through the Bangladesh Genotype Mobility study, and the rest are from ongoing studies (Lao PDR: 21%, Cambodia: 13%, Vietnam: 10%, India: 6%, Myanmar: 2%, and Thailand: 1%). Of the study population, *Plasmodium falciparum, vivax* and mixed infections were at 74%, 20% and 5% respectively. 71% were males, median age was 29, with 1% of children under 5 and 14% aged 5 to 15 years. 85% of cases reported having traveled, and over 64% reported having lived in or visited the forest. Travel patterns were further analyzed to identify mobile population groups, nodes of high traffic and possible sources and routes of spread of malaria. Travel was heterogeneous across demographic groups and spatially from village up to inter-country level, determining risk groups at coarse and fine scales. We aim to collect and analyze data from at least 5000 cases by end of this malaria season. Through working in close partnership with national programs and health workers, this improved understanding of the impact of population movement aims to inform elimination efforts in the region.

45

CLUSTERING OF SUBPATENT *PLASMODIUM FALCIPARUM* AND *P. VIVAX* INFECTIONS AROUND PATIENTS IN A LOW-ENDEMIC SETTING AIMING FOR ELIMINATION: BATU DEGAGA KEBELLE, ADAMA WOREDA, OROMIA, ETHIOPIA

Fitsum G. Tadesse

Armauer Hansen Research Institute, Addis Ababa, Ethiopia

The heterogeneous distribution of infections in settings aiming for malaria elimination challenges finding and treating all relevant infections. In this study we carried out a reactive active case detection: family members and immediate six neighbors of index cases (patients with RDT-confirmed malaria) and controls (who visited the health facility for non-malaria cases) for malaria using RDT and quantitative PCR between October and December 2016 in Batu Degaga kebelle, Adama Woreda, Oromia, Ethiopia. Overall parasite prevalence was 9.7%(90/931) by RDT and 24.0%(218/907) by qPCR. qPCR-detected *Plasmodium falciparum* (*Pf*) infection prevalence was higher in the community surrounding index cases (13.9%) compared to controls (9.5%; *P*=.038) while there was no difference for *P. vivax* (*Pv*) (*P*=.926). Four geographically non-overlapping hotspots of any malaria cases with relative risk of 2.11, 1.90, 1.89 and 1.86 were detected (within 280-590meters radius) using SaTScan. Self-reported previous malaria episodes were higher in individuals who lived within risk areas compared to outside risk areas (33.1%, 177/233 vs 1.5%, 3/203; odds ratio[OR], 32.9; 95% CI, 10.2–106.3). Family members who live in households with ≥1 RDT-confirmed *Pf* individual were considerably more likely to have qPCR-detected *Pf* infection (32.4%, 11/34) compared to individuals in households without RDT-detected infection (5.9%, 47/795; OR, 7.6; 95% CI, 3.5–16.5; *P*<.001). Similar findings were found for *Pv;* (25.0%, 17/68) vs (11.8%, 94/795; OR, 2.5; 95% CI, 1.4–4.5; *P*<.0045), respectively. Outdoor activities (staying outside late in the evening and leaving early morning) and presence of eave opening were found associated with malaria risk. Data on relatedness of infections within and between households is being assessed using microsatellite markers and will be completed in the coming months. The findings in the present study indicate that subpatent infections are clustered around patients that present to health facilities and detected by standard diagnostics. This suggests that interventions targeted to index case households may support malaria elimination initiatives.

46

BIAS IN ROUTINELY COLLECTED MALARIA SURVEILLANCE DATA DUE TO ASYMPTOMATIC INFECTIONS ACCORDING TO TRANSMISSION INTENSITY (A PROXY FOR PROTECTIVE IMMUNITY): A POOLED ANALYSIS OF PAIRED HEALTH SYSTEM AND COMMUNITY CROSS-SECTIONAL SURVEY DATA

Gillian H. Stresman[1], Kimberly Fornace[1], Jordi Landier[2], Andre Siqueira[3], Jacklin Mosha[4], Fitsum Tadesse[5], Shunmay Yeung[1], Umberto D'Alessandro[6], Effie Espino[7], Chris Drakeley[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Shoklo Malaria Research Unit, Mae Sot, Thailand, [3]Fundação Oswaldo Cruz, Rio De Janeiro, Brazil, [4]National Institute for Medical Research (NIMR), Mwanza Medical Research Centre, Mwanza, United Republic of Tanzania, [5]Radboud University Medical Centre, Nijmegen, Netherlands, [6]Medical Research Council - Gambia Unit, Fajara, Gambia, [7]The Research Institute for Tropical Medicine, Manila, Philippines

Routinely collected health systems data is the foundation of most malaria programs, both to estimate burden and to inform control and elimination programs. However, in some communities, the prevalence of infected individuals that do not seek care due to being asymptomatic can be significant. Immunity acquired with repeated exposure modifies the probability that a person will become symptomatic. Therefore, the proportion of infected individuals at any given time that will become symptomatic is expected to be modified according to transmission intensity. The aim of this research was to determine the relationship between the proportion of all infections in the community that are identified within the health system and transmission intensity, as a proxy for levels of protective immunity present in the community. Paired community and health system data in both time and space were collected from 282 clusters in 9 countries. The proportion of infections detected in the health system was estimated by the quotient of the number of infections detected at the facility and the total number of PCR confirmed infections in the community and those detected in the facility. The proportion was modeled according to transmission intensity, measured by overall population prevalence by fitting a linear relationship on the log odds scale using Bayesian Markov Chain Monte Carlo methods to account for differences in health systems and other key factors across the clusters. Preliminary results indicate that the proportion of infections reported by the health system starts to increase when overall malaria prevalence in the community is 5.9% to a maximum of 100% of infections. These findings suggest that in elimination settings, health systems can be relied upon to detect most malaria infections in a community once overall prevalence is sufficiently low.

47

ANTENATAL CLINIC SURVEILLANCE FOR MALARIA ACCURATELY REFLECTS COMMUNITY MALARIA INFECTION PREVALENCE IN A HIGH TRANSMISSION SETTING IN WESTERN KENYA

Aaron M. Samuels[1], Titus K. Kwambai[2], Brian Seda[3], Oliver Towett[3], Allen Hightower[4], Phelix Jangu[3], Isabella Nyang'au[5], Oscar Odunga[5], Samwel Onditi[5], Abdi Mohamed[6], Duncan Earle[7], Laurence Slutsker[7], Richard Steketee[7], Simon Kariuki[3], Meghna Desai[1], Feiko ter Kuile[8]

[1]Centers for Disease Control and Prevention-Kenya, Atlanta, GA, United States, [2]Kenya Ministry of Health, Liverpool School of Tropical Medicine, Kisumu, Kenya, [3]Kenya Medical Research Institute, Kisumu, Kenya, [4]Contractor, Bangkok, Thailand, [5]PATH, Kisumu, Kenya, [6]PATH, Lusaka, Zambia, [7]PATH, Seattle, WA, United States, [8]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Surveillance systems in malaria endemic countries rely on passive detection of laboratory confirmed cases presenting to outpatient health facilities, community health workers, or other monitored outlets. In areas where many infections do not result in clinical symptoms, such as western Kenya where >75% of infections are asymptomatic, this strategy likely does not reflect community transmission dynamics. Community-based cross-sectional studies may provide more accurate estimates of infection, but are not scalable due to cost. Where antenatal care (ANC) attendance is high (>90% in western Kenya), pregnant women may serve as an easy access group as they are routinely screened for malaria during their first ANC visit. We compared 11 months of malaria prevalence data collected through a continuous community-based cross-sectional survey to test positivity rates in women attending first ANC visits collected from routine ANC records, to assess this population as a proxy for community malaria prevalence. Between April 2015 and June 2016 there were 998 first ANC booking visits with RDT results in the 5 health facilities, representing 10 geographic sub-locations. Of these, 110 (11.0%; 95% Confidence Interval [CI]: 9.2–13.1%) were RDT positive, with a test positivity rate range by sub-location of 2.5–20.3%, and by month of 3.8–15.5%. In the same geographic sub-locations over this period, 2108 individuals of all ages were tested for malaria by RDT in cMIS, and 436 (20.7%; 95% CI: 19.0–22.5%) were positive. Prevalence in cMIS by sub-location ranged from 12.3–39.5%, and by month from 8.5–28.4%. The Pearson correlation coefficient between ANC surveillance and cMIS by sub-location was 0.84 (p= 0.0098), and by time was 0.69 (p=0.025). We found a strong correlation between malaria RDT test positivity rate amongst women attending their first ANC booking visit and community malaria infection prevalence estimated by cMIS when comparing proportions over time and by geographic location. This

suggests that in this area with a high first ANC coverage rate, pregnant women may present a sustainable proxy for trends in population malaria infection prevalence.

48

WHAT PROPORTION OF MALARIA CASES IN AFRICAN CHILDREN RECEIVE EFFECTIVE TREATMENT?

Ursula Dalrymple, Ewan Cameron, Peter W. Gething

University of Oxford, Oxford, United Kingdom

Understanding the proportion of malaria infections that receive and adhere to effective treatment and are subsequently cured is vital for measuring progress in lowering the burden of malaria. Using household survey datasets for over 170,000 children over the past decade, we extract information on two-week malaria positivity and fever and treatment history. By coupling this data with a predictive model to distinguish between fevers attributable to malaria and fevers caused by non-malarial febrile illness (NMFI), we estimate the proportion of malaria infections that are removed from the surveyed population by effective treatment. Further, we estimate the proportion of malaria-positive fevers that would not be cured by effective treatment due to co-infections with NMFI, and estimate the rate of inappropriate treatment of NMFI with antimalarial medication. We quantify the proportion of individuals within the household surveys whose infections are not removed as an individual passes through each stage between infection and cure: i) their infection is asymptomatic, ii) they do not seek treatment, iii) they do not receive an antimalarial at the health facility they visit (and the proportion of individuals who receive a parasite-based diagnosis in-clinic), iv) they are non-adherent to the prescribed antimalarials, and v) the treatment fails. By adding quantitative information to the reasons why infections remain untreated, we measure the achievements of malaria interventions through time and identify coverage gaps where further interventions should be targeted.

49

ETHIOPIA: ASSESSMENT OF MALARIA TRANSMISSION DYNAMICS USING MULTIPLEX SEROLOGICAL ASSAY

Ashenafi Assefa[1], Ahmed Ali[2], Wakgari Deressa[2], Heven Sime[1], Amha Kebede[3], Moges Kassa[1], Hiwot Teka[4], Hiwot Solomon[5], Jackie Cook[6], Lorenz Von Seidlein[7], Joseph Malone[8], Brian Wakeman[9], Ya Ping Shi[9], Chris Drakeley[6], Eric Rogier[9], Jimee Hwang[8]

[1]Ethiopian Public Health Institute, Addis Ababa, Ethiopia, [2]Addis Ababa University, Addis Ababa, Ethiopia, [3]African Society for Laboratory Medicine, Addis Ababa, Ethiopia, [4]U.S. President's Malaria Initiative, United States Agency for International Development, Addis Ababa, Ethiopia, [5]Federal Ministry of Health, Addis Ababa, Ethiopia, [6]London School of Hygiene & Tropical Medicine, London, United Kingdom, [7]MORU, Mahidol University, Bangkok, Thailand, [8]U.S. President's Malaria Initiative, Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, [9]Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States

Serological methods are increasingly utilized to estimate malaria transmission in low transmission settings. Malaria burden measures using conventional diagnostic methods in cross-sectional household surveys may incompletely detect the intensity and pattern of malaria transmission over time. This study describes the seroprevalence and pattern of malaria transmission in Ethiopia. Dried blood spot (DBS) samples collected during the Malaria indicator Survey 2015 representing malarious areas of Ethiopia were analysed with bead-based multiplex assays for IgG antibodies to 12 *Plasmodium* spp. antigens. Species-specific responses to MSP1 antigens were used to estimate the seroprevalence for the four human malaria species (*Plasmodium falciparum, P. vivax, P. malariae and P. ovale*). Frequency of seropositivity and seroconversion rates were fitted to models stratified by altitude and administrative regions. Of 8045 DBS samples collected, 7961 serological results were available for analysis. The mean age of participants was 14.8 years (95% CI: 14.7-17.3); 4197 (52.7%) participants were female. National seroprevalence was 26.4 % (95% CI: 25.5-27.5) for *P. falciparum* and 20.6% (95% CI: 19.7-21.5) for *P. vivax*. Estimated seroprevalences for *P. malariae* and *P. ovale* were 3.7% (95% CI: 3.3-4.2) and 1.1% (95% CI: 0.9-1.4), respectively. Seroprevalences were higher at lower altitudes (<2000m) compared to higher altitudes (2000-2500m); OR 2.2 (95% CI: 1.8-2.6) and 1.3 (95% CI: 1.1-1.6) for *P. falciparum* and *P. vivax*, respectively. Among Regions, the *P. falciparum* seroprevalences ranged from 41.4% (95% CI: 36.3-46.8) in Benishangul-Gumuz to 3.6% (95% CI: 0.9-13.3) in Harari Region. For *P. vivax,* the seroprevalence ranged from 37.0% (95% CI: 33.7-40.3) in Amhara to 3.1% (95% CI: 2.0-4.6) in Somali Region. Models fitted to measure transmission patterns show variability by regions, antigen type and within species. Using serology, this study explored the cumulative malaria burden in Ethiopia and the use of multiplex assay on multiple antigens in a low transmission setting as a more sensitive biomarker using samples collected in a national survey.

Although traditionally considered a benign condition, increasing evidence suggests that loiasis (caused by the filarial nematode *Loa loa*) poses a significant public health burden to the c.10 million infected individuals across Central Africa. Recent results have demonstrated a significant impact of high microfilaraemia on mortality, as well as an association between infection and severe cardiac, renal and neurological conditions, in addition to the more common "eyeworm passage" and "Calabar swellings". Mathematical models provide useful tools with which to understand and quantify the population biology and transmission dynamics of filariases, providing a rigorous framework to evaluate and compare different control strategies. We have previously presented a review of *Loa loa* biology and epidemiological dynamics, and here we build on this foundation to develop and parameterise a (deterministic) model of loiasis transmission and control (EPILOA). EPILOA was fitted to infection intensity (microfilariae/ml) data from Cameroon to estimate how exposure to infection varies with host age and sex. After capturing the demographic profiles of infection observed, EPILOA was used to explore the impact of strategies aimed at controlling *Loa loa*, centred around the delivery of anthelmintics. This model provides, for the first time, a means to inform the design and evaluation of interventions directly targeting this neglected but important disease (rather than as a collateral benefit of treating onchocerciasis and/or lymphatic filariasis). This work highlights the significant impact that programmes targeting loiasis directly could have on improving the health of millions across Central Africa, indicates operational research gaps (such as the potential impact of vector control), and identifies the pressing need for a better understanding of key aspects of *Loa loa* lifecycle and population biology.

COMMUNITY TEST AND NOT TREAT (TANT), A COST-EFFECTIVE STRATEGY FOR THE ELIMINATION OF ONCHOCERCIASIS IN CENTRAL AFRICA

Joseph Kamgno[1], Hugues Nana-Djeunga[2], Sebastien Pion[3], Cédric Chesnais[3], Guy-Roger Njitchouang[2], Philippe Nwane[2], André Domche[2], Edgard Ndjomo-Andjembe[2], Wilma Stolk[4], Daniel Fletcher[5], Charles Mackenzie[6], Amy Klion[7], Thomas Nutman[7], Michel Boussinesq[3]

[1]Filariasis Research Center and Faculty of Medicine and Biomedical Sciences University of Yaounde I, Yaounde, Cameroon, [2]Centre for Research on Filariasis and other Tropical Diseases, Yaounde, Cameroon, [3]IRD UMI 233-INSERM U1175-Montpellier University, Montpellier, France, [4]Department of Public Health, Erasmus MC, University Medical Center, Rotterdam, Netherlands, [5]Department of Bioengineering, University of California, Berkeley, CA, United States, [6]NTDs Support Center, Task Force for Global Health, Atlanta, GA, United States, [7]Laboratory of Parasitic Diseases, National Institutes of Allergy and Infectious Diseases, Bethesda, MD, United States

Thirty-one years after the discovery of the effect of ivermectin on onchocerciasis, this drug has substantially reverted the severity of onchocerciasis in endemic countries. The success of onchocerciasis control, especially in African countries, is the result of the Community Directed Treatment with Ivermectin (CDTI). With this success, the paradigm has shifted from the elimination as a public health concern to complete elimination of this blinding disease. Therefore, mass treatment previously indicated for meso- and hyper-endemic communities should now be also distributed in hypo-endemic communities. Despite the success of CDTI, the extension of treatment in hypo-endemic areas remains a great challenge in Central Africa where loiasis is endemic and where mass ivermectin distributions were proscribed by fear of the occurrence of Severe Adverse Events (SAEs). Indeed, subjects heavily infected with *Loa loa* can develop severe encephalopathies after treatment with ivermectin. To overcome this difficulty, a new strategy (TaNT) was developed to help preventing SAEs. To reduce the costs of this intervention and to render this strategy operational, a community TaNT was developed, based on the CDTI model, with a duo of a blood drawer and a LoaScopist to perform the test prior treatment by Community Drug Distributors (CDDs) in each community. This strategy was implemented in the Soa Health District in Cameroon, known to be hypoendemic for onchocerciasis and endemic for loiasis. Adverse Events (AEs) surveillance was done by the research team. A total of 36,070 subjects were tested and 27,596 treated by the community team. Treatment coverage was 45.9%, ranging between 34.4% and 78.5%. A total of 226 (0.6%) were excluded from ivermectin treatment because of high Loa mf loads. During the campaign, 189 (1.3%) complained of AEs. This study reveals that after only two days training, the community team has been able to conduct the TaNT strategy, and importantly no SAE case was recorded. This strategy appears as a viable alternative strategy to accelerate onchocerciasis elimination wherever it is endemic.

52

ASSESSING HYPOENDEMIC ONCHOCERCIASIS IN *LOA LOA* ENDEMIC AREAS OF SOUTHEAST NIGERIA

Lindsay Rakers[1], Emmanuel Emukah[2], Barminas Kahansim[3], Bertram E. Nwoke[4], Emmanuel S. Miri[3], Emily Griswold[1], Emmanuel Davies[5], Cephas Ityonzughul[3], Frank O. Richards[1]

[1]The Carter Center, Atlanta, GA, United States, [2]The Carter Center, Owerri, Nigeria, [3]The Carter Center, Jos, Nigeria, [4]Imo State University, Owerri, Nigeria, [5]Federal Ministry of Health, Abuja, Nigeria

Nigeria has a new national plan for onchocerciasis that moved its objective from control to transmission elimination. Under the control program, ivermectin mass drug administration (MDA) focused on hyper/meso-endemic local government areas (LGAs) designated by Rapid Epidemiological Mapping of Onchocerciasis (REMO) to have ≥20% nodule rates. The new elimination paradigm requires MDA be expanded into hypoendemic LGAs; WHO has suggested MDA where OV-16 antibody rates in adults are ≥2%. Southern Nigeria is coendemic for *Loa loa* and onchocerciasis; if a person has high density *L. loa* microfilaremia (HDLLMF), treatment with ivermectin can cause central nervous system adverse events (CNS-AEs). The country is faced with the challenge of determining 1) if there is onchocerciasis transmission in the untreated *Loa loa* endemic LGAs, and 2) if so, whether MDA can be given there with low risk due to absence of HDLLMF. Our study took place in 2016, in 19 LGAs likely to have onchocerciasis due to their proximity to hyper- or mesoendemic (MDA treated) LGAs. In 110 villages in these LGAs, 50 adults and 50 children (aged 5-10) were tested for HDLLMF by LoaScope and onchocerciasis antibody using an OV-16 rapid diagnostic test (RDT). In a subset of the sample, a blood spot was also taken for confirmatory OV-16 ELISA. The mean prevalence of RDT positives was 0.5% in the 5,401 children sampled (village range 0.0 - 6.0%) versus 3.2% in the 5,355 adults sampled (village range 0.0 - 58.0%). Five LGAs had no RDT positives. Preliminary blood spot results (600 analyzed so far out of 2,200) indicate 96.8% concordance between the OV-16 RDT and ELISA. Combining these results with a previously reported LoaScope assessment showing no HDLLMF, we analyzed our data by proposing MDA at three possible OV-16 thresholds: ≥1% in children, ≥1% of adults (as proposed by WHO), or ≥2% of adults. Each of these yields a different treatment subset of the LGAs tested: 4 (21%), 9 (47%) or 3 (16%) of the 19 LGAs, respectively. If children and adults (≥1%) are both used, 10 LGAs (53%) should be treated.

53

ENVIRONMENTAL FACTORS ASSOCIATED WITH LOIASIS HOTSPOTS IN CAMEROON

Xavier Badia[1], Hannah Betts[1], David Molyneux[1], Samuel Wanji[2], Mark Taylor[1], **Louise A. Kelly-Hope**[1]

[1]Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Department of Microbiology and Parasitology, Faculty of Science, University of Buea, Buea, Cameroon

Loiasis is a vector-borne filarial nematode caused by *Loa loa* and transmitted by *Chrysops* vectors, which are confined to the tropical forests of Central and West Africa. Loiasis is a major impediment to lymphatic filariasis and onchocerciasis elimination programmes due to severe adverse events associated with ivermectin mass drug administration. There is an urgent need to better refine and map high-risk loiasis communities to enable the deployment of new diagnostics and alternative treatment strategies. Understanding the ecology of vectors and factors driving high transmission may help to identify loiasis hotspots. The availability of satellite and remote sensed data provided an opportunity to examine environmental factors associated with *L. loa* prevalence (%) and intensity (mf/ml) in Cameroon. Georeferenced data from 42 villages across five zones within two distinct bio-ecological regions were examined; Equatorial Rainforest in South-West region (deciduous equatorial rainforest; dense-humid equatorial rainforest) and the Savannah in North-West region (grassland savannah, mosaic forest savannah; forested savannah). Using qGIS software, annual precipitation, annual mean temperature, elevation, tree cover and canopy height were extracted from raster maps using a 3km village buffer. Overall temperature (r=0.51 %; 0.41 mf/ml) and tree cover (r=0.48 %; 0.41 mf/ml) were significantly positively correlated and elevation (r=-0.51 %; -0.41 mf/ml) negatively correlated with both *L. loa* prevalence and intensity. Within the Savannah region, significant differences between the three zones 20-50km apart were found, and a linear regression model indicated tree cover and elevation were important predictors explaining 75.9% of the variance in the model for *L. loa* prevalence, and tree cover explaining 57.1% for *L. loa* intensity in this region. Similar results were found between villages 2-5km apart within the high-risk forested zone in this Savannah region. The study highlights that

environmental analysis can help delineate risk at different geographical scales, which may be practical for developing larger scale operational plans.

54

VALIDATION OF THE LOA ANTIBODY RAPID TEST (LART), A NOVEL RAPID DIAGNOSTIC TEST (RDT) TO REFINE LOIASIS MAPPING

Narcisse Nzune Toche[1], Hugues Nana Djeunga[1], Marco Biamonte[2], Yannick Niamsi Emalio[1], Kisito Ogoussan[3], Maria Rebollo[4], Joseph Kamgno[1]

[1]Centre for Research on Filariasis and other Tropical Diseases (CRFilMT), Yaoundé, Cameroon, [2]Drugs & Diagnostics for Tropical Diseases (DDTD), San Diego, CA, United States, [3]NTDs Support Center, Task Force for Global Health, Atlanta, GA, United States, [4]Expanded Special Project for Elimination of Neglected Tropical Diseases (ESPEN), WHO-AFRO, Brazzaville, Republic of the Congo

The elimination of onchocerciasis using ivermectin preventive chemotherapy is contraindicated in areas of Loa co-endemicity due to the risk of severe adverse events. In onchocerciasis hypo-endemic areas, the only alternative is a Test-and-Not-Treat (TaNT) strategy, where each individual is tested for *Loa* microfilaremia to assess their eligibility for ivermectin. This strategy, though successfully implemented in Cameroon with the LoaScope, is expensive and hardly scalable. High resolution maps of *Loa* are needed to minimize the areas where the TaNT approach must be deployed. The Loa Antibody Rapid Test (LART) is a novel lateral flow assay that detects a serological response to Ll-SXP-1, a validated marker of *L. loa*. The present study aimed at validating the performance of this new RDT for *Loa loa* infections using field data. A total of 924 dried blood spots (DBS) were collected in nine Cameroonian ivermectin naïve communities with different levels of *L. loa* endemicity. LoaScope data was available for all individuals and used as gold standard. The DBS were eluted and analyzed with the LART. The intensity of the test lines was visually quantified, by comparing the test line with a printed score card. Based on the Youden index, the optimal cut-off was set at 6, and the resulting sensitivity and specificity were 79.6% (72.2 - 87.1) and 76.3% (73.4 - 79.2), respectively. A strong correlation was observed between seroprevalence and mf prevalence (OR: 12.54; 95%CI: 7.62 - 21.40; $p<0.0001$), with the seroprevalence being approximately 4 times higher than the mf prevalence. Overall, 39% of the people who were amicrofilaremic responded to the LART. The data suggests that the Loa Antibody Rapid Test can be used to draw high resolution maps of *L. loa* infection and set a seroprevalence threshold above which the communities should be excluded from MDA and adopt the TaNT strategy.

55

IMPACT OF REPEATED ANNUAL IVERMECTIN MASS DRUG ADMINISTRATION ON LOIASIS PARASITOLOGICAL INDICATORS IN CAMEROON: IMPLICATIONS FOR ONCHOCERCIASIS AND LYMPHATIC FILARIASIS ELIMINATION IN AREAS CO-ENDEMIC WITH *LOA LOA* IN AFRICA

Wanji Samuel[1], Winston Patrick Ndongmo[1], Fanny Fri Fombad[1], Abdel Jelil Njouendou[1], Benjamin Koudou[2], Moses Bockarie[2], Grace Fobi[3], Jean Baptiste Roungou[3]

[1]University of Buea, Buea, Cameroon, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]African Program for Onchocerciasis Control (APOC), Ouagadougou, Burkina Faso

Loiasis is a filarial infection endemic in the rainforest zone of west and central Africa particularly in Cameroon, Gabon, Republic of Congo, and Democratic Republic of the Congo. Repeated treatments with ivermectin have been delivered using the annual community directed treatment with ivermectin (CDTI) approach for several years to control onchocerciasis in some *Loa loa-Onchocerca volvulus* co-endemic areas. The impact of CDTI on loiasis parasitological indicators is not known. We, therefore, designed this study to explore the effects of several rounds of CDTI on parasitological indicators of loiasis. The study was conducted in the East, Northwest and Southwest 2 CDTI projects of Cameroon. Individuals who consented to participate were interviewed for ivermectin treatment history and enrolled for parasitological screening using thick smears. Ivermectin treatment history was correlated with loiasis prevalence/intensity. A total of 3,684 individuals were recruited from 36 communities of the 3 CDTI projects and 900 individuals from 9 villages in a non-CDTI district. In the East, loiasis prevalence was 29.3% (range = 24.2%–34.6%) in the non-CDTI district but 16.0% (3.3%–26.6%) in the CDTI district with 10 ivermectin rounds (there were no baseline data for the latter). In the Northwest and Southwest 2 districts, reductions from 30.5% to 17.9% (after 9 ivermectin rounds) but from 8.1% to 7.8% (not significantly different after 14 rounds) were registered post CDTI, respectively. Similar trends in infection intensity were observed in all sites. There was a negative relationship between adherence to ivermectin treatment and prevalence/intensity of infection in all sites. None of the children (aged 10–14 years) examined in the East CDTI project harboured high (8,000–30,000 mf/ml) or very high (>30,000 mf/ml) microfilarial loads. In areas where onchocerciasis and loiasis are co-endemic, CDTI reduces the number of, and microfilaraemia in *L. loa*-infected individuals, and this, in turn, will help to prevent non-neurological and neurological complications post-ivermectin treatment among CDTI adherents.

56

INVESTIGATION OF RISK FACTORS FOR TRANSMISSION OF GUINEA WORM DISEASE IN DOGS— CHAD, 2018

Anita Sircar[1], Eugene W. Liu[1], Kolio Matchanga[2], Mbang Mahamat Ada[3], Neloumta Ngarhor[3], Ryan Wiegand[1], Philip Tchindebet Ouakou[3], Honoré Djimrassengar[2], Dieudonné Sankara[4], Hubert Zirimwabagabo[5], Ernesto Ruiz-Tiben[6], Sharon L. Roy[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]World Health Organization, N'Djamena, Chad, [3]Chad Ministry of Public Health, N'Djamena, Chad, [4]World Health Organization, Geneva, Switzerland, [5]The Carter Center, N'Djamena, Chad, [6]The Carter Center, Atlanta, GA, United States

Guinea worm (GW) disease, slated for global eradication, is historically a human disease spread by drinking stagnant water containing microscopic crustaceans infected with larvae of the roundworm *Dracunculus medinensis*, causing clusters of case-patients with worms emerging from the skin. However, dog infections, reported in Chad since 2012, have surpassed the few sporadic human cases reported annually, with 1011 infected dogs in 2016 and 817 in 2017. Chad dog GW infections peak each mass fishing season; lab and field studies have found *D. medinensis* larvae in frog tissues and fish intestines, suggesting a possible paratenic (transport) host. We conducted a case-control study to identify risk factors for GW transmission in dogs and recommend interventions to prevent infections. We used a standardized questionnaire to interview dog owners and their families about their dogs' behaviors, water and food consumption habits. Case-dogs had emerged worms in 2017 confirmed by Chad Guinea Worm Eradication Program (CGWEP) supervisors. Each case-dog was matched to 1–2 controls by age, sex, and residency; controls came from neighboring households without a history of GW disease in animals or humans. We performed univariable conditional logistic regression to calculate odds ratios (OR). We enrolled 73 case-dogs and 143 controls. Consumption of fish entrails was associated with GW disease (OR 2.4; 95% confidence interval [CI]: 1.1–5.2]. There was no association with frog consumption. Water accessible to dogs that was provided to other household animals was protective for high-worm burden dogs (>4 worms) compared to controls (OR 0.2; 95% CI: 0.04–0.9). This is the first epidemiologic study to link lab and field observations of a GW-infected paratenic/transport host with dog feeding habits. CGWEP should emphasize methods for safe disposal of fish entrails while research is ongoing to find ways to safely use this food source for dogs. Further

research is needed to understand the reason for the protective effect of water and capitalize on its underlying influence. However, CGWEP could consider adding potable water provision for dogs to its health messaging.

57

POPULATION GENETICS OF SCHISTOSOME PARASITES IN SCHOOL AGED CHILDREN BEFORE AND AFTER PRAZIQUANTEL TREATMENT

Christina Faust[1], Marco Crotti[1], Elizabeth Adekanale[1], David Oguttu[2], Aidah Wamboko[3], Moses Adriko[3], Andrina Nankasi[3], Arinaitwe Moses[3], Fred Besigye[3], Candia Rowel[3], Diana Ajambo[3], Atuhire Alon[3], Edridah Tukahebwa[3], Alice Norton[4], Joanne Webster[5], Poppy H. Lamberton[1]

[1]Institute of Biodiversity, Animal Health, and Comparative Medicine, University of Glasgow, Glasgow, United Kingdom, [2]Vector Control Division, Ministry of Health, Uganda, [3]Vector Control Division, Kampala, Uganda, [4]Schistosomiasis Control Initiative, London, United Kingdom, [5]Royal Veterinary College, London, United Kingdom

Despite over 14 years of mass drug administration (MDA), there are still schistosomiasis hotspots in Uganda. Here, we describe longitudinal surveys of school-aged children (SAC) to understand effects of praziquantel on parasite genetic diversity and population structure. We recruited SAC (6 – 14 yrs) across three schools on the shores of Lake Victoria in Mayuge District, Uganda from 2003 - 2018. We collected parasite infection intensity and genetic data up to 22 times during the study period. High prevalence (>70%) with mean moderate *S. mansoni* infection intensities were observed at all 'pre-praziquantel' treatment timepoints. We utilized up to 18 microsatellites to examine genetic diversity of parasites between individuals and schools before and after praziquantel treatment. There is a significant reduction in diversity with treatment within individual children but this is not reflected at the intra- and inter- school genetic diversity levels. Some of the parasites collected four weeks after praziquantel treatment cluster together despite being collected in different years, suggesting these parasites have survived repeated treatments. However, high rates of gene flow, coupled with high reinfection rates, rapidly dilutes these genotypes within a few months after treatment. Genetic diversity of parasites increased with host age and was higher in males, with a significant interaction between host age and sex. The majority of genetic diversity was observed within a host, with low genetic differentiation between schools despite large distances between villages. Genetic structure and estimates of the effective population size suggest that the thousands of treatments that have been administered in Mayuge District since 2003 have had minimal effects on populations of this diverse parasite. The findings emphasize a critical need for concerted drug treatment combined with wide uptake of other interventions along the shores of Lake Victoria to have long term impacts on transmission.

58

OÙ SONT LES ESCARGOTS - WHERE ARE THE SNAILS? USING REMOTE SENSING METHODS TO COMBAT SCHISTOSOMIASIS IN NORTHERN SENEGAL

Caitlin M. Wolfe[1], Christopher Haggerty[1], Isabel Jones[2], Andrew Chamberlin[2], Nicolas Jouanard[3], Simon Senghor[3], Chelsea Wood[4], Susanne Sokolow[2], Gilles Riveau[3], Guilio De Leo[2], Jason Rohr[1]

[1]University of South Florida, Tampa, FL, United States, [2]Stanford University, Palo Alto, CA, United States, [3]Espoir Pour la Santé, Saint-Louis, Senegal, [4]University of Washington, Seattle, WA, United States

Schistosomiasis, a neglected tropical diseases caused by the *Schistosoma* parasite, affects more than 240 million people a year. Ever since the construction of the Diama dam across the Senegal River in 1986, schistosomiasis has tormented villages along the Senegal River and its tributaries. The World Health Organization estimates that mass drug administration of praziquantel to treat schistosomiasis reaches less than 10% of the at-risk Senegalese population. Our objective was to assess a novel method of identifying high-density snail habitats in schistosomiasis endemic areas through remote sensing. Firstly, we identified environmental parameters significantly associated with the presence of the snail vectors. Data were collected from 36 water access points in 15 villages between June-August 2017. The number and species of snails and types of vegetation were recorded for each sweep of the net, with data analyzed through logistic regression models to determine whether the presence of certain vegetation was significantly associated with the presence of snails. *Ceratophyllum* was the most significant predictor of snail presence and abundance among lake and river water access sites. This held true across the two different species of snail vectors, *Bulinus* and *Biomphalaria spp*. Secondly, World View 2 images of northern Senegal were analyzed to identify areas containing signature characteristics of *Ceratophyllum* and other environmental parameters significantly associated with snail presence at a subset of sampled water access points. These spectral signatures were then used to predict the presence or absence of snail vectors among all sampled water access points. The third phase of this research is validating this model in previously unsampled sites in northern Senegal. Preliminary results suggest that a signature extracted from remote sensing images may be used to predict the location and abundance of snail vectors with accuracy. Once honed, this method should assist in predicting communities at risk for schistosomiasis in northern Senegal, and perhaps beyond, where ground-based epidemiological surveys are difficult to implement.

59

ANTHELMITHIC TREATMENT UPTAKE AND PREDICTORS IN LAKE VICTORIA FISHING COMMUNITIES, UGANDA: INTERVENTION COVERAGE RESULTS FROM THE LAVIISWA CLUSTER RANDOMIZED TRIAL

Hellen Akurut[1], Emily Webb[2], Richard Sanya[1], Lawrence Lubyayi[1], Margaret Nampijja[1], Moses Kizza[1], Robert Kizindo[1], Moses Ssewankambo[1], Denis Nsubuga[1], James Kaweesa[3], Edridah Tukahebwa[3], Alison Elliott[1]

[1]Medical Research Council/Uganda Virus Research Institute and London School of Hygiene & Tropical Medicine, Entebbe, Uganda, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Ministry of Health, Uganda, Kampala, Uganda

Mass drug administration (MDA) is a cornerstone of the strategy for control of helminths. In schistosomiasis-endemic areas with >50% of school-aged children infected, community-wide MDA with praziquantel is recommended by the World Health Organisation (WHO), with target coverage of >75%. In the Koome islands of Lake Victoria, Uganda, where baseline schistosomiasis prevalence (Kato-Katz) was 52% overall and 67% among school-aged children, we conducted a cluster-randomised trial of community-wide intensive MDA (quarterly single-dose praziquantel 40mg/kg; albendazole 400mg for three days) versus standard, Uganda government intervention (annual praziquantel 40mg/kg; 6-monthly single-dose albendazole). Twenty-six fishing villages were randomised, 13 per trial arm, for four years. At each treatment round, registers of village residents were updated and treatment uptake recorded. During the four year MDA period, 53,930 people were registered in the study area (25,055 and 28,875 in standard and intensive intervention villages, respectively). The age distribution of village residents was bimodal with 16% under-five and 44% 20-35 years; 53% were male. Praziquantel uptake was lower than albendazole uptake (60% versus 65%), more so in the standard arm (praziquantel 58%, albendazole 70% versus intensive arm: praziquantel 61%, albendazole 62%). In the standard arm, albendazole uptake was lower in the treatment rounds at which praziquantel treatment was given. Absence was by far the most common reason for non-treatment (81% albendazole, 78% praziquantel), with refusal the next most common (14% albendazole, 16% praziquantel). Uptake for both treatments was lowest among school-aged children (mainly due to absence at day school), but did not differ by sex. Refusal was more likely with the older age, more common among females. Persistent refusal (all treatment) was seen for 8% and 6% residents for praziquantel and albendazole, respectively. In

schistosomiasis transmission "hot spots", a combination of community-wide and school-based treatment strategies and educational interventions may be required to achieve WHO target coverage.

60

RESEARCH CHALLENGES AND NEEDS FOR CONTROL AND ELIMINATION OF SCHISTOSOMIASIS: NEW DIAGNOSTICS

Donald McManus[1], Catherine Gordon[1], Kosala Weerakoon[1], Pengfei Cai[1], Remi Olveda[2], Darren Gray[3], Allen Ross[4], Yuesheng Li[1], Gail Williams[5]

[1]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [2]Research Institute for Tropical Medicine, Manila, Philippines, [3]Australian National University, Canberra, Australia, [4]Griffith University, Brisbane, Australia, [5]University of Queensland, Brisbane, Australia

Morbidity reduction and eventual elimination through integrated intervention approaches are the focal points of current schistosomiasis control. Precise diagnosis of schistosome infections will be critical in achieving these goals, particularly in areas such as China where extensive control has reduced schistosomiasis to very low levels to the point where elimination is on the horizon. Field surveillance and point of care testing will require sensitive, specific, inexpensive, field applicable diagnostic assays to determine worm burdens and to distinguish active infection and successful cure in high and low prevalence areas and for assessment of treatment failures. This paper will describe three new diagnostic tools for *Schistosoma japonicum* we developed and tested: • A real-time polymerase chain reaction (qPCR)-based (for humans and animals) assay which can be used as a future field diagnostic and surveillance tool in low-transmission zones where schistosomiasis elimination is targeted and for monitoring post-intervention areas to verify that elimination has been maintained. • A novel droplet digital PCR assay capable of identifying pre-patent and patent infections using *S. japonicum* DNA isolated from serum, urine, salivary glands, and feces in a murine model, and validated using clinical samples collected from subjects resident in an area moderately endemic for schistosomiasis in the Philippines. This verified method represents a valuable tool for the diagnosis and surveillance of schistosomiasis, particularly in low-prevalence and low-intensity areas approaching elimination and in monitoring where disease emergence or re-emergence is a concern. • An IgG-based ELISA using a combination of two recombinant *S. japonicum* antigens (SjSAP4 + Sj23-LHD (large hydrophilic domain)) which, on large scale testing with human serum samples from the Philippines provided a high diagnostic outcome with 87% sensitivity and 97% specificity. This combination could be used in future for serological diagnosis of schistosomiasis, thereby representing an important component for monitoring integrated control measures.

61

PRECISION MAPPING IS THE WAY FORWARD TO SHRINK THE MAP AND ACCELERATE THE ELIMINATION OF SCHISTOSOMIASIS

Louis-Albert Tchuem Tchuenté

Centre for Schistosomiasis and Parasitology, University of Yaoundé I, Yaoundé, Cameroon

The major intervention for schistosomiasis control is mass administration of praziquantel to those shown to be, or presumed to be, at-risk of infection, on the basis of disease mapping. However, the current conventional mapping design for schistosomiasis has shown several limitations and may lead to several uncertainties and misclassification of some districts and their eligibility for preventive chemotherapy. Considering the high focality of schistosomiasis transmission, these mapping inaccuracies may result in over-treatment in some areas, and most importantly under-treatment or no treatment in areas that need it most. Thus preventing successful treatment coverage of all populations who need treatment, and jeopardizing the achievement of schistosomiasis elimination. To assess the role a more precise mapping could play in the stage moving towards elimination of schistosomiasis, we conducted studies in several health districts in Cameroon, using a new and innovative approach based on an exhaustive sampling of all schools within these districts. Over 300 schools and 15,000 school children were sampled. The results showed significant variations in schistosomiasis prevalence within health districts and sub-districts. Furthermore, a comparison of maps obtained using the conventional mapping method with those from precision mapping showed significant differences. The precision mapping of schistosomiasis gave high resolution information at the local level, and clearly provided detailed information on high risk zones and locations where intensified interventions should be focused primarily to obtain higher impact. By increasing the map granularity and spatial resolution, the precision mapping provides the best evidence based data to guide intensified interventions in targeted transmission zones, and allows a better and rational utilization of the donated praziquantel and available resources. We therefore believe that it is a promising and innovative tool to shrinking the map of schistosomiasis and accelerating the move towards the elimination of schistosomiasis in sub-Saharan Africa.

62

SCHISTOSOMIASIS MONITORING AND EVALUATION PROGRAMS: THE IMPORTANCE OF COLLECTING ADULT DATA TO INFORM TREATMENT STRATEGIES FOR *SCHISTOSOMA MANSONI*

Jaspreet Toor[1], Hugo C. Turner[2], James E. Truscott[1], Marleen Werkman[1], Anna E. Phillips[1], Ramzi Alsallaq[3], Graham F. Medley[4], Charles H. King[3], Roy M. Anderson[1]

[1]Imperial College London, London, United Kingdom, [2]Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam, [3]Case Western Reserve University, Cleveland, OH, United States, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom

Schistosomiasis remains an endemic parasitic disease affecting millions of people around the world. The World Health Organization (WHO) has set goals for controlling schistosomiasis morbidity by 2020, along with its elimination as a public health problem in certain regions by 2025 (defined by reaching ≤5% and ≤1% prevalence of heavy-intensity infections in school-aged children, respectively). Monitoring and evaluation (M&E) programmes are used to collect data which can inform treatment strategies required in a defined area and can also aid in assessing the progress of treatment strategies. Due to programmatic and financial constraints, data are typically collected from school-aged children (SAC; 5-14 years of age) as they are thought to be most likely to be infected. Using a mathematical model, we incorporate three different age-intensity profiles of infection for *Schistosoma mansoni* with low, moderate and high burdens of infection in adults to investigate how the age distribution of infection impacts the preventive chemotherapy coverage levels required to achieve the WHO goals. We find that for low to moderate prevalence regions, regardless of the burden of infection in adults, treating SAC only may achieve the WHO goals. However, for high prevalence regions with a high burden of infection in adults, adult treatment is required to meet the WHO goals with coverage levels varying with the burden of infection in adults. This highlights that prevalence and intensity of infection data in adults needs to be included within M&E programmes. Collecting data from a broader age-range, specifically the inclusion of adult data at baseline (prior to treatment) and throughout the treatment programme if possible, as well as SAC data will allow for more accurate determination of the optimal treatment strategy for a defined region.

COUPLING DYNAMIC ENERGY BUDGET (DEB) THEORY WITH A MESOCOSM EXPERIMENT TO PREDICT AND VALIDATE THE EFFECTS OF TEMPERATURE ON A HOST-PARASITE SYSTEM

Karena Nguyen[1], David J. Civitello[2], Jason R. Rohr[1]

[1]University of South Florida, Tampa, FL, United States, [2]Emory University, Atlanta, GA, United States

Schistosomiasis, caused by trematodes of the family *Schistosoma*, is a widespread human parasitic disease that might increase in prevalence with global climate change. However, the net effects of temperature on host-parasite systems have been historically difficult to model because parasites and their hosts often have different optimal temperatures across life history traits (e.g. hatching, infectivity, growth, reproduction). Dynamic energy budget (DEB) theory addresses this hurdle by utilizing metabolic principles, which are temperature-dependent, to predict the trajectory of individual life history traits. A DEB-based model for *Schistosoma mansoni* and its intermediate snail host, *Biomphalaria glabrata*, was used in this study to predict parasite cercarial shedding rates and snail growth and reproduction across a temperature gradient (18, 21, 25, 29, 33, and 37°C). Additionally, 16-L mesocosms (n = 4 per treatment) were inoculated with 1-L of local pond water containing zooplankton and algae to mimic a freshwater environment. After algae established, five snails between 3-12 mm were added to each mesocosm. *S. mansoni* miracidia were added in four doses during the first 10 weeks of the experiment. Mortality was monitored daily and DEB predictions were compared to measurements of snail life history traits, sampled weekly for 4 months. Optimal snail growth occurred between 25-33°C, reproduction between 21-29°C, and cercarial shedding between 25-29°C, which aligned with DEB predictions and temperatures where schistosomiasis is endemic. These results validate DEB theory as a tool for predicting the effects of global climate change on the disease dynamics of schistosomiasis and perhaps similar host-parasite systems.

EVIDENCE OF PERENNIAL MALARIA TRANSMISSION UNDER ARID CONDITIONS AND DRY SEASON REFUGIA FOR ANOPHELINE LARVAE: A CASE STUDY AT KANDI IN NORTHEASTERN BENIN, WEST AFRICA

Renaud I. Govoetchan, Martin Akogbéto

Centre de Recherche Entomologique de Cotonou, Cotonou, Benin

In arid settings, droughts usually lead to periods of very low or no malaria transmission. However, in rural Kandi (Sonsoro) in northeastern Benin, several malaria cases are often diagnosed during dry seasons. The underlying factors accounting for this phenomenon remain unknown. For our investigations, the entomo-parasitological profile of the location (Sonsoro) was compared to a site in urban Kandi (Gansosso), meticulously focusing on what happens in the dry season. A GIS approach was used to access in 1-year period the spatial and seasonal distribution of mosquito larval habitats and identify their drought-refugia. Conjointly, adult *Anopheles* vector collections were monthly performed using Human Landing Catches (HLC). Elisa assays for *P. falciparum* circumsporozoite protein were conducted on vector specimens and the entomological inoculation rates (EIR) were determined per season. To provide a global view of drought-malaria prevalence, Rapid Diagnostic Tests (RDTs) were conducted in children < 10 years in both sites. Overall 187 mosquito larval habitats were identified of which 56 were recorded during the dry season (73% in rural site against 27% in the urban). The drought-refugia for mosquito breeding were all of domestic nature mainly canaries, jars, and flower pots. 100% of drought larval habitats identified in rural Kandi contained anopheline larvae against only 20% in urban Kandi. HLC provided 966 mosquitoes belonging to 12 species and *Anopheles gambiae* is the main species sampled (69 %). It represented respectively 94% (628/668) and 13 % (39/298) of the collections in rural and urban Kandi. From wet to dry season, we observed a drastic 96% reduction of EIR in rural Kandi (23 infected bites/man/month to 1 infected/man/month). Same trend was observed in urban Kandi (1 infected bite/man/month to 0 with the drought). RTDs data on 400 children showed that *P. falciparum* infections were significantly higher in rural Kandi (41%) than in urban (7.5%). Our results suggest that a suitable domestic management of anopheline larval habitats in droughts would provide a huge impact on the dynamics of mosquito populations and malaria transmission.

FROM INSIGHT TO INNOVATION: HOW VIDEO-TRACKED *ANOPHELES GAMBIAE* BEHAVIOR LED TO THE 'BARRIER BEDNET' TARGETING INSECTICIDE RESISTANT VECTORS

Gregory P. Murray[1], Natalie Lissenden[1], Hyacinthe K. Toé[2], Vitaly Voloshin[3], Jeff Jones[1], Natalia C. Angarita-Jaimes[3], Josephine E. Parker[1], Christian Kroner[3], Catherine E. Towers[3], N'Fale Sagnon[2], Hilary Ranson[1], David Towers[3], Philip J. McCall[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, [3]University of Warwick, Coventry, United Kingdom

Designing the next generation of long-lasting insecticidal bed nets (LLINs) is a primary goal in malaria vector control today, as the emergence of pyrethroid-resistant vector populations across Africa threatens their future. We approached this challenge by initiating a series of studies on the basic behavior of *Anopheles gambiae s.l.* at human-occupied LLINs, using a state-of-the-art video-tracking system. Initial results provided extraordinary insight into the behavior of *An. gambiae s.l.* at a human-occupied LLIN. Video analyses revealed previously unseen spatial characteristics of mosquito activity that had potential as novel targets. A key feature of host-seeking behavior was that the vast majority of activity occurred above the roof of the human-occupied bednet (*i.e.* outside the net, where contact with the human sleeper's skin would not occur and above the reach of children at all times). Conceivably, a range of insecticides might be delivered via an added 'net barrier' fitted above the net roof and on which mosquitoes might land or collide. The results of a series of completed studies investigating the barrier bednet performance will be presented. Results of video-track recordings of pyrethroid-resistant *An. gambiae* at barrier bednets treated with combinations of pyrethroid, organophosphate and other treatments will be presented and the nature of mosquito-net interaction interpreted. We also investigated the effectiveness of barrier designs and treatments using a novel *in silico* computer model (InVeCTS). Finally, the results of a hut trial carried out in Burkina Faso, targeting a wild pyrethroid-resistant population of *An. gambiae s.l.* using a number of barrier bednet treatments will be presented, during which one barrier design significantly outperformed other LLINs as measured by personal protection (P=<0.01), immediate (P=<0.001) and delayed (P=<0.001) vector mortalities. We present the barrier bednet as a simple affordable method of restoring LLIN effectiveness in areas with high levels of insecticide resistance and consider its potential for malaria prevention in an insecticide resistant Africa.

66

IDENTIFICATION OF CANDIDATE GENES UNDERLYING HUMAN HOST PREFERENCE IN THE MALARIA MOSQUITO *ANOPHELES COLUZZII*

Giridhar Athrey[1], Zachary Popkin-Hall[1], Willem Takken[2], **Michel A. Slotman**[1]

[1]Texas A&M University, College Station, TX, United States, [2]Wageningen University and Research, Wageningen, Netherlands

The malaria mosquito *Anopheles coluzzii* has a strong preference for human hosts, which contributes greatly to its vectorial capacity for malaria. We combined several approaches to study the genetic basis of this important trait. Previously we made use of the fact that *An. coluzzii's* sibling species. *An. quadriannulatus* is largely zoophilic,

by conducting a QTL mapping analysis on backcross between the two species. This identified six autosomal QTL containing numerous olfactory genes. Additionally, we compared gene expression between the two species in the two major olfactory organs, the antennae and maxillary palps, to identify olfactory genes with species- and sex-biased expression. Furthermore, we analyzed sequence data for olfactory receptors, ionotropic receptors and odorant binding proteins obtained from field collected specimens representing six of the species in the *An. gambiae* complex, and identified genes under positive selection in the anthropophilic *An. coluzzii* and *An. gambiae ss.* Taken together, these genetic mapping, expression and selection analyses identify a set of candidate olfactory genes for human host preference in this important malaria vector.

67

NEW INSIGHTS INTO *ANOPHELES* MATING BEHAVIOR: BOTH MALES AND FEMALES OF *ANOPHELES COLUZZII* AND *ANOPHELES GAMBIAE* USE VISUAL MARKERS TO SWARM … BUT EACH IN ITS OWN WAY

Serge B. Poda[1], Abdoulaye Diabaté[1], Olivier Gnankiné[2], Roch K. Dabiré[1], Olivier Roux[3]

[1]Institut de Recherche en Sciences de la Santé (IRSS)/Centre Muraz, Bobo-Dioulasso, Burkina Faso, [2]Université Ouaga 1 Pr Joseph Ki-Zerbo, Ouagadougou, Burkina Faso, [3]Institut de Recherche pour le Dévelopement (IRD), Montpellier, France

Effective malaria vector control strategies require a good understanding of mosquito behaviors. However, in *Anopheles* species, mating behavior has been deeply overlooked. Nowadays, it is known that males of *Anopheles gambiae s.l.* form swarms at dusk in which virgin females come to mate. While *An. gambiae* has been described to swarm over bare ground, *An. coluzzii* swarms over dark markers. However, both the exact way males use these visual cues and whether females also use these cues to join species specific swarms are unknown. In laboratory, we first, tested whether males of the two species use a marker to locate the swarm. The marker was moved during swarming and the relative position of the swarm was recorded. Second, we investigated the male swarm characteristics (height, width and number of mosquitoes) as a function of the presence/absence of a marker and the marker size (20x20cm *vs*. 60x60cm). Finally, we repeated these experiments with virgin females to observe their behavior towards ground visual markers. We observed that *An. coluzzii* males swarmed only in presence of a marker and always right above it. With the large marker, swarms were higher, wider and had more mosquitoes (*ca.* x2) than with the small one. In *An. gambiae*, males swarmed next to the marker and were also able to form a swarm without a marker. However, only the number of swarming mosquitoes and swarm width increased in presence and with larger markers (*ca.* x1.3). The two species instantly followed the marker movements with *An. coluzzii* being over the marker and *An. gambiae* keeping a constant distance of ≈75cm to the marker. The females of the two species exhibited a swarm-like behavior very similar to those of the males. Our findings show that both *An. gambiae* and *An. coluzzii* males use a ground marker to swarm but in a different way and their females also use this visual cue like their specific-specie males to exhibit swarm-like behaviors. It suggests that ground visual markers could be a key cue in specific swarm recognition and location which is highly important for assortative mating in these sibling species. These results raise new avenues to explain diversification within the *An. gambiae* complex.

68

TIMING IS EVERYTHING: *AEDES AEGYPTI* REPRODUCTIVE PHYSIOLOGY EXPLAINS BEHAVIOR

Ethan C. Degner[1], Jade M. Noble[1], Catalina Alfonso-Parra[2], Lena F. Kourkoutis[1], Frank W. Avila[2], Laura C. Harrington[1]

[1]Cornell University, Ithaca, NY, United States, [2]Max Planck Tandem Group in Mosquito Reproductive Biology, Universidad de Antioquia, Medellin, Colombia

Before a female *Aedes aegypti* mosquito reproduces, several events must occur. She must mate, store sperm, blood feed, produce eggs, and finally fertilize eggs as she lays them. Such processes independently are well known to mosquito biologists, but confusion remains about the order of these events and their physiological pre-requisites. We sought to identify the timing and order in which important reproductive events occur. Laboratory-adapted *Aedes aegypti* females blood feed and produce some eggs even when their virginity is enforced, and we used these gravid virgins to test how soon after mating females were able to fertilize their eggs. We demonstrate that gravid females, when forced to lay eggs via a death stressor, gradually gain the capacity to fertilize eggs over 16 h after mating. Readiness to fertilize eggs coincides with drastic changes in sperm activity and morphology, suggesting that sperm processing may be necessary for fertilization. When oviposition was not forced, females naturally began laying eggs 16 h after mating, suggesting that oviposition behavior and fertilization competence are tightly coordinated. Whether wild females produce eggs before mating remains unclear; if this were the case, females would experience a three day delay between mating and fertilization. Given that sperm and female behavior are prepared for fertilization in just 16 h, we tested whether wild virgins sometimes produce eggs. Field-collected females from Medellin, Colombia, included a small proportion of gravid virgins, suggesting that mating may not always be necessary for oogenesis. Thus, females are not physiologically prepared to fertilize eggs until 16 h after mating, and this delay may be mediated by sperm. Oviposition behavior begins at the same time that females become fertilization competent. Finally, preparing to fertilize eggs in 16 h may benefit females that blood feed and produce eggs prior to mating. Understanding reproductive events and their timing in this important disease vector will contribute to a deeper understanding of mosquito behavior, ecology, and the cellular and molecular mechanisms that mediate reproduction.

TEMPERATURE DRIVES ZIKA VIRUS TRANSMISSION: EVIDENCE FROM EMPIRICAL AND MATHEMATICAL MODELS

Blanka Tesla[1], Leah Demakovsky[1], Erin Mordecai[2], Sadie Ryan[3], Matthew Bonds[4], Calistus Ngonghala[3], Melinda Brindley[1], **Courtney Murdock**[1]

[1]University of Georgia, Athens, GA, United States, [2]Stanford University, Stanford, CA, United States, [3]University of Florida, Gainsville, FL, United States, [4]Harvard University, Cambridge, MA, United States

Temperature is a strong driver of vector-borne disease transmission. Yet, for emerging arboviruses we lack fundamental knowledge on the relationship between transmission and temperature. Current models rely on the untested assumption that Zika virus responds similarly to dengue virus, potentially limiting our ability to accurately predict the spread of Zika. We conducted experiments to estimate the thermal performance of Zika virus (ZIKV) in field-derived *Aedes aegypti* across eight constant temperatures. We observed strong, unimodal effects of temperature on vector competence, extrinsic incubation period, and mosquito survival. We used thermal responses of these traits to update an existing temperature-dependent model to infer temperature effects on ZIKV transmission. ZIKV transmission was optimized at 29°C, and had a thermal range of 22.7°C-34.7°C. Thus, as temperatures move toward the predicted thermal optimum (29°C) due to climate change, urbanization, or seasonally, Zika could expand north and into longer seasons. In contrast, areas that are near the thermal optimum were predicted to experience a decrease in overall environmental suitability. We also demonstrate that the predicted thermal minimum for Zika transmission is 5°C warmer than that of dengue, and current global estimates on the environmental suitability for Zika are greatly over-predicting its possible range.

70

HIGH-ACCURACY DETECTION OF MALARIA VECTOR HABITATS USING DRONE-BASED MULTISPECTRAL IMAGERY

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Ministry of Health, Iquitos, Peru, [3]Wadsworth Center, New York State Department of Health, Albany, NY, United States, [4]Department of Biomedical Sciences, School of Public Health, State University of New York, Albany, NY, United States, [5]Division of Infectious Diseases, Department of Medicine, University of California San Diego, La Jolla, CA, United States

Interest in larval source management (LSM) as an adjunct intervention has recently increased mainly because LLINs and IRS are ineffective against malaria transmission by exophagic and exophilic mosquitoes. Knowledge of the characterization of the most productive, positive water bodies would provide a more cost-effective tool and increase the impact of targeted mosquito control on aquatic life stages. The present study explores the use of unmanned aerial vehicles (UAV) for identifying potential *Nyssorhynchus darlingi* (former *Anopheles darlingi*) breeding sites by mapping characteristics of water bodies in four localities in Mazan District, Amazonian Peru. There were two primary goals: 1) to evaluate the feasibility of high-resolution mapping (~0.02m/pixel) in Amazonian areas to detect inaccessible malaria vector breeding sites; and 2) to investigate the relationship between the multispectral profile and *Ny. darlingi* breeding sites. Imagery was acquired during April 2017 in four localities in the Mazan river basin. *Ny. darlingi* larvae collections were performed simultaneously and information about positive and negative breeding sites from two additional surveys was incorporated into the calculations. A supervised Random Forest classification was performed to detect whether or not water bodies harbor *Ny. darlingi* immature stages. Our results showed that multispectral imagery collected from a UAV could discriminate a profile of water bodies where *Ny. darlingi* was most likely to breed. We performed the analysis in Google Earth Engine (GEE) using three classification approaches. The overall accuracy ranged between 89.79% and 97.46% and statistical analysis showed clear differentiation of spectral bands of water bodies positive *vs* negative for *Ny. darlingi*. This work provides proof-of-concept of the use of high-resolution images to detect malaria vector breeding sites in the Peruvian Amazon, where the use of such an innovative methodology could be crucial to maximize resources for the incorporation of LSM into integrated interventions and a powerful additional tool for malaria elimination in the Amazon and elsewhere.

71

ARTEMISININ RESISTANCE AND THE *PFK13* C580Y MUTATION IN GUYANA: A CONFIRMED LINK AND EMERGENCE

Luana Mathieu[1], Horace Cox[2], Angela M. Early[3], Maria-Paz Ade[4], Yassamine Lazrek[1], Quacy Grant[2], Naomi W. Lucchi[5], Venkatachalam Udhayakumar[5], Alexandre J. Seme Fils[6], David A. Fidock[7], Daniel E. Neafsey[3], Pascal Ringwald[8], Lise Musset[1]

[1]Intitut Pasteur de la Guyane, Cayenne, French Guiana, [2]Ministry of Public Health, Georgetown, Guyana, [3]Broad Institute of Massachusetts Institute of Technology and Harvard, Boston, MA, United States, [4]Panamerican Health Organization, Washington, DC, United States, [5]Centers for Disease Control and Prevention, Atlanta, GA, United States, [6]Panamerican Health Organization, Georgetown, Guyana, [7]Columbia University College of Physicians and Surgeons, New York, NY, United States, [8]World Health Organization, Geneva, Switzerland

The emergence and spread of artemisinin resistance in Southeast Asia has raised concerns about malaria control worldwide. Non-synonymous mutations in the propeller domain of the *pfK13* gene have been associated with artemisinin resistance in this Asian region. Recent evidence indicates suspected partial artemisinin resistance in the Guiana shield region of South America, a locality where historically, resistance emerge *de novo*. As a previous retrospective study indicated an independent emergence of *pfk13* C580Y mutation in Guyana, a follow up molecular surveillance was conducted to evaluate the presence and/or extent of artemisinin partial resistance in part of this the Guiana shield region. The *pfk13* gene was genotyped through PCR-based sequencing in 683 blood spots collected in Guyana in 2016-2017. Thirteen samples were found to contain the *pfK13* C580Y mutation, indicating a population frequency of 1.9% [0.8-2.8]. No other mutation was found in the propeller domain of this gene. The impact of this C580Y *pfK13* mutation on the phenotype to artemisinin derivatives in parasites exhibiting a South American genetic background was also evaluated by genome editing. The analysis confirmed that C580Y mutation confers a high level of artemisinin resistance *in vitro*. Therefore, this finding confirms circulating C580Y alleles in Guyana can lead to partial artemisinin resistance. The impact on therapeutic efficacy is being evaluated. During this presentation, the geographic extent of this

new focus of artemisinin partial resistance will be presented as well as the origins and spread of these C580Y mutants under drug pressure, based on whole genome sequencing data.

72

MUTATIONS IN PFCORONIN CONFER RESISTANCE TO ARTEMISININ IN WEST AFRICAN *PLASMODIUM FALCIPARUM* ISOLATES

Aabha Sharma[1], Allison R. Demas[1], Wesley Wong[1], Angela Early[2], Seth Redmond[2], Selina Bopp[1], Daniel E. Neafsey[1], Sarah K. Volkman[1], Daniel L. Hartl[3], Dyann F. Wirth[1]

[1]Harvard T. H. Chan School of Public Health, Boston, MA, United States, [2]The Broad Institute, Cambridge, MA, United States, [3]Harvard University, Cambridge, MA, United States

Global public health efforts for control and elimination of malaria have made considerable progress since the success of the Artemisinin-based combination therapies, which are highly effective against *Plasmodium falciparum*. However, an emerging drug resistance to Artemisinin (ART) in Southeast Asia poses one of the greatest threats to eradicate malaria. If this resistance spreads to the African continent, which bears the highest global malaria burden, efforts to control malaria will be in serious jeopardy. With this in mind we chose two Senegalese field isolates to investigate ART resistance. These field isolates are susceptible to ART treatment and do not have mutations in the propeller domain of PfKelch13, a known marker of ART resistance. After intermittent and step-wise dihydroartemisinin (DHA) pulses started in 2011 and continued over four years, we obtained three independent ART resistant lines. All three parasite lines had a significant increase in their $^{0\text{-}3hr}$Ring Stage Survival Assay (RSA) survival percentage (6%, 7.9% and 9.6% respectively) compared to their parents ($^{0\text{-}3hr}$RSA<1%). They had no change in EC_{50} response to ART derivatives in a 72-hour dose-response assay. Whole genome sequencing of ART resistant lines identified thirteen different single nucleotide polymorphisms (SNPs) in ten genes. There were no mutations in the PfKelch13 gene. One gene, PfCoronin (PF3D7_1251200), which codes for a protein similar in structure to PfKelch13, had new SNPS in its WD-40 propeller domain of all three resistant lines. To test whether the PfCoronin SNPs (G50E, R100K, E107V) were sufficient to confer ART resistance, we generated CRISPR-Cas9 edited parasite lines containing PfCoronin SNPs in both 3D7 and the Senegalese parental backgrounds. Our preliminary results in one of the Senegalese parental backgrounds indicate PfCoronin SNPs are sufficient to confer ART resistance. This suggests that PfCoronin is a determinant of ART resistance in West African parasites. Further investigation of biological mechanism of ART resistance conferred by PfCoronin will make significant contributions to the current understanding of ART resistance.

73

THE EMERGENCE OF MULTIDRUG RESISTANT MALARIA PARASITES IN SOUTHEAST ASIA AND IMPLICATIONS ON FUTURE MALARIA TREATMENT

Mariusz Wojnarski[1], Jessica Lin[2], Panita Gosi[1], Michele Spring[1], Pattaraporn Vanachayangkul[1], Nonlawat Boonyalai[1], Worachet Kuntawunginn[1], Chaiyaporn Chaisatit[1], Kirakarn Kirativanich[1], Piyaporn Saingam[1], Sorayut Chattrakarn[1], Chatchadaporn Thamnurak[1], Kin Soveasna[3], Nicholas Martin[1], Huy Rekol[4], Lek Dysoley[4], Krisada Jongsakul[1], Somethy Sok[3], Prom Satharath[3], Kong Saly[3], Shannon Takala-Harrison[5], David Saunders[1], Mark Fukuda[1], Philip Smith[1], Chanthap Lon[1]

[1]US Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]University of North Carolina, Chapel Hill, NC, United States, [3]Ministry of National Defense, Department of Health, Phnom Penh, Cambodia, [4]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [5]University of Maryland, Baltimore, MD, United States

Thailand and Cambodia have utilized dihydroartemisinin-piperaquine and artesunate-mefloquine as first line treatment for *Plasmodium falciparum*, alternating between these ACTs due to PIP and MQ counteracting resistance mechanisms. The recent identification of 'triple mutant' malaria strain exhibiting molecular markers of resistance to all three components—the artemisinin, mefloquine and piperaquine—threatens the long-term sustainability of this approach and underscores the need for timely surveillance to characterize the rate and geographic extent of such "triple mutants". A total of 528 samples were collected from 2015 to 2017 from Cambodia patients infected with *P.falciparum* to assess temporal increase and geographical differences in parasites bearing copy number amplification in both *pfmdr1* (conferring MQ resistance) and *plasmepsin 2* (conferring PIP resistance) genes and *pf*Kelch13 mutations. We collected samples in Cambodia along the Thai border (military population) and northern and eastern Cambodia (civilians). Out of 218 samples collected in 2015 in civilians, 48 (22%) carried increased copy numbers of MQ and PIP markers of resistance, compared to only 1 (1%) collected in 2016 along Cambodia-Thai border in military. Eastern Cambodia had highest prevalence of doubly amplified parasites (52%). Amplification of *pfmdr1* and *plasmepsin2* was exclusively observed among *pf*Kelch13-580Y mutants suggesting amplification is occurring on a highly artemisinin-resistant genetic background. Analysis of *P.falciparum* malaria parasites for the prevalence of 'triple mutant' phenotype is ongoing for the remaining 316 samples collected in 2017. Origins of the identified triple mutant parasites based on loci flanking and in linkage disequilibrium with resistance genes will be determined. Based on these observations, new drug regimens will be required for treatment of multidrug resistant malaria in Southeast Asia. Triple drug combinations of already marketed drugs may be a solution for possible imminent malaria outbreaks with these multidrug resistant parasite subpopulations that may soon become untreatable by the first-line ACTs.

74

IMPACT OF *CYP2C8*2* ON ARTESUNATE-AMODIAQUINE METABOLISM IN MALI

Mahamadou D. Camara[1], Mamadou Tekete[1], Souleymane Dama[1], Dinkorma I. Ouologuem[1], Aminatou Kone[1], Amadou Bamadio[1], Nouhoum Diallo[1], Hamidou Niangaly[1], Bakary Fofana[1], Ogobara K. Doumbo[1], Steffen Borrmann[2], Jose P. Gil[3], Abdoulaye Djimde[1]

[1]Malaria Research and Training Center, Department of Epidemiology of Parasitic Diseases, School of de Medicine and dentistry, University of Sciences, techniques and technologies of Bamako, Bamako, Mali, [2]Tubingen University, Tübingen, Germany, [3]Karolinska Institute, Stockholm City, Sweden

The clinical role of genetic polymorphism in drug metabolizing enzyme such as the cytochrome P450 (CYP450) protein has been reported for many diseases including malaria. *CYP2C8*2*, a variant shown to reduce CYP2C8 enzymatic activity, was associated with severe side effects following amodiaquine (AQ) administration. *CYP2C8*2* is the most common mutation in Africa and the use of AQ in several antimalarial treatments (ACTs) and preventive strategies (Seasonal Malaria Chemoprevention strategies SMC) in many sub-Saharan Africa countries raise concern on the sustainable efficacy and safety of AQ. This study aimed to assess the impact of the *CYP2C8*2* allele on the Artesunate-Amodiaquine (ASAQ) metabolism and efficacy following uncomplicated malaria treatment with ASAQ. A retrospective pilot study was conducted on archived dried blood spot samples and sera from a malaria clinical trial study (WANECAM) conducted in Mali between October 2011 and December 2015. Samples from Bougoula-Hameau patients treated with ASAQ were collected. All patients were followed for two years. Human DNA was extracted using Qiagen kit and PCR-RFLP was used to identify the *CYP2C8*2* allele. Desethylamodiquine level was measured on day-7 sera by HPLC. We analyzed 159 samples out of 213. Of the

159 samples selected for this study, 76.1 %, 7.5 % and 16.4 % of the patients were carrying the wild type (*Wt/Wt*), mutants (**2/*2*), and both wild and mutant (*Wt/*2*) alleles, respectively. Desethylamodiaquine day-7 median concentration was 75.2, 83.2 and 91.3 ng/mL for the *Wt/Wt*, *Wt/*2* and **2/*2* respectively ($p = 0.01$). We provide for the first time the prevalence of the *CYP2C8*2* variants in Mali. We also show that day-7 desethylamodiaquine concentration was significantly higher in mutants than wild-type *CYP2C8*. These preliminary results indicate that additional studies on AQ and desethylamodiaquine metabolism are needed to improve our understanding of antimalarial treatment failure.

PHARMACOKINETIC AND PHARMACODYNAMIC PROPERTIES OF DIHYDROARTEMISININ-PIPERAQUINE IN SEASONAL MALARIA CHEMOPREVENTION IN YOUNG CHILDREN

Joel Tarning[1], Palang Chotsiri[1], Issaka Zongo[2], Paul Milligan[3], Daniel Compaore[2], Fabrice Somé[2], Daniel Chandramohan[2], Warunee Hanpithakpong[1], Francois Nosten[1], Brian Greenwood[2], Philip Rosenthal[4], Nicholas White[1], Jean-Bosco Ouédraogo[2]

[1]Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [2]Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom, [4]University of California, San Francisco, CA, United States

Young children are the population most severely affected by *Plasmodium falciparum* malaria. Seasonal malaria chemoprevention (SMC) with amodiaquine and sulfadoxine-pyrimethamine is recommended and provides substantial benefit to this vulnerable population in high transmission areas. Resistance to this regimen limits preventive efficacy, and the long-acting artemisinin-based combination, dihydroartemisinin-piperaquine is under study as an alternative regimen. However, the pharmacokinetic and pharmacodynamic properties of artemisinin-based combination SMC therapy are not well characterised. Sparse piperaquine plasma concentration measurements were available for 179 children (aged 2.33-58.1 months) after monthly SMC using dihydroartemisinin-piperaquine for three consecutive months in Burkina Faso. Piperaquine pharmacokinetics were characterised by a flexible transit-compartment absorption model followed by a three-compartment disposition model. Body weight was a statistically significant covariate, resulting in lower drug exposures to piperaquine in smaller children after a standard mg/kg dosage. A covariate-free sigmoidal E_{MAX}-model described the time to malaria re-infections satisfactorily. The model-predicted the minimum inhibitory plasma concentration of piperaquine to range between 33.9 and 45.5 ng/mL. Population-based simulations using the final pharmacokinetic-pharmacodynamic model suggested that small children would benefit from a higher dosage. Increasing the dosage and extending the dose schedule to four monthly doses in 4-20 kg children resulted in a predicted relative reduction in malaria incidence of up to 58% during the high transmission season. Use of a higher dose of dihydroartemisinin-piperaquine and extending the dosing schedule to cover the high transmission period for SMC could improve the preventive efficacy of this regimen substantially.

76

SAFETY, TOLERABILITY, EFFICACY AND PHARMACOKINETICS OF HIGH DOSE, SHORT COURSE PRIMAQUINE REGIMENS IN PAPUA NEW GUINEAN CHILDREN

Brioni R. Moore[1], Roselyn Tobe[2], Moses Laman[2], John Benjamin[2], Sam Salman[3], Ivo Mueller[4], Inoni Betuela[2], Timothy M. Davis[3]

[1]School of Pharmacy and Biomedical Sciences, Curtin University, Perth, Australia, [2]Vector Borne Disease Unit, Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [3]UWA Medical School, University of Western Australia, Perth, Australia, [4]Walter and Eliza Hall Institute of Medical Research, Parkville, Australia

Plasmodium vivax (Pv) is geographically the most widely distributed human malaria parasite with more than 2.2 billion people in the Asia Pacific region at risk. In countries such as Papua New Guinea (PNG) where both *P. falciparum* and Pv are transmitted, the complex biology of Pv represents a challenge to malaria control and chemotherapy. Primaquine (PMQ) remains the only FDA approved drug for elimination of Pv liver stage infection. However, the conventional 14-day treatment regimen is limited by poor adherence and there is an urgent need for shorter regimens. This study evaluated the safety, tolerability, pharmacokinetics and pilot efficacy of short course, high dose PMQ in PNG children. Treatment allocation was conducted in a stepwise design, with three regimens investigated; (i) 0.5 mg/kg daily for 14 days (Group 1), (ii) 1.0 mg/kg daily for 7 days (Group 2), and (iii) 1.0 mg/kg twice daily for 3.5 days (Group 3). Children (5-10 years) with normal G6PD activity and confirmed Pv infection were treated with a course of artemether-lumefantrine (AL) and recruited into the study. On completion of AL, all participants underwent a full clinical examination and received their first nominated dose of PMQ. Safety assessments including monitoring of haemoglobin, methaemoglobin, urinalysis and hepatorenal function were performed after doses 1, 3, and 7 in all patients, and dose 14 for Group 1 participants. Adverse effect questionnaires were administered after each dose. Each child was randomly assigned to 3 paired sparse blood sampling time-points (immediately prior, and 2 hours after PMQ) for drug assay during the treatment period. To evaluate treatment efficacy, participants were followed for 2 months after treatment, including active fortnightly surveillance for malarial illness not reported at a health facility (including finger prick blood sample for PCR) and passive detection of participants presenting at the clinic with malaria confirmed by RDT and PCR outside scheduled study-related assessments. This study will be the first to report the safety, tolerability and efficacy of high dose, short course, PMQ treatment regimens in paediatric patients.

77

RISK OF ANEMIA AND TIME TO HEMATOLOGICAL RECOVERY FOLLOWING ARTEMISININ-BASED COMBINATION THERAPIES AMONG HIV INFECTED INDIVIDUALS STABILIZED ON ANTIRETROVIRAL THERAPY WITH OR WITHOUT MALARIA CO-INFECTION IN SUB-SAHARAN AFRICA: POOLED ANALYSIS OF INDIVIDUAL PATIENT DATA

Clifford G. Banda on behalf of the WWARN-IMPACT Study Group

WorldWide Antimalarial Resistance Network, Cape Town, South Africa

In sub-Saharan Africa (SSA) where malaria is highly prevalent, HIV infection is also endemic. Co-infection and co-treatment of malaria and HIV is therefore frequent, and their occurrence is associated with increased risk of anaemia as a result of haemolysis and decreased red blood cell production. Cases of transient anaemia, observed after artemisinin-based combination treatment (ACT) for uncomplicated malaria, have resulted in a debate on whether the changes in haemoglobin are due to an adverse effect of the ACT or a result of the malaria infection. Recent evidence has shown that the extent of the drop in haemoglobin following treatment offuncomplicated malaria is determined by pre-treatment parasitaemia and parasite clearance rates, but is independent of the antimalarial(s) used. However, it is unclear if this finding is equally true for the HIV-malaria co-infected sub-population on different antiretroviral regimens. To explore the potential impact of HIV-malaria co-infection and antiretrovirals on the risk of anaemia, we pooled longitudinal data of haemoglobin measurements from 39 uncomplicated malaria clinical trials in SSA and used logistic regression, accounting for between study variations, to investigate factors associated with anaemia among HIV infected individuals (n=630) compared with HIV uninfected individuals (n=2,568). Furthermore, we will present comparisons of changes in haemoglobin following intake of different antiretroviral regimens (nevirapine-, efavirenz- and lopinavir/ritonavir-based) and ACTs (artemether-lumefantrine, artesunate-

amodiaquine and dihydroartemisinin-piperaquine) in these sub-groups. Understanding any potential impact that commonly used antiretroviral drugs and ACTs may have on haemoglobin concentrations in high risk sub-groups, such as HIV infected individuals, is an important step in optimising antimalarial treatment in this key vulnerable sub-population.

78

ETHNICITY-RELATED MALARIAL SPLENOMEGALY: THE HYPER-REACTIVE RED CELL FILTRATION TRAIL

Benoît Henry[1], Hilaire Akpovi[2], Camille Roussel[3], Papa Alioune Ndour[4], Aurélie Fricot[3], Mathilde Garré[5], Julien Solinc[3], Geoffroy Volle[3], Charlotte Chambrion[3], Nadine Fievet[6], Jérôme Clain[5], David Courtin[5], André Garcia[6], Audrey Sabbagh[5], Pierre A. Buffet[4]

Fulani subjects are partially protected against clinical malaria, have lower parasitemia but more frequent splenomegaly and anemia, as well as elevated levels of both total IgM and anti-*Plasmodium* antibodies. The triggering mechanisms of this phenotype are poorly understood. This collaborative study explored the genetic, parasitological and behavioral determinants of ethnicity-related malarial splenomegaly. In December, 2017, 482 subjects, living in Northwestern Benin, and belonging to 4 ethnic groups (Fulani, Gando, Bariba, and Otamari) were included. We captured age, gender, ethnicity, temperature, spleen size, malaria rapid diagnostic test (RDT), and rapid haemoglobin determination (Hemocue©). Red blood cells (RBC) from venous blood were analyzed using microsphiltration, a method assessing the ability of RBC to squeeze through narrow spaces between microspheres, as a proxy for their splenic filtration. RBC deformability was also assessed with ektacytometry. In a subgroup, (n=120) the deformability of RBC infected *in vitro* with *Plasmodium falciparum* was also assessed by microsphiltration, as well as parasite growth over 72 hours. As expected, Fulani were more often splenomegalic than subjects from the other groups (41% v 23%, p=0.0003) with a trend towards more frequent anemia. Microsphiltration showed that, compared to other groups, Fulani had more deformable RBC in circulation (p<0.0001). This difference was greater in subjects with a positive RDT. Ektacytometry at high shear stress (30 pascals) also showed an increased deformability of RBC in Fulani (p=0.0057). In vitro, the deformability of RBC after infection with *P. falciparum* and parasite growth were similar across the different ethnic groups. We establish a new link between ethnicity and the deformability of circulating RBC. Our results suggest that, in Fulani, splenic filtration of RBC becomes more stringent upon infection with *P. falciparum*, which may explain anemia, splenomegaly and the partial control of parasitemia. Upcoming work will search for determinants of this peculiar, apparently innate splenic reactivity to plasmodial infection in Fulani.

79

IMPACT OF MALARIA-PROTECTIVE GLYCOPHORIN POLYMORPHISM ON *PLASMODIUM FALCIPARUM* INVASION

Silvia Kariuki[1], Alejandro Marin-Menendez[2], Ellen Leffler[2], Gavin Band[3], Kirk Rockett[3], Alex Macharia[1], Johnstone Makale[1], Wilfred Nyamu[1], Francis Ndung'u[1], Dominic Kwiatkowski[3], Thomas Williams[1], Julian C. Rayner[2]

Malaria has had a major selective effect on the human genome. Mutations that provide partial protection against severe malaria can be found at high frequency in malaria endemic regions, even when they can have major deleterious effects, such as sickle cell hemoglobin and resultant sickle cell anemia in homozygotes. Large genome-wide association studies have identified a number of new human genetic polymorphisms that are associated with protection against severe malaria, most of which are found in or near genes encoding proteins important for the structure and function of red blood cells (RBCs), the primary host cell for *P. falciparum* parasites. These include a novel complex structural variant in the glycophorin gene cluster that encodes the Dantu blood group antigen which confers a similar level of protection against severe malaria as HbS, but for which the mechanisms of protection remain unknown. We used flow cytometry-based *in vitro* assays to investigate the impact of the Dantu polymorphism on *P. falciparum* RBC invasion and RBC membrane protein expression for the first time, using RBC samples from a genotyped cohort of Kenyan children. We observed a strong and linear reduction in the ability of multiple *P. falciparum* strains to invade RBCs from Dantu heterozygote and homozygotes respectively. We also observed a significant reduction in the surface expression of glycophorin A (GYPA) and glycophorin B (GYPB), and a significant increase in glycophorin C (GYPC) expression on the surface of RBCs in these same cells. The reduction in invasion observed in carriers of the Dantu variant allele indicates that this polymorphism could confer protection against malaria infection by significantly reducing parasite invasion into the RBC, perhaps mediated by altered expression of the glycophorin receptors on the RBC membrane.

GENERATION OF AN IMMORTALIZED ERYTHROID CELL LINE FROM HUMAN PERIPHERAL BLOOD FOR THE FUNCTIONAL ANALYSIS OF INVASION IN *PLASMODIUM* SPECIES

Estela Shabani[1], Erik J. Scully[1], Gabriel W. Rangel[1], Martha A. Clark[1], Mudit Chaand[1], Christof Grüring[1], Usheer Kanjee[1], Ryo Kurita[2], Yukio Nakamura[3], Manoj T. Duraisingh[1]

[1]Harvard School of Public Health, Boston, MA, United States, [2]Department of Research and Development, Central Blood Institute, Japanese Red Cross Society, Tokyo, Japan, [3]Cell Engineering Division, RIKEN BioResource Center, Tsukuba, Ibaraki, Japan

Plasmodium invasion and proliferation within host erythrocytes is responsible for the clinical manifestations of malaria. The identification of strain-transcendent host molecules for *P. falciparum* invasion (basigin and CD55) has highlighted the importance of identifying critical host determinants for *Plasmodium* spp. invasion to inform the design of vaccines and antimalarials. Recently, we have used forward genetics in erythroid progenitors derived from primary CD34+ hematopoietic stem cells (HSCs) to identify CD55 as an essential host receptor for *P. falciparum* invasion. However, the use of primary cells is time-consuming, subject to donor variability, and these cells are harder to manipulate genetically. Additionally, the few available immortalized erythroid cell lines do not fully differentiate into enucleated normocytes. In this study, we immortalized erythroid progenitors from peripheral blood using the Tet-inducible HPV16-E6/E7 expression system. This cell line (ejRBC) resembles HSC-derived basophilic erythroblasts based on morphology and surface erythopoietic markers, and can be induced to produce

~95% orthochromatic cells and ~5% reticulocytes in eight days, a period considerably shorter than that reported for other cell lines. ejRBCs are genetically tractable *via* shRNA and CRISPR-Cas9 with high efficiency knockdown and knockout evident at 7-10 days post-transduction. Additionally, the levels of the previously identified *P. falciparum* and *P. vivax* receptors are comparable between ejRBCs and reticulocytes. Terminally differentiated ejRBCs support invasion of sialic acid-dependent and independent *P. falciparum* strains, as well as *P. vivax*. CRISPR-Cas9 knockout of DARC in ejRBCs ablates *P. vivax* invasion without affecting *P. falciparum* invasion, emphasizing the robustness of this model for the functional study of *Plasmodium* invasion. Importantly, this method of immortalizing erythroid progenitors from peripheral blood makes practical the generation of cell lines from individuals from diverse genetic backgrounds and with unique polymorphisms to interrogate the mechanisms of malaria susceptibility.

81

COMBINING RNA-SEQUENCING AND MATHEMATICAL MODELLING TO IDENTIFY MECHANISTIC CORRELATES OF PROTECTION IN MALARIA

Parasite load is a key determinant of severe malaria and is a consequence of pathogen multiplication rate, time and the ability of the host to constraint parasite growth. We aimed to develop a new method to identify the host mechanisms which constrain parasite growth. Using a mathematical model of longitudinal infection dynamics for orientation, we made individualized estimates of parasite multiplication and growth inhibition in Gambian children at presentation with acute malaria and used whole blood RNA-sequencing to identify their correlates. We identified 26 human genes positively correlated with parasite growth inhibition, largely linked together in a network focused around extracellular signal-regulated kinases, which integrate cellular inflammatory and metabolic responses in innate defence. Focusing on two genes which encode secreted products, we identified novel roles for cathepsin G and matrix metallopeptidase 9 (MMP9) as direct effector molecules which inhibit *P. falciparum* growth. Cathepsin G acts on the erythrocyte membrane, cleaving surface receptors required for parasite invasion, whilst MMP9 acts on the parasite. Our findings underline the importance of accounting for the interaction between host and pathogen when seeking to identify correlates of protection, and reveal novel mechanisms controlling parasite growth in humans.

82

TIMING OF HOST FEEDING DRIVES RHYTHMS IN PARASITE REPLICATION

Kimberley F. Prior, Aidan J. O'Donnell, Sarah E. Reece

University of Edinburgh, Edinburgh, United Kingdom

The synchronous manner with which malaria parasites replicate asexually in the blood of the host is responsible for many of the clinical symptoms of malaria, with fevers arising from parasites undergoing synchronous schizogony. How malaria parasites maintain synchrony and coordinate the timing of transitions between their developmental stages (e.g. ring, trophozoite, schizont stages) during asexual cycles is unknown. We reveal that the timing of asexual cycles is driven by the host's circadian rhythms, specifically rhythms in food intake. By feeding mice either in the day-time of night-time we show that the timing of asexual parasite development in *Plasmodium chabaudi* becomes inverted in day-fed hosts relative to the rhythms of parasites in night-fed hosts, with schizogony occurring in the middle of the day or night respectively. Our data suggest rhythms in glucose availability are responsible for rhythms in asexual development, not rhythms in host immunity. Furthermore, the host's circadian clock is not required for rhythms in asexual development. Specifically, parasite rhythms are maintained in clock mutant mice but only when rhythmic food intake is enforced; when hosts eat all day long, parasites lose synchrony. We propose that daily fluctuations in resource availability both directly regulate asexual development and are used by parasites as a time-of-day cue to synchronise their rhythm to those of the host. Because parasite rhythms matter for their fitness, identifying the molecular mechanism underpinning parasite rhythms may expose ways to disrupt parasite development and ultimately lead to a reduction in disease and transmission.

83

SURVIVAL RIGHTS SURVEILLANCE OF CHILDREN PRESENTING TO A LARGE REFERRAL HOSPITAL IN MALAWI

Takondwa C. Chimowa[1], Medson Matchaya[2], Edith Kumwenda[3], Patricia Khomani[3], Bernadette O'Hare[1]

[1]University of Malawi, College of Medicine, Department of Paediatrics and Child Health, Blantyre, Malawi, [2]Ministry of Health, Blantyre District Health Office, Blantyre, Malawi, [3]Baobab Health Trust, Blantyre, Malawi

While medical interventions may prevent children from dying after they fall sick, to eradicate avoidable child mortality, there is a need to ensure that children have access to the most important determinants of health, which are basic rights or survival rights. Our aim was to quantify access to survival rights (adequate water and sanitation, shelter, and an educated mother) of children presenting to a major referral hospital in Southern Malawi. A quantitative observational cross sectional approach was used. Routinely collected socioeconomic data for children attending the hospital's services during three calendar years from January 2013 were analysed. As maternal education is associated with child survival, we included this as a survival right. Data from 98,284 children were included in the study. 35.9% and 3.6% of the children did not have access to an improved sanitation and improved drinking water source respectively. There were not significant differences between Blantyre urban and rural residents. 7.2% of children's guardians (90% mothers) did not have access to any education, with 65% having access to 'some primary' education. We also found that in 90.3% of the households, more than 3 people were living in one room. In conclusion many children did not have access to all their survival rights. Deprivation of the right to shelter was the most pronounced followed by the right to sanitation, then maternal education with the right to access to an improved water source being least deprived. A human rights approach to improving child health with routine surveillance of survival rights or data on the social determinants of health at every health facility could be a useful adjunct to national surveys. The collection of data and advocacy at a local level has the potential to increase access to survival rights.

84

MORTALITY TRENDS FOR THE POLITICALLY VOICELESS AND THE OUTBREAK OF "PEACE"- POST-CIVIL WAR MATERNAL AND CHILD HEALTH BY PEACE TYPE, 1990-2015

Riley G. Jones[1], Rachel C. Jones[2], Joel M. Lanceta[3], Jenevieve S. Kincaid[4], Karoline E. Skogo-Brathen[5]

[1]University of Florida, Gainesville, FL, United States, [2]University of Edinburgh, Edinburgh, United Kingdom, [3]University of Louisville, Louisville, KY, United States, [4]Wilderness Medical Society, Lake Tahoe, NV, United States, [5]King's College London, London, United Kingdom

The outbreak of "peace" after civil war is characterized by deeply entrenched grievances and insecurity with violence often persisting at high levels with disproportionate impacts on different segments of society, particularly for the politically voiceless. This study updates our previous work with an expanded dataset, new health indicators, and more robust statistical analysis to test the assumption that diplomatic negotiations at the end of war protect the health and interests of vulnerable, non-combatant populations such as women and children. Specifically, we examined mortality trends after civil war whereby under-five child mortality rates and maternal mortality ratios are compared between two peace types, a peace imposed by the victor and a negotiated peace between capable warring parties, following five years of peace. The Uppsala Conflict Data Program Armed Conflict Dataset was queried for global civil wars ending between 1990 and 2015 and nominally categorized by peace type. UNICEF under-five mortality rates (U5MR) and UNMMEIG maternal mortality ratios (MMR) at five years after conflict termination were then compared by net change relative to health at the point of peace declaration. Health differences by peace type were compared by one-way analysis of variance at α=0.05 with 95% confidence intervals obtained by Welch-Satterthwaite two-sample t-testing. We found that U5MR fell by 13.0 and 19.2 deaths per 1,000 births in VP and NP, respectively, with no statistical differences seen; we found that MMR fell by 73.7 and 110.1 deaths per 100,000 births in VP and NP, respectively, with no statistical difference seen. Further analysis compared peace time mortality trends to those in continued active war zones. Therein, statistically significant health dividends of peace relative to their continued war-affected peers could not be appreciated until three years after conflict resolution. This study concludes that the maternal and child mortality after civil war does not differ between peace types and quantifies the time delay in which populations exiting civil war experience mortality improvements as the beneficiaries of peace.

85

PATTERN OF MEDICATION PRESCRIPTION IN PRIMARY HEALTH CARE CENTERS IN NIGERIA: IMPLICATIONS FOR SDG3 AND IN ANTI-MICROBIAL RESISTANCE

Ibanga J. Inyang

University of Uyo Teaching Hospital, Uyo, Nigeria

Our aim was to investigate the pattern of medicines prescription in selected peri-urban PHC centres in a state of Nigeria, and also attempt to estimate the cost implications of that prescription pattern. Multiple medication and medicines over-prescription were regular features in the PHC centres, with prescription of over nine ingredients in extreme cases. In some instances, the cost of prescribed medications was over 3/15/2018 ASTMH - Nomination Submissions https://www.astmh.org/awards-fellowships-medals/awards-and-honors/nomination-submissions?aid=305&sid=15354 5/20 500% higher than what would be determined for that of a rational or justified medication for the same presenting complaint. Uptake of nonrational or excessive prescriptions in PHC settings could cause family health expenses that exacerbate financial distress. Also, based on their past experience on the prescription profile, community members may delay visit to health centres in anticipation of the level of prescription charges. Forty-two to 50% of the prescriptions featured anti-biotics, in most cases incomplete dosage which at the cellular level may favour development of anti-microbial resistance. In view of the increasing incidence of antimicrobial resistance as a public health threat, there would be justification to carry out a prospective and wider population study of this subject to better identify and characterize and also quantity incidence of the health system governance and health care provider self-interest attributable factors that underpin this pattern, such that more effective measures could be entrenched to curtail the pattern.

86

THE NEXUS OF CONFLICT, MIGRATION, AND DISEASE: A CASE STUDY OF THE CURRENT AND IMPENDING HEALTH CRISIS OF THE ROHINGYA REFUGEES IN BANGLADESH

Megan Vitek, Elliot Tenpenny

Samaritan's Purse International, Boone, NC, United States

The majority of active and protracted conflicts are located in low or middle income countries - 10 of which have been on-going since 1991 and, per the World Bank, have caused the majority of forcible displacements worldwide. UNHCR reported that there were 65.6 million forcibly displaced persons worldwide by the end of 2016 and this number continues to increase. Predictably, conflict causes a crisis of migration that inevitably leads to a public health crisis. Evidence of this lies in the thousands of those directly injured through warfare in conflicts such as Syria and Iraq, as well as epidemic outbreaks of Cholera in Yemen and Measles seeping into surrounding countries from Venezuela. Taking the most recent conflict within Myanmar as an example, a genocide of the Muslim Rohingya people, what started as an internal conflict, lead to almost 700,000 Rohingya fleeing to Bangladesh from August to December of 2017. As a result of joining an existing Rohingya population and host community, the current appeal for support is for 1,300,000 persons and requested funding totals 950.8 million USD. Nearly 10% of this appeal is slotted for healthcare. In this sector, Samaritan's Purse is actively responding to the current Diphtheria outbreak and planning for the impending Cholera outbreak once the rainy season begins. Diphtheria, an antiquated disease and inactive for decades in the western hemisphere, has ravaged the Rohingya community who were not provided vaccinations by their home country. The majority of patients being children, this bacterial infection leads to a buildup of toxins requiring administration of Diphtheria Antitoxin that is in short supply worldwide and often causes severe adverse reactions. After treating over 1,000 individuals with Diphtheria, Samaritan's Purse presents clinical findings and operational lessons learned, as well as the necessary transition within an active humanitarian and health crisis to also caring for Cholera among the forcibly displaced Rohingya, who are an unfortunate case study of the intersection of conflict, migration, and disease.

87

LESSONS LEARNED FROM COMMUNITY ENGAGEMENT AND OUTREACH PRIOR TO INITIATION OF COMMUNITY-WIDE AUTOPSY PROGRAMS TO IMPROVE MORTALITY SURVEILLANCE, KISUMU, WESTERN KENYA

Peter N. Onyango

Kenya Medical Research Institute- Center for Global Health Research (KEMRI-CGHR), Kisumu, Kenya

Several new international initiatives are underway to help address limited cause-specific mortality data in low-resource settings. KEMRI-CGHR/CDC in Kisumu, Kenya, was selected as a site for two of these new initiatives that use autopsies: Child Health and Mortality Prevention Surveillance program and the Kenya Mortality Study. Extensive community engagement and outreach were required prior to starting enrollment due to the sensitivities of this type of work. Community engagement was done through national administration, Ministry of Health ,and Community health strategy. Engagement involved meetings with local leaders including

MoH department heads, chiefs, and assistant chiefs. Trainings were held for all local partners, including community health volunteers, pathologists, laboratory technologists, hearse drivers, and medical staff at health facilities. Community members were engaged through presentations at community meetings. Site preparation and community engagement took place October 2016 through May 2017. We held 20 community meetings, 7 continuing medical education lectures, and sponsored weekly meetings and monthly health dialogue days with CHVs. Topics covered during meetings included background on the studies, the benefits of knowing mortality rates and causes of death, and autopsy procedure details. We trained 3 pathologists on minimally invasive tissue sampling, 2 lab technologists on tissue histopathology preparation, and 8 hearse drivers on safe body handling. We also provided prophylactic vaccinations to 3 pathologists, 4 pathology technicians, 8 hearse drivers, and 8 mortality surveillance staff. To date, we received 83 death notifications and have enrolled 12 pilot deaths. In conclusion, our community engagement strategy has engaged members of the community and has contributed to a quick rollout with receipt of many death notifications. Trainings have equipped partners to understand the objective and effectively handle study procedures. We need to enhance community engagement by continuing to share information to assist with death notifications.

88

STRENGTHENING COMMUNITY HEALTH SERVICE DELIVERY THROUGH COMPLETE HOUSEHOLD MAPPING AND CENSUS DATA, IN A CASE OF MANYATTA URBAN HDSS

Thomas Misore, Maurice Ombok, David Obor, Stephen Liech, Leonard Oyuga, Janet Agaya

Kenya Medical Research Institute (KEMRI), Kisumu, Kenya

Lack of accurate population-level denominators for underserved urban populations hinders the assessment of disease burden, and affects proper development and evaluation of health care interventions. Through the support of the Child Health and Mortality Prevention Surveillance (CHAMPS) network, the Kenya Medical Research Institute (KEMRI) in collaboration with the Kisumu county department of health, Emory Global Health Institute and Centers for Disease Control and Prevention (CDC) are establishing an urban Health and Demographic Surveillance System (HDSS) in Manyatta informal settlement area of Kisumu town, western Kenya. This study was carried out with an aim of generating surveillance data to advice stakeholders on policy and implementation towards reducing child mortality. After verbal consent was obtained from household heads physical mapping geo-location and unique numbering of all houses was conducted in Manyatta between November 2016 and February 2017. Subsequently, all members of the mapped households were enumerated and their socio-demographic data collected. These Data were collected electronically using smart phones by trained Community Interviewers. We compared the data obtained versus the department of health data used in service provision. The total number of enumerated households was 31,266, which was two and a half times the number of households reported and served by the county health department at 11,868. We noted that although each community health volunteers (CHV) is allocated 100-120 households by the health department, our data shows that they should actually cover 650-800 households. A comparison of the workload also showed that only 11 out of 110 villages met the set criteria of assigning 100-120 households per CHV. As observed, emphasizing the importance of re-assessing census figures for urban area catchments is of paramount importance since CHVs are recruited and allocated duties on the basis of number of households, this finding has important implications for service delivery and health outcomes in Manyatta.

89

DEVELOPMENT OF RUMOR SURVEILLANCE IN SUPPORT OF MINIMALLY INVASIVE TISSUE SAMPLING FOR DIAGNOSING CAUSE OF CHILD DEATH IN BANGLADESH

Md. Saiful Islam[1], Abdullah-Al Masud[1], Muhammad Faruqe Hussain[1], John Blevins[2], Emily D. Lemon[2], Shams El Arifeen[1], Elizabeth A. O'Mara[2], Khatia Munguambe[3], Emily S. Gurley[4]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Emory University, Atlanta, GA, United States, [3]Manhiça Health Research Centre, Mozambique, Mozambique, [4]John Hopkins University, Baltimore, MD, United States

In low and middle-income countries, determining cause of death (CoD) is impaired by limited diagnostic facilities, poor access to health care systems, and limited acceptance of autopsies. Minimally invasive tissue sampling (MITS), a post-mortem procedure to extract small tissue specimens for laboratory analysis could reduce uncertainty of CoD. A study to identify the CoD in Bangladeshi children using MITS could lead to rumors, given the cultural sensitivities around any type of postmortem exam. Our objective was to implement a system to identify and track rumors and misinformation about the MITS procedure to enable management and response to rumors through community engagement. We recruited 1,275 volunteers in 261 villages to notify any rumors being spread in the community, defined as attitudes, expectations, interests, concerns and anxiety towards MITS. Once a rumor was reported, the field team selected respondents for in-depth interviews and group discussions to track, verify and understand rumors. From September 2017 through February 2018, the team identified three rumors from communities where deceased children underwent the MITS procedure. Two rumors indicated that the study was harvesting organs for sale or transplantation. Another rumor was that the MITS procedure had been conducted on a living child, and because of this, there was excessive seepage of fluids from the needle wound sites. Rumors reportedly originated from some villagers who were unfamiliar with the MITS procedure. The team visited the rumor affected villages, talked to residents who started or perpetuated the rumors to understand their concerns and queries, and then convened group meetings to correct misinformation. The rumor surveillance was critical for successfully identifying and responding to tensions between community's perceptions and the study´s objective, improving the acceptability of the procedure and ensuring that families who agreed to MITS did not suffer stigmatization. Rumor surveillance could be used as a part of any public health program where there is a need to identify and act upon public misinformation or other community events in real-time.

90

"BLEEDING BODIES", "UNTRUSTWORTHY BODIES"? A SOCIAL CONSTRUCTIONISTS APPROACH TO THE HEALTH AND WELL-BEING METRICS FOR FEMALE YOUTHS IN KENYA

Elizabeth Opiyo Onyango, Susan J. Elliott

University of Waterloo, Waterloo, ON, Canada

The diverse changes - biological, social, cultural and economic - experienced by female youth and that affect their health and well-being is well researched. What is yet to be understood is how female youths in LMICs socially construct their health and well-being in the time of transition to adulthood in a resource scarce environment and how this impacts on their perception and meanings of health and well-being. Empirical evidence has shown that human experiences and perceptions of space and time are remarkably specific to certain groups and cultures in particular places and times. Using this premise, we employed a social constructionist perspective to explore health and well-being of female youth in Kenya with an objective of highlighting the health indicators that matter to the lay female which are youths essential in well-being assessment. Using an ecological model, we conducted six in-depth interviews (n=6) and four focus group discussions (n=4) with female

youth 15-24 years in different regions in Kenya. The regions were selected based on socio-economic status, urban, arid and semi-arid areas. Phenomenological analysis of the data gave rise to the conceptual categories of the female youth being "bleeding bodies", "unemployed and over dependent bodies", and "untrustworthy bodies", "culturally disadvantaged bodies" and "bodies prone to diverse health risks". We found out that poverty and lack of basic needs contributed to feelings of powerlessness and inability to take charge over one's life in the phase of transition. Strong social support was demonstrated as the only hope and fallback for the youth in these of contexts. These insights are important in formulation of context specific policies that target neglected groups.

91

INTEGRATING ACTIVE AND PASSIVE CASE SURVEILLANCE IN PREDICTIVE DISEASE MAPPING

Luca Nelli[1], Heather M. Ferguson[1], Alfred B. Tiono[2], Hilary Ranson[3], Jason Matthiopoulos[1]

[1]University of Glasgow, Glasgow, United Kingdom, [2]Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Statistical relationships between environmental predictors and disease incidence can be observed either via localised active surveys or via passive case surveillance data collated at health centres. Active surveys can achieve monitoring with high explanatory power, but they are expensive and highly localised. Passive detection allows data collection across a broader scale, promising wider spatial predictions, but with limited explanatory power, due to the lack of detailed aspects of the disease and its drivers. Here, we aimed at achieving the best of both worlds via an inferential framework capable of simultaneously drawing insights from both these types of data.We used a Bayesian latent point approach, incorporating a combination of active data collection in some points, where a full set of covariates were measured, and passive cases detection, where an important covariate (insecticide resistance) was unavailable. We validated our approach on some hypothetical scenarios of reported malaria incidence as a combination of both an ecological process (incidence as a function of some environmental covariates) and an observation process (probability of reporting malaria cases as a function of distance from clinics). Models considering active sampling sites only failed in describing the relationships between the environmental predictors and malaria incidence. Models using passive detection data only gave better results, allowed to estimate the probability of case reporting at health centres and to generate full predictions of incidence in space, but not to infer the latent variable. When jointly considering active and passive cases, we obtained the best estimate of coefficients describing the biological and the observation processes, together with full spatial prediction of both incidence and the latent variable of insecticide resistance.By integrating active sampling and passive case detections in a complementary way, we provide a simple solution to a widespread problem in spatial epidemiology, combining latent process modelling, spatially autoregressive modelling and point sampling distance sampling.

92

HEALTHCARE WORKERS' PERSPECTIVES ON PREPAREDNESS OF HEALTHCARE FACILITIES FOR OUTBREAK OF COMMUNICABLE DISEASES IN NIGERIA: A QUALITATIVE STUDY

Maduka D. Ughasoro

University of Nigeria Enugu Campus, Enugu, Nigeria

The probability of a future outbreak of communicable disease after the recent Ebola virus outbreak is high. The healthcare facilities may not be prepared to respond in case of such eventualities. The Nigerian healthcare workers' (HCWs) knowledge for preparedness, perception of level of preparedness existing in their facilities, militating factors and possible ways to improve were evaluated through a qualitative data collective: Focus Group Discussion and In-depth interview. Among the 193 HCWs that participated in the study, 98.4% (190/193) considered their health facilities to be insufficiently equipped for disease outbreaks. None of the facilities has an emergency operation unit. The HCWs' idea about preparedness centered essentially on universal precaution. Training and routine emergency drill, disease surveillance, and adequate waste management are lacking. None 0% (0/193) of the participants had undergone any form of emergencies drill. Among the suggestions on how to improve on preparedness were: immunization of staff, better communication among different departments in the health sector, routine training, fund and relocating some of the hospital services to an annex. In conclusion, the overall poor level of preparedness which exist in most health facilities cannot contain any outbreak. There is need to look beyond universal precaution to areas like improved communication and information sharing, and routine interpretation of surveillance data by epidemiologist. Institution of emergency operation units in every health institute capable of functioning during non-outbreak periods.

93

KNOWLEDGE OF NEURAL TUBE DEFECTS, ATTITUDES AND PREVENTION PRACTICES AMONG WOMEN SEEN IN PRENATAL CONSULTATION-NIAMEY-NIGER, 2017

Oumarou Batoure[1], Williams Jennifer[2], Samuila Sanoussi[3], Sawadogo Bernard[4], Antaraa Simon[5], Mckenzie Andre[2]

[1]Direction of Immunization, Niamey, Niger, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Head of Neurosurgery Department, National Hospital, Niamey, Niger, [4]West Africa Field Epidemiology Training Program, Ouagadougou, Burkina Faso, [5]Africa Field Epidemiology Network, Kampala, Uganda

Congenital abnormalities are functional, structural, or metabolic abnormalities that occur in the uterus and are identified before or after birth. In Niger, the field of congenital abnormalities has not been sufficiently explored. Our goal was to describe the knowledge of neural tube defects (NTD), attitudes and preventive practices among women seen in prenatal consultation (PNC). We carried out a cross-sectional survey from February to March 2017 among pregnant women seen in PNC (1) in maternity hospitals in Niamey. The sample, calculated with Open Epi was 421.These women were interviewed and the data were collected with a questionnaire. Univariate, bivariate and multivariate analyzes were performed. The prevalence ratio (PR) and the prevalence of 95% OR (POR) were calculated. Variables with $p < 0.25$ in bivariate analysis were integrated in the logistic model. The median age of the respondents: 25 years. There were 60.81% schooled; 24.33% had their first pregnancy. Among the respondents 30.65% knew the NTD; 15.92% had good attitudes; 41.81% had used folic acid (FA). Age (25-49 years) was independent factor of NTD knowledge ($p = 0.0008$); for attitude: age (25-49 years) ($p = 0.03$), FA intake ($p = 0.0002$) and for practice, being literate ($P = 0.01$), information by health workers ($p < 0.0001$), knowledge of other sources of FA ($p = 0.04$). There is a lack of knowledge, attitudes and practices regarding NTDs among women in Niamey. Continuing education for women and the implementation of a mandatory policy for the fortification of certain foods with FA are necessary.

94

ACCESS TO VISCERAL LEISHMANIASIS DRUGS IN EASTERN AFRICA: WHY EFFECTIVE SUPPLY IS SO ELUSIVE?

Temmy Sunyoto

Institute of Tropical Medicine, Antwerpen, Belgium

Visceral leishmaniasis (VL) is fatal without timely treatment. As a neglected tropical disease, the control program in eastern Africa region is hindered by vast challenges. Conflict, population displacements, malnutrition and poverty influence the supply of life-saving drugs to treat VL. The treatment regimens are limited: toxic, complex administration, too expensive, or produced by a single source. Drug shortages are common, leading to

the severe socio-economic burden of the people, often the poor and most marginalized. Despite the external support, effective supply of VL commodities remains uncharted territory. There is no data on the magnitude of drugs shortages and the bottlenecks in procurement. We aim to evaluate access barriers to supply of quality VL drugs and diagnostics, as part of a larger study on access to care. We conduct landscape on policy analysis at the global level, which then narrows down towards mapping of barriers at the regional level. We have launched an online survey for participants working in neglected disease in the region through an e-drugs mailing list. A series of in-depth interviews with key stakeholders at different levels are conducted, including from multilateral and international organizations using a piloted topic guides and conducted by an experienced qualitative researcher(s). A focus will be dedicated to Sudan, the country bearing the highest burden of VL (30,000 cases in 2010-2014). We perform analysis on stock-outs between 2007-2017 will be performed, ranging from the central medical stores to the health facility level. Perspectives from the national, state and health workers will be solicited as well. The data collection is planned to start in May 2018. With the combination of quantitative and qualitative data, we expect to have -for the first time- a clear map of barriers to effective supply of VL drugs and strategies moving forward for this region. Access to available drugs is often overlooked. Thus ensuring supply to the drugs that save lives, should not be neglected further.

95

PILOTING NURSE-LED QUALITY IMPROVEMENT PROJECTS IN NENO DISTRICT, MALAWI

Esnath M. Kapito[1], Maria Openshaw[1], Chiyembekezo Kachimanga[1], Emily Wroe[1], Sharon Rose[2], Sally Rankin[2], Cory McMahon[3], Anatole Manzi[3], Mercy Mhango[4], Kim Baltzell[2]

[1]Partners In Health/ Abwenzi Pa Za Umoyo, Blantyre, Malawi, [2]University of California San Francisco, San Francisco, CA, United States, [3]Partners in Health, Boston, MA, United States, [4]Neno District Hospital, Ministry of Health, Blantyre, Malawi

This abstract describes a component of the authors' ongoing study "Improving Health Outcomes in Mothers and Neonates using the WHO Safe Childbirth Checklist in Neno District, Malawi". There is a persistent gap between the intended quality of maternity care and that experienced by Malawian women, as evidenced by country's high maternal and neonatal mortality rates. In response, the Malawian Ministry of Health (MoH) has decided to focus on quality improvement (QI), through the formation of a national Quality Management Directorate and facility-level QI activities. Guided by the Reproductive Health Directorate, these initiatives have focused on systems-level improvements to maternity care. In Malawi, most maternity care is provided by nurses and midwives at the community and district level. This project uses nurse-midwives as the drivers of QI to conduct projects targeting the most significant challenges or deficits in their workplaces. As part of the Global Action to Improve Nursing and Midwifery care (GAIN) initiative in Neno, a district in southern Malawi bordering Mozambique, 30 local nurse midwives were trained in leadership and QI in two cohorts. GAIN is a collaboration among the University of California San Francisco (UCSF) School of Nursing, Partners in Health/Abwenzi Pa Za Umoyo, and the Malawian MoH. Working on interdisciplinary teams and with guidance from two expert nurse midwife mentors, nurse midwives designed and implemented QI projects in their workplaces in March, 2018. Topics included improving management and documentation of the immediate postpartum period; improving routine neonatal care through checklist use; decreasing rates of puerperal infection; and improving blood pressure monitoring for antenatal mothers. Project targets include complete charting of all postpartum assessment and care, consistent use of a checklist for neonatal care, and documentation of blood pressure for all mothers at every antenatal visit. Given the vital role of nurses in this setting, QI initiatives designed and led by nurses have the potential to eliminate systems-level barriers to comprehensive and safe care for mothers and newborns.

96

ASSESSMENT OF THE DETERMINANTS OF NON-ADHERENCE TO ANTIRETROVIRAL THERAPY DURING PREGNANCY IN THE DISTRICT OF MANHIÇA, MOZAMBIQUE: A PRELIMINARY ANALYSIS

Salésio Macuácua

Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique

Inadequate adherence to antiretroviral therapy (ART) and retention to care among pregnant women and breastfeeding mothers has been an important barrier to effective prevention of mother to child transmission (PMTCT) of HIV infection in sub-Saharan Africa. Intending to address the many challenges of PMTCT implementation, WHO revised international guidelines to recommend lifelong ART treatment for all HIV infected pregnant women at the time of diagnosis in antenatal care and during breastfeeding, regardless of their clinical condition. Mozambique, adopted this strategy in 2013. However, despite commitments, this strategy has been severely stressed by continued high rates of non-adherence to ART and lost to follow up. The aim of this study was to identify the determinants of non-adherence to ART among pregnant women in the district of Manhiça, Mozambique. In this preliminary analysis we used de-identified, aggregate data collected within a large parent study. Data included age groups, marital status, education, occupation, religion, and residence. For select pregnant women, a more detailed in-depth interview was conducted to explore the association of the socio-demographic factors on consumption of ART medications. Non-adherence was determined through pill counts and self-reports, and defined as taking less than 95% of the prescribed ART doses for each of the first two months since initiating prenatal care visits. Preliminary analysis of the 127 participants recruited into this study, based on pill count, only 33% of our population was adherent to ART during each of the two months period following initiation of their prenatal care. In multivariable models of analysis, the characteristics most significantly associated with being non-adherent to one´s ART were decreased age, being a widow, having lower education, and initiating ART during the current pregnancy. It is very likely that greater attention needs to be given to actual pill consumption and clinical measurements such as viral load to better monitor the adherence to ART and retention in care rather than just simply maintaining clinic visits and medication pick-up.

97

MOTIVATION FOR FRONTLINE HEALTH IMPLEMENTERS IN NEGLECTED TROPICAL DISEASE PROGRAM: THE KEY TO SUSTAINABILITY AND ACHIEVING ELIMINATION GOAL FOR NEGLECTED TROPICAL DISEASES IN NIGERIA

Akinola S. Oluwole[1], Luret Lar[1], Oluwatosin B. Adekeye[1], Ruth Dixon[2], Kim Ozano[3], Sally Theobald[3], Laura Dean[3], Sunday Isiyaku[1], Elena Schmidt[2]

[1]SIGHTSAVERS, Kaduna, Nigeria, [2]SIGHTSAVERS, Haywards Heath, United Kingdom, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Neglected Tropical Diseases (NTDs) affect the poorest and most marginalized people in low resource countries. Despite global efforts to combat these diseases, equitable access to freely donated drugs is still a problem. Frontline implementers (Health Facility staff, Community Drug Distributors and Teachers) are the workforce of the NTD control programme and serve as essential link between the health system and endemic populations. There is an evident gap in understanding best practices for capacity strengthening of health workforce and performance management of NTD programme in Nigeria. This study sought to explore current strengths and weaknesses in Human Resource management for NTD programme delivery so as to find solutions to current programmatic

challenges informed by the perspectives of these implementers. The study was conducted in two purposively selected states, Kaduna and Ogun State, to allow for maximum contextual variation. We conducted participatory stakeholder workshops with frontline implementers in 6 LGAs (3 per state). Experiences, challenges and enablers faced by each group were explored, synthesised and analysed thematically according to the WHO Health Systems building blocks. Motivation of implementers to work is affected by challenges they experience, which include lack of supportive supervision by the leadership and governance of NTD programmes, overburdened health workforce due to staff shortages and inadequate health financing resulting to out-of-pocket expenditure. Poor health management information systems for rapid response and management of adverse reactions leading to drug refusals in subsequent treatment rounds also discourages the implementers. Lastly, there is inadequate training of implementers resulting in lack of confidence and poor **service delivery**. Implementation research is required to understand how the health system can be strengthened to produce well motivated workforce for NTD programmes. Since the frontline implementers connects the health system and endemic populations, their motivation is key to sustainability and achieving elimination goal for NTD programme in Nigeria.

98

PERFORMANCE OF COMMUNITY HEALTH WORKERS IN PROVIDING INTEGRATED COMMUNITY CASE MANAGEMENT SERVICES (ICCM) IN EIGHT DISTRICTS OF RWANDA

Noella Umulisa[1], Aline Uwimana[2], Cathy Mugeni[2], Beata Mukarugwiro[1], Stephen Mutwiwa[1], William R. Brieger[3], Kaendi Munguti[4], Aimable Mbituyumuremyi[2]

[1]Maternal and Child Survival Program/Jhpiego Rwanda, Kigali, Rwanda, [2]Malaria and Other Parasitic Diseases Division (Mal & OPDD), Rwanda Biomedical Centre (RBC), Kigali, Rwanda, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [4]US President's Malaria Initiative, United States Agency for International Development, Kigali, Rwanda

Integrated Community Case Management (iCCM) is a proven evidence-based strategy that trains, equips and supports various cadres of community health providers to deliver high-impact treatment interventions in the community. It is an important component of Integrated Management of Childhood Illness (IMCI), which was developed by WHO in the 1990s. Community health workers (CHWs) in each of Rwanda's nearly 15,000 villages were trained in iCCM and equipped for empirical diagnosis and treatment of pneumonia, diarrhea, and malaria; for malnutrition surveillance; and for comprehensive reporting and referral services. This study was designed to evaluate the performance of CHWs in managing malaria, pneumonia and diarrhea in 8 districts of Rwanda. In August 2017, a cross sectional study was conducted among 64 CHWs in 8 districts. Data was collected using interviews and record reviews. Of the 64 CHWs, 35 (54%) were males, and 94.6% of CHWs reported being satisfied with their work. In the previous 3 months, the most common illness seen by CHWs was malaria (38%), followed by pneumonia (33%). Overall, 70% of cases were correctly treated. Malaria was correctly treated at 85%, while pneumonia was correctly treated at 60%. Artemether lumefantrine was found among 67% of CHWs' supplies, while malaria RDTs were the most available commodity at 80% of all CHWs. The results showed that CHWs are providing Integrated Community Case Management services but their performance is affected by drug availability. Strategies to improve drug supply, and supportive supervision from the formal health system are necessary to improve the performance of CHWs.

99

ENGAGING COMMUNITY RESIDENTS IN INTRODUCING MINIMALLY INVASIVE TISSUE SAMPLING (MITS) PROCEDURE FOR CHILDREN IN BALIAKANDI, BANGLADESH

Faruqe Hussain[1], Emily S. Gurley[2], John Blevins[3], Emily Lemon[4], Abdush Suban Mulla[1], Abu Uzayer[1], Afroz Zahan[1], Anisur Rahman[1], Aziz Ahmed[1], Bimal Das[1], Kazi Faisal Alam[1], Syeda Lutfe Famida[1], Shikha Datta Gupta[1], Suruj Ali[1], Shams El Arifeen[1], Md. Saiful Islam[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]Rollins School of Public Health, Atlanta, GA, United States, [4]Emory University, Atlanta, GA, United States

Minimally invasive tissue sampling (MITS), a post-mortem procedure that uses needle to collect specimens has emerged as an alternative to autopsies, the gold standard to diagnose cause of death. In Bangladesh, diagnosing cause of child death is difficult due to poor diagnostic infrastructure, limited access to qualified doctors in rural settings and lack of documented medical histories. Considering the context, we aimed to use MITS to identify the aetiology of death among children less than five years of age in Baliakandi, Bangladesh. A previous small-scale MITS pilot in Bangladesh showed that rural people often confuse MITS with full autopsies, sometimes leading to mistrust between the study team and participants. Therefore, our objective was to engage and inform rural residents about MITS objectives and procedure, and enquire whether the MITS procedure is aligned with their social, cultural and religious practices and their motivations to know the aetiology of child death. Between January - March in 2017, we conducted 14 workshops with community leaders (7) and community members (7) using participatory approach. The majority of the participants reportedly accepted the MITS as it would not require opening the deceased body and believed MITS could be an innovative way to know the aetiology. Some participants provided examples of multiple child loss within families and believed MITS could help knowing the causes of such tragedies in the future. Participants stated that it would be socially and religiously permissible to perform MITS. Collecting samples and soliciting consent might be difficult from distressed and grieving families and due to community perceptions that MITS is not necessary for already known causes of deaths by severe diseases, accidents or drowning. Participants suggested engaging elder community members including religious leaders to address queries and concerns. Participatory community engagement approaches can be useful for population based public health programs through gaining community input and further insights into how to build trust and relations with rural residents to engage them in the program.

100

EMERGENCIES, ETHICS AND COMMUNITY ENGAGEMENT

Elhadji Mamadou Mbaye

IRESSEF : Institut de Recherche en Santé,de Surveillance Epidemioloque et de Formations, Dakar, Senegal

December 2013, the first case of Ebola occurs in southern Guinea. Due to emergency, to the rapidity of its spread and its virulence, experts announce the risk of an international health disaster. Stakeholders in charge of the response against EVD are implementing a series of initiatives on the ground to limit the spread of the epidemic (sorting of patients, quarantine, rapid clinical trials, etc.). These initiatives lead to community resistance that encourages efforts at the local, national and international levels to improve their ethical dimensions (commitment of religious and community leaders, mobilization of AVAREF, development of guidelines at international level to support ethics committees This presentation is based on (1) documentary review, (2) then the exploitation of the data coming from ethical committees and (3) the analysis of the interviews and observations made in the field with communities and stakeholders in charge of the response. The analysis of the data set has shown: (1) an explosion of research and

intervention activities against EVD in West Africa, (2) that raised important ethical concerns because of emergency and lack of knowledge on EVD in West Africa, (3) and mobilization of all actors at different levels of the response to tackle these ethical concerns. In conclusion. the Ebola outbreak has highlighted the fragility of health systems in West Africa and the need for these countries to build the capacity of their ethics committees in developing tools and procedures against the emergence of emerging diseases and re-emergences.

101

SYSTEMATIC REVIEW OF COMMUNICATION STRATEGIES IN NEGLECTED TROPICAL DISEASES ERADICATION, ELIMINATION AND CONTROL PROGRAMS: A CALL FOR ACTION

Claudia Nieto-Sanchez[1], Mario J. Grijalva[2], Koen Peeters Grietens[1], Benjamin Bates[3]

[1]Institute of Tropical Medicine Antwerp, Antwerp, Belgium, [2]Infectious and Tropical Disease Institute - Ohio University, Athens, OH, United States, [3]School of Communication Studies - Ohio University, Athens, OH, United States

Many NTD interventions call for community engagement, health promotion, or behavior change strategies to enhance coverage and adherence. Although communication theories and practitioners have conceptualized and developed strategies, it is unclear whether NTD interventions use these perspectives. To understand how communication practice is operationalized in NTD interventions, this systematic review identified communication actions implemented to address Guinea worm (GW), lymphatic filariasis (LF), schistosomiasis (SC) and Chagas disease (CD). We examined studies published between 2012 and 2017 in five electronic databases. Articles extracted met three criteria: references to communication, guiding theoretical framework (if available) and communication domains, including community participation. Information about media and messages was also collected when available. A total of 114 articles were extracted (GW=11; LF=29; SC=29; CD=45). Behavior change is the most common goal pursued and expected from communication strategies. Risk behaviors are usually addressed through health education and awareness campaigns. Media-based strategies are used for dissemination and persuasion. Community participation is frequently associated with adherence, although more complex definitions have been tested. References to communication theory are scarce. These results illustrate efforts in NTD programing to reach populations at risk; however, they do not account for the complexity of communication dynamics associated with prevention and treatment of this group of diseases. For instance, MDA strategies consistently showed challenges derived from the proliferation of rumors that can be effectively reduced through communication action. Similarly elimination, eradication and control programs did not meaningfully differ in their communication approaches despite the specific demands of each stage. More systematic and strategic use of communication frameworks adjusted to the specific public health goals of NTD interventions and context of affected populations is recommended.

102

VICTOR CHARLIE AND DISEASE PREVENTION: *USARV MEDICAL NEWSLETTER* CARTOONS, INFECTIOUS DISEASE AND THE VIETNAM WAR, 1965-1972

David Adams[1], Jessmarie Gonzalez[2], Colette Ryset[2], Femi Taiwo[3], Valerie Adams[4]

[1]Point University, Savannah, GA, United States, [2]South University, Savannah, GA, United States, [3]Texas A & M University, College Station, TX, United States, [4]Georgia Southern University, Statesboro, GA, United States

The US lost more than 58,230 troops during the Vietnam War. Although most died due to combat-related circumstances, thousands also died due to non-combat causes. Deaths in the latter group were the result of causes that ranged from suicide to heart attack, malaria to hepatitis. While mortality from infectious diseases was relatively rare, morbidity from such maladies proved an ongoing problem for medical officers and field commanders alike. As General Slim quickly learned in the India-Burma Campaign during WWII, troops who were too sick to fight were of little use against the enemy. The medicos of the USARV (United States Army Republic of Vietnam) focused much of their prevention efforts on infectious diseases. As such, they published a type-written, semi-monthly tract, the *USARV Medical Newsletter*. Its purpose? "To provide information of interest and assistance to medical services of the US Armed Forces in RVN [Republic of Vietnam]." Each *USARV Medical Newsletter* offered dryly worded recommendations for preventing and treating infectious diseases from melioidiosis to malaria. Sprinkled throughout the *USARV Medical Newsletter*, however, were roughly sketched, pen and ink, cartoons that addressed topics from the need for safe drinking water to the importance of malaria discipline. Their purpose was to reinforce—with heavy doses of gallows humor—the sober jargon contained in the *Newsletters*' articles. This presentation, based on archival materials from the Vietnam Center and Archive at Texas Tech University, will examine the cartoons of the *USARV Medical Newsletter*. As our findings will show, the often crudely penned cartoons reflected not only the pressing issue of infectious disease among combat troops but also changing attitudes toward the war itself.

103

INTERPROFESSIONAL EDUCATION IN A GLOBAL HEALTH COURSE

James Leathers, Heather Davidson, Neerav Desai

Vanderbilt University School of Medicine, Nashville, TN, United States

Few global health experiences include intentionally-directed interprofessional training. We aim to prospectively evaluate the impact of a global health elective in facilitating interprofessional education (IPE) and promoting cultural sensitivity. We included in our study, medical and nursing students who participated in the 2015 and 2016 cohorts of the Nicaragua Global Health course. The course consisted of a 12-week curriculum conceptually divided into three phases: 1) pre-immersion preparation, 2) in-country immersion in Nicaragua, and 3) post-immersion reflection. The pre-immersion preparation phase included didactic lectures and small group discussions designed to introduce students to concepts of interprofessional collaboration. During the in-country immersion phase, students were organized into small-groups that participated in a variety of interprofessional activities. During the post-immersion phase, students also to prepare a poster presentation on patient education and teaching that was presented to students and faculty at our institution. Students filled out pre- and post-course surveys. We performed quantitative analysis on numeric data and qualitative analysis on open-ended questions. Of 39 total students enrolled in the course, 26 (18 medical and 8 nursing students) participated in the study and filled out the pre- and post-course surveys. Mean competency scores increased for all questions between pre- and post-course surveys, and of these, 5 of 7 reached statistical significance. Qualitative themes identified included: 1) the importance of understanding other team member's roles and relative strengths; 2) the value provided by the breaking down of traditional power dynamics between clinicians. Global health experiences represent a unique and under-utilized opportunity for facilitating IPE. Our global health course may be useful as a model for other educators seeking to prepare similar programs aimed at teaching the principles of IPE.

104

TIME TO ADDRESS THE GROWING SYNDEMIC OF TUBERCULOSIS AND DIABETES: INDIA AS A MODEL HIGH BURDEN COUNTRY

Latha Rajan, Samuel C. Ficenec

Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States

Tuberculosis (TB) is the top cause of death from a single infectious agent globally. The annual global incidence of 10.4 million TB cases in 2016 is alarming. Diabetes mellitus (DM) is an important comorbidity that complicates both treatment and clinical course of TB. Currently, India is the country with the highest incidence. A negative of India's fast-growing economy is that it is undergoing the epidemiological transition to noncommunicable diseases such as Diabetes. India launched an ambitious new strategy in 2018 to end TB by 2025. A successful strategy to achieve this goal should address co-morbid conditions that lead to poor outcomes in TB cases. We undertook this project with the aim of producing an in-depth needs assessment analysis of existing literature on TB-DM in India. Results of our analysis have revealed that TB-DM patients were more likely to experience poor treatment outcomes, longer times to sputum conversion, increased rates of adverse drug reactions, and increased drug. Prospective studies included in our analysis show that TB-DM patients were more likely to experience treatment failure (4.2% vs 0.7%, p=0.04) than TB-only patients. TB-DM patients were more likely to be sputum smear positive at the end of DOTS treatment (RR 3.9, 95% CI: 1.5-10.6, p=0.02). Time to sputum conversion was significantly longer at 64.2 days +/- 10.5 days in TB-DM patients vs 61.5 +/- 7.5 days for TB-only patients. An interesting finding was that TB-DM patients were more likely than TB- only patients to have rifampin resistant TB (27.8% vs 8.8%, p<0.01). Numerous molecular and cellular differences in individuals with co-morbid TB-DM were also found. In 2011 the WHO endorsed a bi-directional screening method for early diagnosis of TB-DM cases. Despite such efforts, India has the highest number of cases in the world with an estimated 29-44% of them being TB-DM cases. With better control of HIV and established HIV-TB programs, it is high time that TB programs pay attention to the growing epidemic of Obesity/Diabetes. Our results provide evidence for adopting comprehensive TB prevention and treatment programs that include important co-morbidities such as DM.

105

BIOSAFETY CAPACITY BUILDING: A CASE STUDY IN PUBLIC-PRIVATE PARTNERSHIPS

Ryan N. Burnette

Merrick and Company, Greenwood Village, CO, United States

Biosafety capacity building has been a foundation to dozens of global health endeavors over the past several decades in various regions, many with limited success. Many shortcoming to realize sustainment of these efforts include transient engagement from international partners, inability of host countries and institutions to sustainably fund and manage resulting programs, challenges with respect to building human resources, and others. Private and public partners have much to offer in terms of capacity building and net results can be augmented when both partners work collaboratively with host nations and institutions. This presentation will detail a series of BSL2 to BSL3 tuberculosis diagnostic laboratory and program upgrades in different provinces of India as a result of a collaborative effort between private, public, and host nation resources. In short, laboratories of this nature had a strong need to increase TB diagnostic capacities, necessitating the inclusion of new liquid culture TB diagnostic systems. However, these new systems required more robust biosafety capacity. Our team led the upgrade of BSL2 laboratories to BSL3 laboratories in four locations. In the subsequent years, this program has expanded to over 20 laboratories. Through good partnership design, involvement of host nation resources, and a unique remote project management application, diagnostic capacity and accuracy of TB diagnostics expanded rapidly and cost-effectively. This case study will demonstrate critical decisions made during the project lifecycle that impacted both execution and resulting plans for sustainability. This presentation will also detail nuances of the public-private partnership that established a framework for close involvement of host nation resources to build internal human resources. Finally, this study will reveal both the lessons learned from the experience and the resulting successes.

106

NUTRITIONAL STATUS AMONG CHILDREN UNDER FIVE AND ITS DISPARITY BETWEEN COMMUNITIES IN SAHEL REGION OF BURKINA FASO: A COMMUNITY-LEVEL INTERVENTION EVALUATION

David Zombre[1], Valery Ridde[2], Manuela De Allegri[3], Kate Zinszer[1]

[1]University of Montreal School of Public Health, Montreal, QC, Canada, [2]IRD-France, Paris, France, [3]Public Health Institute, University of Heidelberg, Heidelberg, Germany

Stunting remains an important public health problem in Burkina and improving financial accessibility can help improve child nutritional status. The objectives of this study were to examine whether living in communities that were exposed to user fees removal combined with healthcare quality improvement and malnutrition management of malnutrition was associated with improved height-for-age z-score and decreased likelihood of stunting and severe stunting among children under five, four years after the interventions' implementation. We carried out an evaluative theory-driven, post-test-only design that included a control group and relied on a representative cross-sectional household survey conducted four years after the intervention onset in 41 communities from intervention district and 51 communities in comparison district. When comparing children living in the intervention district to children living in the non-intervention district, we determined no differences in terms of stunting [OR=1.13; 95% CI= 0.83 –1.54] nor in severe stunting [OR=0.99; 95% CI =0.76–1.26), nor in height of age z-score [(HAZ =-0.03; 95% CI: (-0.21–0.16)]. Our study demonstrated that most of the variance in stunting occurs at the individual level (variance =90.64% [95% CI= (86,62%–93,55%]. We also found that only 2% of the community-level variance of stunting was explained by the intervention in communities. In conclusion, this study provides important information to policymakers on the limits of targeting financial barriers at the community-level in addressing nutritional status at the individual level. In order to achieve better results in improving nutritional status, a population intervention should be designed with individual interventions specifically targeting the proximal determinants of malnutrition, as over 91% of the variance in nutritional status occurs at the individual level.

107

ACHIEVING REGULATORY COMPLIANCE AT RESEARCH-NAÏVE MALARIA CLINICAL TRIAL SITES

Elizabeth Allen[1], Jaishree Raman[2], Aaron Mabuza[1], Lesley Workman[1], Cordelia Leisegang[1], Hendrik Swanepoel[3], Lucille Blumberg[2], John Frean[2], Frans Mbokazi[4], Karen Barnes[1]

[1]University of Cape Town, Cape Town, South Africa, [2]National Institute for Communicable Diseases, Pretoria, South Africa, [3]University of Pretoria, Pretoria, South Africa, [4]Mpumalanga Malaria Elimination Programme, Nelspruit, South Africa

Malaria trials may be conducted in facilities with no previous research experience, serving poor, mobile communities. This was the context for a South African trial assessing the addition of low-dose primaquine to routine ACT malaria treatment. The World Health Organization has recommended this intervention to reduce malaria transmission in low transmission areas, without any G6PD testing. While available data suggest primaquine will not cause haemolysis in G6PD-deficient individuals, some have raised safety concerns. To provide local data to inform its potential licensing in South Africa, PRIM01 investigated the efficacy and safety of adding low-dose primaquine to artemether-lumefantrine for

symptomatic uncomplicated *Plasmodium falciparum* malaria. The trial was conducted within a quality management framework deemed suitable by pharmaceutical sponsors for higher risk trials, but designed as also relevant for lower risk field studies. This comprised over 30 standard operating procedures, a laboratory manual, role-specific training, job descriptions, and risk-based monitoring. Trial sites were selected in collaboration with the provincial Malaria Elimination Programmes and assistants employed to support clinic nurses who volunteered to help with the study. Staff at selected sites were overwhelmingly enthusiastic and dedicated to the success of this trial, however it was challenging to provide them with the required oversight due to their research-naivety, geographical location, limited staffing and infrastructure, and busy clinic schedules. More time than anticipated was needed for training in order to comply with Good Clinical Practice requirements, senior trial personnel had to be on-site much of the time, and ultimately only 2 sites could be supported. While this extended timelines, the quality management system and hard work of all involved resulted in a successful routine regulatory inspection. Though more burdensome than planned due to the context in which it must be conducted, this trial was at the required standard for unregistered medicines and has built capacity for further such trials in South Africa.

108

LYMPHATIC FILARIASIS: COMPASSION AND THE ALLEVIATION OF SUFFERING AS A PUBLIC HEALTH PROBLEM

Marie Collins Donahue[1], Marie Martha D. Desir[2]

[1]University of Notre Dame, Notre Dame, IN, United States, [2]Hôpital Sainte Croix, Léogâne, Haiti

The Global Plan to Eliminate Lymphatic Filariasis (GPELF) was conceived as having two pillars: one to interrupt transmission of the parasites that cause LF, and the other to alleviate the suffering of those with clinically significant manifestations of the disease, predominantly lymphedema, elephantiasis, and hydrocele. An estimated 40 million people worldwide suffer from these conditions, making LF the second leading cause of disability in the world. The World Health Organization requires that the Morbidity Management and Disability Prevention (MMDP) pillar must include a minimum package of care, including: 1) individual treatment to destroy any remaining adult parasites and microfilaria; 2) treatment for episodes of adenolymphangitis (ADL); 3) lymphedema management to prevent progression of disease and episodes of ADL; and 4) surgical management of hydrocele. For over two decades, the Notre Dame Haiti Program has supported the LF Clinic and Reference Center at Hôpital Sainte Croix in Léogâne, Haiti, currently the only site in the country that provides LF care. This clinic provides the minimum package of care described above; surgical management of hydroceles; as well as enhanced services. The latter include compression in the management of lymphedema, and a comprehensive Mental Health Initiative (MHI), whose aim is to reduce the social isolation and stigmatization of LF patients. Our MHI provides individual counseling, community peer support groups, a home visiting program, and a vocational training center to enable patients to better support their families financially. We will describe our comprehensive model of care, including both successes and challenges.

109

EDUCATION, MENSTRUAL HYGIENE, AND FEMALE GENITAL MUTILATION: GENDER DISPARITY AMONG MAASAI YOUTH IN RURAL KENYA

Kristen Zozulin[1], Josephine L. Ndirias[2], David R. Hill[1]

[1]Frank H Netter MD School of Medicine at Quinnipiac University, North Haven, CT, United States, [2]Mukogodo Girls Empowerment Program, Nanyuki, Kenya

Girls' and women's empowerment has taken on increasing significance in the realms of politics and public health. With wider resources and funding available for interventions devoted to the welfare of girls and women, community-specific data are a crucial piece of the puzzle for implementation of sustainable programs. In Kenya, the Maasai are a minority ethnic group that suffer disproportionate rates of illiteracy, female genital mutilation (FGM), HIV, and other indicators of poor health. The aim of this project is to investigate the knowledge, practices, and attitudes of students in Chumvi, Laikipia County, a predominantly Maasai community, with specific emphasis on gender equity. 125 female and 101 male students ages 10-19 years from Chumvi Primary and Secondary schools were surveyed on FGM, HIV, safe sex practices, attitudes towards gender, and menstrual hygiene. Male-to-female student ratios and grade averages from the secondary school were also compared. 28% of female respondents reported missing class due to menstruation. Overall, 35% of female respondents reported they had experienced FGM, which increased to approximately 60% by the age of 17. However, this figure may underestimate the prevalence of FGM in the community, as girls may have felt ashamed to respond honestly. 18% of female students agreed with the statement: 'Girls should not go to secondary school because they should be getting married,' compared to 5% of male students. Female students were more likely to be unsure of the benefits of using condoms to prevent STIs and pregnancy than the males. Within Chumvi secondary school, there was no difference in the numbers of male versus female students or in their grade distributions, suggesting a lack of gender bias in the Chumvi educational system. Despite the challenges presented by language barriers and issues of self-reporting, these results help inform the efforts of organizations and community leaders to address the disparity between the male and female youth in Chumvi.

110

KNOWLEDGE , ATTITUDES, AND PRACTICES OF PEDIATRIC PAIN MANAGEMENT BY NURSES AT A CHILDREN'S HOSPITAL IN LUSAKA, ZAMBIA

Eric Chisupa, Miriam Simbota, **Elizabeth Glaser**

Kamuzu College of Nursing-University of Malawi, Blantyre, Malawi

Pediatric pain management is a frequently neglected area of child health, particularly in lower resource settings where nurses are the most likely clinicians to monitor, evaluate and treat pain. The general objective of our study was to assess the nurses' knowledge, attitude, and practices towards pain and pain management in children at Lusaka Children's Hospital, Lusaka, Zambia. We used a cross sectional sequential mixed methods study design to first survey a convenience sample of 40 nursing staff via the City of Hope Knowledge and Attitudes Survey Regarding Pain, followed up by three focus groups discussions, centred on pain and pain management. We used STATA 15 to analyze the survey for associations using correlations and two-sided Fisher's exact tests, and analyzed the qualitative data using content analysis. Overall the nurses' scored poorly, with a median score on the 43 item survey of 40.7%, (mean 41.5%, 95% CI 38.4%-44.6%). Neither self rated knowledge nor years of experience had any significant association with score, while higher nursing grade was positively and significantly correlated with higher scores (Corr 0.5192, P>0.001) and similarly a higher level of education was positively and significantly associated with a higher score (P= 0.038; Corr 0.3645, P>0.001). In the focus groups, nurses made negative statements about self reported pain, attributing patient and parent reports as attention seeking behaviors, yet at the same time the nurses expressed a positive desire to have training on pediatric pain management augmented by clear hospital policies and protocols. The overall findings suggest that nurses at a pediatric specialty hospital in subSaharan Africa were lacking across multiple areas for providing appropriate pain management. Ministries of Health should emphasize guidelines on pediatric pain management in pre-service curriculum and in-service trainings, and explore forming hospital pediatric pain management teams to address immediate patient needs while also educating and mentoring staff.

111

DO BED BUGS REPRESENT A RISK TO CHAGAS DISEASE-ENDEMIC AREAS IN LATIN AMERICA?

Renzo S. Salazar Sanchez[1], Ricardo Castillo Neyra[2], Melina Vargas Maquera[1], Claudia Chipana Ramos[1], Carlos Condori Pino[1], Katty Borrini Mayorí[1], Michael Z. Levy[2]

[1]Universidad Peruana Cayetano Heredia, Arequipa, Peru, [2]University of Pennsylvania, Philadelphia, PA, United States

Arequipa is a southern Peru city with an urban infestation by *Triatoma infestans*, a triatomine insect vector of Chagas Disease. Over the past ten years, The Ministry of Health has held a vector control campaign. With less than 10% of the city remaining to treat, the control strategy is close to completion. However, in 2011 we recorded, for the first time, the presence of the common bed bug, *Cimex lectularius* in the city, and since then, the reports of infested houses by *C. lectularius* have been increasing each year. We are focused on determining the risk of transmission of *Trypanosoma cruzi*, the etiological agent of Chagas disease by *C. lectularius* in Chagas disease-endemic areas. We confirmed, under laboratory conditions, the vectorial competence of *C. lectularius*, to first acquire *T. cruzi* infection when fed on T. cruzi-carrying mice and subsequently to transmit the parasite to uninfected mice. We additionally showed that infection by *T. cruzi* does not affect the survival of bed bugs, another component of vectorial capacity. Additionally, we studied the survival rate of *C. lectularius* adults exposed to pyrethroid insecticide (deltamethrin), as well as the effect of insecticide on reproduction from colonies collected in different locations on the city and reared under laboratory conditions. We show that 10 days after exposition to insecticide, 42% (10 of 24) of colonies, present survival rates over 75 %, and that insecticide does not affect egg production of exposed females and later eggs hatching ($p = 0.88$). We discuss these outcomes in terms of the impact of bed bug infestation on Chagas disease control strategies in Chagas disease-endemic areas.

112

A COMPARISON OF HOUSE EAVE ASPIRATION TO MOSQUITO SWARM SWEEP NET SURVEY AS MALE MOSQUITO COLLECTION METHODS

Krystal Lorna Mwesiga[1], Paul D. Mabuka[1], Victor Balyesima[1], Matilda C. Collins[2], Jonathan Kayondo[1]

[1]Uganda Virus Research Institute, Entebbe, Uganda, [2]Imperial College London, London, United Kingdom

Sample collections are essential to the study of disease vectors, and many methods have been developed for this. Most traditional malaria vector sampling techniques such as Human Landing Catches, indoor Pyrethroid Spray Catches and $C0_2$-baited traps bias collections towards female mosquitoes. Balanced vector sampling of both males and females is necessary for a more comprehensive understanding of vector dynamics. In some areas, swarm sampling (SWN), is considered the most efficient method for the collection of male mosquitoes. This method, however, requires labour, training and remuneration of part-time technicians as collectors. SWN catches are also influenced by local mosquito mating behaviour, environment and other co-occurring insect swarms. From previous field-tests of a range of techniques, the aspiration of house eaves (ASP-EAV) was identified as a promising male mosquito collection method for use at our field sites. During 2017, to assess whether ASP-EAV could be a viable supplementary or replacement method for SWM, we collected mosquitoes using both methods at three village sites located in the Mukono and Kayunga districts of Uganda. Three collections were made per season (wet and dry) in each village during which all identified swarms were collected using sweep nets and ten household eaves were aspirated using battery powered aspirators over a period of two days.1904 male mosquitoes were collected, of these, 1011 were collected by SWN and 893 by ASP-EAV. These data were analysed for seasonal variation in catch by method and comparisons were also made of the seasonal yield per man hour for each method. We found that ASP-EAV compared well to SWN in both seasons. While SWN caught more mosquitoes, the yield per man hour was lower than with ASP-EAV. The lower number of collectors required for ASP-EAV also reduced chances of sampler error affecting catches. We consider that ASP-EAV is a viable male mosquito collection method at our study sites and could also be an effective substitute for SWN in longitudinal vector abundance studies.

113

A SYNERGISTIC BIOASSAY EVALUATION OF POTENTIAL RESISTANT MECHANISMS OF *ANOPHELES GAMBIAE* TO IVERMECTIN

Patricia Nicolas[1], Martin Gorry[2], Martha Muturi[2], Marta F Maia[3], Carlos Chaccour[1]

[1]ISGlobal, Barcelona, Spain, [2]KEMRI Wellcome Trust Programme, Kilifi, Kenya, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland

Despite remarkable success obtained with current malaria vector control strategies in the last 15 years, additional innovative measures will be needed to achieve the ambitious goals set for 2030 by the World Health Organization. New tools will need to assess insecticide resistance and residual transmission as key challenges. Endectocides such as ivermectin are drugs that kill mosquitoes which feed on treated subjects. Mass administration of ivermectin can effectively target outdoor and early biting vectors, complementing the still effective conventional tools. Although this potential approach has gained important attention, it is not free from potential development of resistance to ivermectin itself. The main aim of this work was to evaluate the potential role of xenobiotic pumps and cytochromes on ivermectin-induced mosquito mortality. We conducted an insectary-based randomized synergistic bioassay using membrane feeding to expose an *Anopheles gambiae* s.s to ivermectin with or without a battery of molecules affecting either the CYP3A4 or the P-glychoprotein. Seven drugs (or drug combinations) have been tested to assess the effect that the inhibition or induction of the said molecules can have on the ivermectin-caused mosquito mortality. In first place, dose-finding experiments were carried out to determine the 10-day LC_{50} of ivermectin. This was followed by synergistic bioassays combining ivermectin with different concentrations of the additional drugs. The main outcome was 10 day mosquito mortality determined by daily manual accounts. Survival analysis was done by Log-Rank test and Cox's regression. A dose-dependent synergism was found between ivermectin and CYP inhibitors like Voriconazole and Ritonavir. P-glychoprotein inducers did not show significant synergism. Other molecules like Cobicistat provided dose-dependent antagonism. Our data indicates that metabolic resistance to ivermectin could occur in the field.

114

GEO-STATISTICAL ANALYSIS OF CONTINUAL ONCHOCERCIASIS TRANSMISSION IN AND AROUND AREAS RECEIVING BI-ANNUAL IVERMECTIN TREATMENT REGIMENS

Francis B. Veriegh[1], Maria-Gloria Basáñez[2], Philip K. Baidoo[3], Adelaide Agyeman[4], Kingsley Badu[3], Michael D. Wilson[5], Daniel A. Boakye[5], Robert A. Cheke[6], Mark Taylor[7], Mike Y. Osei-Atweneboana[1]

[1]Council for Scientific and Industrial Research, Water Research Institute, Accra, Ghana, [2]Department of Infectious Disease Epidemiology, Imperial College, London, United Kingdom, [3]Department of Theoretical and Applied Biology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [4]Council for Scientific and Industrial Research, Science and Technology Policy Research Institute, Accra, Ghana, [5]Noguchi Memorial Institute for Medical Research, University of Ghana, Accra, Ghana, [6]Natural Resources Institute, University of Greenwich, Kent, United Kingdom, [7]Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Ghana has scaled-up efforts aimed at eliminating human onchocerciasis, based solely on ivermectin chemotherapy, by 2025, a year set by the

London Declaration on Neglected Tropical Diseases (NTDs) and the World Health Organization Roadmap for NTDs. Thus, bi-annual ivermectin mass distribution was implemented, particularly in savannah villages showing sub-optimal responses to treatment by 2010, replacing the long-lived strategy of annual rounds of ivermectin treatment. We used entomological techniques and GIS-based geo-statistical tools to assess the impact of semi-annual ivermectin treatments on the number of *Simulium damnosum* s.l. flies harbouring third-stage infective larvae (L3) per 1000 parous flies from 17 selected onchocerciasis endemic communities along the middle savannah belt of Ghana which have been receiving bi-annual rounds of ivermectin treatment. Adult female *S. damnosum* s.l. were collected from the 17 communities, using human landing catches and analysed for *Onchocerca volvulus* infectivity and parity rates using manual fly dissection. A spatial geo-statistical analysis was performed with a GIS tool by interpolating vector infectivity rates using the inverse distance weighted (IDW) method. Raster maps were categorized into two according to start of ivermectin bi-annual treatment in 2010 and a six-year interval so as to obtain suitable maps for algebraic operations. In 2010 there was active transmission of *O. volvulus* in 11 of the 17 communities with vector infectivity rates far in excess of APOC's recommended threshold of 1 L3 per 1000 parous flies. However, after six years of bi-annual ivermectin distribution, 12 out of the 17 communities had zero vector infectivity rates with the other 5 communities having varying levels of vector infectivity rates, all above APOC's stipulated threshold. This geo-statistical approach is useful for delineating areas at risk of transmission despite intense chemotherapeutic interventions and is useful for decision-making in support of onchocerciasis control and epidemiology.

115

MOSQUITO ELECTROCUTING TRAP: A SAFE ALTERNATIVE TRAPPING APPROACH TO MEASURE HUMAN EXPOSURE TO VECTORS COMPARE TO HUMAN LANDING CATCH IN SOUTHWESTERN BURKINA FASO

Antoine Sanou[1], Moussa W. Guelbeogo[1], Luca Nelli[2], Hyacinth K. Toe[1], Jason Matthiopoulos[1], N'fale Sagnon[1], Hilary Ranson[3], Heather M. Ferguson[2]

[1]Centre National de Recherche et de Formation sur le Paludisme (CNRFP), Ouagadougou, Burkina Faso, [2]Institute of biodiversity and evolutionary biology, University of Glasgow, Glasgow, United Kingdom, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Measuring human exposure to mosquito bites is a crucial component of surveillance for vector-borne diseases including malaria. For malaria vectors, the Human Landing Catch (HLC) remains the gold standard approach for direct estimation of this exposure. However, this method is risky as participants risk exposure to potentially-infected mosquito bites. Recently, a safer "Mosquito Electrocuting Trap" (MET) was developed to provide an exposure-free alternative to the HLC for measuring the human biting rate indoors and outdoors. Early prototypes of the MET performed well relative to the HLC in Tanzania, but it has yet to be tested in west Africa. Here we evaluated the performance of the MET relative to the HLC for characterizing mosquito vector population dynamics and biting behaviour in Burkina Faso. A longitudinal study was initiated in October 2016 within 12 villages in Burkina Faso where insecticide resistance levels are high. Host seeking mosquitoes were sampled monthly in each village over 18 months using the HLC and MET respectively. On each night of sampling, collections were made at 4 households, with METs being deployed inside and outside at 2 houses, and the HLC inside and outside at another two. The following night, trapping methods were switched between houses. Malaria vector abundance, species composition, sporozoite rate and location of biting (indoor vs outdoor) was recorded. A total of 34783 were female mosquitoes were collected in 251 days, in which *Anopheles gambiae* s.l. represented ~84%. The ratio of mosquitoes caught by the MET relative to the HLC was ~47% but varied between indoor (40.56% indoors) and outdoor settings (53.28% outdoors). The distribution of malaria vector species in MET and HLC collections was relatively similar (*An gambiae*: HLC: 40%; MET: 45%, *An coluzzii*: HLC: 60%, MET: 56%), as was their malaria infection rate (MET=5%, HLC=6%). The MET collected proportionately fewer mosquitoes than the HLC but remains safer both methods remained similar in predicting species composition and mosquito infection rate.

116

DETECTION OF HUMAN BLOOD IN PERIDOMESTIC AND DOMESTIC KISSING BUGS (*TRIATOMA* SPP.) UTILIZING A RAPID FORENSIC TEST

Norman L. Beatty[1], Nicole Behrens-Bradley[2], Maria Love[2], Finn McCants[3], Shannon Smith[1], Justin O. Schmidt[4], Sarah A. Hamer[5], Patricia L. Dorn[3], Nafees Ahmad[2], Stephen A. Klotz[1]

[1]University of Arizona College of Medicine, Department of Medicine, Division of Infectious Diseases, Tucson, AZ, United States, [2]University of Arizona College of Medicine, Department of Immunobiology, Tucson, AZ, United States, [3]Loyola University New Orleans, Department of Biological Sciences, New Orleans, LA, United States, [4]Southwestern Biological Institute, Tucson, AZ, United States, [5]Texas A&M University, Veterinary Medicine and Biomedical Sciences, College Station, TX, United States

DNA- and proteomics-based techniques have been used to identify the vertebrate hosts upon which triatomines have previously fed. These procedures are time consuming, require access to a laboratory with sophisticated equipment, and trained personnel. The Rapid Stain Identification of Human Blood (RSID-Blood) is a lateral flow, immunochromatographic assay, used to detect as little as 1µL of human blood in forensic samples within 10 minutes after 1-2 hours of specimen preparation. To determine whether the RSID-Blood could be used to identify human blood within triatomines we conducted several experiments following the manufacturer's extraction protocol. All five laboratory-raised *Triatoma rubida* (100%) which fed on human blood through an artificial membrane feeding apparatus tested positive at 12 hours, 3, 5,7, and 14 days post-feeding. Laboratory-raised *T. rubida* having only fed on laboratory mouse (*Mus musculus*) blood within a 2-8 week period all tested negative (15/15) at various stages of engorgement. Peridomestic and domestic triatomines (*T. rubida, T. protracta, T. recurva, T. sanguisuga, T. gerstaeckeri, T. lecticularia*) collected across four states (Arizona, Texas, Louisiana, California) with visible blood meals during hindgut dissection were tested: 9/20 (45%) Arizona specimens, 4/7 (57%) Louisiana specimens, 9/21 (42%) Texas specimens, and the one California specimen were positive; with 23/49 (47%) of the total positive for human blood. Fecal drops (FDs) were also tested using RSID-Blood. Eight different laboratory-raised *T. rubida* having only fed on laboratory mouse blood provided eight FDs which all tested negative. Three triatomines that tested positive from our field collection, two of which were known to have fed on a human, provided three different FDs, all tested positive. In addition, laboratory-raised *T. rubida* that fed on human blood, provided two FDs, which were positive. Our results show that the RSID-Blood can detect human blood in triatomines and their fecal drops. This rapid test may have implications in triatomine fieldwork and other hematophagous vectors such as mosquitos, ticks, and biting flies.

117

INTERACTION OF *RICKETTSIA FELIS* AND *WOLBACHIA* ENDOSYMBIONTS IN CAT FLEAS, *CTENOCEPHALIDES FELIS*

Krit Jirakanwisal, Supanee Hirunkanokpun, Natthida Tongluan, Kevin R. Macaluso

Louisiana State University, Baton Rouge, LA, United States

Cat fleas (*Ctenocephalides felis*) have been identified as a biological vector and reservoir of *Rickettsia felis*. *Wolbachia* spp. are bacterial endosymbionts that are estimated to infect more than 60% of insect species, including cat fleas. The interaction of vertically transmitted endosymbionts within arthropods may influence the dissemination of pathogenic bacteria. However, the interaction between *R. felis* and *Wolbachia* spp. in cat fleas has not been examined. Thus, we hypothesize

that if *Wolbachia* endosymbionts compete with pathogens for stable vertical transmission events in the vector, then the presence of *Wolbachia* will influence vertical transmission of *R. felis* in cat fleas. In order to assess this interaction, fleas were separated and treated with different concentrations of tetracycline to remove *Wolbachia* from fleas. After treatments, fleas were allowed to mate and divided in to two groups. One group was exposed to *R. felis*, another group serving as a *R. felis*-uninfected control for 24 hours. Eggs were collected and allowed to develop to adults, and then the newly emerged adults were assessed for vertical transmission of *R. felis* by quantitative real-time PCR based on *R. felis* outer membrane protein B gene (*ompB*). Results show that the optimal concentrations of tetracycline were 1.0-2.0 mg/ml. Vertical transmission of *R. felis* and *Wolbachia* endosymbionts infected fleas was demonstrated and implied a possible influence of *Wolbachia* on the vertical transmission of this emerging rickettsial pathogen.

118

PHLEBOTOMUS PAPATASI SALIVARY GLAND GENE DIVERSITY IN DISTINCT ECOTOPES OF EGYPT AND JORDAN

Catherine M. Flanley[1], Marcelo Ramalho-Ortigao[2], Iliano V. Coutinho-Abreu[3], Rami Mukbel[4], Hanafi A. Hanafi[4], Shabaan S. El-Hossary[5], Emad El-Din Y. Fawaz[5], David F. Hoel[2], Gwen Stayback[1], Douglas A. Shoue[1], Shaden Kamhawi[3], David W. Severson[1], Akio Mori[1], Mary Ann McDowell[1]

[1]University of Notre Dame, Notre Dame, IN, United States, [2]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [3]NIAID-National Institutes of Health, Rockville, MD, United States, [4]Jordan University of Science and Technology, Irbid, Jordan, [5]U.S. Naval Medical Research Unit No. 3, Cairo, Egypt

Phlebotomus papatasi sand flies inject a host of pharmacological salivary proteins to assist with blood feeding and modulate host defenses. These salivary proteins have been studied for their role in cutaneous leishmaniasis disease outcome with different salivary proteins attenuating or exacerbating lesion size. Studies have shown that while co-administered sand fly saliva exacerbates *Leishmania major* infections in naïve mice, animals pre-exposed to saliva are protected, with the infection attenuated via a delayed-type hypersensitivity immune reaction. The immunogenicity of salivary components results in a hostile environment making it difficult for *L. major* to successfully establish an infection in pre-exposed individuals. These studies highlight the potential of the salivary components to be used as a vaccine. One protein in particular, *P. papatasi* salivary protein 15 (PpSP15) has been intensively studied due to its ability to protect mice against *L. major* challenge. The number of antigenic molecules included in vaccines is restricted thus emphasizing the role of population genetics to identify molecules, like PpSP15, that are not experiencing positive selection pressure. Functionally significant proteins conserved across populations and under purifying selection demonstrate great promise as a vaccine component. Three distinct ecotope study sites in Egypt (Aswan) and Jordan (Swaimeh and Malka) were chosen based on their elevation, rainfall, vegetation, differing reservoir species, and the presence or absence of *L. major*. The objective of this work was to analyze the intra- and inter-population diversity of nine of the most abundantly expressed salivary proteins including SP12, SP14, SP28, SP29, SP30, SP32, SP36, SP42, and SP44 and to predict their ability to elicit an immune response.

119

GENETIC VARIABILITY OF TWO SPECIES OF *TRIATOMA* FROM COASTAL JALISCO, MEXICO

Andrew S. Wilson[1], Caitlyn Moynihan[1], Uyen Nguyen[1], Daniel Beck[1], Victor Sanchez-Cordero[2], Gabrielle Stryker[1]

[1]Central Washington University, Ellensburg, WA, United States, [2]Instituto de Biologia, UNAM, Ciudad Universitaria, Mexico

The subfamily Triatominae contains hematophagous insects that serve as vectors for *Trypanosoma cruzi*, a single-celled parasite that infects mammals, including humans. Chagas disease, caused by infection with *T. cruzi*, is the most serious of the parasitic diseases in Latin America and is considered a neglected tropical disease. Triatominae display a high degree of morphological plasticity without clear genetic support. There are also clear cases where genetic variation is seen without distinct morphological traits. We collected a large sample of *Triatoma spp.* from Estación de Biología, Chamela, in coastal Jalisco, Mexico and examined the within-species genetic variability. Two species of *Triatoma* were collected, 61 *Triatoma bolivari* and 34 *Triatoma longipennis*. The specimens were sequenced for two non-conserved regions of DNA (internal transcribed spacer (ITS-1) and ITS-2) to examine the within-population genetic variability. *T. longipennis* is reported to have high genetic variation across Mexico, however within-population studies have not been undertaken. *T. bolivari,* a rare species of *Triatoma* only found in the dry tropical forest, is thought to have low diversity due to relatively low morphological differences between individuals. Though *T. bolivari* has previously been reported to be a sylvatic species associated with birds, we have found squirrel (*Sciurus colliaei*) to be the most common blood meal in wild-caught specimens. *T. bolivari* is attracted to lighting and has been found to have fed on human blood, suggesting a risk for domestication of this species. As rural populations increase and natural disasters such as hurricane Patricia cause population shifts, a better understanding of *T. bolivari* will be important for establishing adequate vector control.

120

CHARACTERIZING THE VIROME OF *RHIPICEPHALUS MICROPLUS* TICKS FROM COLOMBIA THROUGH RNA-SEQ TECHNOLOGY

Giovan F. Gómez[1], Juan P. Isaza[1], Juan A. Segura[1], Juan F. Alzate[2], Lina A. Gutiérrez[1]

[1]Grupo Biología de Sistemas, Escuela de Ciencias de la Salud, Facultad de Medicina, Universidad Pontificia Bolivariana, Medellín, Antioquia, Colombia, [2]Grupo de Parasitología, Departamento de Microbiología y Parasitología, Facultad de Medicina, Centro Nacional de Secuenciación Genómica -CNSG, Sede de Investigación Universitaria - SIU, Universidad de Antioquia, Medellín, Antioquia, Colombia

Ticks (Ixodida) are hematophagous ectoparasites which harbor and transmit diverse virus species, some of which cause serious diseases with worldwide veterinary and human health impact. *Rhipicephalus microplus* is an important cattle tick species in Colombia, where it causes significant economic losses and despite its importance, its viral profile haven't been studied so far. Considering that Next Generation Sequencing technologies could provide a powerful means of studying viral diversity in ticks, RNA sequencing (RNA-Seq) was used in this study as a surveillance method for virus detection in *R. microplus*. Ticks were collected from Antioquia, in northwestern Colombia and pooled according to the collection site in 3 ticks per pool. RNA was isolated, libraries prepared and sequenced on Illumina HiSeq 4000 (TruSeq Stranded mRNA -PolyA) and NovaSeq 6000 (rRNA-depleted RNA) sequencing platforms. Raw sequence reads were filtered and trimmed according to their quality score (≥Q30). The clean sequence reads were assembled into contigs, which were compared and annotated. Taxonomic assignation of these contigs was achieved by successive searches using the BLASTX algorithm against a protein reference database. Manual annotations were performed using Artemis. The majority of viral contigs (n=30, 53%) were assigned to two putative

viruses: Wuhan tick virus 2 and Lihan tick virus (>98% sequence similarity). Both viruses were discovered in China during 2015 also in the *R. microplus* ticks. In addition, 5 contigs were similar (84-92%) to the Jingmen tick virus reported in China during 2014 in a *R. microplus* ticks pool, while the close relative of other 4 contigs was the Mogiana tick virus, isolated in 2011 from Brazil. This work will be continued with a more in-deep characterization of contigs carrying putative viral sequences. To our knowledge, this is the first report of the occurrence of these viruses in *R. microplus* from Colombia. Our results shed new light on the virus diversity of this tick species and provide the foundation for further studies into the evolutionary history and pathogenic potential of these intriguing viruses.

VARIABLE EFFECTS OF MOSQUITO MIDGUT-EXPRESSED MICRORNAS FOR THE RESTRICTION OF WEST NILE VIRAL ORAL INFECTIVITY OF *CULEX QUINQUEFASCIATUS*

Payal D. Maharaj[1], Bethany G. Bolling[2], Michael Anishchenko[1], Claudia Rueckert[3], Gregory D. Ebel[3], Aaron C. Brault[1]

[1]Centers for Disease Control and Prevention, Fort Collins, CO, United States, [2]Texas Department of State Health Services, Laboratory Services Section, Arbovirus-Entomology Laboratory, Austin, TX, United States, [3]Colorado State University, Fort Collins, CO, United States

The mosquito midgut epithelium serves as the initial site of infection of arboviruses, yet little is known about specific cell populations that dictate infection phenotypes of vectors. To identify mosquito cell biomarkers and assess specific roles of cell populations for midgut infectivity with West Nile virus (WNV), microRNA (miRNA) libraries were generated from C6/36 mosquito cells and dissected *Culex quinquefasciatus* (Cxq) midguts, respectively. Target sequences (three copies) for the twenty most highly expressed Cxq midgut miRNAs were incorporated into the 3'UTR of a WNV cDNA clone. Recombinant WNVs encoding these target sequences (WNV-miR) were generated and growth profiles compared to wildtype WNV (wt-WNV) in target C6/36 and non-target Vero cells. In C6/36 cells, variable inhibition levels were observed with WNV-miRs, ranging from complete to undetectable viral growth which largely correlated with cellular miRNA expression levels. In contrast, WNV-mir growth was indistinguishable from that of the wt-WNV in Vero cells, indicating undetectable off-target miRNA insertional effects. In Cxq orally exposed to WNV-miRs, target sequences for 17 of the top 20 midgut miRNAs resulted in complete loss of Cxq infectivity. Surprisingly, Cxq infectivity with the WNV-miR encoding the target sequence of the 6th highest expressed miRNA, miR-276-3p (65%), was indistinguishable from wt-WNV. The finding that miRNAs with lower expression levels could completely block WNV-miR oral infectivity in Cxq indicates that miRNA expression is unlikely to be uniform within the midgut and that select midgut cells with defined miRNA expression profiles likely serve as critical sites for initial oral infection with WNV.

122

CHARACTERIZATION OF *WOLBACHIA* INFECTIONS FROM NATIVE AUSTRALIAN MOSQUITO VECTORS

Chen Wu[1], Jill Fernandes[2], Greg Devine[1], Leon Hugo[1]

[1]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [2]Queensland Alliance for Agriculture and Food Innovation, Brisbane, Australia

Wolbachia are maternally transmitted intracellular bacteria that naturally infect over 40% of all insect species. *Wolbachia* have become promising biocontrol agents against mosquito-borne diseases due to their unique effects on mosquito reproduction and immunity. However, the phenotypes mediated by *Wolbachia* vary between strains and host-pathogen systems. Discovery of novel *Wolbachia* strains is essential for broadening the application of *Wolbachia* for mosquito control. In this study we identified and characterized the anti-pathogen effects of natural *Wolbachia* infections in Australian mosquitoes. We identified three previously uncharacterized *Wolbachia* strains, in addition to the recently reported strain from *Aedes notoscriptus*, based on detection of *WSP*, *16s* and *FTSZ* genes. We established colonies of two local species, *Ae. notoscriptus* and *Culex sitiens*, and discovered a unique pattern of infection rates fluctuating between 15% and 60% in both colonies. Study on the maternal transmission of *Wolbachia* in *Cx. sitiens* revealed high transmission rates (99.3%) but low cytoplasmic incompatibility (9.9% mortality). We orally inoculated *Ae. notoscriptus* and *Cx. sitiens* with the alphavirus Ross River virus (RRV; $10^{3.31 - 6.48}$ and $10^{5.41 - 6.36}$ $CCID_{50}$ per mosquito, respectively). RRV infection rates varied between 17% - 85% for *Ae. notoscriptus* and 0% - 18% for *Cx. sitiens* with no significant differences between *Wol*$^{+}$ and *Wol*$^{-}$ mosquitoes. However, mean virus load in *Wol*$^{+}$ *Cx. sitiens* was 1000× lower than in *Wol*$^{-}$ mosquitoes (P = 0.0043), suggesting that natural *Wolbachia* infection suppresses virus proliferation in that species. We report on progress towards transinfecting cells (Aag2 and Aa20) and mosquitoes (*Ae. aegypti*) with *Wolbachia*, including oral inoculation trials. We observed substantial uptake of *Wolbachia* in the mosquito digestive tract by fluorescence microscopy however the midgut currently remains a barrier to dissemination. The behaviour of *Wolbachia* in new hosts can be difficult to predict, therefore transinfection and further characterization is required to determine if these strains can induce anti-pathogen effects.

123

SHARED MOSQUITOES, SHARED PROBLEM: VECTOR SURVEILLANCE AS A TOOL FOR PUBLIC HEALTH DIPLOMACY

Rebecca Levine[1], Daniel Impoinvil[1], Asad Islam[1], Joseph Frederic[2], Angel Solis[3], Jean Frantz Lemoine[2], Ronald Skewes Ramm[3], Audrey Lenhart[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Programme National de Contrôle de la Malaria, Port Au Prince, Haiti, [3]Departamento de Prevención y Control de Enfermedades Transmitidas por Vectores y Zoonosis, Santo Domingo, Dominican Republic

The 2016 Zika virus outbreak highlighted the speed at which vector-borne pathogens can spread across countries and regions. While many affected countries shared common entomological risk factors, cross-border communication on vector surveillance or control was uncommon. To improve vector surveillance capabilities and enhance data sharing, binational exercises in vector surveillance were conducted on the island of Hispaniola. Beginning in March 2017, staff from the National Malaria Control Program in Haiti and the National Center for the Control of Tropical Diseases in the Dominican Republic received training in the use of the Epi Info Vector Surveillance application, a novel mobile tool for vector surveillance and automated data analysis. Teams from each country piloted the app and held a binational meeting in July 2017 to discuss results. During this meeting, both countries noted the ease of sharing and reporting data between countries using the app, and decided to explore how cross-border data sharing could be formalized. In November 2017, the programs met in the northern bordering towns of Dajabón, Dominican Republic and Ouanaminthe, Haiti to conduct a binational vector surveillance exercise. Five teams, each consisting of both Haitian and Dominican field workers, spent one day working in Ouanaminthe (47 households visited) and one day working in Dajabón (49 households visited) collecting entomological data using the mobile app. On the final day of the exercise, the collected data from both countries were simultaneously displayed and discussed, with a focus on the utility of collecting and analyzing the indicators in a standardized way. At the conclusion of the exercise, directors from both programs agreed to continue collecting and sharing their entomological data using this platform. In addition to improving and standardizing vector surveillance activities across Hispaniola, these exercises deepened the commitment for binational collaboration in addressing priority public health threats and strengthened the relationship between key stakeholders on both sides of the border.

124

EVOLUTION OF RHS PROTEINS IN BLOOD FEEDING ARTHROPODS AND *WOLBACHIA*

Reagan C. Irby, Anagha Gopakumar, Lily Brooks, Aline R. Bronzato, Jonas G. King

Mississippi State University, Mississippi State, MS, United States

Members of the RHS protein family have been found in the saliva of mosquitoes and appear to be present in the genomes of several disparate groups of arthropods. Recent studies from bacteria have highlighted the likely function of RHS proteins as contact dependent growth inhibitors. Therefore, we hypothesize that RHS proteins act to influence the insect microbiome in certain insect tissues or act as immunomodulators of the vertebrate skin during blood-feeding. This research focuses on the RHS proteins of *Aedes albopictus*, *Cimex lectularius*, and *Wolbachia*. First we conducted phylogenetic and codon-bias analyses of the genomics-supported arthropod RHS proteins. We then determined the presence of an *rhs* gene in the *Cimex* genome, but not in its obligate *Wolbachia* symbiont, using long-PCR and tissue-specific qPCR analysis before and after antibiotic treatment. Using comparative analyses, we then identified the most logical target for functional studies, and RHS proteins are currently being examined through *in vitro* expression and analysis of their putative functional domains. Other ongoing studies are also investigating changes in RHS expression in the absence of *Wolbachia* in antibiotic treated *Cimex lectularius*, and we are working to silence RHS in *Cimex lectularius* to explore its effect on the life history and response to infection of *Cimex lectularius*.

125

METABARCODING, A NEW APPROACH FOR THE COMPREHENSIVE STUDY OF *TRYPANOSOMA CRUZI* TRANSMISSION CYCLES AND TRIATOMINE BEHAVIOR

Eric Dumonteil[1], Maria-Jesus Ramirez-Sierra[2], Silvia Pérez-Carrillo[2], Christian Teh-Poot[2], Claudia Herrera[1], Sébastien Gourbière[3], **Etienne Waleckx**[2]

[1]Tulane University, New Orleans, LA, United States, [2]Universidad Autónoma de Yucatán, Mérida, Mexico, [3]Université de Perpignan Via Domitia, Perpignan, France

Chagas disease, caused by the parasite *Trypanosoma cruzi*, is mainly transmitted to humans and other mammals by blood-sucking insects called triatomines. Establishing transmission cycles is key to understand the epidemiology of the disease, but integrative assessments of ecological interactions shaping parasite transmission are still limited. Current approaches also lack sensitivity to assess the full extent of this ecological diversity. We developed a metabarcoding approach based on next-generation sequencing to simultaneously identify triatomine gut microbiome, vertebrate feeding hosts, triatomine and parasite genetic diversity and their potential interactions. Using a sample of 15 *Triatoma dimidiata*, the main vector in the South of Mexico and Central America, we detected a dynamic microbiome, including 23 bacterial orders. Fourteen vertebrate species served as blood sources. Importantly, bugs fed on multiple hosts, with up to 11 hosts identified per bug, indicating very frequent host-switching. A high clonal diversity of *T. cruzi* was detected, with up to 20 haplotypes per bug. This analysis provided much greater sensitivity to detect multiple blood meals and multiclonal infections with *T. cruzi*, which should be taken into account to develop transmission networks, and characterize the risk for human infection, eventually leading to a better control of disease transmission.

126

EFFECTS OF ESSENTIAL OILS OF *CHENOPODIUM AMBROSIOIDES* ON MALARIA AND ARBOVIRUSES MOSQUITO VECTORS IN MUHEZA TANZANIA

Basiliana Emidi

National Institute for Medical Research, Tanzania, Dar es Salaam, United Republic of Tanzania

Increase in insecticides resistance among mosquito population presents a great challenge to chemicals that are used for mosquitoes control in sub-Saharan African. Currently, there is no approved alternative insecticide to pyrethroid which is used in impregnated bed nets. This study aimed to determine effects of *Chenopodium ambrosioides* essential oils against malaria and arboviruses mosquito vectors. Insecticide susceptibility bioassays were performed according to the World Health Organization guidelines on 2-5 days old human biting mosquitoes. Each of the four species of mosquitoes were exposed to *C. ambrosioides* essential oils (10%) and two classes of insecticides commonly used for malaria vector control. Mosquito mortality rates (%) were determined after 24 hours post insecticide exposure. All mosquito species tested were susceptible to *C. ambrosioides* essential oils (10%). *An. gambiae* s.l. showed possible resistance to Permethrin (0.75%) and Deltamethrin (0.05%) with 93% and 92% mortality rates (%) 24 hours post exposure to insecticides. With Lambdacyhalothrin (0.05%), *An. gambiae* s.l. was resistance with mortality rate of 57%. *An. funestus* was susceptible to all insecticides tested. *Aedes aegypti formosus* was susceptible to all insecticides tested except DDT (4%). All insecticides tested were able to knock down 50% of all mosquito species (KDT50) exposed within 1 hour. *C. ambrosioides* essential oils (10%) took the shortest mean time to knock down 50% of all mosquitoes tested. The mean time ranged from 11.4 to 13.1 min. The mean time taken to knock down 95% of all mosquito species was 17.8 from *C. ambrosioides* essential oils (10%) in *An. gambiae* s.l. This study has revealed that, *C. ambrosioides* essential oils have demonstrated appreciably higher strong insecticidal effects on malaria and arboviruses mosquito vectors. Further studies are needed to determine the long-lasting insecticidal efficacy of essential oils extracts from *C. ambrosioides* for development of novel methods of controlling mosquito vectors.

127

CYP6-Z4 (CYTOCHROME P450-6-Z4)-MEDIATED INSECTICIDE RESISTANCE IN *ANOPHELES STEPHENSI* AGAINST DELTAMETHRIN

Shobhna Mishra, Om Prakash Singh

National Institute of Malaria Research, New Delhi, India

Anopheles stephensi is one of the major primary malaria vector found in Middle-East and South Asia region. In India, this is regarded as urban malaria vector. Control of malaria vectors relies mainly on insecticide-based vector control methods, which has become a challenging and formidable task due to rapid development of resistance against commonly used insecticides. Pyrethroid group of insecticides, which are still effective in India against most of the vectors, are currently choice of insecticides for the control of malaria vectors due to rapid killing action, low mammalian toxicity and degradability in nature. Although there is no report of pyrethroid-resistance in *An. stephensi* in India, we attempted to understand molecular basis of resistance by raising insecticide resistance in this mosquito in laboratory through selection pressure against deltamethrin. We hereby report evidence of Cytochrome P450-6-Z4 (CYP6-Z4)-mediated pyrethroid-resistance in laboratory colony of *An. stephensi*. Cytochrome P450 (CYPs)-Zs are important class of CYPs enzymes known to play a major role in resistance against pyrethroid group of insecticide, by metabolizing the insecticide at a higher rate in mosquitoes. Several CYP6-Z family genes like CYP6-Z1, CYP6-Z2, CYP6-Z3, CYP6-Z4 etc. are known to be overexpressed and responsible for pyrethroid resistance in various other anophelines. To understand the role

of CYP6-Z4 gene, cDNA was synthesized from total RNA of susceptible and laboratory selected deltamethrin-resistant strain of *An. stephensi* mosquito and a quantitative real-time PCR was performed by using gene specific primers. Quantitative real-time data shows that the relative amount of CYP6Z4 transcript was significantly higher in the deltamethrin-resistant strain of *An. stephensi* as compared to the susceptible strain which indicates possible role of this gene in pyrethroid resistance. Further study to characterize this gene in deltamethrin resistant and susceptible strain is under investigation. The study will help in understanding of molecular basis of pyrethroid resistance, which will be helpful in integrated vector management.

128

EVALUATING THE EFFECT OF IVERMECTIN B_{1A} AND B_{1B} COMPOUNDS AGAINST THE MALARIA VECTOR *ANOPHELES DIRUS*

Narenrit Wamaket[1], Oranicha Khamprapa[1], Siriporn Phasomkusolsil[2], Silas Davidson[2], Patchara Sriwichai[1], Phornpimon Tipthara[3], Markus Winterberg[3], Joel Tarning[3], Nicholas White[3], Jetsumon Sattabongkot[1], Kevin Kobylinski[2]

[1]Mahidol University, Bangkok, Thailand, [2]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand

Ivermectin (IVM) is a broad-spectrum medication used to treat onchocerciasis, lymphatic filariasis, strongyloidiasis and scabies. IVM is particularly potent against Anopheline *mosquitoes*, causing significant mortality, delayed re-feeding, and reduced fertility when ingested through a blood meal. IVM *in vitro* activity was assessed by spiking human blood with various concentrations of parent compound (IVM-spiked), blood feeding to *Anopheles dirus* and monitoring subsequent mortality to determine the lethal concentration that kills 50% (LC_{50}) of mosquitoes. IVM *in vivo* activity was assessed in a clinical trial wherein Thai volunteers were treated with IVM at 400 µg/kg (IVM-treated) and their venous blood was membrane fed to *An. dirus*. The *An. dirus* 7-day-LC_{50} of IVM-spiked blood was 56.90 [53.69 - 60.11] ng/ml, whereas IVM-treated blood had a 7-day-LC_{50} of 2.80 [2.65 - 2.95] ng/ml. These results indicate that metabolized IVM (IVM-treated) has a 20-fold greater lethal effect compared to IVM parent compound (IVM spiked). This suggests that IVM metabolized by humans may extend efficacy beyond that predicted from IVM parent compound alone. In nature, IVM is a mixture of two homologs, 22, 23-dihydroavermectin B_{1a} (IVM B_{1a}) and 22, 23-dihydroavermectin B_{1b} (IVM B_{1b}) at a ratio of >90% and <10% respectively. Both IVM B_{1a} and IVM B_{1b} are metabolized by similar pathways in the vertebrate. A recent study in snails demonstrated that the minor IVM B_{1b} is the lethal component, while the major IVM B_{1a} component had no lethal effect. Here we present for the first time, the *in vitro* impact of IVM parent compound, IVM B_{1a}, and IVM B_{1b} on *An. dirus* survival. These results will be used to guide discovery of which IVM metabolites possess mosquito-lethal effect.

129

INSECTICIDE SUSCEPTIBILITY PATTERN AND BIOCHEMICAL ANALYSIS OF *PHLEBOTOMUS ARGENTIPES,* THE VECTOR OF LEISHMANIASIS IN SRI LANKA

Dulani K. Pathirage[1], Nadira D. Karunaweera[1], Parakrama S. Karunaratne[2]

[1]Department of Parasitology, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka, [2]Department of Zoology, Faculty of Science, University of Peradeniya, Peradeniya, Sri Lanka

Phlebotomus argentipes is the known vector of *Leishmania donovani*, the causative organism of leishmaniasis. A major challenge of an effective vector control program is the development of insecticide resistance in the vector. Galgamuwa in North-Central Province and Pannala in North-Western Province of Sri Lanka were selected for sand fly collection. Identification of *P. argentipes* was confirmed using standard taxonomic keys. F1 progeny were exposed to different concentrations of DDT, malathion, deltamethrin and propoxur and LD_{50} was determined using mortality curves. Results were validated with the control mortalities using Abbott's formula. For biochemical analysis, esterase assay, glutathione S-transferase assay, oxidase assay & protein assay were performed with individually homogenized sand flies in 80µl of ice cold distilled water. Another set of population were homogenized in 50µl of ice-cold distilled water for acetylcholinesterase assay. The colony population was susceptible to concentrations of >0.6% DDT and >0.7% Malathion, >0.007% Deltamethrin & >0.015% Propoxur with no survivors after 24-hour recovery period. However, the insects were resistant to lower concentrations than the ones mentioned above & all flies were alive after 24 hour post-exposure recovery period. LD_{50} was determined as 0.6%, 0.7%, 0.007% and 0.016% for DDT, malathion, deltamethrin & propoxur respectively. Most of the flies had protein activity <0.3µmol min^{-1} mg^{-1}, esterase activity <1.00 µmol min^{-1} mg^{-1} and GST activity <0.4µmol min^{-1} mg^{-1}. All protein, esterase & GST activity were < 0.35 equivalent units of monooxygenase amounts. Over half of this population had <30% residual AChE activity in the presence of propoxur. However, 6.5% had >60% residual activity. Hence, the majority of the population is said to be the susceptible to the insecticides used in this study. Further research is being conducted to ascertain the genetic mechanism behind the susceptibility patterns of Sri Lankan *Ph. argentipes* to synthetic insecticides.

130

ASSOCIATION OF F1534L KNOCKDOWN RESISTANCE (*KDR*) MUTATION WITH PYRETHROID RESISTANCE

Om Prakash Singh

National Institute of Malaria Research, Delhi, India

Aedes aegypti is a vector of several arboviral infections including dengue and chikungunya. In absence of specific treatment or vaccine available to control these arboviral infections, suppression of the vector population is the only option to control these infections. One of the potential methods for the control of this vector is the use of pyrethroid group of insecticides for space spray as well as personal protection measures. Knockdown resistance (*kdr*) is one of the mechanism of pyrethroid resistance occur due to mutation in the voltage gated sodium channel (target site of action), resulting in reduced sensitivity of target site to the insecticide. We carried out survey on presence of *kdr* mutations in *Ae. aegypti* in three metropolitan cities of India, i.e., Delhi, Bengaluru and Kolkata. Recently, we discovered a new *kdr* mutation F1534L in *Ae. aegypti* co-occurring with other *kdr* mutations S989P, V1016G and F1534C. The F1534L mutation is being recorded for the first time in *Ae. aegypti*. Mutations S989P and V1016G were in complete linkage disequilibrium and both mutations were having negative linkage disequilibrium with F1534C or F1534L. We established that the new mutation F1534L has significant protection against permethrin and deltamethrin. In the wake of protection conferred by this mutation on pyrethroid insecticides, it is of paramount importance to screen other populations of *Ae. aegypti* for presence of new mutation F1534L.

131

INSECTICIDE RESISTANCE MECHANISMS INFLUENCE MOSQUITO LIFE HISTORY TRAITS AND BEHAVIOR

Katherine Gleave[1], Bruno Gomes[1], Jonathan Thornton[1], Lauren Chappel[2], Frank Mechan[1], Corrado Minetti[1], Lisa Reimer[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]University of Warwick, Warwick, United Kingdom

Insecticide resistance (IR) in disease vectors is at a crucial tipping point. Resistant mosquitoes not only survive longer than their susceptible counterparts, but the associated resistance mechanisms can lead to significant alterations in key physiological functions. Do these changes influence vector behaviour and disease transmission? Exposure to different insecticides (REC-R to temephos, REC-M to malathion, REC-P to

permethrin), and resistance reversal (REC-U) were used to create multi-resistant strains of *Aedes aegypti* from Recife, Brazil. Mosquitoes were reared at two different larval densities to evaluate resource allocation using energetic resources, longevity and fitness. To assess whether IR mechanisms are associated with differing energy reserves, we measured lipid and glycogen content and body size at different ages. The effects of these mechanisms on further life traits were assessed using pupation and eclosion rates, sex ratio and longevity, mating efficacy, fecundity and egg viability. Generalised Linear Mixed Models were used to predict the effects of IR mechanisms on the energetic resources of mosquitoes, using the parameters day post-emergence, larval density and resistant strain. Our model showed an interaction between strain*density and strain*days with regards to lipid content, however no significant interactions where shown for glycogen. Of the strains tested, REC-R (larval exposure to temephos) contained significantly more lipids than all other strains at day 2 at both rearing densities, and significantly higher glycogen levels than all other strains on both days at both densities. Longevity assays showed REC-R females survived significantly longer than other strains. However, there appeared to be a fitness trade-off with fecundity, with REC-R exhibiting poor mating success, and poor fecundity in mated females. Male mosquitoes pupated and emerged one to two days before females, with REC-R adults emerging in greater initial numbers. Differences in sex ratio where observed to be more pronounced when reared under crowded conditions.

132

EFFECTS OF DIFFERENT INSECTICIDE PRESSURES IN GENE EXPRESSION FOR TWO STRAINS OF *AEDES AEGYPTI* (CAYMAN AND RECIFE-R)

Bruno Gomes[1], Lauren Chappell[2], Jonathan Thornton[2], Katherine Gleave[2], Gareth Weedall[3], Simon Wagstaff[2], Lisa Reimer[2]

[1]Oswaldo Cruz Institute (IOC-FIOCRUZ), Rio de Janeiro, Brazil, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Liverpool John Moores University, Liverpool, United Kingdom

Insecticide resistance in *Aedes* mosquitoes is challenging vector control measures for arboviruses. In *Ae. aegypti*, multiple insecticide resistance mechanisms have emerged independently across the globe for different insecticides. The effect of these resistance mechanisms on seemingly unrelated traits (pleiotropy) such as fecundity, immunity, behaviour or vector competence is poorly understood. Here, we perform a broad RNA-seq analysis in two strains of *Ae. aegypti* to infer the gene expression variation associated with different insecticide exposure or genotype within each mosquito strain. We established two sets of mosquito colony lines selected by different insecticide regimes across 10 generations. One set was based on the Cayman strain which contains knockdown resistant alleles (*kdr*) in the voltage gated sodium channel. A total of four new lines with resistance ratios between 6.5 and 213 were established by a combination of genotype and permethrin exposure. Whereas, the second set was based on the Recife-R strain that present metabolic resistance for temephos. In this strain, we establish two new lines exposed for two adulticides (malathion: RR = 3.1; and permethrin: RR = 9.9) and a third was unexposed for resistance reversal of temephos. Five biological replicates of each colony line and baselines were sequenced by RNA-seq. The characterization of molecular mechanisms of resistance indicates a combination of high expression of CYP9s with *kdr* mutations for Cayman resistant lines, while only one P450s (CYP6) was found upregulated for Recife-R permethrin line. Moreover, genes associated with temephos resistance (CYP6N12, CYP6M11, CYP6BB2) maintain a higher gene expression for Recife-R malathion line and a significant reduction for the Recife-R reversal line. Genes associated to pleiotropic effects are under annotation that suggest an upregulation of immunity genes in the Recife-R reversal lines. The differential expression associated with insecticide resistance would be discussed with the support of complementary insectary experiments.

133

CHEMICAL COMPOSITIONS AND LARVICIDAL ACTIVITY OF ESSENTIAL OILS OF *CURCUMA ZEDOARIA* AGAINST THE DELTAMETHRIN RESISTANT OF *CULEX QUINQUEFASCIATUS*

Nataya Sutthanont[1], Siriluck Attrapadung[2], Surang Nuchprayoon[3]

[1]Inter–Department Program of Biomedical Sciences, Faculty of Graduate School, and Lymphatic Filariasis and Tropical Medicine Research Unit, Chulalongkorn Medical Research Center (Chula MRC), Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [2]Department of Medical Entomology, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [3]Department of Parasitology, and Lymphatic Filariasis and Tropical Medicine Research Unit, Chulalongkorn Medical Research Center (Chula MRC), Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand

Culex quinquefasciatus is the important vector of several diseases to the human, including St. Louis encephalitis and lymphatic filariasis. The current way to eliminate the chain of transmission of the vector-borne diseases is to control the vector by using synthetic insecticidal chemicals. However, the continuous exposure of chemicals to the insect population has resulted in the development of resistant strains and is harmful to the environment. Therefore, the novel insecticide is required to reduce the number of diseases carrying vectors. Herbal essential oils have many biological properties with larvicidal effects and ecofriendly uses. Moreover, they have shown potential as natural insecticides. This study aimed to determine the chemical composition of essential oils extracted from *Curcuma zedoaria* fresh (FZEO) and dried (DZEO) rhizomes on *Cx. quinquefasciatus*. The larvicidal activity of FZEO and DZEO were tested against of the both deltamethrin resistant and susceptible strains of *Cx. quinquefasciatus* larvae. The chemical compositions of the oils were identified by GC-MS analysis. The main constituents in both oils were sesquiterpenes and monoterpenes. FZEO contained 37 compounds. AR-tumerone (23.66%), zingiberene (14.74%), β-sesquiphellandrene (10.64%) and eucalyptol (10.57%) were the major components. In contrast, DZEO contained 35 molecules. β-tumerone (16.69%), AR-tumerone (15.55%), eucalyptol (11.57%) and zingiberene (10.12%) were the major components. After 24h of exposition, both deltamethrin resistant and susceptible strains were responsive to the essential oils. FZEO showed a higher larvicidal efficacy against both strains compared to DZEO, in which the LC_{50} for resistant (LC_{50} = 36.19 ppm) and susceptible (LC_{50} = 33.19 ppm) strains are slightly higher than the DZEO, LC_{50} values of 37.30 and 36.32 ppm for both strains, respectively. The larvicidal efficacy of *C. zedoaria* essential oil to eliminate the insecticide resistant or susceptible strains of *Cx. quinquefasciatus* presents a promising new mosquito larvicide. The potential of *C. zedoaria* essential oil is undergoing to use as a natural larvicide.

134

INSECTICIDE RESISTANCE STATUS OF *AEDES* MOSQUITOES IN GHANA

Christopher M. Owusu-Asenso, Yaw A. Afrane, Julius A. Mingle

University of Ghana, Accra, Ghana

This study investigated the insecticide resistance status of *Aedes* mosquitoes in Ghana. To determine phenotypic resistance status of *Aedes* mosquitoes, *Aedes* larvae were collected from five study sites (Accra, Tema, Ada-Foah, Tamale, and Damongo). These were raised to adults in the insectary and 2-5 days old adults were used to undertake WHO susceptibility bioassay. The test results showed that *Aedes* mosquito populations from all study sites were resistant to DDT (6.3 - 84%). Vectors showed resistance to deltamethrin in Tema (68%) and Tamale (85%) and suspected resistance in Accra (91.3%), Ada-Foah (93.5%) and Damongo (93%). Vectors showed resistance to permethrin in Accra (40.0%) and suspected resistance in Tamale (96.3%). *Aedes* mosquitoes showed suspected resistance to bendiocarb in Tema (95.0%) alone.

Aedes mosquitoes were susceptible to organophosphates in all sites. Morphological identification of the adult mosquitoes sampled in the sentinel sites showed that *Ae. aegypti* (93.7%) were the abundant species present in the sites, followed by *Ae. africanus* (6.0%) and *Ae. luteocephalus* (0.3%). The development of resistance by *Aedes* mosquitoes to pyrethroids is likely to have an operational impact on the efficacy of insecticide based vector control interventions.

OPTIMIZATION OF MASS-REARING METHODS FOR *ANOPHELES ARABIENSIS* FOR STERILE INSECT TECHNIQUE APPLICATION

Wadaka Mamai[1], Nanwimtoum Sévérin Bimbile Somda[2], Leanne Lobb[2], Hamidou Maiga[2], Hanano Yamada[2], Rosemay Susan Lees[3], Jeremie Roger Lionel Gilles[2], Jeremy Bouyer[2]

[1]International Atomic Energy Agency/Institut de recherche agricole pour le developpement, Vienna, Austria, [2]International Atomic Energy Agency, Vienna, Austria, [3]LITE/Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Mass-rearing of *Anopheles arabiensis* mosquito is crucial for strategies that use sterile insect technique to suppress vector populations. Production at a large-scale requires the development of standardized rearing procedures to produce good quality males able to compete with wild males for mating with wild females. The aim of this study was to optimize rearing conditions to ensure high egg productivity of *An. arabiensis* in the mass rearing cages and the highest pupae production in the larval rearing unit. Mass production cages of two different volumes, two different sources of blood meal (bovine and porcine) and two different population densities (cages originally loaded with either 15,000 or 20,000 pupae) were tested and evaluated on the basis of eggs produced/cage or per female. Moreover, four different egg quantities (4,000; 5,000; 6,000 and 7,000) and two different water temperatures at the time of egg hatching (22 °C and 27 °C) were tested for effects on time to pupation, pupation and adult emergence rates, sex ratio and adult body size. Neither cage volume nor blood meal source affected egg production per cage or per female. However, increasing population density to 20,000 pupae had a negative effect on eggs produced per cage and per female. The data point out the negative impact of high larval densities (7,000 eggs/tray) and low water temperature (22°C) on *An. arabiensis* pupae production and adult size. With the current mass-rearing tools available at the Insect Pest Control Laboratory and within the tested range, 4,000 eggs per larval rearing tray hatched at a water temperature of 27°C are the optimal conditions, providing the largest number of pupae (105,000 pupae / larval rearing unit (rack) with subsequent large emerged males for release and females for eggs production. Moreover, 15,000 is the optimal number of pupae to be loaded into the *Anopheles* Mass production cages. These results are valuable information to be taken into consideration when mass-rearing *An. arabiensis* for SIT programmes, and others relying on large scale production of mosquitoes.

136

FITNESS COSTS OF TWO PYRETHROID RESISTANCE MECHANISMS IN *AEDES AEGYPTI*: CYP-MEDIATED DETOXIFICATION AND *KDR*, INDIVIDUALLY AND IN COMBINATION

Leticia B. Smith, Laura Harrington, Jeffrey Scott

Cornell University, Ithaca, NY, United States

Aedes aegypti, an important vector of many human diseases, is a serious threat to human health due to its wide geographic distribution and preference for living near humans. Insecticides, especially pyrethroids, are still the primary means to control adult *Ae. aegypti* in endemic areas, especially during disease outbreaks, which has led to its extensive use over the past decades. Consequently, pyrethroid resistance is now found worldwide and is a major obstacle to the control of medically significant arthropod pests. Resistance alleles often have a fitness cost in the absence of insecticides. Understanding these costs and evolution of resistance is critical in integrated resistance management practices for it helps to determine how quickly resistance will be lost under field conditions after pesticide application has ceased. Our goal is to understand how the different resistance mechanisms impact mosquito fitness both independently and in combination. As a first step, such a study is best conducted in a controlled environment with minimal variables. We did this using a life table analysis to measure developmental time, survival, fecundity, egg viability, and body size. In *Ae. aegypti*, the two main mechanism of pyrethroid resistance are mutations in the *voltage-sensitive sodium channel* (*Vssc*) and enhanced cytochrome P450 (CYP)-mediated detoxification. To compare the fitness costs of the different mechanisms without the interference of other genetic variations, we isolated three pyrethroid resistant strains of *Ae. aegypti* that are congenic to the susceptible Rockefeller (ROCK) strain, but containing the different resistance mechanisms. CYP+KDR:ROCK contains both CYP-mediated resistance and *Vssc* mutations S989P+V1016G (*kdr*); KDR:ROCK contains only *kdr* and no CYP-mediated resistance; and CYP:ROCK contains only CYP mediated resistance and no *kdr*. Our preliminary results show that CYP-mediated resistance causes significant fitness costs regardless of the presence or absence of *kdr*. The implications of these results to the control of *Ae. aegypti* will be discussed.

137

EVALUATING THE EFFICACY OF MINI DOUBLE NET TRAP (MDN) FOR SAMPLING HOST SEEKING MOSQUITOES

Alex J. Limwagu, Hamis S. Kifungo, Anna Nyoni, Gasper K. Shubi, Marceline F. Finda, Fredros O. Okumu

Ifakara Health Institute, Morogoro, United Republic of Tanzania

Effective sampling tool that do not expose collectors is essential for monitoring malaria transmission. Human landing catch is considered as a gold standard but it exposed human being to both malaria and non-malaria pathogens. We have introduced a mini-double net trap as a replacement of HLC due to ethical and protection issues. The MDN with different sizes of the outer layer were tested to observe which height is suitable for collecting more mosquito species. The trap was designed with different sizes of the outer layer, i.e. 20cm, 50cm, 80cm from the ground and one with the holes on the side, allocated 100m apart. A Latin square design was used to evaluate the MDN trap. A total of 2,004 mosquitoes were collected using a MDN trap. The trap with holes on the side caught 468 (23.3%), MDN-20cm caught 505 (25.1%), MDN-50cm caught 535 (26.7%) and MDN-80cm caught 496 (24.7%). The MDN trap with the length of 50cm had significantly higher number of *Anopheles arabiensis* than the standard height MDN-20cm [Relative rate, RR=1.37, 95%CI (1.02 - 1.85), *P<0.05*]. MDN-80cm had fewer catches of *An. arabiensis* compared to MDN-20cm, [RR=0.88, 95%CI (0.68 - 1.14), *P=0.*337]. There is not significantly differences in the number *An. arabiensis* capture by MDN with side holes compared to MDN-20cm [RR=1.05, 95%CI (0.767 - 1.44), *P=0.*759]. The number *An. funestus* captured by MDN-50cm, MDN-80cm and MDN with side holes were not significantly different with the MDN-20cm [RR=0.33, 95% CI (0.06 -1.69), *P=0.*184), [RR=0.82, 95%CI (0.24 - 2.82), *P=0.*754) and [RR=0.98, 95%CI (0.30 - 3.20), *P=0.*979) respectively. We can therefore conclude that, MDN trap with the outer layer measuring 50cm from the ground can be considered as the most suitable options for collecting host-seeking mosquito species especially the most abundance vectors, *An. arabiensis*.

138

INSECTICIDE RESISTANCE IN *ANOPHELES ARABIENSIS* POPULATIONS FROM DAKAR AND ITS SUBURBS: ROLE OF TARGET SITE AND METABOLIC RESISTANCE MECHANISMS

Oumou K. Gueye[1], Abdoulaye K. Dia[1], El H. Nang[1], Seynabou M. Diedjou[2], Mamadou D. Sy[1], Abdoulaye Konate[1], Badara Samb[1], Abdoulaye Diop[3], Lassana Konate[1], Ousmane Faye[1]

[1]Universite Cheikh Anta Diop, Dakar, Senegal, [2]Universite Cheikh Anta Diop, Dakr, Senegal, [3]ABT-Association, Dakar, Senegal

Malaria is still a major public health problem in Senegal particularly in Dakar, where recurrent flooding occurring since 2005 complicated the epidemiology of the disease. Despite, the effort deployed to control the disease, high resistance of vectors to insecticide make hypothetical the country ambition to pre-elimination. This study was conducted from 2013 to 2015 to estimate the burden of the insecticide resistance and associated mechanisms in *An. arabiensis* populations from the flooded areas of Dakar the capital city of Senegal. *Anopheles* larvae and pupae were collected by dipping method from natural breeding sites. Bioassays were carried out using WHO test kits and CDC bottle for unfed, 3-5 days old adults mosquitoes. Detection of metabolic resistance was realised using CDC bottle with synergists. Molecular identification of An. gambiae complex species and kdr molecular genotyping was perform by PCR using respectively methods described previously. All populations tested were resistant to all insecticides families except Organophosphates . The presence of metabolic resistance like glutathion-S-transferases (GST) and cytochrome P450 (CYP450) was found. Molecular identification revealed the presence of *An. arabiensis* only. Kdr genotyping showed the presence of L1014F mutation (Kdr-West) and L1014S (Kdr-East). This L1014S mutation was found at high frequencies in almost all districts surveyed, and in association with L1014F. In conclusion, results showed the contribution of both target-site and metabolic mechanisms in conferring pyrethroid resistance to *An. arabiensis* from the flooded areas of Dakar suburbs. This vector is main malaria vector in the Cap Vert Peninsula, due to the presence of permanent larval habitats so-called "Ceane" gardening pits, especially during the dry season, as reported previously. Our findings indicate the need for close monitoring of the urban *An. arabiensis* populations to implement a suitable insecticide resistance management system to preserve core insecticide-based vector control tools in the flooded area of Dakar.

139

SUSCEPTIBILITY OF FIELD-COLLECTED *AEDES AEGYPTI* (L.) TO CONVENTIONAL INSECTICIDES IN COASTAL KENYA

Harun N. Ngugi[1], Francis M. Mutuku[2], Bryson A. Ndenga[3], Lucy W. Irungu[4], Amy R. Krystosic[5], Uriel Kitron[6], Angelle D. LaBeaud[7]

[1]Chuka University, Department of Biological Sciences/University of Nairobi, Department of Zoology, School of Biological sciences, Chuka/Nairobi, Kenya, [2]Technical University of Mombasa, Mombasa, Kenya, [3]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kisumu, Kenya, [4]University of Nairobi, Nairobi, Kenya, [5]Stanford University, California, CA, United States, [6]Emory University, Atlanta, GA, United States, [7]Stanford University, Stanford, CA, United States

Aedes aegypti are the vectors for many important arboviruses in Kenya, and control options are limited. We evaluated the susceptibility of field populations of nonblood-fed *Aedes aegypti* mosquitoes to four conventional insecticides: permethrin, 0.75%; deltamethrin, 0.05%; bendiocarb, 1%; and fenitrothion, 1%; according to WHO standard procedures. We also determined the efficacy and residual activity of a water dispersible formulation of the biolarvicide *Bacillus thuringiensis var israelensis* (Bti) (VectoBac® WG) under semi-field conditions during the dry and wet seasons. Three concentrations of larvicide in 2-L plastic trays were used in this study: 1×, 10× and 20× the manufacturer's recommended dosage (8mg/L, 80mg/L and 160mg/L respectively). Bioassays of adults showed full susceptibility to permethrin and fenitrothion. A low level of resistance was observed for deltamethrin and bendiocarb with 86 and 84% mortality, respectively. Knockdown rate for the first 20 min was notably higher (>90%) for both deltamethrin and permethrin than for bendiocarb and fenitrothion (<10%). Bti was effective under semi-field conditions for an average of 16 days at 8 and 80mg/L and for 22 days at 160mg/L, with 100% mortality during the dry season. In the wet season Bti efficacy at 80 and 160 mg/L lasted for 22 days. The results of this study suggest a need to monitor for developing resistance along the Kenya coast in order to recommend suitable adulticides and dosages for *Ae. aegypti* control, especially given the recent outbreaks of dengue and chikungunya.

140

THE RELATIONSHIP BETWEEN KNOCK-DOWN RESISTANCE (*KDR*) MUTATIONS METOFLUTHRIN INSECTICIDE TREATMENT IN MEXICO

Oselyne Ong[1], Gordana Rasic[1], Mike Dunbar[2], Gonzalo Vazquez-Prokopec[2], Pablo Manrique-Saide[3], Gregor Devine[1]

[1]QIMR Berghofer Medical Research Institute, Herston, Australia, [2]Emory University, Atlanta, GA, United States, [3]Universidad Autónoma de Yucatán, Yucatán, Mexico

The application of any insecticidal vector control intervention requires an understanding of the susceptibility of the target population. Knock-down resistance (*kdr*) mutations in voltage-gated sodium channel (VGSC) genes protect insects against DDT and pyrethroids. In Mexico, pyrethroids are used extensively, in domestic aerosols and by public health authorities, particularly during arbovirus outbreaks. As a result of heavy selection pressure, V1023I and F1565C *kdr* mutations are common in the dengue, chikungunya and Zika vector, *Aedes aegypti*. Volatile pyrethroids like metofluthrin are currently being considered for deployment indoors to prevent mosquito biting. These compounds have lethal and behavioral effects on mosquitoes and appear to retain their efficacy against *Ae. aegypti* carrying *kdr* mechanisms. A prototype metofluthrin "emanator" is being tested as part of a USAID-funded trial in experimental houses and an urban field trial. A genomic analysis of local Mexican strains by double-digest Restriction-site Associated DNA sequencing (ddRAD-seq) revealed selective sweeps around the VGSC gene and P450 gene family, confirming that local strains harbour potentially protective mechanisms against pyrethroids. More specifically, we are monitoring 4 common *kdr* mutations using a cost effective High Resolution Melt (HRM) analysis. Of the mosquitoes characterized to date, there are no S996P mutations in the "super-kdr" region of domain II but an increased frequency of V1023I and F1565C *kdr* mutations in the S6 of domain II and III in mosquitoes surviving metofluthrin treatment. The impact of these mechanisms on *Ae. aegypti* survival in experimental houses will help us interpret the spatial and temporal impacts of metofluthrin in the context of the *kdr* patterns observed during the larger urban field trials. The extent to which these mechanisms differentially affect the lethal impacts and biting behaviors of metofluthrin will also be discussed. Results gained from free-flying mosquitoes with a subset of *kdr* mutations suggest that behavioral effects can be maintained even when mortality is reduced.

141

PLANT-DERIVED EDIBLE OILS AS EMERGING LARVICIDES FOR YELLOW FEVER MOSQUITO, *AEDES AEGYPTI* (DIPTERA: CULICIDAE) CONTROL

Teresia Njoroge, Mary Schuler, May Berenbaum

University of Illinois at Urbana-Champaign, Urbana, IL, United States

Aedes aegypti is the primary vector for dengue, yellow fever, chikungunya and Zika viruses. Plant-derived edible oils are important sources of insecticides that can provide an eco-friendly, efficient and affordable tool for controlling *Ae. aegypti* populations around homes in resource-limited settings. The objective of this study was to evaluate the larvicidal activity of plant edible oils against *Ae. aegypti* larvae. Plant edible oils were purchased from local food stores in Champaign County, Illinois,

USA and tested for their larvicidal activity against *Ae. aegypti* larvae in the laboratory. Bioassays were performed using late third instar larvae and replicated 4 times at concentrations ranging from 500 to 4,000 ppm, with 10 larvae per replicate. For each oil, the lethal concentration killing 50% of larvae (LC_{50}) was determined using probit analysis and compared with its linoleic acid concentration. In addition, stage-specific susceptibility of larvae and oviposition deterrence of selected edible oils were also tested. Among the 13 edible oils tested, hempseed oil was the most toxic, with an LC_{50} of 342.2 ppm, followed by sesame and pumpkin seed oils (661.4 ppm and 829.1ppm), respectively. Moreover, the efficacy of the oils is correlated with percentage content of linoleic acid (R^2= 0.52). The fatty acid profiles of 4 edible oils revealed that oils with high linoleic acid composition are more toxic to *Ae. aegypti* larvae. Larval exposure to 100% linoleic acid yielded a much lower LC_{50} value (94.23ppm) compared to the most toxic oil (hempseed, 342.2ppm), a strong indication that linoleic acid may be the active principle in the oils. Third and fourth instar larvae experienced higher % mortality compared to first and second instar larvae ($p < 0.05$), indicating that they are more susceptible to the edible oils tested. On oviposition deterrence, all the oils tested reported an effective repellency of ≥ 63%. These results demonstrate that some plant edible oils are toxic to *Ae. aegypti* larvae and are very promising in creating new, safe, effective and affordable larvicides for controlling *Ae. aegypti* populations around homes in resource-limited settings.

142

NEAR-INFRARED SPECTROSCOPY TO DETECT MALARIA PARASITES IN *ANOPHELES GAMBIAE* S.S

Marta F. Maia[1], Francesco Baldini[2], Melissa Kapulu[1], Wagah Gorry[1], Lisa Ranford-Cartwright[2], Floyd Dowell[3], Heather Ferguson[2]

[1]KEMRI Wellcome Trust Programme, Kilifi, Kenya, [2]University of Glasgow, Glasgow, United Kingdom, [3]U.S. Department of Agriculture ARS Center for Grain and Animal Health Research, Manhattan, KS, United States

During the past decade there has been a substantial reduction in malaria incidence and related mortality. A few countries have announced plans for malaria elimination, setting ambitious goals for areas so far faced with perennial transmission. Elimination demands efficient programs together with real-time surveillance. Although vector control interventions, such as LLINs and IRS, have been the driving force behind the reduction in malaria cases, surveillance of vectors is restricted by shortage of entomologists and high costs of analyzing large number of mosquito samples. Near-infrared spectroscopy (NIRS) is used to measure the light in the near-infrared region that is absorbed by a mosquito; the spectra depend on its external and internal composition. It is non-destructive, high-throughput and requires no reagents. This study aimed at investigating if NIRS can be used to determine if a mosquito is infected with malaria sporozoites. For this purpose, *Anopheles gambiae* s.s (Keele strain) mosquitoes were infected in the laboratory using cultured *Plasmodium falciparum* parasites. These were kept in insectary conditions for 14 days along with mosquitoes that were given an uninfected blood meal on the same day. After 14 days mosquitoes were killed and scanned using NIRS. Parasite infection was quantified using qPCR. A calibration was developed using 69 uninfected mosquitoes and 69 sporozoite-infected mosquitoes with different infection loads. The calibration was then used to predict an independent set of samples composed of 22 uninfected and 68 sporozoite infected mosquitoes. Results showed the method predicted the independent samples with 100% sensitivity and 88% specificity (22/22 accurately predicted as uninfected; 66/68 accurately predicted as uninfected). The adoption of this new high throughput method to identify infected mosquitoes could deliver a cheap and efficient approach to malaria vector surveillance in endemic regions as well as in regions facing disease importation. Validation with wild mosquito infections is on-going and will verify the applicability of the method to the field.

143

IMPORTANCE OF AN EFFICIENT LARVAL DIET FOR *ANOPHELES DARLINGI* TO *PLASMODIUM VIVAX* IN THE PERUVIAN AMAZON

Carlos Tong[1], Anibal Huayanay[1], Lutecio Torres[1], Gerson Guedez[1], Dionicia Gamboa[1], Joseph M. Vinetz[2], Manuela Herrera-Varela[1], Marta Moreno[2]

[1]Universidad Peruana Cayetano Heredia, Iquitos, Peru, [2]University of California San Diego, San Diego, CA, United States

Anopheles darlingi, the main malaria vector in the Neotropics, was recently colonized under laboratory conditions. Hence it was necessary to optimize larval feeding because the environmental conditions in juvenile stages, such as food availability, impact the survival and reproduction and their susceptibility to *Plasmodium*. The high cost and lack of availability of commercial larval food in the Peruvian Amazon limits our ability to produce mosquitoes of high quality for assays such as transmission blocking or sporozoite production. In this study, we investigate the effectiveness of different larval diet mixtures with local accessible ingredients to promote more affordable and sustainable mosquito production. We evaluated five mixtures: Puripaiche (contains 45% crude protein), LabDiet (23%), Nutrafin (32%), Whiskas (31%), and Conejina (18%). Life tables and wing length (adult body size) were recorded to analyze the effect of foods on larval development and adult emergence. Three- and four-day-old adults were provided with *P. vivax*-infected blood, and on the 7th day post feeding, oocysts were counted in the midgut. All diets resulted in a larval survivorship >70%, with the exception of Conejina, for which the larval survival was 6%. Similarly, the mean time to adult emergence was 24 days (CI: 22-27) for all diets except for Conejina, for which the mean time to emergence was 30 days. Significant differences ($p<0.05$) were found in the wing length of adult mosquitoes: Puripaiche, Nutrafin and LabDiet produced mosquitoes with larger wing lengths (2.79mm, 2.73mm and 2.70mm respectively), whereas Whiskas (2.66mm) and Conejina (2.59mm) yielded smaller mosquitoes. There was no significant difference in the susceptibility to *P. vivax* between diets, with a mean of 12.85 oocysts/mosquito for Puripaiche, 10.75 for LabDiet, and 10.17 for Nutrafin. Overall, Puripaiche, Nutrafin and LabDiet are promising larval diets for the rearing and efficient production of adult mosquitoes.

144

GENDER DIFFERENCES IN THE IMMUNE RESPONSES AGAINST *AEDES AEGYPTI* SALIVARY PROTEINS

Paula Rozo-Lopez[1], Marisol Aguirre-Rojas[1], Mark James[2], Berlin Londono-Renteria[1]

[1]Kansas State University, Manhattan, KS, United States, [2]Kent State University, Kent, OH, United States

Aedes aegypti is one of the most well-characterized mosquito species due to being the primary vector of Dengue, Chikungunya, and Zika in tropical areas. During mosquito blood feeding, a salivary exudate is injected into the host skin to allow the mosquito to successfully uptake blood. Mosquito salivary secretions cause allergic reactions and induce significant antibody responses in humans. Specifically, levels of IgG and IgM antibodies increase in human populations with continued exposure to high numbers of mosquitoes. It has been proposed that antibody responses and vector-transmitted disease infections show some gender-dependent variation in humans due to sex-related physiology and differences in rates of exposure. However, there is little understanding about the influence of gender on antibody response in humans with continued exposure to *Ae. aegypti*. This study provides a secondary analysis of data measuring the levels of antibodies against *Ae. aegypti* saliva in human populations from dengue endemic areas of Colombia. We aim to establish whether there are gender-dependent and age-related antibody responses to mosquito exposure and associations with the presentation of dengue fever infections. Our results showed higher levels of IgG antibodies in males before traveling to dengue-endemic areas (p=0.0463) and higher

IgM antibody levels in females after mosquito exposure and throughout the follow-up period. We also observed a discrete decline in the antibody levels (IgG and IgM) with age, which suggests that age related responses are independent of gender. Moreover, we found a significant positive correlation between the IgG levels against dengue fever and 37/38kDa proteins (r=0.6272, p=0.0217) in females with active DENV. Our results suggest that sex and age should be taken into account when interpreting serum IgG and IgM levels.

145

THE *ANOPHELES FARAUTI* HABITAT AND ITS ASSOCIATION WITH LARVAL DENSITY AND ADULT FITNESS

Kimberley McLaughlin[1], Tanya Russell[1], Allan Apairamo[2], Hugo Bugoro[3], Jance Oscar[4], Nigel Beebe[5], Robert Cooper[6], Weng Chow[6], Tom Burkot[1]

[1]Australian Institute of Tropical Health and Medicine, Cairns, Australia, [2]National Vector Borne Disease Control Programme, Ministry of Health and Medical Services, Honiara, Solomon Islands, [3]National Vector Borne Disease Control Programme, Honiara, Solomon Islands, [4]Malaria, other vector-borne and parasitic diseases, Gizo, Solomon Islands, [5]School of Biological Sciences, The University of Queensland, Brisbane, Australia, [6]Army Malaria Institute, Australian Government Deparment of Defence, Brisbane, Australia

The fitness of adult malaria mosquitoes, defined by size and survivorship, is influenced by density-dependent processes at the larval stage, and simultaneously by density-independent (environmental) processes. Understanding the roles of density-dependent and independent influences is essential for predicting the response of mosquito populations to larval control. Evidence for the existence of density dependent effects on *Anopheles farauti*, the primary vector in the Solomon Islands will be presented together with data on the physical, chemical and biological characteristics of larval habitats and their association with productivity. Methods: Human landing catches were carried out across the Solomon Islands with the wings of the collected mosquitoes measured to determine size variation within the adult population. As well as adult collections, the aquatic stage was also investigated looking at the chemical, physical, and biological factors associated with the presence or absence of the *An. farauti* larvae as well as the productivity of each potential habitat. Size variation was confirmed within the adult mosquito population, and significant factors found that act on the larvae with water temperature (P<0.0001*), pH (P=0.0002*), nitrate (P<0.0001*), ammonia (P=0.0190*), and phosphate (P<0.0001*) associated with increases in larval density. However, there does not appear to be any single dominant factor associated with habitat utilisation and productivity. In conclusion, a lot of information is unknown regarding the aquatic stages of anophelines in the Solomon Islands. This is especially evident for *An. farauti* which is concerning considering the impact it has on human health due to its association with malaria. Looking at the relationship between the larval habitat, larval density, and adult fitness could help influence future control methods to complement the use of insecticide treated nets for malaria control.

146

PRIMATE MALARIA TRANSMISSION IN THE ABSENCE OF HUMAN HOSTS: INVESTIGATING MOSQUITO VECTOR ECOLOGY IN THE LOWER KINABATANGAN WILDLIFE SANCTUARY, SABAH, MALAYSIAN BORNEO

Rebecca E. Brown[1], Chua Tock Hing[2], Heather M. Ferguson[1]

[1]Institute of Biodiversity, Animal Health and Comparative Medicine, Glasgow, United Kingdom, [2]Universiti Malaysia Sabah, Kota Kinabalu, Malaysia

A significant outbreak of the primate malaria *Plasmodium knowlesi* in humans has occurred in Sabah, Malaysian Borneo. The competent vector *Anpheles balabacensis* is responsible for human infections, arising as spill-over events from wild macaque reservoir hosts. Little is known about the ecology of *Plasmodium knowlesi* transmission within reservoir primate hosts in undisturbed forests. Elucidation of these transmission systems is crucial to assess whether human infections could be prevented by interrupting transmission in macaques. With the objective of characterising the macaque malaria transmission cycle, we aimed to determine the abundance and diversity of potential malaria vector species in the vicinity of macaque troops and to identify circulating *Plasmodium* infections of *P. knowlesi* and other primate malaria species. Here we trialled Mosquito Magnet Independence Traps (MMIT) to sample mosquitoes host seeking near macaque sleeping sites within the Lower Kinabatangan Wildlife Sanctuary, Sabah from August to November 2017. This reserve contains high numbers of macaques but very few humans, making it appropriate for studying the monkey-monkey malaria transmission cycle. For 30 nights, a thermal imaging camera was used to select trees for the positioning of one MMIT at a tree hosting sleeping macaques and one MMIT at an unoccupied (control) tree each night. Higher mosquito abundances were found at macaque roosts (n=5489) than at control trees (n=5065). *Anopheles* comprised 4% of collections, including three species: *An. balabacensis*, *An. barbirostris* and *An. donaldi*, previously implicated in malaria transmission. Their combined abundance was higher at control (n=233) than macaque trees (n=124). *Anopheles balabacensis* was more abundant at macaque trees (n=13) than at controls (n=2) and only one *An. balabacensis* was infected with the primate malaria *P. inui*. The low abundances of primate malaria vector species and low *Plasmodium* infection rates were surprising, and specifically that *P. knowlesi* was not detected. Ongoing work screening macaque stool samples will confirm the intensity of *P. knowlesi* in macaques in this area.

147

AEDES AND *ANOPHELES* MOSQUITO CO-CONCURRENCE: IS THERE ANY IMPACT ON HUMAN IMMUNE RESPONSE AGAINST PATHOGENS?

Sapna Menghwar[1], Nicholas Bloedow[1], Tonya M. Colpitts[2], Berlin Londono-Renteria[1]

[1]Kansas State University, Manhattan, KS, United States, [2]Boston University School of Medicine, Boston, MA, United States

Dengue and malaria are among the principal mosquito transmitted diseases. Although, malaria incidence has significantly decreased in the last decade, there is an alarming increase of pathogens transmitted by *Aedes* mosquitoes including Dengue virus. Although, *Anopheles* and *Aedes* prefer very different breeding sites, adults of booth species are often captured in endemic areas, during surveillance efforts. Also, the concept of malaria - dengue co-infection is starting to get more attention in recent years due to an increase in cases in tropical regions. Our preliminary study using 32 samples collected in two different regions of Colombia revealed a significant positive correlation between antibodies against salivary proteins from *Ae. aegypti* and *An. albimanus* in people living in areas endemic for both malaria and dengue in the Caribbean. However, this correlation was not observed in the Pacific Coast, where *An. darlingi* and *An. nuneztovari* are the main vectors of malaria and the presence of *An. albimanus* is uncommon. Interestingly, antibody levels against the salivary proteins and the correlation between them was age dependent with lower antibody levels in younger populations. Correlation between antibodies against the specific pathogens and its vector was more complicated. We observed a negative but significant correlation between IgG against *An. albimanus* and the CSP in older populations (>26 years old) suggesting the potential impact of human-vector contact intensity in immunity against malaria. However, we did not observe a relationship between antibodies against the CSP and salivary proteins in younger populations. In the case of dengue, we found a significant correlation between antibodies (IgM or IgG) against all serotypes and IgG against *Ae. aegypti*, except for DENV4, which is the least transmitted serotype in Colombia. In conclusion, people in tropical areas are exposed to both *Anopheles* and *Aedes* mosquitoes in

any given time increasing the possibility of malaria-arboviral co-infections. More studies are needed to establish the relationship between vectors of different diseases and impact of immunity in disease transmission.

148

DRIVING FORCE AND IMPACT OF URBANIZATION ON THE ECOLOGY OF *AEDES* MOSQUITOES IN YELLOW FEVER AND DENGUE CO-ENDEMIC AREAS IN COTE D'IVOIRE

Julien B. Zahouli[1], Benjamin G. Koudou[2], Pie Müller[3], David Malone[4], Yao Tano[5], Jürg Utzinger[3]

[1]Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Côte D'Ivoire, [2]Centre for Neglected Tropical Diseases, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland, [4]Innovative Vector Control Consortium, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [5]Université Nangui-Abrogoua, Abidjan, Côte D'Ivoire

Aedes mosquito-borne arboviruses have increasingly occurred in rural and urban settings of Africa. We explored the effect of urbanization on *Aedes* ecology along a rural-to-urban gradient in yellow fever (YF) and dengue (DEN) co-endemic areas in Cote d'Ivoire. *Aedes* eggs, larvae and adults were sampled using ovitraps, larval surveys and human-baited double-net traps in rural, suburban and urban areas from January 2013 to December 2014. *Aedes* breeding sites were characterized, and species identified. A total of 51,439 specimens of *Aedes* mosquitoes belonging to 20 species (*Ae. aegypti*, *Ae. africanus*, *Ae. albopictus*, *Ae. angustus*, *Ae. apicoargenteus*, *Ae. argenteopunctatus*, *Ae. dendrophilus*, *Ae. fraseri*, *Ae. furcifer*, *Ae. haworthi*, *Ae. lilii*, *Ae. longipalpis*, *Ae. luteocephalus*, *Ae. metallicus*, *Ae. opok*, *Ae. palpalis*, *Ae. stokesi*, *Ae. unilineatus*, *Ae. usambara* and *Ae. vittatus*) were sampled. The highest *Aedes* species richness was found in rural (18 species), followed by suburban (7 species) and urban (3 species) areas. Conversely, *Aedes* showed higher abundance in urban (n = 51,439; 50.7%) compared to suburban (32.6%) and rural (16.7%) areas. *Aedes*-positive breeding sites were more abundant in urban (2,136/3,374; 63.3%) than suburban (1,428/3,069; 46.5%) and rural (738/2,423; 30.5%) areas. Breeding sites were mainly industrial (i.e., tires, cans and water receptacles), traditional (i.e., clay-pots) and natural (i.e., tree holes and fruit husks) containers in urban, suburban and rural areas, respectively. *Ae. aegypti*, *Ae. dendrophilus*, and *Ae. vittatus* bit humans in rural (4.48 bites/person/day), while *Ae. aegypti* inflicted 99.7% of bites in urban (15.73 bites/person/day) areas. *Ae. aegypti* was the dominant species and displayed bimodal daily feeding cycles in all areas, with stronger magnitude in urban areas. In Cote d'Ivoire, urbanization shifts *Aedes* ecology by restricting of wild *Aedes* species in rural and favoring *Ae. aegypti* in urban areas. Data suggested that while *Aedes* wild species act as bridge vectors of YF and DEN viruses in rural, *Ae. aegypti* raises the risk of inter-human transmission of arboviral diseases in urban areas.

SPATIAL RISK OF URBAN EXPOSURE TO *ANOPHELES* AND *AEDES* MOSQUITO BITES IN AFRICA USING SALIVARY ANTIBODY-BASED BIOMARKERS

Andre Barembaye Sagna[1], Daouda Kassie[2], Agnès Couvray[1], Emmanuel Hermann[3], Gilles Riveau[3], Gérard Salem[4], Florence Fournet[1], Franck Remoue[1]

[1]Institut de Recherche pour le Développement, Montpellier, France, [2]ASTRE, CIRAD, INRA, Univ Montpellier, Montpellier, France, [3]Institut Pasteur de Lille, Lille, France, [4]Institut de Recherche pour le Développement, Paris, France

Urban settings often present low densities of mosquito vectors which do not allow to accurately assess the risk of arthropod-borne diseases based on entomological parameters. This study aims to evaluate the spatial risk of both malaria and arbovirus transmission in a northern urban area of Senegal, West-Africa, using antibody-based biomarkers of human exposure to Anopheles and Aedes mosquito bites. A cross-sectional study was undertaken between August and September 2014 (rainy season) in four urban districts (UDs) of the city of Saint-Louis, Senegal: Leona (LEO), Ndioloffène (NDI), Guet Ndar (GND) and Pikine Sor Diagne (PSD). In each UD, dry blood spots were performed in 809 children aged 6-59 months and ELISA method was used to evaluate IgG antibody (Ab) responses to both gSG6-P1 (Anopheles) and Nterm-34kDa (Aedes) peptides of respective mosquito saliva. The median of IgG response levels to both gSG6-P1 and Nterm-34kDa salivary peptide varied significantly according to UDs and were lower in LEO compared to PSD, GND and NDI ($p<0.0001$). Heat maps of IgG responses to both salivary peptides indicated variations in the spatial distribution of the intensity of Ab responses inside UDs. There were no hot spots of malaria transmission risk (areas with children presenting a high IgG intensity) in LEO. Hot spots of malaria were mainly located in the northern part of NDI and GND, and in the southern part of PSD. As for the risk of arbovirus transmission, there were no hot spots in LEO and PSD. Hot spots of arbovirus transmission risk were located in some patch in the north of NDI and were dispersed throughout the UD of GND. Our results demonstrate that hot spots of both malaria and arbovirus transmission risk actually exist in northern parts of NDI and GND. This highlights that a targeted fight against mosquitoes in these hot spots could be effective against all mosquito-borne diseases. Antibody-based biomarkers could then help national control programs to target and prioritize vector control strategies in areas with common risk of malaria and arbovirus transmission.

LARVAL ENVIRONMENT INFLUENCES MICROBIOTA OF CONTAINER DWELLING MOSQUITOES

Elijah Juma

University of Illinois at Urbana-Champaign, Urbana, IL, United States

Mosquitoes host a community of microbiota that influence their growth, survival and susceptibility to pathogens. These microbiota are known to vary markedly between individuals but our understanding of the factors that influence this variation is still limited. The aim of this study was to determine how the larval environment influences the microbiome of two container-dwelling mosquito species, *Aedes triseriatus* and *Ae. japonicus*. Larvae of the two mosquito species were sampled from tire and tree-hole habitats at South Farms and Trelease Woods study sites in Champaign, Illinois, and their microbiome characterized through MiSeq sequencing of the 16S rRNA gene. Approximately 66% of bacterial operational taxonomic units (OTUs) were shared between mosquito larvae and water samples from the larval environment. *Dysgonomomanas* and an unclassified genus from family *Comamonadaceae* were the dominant bacterial taxa in *Ae. triseriatus* larvae and water samples respectively, but no clear dominance of any bacterial taxa was observed in *Ae. japonicus* larvae. Overall, there was significantly higher number of OTUs observed and predicted in mosquito larval samples compared to water samples. Bacterial OTU richness was significantly higher in *Ae. japonicus* tire samples from both study sites compared to *Ae. triseriatus* tire and tree-hole samples from South Farms or water samples from South Farms. NMDs plots based on Bray-Curtis distances revealed a clear separation of *Ae. japonicus, Ae. triseriatus* and water samples indicating that the bacterial communities differed by sample type. The findings of this study reveal that *Ae. japonicus* and *Ae. triseriatus* harbor distinct bacterial communities some of which are likely acquired from the larval environment.

151

HOST PREFERENCES AND ACTIVITY RHYTHMS OF *ANOPHELES* MOSQUITOES IN CAMBODIA

Amélie Vantaux[1], Sovannaroth Siv[2], Ken Vernick[3], Ivo Mueller[4], Benoit Witkowski[1]

[1]Institut Pasteur in Cambodia, Phnom Penh, Cambodia, [2]National Center for Parasitology, Entomology and Malaria Control Program, Phnom Penh,

Cambodia, [3]Genetics and Genomics of Insect Vectors Unit, Institut Pasteur, Paris, France, [4]Malaria: Parasites & Hosts Unit, Institut Pasteur, Paris, France

The main vector control tools against malaria mosquitoes have been the scaling up of indoor-oriented vector control tools, despite the fact that Southeast Asian mosquitoes populations mainly feed early and outdoors. In Cambodia, the main persistent reservoirs of transmission appear to be located outside of villages, in forests. This study aimed at better characterizing *Anopheles* vector bionomics to inform novel vector control tools development. Mosquitoes were sampled hourly over a 24h period during the rainy and the dry season in three types of sites: villages, forest habitats surrounding the villages, and deep forest. Inherent mosquito host preference was determined using odour-baited traps set side by side in a choice arrangement, releasing either human or cow odors. This allows calculation of the anthropophily index (AI): number of *Anopheles* mosquitoes caught in the human-baited trap over the total number of mosquitoes caught in both traps. A total of 3803 *Anopheles* mosquitoes were caught, with most of them at night, although 25.9% were caught during daytime. Overall *Anopheles* mosquitoes caught in the deep forest were significantly more anthropophilic (AI rainy season=26.5%; AI dry season=32.9±3.1%) than mosquitoes caught in the villages (AI rainy season=4.3±1%, P<0.0001; AI dry season=6.3±4.9%, P<0.0001) or in the forests surrounding the villages (AI rainy season=5.3±1%, P<0.0001; AI dry season=16.5±5.5%, P<0.0001). When considering females collected in the human-baited traps only, similar numbers were collected during the two rainy seasons, with 79.5% collected in the deep forest sites. These results strengthen the hypothesis that forests are the main risk areas for human malaria transmission, and highlight the importance of daytime biting behavior as a potential source for transmission. Molecular biology analyses are ongoing to determine malaria prevalence and transmission risks. In the current context of malaria elimination in Greater Mekong Subregion, there is an urgent need to develop vector control tools adapted to forest transmission settings in order to effectively break malaria transmission.

152

SPATIAL DISTRIBUTION OF PCR -IDENTIFIED MALARIA VECTORS IN CROSS RIVER STATE, NIGERIA

Hala S. Bassaly[1], Reham A. TagEldin[1], Nermeen T. Fahmy[1], Joseph W. Diclaro II[1], Anyanwu A. Alaribae[2], Emmanuel Ezedinachi[2]

[1]US Naval Medical Research Unit-3, Cairo, Egypt, [2]University of Calabar and University of Calabar Teaching Hospital Moor Road Calabar, Cross River State Nigeria, Calabar, Nigeria

Anopheles gambiae sensu lato complex describes a group of seven morphologically indistinguishable members, comprising the main species responsible for malaria transmission in tropical and subtropical Africa. The diverse biological characters of these sibling species as well as their behavioral variations are responsible for the difference in their ability to transmit malaria and susceptibility to pyrethroids. This highlights the need for precise mapping of their spatial distribution to monitor and evaluate malaria threat levels, and to enhance effective implementation of integrated vector control strategies. The present study aimed at developing a GIS- based overlay on the spatial patterns of PCR-identified *A. gambiae* complex species collected from four sites in Cross River State; Calabar and Akpabuyo in southern, Yakurr in central and Ogoja in Northern region representing three different ecological zones. Trapping was conducted every other month from October 2015 until June 2016, covering both dry and rainy seasons, using CDC-UV traps and pyrethrum spray catch. *Anopheles* complex species were identified using molecular techniques based on differences in the rDNA region between species and the molecular forms of *A. gambiae s.s* specimens. A total of 1,386 female *A. gambiae* mosquitoes were collected and identified. DNA was extracted from legs of each specimen and species identification determined by multiplex PCR using specific primers. The molecular forms of *A. gambiae s.s* were determined by RFLP. Results indicated dominant occurrence of *A. gambiae s.s.* (99.2%) across the four sites in comparison to *A. arabiensis* which was detected in small number (0.8%). Out of 1,375 *A. gambiae s.s* specimens, 78.2%, 20%, and 1.8% were *A. coulzzii, A. gambiae* and hybrid forms respectively, a finding that contradicts other studies. *A. coulzzii* is predominant in guinea-savannah and rain forest ecological zones mainly during rainy seasons, while *A. gambiae* is prevalent in mangrove rain forest during dry season. These results provide important insights for strategic planning of malaria control programs in Nigeria.

153

MOON PHASE EFFECT ON MOSQUITO VECTORS OF WEST NILE VIRUS IN MADAGASCAR: BIODIVERSITY, ABUNDANCE, HOST ATTRACTIVENESS AND FEEDING RATES

Luciano Michaël Tantely[1], Hélène Guis[2], Manou Rominah Raharinirina[1], Iavo Randriananjantenaina[3], Eric Cardinale[2], Claire Garros[2], Romain Girod[1]

[1]Institut Pasteur de Madagascar, Antananarivo, Madagascar, [2]Centre de coopération internationale en recherche agronomique pour le développement, Montpellier, France, [3]University of Antananarivo, Antananarivo, Madagascar

West Nile Virus (WNV) infection occurs throughout Madagascar. Its epidemiological cycle involves horses, human, birds and mosquitoes. Our entomological data shows unexpected information on mosquitoes vectors diversity and biology that relates to the collection methods. This study highlights the effect of lunar cycle that has not been previously considered in previous studies in Madagascar. During 2017, the influence of the two lunar phases (full *versus* new moon) on mosquito populations was analyzed in a farm located in the surroundings of Antananarivo city, Madagascar. Each month, mosquito collections were performed twice: one night during the full moon and one during the new moon. Six light traps were used: three indoors (in horse's box stall, in a house, in a cowshed), while three outdoors (near a pigsty, near a chicken coop, near a water point). During 24 night catches, 36,448 specimens belonging to 23 species were collected with *Culex antennatus* (64%) and *Cx. quinquefasciatus* (30%) the most abundant species. *Cx. antennatus* was mostly collected in traps associated with domestic animals while *Cx. quinquefasciatus* in trap placed in house. Each month, the total number of females caught during new moon was 1 to 3,5 times higher than those caught during full moon (ANOVA; F=34.4, DF=3, P<0,05). Larger numbers of mosquitoes, driven mainly by *Cx. antennatus*, were collected during the new moon in the three outdoor traps; and inversely during the full moon in the cowshed. This new moon effect was observed in the house but driven mainly by *Cx. quinquefasciatus*. Lunar phase did not influence the abundance of mosquitoes in horse's box stall and the variation of mosquitos' diversity. The total number of fed and unfed females followed (F=0.709, DF=39, P>0,05) the same pattern than the abundance of mosquitoes collected in the farm. The lunar cycle has an effect on mosquito abundance and host attractiveness and might vary according to the mosquito species. This lunar effect and the location of traps should be taken into consideration for one target species during entomological investigations aiming at unraveling West-Nile virus transmission when using light traps.

154

RELATIONSHIP BETWEEN MICROCLIMATE AND ENVIRONMENTAL VARIABLES AND MOSQUITO ABUNDANCE IN RURAL ECUADOR

Rachel J. Sippy[1], Diego Herrera[2], David Gaus[2], Ronald Gangnon[1], Jonathan Patz[1], Jorge Osorio[1]

[1]University of Wisconsin Madison, Madison, WI, United States, [2]Salud y Desarrollo Andino, Pedro Vicente Maldonado, Ecuador

Mosquito abundance is an important predictor of mosquito-borne illnesses, such as dengue fever. *Aedes aegypti* mosquitos, which spread the dengue virus, have a close relationship with humans, often living only within urban environments. Fine-scale relationships between climate, environment, and mosquito populations in this setting are poorly understood. Using mosquito traps fitted with microclimate sensors, we

determined the relationship of these microclimate and environmental factors with host-seeking mosquito abundance, within a small town (approximately 5500 people) in rural Ecuador over a twelve-month period. Data were analyzed with a negative binomial (all-species mosquitos) or binomial logit (proportion of female *Aedes aegypti*) model with generalized estimating equations. Temperature and relative humidity were variable even at small spatial scales; temperature maximum and minimum relative humidity exhibited the widest range of values across the sampling timeframe. For all-species mosquito abundance, median temperature (effect=-0.23, p=0.0071), minimum relative humidity (effect=0.31, p=0.0017) and median relative humidity (effect=-0.70, p=0.0095) had the strongest associations, but temperature variance and maximum temperature also had statistically significant effects. Seasonality and urbanicity levels also influenced all-species mosquito abundance. Among the sites with any mosquitos, the odds of a captured mosquito being a female *Ae. aegypti* were increased by 45% for each degree increase in median temperature (p=0.006), with seasonality also strongly affecting these odds (p=0.0001). This is one of few studies of microclimate, environment, and mosquito abundance, and may provide important insights into global prediction modeling, as well as local prevention and control efforts.

155

ENVIRONMENTAL AND ENTOMOLOGICAL SURVEYS TO DETECT BREEDING SITES OF *AEDES* SPP. IN SALVADOR, BRAZIL

Raquel Lima Souza[1], Patrícia Moreira[1], Vánio Mugabe[2], Roberto Santos[3], Isabel Guimarães[4], Mitermayer Reis[1], Uriel Kitron[5], Guilherme Ribeiro[1]

[1]Fundação Oswaldo Cruz, Salvador, Brazil, [2]Universidade Federal da Bahia, Salvador, Brazil, [3]Laboratório Central de Saúde Pública, Salvador, Brazil, [4]Centro de Controle de Zoonoses, Salvador, Brazil, [5]Emory University, Atlanta, GA, United States

Larvae and pupae of *Aedes aegypti* and *Ae. albopictus,* the vectors of dengue, chikungunya and Zika viruses in Brazil, are found in natural and artificial water-storage containers, but also in other breeding sites outside human dwellings. During October 2016 we conducted a cross-sectional entomological and environmental study in a residential medium-high socioeconomic level area (0.08 km^2), located in Pituba neighborhood, Salvador, Brazil to describe and estimate the relative contribution of different breeding sites inside and outside human dwellings. We detected 448 breeding sites within private areas, of which 238 (53.0%) held water and 7 (1.6%) contained immatures [7 (1.6%) with *Ae. aegypti*, 1 (0.2%) with *Ae. albopictus*, and 2 (0.4%) with *Culex* spp.]. Adult mosquitoes were captured in 27 (23.3%) of the 116 surveyed properties: *Ae. aegypti* in 20 (17.2%) and *Culex* sp. in 11 (9.5%); no adult *Ae. albopictus* were captured inside the properties. In public areas, we surveyed 108 catch basins, of which 43 (40.0%) contained water, 10 (9.3%) contained immatures [2 (1.9%) with *Ae. aegypti*, 2 (1.9%) with *Ae. albopictus*, and 8 (7.4%) with *Culex* spp.], and 11 (10.1%) contained adult mosquitoes [*Ae. aegypti* in 3 (2.8%), *Ae. albopictus* in 3 (2.8%), and *Culex* spp. in 4 (3.7%)]. We also installed 34 ovitraps in a third of the properties, and found immatures of *Ae. aegypti* in 10 (29.4%) and of *Ae.albopictus* in 3 (8.8%) traps. *Aedes* spp. eggs were detected in 22 (64.7%) of the traps. Our findings demonstrate that catch basins in Salvador accumulate water and serve as larval development sites and as adult resting areas for *Ae. aegypti* and *Ae. albopictus*. Furthermore, breeding sites outside the houses serve as an important source for domestic *Ae. aegypti* infestations. Consequently, determining the rate of house level infestations based only on the presence of larvae in the properties (as is done in Brazil), underestimates the true level of infestation. We suggest that additional surveillance measures targeting capture of adult mosquitoes inside houses are needed. Even more importantly, we emphasize the need to include proximate public areas in *Aedes* surveillance programs.

156

MODELING THE POTENTIAL DISTRIBUTION OF *AEDES AEGYPTI* IN THE CITY OF CORDOBA, ARGENTINA

Elizabet L. Estallo[1], Florencia Sangermano[2], Marta Grech[3], Francisco F. Ludueña-Almeida[1], María Frías-Cespedes[4], Mariela Ainete[4], Walter Almirón[1], Todd Livdahl[5]

[1]Instituto de Investigaciones Biológicas y Tecnológicas (IIByT), Universidad Nacional de Córdoba, CONICET, Centro de Investigaciones Entomológicas de Córdoba (CIEC), FCEFyN, Córdoba, Argentina, [2]Graduate School of Geography, Clark University, Worcester, MA, United States, [3]Centro de Investigación Esquel de Montaña y Estepa Patagónica (CIEMEP). CONICET and Universidad Nacional de la Patagonia San Juan Bosco. Facultad de Ciencias Naturales, Sede Esquel, Chubut, Argentina, [4]Ministerio de Salud de la Provincia de Córdoba, área de Epidemiología, Córdoba, Argentina, [5]Department of Biology, Clark University, Worcester, MA, United States

Aedes aegypti, an urban mosquito, is involved in the transmission of numerous viruses, including dengue, chikungunya and Zika. In Argentina *Ae. aegypti* is the main vector for dengue virus, involved in several outbreaks expanding from northern to central areas since 2009. In order to evaluate potential vector-borne diseases transmission in Córdoba city, Argentina, we aim to identify the environmental, socio-economic and demographic factors driving the distribution of *Ae. aegypti* larval presence through spatial analysis in the form of species distribution models (SDMs). A maximum entropy species distribution model was developed to identify the relationship between known occurrences of *Ae. aegypti* and 11 factors. The model identified suitable breeding areas for *Ae. aegypti*, as location with high Human population density, in close proximity to vegetation, and near water channels. The model goodness of fit was good, with an area under the receiver operating characteristic curve (AUC) greater than 0.8 and presented a fair extrapolation capacity (average test AUC>0.75). Results from this work will allow for target surveillance and prevention measures, as well as for mosquito management within areas of high habitat suitability for the species.

157

ZIKA AND DENGUE VIRUS INFECTIONS IN PREGNANT MOTHERS IN GRENADA

Nikita Cudjoe[1], Trevor Noël[1], Amy Krystostik[2], Randall Waechter[1], Sherice Phillip[3], Veronica Mapp-Alexander[3], Elysee Noel Grossi-Soyster[2], Priyanka Suresh[2], Justin Lee[4], George Mitchell[5], Calum Macpherson[1], A. Desiree LaBeaud[2]

[1]Windward Islands Research and Education Foundation, St. George, Grenada, [2]Department of Pediatrics, Division of Infectious Diseases, Stanford University, California, CA, United States, [3]St. George's University, St. George, Grenada, [4]Qualitative Sciences Unit, Stanford University, California, CA, United States, [5]Ministry of Health, St. George, Grenada

While Zika virus (ZIKV) poses a significant threat to pregnant women and their infants, 80% of infections are asymptomatic. The objective of this study was to document the impact of maternal symptomatic and asymptomatic ZIKV infections on infants in Grenada. During the ZIKV outbreak in 2016, a cohort of pregnant women in antenatal clinics were enrolled, surveyed and blood samples were collected to test for ZIKV and dengue virus (DENV) infection by PCR and pGOLD immunoassay (IgG and avidity). From April to November 2017, 140 offspring of the women were followed and examined. 268 mothers were newly enrolled whom were pregnant or gave birth during the outbreak. Infant assessments consisted of physical examinations, anthropometrics, and serum collection for ZIKV and DENV pGOLD IgG testing. In total, 383 mothers and 388 infants were assessed postpartum. Thirty-five (9%) mothers reported ZIKV symptoms during pregnancy; 16%, 47% and 28% in their 1st, 2nd and 3rd trimesters, respectively. Of the 388 infants, 8% tested positive for DENV IgG, 1% for ZIKV IgG, and 0% had dual exposure. Twenty-three (5.9%) severely and 35 (9.0%) mildly microcephalic cases were discovered. Of the original antenatal cohort, 7 mothers were ZIKV PCR confirmed (5%) at

the prenatal visit: 3 were symptomatic and 4 were asymptomatic. Seven other mothers were viremic for DENV and all were asymptomatic. IgG pGOLD testing revealed that 99% (80/81) had previous DENV exposure, 84% (68/81) had ZIKV exposure, and 83% (67/81) had dual exposure. Most viremic mothers had positive IgG results: 86% (6/7) for ZIKV IgG and 100% for DENV IgG. Avidity testing revealed that 97% of mothers had ZIKV exposure 6 months prior, whereas only 29% had recent DENV exposure. Of the 68 ZIKV-exposed mothers, only 2 of their offspring (3%) were positive for ZIKV IgG. Of the 80 mothers with previous DENV exposure, all of their offspring were DENV IgG positive. DENV and ZIKV transmission are co-occurring and prevalent in Grenadian mothers and are causing asymptomatic infections that may put infants at risk unknowingly. Additional testing will corroborate microcephaly and its association with timing of ZIKV exposure.

158

JUVENILE HORMONE REGULATED MICRORNA-276 IN *AEDES AEGPYTI* FATBODY

Emre Aksoy

University of California, Riverside, Riverside, CA, United States

MicroRNAs are a class of small non-coding RNAs (20-23 nucleotides in length) that play a critical role in gene silencing in eukaryotic organism. Our previous studies characterized the role of miRNAs in blood digestion and lipid secretion in *Aedes* mosquitoes. Inhibition of both of these microRNAs results in biological defects that prevent egg production and reproduction. In adult female mosquitoes, Juvenile Hormone (JH) regulates the cascade responsible for tissue development that is required for the reproductive cycle following acquisition of a blood meal. Currently, the involvement of microRNAs during the post-eclosion (PE) developmental stage are unknown. MicroRNA-276 is an insect specific microRNA and has been shown to be abundant across multiple tissues. A recent study in D. melanogaster characterized the role of mir-276 in circadian rhythms through its regulation of timeless. In *Aedes aegpyti*, JH III activation of kh-r1 and hairy occurs in a light-dependent circadian rhythm during PE development. Here we explore the regulatory role of mir-276 in the fatbody during tissue maturation with the goal of disrupting proper circadian rhythms as a means to inhibit JH III activation to prevent mosquito reproduction. We demonstrate that mir-276 is a JH responsive microRNA through both an *in vivo* JH III topically assay to artificially induce the JH mediated response and through dsRNAi knockdown of the key receptor, methoprene-tolerant, to artificially prevent the JH response. Next, we used a combination of in silico and *in vivo* predictions from our previously published Ago1 CLIP-Seq dataset to create a high-confidence list of mRNA targets for mir-276. We then validated if mir-276 was capable of binding to these targets *in vitro* using a dual luciferase assay in S2 cell line. Finally, we performed antagomir injections to systemically reduce mir-276 levels during the PE developmental stage and measured gene expression of key targets in the JH III pathway. While our results indicate mir-276 is regulated by JH III, the miRNA does not inhibit key components of the JH pathway. It is likely that mir-276 plays another role in regulating gene expression in *A. aegypti*.

159

ENTOMOLOGICAL PATTERN OF MALARIA TRANSMISSION IN THE HIGHLAND FRINGES OF MADAGASCAR:RESULTS FROM A LONGITUDINAL ENTOMOLOGICAL SURVEY

Thiery Nirina Nepomichene, Sanjiarizaha Randriamaherijaona, Sébastien Boyer, Romain Girod

Institut Pasteur of Madagascar, Antananarivo, Madagascar

Knowledge on malaria transmission characteristics in a given area is critical for efficient malaria control guidance. Data on malaria transmission in the Malagasy Highland Fringes (MHF), where mosquito bed-nets are deployed as the primary vector control strategy, is scarce. Entomological data were collected in three sites, three times a year from 2014 to 2016. Field investigations were fitted to the period before, during and after the usual malaria transmission peak. For each survey, mosquitoes were collected hourly by human landing catch from dusk to dawn. During three consecutive nights, five houses per site were sampled indoors and outdoors. Human Biting Rates (HBR) and sporozoite index (SI) were calculated. A total of 2,585, 1,503 and 4,528 *Anopheles* were collected in Ihosy, Maevatanana and Tsiroanomandidy, respectively. In Ihosy, *An. arabiensis* was the most abundant vector (70.6%) while in Maevatanana it was *An. coustani* (17.2%) and *An. gambiae* (15.6%). In Tsiroanomandidy, *An. coustani* (36.3%) and *An. arabiensis* (30.4%) were the most abundant vectors. Nightly 12h collections showed that in Ihosy, *An. arabiensis* was actively biting outdoors (75.0%), with a peak of activity around midnight. In Maevatanana and Tsiroanomandidy, malaria vectors were actively biting outdoors too (>60.0%) but did not show a clear biting peak. In Ihosy, the highest HBR for *An. arabiensis* was observed in February, before the transmission peak. In Maevatanana and Tsiroanomandidy, the highest HBR for *An. coustani* was observed in April during the transmission peak. In Ihosy, the SI value of *An. arabiensis* was 0.38% while in Maevatanana and Tsiroanomandidy, the SI value of *An. coustani* were 0.39% and 1.70%, respectively. These results on malaria vector abundance and behavior could explain the persistence of malaria transmission in the MHF areas. Due to the observed exophagic behavior of these vectors, additional control measures should be explored to reduce the malaria burden. In light of its abundance, the possible role of *An. coustani* as a primary malaria vector in the MHF should be further investigated by integrating studies on its vector competence.

160

THE FEEDING ECOLOGY OF *AEDES ALBOPICTUS* ON LONG ISLAND, NEW YORK

Kara M. Fikrig, Laura C. Harrington

Cornell University, Ithaca, NY, United States

The Asian tiger mosquito, *Aedes albopictus*, is one of the most invasive species in the world and is an important vector of more than 20 viral pathogens, including dengue and Zika viruses. In the Northeastern USA, *Ae. albopictus* is expanding its range and is now detected in New York through the Hudson River Valley. Unfortunately, there is limited knowledge of the feeding ecology of the species in this new context, which is critical to understanding local disease transmission and optimizing control strategies. This study investigates both the blood feeding and sugar feeding tendencies of *Ae. albopictus* in rural and urban settings in Long Island. Mosquitoes were collected using a combination of vegetation aspiration, resting boxes and BG-sentinel traps. Blood meals were identified to species and host populations were enumerated to calculate forage ratios and infer host preference and feeding plasticity, the extent of which is highly variable in the published *Ae. albopictus* literature. Sugar feeding of non-engorged female and male mosquitoes was tested using three different methods: 1) cold anthrone to detect all sugar feeding 2) thin layer chromatography to detect secondary metabolites unique to honeydew feeding and 3) cellulose staining of gut to detect plant tissue feeding. Structural equation modeling was conducted to determine the correlation between the proportion of sugar positive mosquitoes collected with plant species in bloom, vegetation density, temperature, humidity, and precipitation. This provides valuable information because little is known about the sugar feeding habits of *Ae. albopictus,* despite on-going drives to develop attractive toxic sugar baits to control this species. Together, the two main components of this study will give a comprehensive picture of the adult feeding ecology of *Ae. albopictus* on Long Island and will inform local mosquito control departments about disease transmission risk and avenues for control.

Ifakara Health Institute, Dar es salaam, United Republic of Tanzania

Identification of mosquito blood meals is essential for monitoring vectorial capacities and overall importance of these mosquito species in transmission of human pathogens. Currently, for the best approaches for mosquito blood meal identification involve either ELISAs or PCR, both of which are time consuming, expensive, laborious and require many reagents. However, non-molecular techniques such as infrared technology are promising alternatives. Near-infrared spectroscopy has already been proven to detect mosquito age and parity status, but the mid-infrared spectra offers greater resolution for such analyses. We used mid-infrared spectroscopy combined with statistical regressions to identify blood meal sources of laboratory-reared mosquitoes *Anopheles gambiae s.s.* mosquitoes, which had fed directly on either humans, bovine, chicken or goat blood. Blood fed mosquitoes were anesthetized using chloroform and preserved dry in silica gel. A partial least square regression (PLS) method was used to analyze the spectra and predict the unknown samples. The data set was divided into two; a training set with 120 samples, and a test set with 30 samples for each PLS model. Four PLS models, one for each blood meal source, were developed, where human blood meals were compared against: bovine, chicken, goat or all the three hosts together. From the initial results, the human *vs.* bovine model had overall prediction accuracy of 88.3%, human *vs.* chicken gave 93.3%, human *vs.* goat gave 88.3%, and human *vs.* other hosts gave 83.3 accuracy. Our preliminary conclusion is that approach has greater potential for high-throughput determination of mosquito bloodmeals in field surveys. Once fully calibrated, it could vastly improve studies on human-vector interactions and malaria epidemiological surveys, as it is easy to use, cost and time efficient.

162

PUPAL PRODUCTIVITY OF LARVAL HABITATS OF *AEDES AEGYPTI* IN MSAMBWENI, KWALE COUNTY KENYA

Francis M. Mutuku[1], Alawih S. Mwakutwaa[1], Harun N. Ngugi[2], Bryson A. Ndenga[3], Uriel D. Kitron[4], A. Desiree LaBeaud[5]

[1]Technical University of Mombasa, Mombasa, Kenya, [2]Chuka University, Chuka, Kenya, [3]KEMRI, Kisumu, Kenya, [4]Emory University, Atlanta, GA, United States, [5]Stanford University, Stanford, CA, United States

Dengue is endemic in Kenya with recent studies suggesting continuous low transmission year round. Frequent outbreaks occur, especially on the coast. *Aedes aegypti*, the primary dengue vector in Kenya, breeds predominantly in water storage containers and discarded tires. We estimated habitat-specific pupal productivity of *Ae. aegypti* in a south coastal Kenyan village. A total of 78 different water storage containers and discarded tires were inspected daily for *Ae. aegypti* larvae and pupae for 30 days. Containers were categorized as drums, tires, pots, small domestic containers (SDC) or 'others'. Small domestic containers (SDC) included small plastic food containers, tins, bottles, plates, cans, cooking pots (sufuria) and jars. 'Others' included; buckets, jerrycans, polythene bags, fallen leaves, coconut shells, hoof prints, drains, gutters, septic tanks, shoes, cisterns, sinks and animal feeding containers (AFC). Water management behavior including container covering, uses, filling and emptying, and habitat characteristics including size and movability were recorded. Overall, drums and tires were the most productive habitats accounting for 83% of all pupae collected. A poisson regression analysis showed that compared to SDC, the risk of finding pupae was 18% higher in drums, but comparable for the other habitats types. Pupae were more abundant in containers that were larger (15%), were stable (17%), and those that contained water with no particular purpose (60%). In the absence of an effective antiviral and vaccine, control of the immature mosquitoes remains the most viable prevention method. Vector control interventions targeting primarily drums and tires in the study region could likely produce a positive impact on local dengue transmission.

163

EARLY AND LATE NIGHT HUMAN LANDING PERIODICITY OF *AEDES AEGYPTI* FEMALES IN URBAN AND RURAL SITES IN KENYA

Bryson A. Ndenga[1], Francis M. Mutuku[2], Harun N. Ngugi[3], Joel O. Mbakaya[1], Peter Aswani[1], Peter S. Musunzaji[4], Dunstan N. Mukoko[5], Uriel D. Kitron[6], Desiree A. LaBeaud[7]

[1]KEMRI, Kisumu, Kenya, [2]Technical University of Mombasa, Mombasa, Kenya, [3]Chuka University, Chuka, Kenya, [4]Vector Borne Disease Control Unit, Ministry of Health, Msambweni, Kenya, [5]Vector Borne Disease Control Unit, Ministry of Health, Nairobi, Kenya, [6]Emory University, Atlanta, GA, United States, [7]Stanford University, Stanford, CA, United States

Aedes aegypti, the main vector for yellow fever, dengue, chikungunya and Zika viruses, is generally known as a daytime biting mosquito. Hence, there is scarcity of information about the extension of its biting activity into the night. This study aimed to determine the extension of *Ae. aegypti* biting activity into the early and late night hours in Kenya. Hourly human landing catches were conducted quarterly for three consecutive days from 4:30 am to 9:30 pm, indoors and outdoors and rural and urban areas in Kenya from June 2017 to March 2018. A total of 440 *Ae aegypti* mosquitoes were collected: 134 (30.5%) in the morning hours whereas 306 (69.5%) in the afternoon hours. Bi-modal biting activity was observed: the morning peak started from 4:30 am (with the peak between 6:30 am to 7:30 am) to 12:30 pm whereas the afternoon peak started from 12:30 pm (with the peak stretching from 2:30 pm to 7:30 pm) to 9:30 pm. A total of 91 (20.7%) *Ae. aegypti* mosquitoes were collected at night (including dawn and dusk): 24 (5.5%) from 4:30 am to 6:30 am and 67 (15.2%) from 6:30 pm to 9:30 pm. Out of these, more mosquitoes were collected outdoors (76, 83.5%) than indoors (15, 16.5%) and more mosquitoes were collected in the urban site (77, 84.6%) than the rural site (14, 15.4%). The *Ae. aegypti* night blood seeking behaviour observed in this study has epidemiological implications as it extends the period for the risk of arboviruses like dengue and chikungunya transmission in Kenya. Furthermore, appropriate vector control measures can be designed to coincide with this extended *Ae. aegypti* night biting behaviour.

164

ABUNDANCE AND BEHAVIOR OF *AEDES AEGYPTI* IN TWO CITIES WITH HIGH TRANSMISSION OF ZIKA AND DENGUE IN ECUADOR

Leonardo D. Ortega-Lopez[1], Emilie Pondeville[2], Alain Kohl[2], Renato L. Leon-Villalba[3], Mauro V. Pazmino[4], Sergio Torres[3], Heather Ferguson[1]

[1]Institute of Biodiversity, Animal Health and Comparative Medicine, University of Glasgow, Glasgow, United Kingdom, [2]Centre for Virus Research, University of Glasgow, Glasgow, United Kingdom, [3]Laboratorio de Entomologia Medica y Medicina Tropical, Universidad San Francisco de Quito, Quito, Ecuador, [4]School of Engineering, University of Glasgow, Glasgow, United Kingdom

Aedes aegypti is the main mosquito vector of the three viral diseases of high burden in the Americas: Zika, Dengue and Chikungunya. Vector control remains the primary control strategy for these diseases, but the deployment of such strategies is hampered by the lack of robust surveillance data on mosquito vector abundance, behavior and infection rates within major *Foci* of transmission. The recent outbreak of Zika throughout South America highlighted the urgent need for such data, particularly in outbreak settings outside of Brazil where knowledge of local vector ecology is limited. This study aimed to tackle this knowledge gap by investigating the ecology and virus infection rates within 2 cities that were

substantial *Foci* of Zika transmission in Ecuador: Quinindé and Portoviejo. Starting in November 2016, an 8-month longitudinal study was conducted to characterize the abundance, habitat preferences and viral infection rates in *Ae. aegypti* populations within urban and suburban areas. Mosquito samplings were carried out at the intra and peri-domestic areas with BG sentinel traps and Prokopack aspirators. *Ae. aegypti* was significantly more abundant in Portoviejo than in Quinindé. Mosquito preference for resting sites greatly differed between the two cities: in Portoviejo, mosquitoes tended to be six times more abundant inside than outside houses; while in Quinindé, indoor and outdoor abundance of resting mosquitoes was very similar. There were no significant differences in mosquito abundance between urban and suburban areas from both cities, which denotes the importance to carry out surveillance control in suburban areas as much as it is currently being done in urban areas. Preliminary results from molecular analysis confirms the presence of Zika and Dengue virus in *Ae. aegypti* in both urban and suburban areas. These results provide a clear picture of how mosquito ecology is different in two cities with high arbovirus transmission rates within the same country. Therefore, we highlight the importance that arbovirus prevention and vector control programmes should be adjusted to the local conditions.

165

ACCEPTANCE AND WILLINGNESS-TO-PAY FOR ARBOVIRUS VACCINES IN GUATEMALA: A CROSS SECTIONAL SURVEY IN RURAL GUATEMALA

Daniel Olson[1], Anne-Marie Rick[2], Steven Krager[1], Molly M. Lamb[3], Edwin J. Asturias[1]

[1]University of Colorado School of Medicine, Aurora, CO, United States, [2]University of Colorado Center for Global Health, Aurora, CO, United States, [3]University of Colorado School of Public Health, Aurora, CO, United States

Arboviruses including dengue (DENV), chikungunya (CHIKV) and Zika (ZIKV) cause significant morbidity in Latin America. With multiple arbovirus vaccines in development, better understanding of community attitudes and acceptability for these vaccines is needed. In September 2016, a cross-sectional survey assessed arbovirus knowledge, attitudes, vaccine demand and willingness to pay (WTP) at the conclusion of a DENV/norovirus surveillance study in a rural Guatemalan community with high arbovirus endemicity. Factors associated with vaccine demand and WTP were assessed with regression analysis. Among 564 surveyed households, DENV knowledge was high. There was high concern for all three arboviruses, particularly CHIKV. Overall vaccine attitudes were positive with <5% identifying significant barriers to, doubting or refusing previous vaccination. At 50% and 75% efficacy, 75% and 88% of respondents wanted arbovirus vaccines, respectively. DENV vaccine demand at 50% efficacy was associated with increased housing density, non-health-post vaccination location, older children and medical source for information. For each vaccine, 52-55% of respondents were WTP $0-$3.40, while 16-17% were WTP ≥$6.81. WTP at $3.40 and $6.81 levels for all vaccines was associated positively with parental education but negatively with good dengue knowledge. History of purchasing and identifying barriers to vaccines were associated with WTP ≥ $6.81. In conclusion, demand for potential DENV, CHIKV, ZIKV vaccines is high at 50% and 75% efficacy in this Guatemalan community. Associated factors could be leveraged to optimize arbovirus vaccine implementation. Overall low WTP suggests government subsidization may be necessary in resource-poor regions, though a small private market may be supported.

166

PHOSPHORYLATION OF VEEV CAPSID IS REGULATED BY PP1 AND PKC

Brian D. Carey[1], Chelsea Pinkham[1], Tatiana Ammosova[2], Sergei Nekhai[2], Kylene Kehn-Hall[1]

[1]George Mason University, Manassas, VA, United States, [2]Howard University, Washington, DC, United States

Venezuelan equine encephalitis virus (VEEV) is an arthropod borne New World alphavirus. It can cause disease in humans and is characterized by a febrile illness that may progress into encephalitis. The capsid protein of VEEV is a structural protein that binds to the vRNA and interacts with the membrane bound glycoproteins. Capsid has auto-proteolytic activity during translation as well as several non-structural roles during the course of infection. Here we demonstrate that capsid phosphorylation is mediated by the host phosphatase Protein Phosphatase 1α (PP1α) and the host kinase Protein Kinase C delta type (PKCδ). Inhibition of PP1α causes decreased viral titers starting at 8 hours post infection. Confocal microscopy showed that PP1α appears to colocalize with capsid and this relationship is confirmed through co-immunoprecipitation. Mass spectrometry showed that capsid protein is phosphorylated on T93, T108, S124, and T127. Co-immunoprecipitation confirmed the phosphorylation status of capsid and that dephosphorylation by PP1α is necessary for capsid:vRNA binding. In an effort to identify the kinase responsible for this phosphorylation, phosphorylation site prediction software suggests that a member of the PKC family of kinases is responsible for the phosphorylation event. Furthermore, PKCδ, but not other PKC family members, co-immunoprecipitates with VEEV capsid whilst chemical inhibition or siRNA knockdown of PKCδ causes a decrease in viral titer. Finally, in cells transfected with the VEEV structural polyprotein and treated with the PKCδ inhibitor, Rottlerin, there is less phosphorylation of VEEV capsid compared to the solvent control. These data suggest that PKCδ is potentially the kinase that is responsible for the phosphorylation of capsid. Further studies are being performed to confirm this hypothesis as well as to determine the importance of phosphorylation during VEEV infection. These data indicate that the phosphorylation status of VEEV capsid is important during infection and that inhibition of capsid phosphorylation could be a potential target for therapeutics and vaccine development.

167

PROBABLE INTRADOMICILIARY TRANSMISSION OF CHIKUNGUNYA VIRUS DURING THE 2015 OUTBREAK IN YUCATAN, MEXICO

Nina Mendez, **Yaseth Coba-Canto**, Anamaria Alonzo-Ancona, Belem Chan-Canche, Manuel Aranda-Guardia, Martín Inurreta-Diaz

Universidad Marista de Merida, Merida, Mexico

In the second half of 2015, a chikungunya outbreak took place in Yucatan, Mexico with over 1600 laboratory-confirmed cases. Chikungunya is primarily a mosquito-borne disease but can also be transmitted mother-to-child in pregnant women. Our aim in this study was to determine the probable intradomiciliary transmission of chikungunya and which age group and gender was most affected. We conducted a verbal survey of all patients (or their parents in the case of minors) at the O´Horan general hospital who had a clinical diagnosis of chikungunya fever between July-December 2015. The survey included questions about travel, daily mobility, exposure and contact with the vectors inside the household (as a proxy for probable intradomiciliary transmission), and cohabitation with infected individuals within a ten-day-period prior to the onset of symptoms. 803 patients were diagnosed with chikungunya at the O´Horan hospital and all of them completed the survey (participation 100%); 59% were female. Median age was 23.3 (range:1-77) years-old, while 751 (93.5%) reported spending most of the day inside their homes along with the presence of mosquito vectors inside their houses or yards. 239 (30%) mentioned that they cohabitated with a relative who had chikungunya <10 days prior

to their infection, of them, 215 (90%) were housewives who reported having taken care of a chikungunya infected relative. Female adults aged 20-44 were the most frequently affected group (n=151, 19%). In conclusion, Probable intradomiciliary transmission accounted for 30% of chikungunya infections in this study population. Women aged 20-44 were the most affected group in this study population. Mosquito-borne prevention campaigns in endemic regions could emphasize the importance of preventing mosquito bites and isolation of infected individuals in the household. We utilized the Epidemiologic chikungunya surveillance survey developed at O´Horan General Hospital in Merida, Mexico as a data source.

168

AN OUTBREAK OF CHIKUNGUNYA: TRACKING THE EPIDEMIC THREAT IN SALVADOR, BRAZIL

Laura B. Tauro[1], Cristiane W W. Cardoso[2], Raquel Lima[3], Leile C. Nascimento[3], Daniela Rodrigues dos Santos[4], Gubio Soares Campos[5], Silvia Sardi[5], Oliveti Borba dos Reis[2], Mitermayer G. Reis[3], Uriel Kitron[6], Guilherme S. Ribeiro[3]

[1]Instituo Nacional de Medicina Tropical, Puerto Iguazu, Argentina, [2]Secretaria Municipal de Saúde de Salvador, Salvador, Brazil, [3]Fiocruz-BA, Salvador, Brazil, [4]Faculdade de Farmácia, Universidade Federal da Bahia, Salvador, Brazil, [5]Instituto de Ciências da Saúde, Universidade Federal da Bahia, Salvador, Brazil, [6]Emory University, Atlanta, GA, United States

In Salvador, Bahia, the most common arboviruses are Dengue (DENV), Zika (ZIKV) and Chikungunya (CHIKV), although others, such as Yellow fever (YFV), Oropouche (OROV) and Mayaro (MAYV), which can also cause acute febrile illness are expanding their distribution in Brazil. As part of a study of the changing arboviruses scenario in Salvador, we conducted an investigation of 50 reported cases of febrile patients with signs and symptoms compatible with arboviral infections in a poor neighborhood in northeast Salvador between April 15 and June 25, 2017. Blood samples were collected from 45 of the 50 cases; 17 were tested by RT-PCR for CHIKV, ZIKV, DENV, YFV, OROV and MAYV, 45 by ELISA IGM for CHIKV, and 31 by ELISA IgM for DENV. Chikv infection was detected in 70% (35/45) of the cases by RT-PCR (8) or ELISA IgM (27). Half (51%) were male (mean age 32 years). Clinical disease was mild and self-limiting in most cases, not requiring hospitalization. All positive cases presented myalgia, most reported pain in multiple joints and about half developed pruritus and rash. Sequencing revealed that the CHIKV strain responsible for the outbreak belonged to the ECSA genotype, and grouped phylogenetically with the strain isolated from humans in Bahia during the 2015 outbreak and from *Ae. aegypti* and humans in 2016 in several Brazilian states. DENV IgM was detected only in 3 cases, of which 2 also presented CHIKV IgM. A total of 125 adult mosquitoes were aspirated inside houses of 21 cases, with *Cx. quinquefasciatus* being the most abundant (79.2%; 69,7. female) followed by *A. aegypti* (20.8%; 30.8% female). Mosquitoes were tested by RT-PCR, and all were negative for arboviruses. With the current epidemiological scenario in Brazil, investigations of arboviral outbreaks presents a serious public health challenge due the similar clinical symptoms associated with infection. This , complicates epidemiologic surveillance, as well as potential control strategies. In our study, we detected a new outbreak by CHIKV ECSA genotype in a slum community in the periphery of Salvador, showing that four years after the introduction of CHIKV in Brazil, its epidemic potential remains high.

169

A NOVEL QUANTITATIVE PCR ASSAY FOR THE DETECTION OF ROSS RIVER VIRUS

Rebecca A. Kuzma[1], Jessica R. Grant[1], Nils Pilotte[2], Leon Hugo[3], Gregor Devine[3], Colleen Lau[4], Steven A. Williams[1]

[1]Smith College, Northampton, MA, United States, [2]University of Massachusetts Amherst, Amherst, MA, United States, [3]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [4]Australian National University, Canberra, Australia

With over 5,000 infections annually, Ross River virus (RRV) is the most common mosquito-borne disease in Australia. RRV is a mosquito-borne alphavirus endemic to Australia, Papua New Guinea, and parts of the South Pacific. Symptoms of RRV infection include fever, fatigue, and debilitating polyarthritis that is known to persist for long periods of time. RRV is transmitted by a broad range of mosquito vectors, with laboratory transmission confirmed in at least ten species of *Aedes* and *Culex* mosquitoes. In the absence of any comprehensive diagnostic tests and appropriate testing facilities, RRV was believed to be maintained in zoonotic cycles of transmission involving macropod marsupials. The 1979-80 outbreak of RRV infection in the Pacific and the availability of comprehensive diagnostic facilities in Australia, provided strong evidence for cycles of human-mosquito-human transmission without a requirement for intermediate vertebrate hosts. The re-appearance of RRV transmission in Fiji and the large human population born since the 1979-80 outbreak (and so susceptible to RRV infection) highlights the need for a sensitive and specific surveillance system able to detect future outbreaks of RRV infection in this region. To this end, we have designed and validated a real-time quantitative polymerase chain reaction (RT-qPCR) assay that specifically detects RRV at high sensitivity, and differentiates RRV from other alphaviruses, including the genetically similar Getah virus. Mosquitoes and mosquito fecal/excreta samples collected during an ongoing field study in American Samoa were screened for RRV using this assay in order to further validate the use of this screening method in the surveillance of RRV in endemic regions. Our results support the use of this assay for the detection of RRV at low viral concentrations in mosquito vectors through the use of our molecular xenomonitoring platform.

170

INVESTIGATION OF *IN VITRO* INFECTIVITY OF CHIKUNGUNYA IMMATURE VIRUS PARTICLES IN MAMMALIAN AND INSECT CELL LINES

Danillo L. Esposito, Benedito A. Fonseca

Universidade de São Paulo, Ribeirao Preto, Brazil

The recent worldwide outbreak caused by chikungunya virus (CHIKV; *Alphavirus, Togaviridae*) has shown that despite being first isolated in the 1950s, this infection still has several points to be elucidated, not only regarding the correct diagnosis but also the treatment and prevention of this disease. This virus, in spite of a short viremia produces a disease characterized by high fever, myalgia, rash and arthritis/arthralgia; the latter may persist for months or years, causing a major public health impact. The aim of this work was to characterize the immature virus particles of CHIKV, addressing both structural and infectious aspects in both insect and mammalian cells. Immature particles were produced in LoVo cells, which lacks furin activity, necessary for viral maturation. Electron microscopy has shown that immature particles are significantly larger than mature virions (in average, 120 and 75nm, respectively). Mammalian (Vero, HeLa and LoVo) and insect (C6/36) cells were infected at a multiplicity of infection of 0.1 with both immature and mature particles, supernatants were collected at different times post-infection and titrated by plaque assay in Vero cells. Despite presenting a delay in replication, immature particles infected the cells, with the exception of the LoVo lineage, probably due to furin deficiency, reaching viral load values similar to those of mature particles. The presence of viral progeny in LoVo cells was only observed when infected with mature particles and the viral load decreased as the infection progressed. These results demonstrate that, different from what was previously believed, immature particles can infect cells and probably cause a disease, but the success of this infection is dependent on the furin protease.

171

INVESTIGATING THE EFFECTS OF CHIKUNGUNYA IMMUNITY ON MAYARO VIRUS DISEASE AND EPIDEMIC POTENTIAL IN THE NEW WORLD

Emily M. Webb[1], Sasha Azar[2], Sherry L. Haller[2], Huanle Luo[2], Kenneth S. Plante[2], Grace Leal[2], Tian Wang[2], Scott C. Weaver[2], Shannan L. Rossi[2], Albert J. Auguste[1]

[1]Virginia Polytechnic Institute and State University, Blacksburg, VA, United States, [2]University of Texas Medical Branch, Galveston, TX, United States

Mayaro virus (MAYV) and chikungunya virus (CHIKV) are evolutionarily closely related members of the Semliki Forest virus antigenic complex. Similar to CHIKV, MAYV causes an acute febrile illness that can include debilitating, and often persistent arthralgia. MAYV emergence is typically sporadic and geographically restricted, but recent outbreaks and isolations indicate the virus remains a public health concern. Given the disease similarities and the phylogenetic and serological relationship between these viruses, we hypothesize that prior CHIKV immunity may affect MAYV pathogenesis and epidemic potential. To this end, we pre-exposed immune-competent (C57/B6J) and immune-compromised (A129) mice to wild-type CHIKV, two CHIKV vaccines (CHIKV/IRES and EILV/CHIKV), and a live-attenuated MAYV vaccine (MAYV/IRES), and then challenged with MAYV. We observed strong cross-protective effects against MAYV disease for mice pre-exposed to wild-type CHIKV, and moderate but significantly less cross-protection in CHIKV/IRES vaccinated mice. Interestingly, EILV/CHIKV vaccination resulted in enhancement of MAYV disease; however, further studies are warranted to investigate the mechanism underlying this singularity. Immunity to other alphavirus and flavivirus controls provided no protection against MAYV disease or viremia, suggesting the observed cross-protection between MAYV and CHIKV is a result of the close evolutionary relationship between these viruses and not the result of a non-specific immune response to a subsequent viral infection. Mechanistic studies suggest neutralizing antibodies alone can facilitate protection from development of MAYV viremia, but T-cells have a cumulative effect for diminishing MAYV disease. Further experiments such as adoptive transfers are being conducted to determine the degree of cell-mediated cross-protection in C57/B6J and A129 mice. In summary, our data suggest CHIKV immunity may impact the epidemic potential of MAYV and possibly reduce associated disease.

172

RE-EMERGENCE OF CHIKUNGUNYA VIRUS IN COASTAL KENYA 2017-2018

Victor O. Ofula, Albert Nyunja, Samson Limbaso, Samuel Owaka, Edith Koskei, Hellen Koka, Fredrick Eyase, James Mancuso, Rosemary Sang

US Army Medical Research Directorate Kenya, Nairobi, Kenya

Chikungunya virus is an alphavirus which belongs to the Togaviridae family; it's transmitted by *Aedes aegypti* mosquitoes. It causes chikungunya fever, a febrile condition associated with severe joint and muscle pains, fever and headaches. Between 2004 and 2005, Kenya experienced its first outbreak of Chikungunya in Lamu County at the coastal region with over 13,500 cases. Since then, passive surveillance had not shown circulation of the virus. In mid-December 2017 the Arbovirus/VHF laboratory at KEMRI received eight serum samples from hospitals in Mvita and Kisauni sub-counties in Mombasa. After testing for different arboviruses, the results showed that 6/8 were positive for Chikungunya, 5/8 by RT-PCR and 1/8 by IgM ELISA. In January 2018, a team from KEMRI was sent to Mombasa to conduct further investigations to determine the magnitude of the chikungunya outbreak. Hospital visits were made and patients selected based on their clinical presentations. Any patient presenting with sudden onset of fever, headache muscle and joint pains was considered for sample collection. A total of 239 human blood samples were collected from various hospitals in the six sub counties of Mombasa, and shipped to Nairobi for testing. Samples were also received from different parts of the coastal Kenya including Lamu, Taita Taveta and Kilifi, leading to a total, 361 human samples being collected. Of these samples 191/361 (53%) were female patients while the age range was from 6 months to 73 years. The samples were processed and tested using RT-PCR for Alphaviruses and Flaviviruses. In total, 138 out of 361 (38.2%) tested positive for Chikungunya virus. Likoni sub-county had the highest positivity at 55.3% followed by Mvita sub-county with 48.4%. These findings show that chikungunya virus was the cause of the outbreak, and that it's reemerging in the coastal Kenya after more than a ten year lull. Results showed that 38.2% who were positive for chikungunya were within the viraemic phase of the disease. Community awareness campaigns on the public health effects of the virus and preventive measures including vector control need to be instituted to prevent future outbreaks.

173

MOLECULAR EPIDEMIOLOGY OF CHIKUNGUNYA VIRUS FROM ECUADOR DEMONSTRATES TWO INTRODUCTIONS IN 2013 AND THE E1-K211E MUTATION, SUGGESTING PRESENCE OF ENHANCED FITNESS TO *AEDES AEGYPTI*

Irina Maljkovic Berry[1], Anna M. Stewart-Ibarra[2], Wiriya Rutvisuttinunt[1], Efraín Beltrán-Ayala[3], Katherine Figueroa[1], Abhinaya Srikanth[1], Washington B. Cárdenas[4], Cinthya Cueva[2], Mark Polhemus[2], Sadie J. Ryan[5], Timothy P. Endy[2], Richard G. Jarman[1]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]SUNY Upstate Medical University, Syracuse, NY, United States, [3]Universidad Técnica de Machala, Machala, Ecuador, [4]Escuela Superior Politecnica del Litoral, Guayaquil, Ecuador, [5]University of Florida, Gainesville, FL, United States

Chikungunya virus (CHIKV) was first reported in the Americas in 2013, and by the end of 2014 the first cases were described in Ecuador. In Ecuador, *Ae. aegypti* is the primary vector of CHIKV; the presence of *Ae. albopictus* has not been officially reported in the country. Here, CHIKV positive samples were first detected in 2015 from an active surveillance study in Machala, Ecuador, and viral genomes from a subset of the positive samples were sequenced. The 25 full genomes from Ecuador were aligned to all publicly available CHIKV full genomes and a maximum likelihood phylogenetic analysis revealed that they belonged to the Asian lineage of CHIKV. Unsurprisingly, the Ecuadorian genomes clustered within the American sub-lineage. Here, the genomes from Ecuador were found in two well-separated clades. One clade was most closely related to a virus sampled in 2014 in Panama, and the other one to viruses from USA and Nicaragua, sampled in 2014 and 2015. This suggested two separate introductions of CHIKV into Ecuador. TreeTime analyses revealed that both these introductions happened around the same time, Aug-Oct 2013, suggesting that once CHIKV arrived in this region, it flowed into Ecuador from several different geographical locations. All genomes from Ecuador, like the most of the Asian lineage genomes, did not have any *Ae. albopictus* adaptive mutations. Instead, they possessed the E1-A98T mutation, which restricts positive selection of the *Ae. albopictus* adaptive E1-A226V substitution, thereby hampering the emergence of enhanced infection within this vector. However, genomes from Ecuador had E1-K211E mutation, which induces enhanced fitness to *Ae. aegypti*. It remains to be seen how these mutations affect CHIKV adaptation and spread, highlighting the importance of continued surveillance in this region, especially as Ecuador appears to be vulnerable to import of CHIKV from several different locations.

174

DYNAMIC SPATIOTEMPORAL FEATURES OF EPIDEMIC ROSS RIVER VIRUS IN SOUTH EAST QUEENSLAND, AUSTRALIA

Amanda Murphy[1], Wenbiao Hu[2], Cassie C. Jansen[3], Francesca D. Frentiu[2], Gregor J. Devine[1]

[1]QIMR Berghofer Medical Research Institute, Brisbane, Queensland, Australia, [2]Queensland University of Technology, Brisbane, Queensland, Australia, [3]Department of Health, Brisbane, Queensland, Australia

Ross River virus (RRV) is responsible for the most widespread and frequently reported mosquito-borne disease in Australia. The virus transmission dynamics are complex, involving multiple vector and host species. Despite regular outbreaks across varied ecological settings of Australia, as well as Pacific Island countries, the factors which drive transmission risk are largely unknown. This study investigated spatiotemporal influences on changing RRV epidemiology across three major cities of South East Queensland (SEQ) where a large outbreak occurred in 2015: Brisbane, Gold Coast and Sunshine Coast. Notification data for Ross River virus in SEQ were obtained from the Queensland Department of Health for the years 2001-2015. Spatiotemporal and time series seasonal decomposition methods were employed to compare the distribution of RRV incidence in the three regions. RRV cases were found to persist across all seasons and years, with peak incidence occurring in the autumn months: March in Brisbane, and April in both Gold Coast and Sunshine Coast. Among the three areas, the highest annual incidence rates were consistently observed in Sunshine Coast, with a mean annual incidence rate of 73/100,000 (range: 33-149), followed by Brisbane (39/100,000; range: 15-134) and Gold Coast (33/100,000; range: 11-117). RRV spatiotemporal patterns were highly variable in each location across the years, and between coastal and inland suburbs. Our findings indicate that although RRV disease is strongly seasonally-influenced in SEQ, the specific influences on disease occurrence likely vary at the local level, including the density and distribution of both vectors and vertebrate hosts (human and animal), as well as the role of built and natural environments. This study uses spatiotemporal analysis of human notifications as a baseline, with a view to further assessing the ecological drivers of disease risk.

175

INDIVIDUAL AND CONTEXTUAL RISK FACTORS FOR CHIKUNGUNYA VIRUS INFECTION ON RÉUNION ISLAND: A MULTI-LEVEL MODELLING STUDY

Christophe Valingot[1], Adrian Fianu[2], Cyril Ferdynus[3], Vincent Herbreteau[4], Nadège Naty[1], François Favier[1], Olivier Maillard[5], Bertrand Sudre[6], Laetitia Huiart[7], **Patrick Gérardin**[8]

[1]INSERM CIC1410, CHU Réunion, Saint Pierre, Réunion, [2]INSERM CIC1410, CHU Réunion / UMR 1027 (Université Paul Sabatier – INSERM) – Equipe 5 (Equity), Saint Pierre/Toulouse, Réunion, [3]Unité de Soutien Méthodologique, CHU Réunion, Saint Denis, Réunion, [4]UMR 228 (IRD/UM/UR/UG/UA) ESPACE-DEV / IRD, SEAS-OI, Saint Pierre, Réunion, [5]INSERM CIC1410, CHU Réunion / UMR 912 SESSTIM (Université d'Aix Marseille, INSERM, IRD), Saint Denis/Saint Pierre/Marseille, Réunion, Saint Pierre/Marseille, Réunion, [6]European Center for Disease Control (ECDC), Stockholm, Sweden, [7]Unité de Soutien Méthodologique/INSERM CIC1410, CHU Réunion / UMR 912 SESSTIM (Université d'Aix Marseille, INSERM, IRD), Saint Denis/Saint Pierre/Marseille, Réunion, [8]INSERM CIC1410, CHU Réunion / UM 134 PIMIT (Université de La Réunion, CNRS 919, INSERM U 1187, IRD 249), Saint Pierre/Sainte Clotilde, Réunion

Vector borne diseases are driven by multiple individual and contextual factors - which are often analyzed separately. Previous studies on chikungunya risk factors have highlighted the importance of the environment. We used multilevel modelling to investigate the importance of context during a chikungunya epidemic while taking into account both individual and contextual level risk factors. We explored a dataset of 2,242 subjects from a serosurvey conducted in La Réunion completed with spatialized aggregated data at infra-communal (IRIS) level including sociodemographic and climate variables. The importance of context was estimated using the Median Odds Ratio (MOR), the interval Odds Ratio (80% IOR) and the Sorting Out Index (SOI), three indicators used in social epidemiology. Risk factors for chikungunya were identified using mixed-effect (random intercept) logistic regression models, to disentangle contextual and compositional effects (i.e., the possible correlation of individual observations within a same spatial unit). Our multilevel analysis revealed no substantial compositional effect but confirmed the importance of the environment in the risk of infection (MOR 1.57). The most important contextual factors explaining spatial heterogeneity in chikungunya prevalence were the maximum temperature of the month before the infection (OR 3.39), the pluviometry of the preceding month (OR 2.08), the altitude of dwelling <500m (OR 2.26), and the proportion of individual residences >50% (OR 2.00). The pluviometry of the current month (OR 1.71) and vegetation cover >40% (OR 1.36) contributed slightly to the spatial heterogeneity as evidenced by 80% IOR and lower SOI values. Individual factors identified after measuring contextual heterogeneity were low education level (OR 1.93), unemployment (OR 1.47), living in an individual house (OR 1.86) or in a neighborhood at risk (OR 1.37) and the absence of window screens (OR 1.57). This study suggests the interest of using multiple data sources and multilevel modelling for identifying chikungunya risk factors while helping the understanding of contextual heterogeneity of seroprevalence.

176

GENOMIC CHARACTERIZATION OF DENGUE VIRUS TYPE 2 FROM FEBRILE PATIENTS SEEN IN MALINDI DISTRICT HOSPITAL, KENYA DURING THE 2017 DENGUE FEVER OUTBREAK

Gathii Kimita

KEMRI/MRD-K, Kisumu, Kenya

Dengue virus (DENV) is a mosquito-borne *Flavivirus* and the etiological agent of dengue fever (DF). It is the most important arbovirus-affecting humans in terms of clinical cases and geographical expansion. The last 5 decades have seen an unprecedented increase in the number of DF outbreaks in sub-Saharan Africa and Kenya in particular. In May 2017, the coast province was hit by a DF outbreak that was characterized by severe morbidity. In the present study we examine the DENV genomes associated with this outbreak to determine their genotype and their genome characteristics. Serum samples testing positive for DENV2 with PCR were used to obtain the whole genome sequence. Total RNA was extracted and reverse transcribed to cDNA for library preparation. The libraries were then sequenced on the Miseq platform. Resulting sequence reads were assembled and annotated in CLC Genomics Workbench v 8.5. Genome alignments were conducted with the Muscle and phylogenies analyzed with MrBayes v3.2 and MEGA v7. Complete polyprotein gene sequences were assembled with a total length of 10,176 bp. These encoded a typical DENV-2 polyprotein consisting of three structural proteins: capsid, membrane glycoprotein precursor and envelope protein, as well as seven nonstructural proteins, the NS1, NS2A, NS2B, NS3, NS4A, NS4B, and NS5. The closest polyprotein gene homologues were DENV2 from India, accession numbers (KY427084 and JX475906 isolated from Humans in 2010 and 2009 respectively) with 98% nucleotide identity. There was minimal intra-strain sequence variation indicating the clonality of the strains. Phylogenetic analysis revealed that the study strains clustered with the Cosmopolitan DENV2 genotypes from Asia. This is the first description of the complete polyprotein coding gene from DENV2 from Kenya. The sequences contribute to understanding the epidemiology of DF outbreaks in Kenya. The virus responsible for the 2017 outbreak was determined to be DENV2 of the cosmopolitan genotype. More work is required to understand the molecular differences between DENV that are detected routinely in Africa and those detected during outbreaks.

177

DENGUE VIRUS SEROTYPE-1 CIRCULATION IN NEPAL DURING 2016 OUTBREAK

Birendra Prasad Gupta

Tribhuvan University, Kathmandu, Nepal

Dengue is an emerging disease in Nepal. The objective of this study is to present a comprehensive picture of the dengue outbreak in 2016 and to classify the prevailing serotypes. The demographic information was collected along with the clinical evaluation of the patients. Serum samples were collected from suspected dengue fever cases. The samples from fever cases <7 days duration were tested for dengue NS1 antigen employing Panbio (Australia) NS1 ELISA kit. Serum samples of ≥7 days fever were tested for dengue-specific IgM antibodies by MAC ELISA test kit. Serotyping of 1779 serum samples was done by dengue-specific reverse transcriptase polymerase chain reaction (RT-PCR) followed by nested PCR with serotype-specific primers. The number of dengue cases in 2016 clearly out-numbered the dengue cases in 2010-2013. The outbreak occurred during June to November-2016 signifying increased disease transmission in the monsoon and post-monsoon periods with a climax during September. There were 3473 confirmed patients visited/ admitted to hospital. The results showed that the affected patients were primarily adults with a mean age (± standard deviation) of 41.23 (± 35.75) years. The major clinical features of the patient were fever (100%), headache (71.3 %), rashes (11.3%), retro-orbital pain (23.5%), vomiting (23.4%), joint pain (32.1%) and thrombocytopenia (85.7%). Serotyping of 1779 serum samples confirmed the circulation of dengue virus type 1 in Nepal. Our results suggest that the dengue outbreak in Nepal during 2016 was predominantly due to dengue virus type 1 and there is a sudden shift in dominant prevailing serotype of the virus from the 2013 epidemic. It is an evidence of the circulation of serotype 1 after 2006 dengue episode in Nepal. The government should take strict action to control the disease and its vector to combat against an upcoming epidemic with severe outcomes.

178

LIMITING GLOBAL WARMING TO 1.5 DEGREES AND DENGUE FEVER IN LATIN AMERICA

Felipe J. Colon-Gonzalez[1], Ian Harris[1], Timothy J. Osborn[1], Christine Steiner Sao Bernardo[2], Carlos A. Peres[1], Paul R. Hunter[3], Iain R. Lake[1]

[1]School of Environmental Sciences, Norwich, United Kingdom, [2]Universidade do Estado de Mato Grosso, Mato Grosso, Brazil, [3]Norwich Medical School, Norwich, United Kingdom

At the Paris climate conference (COP21) in December 2015, governments agreed to aim to keeping increases in global-mean temperature to well below 2°C above pre-industrial levels, and to aim to limit it to 1.5°C. It is believed that human health would largely benefit from limiting global warming to 1.5°C compared against a business-as-usual scenario. Whether this assumption is true, and what is the magnitude of the associated benefits is fundamentally unknown. An understanding of the potential public health impacts at different levels of warming is essential for effective public health planning and decision-making. Here, we used dengue in Latin America as a study case to predict the health benefits of restricting global warming to 1.5°C. A climate-driven statistical dengue model and five different global circulation models to represent a range of global-mean temperature assumptions were used to this aim. We demonstrate that future global warming is likely to significantly amplify dengue transmission in Latin America if no action for limiting its effects are taken. We project that limiting global warming to 2°C could reduce dengue by about 3 (1-7) million cases annually towards the end of the century compared with a business-as-usual scenario that warms by 3.7°C. Assuming that global warming is further limited to 1.5°C, an additional decrease in dengue cases of 1 (0-1) million per year is observed. We also project that the geographical expansion of the disease towards areas where incidence is currently low would be significantly lower undear a scenario where global warming is limited to 1.5°C. Thus, constraining the level of warming to 1.5°C would lead to significant public health benefits for the region.

179

MOSQUITO SALIVA HAS PROFOUND EFFECTS ON THE HUMAN IMMUNE SYSTEM

Megan B. Vogt[1], Anismrita Lahon[1], Alexander R. Kneubehl[1], Azadeh Aryan[2], Ravi P. Arya[1], Jennifer L. Clinton[1], Brianne M. Hibl[1], Zach N. Adelman[3], Silke Paust[1], Rebecca Rico-Hesse[1]

[1]Baylor College of Medicine, Houston, TX, United States, [2]Virginia Polytechnic Institute and State University, Blacksburg, VA, United States, [3]Texas A&M University, College Station, TX, United States

Mosquitoes transmit viruses that collectively cause over 1 million deaths each year. Not only are mosquitoes responsible for transmitting these diseases, but mosquito saliva has also been shown to enhance pathogenesis of several arboviruses (dengue, Zika, West Nile, etc) in experimental mouse models by modulating the immune response away from a Th1 (anti-viral) immune response and towards a Th2 (anti-parasite) immune response. However, these mouse studies are unable to yield a complete picture of how mosquito saliva affects the human immune system. Therefore, we investigated how mosquito saliva affects humanized NOD/SCID/IL-2$\gamma^{-/-}$ mice (huNSG mice), which are reconstituted with human CD34+ stem cells to recapitulate the human immune system. Hu-NSG mice were bitten by uninfected mosquitoes, and changes in immune cell populations in multiple tissues at multiple timepoints compared to unbitten controls were assessed using flow cytometry. Serum cytokine concentrations were assessed via multiplex bead array. Mosquito saliva alters the frequencies of natural killer T cells, CD4/CD8 double positive T cells, regulatory T cells, monocytes, and macrophages. When analyzed in conjunction with the cytokine results, these results indicate that mosquito saliva caused a mixed Th1/Th2 immune response in human immune cells. Th2 immune responses are known to inhibit aspects of Th1 (anti-viral) immune responses and may contribute to enhanced viral pathogenesis in infected animals. Next, we investigated how the mosquito salivary protein sialokinin impacted the human immune response by exposing hu-NSG mice to mosquito bites from sialokinin knockout mosquitoes. The results showed a shift towards a Th1 immune response. Thus, the absence of sialokinin may prevent mosquito saliva from initiating a Th2 response. These studies are significant because they show that the mouse immune response and human immune response to mosquito saliva are different and highlight the importance of using appropriate models to study human immune responses.

METABOLIC ACTIVITY AS A SURROGATE MARKER OF IMMUNE CELL ACTIVATION FOLLOWING VACCINATION

Adam T. Waickman, Heather L. Friberg, Richard G. Jarman, Jeffrey R. Currier

Walter Reed Army Institute of Research, Silver Spring, MD, United States

The identification and quantification of lymphocytes activated in response to vaccination is a critical first step in characterizing the efficacy of any candidate vaccine platform. Traditionally, this has been accomplished by monitoring the upregulation of defined activation markers on circulating lymphocytes by flow cytometry or by measuring the production of effector cytokines following *ex vivo* stimulation. However, there is significant variability in both the kinetics and magnitude of activation marker up-regulation and cytokine production following stimulation, even within the same type of lymphocyte. Therefore, traditional methodologies for identifying activated lymphocytes may offer a significantly skewed perspective on exactly which immune cells are responding to vaccination or natural infection. Herein, we examine the utility of measuring the metabolic activity of circulating lymphocytes as a marker of activation following immunization with a live-attenuated dengue vaccine. Unlike any

other marker, metabolic upregulation is a universal indicator of lymphocyte activation which can be detected quickly after stimulation and persists throughout the functional stage of an immune response. We observe that assessing the metabolic activity of both *in vitro* and *in vivo* stimulated human T cells is a high effective method for evaluating activation status and identifying antigen-reactive clones. We further characterize and contrast the functional and clonotypic diversity of viral-reactive T cells identified by either conventional methodologies or metabolic parameters using single-cell RNA sequencing. Collectively, these data suggest that metabolic activity is a highly informative parameter of T cell functionality that has multiple applications in the characterization of vaccine-elicited immunity.

DECREASED INCIDENCE OF DENGUE, CHIKUNGUNYA, AND ZIKA INFECTIONS IN CHILDREN THROUGHOUT BELO HORIZONTE, BRAZIL: SURPRISING FINDINGS FROM A PILOT PROJECT IN A REFERRAL EMERGENCY DEPARTMENT IN 2017

Michael J. Maurer[1], Jose Ferreira[2], Elysse Grossi-Soyster[1], Desiree LaBeaud[1]

[1]Stanford University, Palo Alto, CA, United States, [2]Faculdade da Saúde e Ecologia Humana, Vespasiano, Brazil

Infections with chikungunya (CHIKV), dengue (DENV), and Zika (ZIKV) viruses are a significant public health concern throughout Brazil, although the true incidence and demographic drivers for disease transmission remain to be fully described. This pilot project was created to establish a baseline understanding of arboviral disease incidence in urban Brazil and the major contributing factors to disease transmission. Patients aged < 13 years and >1 year were enrolled into the prospective study during January-April 2017 in the emergency department of Hospital Odilon Behrens, a large referral center in Belo Horizonte, Brazil. We enrolled patients based on the inclusion criteria of fever plus one or more prominent symptoms of arboviral infection. A blood sample was obtained from each patient and was tested for ZIKV, CHIKV, and DENV RNA by RT-PCR. The patients and their families also completed a questionnaire to obtain demographics and information regarding disease transmission risk factors. A total of only 22 patients were enrolled in the study during the four months, a significant drop in the incidence of suspected arboviral disease compared to prior years. Of the 22 patients enrolled, zero tested positive for ZIKV, DENV, and CHIKV by RT-PCR. While a drop in DENV infection was anticipated due to an outbreak the 2 years prior to the study, this proved to be an extraordinary reduction in the number of confirmed cases and suspected arboviral infections during 2017. Such a drop is possibly due to improved public health efforts, cross-protection between arboviruses, and improved mosquito control. More research is required further elucidate the major contributors to the decreased incidence of arboviruses throughout Brazil in 2017 compared to prior years.

182

LABORATORY INVESTIGATIONS OF DENGUE AND CHIKUNGUNYA VIRUS INFECTIONS IN GHANA

Joseph H. Bonney[1], Esinam Agbosu[1], Takaya Hayashi[2], Deborah Pratt[1], Shoji Yamaoka[2], Samuel Dadzie[1], Eiji Ido[2], Nobuo Ohta[2]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]Tokyo Medical and Dental University, Tokyo, Japan

Dengue Virus (DENV) and Chikungunya Virus (CHIKV) are globally important causes of human disease which constitute part of the known arthropod-borne viruses (arboviruses). These viral agents co-circulate with overlapping clinical symptoms in endemic areas. In Ghana there is a dearth of data on DENV and CHIKV contrary to what pertains in other parts of the world. Thus, the study seeks to identify and characterize DENV and CHIKV and other endemic arboviruses in selected health facilities in Ghana. Whole blood collected from eligible patients was investigated for immunological markers, IgM and IgG by ELISA as well as the detection and amplification of viral nucleic acids if present. From April 2016 to March, 2017, 513 clinical specimens were collected of which 60% were females. Of the samples collected, 22.7% and 53.7% had anti-DENV IgM and IgG antibodies respectively while 14.3% and 32.4% had anti-CHIKV IgM and IgG antibodies respectively. No viral RNA has been detected for both viruses by RT-PCR. Most clinical samples were received from the Greater Accra and Ashanti regions. The proportion of anti-DENV IgM positives in the Ashanti region was 10 times higher than in the Greater Accra region while anti-DENV IgG positives was 3 times higher in Greater Accra region. Therefore, there is a higher probability of a recent infection of Dengue in the Ashanti region. There are significant differences in the abundance ratio of anti-CHIKV IgM and IgG antibodies between the two regions. These data indicate exposure to DENV and CHIKV and suggest possible circulation of these and other arboviruses in the country which may be contributing to febrile illnesses. There is the need for a nationwide surveillance to identify the overall prevalence of DENV and CHIKV infections.

183

FIELD-DEPLOYABLE PCR SYSTEM FOR RAPID DETECTION OF DENGUE VIRUS INFECTION

Jih-Jin Tsai[1], Li-Teh Liu[2], Ping-Chang Lin[1], Ching-Yi Tsai[1], Pin-Hsing Chou[3], Yun-Long Tsai[3], Hsiao-Fen Grace Chang[3], Pei-Yu Alison Lee[3]

[1]Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, [2]Department of Medical Laboratory Science and Biotechnology, College of Medicine and Life Science, Chung-Hwa University of Medical Technology, Tainan, Taiwan, [3]GeneReach Biotechnology, Taichung, Taiwan

Dengue virus (DENV) infection, a mosquito-borne disease, is a major public health problem in tropical countries. Point-of-care DENV detection with good sensitivity and specificity enables timely early diagnosis of DENV infection, facilitating effective disease management and control particularly at regions of low resource. POCKIT™ Dengue Virus Reagent Set (GeneReach Biotech), a reverse transcription-insulated isothermal PCR (RT-iiPCR), is available to detect all four serotypes of DENV on the field-deployable POCKIT™ system, which is ready for on-site applications. In this study, analytical and clinical performances of the assay were evaluated. The index assay did not react with 14 non-DENV human viruses, indicating good specificity. Compared to the US CDC DENV-1-4 Real Time RT-PCR (qRT-PCR), testing with serial dilutions of virus-spiked human sera demonstrated that the index assay had comparable detection endpoints with the 4 serotypes separately. Excellent reproducibility was observed among repeat tests done by six operators at three sites. In clinical performance, 195 clinical sera collected around Kaohsiung city in 2012 and 21 DENV-4-spiked sera were tested with the RT-iiPCR and qRT-PCR in parallel. The 121 qRT-PCR-positive (11 DENV-1, 78 DENV-2, 11 DENV-3, 21 DENV-4) and 95 qRT-PCR-negative samples were all positive and negative by the RT-iiPCR reagent, respectively, demonstrating high inter-rater agreement (100%; $CI_{95\%}$, 98.81 ~ 100%; $\kappa = 1$). With analytical and clinical performance equivalent to those of the reference qRT-PCR, the index PCR assay on the field-deployable system can serve as a highly sensitive and specific on-site tool for DENV detection. Application of this point of care testing to Solomon Islands conformed to the local needs are under evaluation.

184

DETECTION OF DENGUE AND ZIKA VIRUS ANTIBODIES AMONG SUSPECTED MEASLES CASES IN KENYA

Yvonne Kimata[1], Peter Borus[2], Elizabeth Hunsperger[3], Caroline Tigoi[4], Edith Chepkorir[4], Rebecca Waihenya[1], Rosemary Sang[2]

[1]Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya, [2]Kenya Medical Research Institute, Nairobi, Kenya, [3]Centers for Disease

Control and Prevention, Nairobi, Kenya, [4]International Centre for Insect Physiology and Ecology, Nairobi, Kenya

Dengue (DENV) and Zika (ZIKV) viruses are emerging and re-emerging arboviruses of public health importance worldwide. DENV has been associated with recent multiple outbreaks primarily in coastal and north-eastern regions of Kenya in 2011 to 2016.Serological surveys carried out in the country indicated the presence of ZIKV antibodies. We sought to determine the possible circulation of these viruses among patients seen and sampled at health facilities in Kenya as suspected measles cases for laboratory investigation at the measles reference laboratory. Archived serum samples collected between 2008-2014 from health facilities in Nairobi, Taita-Taveta, Tana River, Mombasa, Kilifi, Kwale, Lamu, Mandera, Garissa and Wajir counties, were randomly selected from the bio-banked samples. The samples were tested for IgM and IgG antibodies against DENV using ELISA commercial kits whereas ZIKV IgM was tested using CDC in-house MAC-ELISA.DENV and ZIKV positive samples were further tested for neutralizing antibodies against 4 flaviviruses: DENV, ZIKV, Yellow Fever (YFV) and West-Nile Virus (WNV) by PRNT. Out of the 392 samples, 6.1% tested positive for DENV IgM, 10.9% tested positive for DENV IgG. The highest prevalence for DENV was observed among those aged 14 years and above and those sampled from Nairobi County between 2008 and 2009.1% tested positive for ZIKV IgM with the highest number of cases sampled from Nairobi County .The prevalence of ZIKV varied significantly with age ($p<0.001$).WNV was most prevalent in those sampled in Garissa and Nairobi. Evidence of past YFV exposure was observed in those sampled in Garissa, Nairobi and Taita-Taveta counties. However, nothing is known about their YFV vaccination status. Results show that these flaviviruses may contribute significantly to the burden of disease. Awareness is recommended among clinicians on the potential of arboviruses to cause measles-like febrile illnesses among patients and the need for additional diagnostic support to determine the true burden of these diseases.

185

DENGUE HOSPITALIZATIONS IN BRAZIL: ANNUAL WAVE FROM WEST TO EAST AND RECENT INCREASE AMONG CHILDREN

Juliane Wunderlich[1], Wladimir J. Alonso[2]

[1]Robert Koch Institute, Berlin, Germany, [2]Laboratory for Human Evolutionary and Ecological Studies, University of São Paulo, São Paulo, Brazil

Dengue is the most common arthropod-borne viral disease and a global health threat due to its presence in almost every tropical region and its alarming incidence increase within the last decade. In Brazil, the number of dengue epidemics has increased dramatically in the last 15 years. To identify factors associated with higher numbers of hospitalizations attributed to dengue in Brazil, we analyzed the seasonal patterns in hospitalization incidence across the different states and compared these with the corresponding climatic patterns. Therefore, we collected information from the public database of hospital stays provided by the Brazilian Unified Health System for the period from 1998 to 2015, and data on mean monthly vapor pressure, temperature, number of wet days and precipitation for the years 2001 to 2014 from the Climatic Research Unit of the University of East Anglia. Fourier analyses were used to characterize the seasonal patterns of dengue hospitalizations and climate in each state. The relative contribution of each age group to the total number of hospitalizations per month and state was also examined, and the cubic spline model was used to detect inter-annual trends. We discovered that the seasonality of dengue hospitalizations in Brazil has a clear zonal gradient that is characterized by the progression of primary peaks from West to East during the first half of the year, which may be associated with the increased vapor pressure and rainfall during this period, leading to increased mosquito abundance and activity. We also found that the proportion of children among hospitalized individuals was especially high during the peak outbreaks in 2007/2008 and 2010. This may be due to the emergence and spread of the new DENV-2 Southeast Asian genotype lineage II since 2007, which has probably arrived from the Caribbean and may have caused an increase in incidence and severity of the disease, particularly among children. Our findings may allow health systems to improve control interventions and contribute to reducing dengue morbidity and mortality by using integrated vector control in conjunction with early diagnosis and prompt supportive care.

186

IMPACT OF DENGUE VIRUS INFECTION ON MOSQUITO OVARY GENE EXPRESSION AND EGG PRODUCTION

Fabiana Feitosa-Suntheimer, Sultan Asad, Alexander Gold, Tonya M. Colpitts

Boston University School of Medicine, Boston, MA, United States

Dengue virus (DENV) is a mosquito-borne flavivirus that causes significant human disease and mortality in the tropics and subtropics. There has been a recent global trend of increased epidemic activity, and dengue infection is considered a serious emerging health problem worldwide. There is no specific therapeutic agent available against dengue virus, and safety issues have continually hampered vaccine development. A novel approach is to develop new preventative measures through an increased understanding of the interactions between the virus and its mosquito vector. Previous studies have suggested that pathogen infection can alter reproductive fitness in mosquitoes, although the majority of these experiments were done using *Anopheles* mosquitoes. It has also been proposed that a reduction in either fecundity/fertility may be an adaptive strategy of the pathogen to increase mosquito survival, although studies remain to be comprehensively undertaken. There is limited evidence to suggest that arboviral infection of *Aedes* can also alter fecundity; thus, further studies on both the effects of DENV infection on fecundity/fertility and the mechanisms behind these effects are required. A comprehensive understanding of how dengue virus impacts fecundity and fertility can enhance our knowledge on pathogenesis in the vector and inform on epidemiology and transmission forecasts. Our hypothesis is that infection with dengue virus alters both gene expression and egg production in the ovaries of *Aedes* mosquitoes. We found that DENV-infected mosquitoes have altered egg production (fecundity) and altered gene expression in ovary tissue, as measured by RNA-Seq analysis, compared to uninfected mosquitoes. We used qRT-PCR analysis to confirm the altered expression of 10 genes with significant changes in expression during infection in mosquito ovaries, and examined the role of these genes during infection for subsequent analysis. Here, we report on the identity and putative roles of genes that have altered expression in the ovaries of dengue virus infected mosquitoes.

187

USING PAIRED SEROLOGY AND SURVEILLANCE DATA TO QUANTIFY DENGUE TRANSMISSION AND CONTROL DURING A LARGE OUTBREAK IN FIJI

Adam Kucharski[1], Mike Kama[2], Conall Watson[1], Maite Aubry[3], Sebastian Funk[1], Alasdair Henderson[1], Oliver Brady[1], Jessica Vanhomwegen[4], Jean-Claude Manuguerra[4], Colleen Lau[5], John Edmunds[1], John Aaskov[6], Eric Nilles[7], Van-Mai Cao-Lormeau[3], Stephane Hue[1], Martin Hibberd[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]National Centre for Communicable Disease Control, Mataika House, Ministry of Health, Suva, Fiji, [3]Institut Louis Malarde, Papeete, French Polynesia, [4]Institut Pasteur, Paris, France, [5]Australian National University, Canberra, Australia, [6]Queensland University of Technology, Brisbane, Australia, [7]World Health Organization Division of Pacific Technical Support, Suva, Fiji

Dengue is a major health burden, but it can be challenging to examine transmission dynamics and evaluate control measures because outbreaks depend on multiple factors, including human population structure, prior

immunity and climate. We combined population-representative paired sera collected before and after the major 2013/14 dengue serotype 3 outbreak in Fiji with surveillance data to determine how different factors influence dengue virus (DENV) transmission and control in island settings. Using surveillance data from 25,494 suspected cases of dengue during 2013/14 and paired sera collected from 263 participants in 2013 and 2015, we analysed the roles of age, environmental factors, geography, pre-existing immunity, climate, and control measures in shaping observed patterns of infection and reported cases. The serological survey suggested that the 10-19 year old age group had the highest risk of acquiring infection (56%, 95% CI: 44-68%), whereas reported disease incidence per capita was highest in the 20-29 age group, many of whom were experiencing their second DENV infection. We did not find strong evidence that demographic or environmental risk factors were linked to seroconversion. Joint mathematical modelling analysis of surveillance data and the serological survey suggested that temperature-driven variation in transmission could not fully explain the sharp decline in cases during April/May 2014. However, there was evidence of an additional reduction in transmission in March 2014, coinciding with a large vector clean-up campaign, which may have contributed to the outbreak decline. By identifying key factors that influence DENV transmission dynamics, these results could also help inform forecasts of outbreaks and evaluation of control measures in other settings.

188

ANTIBODIES AGAINST DENV: REVEALS FROM A NOVEL NEUTRALIZATION ASSAY

Trung Tuan Vu, The Dengue Group

Oxford University Cinical Research Unit, Ho Chi Minh, Vietnam

Dengue is the most prevalent arboviral disease affecting humans. The illness is caused by dengue viruses (DENV). Although a vaccine is recently licensed its efficacy against some viral serotypes is limited, despite apparent protection as measured by Plaque Reduction Neutralization Test (PRNT), the conventionally accepted correlate of protection. We hypothesize false-positive results of PRNT are obtained from non-neutralizing antibodies. We received from collaborators 12 human-derived DENV-specific monoclonal antibodies (mAbs), each of these therapeutically potential mAbs neutralize DENV in the PRNT. We developed an alternative assay, named VIremic Blood Neutralization Assay (ViBNA), to re-characterize the neutralization profiles of these mAbs. ViBNA exploits the use of DENV drawn from acutely infected dengue patients, and considers the biologically relevant endpoint of mosquito infection. Results highlighted a significant discrepancy between assays, with seven out of the 12 mAbs failing to neutralize any DENV serotypes in ViBNA. The results support our hypothesis and have implication for the failure of PRNT to predict the efficacy of dengue vaccine. In addition, antiviral therapy is not available for dengue. Administration of DENV-specific antibodies is considered a potential antiviral approach to reduce disease severity, the symptomatology, and the duration of illness. With ViBNA, we identified five neutralizing mAbs as candidates of antivirals for dengue. A subgroup of these mAbs was diluted and tested for minimum concentrations that mediated DENV neutralization with ViBNA. These concentrations varied between mAbs, ranging from 0.1 µg/mL to 0.4 µg/mL. Results of mAb-dilution experiments have direct implications for the design of dengue clinical trials.

189

INVESTIGATING THE FIRST OUTBREAK OF DENGUE HEMORRHAGIC FEVER IN THE GREATER DARFUR, WESTERN SUDAN

Ayman Ahmed[1], Yousif Ali[2], Babiker Elmagboul[2], Arwa Elaagip[3], Tarig B. Higazi[4]

[1]Institute of Endemic Diseases, University of Khartoum, Sudan, Khartoum, Sudan, [2]General Directorate of Health Emergencies, Federal Ministry of Health, Sudan, Khartoum, Sudan, [3]Faculty of Medical Laboratory Sciences, University of Khartoum, Sudan, Khartoum, Sudan, [4]Ohio University Zanesville, Zanesville, OH, United States

Dengue fever is one of the most rapidly spreading diseases around the world with confirmed presence in 128 countries. An estimated 390 million dengue infections are reported annually with 3.97 billion people at risk of infection worldwide. Dengue in Sudan has historically been confined to Eastern Sudan. Here, we are reporting the first outbreak of the disease in Darfur, western Sudan. A cross-sectional community-based study has been designed to investigate an outbreak of a hemorrhagic fever-like disease in the five states of greater Darfur with a concentration on the internally-displaced population of refugee camps. Blood samples were successfully obtained from 204 individuals out of 560 suspected-cases who visited the health clinics of 29 refugee-camps in East, West, South, North and Central Darfur states between August 2015 and February 2016. All suspected cases presented with fever, 98.6% of cases with bleeding, 52.9% with a headache 48.2% with joint pain, and the mortality rate was 18.2%. IgM ELISA and Polymerase Chain Reaction (PCR) analyses confirmed 32 (15.7%) cases of dengue fever, 6 (2.9%) cases of West Nile virus (WNV) and 3 (1.5%) cases of Crimean-Congo hemorrhagic fever (CCHF). No cases of Zika virus (ZIKV), yellow fever (YF), chikungunya virus (CHIKV), or Rift Valley fever (RVF) were detected. Our analysis showed that most of infections were children and young adults, and *Aedes aegypti* to be the dominant suspected vector in the area with an incidence of 25-86% in water containers. This is the first report of dengue outbreak in Greater Darfur, which seems to be associated with the recent massive human population movement and socioeconomic changes in this war-torn region of Sudan.

190

EMERGENCE AND CO-CIRCULATION OF NEW GENOTYPES AND LINEAGES OF DENGUE VIRUSES DURING 2012-13 AND 2014-15 EPIDEMICS IN SOUTHERN INDIA

Syed Fazil Ahamed[1], Rosario Vivek[2], Carl Britto[3], Mary Dias[4], Kaustuv Nayak[5], Anmol Chandele[5], Murali-Krishna Kaja[5], Anita Shet[6]

[1]Division of Infectious Diseases, St. John's Research Institute, Bangalore, India; The Institute of Trans-Disciplinary Health Sciences and Technology (TDU), Bangalore, India, [2]Division of Infectious Diseases, St. John's Research Institute, Bangalore, India, [3]Oxford Vaccine Group, Department of Paediatrics, University of Oxford and the NIHR Oxford Biomedical Research Centre, Oxford, United Kingdom, [4]Department of Microbiology, St. John's Medical College Hospital, Bangalore, India, [5]ICGEB-Emory Vaccine Centre, International Centre for Genetic Engineering and Biotechnology, New Delhi, India, [6]International Vaccine Access Center, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

High genetic diversity is demonstrated among dengue virus (DENV) serotypes, however, strains circulating in India are not well characterized. We genetically characterized DENV strains among dengue-infected children from 2012-13/2014-15 outbreaks in Bangalore, in southern India. Acute-phase blood samples from children with clinically suspected dengue were collected. DENV serotypes were detected using RT-PCR targeting *Capsid-preMembrane (C-prM)* and *Envelope (Env)* regions; *C-prM* of DENV strains from 99 patients (33 DENV-1, 32 DENV-2, 27 DENV-3 and 7 DENV-1) were sequenced and aligned using ClustalW in BioEditV7.1.9, and compared with 207 GenBank sequences. Phylogenetic analysis was performed by maximum-likelihood method using Kimura 2-parameter model with 1000 bootstrap replicates in MEGA6. In 2012-13 (n=113), DENV-3 (44, 38.9%) and DENV-2 (43, 38.1%) predominated; DENV-1 was less common (22, 19.5%) followed by DENV-4 (1, 0.9%). In 2014-15 (n=499), DENV-1 (329, 65.9%) predominated, followed by DENV-2 (97, 19.4%), DENV-3 (36, 7.2%) and DENV-4 (10, 2.0%). Co-infections with multiple serotypes were seen in 2.7% (n=3) and 5.4% (n=27) in 2012-13 and 2014-15, respectively. Among 7 DENV-1 isolates

from 2012-13, 6 were genotype III (GIII) and 1 belonged to genotype I (GI). The pattern changed in 2014-15 where, 21 were GI and 5 were GIII among 26 DENV-1 isolates. Out of total 32 DENV-2 isolates, 9 clustered with previously reported GIV lineage B strains (GIVb) from India and the remaining 23 clustered separately (GIVc). All 27 DENV-3 sequences were GIII and all the 7 DENV-4 isolates were lineage C of GI (GIc) which further diverged into two clades. This is the first report of a major outbreak due to re-emergence of DENV-1 GI, circulation of new lineage (GIVc) of DENV-2 and two clades of DENV-4 GIc in India, which may explain the severe dengue outbreaks in 2014-15. Our findings highlight the rapidly changing epidemiology of dengue in southern India and the likelihood of its impact on transmission dynamics and disease severity. This study emphasizes active surveillance of DENV strains in predicting outbreaks and for aiding vaccine and anti-viral trials.

191

SEROLOGICAL EVIDENCE OF FLAVIVIRUS CIRCULATION IN HUMAN POPULATIONS IN NORTHERN KENYA: A RISK ASSESSMENT 2017

Edith Chepkorir[1], David P. Tchouassi[1], Samson L. Konongoi[2], Joel Lutomiah[2], Marietjie Venter[3], Rosemary Sang[1]

[1]International Centre for Insect Physiology and Ecology (icipe), Nairobi, Kenya, [2]Center for Virus Research, Kenya Medical Research Institute, Nairobi, Kenya, [3]Center for Viral Zoonoses, Department of Medical Virology, University of Pretoria, Pretoria, South Africa

Yellow fever (YF), dengue (DEN), Zika and West Nile (WN) are important reemerging mosquito-borne flaviviruses. Outbreaks have been reported in Kenya; YF (1992-95), Dengue (2011-2018) and there is concern of reemergence or importation of Zika virus. The potential threat of spillover remains high following recent reports of Flavivirus outbreaks in countries neighboring Kenya and thus, the need for human exposure assessment in border areas. We screened human serum samples collected through a cross-sectional survey in village clusters from two northern Kenyan Counties (West Pokot and Turkana), both bordering Uganda, South Sudan and Ethiopia by serological detection of IgG antibodies against DEN virus using commercial IgG Enzyme Linked Immunosorbent Assay (ELISA) kits (InBios) and virus neutralization for YF at a dilution of 1:20 by plaque reduction neutralization test (PRNT). Sera reactive for YF or DEN were titrated by 90% PRNT for 4 flaviviruses (YF, DEN, Zika and WN viruses) to rule out cross-reactivity. Overall, 29.5% (259/877) of the samples showed seropositivity for DEN virus by ELISA. Employing the criterion for 4-fold greater titre 50 (5.7%) were seropositive for YF virus, 36 (4.1%) for WN, 6 (0.7%) for Zika and one (0.1%) for DEN virus. 21.8% (90/413) of samples from Turkana County neutralized with one of the three flaviviruses (11% with YF, 9% with WN, 0.2% with Zika viruses), nine were classified as indeterminate. In West Pokot County, 2.6% (12/464) were positive with one of the 3 flaviviruses (1.3% with YF, 1.1% with Zika, 0.2% with DEN viruses). The odds of Flavivirus infection was about 11 times higher in Turkana than W. Pokot (OR=10.5, 95% CI= 5.59-21.38). These results suggest Flavivirus exposure in areas of Northern Kenya, bordering epidemic *Foci* of neighboring South Sudan, western Uganda and Omo River Valley in Ethiopia. The presence of YF, WN and Zika antibodies in the population may point to previous vaccinations (YF) or undetected cases. Focused case-based surveillance will be needed to determine accurately the burden and for implementation of preparedness strategies to counter potential threats posed by these viruses.

192

DENGUE VIRUS INFECTS TYPE II PNEUMOCYTES AND HEPATOCYTES AND INDUCES AN INFLAMMATORY RESPONSE IN TARGET ORGANS OF FATAL CASES

Monica Guzman Rodríguez[1], Anilza Bonelo[1], Carlos Pardo-Villamizar[2], Diego Vargas[1], Julio César Mantilla[3], Beatriz Parra[1]

[1]Universidad del Valle, Cali, Colombia, [2]Johns Hopkins School of Medicine, Baltimore, MD, United States, [3]Universidad Industrial de Santander, Bucaramanga, Colombia

In Colombia, dengue disease is a major public health problem, with 60% of its population at risk of infection and a case mortality rate of 3%. The pathogenic mechanisms underlying the severe manifestations of dengue, such as hemorrhage, raise in vascular permeability and shock that can lead to death are still unknown. Studies on the histopathology of fatal cases are crucial for the understanding of this mechanisms. To describe the immunohistopathology of dengue in Colombia, 46 cases of fatal dengue were evaluated; in each case, paraffin-embedded tissues of liver and lung were prepared. To confirm the infection of dengue virus we performed qRT-PCR. The presence of dengue antigen was evaluated by immunohistochemistry. For the characterization of the cellular infiltrates, we performed hematoxylin/eosin and immunohistochemistry staining for the detection of CD3, CD4, CD8 and CD68 cells. We confirmed the presence of dengue virus in 8 cases by RT-PCR, and in 12 cases by immunohistochemistry. In the lung, the antigen was found infecting macrophages, type II pneumocytes and endothelial cells; the presence of alveolar edema and hemorrhage was the most common finding, followed by abundant mononuclear cellular infiltrate, T cells were the major infiltrating cellular subpopulation, located in septum and perivascular regions, macrophages were mainly located in alveoli. The liver was the most affected organ, with macro and micro steatosis, edema zones and vascular congestion, and infiltrates of T cells mainly in portal zones, the dengue antigen was found infecting macrophages, endothelium and hepatocytes. We found that dengue virus infects not only macrophages and endothelial cells but also type II pneumocytes and hepatocytes, which can contribute to the alveolar collapse and hepatic dysfunction respectively. In most cases, the infection induced edema and hemorrhage in liver and lung, with an abundant infiltration of T cells. In liver was prominent the presence of steatosis, compromising most of the cases. These results provide evidence to support the contribution of dengue-induced immunopathology in the multiorganic involvement of fatal dengue.

193

DISTRIBUTION OF DENGUE CASES IN KISUMU CITY AND ENVIRONS

Esther A. Ombewa[1], Noah Mutai[1], Uriel Kitron[2], Angelle Desiree LaBeaud[3], Bryson Alberto Ndenga[1]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]Emory University, Atlanta, GA, United States, [3]Stanford University, Palo Alto, CA, United States

Dengue is the most common mosquito-borne viral infection with an expanding global distribution. But, little is known on its distribution in Kenya. In this study our main aim was to characterize the spatial distribution of dengue cases in Kisumu city and its surroundings. From January 2014-June 2018 children aged 1-17 years having acute febrile illness in our study facilities were enrolled in a cohort and tested for dengue using reverse transcription polymerase chain reaction (RT-PCR). For febrile children with dengue RT-PCR positive results, residences were mapped and location information recorded. We mapped 82 of 100 DENV PCR positive cases. At least 20 sub-locations in Kisumu city and its surroundings had one positive RT-PCR dengue result. The city alone had cases in at least 11 of 25 sub-locations. Of the 20 sub-locations that had positive results, 4 sub-locations had more than 3 dengue cases while the others had 1-3 cases. Of the 82 cases mapped, ~55% (45/82) occurred

within Kisumu city, while~45% (37/82) occurred outside. Dengue cases occur both within the city and in its surrounding locations, with most cases coming from the city. This study points to areas with high transmission of dengue, and results can be used to target vector control measures.

194

DENGUE VIRUS SEROTYPE 2 DETECTED IN FEBRILE CHILDREN IN A PERI-URBAN AREA OF ACCRA, GHANA

Nicholas Amoako

University of Ghana, Accra, Ghana

Accurate diagnosis of non-malarial febrile illnesses remains a big challenge in many malaria endemic countries due to nonspecific clinical presentation and diagnostic limitations. This often results in presumptive treatment of malaria for most febrile episodes. To obtain a snap-shot of the pathogens causing febrile illnesses in Ghana, a hospital-based cross-sectional study was conducted out at out patients departments of two hospitals in Ghana. A total of 166 blood samples from febrile children aged 1-14 years were screened using a customized multi-pathogen real time PCR-based TaqMan probe-array card which simultaneously detects 26 pathogens, including three protozoa, seven bacteria and 16 viruses. All children were physically examined and blood or urine cultures were performed at the request of attending clinician. *Plasmodium falciparum* was the predominant pathogen detected in the children (36.0 % of samples tested). *Salmonella enterica* Typhi (0.6%), *Rickettsia* spp.(3.0), *Coxiella burnetii*, (0.6) and HIV-1(0.6) were also detected in a few of the samples. A notable observation was the detection of dengue virus (1.2%) in two children who were 3 and 14 years old. A sequence analysis of the dengue RNA revealed a close relationship with dengue serotype 2 implicated that was implicated in outbreak in Burkina Faso in 2016. One of the dengue-positive samples was also positive for *Plasmodium*, providing a vivid demonstration of the complex etiology of AFI in malaria-endemic areas. Pathogens were not identified in 58% of the samples tested. In conclusion, the result highlights the importance of dengue as a cause of acute febrile illness and underscores the need of diagnostic testing for dengue and other flaviviruses in malaria endemic areas, in order to facilitate control, including the prevention of nosocomial transmission

ASSESSING THE INTERCONNECTION BETWEEN PSYCHOSOCIAL DISTRESS, IMMUNE RESPONSE, AND DENGUE VIRUS IN MACHALA, ECUADOR

Denisse Vega Ocasio[1], Craig Morrell[1], Anna M. Stewart-Ibarra[2], Timothy D. Dye[1]

[1]*University of Rochester Medical Center, Rochester, NY, United States,* [2]*SUNY Upstate Medical University, Syracuse, NY, United States*

Aedes aegypti (*Ae. Aegypti*), the mosquito that transmits diseases such as dengue virus (DENV), chikungunya, yellow fever and Zika virus infection is now present in nearly every tropical and subtropical region of the world. Almost one billion people around the world are at risk of contracting a mosquito-borne illness and DENV is considered the most common arboviral disease impacting humans. In Latin America, the incidence of DENV has increased from 16.4 cases per 100,000 in the 1980s to 71.5 cases per 100,000 from 2000 to 2007. Biological factors, social stressors, anthropogenic environmental modifications and/or ecological changes such as natural disasters can influence and increase the risk of dengue transmission. Understanding how these factors intersect are essential to explaining how social-biological processes influence disease onset. Research on DENV virus has largely been conducted separately in bench and in public health environments. Little research exists, however, that evaluates the intersection of the social-biological process and how it influences disease progression. We are implementing the Medical Ecological Framework, a novel analytical framework, to propose a study that evaluates the relationship between distress and immune responses to DENV with two specific aims: 1) Describe how distress influences the production of inflammatory cytokines in response to infection. 2) Describe the social conditions, exposure, and experiences related to mosquito-borne diseases from an ethnographic point of view in two different, ecologically-diverse communities of Machala, Ecuador and to seek evidence on how these factors influence stress-related behaviors. We expect to provide new understandings of the intersection of social-biological processes that occur in communities susceptible to mosquito borne-illness. In addition, we seek to implement theories and models of community organization and community building by assuring inclusive and integrated participation across community sectors in the planning process and to build consensus on what can and should be done based on the communities' unique assets and needs.

196

IS THERE A ROLE FOR DEFECTIVE DENGUE VIRUS PARTICLES IN DENGUE EPIDEMIOLOGY?

Kym Lowry, Malik Hussain, **John Aaskov**

Queensland University of Technology, Brisbane, Australia

There is ongoing debate about the relative contributions of the virus and the host in the pathogenesis of dengue. As obligate parasites, dengue viruses (DENV) have a vested interest in not killing their host before they have been transmitted to a new one. Furthermore, DENV dissemination is constrained by the restricted movement of its common *Aedes* mosquito vectors. We have identified sub-genomic RNA in DENV from patients, and in cell culture, composed of short lengths of RNA from the 5′ and the 3′ ends of wild type (WT) DENV genomes and demonstrated that these suppress DENV replication *in vitro*. While some of these sub-genomic RNAs contain all elements necessary for their replication, others do not. We proposed that virions containing these defective genomes, reduce viraemia, attenuate disease and enable viraemic patients to remain mobile and therefore increase exposure to more mosquito vectors. It is not known how these defective genomes are generated, whether they can be transmitted between vectors and hosts, how effective they are in inhibiting virus replication and whether they can interfere with the replication of other viruses. Our *in vitro* data suggests that defective DENV genomes are generated in both vertebrate and invertebrate cells by a variety of mechanisms. For instance, several contain no common junctions between 5′ and 3′ elements of the sub-genomic RNA, while a subset contain a small conserved junction site suggesting targeted recombination. Transfection of the sub-genomic DENV RNA into cells infected with the DENV serotype from which it was derived, or with a range of other flaviviruses, resulted in decreased yields of extracellular WT virus. While each DENV infection appears to produce a unique spectrum of defective genomes, it is not clear whether these compete with each other as well as with the WT genome for the intracellular DENV replicative machinery and whether different defective DENV genomes interfere with the replication of wildtype genomes in the same manner. Defective interfering DENV provide mechanisms to modulate both disease severity and virus transmission.

197

IDENTIFICATION OF SYNONYMOUS CONSTRAINT ELEMENTS IN THE POLYPROTEIN OF DENV-2 HAPLOTYPES FROM METAGENOMIC SEQUENCE DATA

Ma. Jowina H. Galarion[1], Brian Schwem[1], Coleen Pangilinan[1], Merab Chan[2], Raul Destura[1]

[1]*National Institutes of Health, Manila, Philippines,* [2]*Ateneo de Manila University, Quezon City, Philippines*

Despite high mutation rates of the dengue virus (DENV), there are parts of its genome that are under unusually high evolutionary constraint. These regions, called synonymous constraint elements (SCEs), are highly conserved and known to be signatures of overlapping function. This study aims to systematically find SCEs across multiple sequences of DENV to identify probable elements that may have overlapping roles in the viral

life cycle. Metagenomic sequencing was done on 14 serum samples from patients presenting with acute febrile illness. Finding Regions of Excess Synonymous Constraints (FRESCo) analysis tool was used to systematically identify SCEs across DENV haplotype sequences of the structural and non-structural (NS) gene regions. Significant SCEs were identified at the 3' half of the envelope (E) and NS5 gene. While the E-gene is under constant selective pressure due to its roles in host-virus interaction, this study has seen parts of it that are highly conserved. Although parts of the NS5 gene harbor putative functional elements involved in viral replication, other SCEs identified here which has not yet been described elsewhere can serve as initial information to do site-directed mutagenesis studies. The study demonstrates the feasibility of systematically identifying SCEs using haplotype alignment from metagenomic viral sequences. Finally, the highly conservative nature of SCEs may serve as excellent targets for antiviral drug designs.

198

DENGUE IN SOUTHEASTERN BRAZIL: A LARGE OUTBREAK FOLLOWED BY A THREE-YEAR LOW INCIDENCE PERIOD. OBSERVATIONS FROM A PROSPECTIVE COHORT STUDY

Expedito J. Luna[1], Gerusa M. Figueiredo[1], Jose E. Levi[1], Sergio R. Campos[1], Walter M. Figueiredo[2], Angela A. Costa[2], Alvina C. Felix[1], Nathalia C. Souza[1], Claudio S. Pannuti[1]

[1]Universidade de Sao Paulo, Sao Paulo, Brazil, [2]Universidade de Sao Paulo, Araraquara, Brazil

Brazil is the largest contributor to the number of reported dengue cases worldwide. However, those figures may not reflect the true burden of the disease. Accurate data on dengue incidence are necessary for the evaluation of novel control interventions. A cohort study was set up to determine the incidence of dengue in a mid-level endemicity town, Araraquara, state of Sao Paulo, Brazil. A cluster randomized sample of children and adolescents from 2 to 16 years of age was selected and invited to participate. Parents or legal guardians who agreed to have their child enrolled provided a written consent. A baseline blood sample was collected for dengue serological diagnosis. Families are contacted weekly for fever surveillance. If the participant reports a febrile episode, the study nurse visits the household to collect a blood sample for dengue diagnosis. Acute cases are confirmed according to their PCR and NS1 results. Confirmed dengue cases undergo full medical examination. Yearly blood samples are collected for serology. Participants were recruited from Sept 2014 to March 2015; 3,514 participants were enrolled in the cohort. A large dengue outbreak occurred in 2015. There were 290 confirmed cases among the participants in 2015 and 14 in 2016 (cumulative incidence of 8.3% and 0.48%, respectively). All cases were confirmed as DENV1. No confirmed cases were diagnosed in 2017 and none have been confirmed in 2018. Dengue seroprevalence was 13.7% at baseline, 30.9% after one year, 30.8% in the following year, and 33.4% in 2018. The incidence of inapparent infections among previously dengue naïve subjects was 14.4% in 2015/16, 4.6% in 2016/17 and 5.3% in 2017/18. The state of Sao Paulo faced its largest dengue outbreak ever in 2015. Since then, incidence has decreased markedly. No symptomatic cases have been detected among the cohort participants in the past two years, although asymptomatic cases still occurred. While these numbers reflect the national trend of reduction in the number of dengue cases, local factors such as vector density, urban infrastructure, population immunity, circulating serotype, and others, play a role in the transmission dynamics.

199

COMMUNITIES ORGANIZED TO PREVENT ARBOVIRUSES: COPA - A PROSPECTIVE COMMUNITY STUDY TO ASSESS OCCURRENCE OF ARBOVIRAL INFECTION AND EVALUATE VECTOR CONTROL INTERVENTIONS IN PONCE, PUERTO RICO

Liliana M. Sanchez-Gonzalez[1], Gabriela Paz-Bailey[1], Laura E. Adams[1], Kyle R. Ryff[1], Emma Little[1], Matthew Lozier[1], Carmen L. Perez-Guerra[1], Angela F. Harris[1], Ryan R. Hemme[1], Eli Rosenberg[2], Tyler M. Sharp[1], Mark Delorey[3], Stephen Waterman[1], Luisa I. Alvarado[4], Vanessa Rivera-Amill[4]

[1]Dengue Branch - Centers for Disease Control and Prevention, San Juan, PR, United States, [2]University of Albany, Rensselaer, NY, United States, [3]Division of Vector Borne Diseases, Centers for Disease Control and Prevention, Fort Collins, CO, United States, [4]Ponce Health Sciences University and Saint Luke's Episcopal Hospital Consortium, Ponce, PR, United States

The public health response to the spread of arboviruses such as dengue, chikungunya, and Zika has been hampered by a lack of effective interventions to prevent human infections. Vector control programs with substantial community participation can improve acceptance and sustainability, and complement vertical approaches. Identifying effective vector control strategies to control current and emerging arboviruses requires conducting robust epidemiologic evaluations in urban communities with infection and disease in humans as the outcomes evaluated. The purpose of this study is to implement a community-based platform for arbovirus surveillance and research. We will recruit a community cohort to assess arboviral infection incidence and prevalence. Through active surveillance we will establish incidence and etiology of acute febrile illness. We will monitor entomological parameters and we will ultimately evaluate the feasibility and effectiveness of integrated vector control strategies to reduce human arboviral infection. Fourteen groups of communities with high rates of arboviral disease in southern Puerto Rico were identified using surveillance data and constitute the study clusters. We aim to recruit 250 participants per cluster or 3,500 individuals in total. A sero-survey and questionnaire to assess knowledge, attitudes, and vector control practices will be repeated annually, after the initial baseline, for at least five years. We aim to measure a difference of 50% in arboviral infection incidence between intervention and non-intervention clusters over the course of the study period. After the first year of data collection, prevalence rates will be calculated for each cluster. Clusters will be paired based on baseline prevalence rates, and intervention and control status will be randomly assigned. The incidence rate in each cluster will be assessed through annual testing for arboviral infections. Comparisons will be made between the intervention and control clusters using paired t-tests to assess differences between groups. In this presentation we will outline the study design and plans for evaluation of interventions.

DENGUE KNOWLEDGE, ATTITUDES AND PRACTICES AND THEIR IMPACT ON COMMUNITY BASED VECTOR CONTROL IN RURAL CAMBODIA

Emmanuelle Kumaran[1], Dyna Doum[2], Vanney Keo[2], Sokha Ly[3], BunLeng Sam[3], Vibol Chan[4], Neal Alexander[1], John Bradley[1], Marco Liverani[1], Didot B. Prasetyo[5], Sergio Lopes[2], Jeffrey Hii[2], Rithea Leang[3], Muhammad Shafique[2], **John Hustedt**[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Malaria Consortium, Phnom Penh, Cambodia, [3]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [4]World Health Organization, Phnom Penh, Cambodia, [5]United States Naval Medical Research Unit-2, Phnom Penh, Cambodia

The World Health Organization global strategy for dengue prevention aims to reduce mortality rates by 50% and morbidity by 25% by 2020. The adoption of integrated vector management approach using community-

based behavior change methods tailored to the local context is one of the recommended strategies to achieve these objectives. Understanding local knowledge, attitudes and practices is therefore essential to designing culturally appropriate strategies to fit each local context. A Knowledge, Attitudes and Practices survey in 600 randomly chosen households was administered in 30 villages in Kampong Cham, Cambodia which is one of the most populated provinces of Cambodia. KAP surveys were administered to a sub-sample of households where an entomology survey was conducted (1200 households), during which *Aedes* larval/pupae and adult female Aedes mosquito densities were recorded. Participants had high levels of knowledge regarding the transmission of dengue with 96.7% identifying mosquitoes as the dengue vector, and 95.5% able to identify at least one breeding site. *Aedes* breeding and biting prevention methods were similarly high. The majority of participants (97.5%) believed they were at risk and that dengue transmission is preventable (77.8%). However, self-reported vector control practices did not match observed practices recorded in our surveys. No correlation was found between knowledge and observed practices. An education campaign regarding dengue prevention in this setting with high knowledge levels is unlikely to have any significant effect on practices unless it is incorporated in a more comprehensive strategy for behavioral change, such as the Communication for Behavioral Impact method, which includes appropriate theoretical models, creates enabling environment and ensures active community participation in dengue to bring about sustained behavioral changes in target communities.

201

QUALITATIVE ASSESSMENT TO UNDERSTAND COMMUNITY'S ACCEPTANCE, PREFERENCES AND SUSTAINABILITY OF GUPPY FISH (*POECILIA RETICULATA*), PYRIPROXYFEN, AND COMMUNITY ENGAGEMENT FOR DENGUE CONTROL IN KAMPONG CHAM, CAMBODIA, 2016

Sergio Lopes[1], Muhammad Shafique[1], Dyna Doum[1], Vanney Keo[1], Sokha Ly[2], BunLeng Sam[2], Vibol Chan[3], Neal Alexander[4], John Bradley[4], Marco Liverani[4], Jeffrey Hii[1], Rithea Leang[2], **John Hustedt**[4]

[1]Malaria Consortium, Phnom Penh, Cambodia, [2]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [3]World Health Organization, Phnom Penh, Cambodia, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom

Dengue is the most rapidly spreading mosquito-borne viral disease in the world, and Cambodia has one of the highest per-capita incidence rates in the region. Without a widely available vaccine or therapeutics, vector control is the most effective way to fight dengue. Increasing resistance to commonly used insecticides has been reported and alternatives are needed. Three inventions recently trialed in Cambodia include guppy fish, a controlled release pyriproxyfen (PPF) matrix (Sumilarv® 2MR), and Communication for Behavioral Impact (COMBI) activities. The trial explored community perception, acceptability, and willingness to pay for vector control tools through a qualitative assessment. Using a purposive sampling technique, nine in-depth interviews and 12 focus groups discussions (FGD) were conducted at community and health center level. A thematic analysis approach was adopted during data analysis. Free listing and pile sorting were performed to identify and rank all vector control tools available in their community. The majority of individuals (62.5%) preferred guppy fish due to ease of use/rearing, quick reproduction and propensity to eat larvae. FGD participants remarked *"We love guppies as they are attractive, easy to keep, and clean the water."* Respondents were willing to pay 100-500 riel ($0.02-0.1 USD) for a pair of guppies. The next commonly preferred method was PPF (35%) due to its long-lasting effectiveness, convenience and easy maintenance. However, some concerns over the persistent presence of larvae existed. *"We know PPF works well as fewer mosquitoes are around, however, we are afraid the presence of larvae may contain parasites that can spread the disease".* These concerns can often be overcome through health education. Additional concerns about access, availability and affordability of PPF were raised by FGD participants. The least preferred methods included mosquito coils, and chemical sprays due to the smell and health concerns. Results showed that in the presence of well-developed COMBI activities it was possible to achieve high acceptance and demand for guppies and PPF.

202

BUILDING ECOLOGY INTO MODELS TO PREDICT ARBOVIRUS DYNAMICS

Jamie M. Caldwell[1], Francis Mutuku[2], Bryson Ndenga[3], Erin Mordecai[1], Desiree LaBeaud[1]

[1]Stanford University, Stanford, CA, United States, [2]Mombasa Institute of Technology, Mombasa, Kenya, [3]Kenya Medical Research Institute, Kisumu, Kenya

Understanding the ecological conditions that enable arboviruses to emerge and circulate is critically important for understanding disease dynamics, predicting future outbreak events, and breaking transmission cycles. Climate factors (e.g., temperature, rainfall, and humidity), land cover type, and microhabitats can influence vector abundance, distribution, and transmission potential by affecting a variety of vector traits, including survival, reproduction, and development. Using dengue and chikungunya as examples, we will discuss how we are incorporating empirically-derived relationships of climate, land cover, and microhabitats into mathematical models to understand their impacts on the abundance of the *Aedes aegypti* mosquito vector and disease transmission. We will also discuss how we are incorporating many data sources to improve predictions for specific locations, including the use of data from in situ climate loggers, satellites, field entomology studies, and laboratory-confirmed disease cases for urban and rural locations within Kenya. These models can help us predict disease transmission in the near future and understand how global climate change is likely to shift transmission in space and time in the longer term. Further, these results have implications for understanding where other *Aedes aegypti*-vectored diseases could circulate.

203

USE OF A RANDOM FOREST MODEL CONTAINING AUTOCORRELATION, POPULATION, WEATHER, CLIMATE, VEGETATION, AND LAND USE PREDICTORS TO FORECAST DENGUE FEVER CASES AT A CITY LEVEL IN CHINA UNDER IPCC CLIMATE CHANGE SCENARIOS

Megan Clegg[1], Gail Williams[1], Wenyi Zhang[2], Samuel Hundessa[1], Yuming Guo[3]

[1]School of Public Health, Faculty of Medicine, University of Queensland, Brisbane, Australia, [2]Center for Disease Surveillance & Research, Institute for Disease Control and Prevention of PLA, Beijing, China, [3]Department of Epidemiology and Preventive Medicine School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia

Dengue Fever is a vector borne disease that occurs primarily at tropical latitudes. In recent years the incidence rate in many countries has been increasing, and it is thought that as the effects of climate change are realized that this will continue. We then used a random forest model to forecast cases under climate change pathways and identify key areas of risk. The model contained autocorrelation, population, weather, climate, vegetation, and land use variables and was used to predict cases across China. Daily averaged estimates of weather variables were obtained from the IPCC. We used the RCP 4.5 and RCP 8.5 pathways. The dataset was then aggregated to a weekly timescale. Several time periods were selected from the forecast data and the model used to predict cases at the City level. The projections of case counts were converted to basic incidence rates and the difference between these and current incidence rates calculated. For China there was a slight decrease in the minimum temperature and a slight increase in the relative humidity and maximum temperature projected throughout the year compared to the current observations. Wind speed was projected to be either similar or increased

over current observations, dependent on City. Total Rainfall showed increases mid-year. The model used for predictions attained a good fit with the observed data. When projected, seasonal patterns and differences between Cities were observed. The incidence rate plots showed that the areas of risk moved further to the north and west; with areas of highest incidence remaining in similar areas to that currently observed. As the climate warms the risk areas for Dengue Fever in China spread further west and north as more areas become suitable, but the majority of cases remain in key population centres.

204

ANTIVIRAL INVESTIGATION, HIGH PERFORMANCE LIQUID CHROMATOGRAPHY ANALYSIS AND PHYTOCHEMICAL PROFILING OF *BRYOPHYLLUM PINNATUM* (*ODAA OPUO, ABAMODA*) AND *VISCUM ALBUM* (*AWURUSE, AFOMA*)

Robert K. Obi[1], Juliet A. Shenge[2]

[1]Federal University of Technology, Owerri, Nigeria, [2]University of Ibadan, Ibadan, Nigeria

Despite tremendous progress in human medicine, no drugs exist for the complete treatment of these viral diseases. This study was designed to investigate the antiviral potentials of two medicinal plants available locally in South Eastern, Nigeria. Fresh leaves of *Bryophyllum pinnatum* (L) and *Viscum album* (L) were collected from Lagos, South Western, Nigeria. Extraction of the plant materials was done with methanol using the soxhlet extractor and concentrated using the rotary evaporator. Measles, polio, and yellow fever viruses were isolated from their respective vaccines, while herpes simplex virus-1 was isolated from a positive HSV male case. The toxicity profile showed that the minimum non-toxic concentration (MNTC) of *B. pinnatum* (L) was 0.016 µg μL^{-1} with an IC_{50} of 0.063 µg μL^{-1} while that of *V. album* (L) was 0.063µg μL^{-1} and IC_{50} of 0.313 µg μL^{-1}. Result of the antiviral analysis showed that two of the viruses were susceptible to *B. pinnatum* (L) and *V. album* (L). While HSV-1 was sensitive to *B. pinnatum* (L), MV was susceptible to *V. album* (L) at the concentrations of 0.016 µg μL^{-1} (IC_{50} 0.004 µg μL^{-1}) and 0.063µg μL^{-1} (IC_{50} 0.031 µg μL^{-1}; IC_{50} 0.039 µg μL^{-1}) respectively. Polio and yellow fever viruses were resistant to both plants extracts at all the concentration tested. Result of the phytochemical of both plants revealed the presence of various secondary useful metabolites. In conclusion, this study has shown that the solution to measles and herpes simplex-1 viral diseases could be found in the forest zones of Nigeria.

ZIKA VIRUS PREVENTION: US TRAVELERS' KNOWLEDGE, RISK PERCEPTIONS, AND BEHAVIORAL INTENTIONS - A NATIONAL SURVEY

James Herrington[1], Linda Squiers[2], Bridget Kelly[2], Carla Bann[2], Sylvia Becker-Dreps[1], Lola Stamm[1], Mihaela Johnson[2], Lauren McCormack[2]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [2]RTI International, Research Triangle Park, NC, United States

Limited data exist about US travelers' knowledge, risk perceptions, and behaviors related to the Zika virus (ZIKV). Using an internet research panel, in March 2017 we surveyed 1,202 Americans in the continental United States and Puerto Rico who planned to travel to a Zika-affected country, state, or US territory in 2017. We compared levels of knowledge and perceived risk of ZIKV, and intentions to practice ZIKV prevention behaviors across respondents from 3 regions: Puerto Rico, at-risk states, and other states. Over 80% of respondents correctly understood that a person could acquire ZIKV through a bite from an infected mosquito, and over 64% of respondents knew that a pregnant woman could pass the virus to her fetus. Less than half of respondents from at-risk states and other states knew that ZIKV could be transmitted sexually, as compared with three-quarters of respondents from Puerto Rico. Compared with respondents from at-risk and other states, respondents from Puerto Rico were the most knowledgeable for almost all types of knowledge assessed. Knowledge about post-travel precautions was low across all 3 regions. Differences in perceived risk and intentions to practice specific prevention behaviors also varied among regions. Significant gaps exist in US travelers' knowledge about how to prevent ZIKV transmission both during and after travel. Input and collaboration from the travel industry, health care providers, and the media are needed to help educate travelers about how to prevent ZIKV infection and transmission.

ZIKA VIRUS SCREENING IN THE KENYAN OLYMPIC TEAM ATTENDING THE 2016 OLYMPIC GAMES IN BRAZIL

Josphat N. Nyataya, John Waitumbi, Neha Buddhdev, George Awinda, Lucy Kanyara, Zephania Irura, Limbaso Konongoi, Victor Ofula, Rosemary Sang

Kenya Medical Research Institute/Medical Research Unit, Kisumu, Kenya

The 2016 Olympic Games happened at the time of heightened fears of Zika virus (ZIKV) that was causing microcephaly in newborns in Brazil. To avert or track introduction of ZIKV in Kenya, the Ministry of Health developed a public health response that involved screening of the Kenyan contingent before and after traveling to Brazil. Of the 92 team members that were screened, all but one tested negative for ZIKV IgM and IgG. The sero-positive individual had high IgM serum titers before and after travel to Brazil. When tested for potential antibody cross-reactivity to other flaviviruses that have been reported in Kenya, the sample showed high IgM cross-reactivity to West Nile, Tick-Borne Encephalitis and Yellow Fever Virus. Our data supports the low risk predictions of acquiring ZIKV that were made before the Games and will help inform risk assessments for U.S. military personnel traveling to endemic regions under similar circumstances in the future.

207

ZIKA VIRUS UPREGULATES INTERFERONS AND PRO-INFLAMMATORY CYTOKINES IN HUMAN PROSTATE CELLS

Jennifer L. Clinton, Linda L. Tran, Megan B. Vogt, David R. Rowley, Jason T. Kimata, Rebecca R. Rico-Hesse

Baylor College of Medicine, Houston, TX, United States

Zika virus (ZIKV) is an ssRNA Flavivirus, traditionally known to cause Zika fever but recently linked to Guillain-Barré Syndrome and microcephaly. While ZIKV is typically transmitted by *Aedes* species mosquitoes, sexual transmission has also been reported. Secreted ZIKV RNA has been detected in the semen of infected males up to 6 months after initial infection, suggesting that the virus may persist in the urogenital tract and be sexually transmitted for an extended period of time. However, little is known about ZIKV persistence mechanisms that may mediate long-term urogenital tract replication and delayed sexual transmission. We recently demonstrated ZIKV tropism in human prostate cells using three contemporary ZIKV clinical isolates (FLA, FLR, and HN16). Currently, we are investigating the cytokine profiles produced by ZIKV infection of human prostate stromal mesenchymal stem cells (MSCs) and prostate epithelial cells with three ZIKV isolates as compared to dengue virus (DENV). The concentrations of various cytokines were determined by using multiplex immunoassays. Our results show that each ZIKV isolate elicits distinct cytokine profiles in infected MSCs and these are also different from the DENV cytokine profile. Furthermore, the data show an increase in pro-inflammatory cytokines, such as IL-1a, RANTES and MCP-3 in ZIKV-infected MSCs, as well as increased type II interferon and related proteins (IFNg and IP-10). These are consistent with published data showing upregulation of type II interferons promoting ZIKV replication in glioblastoma and placental cells. The results point to an upregulation of specific cytokines and IFNs associated with viral persistence in the urogenital tract, possibly contributing to the long-term presence of ZIKV in semen. Future studies will address the mechanism by which ZIKV upregulates specific cytokines in human prostate cells

and what contributes to the differential cytokine profiles among isolates. Assessing ZIKV urogenital tract tropism and elucidating viral persistence strategies will help develop appropriate treatments or prophylactics to prevent sexual transmission.

A MULTI-COUNTRY EVALUATION OF DIAGNOSTIC ASSAYS FOR ZIKA INFECTIONS AND ACUTE FEBRILE ILLNESS

Barry Fields[1], Jie Liu[2], Govindakarnavar Arunkumar[3], Nicholas Schaad[1], Xiaopong Qi[4], Pongpun Sawatwong[5], Eric Osoro[6], Jaques Boncy[7], Anthony Luyai[1], Maria Renee Lopez[8], Olga Henao[1], Sima Rama[9], Zhonghua Yang[10], Saithip Bhengrisi[5], Eric Ngeno[6], Ito Journel[7], Santhosha Devadiga[3], Doris Marwanga[11], Jennifer Verani[12], Patrick Dely[7], Godfrey Bigogo[13], Sanjay Ramachandran[3], Darwin Operario[2], Derrick Amon[11], Jean Gratz[2], Gersard Joseph[7], Robin S[3], Mohan Papanna[14], Changwen Ke[15], Melvin Ochieng[11], Jocelyne Andre Alboth[7], Yuzhi Zhang[16], Shuyu Wu[16], Mayer Antoine[17], Stanley Juin[17], Maria Beatriz Lopez Castellanos[18], Joseph Bryan[18], Hoda Mansour[19], Hanaa Abo ElSoud[20], Elizabeth Hunsperger[12], Jeanette Rainey[16], Toni Whistler[5], Kayla Laserson[14], Eric Houpt[2], Joel Montgomery[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]University of Virginia, Charlottesville, VA, United States, [3]Manipal University, Manipal, India, [4]China CDC, Beijing, China, [5]Thailand MOPH-US CDC Collaboration, Bangkok, Thailand, [6]Washington State University, Nairobi, Kenya, [7]Ministère de la Santé Publique et de la Population, Port au Prince, Haiti, [8]Universidad Del Valle de Guatemala, Guatemala City, Guatemala, [9]Northrup Grumman Corporation, Atlanta, GA, United States, [10]Yunnan Institutes of Parasitic Diseases, Yunnan, China, [11]Kenya Medical Research Institute, Nairobi, Kenya, [12]Centers for Disease Control and Prevention Kenya, Nairobi, Kenya, [13]Kenya Medical Research Institute, Kisumu, Kenya, [14]Centers for Disease Control and Prevention India, New Delhi, India, [15]Guangdong Provincial CDC, Guangdong, China, [16]Centers for Disease Control and Prevention China, Beijing, China, [17]Centers for Disease Control and Prevention Haiti, Port au Prince, Haiti, [18]Centers for Disease Control and Prevention Guatemala, Guatemala City, Guatemala, [19]Training Programs in Epidemiology and Public Health Interventions Network, Cairo, Egypt, [20]Ministry of Health and Population, Cairo, Egypt

Acute febrile illness (AFI) can be caused by a wide variety of viral, bacterial, or parasitic infections and is an important cause of morbidity and mortality worldwide. The frequency and underlying etiology of AFI varies geographically as well as seasonally and can be influenced by a number of factors including the use of vaccines, environmental or land use changes, urbanization and economic development. We initiated a study combining enhanced case finding, Zika virus testing, and evaluation of multiple diagnostic assays through surveillance platforms in nine countries. The information collected is being used to evaluate the utility of a TaqMan Array Card (TAC) designed to detect 31 viral, bacterial and parasitic pathogens associated with AFI. Individual targets on the TAC assay are being compared with either, an individual Zika PCR assay, or the CDC Trioplex (Zika, dengue, chikungunya) PCR assay as the standard of practice. In addition, a ChemBio Dual Path Platform (DPP) Zika/chikungunya/dengue IgM/IgG lateral flow assay is being evaluated against several ELISA assays designed to identify Zika virus infections. This study is being conducted in Guatemala, Haiti, Peru, Egypt, Kenya, China, India, and Thailand. Each country will enroll 700 patients with some countries also enrolling asymptomatic controls. Preliminary data from 5 countries indicate that the most frequently detected pathogens by TAC are dengue virus, *Plasmodium* spp., *Orientia tustsugamushi*, *Coxiella burnettii*, *Rickettsia* spp., *Salmonella* spp., and *Brucella* spp., in descending order. In addition, the lateral flow serologic assay data suggest considerable IgG cross-reactivity between Zika and dengue antigens. However, this cross-reactivity is lower with the IgM assay and may indicate an increased predictive value. This study will identify priority pathogens associated with AFI in regions of the Americas, Africa, and Asia and will provide insight regarding the utility of diagnostics for the detection of Zika virus and other etiologies of AFI.

209

ZIKA VIRUS IN LONG-TAILED MACAQUES, PENINSULAR MALAYSIA

Chong-Long Chua[1], Frankie Thomas Sitam[2], Yoke Fun Chan[1], Eva S.G. Soh Andu[1], Jeffrine J. Rovie-Ryan[2], Khebir Verasahib[3], I-Ching Sam[1]

[1]University of Malaya, Kuala Lumpur, Malaysia, [2]Department of Wildlife and National Parks Peninsular Malaysia, Kuala Lumpur, Malaysia, [3]National Public Health Laboratory, Sungai Buloh, Malaysia

Zika virus (ZIKV) has reemerged from Asia to cause recent unprecedented outbreaks in the Pacific and the Americas. Non-human primates (NHPs) are suspected to be animal reservoirs of ZIKV in Africa, but little is known of their role in maintaining a sylvatic cycle in Asia. We evaluated ZIKV prevalence in long-tailed macaques (*Macaca fascicularis*), the most common macaque species in Peninsular Malaysia. Serum samples were collected from 234 long-tailed macaques trapped at > 30 sites in the states of Selangor, Negeri Sembilan, Perak, Pahang, Penang and Johor. These comprised 145 samples collected in October - November 2009 and October 2010, and 89 collected in March and August 2016, which coincided with the ZIKV global epidemics, giving a total of 234 samples. None of the samples were positive for ZIKV RNA. Samples were tested for ZIKV neutralizing antibodies by plaque reduction neutralization test (PRNT) on Vero cells. Those with screening ZIKV $PRNT_{50}$ titers ≥20 were confirmed with Zika focus reduction neutralization test (FRNT), and also tested for potentially cross-reacting dengue virus serotype 1 and 2 antibodies by FRNT. A total of 6/234 (2.6%) had ZIKV neutralizing antibodies, and 3 of these had no detectable dengue antibodies, giving a final ZIKV seroprevalence of at least 3/234 (1.3%). Wild long-tailed macaques are exposed to ZIKV, but the low prevalence suggests that they are unlikely to be significant animal reservoirs in Malaysia, with the caveat that the long-term dynamics of ZIKV antibodies and infection in macaques is not known. This reinforces the need for study of other NHPs and mammals as reservoirs of ZIKV in Malaysia, to understand its transmission and mitigate future emergence.

GENETIC DIVERSITY OF THE YOKOSE VIRUS, XYBX1332, ISOLATED FROM BATS (*MYOTIS DAUBENTONII*) IN CHINA

Feng Yun, Zhang Hailin, Yang Weihong, Zhang Yuzhen

Yunnan Institute of Endemic Diseases Control and Prevention, Dali City,Yunnan province, China

A virus (XYBX1332) was isolated from serum specimens of *Myotis daubentonii* (order Chiroptera, family Vespertilionidae) collected in a cave located in the south of China. The virus was shown to have cytopathic effects in mammalian cells (BHK-21 and Vero E6). Genome sequencing indicated that it has a single open reading frame (ORF), with a genome of 10,785 nucleotides in total. Phylogenetic analysis of the viral genome suggests that XYBX1332 is a Yokose virus (YOKV) of the genus *Flavivirus*. Nucleotide and amino acid homology levels of the ORF of XYBX1332 and Oita-36, the original strain of YOKV, were 72% and 82%, respectively. The ORFs of XYBX1332 and Oita-36 encode 3422 and 3425 amino acids, respectively. In addition, the non-coding regions (5′- and 3′-untranslated regions [UTRs]) of these two strains differ in length and the homology of the 5′- and 3′-UTRs was 81.5% and 78.3%, respectively. Serological detection revealed that XYBX1332 exhibits a neutralizing antibody cross-reaction with Japanese encephalitis virus (P3), but not with yellow fever virus (YFV-17D). The isolation of YOKV (XYBX1332) from inland China thousands of kilometers from Yokosuka, Japan, suggests that the geographical distribution of YOKV is not limited to the Pacific islands and that it can also exist in the inland areas of Asia. However, there are large differences between the Chinese and Japanese YOKV strains, in both viral genome and antigenicity.

MAPPING ZOONOTIC SPILLOVER AND URBAN TRANSMISSION TO ESTIMATE YELLOW FEVER VACCINATION IMPACT

Alex Perkins, Rachel Oidtman, Amir Siraj, Sean Moore

University of Notre Dame, Notre Dame, IN, United States

Although there is an effective vaccine for yellow fever (YF), there is growing concern about the potential for large urban outbreaks due to increased urban growth in close proximity to zoonotic transmission and continued expansion of the *Aedes aegypti* mosquito that vectors YF virus (YFV). Efforts to inform YF vaccination through transmission mapping have not distinguished between transmission with zoonotic versus urban origins. We developed a probabilistic framework for disentangling the contributions of these distinct transmission cycles to YF incidence, fitting a combined model of zoonotic spillover and urban transmission to 1,134 YF cases from South America in 2000-2014. Calibrating our model under the assumption that 26.4% (95% CI: 23.0-30.1) of these cases were urban based on their occupations, we estimated rates of zoonotic spillover that, compared to a baseline with no allowance for urban transmission, were lower in areas estimated to have high potential for urban transmission. Disentangling zoonotic and urban components of transmission enabled us to calculate location-specific probabilities of a large urban outbreak, which vaccination reduced by 72.33% (95% CI: 20.86-99.97) on average under three different scenarios about vaccination coverage.

The full spectrum of long-term complications of Zika virus (ZIKV) infection has not been thoroughly described, especially among children without clinical evidence of congenital Zika syndrome at birth, and among children born to ZIKV infected but asymptomatic mothers. We are currently conducting a prospective pregnancy cohort study in Honduras that will allow us to study ZIKV infection in a different context than South American countries. Enrollment in the cohort is ongoing in one health center. Women are enrolled at their first prenatal visit. Data on socio-demographics, ZIKV symptoms during pregnancy, and information to locate women for additional follow-up are collected through interview at enrollment. Maternal blood is collected immediately after enrollment and tested for ZIKV immunoglobulin M (IgM) by enzyme-linked immunosorbent assay (InBios, Seattle, WA). We plan to conduct ZIKV and dengue virus polymerase chain reaction testing. We expect more than 90% of the women to deliver in one of two public hospitals in Tegucigalpa. Longitudinal follow-up will be conducted for children of women with positive ZIKV IgM and a comparison group of children born to women with no evidence of ZIKV infection at enrollment. Neurodevelopment will be assessed with Bayley Scales of Infant and Toddler Development, 3rd edition. From July 2016 to February 2018, we have enrolled 2,143 women at their first prenatal visit. Gestational age at enrollment was <14 weeks for 56.9% of the cohort, 14-28 weeks for 25.2%, and > 28 weeks for 17.9%. Thirty-seven women (1.7%) were symptomatic at enrollment. About half of the enrolled participants have already delivered. Analyses of birth outcome data are ongoing. This study will allow us to better understand the longer-term outcomes of children exposed to ZIKV during pregnancy.

213

GLOBAL RISK ASSESSMENT OF TRAVEL-RELATED YELLOW FEVER SPREAD: A SYSTEMATIC REVIEW

Janaina Figueiredo, Jose Moreira, Patricia Brasil, Andre Siqueira

Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil

Yellow fever (YF) virus is a flavivirus endemic to sub-Saharan Africa and tropical South America. However, due to a rapid increase in trade and travel volume globally, there is an increased risk of importation of YF to non-endemic areas. We systematically review data from travel-associated YF to help estimate the international risk of YF spread into non-endemic areas. PubMed, ProMed, and online repositories from the European Centre for Disease Prevention and Control and the World Health Organization databases were searched from inception to March 2018. We included all reports describing travel-related YF acquired in endemic countries. Variables of interest were extracted and plotted in Tableau software. We identified 497 unique publications and included 25. Between 1924 and 2018, 38 travel-associated YF cases have been reported. European and non-European-travelers accounted for 16 (42.1%) and 22 (57.9%) of the subjects, respectively. The countries that reported the most cases of imported YF cases were China (28.9%), USA (13.2%) and France (13.2%). Forty-two percent of the importation countries had competent YF vectors, but autochthonous YF transmission in the non-endemic area did not occur. Travelers acquired the disease in South America (56.8%) and Africa (42.2%). Brazil (38.9%), Angola (30.6%), Peru (8.3%), and Senegal (5.6%) were the countries most visited among travelers where YF was acquired. The traveler's mean age was 39.4 ± 12.4 years, and males predominated (76.7%). All except two (5.3%) were unvaccinated. YF was diagnosed with molecular assays (48.1%), a combination of assays (37%), and serology (7.4%). Hospitalization data was available for 32 (84.2%) cases, and of those 31 (96.9%) were admitted and 7 (58.3%) went to ICU care. Fifteen (48.4%) patients died from their illness. In conclusion, non-immunized travelers are at-risk of YF complications and capable of seeding local transmission in their countries. There is an urgent need to reinforce the implementation of YF vaccination in travelers visiting high-risk areas.

214

AEDES AEGYPTI SALIVA PROTEIN INTERACTIONS WITH ZIKA VIRUS AND THEIR ROLE IN MAMMALIAN INFECTION

Sultan Asad, Fabiana Feitosa-Suntheimer, Alexander Gold, Tonya M. Colpitts

Boston University School of Medicine, Boston, MA, United States

Aedes aegypti is the primary vector of several flaviviruses including Zika virus. Zika virus-mediated vertical transmission and its association with nervous system disorders like microcephaly in infants prompted the World Health Organization to declare this correlation and potential complication a public health emergency. Zika virus is usually transmitted to human beings in saliva injected by the female *A. aegypti* during blood feeding. The saliva of mosquitoes represents a repertoire of factors including proteins, miRNAs and other biomolecules that are critical in establishing infection of arboviruses along with modulation of host homeostasis and immune response. In this study, we have collected the saliva form sugar and blood fed mosquitoes, performed binding assays with Zika virus and used liquid chromatography with mass spectrometry (LC+MS/MS) to identify interacting partners. Subsequent analysis and experimentation were done to elucidate the role of these mosquito saliva proteins during transmission and infection of Zika virus to mammalian cells. In addition, though studies have been carried out to highlight importance of mosquito salivary proteins, the limitation in most of those studies is the use of salivary gland extracts (SGE) for analysis rather than saliva. Our analysis allows for identification of unique peptides that belong to different functional groups in mosquito saliva. Furthermore, we have fractionated the saliva using reverse phase liquid chromatography and checked the effects of different saliva fractions on Zika virus infection and replication in mammalian cells. The outcome of this study informs the field on *A. aegypti* secretory proteins and an insight into their role in the infection of Zika virus.

215

NEURODEVELOPMENTAL DELAYS ARISING FROM *IN UTERO* EXPOSURE TO ZIKA VIRUS IN SALVADOR, BRAZIL

Adriana V. Faiçal[1], Juliana M. de Oliveira[2], Breno L. de Almeida[2], Emila K. Leão[1], João V. Oliveira[2], Iluska Andrade[1], Maria B. Cabral[3], Nelfa S. Ferreira[2], Lucas O. Reis[2], Cristina Salles[1], Bernardo G. Costa[2], Marcus V. Francisco[2], Cleiton S. Santos[2], Erica D'Agostinho[3], Maria I. Vianna[3], Alan O. Duarte[2], Angelina X. Acosta[1], **Isadora C. de Siqueira**[2]

[1]Universidade Federal da Bahia, Salvador, Brazil, [2]Instituto Gonçalo Moniz-Fiocruz, Salvador, Brazil, [3]Faculdade de Odontologia - Universidade Federal da Bahia, Salvador, Brazil

Since 2015, Brazil has experienced an unprecedented Zika virus outbreak. A devastating consequence of this viral infection is congenital Zika infection (CZI), which is transmitted from pregnant women to newborns. Most descriptions and publications regarding CZI focus on the clinical presentation of newborns and infants with microcephaly. Scarce information is available concerning children without microcephaly born from infected mothers. During 2016, a cross-sectional study enrolled 147 pregnant women who reported an exanthematous disease during the pregnancy. Of these, 101 (68.7%) presented anti-Zika IgG antibodies at the time of delivery. A total of 25 (17%) newborns were diagnosed with microcephaly, while and 122 (83%) were classified as newborns without microcephaly, of these, 91 had positive Zika serology or Zika RT-PCR. In June 2017, we began a prospective follow-up of these infants without microcephaly by evaluating neurodevelopment delays, performing neurological examinations and applying the Bayley Scales of Infant Development III (BSID-III). Auditory evaluations were performed with by Otoacustic emissions (OAE) and Brainstem Auditory Evoked Potential (BAEP). To date, we have evaluated 26 infants. Of these, 53.8% are male and the mean age is 1.7 years. Anti-Zika IgG serology was positive in 77% and five (19.2%) presented positivity for Zika by PCR on samples within 24h of birth. Based on head circumference (HC) at the time of birth, all were classified as normal by the Intergrowth scale and currently fall within normal HC percentiles. Cognitive delay was identified in 8 (31%) infants, language delay in 11 (42.3%) and motor delay in three (11.5%). Our preliminary results indicate that *in utero* exposure to Zika virus could be associated with neurodevelopmental delay, even in children born without microcephaly. Currently, only microcephalic newborns are referred to specialized care, while normocephalic children are maintained in primary health care. We believe that all newborns exposed to Zika *in utero* should be referred to specialized centers for the early detection of neurodevelopmental delays and timely intervention.

216

SERIAL PASSAGING OF ZIKA VIRUS RESULTS IN ENHANCED REPLICATION IN *CULEX* CELLS

Claudia Rückert, Alexis Robison, Jasmine Donkoh, Gregory D. Ebel

Colorado State University, Fort Collins, CO, United States

Zika virus (ZIKV) is a flavivirus that is mainly transmitted by *Aedes aegypti* mosquitoes, which are largely anthropophilic. However, the recent ZIKV outbreak in the Americas has stimulated discussion about the role of other mosquito species in transmission. Other Aedes sp. mosquitoes, such as *Ae. albopictus* and *Ae. vexans* are also competent vectors. The role of *Culex* spp. mosquitoes in ZIKV transmission, however, remains controversial. We previously found that the Puerto Rican ZIKV isolate (PRVABC59) does not efficiently infect colonized *Cx. quinquefasciatus*, *Cx. pipiens* or *Cx. tarsalis* mosquitoes, yet other studies have suggested that *Cx.* spp. mosquitoes may be competent vectors. ZIKV infection of *Culex* mosquitoes may thus depend on the specific mosquito population, the virus isolate or other complex environmental factors. In this study, we aimed to understand whether specific adaptive mutations allow ZIKV to infect and replicate to higher levels in *Cx. tarsalis* cells. We co-cultured susceptible *Ae. aegypti* cells (Aag2) and somewhat refractory *Cx. tarsalis* cells (Chao Ball) at a ratio of 9:1 and infected the triplicate co-cultures with ZIKV (PRVABC59) at MOI 1. After 6 days, we collected supernatant and used 500µl to infect new co-cultures (retaining triplicate passage lineages). We passaged the virus 18 times on slowly increasing proportions of Chao Ball cells, up to a ratio of 1:9 (Aag2:Chao Ball). We also passaged ZIKV three times on Chao Ball cells without co-culture. We then established growth of the passaged viruses on Chao Ball cells and Aag2 cells. We found that passaging enabled ZIKV to replicate to higher levels in Chao Ball cells compared to our input stock. We sequenced the virus passages and identified mutations associated with passaging. In addition, we propagated the passaged ZIKV on Vero cells and determined vector competence of *Culex* spp. mosquitoes to this stock. In conclusion, we have characterized mutations in ZIKV associated with passaging in *Culex* cells and how they impact infectivity of *Culex* mosquitoes.

Zika virus (ZIKV) was first discovered in 1947 in Uganda, but was not considered a public health threat until 2007 when it was found to be the cause of outbreaks in Asia. ZIKV spread to Brazil in 2014, and continues to spread in tropical and subtropical regions of the Americas, where *Aedes aegypti* mosquitoes are abundant. Despite being a zoonotic disease, there is little information about potential sylvatic vectors and animal amplifying hosts nor their role in virus maintenance and transmission. The role of other mosquito species as ZIKV vector, is also unclear. Recent evidence also suggests sylvatic non-human primates have also been exposed to ZIKV in the Americas. We conducted active surveillance for ZIKV among native primates, other non-human vertebrates, and mosquitoes in established field sites, in Mato Grosso (MT) and Mato Grosso do Sul (MS) states in the West-Central region of Brazil, where recent or active ZIKV transmission in humans has been documented. We collected samples during 4 periods from March 2017 to March 2018. Trapping efforts focused on wildlife, mosquitoes, and domestic animals from urban parks and surroundings areas of Cuiabá (MT) and Campo Grande (MS). We collected samples from more than 2000 vertebrates and 12.000 mosquitoes. Whole blood and mosquito samples are being screened for ZIKV RNA, by generic flavivirus real time RT-PCR, and will be confirmed by a ZIKV specific RT-PCR. Plasma samples are being screened and will be confirmed for presence of anti-ZIKV antibodies by neutralization tests. Preliminary serological testing results show that from 759 animal plasma tested, 68 (9%) neutralized ZIKV (ES2916/2015) isolated from human in Espírito Santo state, Brazil. The results of this study will lead to a better understanding of ZIKV's ability to establish a sylvatic cycle outside of human transmission, thus providing essential information for future surveillance and public health intervention efforts.

GENETIC ANALYSIS OF ZIKA VIRUS INFECTIONS FROM AUTOCHTHONOUS TRANSMISSION IN THE PHILIPPINES, 2016-2017

Ava Kristy Sy, **Mary Ann U. Igoy**, Kristine Joy Privaldos

Research Institute for Tropical Medicine, Alabang, Muntinlupa, Metro Manila, Philippines

Zika virus is an emerging arbovirus known to circulate in Africa and South East Asia. In 2015, it was detected in Brazil causing serious birth defects in infants born to infected mothers. This prompted the World Health Organization to declare Zika virus disease as a global public health emergency. In the Philippines, genetic analysis of Zika virus was limited only in the isolated Zika case in 2012. This report presents a comprehensive phylogenetic analysis of Philippine strains after the outbreak in Brazil. A surveillance was initiated in 2016. Serum and urine samples from patients with fever and/or rash were sent to the Research Institute for Tropical Medicine to detect Zika by Real-time RT-PCR and antibody testing. The envelope (1,512nt) gene was amplified by two-step RT-PCR, followed by direct Sanger sequencing. Maximum likelihood phylogenetic analysis was done in MEGA 6 using the General Time Reversible +G model with 1,000 bootstrap replicates. A total of 3,365 samples were tested with Zika RNA detected in 60 (1.78%) samples, of which 21 samples (35%) were sequenced. All Philippine isolates were clustered into the Asian genotype with high similarity to the 2007 Micronesia strain. Likewise, the current Philippine strains have high homology with the reported Zika case in 2012. Analysis of the E gene revealed presence of F279S substitution that might cause virus resistance to neutralizing antibody. Phylogenetic analysis suggests that Zika virus may have been circulating in the country but remained underreported despite the abundance of competent vectors. The data from our study strengthen the hypothesis that Zika virus infections in the country result from autochthonous transmission. Sequencing analysis of Philippine isolates with reference sequence and 4 Brazilian sequences showed that both strains have same F279S substitution. Our findings improved the knowledge on Zika virus strain in the country. The high homology of Philippine sequences with the Micronesia strain that caused outbreaks in the past and the detection of F279S substitution warrant the need for intensifying surveillance and control measures to prevent virus transmission.

OPTIMIZATION OF QUANTITATIVE RT-PCR PROTOCOL FOR ZIKA VIRUS DETECTION IN LOW VIRAL SAMPLE CONCENTRATIONS

Alejandra Garcia Glaessner, Mariana Leguia

Pontificia Universidad Catolica del Peru, Lima, Peru

The 2015 Zika virus (ZIKV) outbreak in Brazil generated increased demand for sensitive molecular diagnostics to detect the presence of ZIKV in various patients. Most of the ZIKV diagnostics to date have been carried out using two qRT-PCR assays developed by Faye et al. and by Lanciotti et al. specifically for this purpose. These protocols use primer sets that target different regions of the ZIKV genome with enough specificity to use them as diagnostic tools. However, the sensitivity of both assays is lower than would be ideal, and in many cases ZIKV cannot be correctly diagnosed if present at low levels (CT values of up to 30). We have developed an improved protocol using optimized primer sets that can detect ZIKV at previously "undiagnosable" low levels (CT values as high as 34). Our efforts focused on the optimization of important primer parameters like primer length, annealing temperature, and GC content. Primers were tested using ZIKV samples of various concentrations and we show that samples that were previously considered false-negatives can give a positive result using our optimized conditions. This assay should address the issue of increased false-negative results during ZIKV diagnostics, and will be a useful tool for healthcare providers interested in a fast, rapid, and sensitive assay for clinical evaluation and diagnostics of ZIKV in samples of low viral concentrations.

220

THE EFFECTS OF MOSQUITO MICROBIOTA ON ZIKV INFECTION AND TRANSMISSION IN *AEDES AEGYPTI*

Sherry L. Haller, Miguel A. Saldana, Shivanand Hegde, Christopher M. Roundy, Scott C. Weaver, Grant L. Hughes

University of Texas Medical Branch, Galveston, TX, United States

The microbiome of mosquitoes is known to impact their susceptibility to infection and their ability to transmit viral pathogens. *Aedes aegypti* mosquitoes are competent vectors of several viruses including dengue virus and Zika virus (ZIKV). Previous work has shown that specific bacteria isolated from mosquito vectors have the potential to reduce their susceptibility to infection by dengue virus through activation of host immune genes. Our studies aim to determine whether the resident microbiome of *A. aegypti* mosquitoes also impacted transmissibility of ZIKV, a medically important virus that has been linked to severe congenital syndromes including microcephaly in newborns and Guillain-Barre syndrome in adults. To test our hypothesis, we cleared the microbiome of lab reared *A. aegypti* mosquitoes collected from the Rio Grande Valley with oral antibiotic treatments and challenged with an American ZIKV strain (PRV-ABC059) after confirming the reduction of resident microbiome. We then compared viral infectivity, dissemination and transmissibility rates with untreated cohorts. Culture dependent and independent approaches were used to quantify the microbial load in antibiotic treated and untreated mosquitoes. In addition we screened a panel of immune-regulatory genes

by qRT-PCR to assess differences in the immune activation status between both groups. Vector competence for emerging and re-emerging viruses is shaped in part by a combination of environmental, genetic and microbial factors. Characterizing the influence of microbiota on ZIKV infection and transmission by its primary mosquito vector and understanding its ability to influence disease dynamics in the America's is critical for determining whether microbes may be harnessed to control the disease's potential spread.

221

CAN THE HOST DENSITY RESCUE THE VIRAL TRANSMISSION? EFFECTS OF THE AVIAN-MOSQUITO COMMUNITIES ON THE ST. LOUIS ENCEPHALITIS VIRUS ACTIVITY

Agustín I. Quaglia, Guillermo Allbrieu Llinás, Marta S. Contigiani, **Adrian Diaz**

Instituto de Virología, Córdoba, Argentina

Arbovirus represents an ecological clustered of arthropod borne viruses. They depend of the interaction among vectors and hosts, and those might be driven by the variations at community, population and individuals vector-host level. Dilution effects predicts an scenario, where the transmission risk, on multi-host systems, is reduced as host diversity increases. Here, we focused on the effects of the structure and composition of the avian-mosquito community on the activity of St. Louis encephalitis virus (SLEV, Flavivirus). Avian and mosquito communities and the frequency of SLEV infection in *Culex* mosquitoes were prospected during three transmission seasons across the periurban-urban landscape in Cordoba city, central area of Argentina. Hypothesis related at community structure and density avian-mosquito level were represented and analyzed by general linear mixed models, when environmental and temporal viral activity heterogeneity were explicitly considered. Then, models performance were ranked following the Information Theory framework. The presence and the transmission of SLEV were not explained by neither of the diversity measures explored. Although, Eared Dove and mosquito density were related with at least two-folds increases in the number of SLEV infected *Culex.* Dilution effect exerted by biodiversity might not be driving the SLEV activity in the Cordoba city, meanwhile viral trait as the generalist host use could provide resilience to transmission when the composition of host and vector change. Finally, the results support an amplification effect by the density of particular community members on the transmission and amplification of SLEV such as Eared Dove.

222

IN VITRO ACTIVITY OF A 2'-C-METHYLURIDINE PROTIDE AGAINST THE ZIKA VIRUS

Jean A. Bernatchez[1], Michael Coste[2], Grace A. Wells[2], Zhe Zhu[1], Sungjun Beck[1], Alex E. Clark[1], Christal D. Sohl[2], Byron W. Purse[2], Jair L. Siqueira-Neto[1]

[1]University of California, San Diego, San Diego, CA, United States, [2]San Diego State University, San Diego, CA, United States

The Zika virus (ZIKV) has been demonstrated to cause the development of microcephaly in newborns and has been linked to Guillain-Barré syndrome in adults; ZIKV remains a significant arboviral threat to world health, as there are no approved treatments for the infection and a new outbreak is likely to happen in the future. Recent reports have shown that sofosbuvir, an FDA-approved nucleoside analogue ProTide used in the treatment of Hepatitis C virus (HCV) infections, has antiviral activity against ZIKV. In this work, we show that the related ProTide of 2'-C-methyluridine has stronger activity (4.2 to 8.5 fold) than sofosbuvir in both neural stem cell and glioblastoma stem cell models of ZIKV infection using phenotypic and cell-viability assays, with selectivity indexes ranging from >4 to 24 for the ProTide of 2'-C-methyluridine for the different assays. Cell imaging reveals that the 2'-C-methyluridine ProTide strongly protects against the virus-induced cytopathic effect (CPE). Using biochemical gel-based assays, we demonstrate that while both the triphosphate form of sofosbuvir and that of 2'-C-methyluridine can act as substrates for the ZIKV NS5 RNA-dependent RNA polymerase, 2'-C-methyluridine triphosphate is better incorporated by the enzyme into RNA under identical conditions. These data suggest that ProTides of 2'-C-methyluridine may represent a new avenue for the development of potent anti-ZIKV compounds.

223

DEVELOPMENT OF A LIVE-ATTENUATED DENV-2-BASED CHIMERIC VACCINE AGAINST ZIKA VIRUS

Claire Y-H Huang[1], Janae Stovall[1], Jill Livengood[2], Whitney Baldwin[1], Holli Giebler[1], Karen Boroughs[1], Michael Egan[2], Hansi Dean[2]

[1]Centers for Disease Control and Prevention, Fort Collins, CO, United States, [2]Takeda Vaccine, Cambridge, MA, United States

The development of a safe and effective Zika virus (ZIKV) vaccine has become a high priority since the widespread epidemic in 2015-16. Here we report the development of a live-attenuated vaccine candidate that invokes a robust immune response and provides full protection against lethal ZIKV challenge in mice following a single immunization. Utilizing the same Dengue virus 2 (DENV-2) PDK-53 vaccine platform that has been used to develop a tetravalent dengue vaccine candidate that is currently in phase 3 trials, we introduced the PrM-E genes of ZIKV to generate chimeric D2/ZK vaccine candidates. In addition, we identified and introduced multiple mutations in the chimeric constructs to improve the fitness and stability of the viruses for efficient growth in Vero cells. We systematically incorporated different combinations of the mutations and have recovered virus from 7 versions of the constructs. Each version was also made in the wild type DENV-2 16681 (parental virus for the PDK-53) backbone for phenotypic comparison. Based on previously established attenuation phenotypes of the DENV-2 PDK-53 vaccine, these chimeric D2/ZK vaccine candidates will be evaluated for plaque phenotype, temperature sensitivity, replication in C6/36 cells, neurovirulence in neonatal mice, and infection/dissemination of mosquitoes. Currently, we have identified multiple chimeric D2/ZK vaccine candidates that were fully attenuated in neonatal mice by direct intracranial inoculation. AG129 mice immunized with one or two doses of the candidates produced high levels of neutralizing antibodies to ZIKV, and were fully protected against lethal ZIKV challenge without any detectable post challenge viremia. In addition, neither a second vaccination nor the wt ZIKV challenge resulted in any further increase in antibody titers acquired after primary immunization, suggesting a single dose was sufficient to induce sterilizing immunity against a lethal ZIKV challenge in AG129 mice.

OVERVIEW OF ZIKA EN EMBARAZADAS Y NIÑOS EN COLOMBIA (ZEN): A PROSPECTIVE COHORT STUDY EXAMINING ZIKA VIRUS INFECTION DURING PREGNANCY AND RISK OF ADVERSE PREGNANCY, BIRTH, AND INFANT OUTCOMES

Veronica Burkel[1], Marcela Mercado[2], Helena M. Rodriguez[2], Diana Valencia[1], Van Tong[1], Maritza González[2], May Bibiana Osorio Merchan[2], Suzanne M. Gilboa[1], Candice Y. Johnson[3], Yamileth Ortiz Gomez[2], Jorge Martín Rodriguez[2], Shin Y. Kim[1], Hernando Miguel Baquero Latorre[4], Elizabeth Ailes[1], Margaret A. Honein[1], Martha Lucía Ospina Martinez[2]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Instituto Nacional de Salud, Bogota, Colombia, [3]National Institute for Occupational Safety and Health (NIOSH), Cincinnati, OH, United States, [4]Universidad del Norte, Barranquilla, Colombia

Since its first case of Zika virus (ZIKV) infection in October 2015, Colombia has reported over 106,000 suspected ZIKV infection cases, including 20,000 pregnant women. ZIKV infection during pregnancy can cause

serious fetal harm, including microcephaly and related brain anomalies. Knowledge gaps remain about the risk associated with ZIKV infection for adverse pregnancy, birth, and infant outcomes. The Colombian INS and U.S. CDC are implementing *Zika en Embarazadas y Niños en Colombia* (ZEN), a prospective cohort study of 1,500 pregnant women, male partners, and their infants in multiple Colombian cities. Pregnant women were enrolled in the first trimester of pregnancy and followed until infants are 6 months old; male partners will be followed through the end of their partner's second trimester. ZEN objectives are: 1) describe sociodemographic and clinical characteristics of the population, 2) identify risk factors for ZIKV infection in pregnant women and their infants, 3) assess the risk for adverse maternal, fetal, and infant outcomes associated with ZIKV infection, and 4) assess modifiers of the risk for adverse outcomes among pregnant women and infants following ZIKV infection. To identify critical windows of infection for adverse outcomes and monitor persistence of ZIKV, sequential ZIKV testing of serum or urine with reverse transcription-polymerase chain reaction (rRT-PCR) will be performed for pregnant women (biweekly until 34 weeks gestation, and monthly until pregnancy end), male partners (monthly until their partner's 27th week of gestation) and infants (biweekly until 6 months of age). Participants are interviewed using structured questionnaires about risk factors for ZIKV infection, symptoms of ZIKV infection, and risk factors for adverse outcomes. Clinical information will be abstracted from medical records of pregnant women and their infants. ZEN enrollment occurred between February 9, 2017 and January 31, 2018. ZEN results will guide recommendations for preventing ZIKV infection, improve counselling of patients about the risks of ZIKV, and help agencies to provide services to affected children and their families.

225

SURVEILLANCE OF MICROCEPHALY AND OTHER CONGENITAL CENTRAL NERVOUS SYSTEM MALFORMATIONS: THE COLOMBIAN EXPERIENCE DURING THE 2015-2016 ZIKA VIRUS EPIDEMIC

Martha L. Ospina[1], Marcela Mercado[1], Romeo Galang[2], Cynthia Moore[2], Maritza Gonzalez[1], Diana Valencia[2], Lilliana Cuevas[1], Oscar Pacheco[1], Antonio Bermudez[1], Van Tong[2], Molly Dominguez[2], Suzanne Gilboa[2], Nataly Rozo[1], **Margaret Honein**[2], Franklyn Prieto[1]

[1]Instituto Nacional de Salud, Bogota, Colombia, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States

The Colombian Instituto Nacional de Salud (INS) has conducted national surveillance of birth defects as part of its SIVIGILA surveillance system. During the 2015-2016 Zika virus (ZIKV) outbreak, INS established an enhanced surveillance protocol to monitor potential increases in microcephaly and other congenital central nervous system (CNS) malformations, to investigate causes, and to direct appropriate follow-up care. SIVIGILA received notification from physicians if microcephaly (head circumference below the 3rd percentile expected for sex and gestational age) or other CNS malformations were diagnosed prenatally. The surveillance protocol required an inpatient neonatal evaluation soon after delivery, including a complete physical and neurological exam, and a head ultrasound. If microcephaly or other CNS malformations were noted, further evaluation was recommended by the protocol. Cases were classified into etiological categories: congenital ZIKV infection, other infectious agents, genetic, multifactorial, additive, and unknown; this classification was based on laboratory evidence and extensive review of the clinical findings from medical records by qualified clinicians. Data reported here are from the implementation of the enhanced protocol to births in 2016. During 2016, SIVIGILA was notified of over 900 cases of microcephaly and other CNS malformations. Based on preliminary analysis, these numbers represent about a 40% increase compared to 2015. Case classification is ongoing. Work is ongoing to review all cases of microcephaly and other congenital CNS malformations reported for 2017. This enhanced surveillance protocol, built on an already existing surveillance platform, serves as a model of a comprehensive approach to investigating complex congenital conditions of unknown etiology and building capacity to detect emerging health public health threats. Adequate identification, notification and classification is essential in order to quantify the number of Zika-associated birth defects, and follow-up care is essential to fully characterize the impact of congenital ZIKV infection during pregnancy.

226

A COMMUNITY INVESTIGATION OF THE YELLOW FEVER OUTBREAK IN SOUTH OMO ZONE, ETHIOPIA, 2012-2014

Ranya Mulchandani[1], Fekadu Massebo[2], Fekadu Bocho[2], Yohannes Negash[3], Claire Jeffries[1], Thomas Walker[1], Louisa Messenger[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Arba Minch University, Arba Minch, Ethiopia, [3]Public Health Emergency Management, Jinka, South Omo Zone, Ethiopia

Yellow Fever (YF) remains an important public health problem across Africa and South America due to its high case-fatality rate. A YF outbreak occurred in South Omo Region, Ethiopia in 2012-2014. This study aimed to analyse historical outbreak data and identify the local *Aedes* vector species, to assess the risk for future YF transmission. From October 2012 to March 2014, 165 cases and 62 deaths were reported, principally in the rural areas of South Ari region (83.6%), south-west Ethiopia. The overall male to female case ratio was 1.4:1. The majority of patients were 15-44 years old (74.5%) and most case deaths were males (76%). In 2014, the Ministry of Health organised a reactive vaccination campaign with a reported coverage of 89%. Between June and August 2017, 688 containers were sampled from across 177 households to identify the key breeding sites for *Aedes* mosquitoes. *Ensete ventricosum* ("false banana") was identified as the primary natural breeding site, and clay pots outside the home as the most productive artificial breeding site. Entomological risk indices from the majority of sites were classified as "high risk" for future outbreaks under current WHO criteria. Of the five villages surveyed, Shepi village had the highest traditional indices with House Index (HI) – 79; Container Index (CI) – 57.9; and Breteau Index (BI) – 237.2. Adult trapping resulted in the identification of members of the *Aedes simpsoni* complex. Molecular arbovirus testing of adult vector specimens found no active presence of YF or other arboviruses. In addition, a Knowledge, Attitude and Practices (KAP) survey was conducted to understand local knowledge levels following this re-emergence of YF. 87.8% of 177 participants had heard of YF, however many participants easily confused transmission and symptoms of YF with malaria, which is also endemic in the area. Significant predictors for KAP score included household location and prior vaccination history. Study results emphasis the need to strengthen local disease surveillance systems and in-country laboratory capacity to facilitate rapid responses to future outbreaks.

227

LOW ZIKA VIRUS SEROPREVALENCE IN KUALA LUMPUR, MALAYSIA

Magelda Montoya[1], Chong Long Chua[2], Yoke Fun Chan[2], Andrew Pastor[1], Eva Harris[1], Jamal I-Ching Sam[2]

[1]Division of Infectious Diseases & Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, [2]Department of Medical Microbiology, Faculty of Medicine, University Malaya, Kuala Lumpur, Malaysia

Zika virus (ZIKV) is an arbovirus that recently caused large epidemics in the Pacific and the Americas. ZIKV was first isolated outside Africa in Malaysian *Aedes aegypti* in 1966. It is unclear why only sporadic cases and a single outbreak (Singapore, 2016) have been reported in Southeast Asia, despite likely endemicity of ZIKV, abundance of *Ae. aegypti*, and recent heightened awareness. We examined if undetected endemic transmission results in high levels of population immunity. We used a Zika NS1 blockade-of-binding (BOB) assay to test 1,086 serum samples

collected in a hospital in Kuala Lumpur, Malaysia, comprising 727 residual diagnostic samples from inpatients and 359 samples from healthy blood donors. Samples were collected in 2012 (before the Pacific outbreaks), August 2014-March 2015 (early stages of the Americas epidemic), and 2017 (after the outbreak in Singapore). Approximately 30 samples were collected for each 10-year age group in each time period from the two populations studied (total n=91-154 per age group). A total of 76/1,086 (7.0%) samples had detectable anti-ZIKV antibodies following duplicate testing. No significant difference in seropositivity between diagnostic and blood bank samples was found; thus, the two populations were combined for further analysis. Seropositivity was not associated with gender or year of collection but was positively correlated with age (odds ratio 1.21 (95% CI 1.08-1.32) for each decade of age, p=0.001). Study limitations include the possibility of cross-reactivity due to other flaviviral infections (although this would lower the ZIKV seroprevalence rate below the 7.0% observed) and possible waning of antibody levels over time, though other studies support stable levels of anti-ZIKV antibodies detected by the Zika NS1 BOB assay over several years. Neutralization assays for DENV1-4 and ZIKV are being performed to confirm the seropositive samples. We conclude that there is low ZIKV seroprevalence in Kuala Lumpur, which thus does not explain the low incidence of Zika cases and outbreaks. Other factors, such as the possible protective effects of prior dengue virus infection, should be explored.

228

FACTORS AFFECTING YIELD DURING THE PRODUCTION OF PURIFIED ZIKA VIRUS

Teresa M. Towle, Jessica Shifflett, Sujatha Rashid

BEI Resources, Manassas, VA, United States

Optimization of virus purification methods is essential for obtaining good virus recovery and ensuring the removal of impurities that may interfere with downstream applications such as vaccine production, diagnostic assay standardization, sequencing, and electron microscopy. While it is well known that loss in virus titer takes place in any purification method, the total virus yield after purification is rarely described, and few studies evaluate the individual steps involved in purification for their capacity to retain infectious virus particles. The multi-step process needed to produce purified virus preparations makes it imperative to examine where virus loss could occur at each step. Here, we describe a method for improving the recovery of infectious Zika virus by determining the optimal conditions for harvest, clarification, precipitation, and purification. For this study, Zika virus was propagated in Vero cells (ATCC® CRL-1586™) under established optimal growth conditions to prevent the formation of defective interfering particles. For harvest, mechanical scraping and pooling the infected monolayer and culture supernatant was compared to freeze-thaw of infected cell pellets, and filter clarification and spin clarification methods were assessed. Finally, precipitation with 10% PEG 6000 or PEG 8000 was evaluated using various treatment methods prior to purification over a sucrose cushion. Sample aliquots were retained after each step in the process and were titrated to quantify the yield of infectious virus particles. The results from these experiments demonstrated that the most important step affecting virus titer was the harvest method. The resulting purified Zika virus from this study is available from BEI Resources as catalog number NR-50684.

229

DENGUE VIRUS CROSS-NEUTRALIZING ANTIBODIES AGAINST ZIKA VIRUS INFECTION

Rungarun Suthangkornkul, Taweewun Hunsawong, Prapapun Ong-ajchaowlerd, Kanittha Sirikajornpan, Butsaya Thaisomboonsuk, Chonticha Klungthong, Kathryn B. Anderson, Alden L Weg, Louis R. Macareo, Damon W. Ellison

U.S. Army Medical Directorate-Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Dengue virus (DENV) and zika virus (ZIKV) are members of the mosquito-borne flaviviridae family that co-circulate in the same regions and impact public health worldwide. The closely related structural proteins, up to 40-50% of amino acid sequence homology between DENV and ZIKV, allow cross-neutralization and infectionenhancement. In this study, the cross-neutralization of DENV antibody against ZIKV infection has been investigated. DENV confirmed cases by serotype (DENV-1 to -4) and immune status (primary and secondary) have been selected (n=5 per group). The cross-neutralization of DENV antibodies against ZIKV infection was done by a flow cytometry-based neutralization assay using human monocyte-derived U937 cells expressDC-SIGN. Cross-neutralization by DENV antibodies was observed in 100% of all secondary DENV and primary DENV-4 infections and 80% for other DENV serotype primary infections. We found that secondary DENV antibodies from secondary infections had significantly (p-value <0.05) higher titer of cross-neutralizing antibodies against ZIKV infection than antibodies from primary DENV infections. We further observed the neutralizing role of DENV IgM and IgG antibodies. It was found that IgM acts in a complimentary manner (p-value >0.05) with IgG against ZIKV infection. We noted that DENV IgG antibodies is the main cross-reactivity antibody for both primary and secondary DENV infections (p-value < 0.05). However, ZIKV neutralizing antibody titers were lower than the homologous DENV serotypes. The results from this study demonstrate the cross-neutralization of DENV antibodies using a flow cytometry-neutralization assay against ZIKV and highlight the need for advanced diagnostics to differentiate between the two different infections.

THE CHANGING TREND OF JAPANESE ENCEPHALITIS VIRUS EPIDEMICS IN CHINA

Huanyu Wang, Fan Li, Shihong Fu, Xiaolong Li, Xiaoyan Gao, Guodong Liang

Chinese Center for Disease Control and Prevention, Beijing, China

Background: Japanese encephalitis (JE) is very prevalent in China. Methods/ Principal Findings: Data on JE in mainland China were collected between 2004 and 2014. We conducted spatial and temporal analyses on data from different age groups. Generally, children aged 0-15 years still represent the major population of JE cases in China, despite the gradual decrease in incidence over years. However, the incidence of JE among adults in several provinces is not ably higher than the national average, especially during the epidemic waves in 2006, 2009 and 2013. Our results indicate that the total number of JE cases in 2013 was significantly higher compared with those in 2011 and 2012. The population aged over 40 years was associated with the greatest increase of JE. JE incidence in the adult group in September and October is significantly greater compared to the other groups. Further analysis using Local Indicators of Spatial Association reveals that the distribution of adult JE cases in the six provinces north of the Yangtze River, between north 30-35°latitude and east 110-130° longitude, is a hotspot for adult JE cases. By the new developed TaqMan Real-time RT-PCR detection system, a total of 3937 batches of mosquitoes collected in nineteen provinces of China between 2004-2016 were detected for Japanese Encephalitis Virus (JEV) and then differentiated for genotype. Two hundred and seventy-five batches were identified as genotype 1 and only one batch were genotype 5. Conclusions/Significance: Unlike the JE epidemics primarily in children below 15 years old in southern China,

a significant outbreak of JE occurred in northern China in 2013, with the older age groups being the primary population affected. Molecular epidemiology of JEV in mosquitoes in China during 2004-2014 discovered that genotype 1 were the predominated strain circulating in China. The increasing incidence of JE in adults has become an important public health issue and poses a new challenge to the successful prevention and control of JE in China as well as other countries in East Asia.

Zika virus (ZIKV) is a mosquito-borne flavivirus mainly transmitted among humans through the bite of infected *Aedes aegypti*. After it was first isolated in Uganda in 1947, ZIKV was shown to circulate in enzootic sylvatic cycles in Africa and Asia but human infections remained sporadic for half a century. The first reported human epidemic caused by ZIKV occurred in 2007 on the Pacific island of Yap in the Federated States of Micronesia. Subsequently, larger ZIKV outbreaks were recorded in French Polynesia and other Southern Pacific islands in 2013-2014. In 2015, ZIKV reached Brazil from where it rapidly spread across South and Central America, infecting millions of people. The emergence of ZIKV caused significant public health concern because of the associated birth defects and neurological complications that have been observed since 2013. Until now, the factors that have fueled the explosiveness and magnitude of ZIKV emergence in the Pacific and the Americas are still largely unknown. Another unresolved question is the lack of major human epidemic of ZIKV in Africa despite seemingly favorable conditions. In order to evaluate the potential role of vector population diversity in the recent patterns of ZIKV emergence, we conducted the first worldwide survey of *Aedes aegypti* susceptibility for ZIKV in natural populations. We established dose-response curves for 8 field-derived mosquito populations spanning the entire geographical distribution of the species, following experimental exposure to 6 ZIKV strains representing the current extent of viral genetic diversity. Our data show that susceptibility to ZIKV infection varies substantially across mosquito populations, ZIKV strains, and their specific pairings. Most importantly, our results reveal that African *Ae. aegypti* are significantly less susceptible than non-African *Ae. aegypti* across all ZIKV strains tested. Thus, low susceptibility of vector populations may have contributed to prevent large-scale human transmission of ZIKV in Africa.

232

DEVELOPMENT OF A LATERAL FLOW ASSAY (LFA) FOR SIMULTANEOUS DETECTION OF NOROVIRUS FROM GENOGROUPS I, II AND IV

Brianda Barrios-Lopez, Patrick Krause, David Anderson, Kathryn Hjerrild, Jean Chen, Syamal Raychaudhuri

INBIOS International, Seattle, WA, United States

Infection with Norovirus (NoV) is a leading cause of acute gastroenteritis frequently associated with large outbreaks in nursing homes, cruise ships and other institutional facilities. On average 20 million cases of NoV infection are identified in the United States each year. NoV is highly contagious - transmission occurs by the fecal-oral route, mostly person to person, but NoV outbreaks may also be associated with contaminated food or water. The symptoms of nausea, vomiting, acute diarrhea and fever usually resolve within 2-3 days, with a median duration for the illness of 4-6 days. Currently the most sensitive NoV diagnostic tests are based on RT-PCR methodology. However, RT-PCR testing is expensive, requires specialized equipment, and its clinical specificity is often poor. There is thus an urgent need for an inexpensive, rapid, sensitive and specific test for NoV that can be applied in the field to immediately identify NoV as the cause of an outbreak allowing implementation of remedial steps at an early stage. NoV is classified into five genogroups, with most human infections caused by genogroups I, II and, to a lesser extent, IV. These genogroups are subdivided into more than 30 genotypes with genotype GII.4 responsible for the majority of norovirus infections globally. Our objective is to develop a sensitive and specific immunoassay-based LFA to simultaneously detect NoV from genogroups I, II and IV. Test lines were sprayed using a combination of genotype-specific monoclonal antibodies (mAbs) which sandwich NoV Virus Like Particles (VLPs) when used in conjunction with a second set of NoV-specific mAbs conjugated to colloidal gold. Human fecal samples are collected and diluted with running buffer for immediate analysis, or placed in a long-term storage buffer for off-site analysis. When fecal samples are spiked with NoV VLPs of genotypes I, II or IV and spotted onto the test strip positive identification of infection can be determined within 30-minutes with a sensitivity down to 5ng/mL NoV VLP. This is the only NoV LFA test available capable of simultaneous early detection of all three genotypes of NoV that infect humans.

THE 2017 MONKEYPOX OUTBREAK IN NIGERIA -REPORT OF OUTBREAK EXPERIENCE AND RESPONSE IN THE NIGER DELTA UNIVERSITY TEACHING HOSPITAL, BAYELSA STATE, NIGERIA

Dimie Ogoina[1], James Hendricks[1], Neni Aworabhi[2], Adesola F. Yinka-Ogunleye[3], Ebitimitula N. Etebu[2], Wari Numbere[3], Uchenna Uchenna Anebonam[3]

[1]Niger Delta University Teaching Hospital, Yenagoa, Nigeria, [2]Bayelsa State Ministry of Health, Yenagoa, Nigeria, [3]Nigeria Centre of Disease Control, Abuja, Nigeria

After 30 years, Nigeria experienced the first outbreak of human monkeypox beginning in September 2017. We hereby present the outbreak experience and response in the Niger Delta University Teaching Hospital (NDUTH), a tertiary hospital situated in South-South Nigeria where the first case and majority of cases of human monkeypox were treated. This was a mixed model study undertaken between 22nd September and 31st December 2017. We report the plans and activities of the monkeypox response team, the opinions and behaviour of staff during the outbreak and the management of suspected cases and false alarms at the hospital. On 22nd September 2017, an 11-year-old boy was admitted at the NDUTH with generalised papulopustular rashes suggestive of monkeypox. Hospital, state and national authorities were immediately notified. With the support and partnership of the Bayelsa State Ministry of Health and

the Nigerian Centre of Disease Control (NCDC), the hospital provided isolation facilities and resources, organised sensitization and training of staff and designated clinical teams for case management. At the onset of the outbreak, fear of being infected and worries concerning the level of outbreak preparedness of the hospital were reported among staff. There were reported absenteeism, avoidance of isolation facilities and reluctance to participate in case management. However, after repeated sensitization and training, the hospital was able to quickly mobilise a multi-disciplinary team for surveillance and case management. There were more than 18 false alarms and 26 suspected monkeypox cases (18 laboratory confirmed cases) seen at the hospital during the study period. Apart from a case of suicide, all patients made good recovery and were discharged. Our results suggest that outbreak response in hospitals is negatively influenced by fear and limited epidemic preparedness. It however emphasizes the place of proactive leadership, partnership, expertise, training and team work in containing infectious disease outbreaks.

234

ZIKA VIRUS AND THE WORLD HEALTH ORGANIZATION CRITERIA FOR DETERMINING RECENT INFECTION USING PLAQUE REDUCTION NEUTRALIZATION TESTING

Matthew J. Ward[1], Jackeline Alger[2], Mabel Berrueta[3], Harry Bock[4], Pierre Buekens[1], Maria Luisa Cafferata[3], Alvaro Ciganda[3], Jorge García[2], Kimberly García[5], Ivette Lorenzana[5], Wendy Lopez[6], Leda Parham[7], Dawn M. Wesson[1]

[1]Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, [2]Departamento de Laboratorio Clínico, Hospital Escuela Universitario; Instituto de Enfermedades Infecciosas y Parasitología Antonio Vidal, Tegucigalpa, Honduras, [3]Instituto de Efectividad Clínica y Sanitaria, Buenos Aires, Argentina, [4]Región Sanitaria Metropolitana del Distrito Central, Secretaría de Salud de Honduras, Tegucigalpa, Honduras, [5]Instituto de Investigaciones en Microbiología, Centro de Investigaciones Genéticas (CIG), Escuela de Microbiología, UNAH, Tegucigalpa, Honduras, [6]Departamento de Laboratorio Clínico, Hospital Escuela Universitario, Tegucigalpa, Honduras, [7]Instituto de Investigaciones en Microbiología, Centro de Investigaciones Genéticas (CIG), Escuela de Microbiología, UNAH, Tegucigalpa, Honduras

The recent Zika virus (ZIKV) epidemic swept across Latin America and the Caribbean, where dengue virus (DENV) is endemic. The antigenic similarities of these closely related flaviviruses left researchers and clinicians with challenges to interpret serological tests. Thirty-six women attending a prenatal clinic in Honduras and with positive DENV IgM ELISAs were screened with a ZIKV IgM ELISA, RT-PCR for ZIKV and DENV 1 - 4, and plaque reduction neutralization tests (PRNT) for ZIKV and DENV-2. PRNT results were interpreted using the World Health Organization (WHO) and Centers for Disease Control and Prevention (CDC) criteria. Using WHO criteria of a PRNT90 titer ≥ 20 and a four-fold difference between ZIKV and DENV titers, we determined that 83.3% of samples had a recent ZIKV infection, compared to 5.6% using CDC criteria. The interpretation of ZIKV PRNTs in a DENV endemic region is highly dependent on the choice of interpretation criteria.

235

TOTIVIRUSES, PARASITES, AND EVERYTHING ELSE

Ahmad Ali Garziz, Henk R. Braig

Bangor University, Bangor, United Kingdom

Totiviridae are unsegmented, icosahedral dsRNA viruses which display a fascinating diversity of hosts, a disparity of host effects, and a divergence of transmission strategies. Hosts include human parasites like Giardia, plant parasitic oomycetes, fungi and yeasts, red macroalgae (seaweed), terrestrial crustaceans like woodlice, insects like flies, mosquitoes, ants and wasps, marine crustaceans like shrimp, but also fish, fresh water snails that are intermediate hosts to parasites, and plants like papaya, notoginseng, maize, and wild petunias. In Leishmania and Trichomonas, the viruses increase the virulence of the parasites (hypervirulence), while in Victoria blight of oats it reduces the virulence of the fungus (hypovirulence). In salmon, smelt, and shrimp, it causes myocarditis and myonecrosis, in golden shiners it is asymptomatic. In Leishmania and many fungi and some plants, it is non-infectious and vertically transmitted, while in Giardia, fish, shrimps, and papaya, it is horizontally transmitted. Using PCR with degenerate primer sets, we are trying to explore the taxonomic boundaries of the vertically transmitted viruses in parasites to estimate the evolutionary age of first infection, the virulence in Giardia, and the evolutionary origin of dsRNA viruses in arthropods, especially sand flies, which are vectors of Leishmania. In a new development, Leishmania species not infected with totiviruses show an infection with Narnaviruses. Both viruses are vertically transmitted. The original concept that the Leishmania clade has only been infected once and subsequently lost the infection in several lineages has been challenged with these new discoveries.

236

EXTENSIVE SEROLOGICAL SURVEY FOR MULTIPLE SPECIES OF EBOLA VIRUSES IN A WIDE DIVERSITY OF BAT SPECIES IN GUINEA, CAMEROON AND THE DEMOCRATIC REPUBLIC OF CONGO

Placide K. Mbala

Institut National de Recherche Biomedicale, Kinshasa, Democratic Republic of the Congo

The animal reservoir(s) and ecology of Ebola viruses (EBV) remains largely unknown, but previous detection of viral RNA and anti-EBV antibodies in bats suggest that they may play a role in zoonotic transmission. Bats were captured in Guinea, Cameroon and the Democratic Republic of Congo (DRC) between November 2015 and August 2017. Samples were screened for cross-reactive EBV antibodies with a high throughput Luminex-based assay to different antigens from four different Ebola viruses; Zaire (EBOV), Sudan (SUDV), Bundibugyo (BDBV) and Reston (RESTV). Cut-off values were calculated using four different more or less stringent methods and samples were considered positive when simultaneous presence of antibodies to NP and GP was observed. 4,022 bats were studied, from at least ten frugivorous (n=1,736) and 27 insectivorous (n=2,286) species. Between 0.05 and 0.92 % (2 to 37) bats have cross-reactive antibodies to EBOV and 0.0 to 0.75 % (0 to 30) to SUDV. Higher reactivity was seen in frugivorous bats. With stringent and less stringent cut-off values, EBOV and SUDV cross-reactive samples were seen in one insectivorous genus (*Mops*) and three frugivorous species (*Eidelon helvum*, *Hypsignatus monstruosus*, *Rousettus aegyptiacus*). With less stringent methods only, cross-reactive antibodies were also seen in three additional frugivorous species, EBOV in *Lissonycteris angolensis* and *Epomophorus sp.* and SUDV in *Micropteropus pusillus.* EBOV and SUDV cross-reactive samples were observed in Cameroun and Guinea, and in DRC only SUDV. All samples from *Epomops franqueti* and *Myonycteris torquata* were negative. We confirmed the presence of cross-reactive EBOV antibodies in three to five frugivorous bat species and one insectivorous genus previously reported seropositive, and one new frugivorous species (*L.angolensis*). EBOV and SUDV apparently co-circulate in certain species and could be widespread across Africa. More studies are needed on significance of EBV antibodies and viral persistance to clarify the role of bats in EBV ecology.

237

MARBURG VIRUS ANGOLA STRAIN: MORE VIRULENT THAN MUSOKE IN CYNOMOLGUS MONKEYS *MACACA FASCICULARIS*?

Paul W. Blair[1], Maryam Keshtkar-Jahromi[1], Kevin J. Psoter[1], Anthony P. Cardile[2]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, United States, [2]United States Army Medical Research Institute of Infectious Diseases, Frederick, MD, United States

From 2004 to 2005, an outbreak of Marburg virus, a filovirus, in Angola led to a case-fatality rate of 90 percent. However, little information is available regarding the virulence of the Angola strain from this outbreak compared to the virulence of other strains. Therefore, we sought to assess time to selected outcomes in non-human primates (NHPs) experimentally infected with either Angola or Musoke Marburg strains. Between 2014 and 2017, eight therapeutic trials at the U.S. Army Medical Research Institute of Infectious Diseases were conducted in *Macaca fascicularis* monkeys challenged with 1000 plaque forming units of Marburg virus administered intramuscularly. The current study population was comprised of 47 control NHPs, of which, 18 were administered Angola strain in three separate trials and 29 with Musoke strain in five trials. Clinical responses including development of rash and oral intake were collected following infection. The primary outcome of interest was time to death or euthanasia post-inoculation comparing strains using Cox proportional hazards regression. Secondary endpoints included time to development of a petechial rash and time to decreased appetite. Following Marburg challenge, all NHPs died and most NHPs experienced decreased food consumption (96%), and petechial rash (93%). Irrespective of strain, petechial rash was preceded by decreased food consumption by 1.1 days (SD 1.9) on average. The median time to death for Angola-infected NHPs was 8.1 days (25th, 75th percentiles: 7.91, 8.90), whereas Musoke-infected NHPs survived for a median of 10.0 days (25th, 75th percentiles: 9.00, 10.88). Angola strain was associated with a statistically significant increased risk of death (HR= 22.10; 95% CI: 7.08, 68.93), development of petechiae (HR= 22.10; 95% CI: 7.08, 68.93) and loss of appetite (HR= 5.87; 95% CI: 2.76, 12.51). In conclusion, this was the first study to compare clinical characteristics in NHPs between these strains. Our data support increased virulence of Angola strain compared to Musoke strain. Pathophysiological mechanisms involved in increased virulence require further study.

238

ADAPTIVE PHENOTYPIC PLASTICITY IN *AEDES* MOSQUITO POPULATIONS AND SPECIES IN RESPONSE TO VARYING TEMPERATURE REGIMENS

Maria G. Onyango, Sean Bialosuknia, Anne Payne, Nick Mathias, Alex Ciota, Laura Kramer

New York State Department of Health, Griffin Laboratories, Slingerlands, NY, United States

The mosquitoes *Aedes aegypti* and *Aedes albopictus* are vectors of several arboviruses of global public health importance (dengue, yellow fever, chikungunya and Zika). The recent past has witnessed an unprecedented geographical range expansion of *Aedes* mosquitoes which will be exacerbated further by climate change in the future. To understand the fitness effect of temperature on *Aedes* mosquitoes, this study compares and describes the impact of varying temperature regimens on the immature and mature development stages of two populations and species [*Ae. aegypti* (Miami, Florida and Poza Rica, Mexico) and *Ae. albopictus* (Long Island, New York population)]. Mosquito were hatched and reared at high (day 32°C/ night 28°C), moderate (day 30°C/ night 26°C) and low (day 28°C/ night 24°C) temperature regimens to simulate current and predicted future conditions during peak transmission. Variation in the hatch rate was observed at both the population and species level (Chi square 342.3, df 5) P<0.0001. Adults of *Ae. aegypti* populations reared at the highest temperature regimen were the first to emerge and the last were *Ae. albopictus* species reared at the lowest temperature regimen. *Ae. aegypti* populations reared at the highest temperature regimen demonstrated an expedited development rate. Increased temperatures did not significantly affect blood feeding frequency (Kruskal-Wallis statistic = 3.484 P (0.6258) or adult longevity [Log rank (Mantel-Cox) test Chi-square 3.593, df 5 P (0.6094)]. Skip oviposition behavior was evident in *Ae. aegypti* Miami and *Ae. albopictus* populations. Adaptive phenotypic plasticity due to temperature variation is evident in the *Ae. aegypti* Miami population in this study. There exists inter-population and species-specific differences in life history traits. In order to more completely characterize the relationship between temperature and virus transmission vector competence of Zika virus was also assessed. Together, these studies provide a comprehensive assessment of the effect of temperature and population on vectorial capacity of *Aedes* mosquitoes in the Americas.

239

NEED FOR REAL TIME ARBOVIRAL SURVEILLANCE DATA TO PREVENT OUTBREAKS. A RETROSPECTIVE STUDY OF ZIKA, CHIKUNGUNYA, AND DENGUE OUTBREAKS IN CALI COLOMBIA 2014 TO 2016

Amy R. Krystosik[1], Angelle D. LaBeaud[1], Diana Dávalos[2], Madhav P. Bhatta[3], Andrew Curtis[4], Robinson Pacheco[2], Paola Buritica[5], Alvaro A. Alvarez[6], Jorge H. Rojas Palacios[7], Mark A. James[8]

[1]Department of Pediatrics, Division of Infectious Disease, Stanford University, Stanford, CA, United States, [2]Department of Public Health and Community Medicine, Universidad ICESI, Cali, Valle del Cauca, Colombia, [3]Department of Biostatistics, Environmental Health Sciences, and Epidemiology, College of Public Health, Kent State University, Kent, OH, United States, [4]Kent State University, the GIS, Health & Hazards Lab, Department of Geography, Kent State University, Kent, OH, United States, [5]Universidad Libre, Facultad de Salud, Cali, Valle del Cauca, Colombia, [6]Caucaseco Scientific Research Center, Cali, Valle del Cauca, Colombia, [7]Secretaría de Salud de Cali, Colombia, Cali, Valle del Cauca, Colombia, [8]Department of Biostatistics, Environmental Health Sciences, and Epidemiology, College of Public Health, Kent, OH, United States

Arboviruses are responsible for a large burden of disease globally. Although current surveillance systems around the world and in Cali, Colombia are insufficient to predict and control future arboviral outbreaks, we hypothesize that spatial and temporal patterns exist which could be used to enable better prediction and planning at the policy level. We queried The National System of Vigilance in Public Health (SIVIGILA) for chikungunya (CHIKV), dengue (DENV), and Zika (ZIKV) viral cases between October 2014 and April 2016 in the urban area of Cali, Colombia. Determination of infection included laboratory or syndromic surveillance. After one case was confirmed by RT-PCR in a municipality, patients not classified as risk groups could have been diagnosed clinically. Laboratory confirmation was based on IgM and IgG detection, NS1 detection, virus isolation, or RT-PCR. All cases were georeferenced using Municipal Secretary of Health software. Spatial and temporal clusters were identified using SatScan in R. The query resulted in 33,443 records. 26,985 were georeferenced: 2,636 CHIKV cases, 3,139 ZIKV cases, and 21,210 DENV cases were included in the final analysis. Of 21,210 DENV cases, 14% were lab-confirmed (0% ZIKV and 0% CHIKV). Acute testing vs clinical diagnosis was 56.5% sensitive, whereas severe dengue had higher sensitivity (85.7%) compared to non-severe dengue (56.1%) and dengue death (57.1%). We observed spatial clustering of acute testing in the north-west of the city (RR= 1.38 and p<0.001), suggests inequality in access to care and diagnostics. Sensitivity of lab vs clinical diagnosis was also clustered spatially, suggesting heterogeneity in clinical training. Patterns in incident cases emerged over time with clear outbreak seasons and concurrent outbreaks and over space in high risk neighborhoods. Despite gaps in the current surveillance system, we identified patterns over time and space. If these data were available prospectively, the public health

system could predict outbreaks, more efficiently allocate limited resources, reduce burden on the public health system, and prevent morbidity and mortality due to arboviruses.

240

SURVEILLANCE OF NOROVIRUS AMONG CHILDREN WITH DIARRHEA IN FOUR MAJOR HOSPITALS IN BHUTAN: REPLACEMENT OF GII.21 BY GII.3 AS A DOMINANT GENOTYPE

Sonam Wangchuk[1], Takashi Matsumoto[2], Hidekatsu Iha[2], Kamruddin Ahmed[3]

[1]Royal Centre for Disease Control, Thimphu, Bhutan, [2]Department of Microbiology, Faculty of Medicine, Oita University, Yufu, Japan, [3]Department of Pathobiology and Medical Diagnostics, Faculty of Medicine and Health Sciences, Universiti Malaysia Sabah, Kota Kinabalu, Sabah, Malaysia

Diarrhea is a major cause of morbidity and mortality among Bhutanese children. Norovirus (NoV) is an important cause of diarrhea worldwide and in Bhutan. In 2010-2012, GII.21 was found the major genotype circulating in Bhutanese children in contrast to globally prevalent GII.4 genotype responsible for NoV infections. The study was conducted in 2013-2014 to update and describe the transformation and distribution of the NoV genotype among Bhutanese children. Total 623 diarrheal stool samples were collected at three-referral hospital and one general hospital from June 2013 through May 2014 from children under 5 years of age. NoV was detected by reverse transcription-polymerase chain reaction (RT-PCR) by amplifying the capsid gene. The RT-PCR results were confirmed by nucleotide sequencing of the amplicons. The proportion of NoV-positive stool samples was 23.6% (147/623), of which 76.9% was NoV GII. The median age of infected children was 15.5 months. NoV GII was most prevalent in the colder months (late November-mid April). The most common genotypes prevalent were GII.3 (42.6%), GII.4 Sydney 2012 (15.8%), and GII.4 unassigned (11.9%). No GII.21 was found in any child in the present study. NoV remains an important cause of diarrhea among Bhutanese children. Genotype GII.3 from a single ancestor strain has spread, replacing the previously circulating GII.21. To develop a NoV infection control policy, further studies are needed.

241

INTERSECTORAL COLLABORATION EFFORTS AND LESSONS LEARNED IN EBOLA VIRUS DISEASE RESPONSE IN NIGERIA-2014

Abimbola Aman-Oloniyo[1], Saheed Gidado[2]

[1]Walden University, Online, Nigeria, [2]Nigeria Field Epidemiology and Laboratory Program, Abuja, Nigeria

The 2014 Zaire species, Ebola Virus Disease (EVD) outbreak was first reported in Guinea and spread to countries including Nigeria which reported the first confirmed case 20th July 2014, had 20 cases and 8 deaths (CFR 40%) and was declared Ebola-free by WHO 20th October 2014. We reviewed the response/collaborative efforts in EVD control in Nigeria We conducted a desk review of the Ebola response activities and collaborative efforts at the National level of administration following the outbreak of EVD in Nigeria between July and September, 2014. Of 20 cases and 8 deaths, healthcare workers (HCWs) who were primary contacts of index case constituted 9(45%) cases 4(50%) deaths; 2 (10%) cases and 1(12.5%) death were secondary contacts; one nosocomial infection also occurred. EVD response efforts involved collaboration of Government, Non-governmental organizations (NGOs) and private sector. Government provided EVD-specific financial resources and was responsible for response coordination (through an Ebola Emergency Operation Center), NGOs/ partners deployed experts/ staff and donated funds/ resources. Private sector donated funds, vehicles, ambulances, protective equipment, call centers, mobile phones (including complimentary airtime). Response activities included trainings of all cadres of HCWs at public and private HFs, sensitization, public enlightenment and community mobilization on EVD, EVD surveillance (active case search and contact tracing (891 of 892 (99.9%) contacts completed follow up), outbreaks and rumour investigation and response, laboratory investigation (62 specimens tested), case management, safe burial, psychosocial support, decontamination, operational research and ports of entry activities involving average of over 10,000 daily passenger screenings. A gap in hospital infection control aided the spread of EVD outbreak in Nigeria; restricted movement of primary contacts may have stemmed the spread. The collaboration of various sectors helped in adequate response activities to control the outbreak of EVD in Nigeria. Improved hospital infection control practices are recommended.

242

PLUG AND DISPLAY VIRUS-LIKE-PARTICLE VACCINES FOR OUTBREAK PATHOGENS

Iona J. Taylor[1], Yu Zhou[1], Yuanyuan Li[1], Siti Naqiah Amrun[2], Olga Dolnik[3], Arianna Marini[1], Stephan Becker[3], Lisa F. P. Ng[2], Sumi Biswas[1]

*[1]University of Oxford, Oxford, United Kingdom, [2]Singapore Immunology Network , Agency for Science, Technology and Research (A*STAR), Singapore, Singapore, [3]Philipps University of Marburg, Marburg, Germany*

A fast and effective response to emerging and outbreak diseases requires a vaccine platform that is adaptable, highly immunogenic, rapidly produced and has a previously demonstrated safety profile. The SpyCatcher/SpyTag biochemical superglue technology enables the rapid and efficient development of highly immunogenic virus like particle (VLP) vaccines against target pathogens. The Spy (from Streptococcus pyogenes) protein was divided into a peptide, SpyTag, and a protein partner, SpyCatcher. Once combined, the two react to form a spontaneous irreversible isopeptide bond. VLPs are a platform technology that is used to produce vaccines against many different diseases. These technologies are particularly suited for the induction of strong antibody responses, which are achieved through presentation of an ordered antigen array to the immune system. The SpyCatcher/SpyTag technology has been used to establish a novel chimeric VLP vaccine platform technology for decorating VLPs simply by mixing with protein antigen in a "Plug-and-Display" manner. This approach overcomes the well-described challenges of producing VLP carriers with complex antigens genetically-fused on their surface, or low conjugation efficiency often reported when using chemical conjugation. The SpyTag-SpyCatcher technology has been used previously to enhance humoral immunogenicity by displaying malaria antigens on VLPs. The application of this technology for the development of vaccines against Ebola and Zika viruses will be discussed. Immunogenicity and neutralisation data from mice immunised with glycoproteins from Ebola and Zika viruses will be presented which demonstrate the versatility and applicability of the platform to generate vaccines against new epidemics and emerging infections.

243

RESPIRATORY PATHOGENS IN CHILDREN ONE MONTH TO FIVE YEARS OF AGE PRESENTING WITH UNDIFFERENTIATED ACUTE RESPIRATORY DISTRESS IN TWO DISTRICT-LEVEL HOSPITALS IN GHANA

Frank Baiden[1], Camilla Eiffe[2], Justice Sylverken[3], Kwadwo Nyarko-Jectey[4], Marco M. Salerno[5], Harry Tagbor[6], **Patrick T. Wilson**[5]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]NHS Paediatric Registrar, London, United Kingdom, [3]Komfo Anokye Teaching Hospital, Kumasi, Ghana, [4]Mampong Municipal Hospital, Mampong, Ghana, [5]Columbia University, New York, NY, United States, [6]University of Health and Allied Sciences, Ho, Ghana

A majority of the one million deaths from pneumonia in children under five each year occur in low- and middle-income countries where advanced

laboratory diagnostics are often lacking. This has led to a lack of accurate epidemiological data. We report diagnostic results of a cohort of children in Ghana presenting with acute respiratory distress that were tested for common respiratory pathogens. This study describes the epidemiology of respiratory pathogens in children one month to five years of age presenting with undifferentiated respiratory distress in two district-level hospitals in Ghana. Nasopharyngeal swabs were obtained at time of presentation and tested by the BioFire FilmArray PCR assay for 17 viral and 3 bacterial pathogens. 2176 children were tested and 1276 (59%) were found to be positive for one or more organisms. Most (83%) were single infections with rhinovirus/enterovirus (36%) being the most common organism detected, followed by respiratory syncytial virus (11%) and parainfluenza (7%). Influenza was detected in less than 3% of children in the cohort. Both respiratory syncytial virus and human metapneumovirus were more frequently detected during the rainy season. 64% of children with respiratory pathogens detected also tested positive for malaria. In conclusion, detection of a respiratory pathogen in children presenting with undifferentiated acute respiratory distress in a lower-middle-income country was common, with rhinovirus/enterovirus most commonly identified. Influenza was infrequently detected, and both respiratory syncytial virus and human metapneumovirus were detected more frequently during the rainy season as compared to the dry season. Malaria was a common co-infection.

244

EVIDENCE OF CIRCULATION OF OTHOBUNYAVIRUSES IN MOSQUITOES FROM VANGA ISLAND, KWALE COUNTY, KENYA

Hellen S. Koka[1], Edith Koskei[1], Albert Nyunja[1], Joel Lutomiah[2], James Mutisya[1], Francis Mulwa[1], Samuel Owaka[1], Fredrick Eyase[1], Rosemary Sang[2]

[1]U.S. Army Medical Research Directorate-Kenya, Nairobi, Kenya, [2]Kenya Medical Research Institute, Nairobi, Kenya

A new site, Vanga island in Kwale County was recently added to the on-going arbovirus surveillance program in Kenya. Vanga island is on the southern tip of Kenya, bordering Tanzania. The area has mangrove plantations and fishing is the main economic activity. No survey has been carried out in this particular geographical location. Approximately 9544 mosquitoes were collected using CO_2-baited CDC light traps and BG-Sentinel traps, identified to species and pooled ≤ 25 mosquitoes per pool. The 649 mosquito pools obtained were homogenized using Minimum Essential Medium supplemented with Foetal Bovine Serum, L-Glutamine and antibiotics. Homogenates were clarified by centrifugation and the resultant supernatants inoculated in monolayers of VERO cells in 24 well plates. The cultures were incubated at 37°C and monitored for cytopathic effects (CPE) daily for 14 days. Cultures showing CPE were harvested and viruses identified by RT-PCR and sequencing. Ten Orthobunyavirus isolates were obtained from pools of *Aedes pembaensis* (5), *Ae. tricholabis* (1), *Culex pipens* (3) and *Cx. zombaensis* (1). The preliminary sequencing results indicate that the isolates have 99% sequence homology to Bunyamwera and Ngari viruses. Specific PCR will be done using the S, L and M segments primers of Bunyamwera and the M segment primers for Batai virus to characterize the isolates further. These findings are important because reassortment and recombination occurs frequently in Orthobunyaviruses and may potentially cause the emergence of new viruses that may be of public health importance in the region. The site borders Tanzania and data from this study will also be able to assist in mapping out risk zones.

245

ASKING THE RIGHT QUESTIONS: A COMMUNITY CONSULTATION APPROACH TO PROMOTING RABIES AWARENESS IN CHILDREN AND YOUNG PEOPLE IN RURAL TANZANIA

Lwitiko Elton Sikana

Ifakara Health Institute, Morogoro, United Republic of Tanzania

Rabies, transmitted largely by dog bites, kills many young people in rural Africa. Solutions are available, but difficult to implement, and awareness-raising often focuses on schools only. Moreover, standard solutions may be limited in village communities by specific socio-economic factors. The aim of the study is to test the efficacy of preventing rabies in young people by involving key community stakeholders in formulating and implementing local action plans and building local support networks. A mixed qualitative and quantitative approach was used. In six randomly selected villages in Kilosa, Tanzania, teachers delivered standard rabies prevention information in schools. In three of the villages, key-informant interviews were also held with health and veterinary staff to help identify key village and professional stakeholders for interactive workshops, where low-resource strategies were discussed and agreed for overcoming limitations to prevention. Extensive KAP surveys were conducted in all six villages before and after the intervention, and rabies bite data will help assess the longer-term impact of the methodology. Findings show that a good understanding of prevention was reported in schools, but there was no mechanism for taking this forward. The interviews and workshops, however, revealed a wide range of local socio-economic obstacles to preventing rabies, and low-cost solutions which emerged from workshops were formulated into action plans to be implemented by each group. The process developed a cross-sector support network for all involved. Disease prevention involves a range of socio-economic factors specific to each community. Delivering standard prevention information is often insufficient to sustain the good practice, and communities need to share ownership of solutions, messages, and strategies. Identification and discussion of issues by a wide range of local stakeholders should, therefore, be an essential first step in interventions. Community-generated action plans can help governments and international bodies develop more integrated and sustainable prevention processes.

IMMUNE RESPONSE PROFILING OF SUSPECTED LASSA FEVER CASES AT IRRUA SPECIALIST TEACHING HOSPITAL DURING 2018 LASSA FEVER OUTBREAK

Eghosasere A. Uyigue[1], Matthew L. Boisen[2], Patience Akhilomen[3], John Aiyepada[3], Ikpowosa Odia[3], Tolulope Kayode[1], Diana S. Nelson[2], Duane S. Bush[2], Blessing Osiemi[3], Micheal Airende[3], Grace E. Okonofua[3], Racheal Ukpetena[3], Ekene Muobonam[3], Omige Omoregie[3], Philomena Eromon[1], Kayla Barnes[4], Katherine Siddle[5], Samar Mehta[5], Dylan Kotliar[5], Bridget Chak[5], Stephan Gunther[6], Luis M. Branco[2], Pardis Sabeti[5], Christian T. Happi[1], Robert F. Garry[7]

[1]Redeemer's University, Ede, Nigeria, [2]Zalgen Labs, LLC, Germantown, MD, United States, [3]Institute of Lassa Fever, Research and Control, IRRUA Specialist Teaching Hospital, Irrua, Nigeria, [4]Broad Institute and Harvard University, Boston, MA, United States, [5]Harvard University, Boston, MA, United States, [6]Department of Virology, Bernhard-Nocht-Institute for Tropical Medicine, Hamburg, Germany, [7]Tulane Health Sciences Center, Tulane University, New Orleans, LA, United States

Lassa fever (LF) is a severe, often fatal, viral hemorrhagic fever endemic in several West African countries. Beginning in January 2018, Nigeria experienced an unusual surge of LF cases and as of March 18th the Nigerian Center for Disease Control reported a total of 1495 suspected cases with 376 laboratory confirmed, 9 probable LF, and 119 deaths for a case fatality rate (CFR) equal to 25%. During this period, ReLASV®

Pan-Lassa rapid tests and ELISA immunoassays (Zalgen Labs, Maryland, USA) were field tested in the Lassa Surveillance Program laboratory at Irrua Special Teaching Hospital (ISTH), Edo State, Nigeria. The ReLASV® Pan-Lassa *in vitro* diagnostics (IVD) utilized a mixture of recombinant Lassa virus (LASV) nucleoprotein (NP) antigens representing the known circulating strains of LASV in West Africa, including LASV lineage II and III in Nigeria. The Pan-Lassa Antigen Rapid Test (RDT) and Antigen ELISA Test are capable of detecting LASV NP antigenemia in LF patient samples. The Pan-Lassa IgG/IgM ELISA Test is capable of detecting NP-specific IgG or IgM in patient samples from the immune response to LASV viremia. During the field trial, suspected LF cases (n=762) were screened at admission by LASV qRT-PCR, 363 cases were positive without utilization of cycle cut-offs. 78% (50/64) of Pan-Lassa RDT positives were confirmed by qRT-PCR. 100% (48/48) Antigen ELISA positives were confirmed by qRT-PCR. Pan-Lassa IgG/IgM ELISA identified 155 of 345 samples as IgG/IgM sero-positive, 94.2% (146/155) were reactive by qRT-PCR. The ReLASV tests were capable of identifying active LF cases as demonstrated by increased CFR for LASV NP antigen positive samples 42.6% (29/68), reduced CFR for IgG/IgM positive samples 12.6% (14/111), and CFR only 3.2% (4/124) for immunoassay negative samples. The ReLASV® Pan-Lassa RDT and ELISA Test have demonstrated capacity to accurately detect active LF cases during point-of-care screening procedures, including testing of LASV antigenemia and IgG/IgM immune response. LF immunoassay screening, combined with qRT-PCR, is an important addition to medical countermeasures for LF surveillance in West Africa.

SILENT POLIO OUTBREAK IN RAHAT, ISRAEL: EPIDEMIOLOGIC FINDINGS BASED ON MODELING OF ENVIRONMENTAL SURVEILLANCE DATA

Andrew F. Brouwer[1], Connor D. Pomeroy[1], Lester M. Shulman[2], James S. Koopman[1], Joseph N. Eisenberg[1], Marisa C. Eisenberg[1]

[1]University of Michigan, Ann Arbor, MI, United States, [2]Tel Aviv University, Tel Aviv, Israel

Israel experienced an outbreak of wild poliovirus type 1 (WPV1) in 2013-14, detected through environmental surveillance of the sewage system. No cases of acute flaccid paralysis were reported, and the epidemic subsided after a bivalent oral polio vaccination (bOPV) campaign. As we approach global eradication, polio will increasingly be detected only through environmental surveillance. We developed a framework to convert quantitative polymerase chain reaction (qPCR) cycle threshold data into scaled WPV1 and OPV1 concentrations for inference within a deterministic, compartmental infectious disease transmission model. We used this approach to estimate the epidemic curve and transmission dynamics, as well as assess alternate vaccination scenarios. Our analysis suggests that the outbreak peaked approximately one month earlier than previous estimates derived from analysis of stool samples, and we estimate the basic reproduction number was 1.36 (95% CI 1.22-1.48). Model estimates indicate that 37% of susceptible individuals (primarily children under 10) were infected with WPV1, mostly prior to vaccination campaign onset, and that the vaccination campaign averted 24% of WPV1 infections. As we approach global polio eradication, environmental monitoring with quantitative PCR can be used as a highly sensitive method to enhance disease surveillance. Our analytic approach brings public health relevance to environmental data that, if systematically collected, can guide eradication efforts.

VIROLOGICAL INVESTIGATION OF ACUTE FLACCID PARALYSIS CASES IN ETHIOPIA; 2007-2017 RETROSPECTIVE STUDY ON DECADES OF VIROLOGICAL FINDINGS

Mesfin Tefera[1], Berhane Beyene[1], Tassew Kassa[1], Yoseph HaileMariam[1], Anjelo Asha[1], Aklog Afework[1], Mekonen Getahun[1], Menberu Tedla[1], Birke Teshome[1], Gelila Demise[1], Wubayehu Kassa[1], Esete Assefa[1], Asefash Getachew[1], Dejenie Shiferaw[1], Hiwot Ketema[1], Ayenachew Bekele[1], Nicksy Gumede-Moeletsi[2], Almaz Abebe[1]

[1]Ethiopian Public Health Institute, Addis ababa, Ethiopia, [2]WHO Africa Regional Office, Brazzaville, Republic of the Congo

Polioviruses are highly infectious human entero-viruses mainly responsible for the clinical syndrome Acute Flaccid Paralysis (AFP). Despite remarkable worldwide success, emergence of potentially neuro-virulent strain of vaccine derived polioviruses (VDPVs) due to prolonged shedding and replication in immuno-compromised individuals (iVDPV) or following persistent circulation in populations with immunity gaps (cVDPV) and transmission from epidemiological blocks which are reservoirs of poliovirus constitute major concerns for the global polio eradication endgame strategy. This study aims to provide critical information on epidemiology and viral etiology of AFP cases reported over the last decade by the Ethiopian AFP surveillance system. Stool specimens collected from AFP patients were transported to the Ethiopian Public Health Institute. Virus isolation was done by inoculating stool suspension into RD and L20B cells lines and observing for any cytopathic effect. Virus isolates were serotyped using Real Time PCR technique. Data entry and analysis was done using Epi-Info software. A total of 25710 specimens were investigated from 2007-2017 and 2808 enteroviruses isolated. Out of these, 1031(36.7%) were polioviruses (PVs) and 1777(63.3%) were non-polio enteroviruses (NPEV). 14 of PV isolates were wild-type1 four of which isolated in 2008, nine in 2013 due to importations form South Sudan and Somalia respectively. The last case of wild-type 1 PV isolated in Ethiopia was in 2014 from Somali region. 15 of the PV isolates were VDPVs (type 2 &3) with genome variation in the VP1 region from corresponding OPV strain. The remaining 1002 virus isolates were vaccine related Sabin strains. Our findings indicate NPEVs being predominant viruses frequently isolated from AFP cases investigated suggesting paramount importance of routine entero-virus surveillance system, study of their transmission dynamics and circulating genotypes so as to determine their role as non polio AFP etiologies. Continued virus tracking and uninterrupted immunization to maintain high herd immunity remain crucial in polio eradication era and post-polio world.

OROV ISOLATION IN A NORTHERN REGION OF PERU: FIRST MOLECULAR IDENTIFICATION AND CLINICAL CHARACTERISTICS

Johanna Martins-Luna[1], Fernando Mazulis[1], Miguel A. Aguilar-Luis[2], Wilmer Silva-Caso[1], Claudia Weilg[1], Luis del Valle[3], Isabel Sandoval[4], Carlos Palomares-Reyes[1], **Juana M. del Valle-Mendoza**[5]

[1]Universidad Peruana de Ciencias Aplicadas, Lima, Peru, [2]Universidad Peruana de Ciencias Aplicadas, Instituto de Investigación Nutricional, Instituto de Investigación de Enfermedades Infecciosas, Lima, Peru, [3]Universidad Politécnica de Catalunya, Barcelona, Spain, [4]Dirección Regional de Salud de Piura, Piura, Peru, [5]Universidad Peruana de Ciencias Aplicadas, Instituto de Investigación Nutricional, Lima, Peru

Oropouche virus (OROV) is an emerging infectious disease that is under-reported due to the lack of molecular diagnostic tools and the clinical similarities with other endemic arboviral diseases. The circulation of OROV in Peru has been previously evidenced in regions such as Cuzco, Cajamarca, and Madre de Dios. In this study, we report the first outbreak

of OROV in the northern region of Piura in Peru that occurred during April to August of 2016. A total of 496 patients were enrolled from a local acute febrile illness surveillance program and their serum samples were analyzed by RT-PCR, for the presence of OROV. On-site health care professionals surveyed the clinical presentation of each enrolled patient and a follow-up was scheduled to detect disease progression, recurrence or deaths. Positive identification for OROV via RT-PCR, was found in 26,4% (n=131) of all samples. Among these, 55% (n=33) were males and the patients that were most affected had 18-39 years (25.2%, n=33). The most common symptoms reported by infected patients were headache with 82.4% (n=108), myalgias with 77.9% (n=102), arthralgias with 69.5% (n=91) and retro-ocular pain with 52.7% (n=69). During this outbreak, some patients had a clinical presentation suggestive of severe OROV infection including 3.1% (n=4) had intense abdominal pain, 0.8% (n=1) had low platelet count, 1.5% (n=2) had melena, and 0.8% (n=1) had gynecological bleeding. No recurrence or deaths were reported during follow-ups. In conclusion, this study reports an outbreak of OROV in a non-endemic northern region of Peru, where positive cases were identified for the first time. The disease caused by OROV remains an emerging and underdiagnosed infection that may be under-reported due to its clinical similarity with other arboviral diseases and the lack of on-site diagnostic methods suitable for endemic areas. This study demonstrates that the inclusion of OROV in the Peruvian national surveillance program is of paramount importance and that further research is required to determine the virulence, pathogenesis, host range and vectors involved in OROV transmission cycles.

RETINOID PROFILES IN PATIENTS WITH SEVERE MALARIA: CASE CONTROL STUDY IN COLOMBIA

Veronica De Los Angeles Hernandez-Morales[1], Anthony Mawson[1], Luis Celis[2], Amal Mitra[1]

[1]Jackson State University, Jackson, MS, United States, [2]Universidad de La Sabana, Bogota, Colombia

The malaria parasites *Plasmodium falciparum* and *P. vivax* selectively absorbs vitamin A from host tissues and appears to depend on it for its metabolism. While essential in low concentration for many biological functions, vitamin A can be toxic in higher concentration. Such observations led to the hypothesis that the pathogenesis of malaria involves an endogenous form of hypervitaminosis A in which merozoite-stage parasites use the vitamin A accumulated in the liver as a cell membrane destabilizer to invade erythrocytes, which then circulate throught the body, inducing signs and symptoms of malaria as an endogenous form of hypervitaminosis A (Mawson, Pathogens and Global Health, 2013; https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4003589/pdf/pgh-107-03-122.pdf). This study was undertaken to investigate the retinoid toxicity hypothesis of malaria in Colombia a country with high rate of infections from malaria in South America To test the hypotheses that acute malaria infection is associated with a retinoid (vitamin A) profile suggesting an endogenous form of hypervitaminosis A. With colleagues at the Universidad de la Sabana in Bogotá and Universidad de Cordoba in Monteria A case-control study will be carried out in Cordoba, in major endemic region of malaria in Colombia, to determine retinoid concentrations and RAR expression in patients with malaria and controls, subject to approval by the Institutional Review Boards of Jackson State University and the Universidad de la Sabana. to obtaining positive results, the research could lead to the development of retinoid profiling for diagnosing malaria in the early stages of infection, as well as potential new treatments aimed at blocking retinoid expression or inhibiting its metabolism.

251

OVERATTRIBUTION OF *PLASMODIUM VIVAX* MALARIAL RECURRENCES TO HYPNOZOITE ACTIVATION

Miles B. Markus

University of the Witwatersrand, Johannesburg, South Africa

The hypnozoite theory of relapse is obfuscating the probability that many homologous *Plasmodium vivax* malarial recurrences are not relapses (hypnozoite origin), but recrudescences (merozoite origin). What is new about this post-2011 argument is that attention will now be drawn, via the conference presentation, to the implications of relatively obscure information which shows that both short-term and long-term recurrences can follow blood-stage-induced primate malaria (hypnozoites do not occur in such infections). It follows that recurrences having the same non-hypnozoite parasite source or sources in the body, whatever it or they may be, most likely take place in mosquito-transmitted (i.e. sporozoite-initiated) *P. vivax* malaria as well. Thus, an unknown percentage of homologous *P. vivax* recurrences are no doubt erroneously being ascribed to activation of hypnozoites. The matter of how and where quiescent plasmodial parasites persist is not merely of academic interest, but of fundamental importance in relation to malaria eradication.

During development within the host erythrocyte malaria parasites generate nascent membranous structures which serve as a pathway for parasite protein transport to modify the host cell. The molecular basis of such membranous structures is not well understood, particularly for malaria parasites other than *Plasmodium falciparum*. To characterize the structural basis of protein trafficking in the *Plasmodium knowlesi*-infected erythrocyte, we identified a *P. knowlesi* ortholog of MAHRP2, a marker of the tether structure that connects membranous structures in the *P. falciparum*-infected erythrocyte. We show that PkMAHRP2 localizes on amorphous structures that connect Sinton Mulligan's clefts (SMC) to each other and to the erythrocyte membrane. Three dimensional reconstruction of the *P. knowlesi*-infected erythrocyte revealed that the SMC is a plate-like structure with swollen ends, reminiscent of the morphology of the Golgi apparatus. The PkMAHRP2-localized amorphous structures are possibly functionally equivalent to *P. falciparum* tether structures. These findings suggest a conservation in the ultrastructure of protein trafficking between *P. falciparum* and *P. knowlesi*.

253

PFEMP1 PROTEINS BINDING NON-IMMUNE IGM AND A2-MACROGLOBULIN ARE FREQUENT IN *PLASMODIUM FALCIPARUM*

Mary Lopez-Perez, Pilar Quintana, Sisse Ditlev, Lars Hviid

Centre for Medical Parasitology, University of Copenhagen, Copenhagen, Denmark

Plasmodium falciparum malaria is particularly dangerous because the infected erythrocytes (IEs) can adhere to the vascular endothelium and to uninfected erythrocytes, causing organ-specific complications. This ability is related to the expression of *P. falciparum* erythrocyte membrane protein 1 (PfEMP1) proteins on the IE surface. Recent evidence obtained by our group support the hypothesis that *P. falciparum* can exploit human serum factors such as non-immune IgM and α_2-macroglobulin (α_2M) to increase PfEMP1 avidity for host receptors and to evade host immune responses. However, only few IgM- and α_2M-binding PfEMP1 proteins have been described. In this study, we aimed to identify and characterize such PfEMP1 proteins in the three parasite lines, NF54-G6, HB3, and IT4/FCR3. We used pVBH-transfected parasites to obtain starting populations with highly heterogeneous *var* gene transcription. IgM- and α_2M-binding IEs were single-cell sorted by FACS, and the *var* gene transcription profile was analyzed by qPCR. The ability of candidate PfEMP1 proteins to bind IgM and α_2M was assessed by flow cytometry (IEs, native PfEMP1) and ELISA (recombinant single- and multi-domain proteins). Several PfEMP1 variants containing DBLε, DBLζ, or DBLδ domains bound IgM and/or α_2M. The data indicate that IgM- and α_2M-binding are more frequent than previously reported and that the domain types involved are conserved. This provides novel insight to how *P. falciparum* exploits human host proteins for its own benefits.

254

DEGRADATION OF ENDOTHELIAL GLYCOCALYX IN *PLASMODIUM FALCIPARUM* MALARIA IN TANZANIAN CHILDREN

Florence M. Savatory

Hubert Kairuki University, Dar es salaam, United Republic of Tanzania

Work by our group has shown that patients with *P. falciparum* malaria have endothelial dysfunction, whichplays a major role in malaria pathogenesis. Adherence of parasitized RBC (pRBC) to endothelial cells induces endothelial activation and results in pRBC sequestration, impaired perfusion, tissue hypoxia, and organ dysfunction. The endothelial glycocalyx (eGC) is a gel-like layer that covers the luminal surface of the vessel. This eGC functions to maintain vascular homeostasis by regulating permeability, modulating blood flow-induced shear stress signals including formation of nitric oxide (NO), and inhibiting endothelialadherence of leukocytes and platelets. We hypothesized that breakdown of the eGC occurs in malaria infection leading to endothelial activation and microvascular dysfunction. Ourobjectivewas to compare levels of glycocalyx breakdown products [glycosaminoglycans (GAG)] in urine of children with *P. falciparum* malaria and healthy control (HC) subjects. The study was done at Hubert Kairuki Medical Center in Dar es Salaam, Tanzania. HC children and children with severe (SM) and moderately severe malaria (MSM) age 1 to 10 years were studied from2016 to 2018.The diagnosis of *P. falciparum* was established by microscopy and RDT.Total urinary GAG levels were measured by dimethylmethylene blue (DMMB) assay and plasma angiopoietin-2 by ELISA. The study thus far included41 HC,24 MSM, and 26 SM.Total urine GAG levels were significantly higher in SM (mean±SD 13.7±6.4g/molcreatinine)andMSM (11.7±6.4) thaninHC subjects (3.6±3.1); p<0.0001.Levels of GAG in malaria patients correlated significantly with malaria severity as judged by statistically significant correlation withperipheral parasitemia, hemoglobin, platelet count, and angiopoietin-2 levels.In conclusion, Tanzanian children with falciparum malaria have evidence of glycocalyx degradation based on significantly increased urinary GAG levels. It is likely that this glycocalyx damage contributes to the pathogenesis of the vascular dysfunction. Agents that protect against glycocalyx damage may be useful as adjunctive treatments for malaria.

255

VISUAL IMAGING OF THE ENDOTHELIAL GLYCOCALYX IN TANZANIAN CHILDREN WITH FALCIPARUM MALARIA

Ayam R. Kalingonji

Hubert Kairuki Memorial University, Dar es salaam, United Republic of Tanzania

The endothelial glycocalyx (eGC) is composed of membrane-bound proteoglycans and glycoproteins interacting with plasma components, which contribute to eGC stability. The eGC acts as a protective barrier for the endothelium. We earlier demonstrated microvascular dysfunction in patients with *Plasmodium falciparum* malaria, and this dysfunction plays a major role in malaria pathogenesis. eGC can be imaged with sidestream dark-field (SDF) microscopy to measure its structure and integrity. We hypothesized that children with falciparum malaria have damaged eGC that can be quantitatively imaged by SDF. We used a "GlycoCheck" camera to study healthy children and those with moderately severe or severe falciparum malaria at the Hubert Kairuki Medical Center in Dar es Salaam, Tanzania. Healthy control (HC) children and children with malaria were studied from 2016 to 2018. Sublingual imaging in many of the children was not possible, so we imaged via skin of the axilla and pinna, with analysis of (*a*) RBC column width (RCW); (*b*) perfused boundary region (PBR); (*c*) total microvascular density (TMD); (*d*) valid microvascular density (VMD); and (*e*) vessel RBC filling (VRF). Of these, the PBR most accurately reflects the eGC measurement. Total urinary glycosaminoglycan (GAG) levels measured by the dimethylmethylene blue assay served as a chemical marker of glycocalyx degradation. We imaged 30 HC, 12 moderately severe (MSM), and 16 severe malaria (SM) subjects. We used microscopy and RDT to establish malaria diagnosis. Our separate unpublished results show eGC damage in malaria based on increased urinary GAG in MSM and SM compared to that in HC children. Pinna imaging revealed no significant differences in the RCW, PBR, or VRF, but TMD and VMD were significantly increased in malaria (TMD mean±SEM 580±57 μm/mm^2 in HC vs. 787±74 in malaria; and VMD 333±39 HC vs. 428±27 malaria; p = 0.039). In conclusion, elevated urinary GAG levels in the malaria group indicate eGC damage, but the PBR as a measure of glycocalyx integrity and depth was not increased. The increased microvascular density may be a reflection of recruitment of vessels into these tissues in response to hypoxia.

256

INFECTIVITY OF ASYMPTOMATIC *PLASMODIUM FALCIPARUM* INFECTIONS TO *ANOPHELES GAMBIAE* IN SENEGAL

Aminata C. Lo, Ablaye Gaye, Oumar Gaye, Babacar Faye

University Cheikh Anta DIOP of Dakar / Senegal, Dakar, Senegal

The transmission of malaria from an infected human host to a susceptible mosquito is mediated by a specialized sexual stage of the *Plasmodium* species commonly known as the gametocyte. Although crucial for malaria transmission, the presence of gametocyte in the blood does not mean infection in humans. After ingestion of gametocytes by the mosquito, the probability of having an infection requires a combination of factors such as maturation and density of male and female gametocytes but also the immune system of both hosts. Thus, the objectives to determine parasite density, evaluate the infectivity of mosquitoes and to assess antibody profile against sexual stage parasite in two areas with different malaria transmission setting in Senegal. A cross sectional study was enrolled at the end of the transmission season. Was included, 1120 asymptomatic volunteers aged 5 years and over. Approximately one teaspoon [5 ml] of blood was collected for each patient for RTDs, microscopy, plasma

collection. For those with RTDs positives, some blood was used for membrane feeding *assay* for mosquito infectivity. From 560 slides in each area, 24.6 % and 2.1 % were positives for the south and the center respectively. 15 individuals were tested for infectivity against a *P. falciparum*-sensitive *Anopheles gambiae* strain in two different localities. In the center of Senegal, 20% of tested individuals were mosquitoes infected and 5% of tested mosquitoes were oocysts infected. But in the south, 30% patients were mosquitoes infected and 9% of mosquitoes tested were oocyst infected. In conclusion, both studies sites, malaria transmission is well maintained by some individuals of both populations hosting the sexual stage of *P falciparum*.

257

BLOOD DONOR VARIABILITY AS A MODULATORY FACTOR IN *PLASMODIUM FALCIPARUM* PHENOTYPING ASSAYS

Laty G. Thiam[1], Yaw Aniweh[1], Makhtar Niang[2], Gordon A. Awandare[1]

[1]West African Centre for Cell Biology of Infectious Pathogens, Accra, Ghana, [2]Pasteur Institute, Dakar, Senegal

Plasmodium falciparum uses multiple ligand-receptor interactions to invade red blood cells (RBCs). Blood stage malaria vaccines mainly target *P. falciparum* antigens involved in RBC invasion. Thus, unraveling the nature of ligand-receptor interactions involved in invasion is crucial in malaria vaccine development. Conducting large scale *P. falciparum* phenotyping studies inevitably involves the use of blood from different blood donors, which could affect the outcome of *in vitro* invasion inhibitory assays. However, the effect of blood donor variability in characterizing *P. falciparum* phenotypic diversity remains unaddressed. Therefore, we are currently investigating variations in invasion efficiency/phenotype observed using different donor RBCs. RBCs were treated with different enzymes and labeled with a fluorescent dye. *P. falciparum* clinical isolates and laboratory lines were maintained *in vitro* in a gassed atmosphere and further used to conduct standard invasion assays. The percentage of invasion was determined by flow cytometry and for all assays, the parasite's invasion phenotype was adjudged by comparing invasion in untreated and enzyme-treated acceptor RBCs. Our data show that invasion efficiency of both *P. falciparum* clinical isolates and laboratory adapted strains is affected by the nature (e.g. blood group or hemoglobin genotype) of the acceptor RBCs. Data with regard to the effect of blood group and sickle cell trait will be presented at the conference. Additionally, our data also show that RBCs from different donors show different levels of sensitivity to enzyme treatments and this sensitivity seemed to be driven by the receptor density on the RBC surface. This suggest that, like the parasite's genetic make-up, the intrinseque properties of the target RBCs may also play a role in the observed invasion phenotype. In conclusion, the data show that blood donor variability is a modulatory factor influencing invasion efficiency. Altogether, the study demonstrates that blood donor variability in *P. falciparum* should be an important consideration in invasion phenotyping assays.

258

DECIPHERING THE ASSOCIATION OF A NOVEL *PLASMODIUM FALCIPARUM* EXPORTED PROTEIN WITH PARASITE-INDUCED STRUCTURES

Philip Ilani, Gordon A. Awandare, Emmanuel Amlabu

University of Ghana, Accra, Ghana

Plasmodium falciparum survives within host erythrocytes by devising strategies for successful export of several proteins beyond the parasitophorous vacuole. This has fostered interest in some of the membranous structures established by the parasite during protein export. We have identified a novel *P. falciparum* exported protein that harbors a canonical PEXEL variant. To functionally characterize the protein, three peptides (P1, P2, and P3) were chemically synthesized based on B-cell epitope mapping and screening for coiled-coil signatures. Stage-specific expression analysis by immunofluorescence assay (IFA) showed that the protein is expressed in late ring, trophozoite and schizont stages. Antibodies were generated against the three peptides but only anti-P3 antibody detected the full-length native parasite protein (50 kDa) in detergent-treated schizont lysates, while anti-P2 antibody detected a truncated fragment (~22 kDa) of the native protein close to the PEXEL motif and anti-P1 antibody did not detect the native protein. We also showed that the export of the protein is Brefeldin A-sensitive by comparative IFA analysis of trophozoite-infected erythrocyte ghosts, selective permeabilization of infected erythrocytes and immunoblotting. Since protein export precedes gametocytogenesis, we have shown the localization of the protein in different stages of gametocytes. Cellular fractionation experiments revealed the differences in the subcellular localization of the protein which was attributed to changes in solubility states of the protein within the parasite-host compartment. Further work on protein-protein interaction experiments is ongoing to substantiate an initial evidence suggesting that the novel *P. falciparum* exported protein (50 kDa) forms a 200 kDa multi-protein complex in trophozoite lysates. It is expected that this study may shed more insights on the association of this protein with parasite-induced membranous structures.

259

EVIDENCE OF ALTERED LIVER FUNCTION AND CYTOKINE RESPONSE PROFILES IN PREGNANT WOMEN WITH MALARIA AND CHRONIC HEPATITIS B

Nsoh Godwin Anabire[1], Gideon Kofi Helegbe[2], Gordon Akanzuwine Awandare[1], Osbourne Quaye[1], Paul Armah Aryee[3], Abass Abdul-Karim[4]

[1]West African Centre for Cell Biology of Infectious Pathogens (WACCBIP), University of Ghana, Accra, Ghana, [2]Department of Biochemistry and Molecular Medicine, School of Medicine and Health Sciences, University for Development studies, Tamale, Ghana, [3]Department of Nutritional Sciences, School of Allied Health Sciences, University for Development Studies, Tamale, Ghana, [4]Zonal Public Health Laboratory, Tamale Teaching Hospital, Tamale, Ghana

The overlap of malaria and chronic hepatitis B (CHB) is common in endemic regions, however, the impact of this co-infection on liver function and immune responses is unknown. This study sought to investigate these interactions in pregnant women reporting to an antenatal clinic in Ghana. Levels of malaria parasitemia, hepatitis B viremia, liver biochemical parameters and inflammatory cytokines were assayed and compared across four categories of pregnant women: uninfected, infected with *Plasmodium falciparum* alone *(Malaria group)*, infected with hepatitis B virus alone (*CHB group*) and co-infected with *P. falciparum* and hepatitis B virus (*Malaria+CHB group*). Relative to the *CHB group*, the *Malaria+CHB group* had lower viremia levels. However, levels of malaria parasitemia were similar in women in the *Malaria* and *Malaria+CHB groups*. Furthermore, levels of markers for liver injury/damage, including alanine aminotransferase, aspartate aminotransferase and total bilirubin were elevated in women in the *Malaria+CHB group* relative to those in the other groups. Similarly, pro-inflammatory cytokines, including tumour necrosis factor alpha (TNF-α), interleukin (IL)-1β, and IL-6 were higher in women with *Malaria+CHB* compared to those in the other categories. In addition, pro-inflammatory cytokine levels had a significant positive correlation with viremia, and negative correlation with parasitemia. For anti-inflammatory cytokines, including IL-10 and IL-4, the pattern was exactly the opposite of that for the pro-inflammatory cytokines. Our findings showed that malaria/CHB co-infection in pregnancy appeared to exacerbate the release of biomarkers for liver damage and inflammatory mediators while reducing immune-modulatory mediators. The exacerbated inflammatory response appears to help control malarial parasitemia in co-infected women.

FUNCTIONAL INSIGHTS ON THE ROLE OF *PLASMODIUM FALCIPARUM* CLAUDIN-LIKE APICOMPLEXAN MICRONEME PROTEIN (PFCLAMP), AN ESSENTIAL GENE

Evelyn B. Quansah, Prince B. Nyarko, Felix Ansah, Gordon A. Awandare, Yaw Aniweh

West African Centre for Cell Biology of Infectious Pathogens, University of Ghana, Accra, Ghana

Malaria is still a public health burden. With the recent reports of artemisinin resistance in *Plasmodium falciparum* coupled with the low efficacy of the available commercially approved vaccine, there is the need to continue developing new targets by functionally characterizing some of the ~60% of the parasite's genes with unknown functions.. This will foster the identification of viable vaccine and possible drug targets for the development of interventions against the parasite. To this, we have studied *Plasmodium falciparum* Claudin-Like Apicomplexan Microneme Protein (PfCLAMP) (3D7_1030200) and its role during the parasite development. It has been shown to be highly conserved in apicomplexans, with its orthologue in *P. falciparum* essential for parasite growth and invasion. We have confirmed the localization of CLAMP at the apical portion of merozoites using specific antibodies raised against the extracellular domain of the protein. We have also demonstrated that CLAMP is differentially expressed across the different asexual stages of the parasite, with the dominant expression being in the late trophozoite and schizont stages. We have shown and validated that some clinical isolates habour multiple copies of the *CLAMP* gene. In addition, CLAMP forms complexes with other proteins, and in this study we have characterized its interacting partners. Altogether, our data demonstrates that CLAMP provides a potentially attractive target for further investigation for drug and vaccine development.

261

INVOLVEMENT OF EPHA2 IN INVASION OF *PLASMODIUM VIVAX* EXO-ERYTHROCYTIC STAGE

Ubonwan Jaihan

Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand

Malaria is a serious health problem. It is widely distributed in the tropical and subtropical regions of the world. It was estimated to cause approximately 0.4 million deaths annually. The initial step of human malaria involves infection of hepatocytes by the parasite. Proteins on the surface of the host hepatocytes are believed to be important for parasite invasion. This has been demonstrated for human malaria parasite *Plasmodium falciparum* and rodent malaria parasites. However, it is not clear whether these proteins are likewise important for *Plasmodium vivax*, the most common malaria parasites that cause recurring infections. This study aims to investigate the role of host cell receptor EphA2 in hepatocyte invasion by *P. vivax*. Our specific aim is to determine whether the abundance of surface EphA2 enhances parasite infection. To achieve this goal, we first stained hepatoma cell line (HC-04) with fluorescent anti-EphA2 antibodies and used fluorescence activated cell sorting (FACS) to harvest cells that had high EphA2 surface expression ($EphA2^{High}$). *P. vivax* sporozoites, freshly harvested from the salivary glands of infected *Anopheles* dirus, were then allowed to infect the sorted $EphA2^{High}$ cells as well as the unsorted cells. After 4 days, we fixed cell cultures with paraformaldehyde and used immunofluorescence staining (IFA) to compared the infection rates of the $EphA2^{High}$ and unsorted HC-04. We found that the infection rates (N = 16) of $EphA2^{High}$ were around 2-4 folds higher than that of the unsorted HC-04. To further demonstrate involvement of EphA2 in *P. vivax* invasion, we performed invasion inhibition assays by pre-incubating the host cells with anti-EphA2 antibodies before sporozoite addition. We found that the antibody reduced sporozoites infection in a dose dependent manner. Overall, our data provide strong experimental support for a role of EphA2 in *P. vivax* infection of hepatocytes.

262

EXPOSURE TO DIFFERENT COMMUNITIES OF VENDOR-ASSOCIATED FECAL MICROBES DETERMINES MALARIA INFECTION SEVERITY AND PREGNANCY OUTCOME IN AN OUTBRED MOUSE MODEL FOR MALARIA IN PREGNANCY

Catherine D. Morffy Smith, Alicer K. Andrew, Caitlin A. Cooper, **Julie M. Moore**

University of Georgia, Athens, GA, United States

Placental malaria, a severe clinical manifestation of *Plasmodium falciparum* infection, is a major cause of pregnancy loss, neonatal mortality, and severe maternal illness. We have developed a novel mouse model for pregnancy maintenance during maternal malaria infection utilizing outbred Swiss Webster mice. When infected with *Plasmodium chabaudi* in early gestation, several inbred mouse strains will abort their pregnancies at mid-gestation. However, outbred Swiss Webster mice infected with *P. chabaudi* in early gestation carry their pregnancies to term, allowing us to explore the immunological balance between parasite clearance and pregnancy success. The composition of the gut microbiota may alter this balance. As described by Villarino *et al.*, C57BL/6 mice sourced from different vendors display gut microbiota-dependent differences in *Plasmodium* infection severity resulting in a susceptible or resistant phenotype. Similarly, *P. chabaudi chabaudi* AS-infected pregnant Swiss Webster mice exposed to susceptibility-conferring fecal microbes develop higher parasite burdens than mice exposed to resistance-conferring fecal microbes following the disruption of the native gut microbiota by broad-spectrum antibiotic treatment. The microbiota-mediated reduction of parasite burden is associated with reduced maternal morbidity and improved fetal outcomes. Specifically, fetal viability and weight at gestational term are increased in infected dams exposed to resistance-conferring fecal microbes relative to infected dams exposed to susceptibility-conferring fecal microbes. To assess post-natal growth, pups from infected and uninfected dams exposed to resistance- and susceptibility-associated fecal microbes were delivered by caesarean section and placed with a foster dam. Although pup growth prior to weaning is not significantly influenced by either infection status or fecal microbe exposure, pups produced by highly susceptible dams displayed a statistically significant reduction in survival in the first days of life, suggesting that these pups may be less fit than pups born to dams with lower parasite burdens.

263

TARGETING SPOROZOITE-HEPATOCYTE INTERACTIONS WITH A PHAGE DISPLAY LIBRARY

Sung-Jae Cha, Marcelo Jacobs-Lorena

Johns Hopkins University, Baltimore, MD, United States

After inoculation by the bite of an infected mosquito, the *Plasmodium* sporozoite enters the blood stream and infects the liver with unique specificity. Prior to liver infection, sporozoites must leave the circulation by traversing the liver sinusoid lining, preferentially trough liver macrophages (Kupffer cells). Using a phage display library we previously selected peptides which structurally mimic (mimotope) a sporozoite ligand (GAPDH) for Kupffer cell recognition and the Kupffer cell receptor (CD68). Importantly we showed that a mimotope peptide of sporozoite GAPDH serves as a vaccine candidate to generate sterile protection. Encouraged by these positive results, we screened the same phage display library to target sporozoite-hepatocyte interactions. The selected hepatocyte-binding peptides competitively inhibit sporozoite invasion of hepatocytes *in vitro*. Antibodies against the selected peptides recognize a ~50 kDa sporozoite surface protein. Significantly, immunization with one of the selected peptides inhibited *Plasmodium* liver invasion. We hypothesize that this peptide is a mimotope (mimics the structure) of a sporozoite surface ligand for hepatocyte invasion. This sporozoite ligand constitutes a potential vaccine antigen targeting malaria liver invasion.

264

SELECTION OF SEVEN-MUTATION *PFCRT-PFMDR1* GENOTYPE AFTER SCALING SEASONAL MALARIA CHEMOPREVENTION WITH SULPHADOXINE-PYRIMETHAMINE AND AMODIAQUINE IN MALI

Hamma I. Maiga[1], Amadou Bamadio[2], Aliou Traore[2], Nouhoum Diallo[2], Modibo Diarra[2], Issaka Sagara[2], Samba Coumare[2], Soma Bahonan[3], Boubou Sangare[2], Hamidou Niangaly[2], Aboubecrine Haidara[2], Yeyia Dicko[2], Aly Tembely[2], Francois Daou[2], Djibril Traore[2], Michel Vaillant[4], Alassane Dicko[2], Estrela Lasry[3], Ogobara K. Doumbo[2], Abdoulaye A. Djimde[2]

[1]INRSP-Mali/MRTC, Bamako, Mali, [2]MRTC, Bamako, Mali, [3]MSF, Bamako, Mali, [4]LIH, Luxembourg, Luxembourg

WHO recommended in 2012 the seasonal malaria chemoprevention (SMC) in the Sahel countries in Africa to reduce Malaria among children less than 5 years of age with sulfadoxine-pyrimethamine and amodiaquine (SP+AQ). This strategy is scaled up in Mali since 2012. The use of millions of doses of SP+AQ could generate potential *Plasmodium falciparum* resistance mutant parasites. The aim of this study was to monitor the prevalence of *Pfdhfr+Pfdhps+pfcrt+pfmdr1* mutations in the target population of the health district of Koutiala. Two cross-sectional surveys were conducted before (August 2012, n=662) and after (June 2014, n=670) a pilot implementation of SMC in Koutiala. Children aged 3-59 months received 3 and 4 rounds of curative dose of SP+AQ over two malaria seasons in 2012 and 2013, respectively. Genotypes of *P. falciparum Pfdhfr* codons 51, 59 and 108; *Pfdhps* codons 437 and 540, *Pfcrt* codon 76 and *Pfmdr1* codon 86 were analysed by PCR on DNA from SMC population samples (after and before) and non-SMC population aged 7 years or above (November 2014, n=500). In SMC population 191 and 85 children before and after SMC implementation respectively were included in the molecular analysis. In the non-SMC population 220 were successfully PCR analysed. In the SMC population, the prevalence of the six-mutation *Pfcrt* [*Pfdhfr-dhps* quintuple + *Pfcrt*-76T] genotype increased significantly after SMC implementation, from 0.0% before to 7.1% (*p=0.0008*). The post-intervention prevalence of six-mutation *Pfmdr1* [*Pfdhfr-dhps* quintuple + *Pfmdr1*-86Y] and seven-mutation *Pfcrt+Pfmdr1* [*Pfdhfr-dhps* quintuple + *Pfmdr1*-86Y + *Pfcrt*-76T] genotypes were both the 1.2% among SMC population. No six-mutation and seven-mutation genotypes were observed neither among SMC population at baseline nor in the non-SMC population *(p=0.30)*. In conclusion, SMC increased the prevalence of the six-mutation *Pfcrt* genotype of *P. falciparum* that can lead to resistance in a population exposed to SMC with SP+AQ. However, there was no significant of six-mutation *Pfmdr1* and seven-mutation *Pfcrt-Pfmdr1* genotypes resistance in general parasite population.

265

PREVALENCE SURVEY OF *PLASMODIUM FALCIPARUM* ANTIMALARIAL DRUG RESISTANCE MARKERS IN CHINA

Fang Huang[1], Shui-Sen Zhou[1], Zhi-Gui Xia[1], He Yan[1], Hong-Ning Zhou[2], Guo-Ding Zhu[3], Li Cai[4], Hong-Wei Zhang[5], Li-Nong Yao[6], Jun Li[7], Li Li[8], Xiang-Li Kong[9], Pascal Ringwald[10], Rabindra Abeyasinghe[11], Xiao-Nong Zhou[1]

[1]National Institute of Parasitic Diseases, China CDC, Shanghai, China, [2]Yunnan Institute of Parasitic Diseases, China CDC, Pu'er, China, [3]Jiangsu Institute of Parasitic Diseases, China CDC, Wuxi, China, [4]Shanghai Disease Control and Prevention, Shanghai, China, [5]Henan Disease Control and Prevention, Zhengzhou, China, [6]Zhejiang Disease Control and Prevention, Hangzhou, China, [7]Guangxi Disease Control and Prevention, Nanning, China, [8]Sichuan Disease Control and Prevention, Chengdu, China, [9]Shangdong Institute of Parasitic Diseases, China CDC, Jinan, China, [10]Drug Efficacy&Response Unit, Global Malaria Programme, World Health Organization, Geneva, Switzerland, [11]Regional Office for Western Pacific, World Health Organization, Manila, Philippines

China has launched national malaria elimination program (NMEP) with an ultimate goal to interrupt the local malaria transmission by 2020. But the increasing imported cases with extensive distribution and dozens of deaths has be as one of the most challenges for national malaria elimination. Over the past 50 years, *Plasmodium falciparum* has developed resistance to all antimalarial drugs that have been used including chloroquine, amodiaquine, sulfadoxine-pyrimethamine, quinine, piperaquine and mefloquine. More recently, the emergence and spread of multidrug resistance including artemisinin and partner drug resistance of *P. falciparum* in Southeast Asia poses a significant risk to malaria control and eradication goals in the world. Therefore, it is urgent to monitor antimalarial drug resistance and track the emergence and spread of drug resistance in China. This was a cross-sectional, observational study using dried blood samples collected from *P. falciparum*-infected individuals at the time of malaria diagnosis from nine provinces which were selected based on the number of reported malaria cases in the past five years. The prevalence of known and candidate molecular markers of resistance to artemisinin, ACT partner drugs and other antimalarials would be measured by PCR and sequencing. Also, this study evaluated the population structure and gene flow of *P. falciparum* either between or within geographic regions using clustering algorithms such as those employed by programs like STRUCTURE or by principal components analysis (PCA). This study will provide evidence of the antimalarial drug resistance to guide the national malaria elimination programme.

OPTIMIZATION OF EMETINE DIHYDROCHLORIDE AS AN EFFECTIVE OPTION FOR MALARIA TREATMENT USING NANOPARTICLE DELIVERY SYSTEM

Muna S. Abubaker

University of Salford, Salford, United Kingdom

The field of drug development experiences very low success rates concerning drugs that enter the market. These are due to toxicity of the therapeutic compounds and poor solubility leading to lowered bioavailability. The major disadvantages of conventional antimalarial drugs are the development of multiple drug resistance and nonspecific drug targeting, resulting in the need for high dose administration and subsequent intolerable side effects that ultimately lead to patient non-compliance. To counteract these trends, research has been done in nanotechnology for the development of new biocompatible systems capable of incorporating drugs, lowering the resistance progress, control and treatment of malaria by target delivery. Targeting drugs specifically to their site of action would indeed enable optimal concentration in parasite-infected RBC. Various materials have been used in the formulation of nanoparticles for drug delivery research. Among these, nanoparticles prepared with albumin are biocompatible, biodegradable, non-antigenic, and relatively easy to prepare. We will present here preliminary data investigating the potential of human serum albumin nanoparticles in enhancing the treatment efficacy of antimalarials. Our preliminary validation data on artemether-loaded HSA nanoparticles show a 50% reduction in the IC_{50} values against *Plasmodium falciparum* K1 in comparison to drug only controls. Therefore, the current study was undertaken to define the efficacy of human serum albumin (HSA) as a nano-carrier strategy to improve drug delivery, enhance treatment efficacy and reduce non-target side effects for emetine dihydrochloride hydrate a drug the discovered through repositioning method at University of Salford. Our *in vitro* results indicated that emetine-loaded HSA nanoparticle permitted ~70% dose reduction compared to emetine only controls. It is expected that this study will eventually lead to a better understanding of nanotechnology delivery system and provide insights into new strategies for developing smart, well-tolerated, and efficacious therapeutic that could be a future ultimate way to cure this disease.

EX VIVO SUSCEPTIBILITY AND GENOTYPING OF *PLASMODIUM FALCIPARUM* ISOLATES FROM PIKINE, SENEGAL

Aminata Mbaye[1], Amy Gaye[1], Baba Dieye[1], Yaye Die Ndiaye[1], Amy K. Bei[2], Muna Affara[3], Awa B. Deme[1], Mamadou S. Yade[1], Khadim Diongue[1], Ibrahim M. Ndiaye[1], Ngayo Sy[1], Ousmane Koita[4], Donald J. Krogstad[5], Sarah Volkman[6], Davis Nwakanma[3], Daouda Ndiaye[2]

[1]Cheikh Anta Diop University, Dakar, Senegal, [2]Cheikh Anta Diop University, Harvard University, Dakar, Senegal, [3]Medical Research Concil Unit the Gambia, Dakar, Senegal, [4]University of Bamako, Dakar, Senegal, [5]Tulane University, New Orleans, LA, USA, Dakar, Senegal, [6]Department of Immunology and Infectious Diseases, Harvard School of Public Health, Dakar, Senegal

The monitoring of *Plasmodium falciparum* sensitivity to anti-malarial drugs is a necessity for effective case management of malaria. This species is characterized by a strong resistance to anti-malarial drugs. In Senegal, the first cases of chloroquine resistance were reported in the Dakar region in 1988 with nearly 7% population prevalence, reaching 47% by 1990. It is in this context that sulfadoxine–pyrimethamine temporarily replaced chloroquine as first line treatment in 2003, pending the introduction of artemisinin-based combination therapy in 2006. The purpose of this study is to assess the *ex vivo* sensitivity to different anti-malarial drugs of the *P. falciparum* population from Pikine. Fifty-four samples were collected from patients with non-complicated malaria and aged between 2 and 20 years in the Deggo health centre in Pikine in 2014. An assay in which parasites are stained with 4′, 6-di-amidino2-phenylindole (DAPI), was used to study the *ex vivo* sensitivity of isolates to chloroquine, amodiaquine, piperaquine, pyrimethamine, and dihydroartemisinin. High resolution melting was used for genotyping of pfdhps, pfdhfr, pfmdr1, and pfcrt genes. The mean IC50s of chloroquine, amodiaquine, piperaquine, dihydroartemisinin, and pyrimethamine were, respectively, 39.44, 54.02, 15.28, 2.23, and 64.70 nM. Resistance mutations in pfdhfr gene, in codon 437 of pfdhps gene, and an absence of mutation at position 540 of pfdhps were observed. Mutations in codons K76T of pfcrt and N86Y of pfmdr1 were observed at 51 and 11% population prevalence, respectively. A relationship was found between the K76T and N86Y mutations and *ex vivo* resistance to chloroquine. In conclusion, an increase in sensitivity of isolates to chloroquine was observed. A high sensitivity to dihydroartemisinin was observed; whereas, a decrease in sensitivity to pyrimethamine was observed in the parasite population from Pikine.

268

A BARCODE OF MULTILOCUS NUCLEAR DNA IDENTIFIES GENETIC RELATEDNESS IN PRE- AND POST-ARTEMETHER-LUMEFANTRINE TREATED *PLASMODIUM FALCIPARUM* IN NIGERIA

Kolapo M. Oyebola[1], Olugbenga Aina[2], Sola Ajibaye[2], Gordon Awandare[3], Alfred Amambua-Ngwa[1]

[1]Medical Research Council Unit of the London School of Hygiene & Tropical Medicine, Banjul, Gambia, [2]Malaria Research Group, Nigerian Institute of Medical Research, Lagos, Nigeria, [3]West African Centre for Cell Biology of Infectious Pathogens, College of Basic and Applied Sciences, University of Ghana, Accra, Ghana

Molecular surveillance for drug resistance in malaria-endemic regions is vital to detect the emergence and spread of mutant strains. We observed 89 malaria patients for efficacy of artemether-lumefantrine treatment of uncomplicated *Plasmodium falciparum* infections in Lagos, Nigeria and determined the prevalence of drug resistance in the population. Parasite clearance rates were assessed using *var* gene acidic terminal sequence (*var*ATS) polymerase chain reaction for patients' samples on days 0, 1, 3, 7, 14, 21 and 28 after commencement of treatment. The genomic finger print of pre- and post-treatment parasites were determined using 24 nuclear single nucleotide polymorphisms (SNP) barcode for *P. falciparum*. Drug resistance associated alleles in chloroquine resistance transporter gene *(crt*-76), multidrug resistance genes *(mdr*1-86 and *mdr*1-184), dihydropteroate synthase (*dhps*-540), dihydrofolate reductase (*dhfr*-108) and kelch domain *(K-13* 580) were genotyped by high resolution melt analysis. Twelve (18.5%) of the participants had detectable parasites three days after treatment, while eight (12.3%) individuals presented with day 28 parasitaemia. Barcode (ϖ) pairwise comparisons showed genetic relatedness of day 0 and day 28 parasite isolates in three (37.5%) of the eight re-appearing infections. No mutation in the *K-13* 580 was observed. Evidence of genetic relatedness between pre- and post-treatment infections despite the absence of K-13 580 warrants genomic investigation in a larger population for signs of reduced ACT efficacy in Nigeria.

269

CHANGES IN THE PREVALENCE OF DRUG RESISTANCE MEDIATING *PLASMODIUM FALCIPARUM* POLYMORPHISMS ACROSS UGANDA OVER TIME

Victor Asua[1], Joanna Vinden[2], Jennifer Legac[2], Andrew Walakira[1], Stephen Tukwasibwe[1], Joaniter I. Nankabirwa[1], Moses R. Kamya[1], Samuel L. Nsobya[1], Melissa D. Conrad[2], Philip J. Rosenthal[2]

[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]University of California San Francisco, San Francisco, CA, United States

Antimalarial drug resistance, mediated in part by known *Plasmodium falciparum* genetic polymorphisms, is worrying. Chloroquine plus sulfadoxine-pyrimethamine (SP) was replaced as the Ugandan treatment regimen by artemether/lumefantrine (AL) in 2006. SP is used to prevent malaria in pregnant women. Recent reports show changing prevalence of key parasite polymorphisms. We conducted surveillance to assess recent trends. Fifty samples were collected in each of 3 surveys every 6 months in 2016-17 from children (6 mo-10 y) diagnosed with malaria by microscopy or rapid test at each of 10 sites across Uganda. Polymorphisms were characterized by PCR and ligase detection reaction fluorescent microsphere assays (transporter and antifolate mutations), copy number (CN) variation was assessed by qPCR, and the K13 propeller domain was sequenced. Prevalences of polymorphisms varied across the country, but temporal trends were similar. For transporters, increasing prevalence of *pfcrt* K76 (65.9-100% at different sites in the most recent survey), *pfmdr1* N86 (all 100%), and *pfmdr1* D1246 (84.6-100%) wild type alleles, all associated with increased susceptibility to aminoquinolines and decreased susceptibility to lumefantrine, were seen. Polymorphisms in antifolate enzymes associated with resistance to SP (*pfdhfr* 51I, 59R, 108T and *pfdhps* 437G and 540E) were very common, and additional polymorphisms associated with higher-level resistance (*pfdhps* 581G 0-44.4% and *pfdhfr* 164I 0-11.4%) were seen, especially in SW Uganda. Other polymorphisms associated with altered sensitivity to lumefantrine (increased *pfmdr1* CN), piperaquine (increased *plasmepsin* CN), and artemisinins (K13 mutations) were uncommon. We identified gradual reversion to wild type transporter alleles with increasing use of AL to treat malaria, persistent prevalence of 5 common antifolate mutations despite decreased use of SP, additional antifolate mutations that predict high level SP resistance, and limited prevalence of additional polymorphisms now mediating ACT resistance in SE Asia. Continued surveillance for drug resistance markers is an important priority.

270

SYNTHESIS, CHEMICAL AND BIOLOGICAL VALIDATION OF ARTEMISININ-BASED PROBES FOR ARTEMISININ'S DERIVATIVES ANTIPARASITIC MECHANISM OF ACTION STUDY IN *PLASMODIUM FALCIPARUM*

Abdoulaye Sissoko[1], Sandrine Houze[2], Romain Duval[1]

[1]Paris Descartes University/UMR216-MERIT/IRD, Paris, France, [2]National Reference Center for Malaria of Paris (CNR du paludisme)/APHP Hospital Bichat, Paris, France

Over 3 billion of people are exposed to malaria, caused by *Plasmodium* genus and responsible for about 416.000 deaths in 2016 worldwide. Artemisinin derivatives (ART) are the first-line treatment in most malaria-endemic countries for nearly two decades. The emergence of As reported previously, *Plasmodium falciparum* resistant parasites to ART in Southeast Asia and the fear of their spread to endemic areas with high transmission rate are threatening this treatment. Although progresses on elucidation of ART's mechanisms of action, its exact targets and detailed mechanism of action have not been fully understood yet. ART is thought to be activated in parasite food vacuole by iron (Fe^{2+} or haem). Once activated, it generates carbon-centered radicals via endoperoxide cleavage which in turn alkylate parasite macromolecules, leading to the parasite death, as reported previously. Mechanistic study of ART, based on its behavior in terms of stability, chemical proteomics and imaging approaches are needed to determine its location in the parasite and to identify its targets. To achieve these objectives, three fluorescent dihydroartemisinin-based probes were successfully synthesized and characterized. Furthermore, their stability was assessed by Fluorescent-High performance/Mass spectrometry in different conditions and their biological activity assessed in ART sensitive and resistant strains (*3D7*, *NF54K13* which are sensitives and *NF54K13C580Y* which carries a C580Y mutation on *PfK13* gene responsible for artemisinin resistance). The best probe has proven to be stable overtime (2hours) and very effective on strains with IC_{50} value 22.52 nM, 11.16 nM and 9.55 nM respectively, compared to some major ART-based probes, as reported previously. To this date, there is no other stability study of ART-based probes in those conditions. Abstract ASTMH-2018 Sissoko Abdoulaye Those results allowed us to validate biologically our chemical tools, making them suitable for proteomics studies which are ART's targets tracking by Fluo-PAGE (ongoing promising experiments).

271

SURVEILLANCE OF ANTIMALARIAL DRUG EFFICACY IN MANGALORE, KARNATAKA, SOUTH INDIA

Rakshita Maskeri, Animesh Jain, Sheetal Ullal, Suchitra Shenoy, Damodar Shenoy, Sharada Rai

Kasturba Medical College, Mangalore, India

Malaria continues to be a devastating disease in India and Mangalore is endemic to malaria. The aim was to assess antimalarial drug efficacy in Mangalore, South India by clinical and parasitological evaluation. This study was conducted at the Urban health centre and District hospital Mangalore. Clinical history and oral temperature were recorded in patients with microscopically confirmed malaria. Peripheral blood smear was done on day 0, 3, 7, 28 and parasite load was calculated. As per the WHO guidelines clinical response was classified as (i) Early Treatment Failure, (ii) Late Clinical Failure (LCF), (iii) Late Parasitological Failure (LPF) and (iv) Adequate clinical and parasitological response. Therapeutic Failure was considered if any of the above criteria was present. Eight hundred thirty two *Plasmodium vivax, P. falciparum* or mixed infection were identified and included. Six hundred fifty nine patients completed the 28 day follow up (79.2%) while one hundred and seventy three were lost to follow up. As per the policy of the National Vector Borne Disease Control Programme (NVBDCP) of India, *P.vivax* was treated with Chloroquine and Primaquine regimen, while *P. falciparum* and mixed infections were treated with ACT Artesunate+Sulphadoxine+Pyrimethamine and Primaquine regimen. There were a total of 6 cases of LCF out of which 3 cases of *P.vivax* infection later developed *P. falciparum* infection before day 28 with clinical symptoms suggesting LCF of *P. falciparum* to chloroquine. There was 1 case of *P.vivax* infection who later developed *P.vivax* infection again on day 15 suggesting LCF of *P. vivax* to chloroquine. There were 2 cases of *P. falciparum* infection which later developed *P. falciparum* infection again before day 28 suggesting LCF of *P. falciparum* to Artesunate+Sulphadoxine-Pyrimethamine. There were 14 cases of LPF out of which 11 were *P. vivax* infection with persistence of parasite on day 7; 3 of *P. vivax* infection who later developed *P. falciparum* infection on day 28 with no clinical symptoms suggesting LPF of *P. falciparum* to chloroquine. This study demonstrates an estimate of around 3% treatment failure to antimalarials in Mangalore.

272

HIGH THROUGHPUT RESISTANCE PROFILING OF *PLASMODIUM FALCIPARUM* INFECTION IN TWO ECOLOGICAL REGIONS OF GHANA USING MOLECULAR INVERSION PROBES AND NEXT GENERATION SEQUENCING

Benedicta Ayiedu Mensah[1], Benjamin Abuaku[1], James Myers-Hansen[1], Kwadwo Koram[1], Ozkan Aydemir[2], Patrick Marsh[2], Nicholas Hathaway[2], Francis Anto[3], Jeffrey Bailey[2], Anita Ghansah[1]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]University of Massachusetts Medical School, Worcester, MA, United States, [3]University of Ghana School of Public Health, Accra, Ghana

A key drawback to monitoring the emergence and spread of antimalarial drug resistance in sub-Saharan Africa is early detection and containment. Next-generation sequencing (NGS) methods offers the resolution, sensitivity and scale required to fill this gap during surveillance of molecular markers of drug resistance. We applied the targeted sequencing approach using Molecular Inversion Probes (MIP) for targeting and MISEQ for high throughput sequencing of five *Plasmodium falciparum* genes (*Pfcrt*, *Pfdhfr*, *Pfdhps*, *Pfmdr1* and *Pfk13*) implicated in anti-malarial resistance to chloroquine (CQ), sulphadoxine-pyrimethamine (SP) and artemisinin, A total of 800 dried blood spots on filter paper were collected from symptomatic children, aged between 6 months and 14 years, infected with *Plasmodium falciparum* mono-infections in the coastal savanna (Cape-Coast) and the forest zones of Ghana (Begoro) from 2014 to 2017. DNA was extracted and sequenced on the MISEQ platform after targeting the drug resistance genes using MIPs and then amplification. Molecular markers associated with CQ resistance (*Pfcrt* and *Pfmdr1*) significantly reduced over the four years of study (χ^2=40.57 P<0.0001 for 76T and χ^2=8.76 p = 0.003 for 86Y) except *Pfmdr1*184F which has remained high over the years (68% to 83%). *Pfcrt* 76T has reverted to wild type K76 in the forest ecological zones in Ghana after 13 years of drug removal. The individual markers that make up quintuplet haplotype (IRNGE) which is associated SP efficacy are almost at fixation except E540 which is very low in Ghana; thus making the IRNGE haplotype non-existent in Ghana. In addition to the *Pfdhps* 437G and 540E mutations, this study identified other mutations 436A (41% - 66%) and 613S (6% - 18%) in Ghana. There was no evidence of markers implicated in artemisinin resistance in Ghana. There was a steady progression towards the re-expansion of the chloroquine sensitive parasite K76 although the progress is faster in the forest region than on the coastal belt. This study also identified other mutations associated with pyrithiamine resistance that forms other haplotype combinations that can exacerbate SP resistance in Ghana.

273

PLASMODIUM FALCIPARUM IN VIVO CLEARANCE TIME AFTER ARTESUNATE TREATMENT IN MALI

Aminatou Kone[1], Antoine Dara[1], Nouhoum Diallo[1], Moctar Coulibaly[1], Aboubecrine Haidara[1], Boubou Sangaré[1], Cheick Oumar Sangaré[1], Issaka Sagara[1], José Pedro Gil[2], Ogobara K. Doumbo[1], Abdoulaye A. Djimde[1]

The molecular mechanisms used by the plasmodium to survive the drug exposure time and expand afterward are unclear. Several studies describe the dormancy phenomenon as a possible way for the parasite to slow down or stop its metabolism in order to over cross the threatening time of drug exposure resulting in post treatment recurrent parasitemia or prolonged parasite clearance time (PCT). In Africa, the few cases of treatment failures with ACTs and delayed PCT are not attributable to the South-East Asian K13 resistance associated mutations. A pilot study in Mali showed that despite high artesunate efficacy and the absence of PfK13 mutations, a significant difference exists between patient's parasite clearance times in two villages. There is the need to investigate parasite and host factor's role in the differential post treatment clearance time. A study is currently being conducted in the Malian village of Faladjé on volunteers over 6 months of age presenting with uncomplicated malaria and treated with artesunate in monotherapy during 7 days. We plan to i)investigate the proportion of viable vs dormant parasite using flow cytometry, ii) assess the relationship between dormancy and parasite clearance time and the occurrence of recurrent parasitemia, and iii) analyze differential parasite transcriptomes under drug pressure. During the last malaria transmission season venus blood and plasma samples were collected for each patient at H0, H8 and H16 Plasma samples were collected prior to treatment and processed on the ArrayCAM® 400-S Microarray Imaging System to assess the role of the host immunity level in the clearance time. To date, 68 patients were included RNA collected and frozen. All the plasma samples were scanned for 250 antigens of *Plasmodium falciparum*. Data analysis is underway and results will be presented at the congress. Result from the study would help in understanding the multifactorial dimension of malaria parasite clearance as well as the molecular or biochemical mechanisms of artemisinin resistance in high transmission areas of sub-Saharan Africa.

274

EMERGING SOUTHEAST ASIAN PFCRT MUTATIONS CONFER *PLASMODIUM FALCIPARUM* RESISTANCE TO THE FIRST-LINE ANTIMALARIAL PIPERAQUINE

Leila Ross[1], Satish Dhingra[1], Sachel Mok[1], Tomas Yeo[1], Krittikorn Kumpornsin[2], Shannon Takala-Harrison[3], Benoit Witkowski[4], Rick Fairhurst[5], Fred Ariey[6], Didier Menard[4], David Fidock[1]

The widely-used antimalarial combination therapy dihydroartemisinin plus piperaquine (DHA+PPQ) has failed in Cambodia. Here, we report genomic analysis that reveals rapid proliferation of novel mutations in the *Plasmodium falciparum* chloroquine resistance transporter PfCRT in Cambodia following DHA+PPQ implementation. Using gene editing, we added these mutations into Dd2 parasites or removed them from contemporary Cambodian isolates. Results show that the PfCRT mutations H97Y, F145I, M343L, and G353V each confer resistance to PPQ, albeit at a steep fitness cost for all but M343L. These mutations sensitized Dd2 parasites to the antimalarial drugs chloroquine, amodiaquine, and quinine. Multicopy *plasmepsin 2*, previously reported as a molecular marker, was not necessary for PPQ resistance. Our studies also identified aberrant digestive vacuole morphologies in gene-edited PPQ-resistant Dd2 parasites, but not in the PPQ-resistant Cambodian isolates. Our findings provide compelling evidence that emerging mutations in PfCRT can serve as a molecular marker and mediate PPQ resistance.

275

PREVALENCE OF *PFK13*-PROPELLER AND *PFCRT* MUTATIONS IN ISOLATES FROM CHILDREN WITH UNCOMPLICATED MALARIA IN SOUTHWEST NIGERIA

Abayomi Sijuade[1], J. Schaer[2], J. Fadare[1], O. Oluwayemi[3], A. Ajetunmobi[4], A. Olalekan[5], F. Mockenhaupt[6], K. Matuschewski[2]

[1]Department of Pharmacology & Therapeutics, College of Medicine, Ekiti State University, Ado Ekiti, Nigeria, [2]Molecular Parasitology, Humboldt-University, Berlin, Germany, [3]Department of Paediatrics, College of Medicine, Ekiti State University, Ado Ekiti, Nigeria, [4]Department of Paediatrics, Federal Teaching Hospital, Ido Ekiti, Nigeria, [5]Department of Chemical Pathology, University College Hospital, Ibadan, Nigeria, [6]Charité Universitätsmedizin Berlin, Institute of Tropical Medicine and International Health, Berlin, Germany

The emergence of resistance in *Plasmodium falciparum* to commonly used antimalarial drugs, such as Artemisinin derivatives, is a major threat to malaria control and elimination worldwide. One of the surveillance strategies to monitor drug resistance is the analysis of single nucleotide polymorphisms (SNPs) of the associated genes. Monitoring of resistance in malaria-endemic areas is essential to identify strategies to prevent the spread of resistances in the population. *P. falciparum* isolates from children attending three outpatient clinics in southwestern Nigeria were collected on filter paper. Genomic DNA was extracted and the *PfK13*-propeller domain amplified by nested PCR and Sanger- sequenced. In addition, the *Pfcrt* gene at codon 76 was monitored using mutation-specific nested PCR and the restriction fragment length polymorphism (PCR-RFLP) method. The *Pf*K13 propeller domain was sequenced for 90 isolates. Five patients (6%) carried the following synonymous mutations, R528R, A627A, Y493Y, I587I and Y493Y. Mutations of the *Pfcrt* gene at codon 76 (K76T) were observed in 42% of 122 isolates. No significant difference between parasitaemia geometric means in wild type and mutant alleles of the isolates was noted. Of note, two (out of the five) isolates that showed synonymous mutations at the *K13* propeller domain simultaneously featured the *Pfcrt* K76T mutant allele. This cross-sectional study highlights the need for continuous molecular surveillance of antimalarial resistance in Nigeria to develop and adjust national antimalarial treatment guidance. Strikingly, emergence of artemisinin resistance has not occurred yet despite the widespread and lasting routine application of artemisinin-combination therapies, which are mostly produced by national drug companies. Our data support the notion of high standard antimalarial drugs in circulation in Nigeria.

276

PREVALENCE OF *PFMDR1*, *PFK13* AND *PFCRT* POLYMORPHISMS DURING A THERAPEUTIC EFFICACY STUDY IN WESTERN KENYA

Winnie Chebore[1], Zhiyong Zhou[2], Nelli Westercamp[2], Kephas Otieno[1], Ya Ping Shi[2], Sheila B. Sergent[2], Samaly dos Santos Souza Souza[2], Venkatachalam Udhayakumar[2], Eric S. Halsey[3], Aaron Samuels[4], Simon Kariuki[1]

[1]Kenya Medical Research Institute, Centre for Global Health Research, Kisumu, Kenya, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States/ United States President's Malaria Initiative, Atlanta, GA, United States, [4]Centers for Disease Control and Prevention, Kisumu, Kenya/ Centers for Disease Control and Prevention, Atlanta, GA, United States

WHO recommends that therapeutic efficacy studies (TES), currently considered the gold standard for monitoring parasite resistance to antimalarial drugs, be conducted routinely in endemic countries and that they incorporate surveillance for molecular markers of drug resistance

along with clinical and parasitological efficacy outcomes. As part of TES conducted in 2016-17 to monitor the efficacy of artemether-lumefantrine (AL) and dihydroartemisinin-piperaquine (DP) for treatment of uncomplicated *Plasmodium falciparum* malaria in western Kenya, we tested for drug resistance markers of *PfK13* propeller domain, *Pfmdr1* and *Pfcrt* genes by sequencing. Additionally, *Pfpm2* gene copy number was assessed by real-time PCR. All the available samples (325 day 0 and 110 recurrent infections) were tested. Sequencing of the *PfK13* gene was successful for 406 samples, of which 11 (2.7%) samples had non-synonymous mutations: 7 had A578S, 2 had S522C, 1 had E596D and 1 had C580F. However, none of these mutations have been associated with artemisinin resistance. For multidrug resistant marker *Pfmdr1*, 418 samples were successfully sequenced. Out of 323 day 0 samples, 1 had N86Y, 192 had Y184F and 30 had D1246Y mutations. Out of 95 samples with recurrent infections, 1 had N86Y, 59 had Y184F and 5 had D1246Y mutations. Overall, 152/418 (36.4%) samples were wild type (NYSND). For *Pfcrt*, 415 samples were successfully sequenced and none had a C72S mutation; 6 samples had M74I, 8 had N75D/E and 8 had K76T mutations. In total, 407/415 (98.1%) samples were wild type (CVMNK). All 12 recrudescent samples (8 from DP and 4 from AL arms) analysed for *Pfpm2* gene copy number had a single gene copy. In summary, we detected no *PfK13* mutations associated with artemisinin resistance in this Kenyan TES. Although a high frequency of *Pfmdr1* Y184F mutations was detected, the implications of the mutation remain unclear. The prevalence of chloroquine resistance markers was very low and there was no increase in *Pfpm2* copy numbers associated with DP resistance. Continued biennial monitoring for resistance mutations is needed for providing timely evidence-based malaria treatment policies.

277

DECLINING RESPONSIVENESS OF CHILDHOOD *PLASMODIUM FALCIPARUM* INFECTIONS TO ARTEMISININ-BASED COMBINATION TREATMENTS TEN YEARS FOLLOWING DEPLOYMENT AS FIRST-LINE ANTIMALARIALS IN NIGERIA

Development and spread of artemisinin-resistant falciparum malaria in Greater Mekong Subregion has created impetus for continuing global monitoring of efficacy of artemisinin-based combination therapies (ACTs). At 14 sentinel sites in six geographical areas of Nigeria, we evaluated treatment responses in 1341 children 6-59 months old and in additional 360 children 6-191 months old with uncomplicated falciparum malaria enrolled in randomised trials of artemether-lumefantrine *versus* artesunate-amodiaquine at 5 years interval in 2009-2010 and 2014-2015 (PACTR201510001189370 and PACTR201709002064150) and at 2 years interval in 2009-2010 and 2012-2015 (PACTR201508001191898 and PACTR201508001193368), respectively after deployment in 2005. Proportions of children with residual asexual parasitemia [asexual parasite positivity] 1 day post-treatment initiation (APPD1) rose from 54 to 62% and 2 days post-treatment initiation (APPD2) from 5 to 26% in 2009-2010 to 2014-2015 (P=0.002 and P<0.0001, respectively). Parasite clearance time increased significantly from 1.6 days (95%CI 1.55-1.64) to 1.9 days (95%CI 1.9-2) and parasite reduction ratio 2 days post-treatment initiation (PRRD2) decreased significantly from a geometric mean of 11000 to 4700 folds per cycle within the same time period (P<0.0001 for each). Parasitemia >75000μL^{-1}, hematocrit >27% 1 day post-treatment initiation, treatment with artemether-lumefantrine and enrolment in 2014-2015 independently predicted APPD1. In parallel, Kaplan-Meier estimated risk of recurrent infections by day 28 rose from 8% to 14% (P=0.005) and from 9% to 15% (P=0.02) with artemether-lumefantrine and artesunate-amodiaquine, respectively. Asexual parasitemia half-time increased significantly from a mean of 1.1 hour to a mean of 1.3 hour within 2 years (P<0.0001). Enrolment in 2012-2015 was significantly associated with 50% increase in mean asexual parasitemia half-time from the baseline. The declining parasitological responses through time to the two ACTs may be due to emergence of parasites with reduced susceptibility or decreased immunity to the infections in these children.

278

PAIRWISE COMPETITIONS OF CLONAL *PLASMODIUM FALCIPARUM* ISOLATES CARRYING DIFFERENT *KELCH13* MUTATIONS QUANTIFY FITNESS RELATIONSHIPS

Katelyn M. Vendrely[1], Lisa A. Checkley[1], Marina McDew-White[2], François H. Nosten[3], Timothy J.C. Anderson[2], Michael T. Ferdig[1]

[1]Eck Institute for Global Health, University of Notre Dame, Notre Dame, IN, United States, [2]Texas Biomedical Research Institute, San Antonio, TX, United States, [3]Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Mahidol University, Mae Sot, Thailand

Drug resistance confers a fitness advantage to parasites exposed to frequent drug pressure, but these mutations often impose a relative fitness cost in the absence of drug pressure. With the emergence of artemisinin (Art) resistance, it is essential to understand the relative competitive fitness of resistant *Plasmodium falciparum* clones in the presence and absence of drug pressure, especially in the context of diverse *kelch13* mutations, to assess their impact on competitive growth outcomes. *In vitro* competitive growth assays provide accurate estimates of relative growth rates of different parasite genotypes as well as a quantitative index of fitness disparities. These readouts can be used to infer relatively fast-growing parasites in monoclonal infections common in Southeast Asia and also provide a glimpse of possible in host dynamics in multi-clone infections. Pairwise competitive growth outcomes of genetically distinct Art-resistant and Art-sensitive clones recently isolated from the Thailand-Myanmar border were evaluated after short perturbations of dihydroartemisinin (DHA) at 700 nM. Our novel *in vitro* 96-well plate competitive growth assays and fluorescent labeled microsatellite markers were used to measure the relative growth densities of each parasite throughout the co-growth period of 80 days. Assessing fitness advantages and costs of Art-resistance *in vitro* could provide insights about how drug resistance will spread and evolve in a competitive environment with infrequent exposure to artemisinin drugs and inform strategies for targeted malaria therapy.

279

RE-EXPANSION OF CHLOROQUINE SENSITIVE HAPLOTYPES IN THE *PLASMODIUM FALCIPARUM* RESERVOIR OF INFECTION IN BONGO DISTRICT, GHANA

Charles A. Narh[1], Kathryn E. Tiedje[1], Michael F. Duffy[1], Anita Ghansah[2], Abraham R. Oduro[3], Kwadwo A. Koram[2], Karen P. Day[1]

[1]School of Bioscience, Bio21 Institute/University of Melbourne, Melbourne, Australia, [2]Noguchi Memorial Institute for Medical Research, University of Ghana, Legon, Accra, Ghana, [3]Navrongo Health Research Centre, Navrongo, Ghana

Widespread resistance to chloroquine (CQ) informed the switch to artemisinin combination therapy (ACT) for malaria treatment in the early 2000s. CQ sensitive *P. falciparum* have since re-expanded in parts of Africa including Ghana, after withdrawal of CQ use. In Ghana, the genomic signatures of clinical isolates suggest artesunate-amodiaquine (ASAQ) and artemether-lumefantrine (AL) exert differential selection at the two drug transporter genes, *Pfcrt* and *Pfmdr1*. What is happening to the spread of resistance genes in the large reservoir of asymptomatic infections compared to clinical cases has been poorly studied. Hence we investigated this question in Bongo District, Ghana at the end of the 2012 dry season. *P. falciparum* isolates were sequenced at *Pfcrt* (codons 72-76; N=170) and *Pfmdr1* (codons 86,184; N=198). The prevalence of the CQ sensitive haplotype, *Pfcrt* CVMNK was 88.2% and the resistant haplotype, CVIET, was 3.5%. For *Pfmdr1*, the prevalences of the wildtype (NY) and mutant (NF) were 17.7% and 69.7%, respectively. To investigate selection of these haplotypes, isolates with single genomes were further typed at microsatellite loci linked to *Pfcrt* (N=48) and *Pfmdr1* (N=46). The percentage of unique multilocus haplotypes was high for *Pfcrt* CVMNK (95.8%) and the diversity was also high (H_e=0.75), suggestive of soft selective sweeps. Our results indicate that the CQ sensitive parasites have re-expanded from a genetically diverse parasite reservoir that predates ACT introduction. For *Pfmdr1* NY and NF, all isolates had unique multilocus haplotypes, and there was no significant difference in the H_e (NY: 0.85, NF: 0.83), suggestive of equal selective advantage. ACTs have a role in diversifying *Pfmdr1*, which warrants further investigation to decipher the patterns of selection. We have shown that the asymptomatic reservoir, which has little exposure to antimalarial drugs at the end of the dry season, harboured highly diverse *Pfcrt* and *Pfmdr1* haplotypes. The treatment policy change has influenced this diversity and as such, it is important to prioritize this reservoir during monitoring programs to inform policy.

280

PLASMODIUM FALCIPARUM TRIPLE MUTANT IN CAMBODIA: PHENOTYPIC CHARACTERIZATION OF RESISTANCE

Mélissa Mairet-Khedim, Nimol Khim, Benoit Witkowski

Pasteur Institute of Cambodia, Phnom Penh, Cambodia

Despite a large reduction of malaria prevalence in part due to Artemisinin based combination therapies (ACTs) implementation, Cambodia is still the epicentre of *Plasmodium falciparum* multidrug resistance. The consecutive use of the artesunate-mefloquine (AS-MQ) and dihydroartemisinin-piperaquine (DHA-PPQ) combinations in this country between 2000 and 2016 has selected for both artemisinin and partner drug resistance. As a result, a high treatment failure rate was observed for these two combinations and ACTs resistance is now widespread in the Greater Mekong Subregion (GMS). The situation is made worst by the recent *P. falciparum* triple-mutant parasites emergence in Cambodia, exhibiting the three genotypes associated with both artemisinin, mefloquine and piperaquine resistance. However, the impact of this triple-genotype combination on treatment efficiency has not yet been studied, and the *in vitro* phenotype of these parasites still has to be characterized. We observed that the *P. falciparum* triple-mutant parasites found in Cambodia (presenting *Kelch13* mutation and amplification of *Pfmdr1* and *Pfplasmepsin2* genes) were not associated with treatment failure in patients. In addition, *in vitro* susceptibility assays (piperaquine survival assay and mefloquine IC_{50} determination) have shown that this triple-resistant genotype was not associated with a triple *in vitro* resistance to both artemisinin, mefloquine and piperaquine. An inverse correlation between piperaquine and mefloquine resistance was even observed *in vitro*, suggesting a too important cost for triple-mutant parasites fitness to express both *Pfmdr1* and *Pfplasmepsin2* genes. Altogether, our results allow a better characterization of triple-mutant *P. falciparum* parasites observed in Cambodia, and are reassuring concerning the dangerousness level of these parasites. Nonetheless, further efforts to strengthen the triple-mutant parasites monitoring remain crucial since the triple combination therapy (artemisinin, mefloquine and piperaquine) is considered by WHO as a possible treatment for uncomplicated *P. falciparum* Malaria.

281

DIAGNOSING A RARE CAUSE OF MASSIVE SPLENOMEGALY IN RURAL RWANDA

Jessica Tuan, Clara Weinstock

University of Connecticut, Farmington, CT, United States

A 21-year-old female with a history of recurrent malaria presented in rural Rwanda with two weeks of hematemesis, malaise, and abdominal pain, in the setting of chronic abdominal distention. On exam, her abdomen was diffusely tender, distended, with grade V massive splenomegaly extending beyond the midline and umbilicus. Labs showed WBC 3,000/uL, Hb 9 g/dL, HCT 27%, PLT 40,000/uL with 6% reticulocytes. Thick smear was negative for malaria and peripheral blood smear showed microcytosis and macrocytosis without malignant cells. In this limited-resource area, anti-malarial antibodies could not be obtained. She was Hepatitis C antibody positive. Abdominal ultrasound showed massive splenomegaly (diameter 30 cm), portal hypertension, and ascites. She was diagnosed with Hyperreactive Malarial Splenomegaly (HMS) and started on three days of artemether/lumefantrine, doxycycline, and folic acid without response. Clinical improvement may take weeks. On day seven, she went into status epilepticus and vomited several times, was intubated, and passed away the next day. Urine culture grew Klebsiella pneumonia on day seven, although she was asymptomatic. It is plausible that a urinary tract infection led to her seizures and respiratory failure from aspiration led to her death. HMS is a diagnosis of exclusion based on Fakunle's major criteria: Gross splenomegaly, elevated IgM, high anti-malarial antibodies, clinical response to antimalarial therapy. In case studies from malaria-endemic areas, excluding other causes of splenomegaly was adequate in diagnosing HMS. Massive splenomegaly presents in certain conditions, such as leukemia, lymphoma, or thalassemia—deemed less probable—and HMS. Hematology was consulted and based on her history, massive splenomegaly, cytopenias, and peripheral blood smear without malignant features, a clinical diagnosis of HMS was made. HMS is a complication of recurrent malaria, in which chronic antigenic stimulation with repetitive Plasmodium species infections is postulated to lead to overproduction of IgM and splenic sequestration. Prompt recognition of HMS is vital, and if left untreated it is often fatal.

282

CORRELATION BETWEEN THROMBOCYTOPENIA AND ANEMIA IN *PLASMODIUM FALCIPARUM* MALARIA AMONG PATIENTS IN KISUMU COUNTY-WESTERN KENYA

Paul Kosiyo[1], Peter Odada[2], John Oluoch[3], Abdallah Fatmah[4], Albert Onyango Mala[4]

[1]Maseno University, Kisumu, Kenya, [2]KEMRI, Kisumu, Kenya, [3]University of Nairobi, Nairobi, Kenya, [4]Jomo Kenyatta University of Science and Technology, Nairobi, Kenya

Malaria is associated with haematological complications which may be avoided by early diagnosis and treatment. Microscopic diagnosis showing presence of malarial parasites remains the gold standard and is needed for

confirmation which requires technical expertise. The study was therefore carried out to determine the correlation between thrombocytopenia and anaemia in *Plasmodium falciparum* malaria. The study was conducted in Kisumu County-Kenya which is a highly endemic malaria region. Both thick and thin blood smears were used to determine *P. falciparum* infection status in a total of 228 patients comprising of 157 infected and 71 non-infected patients presenting with acute febrile illness. All participants' demographics and haematological parameters i.e. Haemoglobin level, platelet count, mean platelet volume and platelet distribution width were analysed. Haemoglobin and platelet count were significantly lower in the malaria infected group (p<0.001). Conversely, mean platelet volume and platelet distribution width were higher in comparison to non-infected group (p<0.001). Severe to moderate anaemia was present in 78 %(n=122) of malaria infected patients against 47 % (n=33) of the non-infected group (p<0.001) while thrombocytopenia was present in 87 %(n=137) of the infected patients against 10 % (n=7) of the non-infected group (p<0.001). There was a positive correlation between anaemia and thrombocytopenia in malaria (r= 0.26, p<0.001). In conclusion, low platelet count and Haemoglobin levels positively correlate and can be important predictors of *P. falciparum* malaria when used in combination with other clinical manifestations. This could help in avoiding unnecessary expensive tests to rule out other febrile conditions. The above findings also have therapeutic implications of avoiding unnecessary platelet infusion in malaria.

283

RELAPSE ACCOUNTED FOR AN OVERWHELMING NUMBER OF VIVAX MALARIA CASES BOTH IN THE MAJOR AND MINOR TRANSMISSION SEASONS OF ETHIOPIA

Lemu Golassa[1], Michael T. White[2]

[1]Aklilu Lemma Institute of Pathobiology, Addis Ababa University, Addis Ababa, Ethiopia, [2]Department of Infectious Diseases Epidemiology, London, United Kingdom

Plasmodium falciparum and *P. vivax* are co-endemic in Ethiopia and the latter accounts for about 40% of malaria cases. A single infection with *P. vivax* and *P. ovale* causes repeated bouts of illness weeks to months after the primary infection. Efforts to control and eventual elimination will be challenged in the absence of drugs able to cure both the blood stage and the liver stage infections, and thereby prevent both relapse and recrudescence. Indeed, the proportion of vivax malaria cases due to relapse in the wet and dry seasons remain unaddressed. Seasonal patterns in malaria cases were analysed using statistical models, identifying the peaks in cases, and the seasonally varying proportion of *P. vivax* cases attributable to relapses. A total of 3,161 febrile patients visited Adama malaria diagnostic center. Finger-prick blood samples were collected for thin and thick blood film preparation. The proportion of patients with malaria detectable by light microscopy was 36.1% (1141/3161) of which *P. vivax*, *P. falciparum*, and mixed infections accounted for 71.4, 25.8 and 2.8%, respectively. Of the febrile patients diagnosed, 2134 (67.5%) were males and 1919 (60.7%) were urban residents. The model identified a primary peak in *P. falciparum* and *P. vivax* cases from August to October, as well as a secondary peak of *P. vivax* cases from February to April attributable to cases arising from relapses. During the secondary peak of *P. vivax* cases approximately 77% (95% CrI 68, 84%) of cases are estimated to be attributable to relapses. During the primary peak from August to October, approximately 40% (95% CrI 29, 57%) of cases are estimated to be attributable to relapses. It is not possible to diagnose whether a *P. vivax* case has been caused by blood-stage infection from a mosquito bite or a relapse. However, differences in seasonal patterns of *P. falciparum* and *P. vivax* cases can be used to estimate the population-level proportion of *P. vivax* cases attributable to relapses. These observations have important implications for initiating therapy that is effective against both blood stages and relapses.

284

STABILIZATION OF RDT TARGET ANTIGENS PRESENT IN DRIED *PLASMODIUM FALCIPARUM*-INFECTED SAMPLES FOR VALIDATING MALARIA RAPID DIAGNOSTIC TESTS AT THE POINT OF CARE

Collins Misita Morang'a[1], Cyrus Ayieko[2], George Awinda[1], Rachel Achilla[1], Caroline Moseti[1], Bernhards Ogutu[3], John Waitumbi[1], Elizabeth Wanja[4]

[1]US Army Medical Research Directorate- Kenya/ Kenya Medical Research Institute, Kisumu, Kenya, [2]Maseno University, Kisumu, Kenya, [3]Kenya Medical Research Institute, Center for Clinical Research, Kisumu, Kenya, [4]United States Army Medical Research Directorate-Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, Kenya

Malaria rapid diagnostic tests (RDTs) are a great achievement in implementation of parasite-based diagnosis as recommended by World Health Organization. A major drawback of RDTs is the lack of positive controls to validate different batches at the point of care. Dried *Plasmodium falciparum*-infected samples with RDT target antigens have been suggested as a possible positive control but their utility in resource limited settings is hampered by rapid loss of activity over time. In this study we evaluated effectiveness of chemical additives to improve long term storage stability of RDT target antigens (HRP2, pLDH and aldolase) in dried *Plasmodium falciparum*-infected samples using parasitized whole blood and culture samples. Samples were treated with ten selected chemical additives mainly sucrose, trehalose, LDH stabilizer and their combinations. After baseline activity was established, the samples were air dried and stored at room temperatures (~25°C). Testing of the stabilized samples using SD Bioline, BinaxNOW, CareStart, and First Response was done at intervals for 53 weeks. Stability of HRP2 at ambient temperature was reported at 21 to 24 weeks while that of PAN antigens (pLDH and aldolase) was 2-18 weeks of storage at all parasite densities. The ten chemical additives increased the percentage stability of HRP2 and PAN antigens. Sucrose alone and its combinations with Alsever's solution or biostab significantly increased stability of HRP2 by 56% at 2000p/µL (p<0.001). Trehalose and its combinations with biostab, sucrose or glycerol significantly increased stability of HRP2 by 57% (p<0.001). Unlike sucrose, the stability of the HRP2 was significantly retained by trehalose at lower concentrations (500p/µL, and 200p/µL). Trehalose in combination biostab increased the percentage stability of PAN antigens by 42%, and 32% at 2000p/µL and 500p/µL respectively (p<0.01). This was also the best chemical combination with the shortest reconstitution time (~<20minutes). These findings confirm that stabilizing RDT target antigens in dried *Plasmodium falciparum*-infected samples provides field-stable positive controls for malaria RDTs.

285

DETECTION OF SUBMICROSCOPIC MALARIAL PARASITES USING THE ILLUMIGENE MALARIA LAMP

Mamadou Alpha Diallo, Mouhamadou Ndiaye, Khadim Diongue, Mame Cheikh Seck, Amy Gaye, Awa Deme, Yaye Die Ndiaye, Daouda Ndiaye

Cheikh Anta Diop University, Dakar, Senegal

In the context of low transmission of malaria, the challenge is to be able to detect low parasite densities which could be missed when using routine microscopy. Yet, those submicroscopic infections may be the reservoirs of the parasites contributing to maintain the disease transmission and this could hamper the malaria elimination efforts. We selected 200 malaria suspected patients in three malaria hypoendemic sites of Senegal. We performed from each patient blood sample 1) a thick and thin smear slide for microscopy, 2) the illumigene Malaria LAMP test S-PREP (raw DNA extraction) and M-PREP (DNA extraction followed by chromatography purification). Slides were stained using 10% Giemsa and were read by WHO level 1 certified microscopists. The results of microscopy were

then compared to those of LAMP. Considering illumigene LAMP S-PREP as standard, we noted sensitivity and specificity of 90% and 100% respectively and an agreement of 91% between the two techniques. Microscopy sensitivity was even lesser (83.3%) when illumigene M-PREP was the standard; however, the specificity remained identical (100%). Thus, the prevalences of submicroscopic malaria infections were 10 % and 16.7% respectively using the illumigene LAMP S-PREP and the illumigene M-PREP protocols. The illumigene Malaria test may be used suitably in malaria low transmission in order to detect submicroscopic malarial parasites. This would help policies targeting parasites reservoirs to interrupt the transmission chain.

AUTOMATED MALARIA PARASITE CLASSIFICATION ON THICK BLOOD SMEARS

Feng Yang[1], Mahdieh Poostchi[1], Kamolrat Silamut[2], Richard J. Maude[2], Stefan Jaeger[1], George Thoma[1]

[1]Lister Hill National Center for Biomedical Communications, National Library of Medicine, National Institutes of Health, Bethesda, MD, United States, [2]Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand

Malaria is a worldwide life-threatening disease. According to the 2017 World Health Organization malaria report, an estimated 216 million malaria cases were detected in 2016, causing approximately 445 000 deaths. Microscopy examination of stained thick and thin blood smears is the gold standard for malaria diagnosis. Thick blood smears contains more blood and are used to detect the presence of malaria parasites, while thin blood smears are used to differentiate parasite species. Microscopy examination is of low cost and is widely available, but is time-consuming. Moreover, the effectiveness of microscopy diagnosis depends on the parasitologists' expertise in the subject. Therefore, the development of a computerized system to aid in malaria diagnosis is an appealing research goal. Using deep learning for machine classification, this work proposes a convolutional neural network (CNN) model for parasite classification to automatically classify preselected malaria parasite candidates in digital images of thick blood smears. Our customized CNN model consists of 3 convolutional layers, two fully connection layers and a softmax classification layer. Following each convolutional layer, a batch normalization layer, an activation layer, and a max-pooling layer are introduced to select feature subsets. Experiments are performed on 1817 blood sample images from 150 infected patients, which were acquired via Mahidol-Oxford Tropical Medicine Research Unit in Bangkok, Thailand, and manually annotated by an experienced parasitologist. For training, a total number of 84,894 positive parasite patches are cropped from the images based on the experts' annotations, and an equal number of negative patches (distractors) are generated using an intensity-based greedy method. A patient-level five-fold cross-validation demonstrates the effectiveness of our customized CNN model in discriminating between positive and negative patches. . We compute the following performance indicators for our system: accuracy (98.78%±0.12%), AUC (99.88%±0.05%), sensitivity (98.58%±0.61%), specificity (98.99%±0.58%), and precision (98.99%±0.57%).

EVALUATION OF THE PERFORMANCE OF SD BIOLINE *PF/PV* TESTS FOR THE DIAGNOSIS OF MALARIA IN A MALARIA ENDEMIC AREA OF ETHIOPIA

Abeba G. Reda

EHNRI, Addis Ababa, Ethiopia

Early and accurate diagnosis of malaria followed by prompt treatment reduces morbidity and mortality in endemic regions. Presumptive treatment of malaria is widely practiced where microscopy or rapid diagnostic tests are not readily available. Introduction of rapid diagnostic tests (RDTs) for the treatment of malaria in many low-resource settings need evaluation of their performance. This study evaluated the performance of RDT in two health centers in Adam and Amaya. This study aim to evaluate the diagnostic performance of SD BIOLINE malaria Ag *Pf/Pv* test relative to microscopy for the diagnosis of *Plasmodium falciparum* and *P. vivax* malaria in Ethiopia. The study was cross-sectional study from November to December 2015 on patients who had malaria symptoms and visited the two health facilities in Oromia Region, Ethiopia. Thin and thick blood smears were prepared from finger prick and stained by 10% Giemsa. Microscopic examination was done under 100x magnifications for *Plasmodium* species identification and determination of parasitemia. The RDT was performed as per the manufacturer instruction. From A total of 547 febrile patients were diagnosed, of which 127 were microscopy positive for *Pf* (n=38) and *Pv*(n=85). The sensitivity, specificity, positive and negative predictive value of SD BIOLINE malaria Ag *Pf/Pv* test were 92.1%, 99.1%, 95.9% and 98.2%, respectively. Therefore, we conclude the diagnostic performance of SD BIOLINE malaria Ag *Pf/Pv* test in this study shows good performance and further study is recommended in different study areas with different epidemiological status.

DETECTION OF MALARIA THROUGH AUTOMATED DIGITAL MICROSCOPY WITH INTEGRATION OF ARTIFICIAL INTELLIGENCE

Dongyoung S. Lee

noul inc., Gyeonggido, Republic of Korea

Traditionally microscopy has been used as gold standard in malaria diagnosis. However, it has limitations to be applied to low resources settings because it needs well-equipped laboratory which is costly and skilful technicians to conduct complicated diagnostic experiments. Accuracy of the result is also limited depending on expertise of technicians and quality of experimental resources. Addressing these challenges, we have developed a fully automated digital microscopy platform. The platform enables diagnosis of the disease by simply dropping finger-pricked blood on a consumable chip (Lab on a Chip technology based), conducting automated blood smearing and staining inside the platform, capturing high-resolution blood images by internal digital microscopy, and analyzing them by artificial intelligence (AI). Its network-compatible platform also provides function for surveillance by delivering real-time data to any malaria control program, and instantly and simultaneously collecting and presenting epidemiological data with in-house developed software. We assessed the platform's performance in Cambodia and Malawi. It took one day to train technicians for their adept operation of the platform. Diagnosis time was 15 to 20 minutes per patient. Its detection level of parasitemia was 20p/μl. The AI's sensitivity was 96.21%, and specificity was 97.94%. Through its embedded 3G network, real-time diagnosis data was collected and shared with other networked systems from remote regions. We found that the digital microscopy platform with AI integrated has potential to overcome limitations of traditional microscopy which is operated by technicians in typical laboratory settings.

Simple and cost-efficient diagnostic methods are needed for the control of malaria, as it occurs mostly in resource-limited settings. Malaria is usually diagnosed from samples of peripheral blood. However, it is still unclear, whether venous or capillary blood samples provide equal diagnostic performance. This study investigated quantitative differences of parasitemia between capillary and venous blood and the diagnostic performance characteristics of the two blood sources. Recruitment took place between September 2015 and February 2016 at two clinical research centers in Gabon and 376 patients were included. Light microscopy and qPCR were used to quantify peripheral parasitemia of paired capillary and venous blood samples. Performance characteristics of capillary and venous samples using microscopy were evaluated against a qPCR gold-standard. Light microscopy revealed a higher parasitemia of +16.6% (95% CI: +0.7 to +35) in capillary samples compared to venous samples. Concordant evidence was produced in qPCR, showing that on average -0.278 (95% CI: -0.473 to -0.083) ct-cycles were required until signal detection in capillary samples. Sensitivity analyses revealed an 8% higher sensitivity of capillary blood samples (81.5%; 95% CI: 77.4 to 85.6) compared to venous blood samples (73.4%; 95% CI: 68.8 to 78.1). Capillary blood sampling improves diagnostic sensitivity and leads to higher results of parasitemia compared to venous blood sampling. Solely using capillary blood for the detection of malaria could constitute a simple and cost-efficient optimization of malaria diagnosis. This finding may have important implications for routine diagnostics of malaria, epidemiological and drug development studies and the assessment of novel diagnostic tools.

COMPARING DETECTION OF MALARIA PARASITES BY POLYMERASE CHAIN REACTION, RAPID DIAGNOSTIC TEST, BLOOD SMEAR, HISTIDINE-RICH PROTEIN 2 (HRP2) ANTIGENEMIA, AND LONG AND SHORT TERM IGG ANTIBODIES

Aida S. Badiane[1], Eric Rogier[2], Udhayakumar Venkatachalam[2], Mamadou A. Diallo[1], Julie Thwing[2], Daouda Ndiaye[1]

[1]Universite Cheikh Anta Diop, Dakar, Senegal, [2]Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States

Declining malaria prevalence in some previously high transmission zones has made measurement of sustained decrease in malaria transmission difficult, and has increased the need for cost-effective methods to detect low density infections. Multiplex detection of parasite antigens and antibodies to malaria antigens is a promising strategy for measuring population exposure to malaria and for detecting infections characterized by low-level parasitemia. Patients seeking care for fever were enrolled, and blood smear and dried blood spots on filter paper were collected at the time of the rapid diagnostic test (RDT) for diagnosis. Smears were read by expert microscopists. Samples were analyzed with PET-PCR, and multiplex assays were used to measure median fluorescence intensity (MFI) of HRP2 antigen and long (PfMSP1 and PfAMA1) and short (PfCSP, PfHRP2, LSA1, GlurpRO, StarpR, and SALSA) half-life IgG antibodies to *Plasmodium falciparum*. We compared the results of RDT, expert microscopy, PCR, HRP2 antigenemia, and IgG antibody markers. Using PET-PCR as the gold standard, blood smear had a sensitivity of 90% and a specificity of 100%, RDT had a sensitivity of 95% and a specificity of 94%, and HRP2 detection by multiplex assay had a sensitivity of 98% and a specificity of 48%. Adding short- and long-half-life antibodies to HRP2 antigenemia increased sensitivity to 100% and decreased specificity to 9%, using the PET-PCR assay as the gold standard for diagnosing active infection. No long- or short-half-life antibodies, either individually or in combination, approached the sensitivity or specificity of RDT, blood smear, or HRP2 multiplex assay, though logistic regression demonstrated a positive association of LSA1, StarpR, and GlurpRO antibodies with PCR positivity. Detection of HRP2 antigenemia by multiplex assay was more sensitive than RDT or smear for *P. falciparum* infection. Testing with a combination of HRP2 antigenemia detection and measurement of long- and short-half-life antibodies was a sensitive predictor of PCR positivity, and could be useful for screening RDT-negative samples from low-prevalence settings for further analysis.

PERFORMANCE OUTCOMES FROM AFRICA-BASED MALARIA DIAGNOSTIC REFRESHER TRAINING COURSES

Matt Worgees[1], Nicole Whitehurst[2], Renion Saye[3], Daouda Ndiaye[4], Emanuel Yamo[5]

[1]Tulane University, New Orleans, LA, United States, [2]Medical Care Development International, Silver Spring, MD, United States, [3]Medical Care

Development International, Bamako, Mali, [4]Cheikh Anta Diop University, Dakar, Senegal, [5]Medical Care Development International, Kisumu, Kenya

Since 2010, the World Health Organization has recommended parasite-based diagnostic testing for all patients suspected of having malaria before a treatment regimen is started. Lack of funding and rigorous programs to support continuous training and monitoring of staff may contribute to poor malaria diagnosis resulting in improper management of illness. The MalariaCare project was tasked with implementing an external quality assurance scheme to support malaria diagnostics and case management across a spectrum of health facilities in participating African countries. A component of this program was a 5-day, competency-based, malaria diagnostic refresher training (MDRT) course for health facility laboratory staff conducting malaria microscopy. The MDRT course provided a method to quantify participant skill levels in microscopic examination of malaria across 3 major diagnosis areas: parasite detection, species identification, and parasite quantification. A total of 817 central, regional, and peripheral-level microscopists from 45 MDRT courses across 9 African countries were included in the analysis. Differences in mean scores with respect to daily marginal performance were positive and statistically significant ($p < 0.001$) for each challenge type when considering the entire cohort of MDRT participants. From pretest to assessment day 4, mean scores for parasite detection, species identification, and parasite quantification increased by 19.1, 34.9, and 38.2 percentage points, respectively. Additionally, sensitivity and specificity increased by 20.8 and 13.8 percentage points, respectively, by assessment day 4. Further, the ability of MDRT participants to accurately report *Plasmodium falciparum* species when present increased from 44.5% at pretest to 67.1% by assessment day 4. The MDRT course has shown to rapidly improve the microscopy performance of participants over a short period of time. Due to its rigor, the MDRT course could serve as a mechanism for measuring laboratory staff performance against prescribed minimum competency standards and could easily be adapted to serve as a national certification course.

292

GENERATION OF ANTIBODIES SPECIFIC TO *PLASMODIUM FALCIPARUM* HISTIDINE RICH PROTEIN-3

Balwan Singh[1], Eric Rogier[2], Amy Kong[2], Sayan Chatterjee[3], Venkatchalam Udhayakumar[2]

[1]AREF, Atlanta, GA, United States, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]IHRC, Atlanta, GA, United States

Rapid diagnostic test (RDT) based detection of malaria infections caused by *Plasmodium falciparum* relies to a large extent based on detecting *Plasmodium falciparum*-specific histidine-rich protein 2 (HRP2). HRP2-based tests comprise a majority of the over 300 million RDTs sold annually worldwide. However, malaria parasites that don't express the HRP2 antigen can lead to false negative test results with this diagnostic method. Histidine-rich protein 3 (HRP3), another soluble antigen specifically produced by *P. falciparum*, shares 85-90% sequence homology with HRP2, and anti-HRP2 monoclonal antibodies are known to cross-react with this protein. *P. falciparum* may lack one or both genes for HRP2 and HRP3 and the ability to distinguish specific reactivity to either protein is essential to surveillance efforts aimed at determining the continued utility of HRP2-based tests in different areas of the world. Here we describe the generation of IgG antibodies specific to *P. falciparum* HRP3 which do not cross-react with HRP2 as determined by ELISA and western blot immunoassays. A 28-amino acid long peptide corresponding to the non-repeat region of HRP3 was synthesized and utilized for rabbit immunizations. Purified IgG antibodies from immunized animals specifically detected native HRP3 antigen in *P. falciparum* Dd2 culture strain supernatants which only expressing HRP3 and not HRP2. Purified native HRP3 from Dd2 culture allowed estimation of the limit of ELISA detection of these antibodies for HRP3 at 250pg/mL. These anti-HRP3 antibodies failed to react to HB3 culture supernatants (only expressing HRP2) and did not bind to recombinant HRP2 protein. An assay that combined detection of HRP2 and HRP3 antigen would offer improve differentiation of parasites that lack HRP3 gene from HRP2 deleted parasites in field surveys and surveillance of the global deletion phenomenon.

293

FIELD EVALUATION OF THE ILLUMIPRO-10 ILLUMIGENE MALARIA DIAGNOSTIC BY AMPLIFICATION OF *PLASMODIUM SPP* DNA: A VIABLE OPTION TO ACCELERATE MALARIA ELIMINATION

Ray Handema, Victor Daka, Justin Chileshe, Michael Nambozi, Webster Kasongo

Tropical Diseases Research Centre, Ndola, Zambia

Malaria is one of the major health problems in Zambia. Zambia has set a goal of eliminating malaria by 2021. By ensuring 100% suspected malaria cases receive parasitological diagnosis and 100% parasitologically confirmed malaria cases receive prompt, effective treatment. Currently, malaria diagnosis relies on parasite detection by microscopy or antigen-based rapid diagnostic tests (RDT). Although microscopy and RDT have been rolled out there are still limitations that compromise their effectiveness. This is particularly important to help identify and manage patients and ultimately elimination of malaria. There is a need to identify newer, more sensitive and specific but cost effective methods for malaria diagnosis. Performance of Illumigene Malaria LAMP, microscopy and RDT against Real Time PCR as the reference standard were evaluated. 282 study participants with signs and symptoms of *Plasmodium* infection were recruited from Nchelenge, Zambia. Whole blood specimens were used. Of the 282 samples RDT positive were 47.9%, microscopy 34%, Illumigene 66% and RT-PCR 64.5%. Sensitivity versus Specificity of RDT, microscopy and Illumigene compared with the gold standard RT-PCR for the diagnosis of Plasmodium species at 95% CI were 69.8% Vs 92%, 53.3%Vs 100% and 94.54% Vs 86% respectively. Performing tests for diagnostic accuracy, Illumigene showed the highest diagnostic sensitivity and strong agreement (k=0.812) with RT-PCR as the reference standard. Sensitivity for both RDT and microscopy were lower. Discordant results were observed across the four tests with low sensitivity and false negatives by RDT and microscopy. Overall, a total of 19.6% and 33.6% did not receive treatment based on RDT and microscopy respectively, creating a transmission reservoir. Though sensitivity of RDT is higher than microscopy, it is not comparable to molecular based methods. The field deployment of molecular testing, should address sensitivity challenges observed with RDT and microscopic tests in this study to achieve malaria elimination. A comparative study in a low malaria endemic region is warranted.

294

DURATION OF MALARIA RAPID DIAGNOSTIC TEST (RDT) POSITIVITY FOLLOWING DEFINITIVE ANTIMALARIAL TREATMENT AMONG CHILDREN IN WESTERN KENYA

Simon Kariuki[1], Nelli Westercamp[2], Mary Owidhi[1], Kephas Otieno[1], Winnie Chebore[1], Meghna Desai[2], Ann M. Buff[2], Aaron Samuels[2]

[1]Malaria Branch, Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [2]Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States

For *Plasmodium falciparum* infections, Rapid Diagnostic Tests (RDTs) targeting the histidine-rich protein (HRP2) antigen are more sensitive than tests targeting the lactate dehydrogenase (pLDH) antigen. Interpretation of HRP2 RDTs in the weeks after effective treatment is a challenge due to antigen persistence. The Kenya Ministry of Health (KMoH) guidelines recommend that symptomatic patients diagnosed and treated for malaria in the last two weeks should be tested by microscopy. We performed a study to evaluate the duration of RDT positivity following definitive antimalarial treatment in children <5 years of age with confirmed

uncomplicated malaria in a high malaria transmission setting in western Kenya. From June 2016 to March 2017, 340 children with *P. falciparum* mono-infection were randomly assigned to treatment with artemether-lumefantrine or dihydroartemisinin-piperaquine. Blood samples collected at day 0, 2, 3 and weekly to day 42 post-treatment were tested by microscopy and three RDTs— CareStart (HRP2), First Response (HRP2/pLDH), and SD Bioline (HRP2/pLDH). The duration of RDT positivity was assessed by Kaplan-Meier analysis with data censored at reinfection or drop out. At 14 days, 80% of HRP2 RDTs remained positive. Median time to negative result was 35 days; 33% (95% CI 27-38%), 34% (95% CI 28-39%), and 34% (95% CI 28-39%) of tests stayed positive at day 42 for First Response, Carestart, and SD Bioline HRP2 tests, respectively. Median time to negative result was <1 day for pLDH RDTs; 9% (95% CI 5-12%), and 5% (95% CI 3-8%) of tests remained positive by day 3 for First Response and SD Bioline, respectively. Duration of positivity and baseline parasite density were positively correlated (<50,000/µl vs. ≥50,000/µl; p<0.035) for HRP2 RDTs only. All HRP2 RDTs had a similar duration of positivity, and the median duration was >2 times the timeframe that KMoH guidelines recommend for testing with microscopy after a previous malaria treatment. Further evaluations of the RDT positivity persistence after definitive antimalarial treatment should be done to inform policy on appropriate timeframes for the use of alternate diagnostics in settings where this is possible.

295

LESSON LEARNED: DEVELOPMENT OF NATIONAL ARCHIVE OF MALARIA SLIDES (NAMS) IN THE DEMOCRATIC REPUBLIC OF CONGO (DRC)

Pharath Lim[1], Daouda Ndiaye[2], Séraphine Kutumbakana[3], Dieudonne Mumba Ngoyi[4], Ange Landela[4], Renion Saye[5], Julie Parks Heinsen[6], Troy Martin[6], Paul Hamilton[6], Luis Benavente[1], Lee Yellot[1], Chris Schwabe[1]

[1]President's Malaria Initiative MalariaCare Project, Medical Care Develpoment International, Silver Spring, MD, United States, [2]Department of Parasitology and Mycology, University Cheikh Anta Diop (UCAD), Dakar, Senegal, [3]President's Malaria Initiative MalariaCare Project, Kinshasa, Democratic Republic of the Congo, [4]Institut national de Recherche Biomédicale (INRB), Kinshasa, Democratic Republic of the Congo, [5]President's Malaria Initiative MalariaCare Project, Bamako, Mali, [6]President's Malaria Initiative MalariaCare Project, PATH, Washington, DC, United States

The accuracy of malaria diagnosis by microscopy has been a challenge in health facilities in the DRC due to inadequate training, quality assurance, and maintenance of microscopy skills. In order to improve quality assured malaria microscopy in the DRC, MalariaCare supported the Institut National de Recherche Biomédicale (INRB) and National Malaria Control Program to develop the National Archive of Malaria Slides (NAMS). This slide bank will be used for microscopy training, supervision and proficiency testing. 51 blood samples of *P. falciparum*, non-*falciparum*, mixed infections and negatives were collected in the DRC from May 2016 through June 2017. The NAMS protocol was developed by the INRB in collaboration with MalariaCare following the WHO protocol and approval by an ethics board. As there was no *P. vivax* present during blood collection, 200 validated *P. vivax* slides were purchased externally. All slides were developed at the INRB and barcode labels were applied to each slide. Two slides per donor were selected for slide validation by six WHO-accredited level 1 microscopists in the DRC and Mali. Each blood donor was validated by PCR to confirm malaria infection and species. The quality of each slide was validated. Microscopy detection of infection showed high sensitivity (98%) and specificity (100%) when compared to PCR, whereas microscopy species detection was 84% (range: 74% - 90%) concurrent with PCR. Among 51 blood donors, there were 3 discrepancies between the PCR and microscopy results and these were excluded from the slide bank. The remaining 48 donor samples were accepted and used to produce 18,369 fully validated malaria slides. The DRC NAMS will be used for national and regional malaria microscopy training and can be used throughout the country to perform proficiency testing and on-site supervision. The NAMS will be an important tool in the DRC's efforts to improve the quality of clinical care and also will assure the ability to develop new generations of laboratory specialists as the country moves towards improved case management and control of malaria.

296

ANTIMALARIAL AND ANTISCHISTOSOMAL EFFICACY OF PYRIDOBENZIMIDAZOLE DERIVATIVES

Godfrey W. Mayoka[1], Sergio Wittlin[2], Jennifer Keiser[2], Kelly Chibale[3]

[1]University of Cape Town, Cape Town, South Africa, [2]University of Basel and Swiss Tropical and Public Health Institute, Basel, Switzerland, [3]University of Cape Town and South African Medical Research Council Drug Discovery Unit, Cape Town, South Africa

Tropical diseases, exemplified by malaria and schistosomiasis-the two most prevalent parasitic infections endemic in Africa, South East Asia and parts of South America-present daunting public health and socio-economic challenges. Besides geographical reasons, poor hygiene and sanitation encourage the transmission of these infections, sustaining a cycle of poverty in these regions. Public health approaches have been instrumental in the control of malaria and schistosomiasis leading to a decline in their prevalence during the last century. Chemotherapy, however, remains a fundamental component in the treatment of these infections with resistance constantly posing a threat to the gains made towards eradicating malaria. Conversely, over reliance of a single drug, praziquantel, for the treatment of schistosomiasis evokes concerns of resistance developing in future. Concerted efforts must, therefore, be sustained in the search for new drugs to curb these diseases of poverty. Phenotypic whole cell screening has continued to deliver new hits for drug discovery and development. Alternatively, drug repositioning, whereby a drug or lead compound provides a medicinal chemistry template to yield analogues for testing in a different disease other than the initial one, has become increasingly popular. Drug repositioning holds the potential to reduce drug development costs and timelines; an appealing substitute in drug discovery for diseases of poverty which have little, if any, commercial incentives to the pharmaceutical industry. In our work, a pyridobenzimidazole hit previously identified after a whole cell screening assay against human *Plasmodium falciparum* has been utilised to generate analogues, several of which have shown potent *in vitro* and *in vivo* antimalarial activities. In a drug repositioning context, exemplified by the antischistosomal efficacy of several known antimalarial agents, we evaluated the antischistosomal activity of these analogues. Further medicinal chemistry optimisation is ongoing to progress these compounds as prospective antimalarial and antischistosomal leads.

IN SILICO STUDY OF PLASMODIUM 1-DEOXY-DXYLULOSE 5-PHOSPHATE REDUCTOISOMERASE (DXR) FOR IDENTIFICATION OF NOVEL INHIBITORS FROM SANCDB

Bakary N. Diallo, Ozlem T. Bishop, Kevin A. Lobb

Rhodes University, Grahamstown, South Africa

Malaria remains a major health concern with a complex parasite constantly developing resistance to the different antimalarials, threatening the efficacy of the current (Artemisinin Combination Therapy) ACT. Drugs with different mechanisms of action are ideal to decrease chances of resistance occurring. Blocking the methylerythritol phosphate pathway through 1-deoxy-D-xylulose 5-phosphate reductoisomerase (DXR) inhibition fits well this profile. Previously, a promising DXR inhibitor, fosmidomycin showed poor drug-like properties. In this study, we intended to find potential inhibitors with better drug likeness from the South African National Compound Database (SANCDB; https://sancdb.rubi.ru.ac.za) using structural bioinformatics tools. *Plasmodium spp* DXR structures in its open and closed conformations were modelled using MODELLER followed

by a High Throughput Virtual Screening (HTVS) with Autodock Vina of the SANCDB compounds to identify hits. Compounds' pharmacological properties using the QED (Quantitative estimate of druggability) scores from FAF-Drugs4 (Free ADME-Tox Filtering Tool) were included in the hit selection process. Finally, selected hits were submitted to 100 ns molecular dynamics (MD) simulations using GROMACS to assess the stability of the protein-ligand complexes. SANC00152 (-8.4 Kcal/mol), SANC00236 (-10.2 Kcal/mol), SANC00339 (-9.2 Kcal/mol), SANC00438 (-9.9 Kcal/mol) and SANC00570 (-8.1 Kcal/mol) were identified as hits from the docking showing good binding affinities with QED scores of 0.46, 0.68, 0.83, 0.78 and 0.68 respectively with one being the best score and zero the poorest. All compounds had different scaffolds from fosmidomycin. Finally, the different protein-hit complexes appeared to be stable during the MD simulations with Root Mean Square Deviation (RMSD) lower than 2.75 nm (maximum RMSD observed). Furthermore, these hits showed stable binding in the protein active site with ligands' RMSDs showing very low values (maximum being 0.15 nm), thus confirming their high binding affinities. Five natural compounds from SANCDB were thus identified as potential DXR inhibitors.

DECIPHERING THE TARGETS OF RETROVIRAL PROTEASE INHIBITORS IN *PLASMODIUM BERGHEI*

Noah M. Onchieku[1], Reagan Mogire[1], Peter Mwitari[2], Francis Kimani[2], Damaris Matoke-Muhia[2], Daniel Kiboi[3], Gabriel Magoma[1]

[1]Pan African University Institute for Basic Sciences Technology and Innovation, Nairobi, Kenya, [2]Kenya Medical Research Institute, Nairobi, Kenya, [3]West Africa Centre for Cell Biology and Infectious Pathogens, University of Ghana, Accra, Ghana

Retroviral protease inhibitors (RPIs) such as lopinavir (LP) and saquinavir (SQ) are active against *Plasmodium* parasites. However, the exact molecular target(s) for these RPIs in the *Plasmodium* parasites remains poorly understood. We hypothesised that LP and SQ suppress parasite growth through inhibition of aspartyl proteases. Using reverse genetics approach, we embarked on separately generating transgenic parasite lines lacking Plasmepsin 4 (PM4), PM7, PM8, or DNA damage-inducible protein 1 (Ddi1) in the rodent malaria parasite *Plasmodium berghei* ANKA. We then tested the suppressive profiles of the LP/Ritonavir (LP/RT) and SQ/RT as well as antimalarials; Amodiaquine (AQ) and Piperaquine (PQ) against the transgenic parasites in the standard 4-day suppressive test. The Ddi1 gene proved refractory to deletion suggesting that the gene is essential for the growth of the asexual blood stage parasites. Our results revealed that deletion of PM4 significantly reduces normal parasite growth rate phenotype ($P = 0.003$). Unlike PM4 knock out (KO) parasites which were less sensitive to LP and SQ ($P = 0.036$, $P = 0.030$), the suppressive profiles for PM7_KO and PM8_KO parasites were comparable to those for the WT parasites. This finding suggests a potential role of PM4 in the LP and SQ action. On further analysis, modeling and molecular docking studies revealed that both LP and SQ displayed high binding affinities (-6.3 kcal/mol to -10.3 kcal/mol) towards the *Plasmodium* aspartyl proteases. We concluded that PM4 plays a vital role in assuring asexual stage parasite fitness and might be mediating LP and SQ action. The essential nature of the newly identified Ddi1 gene warrants further studies to evaluate its role in the parasite asexual blood stage growth as well as a possible target for the RPIs.

METABOLIC DEPENDENCY OF CHORISMATE IN *PLASMODIUM FALCIPARUM*

Ana L. Valenciano[1], Maria L. Fernandez-Murga[2], Nicole Holderman-Munro[1], Ashley Oh[1], Karl J. Shaffer[3], Peter Tyler[3], Fernando E. Merino[1], Maria B. Cassera[1]

[1]Department of Biochemistry and Molecular Biology and Center for Tropical and Emerging Global Diseases (CTEGD), University of Georgia, Athens, GA, United States, [2]Laboratory of Experimental Hepatology, Institute of Sanitary Investigation "La Fe Hospital", Valencia, Spain, [3]The Ferrier Research Institute, Victoria University of Wellington, Lower Hutt, New Zealand

Human malaria accounts for more than 400,000 deaths a year, with *Plasmodium falciparum* being the deadliest of the five species that infect humans. Artemisinin Combination Therapies (ATCs) are the frontline treatment for malaria; however, resistance to artemisinin has been confirmed and is increasing in prevalence. Therefore, there is an urgent need to identify novel inhibitors to overcome parasite resistance, especially inhibitors safe for use in pregnant women and children. Among the potential metabolic drug targets absent in humans is the shikimate pathway for chorismate biosynthesis, which has been postulated to be essential for *P. falciparum's* survival. Interestingly, two recent studies indicated that chorismate synthase is not essential in *P. berghei*. Chorismate is a branching metabolite used to synthesize *p*-aminobenzoic acid (pABA, an intermediate in folate biosynthesis), aromatic amino acids, and *p*-hydroxybenzoic acid (pHBA, an intermediate in ubiquinone biosynthesis). This study aimed to assess the fate of chorismate and its metabolic dependencies. We have identified an inhibitor that targets the shikimate pathway using reversal of growth inhibition, and it was used as a tool to assess the metabolic dependencies of chorismate in *P. falciparum*. The identified inhibitor is cytotoxic for the malaria parasite, specifically affecting the transition of trophozoite to schizont stage. Our results support that the molecular target is within the 5-step AROM multicomplex of the shikimate pathway inhibiting chorismate's production and that folate biosynthesis is the main metabolic fate of chorismate in *P. falciparum*. Inhibition of chorismate biosynthesis does not affect the synthesis of ubiquinone, indicating that the production of pHBA, the precursor of the benzoquinone ring, may not be derived from chorismate or that alternative sources may be used. Further studies will be needed to elucidate the origin of the ring of ubiquinone in *P. falciparum*.

IN SILICO CHARACTERIZATION OF PLASMODIAL TRANSKETOLASES AS POTENTIAL MALARIA DRUG TARGETS

Rita A. Boateng, Ozlem Tastan Bishop, Thommas Musyoka Mutemi

Rhodes University, grahamstown, South Africa

Malaria continues to plague the world, especially sub-Saharan Africa, with high mortality and morbidity. The absence of an approved vaccine and the emergence of drug resistant *Plasmodium* parasite is a public health concern. As a result, calls for the identification of novel targets for more efficacious antimalarials are escalating. Transketolase (TK) is a vital enzyme of the pentose phosphate pathway involved in the production of NADPH and ribose-5-phosphate. The aim of this study was to characterize plasmodial TKs through *in silico* approaches and to identify potential inhibitors from South African Natural Compound Database (SANCBD; https://sancdb.rubi.ru.ac.za). *Plasmodium falciparum* 3D7 TK (XP_966097.1) was retrieved from National Center for Biology Information (NCBI) database. Sixteen homologs from other plasmodial species and one human TK protein sequence were obtained by BLAST. Multiple sequence alignment, phylogenetic tree calculations and motif identification approaches were used to assess important sequence, structural and evolutionary variations. High quality three-dimensional homology models were generated using MODELLER. AutoDock Vina was then used to dock 623 SANCDB compounds against eight TK proteins. Docking results were analyzed to identify potential hits selectively inhibiting plasmodial TKs. Druglikeness of identified hits were evaluated using Molinspiration and SCFBio software. We observed a sequence identity of plasmodial TKs ranged between 79% to 84% compared to *P. falciparum* TK. However, *H. sapiens* TK shared a low sequence identity of 28% to the plasmodial TKs. Sequence-based analysis revealed highly conserved thiamine diphosphate and "TK" regions in the plasmodial TKs sequences, however, *H. sapiens* showed slight differences in residue composition. Active site inhibitors

identified were SANCDB411 and SANCDB620. Identified hits interacted with the Pyrophosphate and Pyrimidine domain catalytic residues and bind selectively across all plasmodial TKs and had good Druglikeness scores.

301

MANAGEMENT OF MALARIA IN NIGERIA WITH NATURAL COMPOUNDS IN RATIONAL DRUG DESIGN

Oluwatosin K. Shittu

Federal University of Technology, Minna, Nigeria

Nigeria have been reported to be country with greatest number of cases of tropical diseases such as malaria. Despite the availability of different therapeutic and vaccine, about 80% of the populations still rely on traditional medicine for their primary healthcare. These are recognized as an accessible, affordable and culturally acceptable form of health care. Some Nigerian researchers and scientists have screened several medicinal plants in order to understand and scientifically justify the tradition believes of their properties or activity. However, there is no new therapeutics that has been generated through their research. This is due to inadequate transfer of methodology, information on the mode of action and synergistic behavior of these medicinal plants. This has created gap between the research and commercialization. However, this gap can be fill with proper rational drug design and modification of natural therapeutics. Therefore, the use of structural biology and enzymology to inform and improve therapeutics developed from natural product is the solution to the problem.

302

ANTIMALARIAL PANTOTHENAMIDE METABOLITES TARGET ACETYL-COA SYNTHESIS IN *PLASMODIUM FALCIPARUM*

Joost Schalkwijk[1], Erik Allman[2], Patrick Jansen[1], Laura de Vries[1], Suzanne Jackowski[3], Peter Botman[4], Christien Beukens-Schortinghuis[4], Karin Koolen[5], Judith Bolscher[5], Martijn Vos[5], Karen Miller[3], Stacy Reeves[3], Helmi Pett[1], Graham Trevitt[6], Sergio Wittlin[7], Christian Scheurer[7], Sybille Sax[7], Christoph Fischli[7], Taco Kooij[1], Roger Bonnert[8], Brice Campo[8], Richard Blaauw[4], Floris Rutjes[9], Robert Sauerwein[5], Manuel Llinas[2], Pedro Hermkens[5], **Koen Dechering**[5]

[1]Radboud University Medical Center, Nijmegen, Netherlands, [2]Pennsylvania State University, State College, PA, United States, [3]St. Jude Children's Research Hospital, Memphis, TN, United States, [4]Chiralix, Nijmegen, Netherlands, [5]TropIQ Health Sciences, Nijmegen, Netherlands, [6]Xenogesis, Nottingham, United Kingdom, [7]Swiss Tropical and Public Health Institute, Basel, Switzerland, [8]Medicines for Malaria Venture, Geneva, Switzerland, [9]Radboud University, Nijmegen, Netherlands

Malaria eradication is critically dependent on novel drugs that target resistant *Plasmodium* parasites and block transmission of the disease. Here we report the discovery of potent pantothenamide bioisosteres that are active against blood-stage *P. falciparum* and also block onward mosquito transmission. These compounds are resistant to degradation by serum pantetheinases, show favorable pharmacokinetic properties and clear parasites in a humanized rodent infection model. Metabolomics revealed that CoA biosynthetic enzymes convert pantothenamides into drug-conjugates that interfere with parasite acetyl-CoA anabolism. *In vitro* generated resistant parasites showed mutations in acetyl-CoA synthetase and acyl-CoA synthetase 11, confirming the key roles of these enzymes in the sensitivity to pantothenamides. These new pantothenamides provide a promising class of antimalarial drugs with a unique mode of action.

303

PLASMODIUM VIVAX SPOROZOITE PLATFORM IN INDIA

Susanta K. Ghosh[1], Sowmya K. B[1], Benudhar Mukhi[1], S. Varadharajan[2], U. Shreehari[1], Satyanarayan Tiwari[1], Anup R. Anvikar[3], Neena Valecha[3]

[1]ICMR-National Institute of Malaria Research, Bangalore, India, [2]National Centre for Biological Sciences, Bangalore, India, [3]ICMR-National Institute of Malaria Research, New Delhi, India

Plasmodium vivax is no more a benign malaria. In recent years, *Plasmodium vivax* is causing serious clinical problems in terms of morbidity and mortality, similar to falciparum. Currently, India is responsible for 81% of deaths from vivax malaria among four countries, with an additional challenge represented by relapse due to the dormant form (hypnozoites) of the parasite. Sporozoite is the only stage that develops in the liver. It is important to produce a huge number of sporozoites in laboratory reared mosquitoes. Here, we report successful establishment of fully temperature and humidity controlled insectarium where numerous fit and healthy *Anopheles stephensi* are grown following modified protocol. These mosquitoes are allowed to feed through membrane feeding cups on the patient blood infected with *P. vivax* malaria. On an average 40,000 to 50,000 sporozoites were harvested per mosquito. These sporozoites are used for vivax liver stage assays for screening new drugs against sporozoites/hypnozoites. This resource can be used for several studies to characterize sporozoites/hypnozoites so that successful elimination of malaria can be achieved.

304

LONG-ACTING INJECTABLE ATOVAQUONE NANOMEDICINES FOR MALARIA PROPHYLAXIS

Rahul P. Bakshi[1], Lee M. Tatham[2], Alison C. Savage[2], Abhai K. Tripathi[1], Godfree Mlambo[1], Matthew M. Ippolito[1], Elizabeth Nenortas[1], Steve P. Rannard[2], Andrew Owen[2], Theresa A. Shapiro[1]

[1]Johns Hopkins University, Baltimore, MD, United States, [2]University of Liverpool, Liverpool, United Kingdom

Chemoprophylaxis is currently the best available prevention from malaria, but its efficacy is compromised by non-adherence to medication. Here we develop a long-acting injectable formulation of atovaquone solid drug nanoparticles that confers long-lived prophylaxis against *Plasmodium berghei* ANKA malaria in C57BL/6 mice. Protection is obtained at plasma concentrations above 200 ng ml^{-1} and is causal, attributable to drug activity against liver stage parasites. Parasites that appear after subtherapeutic doses remain atovaquone-sensitive. Pharmacokinetic-pharmacodynamic analysis indicates protection can translate to humans at clinically achievable and safe drug concentrations, potentially offering protection for at least 1 month after a single administration. These findings support the use of long-acting injectable formulations as a new approach for malaria prophylaxis in travellers and for malaria control in the field.

305

CHARACTERIZATION OF THE MECHANISM OF RESISTANCE OF THE AMINOMETHYLPHENOL, JPC-3210 (MMV892646)

Marina Chavchich[1], Karin van Breda[1], Jye Travis[2], Rowcliffe Kerryn[1], Arba L. Ager[3], Gavin D. Heffernan[4], Guy A. Schiehser[4], Laura R. Jacobus[4], G. Dennis Shanks[1], David P. Jacobus[4], Michael D. Edstein[1]

[1]Australian Defence Force Malaria and Infectious Disease Institute, Brisbane, Australia, [2]The University of Queensland, Brisbane, Australia, [3]University of Miami, Miami, FL, United States, [4]Jacobus Pharmaceutical Company, Princeton, NJ, United States

The nonquinoline 2-aminomethylphenol, JPC-3210 (MMV892646), has recently been selected by Medicines for Malaria Venture (MMV) for

advanced preclinical development. JPC-3210 possesses low nanomolar *in vitro* antimalarial activity against *Plasmodium falciparum* multidrug resistant lines, low cytotoxicity and a low curative oral dose of 4 mg/kg/day in the mouse-*P. berghei* model (modified Thompson test) and at 5 mg/kg (single oral dose) it was curative against the *P. falciparum* FVO strain in *Aotus* monkeys. Pharmacokinetic studies revealed that JPC-3210 has a very lengthy blood elimination half-life in both mice and monkeys of about 5 and 21 days, respectively, which would suggest that if the compound is used, parasites are likely to encounter sub-therapeutic concentrations of JPC-3210 for a considerable time. Therefore, it is important to evaluate the potential for malaria parasites to develop resistance to JPC-3210. In the present study, we exposed 3 independent cultures of artemisinin and mefloquine-resistant *P. falciparum* MRA1240 parasites to escalating concentrations of the compound starting from 4 to 48 nM over 14 months. Following exposure, there was a 6-fold increase in IC_{50}s of JPC-3210 against the resistant lines, as well as 5-fold decrease in susceptibility to mefloquine, whereas no decrease in susceptibility was seen for chloroquine, dihydroartemisinin, piperaquine and pyronaridine. The decrease in susceptibility to mefloquine was consistent with an amplification of *Pfmdr1* gene from 3 to 5 copies in the resistant lines. In addition, whole genome sequencing of the resistant progeny revealed an amplification of the region on chromosome 12, containing a member of ABC transporter family, in one of the isolates and a number of SNPs identified in the resistant lines, which are currently being analysed. Our findings will provide more insights on the potential molecular markers responsible for parasite resistance to JPC-3210. The considerable effort required to induce the JPC-3210 resistant *P. falciparum* lines *in vitro* further supports the preclinical development of JPC-3210 for malaria treatment and prophylaxis.

306

THE AMINOMETHYLPHENOL (JPC-3210; MMV892646) IS HIGHLY EFFECTIVE IN CURING HUMAN MALARIA IN *AOTUS* MONKEYS FOLLOWING SINGLE ORAL DOSE ADMINISTRATION

Fiona McCallum[1], Ivor E. Harris[1], Marina Chavchich[1], Geoffrey W. Birrell[1], Karin van Breda[1], Arba L. Ager[2], Gavin D. Heffernan[3], Guy A. Schiehser[3], Laura R. Jacobus[3], G. Dennis Shanks[1], David P. Jacobus[3], **Michael D. Edstein**[1]

[1]Australian Defence Force Malaria and Infectious Disease Institute (ADFMIDI), Brisbane, Australia, [2]University of Miami (UM), Miami, FL, United States, [3]Jacobus Pharmaceutical Company (JPC), Princeton, NJ, United States

The Medicines for Malaria Venture (MMV) is seeking to develop new antimalarial drugs that have the potential to treat malaria patients with a single oral dose, including those with malaria parasites resistant to current artemisinin based combination therapies. Recently, MMV in partnership with Jacobus Pharmaceutical Company (JPC) initiated advanced preclinical evaluation of a new aminomethylphenol (JPC-3210; MMV892646) that possesses high *in vitro* antimalarial activity against multidrug-resistant *Plasmodium falciparum* lines, low cytotoxicity against mammalian cell lines, and potent efficacy in the *P. berghei*-mouse model. In mouse studies, JPC-3210 is rapidly absorbed, has high oral bioavailability and low metabolism, and possesses a lengthy blood elimination half-life (5-6 days). This provides the potential for the compound to be part of a single dose combination providing a long chemosuppressive action in preventing the recurrence of malaria infections. In the present study, we assessed JPC-3210's potency in the traditional human malaria-*Aotus* monkey model. In descending single oral dose studies, JPC-3210 (20, 10 and 5 mg/kg) rapidly cleared established infections of the amodiaquine, chloroquine, and quinine-resistant FVO strain of *P. falciparum* in naive *Aotus* monkeys (groups of 3 monkeys), with no recrudescence over a 90-day follow-up period. We also showed that single oral doses of 10 and 20 mg/kg of JPC-3210 cured *Aotus* monkeys infected with the chloroquine and antifolate-resistant AMRU1 strain of *P. vivax* malaria. Sequential blood sampling of the treated monkeys revealed that JPC-3210 had a long elimination half-life of about 21 days. Parasitaemia clearance profiles and pharmacokinetics of JPC-3210 in the treated monkeys will be presented. The implication of JPC-3210 as a long acting partner compound for both single dose treatment and malaria elimination will also be discussed.

307

MALARIA PREVENTION: DEVELOPMENT OF IMPLANTABLE MALARIA CHEMOPROPHYLAXIS

Jangwoo Lee[1], Qigui Li[1], Jason Sousa[1], Monica Martin[1], Nathanial Copeland[1], Lisa Xie[1], Diana Caridha[1], Qiang Zeng[1], Norma Roncal[1], Jing Zhang[1], Ping Zhang[1], Hsiuling Lin[1], Patricia Lee[1], Chau Vuong[1], Mara Kreishman-Deitrick[1], Chad Black[1], Joe McDonough[2], Benjamin Furman[2], Sandra Drabik[2], Brian Sorrel[2], Mary McGovern[2], Sunil Sreedharan[3], Raj Patel[3]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]Southwest Research Institute, San Antonio, TX, United States, [3]Titan Pharmaceuticals Inc., South San Francisco, CA, United States

Prevention of malaria is highly dependent on subject compliance with a prescribed daily chemoprophylaxis regimen. However, maintaining drug compliance by U.S. service members can be difficult due to a daily oral dosing requirement, side effects, organizational culture, command emphasis and the demands of the operational environment. The Experimental Therapeutics (ET) Branch at Walter Reed Army Institute of Research (WRAIR) is the U.S. Army's premier research program for the development of anti-malarial drugs. A current effort of ET, in collaboration with the Southwest Research Institute and Titan Pharmaceuticals, is to develop long-term release anti-malarial drug implants. These subdermal implants provide continuous drug release over an extended period and could potentially relieve deployed service members from adherence to a daily oral drug dosing schedule. EVA (ethylene-vinyl acetate) implants containing atovaquone and proquanil were tested in mice to characterize the pharmacokinetic (PK) profile and long-term prophylactic efficacy *in vivo.* The PK profile from this ongoing study exhibited drug release through 16 weeks, and maintained stable plasma levels of atovaquone. Furthermore, after 12 weeks of implantation, the atovaquone implants demonstrated complete protection from malaria infection in mice. The development of long-acting prophylactic implants with greater potency and safety is a novel approach that could greatly improve the compliance of deployed service members in malaria-endemic regions. Furthermore, the products targeted for this Industry collaboration will support the multi-domain battlefield operational concept by allowing ground combat forces to maneuver and perform in an uninterrupted manner in resource-constrained environments. Previously reported doxycycline implant data and these preliminary findings with atovaquone and proguanil allow us to pursue further formulation refinement and *in vivo* characterization in pursuit of a series of long-acting implants infuse with FDA-approved malarial prophylaxis drugs - either an atovaquone/proguanil combination or doxycycline.

308

DISCOVERY OF GSK701, A NOVEL ORALLY EFFECTIVE PRECLINICAL DRUG CANDIDATE FOR THE TREATMENT OF MALARIA

Maria Isabel Castellote Alvaro

GSK, Tres Cantos, Spain

Malaria remains a major global health problem. In 2016 alone, 216 million cases of malaria were reported, and more than 400,000 deaths occurred. Since 2010, emerging resistance to current front-line ACTs (Artemisinin Combination Therapies) has been detected in endemic countries. Therefore, there is an urgent need to replace those drugs compromised by resistance, as well as identifying potential novel therapies that offer significant advantages over the current standard of care. During the past few years, the antimalarial community has focused their efforts on phenotypic screening as a pragmatic approach to identify new hits. Within

the TCAM set of phenotypic hits identified at GSK, a pyrrolidinamide chemical series was selected because its chemical novelty and putative new MoA, offering promising properties as antimalarial. Lead optimization efforts within the pyrrolidinamide series led to the identification of GSK701 as a new preclinical candidate that will offer opportunities linked to its killing profile and potency comparable to artemisinins as well as its new mode of action. The overall properties of GSK701, including the low predicted human dose, constitute a promising profile supporting further development to provide novel antimalarial therapeutic opportunities. A detailed description of the Medicinal Chemistry identification and development of GSK701 will be provided in this comunication.

309

CHARACTERIZING THE RESISTANCE TO CLINICALLY-RELEVANT *PLASMODIUM FALCIPARUM* DIHYDROOROTATE DEHYDROGENASE INHIBITORS IN *IN VITRO* AND *IN VIVO* CONTEXTS

Rebecca Mandt[1], Maria Jose Lafuente-Monasterio[2], Tomoyo Sakata-Kato[1], Madeline R. Luth[3], Delfina Segura[2], Alba Pablos[2], Sabine Ottilie[3], Elizabeth Winzeler[3], F. Javier Gamo[2], Dyann Wirth[1], Amanda K. Lukens[1]

[1]Harvard TH Chan School of Public Health, Boston, MA, United States, [2]Tres Cantos Medicines Development Campus, GlaxoSmithKline, Tres Cantos, Spain, [3]University of California San Diego, San Diego, CA, United States

As resistance to front-line antimalarials poses an ever-growing threat, the identification of novel drug targets will be crucial to the continued success of control and eradication efforts. Inhibitors of the dihydroorotate dehydrogenase (DHODH) target have advanced through the drug-development pipeline, including the triazolopyrimidine DSM265, which was recently assessed in Phase 2 clinical trials. We previously demonstrated that resistance to other DHODH inhibitors can be acquired through single point mutations in the *dhodh* locus, suggesting a potential drawback to the clinical use of such compounds. To investigate how resistance to DSM265 occurs, we performed *in vitro* selections with DSM265 and its close analog DSM267. To identify resistance pathways that may be more likely to occur in a clinical setting, we additionally developed a novel platform to select resistant parasites in a humanized mouse model. In both *in vitro* and *in vivo* systems, resistance arises rapidly. Sequencing of resistant parasites identified a variety of mutations in the *dhodh* locus, most of which line the species-selective inhibitor binding site. Interestingly, we identified similar mutations *in vitro* as *in vivo,* suggesting that *in vitro* selections are a relevant model of resistance evolution for this target. To explore the fitness consequences of these mutations, we performed *in vitro* competitive growth assays between wild-type and mutant clones. Previous studies have shown that DHODH:E182D mutant parasites are less fit than wild-type clones, suggesting they are unlikely to compete in natural populations. In contrast, we show that DHODH:C276Y, one of the most common mutations arising from our *in vitro* selections, does not confer a fitness cost. Taken together, these results predict that resistance to DSM265 could arise and spread readily in natural parasite populations. However, we also find that many DSM265-resistant clones exhibit increased sensitivity to other chemotypes of DHODH inhibitors (i.e. collateral sensitivity). This finding indicates the potential of a well-designed combination therapy approach to slow the emergence of resistance.

310

INCORPORATING AN INNOVATIVE *IN VITRO PLASMODIUM CYNOMOLGI* ASSAY INTO THE EXPERIMENTAL THERAPEUTICS' DRUG SCREENING PARADIGM FOR THE DISCOVERY OF NOVEL COMPOUNDS AGAINST *PLASMODIUM* HYPNOZOITES

Samantha Aylor[1], Alison Roth[2], Ratawan Ubalee[3], Silas Davidson[3], Norman Waters[1], Mara Kreishman-Deitrick[1], Chad Black[1], Jangwoo Lee[1], John Adams[2], Brian Vesely[1]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]University of South Florida, Tampa, FL, United States, [3]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Experimental Therapeutics at the Walter Reed Army Institute of Research has played a major role in the discovery and development of many successful antimalarials by utilizing a sophisticated gated-tier system for hit-to- lead discovery of active compounds against *Plasmodium* parasites. This deliberative drug screening paradigm searches for compounds that are active against several species and life cycle stages, with an emphasis on *P. f* and *P. v* malaria. To achieve global eradication, it is imperative to develop drugs that not only target blood stage parasites, but ones that also inhibit the development of dormant liver stage forms, as hypnozoites are the life cycle stage in certain malaria species that can cause relapsing infections. However, a critical gap in current methods for liver stage screening is the ability to screen for hypnozoite inhibition *in vitro* before advancing a compound to the low-throughput and costly non-human primate model. Therefore, in collaboration with the University of South Florida, WRAIR has adapted a method utilizing a 384-well *in vitro P. cynomolgi* culture system to produce viable dormant liver stage parasites in primary NHP hepatocytes and has begun incorporating this assay into the ET drug screening paradigm. Using USF's innovative *in vitro* approach, we have been able to successfully screen hundreds of experimental compounds in both causal prophylactic and radical cure mode and have identified several positive drug hits targeting hypnozoites. Currently our assay is run in 8-point replicates with 4-fold compound dilutions, and sporozoites are sourced from *Anopheles dirus* mosquitoes maintained by the Entomology group at AFRIMS in Bangkok, Thailand. AFRIMS Entomology can produce 1.5 billion *P. cynomolgi* sporozoites per month, giving us substantial access to highly viable parasites and allowing us to continue assay optimization and increase throughput. Here, we discuss how our *in vitro* results correlate with *in vivo* models for known malaria drugs, provide initial causal prophylactic and radical cure data on novel compounds, and present the progress of incorporating this assay into our drug screening paradigm.

311

KINETIC DRIVERS OF ANTIBACTERIAL DRUGS AGAINST *PLASMODIUM FALCIPARUM*: IMPLICATIONS FOR CLINICAL DOSING

Emily Caton, Elizabeth Nenortas, Rahul P. Bakshi, Theresa A. Shapiro

Johns Hopkins University, Baltimore, MD, United States

Antibacterial drugs are an important component of the antimalarial armamentarium, and recommended dosing regimens for the two indications are similar. We examined the pharmacokinetic-pharmacodynamic relationships of chloramphenicol, tetracycline, ciprofloxacin and clindamycin against *Plasmodium falciparum* using our custom glass hollow fiber *in vitro* system that exposes parasites to dynamically changing drug concentrations. To identify the driver of antimalarial efficacy (concentration or time of exposure), the same total dose and AUC (area under the concentration-time curve) of drug was deployed against parasites as either a single short-lived high peak concentration (bolus) or as a constant low concentration (infusion). Parasites counts at 96 h were compared with those of untreated controls.

All four antibacterials were unambiguously time-driven against malaria parasites. For the same total dose and AUC, in ≥ triplicate determinations, efficacy of bolus *vs.* infusion regimens was 25 *vs.* 54% ($p = 0.04$) for chloramphenicol, 26 *vs.* 44% ($p = 0.01$) for tetracycline, 34 *vs.* 70% ($p = 0.001$) for ciprofloxacin, and 40 *vs.* 73% ($p = 0.01$) for clindamycin. On average, antimalarial activity doubled when drug was deployed to favor time. For ciprofloxacin in particular, this finding is in sharp contrast to its concentration-driven antibacterial action, and suggests that dosing regimens tailored for bacteria may be inappropriate against malaria. In keeping with this is the reportedly variable clinical efficacy of antibacterials against *falciparum* malaria, especially as monotherapy, which may reflect the inability of current dosing regimens to provide suitable PK. Finally, the finding that a given drug may have a kinetic driver that varies depending on the target organism, despite (apparently) having the same operative molecular mechanism of action, offers a possible window into the now totally empirical kinetic driver, suggesting that governance by concentration *vs.* time of exposure may be dictated by events downstream from the molecular mechanism of action. XX1850 words allowed; now 1779.

312

EVALUATION OF ACTION OF ANTIMALARIAL DRUGS USING MICROCAPILLARY CYTOMETRY

Kimvan T. Tran[1], Julie Clor[1], Rekha Kannan[1], James Mulry[2], Beatrice Greco[3], Kamala Tyagarajan[1]

[1]Milliporesigma, Hayward, CA, United States, [2]Merck Global Health Institute, Darmstadt, Germany, [3]Merck Global Health Unit, Basel, Switzerland

The increasing literature of *Plasmodium* resistance to several antimalarial drugs amplifies the need for discovery of more effective drugs along with *in vitro* methods and technologies to assess parasite susceptibility. Many of the existing assays today are challenging in either being manually laborious, or requiring complex instrumentation, expert operators, or in being less sensitive/reproducible. Hence there is a need for reproducible and reliable *in vitro* assays/platforms that can be used in many environments easily and provide information on parasite susceptibility/infectivity as well as status of key parasite proteins on the same system. We have recently demonstrated the capability of a simple, low cost, easy to use cytometry platform, the Muse® Cell Analyzer to provide parasitemia related information using a red blood cell assay as well as being able to confirm presence of key parasite proteins such as HRP2 and LDH with high sensitivity. In this study, we evaluated *in vitro* effects of Chloroquine (CQ), Mefloquine (MQ), Quinine (QN), Dihydroarteminisin (DHA) and Doxycycline (DOX) on *P. falciparum* cultures 3D7 and D10 at different times and dosage of treatment. Samples were analyzed for parasitemia levels by Muse® Parasitemia Assay. HRP2 and LDH proteins were characterized by Muse® *Pf/Pv* Assay. The relative effects of the drugs in this study were compared based on inhibitory concentrations required, time for action and capability to reduce recurrent parasitemia. The inhibitory concentration of tested drugs varied in the range of 6.25nM - 200nM for CQ, MQ, QN, DHA or 10μM - 50μM for DOX due to the differences in each drug's mechanism of action and potencies. Our studies will present combined information on parasitemia and key parasite protein detection levels with treatment. The availability of multiple methods to characterize *Plasmodium* cultures in a simple, easy to use microcapillary- based cytometer such as Muse® Cell Analyzer can greatly facilitate screening for conditions and drugs that modulate malarial parasite activity and infection levels.

313

COMPARISON OF PROTEIN ENERGY MALNUTRITION AND *PLMODIUM FALCIPARUM* MALARIA LEVELS IN COMMUNITY BASED EDUCATION AND SERVICE IN TWO CATEGORIES OF CENTERS IN WESTERN KENYA

Arthur V. Kwena

Moi University, Eldoret, Kenya

Nutritional status and levels of P. falciparum malaria in children in two categories of COBES centres: Those with the programme on Academic Model Providing Access To Healthcare (AMPATH) and those that were non-AMPATH were determined. The overall objective was to ascertain if the presence of AMPATH had any effect in reduction of malnutrition and malaria in the centres. For the nutritional status, cross-sectional studies were carried out between March 2008 to May, 2013, in 16 COBES centres in Western Kenya. Cluster sampling technique was used with each health centre as the sampling unit. Anthropometric measurements were performed on all children aged 5-59 months within the households sampled. The parameters considered included Age (in months), Weight (Kgs) and the mid upper arm circumference (cms). The WHO recommended Z- score values as well as the Kenya Government Ministry of health recommended charts based on anthropometric measurements were used as standards. Analysis of nutritional data was carried out using Epi-info 2000 computer program to determine the Z- score values from anthropometric data. For Malaria, the health centre records were assessed for the prevalence during the period of study and compared for both the AMPATH and NON-AMPATH centres. A total of approximately 700 children were measured for anthropometry in the seven Health Centers: (Stunting- HAZ<-2, Wasting-WHZ <-2, underweight –WAZ<-2 and MUAC, < 12.5mm). Meteitei (non-AMPATH) had the highest malnutrition prevalence (53% HAZ, 15% WHZ, 27% WAZ and 18.1 MUAC) whereas Chulaimbo (AMPATH) showed the lowest prevalence (7% HAZ, 3% WAZ). Other centres showed mixed prevalence. Malaria was the leading cause of mortality and morbidity in all the COBES centres except for only two. AMPATH COBES centres showed improved nutrition status compared to non-AMPATH COBES centres. Presence of AMPATH had no effect on prevalence of malaria.

314

THE EFFECT OF PREGNANCY-ASSOCIATED MALARIA ON INFANT GROWTH AND NEUROCOGNITIVE DEVELOPMENT

Sarah Boudova[1], Titus H. Divala[2], Randy Mungwira[3], Jenny Walldorf[4], Tamiwe Tomoka[5], Patricia Mawindo[6], Terrie Taylor[7], Miriam K. Laufer[1]

[1]Institute for Global Health, Division of Malaria Research, University of Maryland School of Medicine, Baltimore, MD, United States, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Università degli Studi di Siena, Siena, Italy, [4]Centers for Disease Control and Prevention, Atlanta, GA, United States, [5]University of Malawi College of Medicine, Blantyre, Malawi, [6]Blantyre Malaria Project, Blantyre, Malawi, [7]Michigan State University, East Lansing, MI, United States

Pregnancy-associated malaria is associated with adverse outcomes for children and may cause neurocognitive deficits through the influence of inflammatory mediators. We have shown that placental malaria infection is associated with an increased risk of malaria infection and disease during infancy. Here we aimed to determine the influence of maternal malaria on infant growth and neurocognitive development. We followed 307 mother-infant pairs from 20-26 weeks gestation through the first two years of life. All pregnancies were dated using ultrasound in the second trimester and women received malaria prevention interventions during pregnancy. Biometric information was collected quarterly and the Malawi Developmental Assessment Tool was administered at six, 12 and 24 months. We detected significant differences in growth and neurocognitive development between preterm and term infants. In our study, malaria

infection was not associated with low birthweight or preterm delivery. Among the mother-infant pairs, 230 had no malaria during pregnancy, 39 had peripheral malaria infection only and 39 had placental malaria (six had active infection at delivery). However, there were no significant differences in gross motor, fine motor, social or language skills based on maternal malaria status at six, 12 or 24 months. Less than five percent of children failed any developmental milestone at any visit. Malaria infection in the mother was not associated with differences in infant weight, length or head circumference at any of the quarterly visits. In sum, placental malaria and maternal peripheral malaria infection had not impact on infant growth or neurocognitive development. While it is possible that our power was limited due to low numbers of placental malaria cases and few cases of chronic infection, these reassuring data suggest that when malaria prevention measures are implemented as recommended, infants are protected from developmental and growth delays when exposed to malaria infection *in utero*.

315

PREVALENCE OF *PLASMODIUM FALCIPARUM* INFECTION AND ANTIMALARIAL RESISTANCE AMONG PREGNANT WOMEN ATTENDING ANTENATAL CARE IN MONROVIA, LIBERIA

Guillermo Martínez Pérez[1], Raquel González[1], Christine K.Tarr Attia[2], Azucena Bardají[1], Adelaida Sarukhan[1], Dawoh Peter Lansana[2], Himanshu Gupta[1], Ana Meyer García-Sípido[3], Quique Bassat[1], Alfredo Mayor Aparicio[1]

[1]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [2]Saint Joseph's Catholic Hospital, Monrovia, Liberia, [3]Fundación Juan Ciudad, Madrid, Spain

Provision of malaria care in Liberia was severely disrupted during the 2014-16 Ebola outbreak. Once the epidemic ended, there was an urgent need to restore a functional malaria control strategy for the most vulnerable (i.e. pregnant women). National-level data on the burden of *Plasmodium falciparum* (*Pf*) infection in pregnant women has never been collected. In mid-2016, we conducted a cross-sectional study at the Saint Joseph's Catholic Hospital, a maternal referral hospital in Monrovia. The study aimed to determine *Pf* prevalence among pregnant women at the first antenatal care (ANC) visit before intermittent preventive treatment (IPTp) was given, and to assess molecular markers of drug resistance. 195 women aged 14 and older participated. Their mean age was 27.3 years, and 28% of them slept under an insecticide-treated net the night before. Twenty-four women (12%) were shown to be *Pf*-infected by real-time qPCR. Only three of them had fever, and ten had low-density infections (<10 parasites/µl). Mean hemoglobin levels were lower in *Pf*-infected than in non-infected women (10.8 vs 11.2 mg/dL). Infection was only significantly associated with younger age, fever and first gravidity. qPCR tests of *Pf* isolates showed absence of *pfdhps* K540E, the epidemiological marker of the quintuple mutation, and a >5% prevalence of polymorphisms associated with resistance to Sulfadoxine. This study shows that midwives in Liberia could expect at least one in eight women to be *Pf*-infected in their first ANC. The risk of being *Pf*-infected is higher among the young primigravidae. Drug resistance analyses showed no compromised efficacy of IPTp. However, most of the women had either submicroscopic or asymptomatic malaria, indicating that they -and their newborn- could develop ill health in the long term. To strengthen malaria control and further protect the most vulnerable, updated robust epidemiological data are crucial. In Liberia, where massive annual malaria surveys cannot be funded, ANC-based prevalence and drug resistance surveillance could be set up, capitalizing on the investment in molecular technologies that the country received during the Ebola crisis.

316

SPATIO-TEMPORAL HETEROGENEITY OF MALARIA MORBIDITY IN GHANA: ANALYSIS OF ROUTINE HEALTH FACILITY DATA

Timothy A. Awine[1], Keziah Malm[2], Nana Yaw Peprah[2], Sheetal P. Silal[1]

[1]University of Cape Town, Cape Town, South Africa, [2]NMCP, Ghana Health Service, Accra, Ghana

Malaria incidence is largely influenced by vector abundance. Among the many interconnected factors relating to malaria transmission, weather conditions such as rainfall and temperature are known to create suitable environmental conditions that sustain reproduction and propagation of anopheles mosquitoes and malaria parasites. In Ghana, climatic conditions vary across the country. Understanding the heterogeneity of malaria morbidity using data sourced from a recently setup data repository for routine health facility data could support planning. Monthly aggregated confirmed uncomplicated malaria cases from the District Health Information Management System and average monthly rainfall and temperature records obtained from the Ghana Meteorological Agency from 2008 to 2016 were analysed. Univariate time series models were fitted to the malaria, rainfall and temperature data series. After pre-whitening the morbidity data, cross correlation analyses were performed. Subsequently, transfer function models were developed for the relationship between malaria morbidity and rainfall and temperature. Malaria morbidity patterns vary across zones. In the Guinea savannah, morbidity peaks once in the year and twice in both the Transitional forest and Coastal savannah, following similar patterns of rainfall at the zonal level. While the effects of rainfall on malaria morbidity are delayed by a month in the Guinea savannah and Transitional Forest zones those of temperature are delayed by two months in the Transitional forest zone. In the Coastal savannah however, incidence of malaria is significantly associated with two months lead in rainfall and temperature. In conclusion, data captured on the District Health Information Management System has been used to demonstrate heterogeneity in the dynamics of malaria morbidity across the country. Timing of these variations could guide the deployment of interventions such as indoor residual spraying, Seasonal Malaria Chemoprevention or vaccines to optimise effectiveness on zonal basis.

317

THE USE OF GPS DATA LOGGERS TO DESCRIBE SPATIO-TEMPORAL MOVEMENT PATTERNS AND THE IMPLICATIONS FOR MALARIA CONTROL IN THREE EPIDEMIOLOGIC SETTINGS IN SOUTHERN AFRICA

Marisa Hast[1], Kelly M. Searle[1], Jailos Lubinda[2], Harry Hamapumbu[3], James Lupiya[4], Edmore Mamini[5], Timothy M. Shields[1], Sungano Mharakurwa[5], Lovemore Gwanzura[5], Shungu Munyati[5], Jennifer C. Stevenson[3], Philip E. Thuma[3], Mike Chaponda[4], Modest Mulenga[4], William J. Moss[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Ulster University, Coleraine, United Kingdom, [3]Macha Research Trust, Macha, Zambia, [4]Tropical Diseases Research Centre, Ndola, Zambia, [5]Biomedical Research and Training Institute, Harare, Zimbabwe

Human mobility has been identified as a driver of malaria transmission at both large and small spatial scales. However, the contribution of individual movement patterns in different epidemiologic settings has not been comprehensively examined. Between 2013 and 2017, three population movement studies using global positioning systems (GPS) data loggers were conducted in rural southern Africa as part of the Southern and Central Africa International Centers of Excellence for Malaria Research. The three sites included were: Choma District, Southern Province, Zambia, a pre-elimination setting with declining malaria transmission; Nchelenge District, Luapula Province, Zambia, a high-transmission setting with ineffective malaria control; and Mutasa District, Manicaland Province,

Zimbabwe, a moderate-transmission setting with seasonal malaria. At each site, participants aged 13 years and older were invited to carry a GPS data logger for one month during all daily activity. GPS devices were motion-activated and recorded coordinates, date, and time every 2.5 minutes while in motion. At logger distribution and final collection, participants completed a survey and provided a finger prick blood sample for *hrp-2* RDT and *cytb* PCR testing. Data were uploaded into ArcGIS and R statistical programs to create movement tracks and density maps, and patterns in activity space were compared across participants. In Choma, Nchelenge, and Mutasa Districts, respectively, 69, 84, and 180 participants were enrolled. Distinct movement patterns were informative in characterizing malaria transmission at each site. Seasonal long-distance movement could explain parasite importation in Choma District. High local mobility in Nchelenge District was expected to reduce the effectiveness of targeted intervention strategies. Extensive cross-border movement into Mozambique from Mutasa District was linked to importation of cases and attenuation of malaria control activities. The different movement patterns characterized in these studies have implications for malaria control strategy across epidemiologic settings in southern Africa.

318

EPIDEMIOLOGY OF *PLASMODIUM VIVAX* MALARIA INFECTION IN NEPAL

Komal R. Rijal[1], Bipin Adhikari Adhikari[2], Prakash Ghimire[3], Megha R. Banjara[3], Borimas Hanboonkunupakarn[4], Mallika Imwong[5], Kesinee Chotivanich[4], Bhim Acharya[6], Vivek Kumar Lal[6], Garib Das Thakur[6], Nicholas PJ Day[2], Nicholas J. White[2], Sasithon Pukrittayakamee[4]

[1]Central Department of Microbiology, Tribhuvan University, Kirtipur, Kathmandu, Nepal and Department of Clinical Tropical Medicine, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, Kathmandu, Nepal, [2]Mahidol- Oxford Research Unit, Bangkok, Thailand, [3]Central Department of Microbiology, Tribhuvan University, Kirtipur, Kathmandu, Nepal, [4]Department of Clinical Tropical Medicine, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [5]Mahidol- Oxford Research Unit, Faculty of Tropical Medicne, Mahidol University, Bangkok, Thailand, [6]Epidemiology Diseases Control Division, Teku, Kathmandu, Nepal

Malaria is endemic in the southern plain of Nepal (the Terai) which shares a long and porous border with India. More than 80% cases of malaria in Nepal are caused by *Plasmodium vivax*. Nepal is currently at the malaria pre-elimination stage with a target of elimination by 2025. The main objective of this study was to review the changing epidemiology of *P. vivax* malaria infections as recorded by the national malaria control programme of Nepal between1963 and 2016. National malaria data was retrieved from the National Malaria programme in the Ministry of Health, Government of Nepal. The epidemiological trends and malariometric indicators were analyzed. The most recent malaria risks in known endemic districts (Kailali, Kanchanpur and Jhapa) were mapped by GIS Arc version 10.2. *Plasmodium vivax* malaria has predominated over *P. falciparum* in the past 53 years, with *P. vivax* malaria comprising 70-95% of the annual malaria infections. In 1985, a malaria epidemic occurred with 42,321 cases (82 % *P. vivax*, 17% *P. falciparum*). Nepal had experienced further outbreaks of malaria in 1991 and 2002. Although the total number of malaria cases was declining, *P. falciparum* cases increased from 2005 to 2010, but since then declined. Analyzing the overall trend between 2002 (12,786 cases) until 2016 (1,009 cases), shows a case reduction by 92%. In contrast imported malaria cases showed an increasing proportion from 18% of cases in 2001 to 50% in 2016. In conclusion, the current trends of malariometric indices indicate that Nepal is making a significant progress towards achieving the goal of malaria elimination by 2025. The majority of cases are due to *P. vivax,* a complex parasite with latent hypnozoites reservoir causing relapse. In Nepal, imported malaria comprises an increasing proportion of all cases. The Malaria control program in Nepal needs to direct strategies to counter importation of malaria to high risk areas and to conduct collaborative cross border malaria control activities.

319

MALARIA IN THE FIRST TRIMESTER, BUT NOT IN THE 2ND AND 3RD TRIMESTER OF PREGNANCY, IS ASSOCIATED WITH MATERNAL ANEMIA: A PRE-CONCEPTIONAL COHORT STUDY IN BENIN

Manfred M. Accrombessi[1], Emmanuel Yovo[1], Nadine Fievet[2], Gilles Cottrell[2], Gino Agbota[1], Achille Massougbodji[1], Michel Cot[2], Valérie Briand[2]

[1]Institut de Recherche Clinique du Benin (IRCB), Cotonou, Benin, [2]Institut de Recherche pour le Développement (IRD), UMR216- MERIT Mère et enfant face aux infections tropicales, Université Paris Descartes, Paris, France

In Africa, preventive drug strategies against malaria in pregnancy are recommended from the 2nd trimester, and bed nets are rarely distributed before the 1st antenatal care visit at approximately 4 months of pregnancy. Therefore, women remain insufficiently, or not, protected during the 1st trimester, when malaria may be particularly deleterious for the mother and the foetus. For the first time, we assessed the effect of malaria according to the timing of infections during pregnancy on maternal anaemia using a specifically-designed study. From June 2014 to March 2017, 1214 women of reproductive age were recruited and followed up monthly until 411 became pregnant. Pregnant women were then followed up from 5-6 weeks of gestation until delivery. Microscopic malarial infections were detected monthly during pregnancy using thick blood smear. Maternal haemoglobin (Hb) level was assessed in the 1st trimester and in the 3rd trimester of pregnancy. A logistic regression model was used to assess the effect of malaria at different timings during pregnancy on maternal anaemia in late pregnancy (Hb below to 110 g/L). The prevalence of maternal anaemia in late pregnancy was 58.6%. The prevalence of malaria infection was 21.8%, 17.7% and 14.6% in the 1st, 2nd and 3rd trimester of pregnancy, respectively. After adjustment for potential confounders, malaria in the 1st trimester was significantly associated with maternal anaemia (aOR=2.7 [1.4-5.3]; P=0.003), whereas no effect was found for malaria in the 2nd and 3rd trimesters. These results suggest an independent effect of malaria in the 1st trimester of pregnancy on maternal anaemia despite immediate treatment of malarial infections. They argue in favour of additional preventive drug-related measures against malaria starting before or in the 1st trimester of pregnancy.

320

HETEROGENEITY OF HUMAN EXPOSURE TO MALARIA VECTOR IN URBAN SETTING BY USING IMMUNO-EPIDEMIOLOGICAL SALIVARY BIOMARKER

Dipomin F. Traore[1], André B. Sagna[2], Akré M. Adja[3], Dounin D. Zoh[1], Kouassi N. Lingué[1], Issa Coulibaly[1], Bertin N. Tchiekoi[1], Serge B. Assi[1], Anne Poinsignon[2], Mamadou Dagnogo[4], Franck Remoue[2]

[1]Institut Pierre Richet, Bouaké, Côte D'Ivoire, [2]Institut de Recherche pour le Développement (IRD), Montpellier, France, [3]Unité de Formation et de Recherche Biosciences (UFR Biosciences) Université Félix Houphouët Boigny, Abidjan, Côte D'Ivoire, [4]Unité de Formation et de Recherche Sciences de la nature (UFR SN) Université Nangui Abrogoua, Abidjan, Côte D'Ivoire

Urban malaria represents an underestimated serious health concern in African countries. This study aims to evaluate the risk of malaria transmission and the effectiveness of insecticide treated nets (ITNs) use for vector control in urban area. New, sensitive and large-scale monitoring indicators which measure the real and quantitative Human-Vector contact was here used. It is based on the human IgG antibody responses to the gSG6-P1 salivary peptide of the *Anopheles* saliva previously validated as pertinent biomarker of Human exposure to *Anopheles* bites, in several epidemiological contexts. Two multidisciplinary cross-sectional studies were undertaken in three neighborhoods (Dar-es-salam, Kennedy and N'gattakro) of Bouaké city (Ivory Coast) during the rainy and the dry

seasons. Blood samples were obtained from children aged 6 months to 14 years-old for immunological tests and ITNs use information's were collected by sociological questionnaire. The specific IgG level of children was significantly higher in rainy season compared to dry season whatever the studied districts (all difference at P<0.001; Mann Whitney test). Interestingly, the specific IgG level was different between to the three neighborhoods in dry season when exposure to *Anopheles* bites decrease (P= 0.032; Kruskal-Wallis test). This result shows the considerable heterogeneity of children exposure to Anopheles vector between neighborhoods in urban context. Surprisingly, no difference were observed between children who declared sleeping always under ITN and those who affirm never sleeping under ITN in rainy season and dry season (p= 0.337; p= 0.094 respectively). This study highlights the high risk of malaria exposure in African urban settings and its heterogeneity within city. The *Anopheles* salivary biomarker could be a suitable tool for accurately and quantitatively assessing the risk of transmission and effectiveness of malaria control methods in urban areas.

321

EFFECT OF THE ABO BLOOD GROUP ON SUSCEPTIBILITY TO SEVERE MALARIA AND RELATED OUTCOMES: A SYSTEMATIC REVIEW AND META-ANALYSIS

Abraham Degarege[1], Merhawi T. Gebrezgi[1], Gladys Ibanez[1], Mats Wahlgren[2], Purnima Madhivanan[1]

[1]Department of Epidemiology, Robert Stempel College of Public Health & Social Work, Miami, FL, United States, [2]Department of Microbiology, Tumor and Cell Biology (MTC), Karolinska Institute, Stockholm, Sweden

Understanding how the ABO blood group interacts with *Plasmodium falciparum* malaria will provide insights on the pathogenesis of *falciparum* malaria and provide direction for basic research that may help the development of novel antimalarial treatments and vaccines. Specifically, investigating the genetic basis that reduces susceptibility to severe *P. falciparum* infection may lead the formulation of personalized strategies designed to prevent deaths due to severe *P. falciparum* infection. We systematically summarized information on the effect of ABO blood group on severe *P. falciparum* infection, level of parasitemia and hemoglobin. We searched literature published in Pubmed, Embase, Web of Science, CNAHL and Cochrane Library from inception to February 04, 2017 without restriction. We retrieved 1,923 articles were from five databases: Embase (n=728), PubMed (n=620), Web of Science (n=549), CINAHL (n=14) and Cochrane Library (n=12). After removal of duplicates and two levels of screening, we selected 24 articles for inclusion in the systematic review and 22 for the meta-analysis. A meta-analysis of 15 studies showed an increased odds of severe *P. falciparum* infection (*vs* uncomplicated *P. falciparum* infection) among individuals with blood group A (summary Odds Ratio [OR] 1.34; 95% Confidence Interval [CI] 1.06, 1.62); B (OR 1.48; 95%CI:1.16, 1.79); AB (OR 1.43; 95%CI: 1.00, 1.87); or non-O (A, B or AB) (OR 1.61; 95%CI: 1.31, 1.91) compared with blood group O. A meta-analysis of four studies showed a significantly greater level of *P. falciparum* parasitemia among individuals with blood group A than those of blood group O (mean difference: 1769.2; 95%CI: 848.9, 2689.4). However, a meta-analysis of four studies showed lack of significant difference in hemoglobin level among *P. falciparum* infected individuals of blood group A as compared with those of blood group O. This study suggests that individuals with blood group A, B and AB are more susceptible to severe *P. falciparum* infection and blood group O has a protective effect. However, the ABO blood group may not affect *P. falciparum* infection related reduction in hemoglobin level.

322

REACTIVE CASE DETECTION AND EPIDEMIOLOGY OF *PLASMODIUM FALCIPARUM* MALARIA IN THE WESTERN KENYA HIGHLANDS

Ebenezer K. Aidoo[1], Yaw A. Afrane[2], Maxwell G. Machani[3], Winnie Chebore[3], Bernard W. Lawson[1], Harrysone Atieli[4], Simon Kariuki[3], Diabin Zhong[5], Ming-Chieh Lee[5], Cristian Koepfli[5], Guofa Zhou[5], Andrew K. Githeko[3], Guiyun Yan[5]

[1]Department of Theoretical & Applied Biology, College of Science, Kwame Nkrumah University of Science & Technology, Kumasi, Ghana, [2]Department of Medical Microbiology, College of Health Sciences, University of Ghana, Korle- Bu, Accra, Ghana, [3]Kenya Medical Research Institute / Centre for Global Health Research, Kisumu, Kenya, [4]School of Public Health, Maseno University, Maseno, Kenya, [5]Program in Public Health, College of Health Sciences, University of California, Irvine, CA, United States

Identifying asymptomatic infections using index cases can help to understand the epidemiology of malaria and guide control activities. Reactive case detection and the genetic composition of parasites identified through these activities were investigated, between October 2015 and September 2016 in Marani, western Kenya. Fifty index cases were followed up, and 108 index case household members were screened by PCR, as well as 612 neighbours within a 100m radius and 510 controls matched with index cases and located at a distance of ≥ 500 m. In the index case and neighbour households, the prevalence of infection was approximately twice as high as in control households (by PCR: Index cases households: 28.9%, neighbours: 25.3% controls: 12.9%). Assuming all malaria cases were followed up, only a small proportion (<10%) of the asymptomatic reservoir in the population would have been identified. 127 isolates (34 index cases, 11 index household members, 57 neighbours and 25 controls) were genotyped using markers *msp1* and *msp2*. Except for the index cases, (heterozygosity = 0.90), genetic diversity was similar across all the populations (0.80) with higher mean multiplicity of infection in neighbours (1.81) relative to all the study population. Across all population, moderately higher proportions of related genotypes were observed in index case households (27.7%). In conclusion, reactive case detection is effective in identifying additional cases, but likely has limited effect on transmission at the population level. The higher prevalence of infection in index case households and the parasite genetic relatedness indicate small-scale transmission of parasites within high-risk *Foci*.

323

EPIDEMIOLOGY OF MALARIA TRANSMISSION IN TWO NEIGHBORING VILLAGES IN THE RURAL COMMUNE OF ANDRIBA, MADAGASCAR

Jessy Marlène Goupeyou-Youmsi[1], Tsiriniaina Rakotondranaivo[1], Mandaniaina Radotiana Andriamiarimanana[1], Tsikiniaina Rasoloharimanana[1], Rado Lalaina Rakotoarison[1], Emma Rakotomalala[1], Romain Girod[1], Catherine Bourgouin[2], Ousmane Ndiath[1], Inès Vigan-Womas[1]

[1]Institut Pasteur de Madagascar, Antananarivo, Madagascar, [2]Institut Pasteur, Paris, France

Malaria remains a major health concern in the island of Madagascar, with *Plasmodium falciparum* and *Plasmodium vivax* as the major parasite species mainly transmitted by *Anopheles gambiae* s.l. and *Anopheles funestus.* However, *Anopheles mascarensis* endemic to the island and *Anopheles coustani* can also act as local or minor vectors. In a region of moderate to high malaria transmission, the prevalence of malaria cases in two nearby villages with apparent similar pattern was significantly different. To try deciphering the basis of this difference, we conducted a multidisciplinary study including Entomology, Parasitology and Immunology. Surveys were conducted from November 2016 to April 2017 at 3 time periods. Mosquitoes were collected by human landing and pyrethrum spray catches. From 1650 caught *Anopheles*, the mean

aggressive density of *An. coustani*, *An. arabiensis*, *An. funestus* and *An. mascarensis* was 10.4, 5.7, 2.5 and 0.9 respectively. The abundance of caught *Anopheles* was similar in both villages. Detection of *Plasmodium* carriage by a TaqMan assay in those mosquitoes is in progress. *Plasmodium* prevalence in the human population was determined by Rapid Diagnostic Test, microscopy and Real-Time PCR. Prevalence and specificity of antibodies against *Plasmodium* antigens as well as an *Anopheles*-specific salivary antigen were determined using a multiplex bead-based serological assay. Malaria prevalence in the population was higher in one village compared to the other, as previously observed. Serological results suggest different kinetics in *P. vivax* transmission between the two villages. No clear serological differences were observed for *P. falciparum*. Our current data confirm the epidemiological variations observed during the malaria transmission season in the two villages surveyed, with an increase in antibodies against *Plasmodium* antigens at the middle of the transmission season. The detail entomological analysis should provide relevant information that might explain the differential pattern of malaria prevalence between the two villages and possibly guide for adapted malaria transmission control.

324

PREVALENCE OF *PLASMODIUM FALCIPARUM* INFECTION IN MOZAMBICAN PREGNANT WOMEN

Glória G. Matambisso

Manhica Health Research Center, Matola, Mozambique

Continued monitoring of malaria in pregnancy is lacking in most endemic settings, in spite of its significant disease burden. Increases in malaria-related harmful effects observed among Mozambican pregnant women after drastic malaria declines during the last decade suggest that close monitoring of the transmission is needed to quickly identify rebounds in adverse outcomes, especially in areas embarking on malaria elimination. It has been suggested that malaria prevalence among pregnant women can be a good approximation of the prevalence of malaria in children obtained from household surveys. In Manhiça, malaria hospital admission in the District Hospital followed similar trends to malaria prevalence among pregnant women, pointing towards the value of malaria prevalence among pregnant women delivering at health facilities as a proxy of malaria in the underlying community. We are conducting a three-year *prospective observational* study at three health centers with different levels of malaria transmission in Maputo Province (Manhiça District Hospital [Manhiça District], Ilha Josina Health Center [Manhiça District] and Magude Health Center [Magude District]). The number of women recruited until 9th February 2018 is 640 for Ilha Josina Health Centre; 4493 for Manhica Health Center and 2380 for Magude Health Center. At the first antenatal visits, the prevalence of maternal anemia (Hb < 11 g/dl) was 62.39% in Manhiça; 49.57% in Magude and 56.55% in Ilha josina. At maternity visits, the prevalence of maternal anemia was 64.83% in Manhiça; 56.71% in Magude and 32.14% in Ilha Josina. At the first visit, the prevalence of *Plasmodium falciparum* infection (qPCR) was 9% in Manhiça, 37% in Josina Island and 6% in Magude. Key findings The lower prevalence of *Plasmodium falciparum* infection in Magude (6%) when compared to Manhica (9%) and Ilha Josina (37%) may be a result of the activities carried out in this District in the context of elimination of malaria.

325

ECONOMIC BURDEN OF MALARIA: A CASE STUDY OF WORKERS ABSENTEEISM IN A BANANA PLANTATION IN ZIMBABWE

Akim T. Lukwa[1], Richard Mawoyo[2], Caleb Marange[3], Moses Zimba[4], Olufunke Alaba[1]

[1]University of Cape Town, Cape Town, South Africa, [2]Ministry of Health and Child Care Zimbabwe, Mutare Provincial Hospital, Mutare, Zimbabwe, [3]Burma Valley Rural Health Centre, Mutare, Zimbabwe, [4]University of Zimbabwe, Department of Biological Sciences, Harare, Zimbabwe

Absenteeism in this era has attracted attention across a number of areas, as the latter results in lost man hours hence bearing a direct impact on productivity and performance. Man lost hours are as a result of time taken off seeking treatment, this study assessed the impact of malaria on productivity in a banana plantation through absenteeism reducing the labour units on hand and therefore reducing overall farm production as well as economic gains both to the workers and the plantation. The study was carried out at Matanuska banana producing farm in Burma Valley, Zimbabwe. Raw data on absenteeism was obtained in retrospect from the Farm Manager, with malaria infection detected using the Rapid Diagnostic Test (RDT) kit. In the study the following measures of absence were determined; incidence of absence, absence frequency, frequency rate, estimated duration of spells , severity rate, incapacity rate , number of absent days, number of scheduled working days , absenteeism rate. The study followed up a total of 143 employees over a 5 month period in a cohort study. Results reflected malaria positivity to be 21%, 31.5%, 44.8%, 35.7% and 12.6% in January, February, March, April and May 2014 respectively. Initially one spell of absence was observed [194 (86.6%)] followed by 2 spells of absence [30 (13.4%)] and the latter spells were common for all employees. However the duration of spells of absence as a result of malaria ranged from 1.5 to 4.1 working days, with spells dominating among general workers hence the most affected group. An incidence of absence reflected at 93.3% (143/155) with spells of absence over a 5 month period totalling 224. The frequency rate of absenteeism was 1.6 with severity rate of absence being 2.4. The incapacity rate was 3.7. In conclusion, final absenteeism rate was 2.99% (below the 4% excessive rate), but however malaria contributed significantly to worker absenteeism.

326

FALCIPARUM PREDOMINANT MALARIA OUTBREAK IN HUNKUND TALUK, BAGALKOTE DISTRICT, KARNATAKA, INDIA, 2015 TO 2016

Sree Kalpana Mohan Kumar[1], Balakrishnan Natarajan[2], Sunandha P.[3], Nazneen N[3], Harshavardhan M[3], Srinivas Venkatesh[4], Agarwal C.S[4]

[1]Department of Public Health, Namakkal, India, [2]National Center for Disease Control, Bangalore, India, [3]State Surveillance Unit, Bangalore, India, [4]National Center for Disease Control, Delhi, India

India accounts for 58% of malaria cases in South East Asia region. Four villages of Hungund taluk, Bagalkote district in Karnataka state, India reported clustering of malaria cases on 15th of November, 2015. We investigated to describe the outbreak and to give recommendations. Our study population included residents of all four villages, Hirekodagalli, Gugglemaari, Gudur and Hanumnal. We surveyed fever cases in fever clinic, between 20th of November, 2015 and 31 of March, 2016. We defined a confirmed case of Malaria as any patient whose blood smear was positive for plasmodium falciparum or plasmodium vivax. We collected line list of confirmed malaria cases from fever clinics. We calculated attack rates by village, age groups and gender. There were 601 falciparum cases and 213 vivax cases. Sixteen cases had mixed infections. Falciparum cases started on 26th October, 2015, with peak between 27th and 29th October and started coming down after 1st of December, 2015. Last case occurred on 18th of February, 2016. Attack rate of Falciparum cases was 15% (601/4111). Median age was 22 years (range: 1.5 – 81 years). Falciparum incidence was highest (24%) in Gugglemaari village. Vivax cases started on 26th of October peaked between 27th October and 16th of November and last case occurred on 21st of December, 2015. Attack rate of vivax cases was 5% (213/4111). Median age was 22 years (range: 3 to 80 years). Highest attack rate (7%) was in Gugglemaari (69/959) and Gudur (45/668) while attack rate was 4% in Hirekodagalli (83/2024) and 3% in Hanumnal (15/460). In conclusion, there was malaria outbreak between 26th October, 2015 and 18th February, 2016 in four villages of Hungund

taluk. Falciparum accounted for majority of cases and Gugglemaari village was most affected. We recommend identifying entomological and environmental factors for the outbreak.

CHANGING MALARIA EPIDEMIOLOGY IN KWAZULU-NATAL, A PROVINCE IN SOUTH AFRICA TARGETING ELIMINATION BY 2020

Rajendra Maharaj[1], Bheki Qwabe[2], Moses Mkhabela[2], Ishen Seocharan[1]

[1]Medical Research Council, Durban, South Africa, [2]KwaZulu-Natal Department of Health, Jozini, South Africa

KwaZulu-Natal, a province in South Africa targeting malaria elimination by 2018 had to revise its timelines due to challenges experienced within the province. Malaria transmission is unstable and seasonal with the peak transmission season being between October and May. The main vector is *Anopheles arabiensis* and the most common parasite, *Plasmodium falciparum*. The majority of the local cases are reported from the Umhlabuyalingana border municipality and imported cases from Ethekwini municipality. Retrospective and current data was sourced from the Malaria Information System that is housed within the Provincial Department of Health. The data was subjected to trends analysis to identify the changing epidemiology in the province. Malaria cases have decreased drastically in KwaZulu-Natal from 42 000 in 2000 to 402 in the first two months of 2017. Due to the decreases in mortality and morbidity, South Africa adopted an elimination agenda in 2012. Although the number of local cases in KwaZulu-Natal decreased to 53 in the 2016/2017 malaria season, the numbers increased to 149 in the first 3 months of 2018. The proportion of imported cases remained consistent at an average of 80% of all reported cases, with the majority of cases originating from Mozambique. The incidence of local malaria increased from 0.07 in 2014 to 0.1 in 2017. Between 2014 and 2017 the number of cases in pregnant women and children under 5 years halved. The main intervention, indoor residual spraying with DDT or a carbamate, was around 69% for 2017. A new potential vector has also been identified in the province which may have contributed to the low levels of transmission. KwaZulu-Natal is on track for achieving elimination but the changing epidemiology continues to be a challenge. The main factors hampering elimination efforts appear to be imported cases that may be causing secondary local cases, as well as the decrease in spray coverage that left more people unprotected. The root causes of the low levels of residual malaria need to be investigated and addressed for KwaZulu-Natal to achieve elimination.

328

GAMETOCYTEMIA IN FEBRILE PATIENTS FROM DIVERSE ECO-REGIONS OF KENYA

Stephen Ocholla

US Army Medical Research Unit-Kenya, Nairobi, Kenya

While asexual malaria parasitemia determines disease severity, gametocytemia is crucial in the disease transmission. This study used qPCR that targets the 18S rRNA and the Pfs25 mRNA to enumerate asexual parasitemia and gametocytemia respectively in 1,436 blood samples collected from patients presenting with acute febrile illness (AFI) at hospitals located in Kisii highlands, Lake Victoria basin, Nairobi metropolitan, arid and semi arid areas, and the coast region. Overall, the prevalence of asexual parasitemia was 66.3% (952/1436) and 28.8% (414/1436) for gametocytemia. Of the 952 patients with asexual parasitemia, 378 (39.7%) had gametocytemia. There was no correlation between asexual parasitemia density and gametocytemia. Only 9.5% (36/414) of individual with gametocytemia did not have asexual parasitemia. Regionally, the arid and semi arid areas had the highest gametocytemia in absence of asexual parasitemia, 24.8% vs 3.6% in other eco-regions. In addition, gametocyte density in patients without asexual parasitemia was significantly higher ($p<0.0001$) compared to patients with asexual parasitemia. In conclusion, while it's clear that gametocytemia is a function of asexual parasitemia, it remains to be determined why a large proportion of gametocytemia in the arid and semi arid areas is without asexual parasitemia and two, why 60% of asexual parasitemia do not have gametocytemia.

329

QUANTIFICATION OF STAGE-SPECIFIC *PLASMODIUM FALCIPARUM* GAMETOCYTE RNA TRANSCRIPTS TO EVALUATE THE IMPACT OF HIV STATUS ON GAMETOCYTEMIA IN WESTERN KENYA

Deborah Stiffler[1], Janet Oyieko[2], Carolyne Kifude[2], David Rockabrand[1], Nathaniel Dizon[1], John Waitumbi[2], Shirley Luckhart[3], V. Ann Stewart[1]

[1]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [2]US Army Medical Research Directorate-Kenya (USAMRD-K)/ Kenya Medical Research Institute (KEMRI), Kisumu, Kenya, [3]University of Idaho, Moscow, ID, United States

Plasmodium falciparum and human immunodeficiency virus (HIV) have overlapping endemicities in sub-Saharan Africa, but co-infection remains poorly studied, especially the impact of HIV status on *P. falciparum* gametocyte carriage. We developed a multiplex qRT-PCR panel to quantify the gametocyte RNA transcripts of *Pfs16*, *Pfs48/45*, and *Pfs25*, which are early, intermediate, and late stage gametocyte markers, respectively. Quantitative expression of these markers was used as a sensitive surrogate for gametocytemia in a set of malaria positive samples from adults seeking voluntary HIV testing in Kisumu, Kenya as part of a larger cross-sectional molecular epidemiology study of pre-treatment HIV^+ individuals. The late stage marker *Pfs25* is considered the gold standard for molecular detection of *P. falciparum* gametocytes because *Pfs25* is highly expressed on mature gametocytes, and earlier gametocyte stages are thought to remain sequestered. We found that *Pfs16* was expressed more frequently than *Pfs25* in peripheral samples, and that detection could occur without concurrent *Pfs25* expression, suggesting that there are at least some early stage gametocytes in circulation. Additionally, we compared the expression of our markers of interest between HIV^+ and HIV^- patients in order to determine whether HIV status impacts malaria transmission. Our preliminary studies found that HIV^+ patients have a statistically significant lower overall prevalence of gametocyte detection when compared to HIV^- patients. However, in gametocyte positive samples, expression of *Pfs16* and *Pfs25* is statistically higher in HIV^+ patients as compared to HIV^- patients, and HIV^+ patients are more likely to be concurrently positive for all three gametocyte markers. Thus, HIV^+ individuals are carrying more gametocytes. Additional analyses and *in vitro* work are planned to investigate the mechanism of increased expression of these markers in our HIV^+ cohort. Our data highlights the importance of treating HIV^+ patients with gametocidal drugs to decrease malaria transmission, particularly in areas where co-infection is common.

330

ADHERENCE TO ANTIMALARIAL TREATMENT IN THE CONTEXT OF REACTIVE CASE DETECTION IN ZANZIBAR

Abdul-wahid H. Al-mafazy[1], Abdullah S. Ali[1], Bakari Fakih[2], Logan H. Stuck[3], Joshua Yukich[4], Manuel W. Hetzel[5]

[1]Zanzibar Malaria Elimination Programme, Zanzibar - Tanzania, United Republic of Tanzania, [2]Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, [3]Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, [4]Tulane School of Public Health and Tropical Medicine, New Orleans, New Orleans, LA, United States, [5]Swiss Tropical and Public Health Institute, University of Basel, Basel, Switzerland

Adherence to antimalarial treatment is a central building block of effective malaria control and elimination. While patient adherence to treatment regimens has been investigated in different settings, there is a dearth of evidence on adherence by asymptomatic individuals who are provided

treatment in the context of reactive case detection strategies. This study aimed to assess adherence to the first-line treatment artesunate-amodiaquine (AsAq) by symptomatic and asymptomatic individuals detected and provided treatment by the expanded surveillance system of the Zanzibar Malaria Elimination Programme (ZAMEP). A rolling cross-sectional survey in six districts in Zanzibar followed passively and actively detected infected individuals of all ages on the 3rd day after receiving antimalarial treatment, when they were expected to have completed a full AsAq treatment course. Treatment adherence was assessed by inspection of the blister package and structured interviews with patients or caretakers. A total of 495 study participants were analyzed. The overall patients' adherence to AsAq was 85% (95% CI: 81% - 88%). The adherence by symptomatic study participants was 88% (95% CI: 84% - 93%) and 75% (95% CI: 71% - 79%) by asymptomatic participants. Study participants' health condition was found to be a determinant of adherence to AsAq (OR = 2.8, P = 0.001). Common self-reported reasons for non-adherence were *not feeling sick*, *rapid recovery rate*, *a perception that the drug is too strong*, and *forgetting to take the pills.* In conclusion, we found moderate and high levels of adherence to AsAq among treated asymptomatic and symptomatic study participants respectively. Presence of signs and symptoms prior treatment influenced intake on the treatment. Further efforts focusing on IEC/BCC activities are needed to improve correct and completion of dose uptake by both treated patients.

PLACENTAL MALARIA AND INCIDENCE OF ANEMIA IN INFANCY

Seyram Kaali, The Kintampo Birth Cohort Study team members
Kintampo Health Research Centre, Kintampo, Ghana

Several factors contribute to anemia in infancy. In malaria endemic areas, the independent effect of placental malaria (PM) on infant hemoglobin has been sparingly studied. We investigated the effect of PM on the incidence of anemia among a cohort of 1855 mother-infant pairs in the Kintampo area, a high malaria transmission area of Ghana. Placental malaria was determined by placental histology. Haemoglobin was measured using a Micros 60 haematology auto analyzer. Multivariate cox regression analysis was used to determine the association between PM and incidence of first or only episode of anemia. The incidence of first or only episode of anemia was similar among infants of mothers with or without placental malaria, irrespective of gravidity. Glucose-6-Phosphate Dehydrogenase Deficiency (G6PD) was strongly associated with infant anemia (adjusted hazard ratio [aHR] 1.43, 95% Confidence Interval 1.13 - 1.81 p<0.01). Similarly, infants who lived in rural areas had 29% higher incidence of anemia compared with their peers who lived in urban areas. There was no evidence that exposure to PM *in-utero* influenced hemoglobin level during the first year of life. Other factors such as G6PD deficiency, infant exposure to malaria and residence in rural areas are more likely to influence hemoglobin levels in the study area.

332

IMPLEMENTATION OF PROACTIVE CASE DETECTION AND COMMUNITY CASE MANAGEMENT IN MODERATE MALARIA TRANSMISSION DISTRICTS IN SENEGAL, 2017

Seynabou Gaye[1], Alioune B. Gueye[1], Fatou B. Fall[1], Medoune Ndiop[1], Moustapha Cisse[1], Katharine Sturm-Ramirez[2], Mame Birame Diouf[3], Julie I. Thwing[4]
[1]Senegal National Malaria Control Program, Dakar, Senegal, [2]Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, and US President's Malaria Initiative, Dakar, Senegal, [3]United States Agency for International Development and US President's Malaria Initiative, Dakar, Senegal, Dakar, Senegal, [4]Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States

Since 2014, the Senegal National Malaria Control Program has scaled up a proactive case detection approach to integrated community case management. In addition to being available for consultation (passive case detection), community health workers (CHWs) in low access villages visit every home in their community weekly during malaria transmission season to offer rapid diagnostic tests (RDTs) to people of all ages with fever, artemisinin-based combination therapy (ACT) to those who test positive, and treatment to children < 5 years with diarrhea or pneumonia. From 2014 to 2016, this approach was scaled up in 708 villages in high malaria burden districts, resulting in a three-fold increase in the number of people diagnosed and treated for malaria by CHWs. In 2017, an additional 24 districts with parasite prevalence < 1% implemented this approach. Data reported by the CHWs regarding patients seen during their proactive (in 2017) and passive case detection activities (in 2016 and 2017) were analyzed. In the new districts, 45% (490/1,094) of the CHWs participated in proactive case detection. These CHWs averaged 14 weeks of proactive case detection activities, treating 12,146 children for diarrhea and 12,705 children for pneumonia, and performing 19,136 RDTs (39 per CHW), 2,836 of which were positive (6 per CHW), and 99% of whom received an ACT. In addition, all 1,094 CHWs performed 19,633 RDTs (18 per CHW) and detected 4890 malaria cases (4 per CHW) as part of passive case detection work during the same period. While the total number of CHWs increased by 71% in 2017 compared to 2016, RDTs performed and cases diagnosed during passive case detection increased by 115% and 122%, respectively. Combining proactive and passive case detection, the total numbers of RDTs performed and cases detected by CHWs increased from 2016 to 2017 by 324% and 251%, respectively. While initially targeted to high transmission zones, proactive case detection substantially increased the number of RDTs performed and cases detected and treated in low access villages in low transmission zones, reducing the population infected with malaria, and potentially reducing transmission.

UNDERSTANDING SUSTAINED FOCAL MALARIA TRANSMISSION IN THE PRESENCE OF REACTIVE CASE DETECTION IN RURAL SOUTHERN ZAMBIA SUSTAINED FOCAL MALARIA TRANSMISSION IN THE PRESENCE OF REACTIVE CASE DETECTION IN RURAL SOUTHERN ZAMBIA

Kelly M. Searle[1], Ben Katowa[2], Michael Musonda[2], Harry Hamapumbu[2], Tamaki Kobayashi[1], Jennifer C. Stevenson[2], Douglas E. Norris[1], Philip E. Thuma[2], William J. Moss[1]
[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Macha Research Trust, Choma, Zambia

Reactive case detection is currently conducted in Southern Province, Zambia to enhance surveillance and clear the asymptomatic reservoir. After an index case is confirmed with malaria by RDT, household members and neighbors within 140-meters are tested with an RDT and treated with ACT if positive. A subset of index cases was evaluated by a study team who administered a questionnaire, performed an RDT, and collected a DBS for detection of *Plasmodium falciparum* DNA by qPCR and genotyping. CDC light traps were used for indoor mosquito collections adjacent to sleeping areas and outdoor collections near animal sheds. As part of the study, the screening radius was extended to 250 meters and follow-up visits were performed 30 and 90 days after the initial visit. Enrollment began in March 2016, with data collection concluding in June 2018. The qPCR results will be used to determine prevalence in index and neighboring households and monitor changes over time and space. A molecular barcode will be used to determine parasite genetic relatedness between households and over follow-up. Data on individual characteristics, parasite haplotypes, household characteristics, and indoor and outdoor vector counts will be used to determine factors associated with infection, local transmission, and importation. Individual and household level comparisons will be made between those with and without *P. falciparum* infection.

Households transmission chains will be identified as those with new infections on follow-up visits that are genetically related to previous infections. Household level comparisons will be made between these households, those with no malaria, and those that have infections that are not genetically linked. Results from the first year showed a decrease in prevalence from 11% on the initial visit to 1% on the final visit in index households. Similar decreases were not observed in neighboring households in both screening radii. Within household transmissions were identified between visits in index households only. Additional analyses will provide results essential for understanding factors sustaining transmission in the presence of reactive case detection.

334

A COMMUNITY-RANDOMIZED TRIAL ASSESSING THE EFFECTIVENESS OF TARGETED ACTIVE MALARIA CASE DETECTION AMONG HIGH-RISK POPULATIONS IN SOUTHERN LAO PDR: STUDY DESIGN AND BASELINE SURVEY RESULTS

Andrew A. Lover[1], Emily Dantzer[1], Bouasy Hongvanthong[2], Sophia Hocini[1], Khampeng Phongluxa[3], Francois Rerolle[1], Ratanaxay Phetsouvanh[4], Ronaldo Estera[5], Jennifer L. Smith[1], Joshua Yukich[6], Jimee Hwang[7], Bryan Greenhouse[1], Roly Gosling[1], Adam Bennett[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Center for Malariology, Parasitology and Entomology, Ministry of Health, Vientiane, Lao People's Democratic Republic, [3]National Institute of Public Health, Ministry of Health, Vientiane, Lao People's Democratic Republic, [4]Department of Communicable Disease Control, Ministry of Health, Vientiane, Lao People's Democratic Republic, [5]Health Poverty Action, Vientiane, Lao People's Democratic Republic, [6]Tulane School of Public Health, New Orleans, LA, United States, [7]US Centers for Disease Control and Prevention/University of California San Francisco, San Francisco, CA, United States

In the last decade, important progress has been made towards malaria elimination goals in the Greater Mekong Subregion (GMS), and Lao PDR (Laos) is currently committed to national malaria elimination by 2030. However, substantial gaps in early diagnosis and treatment remain, especially in addressing the asymptomatic parasite reservoir in mobile, migrant, ethnic minority and vulnerable (MMEV) populations who may not be captured in formal public sector facilities. Novel diagnostics are needed to address the parasite reservoir not captured by standard rapid diagnostic tests or microscopy have been developed, including the Alere ultra-sensitive RDT (SD Bioline/Roche) for point-of-care *Plasmodium falciparum* detection. To assess the impact of these novel diagnostics on malaria transmission, two novel interventions will be trialed using a split-plot community randomized trial in 56 villages in Champasak province, Lao PDR. This spilt-plot design includes random allocation to intervention or control (standard of care) at two different spatial scales. The primary intervention will be three rounds of mass test and treat (MTAT) with uRDTs among all consenting households in randomized intervention villages. The secondary intervention will be focused test and treat (FTAT) using peer navigators to target MMEV populations in all areas outside villages, randomized by health center catchment areas (HCCAs). The total study population of includes approximately 85,000 persons in 14 HCCAs. A baseline survey to capture household-level data, and to assess the feasibility and acceptability of the intervention was completed December 2017; amongst 4,903 persons tested, there were five persons positive for *P. falciparum*, and one positive for *P. vivax* by rapid diagnostic test; PCR-based results are expected in March 2018, with FTAT scheduled to start in April 2018, and the first round of MTAT to begin in May 2018. Evaluation of each intervention will be based upon a 50% reduction in *P. falciparum* prevalence from an endline survey October-November 2018 and routinely collected incidence data December 2017-November 2018.

335

UNDERSTANDING THE EPIDEMIOLOGY OF IMPORTED MALARIA CASES IN VIETNAM AMONG INTERNATIONAL LABORERS

Kristina J. St. Clair[1], Sara E. Canavati[2], Gerard Kelly[2], Thu Minh Nguyen[2], Thang Duc Ngo[3], Tho Huy Tran[3], Hoi Thi Le[4], Trung Vu Nguyen[4], Duong Thanh Tran[4], Kinh Van Nguyen[4], Nicholas J. Martin[1], Kimberly Edgel[1]

[1]Naval Medical Research Unit Two, FPO-AP, AE, United States, [2]Vysnova Partners, Inc., Bethesda, MD, United States, [3]National Institute of Malariology, Parasitology, and Entomology, Hanoi, Vietnam, [4]National Hospital for Tropical Diseases, Hanoi, Vietnam

Vietnam witnessed a 97% decline in malaria cases between 1991 and 2014, prompting a national goal for elimination by 2030. As local malaria transmission declines, a greater focus on the importation and potential reintroduction of malaria parasites is essential to support elimination objectives. Challenges to elimination in Vietnam include an increasing risk of malaria importation from a growing labor force traveling to endemic countries abroad, as well as the continued threat of locally developing or imported multi-drug resistant malaria. Currently, little understanding exists on the epidemiology of imported malaria in Vietnam from returning international laborers. In 2017, a study was conducted at the National Hospital for Tropical Diseases (NHTD) in Ha Noi to describe the clinical and epidemiologic characteristics of suspected malaria patients recently returning from African or other Southeast Asian countries. Eligible participants were comprised of patients admitted to NHTD with a recent history of living or travelling abroad and exhibiting clinical symptoms of malaria. Travel histories, blood samples and clinical data were collected and analyzed. 31 participants were enrolled in the study. 87% (n=27) were males with a mean age of 36.5 years. 77% (n=24) reported to have had malaria at least once, with 16% (n=5) reporting to have had malaria more than 10 times. Angola (48%, n=15) and Cameroon (16%, n=5) were the most common countries visited. Work (68%, n=21) and business (16%, n=5) were the most common reasons for travel. 92% (n=29) tested positive for malaria by blood film examination, with 62% (n=18) diagnosed with *Plasmodium falciparum*. Day 3 parasite clearance rates were 50% (n=9) and 60% (n=3) for *P. falciparum* and *P. vivax*, respectively. Data from these studies indicate that imported malaria from returning international laborers is a potential threat to elimination efforts in Vietnam that requires further attention. Additional scaled research and detailed investigation into appropriate malaria prevention and intervention strategies targeted towards international laborers, both at pre-departure and upon return is required.

336

HEALTH CARE PROVIDERS ANTIMALARIAL PRESCRIPTION PRACTICES DURING MALARIA IN PREGNANCY IN LIBERIA

Victor S. Koko[1], Eric Diboulo[2], Agnes Janafo[1], Paye Nyansaiye[1], Oliver Pratt[1]

[1]Ministry of Health/National Malaria Control Program, Monrovia, Liberia, [2]Measure Evaluation, Chapel Hill, NC, United States

Malaria is among the top three diseases for outpatient attendance (42%) and the leading cause of inpatient deaths 39% in Liberia. Over the past years, the National Malaria Control Program has had recurrent stock outs of antimalarial commodities (ACTs and mRDTs), quantifications and distribution to health facilities. This challenge affected the full implementation of national malaria treatment guidelines for pregnant women. We retrospectively reviewed medical records of pregnant women who attended selected health facilities from January 2015 to December 2016 to evaluate antimalarial prescription practices amongst pregnant women by health care providers. A total of 931 eligible records were reviewed. The recorded antimalarial prescribed for pregnant women in 2015, ACT accounted for 62%, 95% CI: [59.29-66.23] of all drugs prescribed for the study participants followed by Quinine at 36%, 95%

CI: [32.99-39.18] with Artemether being the least at 0.21% 95% CI: [0.08-0.51] and other drugs accounting for 1.29% 95% CI: [0.56-2.01]. At the same time, 1,317 records were reviewed in 2016 with a declined and slight increment observed in ACT and Quinine prescription at 53% 95% CI: [50.30-55.69] and 44% 95% CI: [41.51-46.88] respectively. Artemether accounted for 0.38% 95% CI: [0.05-0.71] while other was 2.43% 95% CI: [1.60-3.26]. The findings have important Health system and planning implications. Therefore, Service providers should bear in mind that as per the National treatment protocol, quinine and ACT are used - for both second and third trimester, while quinine only is used in the first trimester. However, this result could be a consequence of either non-compliance to protocol or stock out of quinine as quinine is the first line drug of choice for MIP in Liberia.

337

DETERMINING THE MEAN TIME INTERVAL BETWEEN TWO SUCCESSIVE EPISODES OF MALARIA AMONGST PREGNANT WOMEN

Victor S. Koko[1], Eric Diboulo[2], Paye Nyansaiye[1], Oliver Pratt[1]

[1]Ministry of Health/National Malaria Control Program, Monrovia, Liberia, [2]Measure Evaluation, Chapel Hill, NC, United States

In Liberia, malaria is among the top three diseases for out-patient attendance (42%) and the leading cause of inpatient deaths 39%. Over the past years, the National Malaria Control Program has had recurrent stock outs of antimalarial commodities (ACTs and mRDTs), aged specific time interval of malaria episodes (the average number of days from one episode to the subsequent episode), quantifications and distribution to health facilities. This challenge affected the full implementation of national malaria treatment guidelines for pregnant women. The study used health facility-based patients' records to retrospectively determine the mean time interval between two successive malaria episodes amongst pregnant women. A facility-based retrospective, cross sectional survey design was used to collate data across fifteen randomly selected health facilities. Patient's facility-based unique Identification Number (ID) was used to link up the individual health facility attendance and to determine the mean time interval between two successive malaria episodes amongst pregnant women. Ninty-five (95), 95% CI; [85.56-103.96] days was recorded as the mean time interval between 2 successive malaria episodes with minimum interval of 16 and maximum interval of 326 days in 2015. The statistics were slightly different in 2016 as the mean time interval was 99.99 days, 95% CI; [91.79-108.18] with a minimum time interval of 15 days and a maximum time interval of 327 days in 2016. The results have planning implications as well as Health system. Decision makers should consider accounting for the anticipated time interval between two successive malaria episodes in pregnant women thereby carrying out proper quantification during program planning and implementation as the overall implication could lead to over or under planning.

338

EVALUATION OF SEROLOGIC MARKERS OF RECENT EXPOSURE TO *PLASMODIUM VIVAX* IN A MODERATE TRANSMISSION REGION OF THE PERUVIAN AMAZONIAN

Jason Rosado[1], Michael T. White[1], Rhea Longley[2], Alejandro Llanos-Cuentas[3], Joseph Vinetz[4], Dionicia Gamboa[5], Ivo Mueller[1]

[1]Unit of Malaria: Parasites and hosts, Department of parasites and insect vectors, Institut Pasteur, Paris, France, [2]Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [3]Instituto de Medicina Tropical "Alexander von Humboldt", Universidad Peruana Cayetano Heredia, Lima, Peru, [4]Division of Infectious Diseases, Department of Medicine, University of California San Diego School of Medicine, San Diego, CA, United States, [5]Laboratorio ICEMR-Amazonia, Laboratorios de Investigación y Desarrollo, Facultad de Ciencias y Filosofia, Universidad Peruana Cayetano Heredia, Lima, Peru

Plasmodium vivax is now the dominant parasite throughout the Americas. Key to its elimination is the ability to detect and treat people with asymptomatic blood-stages and those that are at high risk of relapsing. Novel serological markers of recent exposure to *P. vivax* infection have been validated by our team in longitudinal cohort studies in Thailand, Brazil, Papua New Guinea and the Solomon Islands. Using the Luminex® platform, we evaluated responses to a panel of 26 *P. vivax* antigens in 590 Peruvian individuals, who have been followed for between 13 and 37 months in two communities from Loreto, Peru. Healthy donors from non-endemic countries were included as negative controls (n = 274). The prevalence of *P. vivax* by qPCR at the time of serum collection was 21.19%; 93% of these were sub-patent infections. 64% (n = 378) of the cohort participants had at least one qPCR infection in the last 9 months. Using multivariate linear regression models, antibody titers showed a dependent relationship with age and the number of qPCR infections in the last 6 months. In order to identify people at high risk of relapsing *P. vivax* infections, we used classification algorithms and selected a 5-antigen combination that maximizes information on an individual's recent infection (≤ 9 months). After cross-validation, our model accurately classified whether an individual had a recent infection in the last 30 days (AUC = 0.73), 3 (AUC = 0.74), 6 (AUC = 0.79) and 9 months (AUC = 0.83). These analyses suggest that antibodies responses to the 5 novel antigens is higher in individuals with recent exposure to *P. vivax*, even in a setting with high proportions of submicroscopic infections, and thus, potentially allowing the identification of liver-stage carriers.

339

RISK FACTORS ASSOCIATED WITH MALARIA IN-HOSPITAL DEATHS IN THREE REFERRAL HOSPITALS FROM A HIGH-BURDEN MALARIA REGION IN NORTHERN MOZAMBIQUE

Annette Cassy[1], Baltazar Candrinho[2], Kulssumo Mussa[1], Eduardo Samo Gudo[1], Abuchahama Saifodine[3]

[1]National Institute of Health, Maputo, Mozambique, [2]National Malaria Control Program, Maputo, Mozambique, [3]President's Malaria Initiative, USAID, Maputo, Mozambique

Malaria is a leading cause of hospitalization and inpatient mortality in Mozambique. However, few studies have examined the factors associated with malaria related inpatient deaths. The present study describes factors associated with inpatient deaths in a high burden malaria region in Northern Mozambique. This study was based on data obtained from patient records, admitted between June 2015 and May 2016. Data was collected from three health facilities representing the various levels of care: a primary health care clinic, a secondary level facility and a tertiary hospital. These health facilities report the highest number of malaria deaths at their respective attendance level. Logistic regression was used to conduct univariate and multivariate analysis of selected risk factors for malaria mortality. A total of 957 confirmed malaria cases were registered at the three facilities, from which 893 (93.3%) cases had complete data. Among the 893 patients, 390 (43.7%) were children under the age of five years and 488 (54.6%) were women, of which 117 (24.0%) were pregnant. There were 75 cases of death, corresponding to an overall case fatality rate of 8.4%. There were 25 deaths among children under the age of five years. No deaths were recorded among pregnant women. Case fatality was associated with being aged 5 years or older, severity of disease, presence of complications, patient chart inadequately filled and admission to a primary health care facility. Furthermore, although case fatality decreased as length of hospitalization increased, half of the deaths occurred 3 days after admission. Case fatality was not associated with sex, presence of co-morbidities, pre-treatment referral or antimalarial treatment 21 days prior to admission. The malaria case fatality rate remains high in this region. Reducing inpatient malaria deaths will require improvements in early diagnosis and treatment of uncomplicated cases, better identification

and treatment of severe cases, and improvements in the quality of treatment provided during admission, particularly at the primary health care level.

TRANSFORMING SURVEILLANCE INTO A CORE INTERVENTION; THE PATH TO BUILDING A STRONG MALARIA SURVEILLANCE SYSTEM IN UGANDA

Daniel J. Kyabayinze[1], Damian Rutaazana[1], Catherine Maiteki-Sebuguzi[1], Paul Mbaka[2], Jimmy Opigo[1], Peter K. Mbabazi[1], Sandra Nabatanzi[1], Innocent Komakech[2], Charles Katureebe[2], Felix Ocom[2], Miriam Nanyunja[2], Bayo S. Fatunmbi[2]

[1]National Malaria Control Programme, Kampala, Uganda, [2]World Health Organization, Kampala, Uganda

The 3rd Pillar of the WHO Global Technical Strategy for malaria guides countries to transform malaria surveillance into a core intervention to fast track malaria reduction efforts. It is estimated that only 30% of the malaria cases in Uganda are captured by the surveillance system. Uganda rolled out a systematic multifaceted approach to improve the functioning of the surveillance system. We present current framework, results and experience of the process of strengthening malaria surveillance in Uganda in the period August 2016 to March 2018. First, Uganda conducted an assessment of surveillance monitoring and evaluations (SME) system that subsequently guided their interventions. Strategic policies, guidelines, training circular and tools were developed to support capacity and health systems strengthening activities. The second phase implemented activities as recommended from the SME assessment at all levels. At national level a team of 33 trainers were re-trained in SME, 30 on epidemic preparedness and response and 34 on entomological surveillance. The cascaded training covered 589 health workers trained from 82/116 (71%) districts, entomology surveillance training of 40 expert trainers that cascaded skills to 27 districts. A prioritised national research agenda was developed and national team of 20 trained in mapping. A web-based platform with active dashboard for malaria information developed to ease access and share of evidence on malaria. Follow-up of all malaria deaths, documenting and taking action on circumstances surrounding each malaria mortalities was initiated as offshoot of the weekly reports - with status, action and recommendations shared with stakeholders. Electronic database and capture tools are being update to include IPT3, data validation and data quality analysis performed in an integrated approach. Routine entomological surveillance strategies are also being developed. Implementing partners have been supported to follow-up and take to scale all SME assessment recommendations. Partnerships with members of Parliament (350) who will use the Malaria Score Card tool for decision making have been initiated.

RTS,S/AS01 MALARIA VACCINE MISMATCH OBSERVED AMONG *PLASMODIUM FALCIPARUM* ISOLATES FROM SOUTHERN AND CENTRAL AFRICA AND GLOBALLY

Julia C. Pringle[1], Giovanna Carpi[1], Jacob Almagro-Garcia[2], Sha Joe Zhu[3], Tamaki Kobayashi[1], Modest Mulenga[4], Mike Chaponda[4], Thierry Bobanga[5], William J. Moss[1], Douglas E. Norris[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Big Data Institute, Li Ka Shing Centre for Health Information and Discovery, University of Oxford; Medical Research Council (MRC) Centre for Genomics and Global Health, University of Oxford; The Wellcome Trust Sanger Institute, Oxford; Hinxton, United Kingdom, [3]Big Data Institute, Li Ka Shing Centre for Health Information and Discovery, University of Oxford, Oxford, United Kingdom, [4]Tropical Diseases Research Centre, Ndola, Zambia, [5]Université Protestante au Congo and University of Kinshasa, Kinshasa, Democratic Republic of the Congo

The RTS,S/AS01 malaria vaccine encompasses the central repeats and C-terminal of *Plasmodium falciparum* circumsporozoite protein (PfCSP). Although no studies from Phase II clinical trials observed evidence of strain-specific vaccine-induced immunity, recent studies have shown a decrease in vaccine efficacy against non-vaccine strain parasites. In light of goals to reduce malaria morbidity and mortality, anticipating the effectiveness of RTS,S/AS01 is critical to planning widespread vaccine introduction. We deep sequenced C-terminal *Pfcsp* amplicons from 77 individuals living in Luapula Province, Zambia and neighboring Haut-Katanga Province, Democratic Republic of Congo (DRC) and compared the translated amino acid haplotypes to the 3D7 vaccine strain. Further, to contextualize the genetic diversity sampled in in Zambia and the DRC with the global *Pfcsp* diversity, we analyzed 3,809 additional *Pfcsp* sequences from the Pf3k database and constructed a haplotype network representing 15 countries from Africa and Asia. In our study sites in Zambia and the DRC, only ten of the 193 unique *Pfcsp* sequences (5.2%) matched 3D7 at all 84 amino acids. The median number of amino acid differences from 3D7 was seven. The nucleotide diversity observed in our samples was similar to the diversity observed in the global haplotype network. This small sample of *P. falciparum* isolates from the border region between Zambia and the DRC, an area for which little previous *P. falciparum* genetic data has been reported, reveals substantial genetic differences between the RTS,S/AS01 vaccine strain and circulating parasites, consistent with the genetic diversity from 13 other African and Asian countries represented in the Pf3k database. These observations underscore the need for additional research assessing genetic diversity in *P. falciparum* and the impact of PfCSP diversity on the efficacy of RTS,S/AS01.

342

ANALYSIS OF WITHIN-HOST EVOLUTION OF *PLASMODIUM FALCIPARUM* DURING TREATMENT

Javan O. Okendo[1], Ben Andagalu[2], Nicola Mulder[1]

[1]Computational Biology Division, Institute of Infectious Diseases and Molecular Medicine, University of Cape Town, Cape Town, South Africa, [2]Malaria Drug Resistance Laboratory, United States Army Medical Research Directorate/Kenya Medical Research Institute, Nairobi, Kenya

Antimalarial drugs impose strong selective pressure on *P. falciparum* parasite genomes and leave signatures of selection. The evolutionary basis of drug resistant malaria in endemic and epidemic settings continues to remain an ongoing scientific priority whose solution carries a significant effect on treatment outcomes. To understand these evolutionary changes, we used various approaches to test the neutral models of evolution using *P. falciparum* genomic data which were collected from Kombewa and Maseno in Kisumu, Kenya between 2013 and 2015. The (dS/dN) ratio was used to predict the effect of selection on protein coding loci of the *Pfk13* gene. A logistic regression model was used to test the association between IC_{50s} and the SNPs. mCSM and SDM were used to detect the effects of mutations on the *Pfk13* gene while the PRIMO web server was used to locate the SNPs on the Kelch13 propeller domain. Modeller V9.1 was used to predict the structure of the Kelch 13 propeller domain and the Posview webserver used to predict ACT/kelch 13 interactions. Population differentiation was done using Microsatellite analyzer to calculate F_{ST} and customized R scripts with the relevant population genetics packages were used in the analysis. In 2013, Tajima's D genomic summary statistics was 4.53194, Fu & Li D* 2.13380, and Fu &Li F* 3.62142. However, in 2015 Tajima's D was -2.42910, Fu and Li's D* -5.2712, and Fu and Li's F* -5.0045. The dS/dN in 2013 was 1.0299, while 2015 dS/dN was 2.6884. Kenyan SNPs occur on the intra or inter blade domains on *PfK13* propeller domain. The F_{ST} analysis showed minimal population differentiation of the parasites during treatment. There was no significant association between SNPs and IC_{50} values but SNPs at codon D547E showed association with Artesunate and D559E with AQ and MQ IC_{50} respectively. Even though there is an exponential increase in the number of non-synonymous point mutations in the *Pfk13* gene, the Kenyan *P. falciparum* strains remain sensitive to ACT drugs. Further research needs to be done by deep sequencing this location of chromosome 13 as it will provide more power for finding novel SNPs for further validation.

343

GENETIC CHARACTERISTICS OF *PLASMODIUM VIVAX* ISOLATED FROM NORTHERN MALI

Moussa Djimde[1], Antoine Dara[2], Aboubecrin Sedhigh Haidara[1], Nouhoum Diallo[1], Ogobara K. Doumbo[1], Abdoulaye A. Djimde[1], Nicola Mulder[3]

[1]Malaria Research and Training Center, University of Sciences, Techniques and Technologies of Bamako, Mali, Bamako, Mali, [2]University of Maryland, Baltimore, MD, United States, [3]University of Cape Town, Faculty of Health Sciences, Computational Biology Division, Cape Town, South Africa

The surprising presence of *Plasmodium vivax* in Mali where the population is mostly Duffy negatives is one more threat to public health. There is a need to investigate the origin and reaction to antimalarial drugs of *P. vivax* isolates in Northern Mali, which is our key objective in the present work. *P. vivax* DNA was extracted from 7 Rapid Diagnostic Tests (RDT) followed by selective Whole Genome Amplification (sWGA). The whole genomes were then sequenced using the Illumina platform, and the Next Generation Sequence data analysed. For population differentiation analysis we used 22 additional *P. vivax* whole genome from 6 other countries, which we downloaded from the European Nucleotide Archive. The population differentiation analysis revealed significant variant differences between *P. vivax* populations in urban and rural areas of Northern Mali. These were located in chromosomes 2, 3, 4, 5, 12, 13 and 14. With regard to variant effects, the ratio of Transition/Transversion was 1.1, while the rate of variants with high effect was 1.62%. We did not identify *P. falciparum* orthologous genes *pvcrt-o* or *pvmdr-1* expressing variants which would lead to antimalarial drug resistance. Pairwise differentiation suggests polymorphisms between *P. vivax* strains isolated in rural and urban areas of Northern Mali. The Neighbour-Joining analysis shows clearly that taxa from Mali cluster together and are genetically distinct to those from Mauritania which share a border with Mali. The strains isolated in Northern Mali are genetically closer to those from Madagascar, India and Latine America. *In conclusion,* the results suggest that Northern Mali strains remain sensitive to Chloroquine and Primaquine. This study confirms that *P. vivax* strains, genetically distinct from those of Mauritania, are circulating in Mali.

344

PARTIAL GENOME DRAFT OF *PLASMODIUM SIMIUM*, A VIVAX-LIKE PARASITE OF NEW WORLD MONKEYS

Thais Crippa de Oliveira[1], Priscila Thihara Rodrigues[1], Lais Camolese Salla[1], Ana Maria Ribeiro Duarte[2], João Marcelo Alves[1], Marcelo Urbano Ferreira[1]

[1]University of Sao Paulo, Sao Paulo, Brazil, [2]Superintendency for the Control of Endemics, Sao Paulo, Brazil

Plasmodium simium was originally described in non-human primates from São Paulo, southeast Brazil, and subsequently was found in two genera of the Atelidae family, *Alouatta caraya and A. clamitans*, of the Atlantic Forest of South and Southeast Brazil. Studies suggest that *P. simium* is morphologically and genetically indistinguishable from *P. vivax*, which is consistent with one or more host switches between humans and monkeys in recent evolutionary times. The direction of the host switch (whether from monkeys to humans or vice-versa) remains under debate, although available phylogenetic data renders a lateral transfer from New World monkeys to humans very unlikely. Here we describe the first genome draft of the *P. simium*, isolate RS, derived from a field-collected blood sample from a howler monkey in Southeast Brazil. Because of extensive contamination with host DNA, we carried out selective whole-genome amplification using two previously described two different primer sets (pvset1 and pvset1920) and protocols (Cowell, et al, 2017, doi: 10.1128/mBio.02257-16). A DNA library was prepared using the TruSeq Nano DNA Kit (Illumina) and sequenced using Illumina HiSeq 2500. We mapped high-quality reads (quality scores >30) onto two *P. vivax* reference genomes, Sal-I version 10.0 and PvP01, using BWA. We used GATK version 2.0 for SNP calling. GATK Best Practices was used to annotate SNPs after SNPs files from different set of primers were merged in one single file. We obtained an average coverage of 129× (pvset1) and 76× (pvset1920), with a G+C content of 44-50% Overall, between 92-96% of the reads were identical to *P. vivax* reference genomes[MU1] , but only 35-51% of the Sal-I and PvP01 genomes, respectively, were covered by at least 6 reads from the *P. simium* isolate RS. A total of 3083-2658 SNPs (pvset1-pvset1920) were found compared to Sal-I and 4152-3898 SNPs (pvset1-pvset1920) compared to PvP01. These preliminary genome data may help to illuminate the origins and phylogenetic relationships of this little studied zoonotic malaria parasite.

345

HUMAN MIGRATION AND THE SPREAD OF MALARIA PARASITES TO THE NEW WORLD

Priscila Thihara Rodrigues[1], Hugo O. Valdivia[2], Thais C. Oliveira[1], Lais C. Salla[1], João Marcelo Alves[1], Ana Maria R. Duarte[3], Crispim Cerutti-Junior[4], Julyana C. Buery[5], Cristiana F. Brito[6], Julio C. Souza, Jr[7], Zelinda M. Hirano[7], Rosely S. Malafronte[8], Simone Ladeia-Andrade[9], Toshihiro Mita[10], Ana Maria Santamaria[11], Jose E. The Americas were the last continent to be settled by modern humans, but how and when human malaria parasites arrived in the New World is uncertain. Here, we apply phylogenetic analysis and coalescent-based gene flow modeling to a global collection of *Plasmodium falciparum* and *P. vivax* mitogenomes to infer the demographic history and geographic origins of malaria parasites circulating in the Americas. Importantly, we examine *P. vivax* mitogenomes from previously unsampled forest-covered sites along the Atlantic Coast of Brazil, including the vivax-like species *P. simium* that locally infects platyrrhini monkeys. The best-supported gene flow models are consistent with migration of both malaria parasites from Africa and South Asia to the New World, with no genetic signature of a population bottleneck upon parasite's arrival in the Americas. We found evidence of additional gene flow from Melanesia in *P. vivax* (but not *P. falciparum*) mitogenomes from the Americas and speculate that some *P. vivax* lineages might have arrived with the Australasian peoples who contributed genes to Native Americans in pre-Columbian times. Mitochondrial haplotypes characterized in *P. simium* from monkeys from the Atlantic Forest are shared by local humans. These vivax-like lineages have not spread to the Amazon Basin, are much less diverse than *P. vivax* circulating elsewhere in Brazil, and show no close genetic relatedness with *P. vivax* populations from other continents. Enslaved peoples brought from a wide variety of African locations were major carriers of *P. falciparum* mitochondrial lineages into the Americas, but additional human migration waves are likely to have contributed to the extensive genetic diversity of present-day New World populations of *P. vivax.* The reduced genetic diversity of vivax-

like monkey parasites, compared with human *P. vivax* from across this country, argues for a recent human-to-monkey transfer of these lineages in the Atlantic Forest of Brazil.

346

GENETIC ANALYSIS OF RELAPSING *PLASMODIUM VIVAX* FROM INDONESIAN SOLDIERS RETURNING TO A MALARIA-FREE AREA USING TARGETED AMPLICON DEEP SEQUENCING

Rintis Noviyanti[1], Leily Trianty[1], Christian Parobek[2], Agatha M. Puspitasari[1], Dorothya R. Lestari[1], Sujata Balasubramanian[2], Zackary Park[2], Retno A. Utami[1], Saraswati Soebianto[3], Jeny Jeny[3], Frilasita Yudhaputri[1], Aditya Perkasa[1], Farah N. Coutrier[1], Yusrifar K. [1]Eijkman Institute for Molecular Biology, Jakarta Pusat, Indonesia, [2]University of North Carolina School of Medicine, Chapel Hill, NC, United States, [3]Eijkman-Oxford Clinical Research Unit, Jakarta Pusat, Indonesia, [4]Health Services, Army of the Republic of Indonesia, Jakarta Timur, Indonesia, [5]University of Indonesia, Jakarta Pusat, Indonesia

In the era of malaria elimination, identification of *Plasmodium vivax* relapse is a key to reduce malaria transmission. Hypnozoite dormancy and reactivation, largely remains a mystery. Relapse episodes in clinical settings are often confounded by re-infection in malaria endemic areas. We performed genetic studies in cohorts of soldiers returning from high-endemic area in Papua, Indonesia to non-malaria endemic areas using amplicon deep sequencing. 127 relapsing isolates collected from 94 individuals which were amplified in duplicate at a 117bp hypervariable pvmsp1 region were sequenced using Ion-Torrent technology. A median of 4314 pvmsp1 high quality sequencing reads in each isolate was used to identify unique variants and determine multiplicity of infection (MOI) via Seekdeep. 28 pvmsp1 haplotypes were detected among 94 individuals, with two-thirds (19/28) appearing in more than one isolate. Multiplicity of infection (MOI) in the returning soldier relapse episodes was relatively low (mean MOI = 1.6, range 1-4). 55% of first relapses were monoclonal, 71% of second relapses were monoclonal ($p = 0.05$), with the majority of paired relapses exhibiting a similar or decreased genetic complexity over time. Of the 33 twice relapsers, 8 displayed the identical clone at both relapses, while 11 were completely heterologous/different. Overall, our findings suggest the soldiers were exposed to multiple parasite genotypes during the yearlong deployment, but were more likely to experience clonal relapses, with decreasing genetic complexity over time, suggesting that early relapse genotypes were more prevalent, or simply decreasing hypnozoite burden over time.

347

GENETIC VARIABILITY IN THE *PLASMODIUM VIVAX* VACCINE CANDIDATE ANTIGENS FROM CENTRAL INDIA

Priyanka P. Patel[1], Praveen K. Bharti[2], Devendra Bansal[3], Rajive K. Raman[4], Pradyumna K. Mohapatra[5], Rakesh Sehgal[6], Jagadish Mahanta[5], Ali A. Sultan[3], Neeru Singh[1]

[1]National Institute for Research in Tribal Health (NIRTH)-ICMR, Jabalpur, Madhya Pradesh, India, [2]National Institute for Research in Tribal Health (NIRTH)-ICMR, Jabalpur-Madhya Pradesh, India, [3]Department of Microbiology and Immunology, Weill Cornell Medicine - Qatar, Cornell University, Qatar Foundation - Education City, Doha, Qatar, [4]Community Health Centre Janakpur, Baikunthpur, Chhattisgarh, India, [5]Regional Medical Research Centre (RMRC)-ICMR, Dibrugarh , Assam, India, [6]Department of Parasitology, Postgraduate Institute of Medical Education and Research -ICMR, Chandigarh, Punjab, India

The genetic diversity and evolutionary plasticity constitute major obstacles for malaria control and its elimination. Outside sub-Saharan Africa, *Plasmodium vivax* is the most widespread. Unlike *P. falciparum*, *P. vivax* forms dormant liver stages (hypnozoites) which causes recurring (Benign tertian) malaria. The unique biology of *P. vivax* and its epidemiology makes elimination more challenging with existing tools. Considering the high antigenic diversity in *P.vivax*, a next generation multi-allelic or multivalent vaccine is urgently needed to achieve the elimination. In this study, we have investigated genetic diversity in *P. vivax* vaccine candidates expressed during different stages of parasite lifecycle in field isolates, which includes merozoite surface protein -3 (*Pvmsp-3*), circumsporozoite protein *(Pvcsp*) and transmission blocking ookinete surface protein (*Pvs25*) . Samples were collected at Janakpur CHC hospital, district Korea Chhattisgarh, India. Amplification and DNA sequencing of *Pvcsp*, *Pvs25* and *Pvmsp-3* genes was performed using designed primers through polymerase chain reaction (PCR). Out of 58 samples, 40 samples were successfully sequenced and analyzed using reference strain *of P.vivax* (Salvador-I). *Pvcsp* gene analysis shows that majority of samples harbored VK210 type (72.5 %) in comparison with VK247 (27.5%) whereas in case of *Pvs25* gene, all sequenced isolates contains two non-synonymous nucleotide substitutions (G289C, T389C) which gives corresponding amino acid changes (E97Q, I130T). Subsequently, highly polymorphic *Pvmsp*-3 marker gene showed presence of two allelic size variants in field isolates. The frequency of Type-A variant was highest in 92.5% isolates followed by 7.5% of Type-B. Overall, a total of 25 polymorphisms were detected among all *Pvmsp*-3 allelic types. This study gives a best picture of antigenic repertoire in field isolates from a highly endemic Chhattisgarh state (Central Indian isolates) of India. Better understanding the geographic distribution of genetic diversity of this vaccine candidate gens will be key to designing and implementing efficacious vaccines.

348

GENETIC DIVERSITY OF *MSP1*, *MSP2* < *GLURP* GENES ACCORDING TO HUMAN GENETICS RESISTANCE FACTORS (HEMOGLOBIN AND G6PD) IN *PLASMODIUM FALCIPARUM (P.F)* ISOLATES FROM SUBJECTS IN BURKINA FASO

Emilie S. Badoum

Centre National de Recherche et de Formation sur le Paludisme (Burkina Faso), Ouagadougou, Burkina Faso

The genetic diversity &lt antigenic variation of the parasite are main factors responsible &gt the slow acquisition of protection against malaria. There are innate genetic factors mechanisms that allow human to resist malaria. A number of genetic association studies have shown a role &gt human genetic variation in resistance to infections. However, little attention has been devoted to the possible influence of human genetic variation on genetic diversity of *P.f*. *Msp1*, *msp2* &lt *glurp* have been widely used as markers to study genetic diversity, multiplicity of infections, level of malaria immunity transmission. The aim of this study is to analyse the genetic diversity of *msp1*, *msp2,* &lt *glurp* genes of *P.f* according to human genetic resistance factors as hemoglobin &lt G6PD deficiency from subjects with uncomplicated malaria, living in malaria endemic area. This was a cross-sectional study, carried out at Banfora &lt Sapone (Burkina Faso) where 464 subjects were enrolled. Samples were extracted &lt then analyzed by a nested PCR of *msp1, msp2* &lt *glurp* genes while the human genetic background was assessed by RFLP-PCR. The distribution of the *msp1* &lt *msp2* allelic families was not different according to the type of hemoglobin ($p=0.669$ &lt 0.925 respectively) but there were different according the type of G6PD ($p=0.004$ &lt 0.033 respectively). The K1 allele family (91.59 %) is the most widespread *msp1* allelic family while in the *msp2* alleles , the 3D7 family is the most common (89.22% versus 69.18% FC27) &lt this difference is statistically significant ($p<0.0001$). The *glurp* gene (92.03%) is the most widespread gene &lt there was no difference in its distribution according to the human factors of resistance. Our results on the polymorphism of *msp1* &lt *msp2* genes according to the type of G6PD suggest a correlation between the distribution of G6PD types &lt the severity of malaria.

349

WHAT DRIVES THE SPATIAL AND TEMPORAL PATTERNS OF GENETIC DIFFERENCES BETWEEN *PLASMODIUM FALCIPARUM* MALARIA INFECTIONS IN KILIFI COUNTY, KENYA?

Josephine Malinga[1], Polycarp Mogeni[2], Irene Omedo[2], Peter Pemberton-Ross[1], Phillip Bejon[2], Amanda Ross[1]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]Kenya Medical Research Institute-Wellcome Trust Research Programme, Kilifi, Kenya

Knowledge of how malaria infections spread locally is important for the design of interventions to reduce and interrupt transmission. A previous analysis of 1602 genotyped infections in Kilifi found an interaction between time and geographic distance on genetic distance. The mean number of single nucleotide polymorphisms (SNP) different was lower for pairs of infections with both a short time interval and short geographic distance. We sought to determine the processes and parameter values that are consistent with this observed pattern. We estimate the distribution of geographic distances between parent and offspring infections, and investigate whether specific immunity functions are necessary to account for the observed pattern. Methods for a setting with moderate transmission and a low proportion of the total infections sampled are limited. We developed a stochastic simulation model of households, people and infections parameterizing the model for the total number of infections, population and house density for Kilifi. The acquisition of new infections, mutation, recombination, geographic location and clearance were simulated. We used 53 SNPs with minor allele frequencies greater than 5%, and fit the model to the observed numbers of SNP differences. The method was able to recover the mean geographic distance from simulated data with known values. The observed interaction could be reproduced for at least some parameter values for the baseline model and the model variants with immunity functions. Although we cannot rule out genotype-specific immunity or a limit on the number of infections, they are not necessary to account for the observed pattern. The measure of goodness-of-fit did not support mean distances of less than 400m alone. However, the results were consistent with a mixture of distributions of longer and shorter mean distances, perhaps through human and vector movement. This is the first study that we know of which has attempted to estimate the mean distance between parent and offspring infections from data with a low coverage of infections in a setting with moderate transmission, and has implications for the design of studies.

WHOLE GENOME SEQUENCING TO MEASURE COMPLEXITY OF INFECTION AND GENETIC DIVERSITY IN *PLASMODIUM VIVAX* CLINICAL ISOLATES FROM THE CHINA-MYANMAR BORDER

Sonia Agrawal[1], Fang Huang[2], Biraj Shrestha[1], Matthew Adams[1], Sandra Ott[3], Lisa Sadzewicz[3], Hui Lui[4], David Serre[3], Shannon Takala-Harrison[1], Myaing Nyunt[5], Joana Carneiro Da Silva[3], Christopher Plowe[5]

[1]Institute for Global Health, University of Maryland School of Medicine, Baltimore, Baltimore, MD, United States, [2]National Institute of Parasitic Diseases, Chinese Centre for Disease Control and Prevention, Shanghai, China, [3]Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, Baltimore, MD, United States, [4]Yunnan Institute of Parasitic Diseases, Puer, China, [5]Global Health Institute, Duke University, Durham, NC, United States

Plasmodium vivax malaria has been refractory to malaria elimination efforts along the China-Myanmar border. Better understanding of the genomic epidemiology of *P. vivax* could inform these efforts by improving our understanding of parasite population structure, potentially leading to tools for distinguishing between local and imported infections. Most population genetic studies of *P. vivax* have relied on small numbers of microsatellite markers or single nucleotide polymorphisms or targeted a few polymorphic protein-coding genes, limiting their power to measure population structure or to detect the presence of multiple, genetically-different parasites in a single infection. The objective of this study was to assess complexity of infection and genetic diversity of *P. vivax* in clinical isolates collected from individuals symptomatic for malaria and living near the China-Myanmar border, a region that has experienced a recent increase in *P. vivax* malaria cases. We analyzed whole genome sequence data of 69 leukocyte-depleted, RDT-positive, field samples with low *P. vivax* genomic DNA obtained from a refugee camp located adjacent to the border between Laiza Township in Myanmar's Kachin State and the town of Nabang in China's Yunnan Province. The average sequencing coverage ranged from 34 - 411X for each sample, with more than 76% of *P. vivax* Salvador I reference genome covered with atleast 20 reads. Preliminary results show that the vast majority of the infections were monoclonal (90%) with a single strain significantly different from the reference strain, 5 infections with two strains (50:50, 30:70, 20:80 frequency) and 2 infections with three or more strains in varying proportions. Our analyses show that the whole genome sequence data can be used to conduct high resolution complexity of infection inference in field-collected samples in this region of low transmission. The sequence data obtained is being analyzed to assess genetic diversity and will facilitate the study of *P. vivax* geographical variations that may help to estimate parasite movement and distinguish transmission sources and sinks in this elimination setting.

351

COMPARING AND VALIDATING GENE CO-EXPRESSION NETWORKS IN *PLASMODIUM FALCIPARUM* PARASITE

Kaitlynn Meis[1], Qi Li[2], Geoffrey Siwo[1], Meng Jiang[2], Michael Ferdig[1]

[1]Eck Institute for Global Health, Department of Biological Sciences, University of Notre Dame, South Bend, IN, United States, [2]Interdisciplinary Center for Network Science & Applications, University of Notre Dame, South Bend, IN, United States

Biological systems are complex, requiring comprehensive interrogation. Traditional differential expression approaches to the analysis of whole transcriptome data generally consider each gene in isolation outside of its broader regulatory context, failing to leverage the information available in the interactions among genes. The application of network science approaches to large-scale biological data can provide a global view of the intricate webs of interactions that make up these biological systems while also facilitating more integrative analyses. Given the wealth of available data, ample opportunity exists to generate new insights into gene-gene interactions, gene neighborhoods, gene function, and pathways by utilizing network views of these systems. Network science is a new and rapidly evolving field that relies on a wide range of network construction methods and thresholding criteria, each with distinctive strengths and weaknesses. With these methods oftentimes resulting in very different networks, development of network validation can provide a measure of how well each of the networks captures relevant biological information. By relying on the expectation that genes with similar function are more likely to be co-expressed, we have established a validation pipeline for *P. falciparum* gene co-expression networks that determines how well the structure of the network captures relationships between genes that are known to be functionally related. Using this pipeline and a published gene expression dataset, we have investigated and ranked the performance of several network construction methods to establish a high-quality baseline network for further investigations in *P. falciparum*.

Plasmodium vivax is the main cause of malaria in the Peruvian Amazon and in recent years malaria incidence is rising in this region. Population genetic tools could be key components for the design and targeting of control strategies. These tools allow to measure the individual contribution of the factors associated with transmission and can discriminate between the endogenous transmission and imported cases. In this work, infections caused by *P. vivax* were collected in 2 basins, Mazan (MZ) and Napo (NP), located in the Peruvian Amazon. Thus, 173 infections were genotyped with 16 microsatellites. The genetic diversity and level of inbreeding in each basin was evaluated, and a Bayesian method was used to identified the number of genetic clusters, and autochthonous, introduced and imported infections. Finally, epidemiological factors associated with the genetic clusters and its effect on the clinical manifestations were determined. Results showed that MZ presented a greater genetic diversity (*He* = 0.71), high proportion of polyclonal infections (35.2%), and lower linkage disequilibrium (I_A^S 0.07) with respect to NP (*He* = 0.39, 18.8%, I_A^S 0.21). Five genetic clusters and 20 (22.7%) imported/introduced infections were identified in MZ, while in NP only 2 clusters were observed and just 3 (3.5%) infections were imported. In addition, in MZ cluster 2 was associated with people who traveled outside their community in the last month (OR = 4.33, p = 0.04); while the parasitemia of the infection (OR = 1.10, p = 0.04), being infected by a parasite belonging to cluster 1 (OR = 4.83, p = 0.03) , and living with someone who has left the community in the last month (OR = 4.48, p = 0.01) increased the probability of presenting symptoms. Our results suggest that human mobilization encourages the entry of new genetic clusters in MZ, so malaria control strategies that consider this factor are required.

Previous studies of antibody responses to *Plasmodium falciparum (Pf)* malaria have focused on IgG, less frequently, IgM, and rarely, IgA, which is typically associated with response to antigens presented to mucosal sites. However, when we comprehensively assessed antibody responses in a controlled human malaria infection (CHMI) study, we observed IgA responses to *Pf* on protein microarrays in U.S. malaria-naïve volunteers who received 1-5 bites from aseptic *Anopheles stephensi* mosquitoes infected with the *Pf* NF54 strain. We then examined IgA responses to naturally acquired malaria in 1- to 6-year-old Malian children (median = 4 years) exposed to intense seasonal malaria transmission. Serum from the malaria-naïve group collected at baseline and 4 weeks following CHMI (n=35 pairs) and from Malian children collected 6-41 days before and 14-42 days following a clinical malaria episode (n=48 pairs) was probed with a protein microarray containing 823 *Pf* antigens from the 3D7 clone of NF54. For each antigen, a paired *t* test with α=0.05 was used to compare baseline and post-infection $\log_2$-transformed antibody levels. In the naïve group, IgA increased for 64% (n=527) of the *Pf* proteins. In Malian children, the IgA response rate was lower, with increased antibodies compared to baseline for 10% (n=85) of *Pf* proteins; 64% of the 85 proteins (n=54) were also the target of antibodies in the naïve group. For most antigens, IgA responses were higher in the naïve group than in Malian children. We conclude that the immunoproteome following first infection in a malaria-naïve adult by CHMI differs from the immunoproteome of a child living in a high transmission setting. Lower levels of seroreactivity in Malian children may reflect their nascent immune systems and/or exposure to diverse *Pf* strains, as opposed to the CHMI strain that is homologous to the protein microarray antigens. Future directions include exploration of possible sites of IgA induction, including mucosal-associated invariant T cells in the liver and gut-associated gamma-delta T cells, leading to new insights into *Pf* immune responses.

354

A SINGLE NUCLEOTIDE POLYMORPHISM IN A *PLASMODIUM BERGHEI* APIAP2 TRANSCRIPTION FACTOR ALTERS THE DEVELOPMENT OF HOST IMMUNE RESPONSE

Munir Akkaya[1], Abhisheka Bansal[1], Patrick W. Sheehan[1], Mirna Y. Pena[1], Alvaro Molina-Cruz[1], Lindsey M. Orchard[2], Clare K. Cimperman[1], Chen-Feng Qi[1], Philipp Ross[3], Manuel Llinás[2], Louis H. Miller[1], Susan K. Pierce[1]

Malaria is a deadly infectious disease caused by parasites of the *Plasmodium* genus that results in the deaths of over 400,000 individuals each year, mostly among young children in Africa. Antibodies play a central role in malaria immunity but the acquisition of protective antibodies in malaria endemic regions is a remarkably slow process that takes years of repeated infections, suggesting that the parasite itself may interfere with the generation of B cell immunity. However, at present we have little knowledge of *Plasmodium* virulence factors that influence host immunity. Here we provide evidence that a single nucleotide polymorphism resulting in a serine (S) to phenylalanine (F) change in the DNA-binding domain of an ApiAP2 transcription factor of the rodent parasite *Plasmodium berghei* (Pb) NK65 strain alters the outcome of infection in a mouse model. Infection with PbNK65F as compared to PbNK65S resulted in the differential expression of only 46 genes, most of which are predicted to play roles in antigenic variation and immune invasion. Although both infections were lethal, compared to PbNK65S infection, infection with PbNK65F resulted in a larger expansion of germinal center B cells, plasma cell lineage B cells and T follicular helper cells by a γ-interferon dependent process and higher levels of infected red blood cell-specific TH1-type IgG2a and 2c antibodies. Indeed, under the cover of the antimalarial drug chloroquine, or following sublethal infection, PbNK65F but not PbNK65S

infections resulted in the generation of protective immunity to subsequent challenges. Thus, our results demonstrate that a Pb ApiAP2 transcription factor functions as a parasite virulence factor in *Plasmodium* infections.

355

EFFECT OF ALLELIC POLYMORPHISM ON MALARIA PARASITE SPECIFIC *EX VIVO* IFN-Γ RESPONSES TO APICAL MEMBRANE ANTIGEN 1 IN A MALARIA EXPOSED POPULATION

Omarine Nlinwe Nfor Epse Njimanted[1], Asamoah Kusi Kwadwo[2], Martha Sedegah[3]

[1]The University of Bamenda, Bambili, Cameroon, [2]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [3]Naval Medical Research Center, Silver Spring, Maryland, MD, United States

Despite extensive genetic diversity in the *P. falciparum* Apical Membrane Antigen 1 (AMA1), the leading vaccine candidate antigens, vaccines continue to be formulated using recombinant antigens representing a few strains. There is limited data on the potential effect of antigenic polymorphisms on T cell responses, hence knowledge on the efficacy of vaccines based on such peptides is limited. This study was designed to investigate the effect of allelic polymorphism on malaria parasite *ex vivo* T cell-specific IFN-γ response to the malaria parasite vaccine candidate antigen AMA1, in a malaria exposed population. Seven study subjects with known HLA A and/or B super types were recruited for the study. The known HLA class 1 allele types were used to predict their recognition of 9-10mer peptides from the *P. falciparum* AMA1 antigen (3D7 strain) using the NetMHC algorithm. Full length sequences of the 3D7 strain *Plasmodium falciparum* AMA1 peptides were aligned with corresponding AMA1 sequences from 7G8, FVO, tm284, FC27 and AAN35928 parasite strains for identification and chemical synthesis of sequences with regions showing variability. 133 synthesized peptides grouped into 65 allelic sets, were used to stimulate study subjects' peripheral blood mononuclear cell (PBMCs) in IFN-γ ELISpot assays. A total of 4/7 (57.14%) of the study subjects responded positively to stimulations from one or all two/three corresponding peptides, in 22 allelic sets. Stimulation responses (sfc/million) within corresponding peptides in 10/22 (45.45%) of the allelic sets were found to be significantly different ($p < 0.05$). The site of amino acid substitutions at positions 1 and 6 of the allelic peptides accounted for 53.33% of all amino acid substitutions. In conclusion, although only 45.45% of the tested allelic sets were found to produce significantly different responses, the position of substituted amino acid could be a determining factor in differentiating between immunologically relevant and irrelevant allelic polymorphism in the study strains.

[1]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [2]Centro de Investigação em Saúde de Manhiça (CISM), Manhiça, Mozambique, [3]Baylor College of Medicine (BCM), Houston, TX, United States, [4]National Institutes of Health (NIH), Bethesda, MD, United States, [5]Walter Reed Army Institute of Research (WRAIR), Silver Spring, MD, United States, [6]Burnet Institute, Melbourne, Australia, [7]Monash University, Melbourne, Australia, [8]Edinburgh University, Edinburgh, United Kingdom, [9]Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States

Exposure to multiple parasites in African people may lead to harboring two or more simultaneous infections. These co-infections could generate immune responses with different profiles that may impair the ability of the immune system to fight one of the coexisting pathogens. Intestinal parasites mainly induce a T_H2 (and IgE) response, whereas immunity to *Plasmodium falciparum* is acquired through a T_H1 (and IgG) profile. We have previously found that the induction of certain T_H2 cytokines is associated with a lack of malaria protection in RTS,S vaccinated children. We also found that CSP, the main component of RTS,S, and certain *Plasmodium falciparum* blood stage antigens, can induce IgE responses, and high levels of IgE against merozoite surface proteins were associated with a higher risk of developing clinical malaria. We hypothesize that the induction of T_H2 cytokines and IgE by *P. falciparum* antigens are due in part to an immune deviation caused by previous or current infections with intestinal parasites. In order to investigate the possible role of parasite co-infections on immune deviation, we have applied the quantitative suspension array technology to measure total IgG, IgG_{1-4} and IgE responses against a multiplex panel with antigens of *P. falciparum* (AMA-1, EXP-1, EBA-140, LSA-1, MSP-1, MSP-2, MSP-5*), Giardia lamblia* (VSP3), *Cryptosporidium parvum* (Cp17), *Ascaris lumbricoides* (As16, As37), *Trichuris trichiura* (Tm-WAP, Tm16), *Necator americanus* (Na-GST-1, Na-SAA-2), *Ancylostoma duodenale* (Ay-CP-2) and *Strongyloides stercoralis* (NIE), using plasma samples from children and adults from Southern Mozambique, for which their infection status for malaria, intestinal helminths and protozoa is known. We will present results on the possible mutual influence of intestinal parasites and *P. falciparum* infections on the respective total IgG, IgG_{1-4} and IgE responses. Future studies will focus on the study of IgM responses, the profiling of cytokines, chemokines and growth factors and cellular populations.

SIGNALING INDUCED BY TLR2 AND TLR4 COLLECTIVELY MEDIATE LUNG AND LIVER PATHOLOGY IN MOUSE MALARIA MODELS

Xianzhu Wu, Ramesh Thylur, Kishore Punnath, D. Channe Gowda

Penn State University College of Medicine, Hershey, PA, United States

Malaria still remains a major health problem in many countries around the world and is caused by the *Plasmodium* family of parasites. Like many other infectious diseases, malaria is a host immune response-driven disease that presents various multiple systemic clinical conditions as well as single or multiple organ-related pathologies, including cerebral malaria, acute respiratory disease syndrome, and liver pathology. Despite several decades of extensive research efforts worldwide, neither an immunotherapeutic to treat the disease nor an effective vaccine is available. A major constraint in realizing these goals is thought to be due to incomplete understanding of molecular and cellular processes involved in the development of immunity to malaria. Although malaria immunity has been extensively studied in mouse models and in humans for the past several decades, efforts have been predominantly focused on adaptive immunity, aiming to identify vaccine candidates. Thus, there have been relatively meager efforts in dissecting host-parasite interaction and cellular signaling mechanisms that initiate innate immunity. In-depth knowledge of these processes is important since innate immunity is the key for the development of suitable adaptive immunity. Previously, we and others showed that TLR-mediated signaling plays important roles in malaria parasite-induced innate immune responses, which contribute to protective immunity or pathogenesis. In the present study, using mouse malaria models, we found that TLR2 and TLR4 specifically contribute to malaria-induced acute respiratory syndrome and liver pathology. Parasite sequestration in the organs and consequent TLR-mediated signaling and inflammatory responses initiated by a parasite factor results in the recruitment of leukocytes, leading to exacerbated inflammatory responses in the organs causing tissue damage and pathology. The molecular and cellular mechanisms that contribute to the observed organ pathologies will be discussed.

358

SELF-REACTIVE IMMUNOGLOBULIN G CONTRIBUTES TO ASYMPTOMATIC *PLASMODIUM FALCIPARUM* MALARIA IN AN ENDEMIC AREA OF IVORY COAST

David Koffi[1], Nicholas Tchitchek[2], Landry Tiacoh[1], Fabien Herbert[3], Andre Offianan Toure[1], Joseph Allico Djaman[1], Sylviane Pied[3]

[1]Pasteur Institute of Cote D'Ivoire, Abidjan, Côte D'Ivoire, [2]CEA, DSV/iMETI, Immunology of viral infections and autoimmune diseases research unit, UMR1184, IDMIT infrastructure, Fontenay-aux-Roses, France, [3]Pasteur Institute of Lille, Lille, France

Despite considerable research, the mechanisms of natural acquired immunity to malaria in asymptomatic carrier are only partially understood. Among them the role play by self-reactive antibodies has not been clarified yet. This study aims to analyze the contribution of self-reactive antibody repertoire in asymptomatic malaria in Ivory Coast and also determine the impact of transmission level on these auto-antibody responses. Blood samples, n = 94 of patients consulting for symptomatic malaria (MM) attacks and living in three different malaria endemic settings (rural and peri-urban), n=47 asymptomatic carriers (AS) of parasites and n= 38 endemic control (EC) were enrolled. Anti-IgG antibodies against a whole parasite (3D7), brain extract and Anopheles salivary gland peptide gSG6-P1 were quantified by the enzyme-linked immunosorbent assay (ELISA). Human self-reactive antibody repertoires were analyzed by quantitative immunoblotting (Panama blot). The association of self- and parasite-specific- antibody repertoires was evaluated using Kruskal-Wallis test and Spearman's rank correlation. The level of total IgG response against 3D7 in AM was lower than those of MM. Moreover, children with AM exhibited a high level of auto-antibodies recognizing brain antigen as γ- , β-actin, Glutaryl-CoA dehydrogenase, Succinate-CoA ligase, and Acetyl CoA dehydrogenase. In addition, a significant correlation between the exposure marker (IgG against gSG6-P1) and auto-antibody responses was found ($p<0.01$). Then the reactivity of serum IgG against antigenic bands S6, S10, S11, S12, and S13 of brain extract (molecular weight between 50-75 kDa) discriminate different transmission sites. These results showed that exposure or parasite pressure seem to cause a quantitative and qualitative change in self antibody immune reactive profile. More the intense production of autoantibody in asymptomatic malaria carriers with decreased IgG to 3D7 represents an active immune response and highlights their potential role in mediating disease resistance or tolerance. However, their functional protective role needs further investigation.

359

IMPACT OF RECURRENT MALARIA ON VΔ2 ΓΔ T CELL *IN VITRO* ANTI-PARASITIC ACTIVITY

Kathleen W. Dantzler[1], Rafael B. Polidoro[2], John Rek[3], Moses Kamya[4], Grant Dorsey[5], Margaret Feeney[5], Judy Lieberman[2], Prasanna Jagannathan[1]

[1]Stanford University, Palo Alto, CA, United States, [2]Harvard Medical School, Boston, MA, United States, [3]Infectious Disease Research Collaboration, Kampala, Uganda, [4]Makerere University, Kampala, Uganda, [5]University of California San Francisco, San Francisco, CA, United States

Clinical immunity to the most deadly human malaria parasite, *Plasmodium falciparum (Pf),* develops slowly over an individual's lifetime; while immunity limits symptomatic infections in older children and adults, protection against parasite replication is partial. Immune mediators, such as pro-inflammatory cytokines produced from innate-like γδ T cells, can reduce parasitemia but can also lead to excessive inflammation that exacerbates pathology. Repeated malaria exposure among Ugandan children is associated with reduced percentages of the Vδ2 γδ T cell subset, decreased cytokine production and proliferation in response to malaria antigens, and increased expression of immunoregulatory genes. This loss and dysfunction of the Vδ2 γδ T cell subset is further associated with a reduced likelihood of symptoms upon subsequent *Pf* infection. Aiming to investigate the role of attenuation of the γδ T cell pro-inflammatory response in the development of clinical anti-malarial immunity, we are currently examining the mechanistic processes driving altered function of γδ T cells after repeated malaria infection. We optimized an *in vitro* assay to test inhibition of *Pf*-infected red blood cell (iRBC) growth by Vδ2 γδ T cells and observed a significant reduction in parasite reinvasion after γδ T cells from malaria-naïve individuals were incubated with *Pf*-iRBC. We are evaluating how recurrent *in vivo* malaria impacts the ability of γδ T cells to inhibit parasite reinvasion using samples obtained longitudinally from Ugandan children with varying malaria exposure. Further, we will test the hypothesis that altered γδ T cell functional responses after repeated infection are due to transcriptional and/or epigenetic regulation. By deepening our understanding of the molecular mechanisms driving inefficient acquisition of antimalarial immunity in children, this work could enable novel therapeutic approaches that reverse this phenomenon.

360

THE ROLE OF REGULATORY T CELLS IN THE CONTROL OF PARASITE GROWTH AND CLINICAL OUTCOMES FOLLOWING CONTROLLED HUMAN MALARIA INFECTION IN SEMI-IMMUNE KENYAN ADULTS

Richard A. Morter[1], Diana Nyabundi[1], Jedidah Mwacharo[1], Melissa Kapulu[1], Domtila Kimani[1], Joyce Ngoi[1], Patricia Njuguna[1], Mainga Hamaluba[1], Bernhards Ogutu[2], Yonas Abebe[3], Peter F. Billingsley[3], B. Kim Lee Sim[3], Eric R. James[3], Thomas L. Richie[3], Stephen L. Hoffman[3], Adrian V. Hill[4], Philip Bejon[1], Katie J. Ewer[4], Francis M. Ndungu[1]

The understanding of naturally-acquired immunity to malaria, caused by *Plasmodium falciparum,* has been hindered by a lack of appropriate animal models and conflicting results from immunoepidemiological studies. Controlled human malaria infection (CHMI) provides a more appropriate and reliable model to investigate protective and non-protective immune responses to malaria in more detail. 144 semi-immune Kenyan adults were each infected by direct venous inoculation (DVI) with 3,200 aseptic, purified, cryopreserved *P. falciparum* sporozoites (Sanaria® PfSPZ Challenge) and followed up for 21 days with twice-daily (days 7 – 14) or daily (days 15 – 21) qPCR monitoring of parasitaemia. 45.8% (*n*=66) of participants developed parasitaemia and met the diagnostic threshold for treatment (500 parasites/µl of blood) before day 21. 41% (*n*=59) exhibited low parasite growth or managed to clear parasites before day 21 and did not meet the criteria for diagnosis. 13.2% (*n*=19) had no parasites detectable by the qPCR assay at all timepoints. In contrast, in prior studies in malaria-naïve populations in the US or EU, all subjects administered 3,200 PfSPZ by DVI met the diagnostic threshold for treatment. We hypothesise that varying levels of naturally-acquired immunity underlie the differing parasite growth rates observed with CHMI. Regulatory T cell (Treg) activity has been associated with increased *P. falciparum* growth rates in malaria naïve adults undergoing CHMI, but their role in naturally acquired immunity is unclear. We will examine whether Treg frequency and transcriptional phenotype, before and during CHMI in semi-immune adults correlates with parasite growth and clinical outcomes. We will then determine if functional relationships exist between Treg activity, antigen-specific effector $CD4^+$ and antibody responses using *in vitro* assays. We will also determine whether the balance of pro- and anti-inflammatory cytokines can predict outcomes following CHMI. These data will improve our understanding of which components of the immune response are important in malaria, to inform vaccine design. A complete dataset will be presented at the meeting.

361

PROPORTIONS AND FUNCTION OF *PLASMODIUM FALCIPARUM* CIRCUMSPOROZOITE-SPECIFIC B CELLS IN VACCINATED AND NATURALLY EXPOSED INDIVIDUALS

Racheal Aye[1], Philip Bejon[1], Eunice Nduati[1], Ian Cockburn[2], Francis M. Ndungu[1]

[1]KEMRI-Wellcome Trustthe , Kilifi, Kenya, [2]Australian National University, Canberra, Australia

Repeated exposure to *Plasmodium falciparum* (*Pf*) infections results in the expansion of atypical memory B cells (aMBCs) that have been shown to be dysfunctional in-vitro suggesting that Pf impairs the B cell/antibody response to malaria. It is unclear whether PfCSP-specific memory B cells induced by either vaccination or natural exposure are functional. The aim of this project is to characterize the B cell response to circumsporozoite protein (RTS, S), the antigen in RTS, S/AS01 vaccine, in vaccinated and naturally exposed individuals. We hypothesize that only a subset of antigen-specific B cells are able to produce antibodies that neutralize *Pf*. Specifically, we used PfCSP-tetramer multiparameter flow cytometry and ELISA to determine the proportions of CSP-specific B cells and antibody levels in children with varying amounts of exposure to malaria following vaccination with RTS, S/AS01. PfCSP specific B cells and antibody levels are maintained at higher levels in RTS, S vaccinees compared to controls (p= 0.01 and <0.0001 respectively) at 6.5 months of immunization. The proportions of PfCSP- specific B cells in the vaccinees decrease significantly by month 74, however vaccinees maintain higher anti-CSP serum antibody levels compared to controls (p=<0.0001). To determine whether the function of CSP-specific B cells is compromised, we will compare gene transcription profiles of these cells with those of the more effective tetanus vaccine isolated from the same individual using single cell RNAseq. Additionally, recombinant CSP-specific antibodies will be made and their ability to neutralize sporozoites *in vitro* and *in vivo* tested. The data will help determine whether the deficit in protection following immunization with RTS, S is at least partly the result of the quality of the antibodies produced, a problem of the level of the B-cell response itself, or a result of both.

362

NATURALLY ACQUIRED IMMUNITY TO *PLASMODIUM VIVAX* MEROZOITE SURFACE PROTEIN-1, DUFFY BINDING PROTEIN AND CIRSCUMSPOROZOITE PROTEIN AND RISK OF RECURRENCE FOLLOWING RADICAL TREATMENT

Julio A. Ventocilla[1], Meddly Santolalla[2], Andres Lescano[3], Hugo Valdivia[2], Danett Bishop[2], Christian Baldeviano[2]

[1]NGO PRISMA, Lima, Peru, [2]Naval Medical Research Unit-6, Lima, Peru, [3]Universidad Peruana Cayetano Heredia, Lima, Peru

Plasmodium vivax (Pv) is the most geographically widespread parasite causing malaria worldwide and represents a challenge to malaria elimination. Currently some vaccine candidates such as Merozoite surface protein-1 (MSP-1), Duffy binding protein (DBP) and Cirscumsporozoite protein (CSP) are in pre-clinical or early phase-I clinical trials. However, little is known about the relationship between naturally acquired immunity response against these vaccine candidates and recurrence events. In order to understand this relationship we measured antibodies against MSP-1, DBP and CSP using plasma samples from a clinical trial aimed at assessing the efficacy of 3 Primaquine regimes to prevent possible Pv relapses in the Peruvian Amazon. Patients were followed for 210 days after treatment and from 485 patients we identified 90 recurrent cases. Six microsatellite markers were used to distinguish homologues (probable relapse) or heterologous recurrence (probable re-infection). Relationship between antibodies titters and the risk of recurrence was analyzed. Our results showed that the median of antibodies titters IgG against MSP-1 in non-recurrence group was 4.1 and 3.6 times higher vs. homologous (n=48) and heterologous (n=42) recurrence, respectively (p<0.001). Furthermore, titters of antibodies IgM against MSP-1 in non-recurrence group was 0.4 and 0.6 times lower vs. homologous and heterologous recurrence, respectively (p<0.001). Antibodies IgG against DBP in non-recurrence group was 1.6 and 1.1 times higher compared with homologous and heterologous recurrence, respectively (p=0.054). We did not observe difference in IgG titters against CSP between groups. Multivariate regression model showed strong protection against recurrence associated with upper quintiles 4-5 (OR=0.08, p<0.001) of antibodies IgG against MSP-1 and higher protection against homologous recurrence. Our results suggest that the intensity of antibodies IgG against MSP-1 during acute infection is associated with protection against recurrence and potentially relapses compared with DBP or CSP and support the potential of MSP-1 as a Pv vaccine candidate.

363

MALARIA IN PREGNANCY: IMPACT OF MICROSCOPIC AND SUB-MICROSCOPIC INFECTIONS ON NEWBORN CHILDREN'S CORD BLOOD IMMUNE RESPONSES

Ronald Ottichilo[1], Ruth Nyakundi[2], Dunstan Mukuko[3], Francis Mutuku[4], Desiree LaBeaud[5], Charles King[6], Indu Malhotra[6]

[1]Vector Borne and Neglected Diseases Unit Ministry of Health Kenya, Nairobi, Kenya, [2]Institute of Primate Research, Nairobi, Kenya, [3]Vector Borne and Neglected Diseases unit Ministry of Health Kenya, Nairobi, Kenya, [4]Technical University of Mombasa, Mombasa, Kenya, [5]Stanford University School of Medicine, California, CA, United States, [6]Case Western Reserve University, Cleveland, OH, United States

In endemic regions, newborns are often exposed to malaria *in utero*. Such exposure affects susceptibility to malaria through mechanisms that are poorly understood. We examined the relationships between burden and timing of malaria in pregnancy on newborn's cellular immune responses. 363 Kenyan women were followed from early pregnancy until delivery. Malaria infection was detected at prenatal visits and delivery by standard microscopy and PCR. Their newborns' cord blood lymphocyte responses to malarial blood stage-antigens were analyzed for proliferation and production of TNF-α, IL-6, IFN-γ, IL-2, IL-12p70, IL-5, IL-13, IL-10 cytokines. Cytokines were quantified via the Bio-Plex assay. The Prevalence of malaria parasites among mothers was 47% (172/363), more than half (60%) of these were sub-microscopic. Newborns from mothers with submicroscopic infection expressed higher levels of inflammatory ($P < 0.01$), Th1 ($P < 0.001$), Th2 ($P < 0.001$), and regulatory ($P < 0.01$) cytokines as compared to the unexposed. In contrast, there was no significant difference in newborns from mothers having microscopically detected infections to the unexposed. Parasitemia occurring at prenatal visits, but not at delivery, yielded a mixed pro- and anti-inflammatory response pattern at birth, whereas parasitemia occurring only at delivery was associated with elevated IL-13 response. Density and timing of MiP appear to influence fetal effector responses. The observed patterning may be important for subsequent anti-*Plasmodium* response during early life.

PLASMODIUM FALCIPARUM STRAINS SPONTANEOUSLY SWITCH INVASION PHENOTYPE IN SUSPENSION CULTURE

Prince B. Nyarko[1], Gordon A. Awandare[1], Yaw Aniweh[1], Reuben Ayivor-Djanie[1], Jose A. Stoute[2]

[1]University of Ghana, Accra, Ghana, [2]Pennsylvania State University College of Medicine, Hershey, PA, United States

The extensive redundancy in the use of invasion ligands by *Plasmodium falciparum*, and its unique ability to switch between invasion pathways have hampered vaccine development. *P. falciparum* strains Dd2 and W2mef have been shown to change from sialic acid (SA)-dependent to SA-independent phenotypes when selected on neuraminidase-treated erythrocytes. Following an observation of increasing ability of Dd2 to invade neuraminidase-treated cells when cultured for several weeks while shaking, we systematically investigated this phenomenon by comparing

invasion phenotypes of Dd2, W2mef and 3D7 strains of *P. falciparum* that were cultured with gentle shaking (*Suspended*) or under static (*Static*) conditions. While *Static* Dd2 and W2mef remained SA-dependent for the entire duration of the investigation, *Suspended* parasites spontaneously and progressively switched to SA-independent phenotype from week 2 onwards. Furthermore, returning *Suspended* cultures to *Static* conditions led to a gradual reversal to SA-dependent phenotype. The switch to SA-independent phenotype was accompanied by upregulation of the key invasion ligand, reticulocyte-binding homologue 4 (RH4), and the increased invasion was inhibited by antibodies to the RH4 receptor, CR1. Our data demonstrate a novel mechanism for inducing the switching of invasion pathways in *P. falciparum* parasites and may provide clues for understanding the mechanisms involved. The data further demonstrate the likely role of non-immune factors to phenotypic variation in *P. falciparum*, and highlights the possible contribution of in-vivo physiological conditions towards parasite diversity.

365

EFFECT OF MALARIA PATHOLOGY ON CD4 CELLS

Emmanuel C. Amadi[1], Emmanuel A. Eze[2], Vincent Chigor[2], Victoria Ayawan[3]

[1]Enugu State University of Science and Technology, GRA, Enugu, Nigeria, [2]University of Nigeria, Nsukka, Nigeria, [3]Caritas University, Enugu, Nigeria

Understanding immunity in *Plasmodium* infection can help in the treatment and vaccine production. The effect of malaria pathology on CD4 cell count was carried out at a Teaching Hospital in Enugu Nigeria between March–July 2017. Patients on doctor's provisional diagnosis of malaria were examined for *Plasmodium* infections and the degree of parasitaemia (0, +, ++, and +++). Positive samples (+, ++ and +++) and negative ones (0) were thereafter examined for their CD4 cell counts. 30 patients were studied. All the *Plasmodium*-negative specimens showed normal range of CD4 cell count (509 – 1488); with mean value of 1109. The + parasitaemia showed lower ranges of CD4 count (262 – 954); mean = 613; with immune falls in three (262, 425 and 427). The ++ parasitaemia showed crash in the CD4 cells count (35, 152, 22 and 494) except one with 542 count; mean = 291. The +++ parasitaemia showed not much low ranges of CD4 cell count (318 – 994) because most parasitaemia were not due to P. *falciparium*; with a crash in only one (318); mean = 566. The CD4 cells falls and crashes were detected only in *Plasmodium falciparium* parasitaemia infections. In conclusion, *Plasmodium falciparium* infection causes immunosuppression in patients. Corollary, it means is that malaria infection in the immunodeficients and AIDS patients will accelerates the complications as well as death, unlike prevailing reports.

PRODUCING MALARIA INDICATORS THROUGH DISTRICT HEALTH INFORMATION SOFTWARE: PRACTICES, PROCESSES AND CHALLENGES IN KENYA

George Okello[1], Rene Gerrets[2], Scholastica Zakayo[3], Sassy Molyneux[3], Caroline Jones[1]

[1]KEMRI-Wellcome Trust Research Programme, Nairobi, Kenya, [2]University of Amsterdam, Amsterdam, Netherlands, [3]KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya

Globally, there is increasing interest in malaria indicators produced through routine information systems due to their potential to provide near real-time data for driving malaria control decisions. Deficiencies in routine health information systems are well recognized and interventions such as the computerization of District Information Systems have been implemented to improve data quality, demand and use. However, little is known about the micro-practices and processes that shape routine malaria data generation at the frontline. This study critically examined how data for constructing routine malaria indicators are constructed and reported through the District Health Information Software (DHIS2) in Kenya. The study was conducted over 18-months in four frontline health facilities and two sub-county health records offices located in two malaria endemic counties. The study employed an ethnographic approach to data collection which involved observations, document review, records review, and interviews (n=27). Data were analysed using a thematic content analysis approach. Routine malaria data generation at the frontline was undermined by a range of factors such as understaffing, human resource management challenges, stock-out of essential commodities, poorly designed tools, and unclear instructions for data collection and collation. In response to these challenges, health workers adopted various coping mechanisms such as informal task shifting and use of improvised tools which sustained the data collection process but undermine data quality. Data quality problems were concealed in aggregated reports entered in the DHIS2. Problems were compounded by inadequate data collection support systems such as supervision. Challenges to routine malaria data generation and reporting are embedded within the broader challenges faced by the health system. The DHIS2 is one component of the health system and interventions to improve reporting practices will shape and be shaped by the functioning of other system components. Any intervention seeking to improve routine malaria data generation must, therefore, look beyond malaria or the health information system-specific initiatives to also include those that address the broader contextual factors that shape malaria data generation.

IDENTIFICATION OF THE MALARIA OXIDOREDUCTASE ENZYME INVOLVED IN HYDROGEN PEROXIDE PRODUCTION FROM PRIMAQUINE METABOLITES

Piyaporn Jirawatcharadech, Grazia Camarda, Cristina Yunta-Yanes, Mark J.I. Paine, Stephen A. Ward, Giancarlo Biagini

Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Malaria is a major vector-born disease that affects populations in tropical and subtropical areas. The achievement in malaria elimination and control requires effective tools to block transmission and to prevent re-establishment of malaria. Primaquine is the only currently available anti-malarial that has gametocytocidal activity against *Plasmodium falciparum* and ability to kill liver stages, including hypnozoites in relapsing strains (*P. vivax* and *P. ovale*). In terms of the malaria elimination and control agenda, primaquine becomes one of the most important tools we have for deployment alongside other anti-malarial drugs targeting asexual stages. However, primaquine cannot be given safely to all malaria patients because of haemolytic toxicity in patients who suffer from glucose-6-phosphate dehydrogenase deficiency. Despite more than seventy years of investigation, the mechanism of action of primaquine remains poorly understood. Primaquine efficacy requires biotransformation from the unmodified primaquine core to as yet undefined active metabolite/s. Recent literature shows clear evidence for a role of CYP2D6 in the production of active metabolites. It is hypothesised that the anti-malarial activity occurs via hydrogen peroxide, oxidative stress, and oxidative damage produced from the redox cycling of CYP 2D6 mediated primaquine metabolites. However, this still doesn't explain the unique susceptibility of malaria parasites to primaquine or it's metabolites. Here, for the first time we report on a *P. falciparum* enzyme having reductase activity that is able to complete the redox cycling of primaquine metabolites within the parasite. The gene was cloned and expressed in *E. coli*. The purified protein shows an ability to use primaquine metabolites in the generation of hydrogen peroxide. Our observations do support a clear mechanism of action primaquine that will prove invaluable in the design of newer safer analogues.

MEASURING COVERAGE OF TREATMENT WITH ACT AMONG UNDER-FIVES IN POPULATION SURVEYS: THE IMPORTANCE OF VISUAL AIDS, PACKAGING AND PRESCRIPTION REVIEW FOR SURVEYS IN SETTINGS WITH A DIVERSE DRUG MARKET AND IMPERFECT HEALTH WORKER ADHERENCE TO NATIONAL TREATMENT GUIDELINES

Ruth Ashton[1], Bakary Doumbia[2], Diadier Diallo[3], Thomas Druetz[4], Cameron Taylor[5], Fred Arnold[5], Seydou Fomba[6], Diakalia Koné[6], Jules Mihigo[7], Erin Eckert[8], Thomas Eisele[4]

[1]MEASURE Evaluation, Center for Applied Malaria Research and Evaluation, Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, [2]Info-Stat, Bamako, Mali, [3]MEASURE Evaluation, ICF, Bamako, Mali, [4]Center for Applied Malaria Research and Evaluation, Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, [5]The DHS Program, ICF, Rockville, MD, United States, [6]Programme National de Lutte Contre le Paludisme, Bamako, Mali, [7]President's Malaria Initiative, United States Agency for International Development, Bamako, Mali, [8]President's Malaria Initiative, United States Agency for International Development, Washington, DC, United States

Nationally representative household surveys are the standard approach to monitor access to and treatment with artemisinin-based combination therapy (ACT) among children under five years (U5). A prospective case-control study was performed in Mali to validate caregivers' recall of treatment received by U5s when seeking care for fever from rural and urban public health facilities, community health workers (CHWs), and urban private facilities. Clinician-recorded consultation details, without independent direct observation, were the gold standard. Consenting caregivers were followed- up for interview at home within two weeks using standard questions from Demographic and Health Surveys and Malaria Indicator Surveys. Among 1,602 caregivers in the study, recall of ACT received by their child had sensitivity of 43% and specificity of 90%. Higher sensitivity of ACT recall was associated with seeking care from a CHW, being literate, and higher socioeconomic status. Use of visual aids showing common drugs, review of prescriptions, and retained packaging improved ACT recall sensitivity to 92%, with specificity of 72%. Participants enrolled during the seasonal malaria chemoprevention (SMC) campaign had higher false-positive reports of ACT received by their child, compared to those enrolled pre-SMC. Caregivers rarely reported receiving the SMC drug combination from consultations at facilities or CHW sites. Health worker adherence to case management guidelines was inconsistent. Only 50% of febrile U5s were tested for malaria. Most (95%) of the 573 children with confirmed uncomplicated malaria received any antimalarial drug, but only 63% received ACT; 25% injectable artesunate; and a few received artemether, amodiaquine, or quinine. Furthermore, 36% of children with a negative test were prescribed ACT. Use of injectable artesunate was highest at public rural facilities. These findings emphasize the need to include visual aids, prescription, or packaging review alongside standard survey questions to assess ACT coverage, particularly in a context where clinicians do not consistently prescribe ACT for uncomplicated confirmed malaria.

369

DETECTION OF *PLASMODIUM SP.* IN NON-HUMAN PRIMATES AND MOSQUITOES IN FOREST FRAGMENTS IN COLOMBIA

Silvia Rondón, Cielo León, Andrés Link, Camila González

Universidad de los Andes, Bogotá, Colombia

Plasmodium parasites infect non-human primates (NHP) in tropical regions around the world. In Latin America, NHP are potential reservoirs of *Plasmodium brasilianum*/*Plasmodium malariae*, and some NHP species have been found infected with *Plasmodium falciparum* and *Plasmodium simium*, as reported previously. Considering the risk of infection to humans associated with the presence of NHP and *Anopheles* infected with *Plasmodium spp.,* this study aimed to determine the circulating species of *Plasmodium* in vectors and NHP species living in fragmented forest areas in Colombia. Sampling was conducted in five different forest fragments. Primates were followed and faecal samples were collected immediately after defecation, and placed in tubes with RNA*later* solution. Samples from 75 *Ateles hybridus,* 25 *Cebus versicolor*, 58 *Alouatta seniculus* and eight *Aotus griseimembra* were collected. Blood samples from four *A.hybridus,* nine *C. versicolor*, five *A. seniculus* and seven *A. griseimembra* were obtained. Adult mosquitoes were sorted after capture and most female *Anopheles* were preserved in RNA*later* buffer, the remaining were kept dry for taxonomic identification. *Plasmodium sp*. detection was performed through PCR, and second reactions were conducted for *Plasmodium falciparum, Plasmodium malariae* and *Plasmodium vivax* detection, using ribosomal and mitocondrial primers. PCR products were visualized on agarose gel and positive samples were sequenced. Mosquito identification was confirmed through DNA barcoding. From faecal samples it was found *P.falciparum* infecting *A.seniculus*, while *P. malariae* infected *A. seniculus, A. hybridus* and *A. griseimembra*. *P. vivax* infected *A. hybridus, A. seniculus* and *C. versicolor*. From blood samples it was found *P. malariae* infecting all the four NHP species tested and *P.vivax* infected *A. hybridus*. Infection with *P.vivax* was confirmed in three *Anopheles* species and one was positive for *P. malariae.* This scenario suggests important epidemiological implications in the human - NHP interface and the associated risk of Malaria transmission.

370

QUALITATIVE INSIGHTS INTO HUMAN BEHAVIOR AND RESIDUAL MALARIA TRANSMISSION IN UNGUJA ISLAND, ZANZIBAR: FINDINGS FROM IN-DEPTH INTERVIEWS AND DIRECT OBSERVATION OF COMMUNITY EVENTS

April Monroe[1], **Kimberly Mihayo**[2], Steven Harvey[3], Sarah Moore[4], Matthew Lynch[1], Hannah Koenker[1], Abdullah Ali[5], Dickson Msaky[2], Khamis Haji[5], George Greer[6], Samson Kiware[2], Fredros Okumu[2]

[1]USAID VectorWorks Project, Johns Hopkins University Center for Communication Programs, Baltimore, MD, United States, [2]USAID VectorWorks Project, Ifakara Health Institute, Dar-es-Salaam, United Republic of Tanzania, [3]Johns Hopkins University, Baltimore, MD, United States, [4]Swiss Tropical and Public Health Institute, Basel, Switzerland, [5]Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania, [6]US President's Malaria Initiative, US Agency for International Development, Dar-es-Salaam, United Republic of Tanzania

Zanzibar has experienced dramatic declines in malaria transmission, owing to its comprehensive malaria control program. This includes wide-scale deployment of insecticide treated nets (ITNs) and targeted indoor residual spraying (IRS). Despite high coverage of these indoor interventions, low-level residual transmission persists. This study used complementary qualitative approaches to better understand human behaviors that can drive residual transmission. A total of 62 in-depth interviews were conducted with community members and local leaders across six sites in Unguja, Zanzibar. 19 semi-structured community observations were conducted to capture nighttime activities and special events. Data was coded and analyzed using a thematic approach. Nighttime activities, sleeping patterns, prevention measures, and migration patterns emerged as important themes. Nighttime activities were largely categorized into routine social activities, household chores, livelihood activities and special events. Many activities took place outdoors, in the peri-domestic setting, or away from home, with some lasting throughout the night. Gender variations were observed, with men routinely spending more time outdoors and away from home than women and children. Outdoor sleeping was reported and observed, especially during 'special' socio-cultural events, including weddings, funerals, and religious ceremonies. Participants reported having few methods of prevention while outdoors, when traveling, or away from home, and generally perceived higher risk of infection while outdoors. Travel and migration, particularly seasonal workers coming from mainland Tanzania, was also perceived as a key

factor related to malaria transmission. Study findings highlight gaps in prevention when people are outdoors, away from home, traveling, or at large social gatherings. Supplemental prevention measures are needed where ITNs and other indoor-based interventions are insufficient. Programs aimed at providing education and prevention tools at the community level to visitors should also be explored.

371

SIMULTANEOUS ZOONOTIC MALARIA AND SYLVATIC YELLOW FEVER HUMAN INFECTION IN RIO DE JANEIRO ATLANTIC FOREST, BRAZIL

Anielle de Pina-Costa[1], Myrna Bonaldo[1], Cesare Bianco-Junior[1], André Machado Siqueira[1], Filipe Vieira Abreu[1], Ieda Pereira Ribeiro[1], Denise Anete Alvarenga[2], Cristiana Ferreira Brito[2], Ricardo Lourenço-de-Oliveira[1], Maria Fátima Ferreira-da-Cruz[1], Claudio Tadeu Ribeiro[1], Patricia Brasil[1]

[1]FIOCRUZ, Rio de Janeiro, Brazil, [2]FIOCRUZ, Minas Gerais, Brazil

The number of autochthonous malaria cases has been increasing in the Atlantic Forest (AF) of Brazil (Rio de Janeiro state) since 2015-16. The cases have been diagnosed as *Plasmodium vivax*, based on the morphology of the parasites. As the *P. vivax-like* non-human primate malaria parasite species *Plasmodium simium* is locally enzootic, we performed a molecular epidemiological investigation to determine whether zoonotic malaria transmission was occurring. Blood samples of humans from 2015-16 presenting malaria as well as from local howler monkeys were examined. Additionally, sequencing of the parasite mitochondrial genome was applied. This study shows that these parasites are *P. simium*, a closely related parasite species whose natural hosts are non-human primates (NHP) native to the AF. Some, if not most, of the autochthonous cases previously diagnosed as *P. vivax* in the region are likely to have been *P. simium* acquired via mosquitoes infected from monkeys, thereby making this part of Brazil the site of a second global focus of zoonotic malaria. Since late 2016, Brazil has been suffering a rapid expansion of a severe sylvatic yellow fever virus (YFV) outbreak, which has reached one of the most populated zones of the country, heretofore a yellow fever-free zone for more than 70 years. In 2017-18, an outbreak of YFV started in the same area of the AF were *P. simium* has been reported. The natural host of the virus and *Plasmodium* are the same. Interestingly, from 24 YF confirmed human cases (by qRT-PCR), we also identified co infection with *Plasmodium* in two individuals by retrospective PCR. The mechanism by which a patient may become infected by both *Plasmodium* and YFV is consecutive bites from two different infected mosquitoes or species (e.g., anopheline vectors for malaria and *Haemagogus* or *Sabethes* spp. for YFV). Thorough screening of the local NHP is required to evaluate the extent of this newly recognized zoonotic threat to public health in Brazilian Atlantic Forest. This situation has immediate implications for public health in this region, and further and more profound consequences for the control and eventual elimination of malaria and YF in Brazil.

THE CHALLENGE OF SCALING UP AND SUSTAINING DIGITAL SOLUTIONS: "SMS FOR LIFE" - A CASE STUDY FROM A HEALTH SYSTEMS INTEGRATION PERSPECTIVE

Carmen Sant Fruchtman[1], Selemani Mbuyita[2], Marcel Braun[3], Mary Mwanyika-Sando[2], Don de Savigny[1]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]Africa Academy for Public Health, Dar es Salaam, United Republic of Tanzania, [3]Novartis Social Business, Basel, Switzerland

Malaria remains a major public health concern in Tanzania with 5.2 million reported cases in 2016. The program "SMS for Life" used Short Messaging Service (SMS) to monitor antimalarial stock levels at public health facilities and address the stock-out problem in Tanzania. After a successful pilot in 2010, the proportion of health facilities that had no stock of one or more antimalarials declined from 78% during the first week of the program to 26% at week 21. The nation-wide scale up was implemented across all 5600 public health facilities. However, a study in 2013 showed that Tanzania continued to experience antimalarial stock-outs. The program was discontinued without replacement in 2016. This case study documents the evolution of the program from a health systems integration perspective to draw lessons for mHealth approaches to supply chain management at scale. We reviewed internal and external documentation on "SMS for Life". Using purposive and snowball sampling methods, semi-structured interviews were conducted among identified relevant stakeholders at international, national, district and health facility levels. Data from semi-structured interviews and document review were triangulated and analyzed. Additionally, a social network analysis was done to describe the relationship among the actors involved in the program. We analyzed the implementation of the program in terms of system thinking against health system building blocks framework and the WHO MAP framework. The results provide details on the roles of stakeholders, as well as, the variables and evidence considered in the decision-making processes. We also identified factors that led to the termination of the program in Tanzania. "SMS for Life" was viewed to have performed well on a technical level, but insufficient ownership and system integration were identified as major barriers to sustainability at scale. A new version of "SMS for Life" is currently being planned and the identification of the bottlenecks in Tanzania will inform planning to ensure integration and long-term results. Findings of this study will also help overcome similar barriers in other mHealth programs.

373

MASSIVE OVER-TREATMENT OF UNCOMPLICATED MALARIA CASES WAS ASSOCIATED WITH IN-SERVICE TRAINING AND SMS INTERVENTION IN A QUASI-EXPERIMENTAL STUDY IN GHANA

Harriet Affran Bonful[1], Adolf Kofi Awua[2], Doris Tsepetse[3], Richard M. Adanu[4], Dorothy Abudey[5], Akosua Gyasi[6], Keziah Malm[6], Priscilia Awo Nortey[1], Augustine Ankomah[4], Kwadwo Ansah Koram[7]

[1]Department of Epidemiology and Disease Control, School of Public Health, College of Health Sciences, University of Ghana, Accra, Ghana, [2]Cellular and Clinical Research Centre, Ghana Atomic Energy Commission, Accra, Ghana, [3]Research and Development Division, Ghana Health Service, Accra, Ghana, [4]Department of Population and Family Health, School of Public Health, College of Health Sciences, University of Ghana, Accra, Ghana, [5]Greater Accra Regional Health Administration, Ghana Health Service, Accra, Ghana, [6]National Malaria Control Program, Ghana Health Service, Accra, Ghana, [7]Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Accra, Ghana

Failure to test for malaria before treatment and failure to follow negative test results are still prevalent despite the current in-service training strategy deployed by the National Malaria Control Program (NMCP) of Ghana to improve prescriber adherence to malaria case management guidelines. Addition of a one-way SMS intervention post training may improve adherence to guidelines through knowledge retention. The aim herein was to assess the effectiveness of this addition in the Greater Accra Region (GAR). A quasi-experimental trial with a non-equivalent control group was conducted in La-Nkwantanang Madina (Arm 1), Ga South (Arm 2) and La Dade-Kotopon (Arm 3). Prescribers in Arms 1 and 2 received a three-day standard training on malaria case management. Within 8 weeks, prescribers in Arm 1 were repeatedly sent 10 discrete SMS messages every other week. Prescribers in Arm 3 received no intervention. Data were managed and analysed using Stata version 13.0. The primary outcome was the proportion of febrile patient records with negative malaria tests results prescribed ACTs. Analysis was by intention to treat. The effects of the interventions were estimated using differences in difference analysis after adjusting for confounding. As much as 2519 and 2356 patient records at baseline and end line respectively were compared. At baseline, 40.0% of the febrile patients were tested whilst 42.7% of the remaining febrile patients were treated presumptively. 93.0% of 158 febrile patients

with confirmed malaria were treated with ACTs and 21.4% of 679 febrile patients with negative malaria test results were prescribed ACTs at baseline. The training alone intervention resulted in only a 21.2% percentage point increase in the proportion of febrile patients tested for malaria. The training plus SMS intervention was associated with a 34.9 percentage point increase in overtreatment. Increasing test rates can potentially lead to overtreatment if the diagnostic capacities of facilities for other febrile illnesses and alternative treatment options for prescribers are not enhanced.

374

INVESTIGATING THE FUNCTION OF PUTATIVE MITOCHONDRIAL PROTEINS OF *PLASMODIUM FALCIPARUM* IN *SACCHROMYCES CEREVISIAE*

Praveen Balabaskaran Nina[1], Savitha Chellappan[2], Subarna Roy[2], Wahida Tabassum[3], Mrinal Bhattacharyya[3]

[1]Central University of Tamil Nadu, Thiruvarur, India, [2]National Institute of Traditional Medicine, Belagavi, India, [3]Central University of Hyderabad, Hyderabad, India

Plasmodium falciparum contains a minimalistic, but essential mitochondrion in all stages of its life cycle. Several mitochondrial processes such as division, genome replication, membrane biogenesis that are very well understood in higher eukaryotes are very unclear in *Plasmodium*. Furthermore, very little is known about the regulation of mitochondrial structure and function. Understanding the molecular mechanisms of some of these essential processes would require functional studies of the key proteins. Here, we use the yeast heterologous system, *Sacchromyces cerevisiae* to understand the function of three putative mitochondrial proteins that may be involved in key processes. We show that PfSURF1, the putative orthologue of human and yeast SURF1/SHY1, involved in cytochrome c oxidase assembly, partially complements a haploid *S. cerevisiae* strain harboring the null allele *shy1*. Prohibitins (PHB1 and PHB2) are mitochondrial proteins, and have been shown to regulate the structure and function of mitochondria in other eurkaryotes. Using the yeast two-hybrid system, we show that putative *Plasmodium* prohibitins (PfPHB1 and PfPHB2) interact with each other, which suggests that they could form supercomplexes of heterodimers in *Plasmodium*, the functional form required for optimum mitochondrial function.

375

COMPENSATORY HEME SCAVENGING MECHANISMS IN MALARIA-INFECTED PREGNANT WOMEN CORRELATE WITH BIRTH OUTCOMES

Annette Nti[1], Hassana Salifu[1], Mingli Liu[1], Pauline Jolly[2], Jonathan K. Stiles[1]

[1]Morehouse School of Medicine, Atlanta, GA, United States, [2]University of Alabama, Tuscaloosa, AL, United States

Malaria caused 445,000 deaths globally in 2016, with pregnant women and children at the highest risk. Malaria in pregnancy involve severe symptoms and outcomes including anemia, higher rates of miscarriage, premature delivery, low birth weight neonates, intrauterine, neonatal and maternal death. Current effective treatment for malaria targets parasite burden. Therefore, there is an urgent need to understand the causes of poor birth outcomes and to identify novel interventions as well as predictive biomarkers to determine at-risk individuals. However recent studies have shown that malaria pathogenesis is mediated by parasite derived factors as well as host factors such as heme, a by-product of parasite infected erythrocyte destruction. Our lab has previously determined that free serum heme levels and cytotoxicity in pregnant women were dependent on the robustness of their heme scavenging systems. We hypothesize that individuals with effective heme scavenging mediators will result in improved birth outcomes and that alternatively, those individuals with poor heme regulation will have poor birth outcomes. We assessed archived serum samples obtained from pregnant women in Ghana for heme- oxygenase 1 (HO-1), haptoglobin, and hemopexin levels to correlate results with birth outcomes. The results indicate that high serum levels of HO-1, haptoglobin and hemopexin in pregnant women asymptomatic for malaria had better birth outcomes than malaria-infected pregnant women that did not have high serum levels of these mediators. We conclude that the heme scavenging mechanisms heme-oxygenase 1, haptoglobin and hemopexin have the potential to provide novel prognostic biomarkers for pregnant women at risk for poor birth outcomes.

376

SETTING PRIORITIES IN MALARIA RESEARCH FOR MALAWI: THE PROCESS

Nyanyiwe M. Mbeye[1], Anja Terlouw[2], Kamija Phiri[1], Michael Kayange[3]

[1]Malawi College of Medicine, Blantyre, Malawi, [2]Malawi-Liverpool Welcome Trust, Blantyre, Malawi, [3]National Malaria Control Programme, Ministry of Health, Lilongwe, Malawi

Research plays a pivotal role in understanding social and economic trends and disease epidemiology. In addition, it is vital in informing development of health interventions and health systems innovations and taking them to scale. In resource-limited settings like Malawi, it is vital that public funds are used wisely to maximal effect. It is of great importance therefore to ensure that priorities for research are within context, evidence informed and set apriori for health research investments. We describe the process undertaken to develop priorities in malaria research for Malawi. The National Malaria Control Programme engaged stakeholders comprising of malaria researchers, experts, academicians, program implementers and development partners to define malaria themes, identify and analyse gaps in research. At the start, the stakeholders received an orientation to evidence based guideline development as well as evidence synthesis. This was followed by a series of stakeholder meetings to analyze current malaria control interventions; review current and previous research conducted in Malawi; develop broad priority research areas; map research evidence on the identified priorities to determine the research landscape and gaps and finally rank the identified priorities using the Essential National Health Research (ENHR) strategy. A comprehensive evidence informed five year national malaria research agenda for Malawi was formulated. The agenda highlights broad research priorities under the four main malaria themes which include case management, vector control, malaria in pregnancy and cross cutting (monitoring and evaluation and behavior change and communication). These research priorities were appropriately ranked using the ENHR strategy to guide appropriate allocation of the limited resources. In conclusion, in settings with limited resources, the process of formulating a national research agenda should involve thorough consultations and review of the appropriate evidence to support the need for further research.

377

CLINICAL FEATURES AND OUTCOME OF MALARIA IN CHILDREN SUFFERING FROM SICKLE CELL DISEASE: A RETROSPECTIVE DESCRIPTION OF 35 CASES

Celeste M. Musasa[1], Thierry L. Bobanga[2]

[1]Universite Protestante Au Congo, Kinshasa, Democratic Republic of the Congo, [2]Universite Protestante Au Congo, Universite de Kinshasa, Kinshasa, Democratic Republic of the Congo

The Democratic Republic of Congo (DRC) has two remarkable features, the extremely high prevalence of malaria and sickle cell disease (SCD). Both conditions bring together a high rate of morbidity and mortality in children mostly. Therefore, there has been only one report on the clinical features in the sickle cell pediatric population suffering from malaria in our country. The aim of this study was to contribute to the improvement of the management of malaria in children with sickle cell disease. We carried out a retrospective study in Evangelical Hospital of Vanga in rural zone

of Kwilu Province, Democratic Republic of Congo, for the period from January 2015 to December 2016, to children aged from 0 to 15 years. We analyzed the data of 35 children with SCD who developed malaria and which files were available. Of the 35 homozygous sickle cell children with malaria, the most represented were between 5 to 10 years (60%) with a F: M ratio of 1.19. The pain crisis (100%), fever (60%), severe anemia (51.42%) and jaundice (40%) were the most frequent clinical manifestations The hemoglobin level of less than 6 g / dL was found in 51.43% of children in the series. Malaria affected 45.72% of the studied population and caused 8.57% of deaths; 50% of hospitalized children were treated as severe malaria.

378

THE ETHIOPIAN EXPERIENCE IN ESTABLISHING MALARIA SENTINEL SITE SURVEILLANCE

Adugna W. Gemeda[1], Ashenafi Assefa[1], Wondatir Nigatu[1], Adugna Abera[1], Yonas Wuletaw[1], Wondimeneh Mekuriaw[1], Bekretsion Gidey[1], Berhanu Berga[2], Hiwot Solomon[3], Achamyelesh Sisay[3], Dereje Dilu[3], Gashu Fentie[3], Kebede Etana[3]

[1]Ethiopian Public Health Institute (EPHI), Addis Ababa, Ethiopia, Ethiopia, [2]GIS Expert, Addis Ababa, Ethiopia, Ethiopia, [3]National Malaria Control Program, Ministry of Health of Ethiopia, Addis Ababa, Ethiopia, Ethiopia

The Ethiopian Ministry of Health embarked on eliminating malaria from low transmission settings in 2020 and throughout endemic areas in 2030. However, the country experiences complex malaria epidemiology mainly occurrences of both *P.falciparum* and *Plasmodium vivax* and associated challenges in implementation. This calls for strong surveillance system that track epidemiological and entomological as well as monitoring seasonal climate forecast at local level for targeted action. Accordingly, in 2016, the National Malaria Control Program identified and approved 25 health centers to enhance health-facility-based malaria surveillance. Next, a characterization survey was conducted using interview and observation of potential entomological investigation posts from April to May 2017. GPS reading of the 25 sentinel sites and adjacent entomological posts was recorded for mapping. Above two-thirds of the sites were recruited from lowland (below 1,500m) and the rest from highlands (above 1,500-2000m). There was high variability among the sites in terms of institutional capacity. Annual malaria cases treated *per* annum vary. Findings were summarized for each site for further recommendation in implementing phased-approach of implementation.

379

EVALUATING THE CONTRIBUTION OF THE PRESIDENT'S MALARIA INITIATIVE TO REDUCTION OF MALARIA BURDEN IN PRIORITY UNTRIES IN SUB-SAHARAN AFRICA USING GENERALIZED STIMATING EQUATIONS AND MATCHING PROCEDURES

Yazoume Ye[1], Dwomoh Duaw[2], Samantha Herrera[1]

[1]MEASURE Evaluation/ICF, Rockville, MD, United States, [2]University of Ghana School of Public Health, Department of Biostatistics, Accra, Ghana

The President's Malaria Initiative (PMI) launched in 2005 as a key player in malaria prevention and treatment in sub-Saharan Africa (SSA). Several country-specific evaluations have demonstrated great progress in reducing under-five mortality associated with scaling up malaria interventions in PMI priority countries. However, documentation of PMI's specific contributions was limited, until the publication of Jakubowski. et al. 2017. It used difference-in-difference analysis to show higher reduction of under-five mortality in PMI-supported countries than in others. To generate more evidence, this study used rigorous statistical analyses to assess reduction in mortality attributable to PMI support. The study employed Generalized Estimating Equations (GEEs) and a series of matching procedures to evaluate the impact of PMI on under-five mortality and on population coverage of insecticide-treated nets (ITNs), indoor residual spraying (IRS), and artemisinin combination therapy (ACT) in SSA. The analyses used country-level secondary data and controlled for several country-level characteristics assumed to influence outcome measures of interest, PMI program participation, or both. The Mahalanobis distance metric, with 1:1 nearest neighbor matching adjusting for bias in population size and the particular country, showed a reduction in under-five mortality by approximately 12 per 1000 live births (95% CI: 20.6-3.1; p=0.012). There were statistically significant increases in the population coverage of ITN, IRS, and ACTs in PMI countries over the implementation period. ITN use in the population was 0.23% higher (95% CI average treatment effect on the treated: 0.17-0.30; p<0.001) in PMI- recipient countries than non-PMI countries. PMI contributed significantly to increasing coverage of malaria control interventions and reducing under-five mortality in SSA.

380

CONTRIBUTION OF QUARTERLY MALARIA DATA REVIEW AND VALIDATION TO DATA QUALITY AND MALARIA SERVICES IMPROVEMENT

Mathurin Dodo[1], Ousmane Badolo[1], Stanislas Nebie[1], Moumouni Bonkoungou[1], Thierry Ouedraogo[1], Youssouf Zongo[1], Maria Gouem[1], Youssouf Sawadogo[1], Danielle Burke[2], Bethany Arnold[2]

[1]Jhpiego, Ouagadougou, Burkina Faso, [2]Jhpiego, Baltimore, MD, United States

The PMI-funded Improving Malaria Care Project (IMC), aims to improve the quality of prevention, diagnosis and treatment of malaria in Burkina Faso. IMC also supports the NMCP to improve the quality of malaria data collected and used for decision-making through quarterly review of provider-collected malaria data. In 2016, IMC supported the NMCP to develop the malaria data review and validation manual, including a data review sheet. IMC supports 25 Health Districts to organize a quarterly malaria data review workshop with all health facility managers (HFM) who collect data. Before the workshop, the district data manager (DDM) captures data from monthly reports sent by health facilities (HF) in the online national DHIS2. The regional data manager (RDM) extracts malaria data from DHIS2, pastes in the data review file and creates a data sheet. Automatically, the data review sheet highlights in red the cells of each HF where the system detected an error. During the workshop, the RDM shows the errors for each indicator and asks the HFM to verify their reports. Generally 3 kinds of errors are noted; errors in understanding (e.g. confusing number of confirmed malaria cases treated with number of suspected malaria cases treated), typing errors, and miscalculations. By correcting these errors, the RDM and the DDM explain indicator definitions and prevention and treatment guidelines to providers. After 2 rounds of malaria data review in Boromo, Dano and Koupela districts, we noted that providers improved their understanding of indicator definitions and knowledge of prevention and treatment guidelines. The on-site data review in 41 HF showed that 88% (192/218) of providers comply with data reporting and case management guidelines. Furthermore, the percentage of HF with mistakes in their data dropped from 87% to 41% in Boromo, from 94% to 38% in Dano, and from 84% to 32% in Koupela. The indicators with errors in understanding decreased from 15 to 3 in Boromo, from 16 to 3 in Dano, and from 13 to 4 in Koupela. Thus, by improving data quality through review at the district level with providers, we are building provider's capacity and improving the quality of malaria services.

381

IMPACT OF ANTIMALARIAL INTERVENTIONS ON MALARIA MORBIDLY AND MORTALITY IN HOSPITALS FROM 2001 TO 2017, SENEGAL

Moustapha Cisse, Medoune Ndiop

NMCP Senegal, Dakar, Senegal

The Senegal National Malaria Control Program and partners accelerated malaria control in the last decade, with nationwide roll-out of artemisinin-

based combination therapy (ACT) starting in 2006, and rapid diagnostic tests (RDTs) starting in October 2007. Since 2003, insecticide-treated nets (ITNs) have been distributed through health facilities to pregnant women and children under five years, and since 2008, mass campaigns of ITN distribution have targeted children under five years, with universal coverage in 2010, 2014, and 2016. Since 2007, indoor residual spraying has been implemented in seven districts. We assessed the trends of malaria cases, hospitalizations and deaths at 37 hospitals and in all 76 districts during the period of the scale-up of malaria control interventions. Data collected from all hospitals and districts from 2001-2017 were used to assess the impact of accelerated malaria control. Numbers of outpatient and inpatient cases and deaths were compared between the 2001-2007 period and the accelerated - intervention period of 2008-2017. From 2001 to 2007, the proportion of suspect cases confirmed increased slightly from 2.2% to 4.0%. With the introduction of RDTs, this increased to 99.55% in 2017, with a mean test positivity rate of 19.5%. The proportion of all consultations due to malaria decreased from 39.7% in 2001 to 26.9% in 2007 (pre-RDT). After the introduction of RDTs and change in definition from clinical to biological onfirmed, the proportion of all consultations due to malaria decreased from 9.1% in 2008 to 3.26% in 2017. The proportion of patients hospitalized for malaria accounted for 11.5% of all hospitalizations in 2001 and decreased to 4% in 2017. From 2001 to 2007, the proportion of hospitalized deaths attributable to malaria decreased from 24.5% in 2001 to 8.1% in 2007. From 2008 to 2017, the proportion of hospitalized deaths attributable to malaria decreased from 7.1% to 1.73%. We conclude that malaria morbidity and mortality has decreased substantially during the scale up of malaria control interventions

382

FROM PRESUMED TO CONFIRMATION DIAGNOSIS: IMPROVING TESTING AND TREATMENT OF MALARIA IN CHILDREN UNDER FIVE IN RURAL COMMUNITIES IN MADAGASCAR

Andritiana Tsarafihavy[1], Thomas Razanakatovo[1], Riana Ramanantsoa[1], John Yanulis[1], Aishling Thurow[2], Thomas Hall[3], Laurent Kapesa[4], Jocelyn Razafindrakoto[4]

[1]Management Sciences for Health, Antananarivo, Madagascar, [2]Management Sciences for Health, Medford, MA, United States, [3]Management Sciences for Health, Arlington, VA, United States, [4]President's Malaria Initiative/United States Agency for International Development, Antananarivo, Madagascar

Since 2008, the National Malaria Control Program (NMCP) of Madagascar has scaled-up the implementation of Community Integrated Management of Childhood Illnesses with the introduction of malaria rapid diagnostic tests (RDT) at the community level. With support from the President's Malaria Initiative, the USAID Mikolo Project supports community health volunteers (CHV) to manage uncomplicated malaria cases. We assess the effectiveness of applied fever cascade management at the community level in improving malaria treatment among children under five (CU5). The USAID Mikolo Project has trained and equipped 5,364 CHVs throughout eight regions of Madagascar to correctly manage fever cases based on the 2013-2017 NMCP objectives: test over 80% of fever cases for malaria using RDTs, and treat over 80% of confirmed (RDT-positive) cases with artemisinin-based combination therapy (ACT). In order to ensure quality case management, the project introduced a quality improvement approach consisting of continuous supervision, training, and performance evaluations. Additionally, the project established a community logistics system that tracks and forecasts stock needs to ensure continuous supplies of RDTs and ACTs. Between 2013 and 2017, around 440,000 fever cases in CU5 were correctly managed by CHVs. With the implementation of the quality improvement approach for better case management, and with the establishment of the community supply chain system ensuring availability of stocks, the percent of fevers tested with RDTs increased from 70% in 2013 to 89% in 2017, and the rate of confirmed malaria cases treated with ACT increased from 35% in 2013 to 86% during the same period. Finally, presumptive treatment of fevers (treating with ACT without a confirmed RDT) has decreased considerably—from 39% in 2013 to almost 0% in 2017 (the 14% not treated by ACT by CHVs were directly referred to a health center instead of presumptively treated). Overall, the increased quality of fever case management services provided by CHVs has improved the cascade of malaria treatment in CU5 at the community level in Madagascar.

383

USE OF INSECTICIDES-TREATED NETS (ITNS) AND ASYMPTOMATIC MALARIA CARRIAGE IN AREA WITH HIGH TRANSMISSION, KALIFABOUGOU, MALI

Moussa Niangaly[1], Djeneba Togola[1], Daouda Diarra[1], Adama Djiguiba[1], Dramane Diakite[1], Taourou Doumbia[1], Aissat Ongoiba[1], Kassoum Kayentao[1], Boubacar Traore[1], Ogoba K Doumbo[1], Peter D Crompton[2]

[1]Malaria Research and Training Center, Bamako, Mali, [2]National Institute of Allergy and Infectious Diseases/National Institutes of Health, United States, Mali

Much progress has been made in the fight against malaria. However, it remains the major public health problem in worldwide (216 million cases) and particularly in sub-Saharan Africa (194 million cases) according to WHO malaria report 2017. Malaria is still one of the top five causes of under-five mortality with 80% of morbidity in Sub-Saharan Africa (WHO 2018). In Mali, malaria morbidity and mortality are still high, 1.700.000 and 2.309 respectively (PNLP 2015). The incidence of the disease is still high although the coverage of ITN use is increasing (54%) in Sub-Saharan Africa (WHO 2017) and 93% in Mali (PNLP 2015). In the context of malaria eradication and elimination, we would like to assess the role of ITNs on asymptomatic malaria. This study was undertaken to 1) evaluate the association between the use of ITNs and malaria incidence in a cohort from May to November 2013; 2) to determine the incidence of malaria in the study population; 3) determine the frequency of the use of ITNs in the study population and 4) to determine the association between the use of ITNs and the incidence of malaria, asymptomatic malaria carriers and the episodes number. This study is part of a cohort study of 582 volunteers initiated in May 2011 in Kalifabougou, Mali. However this assessment was conducted on data collected from May 2013 to December 2013. Data were collected on asymptomatic malaria measured during monthly visits using blood smear. ITNs used was also assessed in May and December 2013. ITNs was used by 98% of the participants of which 81% were regular users. Permanent users of ITNs represented 75% while non-permanent users represented 74% (p>0.05). There was an association between the use of ITN and the occurrence of asymptomatic malaria (p=0,032). 14% were carriers of malaria parasites, among ITNs regular users, versus 22.2% among the non-regular users. In conclusion, our results showed that the permanent use of ITNs are associated with the reduction of asymptomatic malaria carriage.

384

CHANGES IN CARDIAC REPOLARIZATION FOLLOWING REPEATED DOSING OF DIHYDROARTEMISININ-PIPERAQUINE IN PREGNANCY

Julie R. Gutman[1], Jobiba Chinkhumba[2], Eric Sigmon[3], Megumi Itoh[1], Enala Mzembe[2], Fatsani Gadama[2], Monica P. Shah[1], Michael Kayange[4], Peter Fischbach[3], Don P. Mathanga[2]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Malaria Alert Centre (MAC), University of Malawi College of Medicine, Blantyre, Malawi, [3]Children's Healthcare of Atlanta, Atlanta, GA, United States, [4]National Malaria Control Program, Lilongwe, Malawi

Malaria in pregnancy (MiP) remains a key cause of adverse maternal and infant outcomes. Alternatives to sulphadoxine-pyrimethamine (SP) are needed for intermittent preventive treatment (IPTp). Dihydroartemisinin-

piperaquine (DP) is a long acting antimalarial with the best potential to replace SP for IPTp, but it prolongs the cardiac QT interval. The effect with repeated dosing is not known. As part of a larger trial comparing the efficacy of IPTp-DP to IPTp-SP for prevention of MiP, we assessed QT prolongation with repeated dosing of DP. A subset of 34 pregnant women randomized to receive IPTp-DP monthly from enrolment (16-28 weeks gestational age) to delivery were included. Pre- and post-dose (obtained 4-6 hours after the last daily dose) 12-lead electrocardiograms (EKG) were obtained with each course. Women were excluded from the study for a machine reported QT corrected by Fridericia's formula (QTcF) ≥450ms at baseline or ≥480ms at any subsequent visit. A cardiologist reviewed all EKGs and calculated the QTcF and QT corrected with Bazett's formula (QTcB). Mean difference in the QTcF (ΔQTcF) and QTcB (ΔQTcB), between the post and the baseline measurement, as well as the course specific pre-dose measurement, was calculated for each dose. Post-dose EKG measurements were obtained from 30 women who received between 1-6 courses of IPTp-DP. At enrolment, the average QTcB was 427msec (range 384-465) and QTcF was 403msec (range 372-436). The pre-dose measurement was shorter at subsequent time points when compared to enrolment: ΔQTcB range -6.9 to -0.4 msec and ΔQTcF -11.8 to -1.7 msec. The mean difference from baseline to successive post-dose measurements was 16.1 and 15.6 msec overall for ΔQTcB and ΔQTcF, respectively, and 21.1, 14.9, 12.1, 12.4, 19.2, and 16.0msec for ΔQTcB and 24.4, 15.4, 11.3, 9.0, 12.4, 9.0 for ΔQTcF, for the 1st, 2nd, 3rd, 4th, 5th, and 6th doses, respectively. The mean differences comparing the post-dose to the pre-dose measurement for each specific course were similar. While IPTp-DP was associated with an increase in the QT interval, this was on average small, and did not increase in magnitude with successive doses.

385

FACTORS ASSOCIATED WITH INSECTICIDE-TREATED NET USAGE AMONG WOMEN OF CHILDBEARING AGE IN MALAWI: A MULTILEVEL ANALYSIS

Owen Nkoka

School of Public Health, College of Public Health, Taipei Medical University, Taipei, Taiwan

Use of insecticide treated net (ITN) has been the cornerstone for malaria prevention in most malaria-endemic countries. Despite reportedly high ITN coverage in Malawi, discrepancies in ITN use have been observed. Prior studies have identified individual factors that affect the use of ITNs among pregnant women. However, studies have generally not assessed how community factors, and women empowerment status influence ITN usage among women of childbearing age (WOCBA). This study aimed to identify individual- and community-level factors influencing ITN usage among groups of WOCBA in Malawi. Individual- and community-level factors influencing ITN usage in Malawi were assessed through interviews with 16,130 WOCBA (15-49 years) across 850 communities who participated in the 2015-16 Malawi Demographic Health Survey. Multilevel logistic regression analysis was used. ITN use was similar between pregnant women and nonpregnant women with children under 5 years (45.9% and 46.9%, respectively) but slightly lower among nonpregnant women without children under 5 years (39.1%). Both individual and community characteristics were associated with ITN use among WOCBA and varied significantly across subgroups. Specifically, nonpregnant women with children under 5 years living in communities where women had high autonomy in health care decisions had an 18% greater odds of using an ITN compared with those from communities where women had low health care autonomy (adjusted odds ratio [aOR] = 1.18; 95% confidence interval [CI]: 1.00-1.38). Distance to health care facility influenced ITN usage among pregnant women; those who did not regard distance as a problem had a 44% greater odds of using an ITN than those for whom distance was seen as a problem (aOR = 1.44; 95% CI: 1.09-1.89). Number of household members, region, urbanization, and community ITN coverage influenced ITN usage across all WOCBA groups. The findings confirmed the importance of assessing various factors affecting ITN usage among groups of WOCBA. Both individual- and community-level factors should be considered when designing and implementing ITN programs in Malawi.

386

THE EFFECTIVENESS OF INTERMITTENT PREVENTIVE TREATMENT IN PREGNANCY WITH ALTERNATIVE ANTIMALARIALS COMPARED TO SULFADOXINE-PYRIMETHAMINE FOR THE PREVENTION OF LOW BIRTH WEIGHT: A SYSTEMATIC REVIEW AND META-ANALYSIS

Monica P. Shah[1], Rewa Choudhary[2], Ryan Wiegand[3], Julie Gutman[1]

[1]Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Emory University School of Medicine, Atlanta, GA, United States, [3]Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States

Despite widespread drug resistance rendering malaria treatment with sulfadoxine-pyrimethamine (SP) ineffective, intermittent preventive treatment during pregnancy with SP (IPTp-SP) remains a key strategy to prevent low birth weight (LBW). Although alternatives to SP for IPTp have demonstrated increased effectiveness for malaria outcomes, results for the prevention of LBW have been mixed. We conducted a meta-analysis comparing the effect of IPTp with alternative antimalarials to IPTp-SP for the prevention of LBW and malaria parasitemia. We searched multiple databases in accordance with PRISMA guidelines for systematic reviews. Studies comparing IPTp-SP to IPTp with non-SP or SP combination antimalarials (alternative antimalarials) and reporting LBW prevalence (primary outcome) were included. Meta-analyses with study-specific random effects were used to estimate pooled risk ratios (RR) and 95% confidence intervals (CIs) for the prevention of LBW and peripheral and placental malaria infection at delivery by microscopy (secondary outcomes). Our search identified 1,179 records; 6 full-text articles were included in meta-analyses following screening of titles, abstracts, and full-text articles for eligibility. IPTp with alternative antimalarials provided no additional protection against LBW (RR: 0.94, 95% CI: 0.84, 1.05) compared to IPTp-SP, but significantly reduced the prevalences of both peripheral (RR: 0.62, 95% CI: 0.42-0.91, p=0.015) and placental (RR: 0.65, 95% CI: 0.44-0.97, p=0.035) malaria infection at delivery. The lack of pooled effect of IPTp with alternative antimalarials on LBW but significant reductions on malaria outcomes compared to IPTp-SP suggests that either IPTp-SP may be preventing LBW through a non-antimalarial mechanism (i.e. as an antibiotic) or that the maximum protection against LBW has been achieved by IPTp-SP. Future studies should examine the effect of IPTp with alternative antimalarials in combination with an antibiotic. Malaria control programs should continue to promote IPTp-SP among pregnant women living in areas of high malaria transmission in accordance with current guidelines.

387

ACCELERATING IPTP3 UPTAKE IN MALAWI

John K. Munthali[1], Thomas Hall[2]

[1]Management Sciences for Health, Lilongwe, Malawi, [2]Management Sciences for Health, Arlington, VA, United States

In 2013, Malawi adopted the World Health Organization's updated policy recommendation on use of Intermittent Preventive Treatment in pregnancy (IPTp). Support from the U.S. President's Malaria Initiative, working through USAID funded health projects, enabled collaboration between the National Malaria Control Program (NMCP) and the Reproductive Health Directorate (RHD) of the Ministry of Health to build capacity to implement the updated IPTp policy. These partners updated the National Malaria Treatment Guidelines to be in line with the new policy and developed appropriate training manuals. Over 90% of health workers from 603 facilities in Malawi were trained on the new IPTp policy and guidelines.

Post-training assessment scores of health staff increased by an average of 40 percentage points. Frequent supportive supervisions, coaching, and mentoring followed trainings to ensure compliance to new IPTp guidelines. Community volunteers and local community based organizations, such as community health action groups (CHAGs), were also engaged in order to identify and solve local problems, as well as encourage pregnant women to attend antenatal care (ANC) and receive malaria prevention services. Significant gains in IPTp3 coverage have been observed in Malawi since 2014 following policy change. In 2014, IPTp3 coverage in the Malaria Indicator Survey (MIS) was 13%, it increased to 30% in 2015 (Malawi Demographic Health Survey), and 43% in 2017 (MIS). Malawi's experience shows that collaboration between NMCP and RHD, as well as between clinics and communities has not only improved knowledge of the new policy, but resulted in increased uptake of services and protection of pregnant women from malaria.

388

DECREASE OF MALARIA BURDEN AMONG CHILDREN UNDER FIVE YEARS AND OTHER AGE GROUPS IN SMC REGIONS IN SENEGAL

Alioune Badara Gueye, Medoune Ndiop, Ibrahima Diallo, Seynabou Gaye, Mamadou Lamine Diouf, Doudou Sene

National Malaria Control Program, Dakar, Senegal

Senegal, a West African country, has made great strides in malaria control during the last decade, but its four southeastern regions continue to suffer a high malaria burden. In 2014, Senegal introduced seasonal malaria chemoprevention (SMC), a treatment of sulfadoxine-pyrimethamine and amodiaquine monthly during the rainy season, for children aged 3 -120 months in the four high transmission regions. The Ministry of Health also increased access to care, particularly for children under five years, through a variety of initiatives, and increased access to malaria diagnostic testing. We analyzed routine malaria information system data, provided by all publicly supported health facilities, for the four regions that received SMC and for which completeness of reporting was more than 99%, for the period from 2013 (the year before introduction) to 2017. Data were analyzed for children under 5 years and for non-pregnant patients 5 years and older. From 2013 to 2017, the number of severe malaria cases among children under five decreased from 1384 to 819 corresponding to 40,8% ; in the same period and for the same age group , the proportional mortality (proportion of deaths due to malaria out of all malaria deaths) also moved from 36,6% to 9,4%. We also observed the same results in all population from 2013 to 207 with a decreasing of severe malaria cases from to 6092 to 3592 corresponding to 40,4% and a reduction of proportional mortality from 20,4% to 7,6%. In the other age groups, we noticed in the same period a decrease of 36,6% in severe malaria cases among non-pregnant patients 5 years and older 54,5% among pregnant women. The proportional mortality was also reduced from 17% to 7% and 3,8% to 2,4% respectively among non-pregnant patients 5 years and older and pregnant women. This results in each age group show the contribution of Seasonal Malaria Chemoprevention in the reduction of malaria burden in the Southeastern part of Senegal.

389

PERCEPTION OF G6PD DEFICIENCY AND PRIMAQUINE RISK AND BENEFIT IN A MALARIA RISK POPULATION IN NORTHWEST CAMBODIA

Darapiseth Sea*[1], Soklyda Chann*[1], Somethy Sok[2], Samon Nou[1], Mitra Feldman[3], Bertha Nyagaya-Wojnarski[3], Sabaithip Sriwichai[3], Sohei Hom[1], Sokna Ly[1], Chandara Sok[1], Pheaktra Oung[1], Nareth Kong[1], Vannak Pheap[1], Kheangheng Thay[1], Vy Dav[1], Worachet Kuntawunginn[3], Threechada Boonchan[3], Nillawan Buathong[3], Nichapat Uthaimongkol[3], Mali Ittiverakul[3], Khlok Hout[4], Khourn Pong[4], Huy Rekol[5], Lek Dysoley[5], Michele Spring[3], Philip L. Smith[3], Mark M. Fukuda[3], Chanthap Lon[3], Mariusz Wojnarski[3]

[1]US Armed Forces Research Institute of Medical Sciences, Phnom Penh, Cambodia, [2]Ministry of National Defense, Department of Health, Phnom Penh, Cambodia, [3]US Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [4]Provincial Health Department, Samrong City, Cambodia, [5]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia

The treatment of Plasmodium vivax (Pv) malaria with primaquine (PQ) can result in life-threatening hemolysis if given to a glucose-6-phosphate dehydrogenase deficient (G6PDd) patient. Therefore, patients should be educated on the limitations of testing and the risks and benefits of taking PQ. We conducted operational research to gain a better understanding of the knowledge of G6PDd screening and PQ treatment among populations from a malaria endemic area in northern Cambodia. Educational materials were developed on G6PD testing, PQ benefits and the risks associated with both single low dose (SLD) and two-week radical cure treatment. Health care workers and village malaria workers used these materials to counsel healthy male test volunteers. Between December 2017 and March 2018, 1,543 G6PD test volunteers were recruited of which 251 (16%) were classified as being G6PDd. Eight hundred fifty-five volunteers (55%) completed pre- and post-counseling questionnaires. Pre-counseling, 653 (79.73%) participants said they would take SLD PQ if recommended, increasing to 816 (99.63%) post-counseling. Similarly, while 656 (79.32%) indicated a willingness to take radical cure PQ treatment before counseling, this increased to 819 (99.03%) after counseling. One hundred thirty six (15.98%) volunteers perceived SLD PQ as low risk for G6PDd patients, before counseling, this increased to 730 (85.78%) post counseling. 164 (19.34%) considered SLD PQ low risk for G6PD normal patients pre counseling vs. 814 (95.99%) post-counseling. Before counseling, 128 (15.13%) volunteers perceived radical cure PQ treatment a high risk for G6PDd patients, this increased to 804 (95.04%) after the counseling. 157 (18.62%) volunteers thought radical cure PQ treatment was a low risk for G6PD normal patients, compared to 808 (95.85%) post counseling. Although malaria elimination efforts have highlighted the need to deploy radically curative doses of PQ, this is the first study to our knowledge seeking to characterize community level understanding of G6PD and the risk and benefits of PQ for vivax radical cure. Additional results will be presented.

390

STRATEGY FOR IMPROVING THE TREATMENT OF SEASONAL MALARIA CHEMOPREVENTION AMONG CHILDREN FROM 3 TO 120 MONTHS OF AGE IN GOUDOMP HEALTH DISTRICT, SENEGAL: A 3-DAY DIRECTLY OBSERVED TREATMENT INITIATIVE

Malick Anne[1], Ibrahima Mamby Keita[1], Kader Dieye[1], Alioune Gueye[2], Amadou Yéri Camara[1], Doudou Sene[2], Mamadou Coulibaly[1], Khadim Niang[3], Youssoupha Ndiaye[1]

[1]Senegal Health Ministry and Social Action, Dakar, Senegal, [2]National Malaria Control Program, Dakar, Senegal, [3]Institut of health developement, Mbour, Senegal

Despite significant progress, malaria remains a public health problem in sub-Saharan African countries. In high-transmission areas, more than two-thirds of deaths occur in children under five. WHO recommended in 2012, Seasonal Malaria Chemoprevention (SMC) whose goal is to maintain therapeutic antimalarial drug concentrations throughout the period of highest malaria risk.Senegal has introduced this new intervention in its malaria prevention system and management policy since 2012. Goudomp health district in South Senegal started this intervention in 2014 and recorded 95% coverage in 2016 mass campaign. However, a survey leaded by parasitology unit in 2016 showed only 46% of full treatment coverage, meaning children have taken all doses. The research hypothesis was the SMC through the Direct Observed Treatment (DOT) and communication approach by community health workers improve the coverage up to 90%. The choice of units included was reasoned, taking into account the location of health structures and certain accessibility criteria. Volunteers were trained to administrate drug and deliver messages to parents and caregivers for 2 days, following the first administration made by these latter. All visit were done by volunteers. A social mobilization committee had been set up to strengthen communication and management of refusal cases. Mothers and care givers were informed and sensitize to report any occurred adverse effects. During the mass campaign, 3375 households were daily visited by volunteers. We obtained 90.5% coverage of full treatment under DOT in six units; 41 cases of minor side events have been reported and managed with good clinical response. During household visits, key messages were delivered to parents and caregivers on the importance of SMC for malaria prevention. DOT intiative to strengthen SMC coverage for full treatment with integrated communication has been successful in Goudomp health districts, and scale up with follow up of side events and efficiency studies can be considered

391

EXPLORATION OF FACTORS ASSOCIATED WITH BED NET MAINTENANCE IN KENYA USING A NOVEL BED NET CARE ADHERENCE SCORE

Ellen M. Santos[1], Jenna E. Coalson[1], Nancy Stroupe[1], Kacey C. Ernst[1], Maurice Agawo[2], Stephen Munga[2]

[1]University of Arizona, Tucson, AZ, United States, [2]Kenya Medical Research Institute, Nairobi, Kenya

Bed net care practices are important to their effectiveness as malaria prevention tools. Using data from a cross-sectional household survey conducted in high (>1500m) and low (<1200m) altitude sites in western Kenya, we developed a bed net care adherence score combining washing, drying, retreating, and repairing behaviors. Households were surveyed about bed net perceptions, ownership, use, and barriers to use from July-August 2015. We hypothesized knowledge of net care practices and *Plasmodium* transmission, perceived malaria risk, and believed ability to prevent malaria to be associated with net care adherence. There were 1,217 surveyed households, of which 82.4% owned ≥ 1 net. Of highland households, 203 (31.6%) own no nets compared to 11 (1.9%) of lowland households. Reported care practices of 1,766 nets were scored and categorized into low, moderate, and high adherence to recommendations. Low adherence was rare (4.5% of nets); moderate adherence was common (54.1%). Among households with high net care knowledge, 145 of their nets (78.4%) received highly adherent care. Among households that believe they can prevent malaria, 224 of their nets (59.7%) received highly adherent care compared to 331 (39.4%) of households that are not confident they can prevent malaria (p<0.001). Net care knowledge and confidence to prevent malaria may be associated with high net care adherence. Of households with accurate *Plasmodium* transmission knowledge, 307 of their nets (48.5%) received highly adherent care compared with 12 (33.3%) nets among households with low transmission knowledge (p<0.001). Interestingly, 89 (17.7%) of nets owned by households that perceive high malaria risk received highly adherent care, where 147 (22.5%) nets of households that perceive low malaria risk receive highly adherent care (p<0.001). High malaria risk perception may not be associated with greater net care. Further evaluations are planned to measure the relationships of these factors with high adherence. Results will guide malaria education interventions to tailor messaging, and ultimately aid in the effectiveness and longevity of bed nets as malaria prevention tools.

392

PROGRESS TOWARD UNIVERSAL BED NET COVERAGE IN WESTERN KENYA HAS NOT ENSURED UNIVERSAL USAGE, PARTICULARLY AMONG SCHOOL-AGE CHILDREN

Jenna E. Coalson[1], Ellen M. Santos[1], Nancy Stroupe[1], Maurice Agawo[2], Stephen Munga[2], Kacey C. Ernst[1]

[1]University of Arizona, Tucson, AZ, United States, [2]Kenya Medical Research Institute, Nairobi, Kenya

Insecticide-treated nets (ITN) are an effective tool for malaria control, and the WHO recommends universal coverage of one net for every two people in endemic areas. However, universal coverage does not guarantee universal usage, defined as all household members sleeping under an ITN. We assessed whether household ITN ownership in western Kenya meets the WHO target, and investigated the alignment between universal coverage and universal usage. Households from high (>1500m) and low (<1200m) altitude sites in western Kenya were randomly selected for a cross-sectional survey from July-August 2015. The lowlands experience perennial, highly endemic malaria; the highlands have lower prevalence with seasonal outbreaks. Household members completed detailed surveys about ITN ownership, use, and barriers to use. Household net ownership was categorized as adequate (≤2 people per net), inadequate (>2 people per net), or none. The survey included 574 lowland and 643 highland households, with 1,679 and 2,742 members, respectively. ITN ownership was common in the lowlands, with only 11 households (1.9%) having none, but inadequate coverage remains, with 149 households (26.0%) below the WHO target. In the highlands, only 241 households (37.5%) owned adequate nets. Inadequate coverage still resulted in high usage in the lowlands but not the highlands, with all members using a net in 81% of inadequately covered lowland households but 35% of highland households. In households with adequate nets, there was no significant difference in use by age (~3% of all ages being non-users), but school-age children (5-15 years) were significantly less likely than other age groups to use ITNs in households with inadequate nets (37% non-users versus 10% of children under 5 and 17% of adults ≥16 years, p<0.0001). ITN ownership is high in our study sites in Western Kenya, particularly in the endemic lowlands, but additional efforts are needed to reach WHO recommended coverage levels. In cases of inadequate coverage, perceived risk of malaria may drive prioritization of use among household members, with implications for continued sources of transmission in these regions.

UNDERSTANDING THE GAP BETWEEN ACCESS AND USE OF INSECTICIDE-TREATED NETS IN GHANA: A QUALITATIVE STUDY ACROSS THREE ECOLOGICAL ZONES

April Monroe[1], Sixte Zigirumugabe[2], Hannah Koenker[1], Matthew Lynch[1], Sylvester Segbaya[3], Richard Kpabitey[3], Nana Yaw Peprah[4], Keziah Malm[4], Danielle Piccinini[1], Bolanle Olapeju[1], Stella Babalola[1], Collins Ahorlu[5]

[1]USAID VectorWorks Project, JHU Center for Communication Programs, Baltimore, MD, United States, [2]US President's Malaria Initiative, US Agency for International Development, Accra, Ghana, [3]USAID VectorWorks Project, JHU Center for Communication Programs, Accra, Ghana, [4]Ghana National Malaria Control Program, Accra, Ghana, [5]Noguchi Memorial Institute for Medical Research, Accra, Ghana

Mass and continuous distribution channels have significantly increased access to insecticide-treated nets in Ghana. Despite these gains, a gap remains between access and use. A qualitative research study was carried out to explore individual and contextual factors influencing net use, among those with access. The study was carried out across three purposively selected sites from the three epi-ecological zones in Ghana. A total of 18 focus group discussions (FGDs) and free listing and ranking activities were carried out with community members, health workers, and community leaders. Seven case studies were created based on follow-up home visits and interviews with select FGD participants. FGDs and case study interviews were audio recorded, transcribed verbatim, and analyzed thematically. An iterative process was used by which emerging themes were shared and built upon during data collection. Key barriers included environments where ITN use is difficult, such as outdoors, the perception that ITNs provide limited value due to exposure to mosquito bites during early evening hours and nighttime activities, experiences with skin irritation even after airing the ITN, lack of airflow and congestion in the sleeping space, and in some cases, a lack of information on ITNs and malaria prevention. Having a personal experience getting malaria, or having a loved one fall ill, was one of the most powerful motivators of consistent ITN use. Growing up using an ITN, or developing a habit of use, were also listed as facilitating factors. The economic benefit associated with prevention over treatment was also discussed. Providing visual representations on how to use an ITN in challenging environments, positioning ITN use within the broader context of malaria prevention, increasing saliency of malaria risk, highlighting the cost and time benefits of prevention over treatment, development of a net use culture beginning in primary schools, and increasing knowledge of malaria transmission were identified as opportunities. This information will be used to inform social and behavior change messaging and innovative approaches to addressing the net use gap in Ghana.

394

INTERMITTENT PREVENTIVE TREATMENT WITH SULPHADOXINE PYRIMETHAMINE (SP) AMONG PREGNANT WOMEN IN KINTAMPO AREA OF GHANA - FINDINGS FROM 2011 TO 2015

Felix Boakye Oppong[1], Stephaney Gyaase[1], Edward Apraku Anane[1], Charles Zandoh[1], Obed Ernest Nettey[1], Seth Owusu-Agyei[2], Kwaku Poku Asante[1]

[1]Kintampo Health Research Centre, Kintampo, Ghana, [2]University of Health and Allied Sciences, Ho, Ghana

Malaria in pregnancy is a major public health problem in Ghana. It continues to contribute to the risk of spontaneous abortion, preterm delivery, low birth weight, and increases the risk of perinatal mortality. The World Health Organization (WHO) and the Ghana National Malaria Control Program recommend Intermittent Preventive Treatment in pregnancy with sulphadoxine-pyrimethamine (IPTp-SP) to prevent malaria-related adverse outcomes. However, the coverage of the recommended three or more doses of IPTp-SP has been found to be low in some parts of Ghana. The objective of this study was to determine the coverage of IPTp-SP among pregnant women in the middle belt of Ghana, and to explore the impact of socio-demographic characteristics on the uptake of IPTp-SP. Data from the Kintampo Health and Demographic Surveillance System (KHDSS) on the use of IPTp-SP among pregnant women from 2011 to 2015 was used. A logistic regression model was used to assess the determinant of IPTp-SP. In accounting for the possible correlation induced by the repeated observations, Generalized Estimating Equation (GEE) was applied. A total of 17,484 pregnant women from 2011 - 2015 were included in the study. The coverage of the recommended three or more doses of IPTp-SP among all pregnant women in the period was 40.6% (N= 4,065), 44.0% (N= 4,570), 45.9% (N= 4,547), 20.9% (N= 4,295), and 32.4% (N= 3,870) for 2011, 2012, 2013, 2014 and 2015 respectively. In the adjusted model, participants with secondary education (OR 1.5, 95% CI 1.25 - 1.75), aged 20 – 29 years (OR 1.5, 95% CI 1.30 - 1.65), primigravidae (OR 1.2, 95% CI 1.05 - 1.27), married (OR 1.2, 95% CI 1.07 - 1.25), and the least poor (OR 1.5, 95% CI 1.36 - 1.71) were significantly more likely to take the recommended three or more doses of IPTp-SP. However, participants in medium households (OR 0.8, 95% CI 0.71 - 0.87), Muslims (OR 0.8, 95% CI 0.71 - 0.84), and those from Northern tribes (OR 0.9, 95% CI 0.77 - 0.93) were significantly less likely to take three or more doses of IPTp-SP. These factors should be considered in the development and implementation of strategies aimed at improving the intake of IPTp-SP.

395

PREDICTORS OF INSECTICIDE TREATED NET USE AMONG UNDER-FIVE YEARS OLD CHILDREN IN MAINLAND TANZANIA: FURTHER ANALYSIS OF MALARIA INDICATOR SURVEY 2015-16

Frank Chacky[1], Maximillian Msuya[2]

[1]Tanzania MoH; National Malaria Control Programme, Dar es Salaam, Tanzania, United Republic of, [2]Tanzania MoH; Health System Strengthening, Dar es Salaam, Tanzania, United Republic of

Tanzania is currently under epidemiological transition from meso-endemic to hypoendemic levels. The country is characterized by marked heterogeneity. The use of Insecticide Treated Net (ITN) is one of the key intervention to protect vulnerable groups including under-five children. According to the 2015-16 Malaria Indicator Survey (MIS), the average net use among children under five was 54.4% with some variation across regions; highest in Geita (86%), Katavi (85%) and lowest in Manyara (13%), Rukwa (15%) regions. Further analysis of the MIS datasets for Mainland Tanzania aimed at exploring predictors of ITN usage among under-five children focusing socio-economic and geographical factors to explain variability, differentials and relationship between variables. Data were analyzed using STATA software version 15.1 whereby "svy" commands were used for performing bivariate and logistic regression on ITN use among under-five children. A total of 9,843 records from this age group were reviewed. Permission to use these datasets was granted by ICF Macro. Result shows that the estimated odds of ITN use for older children is 8.2% less than young children. The odds for children living in high altitude areas (>1750 meters above sea level), rural setting, and from households with more than 5 people shows they are less likely to use ITN by 57.7%, 29.7% and 49.8% respectively. ITN use is not associated with the distance of the household to the nearest health facility. The estimated odds of mosquito net use are 60.6% more for each additional mosquito net in the household while wealthier families were 50.9% more likely to use mosquito net than those living in the poorest families. In addition, mosquito net use is high among households with sufficient number of mosquito nets. Finding reveals children living in high altitude are less likely to use mosquito net than those living in low altitude; probably due to low temperature leading to low mosquito vector density. Hence, stratification of malaria interventions should be considered to ensure effective use of diminishing resources.

396

PERCEPTION OF THE MOTHERS AND THE CHILD MINDERS OF THE REGION OF SÉDHIOU ON THE SEASONAL MALARIA CHEMOPREVENTION IN 2017: ARE THE ABSENCES AND THE DISEASES OF THE CHILDREN - NO CASES OF DISGUISED REFUSALS?

Amadou Yéri Camara[1], Diabel Drame[2], Malick Hann[3], Bou Diarra[4], Kissouma Diedhiou[5], Gueye Badou[6]

[1]Region Medicale de Sedhiou, Sedhiou, Senegal, [2]District Sedhiou, Region Medicale de Sedhiou, SEDHIOU, Senegal, [3]District Doudomp, Region Medicale de Sedhiou, Sedhiou, Senegal, [4]District Bounkiling, Region Medicale de Sedhiou, Sedhiou, Senegal, [5]Africare, Region Medicale de Sedhiou, Sedhiou, Senegal, [6]PNLP, Dakar, Senegal

In the South of Senegal, the region of Sédhiou applies the Seasonal Malaria Chemoprevention (SMC) recommended by the WHO at the children from 3 to 120 months with 3 passages a year. Used Amodiaquine can give unwanted effects which could be sources of refusal. However according to the passages, the number of refusals decreases compared with the cases of sick or absent children by which the number increases that is why we wondered if it did not constitute cases of disguised refusals. The documentary revie) and the survey investigates qualitative were used with 8 focuses group and 19 individual interviews. And was noted 544 cases of vomitings, on 2079 of sick children and 4621 of the absent children while we noted that 116 cases of refusal. All the women recognized that the CPS served to prevent the malaria and some people ask for it even for them. The posology of the SMC is known as well by the women and they give medicine rather in the evening to avoid the side effects. **FD 26 years mother of 4 children:** " my children run to put themselves under the bed as soon as they see the agents giving medicine because they are bitter and they vomit when they take them but I make them go out so that they take them and for the second and the third dose I give them to them in the evening like that, they have nothing, it is because I know the value of this medicine ". For the absent and sick cases of child, the conversations are in favour of real cases of disease and the absent children took medicine left with their mom their return. It was noted as well as children declared absent were found hidden in the rooms of their parents. The importance of the SMC is well known by the women however the unwanted effects especially digestive create reluctances for the parents who think that the medicine is too powerful but effective for the prevention of the malaria so that they developed a particular strategy to limit these effects to know the taking in the evening in the bedtime. However the increase of the absent and sick children seems to be a new shape of refusal.

397

THE ROLE OF ACTIVE CASE DETECTION IN MALARIA ELIMINATION: *WHAT ARE THE CHALLENGES?*

Faiza B. Abbas[1], Abdullah Suleiman Ali[1], George Greer[2]

[1]Zanzibar Malaria Elimination Program, Zanzibar, Tanzania, United Republic of, [2]President's Malaria Initiative, United States Agency for International Development, Dar Es Salaam, Tanzania, United Republic of

Zanzibar has made significant progress in reducing malaria burden, with malaria prevalence reported to be 0.7% by microscopy in children under five in the 2015-16 Tanzania Demographic and Health Survey. Considering this and other key impact indicators, in 2014 the Ministry of Health changed the name and strategies of the program from Zanzibar Malaria Control to Zanzibar Malaria Elimination Program. In this context intensive malaria surveillance, which includes case investigation and classification, was implemented in 2013. In our program, tracking and follow up investigations and prompt reporting of each malaria case is imperative. Active case detection involves both reactive and proactive case detection. Reactive is triggered whenever a case is identified by passive case detection at health facility. It involves visits to the households of index case, screening family members and neighbors. Proactive is the screening of a focal population in hotspots with at least five index cases reported in a village within 7 days. This study presents findings of reactive case detection. Reactive case detection is conducted by the district response teams, in collaboration with village leadership. In 2017, reactive case detection was conducted in 32 villages following reporting of 3609 confirmed index cases. A total of 16,163 household's members were screened for malaria parasites from the targeted 19,617 community members. Eighty three (0.5%) members were found positive. Reactive case detection requires adequate resources to ensure intended target is reached. Regardless of intensive community involvement refusal among the community members is always reported . In some instances, non-targeted community members request for malaria testing of which interferes with the planned budget and logistics. Reactive case detection is one of the core interventions towards malaria elimination. The system requires high involvement of community members, and sufficient resources. Active case detection is an expensive and complex intervention which needs proper planning.

THE RISK OF PLASMODIUM VIVAX PARASITAEMIA AFTER PLASMODIUM FALCIPARUM INFECTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

Robert J. Commons[1], Julie A. Simpson[2], Mohamed S. Hossain[3], Kamala Thriemer[1], Nicholas M. Douglas[1], Georgina S. Humphreys[4], Carol H. Sibley[5], Philippe J. Guerin[4], Ric N. Price[6]

[1]Menzies School of Health Research, Darwin, Australia, [2]Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia, [3]International Centre for Diarrhoeal Disease Research, Dhaka, Bangladesh, [4]WorldWide Antimalarial Resistance Network, Centre for Tropical Medicine and Global Health, Nuffield Department of Clinical Medicine, University of Oxford, Oxford, United Kingdom, [5]WorldWide Antimalarial Resistance Network, Centre for Tropical Medicine and Global Health, Nuffield Department of Clinical Medicine, University of Oxford and Department of Genome Sciences, University of Washington, Oxford, United Kingdom, [6]Menzies School of Health Research and WorldWide Antimalarial Resistance Network, Centre for Tropical Medicine and Global Health, Nuffield Department of Clinical Medicine, University of Oxford, Darwin, Australia

In Thailand, there is a high risk of *Plasmodium vivax* parasitaemia following treatment of *P. falciparum* infection. To inform the benefits of universal radical cure for patients with *P. falciparum*, the risk of *P. vivax* after *P. falciparum* was quantified across a range of co-endemic settings. A systematic review identified prospective clinical studies of antimalarial efficacy for uncomplicated *P. falciparum* malaria, published before January 2018 undertaken in areas co-endemic for *P. vivax*. The primary outcome was risk of *P. vivax* parasitaemia following *P. falciparum* infection at day 42. Secondary outcomes were risk of *P. vivax* at day 28 and 63 and risk of any parasitaemia. Estimates were pooled using meta-analysis and heterogeneity was investigated using meta-regression. We included 153 studies enrolling 31,262 patients. The risk of any recurrent parasitaemia by day 42 was 18.4% (95%CI 15.2-21.8; I^2=94.8%; 117 estimates) with 37.1% (28.2-46.2, I^2=92.2%) of these due to *P. vivax*. The risk of *P. vivax* parasitaemia was 5.6% (4.0-7.5; 92.7%; 117 estimates) by day 42 and 24.0% (18.0-30.6; 95.2%; 30 estimates) by day 63. *P. vivax* appeared later than *P. falciparum* recurrences and the risk was greater following rapidly-eliminated drugs and in studies undertaken in areas of short-relapse periodicity. The risk of *P. vivax* parasitaemia within 42 days of treatment with artemether-lumefantrine was 15.3% (4.1-31.4; 97.8%; 10 estimates). Partner drugs such as mefloquine or piperaquine delayed recurrence compared to lumefantrine, however, the risk of *P. vivax* parasitaemia was >15% by day 63 following all ACTs. In summary, following *P. falciparum* treatment, the risk of *P. vivax* parasitaemia is far greater than expected from reinfection alone. In co-endemic settings, universal radical cure with

an ACT and hypnozoitocidal agent, for patients with *P. falciparum* or *P. vivax*, has the potential to reduce all-cause recurrent parasitaemia and facilitate malaria elimination.

399

GENETIC STRUCTURE OF *PLASMODIUM FALCIPARUM* IN AN ENDEMIC AREA OF THE PACIFIC COAST OF SOUTH AMERICA

Claudia A. Vera[1], Silvia Ayala[1], Julio Valencia[2], Luis E. Castro[3], Fabián E. Sáenz[1]

[1]Center for Research on Health in Latin America, Quito, Ecuador, [2]Ministry of Health, Esmeraldas, Ecuador, [3]Ministry of Health, Guayaquil, Ecuador

Ecuador plans to eliminate malaria by 2023; indeed, the country has seen a decrease in the number or cases from more than 100 000 in 2001 to only 558 in 2015. Nevertheless, the number of cases has increased in recent years and approximately 1280 infections were reported in 2017, 30 % of which were caused by *P. falciparum.* Most malaria population genetics studies performed in Latin America indicate high clonality and clear structure of *P. falciparum* populations. An outbreak of *P. falciparum* in Northwest Ecuador was the result of a clonal expansion of parasites circulating at low levels in the country or re-invading Ecuador from neighboring territories. However, general characteristics of *P. falciparum* circulating in Ecuador have not been determined. The main goal of this study was to genetically characterize and geographically map the population structure of *P. falciparum* in Northwest Ecuador and determine how the *P. falciparum* population structure changed across time. For this purpose, seven neutral microsatellites markers in two groups of samples from two locations were used (79 samples collected from 2002 to 2006 and 109 samples collected from 2013 to 2016). We found that the genetic population structure of *P. falciparum* in Ecuador has changed from 2002 to 2016 while diversity decreased. Our analyses showed that parasites from border locations have higher diversity than parasites from inland locations and that Ecuadorian *P. falciparum* share genotypes with both Colombian and Peruvian parasites. In addition, *P. falciparum* genotypes not previously reported, were found in Ecuadorian locations. The *P. falciparum* diversity found in Ecuador could be a product of migration or the result of haplotypes circulating in the country in low proportions. Studies of the genetic characterization of *P. falciparum* in eliminating areas help determine the possible origin of parasites in order to create strategies to prevent the entrance of new lineages and achieve local elimination of malaria.

A MIXED METHOD STUDY OF HEALTH SEEKING BEHAVIOR FOR FEBRILE ILLNESSES AND ITS IMPLICATIONS FOR MALARIA CONTROL AND ELIMINATION IN SAVANNAKHET PROVINCE, LAO PDR

Bipin Adhikari[1], Koukeo Phommasone[2], Tiengkham Pongvosa[3], Palingnaphone Koummarasy[2], Xayaphone Soundala[2], Gisela Henriques[1], Pasathorn Sirithiranont[1], Daniel M Parker[4], Lorenz von Seidlein[1], Nicholas J White[1], Nicholas PJ Day[1], Arjen M Dondorp[1], Paul N Newton[2], Phaik Yeong Cheah[1], Christopher Pell[5], Mayfong Mayxay[2]

[1]Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [2]Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit (LOMWRU), Microbiology Laboratory, Mahosot Hospital, Vientiane, Lao People's Democratic Republic, [3]Savannakhet Provincial Health Department, Savannakhet Province, Laos, Savannakhet, Lao People's Democratic Republic, [4]Department of Population Health and Disease Prevention, University of California, California, CA, United States, [5]Centre for Social Science and Global Health, University of Amsterdam, Amsterdam, Netherlands

Health seeking behavior is shaped by interactions between individual and societal factors as well as health services. Analyses of the determinants of health seeking behavior are important for malaria control and elimination. The main objective of this study was to explore factors affecting the health seeking behavior for febrile illnesses in Lao PDR. Household heads or their representatives (n=281) were interviewed using a structured questionnaire. 8 to10 people from each study village (n=100) were included for focus group discussions (FGDs). Most respondents were *Lao Theung* (269/281; 95.7% that comprised ethnic groups: *Mang Kong*: 200/281; 71.7% and *Tree*: 64/281; 22.7%), males (201/281; 71.5%) and almost half were from the age group 31-50 years (138/281; 49.1%). Geographic proximity to a health centre (AOR=6.5; CI=1.74-24.25; for those < 3.5km versus those > 3.6km) and previous experience of attending a health centre (AOR=4.7; CI=1.2-19.1) were both strong predictors of visiting a health centre when febrile symptoms were experienced as opposed to traditional healers. Attending local health centers/hospitals was often constrained by the transportation and finances. The first choice for treatment for most participants was local health centres, even though there was a mix of seeking health care from traditional healers as well. Participants indicated that they navigate more than one type of health care system (health centre/hospitals and traditional healers). Decisions about where and when to attend formal health care facilities depended on finances, travel capabilities (distance to the health centre, road conditions, availability of transport), severity of symptoms and recognition of the illness (more likely to attend health centres/hospitals if considered severe). Reducing health care costs and increasing the ease of access to health care facilities may lead to improved health care attendance. Current and future malaria control programs can only benefit by addressing these factors in addition to collaboration with the existing network of health workers, village health volunteers and traditional healers.

401

IMPACT OF MOSQUITO LARVAL SOURCE REDUCTION ACTIVITIES OF TRAINED SCHOOL AGED CHILDREN IN THE CONTROL OF MALARIA IN NIGERIA

Olufunmilayo A. Idowu, Idris Otun

Federal University of Agriculture, Abeokuta, Abeokuta, Nigeria

Malaria prevention in Nigeria is focused almost entirely on the use of Long Lasting Insecticide Treated Bed-Nets (LLIN) with little or no attention on Larva Source Reduction (LSR). Involvement of school-aged children in health interventions have been found to be positive, therefore, this study was carried out to measure the impact of mosquito LSR activities of school-aged children (6-12 years) in the control of malaria. A total of 24 primary school-aged children were trained and engaged for LSR activities in the intervention community while no training was carried out in the control community. There were pre and post intervention assessment of social, entomological and parasitological indices in the study communities. The activities of the children were observed to significantly ($P<0.05$) reduce potential mosquito breeding sites and containers as well as larval abundance in the intervention community with a reduction in House Index (HI), Container Index (CI) and Breteau index from 66.67% to 16.67%, 46.91% to 8.02% and 211.1 to 33.3 respectively. Population of Indoor resting mosquitoes and an overall malaria parasite prevalence also reduced significantly in the intervention community from 40.8% to 23.0% ($P<0.05$). There were no significant reductions in any of the parameters measured in the control community. Knowledge of participants about mosquito breeding sites, consciousness to cover any water-holding containers and environmental hygiene were all observed to improve significantly ($P<0.05$) in the intervention community with 84.6% of respondents attributing their behavioral changes to the influence of the activities of the children. The LSR activities of the trained children in this study were seen to positively impact the intervention community; therefore, children participation in mosquito LSR may be a good strategy for malaria elimination

402

CASEIN DIETS PREVENT EXPERIMENTAL CEREBRAL MALARIA BY ENHANCING HOST PRO-INFLAMMATORY IMMUNE RESPONSES

Yonghui Feng[1], Xiaotong Zhu[2]

[1]The First Hospital of China Medical University, Shenyang, China, [2]China Medical University, Shenyang, China

Malaria and malnutrition are the major causes of morbidity and mortality in under-five children in developing countries. Based on the fact that casein hydrolyzate can regulate host immune responses, we investigate the related immune mechanisms in casein diet preventing experimental cerebral malaria (ECM). Female 6–8-weeks-old C57BL/6 mice were fed with different doses (5%, 20%, 35%) of casein diet or control diet for one month before infection with Pb ANKA to establish ECM. Thymus was weighed and αβ T cells and γδ T cells were assayed by FACS on Day 0 post infection. Splenic DCs, Th1 cells, Tregs and macrophages were determined by FACS on Day 3 post infection. The levels of cytokines from splenic supernatants were measured by ELISA or Greiess assay. 11 amino acids in the serum were assayed by API 4000 LC-MS/MS with Non-derivatized MSMS kit. Casein diets can reduce the parasitemia and prolong survival of ECM mice. Thymus atrophy was found in 5% casein diet group while γδ T cells were significantly increased in all casein diet groups. On d3 p.i., casein diets increased splenic Th1 cells and macrophages ($P<0.05$), and the similar trend was observed in IFN-γ, TNF-α and NO levels ($P<0.05$). Casein diet didn't affect the number of Tregs and IL-10 levels. L-Pro/L-Leu/L-Val/L-Tyr/L-Arg levels in the serum were significantly elevated in 20% Casein diet group. These data present the mechanism of casein diets in preventing ECM by improving host pro-inflammatory immune responses to control malaria infection.

IMPACT OF MASS TREATMENT WITH DIHYDROARTEMISININ PIPERAQUINE ON MALARIA TRANSMISSION DYNAMICS IN THE GAMBIA: A PROSPECTIVE STUDY

Julia Mwesigwa[1], Jane Achan[1], Miriam Wathou[1], Nuredin Ibrahim Mohammed[1], Musa Jawara[1], Aurelia Prom[1], Fatoumatta Kanuteh[1], Jean-Pierre Geertruyden[2], Umberto D'Alessandro[1]

[1]Medical Research Council Unit The Gambia at LSHTM, Banjul, Gambia, [2]University of Antwerp, Antwerp, Belgium

Mass drug administration (MDA) aims to reduce malaria transmission in addition to on-going control interventions. This study aimed to determine the impact of MDA on the dynamics of malaria, clinical disease, efficacy of dihydroartemisinin piperaquine (DP) and risk of re-infections immediately after and during the transmission season. All residents older than 6 months were enrolled in a prospective cohort from six village pairs. Annual single round MDAs with DP were carried out in 2014 and 2015 to all residents at the start of each transmission seasons (June). Individual finger prick samples were collected monthly (July to December) for slide microscopy and PCR. A total of 4312 subjects were enrolled, in both intervention years, both coverage (3 doses) (2014: 68.22%: 2015: 65.60%) and compliance (2014: 83.11% and 2015: 85.93%) were high. Monthly malaria prevalence was significantly lower in from July to September following MDA than in April 2014 and was significantly lower during the 2014 transmission season, after MDA, than in the 2013 transmission season. DP efficacy to malaria at days 28 and 42 for three doses was (AOR=0.62, 95% CI:0.38-0.99), and (AOR=0.51, 95% CI: 0.29-0.90) respectively and for clinical malaria in 2014 (AOR=0.44, 95% CI: 0.30-0.64) and (AOR=0.59, 95% CI:0.46-0.74) in 2015. Gametocyte carriage declined in July (4/55, 7.27%), August (2/70, 2.85%) and November after the first MDA round. Individuals infected before MDA had 2 times at higher odds of re-infection in July (AOR=2.53, 95% CI:1.49-4.29) and during the transmission season (AOR=2.49, 95% CI:1.72-3.62). A single annual MDA round was able to reduce both malaria prevalence and clinical disease incidence, at least in the first months of the transmission season. However, several MDA rounds, some of them targeting the human reservoir of infection during the dry season, may be needed to obtain a more marked reduction of transmission.

403

IMPACT OF MASS TREATMENT WITH DIHYDROARTEMISININ PIPERAQUINE ON MALARIA TRANSMISSION DYNAMICS IN THE GAMBIA: A PROSPECTIVE STUDY

Julia Mwesigwa[1], Jane Achan[1], Miriam Wathou[1], Nuredin Ibrahim Mohammed[1], Musa Jawara[1], Aurelia Prom[1], Fatoumatta Kanuteh[1], Jean-Pierre Geertruyden[2], Umberto D'Alessandro[1]

[1]Medical Research Council Unit The Gambia at LSHTM, Banjul, Gambia, [2]University of Antwerp, Antwerp, Belgium

Mass drug administration (MDA) aims to reduce malaria transmission in addition to on-going control interventions. Monthly malaria prevalence was significantly lower in from July to September following MDA than in April 2014 and was significantly lower during the 2014 transmission season, after MDA, than in the 2013 transmission season. DP efficacy to malaria at days 28 and 42 for three doses was (AOR=0.62, 95% CI:0.38-0.99), and (AOR=0.51, 95% CI: 0.29-0.90) respectively and for clinical malaria in 2014 (AOR=0.44, 95% CI: 0.30-0.64) and (AOR=0.59, 95% CI:0.46-0.74) in 2015. Gametocyte carriage declined in July (4/55, 7.27%), August (2/70, 2.85%) and November after the first MDA round. Individuals infected before MDA had 2 times at higher odds of re-infection in July (AOR=2.53, 95% CI:1.49-4.29) and during the transmission season (AOR=2.49, 95% CI:1.72-3.62). A single annual MDA round was able to reduce both malaria prevalence and clinical disease incidence, at least in the first months of the transmission season. However, several MDA rounds, some of them targeting the human reservoir of infection during the dry season, may be needed to obtain a more marked reduction of transmission.

404

MOTIVATION AND MANAGEMENT OF PARTICIPANT FATIGUE IN LONG -TERM RESEARCH: LESSONS FROM TARGET MALARIA RESEARCH

Elinor W. Chemonges

Uganda Virus Research Institute, Entebbe, Uganda

Despite registered progress in malaria control in sub-Saharan Africa, malaria still ranks high on the research agenda for development of new malaria control interventions. Scientists and donors derive motivation for continued research from anticipated progress/ acknowledgment on their contributions to solutions and increased knowledge base on malaria vectors and control methods. On the other hand, malaria endemic communities face the sting of the disease by deaths witnessed, high treatment expenses and declining efficacy of some existing methods. Paradoxically, it is in such communities that researchers seek cooperation of participants to contribute to research. Gaps in stakeholder engagement point to participant fatigue and declining levels of motivation hence Target Malaria's strategy to have a dedicated team of stakeholder engagement experts at the onset to ensure acceptance and consents for research activities. Early laboratory results indicate promise of the technology using genetically modified vector strains as a tool to reduce

malaria transmitting vector populations. Though still in its early stages, Target Malaria recognizes the value of co-development and has used qualitative research methods of observation, key informant interviews, focus group discussions with stakeholders to collect stakeholder concerns, complaints and suggestions to inform progress of the research. One of the challenges so far encountered is the quest by research participants seeking tangible (such as material and monetary) benefits as motivation to contribute to research progress at field study sites. In conformity to the ethical requirements against payment of research participants - undue influence/ or coercion, lessons have been learnt on innovative approaches to motivate research participants without giving tangible benefits while addressing participant fatigue. Analysis of emerging concerns point to the value of co-development in long-term research as a factor that increases motivation, reduces fatigue among participants and has potential to increase uptake of innovative malaria control technologies.

405

IMPLEMENTING REACTIVE CASE TREATMENT TO REDUCE MALARIA PARASITE CARRIAGE: HOW ADAPTABLE ARE LOCAL COMMUNITY STRUCTURES?

Joseph Okebe[1], Fatou Jaiteh[2], Edgard dabira[1], Yoriko Masunaga[2], Amadou Bah[1], Joan Muela-Ribera[3], Julie Balen[4], Koen Peeters Grietens[2], Umberto D'Alessandro[1]

[1]Medical Research Council Unit The Gambia at the London School of Hygiene & Tropical Medicine, Banjul, Gambia, [2]Medical Anthropology Unit, Department of Public Health, Institute of Tropical Medicine, Antwerp, Belgium, [3]Medical Anthropology Research Center (MARC), Universitat Rovira i Virgili, Tarragona, Spain, [4]School of Health and Related Research, The University of Sheffield, Sheffield, United Kingdom

Interventions to clear the human reservoir of infection typically involve mass treatment of at-risk populations. These campaigns usually operate as vertical programs, in parallel to local health systems, requiring substantial investments to set up and operate, and face the challenge of adequate coverage and compliance. The Gambia has recorded significant reductions in malaria burden, especially in its western and central regions, and is considering options for elimination. As part of a trial on the impact of reactive treatment of contacts of clinical malaria cases on parasite carriage, we considered the feasibility of delivering treatment to affected compound members using the existing local health and social structures. In a stepwise iterative approach, we designed and evolved a process to deliver a full, weight-derived course of antimalarial treatment to all members of a compound within 24 hours of a case of malaria being diagnosed. Drug distribution and reporting of adverse events were progressively devolved from study personnel to the local village health workers (VHW). The study team monitored treatment adherence and comprehension of dosing via phone calls and house visits when required. There were 17 cases from 12 compounds (population 367) in five villages reported during the 2017 transmission season. Most (16/17) were diagnosed and treated by the VHW who also delivered treatment to 273 of the 350 (78%) compound members present at the time of the event. There was no refusal to participate. Adherence, measured by number of individuals who completed three doses, was 94% (253/273). There were 27 mild adverse effects reported which resolved without intervention. Community systems, VHWs and compound heads represent an effective and acceptable platform for the delivery of reactive treatment to at-risk populations. The feasibility of this approach for other interventions and settings needs further evaluation.

406

SOCIAL STRUCTURAL IMPLICATIONS OF MALARIA VACCINE TRIALS IN EQUATORIAL GUINEA

Esther L. Eburi-Losoha[1], Ally Olotu[2], Antonio Sama[1], Stephen Manock[3], Carl Maas[4], Guillermo Garcia[1], Carlos Cortes[1], Salim Abdullah[2], Stephen Hoffman[3]

[1]Medical Care Development International, Malabo, Equatorial Guinea, [2]IHI, Bagamoyo, Tanzania, United Republic of, [3]Sanaria, Maryland, MD, United States, [4]Marathon Oil, Malabo, Equatorial Guinea

The Equato-Guinean Malaria Vaccine Initiative (EGMVI) was established in 2014. The goal of the EGMVI is to reach elimination on the island of Bioko, in conjunction with the Bioko Island Malaria Control Program. New strategies to achieve this goal are being planned through. the inclusion of the PfSPZ Vaccine with other standard malaria control interventions. The EGMVI recently completed the second phase of clinical trials to determine product safety and efficacy, in route toward applying the vaccine on Bioko's population. Before entering Phase III trials, it will be important to understand the community perception of the candidate malaria vaccine. The primary goal is to understand the potential impact of malaria vaccine clinical trials on socio-economic and health (SEH) aspects of trial participants in their respective communities. Understanding attitudes towards the vaccine, perceived benefits and concerns, are important for designing communication strategies, and will inform how SEH dynamics may impact subsequent vaccine uptake. Mixed-methods will used to analyze data from participants from several neighboring communities where clinical trials are held. Data will come from qualitative focus group discussions and in-depth interviews. Quantitative surveys will be administered to capture data on individuals from trial and non-trial communities. Health professionals and community stakeholders will also be surveyed. Findings suggest that participant motivation to participate and to recommend their family members and friends to participant in trials will influence subsequent vaccine uptake. Identified desired channels of vaccine administration and its implications for the cost effectiveness of a mass vaccination on Bioko Island will be discussed.

407

UNDERSTANDING MOBILE POPULATIONS BEYOND MOBILITY: INSIGHTS FROM SOCIAL INQUIRY FOR MALARIA ELIMINATION

Koen Peeters Grietens[1], Charlotte Gryseels[1], Thuan Thi Nguyen[2], Xuan Xa Nguyen[2], Srun Set[3], Sokha Suon[3], Claudia Nieto[1], Joan Muela[4], Annette Erhart[5], Umberto D'Alessandro[5]

[1]Institute of Tropical Medicine, Antwerp, Belgium, [2]National Institute of Malariology, Parasitology and Entomology, Hanoi, Viet Nam, [3]National Institute of Malariology, Parasitology and Entomology, Phnom Penh, Cambodia, [4]Universitat Rovira i Virgili, Tarragona, Spain, [5]MRC Unit The Gambia, Fajara, Gambia

Recent studies acknowledge the impact of human population movements on maintaining (a)symptomatic malaria reservoirs, spreading (resistant) parasites and increasing exposure to vectors. Drawing on social inquiry into human mobility as part of interdisciplinary research into malaria transmission dynamics and the effectiveness of malaria control strategies carried out by the authors in South-East Asia (SEA), Sub-Saharan Africa (SSA) and Latin America, we aim to highlight overlooked factors in defining mobile populations despite their key importance for heterogeneous elimination settings. Effective control strategies require scientific knowledge to distinguish and characterize different types of mobile populations as each group represents specific risk factors and hence different and appropriate interventions. Absent populations are even more difficult to deal with: nation states and more specifically public health institutions lack the capacity and the tools to efficiently target these populations. This is made more difficult by the lack of data on mobility as this is a common exclusion criterion in most biomedical and clinical studies, limiting available data on infection, transmission dynamics

and vulnerability. An additional, rarely recognized challenge is that for specific ethnic groups, mobility is a defining characteristic of their social identity, often constructed in opposition to sedentary populations whose attitudes historically vary between trust and distrust. Indeed, nomadic cattle herders in SSA often distrust 'sedentary' health interventions while ethnic minorities in SEA (*e.g.* Vietnam), representing the main hotspots of residual malaria transmission, hesitate between assimilation and resistance to official state-based policies, including malaria control. Similar considerations apply to indigenous people in the Americas (*e.g.* Ecuador and Peru). Malaria elimination will be possible only if mobile populations are adequately targeted and involved by interventions.

408

COMMUNITY LAB OF IDEAS FOR HEALTH (CLIH): HORIZONTAL DIALOGUE AND NEGOTIATION OF RELEVANCE FOR MALARIA ELIMINATION TRIAL IN THE GAMBIA

Yoriko Masunaga[1], Fatou Jaiteh[2], Julie Balen[3], Umberto D'Alessandro[2], Joseph Okebe[2], Koen Peeters Grietens[1], Joan Muela Ribera[4]

[1]Institute of Tropical Medicine, Antwerp, Belgium, [2]Medical Research Council Unit The Gambia, Fajara, Gambia, [3]University of Sheffield, Sheffield, United Kingdom, [4]Partners for Applied Social Sciences International, Tessenderlo, Belgium

Despite decades of the scientific attention and financial efforts, malaria remains as a global threat. It is therefore timely to consider innovative medical but also social approaches, such as community participatory strategies. "Community Lab of Ideas for Health (CLIH)" approach was developed in the context of a clinical trial on reactive case detection and treatment for malaria in The Gambia (*Reactive Household-based Self-administered Treatment: RHOST)*. The trial treated both passively detected malaria patients and all individuals (possibly asymptomatic) residing in the patient's compound in order to interrupt transmission. As part of the trial, a mixed-methods anthropological study was conducted to understand communities and tailor the intervention to the local context. A platform (*lab*) was created for the dialogue between communities and the project including researchers from different collaborating disciplines. This CLIH served to exchange ideas and co-create the required relevance of and trust in the intervention for both the project and communities. This relevance was largely defined around the economic burden of malaria instead of its definition in terms of health outcomes. Income opportunities lost and the spiral of poverty functioned as a common language around which this relevance could be negotiated. An additional key function was the reinforcement of mutual trust through negotiating the accountability of the project in relation to the micro-politics of the community and the reinforcement of local resources, in this case the Village Health Worker, to sustain and enhance the existing health system. Adherence to the treatment (Dihydroartemisinin-Piperaquine) for reactively identified contacts of malaria patients, at least in large part attributable to the CLIH, was as high as 94%, suggesting the relevance and additional potential for CLIH and other participatory applications.

409

IMPROVING THE EFFICIENCY OF REACTIVE SCREEN-AND-TREAT FOR MALARIA ELIMINATION IN SOUTHERN ZAMBIA

Fiona R. Bhondoekhan[1], Harry Hamapumba[2], Mukuma Lubinda[2], Japhet Matoba[2], Kelly M. Searle[1], Timothy M. Shields[1], Douglas E. Norris[1], Jennifer C. Stevenson[3], Philip E. Thuma[3], William J. Moss[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Macha Research Trust, Choma District, Zambia, [3]Johns Hopkins Malaria Research Institute, Baltimore, MD, United States

Malaria screen-and-treat (Step-D in Zambia) is a reactive case detection strategy in which malaria cases confirmed at health centers trigger community health workers (CHWs) to screen for secondary cases within 140 m of the index case household with P*f*HRP2 RDTs. Few studies have evaluated whether an evidence-based strategy using environmental features that characterize household surroundings can improve the efficiency of secondary case identification. This study conducted in the catchment area of Macha Hospital, Choma District, Zambia, extended the screening radius to 250 m and assessed whether local environmental factors can guide CHWs to identify secondary cases more efficiently. Demographic information, bed-net use, and household construction were obtained from surveys. Households were stratified into malaria positive and negative secondary households using RDT and qPCR results. High resolution satellite imagery was imported into ArcGIS and used to generate local environmental features (i.e. number of animal pens within 100 m, distance to nearest animal pen, distance and elevation difference between index and secondary houses) and large-scale features (i.e. distance to main road and nearest stream category). Generalized estimating equations were used to estimate the difference in odds between positive vs. negative secondary households for each predictor. From January 12, 2015 to July 26, 2017, 4,202 individuals residing in 692 households were enrolled. 165 participants tested positive for malaria by RDT or qPCR, 66% of whom resided in index households. Parasite prevalence was 8.6% and 1.9% in index and secondary households, respectively. Stratification resulted in 488 negative secondary and 45 positive secondary households. Results from the regression model revealed 50%, 90%, and 50% significantly higher odds of a secondary household being malaria positive if the nearest stream category was 3, 4, or 5, respectively. Screening for secondary households within a low-transmission setting in rural southern Zambia could be optimized by using streams as environmental features to guide more efficient reactive case detection.

410

QUALITY CONTROL AND QUALITY ASSURANCE: RECOMBINANT HUMAN G6PD PLUS HEMOGLOBIN AS A RESOURCE FOR ROBUST G6PD TESTING IN *PLASMODIUM VIVAX* RADICAL CURE

Maria Kahn

PATH, Seattle, WA, United States

Quality Control and Quality Assurance: Recombinant human G6PD plus hemoglobin as a resource for robust G6PD testing in *Plasmodium vivax* radical cure Maria Kahn, ChangCheng Zhu, Sampa Pal and Gonzalo Domingo PATH, Seattle, WA

Robust glucose-6-phosphate dehydrogenase (G6PD) tests are currently under development to meet the needs for radical cure of *Plasmodium vivax* with 8-aminoquionlines. A large gap for the support of point-of-care testing is the availability of reagents to support quality control of G6PD diagnostic test along the supply chain from the manufacturer to the end user. While reagents and systems exist to support QC of laboratory screening tests for G6PD deficiency, they are not configured appropriately to support point-of-care testing. Here we have demonstrated the feasibility of using lyophilized recombinant human G6PD as a QC reagent for novel point-of-care tests for G6PD tests. For the calibration of quantitative G6PD tests, a combination of recombinant G6PD plus hemoglobin was used to create panels of normal, intermediate and deficient controls. Both recombinant human G6PD and hemoglobin were combined and lyophilized with appropriate excipients to produce the integrated G6PD-Hb control reagent in different concentrations. Lyophilized material demonstrated stable G6PD enzyme activity and hemoglobin concentration on reconstitution. Real time and accelerated stability data performed over at least 6 months and over five different temperatures will be presented. These control reagents will be essential to support the framework for a sustainable QC/QA system of robust point-of-care G6PD testing for *Plasmodium vivax* radical cure.

411

MALARIA ELIMINATION IN ZANZIBAR - WHY HAS IT NOT YET SUCCEEDED ?

Anders Björkman[1], Mwinyi Msellem[2], Ulrika Morris[1], Wahid Al-Mafazy[3], Humphrey Mkali[4], KA Haji[3], Deler Shakely[5], Andreas Mårtensson[6], Abdullah S. Ali[3], Abdullah S. Ali[3]

[1]Karolinska Institutet, Stockholm, Sweden, [2]Mnazi Moja Hospital, Zanzibar, United Republic of Tanzania, [3]Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania, [4]MEASURE Evaluation, Dar es Salaam, United Republic of Tanzania, [5]Sahlgrenska Academy, Gothenburg, Sweden, [6]Uppsala University, Uppsala, Sweden

Malaria control in Zanzibar has successfully and uniquely reduced the hyperendemic situation before 2004 to presently low hypoendemicity, a pre-elimination stage with an astounding public health impact. However, epidemiological analyses reveal several obstacles and challenges that necessitate new tools and strategies in order to achieve full elimination on the isles. Some challenges relate to genetic shifts of the parasite and mosquito populations to escape diagnosis and treatment as well as vector control interventions respectively . Piloted new interventions and strategies have only provided partial impact, not significant enough to fully respond to the new challenges. The Zanzibar malaria control/elimination coverage, impact and transmission dynamics will be presented and a research and operational road map will be proposed in order to bend the present curve and potentially provide proof of concept of malaria elimination from a high malaria endemic area typical of sub-Saharan Africa.

412

PREVENTION OF MALARIA REINTRODUCTION THROUGH ELIMINATION ACTIVITIES AND MALARIA CASE INVESTIGATION AND CLASSIFICATION IN SAMPOV LOUN OPERATIONAL DISTRICT, CAMBODIA

Sokomar Nguon[1], Samphornarann Top[1], Linna Khorn[1], Sovann Ek[1], Kongmeng Seak[1], Yom An[1], Saman Sen[1], Sidavy Kun[1], Rida Slot[2], Gunawardena Dissanayake[2], Rekol Huy[3], Pisal Heng[3], Huch Chea[3], Sovannaroth Siv[3], Po Ly[3], Bunthy Om[4], Maysak Meas[4], Tamar Gabunia[1], Sharon Thangadurai[1], Paul Bacon[1], Neeraj Kak[5], Soy Ty Kheang[1]

[1]University Research Co., LLC, Phnom Penh, Cambodia, [2]President's Malaria Initiative, U.S. Agency for International Development, Phnom Penh, Cambodia, [3]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [4]Sampov Loun Operational District, Battambang, Cambodia, [5]University Research Co., LLC, Chevy Chase, MD, United States

Since July 2015, the Cambodia National Malaria Program (CNM) has been implementing malaria elimination activities in Sampov Loun Operational District (SPL OD) with support from USAID | PMI. A 1-3-7 active surveillance strategy is applied to ensure every case detected is notified within 24 hours, investigated within 3 days, and responded to within 7 days. Through the 1-3-7 strategy, after a case is notified, a team led by the OD malaria supervisor with health facility staff and a village malaria worker, conducts a case investigation. The investigation collects the patient profile, current diagnosis result, travel history during the last three weeks and malaria history during the last three months. Case classification determines if the case is locally transmitted (indigenous) or imported from outside SPL OD. Simultaneously, response activities through reactive case detection (Re-ACD) surrounding the index case include screening of index household (HH) members, co-travelers, and surrounding HH members who present suspected malaria symptoms, assessing net availability and top up, and providing health education. From July 2015 to February 2018, results show a high percentage of timely notification, investigation, and response increasing from 20-52% within the first 3 months to 85-100% in all 1-3-7 categories. To-date, 596 cases were investigated and classified. From July 2015 - March 2016, 28 indigenous cases were identified within 9 of 127 villages. Since March 2016, no indigenous *Pf* malaria cases were detected. Other response activities included health education to 3,091 people, 250 insecticide-treated nets (ITNs) topped up and 1,752 individuals surrounding index cases screened through Re-ACD. Re-ACD identified no cases among index and surrounding HHs, however 3% of co-travelers were diagnosed with malaria. These findings suggest a positive impact from the package of response activities in preventing reintroduction of locally transmitted *Pf* cases in SPL OD since April 2016 (as of February 2018). Screening household and neighbor contacts identified no new infections and is likely not a cost-effective use of resources in this setting.

413

VILLAGE-BASED STRATIFICATION IN MYANMAR FOR MONITORING AND TO INFORM SELECTION OFMALARIA INTERVENTIONS

Sway M. Htet[1], Saw Lwin[1], Ye H. Naing[1], Saw N. Naung[1], Thant Z. Aung[1], Bo B. Ko[1], Kaung M. Min[1], San K. Khine[2], Zayar Kyaw[2], Aung Thi[2], Kyaw M. Tun[1]

[1]University Research Co.,LLC, Yangon, Myanmar, [2]Vector Borne Disease Control, Naypyitaw, Myanmar

Current malaria endemicity in Myanmar shows focal characteristics. Even within one township, the level of malaria transmission can significantly vary depending on environmental and socio-economic-demographic factors. In 2013, University Research Co.(URC), implementer of the PMI-supported Control and Prevention of Malaria Project, developed a Village-Based Stratification (VBS) framework using Annual Blood Examination Rate (ABER) and village-based Test Positivity Rate (TPR) to monitor malaria endemicity and choose appropriate interventions. The project applied the VBS by specifying village population, collecting patients' addresses, monitoring adequacy of community diagnosis with an ABER ≥10%, and stratifying villages according to the number of cases reported in the previous year. Villages were stratified into 3 categories using the TPR criteria: high transmission (TPR ≥5%, red color), moderate-low transmission (TPR >0-<5%, yellow), and no transmission (no cases detected the past year, green). The VBS framework was applied to 272 villages of South Rakhine State and Tanintharyi Region with a sufficient ABER≥10% for 4 consecutive years and the following results were obtained: 100 villages with TPR ≥5%, 103 villages with a TPR >0-<5%, and 69 villages with no malaria, as stratified in September 2014, changed into TPR ≥5% for 34 villages, TPR >0-<5% for 68 villages, and no malaria for 170 villages, in September 2017. In 2016, URC modified the VBS according to the new stratification criteria adopted by the National Malaria Control Program using Annual Parasite Incidence (API) instead of TPR for categorization into high-moderate-low transmission, potential transmission (receptive with no current transmission), and malaria free. Villages with malaria in the previous year are stratified by tercile, tailoring API data for best applicability. Stratification can be done using existing routine surveillance data and is very useful for monitoring progress and providing strategic information to target appropriate interventions for different strata in developing countries with limited resources.

414

ASSESSMENT OF MALARIA SERVICES OFFERED BY PRIVATE PROVIDERS IN RURAL, UNDER-SERVED AREAS OF TANINTHARYI REGION, MYANMAR

Bo Bo Thet Ko[1], Saw Lwin[1], Feliciano Monti[2], Taylor Price[3], Hala Jassim AlMossawi[4], Khin Than Win[1], Thin Thin Chit[1], Sai Nay Min Shein[1], Zar Ni Htun[1], Kyaw Myint Tun[1]

[1]University Research Co., PMI Defeat Malaria Project, Yangon, Myanmar, [2]USAID/U.S. President's Malaria Initiative, Yangon, Myanmar, [3]University Research Co., LLC, PMI Defeat Malaria Project, Washington, DC, United

States, [4]University Research Co., LLC, PMI Defeat Malaria Project, Washington, DC, United States

In Myanmar, a move towards malaria elimination requires expanding coverage of malaria services to all populations at-risk, in particular those living in rural, under-served areas where neither health facilities nor village malaria workers are available. To assess the extent and type of malaria services provided by private providers (PPs) in under-served areas, the PMI-supported Defeat Malaria project conducted in August 2017 a mapping of PPs in 179 villages of Tanintharyi Region. The survey identified 118 private practitioners and 1,145 drug stores, of whom only 12 (1%) sold anti-malarial drugs. Of the 130 PPs offering malaria services (118 private practitioners and 12 drug sellers), 41 (32%) had not received any malaria training, 42 (32%) did not have any malaria rapid diagnostic tests (RDT), and 45 (35%) did not have artemisinin-based combination therapy (ACT) or other anti-malaria drugs. Eighty-five of the 130 PPs were identified as prescribers of anti-malarial drugs, and 14 (16%) of them had artesunate and/or artemether monotherapies, while the remaining used ACTs. PPs were present in 86 (48%) of the 179 villages, and people from the other 93 villages received malaria health services from nearby public facilities. From qualitative key informant interviews by convenience sampling with 20 (15%) PPs it emerged that anti-malarial drugs were not available in most drug stores due to low demand, restriction of selling unregistered drugs and anti-malaria monotherapy, and free provision of drugs by NGOs and public facilities. Most PPs weren't aware of the national malaria drug policy. Ninety-one (70%) PPs had previously referred patients to public facilities or NGOs. Not all PPs could provide malaria services due to lack of malaria training, RDTs or ACTs, or an appropriate referral mechanism. PPs from rural, under-served areas should be appropriately trained, supported for malaria service provision, encouraged to engage in a timely referral mechanism and case reporting, and receive information on Myanmar's national malaria treatment policy.

415

MALARIA ELIMINATION IN NORTHERN AND CENTRAL LAO PDR: ASSESSING TECHNICAL, OPERATIONAL, AND FINANCIAL FEASIBILITY

Valerie K. Scott[1], Andrew Lover[1], Emily A. Dantzer[1], Bouasy Hongvanthong[2], Adam Bennett[1]

[1]Malaria Elimination Initiative, Global Health Group, University of California San Francisco, San Francisco, CA, United States, [2]Center for Malariology, Parasitology and Entomology (CMPE), Ministry of Health, Vientiane, Lao People's Democratic Republic

Northern and Central Lao PDR is rapidly accelerating towards malaria elimination. In 2017, there were 454 reported malaria cases across 13 provinces, accounting for only 5% of the national malaria burden. Nearly two-thirds of cases occurred in just four districts. Based on these trends, the Center for Malariology, Parasitology, and Entomology (CMPE) established goals to eliminate *Plasmodium falciparum* malaria by 2020 and *P. vivax* malaria by 2025 from these areas of Lao PDR. In support of these goals, the first malaria elimination feasibility assessment for Northern and Central Lao PDR was conducted in early 2018 to inform strategic decisions and operational planning. In accordance with the 2014 WHO elimination scenario planning tool, this assessment examines technical, operational, and financial feasibility. The technical assessment integrates national surveillance data analysis, findings from a population-based parasitemia and risk factor survey and qualitative research, and mathematical modelling to predict the impact of various intervention scenarios on malaria transmission. A comprehensive literature review and semi-structured interviews with key stakeholders were also conducted. Achieving elimination in Northern and Central Lao PDR in line with national strategic timelines is feasible using currently available tools. Key technical strategies required include strengthening case management (training, supportive supervision, expanded community-based care); improving coverage and targeting of vector control; and introducing case-based surveillance and rapid response. Operational capacity must be strengthened to support these technical strategies, including improvements in availability of trained staff, access to district funds, stock management, communications, and program management. Interventions, training, and staffing were costed using an activity-based approach to estimate resource needs. Sustained investment in high quality interventions and operations will be required to achieve malaria elimination and prevent resurgence in Northern and Central Lao PDR, paving the way for national elimination.

416

COMBINING SEROLOGICAL AND CLINICAL INCIDENCE METRICS FROM EASY ACCESS GROUP SURVEYS AND ROUTINE SURVEILLANCE TO GUIDE ELIMINATION ACTIVITIES IN HAITI

Lotus L. van den Hoogen[1], Thomas Druetz[2], Eric Rogier[3], Gillian Stresman[1], Vena Joseph[2], Kevin K. Tetteh[1], Alyssa Young[4], Alexandre Existe[5], Jacques Boncy[5], Ruth Ashton[2], Thomas P. Eisele[2], Michelle A. Chang[3], Jean F. Lemoine[6], Chris Drakeley[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Tulane University School of Public Health & Tropical Medicine, New Orleans, LA, United States, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Clinton Health Access Initiative, Boston, MA, United States, [5]Laboratoire National de Santé Publique, Port-au-Prince, Haiti, [6]Ministère de la santé publique et de la population, Port-au-Prince, Haiti

The island of Hispaniola is the last remaining endemic area of malaria in the Caribbean. In Haiti, nation-wide PCR/RDT prevalence was below 1% in 2011, 2012, 2015 and 2017. However, heterogeneity is pronounced and there is limited insight to date as to how cases detected through routine surveillance relate to malaria transmission in the community. We aim to compare transmission intensity estimates by health facility catchment area using antimalarial antibody responses in multiple populations sampled to support elimination activities by Haiti's Ministry of Public Health and Population. Data sources included a sample of easy access group venues (EAG; 9 health facilities, 23 schools; n=4233) and routine health surveillance (RHS; 9 health facilities) in the Artibonite Valley in Haiti. Antibody responses (IgG) against 23 malarial antigens were assessed in the EAG survey using a multiplex bead assay (including 6 markers of sero-incidence). All the cases recorded at health facilities were confirmed with malaria rapid diagnostic tests. Spearman's rank sum agreement was used to assess the crude agreement according to venue type and metrics by age groups. The optimal combination of antibody metrics from the Artibonite data was then applied to data from an EAG survey (n=4922; 16 health facilities, 25 schools) and RHS (16 health facilities) in the Grand'Anse Department in southern Haiti. Serological metrics from EAG surveys may help in identifying communities with ongoing malaria transmission to guide elimination activities in Haiti.

417

PERCEPTION OF MALARIA RISK AND ACCEPTABILITY OF REACTIVE, FOCAL ADMINISTRATION OF PRESUMPTIVE TREATMENT AND INDOOR RESIDUAL SPRAYING, A QUALITATIVE STUDY FROM THE MALARIA ELIMINATION SETTING OF NAMIBIA

Cara Smith Gueye[1], Kathryn Roberts[1], Henry Ntuku[2], Flavian Libita[2], Braster Kakula[2], Alysse Maglior[1], Valerie Scott[1], Agnes Mwilima[3], Petrina Uusiku[4], Michelle Hsiang[1], Kimberly Baltzell[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Global Programs for Research and Training, Windhoek, Namibia, [3]Ministry of Health and Social Services Zambezi Namibia, Katima Mulilo, Namibia, [4]Ministry of Health and Social Services Namibia, Windhoek, Namibia

To reduce and interrupt malaria transmission in elimination settings, reactive, focal presumptive treatment and indoor residual spraying (IRS)

target the parasite reservoir in humans and mosquitoes. However, low acceptance of treatment without evidence of malaria infection, or of reactive, focal IRS could limit widespread implementation and success. As part of a cluster randomized trial in Zambezi Region, Namibia, comparing reactive focal screening and treatment to presumptive treatment, and reactive focal IRS to no IRS, qualitative data collection was conducted prior to (August 2015) and during two rounds of trial implementation (June - August, 2016 & 2017). Data collection included: 15 focus group discussions (FGDs) and six interviews prior to interventions, and 34 FGDs and four key informant interviews during and after the interventions. Pre-trial findings show that most participants believed malaria interventions are effective, but IRS and long-lasting insecticide treated nets (LLINs) are not always available. Some respondents expressed discomfort accepting medication without symptoms or testing, but with education would be more likely to accept. Potential barriers included use of traditional healers, distrust of public sector health staff and interventions for their potentially stigmatizing effects. Practices that could influence acceptance included offering community-based care and ongoing community sensitization and education. During the trial, perceptions of malaria risk were closely related to presence of illness in the community. Reasons for participating included effective recruitment, the opportunity to learn, feeling unwell, and level of disease in the community. Most refusals were attributed to being busy or away from home. When considering improvements, members suggested they be informed of visits in advance to prepare, more interventions in more areas, and to fill gaps in LLIN distribution. The community preferences identified during the trial led to an increase in efforts to inform communities in advance and better coordination of the clinical teams to increase acceptance of trial interventions.

418

THE CONTRIBUTION OF MALARIA VULNERABLE PEOPLE LIVING WITH HIV/AIDS TO MALARIA CONTROL

Ewurama D. Owusu[1], Sampson K. Djonor[1], Charles A. Brown[1], Petra F. Mens[2], Martin P. Grobusch[2]

[1]University of Ghana, Accra, Ghana, [2]Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands

Ghana has made many strides in the fight against malaria. However, the shared geographical location of HIV and malaria may influence interactions of these diseases. People living with HIV/AIDS are vulnerable to malaria in malaria-endemic settings. Our research looked at diagnostics of malaria in people living with HIV/AIDS (PLHA) using a rapid diagnostic test that is locally common, expert microscopy and PCR. We also studied their knowledge and practices with regard to malaria prevention in rural and urban Ghana. Locally available HRP2-based malaria rapid diagnostic tests were comparable to the PCR gold standard. However, few false negatives detected did not test positive for the *pfhrp2/3* gene. Residents in the rural area were less informed of malaria and its preventive measures than those in the urban areas. Their knowledge was associated with increased odds for malaria. The common practice in both areas was the low use of insecticide treated mosquito nets even though many people owned them. Further focus of national malaria control program may help in the exponential decline of malaria in Ghana. Perhaps, an integrated control program for both HIV and malaria may prove to be beneficial.

Passively collected routine health facility data are an underutilized source of information for estimating the burden of malaria, identifying remaining hotspots, and developing risk maps for targeting scarce resources. We extracted routinely collected monthly health facility data from January 2013 until December 2016 to describe risk factors, identify hotspots, and generate spatial risk maps of malaria in Aceh Besar and Aceh Jaya districts, in Aceh Province, Indonesia. Demographic, employment, location of residencies, and parasitological data, including date of febrile, date of diagnosis and date of treatment were assembled from Primary Health Center registry books. Case locations were geo-located based on village names using Google Maps and other map resources. The resulting geo-database was then integrated into a Geographic Information System using the open-source QGIS software. We included 2,412 malaria positive individuals from both districts in the analysis. Number of malaria positive individuals decreased from 1,532 patients in 2013 to 133 patients in 2016. *Plasmodium vivax* was the most dominant infection (88.4%), altogether with other species of *Plasmodium* malaria infections, such as *P. falciparum* (9.2%), *P. malariae* (0.1%), *P. knowlesi* (0.2%) and mixed infections (3%). Most individuals with positive malaria were forest-related workers (96.4%), such as miners (77.1%), farmers (11.9%) and loggers (7.3%). Multivariable logistic regression will be used to establish socio-demographic and environmental risk factors including forest cover, and geostatistical analyses will be conducted to produce species-specific risk maps.

QUANTIFYING MOVEMENT PATTERNS OF MOBILE MIGRANT POPULATIONS DURING A MALARIA FOCAL TEST AND TREAT INTERVENTION IN SOUTHERN LAO PDR

Sophia Hocini[1], Francois Rerolle[1], Andrew Lover[1], Emily Dantzer[1], Bouasy Hongvanthong[2], Rattanaxay Phetsouvanh[3], Adam Bennett[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Center for Malariology, Parasitology, and Entomology, Ministry of Health, Vientiane, Lao People's Democratic Republic, [3]Department of Communicable Disease Control, Ministry of Health, Vientiane, Lao People's Democratic Republic

In the Greater Mekong Subregion, mobile and migrant populations (MMPs) are considered at higher risk for malaria infection due to forest-going and travel-related behaviors. In the Lao People's Democratic Republic (PDR), MMPs engage in a diverse set of forest-based activities for economic gain and general livelihood, increasing their risk for malaria. Much remains unknown about MMPs in Lao PDR, and more evidence is needed to properly characterize and respond to these at-risk populations. In particular, movement patterns are an important component of MMP behavior and necessitate further research to better clarify links between mobility and malaria occurring outside of village settings. As part of a larger active case detection trial in Champasak province, Southern Lao PDR, a focal test and treat intervention employing 30 peer navigators

(PNs) to seek out non-village based MMPs is underway across 15 health center catchment areas (HCCAs). An estimated subset of 50 PN-identified MMPs will be recruited to carry "i-Got-U" GPS loggers to characterize and quantify mobility patterns. Evaluated outcomes will include time spent outdoors, outdoor movement during evening and dawn hours, time spent in the forest, distances traveled, and frequency of travel by MMPs. MMP travel proximity to borders, bodies of water, forest fringe, and deeply forested areas will also be assessed. Data collection is ongoing through September 2018 and will be followed by a cluster analysis to compare mobility patterns of PNs and identified MMPs. PN movement will be analyzed in the context of the study to reveal coverage across HCCAs and to support analyses of MMP movement patterns. Collected GPS data will be used to examine the locations of identified MMPs, MMPs with malaria, and areas with the highest densities of MMPs, as well as possible transmission hotspots. These parameters of MMP movement patterns will be used to inform development of mathematical models of malaria transmission in high-risk mobile forest-goer populations. Findings from this study will help to further define MMP behavior and its possible impacts on malaria transmission in Southern Lao PDR.

MODELLED PREDICTED PUBLIC HEALTH IMPACT AND COST-EFFECTIVENESS OF CHILDHOOD RTS,S/AS01E MALARIA VACCINE IN MALAWI, USING A MARKOV STATIC MODEL

Latif Ndeketa

Malawi-Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, Malawi

The RTS,S/AS01E is the most advanced malaria vaccine to date being assessed in Malawi, Ghana and Kenya as part of a large-scale pilot implementation programme involving over 700,000 children. As its incorporation into existing immunisation programmes will have substantial cost implications, cost-effectiveness studies provide an essential tool for countries to consider vaccine introduction. We explored the predicted health impact and cost-effectiveness of the RTS,S/AS01E malaria vaccine on the childhood population of Malawi. We calculated the Incremental Cost Effectiveness Ratio (ICER) per disability adjusted life years (DALYs) averted by vaccination and compared it to Malawi's mean per capita Gross Domestic Product. We used a previously validated and published Markov model, which simulated the malaria progression in a 2017 birth cohort of Malawian children less than 15 years old. In the simulation, we used a 46% vaccine efficacy as demonstrated in the phase 3 trials, 75% RTS,S/A01 coverage, estimated $5 cost of the vaccine, treatment costs for clinical malaria from previous publications and Malawi specific indicators for malaria interventions such bet net use and antimalarial use. Both health service and societal perspectives were explored. The ICER/DALY was $115, lower than the 6 year mean GDP per capita of $398.6 for Malawi. Sensitivity analyses exploring the impact of variation in vaccine costs, vaccine coverage rate and coverage of 3 doses and 4 doses showed vaccine implementation would be cost-effective across a wide range of scenarios. RTS,S/AS01 was predicted to avert a median of 93 940 (range 20 490-126 540) clinical cases and 394 (127-708) deaths for the three-dose schedule, or 116 480 (31 450-160 410) clinical cases and 484 (189-859) deaths for the four-dose schedule, per 100 000 fully vaccinated children. We predict the introduction of the RTS,S/AS01 vaccine in the Malawian EPI to be to be highly cost effective.

FUNCTIONAL ACTIVITY AND HOST IMMUNE RESPONSE OF *PLASMODIUM VIVAX* RETICULOCYTE BINDING PROTEIN 2P1

Anongruk Chim-Ong[1], Thitiporn Surit[2], Sittinont Chainarin[1], Jetsumon Sattabongkot[3], Wanlapa Roobsoong[3], Liwang Cui[4], Wang Nguitragool[1]

[1]Department of Molecular Tropical Medicine, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [2]Department of Clinical Tropical Medicine, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [3]Mahidol Vivax Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [4]Department of Entomology, Pennsylvania State University, University Park, PA, United States

Plasmodium vivax only infect immature red blood cells called the reticulocytes. This host cell tropism is believed to be mediated by the reticulocyte binding protein family of the parasite. Sequencing of cDNA from clinical *P. vivax* isolates confirmed the presence of six genes of this family that are transcriptionally active and likely encode proteins (PvRBP1a, PvRBP1b, PvRBP2a, PvRBP2b, PvRBP2c, and PvRBP2p1). Among these proteins, PvRBP2p1 is most similar to PfRH5, a strong candidate for vaccine development against *P. falciparum*. Both PfRH5 and PvRBP2p1 are composed of only the N-terminal red blood cell binding domain and lack the transmembrane domain possessed by other members of the family. This research aims to evaluate the roles of PvRBP2p1. Using *E. coli*, we expressed full-length recombinant PvRBP2p1. Using this protein in erythrocyte binding assays, we found that, unlike some well characterized PvRBPs, PvRBP2p1 binds both mature erythrocytes and reticulocytes. We also found that treatment of erythrocytes with trypsin or chymotrypsin significantly reduces binding activity. To localize the

protein, antibody was raised in rabbits against recombinant PvRBP2p1 and used in immune-fluorescence assays. The protein was found only in very mature schizonts and localized at the apical end of merozoites. We then used ELISA to measure antibody levels to PvRBP2p1 in *P. vivax* infected individuals. Interestingly, a statistically significant negative correlation was found between PvRBP2p1 antibody level and parasite density in blood. Interestingly, the levels of anti-PvRBP2p1 antibody in patients were generally lower than that of an asymptomatic carrier. These results suggest that the anti-PvRBP2p1 antibodies may play a protective role, possibly by inhibiting erythrocyte invasion. In summary, we provide evidence that PvRBP2p1 may be a good candidate for vaccine development against blood stage *P. vivax* infection.

VOLUNTEERS PERSPECTIVES OF CLINICAL TRIAL PROCEDURES: LESSONS FROM THE PILOT STUDY FOR MALARIA CLINICAL TRIAL PROCEDURES OF RECRUITMENT AND SCREENING OF ADULT VOLUNTEERS WITH OR WITHOUT HIV IN TANZANIA

Florence Milando, Kamaka Kassim, Ramla Rashidi, Gloria Nyaulingo, Bakari Mwalimu, Saumu Ahmed, Munira Qassim, Said Jongo

Ifakara Health Institute, Bagamoyo, United Republic of Tanzania

Malaria Control strategies have resulted in a successful reduction of malaria transmission in Africa. This success raises the optimism and possibility of elimination and eradication of malaria through the use of the vaccine.Clinical trial volunteer recruitment and retention are essential to the success of any clinical study. Yet little is known about perspectives of volunteers on clinical trial procedures and what makes them opt for participating in the trial. This study was ubdertken to explore volunteers perspectives on recruitment and screening procedures in Malaria clinical trial in Tanzania. This was a was cross-sectional study conducted in September and December 2017. An exit structured questionnaire was administered to the purposefully selected 148 volunteers who participated in a pilot study of Malaria clinical trial procedures of recruitment and screening of adult volunteers aged 18 to 45 years with or without HIV in Tanzania.The descriptive analysis of the collected data was done by using STATA statistical package. A total of 148 participants were interviewed with Overall mean ± SD age was 29.8 ± 6.7 years. Almost two-thirds (62%) of the volunteers to participate because they wanted to know their health status.More than 90% of the volunteers strongly approved study procedures.Majority of the volunteers (91.5%) had a positive perception regarding female volunteers in reproductive age to take measures for prevention of pregnancy while participating in future trials. Lastly, the majority of volunteers (92.4%) had a positive perception regarding the storage of urine, stool and blood samples up to 15 years for further analyses with the appropriate ethical approval as required. In conclusion, the results of the study indicated that volunteers hold a positive perception of the study procedures.In addition, the common reasons to participate in the study for volunteers was knowing their health status. This implies that community members are aware of the importance of undergoing a medical checkup and failing to fulfill this need recruitment and retention of volunteers in the clinical study will be a challenge.

A PRE-CLINICAL PRIME-AND-TRAP MALARIA VACCINE BASED ON CD8$^+$ LIVER RESIDENT MEMORY T CELLS

Tayla M. Olsen[1], Brad C. Stone[1], Vorada Chuenchob[2], **Sean C. Murphy**[1]

[1]University of Washington Medical Center, Seattle, WA, United States, [2]Center for Infectious Disease Research, Seattle, WA, United States

Tissue resident memory CD8$^+$ T cells (Trm) in the liver are critical for long-term protection against pre-erythrocytic *Plasmodium* infection. Protection can be achieved by repeated, intravenous vaccinations with radiation attenuated sporozoites (RAS). To reduce dosing frequency, we tested a DNA vaccine designed to induce potent CD8$^+$ T cell responses against the SYVPSAEQI epitope of *P. yoelli* circumsporozoite protein (CSP). In a heterologous prime-and-trap regimen, CSP-specific CD8$^+$ T cells were primed using a gene gun-delivered DNA vaccine and boosted with a single dose of RAS with or without a concurrent DNA booster. These regimens attracted expanding CD8$^+$ T cell populations to the liver where they became Trm cells. Vaccinated in this manner, BALB/c mice were completely protected against challenge, which was not reliably achieved following one dose of RAS or multiple doses of DNA-only vaccines. Our study demonstrates that potent CD8$^+$ T cell priming by DNA vaccination synergizes with naturally liver-targeted RAS vaccination and highlights a translational pathway for improving the efficacy of T cell-mediated malaria vaccines in humans.

PLASMODIUM BERGHEI SERINE/THREONINE PROTEIN PHOSPHATASE (PP5) IS ESSENTIAL FOR GAMETOGENESIS

Xiaotong Zhu[1], Yonghui Feng[2], Yaming Cao[1]

[1]China Medical University, Shenyang, China, [2]The First Hospital of China Medical University, Shenyang, China

Gametocytes and their following development in the mosquito vector is a complex differentiation process relies on multiply signaling transduction mediated by phosphorylation. These development steps are crucial for the parasite to complete its life cycle and transmission to a new vertebrate host. However, the functions of phosphatases involved in gametogenesis are poorly understood. Here, we present a *Plasmodium berghei* protein, Ser/Thr Protein Phosphatase 5 (*Pb*. PP5), which is highly conserved among *Plasmodium* species. Removal N-terminus TPR domains of recombinant *Pb*. PP5 protein could elevate enzyme activity by seven folds, and recombinant *Pb*. PP5^{yPP2Ac} has moderately sensitive to okadaic acid (IC_{50}=5.36 nM). Furthermore, *Pb*. PP5 is expressed in cytosol of most asexual and sexual stage parasites, except for merozoite and ookinete stages, in which some of the *Pb*. PP5 protein located beneath parasite plasma membrane. Target disruption of *pb. pp5* gene has no influence on blood stage parasite multiplication. Meanwhile, parasites lacking *Pb*. PP5 are competent for gametocytogenesis, but exflagellation of male gametocytes, following developments of ookinetes *in vitro* and oocysts *in vivo* are completely blocked. In addition, anti-*Pb*. PP5 sera moderately blocked the parasite development in the gametocytes exflagellation and ookinetes conversion. Furthermore, mosquitoes fed on mice passive transferred immunized anti-*Pb*. PP5 sera had 20 % reduction in the prevalence of infection and almost 57.6 % reduction in oocyst density, indicating blocked transmission of the parasites to mosquitoes. These results and the high degree of conservation of *Pb*. PP5 in *Plasmodium* species suggest that this protein could be an attractive target for the development of novel drugs to block the spread of malaria, and might be a potential novel transmission blocking vaccine target candidate.

THE EFFECT OF THE RTS,S/AS01E VACCINE FOURTH DOSE ON ANTIBODY RESPONSES TO CSP AND HBSAG IN CHILDREN FROM MOZAMBIQUE

Chenjerai Jairoce[1], Lina Sanchez[2], Marta Vidal[2], Itziar Ubillos[2], Hèctor Sanz[2], Ruth Aguilar[2], Augusto J. Nhabomba[1], Inocencia Cuamba[1], Nana Aba Williams[2], Núria Díez-Padrisa[2], Sheetij Dutta[3], Pedro Aide[1], Joseph J. Campo[2], Gemma Moncunill[2], Carlota Dobaño[2]

[1]Centro de Investigação em Saúde de Manhiça (CISM), Maputo, Mozambique, [2]ISGlobal, Hospital Clínic - Universitat de Barcelona,

Catalonia, Spain, [3]Walter Reed Army Institute of Research, Maryland, MD, United States

RTS,S/AS01E is a first generation vaccine and the most advanced in development globally. However, its efficacy as given to infants and children is moderate, the duration of protection is limited, and a fourth dose, although beneficial for vaccine efficacy, seems not to induce the expected IgG levels against the immunodominant epitope of the circumsporozoite (CSP) antigen. The mode of action, immune correlates of protection and factors affecting immunogenicity and vaccine efficacy of RTS,S/AS01E are still to be elucidated. Preliminary data from our consortium measuring baseline (Month [M] 0) and peak immune responses one month after primary vaccination (M3) showed that RTS,S/AS01E induced IgM and IgG subclass responses to the CSP and hepatitis B (HBsAg) vaccine antigens, predominantly IgG1 and IgG3, with lower IgG2 and IgG4. Moreover, age, transmission intensity, prior malaria episodes, maternal IgGs, nutritional status, as well as baseline immune status had an impact on the outcome of RTS,S/AS01E vaccination. Recognizing the requirement of vaccines for induction of long-lasting immunity as well as RTS,S/AS01E limitations, we aimed to assess the immunogenicity and duration, over time, of antibodies induced with and without the fourth dose. Samples from children and infants given a forth dose of RTS,S/AS01E or a comparator (including malaria cases and controls) were analyzed. We measured IgM, IgG, IgG1, IgG2, IgG3 and IgG4 levels to RTS,S/AS01E vaccine antigens in plasma samples from M20, M21 & M32 (end-of-follow-up) from a subset of infants (aged 6-12 weeks at first vaccine dose) and children (aged 5-17 months) from the Manhiça-Mozambique trial site by quantitative suspension array technology. We will present data on the comparison between the isotypes and subclasses of antibodies to CSP (NANP, C-tem and full length) and HBsAg measured in the later time points of the trial, and relate them to baseline and peak responses to gain insight into the kinetics of responses and immunogenicity of the vaccine with and without the fourth dose.

427

DEVELOPMENT OF METHODS CHARACTERIZING THE AMA1-RON2 COMPLEX

Daming Zhu[1], Weili Dai[1], Holly McClellan[1], Dennis Braden[1], Patricia A. Gonzales Hurtado[1], Prakash Srinivasan[2], Louis H. Miller[3], Patrick E. Duffy[1]

[1]Laboratory of Malaria Immunology and Vaccinology, Rockville, MD, United States, [2]Johns Hopkins Malaria Research Institute, Baltimore, MD, United States, [3]Laboratory of Malaria and Vector Research, Rockville, MD, United States

It has previously shown that the rhoptry neck protein 2 (RON2) binds to the hydrophobic groove of the apical membrane antigen 1 (AMA1). The coupling is an essential step in the invasion of red blood cells (RBCs) by *Plasmodium falciparum* (Pf) merozoites. Vaccination with AMA1 alone induced high-titer invasion-blocking antibodies in a human challenge trial; however, the vaccine failed to provide protection even against homologous challenge. Recent study showed that immunization with an AMA1-RON2 peptide complex, but not AMA1 alone, provided complete protection against a lethal *Plasmodium yoelii* challenge in mice when Freund's adjuvant was used. This result indicates that the AMA1-RON2 complex is a promising vaccine candidate against malaria. To prepare clinical trials using AMA1-RON2 complex as a candidate vaccine, the identity and integrity of the AMA1-RON2 complex must be assessed. Due to the fact that the complex is formed by non-covalent interactions, the characterization methods must be carefully designed so that the complex is not dissociated during the evaluation. In this study, we developed a native Tris-glycine gel method to separate and identify the AMA1-RON2 complex, which was further identified and confirmed by Western blotting using anti-AMA1 monoclonal antibodies (mAbs 4G2 and 2C2) and anti-RON2 polyclonal Ab coupled with mass spectrometry. The formation of complex was also confirmed by Capillary Isoelectric Focusing (cIEF). A short term (48 h and 72 h at 4ºC) stability study of AMA1-RON2 complex was also performed. The results indicate that the complex was stable for 72 hours at 4ºC. Our research demonstrated that the native Tris-glycine gel separation/Western blotting coupled with mass spectrometry and cIEF can fully characterize the identity and integrity of the AMA1-RON2 complex and provide useful quality control data for the subsequent clinical trials.

Erythrocyte invasion by *Plasmodium falciparum* is an indispensable step for its blood-stage life cycle and successful transmission to new human hosts. The invasion process is mediated by multiple ligand-receptor interactions and is an attractive step to identify critical invasion ligands that could be developed as malaria vaccine candidates. Several major ligands such as AMA-1, despite being essential, failed to elicit strain-transcending invasion inhibitory antibodies due to high antigenic polymorphisms. It is thus imperative to identify conserved vaccine targets that could generate broadly-neutralizing anti-parasitic antibodies. Here we report the vaccine potential of three essential and conserved merozoite antigens PfRH5/CyRPA/MSP-1, that induce broadly-neutralizing antibodies against diverse *P. falciparum* clinical isolates from malaria endemic regions of Mozambique, Africa. The isolates were adapted to laboratory culture and after minimal *in vitro* cultivation were characterized for their invasion phenotypes by analysing their ability to invade enzymatically-treated erythrocytes. The parasite neutralizing efficacy of antibodies targeting different merozoite ligands was evaluated using the standard *in vitro* growth inhibition assay. Majority of the isolates invaded neuraminidase-treated cells in a sialic acid independent manner and showed varied sensitivities to trypsin and chymotrypsin treatment, implying the usage of alternate invasion pathways. Invasion by few isolates was resistant to all three enzymes. All isolates irrespective of their invasion phenotype were potently neutralized by individual antibodies against RH5, CyRPA and MSP-Fu (MSP3-MSP1 fusion chimera) with 80-90% inhibition (10 mg/ml total IgG). Importantly, antibody combinations against these three antigens elicited potent strain-transcending inhibition at lower IgG concentrations in a synergistic or additive manner, thus validating the vaccine potential of PfRH5, CyRPA and MSP-1. Our study strongly suggests the inclusion of PfRH5, CyRPA and MSP-Fu in a multi-component cocktail blood-stage malaria vaccine.

CHARACTERIZATION OF FUNCTIONAL HUMAN MONOCLONAL ANTIBODIES TO *PLASMODIUM VIVAX* RETICULOCYTE BINDING PROTEIN 2B (*PV*RBP2B) ISOLATED FROM NATURALLY EXPOSED INDIVIDUALS

Anugraha Gandhirajan[1], Li-Jin Chan[2], Lenore Carias[1], Camila França[2], Sebastien Menant[3], Yi Jun Chen[3], Calum McConville[3], Ivo Mueller[2], Wai-Hong Tham[2], Christopher L. King[4]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]The Walter and Eliza Hall Institute of Medical Research & Department of Medical Biology, The University of Melbourne, Parkville, Australia, [3]The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, [4]Case Western Reserve University & Veterans Affairs Medical Centre, Cleveland, OH, United States

Plasmodium vivax (*Pv*) preferentially invades reticulocytes to complete their life cycle and establish infection in humans. The interactions of *P. vivax* merozoite ligand, reticulocyte binding protein 2b (*Pv*RBP2b) and Transferrin receptor 1 (TfR1) on reticulocytes, mediates the successful invasion of host cells. We isolated human monoclonal antibodies (humAbs) to *Pv*RBP2b from naturally exposed individuals and characterized whether they inhibit *Pv*RBP2b: TfR1 interaction and block *Pv* invasion of reticulocytes. *Pv*RBP2b specific single memory B cells were isolated from Cambodians using fluorescence activated cell sorting. Each cell specific cDNA library was produced and nested PCR was performed to pull out variable heavy *iggh* and light chain *iggl* genes. Paired *iggh* and *iggl* were cloned into IgG1 expression vector, expressed and purified. Inhibition of the *Pv*RBP2b-TfR1 interaction with humAbs was studied using a flow cytometry-based red blood cell binding assay. Epitope recognition by humAbs were mapped using different *Pv*RBP2b recombinant fragments. Competition ELISA was performed with a panel of well characterized inhibitory murine monoclonal antibodies to evaluate the humAbs' mode of recognition. Sequencing of 290 antibody variable heavy genes from *Pv*RBP2b- specific memory B cells identified 36 distinct clonal groups. Currently we have cloned and expressed 17 humAbs from 16 clonal groups. Eight humAbs range from partial to complete inhibition of *Pv*RBP2b binding to reticulocytes. Current epitope evaluation indicates some humAbs recognize similar epitopes to previously characterized inhibitory murine mAbs and others recognize unique epitopes. Notable four humAb are more potent inhibitory antibodies compared to any of the previously characterized murine mAbs. Isolation and characterization of humAbs to critical *Pv* invasion ligands leads to greater understanding of the mechanisms of naturally acquired immunity to *Pv* blood stage infection. The potential of passive transfer of inhibitory humAbs into non-human primates or humans can confirm their protective potential and allows novel approaches for malaria vaccine design.

IMMUNOGENICITY AND EFFICACY OF MALARIAL CELTOS AND CSP VACCINE ANTIGENS ADMINISTERED WITH GEL-DEPOT ADJUVANT

Lisa M. Shollenberger[1], Jaqueline V. Dixon[1], Alma G. Mendoza[1], Justine Shiau[1], Neeraja Punde[2], Ashutosh K. Pathak[1], Demba Sarr[1], Courtney Murdock[1], Donald Champagne[1], Evelina Angov[3], Donald A. Harn[1]

Half of the world's population is at risk for malaria, yet there is currently no highly effective subunit vaccine. The most promising vaccines for malaria require 3+ injections to induce modest levels of protection. Thus, there is a critical need to develop a robust vaccine that requires fewer doses. To achieve this result, the field is utilizing recent advances in vaccine adjuvant and delivery technologies. Our lab pioneered the use of a self-assembling matrix as a non-immunostimulatory vaccine adjuvant. The gel-depot adjuvant utilizes the RADA16 peptide, allowing slow release of the immunogen from the mobile phase of the matrix. This self-assembling vaccine matrix is a 3-dimensional vaccine adjuvant that increases antigen persistence, thereby enhancing immune responses to vaccine antigens. This non-reactogenic matrix adjuvant is stable without a cold-chain and eliminates local and systemic reactogenicity caused by molecular adjuvants. Here, we optimized delivery parameters for *Plasmodium berghei* (Pb) CelTOS and CSP in mice. First, we optimized the (1) injection route and (2) RADA16 concentration, which alters the kinetics of immunogen release. Then, using optimal concentration and route parameters, we optimized the (3) prime-boost interval. Compared to conventional delivery of these two antigens, we found gel-depot delivery works best via intradermal and subcutaneous routes. Evaluating time between boost, we observed that an 8 week interval is best, perhaps due to the slow release kinetics of antigen from the gel-depot. We are currently evaluating immunogenicity and efficacy of our optimized gel-depot adjuvant delivery of Pb CelTOS and CSP by sporozoite challenge. Future work includes testing *P. falciparum* CelTOS and CSP proteins in mice using optimized delivery conditions, which will include evaluations of efficacy and durability. These studies are the first phase of our long-term goal of generating a functional malaria subunit vaccine for humans. Enhancement of vaccines by non-immunostimulatory vaccine adjuvants may represent a fundamental paradigm shift in how vaccines are developed and delivered.

431

A ROBUST NONHUMAN PRIMATE MODEL WITH INDUCED STERILE IMMUNITY AGAINST *PLASMODIUM VIVAX* AS A PLATFORM FOR DEVELOPING VACCINE CANDIDATES

Nicanor Obaldia[1], Marlon Nunez[2], Manoj Duraisingh[1], Matthias Marti[3]

[1]Harvard School of Public Health, Boston, MA, United States, [2]Instituto Conmemorativo Gorgas de Estudios de la Salud, Panama, Panama, [3]Institute of Infection Immunity & Inflammation, College of Medical Veterinary and Life Sciences of the University of Glasgow, Glasgow, United Kingdom

Malaria is caused by parasites of the genus *Plasmodium* that are transmitted to humans by the bites of *Anopheles* mosquitoes. After the elimination of *Plasmodium falciparum* it is predicted that *Plasmodium vivax* will remain a major cause of morbidity and mortality outside of Africa, stressing the importance of developing a vaccine against *P. vivax* malaria. Current studies to develop a *P. vivax* vaccine are focused on inducing stronger antibody responses. At present, there is no benchmark to assess the level of protection needed to achieve sterile protection in both *Aotus* and humans. Here we repeatedly infected six Aotus monkeys with blood stages of the homologous *P. vivax* Sal-1 and challenged them with the heterologous AMRU-1 strains. Blood samples were collected across the experiment to measure parasitemia and humoral immune responses, including correlates of protection against whole parasite and specific blood stage antigens using ELISA and a *P. vivax* protein microarray. Sterile immunity was achieved after the second homologous Sal1 infection in 4 of 4 monkeys. In these animals, antibody levels increased rapidly to 3.0 log10 after the first infection, boosting to 4.0 log10, thirty days after the second infection; by the third infection on day 166 PI, antibody levels decreased slightly to 3.5 log10 but increased to more than 4.0 log10 between 108-275 days PI. After the fourth infection with the heterologous AMRU1 strain, antibody levels reached a maximum of 4.3 log10. ELISA titers at different levels of infection showed a negative correlation vs mean (r = -0.93; Pearson correlation) and cumulative parasitemia (r = -0.90), but a positive correlation vs peak parasitemia (r = 0.74). Work linking parasite densities against antigen-specific immune responses and changes in parasite transcriptional profiles during repeated infection is ongoing. In conclusion, this study provides the first benchmark for achieving sterile immunity in the *Aotus P. vivax* animal model. These experiments provide a template for testing the efficacy of candidate blood stage *P. vivax* malaria vaccines in this non-human primate model.

432

STRATEGIES FOR IMPROVING THE THROUGHPUT AND SENSITIVITY OF TESTING MALARIA T-CELL VACCINE ANTIGENS IN MICE

Brad Stone, Zachary P. Billman, Tayla M. Olsen, Kevin Zhou, Sean C. Murphy

University of Washington, Seattle, WA, United States

Subunit T cell vaccine development for malaria is faced with a problem of too many possibilities – there are thousands of candidate antigens, yet no proven *in vitro* or *in silico* methods for efficiently selecting those that are genuinely protective. In addition, many antigens are cross-presented on APCs but are not presented by hepatocytes. Such antigens can be highly immunogenic but completely non-protective. To overcome these limitations, we have developed a novel strategy for rapidly and sensitively assessing the ***protective*** efficacy of large numbers of candidate T cell antigens. In the 'acute challenge' model, large numbers of DNA vaccines targeting individual antigens are built in parallel using codon-optimized, 500 bp synthetic DNA fragments. Coding sequences are designed to eliminate signal sequences and are cloned in-frame as ubiquitin fusion proteins to minimize the induction of antibody responses. Small groups of mice are DNA vaccinated twice against single candidate antigens using a gene gun and challenged at the peak of the immune response following the boost, a time point where 10-30% of CD8+ T cells are specific to the vaccine antigen. Protection is assessed by challenge with 2-5x10^4 wild-type, luciferase-expressing *P. yoelii* parasites and IVIS imaging 40-44 hr later. The acute challenge model allows rapid, sensitive detection of both complete and partial protection. Cryopreserved splenocytes can be quickly assessed by ELISPOT to confirm that a T cell response was generated against vaccine-encoded antigens. The extremely high T cell frequencies induced by this approach avoid miscategorizing antigens due to poor immunization (vaccination failure) or low assay sensitivity (assay failure). Importantly, evaluating protection definitively identifies liver stage antigens that are processed and presented by hepatocytes at protective time points, in contrast to immunogenicity-based assays that often detect non-protective, cross-presented antigens. This strategy should be considered as a first line approach for broadening the repertoire of liver stage vaccine antigens prior to studies focused on immune memory formation.

433

MALARIA TRANSMISSION IN THE COMMUNITY AS MEASURED BY DIRECT SKIN FEEDS AND BY COLLECTION OF WILD MOSQUITOES DURING A VACCINE TRIAL IN BANCOUMANA, MALI

Daman Sylla[1], Adama Sacko[1], Jen C. Hume[2], Abdrahamane Fofana[1], Emily Kelnhofer[2], Boubacar Coulibaly[1], Makan Camara[1], Lakamy Sylla[1], Salif Kone[1], Issa Traore[1], Moribo Coulibaly[1], Moridie Sidibe[1], Karim Sawadogo[1], Mahamadoun A. Maiga[1], Issaka Sagara[1], Sara A. Healy[2], Ogobara K. Doumbo[1], Sekou F. Traore[1], Patrick E. Duffy[2], Mamadou B. Coulibaly[1]

[1]MRTC, University of Science, Techniques and Technologies, Bamako, Mali, [2]National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States

Vaccines that interrupt malaria transmission such as transmission blocking vaccines (TBV) could play a key role in the elimination or eradication phase of the disease. Standard Membrane Feeding Assays and Direct Membrane Feeding Assays are used to assess the efficacy of TBV *in vitro* using a membrane feeding to allow mosquito feeding on infective blood and to assess serum transmission blocking activity. Direct Skin Feeds (DSF) are now being assessed as a closer representation of natural transmission conditions, by allowing mosquitoes to feed directly on the skin of vaccine trial subjects. However, the comparability of DSF to natural feeding of mosquitoes in the community for quantifying transmission has not been studied. Here, we measured infections in mosquitoes fed by DSF vs wild caught bloodfed mosquitoes from September to November 2017 as part of a transmission blocking vaccine study. A total of 127 healthy adult volunteers participated in DSF and mosquitoes were collected in volunteers' rooms twice a month by spray catches (SC) and by live room searching (LC). For wild caught mosquitoes, *Plasmodium* infection rates in salivary glands at time of capture were determined by ELISA for SC collected mosquitoes, and oocyst counts in midguts by microscopy 7 days post LC collection. DSFs were performed twice weekly for 12 weeks using two cups of 30 mosquitoes administered to the forearm for 15 minutes. Infection was determined by dissection and oocysts counts 7 days post feeding. Salivary gland sporozoite infection rate was 1.8% (n=731) among SC mosquitoes, and the oocyst infection rate was 1.6% (n=1,061) among LC mosquitoes. By comparison, the infection rate in DSF experiments was 0.2% (n=61,451). Survival rates were 64.0% for wild LC mosquitoes and 73.4% for mosquitoes used in DSFs. Several factors could contribute to the lower rate of infection in the DSF vs wild-caught mosquitoes, such as infectivity of human bloodmeal source (e.g., wild caught but not DSF mosquitoes may feed on children or pregnant hosts with higher parasite levels), inherent susceptibility of wild vs laboratory-maintained mosquitoes, or effects of the vaccine.

434

QUALITY CONTROL OF INSECTARY REARED MOSQUITOES FOR LARGE-SCALE PRODUCTION TO SUPPORT THE ASSESSMENT OF TRANSMISSION BLOCKING VACCINES USING ARTIFICIAL FEEDS

Sidiki Kamissoko[1], Daman Sylla[1], Adama Sacko[1], Jen C. Hume[2], Abdrahamane Fofana[1], Emily Kelnhofer[2], Boubacar Coulibaly[1], Lakamy Sylla[1], Moussa Diallo[1], Issa Traore[1], Daouda Ouologuem[1], Chata Doumbia[1], Gaoussou Fofana[1], Abdoulaye Keita[1], Moridie Sidibe[1], Aboubacar Tembely[1], Mariam Doumbia[1], Diango Cisse[1], Sekou F. Traore[1], Patrick E. Duffy[2], Mamadou B. Coulibaly[1]

[1]MRTC, University of Science, Techniques and Technologies, Bamako, Mali, [2]National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States

With the renewed interest in assessing transmission blocking vaccines using Standard Membrane Feeding Assays, Direct Membrane Feeding Assays and Direct Skin Feeding Assays, consistent, controlled laboratory mosquito production is becoming a point of interest. Mass production is needed in many cases and it is imperative to use high quality mosquitoes to ensure good entomological outcomes from the vaccine trials. To date, there are no agreed quality control procedures for large-scale production of mosquitoes in insectaries for such vaccine trials. Here, we attempt to match the performance of our laboratory colony of *Anopheles coluzzii* mosquitoes to a level that provides continued high quality entomological outcomes for malaria vaccine trials. Mosquito performance was measured by determining a number of parameters: feeding rate, proportion of blood fed females that laid eggs, larval hatching rate, pupae emergence rate, adult mosquito size, adult longevity and sex ratio of mosquitoes. In total, 50 3-day old females were used in each of 3 replicate experiments. Females were blood fed and feeding rates were determined. The females were allowed to oviposit collectively and the proportion of females that laid eggs was determined. The progeny were reared under identical conditions and all above parameters were assessed. The average feeding rate was 90% (n=150). Approximately 69% (n=150) of the blood fed females laid eggs, and the average number of eggs laid per female was 53.3. The hatching rate was 78% and the emergence rate (from pupae to adult) was 85% (n=5,073). The sex ratio was 52% males and 48% females (n=4,312). The average size of the adults was 3.15±0.03 mm for male and 3.3±0.03 mm for female (n=300). The longevity was 5 weeks for male and 6 weeks for female. Though these parameters and results can be influenced by many external factors, this study could be a basis to set quality control standards for large-scale mosquito production to support experiments that require high numbers of good quality mosquitoes.

435

CAUSES OF SCREENING FAILURE DURING A TRANSMISSION BLOCKING VACCINE TRIAL AROUND DONEGUEBOUGOU, MALI

Cheick O. Guindo[1], Abdoulaye Katile[1], Bourama Kamate[1], Merepen A. Guindo[1], Amatigue Zeguime[1], M'Bouye Doucoure[1], Boucary Ouologuem[1], Souleymane Traore[1], Sidiki Perou[1], Mahamadoun S. Sissoko[1], Issaka Sagara[1], Sara A. Healy[2], Patrick E. Duffy[2], Ogobara K. Doumbo[1]

[1]MRTC, University of Science, Techniques and Technologies, Bamako, Mali, [2]National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States

A safe and effective malaria vaccine is a necessary tool to improve malaria control and pursue its eradication. Screening is a crucial step during a trial that relies on reference values to include or exclude volunteers in vaccine trials. We are conducting a trial of the malaria transmission blocking vaccine Pfs230D1M-EPA/AS01 in the healthy adult population in Doneguebougou and surrounding villages, 30 km north of Bamako. After obtaining informed consent, each volunteer has undergone clinical and laboratory assessments to evaluate the frequency of different diseases and as well as abnormal laboratory values to ascertain inclusion/exclusion criteria. In February 2017, we screened 169 volunteers and enrolled 110 into the trial. The eligibility rate was 78.7% (133/169). Withdrawal of consent and travel before or at the time of enrollment were 9.5% (16/169) and 4.1% (7/169) respectively. The most common causes of screening failure were due to viruses 16.6% (28/169) with 11.8% for hepatitis B, 3.6% for hepatitis C and 1.2% for HIV. Our results are consistent with those of the PfSPZ1 study of Donegeubougou in 2014 where the most common causes of screening were also due to the viruses with 21.8% for hepatitis B, 2.0% for hepatitis C and 2.0% for HIV. Their rate is slightly higher than for us and this could be explained by the fact that they did more screening than us. Biochemical abnormalities accounted for 1.2% (2/169) for both elevated creatinine and elevated alanine aminotransferase (ALT). The associated presence of hematuria and proteinuria was 1.2% (2/169). Of the 5 volunteers who failed the clinical examination, 1.8% (3/169) were due to QT_C interval> 450ms, and 0.6% (1/169) each for tachycardia and for high blood pressure. QT_C interval > 450ms and hepatitis B are the most common causes of clinical and laboratory screening failure in our vaccine study.

HEMATOLOGICAL NORMAL RANGES IN HEALTHY CHILDREN AND ADULTS FROM BANCOUMANA, MALI, A MALARIA VACCINE TESTING SITE

Amatigue Zeguime[1], M'Bouye Doucoure[1], Issaka Sagara[1], Sintry Sanogo[1], Boucary Ouologuem[1], Amadou Konate[1], Souleymane Traore[1], Moussa B. Kanoute[1], Mahamadoun H. Assadou[1], Mamady Kone[1], Kourane Sissoko[1], Boubacar Traore[1], Jordyn Manucci[2], Jen C. Hume[3], Patrick E. Duffy[3], Ogobara K. Doumbo[1]

[1]MRTC, University of Science, Techniques and Technologies, Bamako, Mali, [2]DIR/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Bethesda, MD, United States, [3]National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States

Clinical trials require the selection of healthy volunteers with normal laboratory parameters, which are defined in apparently healthy subjects from the target population stratified by sex and age. These locally normal ranges are critical in clinical trials to select healthy volunteers and assess the safety of investigational products. The Malaria Research and Training Center (MRTC) and LMIV/NIAID/NIH are monitoring the dynamics of malaria transmission in a community where transmission blocking vaccines are being tested. We enrolled 829 subjects from Bancoumana in February 2018 (before malaria transmission season) to study the dynamics of malaria transmission across the community. All volunteers underwent the following laboratory assessments: Complete Blood Count (CBC) with Hemoglobin (HGB x mg/dl), differential (White Blood Cell (WBCx10^3/µl), Absolute Neutrophil Count (ANC x 10^3/µl), and Absolute Lymphocyte Count (ALC x 10^3/µl). CBC variables in the population were described using median and percentiles (2.5 and 97.5). Here, we report the median and range values for these laboratory assessments in the following demographic categories of enrolled subjects: infants aged 0-5 years, children aged 6-14 years, and adults aged 15 and over, separated by male and females. None of the values were statistically significantly different between the sexes. In infants and children, reference values slightly differed from those found about 10 years ago in Doneguebougou by the clinical CAP laboratory. In terms of median values in adults, these results are similar to those reported previously among Malian adults. These findings add to the baseline knowledge of healthy individuals in West Africa and can be useful in the future for further studies.

437

SCHISTOSOMIASIS AND HELMINTH PREVALENCE AMONG ADULTS IN A MALARIA VACCINE TESTING SITE, BANCOUMANA, MALI

Kourane Sissoko[1], Issaka Sagara[1], Sara A. Healy[2], Mahamadoun H. Assadou[1], Sibiri Sissoko[1], Mamady Kone[1], Merepen A. Guindo[1], Amadou Konate[1], Moussa B. Kanoute[1], Aicha D. Doumdia[1], Bourama Samake[1], Sintry Sanogo[1], M'Bouye Doucoure[1], Patrick E. Duffy[2], Ogobara K. Doumbo[1]

[1]MRTC, University of Science, Techniques and Technologies, Bamako, Mali, [2]National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States

Endemic helminth infections in sub-Saharan Africa, such as helminthiasis and schistosomiasis, are known to elicit a wide range of immunomodulating responses and may impact the efficacy of vaccination. The potential impact of co-infections on vaccine immunogenicity will depend on the prevalence of local helminth and schistosomiasis infection. The aim of this study is to evaluate frequency of *Schistosoma haematobium* infection and intestinal helminths among adult volunteers involved in a phase 1 malaria transmission-blocking vaccine trial in Bancoumana, Mali. From February to March 2015, we examined the presence of *S. haematobium* and intestinal helminth co-infections in Bancoumana in adults aged from 18 to 50 years old. Bancoumana is a village located 60 km southwest of Bamako and has a population of about 10,000 people. The co-infection was assessed by testing volunteers screened to be enrolled in a malaria transmission-blocking vaccine trial. Microscopy of urine on Whatman paper and stool PCR were done respectively to detect *S. haematobium* and *S. mansoni* and 8 common gastrointestinal pathogens in each volunteer. In total, urine was collected from 359 participants in the study and the overall prevalence of *Schistosoma haematobium* infection was 6.7% (24/359). The sex distribution showed an infection frequency of 6.6% (17/257) in males and 6.8% (7/102) in females; infection frequency was not statistically different between sexes (p=0.07). Urine filtration showed that *Schistosoma mansoni* infection was not present. Subjects positive for *Schistosoma haematobium* received standard treatment using Praziquantel. Stool PCR results are pending at this time but will be discussed and compared to urine infection levels to determine overall burden of helminth prevalence.

438

NUMEROUS AUTO-DISSEMINATION STATIONS ARE REQUIRED FOR THE USE OF *ANOPHELES GAMBIAE SENSU LATO* IN THE TRANSFER OF LARVICIDES TO LARVAL BREEDING HABITATS

Oscar O. Mbare[1], Steve Lindsay[2], Ulrike Fillinger[1]

[1]International Centre of Insect Physiology and Ecology, Mbita, Homa Bay County, Kenya, [2]Durham University, Durham, United Kingdom

Larval control is an effective tool for malaria vector control in some settings. Larviciding for malaria control is limited by the difficulty to identify and treat the numerous breeding habitats of these mosquitoes. Novel strategies to apply mosquito larvicides to *Anopheles* breeding habitats are necessary to improve the cost-effectiveness. This study explored the potential of gravid *Anopheles gambiae* sensu stricto to auto-disseminate pyriproxyfen (PPF) to breeding habitats to prevent adult vector production. Cage tests were implemented to assess the best method to contaminate netting with PPF to allow the females to pick up most of the insecticide when in contact. The attractiveness of 6-day old soil infusion and cedrol to the females were compared in semi-field systems. One test and two control semi-field systems were used to investigate the transfer of PPF by females from dissemination stations to open ponds. Dissemination stations were ponds covered with netting material dusted with PPF. Transfer of PPF was assessed by observing adult emergence in larvae introduced into the three open ponds. Cage bioassays showed that gravid *An. gambiae s.s.* transferred most PPF from netting contaminated with PPF dust than when netting was contaminated with PPF formulated in oil. Ponds with water treated at 20 ppm cedrol were twice as attractive as untreated ponds, ponds treated with water treated at 5 ppm cedrol or 6-day old infusion were 1.2-1.5 times more attractive than untreated pond. Transfer of PPF by gravid females was not recorded in any of the control semi-field systems. Transfer of PPF was demonstrated in the test semi-field system, and it was dependent on the distance of the open pond from dissemination station. Overall the adult emergence rates of larvae introduced into open ponds in test semi-field system were 8-10 times reduced compared to emergence rates in the two control semi-field systems. These results provide proof of principle of the feasibility of auto-dissemination for the control of Afrotropical malaria vectors. Numerous auto-dissemination are required for effective auto-dissemination for control of Afrotropical malaria vectors.

SPATIAL EFFECTS OF MALARIA INTERVENTIONS ON MALARIA MORBIDITY IN CHILDREN UNDER 5 YEARS IN NIGERIA

Xi Cheng, Yuan Hong, Jan Ostermann

University of South Carolina, Columbia, SC, United States

Malaria is a significant public health problem in Nigeria. In 2014, Malaria accounted for 21% of estimated deaths in children under five, approximately 60% of outpatient care utilization, and 30% of hospitalizations among children under five. Since 2010, a substantial expansion of malaria interventions has been initiated, however, the malaria burden in Nigeria has declined disproportionately among regions nationwide. The objective of this study is to estimate the geographical variation of parasitaemia prevalence and quantify the effects of malaria interventions at the state level in Nigeria. Using the 2010 and 2015 Nigeria Malaria Indicator Survey, a spatial multilevel model will be fitted to assess the association between parasitaemia prevalence and its determinants in both years. A two-level intrinsic conditional autoregressive model was used to account for spatial correlations. State level estimates of parasitaemia prevalence were predicted and averaged by stratum-specific population estimates. Given the limited sample size in each state, the standard errors and confidence intervals for the prevalence were calculated using the weighted bootstrap method which is robust under complex survey sampling designs. The mothers' education and wealth index were identified as important predictors of parasitaemia prevalence. Population adjusted prevalence was highest in the south west regions and had varying changing pattern from 2010 to 2015. For instance, the prevalence in the state of Niger decreased from 73% (95%CI 66% - 79%) to 29% (95%CI 20%-38%) while the prevalence in the state of Taraba increased from 12% in 2010 to 41% in 2015. Artemisinin-based Combination Therapy had an overall significant effect on malaria risk after adjusting the local endemicity levels in both years and the effect became stronger in 2015. Insecticide-treated nets were shown to have a significant effect in 2010, however the effect was diminished in 2015. The predicted results and maps in this study provide visual aids for decision-makers to access the effects of interventions and identify the priority area where the targeted strategy and resources were needed.

440

ENTOMOLOGICAL IMPACT OF INDOOR RESIDUAL SPRAYING WITH PIRIMIPHOS-METHYL: A PILOT STUDY IN AN AREA OF LOW MALARIA TRANSMISSION IN SENEGAL

Ousmane Sy

UCAD, Dakar, Senegal

Scaling-up of effective anti-malarial control strategies in Central-West region of Senegal has resulted in the sharp decline in malaria prevalence in this area. However, despite these strategies, residual malaria transmission has been observed in some villages (hot spots). The objective of this study

was to assess the impact of indoor residual spraying (IRS) with pirimiphos-methyl on malaria transmission in hot spot areas. The malaria vector population dynamics were monitored in each of the six selected villages (4 of which used IRS, 2 were unsprayed control areas) using overnight human landing catches (HLC) and pyrethrum spray catches (PSC). The host source of blood meals from freshly fed females collected using PSC was identified using the direct ELISA method. Females caught through HLC were tested by ELISA for the detection of *Plasmodium falciparum* circumsporozoite protein (CSP) and *Anopheles gambiae* complex was identified using PCR. Preliminary data shown that the densities of *Anopheles* populations were significantly lower in the sprayed areas (179/702) compared to the control. Overall, malaria transmission risk was 14 times lower in the intervention zone (0.94) compared to the control zone (12.7). In the control areas, three *Anopheles* species belonging to the Gambiae complex (*Anopheles arabiensis*, *Anopheles coluzzii* and *Anopheles melas*) maintained the transmission, while only *An. coluzzii* was infective in the sprayed areas. In conclusionThe preliminary data from this pilot study showed that IRS with the CS formulation of pirimiphos-methyl is likely very effective in reducing malaria transmission risk. However, additional studies including further longitudinal entomological surveys as well as ecological and ethological and genetical characterization of vectors species and their populations are needed to better characterize the entomological impact of indoor residual spraying with pirimiphos-methyl in the residual transmission areas of Senegal.

EX-POST RICE FARMERS WILLINGNESS TO PAY FOR MALARIA LARVAL SOURCE MANAGEMENT: THE CASE OF RUHUHA COMMUNITY IN EASTERN RWANDA

Alexis Rulisa

Rwanda Biomedical Center/Radboud University Nijmegen, Kigali, Rwanda

With the aim to ensure sustainability and integrate this Bti intervention in rice fields to complement the existing malaria control strategies, we assessed the change in rice farmers' WTP levels after the experience of Bti intervention and perceived benefits, as well as its effectiveness in reducing malaria risk. The WTP was assessed through the contingent valuation method using a bidding game procedure and the impact of Bti spraying on the maximum WTP for that intervention was estimated using difference-in-differences technique, combined with propensity score matching. This evaluation conducted in 2017 (*ex post*) among 288 rice farmers made use of mixed methods, a quantitative panel study (longitudinal) comparing with data collected in 2015 (*ex ante*) and two focus group discussions. After two Bti experiments conducted in a period of two years, the mean *lumpsum* WTP after Bti spraying was significantly higher in the self-organized group (treated without supervision) than in the comparison group and the treated group with supervision ($p<0.05$). The mean *progressive* WTP after Bti spraying was significantly higher in the treated group with supervision than in the comparison group ($p<0.001$) and lower in the self-organized group (treated without supervision) than in the treated group with supervision ($p<0.001$). The size of land significantly increased between the two experiments ($p<0.001$), making higher the total contributions using the *progressive* option than *lumpsum*. In both experiments, all participants were still willing to financially contribute any amount of money for Bti, except one farmer who was not able but would wish so. Our study findings suggest that the *ex post* WTP was higher than the *ex ante,* especially for treatments involving self-organization of the farmers whose fields were sprayed without external supervision. This self-organization aspect confirms the community empowerment, ownership and participation; which is a key success factor for sustainability of the intervention. The average maximum WTP in both experiments is far lower than the actual cost of Bti (less than 25%).

442

BLOOD FEEDING BEHAVIOR OF MALARIA VECTORS IN THE ERA OF INTENSIVE VECTOR CONTROL EFFORTS IN WESTERN KENYA

Teshome Degefa[1], Delenasaw Yewhalaw[1], Guofa Zhou[2], Harrysone Atieli[3], Andrew K. Githeko[4], Guiyun Yan[2]

[1]School of Medical Laboratory Sciences, Institute of Health, Jimma University, Jimma, Ethiopia, [2]Program in Public Health, University of California, Irvine, CA, United States, [3]School of Public Health, Maseno University, Kisumu, Kenya, [4]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya

Regular monitoring of the feeding behaviors of malaria vectors is crucial to determine the frequency of human-vector contact and implement effective vector control interventions. This study was conducted to assess the feeding preferences of malaria vectors in western Kenya. *Anopheles* mosquito collections were done from September 2015 to April 2016 in Ahero and Iguhu sites using CDC light traps (indoor and outdoor), pyrethrum spray catches (indoor) and pit-shelters (outdoor). Data on insecticide-treated nets (ITN) ownership and the number of potential blood-meal hosts available in the area were collected using questionnaires. Polymerase chain reaction (PCR) was used to identify *Anopheles gambiae* species complex. Mosquito blood-meal sources were determined using ELISA. The proportion of households owning at least one ITN was 88.5% and 80.5% in Ahero and Iguhu, respectively. A total of 10,864 *Anopheles* mosquitoes comprising *An. gambiae* s.l. (71.4%), *An. funestus* s.l. (12.3%), *An. coustani* (9.2%) and *An. pharoensis* (7.1%) were collected. Most (61.8%) of the anophelines were collected outdoors. PCR result (n = 581) revealed that 98.9% *An. arabiensis* and 1.1% *An. gambiae* s.s. constituted *An. gambiae* s.l. in Ahero while this was 87% *An. gambiae* s.s. and 13% *An. arabiensis* in Iguhu. The human blood index (HBI) and bovine blood index (BBI) of *An. arabiensis* was 2.5 and 73.1%, respectively. *Anopheles gambiae* s.s. had HBI and BBI of 50 and 28%, respectively. The HBI and BBI of *An. funestus* was 60 and 22.3%, respectively. Forage ratio estimate revealed that *An. arabiensis* preferred to feed on cattle, *An. gambiae* s.s. showed preference for both human and cattle, while *An. funestus* preferred human over other hosts. Compared with data collected two decades ago before the scale-up of ITNs, the HBI of *An. gambiae* s.s. has decreased by 20% with proportionate increment in its BBI. This suggests an increasing tendency of *An. gambiae s.s.* to feed on cattle. *Anopheles arabiensis* was highly zoophagic while *An. funestus* still showed anthropophagic behavior. Additional control tools that complement the existing interventions are required to control zoophagic vectors.

443

EVALUATION OF TOXICITY AND CROSS-RESISTANCE OF NOVEL CANDIDATE INSECTICIDES CLOTHIANIDIN, NEONICOTINOID, AND CHLORFENAPYR, PYRROLE, AGAINST WILD AND LABORATORY *ANOPHELES ARABIENSIS* IN JIMMA, ETHIOPIA

Kendra Dagg[1], Seth Irish[2], Josephat Shililu[3], Delenasaw Yewhalaw[4], Louisa A. Messenger[2]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Abt Associates, Addis Ababa, Ethiopia, [4]Jimma University, Jimma, Ethiopia

Insecticide-based preventative measures are an integral part of malaria control programs. However, the evolution of resistance threatens to undermine progress. Chlorfenapyr and clothianidin are two insecticides included in control products because of their unique modes of action. Prior to their use in any program, it is important to establish toxicity towards local vector populations and assess cross-resistance with other insecticides commonly used for vector management. To investigate the effectiveness of these insecticides against the predominant Ethiopian malaria vector species, *Anopheles arabiensis*, diagnostic doses and cross-resistance

were tested, using standard intensity resistance bioassays, against both a laboratory-reared susceptible strain and a wild, multi-insecticide resistant population of *An. arabiensis*, from Asendabo, Oromia Region. A range of doses was tested for chlorfenapyr and clothianidin and the identified diagnostic dose was used to assess cross-resistance to deltamethrin, permethrin, malathion, propoxur, and bendiocarb. Complete mortality was observed with the laboratory strain using the recommended diagnostic doses for chlorfenapyr (100 µg/bottle) and clothianidin (2%/filter paper). Field populations were resistant to the organophosphate, malathion (83% mortality), capable of surviving 2X, 5X and 10X the diagnostic dose of both deltamethrin and permethrin, but susceptible to carbamates bendiocarb and propoxur. Interestingly, field populations of *An. arabiensis* were significantly more susceptible to clothianidin, reaching 100% mortality by day 2 compared to the laboratory strain (100% mortality by day 3). This study demonstrated that the putative diagnostic doses of chlorfenapyr and clothianidin are appropriate for monitoring resistance within *An. arabiensis.* The unique mode of action leading to an absence of cross-resistance makes chlorfenapyr and clothianidin potential candidates for inclusion in national vector control programs, particularly in areas with high pre-existing or emergent resistance to multiple insecticide classes.

444

THE IMPACT OF PERIODIC DISTRIBUTION CAMPAIGNS OF LONG LASTING INSECTICIDAL TREATED BED NETS ON MALARIA VECTOR DYNAMICS AND HUMAN EXPOSURE IN DIELMO, SENEGA

Seynabou Sougoufara[1], Omar Thiaw[2], Aurelie Cailleau[3], Nafissatou Diagne[2], Myriam Harry[4], Charles Bouganali[2], Pape Mbacke Sembene[5], Souleymane Doucoure[2], Cheikh Sokhna[2]

[1]Keele University, School of Life Sciences, UMR Vecteurs-Infections Tropicales, Newcastle under lyme, United Kingdom, [2]Vecteurs-Infections Tropicales et Méditerranéennes, Dakar, Senegal, [3]Unité d'Entomologie Médicale (UME), Institut Pasteur Dakar, Dakar, Senegal, [4]UMR EGCE (Évolution, Génomes, Comportement, Écologie) CNRS, IRD- Univ. Paris-Sud, IDEEV, Univ. Paris-Saclay, Paris, France, [5]Département de Biologie Animale, Faculté des Sciences et Techniques / Université Cheikh Anta Diop de Dakar, Dakar, Senegal

The implementation of long-lasting insecticidal-treated bed nets (LLINs) have contributed to halving the mortality rate due to malaria since 2000 in sub-Saharan Africa. However, some resurgences of malaria transmission have occurred in some areas following the introduction of indoor interventions, underscoring the fragility of these strategies. Thus, to achieve the World Health Assembly's new target to reduce the burden of malaria over the next fifteen years by 90%, it is necessary to understand how the spatiotemporal dynamics of malaria vectors and human exposure to bites are modified in the context of scaling-up global efforts to control malaria transmission. This study was conducted in Dielmo, Senegal, before the introduction of LLINs, Period 1 (P1), following the introduction of LLINs (P2) and two rounds of LLINs renewals (P3, P4). Mosquitoes were sampled indoors and outdoors using human landing catches. Variations in mosquitoes' biting rates and human exposure were analyzed using a General Linear Mixed Model with the response variable, the mosquito bites and the fixed factors being, the species, the month, the collection site and the periods (P1, P2, P3 or P4). Data analysis showed that the implementation of LLINs is correlated to a significant decrease in the biting densities of the main malaria vectors *An. gambiae* s.l and *An. funestus*. The bulk of bites occurred during sleeping hours, but the residual vector populations had a higher propensity to bite outdoors after the renewal of LLINs in P3 and P4. The shift of outdoor biting could be due to a phenotypic plasticity or the occurrence of several species which exhibits different behaviors in their responses to vector control tools. In this study, the relative protection provided by LLINs to malaria exposure in users relative to non-users (P*f) decreased from 63% in P1 to 45% in P4, due to the increased proportion of outdoor biting after the renewals of LLINs. In addition, the resurgence of malaria in villagers not using bed nets and staying outdoors showed the need to combine LLINs with complementary control measures against residual exposure to achieve the goal of eliminating malaria transmission.

445

MODELLING ALLEE EFFECTS IN A TRANSGENIC MOSQUITO POPULATION DURING RANGE EXPANSION

Melody Walker[1], Julie Blackwood[2], Vicki Brown[3], **Lauren M. Childs**[1]

[1]Virginia Tech, Blacksburg, VA, United States, [2]Williams College, Williamstown, MA, United States, [3]University of South Wales, Pontypridd, United Kingdom

As mosquito populations expand their range, they may undergo mate-finding Allee effects such that their ability to successfully reproduce becomes difficult at low population density. With new technology, creating target specific gene modification may be a viable method for mosquito population control. We develop a mathematical model to investigate the effects of releasing transgenic mosquitoes into newly established, low-density mosquito populations. Our model consists of two life stages (aquatic and adults), which are divided into three genetically distinct groups: heterogeneous and homogeneous transgenic that cause female infertility and a homogeneous wild type. We perform analytical and numerical analyses on the equilibria to determine the level of saturation needed to eliminate mosquitoes in a given area. This model demonstrates the potential for a gene drive system to reduce the spread of invading mosquito populations. The impact of mosquito population size on the transmission of infectious diseases such as malaria and dengue has been well established. We use our model to determine how the basic reproductive number, R_0, will change with the introduction of transgenic populations during range expansion.

446

GENOMIC AND MOLECULAR CHARACTERIZATION OF THE BACTERIAL POPULATIONS OBSERVED IN THE WATER OF BREEDING SITES AND IN LARVAE OF *ANOPHELES COLUZZII* AND *ANOPHELES GAMBIAE* IN NANGUILABOUGOU AND KOUROUBABOUGOU

Assétou D. Diarra

University of Sciences Technics and Technologies of Bamako, Bamako, Mali

The microbiota composition of mosquitoes is influenced by their aquatic breeding environment. The exact factors that define the structure of the mosquitos' microbiota including malaria vectors are currently unknown. From June 2014 to November 2015 we conducted genomic and molecular characterization study of the bacterial populations observed in the breeding sites water and larvae of *Anopheles gambiae and An. coluzzii* the two majors vectors of malaria in Kouroubabougou and Nanguilabougou. The samples were collected from two breeding sites with different ecological settings. The inventory of the bacterial populations, was conducted to better understand their frequencies distribution in larvae and in their respective breeding sites water. Frequencies of the identified bacteria were associated with the allelic polymorphism of the *TEP-1* gene in *An. coluzzii* and *An. gambiae*. We collected 149 samples in which we identified 11 species, 49 genera and 82 strains. The bacterial species populations were composed of *Bacillus sp*. The species *Bacillus anthracis* and *Bacillus thuringiensis* were present only in *An. coluzzii* in Nanguilabougou and Kouroubabougou. *Bacillus cereus, Bacillus amyloliquefacins* and *Bacillus subtilus* were observed only in Nanguilabougou and in *An. coluzzii*. *Enterobacter cloacae* and *Enterobacter ludwigii* were present in *An. gambiae* with the *S1/S1* TEP1 genoptype in Nanguilabougou. *Bacillus cereus, Bacillus amyloliquefaciens* and *Bacillus subtilis* were more associated with the TEP1 genotype of *S1/S1* in *An. gambiae* in the village of Kouroubabougou. In this study we used the classical method of bacteria culture and the associated

molecular, genomics and bioinformatics tools to identify and characterize the bacterial populations. An optimization of the method for future studies would involve the metagenomics analysis approaches to increase the maximum size of identified bacteria species and strains. This will help to determine, the factors that might promote a specific microbiome associated with the population-dynamics of *An. coluzzii* and *An. gambiae* in Mali.

447

THE IMPLEMENTATION AND THE IMPACT OF ADAPTING TECHNOLOGIES TO SUPPORT RESIDUAL MALARIA TRANSMISSION: A CASE STUDY IN UNGUJA, ZANZIBAR

Dickson Samwel Msaky[1], Revocatus Musiba[1], Gasper Shubis[1], Godlove Chila[1], Kimberly Mihayo[1], Juma Mcha[2], Khamis Khaji[2], Brain Tarimo[1], Samson Kiware[1]

[1]Ifakara Health Institute, Dar es salaam, United Republic of Tanzania, [2]Zanzibar Malaria Elimination Program, Unguja, Zanzibar, United Republic of Tanzania

A recent project was carried out in Unguja, Zanzibar to understand mosquito and human behaviours that may allow malaria vectors to avoid contact with insecticide treated nets (ITNs) and indoor residual spraying (IRS) thereby maintaining malaria transmission. The project adapted a secured web-based applicationknown as Ifakara Entomology Bioinformatics System(IEBS) to ensure a collection of high quality mosquito data with capability to link mosquito and human behaviour data. The development of IEBS and its functionality has been described elsewhere, here, we present the implementation and the impact of IEBS in supporting a residual malaria transmission study in Zanzibar. The system was adapted to collect data in standardized formats, link field data with laboratory results, label samples properly, and provide quality data control. Also, to produce a cleaned data file with a data dictionary and meaningful reports containing key entomological indicators on time. The system has contributed to the successful completion of the project by overcoming data management challenges facing most entomological studies. High-quality data is available to address the project's objectives and key information such as species composition and their host preference, infection status, biting and resting behaviours are readily accessible in IEBS's dashboard. The information on where, how, and when each mosquito sample was collected including their storage information is also available in the system. In addition, IEBS's capability to link mosquito and human behaviours data to a household level that can also be referenced to existing malaria cases information is very important in addressing critical questions requiring datasets from these sources. A system such as IEBS can contribute toward periodic collection of quality mosquito-based data which is essential to inform vector control strategies in eliminating malaria transmission.

448

FIRST REPORT ON EFFICACY OF REPELLENT-IMPREGNATED FOOTWEAR FOR PERSONAL PROTECTION AGAINST MALARIA MOSQUITOES

Peter Onyango Sangoro

Ifakara Health Institute, Morogoro, United Republic of Tanzania

Despite significant impact achieved by long-lasting insecticidal nets (LLINs) and indoor residual spraying (IRS), these tools are insufficient for complete disruption of malaria transmission across endemic regions. This study investigated the hypothesis that commonly used foot-wear, if impregnated with effective repellents, could complement the gains achieved by the existing interventions. We developed low-cost sandals fitted with transfluthrin-impregnated hessian bands, and assessed their protective efficacy against outdoor-biting mosquitoes. Semi-field experiments were conducted with sandals affixed with hessian bands measuring 48cm^2 or 240cm^2, and either size treated with technical grade transfluthrin solution at 3%, 5% and 8%. Untreated sandals with similar hessian surface areas were used as controls. Mosquito landings on volunteers were compared to assess protective efficacy afforded by the treatments, relative to control. In semi-field tests, sandals fitted with 48cm^2 hessian bands impregnated with 8%, 5% and 3% transfluthrin reduced mosquito landings by 68.87%, Incidence rate ratio (IRR)=0.31 (95% C.I. 0.25-0.38), p<0.0001), 62.52%, IRR=0.37 (0.28-0.50), p<0.0001) and 22.95% IRR=0.77 (0.62-1.96), p=0.018) respectively. Sandals affixed 240cm^2 bands and treated with 8% transfluthrin reduced landings by 57.91%, IRR=0.42 (0.29-0.61, p<0.0001) while bands measuring 48cm^2 and treated with 8% transfluthrin reduced landings by 54.44%, IRR=0.45 (0.32-0.65, p<0.0001). In field experiments, the 48cm^2 band sandals treated with 8% transfluthrin conferred 77.63%, IRR=0.22 (0.14-0.37, p=<0.0001) and 68.32%, IRR=0.32 (0.25-0.41, p<0.0001) protection against all mosquitoes relative to controls. In conclusion, transfluthrin-impregnated footwear conferred significant protection against mosquito bites in semi-field and field settings. However, Various improvements, optimization and validation of this approach is required. Nonetheless, this approach could potentially constitute a complimentary tool against mosquito-borne diseases.

449

CHARACTERIZATION OF OUTDOOR MOSQUITO BITING AND RESTING BEHAVIORS AS ONE OF THE DRIVERS OF ONGOING MALARIA TRANSMISSION IN ZANZIBAR

Revocatus M. Musiba[1], Brian B. Tarimo[1], April Monroe[2], Dickson Msaky[1], Kimberly T. Mihayo[1], Godlove T. Chila[1], Gasper Shubis[1], George Greer[3], Juma Mcha[4], Abdullah Ali Ali[4], Fredros Okumu[1], Samson Kiware[1]

[1]USAID VectorWorks Project, Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania, [2]USAID VectorWorks Project, Johns Hopkins University Center for Communication Programs, Baltimore, MD, United States, [3]US President's Malaria Initiative, US Agency for International Development, Dar es Salaam, United Republic of Tanzania, [4]Zanzibar Malaria Elimination Program (ZAMEP), Unguja, Zanzibar, United Republic of Tanzania

Current vector control interventions, notably long-lasting insecticide treated nets (LLINs) and indoor residual spraying (IRS) have contributed significantly to the reduction in malaria burden. However, in certain settings, residual transmission persists, despite over 80% coverage with LLINs and IRS. We conducted a study in Unguja island of Zanzibar to determine the magnitude and drivers of residual malaria transmission by assessing when and where it occurs. Six sites from three districts with greater than 5/1000 annual parasite incidence and which received IRS in 2016 were selected by using a stratified random sampling approach. A total of 135 households were chosen ranging from 20-25 households per site and consented for the study. Mosquito vector surveillance was carried out indoors and outdoors from 6:00PM-7:00AM using human-baited double net (HDN) trapping, a standardized exposure-free method. Additional collections were done indoors using mouth aspirators to retrieve resting mosquitoes from wall and ceiling surfaces, and outdoors using resting bucket traps and pit traps. Out of 689 malaria vectors collected, PCR analysis shows that 98.4% were *Anopheles arabiensis*, 1% *Anopheles merus* and 0.6% *Anopheles gambiae s.s.* Sporozoite ELISA analysis indicates that all mosquitoes were negative for the malaria parasite. The results show more *An. arabiensis* were collected outdoors (~85%) compared to indoors (~15%) indicating a high proportion of outdoor biting, which could be one factor contributing to ongoing residual transmission in Zanzibar. Furthermore, results show that large numbers of *An. arabiensis* were caught in outdoor resting sites, where the pit trap (67.2%) collected more mosquitoes compared to the outdoor HDN trap (32.8%). Therefore, testing of novel techniques targeting outdoor biting and/or resting mosquitoes, is warranted in these settings. If found to be effective, these new approaches would complement the existing interventions against mosquitoes that bite and/or rest outdoors, hence contributing toward malaria elimination.

450

FITNESS COST OF L119F-GSTE2 METABOLIC RESISTANCE ON THE LIFE TRAITS OF *ANOPHELES FUNESTUS* FIELD POPULATION FROM MIBELLON, CAMEROON

Magellan Tchouakui, Doumani Djonabaye, Charles Wondji

LSTM_CRID, Yaounde, Cameroon

Poor understanding of the fitness cost of resistance on mosquito field populations is a serious threat for implementation of successful resistance management strategies. To better inform resistance management, we evaluated the fitness cost of L119F-GSTe2 (first DNA-based molecular marker of metabolic resistance in *Anopheles funestus*) related to distinct aspects of development and reproduction of natural *An. funestus* s.s. populations. *An. funestus* s.s. field mosquitoes were collected in Mibellon (Cameroon). A cocktail polymerase chain reaction (PCR) was used for molecular identification and a new allele-specific PCR (AS-PCR) performed to genotype the L119F-GSTe2 mutation (associated with DDT and permethrin resistance). We compared the fecundity, fertility, larval and pupal developmental time and adult longevity as well of L119F-RR homozygous resistant mosquitoes to that of the L119F-RS heterozygotes and L119F-SS homozygous susceptible mosquitoes. In this *An. funestus* s.s. field population, L119F-SS mosquitoes had more chance to lay eggs compared to L119F-RS and L119F-RR, interestly, L119F-RR mosquitoes produced significantl lower number of eggs compared to L119F-RS and L119F-SS ($P = 0.003$) suggesting a fitness cost of L119F mutation on fecundity of females mosquitoes. Otherwise, assessment of the odd ratio for pupae formation showed that L119F-RS developed significantly faster than L119F-RR ($1.04< OR <5.26$; $0.0001<P<0.42$) and slightly faster than L119F-SS ($1.38< OR <1.39$; $0.03<P<0.08$). However, L119F-RR showed higher longevity compared to other genotypes ($2.2< OR<7.5$; IC 95%: 1.04 - 21.28; $0.001< P< 0.050$). These results suggest that L119F-GSTe2 mutation have a detrimental impact on some life-traits of *Anopheles funestus* field mosquitoes indicating that resistance management strategies such as insecticide rotation could help reverse the DDT/ pyrethroids resistance. However, increase longevity observed in resistant mosquitoes could be problematic if not well managed.

451

INHIBITION OF *PLASMODIUM* INFECTION IN *ANOPHELES* MOSQUITOES BY GENETICALLY ENGINEERED *ASAIA SP.* BACTERIA

Christina L. Grogan, David J. Lampe

Duquesne University, Pittsburgh, PA, United States

Plasmodium sp., the parasite that causes malaria, is transmitted by *Anopheles sp.* mosquito vectors. The symbiotic bacteria within the mosquito midgut can be transgenically modified to affect the mosquito's phenotype, otherwise known as *paratransgenesis*; this strategy can be used to engineer the bacteria to secrete anti-*Plasmodial* effector molecules outside of the cell and into the mosquito midgut to combat the parasite. One such bacterial candidate is *Asaia sp.*, a Gram-negative, rod-shaped bacterium that has been shown to colonize the midgut, ovaries, and salivary glands within the *Anopheles* mosquito. However, common secretion signals, such as the *E. coli* Type II OmpA and TolB leader peptides, and signals from closely-related species do not function in *Asaia*. Also, a genetic library screen had found only one native secretion signal that provided sufficient secretion of protein into the supernatant. Therefore, the *Asaia sp. SF2.1* genome sequence was used to identify Type II secreted proteins, and further processed using SignalP4.1 to identify the leader signals. The top 20 of these signals were cloned into the plasmid pNB92, which contains a constitutive promotor and the C-terminal domain of *E. coli* alkaline phosphatase. Of these constructs, 13 were stable in the *Asaia sp. SF2.1* lab strain. Strains were grown overnight to log phase and separated into the supernatant, lysate, and cell surface fractions. Secretion of alkaline phosphatase was tested by ELISA and Western blot assays for the abundance of protein into the different fractions. Of the 13 signals, five mediated very efficient secretion. To ensure alkaline phosphatase is active when secreted, another multiwell plate assay using PNPP substrate was used. This is important because some of the anti-malarial effector molecules being used contain disulphide bonds, which are formed in the periplasm and are important for proper protein folding and function. Alkaline phosphatase was active when secreted with all five signals. *Asaia* strains with these signals expressing scorpine, a strong anti-*Plasmodial*, have shown significant oocyst reduction in *in vivo Plasmodium* inhibition experiments.

452

PURSUING EFFECTIVE LLIN COVERAGE AND UTILIZATION IN NEW AREAS OF NORTHERN RAKHINE STATE, MYANMAR

Kyaw M. Tun, Saw Lwin, Ye Hein Naing, Sway Minn Htet, Khant Maung Maung, Saw Naung Naung, Zaw Myo Htet, Kaung Myat Min, May Aung Lin, Saw Simon

University Research Co.,LLC, Bahan Township, Yangon, Myanmar

The PMI-supported Defeat Malaria project works with communities, partners and the National Malaria Program to optimize access to effective malaria interventions based on situational analyses and ongoing monitoring. Long lasting insecticidal nets (LLINs) continue to play a critical role in vector control for reducing malaria transmission. A baseline assessment to plan effective LLIN distribution in Northern Rakhine State (NRS) was conducted in June 2017. The assessment comprised of quantitative interviews with 422 household representatives selected by multi-stage sampling (random selection of villages, systematic sampling of households) from 6 new townships assisted by Defeat Malaria in NRS (Kyauktaw, Minbya, Myebon, Pauktaw, Ponnagyun, Sittwe). Bed-net data were collected at the household level using a bed-net characteristics assessment tool, with observation of available nets. Only 6.6% and 2.1% of respondents previously received malaria related messages about the importance of sleeping under LLINs and that mosquitos spread malaria, respectively. The survey revealed that 91% of households owned at least one LLIN, 62% owned at least one LLIN for every two persons, and 67% of household members slept under a LLIN the previous night. Of households possessing at least one bed-net, they comprised LLINs (78%), ordinary nets (21%), and ordinary nets treated with insecticide (<1%). Nearly 4% owning LLINs reported they washed them more than 5 times within the previous 3 months due to bedwetting of children. More than 90% reported LLINs were dried under the sun after washing. In Minbya Township, anecdotal reports showed that several people preferred ordinary nets to LLINs as the hole size of LLINs permits the entry of ticks. Distribution of LLINs should be coupled with appropriate informational materials and inter-personal communication promoting continuous and correct use by all household members. LLIN monitoring should be conducted through observation of available bed-nets with enquiry of quality aspects of LLIN and participatory learning with communities for better action to achieve and maintain LLIN coverage and utilization targets.

453

STANDARDIZED MONITORING OF DURABILITY OF LONG-LASTING INSECTICIDAL NETS IN FIVE COUNTRIES IN AFRICA AND ASIA

Albert Kilian[1], Ana Paula Abílio[2], Emmanuel Obi[3], Ameir H. Khamis[4], Paul Mansiangi[5], Si Thu Thein[6], Sean Blaufuss[7], Lilia Gerberg[8], Hannah Koenker[7]

[1]USAID Vectorworks Project, Tropical Health LLP, Montagut, Spain, [2]USAID Vectorworks Project, National Health Institute, Maputo, Mozambique, [3]USAID Vectorworks Project, Tropical Health LLP, Abuja, Nigeria, [4]USAID Vectorworks Project, Zanzibar Malaria Elimination Programme, Stone Town, United Republic of Tanzania, [5]USAID Vectorworks Project, School of Public Health University Kinshasa, Kinshasa, Democratic Republic of the Congo, [6]USAID Vectorworks Project, Population Services International,

Yangon, Myanmar, [7]USAID Vectorworks Project, Johns Hopkins University Center for Communication Programs, Baltimore, MD, United States, [8]US President's Malaria Initiative, US Agency for International Development, Washington, DC, United States

Following the 2014 WHO recommendation on measurement of durability of Long-lasting Insecticidal Nets (LLIN) the US President's Malaria Initiative (PMI) has developed a standardized protocol and tools to support countries to carry out monitoring of LLIN durability following their mass distributions (see www.durabilitymonitoring.org). The basic design is that of a representative cohort of 345 campaign LLINs per site which is established within six months after distribution and followed with annual assessment of attrition, net integrity, and insecticidal effectiveness for 36 months. Primary outcomes are the proportion of cohort nets surviving in serviceable condition at each time point and the median survival in serviceable condition in years. The USAID/PMI funded VectorWorks project is supporting five countries in durability monitoring with a total of 12 sites: Mozambique, Nigeria, Tanzania/Zanzibar, Democratic Republic of Congo (DRC) and Myanmar. In Mozambique (3 sites) and Nigeria (3 sites) the same or a very similar brand of LLIN is compared between areas with different environment and net use, care and repair behavior while in Zanzibar, DRC and Myanmar different LLIN brands are compared between two similar sites. To date, 5 sites have completed the 24 months and 7 sites the 12 months data collection and all LLIN brands have shown sufficient insecticidal effectiveness, i.e. >80% of samples passed the WHO criteria for optimal effectiveness. After 12 months the proportion of campaign LLIN surviving in serviceable condition varied between 69% and 98% corresponding to a median survival estimate between 1.5 and 5.6 years. The biggest differences were found in the comparisons of the same LLIN brand between different sites after 24 months: Nigeria 2.7 to 5.6 years and Mozambique 2.7 to 3.7. Among the comparisons of two different LLIN a significant difference was found in Zanzibar after 12 months (2.3 vs. 3.5 years, p=0.02) and DRC (1.5 vs. 2.4 years, p=0.0001) while in Myanmar the difference (3.5 vs. 4.2 years) was not statistically significant. Complete 24 month data and 36 months data from 5 sites will be available in September 2018.

OXIDATIVE STRESS-INDUCED DIFFERENTIAL PACKAGING OF PROTEINS IN ENTEROTOXIGENIC *ESCHERICHIA COLI* OUTER MEMBRANE VESICLES AND ITS IMPACT ON HOST-PATHOGEN INTERACTIONS

Nichole Orench-Rivera, Meta J. Kuehn

Duke University, Durham, NC, United States

Enterotoxigenic *Escherichia coli* is the leading cause of traveler's diarrhea worldwide and it remains an important causal agent of diarrheal disease, especially among children of lower income countries. Because it must adjust to different ecological niches such as fruit and vegetable surfaces, water, and its animal or human host; its cell envelope must undergo remodeling. In Gram-negative bacteria, the cell envelope is the first barrier against environmental stress and studies have shown that the process of outer membrane vesiculation is essential for bacterial growth and survival during stressful conditions. Recent studies in our lab revealed that outer membrane vesicles (OMVs) can contain varying ratios of lipopolysaccharide (LPS) types during cell envelope remodeling under stress in *Salmonella enterica*, suggesting a role for vesicles in membrane remodeling. In this study, outer membrane vesicles and outer membrane fractions from ETEC were isolated from bacterial cultures, purified via density centrifugation, and submitted for proteomic analysis using quantitative one-dimensional liquid chromatography, tandem mass spectrometry (1D-LC-MS/MS) to quantify differences in protein expression in vesicles and membranes during oxidizing and non-oxidizing conditions (plus or minus Hydrogen Peroxide). Protein packaging into vesicles was determined by calculating the $\log_2$ of the ratio of protein expression in OMVs/outer membranes for both treatment conditions. Results indicated that two distinct sets of proteins were shown to be differentially packaged into OMVs as a function of peroxide treatment. Upon further analysis implementing a Bayesian hierarchical model, lipoproteins were observed to be preferentially exported during stress, in contrast to integral proteins, which were preferentially retained in the outer membrane. These results suggest possible roles for previously uncharacterized lipoproteins in the oxidative stress pathway and allow us to speculate about potential roles for OMVs in membrane remodeling of pathogenic bacteria undergoing environmental shifts both outside and inside the human host.

BURDEN OF ACUTE GASTROINTESTINAL INFECTIONS IN OUAGADOUGOU, BURKINA FASO

Rene Dembele[1], Elisa Huovinen[2], Denis Yelbeogo[3], Marku Kuusi[2], Guetawendé Sawadogo[3], Kaisa Haukka[4], Isidore J. Bonkoungou[5], Anja Siitonen[4], Alfred S. Traore[6], Nicolas Barro[6]

[1]Laboratoire d'Epidémiologie et de Surveillance des Bactéries et Virus transmissibles par les Aliments, CRSBAN/UFR-SVT, Université Ouaga 1, Joseph KI-ZERBO/University of Dedougou, Dedougou, Burkina Faso, [2]Epidemiological Surveillance and Response Unit, Department of Infectious Disease Surveillance and Control, National Institute for Health and Welfare (THL), Helsinki, Finland, [3]Service de Surveillance Epidémiologique, Direction de la Lutte contre la Maladie (DLM)/Ministère de la Santé, Ouagadougou, Burkina Faso, [4]Bacteriology Unit, Department of Infectious Disease Surveillance and Control, National Institute for Health and Welfare (THL), Helsinki, Finland, [5]Laboratoire d'Epidémiologie et de Surveillance des Bactéries et Virus transmissibles par les Aliments, CRSBAN/UFR-SVT, Université Ouaga 1, Joseph KI-ZERBO/Laboratoire National de Santé Publique, Ouagadougou, Burkina Faso, [6]Laboratoire d'Epidémiologie et de Surveillance des Bactéries et Virus transmissibles par les Aliments, CRSBAN/UFR-SVT, Université Ouaga 1, Joseph KI-ZERBO, Ouagadougou, Burkina Faso

Gastrointestinal infections are one of the major health problems in developing countries. The present study aims to estimate the prevalence of gastrointestinal infections in Ouagadougou, the capital of Burkina Faso. A door-to-door survey of selected residents in Ouagadougou city was conducted. Of the Ouagadougou's 30 districts, nine most populated ones were selected to the study. The residents of these districts have middle incomes as those of the secondary cite of Burkina Faso. The overall prevalence of gastrointestinal infections in the 30 days prior to the interview was 77/491 (15.7%): among children 44/223 (19.7%) and among adults 33/268 (12.3%). Diarrhea and abdominal pain were the most common symptoms among 33 adult cases while diarrhea and vomiting were the most common among children. None of the cases were hospitalized and a stool sample was taken in three of 77 cases. Medication for gastrointestinal infections was received by 55% percent of adults and 77% of children. Our results shown that antibiotics with and without prescription were the most common medicine used. Washing hands before meals and boiling milk before drinking had a protective effect against gastrointestinal infections.

456

A RANDOMIZED, OBSERVER-BLINDED, PHASE I STUDY TO ASSESS THE SAFETY AND IMMUNOGENICITY OF VI-DT CONJUGATE VACCINE COMPARED TO VI-POLYSACCHARIDE (TYPHIM VI®, SANOFI PASTEUR) TYPHOID VACCINE IN HEALTHY FILIPINO ADULTS AND CHILDREN

Samuel T. Tesema, Sushant Sahastrabuddhe

International Vaccine Institute, Seoul, Republic of Korea

As the currently licensed typhoid vaccines have limitations and cannot be administered in children less than 2 years of age, the International vaccine Institute developed a typhoid conjugate vaccine (Vi-Polysaccharide conjugated to diphtheria toxoid (Vi-DT)) which was transferred to SK Chemicals in Korea. After completing the preclinical study phase I clinical

trial was conducted in the Philippines. In this randomized, observer-blinded Phase I study to assess the safety and immunogenicity of Vi-DT compared to Vi-Polysaccharide vaccine, 2-45-year old participants (stratified into 3 age cohorts) were randomized to Test (Vi-DT) and Comparator (Vi-Polysaccharide) vaccine administered at 0 and 4 weeks. The objectives were to evaluate the safety and immunogenicity (anti-Vi IgG and serum bactericidal antibody, SBA) of 25 µg of Vi-DT comparatively to Vi-Polysaccharide (Typhim Vi®, Sanofi Pasteur) vaccine. 48 participants in each age cohort for a total of 144 participants were enrolled and randomized to Vi-DT vs. Comparator equally. No SAE was reported in either group. No subject was discontinued from the study due to AE. All solicited and unsolicited AEs were mild or moderate in both groups with the exception of a 4-year old girl in Test group with severe (grade 3) fever that resolved without sequela. All subjects (100%) in Test group showed seroconversion after 1st and 2nd doses while 97.1% and 97.2%, respectively in Comparator group. Vi-DT showed 4-fold higher GMT of anti-Vi IgG than Comparator. No further increase of GMT was observed after the 2nd dose. SBA seroconversion rate in Test group was higher than Comparator group after first dose (71% vs. 52.2%) and second dose (70.4% vs. 51.4%). SBA GMT showed similar pattern post first and second doses. Anti-DT responses post first dose in the test group were higher, 26-fold rise compared to baseline value, while a 0.93-rise in the Comparator group. The results of this first-in-human Phase I trial of Vi-DT show that the vaccine is safe, generally well-tolerated and immunogenic in participants aged 2-45 years. These results allow pursuing the clinical development of Vi-DT in children 6 to 23 months of age.

"CHOLERA CONFERENCE": OUTBREAK DURING AN INTERNATIONAL SCIENTIFIC CONFERENCE, KENYA, 2017

Valerian Mwenda[1], Alexis Niyomwungere[1], Mark Obonyo[1], Elvis Oyugi[1], Jane Githuku[1], Emmanuel Okunga[2], Zeinab Gura[1]

[1]Field Epidemiology and Laboratory Training Programme, Ministry of Health, Nairobi, Kenya, [2]Disease Surveilance and Response Unit, Ministry of Health, Nairobi, Kenya

Cholera, pervasive in Kenya since 2015, has typically affected informal settlements and other low income communities. On 20 June 2017, officials were alerted to a suspected cholera outbreak among attendees of an international scientific conference with >400 participants, in Nairobi. The Kenya Ministry of Health investigated from June 21 to identify cause of the outbreak. We carried out a retrospective cohort study; a cohort member was any conference attendee. A suspected case had acute watery diarrhea (AWD) within 20-28 June 2017; confirmed case was culture-positive. We administered a structured questionnaire by telephone, email and online survey, collecting syndromic and exposure information. We calculated food-specific attack rates, risk ratios and in a nested case-control analysis (non-cases as controls) calculated adjusted odds ratios (aOR) to identify factors independently related to being a case. There were 456 registered participants: 88% from Nairobi County, 10% from other Kenyan Counties and 2% international. We interviewed 55% (249/456) of participants (70% by telephone, 28% online survey and 2% by email). Of those interviewed, 55% (137/249) had AWD; of these, 36% were hospitalized (median duration 3 days, range 2-11 days), 13% were culture-confirmed for cholera, 2 were international participants. Attack rates were 41% females, 50% males; 44% age 20-39 years and 50% ≥40 years. RDT positivity was 67% (8/12). Most cases presented with AWD (95%) and abdominal pain (73%). Cases peaked on conference day two, with a point-source pattern. Average incubation period was 35(11-59) hours. Eating chicken (aOR 2.49, 95% CI 1.22-5.06) on 20 June was associated with illness; drinking soda was protective (aOR 0.20, 95% CI 0.08-0.52). Chicken served over lunch on 20 June was the most probable source; however we were not able to identify exact contamination point. Improved food industry/health sector collaborations can allow trace-back during food-borne outbreaks for cholera and other pathogens.

458

LONGITUDINAL ASSESSMENT OF ENTERIC PATHOGEN EXPOSURE IN MALAWI CHILDREN

Angeziwa C. Chirambo

Malawi Liverpool Wellcome Trust, Blantyre, Malawi

Enteric pathogens are the main cause of diarrhea infection although a high burden of enteric pathogens has also been reported in the absence of diarrhea. Diarrhea is the leading cause of morbidity and mortality in under five children. In Africa, about 440million cases and 350000 deaths are reported annually. Children in developing countries like Malawi are exposed to risk factors that predispose them to increased enteric infection burden. Sixty healthy children were recruited at 6months and followed up once every month until 18 months. Stool samples were collected every month. Stool samples were tested using Enteric TaqMan array card assay, which uses real-time polymerase chain reaction for the simultaneous detection of multiple enteropathogen. Analyses to determine pathogen exposure events at different time points were performed. A total of 1526 targets (grouped depending on pathogen) were detected from 442 samples tested from all time points. E. coli (EAEC, EPEC and ETEC) and Enterovirus constituted 60% of the positive targets. There was a very high rate of multiple pathogen detection per sample with 1.6%, 10.7% and 87% of samples having 0, 1 and >2 positive detection. Longitudinal analysis shows continuous exposure to E. coli and Enterovirus with no significant difference at different time points. Giardia infection was associated with children greater than 15 months while cryptosporidium was common in 7 to 12 months olds. A high rate of of individual variability was observed in pathogen detection at different time points. Malawian children are exposed to multiple pathogens very early in life. E. coli which may have adapted to the gut microbiota of Malawian children may not be clinically significant but need to be further studied for the immunological implication it may have in vaccine response and also its role in other enteric pathogen infections.

459

GUT MICROBIOTA PROFILES OF CHILDREN BEFORE AND AFTER DRINKING CHLORINATED WATER

Shirajum Monira[1], Christine Marie George[2], Fatema Zohura[1], Sazzadul Islam Bhuyian[1], Farzana Begum[1], Tahmina Parvin[1], David Sack[2], R. Bradley Sack[2], K. M. Saif-Ur-Rahman[1], Mahamud-ur Rashid[1], Kazi Zillur Rahman[1], Maqsud Hossain[3], Munirul Alam[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]NSU Genome Research Institute, North South University, Dhaka, Bangladesh

Household members of cholera patients are at elevated risk of cholera infections during the first one week period than the general population as they live in close association sharing food and drinking water that are often found contaminated. We investigated the gut microbiota of household children before and after drinking chlorinated water, which was part of a randomized control trail of cholera hospital based intervention for 7 Days (CHoBI7), to see whether drinking chlorinated water had any effect on their intestinal microbiota. For this, bacterial community DNA was extracted from fecal samples of five children (age 3-7 yrs) living in urban slum of Dhaka, at day 0 (before intervention) and at day 8 of drinking chlorinated water. Illumina MiSeq sequencing of the microbial community DNA in stool samples revealed the presence of bacteria belonging to family Vibrionaceae at day0, but not at day 8. A total of 65 bacterial families were observed at day 0, which reduced to 60 with 6 families that were unique at day 8. Eleven families were unique at day 0 of which 6 belonged to the phylum Proteobacteria that included mostly pathogenic bacteria, and 5 of these families belonging to Proteobacteria were lost due to drinking chlorinated water, as observed at day 8. None of these five children developed cholera or any other diarrheal illness during this most risky one week period. While the phyla Bacteroidetes,

Firmicutes, Proteobacteria and Actinobacteria were predominant with the relative abundance of (mean ± SEM %) 62 ± 6, 32 ± 7, 4 ± 1 and 1 ± 0.7 at day 0, respectively, the proportion changed at day 8, when bacteria belonging to the phylum Firmicutes increased [49% ± 12 (p=0.057)] over Bacteroidetes [39% ± 12 (p=0.034)] as observed for all five children at day 8. Furthermore, the proportion of beneficial Firmicutes belonging to the family Lachnospiraceae, Bifidobacteriaceae, Clostridiaceae, Ruminococcaceae, increased due to chlorination of drinking water. The observed decrease of harmful Proteobacteria and increase of beneficial Firmicutes suggest chlorination to be a means to prevent environmental enteropathy-related gut microbiota dysbiosis and ill health.

460

CLINICAL PREDICTORS OF BACTERIAL DIARRHEA AMONG INTERNATIONAL TRAVELERS TO NEPAL

Melissa A. Pender[1], Timothy Smith[1], Prativa Pandey[2], Siriporn Sornsakrin[3], Ladaporn Bodhidatta[3], Daniel T. Leung[1]

[1]University of Utah School of Medicine, Salt Lake City, UT, United States, [2]CIWEC Travel Medicine Center, Kathmandu, Nepal, [3]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Acute diarrhea is a common illness among international travelers, affecting approximately 20% of individuals traveling to at-risk countries and contributing to approximately one-third of post-travel medical visits. Clinicians and travelers have limited tools to differentiate bacterial from non-bacterial causes of traveler's diarrhea (TD). Therefore, TD is typically treated empirically with antibiotics based on symptom severity, regardless of etiology. Development of a clinical prediction rule to assess the etiology of TD may aid clinicians in correctly identifying episodes of bacterial diarrhea as well as limiting inappropriate use of antibiotics. We collected de-identified clinical data from 284 international travelers who presented with acute diarrhea to the CIWEC Travel Medicine Center in Kathmandu, Nepal. Both conventional and molecular methods were used to determine diarrheal etiology from stool samples. Logistic regression and machine learning algorithms were used to identify predictors of bacterial diarrhea based on clinical and demographic variables. Categories of variables included age, gender, nationality, purpose of travel, presenting symptoms, symptom duration, temperature, stool grade, and stool microscopy results. Diarrheal etiologies among the 284 cases were identified as follows: 98 bacterial, 51 viral, 73 mixed pathogens, 6 protozoal/parasite, 55 no pathogen detected, and one unknown. Random forest and logistic regression analyses indicated that the strongest predictors of bacterial over viral or non-detected etiologies included red blood cells noted on stool microscopy, a non-Asian country of origin, temperature greater than 38°C, number of diarrheal episodes in the last 8 hours, and mucous noted on stool microscopy. Our preliminary analysis demonstrated multiple promising variables for the clinical prediction of bacterial diarrhea. By the time of presentation, internal cross-validation of a clinical prediction rule and external validation against an independent data set will be completed.

461

DETECTION OF *TROPHERYMA WHIPPLEI* IN CAMBODIA FROM PATHOGEN-NEGATIVE STOOL SAMPLES

Sasikorn Silapong

Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Tropheryma whipplei is a rod-shape Gram-positive bacterium responsible for a disease called Whipple's Disease (WD). There are five common clinical features of WD including classic, localized, acute, acute asymptomatic, and opportunistic (associated with immunosuppression) infections. The most prominent symptom of WD is gastroenteritis, but endocarditis, encephalitis, pneumonia, and bacteremia may also occur. Diarrhea, abdominal pain, and steatorrhea are among the most frequently observed symptoms in classic WD. The majority of WD patients are male Caucasians, although this disease rarely occurs in Asian and African patients, this population may be carriers. There has only been one report of *T. whipplei* in Southeast Asia (SEA) from stool samples of healthy Laotian kindergarteners. *T. whipplei*, however, was detected in saliva, urine, blood, stool, and lymph nodes, etc. Detection of *T. whipplei* was previously based on two rounds of real-time PCR. In this study, a duplex real-time PCR detection was developed and optimized for the detection of *T. whipplei* and applied to a set of pathogen-negative stool samples previously negative for any enteric pathogens routinely tested. Samples positive for *T. whipplei* were further confirmed by sequencing of PCR products. Preliminary, 88 pathogen-negative cases and 83 controls stool samples from a diarrhea surveillance study among local population in Battambang, Cambodia, which included children aged 3 months to 5 years and active military personnel aged 18-60 years, were selected for testing. Two cases (one adult and one child) and 3 controls (all children) were positive for *T. whipplei*. This accounts for 3% detection. Detection efforts are ongoing and additional samples will be tested. These results add to the general epidemiology of *T. whipplei* in the SEA region, specifically in Cambodia, in addition to those previously reported in Laos.

462

IMPACT OF ROTAVIRUS VACCINATION ON DIARRHEA RATES ACROSS PROVINCES OF PERU WITH VARYING PIPED WATER ACCESS, PIPED SEWER CONNECTION ACCESS, AND POVERTY LEVELS

Miranda J. Delahoy[1], Cesar P. Carcamo[2], Luís Angel Ordoñez Ibarguen[3], Benjamin Lopman[1], Gustavo F. Gonzales[2], Kyle Steenland[1], Karen Levy[1]

[1]Emory University, Atlanta, GA, United States, [2]Universidad Peruana Cayetano Heredia, Lima, Peru, [3]Ministerio de Salud del Perú (Ministry of Health, Peru), Lima, Peru

Peru has undergone rapid economic growth over the past decade, accompanied by declines in poverty and increases in access to piped water and sewer connections. Rotavirus vaccination was added to the national immunization program in 2009. Little is known about the impact of recent health/infrastructure developments on diarrhea rates in Peru. We analyzed spatially detailed data on clinic visits for diarrhea from 2005-2015 and on infant rotavirus vaccinations provided by The Peruvian Ministry of Health. Household data on access to piped water/sewer connections and poverty levels were obtained from the Peruvian National Institute of Statistics and Informatics. We examined rates of childhood diarrhea in the provinces of Peru by fitting three Poisson mixed models to investigate the impact of rotavirus vaccination on diarrhea rates, controlling separately for access to piped water, access to a sewer connection, and the percent of the population living in poverty. The rate of clinic visits for diarrhea in children under 5 years old in Peru decreased by approximately one third from 2005 to 2015. Across all models, there was a significantly lower rate of childhood diarrhea when provinces were vaccinating at least 50% of infants, controlling for each covariable of interest and accounting for long-term secular trends. Diarrhea reductions were similar to those published for other countries in Latin America after rotavirus vaccine introduction. This is the first nationwide analysis of the impact of rotavirus vaccination on diarrhea in Peru; our approach is unique in accounting for other factors that may contribute to long-term diarrhea trend.

SUSCEPTIBILITY TO SYMPTOMATIC ENTEROTOXIGENIC *ESCHERICHIA COLI* INFECTIONS IN NON-SECRETOR NICARAGUAN CHILDREN

Johann Perez[1], Fredman Gonzalez[1], Johan Nordgreen[2], Filemon Bucardo[1], Samuel Vilchez[1]

[1]National Autonomous University of Nicaragua–Leon, Leon, Nicaragua, [2]Linköping University, Linköping, Sweden

Enterotoxigenic *Escherichia coli* (ETEC) is an important causative agent of Diarrhea in Children and adults from all over the world, including

Nicaragua. A study conducted in Bangladesh have suggested that children with Lewis blood group "a" antigen (Le^a) have more often symptomatic than asymptomatic Enterotoxigenic *Escherichia coli* (ETEC) infections (*P<0.001*). Furthermore, another study carried out with the same population showed that two non-synonymous *FUT2* single nucleotide polymorphisms (rs200157007-TT and rs601338-AA) are associated with symptomatic but not asymptomatic ETEC infection irrespective of the child's Lewis secretor status. Based on the above observations, we conducted the present study in order to investigate if a Non Secretor Status makes also Nicaraguan children more susceptible to symptomatic ETEC infections. A total of 234 children ≤5 years of age (91 symptomatic and 143 asymptomatic) participated in a community- and hospital-based study of acute diarrhea in León, Nicaragua, during 2014–2017. In brief, clinical cases were evaluated according to the World Health Organization strategy for diarrhea management and fecal and saliva samples were collected from each child. PCR was used to detect the ETEC pathotype. The Lewis phenotype and Secretor status was determined by an ELISA based assay. In general ETEC was detected in 14.1% (33/234) of the children, with14.3% ETEC positive cases in the symptomatic and 14.0% of the asymptomatic children. We found no association between the Lewis phenotype and symptomatic ETEC infection. However, we could see a higher proportion of symptomatic than asymptomatic ETEC infections in Non-secretors Children (23.1% symptomatic and 12.0% asymptomatic), and similar proportions of ETEC infections in Secretors children (12.5% symptomatic and 14.7% asymptomatic). In conclusions, our results also suggest that a Non secretor status is a host feature affecting susceptibility to ETEC infection and have implications in the current vaccine efforts.

464

PREVALENCE AND PHENOTYPES OF ANTIBIOTIC RESISTANCE IN *E. COLI* ISOLATED FROM THE MAL-ED BIRTH COHORT STUDY IN RURAL TANZANIA

Molly E. Fleece[1], Rosemary Nshama[2], Thomas Walongo[2], Jean Gratz[1], James Platts-Mills[1], Esto Mduma[2], Eric Houpt[1]

[1]University of Virginia, Charlottesville, VA, United States, [2]Haydom Lutheran Hospital, Haydom, United Republic of Tanzania

The emergence and spread of antimicrobial resistance is a serious global public health crisis. Drug-resistant gram-negative bacteria, like *Escherichia coli*, are particularly concerning given their significant morbidity and mortality. Despite the increasing prevalence of drug-resistant gram-negative bacteria worldwide, there are significant knowledge gaps in low resource countries. We aimed to characterize the prevalence and phenotypes of drug-resistant *E. coli* carriage in children up to age 5 from stool collected in the Etiology, Risk Factors, and Interactions of Enteric Infections and Malnutrition and the Consequences for Child Health and Development (MAL-ED) birth cohort study in rural Tanzania. 262 children were enrolled in the MAL-ED Tanzania site. We randomly selected 100 children who had *E. coli* specimens archived every 6 months through 60 months. Up to 5 lactose-fermenting colonies were selected from growth on MacConkey agar. Drug susceptibility testing of 18 antibiotics was performed by disk diffusion. CLSI interpretive criteria were used for determination of resistance. Multi-drug resistance (MDR) was defined as non-susceptible to at least 1 antibiotic in at least 3 antimicrobial categories. 823 *E. coli* specimens were available for testing. Antibiotic resistance was identified in some samples for all drugs except ertapenem, which was 100% susceptible. The highest rate of resistance was for ampicillin (93%) followed by cefazolin (92%) and cotrimoxazole (90%). 15 (1.8%) specimens met criteria for extended-spectrum beta-lactamase (ESBL) based on combination disk testing with cefotaxime/cefotaxime-clavulanate and ceftazidime/ceftazidime-clavulanate. 696 (84.6%) specimens met criteria for MDR. In conclusion, while ESBL *E. coli* carriage appears to be rare in this community, the prevalence of MDR *E. coli* carriage is high. Drug-resistance is common at 6 months of age.

465

AR-12 AND SILDENAFIL COMBINATION THERAPY FOR THE TREATMENT OF INTRACELLULAR *S. TYPHIMURIUM* INFECTIONS

Erica N. Pino, Md. Shamim Hasan Zahid, Monica M. Johnson, Eric M. Bachelder, Kristy M. Ainslie

University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Salmonella enterica is a gram-negative bacterium and a major contributor to bacterial foodborne illness which, according to The World Health Organization, infects over 550 million people worldwide and results in 230,000 deaths each year. Importantly, multi-drug resistant (MDR) strains of *S. enterica* are continually increasing, sparking significant health concerns globally. To overcome antibiotic-resistance, host-directed therapies, which act on the host cell rather than on the pathogen, have been developed to circumvent resistance mechanisms by reducing or eliminating selective pressure on the pathogen. AR-12 (OSU-03012), a celecoxib derivative that has completed Phase I clinical trials for its anti-tumor activity, has been identified as a host-directed therapy against a number of intracellular pathogens. Previous work in our lab has shown that AR-12 reduces *S. enterica* serovar Typhimurium bacterial burden *in vitro* and *in vivo*; however, AR-12 is toxic to the host cell, resulting in a narrow therapeutic window. Furthermore, it has been reported that treatment with AR-12 in combination with FDA-approved Sildenafil, indicated for treatment of erectile dysfunction and pulmonary arterial hypertension, results in decreased bacterial viability compared to AR-12 treatment alone in various extracellular bacteria strains. In the current study, we evaluated the anti-infective properties of AR-12 in combination with Sildenafil as a potential host-directed therapy against intracellular S. Typhimurium infection. A synergistic response was observed following treatment of sub-optimal doses of AR-12 and Sildenafil to clear intracellular *S.* Typhimurium infections *in vitro*, as defined by the Chou-Talalay Combination Index. These results suggest that a combination of two host-directed therapeutics is a promising approach in the treatment of intracellular *S.* Typhimurium by mitigating cellular toxicity associated with treatment by therapeutic doses of AR-12 alone. Furthermore, this treatment strategy may prevent the emergence of resistant strains by reducing selective pressure on the pathogen.

466

EXTENDED SPECTRUM BETA-LACTAMASE PRODUCING *KLEBSIELLA PNEUMONIAE* BACTERAEMIA AND REDUCED SUSCEPTIBILITY TO CARBAPENEM IN LAGOS, NIGERIA

Kabiru O. Akinyemi[1], Bamidele A. Iwalokun[2], Rukayat Ayoola[1], Elsse O. Alafua[1], Rebecca Abegunrin[1], Christopher O. Fakorede[1], Muyiwa Adunmo[1], Samuel O. Ajoseh[1]

[1]Lagos State University, Ojo, Nigeria, [2]Nigerian Institute of Medical Research, Yaba, Nigeria

Klebsiella. pneumoniae exhibiting extended spectrum beta -lactamase (ESBL) production is increasing worldwide and mechanism is associated with the rapid dissemination of the genes under the selective pressure of antibiotic. Carbapenem usage has increased in clinical practice as a result of expanding resistance to other β-lactam antibiotics but its use in Nigeria is usually reserved for live threatening gram negative infections. The observed treatment failures associated with *Klebsiella*-associated bacteremia in recent times necessitated the investigation of the burden of ESBL producing *K. pneumoniae* and carbapenem resistant strains. A total of 127 patients with pyrexia of unknown origin attending referral public hospitals between April and September 2015 were recruited. Samples were cultured, isolates were identified and antimicrobial susceptibility test was performed on all the isolates .Detection of carbapenemase enzyme activity was carried out. Isolates were screened for ESBL production by the Double Disc Synergy test (DDST).Three gene makers; *bla* CTX-M1, *bla*SHV and *bla*TEM were used to characterize ESBL. Clonal relatedness

of the isolates was assessed by Random Amplified Polymorphism DNA (RAPD)- PCR typing technique. Specifically, 34% (43/127) *K. pneumoniae* bacteremia was identified. The overall prevalence of, ESBL and carbapenem resistant was 69.8% and 7.0% respectively. Of the ESBL producing isolates, 14.7% contained either of *bla*CTX-M1 or *bla*SHV gene makers. None of the three markers were detected in carbapenem resistant isolates. Four distinct RAPD types were exhibited by test isolates. There was no correlation between antibiotic resistance phenotype and RAPD fingerprints. This study revealed circulation of ESBL producing bloodstream *K. pneumoniae* and strains carrying *bla*CTX-M-1 and *bla*SHV genes in our environment. The observed emerging carbapenem resistance strains potent an early warning signal for the prudent use carbapenem antibiotic to prevent wide spread resistant. Further studies on the application of modern molecular techniques to assess the diversity and clonal relatedness of strains are in sight.

467

ESTABLISHING NEONATAL AND PEDIATRIC INTENSIVE CARE UNITS, OUTREACH EDUCATION TO LOCAL HEALTH FACILITIES, AND IMPLEMENTATION OF NEONATAL RESUSCITATION PROGRAM: IMPACT ON NEONATAL AND CHILD MORTALITY & MORBIDITY: MENDEFERA REGIONAL REFERRAL HOSPITAL, SOUTHERN REGION, ERITREA, A 6 YEARS EXPERIENCE

Samson Abay Asmerom

Eritrean Ministry of Health, Asmara, Eritrea

The United Nations' Millennium Development Goal 4 was to reduce the global under-five mortality rate by two-thirds by 2015. While Eritrea did achieve this goal, disparities between rural and urban areas remain with regard to infant and child survival. Mendefera Regional Referral Hospital serves a population of 800,000, receives referral from 65 different level health facilities. It is where interns, midwives and nurses do their rotations. With only one pediatrician to oversee the pediatric care of the hospital and the southern region and after conducting outreach education program to referring health facilities, establishing neonatal & pediatric intensive care units and Implementing " Helping Babies Breathe"(HBB) program; Decreased in-hospital stay (from 5.4 days in 2009 to 3.3 days in 2016), drop in hospital admission rate (from 1846 in 2009 to 440 in 2015), less referral-outs to regional hospital from local health facilities (from 614 in 2009 to 113 in 2015) were seen. Deaths related to pneumonia, gastroenteritis and malnutrition deceased with overall child mortality going down (from 92 deaths in 2009 to 20 in 2016). Neonatal mortality decreased by 51% (term by 45% & Preterm by 55% from 2012 to 2016), as well as incidents of perinatal asphyxia (by 45%) and meconium aspiration syndrome (by 70%). Overall, neonatal mortality decreased (by 40%) in the region. Establishing hospital systems and regional health activities that prioritize the neonate and the critically ill child with a reliable standardized protocol that strengthens local health facilities results in significant decrement in neonatal/child morbidity and mortality. It is not resource intensive. High-tech machines are not needed to improve pediatric care in Eritrea. Most of the childhood killer diseases can be managed using basic caring units (NICU & PICUs) and regular training of the staff. Intensive care unit is not a luxury in an African set up but a necessity and is feasible, cost effective produces highly motivated staff with improved skill of management. Conducting basic neonatal resuscitation program brings about significant change.

468

RISK FACTORS FOR DIPHTHERIA DURING THE OUTBREAK IN INDONESIA

Dominicus Husada, Desi Primayani, Leny Kartina, Dwiyanti Puspitasari, Parwati S. Basuki, Ismoedijanto Moedjito

School of Medicine, Airlangga University/Dr. Soetomo Hospital, Surabaya, Indonesia

Diphtheria outbreak in East Java Indonesia has been noted since 2011. Most of the patients were children. Some risk factors were presumed as having the influential contribution. The objective of this study was to evaluate the risk factors for diphtheria in children during the East Java outbreak 2011-2015 All children aged under 18 years who were recorded during the outbreak with proven culture results of toxigenic *C. diphtheriae* were recruited as participants. The control group was healthy children that have close contact with diphtheria cases but with negative culture results. All participants were reviewed, visited, interviewed, and underwent physical examinations. Immunization cards were checked. The house and surrounding environment were observed. Pearson chi-square and logistic regression tests were used ($p<0.05$ considered as significant). There were 97 patients and 194 controls in the study, mostly lived in the northern and eastern part of the province (86.6%). Most parental education was the elementary school. Incomplete primary diphtheria immunization was significantly found in the case group (68.0 vs 44.3%, $p<0.001$). Most parents did not have sufficient knowledge about diphtheria and its prevention (83.5 vs 73.2%, $p=0.005$). Significant risk factors in multivariate analysis were incomplete primary immunization, contacts with seasonal workers, and pesantren (traditional school) dormitory inhabitants. Significant risk factors for incomplete primary diphtheria immunization was the inadequacy of parental knowledge (OR 2.756; 95% CI 1.551-4.897). As the conclusions, the significant risk factors for this outbreak were incomplete primary diphtheria immunization, contact with seasonal workers, and traditional school dormitory status. This data and result finding were not available in this area previously and would become the basis for better outbreak management.

469

THE THERAPEUTIC POTENTIAL OF ANTIBIOTICS AND VITAMIN A IN TREATING MULTIDRUG RESISTANT INVASIVE NON-TYPHOIDAL *SALMONELLA* INFECTION

Annica Stull-Lane[1], Kristen Lokken[2], Vladimir Diaz-Ochoa[1], Nicoel White[1], Ariel Muñoz[1], Daniela Hampel[3], Xiaowen Jiang[3], Charles Stephensen[3], Renée Tsolis[1]

[1]Department of Medical Microbiology and Immunology; University of California Davis, Davis, CA, United States, [2]Department of Microbiology; New York University, New York City, NY, United States, [3]US Department of Agriculture; Western Human Nutrition Research Center, Davis, CA, United States

There are approximately 3.4 million cases and 680,000 deaths globally each year due to invasive non-typhoidal *Salmonella* (iNTS) infection, a severe septic manifestation of a common cause of gastroenteritis. Children in sub-Saharan Africa are disproportionately affected, as the risk factors for iNTS include young age, malnutrition and concurrent malaria infection. The mortality rate from iNTS is 20-25% and this is in part due to the emergence of multidrug resistant strains. The *Salmonella* clinical isolate D23580 has an integron that confers resistance to five different antibiotics and is more prone to lead to invasive disease. Better therapeutics are needed to alleviate iNTS disease in vulnerable populations. Vitamin A is an important micronutrient in immune cell development and has been successfully used to prevent diarrhea when given prophylactically in global health interventions. However, there is yet to be a study assessing vitamin A as treatment with antibiotics once a patient presents to the hospital with iNTS. Our study seeks to assess the therapeutic potential of vitamin A with antibiotics in a mouse model of iNTS, utilizing the multidrug resistant clinical isolate D23580. Our results will inform the efficacy of a clinical trial

assessing routine care of antibiotics alone to co-treatment of antibiotics with vitamin A with the goals of decreasing mortality rate and improving human health outcomes globally.

470

PASTEURELLA MULTOCIDA INFECTIONS IN DOG OWNERS WITH OPEN WOUNDS

Don W. Kannangara, Dhyanesh Pandya, Renu Toshniwal, Pritiben Patel, Sidra Sindhu

St Luke's University Health Network, Phillipsburg, NJ, United States

Pasteurella multocida (PM) infections in humans usually result from cat or dog bites. PM is a gram-negative coccobacillus, which is part of normal flora in the upper respiratory tract of mammals.Rare infections without bites have been reported. PM infections could be life threatening. Serious complications include septic arthritis, tenosynovitis, osteomyelitis, bacteremia, meningitis, brain abscess, spontaneous bacterial peritonitis and brain abscess. We present the cases of two dog owners seen within the last 6 months, with unsuspected infections caused by PM. The first patient, owner of three dogs with a small toe ulcer and a chronic shin ulcer presented with sepsis: Fever (T 101.2F}, chills, tachycardia (101/bpm), Leukocytosis (WBC 18,900 with 14% bands). The patient had a history of prior wound infections with MRSA, MSSA and *Enterobacter.* Based on prior history, he was treated with meropenem and vancomycin. Blood cultures on second day grew gram-negative bacilli that were later identified as PM. The patient was penicillin allergic. His isolate was susceptible to doxycycline. The patient was treated with doxycycline. He recalled one of the dogs licking the toe ulcer. The second patient with a small submetatarsal ulcer of the right hallux and diabetes mellitus type II, presented with a diabetic foot infection. The wound cultures grew PM and MSSA. She owned 2 dogs.She admitted to walking bare-footed at home and suspected "dog drool" on the floor may have contaminated her ulcer. She was treated with intravenous ceftriaxone. The take home message is that dog owners with open wounds must protect their wounds to prevent contamination with dog saliva. In dog owners, especially with open wounds, possibility of PM infections should be considered. The organism in both cases was susceptible to penicillin, ceftriaxone and doxycycline. Some PM infections are life threatening and these cases should serve as a warning to dog owners.

INCREASING ELECTIVE *HAEMOPHILUS INFLUENZA* TYPE B VACCINE COVERAGE IN THAILAND

Ali Sawani[1], Detchvijitr Suwanpakdee2[2], Veerachai Watanaveeradej[2], Alden Weg[3], Damon Ellison[3], Chonticha Klungthong[3], Phirangkul Kerdpanich[2], Danabhand Phiboonbanakit[2], Stefan Fernandez[3], Louis Macareo[3], Richard Jarman[4], Sriluck Simasthien[2], Kathryn Anderson[1]

[1]University of Minnesota, Minneapolis, MN, United States, [2]Phramongkutklao Hospital, Bangkok, Thailand, [3]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [4]Walter Reed Army Institute of Research, Silver Spring, MD, United States

Thailand is one of only three countries not to include the *Haemophilus influenza* type b (Hib) vaccine as part of the childhood vaccination program. Few reports have been published on Hib vaccine coverage in Thailand. We compared patient demographics and medical history to identify factors associated with elective Hib vaccination. Our study included pediatric patients (age < 18 years) hospitalized with influenza-like illness at a public hospital in Bangkok, Thailand between 2009 and 2015. Records from 139 children were included in the analysis. A retrospective review was conducted to analyze characteristics associated with increased likelihood of Hib vaccination. 46 patients (33%) had received at least 1 dose of Hib vaccine. Females composed 44.6% of the total population, and 47.8% of the vaccinated population. Patients who received PCV vaccination were more likely (OR 16.1; 95% CI, 3.4-75.5) to receive Hib vaccination, as were patients who had ever received influenza vaccination (OR 6.1; 95% CI, 2.6-14.4). A significant trend towards increased vaccine coverage over time was found. Children born between years 1994-1998, 1999-2003, 2004-2008, 2009-2013, and 2014-2015 had 6.6%, 25.5%, 39.6%, and 60% Hib coverage respectively (p=0.004). No significant difference in vaccine coverage was found between public and private insurance. Children from outside of Bangkok were equally likely to be vaccinated as those from the Bangkok-metro area. Patients with asthma, neurological disease, metabolic disorders, or developmental delay showed no increased likelihood of vaccination. Hib is not part of the childhood vaccine schedule in Thailand, and recipients must pay out of pocket. We report an increasing trend towards voluntary vaccination over time, as well as increased likelihood of receiving other elective vaccines not included in the national vaccine program, such as PCV and influenza. This trend was consistent across all insurance types, cash payees, medical comorbidities, and place of residence. The results suggest increased interest in elective vaccines to prevent childhood illness across all socioeconomic status despite financial burden.

472

GEOGRAPHICAL DISTRIBUTION AND ASSOCIATED SEROVARS OF LEPTOSPIROSIS IN INDIA

Govindakarnavar Arunkumar[1], Anup Jayaram[1], Anjana Krishnan[1], Santhosha Devadiga[1], Jazeel Abdulmajeed[1], Mohan Papanna[2], Robin S[1], Aswathyraj Sushama[1], Prasad Varamballi[1], Sudheesh Nair[1], Giselle D'Souza[1], Sarthak Pattanaik[1], Hindol Maity[1], Jagdish Prasad[3], Kayla F. Laserson[2]

[1]Manipal Academy of Higher Education, Udupi, Karnataka, India, [2]U.S. Centers for Disease Control and Prevention, India Office, New Delhi, India, [3]Directorate General of Health Services, MOHFW, New Delhi, India

Leptospirosis is prevalent worldwide and endemic in India. Outbreaks of leptospirosis have been reported from the coastal regions of India causing significant morbidity and mortality. However, the available data are mostly from tertiary health-care settings. In 2014, as part of Global Health Security Agenda, we initiated hospital-based acute febrile illness (AFI) surveillance in 32 district/sub-district hospitals in 10 states of India. We defined AFI as documented or reported fever <15 days duration; we enrolled and collected demographic, clinical and epidemiological data using a questionnaire, along with blood samples from all eligible admitted AFI cases. A positive real-time PCR and/or a positive anti-leptospira IgM ELISA in serum with an index value of ≥1.5 was considered positive for leptospirosis. A randomly selected sample of 100 IgM ELISA positive samples were subjected to microscopic agglutination test. We enrolled 27,431 AFI patients from June 2014 to July 2017; of these, 14,134 (51.5%) were positive for any pathogen. The major etiologies were influenza (16.6%), dengue (9.7%), scrub typhus (8.6%), leptospirosis (8.1%), malaria (4.7%) and KFD (2.2%). Percentage positivity of leptospirosis varied by state from 3.1 - 14.5 and was highest in Tripura (14.5%), Kerala (13%), Assam (9.9%), and Karnataka (9.2%) The median age of cases was 34 years (IQR: 22, 45); 53% were male. Predominant clinical symptoms were headache (84.44%), vomiting (36.23%), abdominal pain (30.72%), and redeye (10.49%). A significant proportion of cases were icteric leptospirosis (60%). Major leptospira serovars identified included bratislava, autumnalis, georgia, mankarso, pomona, pyrogenes, canicola and alexi. While 63 (3.1%) cases were referred to higher centers, only two cases died. AFI surveillance has identified leptospirosis as the fourth most common pathogen causing AFI in India and has revealed wide geographic spread. This study underscores the importance of introducing routine diagnostic testing for leptospirosis at sub district and district level hospitals for rapid case detection and appropriate clinical management to reduce morbidity.

473

WITHIN-HOST MODELING OF *SALMONELLA TYPHIMURIUM* GROWTH DYNAMICS USING TIMER DATA

John Huber[1], Dirk Bumann[2], Olivier Restif[1]

[1]University of Cambridge, Cambridge, United Kingdom, [2]University of Basel, Basel, Switzerland

Fluorescence-based assays enable the measurement of biological parameters at the resolution of a single cell, marking an advance beyond previous, population-level techniques to study within-host bacterial infection. One such method, known as TIMER, uses the ratio of two fluorophores to measure the rate of most recent division in *S.* Typhimurium infection, providing insight into the role of division rate heterogeneity in bacterial persistence. Nevertheless, quantifying the contribution of heterogeneity in the biological and assay parameters to the measured fluorescence intensities is necessary for proper inference of within-host dynamics. To provide such a capability, we developed an individual-based model that infers biological and assay parameters using Approximate Bayesian computation with Sequential Monte Carlo simulation. When applied to simulated data, our model infers these parameters with a high level of accuracy and appropriate levels of uncertainty. Moreover, variance-based global sensitivity analysis suggests that TIMER can measure differences in the rates of most recent division, though variability in assay parameters may confound these estimates. Finally, applying our approach to experimental data, we evaluate three hypotheses regarding the relationship between heterogeneity in division rates and the emergence of tolerance during antibiotic treatment: (i) the level of antibiotic tolerance correlates with the division rate, (ii) the existence of a non-dividing subpopulation with high antibiotic tolerance drives persistence, and (iii) tolerance emerges through an alternative, growth-independent mechanism.

474

CLINICAL AND EPIDEMIOLOGICAL ASPECTS OF DIPHTHERIA: A PRIMER FOR THE MODERN WORLD

Shaun Truelove, Lindsay Keegan, William J. Moss, Justin Lesssler

Johns Hopkins University, Baltimore, MD, United States

Diphtheria, once a major cause of childhood morbidity and mortality, has all but disappeared as a public health threat since the discovery and widespread use of diphtheria toxoid vaccine. However, recent outbreaks such as those in Venezuela and Yemen, and among Rohingya refugees, highlight the risk from this disease when unrest, infrastructure failure, or marginalization interrupt routine vaccination services and healthcare access. Diphtheria has been rarely studied for nearly a century, leading to gaps in knowledge about its transmission and control. Misconceptions about the epidemiology of diphtheria, including the impact of vaccination and treatment, can hamper control efforts. We reviewed 82 published studies of diphtheria and re-analyzed their data to characterize key aspects of the natural history and transmission of diphtheria and the implications for control. We estimate that diphtheria has a mean incubation period of 1.7 (95% CI, 1.0-3.0) days, and those developing symptoms remain infectious for 17 (95% CI, 16-18) days. In an unvaccinated population, the reproductive number for symptomatic diphtheria is 1.4-4.0. Asymptomatic cases remain colonized for an average of 18 (95% CI, 13-25) days and infect 40% as many people as symptomatic ones. Three doses of DTP vaccine are 82% (95% CI, 77-86) effective against symptomatic disease, but vaccinated individuals can remain colonized and transmit *Corynebacterium diphtheriae*. Although protection from vaccination is incomplete, given the range of reproductive numbers, vaccination coverage of 56-92% with three doses should be adequate to eliminate transmission. Given the mechanisms of vaccine protection, antibiotics are critical to reduce the infectious reservoir and control outbreaks. Detection and treatment of approximately three-quarters of all asymptomatic cases is important for rapid containment.

475

PROGRESS TOWARD GLOBAL ADOPTION OF THE WORLD HEALTH ORGANIZATION STANDARDIZED ULTRASOUND CLASSIFICATION OF CYSTIC ECHINOCOCCOSIS

Elaine M. Mirabile, Nadia Solomon, Paul J. Fields, Calum N. Macpherson

St. George's University, True Blue, Grenada

Cystic echinococcosis (CE) is a parasitic zoonosis for which ultrasound (US) is the gold standard modality for diagnosis. In 2003 the WHO published a standardized US classification of CE, which became the basis for WHO treatment guidelines. Use of a standardized classification also facilitates global comparisons of treatment outcomes and epidemiological studies. In 2014, however, adoption of the classification was called into question by a publication indicating that, between 2004 and 2014, only half of studies utilizing a classification used the WHO classification. More recent studies have demonstrated that the WHO classification best reflects the natural history of CE and is used with high reliability by experts in the field; despite these attributes, the classification's impact is ultimately limited by the extent of its adoption. A PubMed search using the terms "Echinococcus granulosus ultrasound," "Echinococcus granulosus classification," "cystic echinococcosis ultrasound," and "cystic echinococcosus classification" revealed publications on human CE using a US classification (as identified in an available abstract or full text). Classification(s) used, year of publication and country of first author's institution were recorded. From 2004 to 2010, the WHO classification was used in 50% or fewer of included publications for 6 of the 7 years. After 2011, it appeared in a low of 75% (2013) to a high of 96% (2017) of included publications. Of all included studies published from 2004 to 2017, the WHO classification was referenced in 18% (3/17) from Africa, 64% (32/50) from Asia, 79% (89/113) from Europe, 89% (8/9) from North America and 100% (9/9) from South America. These findings suggest that the WHO classification has been progressively taking preference internationally as the US classification of choice for staging CE. Continued use of the classification developed by Dr. Hassen Gharbi of Tunisia in 1982, used widely prior to development of the WHO classification (which reversed two stages in order to more closely reflect the natural history of CE), suggests that adoption of a new classification takes time and varies regionally.

476

HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH ALVEOLAR ECHINOCOCCOSIS - A CROSS-SECTIONAL STUDY

Julian Schmidberger, Henriette Weimer, Patrycja Schlingeloff, Wolfgang Kratzer, Tilmann Gräter, Beate Grüner

University Hospital Ulm, Ulm, Germany

The Alveolar echinococcosis (AE) is a rare zoonosis caused by the parasite Echinococcus multilocularis. To date, nothing is known about the health-related quality of life (HRQoL) in patients with AE. The aim of the study was to evaluate the HRQoL in patients with AE in comparison of the healthy population. We used the SF-36 questionnaire to evaluate the HRQoL in patients with AE. The SF-36 scale scores were obtained according to the developers algorithms. SAS Version 9.2 was used for the statistical analysis of AE-cases (n=30) and the healthy control group (n=35). The analysis showed that the HRQoL in people with AE is reduced in comparison with the control population. The study group consisted of 15 (50,0%) men and 15 (50,0%) women; the control group of 16 (45.7%) men and 19 (54.3%) women. The mean age of the patients was 55.73±16.65 years, while that of the control group was 54.57±15.34 years. The physical quality of life in patients with AE (45.21±11.42) was not significantly less than that of the control group (50.54±10.52); p=0.0568. Nevertheless, AE-patients show lower SF-36 scores for the physical quality of life. For the mental quality of life, patients with AE had a significantly lower score (45.46±10.57) than the control group (51.57±9.04); p=0.0154. The HRQoL in people with AE is reduced in

comparison with a control population. Assessment of the physical and mental quality of life in patients with AE may help to evaluate the patient outcome.

477

CHARACTERIZATION OF THE HU DENSITY OF CYSTOID LESIONS OR CYSTOID AREAS WITHIN LESIONS DUE TO HEPATIC ALVEOLAR ECHINOCOCCOSIS USING THE EMUC-CT CLASSIFICATION

Tilmann Graeter, Wolfgang Kratzer, Agata Engler, Rong Shi, Beate Grüner, Julian Schmidberger

University Hospital Ulm, Ulm, Germany

The EMUC-CT classification for the diagnosis of hepatic alveolar echinococcosis describes cystoid portions as a subcriteria for primary morphology Type I and II. Type IIIa/b are "Primarily cystoid" lesions and Type IV lesions are designated as "Small cystoid/metastasis-like" ones. Aim of the study was, to evaluate CT-scans regarding the density of cystoid lesions or cystoid portions of AE-lesions classified after EMUC-CT by measuring the Hounsfield Units (HU). This shall help to differentiate such regions against normal cysts and may show differences between the types concerning their cystoid structures. The HU density of cystoid areas of n=170 AE-lesions of different patients classified after EMUC-CT was measured. Patients were chosen who had not yet or had just shortly been treated by benzimidazoles. Measurements were performed by two raters independently within the same transversal section of a CT-scan showing cystoid regions. The measurements were performed in two different places which the raters subjectively regarded as to be the most hypodense ones by using a defined sized Region of Interest (ROI). The statistical analysis was performed using SAS V.9.2. HU determination of all cystoid areas, evaluated in Type I-IV lesions showed a mean value of 23,13±16,83 and thus differed clearly from normal cysts (HU~0). HU values of Type I, II and IIIa/b each showed significant differences versus Type IV (p<.0001). Measurements in Type IV show the highest mean value. So HU measurement of the density of cystoid regions in hepatic AE lesions offer a good differentiation against normal cysts. Thus, AE lesions with very hypodense strutures were correctly named "cystoid" and not "cystic" within EMUC-CT. The range of the detected values can be explained by the fact that cystoid areas at times derive from necrosis and sometimes from alveolar conglomerates. The highest mean value of Type IV is result of the fact that some of those lesions still show a tiny central alveola with surrounding hypodense fibrotic tissue and some of them lost the central alveola. This circumstance is depicted in the designation of Type IV as "small-cystoid/metastasis-like" by EMUC-CT.

478

EVALUATION OF THE INTERRATER RELIABILITY IN USING THE EMUC-CT CLASSIFICATION IN A GREAT COLLECTIVE OF PATIENTS WITH HEPATIC ALVEOLAR ECHINOCOCCOSIS

Tilmann Graeter, Wolfgang Kratzer, Rong Shi, Beate Grüner, Julian Schmidberger, Julian Schmidberger

University Hospital Ulm, Ulm, Germany

Computed tomography, mostly combined with PET, provides one of the most important diagnostic tools in suspected alveolar echinococcosis (AE). The recently established "Echinococcus multilocularis Ulm classification for computed tomography" (EMUC-CT) depicts the various morphologies of liver lesions due to AE. The classification scheme assigns morphological criteria of hepatic AE to five groups of primary morphologies (type I-V), some of them including subcriteria, and to six calcification patterns. The aim of the actual study was, to evaluate the interrater reliability in using the EMUC-CT classification in a great collective of patients with hepatic AE. Retrospectively the contrast enhanced CT scans in venous phase of n=121 different Patients with hepatic AE were evaluated. The cases were at first classified by the reference reader who at the same time taught the second reader how to use the classification. The reference reader was an experienced consultant in radiology and the second reader a resident with more than three years of experience in radiology. At least one week after the reference reader had classified the collective, the second reader began to re-classify all the cases separately from the reference reader. Calculation of Interrater-Reliability (Cohens-Kappa) was performed with SAS V. 9.2. The interrater reliability of the primary morphologies showed 0.8268 (95% KI: 0.7453-0.9084) with p<.0001. Concerning the subcriteria, the accordance was 0.8940 (95% KI: 0.8225-0.9656) with p<.0001. For the patterns of calcification, the interrater reliability showed a concensus of 0.6603 (95% KI: 0.5602-0.7604) with p<.0001. Further sub-analysis were performed. In summary the interrater reliability in using the EMUC-CT classification was high. The actual study could show this in a great collective of AE cases for the first time. The results encourage to use the classification in diagnosis of hepatic AE. For this, in order to use it properly, it certainly is crucial to be closely familiar with the application of the very detailed classification scheme which comprehensively covers the complex CT-morphological appearance of AE.

479

CYSTIC AND ALVEOLAR ECHINOCOCCOSIS A ZOONOTIC INFECTIONS WITH DIFFERENT EPIDEMIOLOGY AND CLINICAL COURSE

Frantisek Stejskal[1], Martin Oliverius[2], Milan Trojanek[3], Libuse Kolarova[4]

[1]Department of Infectious Diseases, Regional Hospital, Liberec, Czech Republic, [2]Department of Surgery, 3rd Medical Faculty, Charles University, Prague, Czech Republic, [3]Department of Infectious Diseases, 2nd Medical Faculty, Charles University and Bulovka Hospital, Prague, Czech Republic, [4]Department of Immunology and Microbiology, 1st Medical Faculty, Charles University, Prague, Czech Republic

Human echinococcosis is caused by larval stages of several *Echinococcus* species, small intestinal flatworms of canines. Two most important species are *E. granulosus* causing cystic echinococcosis (CE) with nearly worldwide distribution, and *E. multilocularis* causing alveolar echinococcosis (AE), an emerging infection in the western, central and eastern Europe. The human diseases are rare in the Czech Republic (CZ). CE is relatively benign, however, AE is potentially life-threatening due to progressive tumor-like growth in liver and risk of metastatic dissemination. There have been treated total 12 patients (4 women, 8 men) with CE since 2005, and 13 patients (9 women, 4 men) with AE since 2012 at our departments. CE seems not to be more endemic in the CZ. Ten CE cases were diagnosed in migrants from endemic regions: Bulgaria (3x), Romania, Macedonia, Montenegro, Russia, Kazakhstan, Tajikistan, and Uzbekistan. Two patients are Czech citizens: a 68-year old female acquired infection in the CZ in past, probably, a 36-year old man is living in the CZ, but he travelled to eastern Europe and Asia for many times. The age of CE patients was between 28 and 68 years at the time of diagnosis. 10 patients had cysts in liver only, 1 patient in lung only and 1 patient in both liver and lung. Serology for echinococcosis was positive in all patients. The treatment involved surgery and temporary albendazole in 10 patients, temporary albendazole only in 1 patient and "wait and watch" in 1 patient. All AE cases were acquired in the CZ (12 patients) or in Slovakia (1 patient). The age of AE patients was between 7 and 70 years at the time of diagnosis. 12 patients had lesions in liver only, 1 patient had the main mass in liver and multiple metastasis in lung. Serology for echinococcosis was borderline or positive at all patients. The treatment is based on long-term continuous albendazole administration, which is not tolerated in 1 patient (treated with mebendazole). In addition, 7 patients underwent liver resection, 2 patients liver transplantation and one patient died from AE unrelated reason.

480

CELL-FREE DNA (CFDNA) IN URINE AS A NOVEL DIAGNOSIS FOR HUMAN NEUROCYSTICERCOSIS

Luz M. Toribio Salazar[1], Miryam de los Angeles Romano[2], Clive J. Shiff[2], Javier Bustos[1], Armando Gonzalez[3], Bob Gilman[4], Hector Hugo Garcia[3], For the neurocysticercosis working group of Peru[3]

[1]Department of Microbiology. Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Molecular Microbiology and Immunology Department, Johns Hopkins University, Bloomberg School of Hygiene and Public Health, Baltimore, MD, United States, [3]Cysticercosis Unit, Instituto Nacional de Ciencias Neurologicas, Lima, Peru, [4]Department of International Health, Johns Hopkins University Bloomberg School of Hygiene and Public Health, Baltimore, MD, United States

Diagnosis of Neurocysticercosis (NCC) is difficult because it is based on a combination of clinical, epidemiological, radiological and immunological findings. Most commonly diagnosis for this condition is Western Blot (WB) which recognizes antibodies in serum samples, however it does not a direct test, is not quantitative and cannot distinguish between a past and current infection. As is important to recognize active infections, current researches are focused on the detection of antigen; furthermore, molecular approaches targeting products of the parasite have been reported in cerebroespinal fluid (CSF), but this process is invasive. Nevertheless, parasite fragments from various parasitic infections have been detected in urine, seeing that, this report aim to demonstrate that this is also the case with *Taenia solium*. In our work, we collected 25 urine samples of positive patients confirmed by WB and radiology from the "Instituto Nacional de Ciencias Neurológicas" in Peru, 50 ml of urine were filtered through Whatman N°3 filter paper, DNA was extracted with QIAamp DNA mini kit (QIAGEN) and the product was amplified using conventional PCR with two different sets of primers which recognize highly repetitive sequences in *T solium* genome. The PCR products were visualized in agarose gel and positive samples were confirmed by sequencing and by BLAST analysis. Our results report that we detected at least 9 positive of the 25 urine samples. Thus, in this study we demonstrate, for the first time, that cfDNA of *T. solium* is present in the urine of patients, this detection using non-invasive clinical samples offers significant benefits for the accurate diagnosis of NCC.

481

TOWARDS THE DESIGN AND OPTIMIZATION OF INTERVENTION STRATEGIES AGAINST *TAENIA SOLIUM* TAENIOSIS/CYSTICERCOSIS BY MULTI-MODEL COMPARISON

Matthew A. Dixon[1], Uffe C. Braae[2], Peter Winskill[1], Brecht Devleesschauwer[3], Wendy E. Harrison[4], Martin Walker[5], Maria-Gloria Basáñez[1]

[1]Imperial College London, London, United Kingdom, [2]Ross University School of Veterinary Medicine, Basseterre, Saint Kitts and Nevis, [3]Scientific Institute of Public Health (WIV-ISP), Brussels, Belgium, [4]Schistosomiasis Control Initiative, London, United Kingdom, [5]Royal Veterinary College, London, United Kingdom

The cestode *Taenia solium* causes the neglected tropical disease (NTD) neurocysticercosis, the leading cause of preventable epilepsy in *T. solium* endemic low and middle-income countries. The 2012 World Health Organization's roadmap on NTDs had proposed that, by 2015, a validated strategy should be available for the control and elimination of *T. solium* taeniosis/cysticercosis and that, by 2020, appropriate control and elimination interventions should be scaled up in selected countries. With 2020 on the horizon, mathematical or computational models of *T. solium* transmission are urgently needed to inform and optimize the design of intervention strategies targeting control and elimination. Here we present the findings of a systematic review to identify and compare existing *T. solium* transmission models, and related transmission models of other Taeniidae family infections. We compare approaches to model design, the capacity of different models to project the impact of different intervention strategies and identify gaps requiring further model development. We also provide a comparative simulation analysis of two recent *T. solium* transmission models: the deterministic, population-based, model EPICYST and the individual-based, stochastic model cystiSim. We highlight areas of concordance and disparity, and discuss our findings in the context of epidemiological, clinical, economic, and longitudinal intervention data needs, and future developments of the *T. solium* transmission models. We argue that this work provides a foundation for enhanced future collaboration and partnership between epidemiologists, modellers, implementers and stakeholders invested in cysticercosis control and elimination.

482

TREATMENT OF INDIVIDUALS LIVING WITH NEUROCYSTICERCOSIS AND HIV/AIDS: A SCOPING REVIEW

Paul D. Jewell[1], Annette Abraham[2], Veronika Schmidt[2], Kevin G. Buell[1], Javier Bustos[3], Hector H. Garcia[3], Matthew A. Dixon[1], Martin Walker[4], Maria-Gloria Basanez[1], Andrea Winkler[2]

[1]Department of Infectious Disease Epidemiology, and London Centre for Neglected Tropical Disease Research, Imperial College London, London, United Kingdom, [2]Department of Neurology, Klinikum rechts der Isar, Technical University of Munich, Munich, Germany and Centre for Global Health, Institute of Health and Society, University of Oslo, Oslo, Norway, [3]Universidad Peruana Cayetano Heredia, Lima, Peru, [4]Department of Pathobiology and Population Sciences, and London Centre for Neglected Tropical Disease Research, Royal Veterinary College, Hatfield, United Kingdom

Neurocysticercosis (NCC), due to infection with cysts of *Taenia solium*, is the single most important risk factor for acquired epilepsy globally. Many regions endemic for NCC are also endemic for HIV, yet literature on HIV and NCC co-infection is sparse and no current treatment guidance exists for this patient group. This study aims to scope the currently available literature on NCC and HIV co-infection, with focus on clinical characteristics, diagnostics and treatment outcomes. The scoping literature review methodological framework and PRISMA guidelines were followed. A total of 13,777 records identified through database searching and 45 additional records from other sources, were reduced to 57 included studies after a standardised selection process. Included studies were analysed for data relating to the study aims. The one identified experimental study demonstrated poor outcomes in surgical treatment (ventriculoperitoneal shunt insertion) of intraventricular NCC in HIV-positive patients. Twelve observational studies were identified, in which prevalence of NCC was shown to be similar in HIV-positive and -negative populations, with no significant association with CD4 count. Of the 26 cases of HIV and NCC co-infection extracted from 21 case series/reports, 15 suffered with seizures (58%) and 14 with headaches (54%). Fourteen (54%) cases had positive serum serology (7 ELISA-Ab +ve, 5 EITB-Ab +ve) and two case studies reported negative serum serology. Four (14%) were treated surgically, 15 (58%) received albendazole, three (12%) praziquantel and 13 received adjuvant steroid. Fifteen patients were reported to have clinically improved, and two died, one due to an adverse response after starting albendazole, dexamethasone and anti-retroviral therapy. Nine patients received at least two of either anti-helmintic, anti-epileptic and/or anti-retroviral medications. This review demonstrates that evidence to guide treatment of NCC and HIV co-infection is lacking. We will discuss issues relating to T. solium-NCC diagnosis and use of multiple medications in this patient group, and we will highlight pressing research needs.

483

ASSOCIATION BETWEEN CLINICAL-RADIOLOGICAL CHARACTERISTICS AND SUICIDAL IDEATION IN PATIENTS WITH CALCIFIED NCC AND DEPRESSION

Fiorella Fernandez

Universidad Peruana Cayetano Heredia, Lima, Peru

Neurocysticercosis (NCC) is an infection of the central nervous system caused by *Taenia solium*. It is the first cause of seizures in underdeveloped countries and there is evidence linking NCC with neuropsychiatric disorders. Depression is one of the most common mental disorders in the world and a major cause of disability, contributing to the overall global burden of disease. The objective of this study was to evaluate the association between the presumptive diagnosis of suicide attempts or suicidal ideation and the clinical-radiological characteristics of calcified NCC and depression. A total of 136 patients were included. Calcified NCC was diagnosed by Computed axial tomography (CT). Depression and suicide attempts or suicidal ideation were evaluated through International Neuropsychiatric Interview (MINI). Multivariate methods of analysis was performed with generalized linear models, poisson family and log link function.The frequency of suicidal ideation was 52.6% in the study population with depression ($p < 0.01$), this is a statistically higher frequency than that reported for the general population. Patients with seizures had a slightly higher frequency of suicidal ideation (53.8%) compared to patients without seizures (46.2%), this association was not significant (p 0.399). Occupations in the home are specifically related to the group of women where an association is seen. Regarding occupation, there was an association between being a housewife and having suicidal ideation ($p < 0.05$). The number and location of the calcifications did not present associations with statistical significance with suicidal ideation. We have found a high frequency of suicidal ideation in patients with depression and Calcified NCC. There was no association between clinical-radiological characteristics and suicidal ideation. We suggest the development of future studies because we could promote assessment of suicidal behaviors and its evaluation in early stages of the disease.

484

EVALUATION OF CROSS-REACTIVITY OF *TAENIA HYDATIGENA* AND *ECHINOCOCCUS GRANULOSUS* IN THE ENZYME-LINKED IMMUNOELECTROTRANSFER BLOT ASSAY IN PIGS

Luis A. Gomez-Puerta[1], Ana Vargas-Calla[2], Yesenia Castillo[3], Maria T. Lopez-Urbina[2], Hector H. Garcia[3], Armando E. Gonzalez[2], Seth E. O'Neal[4]

[1]Universidad Nacional Mayor de San Marcos and Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Universidad Nacional Mayor de San Marcos, Lima, Peru, [3]Universidad Peruana Cayetano Heredia, Lima, Peru, [4]Oregon Health & Science University and Portland State University, Portland, OR, United States

Taenia solium is an important zoonosis that infects humans as the definitive host (taeniasis) and pigs as the intermediate host (cysticercosis). Serologic diagnosis of porcine cysticercosis is limited to antigen detection using ELISA, which is known to cross-react with other *Taenia* species, and antibody detection using the lentil lectin glycoproteins Western blot test (LLGP-EITB), which has not been adequately evaluated for cross-reactivity to other parasites of pigs. Recent findings from field studies suggest that the GP50 antigen band of the LLGP-EITB may cross-react to *Taenia hydatigena*, a common and similar parasitic infection of pigs. The objective of this study was to evaluate the specificity of the LLGP-EITB assay in pigs infected experimentally with *T. hydatigena* and *Echinococcus granulosus*. A total of 12 three month-old Landrace pigs were obtained from a commercial grange in an area where *T. solium* is not endemic. All animals were confirmed to be negative at baseline on the LLGP-EITB. The pigs were divided into two equal groups; 6 pigs were each given an oral challenge with a single gravid proglottid of *T. hydatigena*, while the other 6 pigs were each given an oral challenge with 50 gravid proglottids of *E. granulosus*. Serum samples were collected on day 0 and every 2 weeks after challenge. At 12 weeks post-challenge all pigs underwent a detailed necropsy. *T. hydatigena* cysticerci were found in 2 of 6 pigs from the first group, while hepatic echinococcosis was observed in all 6 pigs from the second group. Four of the *T. hydatigena* exposed pigs were positive on EITB, with the positive reaction limited to the GP50 diagnostic band only, and two of these pigs had cysts after necropsy. On the other hand, only one *E. granulosus* exposed pig was positive to EITB, the reaction again limited to GP50 only, and only on the week 12 blood sample, despite the fact that all 6 of these pigs formed hepatic echinococcosis. These results provide definitive evidence that the GP50 diagnostic band in pigs cross-reacts against *Taenia hydatigena*.

TO REALLY KNOW THE PARASITE: EVIDENCE WORKSHOP OF CYSTICERCOSIS-TAENIASIS TO PROMOTE CYSTICERCOSIS KNOWLEDGE, PREVENTION, AND SURVEILLANCE IN NORTHERN PERU

Michelle Beam[1], Angela G. Spencer[2], Ruth Atto Espinoza[3], Roberto Carlos Camizán Castro[3], Fernando Urizar Cornejo[3], Lauralee Fernandez[2], Ian Pray[2], Brian Garvey[1], Percy Vilchez[3], Claudio Muro[3], Ricardo Gamboa[3], Luz Maria Moyano[3], Josefina Coloma[4], Hector H. Garcia[5], Seth E. O'Neal[2]

[1]Oregon Health & Science University, Portland, OR, United States, [2]Oregon Health & Science University - Portland State University, Portland, OR, United States, [3]Center for Global Health Tumbes, Universidad Peruana Cayetano Heredia, Lima, Peru, [4]University of California Berkeley, Berkeley, CA, United States, [5]Department of Microbiology, Universidad Peruana Cayetano Heredia, Lima, Peru

Taenia solium cysticercosis is a common cause of epilepsy in developing nations. We created a 4-hour workshop to promote knowledge, prevention, and control in four villages (pop. 838) in Perú as part of an ongoing study of community-engaged surveillance and control. Adolescents and adults were invited to a "Healthy Pig Fair." Children were invited to an age-adapted "Tapeworm Birthday Party." We promoted the events via door-do-door visits and posters highlighting the opportunity to view the parasite in a microscope. The workshop included dialogue on economic losses due to pig infection using data from participating villages, followed by dissection of larval cysts from a recently-slaughtered heavily infected pig, evagination of cysts, and viewing of nascent tapeworms with light microscopes. Participants recorded observations of larvae on worksheets and learned about microscopic eggs and the *T. solium* life cycle. To measure knowledge change, we analyzed data from a community survey of adult heads of households, comparing individual knowledge 2 months pre-workshop (baseline) to knowledge 2-3 months post-workshop. We also gathered data from workshop participants in a post-workshop survey and focus group. Knowledge of the three *T. solium* life cycle stages increased significantly in the villages. Comparing knowledge gains for survey respondents who attended the workshop (n=52) to non-attendees (n=138) revealed both groups' knowledge increased, with greater gains for attendees. Knowledge of human-to-pig transmission increased by 39% and 22%, respectively, and knowledge of pig-to-human transmission increased by 43% and 9%. Only workshop attendees had significant gains in knowledge of human-to-human transmission (13% vs. 5%). Increased knowledge and participant willingness to publicly share experiences with *T. solium* in focus groups support the workshop's effectiveness. The use of local evidence, experiential learning, and community participation created a space to decrease stigma and influence knowledge and risk perception, all of which are barriers to behavior change in community interventions to prevent cysticercosis.

DETECTION OF *TAENIA* EGGS IN SOIL AFTER MASS ANTI-HELMINTHIC TREATMENT: RESULTS FROM A COMMUNITY-WIDE SOIL SAMPLING IN NORTHERN PERU

Ian W. Pray[1], Ricardo Gamboa[2], Mayra Elizalde[2], Luis A. Gomez[3], Percy Vilchez[2], Claudio Muro[2], Luz M. Moyano[2], Armando E. Gonzalez[3], Hector H. Garcia[4], Seth E. O'Neal[1], for the Cysticercosis Working Group in Peru[4]

[1]School of Public Health, Oregon Health and Science University and Portland State University, Portland, OR, United States, [2]Centro de Salud Global, Universidad Peruana Cayetano Heredia, Tumbes, Peru, [3]School of Veterinary Medicine, Universidad Nacional Mayor de San Marcos, Lima, Peru, [4]Department of Microbiology, Universidad Peruana Cayetano Heredia, Lima, Peru

Taenia solium, the cestode parasite that causes cysticercosis, is transmitted from humans to pigs when carriers of the adult intestinal tapeworm defecate outside and pigs consume the infected feces. Lack of sanitation and open-field defecation are important risk factors for *T. solium* transmission, however, the role of contaminated soil in this transmission is unclear. Specifically, do *T. solium* eggs persist in soil, how long do they persist, and what concentration of eggs can be found in naturally infected soil? In this study, we sought to determine the proportion of households with *T. solium* eggs present in the soil in a village in northern Peru (pop. ~1,000). Five months prior to soil collection, all inhabitants of the study village were offered niclosamide for treatment of intestinal tapeworms. We then collected soil samples from the reported defecation sites of participating households, either from within the open defecation area or in front of the latrine if used. To do this, we removed visible fecal material from the indicated area, and placed 200 grams of topsoil in a plastic container for transport to the Center for Global Health. Each soil sample was evaluated for the presence of *Taenia spp.* eggs and other soil-transmitted helminths using light microscopy and a sugar-Percoll sedimentation technique previously validated by our group. A total of 336 soil samples were collected from 317 households. We found that 2.9% (10/336) of soil samples contained *Taenia spp.* eggs, and the average number of eggs detected per positive sample was 4. The proportion of households with contaminated soil was greater for open defecation sites (5.5%, 3/51) compared to soil collected from outside the latrine (2.7%, 7/255), although this difference was not statistically significant (p=0.27). Other parasites detected included *Strongyloides spp.* (52%), *Ascaris spp.* (39%), *Enterobius spp.* (16%), and *Trichuris spp.* (6%). Definitive speciation of *Taenia spp.* and other parasites with PCR is pending. These results show that *Taenia spp.* eggs are prevalent in the soil of endemic communities, and that contaminated soil could play a role in ongoing transmission of the parasite.

METHODOLOGY OF AN OPEN CLINICAL COHORT OF INDIVIDUALS WITH EPILEPSY IN THE CONTEXT OF A CYSTICERCOSIS ELIMINATION DEMONSTRATION PROGRAM: TUMBES PROJECT

Luz Maria Moyano Vidal[1], Rocio Rimac[2], Seth E. O´Neal[3], Exgar Oliva[1], Narcisa Reto[1], Mayra Elizalde[1], Ricardo Gamboa[1], Isidro Gonzales[4], Luis Larrauri[4], Hector H. Garcia[5], for The Cysticercosis Working Group of Peru[1]

[1]Center for Global Health, Universidad Peruana Cayetano Heredia, Tumbes, Peru, [2]Center for Global health, Universidad Peruana Cayetano Heredia, Tumbes, Peru, [3]School of Public Health, Oregon Health & Science University and Portland State University. Center for Global Health, Universidad Peruana Cayetano Heredia, Portland, OR, United States, [4]Unidad de Cisticercosis, Instituto de Ciencias Neurológicas, Lima, Peru, [5]Center for Global Health, Universidad Peruana Cayetano Heredia. Unidad de Cisticercosis, Instituto de Ciencias Neurológicas, Department of International Health, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States, Lima, Peru

Epilepsy is a neurological condition characterized by recurrent and unpredictable interruptions of normal brain function. Aleading cause of epilepsy in LMIC countries isneurocysticercosis (NCC), a helminthicinfection of the central nervous system. In 2006, we opened a primary-care health center staffed with general practitioners under the supervision of a neurologist, to attend people with epilepsy (PWE) identified during a large-scale cysticercosis elimination demonstration program for cysticercosis in Tumbes, Peru. The main objectives of the cohort werea) to evaluate incidence of epilepsy and epilepsy due to NCC in the context of an ongoing elimination program, b) to determine mortality of PWE, c) to assess the feasibility of managing PWE in a primary-care setting where neurology specialists are limited, d) to assess treatment compliance of PWE in this setting, and e) to assess withdrawal of antiepileptic treatment. Between 2006-2017, we enrolled 1813 PWE at the clinic in an open cohort; 586(32.3%) were identified through population-based screening while the remaining 1227 (67.7%) were referred to the clinic by others. 930 (51.3 %) were women, the mean age was 35.9(SD 17.6) ,1493 (82.4 %)were from Tumbes and 320 (17.6%) from neighboring regions; 1038 (57.3%) resided in rural areas.1523(84.0%) had active epilepsy at enrollment. Main seizure types by individual included 1311(72.3%) focal, 496 (27.4%) generalized, and 6 (0.3%) indeterminate. Etiology was symptomatic epilepsy in 905(49.9%), of which 556 (61.4%) had NCC and 349 (38.6% had other etiologies. Those without symptomatic epilepsy included 818 (45.1%) with idiopathic epilepsy, 73 (4.0%) withcryptogenic epilepsy and 17 (0.9%) with undetermined epilepsy. Antiepileptic drug therapy was started in 1463 (80.7%) upon enrollment, the majority (89%) with monotherapy (carbamazepine or phenytoin). The clinic has successfully established a large, representative cohort of PWE from the community setting. Data from this cohort is being analyzed to characterize epilepsy in our region. NCC is an important cause of epilepsy in Tumbes, found in 556/1813 (30.7%) of PWE.

488

VALIDATION OF A LOW-COST SEDIMENTATION TECHNIQUE FOR THE DETECTION OF *TAENIA* SPP. EGGS IN SOIL

Ricardo Gamboa[1], Mayra Elizalde[1], Ian W. Pray[2], Luis A. Gomez[3], Percy Vilchez[1], Claudio Muro[1], Luz M. Moyano[1], Armando E. Gonzalez[3], Hector H. Garcia[4], Seth E. O'Neal[2], for the Cysticercosis Working Group in Peru[4]

[1]Centro de Salud Global, Universidad Peruana Cayetano Heredia, Tumbes, Peru, [2]School of Public Health, Oregon Health and Science University / Portland State University, Portland, OR, United States, [3]School of Veterinary Medicine, Universidad Nacional Mayor de San Marcos, Lima, Peru, [4]Department of Microbiology, Universidad Peruana Cayetano Heredia, Lima, Peru

Cysticercosis, a cystic larval infection in humans and pigs, is caused by ingestion of eggs from the adult *Taenia solium* tapeworm. Open defecation by human carriers, and resulting contamination of soil with *T. solium* eggs, may contribute to transmission among pigs and other humans, however, an acceptable and inexpensive method for detecting *Taenia spp.* eggs in soil has not yet been developed. In this study, we validated a new sedimentation technique for detecting *Taenia* spp. eggs in soil that uses low-cost materials available in Peru. For this validation, we used soil collected from the grounds of Center for Global Health in Tumbes, Peru. Three 200g samples of soil were seeded with 200, 100, and 50 *T. solium* eggs each, representing concentrations of 1, 0.5, and 0.25 eggs per gram of soil (EPG), respectively. Each sample was homogenized with a 10% solution of commercially available dish-soap, and filtered through tri-folded surgical gauze. Three 10mL samples of each filtrate were then collected and centrifuged with 10ml of 1.5X sucrose. The interphase of each solution was collected, suspended in saline, and aggregated into a single tube containing 5mL of Percoll. After centrifugation, a 1mL pellet containing the parasitic eggs was recovered and examined microscopically (10X) to determine the number of *T. solium*

eggs recovered from each sample. For each seeded 200g sampled of soil, 30mL (7% of total volume) of filtrate were analyzed for *T. solium* eggs. For soil seeded at 1 EPG (200 eggs total), 11 *T. solium* eggs were recovered, representing 83% of the eggs expected in 30mL of filtrate. For soil seeded at 0.5 EPG (100 eggs) and 0.25 EPG (50 eggs), recovery rates were each 30%. Based on these results, we calculated that this sedimentation technique provides adequate power (>80%) for detecting egg contamination if present at 1 EPG in soil collected from natural conditions. This technique was recently used to detect *T. solium* eggs in the soil of an endemic Peruvian village, and may lead to more opportunities in the future to study the role of soil as a vehicle for *T. solium* transmission.

THE CASE OF ERADICATION OF SICKLE CELL ANEMIA DEATHS IN AFRICA

Cornelius C. Nwora

Texas Southern University (TSU), Houston, TX, United States

Sickle Cell Disease (SCD) causes the greatest burden to both survival of children under five years (U5Y) and to the Public Health Management (PHM) in the endemic areas of Africa, India and other developing areas of the world. It is the most dangerous - in terms of rate of morbidity and mortality, of all known hemoglobinopathies. Several confounding factors (both natural and inflicted), in the milieu of 'hypoxia' contribute to the expression of symptoms in SCD patients."In the late 1960s and early 1970s, as sickle cell anemia was caught up in the torrent of U.S. congressional and presidential politics, the malady became widely characterized as a "neglected disease," a disease of a people whose "pain and suffering" had been ignored for too long, and a disease finally achieving its moment of national recognition". [1], [3].A neglectful healthcare policy gave way to present epidemic proportions, with an annual rate of 150,000 babies born with SCD in Nigeria - the highest recorded incidence of SCD in the world. [5]. SCD patients have compromised immunity, with increased incidence of meningitis, septicemia and a high mortality. [6]. WHO indices for Nigeria showed she suffers a 10 to 40% carrier state, with a prevalence of 2% [9]. A further 75% infant cases, and 80% share of the mortality in the whole of Africa. [11].A cure for SCD is possible with gene therapy, but this is technologically complex and expensive especially in low resource settings. It is nearly impossible to eradicate SCD because of its pathophysiology, but we can ameliorate the rate of death due to complications of stroke during the crisis moments. Transcranial Doppler (TCD) scanning, is the technique of choice to evaluate and diagnose the probable onset of stroke in SCD patients. Unlike Ebola - a deadly disease with a quick swift decimating rocket style, Malaria and SCD are silent killers with a 'chameleon' tactics and seeking the most vulnerable of all - our children, especially the U5Y age group. Peter Piot, the Belgian microbiologist who discovered Ebola in 1976 said: "we shouldn't forget that this is a disease of poverty, of dysfunctional health systems - and of distrust." [17].

U.S. TRAVELERS' CONCERN ABOUT ZIKA INFECTION AND WILLINGNESS TO RECEIVE A HYPOTHETICAL ZIKA VACCINE

Nadja A. Vielot[1], Lola Stamm[2], James Herrington[3], Linda Squires[4], Bridget Kelly[4], Lauren McCormack[4], Sylvia Becker-Dreps[1]

[1]Department of Family Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [2]Department of Epidemiology, UNC Gillings School of Global Public Health, Chapel Hill, NC, United States, [3]Department of Health Behavior, UNC Gillings School of Global Public Health, Chapel Hill, NC, United States, [4]RTI International, Research Triangle Park, NC, United States

The ongoing Zika pandemic has affected many countries that are common travel destinations. We assessed willingness to receive a prophylactic Zika virus (ZIKV) vaccine, currently under development, among travelers to areas with reported autochthonous ZIKV transmission. We surveyed United States (U.S.) residents aged 18-44 years who had ever heard of ZIKV and planned to travel to Florida and/or Texas (n=420) or a U.S. territory or foreign country (n=415) in 2017, using a nationally representative internet panel. Travelers to Florida and/or Texas reported less concern about ZIKV infection than travelers to other destinations (27.4% vs. 35.5%, p=0.01). Female sex, Hispanic ethnicity, discussing ZIKV with medical professionals, ZIKV risk perception, and self-efficacy for ZIKV prevention predicted concern about ZIKV infection in both groups. Travelers to Florida and/or Texas (43.4%) and other destinations (44.1%) were equally willing to receive a ZIKV vaccine. Hispanic ethnicity, discussing ZIKV with medical professionals, and concern about ZIKV infection predicted vaccine willingness in both groups. Likelihood of using existing ZIKV prevention methods, confidence in the U.S. government to prevent ZIKV spread, self-efficacy for ZIKV prevention, and knowledge about ZIKV symptoms further predicted vaccine willingness in travelers to other destinations. In multivariable analyses, only concern about ZIKV infection was associated with vaccine willingness in both groups (Prevalence Ratio [95% Confidence Interval]: Florida and/or Texas: 1.34 [1.06, 1.69]; Other: 1.82 [1.44, 2.29]). Targeted communications can educate travelers about ZIKV risk to generate ZIKV vaccine demand regardless of intended destinations, and targeting travelers who are pregnant or planning pregnancy.

491

REDUCING ANTIBIOTIC USE FOR TRAVELERS' DIARRHEA

Mark Grabowsky

PanTheryx, Inc, Bouder, CO, United States

Travelers often self-treat mild or moderate diarrhea with antibiotics (abx), even though it is seldom required, and may lead to bacterial resistance and other serious adverse effects. We studied the effect of providing a novel anti-diarrheal product (DiaResQ®, PanTheryx, Inc) to clients at 7 travel clinics in Colorado on reducing abx self-treatment by international travelers. Pre-travel, clinicians discussed with clients that this product was the preferred option to for diarrhea instead of abx; and either, both or neither were provided on client request. We conducted a telephone survey of returned travelers >18 years of age to assess occurrence of diarrhea and self-treatments. Clinic records of these travelers were reviewed for demographics, travel details, and products provided or prescribed. Out of 3005 answered calls, 448/598 (79.1%) respondents participated in the survey. For calls not answered, 33/359 (9.2%) responded to a follow-up email, for a total of 481 responses, of which 158 (32.8%) reported having diarrhea. The traveler's mean age was 43.9 years (+/- 15.1), 54.3% female, mean trip length 18.4 days (+/- 20.7) with 59.8% ≤ to 14 days. Pre-travel, 42.3% received abx and 35.5% received the product, with 12.7% receiving both. Receiving the product and reported incidence of diarrhea did not differ by age, gender, length or trip or travel destination. During travel, among those who reported diarrhea, 31.1% used abx and 43.1% used the product. Receiving the product was associated with reducing abx use from 58.3% to 22.2% (61.7% reduction, RR=.54, p<.01) while among those using the product abx use fell from 57.5% to 25.0% (56.5% reduction, RR=.57, p<.01) and loperamide use fell from 22.1% to 7 .7% (65.2% reduction, RR=.85, p< .01). Combining previously reported changes in prescribing practices with these changes in client use gives an overall 76.0% reduction in self-treatment with abx by these travelers. For each 1000 travelers with diarrhea who received the product there would be 239 fewer self-treatments with abx. This non-drug option substantially reduces travelers' self-treatment of diarrhea with abx and loperamide.

492

WHO STAYS AND WHO GOES: PREDICTORS OF HOSPITAL ADMISSION AMONG PATIENTS PRESENTING WITH FEBRILE ILLNESS IN A RURAL UGANDAN HEALTH CENTER

Jonathan L. Chang[1], Raquel Reyes[2], Michael Matte[3], Moses Ntaro[3], Edgar Mulogo[3], Matthew O. Wiens[4], Steven R. Meshnick[2], Mark J. Siedner[5], Ross M. Boyce[2]

[1]Duke University School of Medicine, Durham, NC, United States, [2]University of North Carolina, Chapel Hill, NC, United States, [3]Mbarara University of Science & Technology, Mbarara, Uganda, [4]The University of British Columbia, Vancouver, BC, Canada, [5]Massachusetts General Hospital, Boston, MA, United States

Fever is a common reason for presentation to care in rural, low-resource settings. However, not much is known about clinical decision making in such settings. In this prospective, observational, single-center cohort study of patients presenting with fever to a health center in rural western Uganda, we examined demographic and clinical factors predictive of an initial disposition of inpatient admission after clinical evaluation, but before laboratory testing. We then assessed the impact of laboratory results and system factors associated with a change between initial and final disposition plans. 4,924 patients with suspected febrile illness were included in the primary analysis. The strongest predictors for an initial disposition of admission after clinical examination were impaired consciousness (adjusted risk ratio [aRR], 3.18; 95% confidence interval [CI], 2.41 to 4.20) and documented fever (aRR, 2.29; 95% CI, 1.81 to 2.88). Providers initially planned to discharge many patients with significant vital sign abnormalities, including tachypnea (8.0%) and hypotension (1.3%). Anemia strongly predicted a final disposition of admission after an initial disposition of discharge (aRR, 35.16; 95% CI, 18.74 to 65.96); however, other laboratory abnormalities including hypoglycemia, acidosis, and hyperlactatemia did not impact disposition planning (all $P \geq 0.20$). In those with an initial disposition of admission, living farther than the two neighboring villages was associated with a final disposition of discharge (aRR, 2.14; 95% CI, 1.10-4.18). In conclusion, a significant number of patients with abnormal vital signs and laboratory results are not admitted for inpatient care. Geographic factors may influence a patient's final disposition contrary to a provider's initial disposition plan. Future work should assess the longer-term repercussions of discharge with severe illness and a broader study population.

493

INVESTIGATION OF DROUGHT ASSOCIATED SCABIES OUTBREAK IN ETHIOPIA

Wendemagegn Embiale Yeshanehe[1], Ashenafi Ayalew[2]

[1]Bahir Dar University, Bahir Dar, Ethiopia, [2]Amhara Regional Health Bureau, Bahir Dar, Ethiopia

The impact of the severe drought in Ethiopia attributed to El Niño weather conditions has led to high levels of malnutrition that increased the potential for diseases outbreak. Currently Ethiopia is experiencing a scabies outbreak in drought-affected areas where there is shortage of safe water for drinking and personal hygiene as a direct result of the drought. Following a house to house census to assess the prevalence of scabies a detailed study has been done looking at the disease burden. Following the outbreak report in September 2015 we undertook "training of trainers" to relevant health workers on scabies. The training was cascaded to the health extension workers in the affected areas. Screening and management guideline and protocol were also distributed. A house to house data collection was undertaken to assess the prevalence of scabies. 1125770 people in the 68 districts in Amhara Region were surveyed using a simplified tool. A subsequent detailed data were collected from two zones and six woredas from 474 participants who had been diagnosed with scabies. This looked at the specificity of scabies diagnosis, age distribution, severity, duration of illness, super infection and other socio-demographic variables. The house to house census has registered 1125770 populations. 379,000 confirmed cases of scabies have been identified, with mean prevalence of 35.3% (0.2 to 60.7%). The detailed study has revealed that the specificity of scabies diagnosis by the health extention workers was 98.3%, mean duration of illness was 5 months with SD of +/- 2.8. 42% of patients were recorded to have severe illness. 75.1% of cases have affected family members. 39% of cases are school aged children and 30 % of them were noted to have bacterial super infection. 11% of the students have dropout from school because of scabies or/and drought. We concluded that the scabies burden in the region is enormous complicated by the nutritional shortage emergency and water scarcity. A coordinated response in case identification and intensified case management is mandatory to control the epidemic.

494

CERVICAL CANCER SCREENING AND TREATMENT ON THE DOMINICAN REPUBLIC/HAITIAN BORDER

Dale C. Betterton[1], **Dorothy M. Davison**[1], Douglas Creedon[2], Camila Altagracia Perozo De La Rosa[3]

[1]International Medical Alliance of TN, Knoxville, TN, United States, [2]Baylor College of Medicine at the Children's Hospital, San Antonio, TX, United States, [3]Dominican Republic Ministerio de Salud Publica and Hospital General Melenciano de Jimani, Jimani, Dominican Republic

Cancer mortality is a major global health problem, with cervical cancer (CC) the third most prevalent cancer worldwide, 75% of associated deaths occurring in LMICs. In 2009 our NGO instituted a first world CC screening and treatment program on the LMIC Haitian/Dominican Republic border. Haiti, with a CC incidence of 94/100,000 women, lacks a national CC screening program, and the Dominican Republic, with a CC incidence of 37/100,000 women, has such a program, but with suboptimal coverage and costly, difficult to access referral care. We are based in the Dominican border town of La Descubierta and four surrounding villages, available for some 4,000 unselected Dominican and Haitian women, many never pap screened. Donated supplies and equipment are obtained, and ThinPrep paps, HPV reflex testing and biopsy specimens are collected and shipped to the US for pathology services. Volunteer gynecologists and staff pursue precancerous results with colposcopy, biopsies, LEEPs and cryotherapy, care not available publicly or privately on the frontier. Patient records, photos and path reports are entered into an electronic database, and patients are found and encouraged to return for follow up with free transport, a meal and a gift bag of toiletries. Over nine years, through March 2018 (still ongoing,) 1413 women are enrolled, with: 354 abnormal (ASCUS or higher) paps, 25% of all women; a positive HPV rate of 20.3% (estimated 15.9% in Caribbean region); 19 cancers (5 deceased), a yearly CC incidence rate of 149/100,000 women; and prior abnormal results - 3 Ca in situ, 1 AGCUS, 29 ASCUS, 39 LGSIL and 15 HGSIL - now negative after treatment and repeated testing. To date, 2459 visits, 2063 paps, 273 colposcopies, 238 biopsies, 92 ECCs, 44 LEEPs, 2 conizations and 8 cryosurgeries have been done. Thus, on the LMIC Haitian/Dominican Republic border, deficient in resources, health infrastructure and often official and cultural beneficence, we are able to sustain an effective first world, tissue-based (not "See and Treat") CC screening and treatment program for poor Dominican and migrant Haitian women.

495

RAPID DETECTION OF *MYCOBACTERIUM ULCERANS* INFECTION BY RECOMBINASE POLYMERASE AMPLIFICATION

Michael Frimpong[1], Hubert Ahor[1], Francisca Naana-Sarpong[1], Mark Wansbrough-Jones[2], Richard Phillips[1]

[1]Kumasi Centre for Collaborative Research in Tropical Medicine, Kumasi, Ghana, [2]St. George's University of London, London, United Kingdom

The current control strategy for Buruli ulcer emphasizes early diagnosis and prompt treatment, with the goal of avoiding the complications associated with advanced stages of the disease. There is no diagnostic test for the disease appropriate for use at the primary health care level where

most cases are detected and treated. Diagnosis based on clinical signs is unrealiable in inexperienced hands and complicated by infections that have similar presentations. A diagnostic test for the early detection of Buruli ulcer in symptomatic patients with sufficient positive predictive value to put patients on appropriate treatment is a priority according to the WHO. The aim of this study was to develop and evaluate the use of RPA for the detection of *Mycobacterium ulcerans* (*M. ulcerans*) the causative agent of Buruli ulcer at the point of patient care. Specific fragment of IS2404 of *M. ulcerans* was amplified in 15 minutes at a constant 42ºC using the RPA method. The amplification product was analyzed on a real-time portable fluorometer. The method was tested for sensitivity and specificity with molecular standard of IS2404 DNA fragment, various *M. ulcerans* strains, other mycobacteria and environmentally associated bacteria. Additional investigation was done to assess the assay performance as a diagnostic tool using archived DNA from clinical samples of symptomatic patients. All results were compared with that of a highly sensitive IS2404 PCR. The detection limit was 10 copies of IS2404 in 15 minutes using plasmid standard and 125 fg with genomic *M. ulcerans* DNA equivalent 25 genomic copies. The assay was highly specific in detecting all 7 strains of *M. ulcerans* from different part of the globe with no observed cross reactivity with other mycobacteria and clinically relevant bacteria species. The clinical specificity of the BU-RPA assay was 100%, whiles the sensitivity was 86%. We have developed a real-time isothermal RPA assay for the detection of *M. ulcerans* as a cheaper alternative to PCR. Combining this assay with a simple extraction protocol will maximize its use as point of care test for confirming suspected cases of Buruli ulcer.

496

NUTRITIONAL AND ENVIRONMENTAL FACTORS ASSOCIATED WITH SPECIFIC DIARRHEAL PATHOGENS AMONG GUATEMALAN CHILDREN

Molly M. Lamb[1], Mario A. Melgar[2], Mirella Diva Calvimontes[2], Ingrid L. Contreras-Roldan[3], Samuel Dominguez[4], Christine C. Robinson[5], Edwin J. Asturias[4], Stephen Berman[4], James T. Gaensbauer[4]

[1]University of Colorado School of Public Health, Aurora, CO, United States, [2]Hospital Roosevelt, Guatemala City, Guatemala, [3]Universidad de Valle de Guatemala, Guatemala City, Guatemala, [4]University of Colorado School of Medicine, Aurora, CO, United States, [5]Children's Hospital Colorado, Aurora, CO, United States

Description of prevalence and diversity of diarrheal pathogens in children in low and middle income countries (LMICs), as well as nutritional and environmental risk factors associated with pathogen acquisition, will inform preventative public health measures. From 4/2015 to 3/2016, subjects 6—35 months old with acute, non-bloody diarrhea were enrolled in a diarrheal treatment trial at rural (N = 172) and urban (N = 144) sites in Guatemala. Baseline stool samples were tested for 23 diarrheal pathogens (bacterial, parasitic, and viral) by multiplex PCR (FilmArray GIP® Biofire). Associations between nutritional and environmental characteristics and specific pathogen infection were tested using multivariable generalized linear models. Simultaneous infection with multiple pathogens was common (mean per child: 4.8 rural, 2.7 urban). The most prevalent pathogens were campylobacter, toxigenic *C. difficile*, *E. coli* pathotypes (EAEC, EPEC, ETEC, STEC O157:H7), shigella, cryptosporidium, giardia, adenovirus, norovirus, and sapovirus. In multivariable models adjusted for rurality (proxy for poverty and sanitation), acute malnutrition was associated with toxigenic *C. difficile*, shigella, cryptosporidium and norovirus. Chronic malnutrition was associated with shigella and giardia. Presence of domestic animals (pigs, fowl, dogs, cats) in the house did not increase risk of putative animal-associated pathogens (campylobacter, *C. difficile*, ETEC, STEC O157:H7, shigella, and cryptosporidium). Age, gender, household crowding and number of children under age 5 did not confound these associations. Guatemalan children with acute or chronic malnutrition were more susceptible to certain pathogens, suggesting that both preventative efforts and therapeutic interventions for diarrheal illness should prioritize malnourished children, and account for different pathogen spectrums between acute and chronic malnourishment. The presence of domestic animals was not associated with any specific etiology, suggesting that modes and frequency of diarrheal pathogen transmission in LMIC households is complex and incompletely understood.

497

SYSTEMATIC REVIEW AND META-ANALYSIS OF THE DIAGNOSTIC ACCURACY OF LEPTOSPIROSIS LATERAL FLOW IGM POINT-OF-CARE TESTS

Michael J. Maze[1], Katrina J. Sharples[2], Matthew P. Rubach[3], John A. Crump[2]

[1]University of Otago, Christchurch, New Zealand, [2]University of Otago, Dunedin, New Zealand, [3]Duke University Medical Centre, Durham, NC, United States

Leptospirosis is underdiagnosed by clinicians in low- and middle-income countries, as traditional laboratory methods for diagnosis are unavailable. Lateral flow assays that use antigen derived from heat-treated whole cell *Leptospira* serovar Patoc strain Patoc 1 (LFA) are among the most promising point-of-care assays. We aimed to estimate the sensitivity and specificity of LFA by conducting a systematic review and meta-analysis. On 4 July 2017 we searched three medical databases for relevant articles. Two reviewers determined article relevance using pre-determined inclusion/exclusion criteria. For included articles we assessed study quality using quality assessment of diagnostic accuracy studies 2 (QUADAS-2) domains, characteristics of participants and testing methods. We estimated sensitivity and specificity for each study against the study-defined case definition as the reference standard, and performed a meta-analysis using a random-effects bivariate model. We assessed for publication bias using Deeks' funnel plot assymetry test. Our search identified 225 unique reports, of which we included 11 (4.9%). We considered one (9.1%) study to be high quality. Case definitions of leptospirosis were consistent with World Health Organization or Centers for Disease Control and Prevention definitions in one (9.1%) study. We did not find evidence of publication bias (p=0.63). Our estimate of pooled sensitivity and specificity was 80.1% (95% confidence intervals [CI] 71.5%) and 89.5% (CI 80.0-94.8%), respectively. The evidence base for determining the sensitivity and specificity of LFA is small. Most published studies are at moderate or high risk of bias, and case definitions vary markedly. Further well-conducted studies that use robust case definitions may alter estimates of diagnostic accuracy.

498

USE OF ELECTRONIC HEALTH RECORDS TO IMPROVE PATIENT OUTCOMES IN RESOURCE CONSTRAINED SETTINGS

Jose Luis Burgos[1], **Jennifer Schneider**[2], Patricia Lopez[2], Robert Lundquist[1]

[1]University of California San Diego, San Diego, CA, United States, [2]NotesFirst, Ontario, CA, United States

On April 30, 2011, the Health Frontiers in Tijuana, Mexico (HFiT) student-run free clinic was established in Tijuana's *Zona Norte*. HFiT serves vulnerable populations, including substance users, sex workers, the homeless, deportees, and indigent patients. HFiT patients often reside within the *Zona Norte*, although persons from more than 60 miles away have also received care at HFiT. HFiT was founded as a partnership between the University of California, San Diego School of Medicine (UCSD) and Tijuana's Autonomous University of Baja California School of Medicine (UABC), the only publicly funded medical school in Tijuana. The great need for healthcare for marginalized populations, combined with the desire of both UCSD and UABC to impact local communities, led to the planning and founding of the HFiT clinic. HFiT is the product of a true, binational partnership between the UCSD School of Medicine, the Universidad Autonoma de Baja California School of Medicine (UABC), and Desayunador Salesiano "Padre Chava", a community grass roots organization in Tijuana. HFiT provides accessible, quality healthcare for the

underserved in Tijuana's Zona Norte in a respectful environment where students, health professionals, patients, and community members from the border region learn from one another. The HFiT clinic trains future clinicians about global health and health care for the underserved and at the same time brings essential clinical services to a large number of vulnerable individuals living in our border region. In an effort to improve patient care, data collection, and outcome management, the HFiT provider community began utilizing an electronic medical record (EMR) developed by NotesFirst. NotesFirst has developed an EHR platform specifically in support of doctors and healthcare providers in lower-middle income regions. This technology has specific application both for electronic patient documentation at the point-of-care, and also in settings where the patient population is in flux, such as following a public health emergency, natural disaster, or political turmoil.

499

FIVE YEAR MORTALITY AMONG CHILDREN AGED 0 TO 14 YEARS IN UNIVERSITY COLLEGE HOSPITAL, SOUTHWEST NIGERIA

Temidayo A. Fawole

University College Hospital, Ibadan, Nigeria

Childhood mortality statistics is a crucial health index of a population, a reflection of the health system and health seeking behaviour of the population. Causes of childhood mortality are usually from preventable diseases, especially in low and middle-income countries like Nigeria. It understanding will enhance formulation and implementation of strategic policies to reduce childhood mortality.This study seeks to determine the causes of mortality among children aged 0 to 14 years admitted in University College Hospital, Southwest Nigeria from January 2012 to December 2016. It was a cross-sectional trend analysis of secondary data analysis of mortality statistics of children aged 0 to 14 years admitted in University College Hospital, Ibadan from January 2012 to December 2016 using extracted data from the department of Medical Records. The health data was extracted from the hospital's statistic register and patients case note. Annual number of children aged 0 to 14 years admitted along with recorded deaths during the five years period were extracted from the statistic register. Mortality rates was calculated for the five years. Cause of deaths were also extracted from the register and socio-demographics of the patients and parents were extracted from the patients case notes. The median age of participants was 2.55 ± 0.0years, with 56.7% being under-1 year. There was male preponderance of 55.1% with the majority being of Yoruba tribe (88.2%) and 80.9% living in urban areas. Mortality was highest among the under-1 with 60.4%, 66.0%, 57.6%, 59.6% and 64.6% for years 2012 through 2016. The overall mortality rate was highest in 2012 (12.1%) and lowest in 2015 (6.9%). Overall causes of childhood mortality show congenital diseases 41.4%, infectious diseases 29%, non-infectious diseases 17.4% and other causes of deaths 12.2%. Other causes of mortality include malnutrition, eye diseases, heart diseases, gun shot and kerosene ingestion. The major cause of childhood mortality in this study was congenital diseases, followed by infectious diseases. Sepsis, respiratory diseases and malaria rank highest among the infectious group for the five years.

500

COST-EFFECTIVENESS OF PODOCONIOSIS LYMPHOEDEMA TREATMENT IN NORTHERN ETHIOPIA: RESULTS FROM THE GOLBET TRIAL

Annabelle Clarke[1], Natalia Hounsome[1], Meseret Molla[2], Henok Negussie[1], Moses Ngari[3], James A. Berkley[3], Esther Kivaya[3], Tsige Amberbir[4], Fikre Enquoselassie[5], Gail Davey[1]

[1]Brighton and Sussex Medical School, Brighton, United Kingdom, [2]Centre for Environment and Development Studies, Addis Ababa University, Addis Ababa, Ethiopia, [3]KEMRI/Wellcome Trust Research Programme, Kilifi, Kenya, [4]International Orthodox Christian Charities Podoconiosis Project, Debre Markos, Ethiopia, [5]School of Public Health, Addis Ababa University, Addis Ababa, Ethiopia

Podoconiosis is a non-filarial geochemical lymphoedema that occurs in the tropical volcanic highlands and causes life-long disability and reduced labour productivity among subsistence farmers. We conducted a pragmatic, randomised controlled trial of a hygiene and foot-care intervention for people with podoconiosis in the East Gojjam zone, northern Ethiopia. Participants were allocated to the immediate intervention group or the delayed intervention group (control). The intervention included training in foot hygiene, skin care, bandaging, exercises, and use of socks and shoes, and was supported by lay community assistants. Cost-effectiveness analysis was conducted using the cost of productivity loss due to acute dermatolymphangioadenitis (ADLA), a complication characterised by fever, rigors, and a rapid increase in pain and swelling of the leg. The health outcome in the cost-effectiveness analysis was quality of life measured using the Dermatology Life Quality Index II (DLQI). The cost of the foot hygiene and lymphoedema management kit was 550 EBT ($66) per person per year. The cost of delivery of the intervention, including transportation, storage, training of lay community assistants and administering the intervention was 1355 ETB ($163) per person. Participants who received the intervention spent on average 42 (SD=30) days off economic activity due to ADLA, resulting in a productivity loss of 1704 ETB (SD=1232). Participants from the control group lost on average 55 (SD=31) days per year due to ADLA, costing 2237 ETB (SD=1253). Dermatological quality of life measured using DLQI was higher (scores were lower) in the intervention group (9.35, SD=4.23) compared to the control group (11.3, SD=3.7). Subgroup analyses demonstrated that participants with a monthly family income <1000 ETB ($119) had lower productivity loss and higher dermatological quality of life as a result of the intervention, compared to participants with an income >1000 ETB. Results of our analyses suggest that the proposed lymphoedema management strategy is more effective and less costly for people from the poorest families.

501

GUINEA-WORM DISEASE. A SYSTEMATIC REVIEW OF CASE REPORTS ABOUT THE FIRST NEGLECTED TROPICAL DISEASE TO BE ERADICATED

Diego Abelardo Álvarez Hernández[1], Rodolfo García Díaz Arana[2], Alberto Manuel González Chávez[3], Alejandro Acuña Macouzet[2], Rosalino Vázquez López[2], Ana María Fernández Presas[4]

[1]Fundación Carlos Slim, Mexico City, Mexico, [2]Universidad Anáhuac México Campus Norte, Mexico State, Mexico, [3]Hospital Español de México, Mexico City, Mexico, [4]Universidad Nacional Autónoma de México, Mexico City, Mexico

Guinea-worm disease is a parasitic disease caused by *Dracunculus medinensis*. It affects people living in rural and isolated communities who depend mainly on open surface water sources for drinking water. Although it mortality is low, morbidity is considerably high and may cause huge disabilities which are devastating. Diagnosis is clinically performed, and no specific treatment nor vaccines are available. The objective of our review was to describe the epidemiology of Guinea-worm disease published cases. A systematic review was conducted following the "*PRISMA*" guideline. PubMed database was searched using the search terms "*Dracunculiasis*" or "*Guinea-worm disease*" and limited to case reports published in English or Spanish, but without time frame. Full text articles were assessed for relevance and data extraction was performed as an iterative process. During the initial search 26 articles were obtained, from which 19, containing 25 cases were included. Females were more affected than males (13 vs 12) and the medium age of presentation was of 25 years (+/-SD 16.69). The 67% of the patients came from Africa and Nigeria was the country which reported the most (36%). Pain (60%), swelling (36%) and fever (16%) were the most common initial clinical manifestations, and the presence of an ulcer containing the Guinea-

worm was found during physical examination in only 40% of the cases. Diagnosis was most commonly done through histopathology (56%). Surgery was performed in 48% of the cases and mechanical extraction in 36%. The decision to do not perform no treatment at all was taken in 16% of the cases. Mortality rate was of 4%. Guinea-worm disease has been set as the first neglected tropical disease to be eradicated, and as it seems to come to an end, there are few case reports published in the literature. We consider that the trends presented in our systematic review, rather than being analyzed from a historic point of view, should be taken as a lesson by health professionals to enhance the active surveillance of the remaining cases. No patient should be left behind and reemergence must be prevented.

502

SURGICAL SITE INFECTION BY MYCOBACTERIUM ABSCESSUS: LESSONS LEARNED FROM AN OUTBREAK INVESTIGATION IN BANGALORE, INDIA

Justy Antony Chiramal[1], Priyadarshini A. Padaki[2], Alice Joseph[3], Tabitha Isaac[3], Rosario Vivek[2], Joy Sarojini Michael[4], Savitha Nagaraj[2]

[1]Qure.ai, Fractal Analytics, Mumbai, India, [2]St John's National Academy of Health Sciences, Bangalore, India, [3]Seventh Day Adventist Hospital, Bangalore, India, [4]Christian Medical College, Vellore, India

Mycobacterium abscessus, a rapidly growing NTM (Non-Tuberculous Mycobacteria) has been implicated in Surgical Site infection outbreaks lately. We investigated an outbreak of delayed surgical site infection in a 50 bedded Mission Hospital in Bangalore. We identified these cases by a retrospective-prospective study using the case definition of delayed onset nodule/sinus development +/- discharge at the surgical site that had initially fully healed. 18 tissue/discharge samples were sent for microbiological isolation. Environmental sampling was done including water from various inlets for source identification. 42 cases (40 Females) presented with symptoms, 46 days post surgery (range 9 to 134 days), among a total of 373 cases operated from January to June 2017. Cases were 35 Caesarean Section (19 Emergency), 2 hysterectomy, 3 hernia repair, 1 Laparoscopic removal of IUCD and 1 Tubal Ligation. None had fever or loss of weight/appetite. All tested negative for HIV, 5 had Gestational diabetes mellitus. All were prescribed a combination of Levofloxacin, Clarithromycin and Injection Amikacin, pending cultures. 4 cases that did not respond to first 2 weeks of antibiotics underwent Surgical debridement. 10 out of 18 samples were smear positive for Acid Fast Bacilli and 2 grew mycobacteria sensitive to all antibiotics except Tetracycline and Ofloxacin. Species was identified through Line Probe Assay. Cultures of water samples grew an array of microorganisms making Mycobacterial isolation difficult. Corrective measures taken included- setting up an HIC (Hospital Infection Control) Team to ensure compliance to infection control policies, changing the Theatre layout and installing a Reverse osmosis water plant. At 9 month follow up, 26 patients were healed, 12 were lost to follow up. 4 patients who refused treatment persisted to have sinuses. Unlike other outbreaks, follow up was challenging with majority being healthy nursing mothers. This study highlights that a ubiquitously present organism like NTM can cause outbreaks even among routine surgeries, thus emphasising the role of HIC and importance of sterile precautions like water quality.

503

HIGHLIGHTING THE NEED FOR APPROPRIATE CASE-MANAGEMENT OF UNDER-FIVE DIARRHEA AND PNEUMONIA IN PUBLIC HEALTH FACILITIES OF UTTAR PRADESH AND BIHAR, INDIA

Ashutosh Mishra[1], Punit Mishra[1], Prince Bhandari[1], Lopamudra Ray Saraswati[1], Animesh Rai[1], Ambrish Kumar Chandan[1], Clara Burgert[2], Amanda Honeycutt[3], Katie Moran[3], Margaret Baker[2]

[1]RTI Global India Private Limited, New Delhi, India, [2]RTI International, Washington, DC, United States, [3]RTI International, Durham, NC, United States

Under-five mortality rate is high in India; majority of these deaths are due to pneumonia (29%) and diarrhea (21%). This multi-faceted study was undertaken to understand case-management of childhood diarrhea and pneumonia. Across ten districts in Uttar Pradesh and Bihar, we interviewed 1283 caregivers, 817 Accredited Social Health Activists (ASHAs), and 769 informal private providers. Additionally, in 64 public health facilities, we observed the treatment given to 423 under-five children diagnosed with pneumonia and 891 with diarrhea, interviewed 232 facility based providers, and performed a supply audit. We found that more than 95% of the caregivers (95% CI: 94%-97%) went to private providers, and rest visited public providers. Only around 6% (4%-7%) visited ASHAs as majority did not consider them as a health provider. Knowledge of pneumonia and diarrhea was poor across all provider types. Skills, measured using video vignettes for ASHAs and informal private providers, and by observing the treatment provided by facility based providers, was even lower. Counting respiratory rate for one minute, the most important diagnostic tool for pneumonia, was done for only 2% of pneumonia cases (1%-4%). 13% (10%-15%) of diarrhea cases were assessed for dehydration using the skin pinch test. 12% (9%-15%) of pneumonia cases and 17% (14%-19%) of diarrhea cases were given appropriate treatment. Of all severe pneumonia (291) and severe diarrhea (39) cases, only 3% (1%-5%) were admitted, and 4% (2%-6%) got appropriate treatment. We developed a mathematical model (ADAPT) to examine the potential impact of increasing evidence-based interventions to prevent, diagnose, and treat pneumonia and diarrhea, and that of changes in the mix of providers from whom patients seek care. Results showed that with a 20-percentage point improvement in quality of care within facilities, and diversion of traffic to public facilities from 1% to 41%, more than 36,000 lives could be saved annually in these two states. There is an urgent need for improved quality of care for children in India and we have provided information to help stakeholders design the appropriate strategies.

504

MICRONUTRIENT LEVELS IN A PEDIATRIC UGANDAN COHORT WITH SICKLE CELL ANEMIA

Thomas F. Siegert[1], Sarah E. Cusick[2], Russell E. Ware[3], Robert O. Opoka[4], Chandy C. John[5]

[1]University of Washington School of Medicine, Seattle, WA, United States, [2]Department of Pediatrics, University of Minnesota, Minneapolis, MN, United States, [3]Division of Hematology, Department of Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States, [4]Department of Paediatrics and Child Health, Makerere University, Kampala, Uganda, [5]Ryan White Center for Infectious Diseases and Global Health, Department of Pediatrics, Indiana University, Indianapolis, IN, United States

Micronutrient deficiency has been associated with morbidity in children with sickle cell anemia (SCA) living in the US and Europe, but there is limited information on micronutrient deficiency in children with SCA living in Africa. We assessed baseline micronutrient levels in Ugandan children age 1-4 years enrolled in the Novel use Of Hydroxyurea in an African Region with Malaria (NOHARM) study, a randomized controlled trial that compared hydroxyurea therapy vs. placebo. We measured

serum concentrations of vitamin A (HPLC), vitamin B12 (microbiological assay), vitamin D (mass spectrometry), vitamin E (HPLC), and plasma concentrations of folate (chemiluminescence assay) in 99 randomly selected children in the NOHARM study using blood collected prior to the start of study treatment. Median (IQR) concentrations were: vitamin A (retinol), 26.6µg/dL (20.8-30.4); vitamin B12, 622.0pg/mL (461.3-870.3); vitamin D (25OH-D), 29.0ng/mL (25-35ng/mL), and vitamin E (α-tocopherol), 20.6µmol/L (17.1-25.1). Median folate level was beyond the upper limit of detection (>52.1nmol/L). Prevalence of vitamin deficiency was: vitamin A (retinol <20µg/dL), 18.2%; vitamin B12 (<200 pg/ml), 3.0%; vitamin D (25OH-D <20ng/mL), 6.1%, and vitamin E (α-tocopherol <11.6µmol/L), 1.0%. No folate-deficiency (folate <10nmol/L) was present, likely due to routine folic acid supplementation for chronic hemolysis in this population. 52.5% of children were vitamin D-insufficient (25OHD <30ng/mL). C-reactive protein (CRP) was negatively correlated with retinol (Spearman rho=-0.240, p=0.02) but not with other micronutrients. Inflammation and hemolysis may alter interpretation of some nutritional biomarkers in children with SCA. However, vitamin D insufficiency was common in children with SCA and unrelated to inflammation. Future studies will assess whether baseline micronutrient deficiencies are associated with subsequent SCA-related morbidity.

504

MICRONUTRIENT LEVELS IN A PEDIATRIC UGANDAN COHORT WITH SICKLE CELL ANEMIA

Thomas F. Siegert[1], Sarah E. Cusick[2], Russell E. Ware[3], Robert O. Opoka[4], Chandy C. John[5]

[1]University of Washington School of Medicine, Seattle, WA, United States, [2]Department of Pediatrics, University of Minnesota, Minneapolis, MN, United States, [3]Division of Hematology, Department of Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States, [4]Department of Paediatrics and Child Health, Makerere University, Kampala, Uganda, [5]Ryan White Center for Infectious Diseases and Global Health, Department of Pediatrics, Indiana University, Indianapolis, IN, United States

Micronutrient deficiency has been associated with morbidity in children with sickle cell anemia (SCA) living in the US and Europe, but there is limited information on micronutrient deficiency in children with SCA living in Africa. We assessed baseline micronutrient levels in Ugandan children age 1-4 years enrolled in the Novel use Of Hydroxyurea in an African Region with Malaria (NOHARM) study, a randomized controlled trial that compared hydroxyurea therapy vs. placebo. INTERVENTIONS TO REDUCE PEDIATRIC TUBERCULOSIS MORTALITY IN INDIA AND NIGERIA USING MAP-IT: A MATHEMATICAL MODEL TO ESTIMATE INTERVENTION IMPACTS ON PEDIATRIC TUBERCULOSIS MORTALITY

Allyson Drew[1], Jennifer Griffin[1], Emily MacGuire[1], Doris Rouse[1], Cherise Scott[2], Irina Usherenko[2]

[1]RTI International, Durham, NC, United States, [2]TB Alliance, New York, NY, United States

Tuberculosis (TB) is a leading cause of pediatric morbidity and mortality in low income countries. Mathematical models, such as the Model for Assessment of Pediatric Interventions for TB (MAP-IT), a user-friendly, web-based, non-stochastic model, can be used to estimate the impact of TB interventions on pediatric TB-associated mortality. We used MAP-IT to model scenarios of improved availability and utilization of single and packaged TB preventive, diagnostic, and treatment interventions to estimate the impact on pediatric TB-associated mortality in India and Nigeria, two high-burden countries, from 2017-2021. The current-care scenario estimated 276,800 and 82,500 TB-associated pediatric deaths from 2017-2021 in India and Nigeria, respectively. In India, interventions the greatest impact on pediatric mortality were improved pediatric fixed dose combination (FDC) regimes (15.2%); improved clinical diagnosis (12.6%); and improved contract tracing (2%). In Nigeria, improved pediatric FDCs and clinical diagnosis had the greatest individual impact on pediatric mortality, with 8.7% and 8.6% reductions in pediatric mortality, respectively. Packaging TB interventions maximized the impact on pediatric TB mortality, with three-quarters of mortality prevented in both India and Nigeria. \ Improved pediatric FDCs and clinical diagnosis had the greatest individual impact on pediatric TB mortality. However, packaged TB interventions have the greatest impact on the number of lives saved. Intervention strategies must address obstacles to implementation, including service access, financing, availability of interventions, and education. In conclusion, MAP-IT estimates indicate packaged interventions including improved diagnostics and child-friendly FDCs regimens had the greatest impact on pediatric TB mortality in two high-burden countries.

506

PEDIATRIC DISCHARGE FROM HOSPITAL: KENYAN HEALTHCARE WORKERS' PERCEPTIONS AND REPORTED PRACTICES

Shadae Paul[1], Kirk Tickell[1], Benson Singa[2], Donna Denno[1], Scott Ickes[3]

[1]University of Washington, Department of Global Health, Seattle, WA, United States, [2]Kenya Medical Research Institute, Nairobi, Kenya, [3]Wheaton College, Department of Applied Health Services, Wheaton, IL, United States

Children discharged from hospital in low- and middle- income countries (LMICs) are at increased risk of mortality during the subsequent 6 months compared to community peers. Outcomes may be improved by quality care at discharge, yet little is known about factors influencing its provision. This study aims to assess healthcare worker (HCW) attitudes, perceptions, and reported practices regarding discharge care of inpatient children. All clinicians (doctors, clinical officers), nurses, and nurse and clinical officer trainees involved in pediatric discharge care at 10 Western Kenyan hospitals are recruited to complete a 28-question survey. A subset will be invited for in-depth interviews. To date, 43 HCWs from three hospitals have completed the survey. Interim results indicate that 72% believe that children discharged from hospital are less likely to die compared to community children, although 60% reported that >90% of readmissions could be prevented with better discharge and follow-up care. Most respondents (97%) report discharge care to be very important, and as consequential as inpatient tasks, to patient outcomes. Participants

almost unanimously indicated that the range of discharge care tasks are implemented at their facility, and any single task is performed by diverse cadres. Only 35% of HCWs indicated that their hospital delivers pediatric discharge care "very well" compared to ideal practices. We plan for 60 additional surveys and 30 interviews to be completed by July 2018. Interim survey results suggest HCWs underestimate post-discharge mortality burden, but are able to identify several important and potentially modifiable barriers to effective care such as take-home medication stock-outs, provider-caregiver miscommunication, and lack of family valuation of and adherence to discharge care instructions. Although participants indicated that currently available guidelines are "very informative" for discharge care delivery, these resources are heavily inpatient management focused and provide limited discharge care guidance. Additional research is needed to understand how to improve pediatric discharge care in LMICs.

507

THE IMPACT OF POLYPARASITISM ASSOCIATED WITH PREGNANCY IN LAMBARÉNÉ AND SURROUNDINGS AREAS IN GABON

Yabo J. Honkpehedji[1], Eliane Ngoune Feugap[1], Esther Askani[2], Wiebke Woolfman[2], Rela Manego Zoleko[1], Jeannot F. Zinsou[1], Jean-Claude Dejon-Agobé[1], Yoanne D. Mouwenda[1], Madeleine E. Betouke-Ongwe[1], Fabrice L. Mouengni[1], Ghyslain Mombo-Ngoma[1], Bertrand Lell[1], Peter G. Kremsner[2], Maria Yazdanbaksh[3], Meral Esen[2], Ayôla A. Adegnika[1]

[1]Centre de Recherches Medicales de Lambarene, Lambarene, Gabon, [2]Institut für Tropenmedizin, Eberhard Karls Universität Tübingen, Tübingen, Germany, [3]Department of Parasitology, Leiden University Medical Center, Leiden, Netherlands

The burden of parasites, particularly soil-transmitted helminths, schistosomiasis and *malaria*, is often very high in pregnant women in Sub-Saharan African countries such as Gabon. Having multiple parasite infections in these endemic areas is common because of the coexistence of their vectors. Thus, anemia associated with parasites is a major factor in women's health, especially during pregnancy and is an important contributory factor in poor health outcomes for newborns. We aimed to investigate the impact of polyparasitism among pregnant women attending antenatal care in Lambaréné. Pregnant women in their third trimester were recruited in two cross-sectional studies. The diagnosis of helminthiasis and malaria were determined by microscopy using stool and urines as well as blood and tissue specimens respectively. Logistic regression models were applied to assess the association between the infection status of mothers and pregnancy outcome variables (low birth weight, *In utero* growth retardation, maternal anemia and prematurity). A total of 927 pregnant women were enrolled in this analysis with a median age of 24 years. Parasites such as *Plasmodium falciparum* detected in mother peripheral blood and placenta tissue were respectively 30.5% (255/836) and 16.5% (70/424), Soil-transmitted helminths and *Schistosoma haematobium* were 37.6% (311/827) and 24%(199/830). At least 65.6 % (438/668) of the pregnant women had one parasite, polyparasitism was found with two, three and more than four parasites in respectively 21.6% (157/726), 3.3% (24/731) and 0.7% (5/668). The mean birth weight was 2950g and 19% (170/893) had low birth weight. The pregnancy outcomes observed in this analysis were all associated with malaria and polyparasitism with four parasites. Polyparasitism increased the risk of having low birth weight in our study. The prevalence of polyparasitism with more than three parasites was low in our study, but highly associated with the poor pregnancy outcomes. Therefore, public health measures and intensive antenatal care services are vital to promoting safe pregnancy in resource-limited settings.

508

MALNUTRITION AMONG RESIDENTS OF THE VELLORE DEMOGRAPHIC SURVEILLANCE SYSTEM, SOUTH INDIA

Samarasimha Reddy N, Venkata Raghava Mohan, Gagandeep Kang

Christian Medical College, Vellore, India

Malnutrition, which includes obesity and under-nutrition, has significant public health impact in terms of morbidity, mortality, and economic loss. Anthropometric measurements of population in a Demographic Surveillance System (DSS) give us a chance to describe the distribution of malnutrition in different age groups. In 2015, the Vellore Demographic Surveillance System (VDSS), which covers a total population of 154,452 residents, collected anthropometric measurements of all available individuals in 22 urban wards and 21 rural villages in Vellore, Tamil Nadu, India. Z scores were calculated based on the World Health Organisation (WHO) growth standards using the WHO Anthro plus software. Anthropometric measurements were obtained for 89,308 (58%) residents of which 9,916 (11%) were children less than 5 years of age, 17,736 (20%) were 5-19 years of age and 61,656 (69%) were adults. Among children <5 years, stunting (HAZ SD<-2) was seen in 2,489 (25%; 95% CI 24.25-25.96), underweight (WAZ SD<-2) in 2,343 (24%; 95% CI 22.8-24.47) and wasting (WHZ SD<-2) in 1,072 children (11%; 95% CI 10.21-11.43). Multivariate regression analysis showed that children residing in urban areas (adjusted odds ratio (AOR) 1.16; 95% CI 1.03-1.30), overcrowded dwellings (AOR 1.25; 1.06-1.46) and houses using solid fuel (firewood) for cooking (AOR 1.36; 95% CI 1.13-1.63) were significantly at higher odds of being stunted. In the age group of 5-19 years, thinness (Body mass index, BMI, for age (BAZ) SD <-2) was seen in 4,081 (23%; 95% CI 22.39-23.63), overweight (BAZ SD >1) in 1,657 (9%; 95% CI 8.92-9.77) and obesity (BAZ SD >2) in 700 individuals (4%; 95% CI 3.66-4.24). Among adults (>19 years), undernutrition (BMI <18.5) was present in 7,796 (13%; 95% CI 12.38-12.90), overweight (BMI 25-29.9) in 16,771(27%; 95% CI 26.85-27.55) and obesity (BMI ≥30) in 8,138 individuals (13%; 95% CI 12.93-13.46). The burden of under-nutrition is high in children and the prevalence of overweight and obesity is high among adults indicating the need for strategies to handle the dual challenges in southern India.

509

PITFALLS OF PREDICTING LEPTOSPIROSIS BY COMMON CLINICAL AND BIOCHEMICAL MARKERS

Janith Warnasekara[1], Dinesha Jayasundara[2], Indika Senavirathna[3], Sisira Siribaddana[4], Kularathna Sam[5], Joseph Vinetz[6], Suneth Agampodi[1]

[1]Department of Community Medicine, Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka, Anuradhapura, Sri Lanka, [2]Department of Microbiology, Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka, Anuradhapura, Sri Lanka, [3]Department of Biochemistry, Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka, Anuradhapura, Sri Lanka, [4]Department of Medicine, Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka, Anuradhapura, Sri Lanka, [5]Department of Medicine, Faculty of Medicine,University of Peradeniya, Kandy, Sri Lanka, [6]Division of Infectious diseases, School of Medicine, University of California, San Diego, Anuradhapura, Sri Lanka

Blood biochemistry, together with clinical parameters is being used to diagnose leptospirosis and differentiates it from dengue in resource poor setting, due to lack of point of care diagnostic methods. The objective of this study was to investigate the usability of commonly use predictors of leptospirosis. We carried out a prospective study from April 2016 to January 2018 at four major leptospirosis endemic areas in Sri Lanka. All undifferentiated afebrile patients were recruited as "possible" cases of leptospirosis and the clinical features and blood biochemistry and symptoms was monitored daily until the 10th day of illness. We specifically

looked at WBC, platelets and heamatocrit, which have been reported in literature as markers to differentiate leptospirosis from dengue. In addition, the clinical symptoms listed in leptospirosis case definition were also monitored. Case confirmation was done using a real time PCR & previously validated lateral flow immune assay (both done on all cases). Of the 624 screened, 269 confirmed as leptospirosis. At least one WBC count was more than 11000/mcL in 55(27.8%) patients while 47(23.7%) had at least one count less than 4000/mcL. At least one platelet count was less than 150000/mcL in 159(82%) confirmed cases. More than 20% increased in heamatocrit from baseline was observed in 23.3%(n=44). Fever was not an admission symptom in 28(13.1%) patients, while headache, myalgia, conjunctival suffusion and jaundice were not evident at the hospital admission among 46(21.4%), 45(20.9%), 171(79.5%), 177(82.7%) respectively. Among patients who were positive only for antibodies, WBC count was higher through out the illness compared to the patients diagnosed using PCR while the platelet count had gradual drop with the disease progression in antibody positive patients. The common clinical and biochemical markers are misleading and differentiation with conditions like dengue is extremely difficult. Immune response associated changes in blood biochemistry may be explaining the previous observations among leptospirosis patients diagnosed primarily with antibodies.

510

THE EFFECT OF OBSTETRIC ULTRASOUND DURING THE FIRST STAGE OF LABOR ON TIME TO DECISION MAKING ON DEFINITIVE MODE OF DELIVERY AT MBARARA REGIONAL REFERRAL HOSPITAL IN WESTERN UGANDA

Sudi Mohamed[1], Sarah Boudova[2], Janie Anne Zuber[3], Daniel Atwine[4], James Campbell[3]

[1]Mbarara University of Science and Technology, Mbarara, Uganda, [2]Institute for Global Health, Division of Malaria Research, University of Maryland School of Medicine, Baltimore, MD, United States, [3]Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [4]Mbarara University of Science and Technology Epicenter, Mbarara, Uganda

Mbarara Regional Referral Hospital (MRRH) is a tertiary care hospital that serves the western region of Uganda and neighboring countries. MRRH delivers an average of 12,000 pregnancies per year. Only a small fraction of these pregnancies are ever evaluated by prenatal ultrasound. Ultrasound has been shown previously in African settings to predict successful vaginal births, to detect the need for operative vaginal delivery and to alter management plans. A program recently introduced to MRRH for training the resident doctors in the basics of obstetric ultrasound aims to increase the use of prenatal ultrasound near the time of delivery. We are interested in assessing the impact of this program. We have designed an open label randomized controlled trial of the impact of ultrasound during the first stage of labor on time to decision making for the definitive mode of delivery. At the time of admission mothers in the first stage of labor with no particular indication for ultrasound will be consented and randomized either to be evaluated by ultrasound, or to not be evaluated by ultrasound (the standard of care in this setting). These women will be followed until discharge. We will collect data on time to decision on delivery mode, time to delivery, adverse maternal and fetal outcomes and maternal satisfaction with care. Data analysis will be done both by intention to treat and per protocol. We anticipate that obstetric ultrasound utilized during the first stage of labor will reduce time to decision making for mode of delivery. This is expected to improve maternal and fetal outcomes as well as maternal satisfaction. Monitoring the impact of new programs is critical for evidence-based medicine. While ultrasound is periodically used in high risk pregnancies at MRRH, it has never been introduced to the general obstetric population. This study will inform hospital policy with regards to the optimal use of obstetric ultrasound during the first stage of labor and will provide evidence to advocate for the expansion of this technology to other regional referral hospitals in Uganda, aiming ultimately to achieve sustainable improvements in maternal and child health.

511

FEMALES OF HBAS GENOTYPE HAVE REDUCED CONCENTRATION OF THE MALARIA PROTECTIVE *DEOXYHEMOGLOBIN S* THAN MALES

John N. Waitumbi[1], Carolyne Kifude[1], Carol Hunja[2], Bernhards Ogutu[1]

[1]KEMRI/USAMRD-K, Kisumu, Kenya, [2]South Eastern Kenya University, School of Pure and Applied Sciences, Department of Biology, Kitui, Kitui, Kenya

The quantity of the intra-erythrocytic deoxyhemoglobin S (Hb S) affects the level of protection against malaria and also the sickling phenomenon. This study reports on significantly lower concentration of Hb S in females than males. Data came from 350 children, aged 12-47 months who participated in a phase 2b malaria vaccine trial. Hemoglobinopathy and G6PD deficiency typing was necessary to ascertain equal representation of these malaria protective traits across the vaccine cohorts. Hemoglobin types (HbAA, HbAS) and % Hb S were evaluated by HPLC. Alpha thalassemia (alpha-thal) and G6PD genotypes were evaluated by PCR. The overall prevalence for HbAS was 20%, 46% for 3 alpha genes and 10% for 2 alpha genes and 14% for G6PD A-. More females of HbAS/ $\alpha\alpha/\alpha\alpha$ genotype had low Hb S than males and had mean % Hb S of 37.5 % + 5.4 SD, compared to 42.0% + 2.5 SD in males of same genotype (P=0.0415). Consistent with reduction of the malaria protective Hb S in females, parasite load was three times higher in females of HbAS without alpha gene deletion (geo mean 3,118, 95% CI: 1779-5465) than males (1,676, 95% CI: 752-3733). The X-chromosome linked G6PD deficiency did not influence the level of Hb S. We conclude that, the low Hb S in these females explains the resultant higher malaria parasite load. We speculate that the low Hb S in females could also explain observations suggesting that the sickling phenomenon tends to be less severe in females than males.

512

CLINICAL IMPACT OF MERCURY TOXICITY AMONG INDIGENOUS PEOPLES OF THE PERUVIAN AMAZON

Leahnne Giffin[1], Kimberly Kucharski[1], **Katherine Myers**[1], John W. Sanders[1], Juan F. Sanchez[2], Alycia Silman[3], Claudia Vega[3], David J. Gonzalez[4], Luis E. Fernandez[3]

[1]Wake Forest School of Medicine, Winston Salem, NC, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]Wake Forest University, Winston Salem, NC, United States, [4]Stanford University, Palo Alto, CA, United States

An estimated 10,000 indigenous peoples live in Madre de Dios, located in the Southern Peruvian Amazon Basin, a region in a state of emergency concerning mercury levels in the region's rivers, some attributed to illicit gold mining but some unexplained. Measurements in 2014 found a mean hair total mercury concentration of 26.3±12.8 µg/g with a range of 1.5 to 53.1 µg/g (WHO safe level of 6 µg Hg/g). Mercury, in different forms, can result in varied presenting toxicities. Because the source and impact of the mercury in these indigenous communities is as of yet undetermined, this pilot study aimed to assess possible mercury-related toxicities as part of an integrated environmental and health assessment. Full physical exams with a focus on nervous system function were conducted on 35 individuals in the isolated Matsigenka community of Maizal. Neurologic assessments were modified for participants older or younger than 10 years. Additionally, urine and blood samples were taken to assess for proteinuria and anemia. Hair samples were obtained to measure mercury levels. Surveys were conducted to determine possible mercury exposure. Environmental samples were also collected. The median age for 13 adults was 29 (22 - 65) and for 22 children was 5 (1 - 11). Physical exam findings were largely normal excepting decreased head circumference in children (69.6% below the 3rd percentile for age). Neurologic assessment among adults revealed normal executive function (79%), possible diminished short-term memory (36.7%), and abnormal cerebellar function (61.6%).

Neurocognitive assessment among children revealed no appreciable deficits but was complicated by language and cultural barriers. Mild anemia was detected in 62.2% (84.6% of adults 45.5% of children) and 21% had at least trace proteinuria. Mercury levels are pending at time of submission. Preliminary analysis shows no overt signs of chronic or acute mercury toxicity in this population. Abnormal findings in neurologic functioning need to be correlated with pending mercury levels. More studies are needed to develop and validate neurocognitive assessment tools for isolated, indigenous populations.

513

NATURAL HISTORY OF SAPOVIRUS INFECTION IN A NICARAGUAN BIRTH COHORT: THE SAPOVIRUS-ASSOCIATED GASTROENTERITIS [SAGE] STUDY

Fredman Gonzalez[1], Nadja A. Vielot[2], Yaoska Reyes[1], Christian Toval[3], Margarita Paniagua[1], Natalie McCarter Bowman[2], Jan Vinje[4], Filemon Bucardo[1], Sylvia Becker-Dreps[2]

[1]National Autonomous University of Nicaragua (UNAN) -León, Leon, Nicaragua, [2]Department of Family Medicine University of North Carolina, Chapel Hill, NC, United States, [3]Center for Demographic and Health Research – León, León, Nicaragua, [4]National Calicivirus Laboratory, Centers for Disease Control and Prevention, Atlanta, GA, United States

With the advent of rotavirus vaccines, norovirus and sapovirus are now the main viral causes of acute gastroenteritis (AGE) in children. Unlike for norovirus, data on the natural history, development of immunity, and transmission modes for sapovirus are scarce, as most epidemiological AGE studies do not test for sapovirus. We launched a birth cohort and nested case-control study in León, Nicaragua to understand the burden of sapovirus-associated gastroenteritis. We will recruit 400 mother-infant pairs from antenatal care patients in local health posts. Trained field workers recruit mothers aged ≥15 years at home within 15 days of birth. Enrolled mothers provide monthly AGE risk factor data and report weekly if children had AGE in the last week. Mother-infant pairs provide the following routine clinical specimens: breastmilk (baseline, monthly); blood (mother: baseline; child: baseline, 6 weeks, 5 months, semi-annually thereafter); saliva and stool (child: baseline, monthly). During AGE episodes, we collect stool to test for sapovirus in addition to rotavirus and norovirus using real-time polymerase chain reaction. When sapovirus is detected, field workers collect risk factor data from all household contacts of the case. To assess transmission dynamics and duration of viral shedding, a nurse collects one stool sample from each household contact and follow-up stool samples from the case until sapovirus-negative. A trained lab technician collects environmental swab samples from the case household including toilet handle, kitchen faucet, kitchen knife, child's toy, and the mother's hands. We interview two age-matched control households to collect risk factor data; one also provides stool and environmental samples. Enrollment began June 12, 2017. As of March 15, 2018, 357 of 870 eligible mother-infant pairs have been enrolled. 109 stool samples were collected from 138 AGE cases, of which 2 were sapovirus-positive. Weekly surveillance continues until children reach 3 years. This study will yield critical data on sapovirus natural history, immunity, and transmission in children.

514

RELATIONSHIP OF DEMOGRAPHIC VARIABLES AND CLASSIFICATION OF LEPROSY CASES IN GEORGIA SINCE THE EARLY 1900S

Carter McCormick[1], Jacqueline Lea[2], Barbara Stryjewska[2], Jessica Fairley[1]

[1]Emory University, Atlanta, GA, United States, [2]National Hansen's Disease Programs, Baton Rouge, LA, United States

Leprosy (also known as Hansen's Disease) is a disease that is diagnosed in approximately 160 people in the USA each year. Recent studies have shown different forms of transmission in the southern US (zoonotic versus person-to-person), but epidemiologic data are lacking about factors associated with multibacillary infection, the most infectious form. Additionally, no work has been done to evaluate if country of origin, between domestic and international birth locations, has a relationship with the type of leprosy diagnosed. We collected data from patient files and surveillance reports on 123 leprosy patients from the National Hansen's Disease Program who had been reported by or lived in the state of Georgia since the early 1900's. Of the 123 patients, 31.71% were born in the USA and 68.29% were born in other countries. Most patients had multibacillary leprosy for both domestic (69.23%) and foreign born (63.10%). Patients born domestically were on average younger than those foreign born, but both had more male patients. A logistic model was built to examine the relationship between country of origin and type of leprosy, based on the World Health Organization's classifications of multibacillary and paucibacillary. We controlled for age, sex, and ethnicity. While the model showed no significant relationship between country of origin and type of leprosy, being Asian or Pacific Islander (97.36% of which were foreign born) was associated with a higher risk of multibacillary infection when controlled with the other variables (aOR = 5.714; 95% CI: 1.254 - 26.287). Leprosy is known to be highly endemic in Micronesia and other areas in Asia. There have been several articles describing the epidemiological data of Asians and pacific islanders in the USA, such as the Marshallese in Arkansas and Micronesians in Hawaii. However, more research should be done to see if these population is at greater risk for multibacillary leprosy. With the global community dedicated to the elimination of leprosy, understanding which populations are at greater risk for this more infectious type of leprosy is important to create targeted interventions and prevention strategies.

515

ARBOVIRUS AND MALARIA CO-INFECTIONS AMONG FEBRILE KENYAN CHILDREN

Melisa M. Shah[1], Malaya K. Sahoo[2], Amy R. Krystosik[3], Francis M. Mutuku[4], Bryson A. Ndenga[5], Victoria Otuka[5], Charles Ronga[5], Philip K. Chebii[6], Priscillah W. Maina[6], Zainab Jembe[7], Benjamin A. Pinsky[1], A. Desiree LaBeaud[3]

[1]Infectious Diseases and Geographic Medicine, Stanford University, Stanford, CA, United States, [2]Department of Pathology, Stanford University, Stanford, CA, United States, [3]Department of Pediatrics, Division of Infectious Disease, Stanford University, Stanford, CA, United States, [4]Department of Environment and Health Sciences, Technical University of Mombasa, Mombasa, Kenya, [5]Kenya Medical Research Institute, Kisumu, Kenya, [6]Department of Pediatrics, Msambweni County Referral Hospital, Msambweni, Kenya, [7]Department of Pediatrics, Diani Health Center, Ukunda, Kenya

Although malaria parasites and arboviruses circulate in Kenya with overlapping endemicity, estimates of febrile illness among children due to arboviral infections remain limited. The effects of malaria and arbovirus co-infection on childhood morbidity is even less studied. From an ongoing febrile cohort in Western and Coastal Kenya (NIH R01 AI102918), we recruited pediatric patients presenting to outpatient care in four varied clinical sites. Using multiplexed real-time reverse transcriptase polymerase chain reaction (rRT-PCR) assays, we studied the rates of arbovirus viremia and malaria parasitemia among febrile children under the age of 17 years presenting with lymphadenopathy and joint pain. Specifically, 105 complementary DNA (cDNA) samples were tested for dengue (DENV), chikungunya (CHIKV), Zika (ZIKV), West Nile (WNV), Yellow Fever (YFV), Rift Valley Fever (RVFV), and O'nyong-nyong (ONNV) viruses, and pan-*Plasmodium* parasites. Overall, 65/105 (62%) of febrile children were parasitemic by rRT-PCR. 35/105 (33%) of patients were viremic with DENV. 23/105 (22%) presented with DENV-malaria co-infection. 9/105 (9%) presented with CHIKV viremia, 3/105 (3%) of which were co-infected with malaria. There were 2 children with malaria parasites, DENV viremia, and CHIKV viremia. There were no significant differences in age, gender, reported symptoms, bednet use, or hospitalization rates between patients presenting with arbovirus-malaria coinfections and those with solo malaria

parasitemia. Socioeconomic status was similar between the two groups with the exception that co-infected children were more likely to live in a home with dirt floor rather than concrete floor. There were no cases of WNV, YFV, ZIKV, RVFV, or ONNV detected. Given the large number of co-infections detected, we plan to analyze a total of 1255 pediatric cDNA samples to further investigate differences in disease severity and risk factors for arbovirus and malaria co-infections. This study will inform interventions to better care for febrile children visiting outpatient clinics in Kenya.

516

THE INTRODUCTION OF INFANT FORMULA AMONG CHILDREN FROM PERI-URBAN SHANTYTOWNS OF LIMA, PERU (1995 - 2016)

Mayra R. Ochoa[1], Jessica D. Rothstein[2], Lilia Cabrera[3], Robert H. Gilman[2], Mayuko Saito[4], Mónica J. Pajuelo[1]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]Asociación Benéfica PRISMA, Lima, Peru, [4]Tohoku University Graduate School of Medicine, Sendai, Japan

Exclusive breastfeeding (EBF) during the first 6 months of life is considered the first line of nutritional child protection. In Peru, breastfeeding rates have historically been high [66%, Demographic and Health Survey (DHS) 2017]. However, in recent years there has been a reported decline in EBF rates, and presumably increased in the introduction of infant formula (IF) at earlier ages. Surveys such as the DHS are limited to characterize the age of the introduction of IF due to their cross-sectional nature. Over the past three decades, we have carried out three cohort studies in two peri-urban communities in Lima, with daily active surveillance of gastroenteritis and child feeding practices via verbal report from the mother. This offers an excellent opportunity to compare breastfeeding practices among three birth cohorts during other decades (1995-1997, 2007-2010, 2016-2018). We conducted secondary data analysis of the rates of exclusive or predominant breastfeeding (in which some water is allowed), and conducted a survival analysis to calculate the age of introduction of infant formula. A total of 304, 289 and 345 children were recruited in each cohort during the first two months of life. The percentage of children who received exclusive or predominant breastfeeding during the surveillance period was 13.48%, 5.19% and 9.57% [95%Confidence Interval (CI):10.07—17.83%; 3.14—8.45%; 6.87—13.17%] during 1995-1997, 2007-2010 and 2016-2018, respectively. The percentage of children who received IF or mixed feeding during the first 6 months of life was 27.6%, 86.2% and 58.6% (CI:22.9—33.0%; 81.7—89.7%; 53.3—63.7%), respectively. The percentage of children with EBF among our current study (2016-2018) was lower than that reported by DHS. Finally, the average age at which IF was introduced has decreased over the last two decades, and was calculated to be 4 months, 3 months, and 1 month for each cohort, respectively.

517

ETIOLOGIES OF GASTRO-INTESTINAL PERFORATIONS IN KILIMANJARO, TANZANIA. PROSPECTIVE HOSPITAL-BASED SENTINEL SURVEILLANCE

Blandina T. Mmbaga[1], Alex Mremi[2], Patrick Amsi[3], Manjira Emmanuel[3], Nathaniel Kalengo[3], Manuella Carugati[4], Venance P. Maro[5], John A. Crump[6], Lobulu Maugau[7], Chilonga Kondo[3], Matthew P. Rubach[8]

[1]Kilimanjaro Christian Medical Centrer and Kilimanjaro Clinical Research Institute, Moshi, United Republic of Tanzania, [2]Kilimanjaro Christian Medical Centre; Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania, [3]Kilimanjaro Christian Medical Centre, Moshi, United Republic of Tanzania, [4]Centre for for International Health, University of Otago, Dunedin, New Zealand, Moshi, United Republic of Tanzania, [5]Kilimanjaro Clinical Research Institute, Moshi, United Republic of Tanzania, [6]Duke Global Health Institute, Duke University, Durham, North Carolina, USA, Centre for for International Health, University of Otago, Dunedin, New Zealand, Division of Infectious Diseases, Duke University Medical Center, Durham, NC, United States, Otago, New Zealand, [7]Mawenzi Regional Hospital, Moshi, United Republic of Tanzania, [8]Duke Global Health Institute, Duke University, Division of Infectious Diseases, Duke University Medical Center, Durham, NC, United States

Gastro-intestinal (GI) perforations are highly morbid and potentially fatal events, especially in low income countries where rapid access to surgical interventions and access to adequate post-operative services remain limited. Establishing the etiologies of GI perforation events is fundamental to prioritizing disease prevention efforts. As part of a study to assess the incidence in our catchment of typhoid fever complicated by intestinal perforations, we have conducted two years of prospective sentinel surveillance at two referral hospitals in the Kilimanjaro Region, Tanzania. From March 2017-March 2018, we screened 2,339 surgical admissions, and captured 23 GI perforation events-- 10 gastric, 5 duodenal, 5 ileal, and 3 appendiceal. Of those with perforation, the median age was 47 (range 3-82) years, 20 (87%) were males, and 3 (13%) died in-hospital. Of 23 perforations with samples submitted for histopathology, all had intra-operative tissue or peritoneal fluid submitted for aerobic culture. The histopathologic diagnoses were peptic ulcer disease (n=10), typhoid perforation (n=4), ruptured appendix (n=3), and ulceration or fibrous reaction not otherwise specified (n=3). Microbiologically, 16 had polymicrobial infections, with a total of 40 isolates. *E. coli* (n=10 cases) and *Klebsiella* spp. (n=7 cases) were the most common isolates. *Salmonella enterica* were not recovered from any of the surgical samples. Further histologic confirmation, including immunohistochemistry for *H. pylori* and *S. enterica* serovar Typhi, is in progress. Based on these interim results, peptic ulcer disease and typhoid fever are the most common causes of GI perforation in Kilimanjaro, Tanzania. As both diseases are preventable and treatments are readily available to prevent progression to these severe complications, our interim results have direct implications for health policy and clinical practice in northern Tanzania.

518

UNPRECEDENTED HUMAN INFECTION WITH *RICKETTSIA PARKERI* STRAIN ATLANTIC RAINFOREST IN NORTHWESTERN COLOMBIA: CASE REPORT

Leidy Y. Acevedo-Gutiérrez[1], Margarita Arboleda[2], Dayro Ospina[3], Alejandra M. Avila[4], Francisco J. Díaz[5], Juan D. Rodas[1]

[1]Grupo Centauro. Universidad de Antioquia, Medellín (Antioquia), Colombia, [2]Instituto Colombiano de Medicina Tropical, Apartadó (Antioquia), Colombia, [3]Clínica Chinita, Apartadó (Antioquia), Colombia, [4]Universidad Pontificia Bolivariana, Medellín (Antioquia), Colombia, [5]Grupo de Inmunovirología. Universidad de Antioquia, Medellín (Antioquia), Colombia

Ticks are, along with mosquitos, one of the main vectors of infectious diseases worldwide. In Colombia, there are several reports of Rocky Mountain spotted fever (RMSF) caused by *Rickettsia rickettsii*, but other rickettsial diseases have also been suspected. The goal of this study was to describe the clinical, serological and molecular findings of a new human rickettsiosis in our country. The study patient was a 47-years-old male, previously healthy, and resident in a rural area of the municipality of Turbo (Antioquia), that worked as a farmer. He sought health care because a history of fever, chills, weakness, nausea and hiporexia, after a tick-bite on the abdomen at the level of left iliac spine. When the patient consulted, appear to be normal at the physical examination, without fever and showing just the scar at the inoculation site. The lesion was accompanied by adenomegaly and lymphangitis in the inguinal area. The physician suspected rickettsiosis and sent samples for hematological, biochemical, molecular and serological tests with acute and convalescent phase sera. At the same time, the physician started treatment with doxycycline 200 mg/day. The hemathological and biochemical test were normal, but the creatinine phosphokinase was slightly high. Through

Indirect Immunofluorescence (IFI) using six rickettsia species, we found antibodies against Spotted Fever Group (SFG) with titers between 256 and 1024 but without quadruple difference among the different antigens. PCR showed amplification of genes *sca4*, *gltA* and *ompB* for *Rickettsia* spp. that after being sequenced revealed close homology to *Rickettsia parkeri* strain Atlantic rainforest. These are the first evidences of a new tick-borne rickettsiosis, of minor virulence, in our country; that could explain some of the acute undifferentiated febrile diseases in some Colombian regions.

519

CHIKUNGUNYA VIRUS OUTBREAK AND MALARIA CO-INFECTION: IMPACT ON CLINICAL MANIFESTATIONS AND DISEASE SEVERITY IN THE SOUTHERN COAST OF KENYA

Carren M. Bosire[1], Francis Mutuku[1], Amy Krystosik[2]

[1]Technical University of Mombasa, Mombasa, Kenya, [2]Stanford University, Stanford, CA, United States

Chikungunya virus (CHIKV), an arbovirus endemic and underdiagnosed in East Africa, causes acute febrile illness and long-term sequelae. In late 2017, an outbreak of CHIKV was documented in Mombasa, Kenya, close to our coastal Kenya study sites. The objective of this study was to determine the impact and severity of this CHIKV outbreak (November 2017 to present date (March 2018)) on the Southern Kenyan Coast and document co-infection with malaria. Our ongoing study (NIH R01AI102918) recruits acutely febrile children aged 1 to 17 years in Ukunda (urban) and Msambweni (rural) health facilities. At the acute visit, physical examination, pediatric quality of life surveys (pedsQL), household demographic and behavioral questionnaires were administered and blood was drawn for CHIKV (RT-PCR) and malaria (microscopy or *Pf* rapid diagnostic test) testing. Of the 259 acute-febrile participants tested, 171 (74.7%) had CHIKV viremia, 87 (33.6%) had malaria parasitemia (98.5% *pf*) and 58 (22.4%) were co-infected with both CHIKV and malaria. Co-infections reported headache more frequently (50%). Those with CHIKV viremia showed more severe clinical manifestations (PedsQL score 77±0.9) compared to other cause febrile illness (PedsQL score 85±1.4). 20 (8.7%) reported local travel, with only 4 (1.7%) reporting travel to Mombasa (epicenter of the ongoing outbreak), suggesting local transmission on the South Coast. These results indicate that CHIKV transmission and co-circulation with plasmodium are on-going in coastal Kenya and that CHIKV is more clinically severe compared to other cause-febrile illness. There is need for robust vector control interventions and ongoing vector and human surveillance in the area to detect and respond rapidly to future outbreaks.

520

GROUP B STREPTOCOCCUS IN PREGNANCY AND NEONATAL COLONIZATION AT PRIMARY HEALTH CARE INSTITUTION NIGERIA

Joseph Omololu-Aso

Obafemi Awolowo University, Ile Ife, Nigeria

Studies in some sub-Saharan African countries like Zimbabwe, Malawi, Kenya, and the Gambia revealed that Group B Streptococcus (GBS) is emerging as the main cause of neonatal sepsis and meningitis. However, in Nigeria, information on GBS disease prevalence remains sparse. We sourced to isolate GBS from the rectovaginal and neonatal samples that were obtained from a tertiary hospital in a populated area of Osun state and give an updated information on the antibiotic susceptibility patterns, using demographic and clinical parameters. One hundred and seventy samples were collected from consenting mothers and neonate from June 2016 to January 2017. Ninety-Eight (98) GBS isolates were recovered from vaginal, rectal of the pregnant woman at the point of labour and Umbilical cord of the neonate within 24hrs of birth. cultures for the isolation and identification of Group B Streptococcus (GBS) were carried out using the CDC recommended microbiological methods. The presence of resistant genes was examined using PCR . The prevalence rate of GBS maternal and neonatal colonization were 29.4% and 20.6% respectively while 4% of the colonized neonates had nosocomial GBS colonization. There was no significant association between GBS colonization status and age (p >0.05)), parity (p >0.05), obstetric risk factors (p >0.05) and sex of neonate. There was no incidence of GBS infection observed. Resistance to augmentin (88.8%), ampicillin (60.2%), penicillin (47%), tetracycline (34.7%), ceftriaxone (19.4%), clindamycin (13.3%), vancomycin (10.2%) and erythromycin (7.1%) were observed. one of the 8 representatives of the multidrug resistant isolates harboured tetM gene while other resistant genes examined were negative in all MDR isolates. High prevalence of maternal and neonatal GBS colonization has been established among pregnant women and neonates in the study area. However further research is called for using larger sample size and multiple curve studies for adequate extrapolation into the general population.

NOTES ON THE WEST INDIES: GEORGE PINCKARD AND LATE 18TH CENTURY TROPICAL MEDICINE

Valerie Adams[1], David Adams[2], Femi Taiwo[3]

[1]Georgia Southern University, Statesboro, GA, United States, [2]Point University, Savannah, GA, United States, [3]Texas A & M University, College Station, TX, United States

The British and French fought bitterly for the West Indies in the late 18th century. By the mid-1790s, their forces jockeyed for control of cane-producing islands throughout the region. Both countries committed tens of thousands of troops to this effort, hoping to gain economic control over production and exports of cane-based products as well as strategic military outposts. Infectious disease, not least those that are mosquito-borne, ravaged officers and men alike. As such, military physicians and surgeons busied themselves with cases of yellow fever, malaria, and filariasis. Far more combatants succumbed to tropical diseases than to wounds. This case study will highlight the experiences of Dr. George Pinckard. A member of Sir Ralph Abercromby's "expedition" to the West Indies, he kept a detailed account of his experiences in the region, published in three volumes in 1806 as *Notes on the West Indies: Written During the Expedition Under the Command of the Late General Sir Ralph Abercromby*. Pinckard's *Notes* highlight important aspect of tropical medicine and diseases in the late 18th century.

522

NO EVIDENCE OF PARASITIC INFECTION IN A SURVEY OF SCHOOL CHILDREN FROM THE MISSISSIPPI DELTA

Richard Bradbury[1], Meredith Lane[1], Irene Arguello[2], Gretchen Cooley[1], Sukwan Handali[1], Silvia Dimitrova[1], Sam Jameson[2], Kathryn Hellmann[2], Michelle Tharp[3], Sheryl Hand[4], Paul Byers[4], Susan P. Montgomery[1], Lisa Haynie[3], Alfio Rausa[5], Brian Kirmse[2], Charlotte V. Hobbs[2]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Department of Pediatrics, University of Mississippi Medical Center, Jackson, MS, United States, [3]University of Mississippi Medical Center, Delta Mercy Project, Jackson, MS, United States, [4]Department of Health, Jackson, MS, United States, [5]Department of Health, Greenwood, MS, United States

Although recent data from high-risk areas in the American South have suggested a high prevalence of parasitic disease, such data on children living in Mississippi are lacking. We enrolled 166 children (median age 8, range 4-13) from a school-based health clinic in Sharkey County, within the Mississippi Delta. We collected data regarding whether subjects resided in homes with flushable toilets, owned pets (dog or cat), were exposed to soil, or had prior diagnosis or treatment of parasitic disease. Samples for stool microscopy and molecular testing were also collected. Microscopy included Kato-Katz and saturated salt flotation. In parallel, real time PCR with primers specific for *Necator americanus, Ancylostoma duodenale, Ascaris lumbricoides, Trichuris trichiura,* and *Strongyloides stercoralis* (as

described by N. Pilotte, S. Williams and others), was performed. Dried blood spots were obtained for detection of antibodies to *Toxocara* spp., *Strongyloides stercoralis, Fasciola hepatica*, *Cryptosporidium parvum* and *Giardia duodenalis*. Of 166 children surveyed, all reported living in households with flushable toilets, 34% reported having a pet dog or cat and 11% reported soil exposure (not wearing shoes when outside). None of the children had prior diagnosis or treatment of parasitic disease. Of 100 stool samples collected, a subset of 18 processed for microscopy were negative, and all were negative by real time PCR. Antibodies to *Toxocara* spp. were detected in 4/100 (4%), whereas antibodies to *S. stercoralis,* and *F. hepatica* were all negative. Serological evidence of exposure to *Cryptosporidium* and *Giardia* was uncommon (2% and 0%, respectively). Overall prevalence of parasitic infection was low in this population, but larger studies of at-risk populations, including adults, are indicated.

523

INFLUENZA-LIKE ILLNESS AND DIARRHEA RATES IN FOUR CAMBODIAN VILLAGES: FIVE-YEAR REVIEW

Dennis Faix[1], Malen Luy[1], Yi Chenda[1], Chum Bolin[1], Shannon D. Putnam[1], Heng Sopheab[2]

[1]Naval Medical Research Unit-2, Phnom Penh, Cambodia, [2]National Institute of Public Health, Phnom Penh, Cambodia

Cambodia is an agriculturally productive country in Southeast Asia with large poultry populations, mostly in backyard flocks, often with adjacent pig populations. Highly pathogenic avian influenza has been identified in Cambodia, most recently in January 2018. As of November 2017, a total of 56 human cases (including 37 deaths) and 49 poultry outbreaks of influenza A(H5N1) had been recorded in Cambodia. Establishing baseline rates of diarrheal and influenza-like illness (ILI) for vulnerable communities is key to general public health and pandemic preparedness. From February 2013 through December 2017 a total of 5,531 subjects in 4 villages were enrolled and followed weekly resulting in 835,178 person-weeks of observation with 3,681 diarrhea (≥3 loose stools in 24 hours) and 3,885 ILI (T>38°C and cough or sore throat) cases. Overall, the average monthly incidence of diarrhea was 4.65 cases/1,000 person-weeks (range 0-40, SD=2.68), and ILI was 4.27 cases/1,000 person-weeks (range 0-60, SD 4.47). Defining an outbreak as a monthly incidence rate greater than 2 standard deviations above the mean, villages experienced between 0-36 months of diarrhea outbreak cases and 0-14 months of respiratory outbreak cases. One village had consistently high rates of diarrheal disease, and one village had consistently low rates of both ILI and diarrheal disease. The incidence rate and outbreaks of ILI were larger, but seasonal, while diarrheal disease was endemic throughout the study period. Active surveillance, although resource intensive, is more sensitive, and gives accurate estimates for disease incidence rates, facilitating planning and prioritizing public health interventions and further research into appropriate countermeasures.

524

DESCRIBING THE ETIOLOGY AND EPIDEMIOLOGY OF ACUTE FEBRILE ILLNESSES IN TWO PROVINCES IN SOUTHERN CHINA

Shuyu Wu[1], Yuzhi Zhang[1], Changwen Ke[2], Zhonghua Yang[3], Xiaofang Guo[3], Lina Yi[4], Songwang Wang[5], Xiaopeng Qi[5], Nicolas D. Schaad[6], Jie Liu[7], Barry Fields[6], Jeanette J. Rainey[1]

[1]China Office, U.S. Centers for Disease Control and Prevention, Beijing, China, [2]Guangdong Provincial Center for Disease Control and Prevention, Guangdong, China, [3]Yunnan Institute of Parasitic Diseases, Yunnan, China, [4]Guangdong Provincial Institute of Public Health, Guangdong, China, [5]Chinese Center for Disease Control and Prevention, Beijing, China, [6]U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [7]University of Virginia, Charlottesville, VA, United States

Due to the lack of appropriate diagnostic testing, little information is available on the etiology of acute febrile illnesses (AFI) in Guangdong and Yunnan Provinces in Southern China. Both provinces experience recurring outbreaks of dengue due to the presence of *Aedes aegypti* and *albopictus* mosquitos, and are at-risk of Zika virus importations from international travelers. We implemented an AFI surveillance project in Guangdong and Yunnan to determine if Zika and other AFI etiologies are circulating or co-circulating in Southern China. At five sentinel hospitals, we enrolled patients between 2 to 65 years of age presenting with AFI (i.e., fever ≥37.5°C with onset within past 7 days and no clear source of infection). We collected clinical and epidemiologic data and blood specimens for testing using the Trioplex (Zika, dengue, chikungunya) PCR assay and TaqMan® Array Card (TAC, 31 viral, bacterial and parasitic pathogens) diagnostic platforms. Data were entered into a web-based data collection system. From June 2017 to March 2018, we enrolled 243 AFI patients (199 from Yunnan, 44 from Guangdong); 14 outpatients and 229 inpatients. The median age was 39 years (ranging 3-65 years). Among adult case-patients (≥18 years of age), 115 (47%) were farmers, 21 (9%) were officer workers, and 11 (4%) were home makers. Ten patients (4%) reported international travel (Laos [3], Venezuela [2], Thailand [1], Myanmar [1], Indonesia [1], Uganda [1] and United States [1]) prior to AFI onset. Of the 215 case-patients for whom TAC testing results are available, 153 (71%) were positive for dengue, 11 (5%) for *Orientia tsutsugamushi*, and 6 (3%) for *Coxiella burnetii*. Other etiologies included *Rickettsia*, *Plasmodium*, *Salmonella enterica* Typhi, and hepatitis E. One patient was co-infected with *C. burnetii* and hepatitis E and another with *C. burnetii* and *Rickettsia*. All patients tested negative for Zika. Further diagnostic testing and analysis is ongoing. This project addresses a knowledge gap about the cause of AFI in Southern China. We anticipate our findings can help improve AFI case management and assist with prioritization of public health interventions.

525

UTILITY OF POINT OF CARE ULTRASOUND BY INTERNAL MEDICINE TRAINEES IN A RESOURCE-LIMITED SETTING

Ayako Wendy Fujita, Michelle Fleshner, Divya Bhamidipati

University of Pittsburgh Medical Center, Pittsburgh, PA, United States

Point-of-care ultrasound (POCUS) is a quick, inexpensive, and noninvasive tool for bedside diagnosis. Few studies have looked at the utility of POCUS in resource-limited settings. This study aimed to investigate the ability of POCUS to assist with diagnosis and management when used by internal medicine trainees in Malawi. This was a descriptive analysis of POCUS studies conducted at Kamuzu Central Hospital in Lilongwe, Malawi through the University of Pittsburgh Medical Center (UPMC) Internal Medicine program. Residents in the Global Health and Underserved Populations track underwent a week-long ultrasound training course. A SonoSite Nanomaxx with a cardiac probe was used. Residents recorded each POCUS study and information including: type of study, indication for scan, findings, and whether POCUS changed diagnosis or management. Patient identifying information was removed. A total of 48 studies were performed by three residents over two weeks. Abdominal ultrasounds were performed most often (n=21), followed by echocardiograms (n=20). POCUS changed the diagnosis in 11 studies (23%) and the management in 12 studies (25%). Two studies led to new diagnoses of extrapulmonary tuberculosis. Six resulted in medication change, three prompted additional testing, and two revealed an indication for a procedure. Of note, three studies helped distinguish pericardial effusion from dilated cardiomyopathy, and in two studies, unnecessary thoracenteses were avoided. POCUS performed by internal medicine trainees changed diagnosis or management in a significant number of studies, suggesting its utility in resource-limited settings. Limitations of the study include small sample size, performer subjectability, possession of only a cardiac probe, and inability to generalize results to other resource-limited settings. Future studies will include more trainees at additional international sites and validation of trainee interpretations by consultants.

526

ENDING MASS TREATMENT FOR LYMPHATIC FILARIASIS IN 87 HEALTH DISTRICTS IN CAMEROON

Biholong Benjamin[1], Ebene Clarisse[1], Julie Akame[2], Patrick Mbia[2], Carine Fokam[2], Michel Hendji[2], Yaobi Zhang[3], Steven Reid[4], Georges Nko'Ayissi[5]

[1]Ministry of Public Health, Yaounde, Cameroon, [2]Helen Keller International, Yaounde, Cameroon, [3]Helen Keller International, Regional Office for Africa, Dakar, Senegal, [4]Helen Keller International, New York, NY, United States, [5]Ministry of Public Health, Unité de Coordination des MTN, Cameroon, Yaounde, Cameroon

According to WHO recommendations, countries may be able to stop mass drug administration (MDA) for lymphatic filariasis (LF) if health districts (HDs) complete ≥5 rounds of MDA with epidemiological coverage >65% and antigenemia prevalence <2%. In 2016, 87 HDs from 9 regions of Cameroon achieved this criteria and in 2017 all conducted a transmission assessment survey (TAS1). A cross-sectional cluster survey was conducted in all 87 HDs which were grouped into 30 evaluation units (EU) according to their epidemiological profile and geographical location. The Survey Sample Builder (SSB) provided the clusters as well as the population sizes required for the sampling. The sampled population consisted of children aged 6-7 years. The survey was conducted in the school settings in regions with school attendance rates >75% and in communities in other regions. The Filariasis Test Strip (FTS, Alere™) was used to diagnose circulating filarial antigen. Data management included electronic data capture through smartphones using ODK technology, storage on an ONA platform and processing through an electronic template with control measures. The teams performed calibrated blood smears (CBS) in *Loa loa* co-endemic areas, when the same child got tested positive with two consecutive FTS. A total of 47,977 children were tested. 16 children had an initial positive FTS. Among these, 9 children had a second positive FTS, but none of them showed the presence of *Loa loa* in the day-performed CBS. The prevalence of antigenemia calculated on the basis of the second FTS is 0.01% (95% CI: 0.01 - 0.04%). In conclusion, this TAS1 conducted in accordance with the WHO criteria showed that the transmission of the disease has been interrupted in the 87 HDs which were previously endemic with LF. Cameroon has achieved the criteria to end MDA in 125 of 137 HDs. The National Program should stop the MDAs in these HDs and start preparing the LF surveillance phase.

527

LYMPHANGIOGENIC POTENTIAL OF *WITHANIA SOMNIFERA,* A NOVEL THERAPEUTIC AGENT TARGETS HOST-PARASITE INTERACTION IN FILARIAL INDUCED SECONDARY LYMPHEDEMA

Anand Setty Balakrishnan

Madurai Kamaraj University, Madurai, India

Lymphatic filariasis is a major parasitic infection caused by nematodes *Brugia malayi* and *Wuchereria bancrofti*. In secondary lymphedema, the natural ability of lymphatic vessels to form new lymphatic channels is compromised. Research studies highlights the therapeutic effects of *Withania somnifera (WS)* extracts; however studies addressing the influence of *WS* extracts are necessary in understanding the inhibitory mode of lymphedemal pathogenesis from reversible to irreversible state. It was assumed that both parasitic products and the host inflammatory responses lead to lymphatic dysfunction and lymphangiogenesis. Hence, our present study aimed at evaluating the anti-bacterial and lymphangiogenic property of *Withania somnifera* (Ashwagandha), a highly revered ayurvedic plant in India. The anti-bacterial activity of the aqueous extract of *WS* was carried out by Disc diffusion and Agar well diffusion methods against lymphedema associated *Staphylococcus epidermidis* (MTCC435). We induced co-infection in the normal HaCaT dermal keratinocyte using *Staphylococcus epidermidis* (1×10^5 CFU) and filarial worm homogenate (50ng/ml) for 2hrs at 37°C in 5% CO_2 incubator. High Content Screening Images showed no changes in morphology. RT-PCR data reveals that expressions of Integrin $\alpha5$, Integrin $\alpha9$ and eNOS were attenuated during co-infection. *WS* (50µg/ml) recovers the expression of integrin $\alpha5$ ($p=0.043$) significantly. *In-vitro* lymphangiogenic activity of *WS* extract was evaluated by 2D matrigel using HDLECs in response to whole *Brugia* worm homogenates. These studies showed that adult worm homogenate attenuated the tubular network formation and branching points ($p=0.0001$). Interestingly *WS* extract restored the endothelial tube formation in a dose dependent manner. Taken together, *Withania somnifera* efficiently kills bacteria, augments lymphangiogenesis and may supports reduction of swelling in lymphedema subjects. Thus, *Withania somnifera* can be a novel therapeutic agent in the treatment of filarial induced secondary lymphedema.

528

EXPRESSION CLONING AND ANALYSIS OF A PUTATIVE *BRUGIA MALAYI* POU-HOMEODOMAIN TRANSCRIPTION FACTOR

Nicole Frumento, Steven A. Williams

Smith College, Northampton, MA, United States

Neglected tropical diseases (NTDs) are a series of diseases that afflict individuals living predominantly in developing countries. One of the most impactful NTDs is lymphatic filariasis (LF), a disease caused by the filarial parasitic nematodes *Brugia malayi*, *Brugia timori* and *Wuchereria bancrofti*. Current efforts to combat these diseases have been met with considerable success, but the concern of possible drug resistance underscores a need for the development of novel anthelmintic therapeutics that cause minimal harm to the human host. Expression of the parasite's genome undergoes dramatic changes when the parasite is transmitted from the mosquito vector into the human host. Despite the critical need to understand these gene expression changes, little is known about promoters and transcription factors in filarial parasites. The aim of this study is to identify the transcription factors in *B. malayi* that could serve as potential drug targets to help combat filariasis. Through a comparative analysis between whole genome datasets of *B. malayi* and *C. elegans,* we were able to identify the putative transcription factor Bma-UNC-86 as the best candidate for this initial project. In *C. elegans*, UNC-86 has the critical role of initiating and maintaining the expression of the LIM-homeobox gene *mec-3,* thus enabling mechanosensory function. Bioinformatics analyses revealed high homology between the binding sequences of UNC-86 in the promoter region of its target gene, *mec-3*, in both *C. elegans* and *B. malayi*, as well as in three closely related parasitic nematodes, *Brugia pahangi*, *Loa loa*, and *Onchocerca volvulus*. The putative transcription factor Bma-UNC-86 was then cloned and expressed in *E. coli. E. coli* was later induced to produce large quantities of the UNC-86 protein, which was purified and used to perform binding assays with the *mec-3* promoter isolated from *B. malayi*. Data comparing the UNC-86 binding sequences in the *mec-3* promoter of *C. elegans* and *B. malayi* will be presented along with the results of isolation and purification of the Bma-UNC-86 protein and its binding to the *B. malayi mec-3* promoter.

529

BRUGIA MALAYI C-JUN-N-TERMINAL KINASE (BMJNK) AND ITS ROLE IN PARASITIC ANTI-STRESS RESPONSES

Anna Morales, Agnieszka Chojnowski, Tamara Kreiss, Ulrich Gubler, John J. Siekierka

Montclair State University, Montclair, NJ, United States

Lymphatic filariasis, also known as elephantiasis, is a parasitic disease caused by thread-like nematodes and affects millions of individuals throughout the tropics. It is globally considered a neglected tropical disease associated with acute and chronic morbidity. Current treatment protocols for the disease are highly lacking. One of the key mechanisms by which parasitic nematodes have evolved to successfully establish infection

in their hosts is via evasion of reactive oxygen species (ROS) generated by the host's innate immune system. It has been previously demonstrated that inhibition of the filarial parasite B. malayi stress-activated protein kinase, BmPMK-1, with small molecule inhibitors renders the parasite unable to respond to oxidative stress, as reported previously. A second stress-activated enzyme, c-Jun-N-terminal kinase (JNK), forms a second component of the anti-ROS pathway. In addition, in C. elegans, JNK plays a role in coordinated locomotion, adult lifespan and response to heat and heavy metals. In this work, a recombinant JNK-1 ortholog (BmJNK) from the filarial parasite B. Malayi was expressed and activated in both mammalian and bacterial systems in effort to evaluate the role of this pathway in anti-ROS responses and its potential as a therapeutic target. Inhibition of BmJNK activity was demonstrated using a panel of known human JNK protein kinase inhibitors, along with their evaluation for their in-vitro potency against B. malayi. The results of this work establish BmJNK as a second key regulator of filarial parasite anti-oxidative stress responses and provide strong incentive for further interrogation of this protein as a promising therapeutic target.

530

LECTINS COMPLEXED WITH CIRCULATING FILARIAL ANTIGENS IN HUMAN SERA: A SOURCE OF POTENTIAL DIAGNOSTIC TOOLS

Marla I. Hertz[1], Amanda Dugan[2], Laura L. Kiessling[2], Philip J. Budge[1]

[1]Washington University in St. Louis, St. Louis, MO, United States, [2]Massachusetts Institute of Technology, Cambridge, MA, United States

Lymphatic filariasis surveillance programs rely on rapid diagnostic tests (RDTs) that detect a 250 kDa *Wuchereria bancrofti* circulating filarial antigen via a glycan epitope (the AD12 epitope). This glycan is also present on glycoproteins of other nematodes, and contributes to false positive *W. bancrofti* RDT results in some patients with loiasis. We sought to identify human binding partners for AD12-epitope-containing circulating filarial antigens of *W. bancrofti and L. loa* that might serve as tools to discriminate between AD12 epitope-containing filarial glycoproteins. Using a monoclonal antibody specific for the AD12 epitope, we immunoaffinity purified circulating filarial antigens from sera of *W. bancrofti*- and *L. loa*-infected persons and identified co-precipitating human proteins by mass spectrometry. Among proteins co-precipitating with filarial glycoproteins of both species were multiple human and filarial lectins. Further experiments to confirm an interaction between specific lectins and AD12 glycoproteins are ongoing. Further study of these co-precipitating factors may yield novel tools for diagnostics, as well as insight into the poorly-defined innate immunity against filarial infection.

531

DEVELOPMENT OF REPEAT-BASED PCR ASSAYS FOR HIGHER SENSITIVITY DETECTION OF *PLASMODIUM FALCIPARUM* AND *WUCHERERIA BANCROFTI*

Michael F. Zulch, Nils Pilotte, Jessica R. Grant, Steven A. Williams

Smith College, Northampton, MA, United States

Molecular xenomonitoring (MX) can be utilized as a high-throughput method to monitor mosquito-transmitted diseases such as lymphatic filariasis and malaria. By providing an indirect measure of human infection without relying on human sampling, MX can facilitate the early detection of disease emergence or re-emergence in endemic regions of the world. MX can also be used for intervention monitoring. MX relies on PCR to provide both ultra-sensitive and species-specific pathogen detection. Through successful intervention efforts, the incidences of both malaria and lymphatic filariasis are declining. However, to maintain this progress, it is critical that the assays we have are sensitive enough to detect a decreasing number of targets. When designed and optimized correctly, a PCR assay is capable of detecting very limited numbers of target molecules in a given sample. By designing PCR assays based on repetitive genomic elements, an assay's sensitivity is increased because these targets are more highly represented in eukaryotic genomes. Here we report two novel repeat-based PCR assays for the detection of the causative agent of lymphatic filariasis, *Wuchereria bancrofti*, and the causative agent of malaria, *Plasmodium falciparum*. These new PCR assays show improved performance over currently used detection methods when tested using both control DNA and DNA isolated from field-collected mosquitoes.

532

THE STAGE-SPECIFIC TRANSCRIPTOME OF *BRUGIA MALAYI*, *AEDES AEGYPTI*, AND ITS *WOLBACHIA* ENDOSYMBIONT *W*BM THROUGH 16 POINTS IN THE NEMATODE LIFECYCLE

Matthew Chung[1], Michelle L. Michalski[2], Laura Teigen[2], Silvia Libro[3], Nikhil Kumar[1], Robin E. Bromley[1], Lisa Sadzewicz[1], Luke J. Tallon[1], Jeremy M. Foster[3], Julie C. Dunning Hotopp[1]

[1]University of Maryland Baltimore, Baltimore, MD, United States, [2]University of Wisconsin Oshkosh, Oshkosh, WI, United States, [3]New England Biolabs, Ipswich, MA, United States

Brugia malayi is one of three filarial nematodes that cause human lymphatic filariasis. We used RNASeq, edgeR, and WGCNA to identify the transcriptomic alterations in *B. malayi,* its *Wolbachia* endosymbiont *w*Bm, and its invertebrate host, *Aedes aegypti,* across the *Brugia* life cycle. A principal component analysis of the 10,398 differentially expressed *Brugia* genes reveals that the samples group into four clusters: (1) the adult male samples, (2) the adult female, embryo, immature microfilariae, and mature microfilariae samples, (3) the 18 hpi and 4 dpi of the vector samples (L1 to L2) and (4) the samples ranging from 8 dpi in the vector to the 20 dpi male and 24 dpi female samples in the definitive host (vector L3 to mammalian L4). Using WGCNA, differentially expressed genes were grouped into modules based on similarities in expression profile. Kinases, phosphatases, PapD-like proteins with major sperm protein domains, calcineurin-like phosphodiesterase, and BTB/Kelch-associated domains were significantly overrepresented in the 1,481 genes upregulated in adult males. DNA binding proteins, transcriptional regulators, and ATP-binding proteins were significantly over-represented in the 1,615 genes that are upregulated in the adult female, embryo, immature microfilariae, and mature microfilariae life stages while G-protein coupled receptors were significantly under-represented. Ribosomal components and translational processes are significantly overrepresented in the 1,032 upregulated genes 18 hpi and 4 dpi of the vector. The differential gene expression profile shows that these genes are more highly upregulated in the L1 life stage, at 18 hpi, relative to the L2 life stage, at 4 dpi. This suggests that DNA replication was important in the prior life stages, generating proteins becomes the dominant process in L1s and L2s. These results as well as those from the rest of the life cycle, the invertebrate host, and the *Wolbachia* endosymbiont *w*Bm will be presented along with functional validation of differentially expressed genes from adult females.

533

ONCHOCERCIAISIS: DISCOVERY OF NOVEL THERAPEUTIC AGENTS FROM SELECTED MEDICINAL PLANTS TO SUPPORT CONTROL AND ELIMINATION EFFORTS

Elvis Monya

Biotechnology Unit, Buea, Cameroon

Onchocerciasis is the world's second leading infectious cause of blindness. Its control is currently hampered by the lack of a macrofilaricidal drug and by severe adverse events observed when the lone recommended microfilaricide, ivermectin is administered to individuals co-infected with *Loa loa.* Therefore, there is the need for a safe and effective macrofilaricidal drug that will be able to cure the infection and break transmission cycles, or at least, an alternative microfilaricide that does not kill *L. loa* microfilariae (mf). Seventeen organic crude extracts from three medicinal plants, *Tragia benthami*, *Piper umbellatum* and *Chromolaena odorata* were screened *in vitro* against the bovine model, *Onchocerca*

ochengi parasite *and L.loa* mf. Activity of extracts was assessed on adult male worms and mf by microscopic evaluation of motility reduction, while percentage inhibition of MTT conversion to formazan was used to assess activity on female worms. Cytotoxicity and acute toxicity of active extracts were tested on monkey kidney cells and Balb/c mice, respectively. Phytochemical screening of active extracts was also done using standard methods. At 500 µg/mL, all extracts showed 100 % activity on *Onchocerca ochengi* males and microfilariae, while 12 of them showed 100 % activity on female worms. The methylene chloride extract of *Piper umbellatum* leaves was the most active on adult males and mf (IC_{50}s: 16.63 µg/mL and 31.25 µg/mL, respectively). On female worms, the methylene chloride extract of *Chromolaena odarata* was the most active with an IC_{50} value of 16.23 µg/mL. Extracts active on *O. ochengi* worms were also highly active on *L. loa* microfilariae, with IC50s of 35.12 - 13.9 µg/mL. Active extracts were generally more toxic to the worms than to cells and showed no acute toxicity to Balb/c mice. Phytochemical screening revealed the presence of saponins, steroids, tannins, tritepenoids and flavanoids in the promising extracts. These results unfold potential sources of novel anti-Onchocerca lead compounds and validate the traditional use of these plants in onchocerciasis treatment.

534

A SINGLE-CENTER, FIRST-IN-HUMAN, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, PARALLEL-GROUP STUDY TO INVESTIGATE THE SAFETY, TOLERABILITY AND PHARMACOKINETICS OF ESCALATING SINGLE DOSES OF EMODEPSIDE (BAY44-4400) IN HEALTHY MALE SUBJECTS

Jean Yves A. Gillon[1], Frans van den Berg[2], Karen Dequatre Cheeseman[1], Nathalie Hopchet[2], Sophie Delhomme[1], Claudia Peña Rossi[1], Frederic Monnot[1], Nathalie Strub-Wourgaft[1], Maria-Luisa Rodriguez[3], Rob Don[1]

[1]DNDi, Geneva, Switzerland, [2]Hammersmith Medicines Research Ltd, London, United Kingdom, [3]Bayer AG, Wuppertal, Germany

Onchocerciasis (river blindness) is caused by the parasitic nematode *Onchocerca volvulus*. It is the world's second-leading infectious cause of blindness with visual impairment and blindness being the most severe complications of the disease. Programs for the treatment and control of onchocerciasis through mass drug administration (MDA) of ivermectin have been in place for over 20 years. Ivermectin targets the microfilarial stage of the parasite and temporarily sterilizes, but does not kill the adult worms. Therefore, programs require population at risk to be given ivermectin at regular intervals for many years, which is a large economic burden and its implementation being difficult in endemic countries. Thus, there is an urgent need for a macrofilaricide, targeting adult *Onchocerca* worms, as an alternative treatment for case management, to shorten MDA or tackle difficult to treat areas. Emodepside is a cyclooctadepsipeptide anthelmintic drug registered for animal health and marketed by Bayer AG in combination with praziquantel or toltrazuril. Emodepside targets different life stages of *O. volvulus*, including the adults and is being investigated for the oral treatment of onchocerciasis in human. A First-In-Human clinical study investigated the safety, tolerability and pharmacokinetics of single doses of emodepside in healthy male subjects. The trial was conducted in compliance with ICH guidelines and relevant EU Directives. Primary endpoints were safety and tolerability variables (adverse events; physical and neurological findings; vital signs; electrocardiograms; clinical laboratory variables and in the last cohort, also ophthalmology assessments) and pharmacokinetics variables. Emodepside (single dose, 1 to 40 mg) or placebo was administered to 8 subjects (randomized 6:2) in each cohort as an oral solution. Overall, emodepside was found to be safe up to 40 mg and well tolerated up to 20 mg, with rapid absorption, dose-proportional increase in exposure (AUC and Cmax) and a long terminal half-life of approximately 500 h.

535

EXPERIMENTS TO IDENTIFY THE INTENDED USE TO DETECT ACTIVE INFECTIONS FOR THE *ONCHOCERCA VOLVULUS* URINARY BIOMARKER *N*-ACETYLTYRAMINE-*O*,β-GLUCURONIDE (NATOG)

Vitaliano A. Cama[1], Ole Lagatie[2], Ediage E. Njumbe[3], Tom Lakwo[4], Sindew Mekasha[5], Naomi Awaca[6], Yassa Ndjakani[7], Renata Mendizabal[8], Nicholas Ayebazibwe[9], Paul T. Cantey[1], Guilherme Ogawa[1], Lieven J. Stuyver[2]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Janssen Diagnostics, Beerse, Belgium, [3]Janssen Diagnostics, Antwerp, Belgium, [4]Uganda Vector Control Division, Kampala, Uganda, [5]Ethiopian Public Health Institute, Addis Ababa, Ethiopia, [6]Ministry of Health, Kinshasa, Democratic Republic of the Congo, [7]CDC - DRC, Kinshasa, Democratic Republic of the Congo, [8]Universidad del Valle de Guatemala, Guatemala, Guatemala, [9]AFENET, Kampala, Uganda

Efforts to eliminate the filarial nematode *Onchocerca volvulus* are based on mass drug administration programs with the microfilaricide ivermectin. Monitoring the efficacy of these programs is largely dependent on existing diagnostic tools that either cannot identify active infections (Ov16 IgG4 serology) or perform poorly in low transmission settings (skin snip microscopy). There is a need for tests to identify infected patients in elimination of transmission settings. Urine *N*-acetyltyramine-*O*,β-glucuronide (NATOG) was recently identified as a specific biomarker for active onchocerciasis. We tested NATOG levels in urine from cases (mf+ and/or qPCR+) and controls (Ov16 ELISA negative, skin snip negative) to evaluate whether it would be an effective biomarker for active infections. The 51 cases consisted of 28 individuals from Kitgum/Lamwo Districts in Uganda, 4 from Jimma Zone in Ethiopia, and 19 from Orientale Province in the Democratic Republic of Congo. The 85 controls lived in areas post-endemic for onchocerciasis; 48 individuals were from Suchitepequez/Chimaltenango Provinces in Guatemala and 37 were from Hoima district in Uganda. Of the 51 cases, 17 (33%) had NATOG levels above the 13 µM threshold for a positive test. Geographical variability was observed as 75% of 4 cases from Ethiopia and 68.4% of 19 cases from DRC were positive, while in Uganda only 3.8% of 28 cases had positive results. The post-endemic population control samples were all negative for NATOG (specificity = 100%). Thus, while NATOG appears to be specific biomarker for onchocerciasis, it has limited sensitivity. Only 1/3 of cases had positive results, though these results appear to have been driven by NATOG levels detected in samples from Ugandan case patients. The explanation for this finding is unclear. Further work is needed to clarify the intended use of NATOG to detect active infections in multiple settings. A highly sensitive test that identifies active infection would assist programs measure progress towards the elimination of transmission.

UPDATE ON THE BIOLOGY AND ECOLOGY OF *CULICOIDES* SPECIES OF THE SOUTH WEST REGION OF CAMEROON WITH IMPLICATIONS ON THE TRANSMISSION OF *MANSONELLA PERSTANS*

Wanji Samuel[1], Anizette Chi Kien[1], Dizzle Bita Tayong[1], Rene Ebai[1], Vera Opoku[2], Winston Patrick Ndongmo[1], Abdel Jelil Njouendou[1], Raymond Nsaidzedze Ghani[1], Manuel Ritter[3], Yaw Alex Debrah[2], Laura E. Layland[4], Peter Ayuk Enyong[1], Achim Hoerauf[4]

[1]University of Buea, Buea, Cameroon, [2]Kumasi Centre for Collaborative Research (KCCR), Kumasi, Ghana, [3]Institute of Medical Microbiology, Immunology and Parasitology (IMMIP), University Hospital Bonn, Bonn, Germany, [4]Institute of Medical Microbiology, Immunology and Parasitology, University Hospital of Bonn, Bonn, Germany

Culicoides are tiny and stout blood sucking flies that have a worldwide distribution. Where present, they constitute a biting nuisance or are

involved in the transmission of pathogens to humans, domestic and wild animals. Data on the *Culicoides* species of the Southwest region of Cameroon date as far back as the 1950s. Since then there have been ecological transformation in the area due to agriculture and deforestation which may have affected the *Culicoides* fauna. Furthermore, the role of the different species of *Culicoides* of this region on the transmission of *Mansonella sp* is not fully elucidated. We therefore designed this study to fill these gaps in scientific knowledge. Eight species of *Culicoides* (*C. bedfordi, C. inornatipennis, C. fulvithorax, C. grahamii, C. imicola, C. milnei, C. neavei and C. kumbaensis)* were collected using light traps and human baits during this study. *C. grahamii* was the most abundant species, followed closely by *C. milnei*. Three species (*C. milnei, C. grahamii* and *C. inornatipennis)* were common to all breeding sites. Only four species (*C. inornatipennis, C. fulvithorax, C. grahamii,* and *C. milnei)* were collected on humans. Anthropophylic species were more abundant ($p < 0.001$) in the evening (4-7 pm) compared to the morning period (6-9 am). *Culicoides milnei* was the potential host for the development of *Mansonella perstans* microfilariae. The biting cycle of the main vector *C. milnei* shows 3 peaks (9-10pm, 1-2 am, 3-4 am), the highest being from 9-10pm. *Culicoides milnei* has been demonstrated to be the major vector of *M. perstans* in this part of Cameroon and its activity takes place essentially in the night with the most prominent peak between 9 and 10 pm. The findings from this study offer opportunities to carry out transmission surveys for Mansonellosis due to *M. perstans.*

537

EVALUATION OF URINARY N-ACETYLTYRAMINE-O,β-GLUCURONIDE (NATOG) AS BIOMARKER FOR *ONCHOCERCA* INFECTION AND/OR *ONCHOCERCA* ASSOCIATED EPILEPSY

An Hotterbeekx[1], Ole Lagatie[2], Lieven J. Stuyver[2], Michel Mandro[3], Germain Abhafule[3], Deogracias Rossy[3], Swabra Nakato[1], Joseph F. Siewe[1], Robert Colebunders[1]

[1]University of Antwerp, Wilrijk, Belgium, [2]Janssen R&D, Beerse, Belgium, [3]Provincial Health Division of Ituri, Bunia, Democratic Republic of the Congo

Infection with *Onchocerca volvulus* (OV) is associated with skin and eye disease and possibly also epilepsy (onchocerca associated epilepsy (OAE)), placing a large burden on affected people and their families. Currently there is no biomarker to diagnose OAE. We investigated the potential of the OV metabolite N-acetyltyramine-O,β-glucuronide (NATOG), which is excreted in the urine of infected individuals as a biomarker for active OV infection and/or OAE. OV infection was diagnosed by counting skin microfilariae (mf), nodule count and OV16 IgG4 rapid test (SD bioline). Urine was collected from uninfected individuals without epilepsy (controls, N=20), OV infected individuals without epilepsy (N=20) and infected individuals with mild (N=105) or severe epilepsy (>2 epileptic seizures/month, N=93) in the Democratic Republic of Congo. NATOG concentrations were determined by liquid chromatography tandem mass spectrometry. One-way ANOVA was performed (GraphPad Prism) with α=0.05. We observed a significant trend of increased NATOG levels with increased mf in the skin ($P<0.001$), and there was significantly more NATOG in the urine of individuals with severe epilepsy compared to mild epilepsy ($P=0.002$). No significant difference in urinary NATOG was observed between OV infected and non-infected individuals without epilepsy ($P=0.09$) and there was no increased level of NATOG with an increased number of OV nodules ($P=0.18$). However, there was significantly more urinary NATOG in the urine of OV infected individuals when comparing the entire population (with and without epilepsy ($P=0.015$)). Moreover, there was an increasing trend in NATOG levels from controls to OV infected people, people with mild epilepsy and people with severe epilepsy ($P=0.016$). In conclusion, urinary NATOG only is not an informative biomarker for OAE. Despite an association between urinary NATOG and mf count, there was no significant difference between infected and uninfected individuals without epilepsy. However, there was an increasing trend with more severe epilepsy and urinary NATOG was higher in infected individuals with epilepsy.

538

ELEVATED PLASMA INOSINE AND HYPOXANTHINE CONCENTRATIONS, AND URINE *CIS*CINNAMOYL GLYCINE CONCENTRATIONS AS BIOMARKERS FOR ACTIVE *ONCHOCERCA VOLVULUS* INFECTIONS

Ole Lagatie[1], Emmanuel Njumbe Ediage[2], Dirk Van Roosbroeck[2], Stijn Van Asten[3], Ann Verheyen[1], Linda Batsa Debrah[4], Alex Debrah[5], Ruben T'Kindt[6], Koen Sandra[6], Lieve Dillen[2], Tom Verhaeghe[2], Rob Vreeken[3], Filip Cuyckens[3], Lieven J. Stuyver[1]

[1]Janssen Diagnostics, Janssen R&D, Beerse, Belgium, [2]Bioanalysis, Janssen R&D, Beerse, Belgium, [3]Analytical Sciences, Janssen R&D, Beerse, Belgium, [4]Kumasi Centre for Collaborative Research into Tropical Medicine, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [5]Faculty of Allied Health Sciences, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [6]Research Institute for Chromatography, Kortrijk, Belgium

The neglected tropical disease onchocerciasis, or river blindness, is caused by infection with the filarial nematode *Onchocerca volvulus*. Current estimates indicate that 17 million people are infected worldwide, the majority of them living in Africa. Today there are no non-invasive tests available that can detect ongoing infection and that can be used for effective monitoring of elimination programs. In addition, to enable pharmacodynamic studies with novel macrofilaricide drug candidates, surrogate endpoints and efficacy biomarkers are needed but are non-existent. We describe the use of a multimodal untargeted mass spectrometry based approach to identify onchocerciasis associated metabolites in urine and plasma and of specific lipid features in plasma of infected individuals (*O. volvulus* infected cases: 68 individuals; lymphatic filariasis cases: 8 individuals; non-endemic controls: 20 individuals). This work resulted in the identification of the plasma metabolites inosine and hypoxanthine as biomarkers for filarial infection, and of the urine metabolite *cis*-cinnamoylglycine as specific biomarker for *O. volvulus*. During the validation study, metabolite-specific cutoffs were determined (inosine: 24.2 ng/ml; hypoxanthine: 1380 ng/ml; CCG: 29.7 ng/ml) and sensitivity (inosine: 74.5%; hypoxanthine: 86.2%; CCG 82.9%) and specificity (inosine: 95.7%; hypoxanthine: 89.2%; CCG 82.2%) profiles were established. With the availability of targeted LC-MS procedures, the full potential of these 3 biomarkers in macrofilaricide clinical trials, MDA efficacy surveys, and epidemiological transmission studies can be investigated. These large-scale validation approaches are necessary prior to the definition of an intended use for any of these markers.

539

A LONG-TERM *BRUGIA MALAYI* LYMPHATIC ENDOTHELIAL CO-CULTURE SYSTEM AND ITS VALIDATION AS AND ANTI-*WOLBACHIA* DRUG ASSESSMENT MODEL

Amy E. Marriott, John Archer, Andrew Steven, Mark J. Taylor, Joseph D. Turner

Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Filarial parasites are the causative agents of lymphatic filariasis (LF) and onchocerciasis. Current elimination programmes rely on up to 12 annual mass drug administrations with standard anti-filarial drugs, targeting only the microfilarial (mf) stage of infection. There is therefore a need to identify new short-course curative drugs (macrofilaricides) in order to accelerate elimination time frames. A promising drug target is the filarial endosymbiotic bacteria, *Wolbachia*, which can be depleted with antibiotics to initiate slow, safe killing of adult parasites. Reproductively active adult female parasites have a limited life-span in culture, therefore filarial drug screens heavily rely on *in vivo* models. Here, we have developed a long term *in vitro* co-culture system to maintain adult female stages of the human lymphatic filariae, *Brugia malayi,* using primary human lymphatic endothelial cells (LEC) To optimise the model, we examined motility and survival, uterine release, metabolic activity and *Wolbachia* titres of female

B. malayi following aseptic isolation from infected immunodeficient mice and cultured parasites over periods up to 28 days. Readouts were compared against freshly isolated *ex vivo B. malayi* or human embryonic kidney (HEK) cell monolayer co-cultures as non-specific feeder cells. Having verified LEC monolayers stably supported these parameters for 14 days+, we then assessed *Wolbachia* reductions and dynamics after treatment with physiologically relevant doxycycline exposures. Doxycycline induced significant reductions in *Wolbachia* after continuous treatment for 7 or 14 days, whilst drug removal after 7 days led to non-significant reduction after 7 days washout. This was in parallel with previous *in vivo* data. Thus, we have robustly validated an *in vitro* co-culture system which may be used to examine anti-*Wolbachia* agents for superiority compared with doxycycline.

IMPROVING COMMUNITY VOLUNTEER ENGAGEMENT AND IMPLEMENTATION OF MASS DRUG ADMINISTRATION FOR LYMPHATIC FILARIASIS THROUGH MICROPLANNING: A CASE STUDY OF PORT-AU-PRINCE, HAITI

Alain Javel[1], Carl Fayette[1], Franck Monestime[1], Ellen Knowles[2], Eurica Denis[1], Cudjoe Bennett[2], Jean-Frantz Lemoine[3], Tara A. Brant[4], Caitlin M. Worrell[4]

[1]IMA World Health, Port-au-Prince, Haiti, [2]IMA World Health, Washington, DC, United States, [3]National Program to Eliminate Lymphatic Filariasis, Ministry of Public Health and Population, Port-au-Prince, Haiti, [4]Centers for Disease Control and Prevention, Atlanta, GA, United States

Achieving and maintaining adequate mass drug administration (MDA) coverage for lymphatic filariasis (LF) in urban areas remains challenging. Declining MDA coverage in areas of metropolitan Port-au-Prince (PaP), Haiti is putting the country at risk of not meeting the global goal of eliminating of LF. The Ministry of Public Health and Population (MSPP) and partners proposed a two-phase microplanning protocol in five communes of PaP to improve MDA implementation. In phase one, the 2017 MDA distribution posts were geolocalized to identify access gaps, defined as a maximum walking distance of >500 meters to the nearest distribution post. Supervision area (SA) boundaries were delineated in consultation with community leaders (CLs). Access gaps were identified in 60% of SAs. In phase two, 10 two-day microplanning workshops were held with a total of 73 CLs, 240 community promoters (CPs), and 43 other key MDA stakeholders. The objectives were to review past performance and engage stakeholders in MDA improvement planning; identify and address gaps in SAs; review MDA distribution post analysis and modify strategies to improve access; and review roles and responsibilities of MDA personnel. Retrospective pre-testing was used to evaluate microplanning workshops. Participants used a five-point scale to rate their understanding of past performance, SA boundaries, roles and responsibilities, and their perceived engagement by MSPP. They simultaneously rated their previous year's attitudes and their attitudes following the two-day microplanning workshop. Scores were analyzed using paired t-tests. In comparison to rankings of the previous year, there was an increase in participant understanding of: past performance by 1.34 points (standard deviation [SD]=1.05, p<0.001); the borders of SAs by 1.14 points (SD=1.3; p<0.001); their roles and responsibilities by 0.71 points (SD=0.95, p-<0.001); and sense of engagement by 1.03 points (SD=1.08, p<0.001). Participatory stakeholder workshops during MDA planning increases engagement and may improve personnel performance and contribute to achievement of drug coverage targets.

541

COMPARISON OF LYMPHATIC FILARIASIS MASS DRUG ADMINISTRATION COVERAGE IN COASTAL REGION OF KENYA, 2016 - 2017

Sultani Matendechero, Mwatha Stephen, Ngugi Jeremiah, Wyckliff Omondi, Cecilia Wandera

Neglected tropical medicine, Nairobi, Kenya

Lymphatic Filariasis (LF) is one of the diseases targeted for elimination. It has affected over 120 million in the world and about 3.5 million people in Kenya. We aimed to compare the reporting rates and coverage of LF in 6 counties within the coastal region. This was a programmatic operation where mass drug administration (MDA) of albendazole (ALB) and diethylcarbamazine (DEC) was distributed in 6 counties in both 2016 and 2017 in the endemic coastal region of Kenya. A register of all residents living in the area was developed just before the MDA by community health volunteers (CHV). The registered data was used to estimate the number of tablets needed by each of them. The CHVs distributed the tablets in houses they had registered. The target population were aged two years and above but excluded pregnant women. However, coverage denominator was the total population in the target counties and sub counties. Data was collected and aggregated using registers and tally sheets then analyzed using Microsoft Excel and Epi-Info. A population of 2,209,277 was targeted in 2016 and 3,017,897 in 2017. County reporting rates were above 93% in both years. The targeted population improved across the 6 coastal counties with Kwale County having the greatest increase in target population from 202,358 in 2016 to 588,388 in 2017. County coverage in 2017 was between 71.1% in Kwale and 86.5% in Tana River county while in 2016 was 63.3% in Mombasa and 92.5%. Tana River, Mombasa and Kilifi counties had improved coverage from 65.7%, 63.3% and 77.6% to 86.5%, 73.6% and 83.3% respectively. The other 3 coastal counties had a slight decrease in coverage. Two counties in 2016 compared to 3 in 2017 achieved the 80% recommended coverage. There is an improvement on the numbers targeted and the coverage across the 6 coastal counties.

542

ACCEPTABILITY OF A TRIPLE DRUG REGIMEN FOR ELIMINATION OF LYMPHATIC FILARIASIS: RESULTS OF A MULTICENTER COMMUNITY BASED STUDY

Alison Krentel[1], Shruti Mallya[1], Nandha Basker[2], P. Jambulingam[2], Madsen Beau De Rochars[3], Abdel N. Direny[4], Jean Frantz Lemoine[5], Adriani Lomi Ga[6], Taniawati Supali[7], Joshua Bogus[8], Cade Howard[9], Zebedee Kerry[10], Leanne Robinson[10], Myra Hardy[11], Andrew C. Steer[11], Josaiah Samuela[12], Joseph K. Burns[1], Charles W. Goss[8], Ken B. Schechtman[8], Peter U. Fischer[8], Christopher L. King[9], Gary J. Weil[8]

[1]Bruyere Research Institute, Ottawa, ON, Canada, [2]Vector Control Research Centre, Pondicherry, India, [3]University of Florida, Gainesville, FL, United States, [4]RTI Envision, Washington, DC, United States, [5]Ministère de la Santé Publique et de la Population (MSPP), Port au Prince, Haiti, [6]Government of East Nusa Tenggara, Kupang, Indonesia, [7]Universitas Indonesia, Jakarta, Indonesia, [8]Washington University, St. Louis, MO, United States, [9]Case Western Reserve University, Cleveland, OH, United States, [10]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [11]University of Melbourne, Melbourne, Australia, [12]Ministry of Health and Medical Services Fiji, Suva, Fiji

A recent multicenter community-based safety trial compared a standard two-drug treatment (DEC, albendazole, DA) with a three-drug treatment (ivermectin, DEC, albendazole, IDA) for lymphatic filariasis (LF). Acceptability was measured using mixed methods. In each country, acceptability of the treatments was assessed with a survey of 400 randomly selected participants (age ≥14 yrs) within four months of treatment. The mean acceptability score (MAS, range 9 – 36) was

calculated based on 9 indicators. A score of ≥18 was considered acceptable. Focus group discussions were conducted in each country in communities where IDA was administered. 1621 participants were surveyed in 4 countries (n=759 DA arm; n=862 IDA arm). Mixed model analyses revealed no significant difference in acceptability by treatment arm, microfilaremia status, gender or age. MAS was above 18 for all 4 countries, yet scores differed among the countries (India= 26.8+/-2.1; Haiti= 29.1+/-3.7; Indonesia 30.6+/-2.8; PNG= 32.6+/-3.5) (p<0.001). Variables significantly associated with higher MAS included personal knowledge of people with LF, personal concern about getting LF, being happy about quantity of pills, and knowing participation in mass drug administration (MDA) is important for the community. MAS were significantly higher in participants who felt better after taking pills, had improved energy, and perceived reduced itching or skin sores. 12 focus group discussions were analyzed for emergent themes. These results identified the safety study team's prompt management of adverse events (AEs), trust in the drug administration process, and professionalism as key factors affecting acceptability. A history of many rounds of MDA prior to the safety trial may have contributed to lower MAS in India and Haiti. In conclusion, both LF treatments were equally acceptable with high scores in all 4 country studies. Key features of drug distribution during the safety trial were appreciated by communities. Knowledge of LF in the community, being informed about treatment and the importance of personal participation in MDA for community benefit emerged as important messages.

543

CONSENSUS DIAGNOSTIC CRITERIA FOR SCABIES ALLOW INTEGRATED MAPPING AND SURVEILLANCE OF NEGLECTED TROPICAL DISEASES

Daniel Engelman[1], Claire Fuller[2], Andrew C. Steer[3]

[1]Centre of International Child Health, Melbourne, Australia, [2]International Foundation for Dermatology, London, United Kingdom, [3]Murdoch Children's Research Institute, Melbourne, Australia

Scabies was added to the list of WHO neglected tropical diseases (NTDs) in 2017, and the WHO noted the need for further mapping of disease prevalence in many regions. Opportunities exist for integrated mapping of scabies with other NTDs such as filariasis, onchocerciasis, trachoma and STH, but have been limited by a lack of diagnostic standardisation. We aimed to develop consensus criteria for the diagnosis of scabies to facilitate this integration. We conducted an iterative, consensus (Delphi) study involving international experts in the diagnosis of scabies. Panel members were recruited through expression of interest and targeted invitation of known experts from a range of global settings. The Delphi study consisted of four rounds of anonymous surveys, moving from generation and ranking a long list of possible features (rounds 1 - 2), to development and refinement of a series of draft criteria (rounds 3 - 4). Panel participants (n=30) were predominantly highly experienced clinicians, representing a range of clinical settings and all continents. Based on initial rounds, a draft set of criteria were developed, incorporating three levels of diagnostic certainty - Confirmed Scabies, Clinical Scabies and Suspected Scabies. In the final round, there was a very high level of agreement (>90%) for all levels of criteria and subcategories. Adoption of the criteria was supported by 96.4% of panel members. Consensus criteria for the diagnosis of scabies have been established with very high agreement. The 2018 criteria for the diagnosis of scabies can be used as part of integrated NTD mapping to further define the burden of scabies, and for surveillance after control interventions. Formal validation is the next step.

544

DEVELOPING THE FIRST NATIONAL DATABASE AND MAP OF LYMPHATIC FILARIASIS CLINICAL CASES IN NEPAL

Pradip Rimal[1], Bhim Acharya[1], Bebik Kumar Lal[1], Tulasi Adhikari[1], Hannah Betts[2], Mark Taylor[2], Hayley Mableson[2], Louise A. Kelly-Hope[2]

[1]Department of Health Services, Kathmandu, Nepal, [2]Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Lymphatic filariasis (LF) is widely endemic in Nepal with an estimated 25 million people at risk of infection across 61 endemic districts. The National LF Programme is making good progress towards the elimination targets and in recent years has scaled up managing morbidity and preventing disability (MMDP) activities. This study highlights the LF Programme's approach in determining the number of people affected by lymphoedema and hydrocele, and developing the first national database and morbidity map. This information is essential for validation of LF elimination as a public health problem. The first data on morbidity was collected during national mass drug administration (MDA) campaigns in 2012 when community drug distributers (CDDs) identified and reported 28,855 LF clinical cases (6049 lymphoedema; 19247 hydrocoele cases) across 46 districts. Overall, the highest number of cases were reported in the lowland Terai region of the country and this information has helped to initiate more than 7000 hydrocoele surgeries across 40 district hospitals. To obtain more detail data and to better understand the spatial-epidemiological patterns, extensive patient searching is being conducted across all endemic districts over the next 12 months with specific georeferenced data on the patient's age, sex, condition severity (mild, moderate, severe) and number of acute dermato-lymphangioadenitis (ADLAs; acute attacks). The use of an innovative SMS mHealth tool is helping to created readily accessible databases, and district and regional disease burden and disability maps. Four districts have been mapped to-date with 7541 cases (2049 lymphoedema; 5551 hydrocoele) found, a further eight districts are currently in progress and a further 20 districts planned for November 2018. This information will allow the Nepal LF Programme to appropriately plan and deliver a basic package of care to those suffering from the disabling and debilitating clinical manifestations of LF across the country.

545

AN ASSESSMENT OF MOSQUITO COLLECTION TECHNIQUES FOR XENOMONITORING OF ANOPHELINE-TRANSMITTED LYMPHATIC FILARIASIS IN GHANA

Millicent Opoku[1], Corrado Minetti[2], Worlasi D. Kartey-Attipoe[1], Sampsom Otoo[1], Joseph Otchere[1], Bruno Gomes[2], Dziedzom K. de Souza[1], Lisa J. Reimer[2]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Anopheles mosquitoes are the main vectors of lymphatic filariasis (LF) in Ghana. Monitoring vectors is relevant to ascertain transmission of LF. This may require the best sampling method that can capture high numbers of specific species to give indication of transmission. Gravid anophelines are good indicators for assessing transmission due to close contact with humans through blood meals. It is not clear which sampling method will be appropriate for xenomonitoring of anopheline-transmitted Lymphatic Filariasis. This study compared the efficiency of an Anopheles gravid trap (AGT) with other available mosquito collection methods including the box and CDC gravid, light, exit and BG-sentinel traps, indoor resting collection and pyrethrum spray catches across two endemic regions of Ghana. The AGT showed high trapping efficiency by collecting the highest mean number of anophelines per night in the Western (4.6) and Northern (7.3) regions compared to other outdoor collection methods. Additionally, indoor resting collection was similarly efficient in the Northern region (8.9) where vectors exhibit a high degree of endophily. AGT also,

showed good trapping potential for collecting *An. melas*, which is usually difficult to catch with existing methods. Screening of mosquitoes for infection showed, 3.86%, *W. bancrofti* and 3.57%, *Plasmodium spp.*, in *Mansonia spp.*; 0.80%, *W. bancrofti* and 2.15% *Plasmodium spp.* in *An. gambiae* from the Western region; and a 3.01% *W. bancrofti* and 3.27% *Plasmodium spp.* from the Northern region. The AGT has shown to be appropriate for surveying *Anopheles* populations and can be useful for xenomonitoring both LF and malaria.

546

CHALLENGES SURROUNDING THE CONTROL OF SOIL-TRANSMITTED HELMINTH INFECTIONS AND SCHISTOSOMIASIS IN THE PHILIPPINES: PERSPECTIVES OF HEALTH OFFICIALS, HEALTH WORKERS AND COMMUNITY MEMBERS IN TWO RURAL PROVINCES

Anna D. Cohen, Eva Chernoff, Judy Chang

University of Pittsburgh School of Medicine, Pittsburgh, PA, United States

In the Philippines, the spread of Soil-Transmitted Helminth (STH) and Schistosomiasis (SCH) infections among school-aged children is controlled through school-based mass drug administration (MDA) of preventive chemotherapy in accordance with World Health Organization guidelines. The Philippine Department of Health (DOH) has also called for improved water, sanitation, and hygiene (WASH) provisions in schools to complement these disease control efforts. However, they have not successfully met their program targets for MDA or WASH in many rural provinces, including Llorente and Oras. Implementation of health policies is further complicated by the newly decentralized health structure in the Philippines, in which local government units (LGUs) enact national guidelines set forth by the DOH. Our objective was to understand the practices and beliefs regarding MDA and WASH in schools from the perspectives of community members, healthcare workers, and government officials within Llorente and Oras. We performed 12 qualitative, semi-structured key informant interviews with members of the DOH and LGUs, and 8 focus groups with community health workers, schoolteachers, and parents. Interviews were either transcribed verbatim in English or translated with the assistance of an interpreter, and were coded in an open, iterative fashion. Codes were then reviewed to identify patterns and themes. Our participants consistently identified the following community-wide challenges as barriers to successful program implementation: 1) lack of health education; 2) limited support from officials in the form of funds and infrastructure; 3) local distrust and misunderstanding of the programs; and 4) persistence of open defecation. Informants attributed the slow progress of STH and SCH control in school-aged children to poor coordination of public health efforts between DOH and community members; and unreliable support of health and hygiene initiatives from LGUs. This study emphasizes the need for leaders of decentralized health systems to evaluate how they partner and engage with both community members and LGUs in implementing MDA and WASH programs.

547

IMPACT OF PRE MDA TRAINING ON SCALING UP COVERAGE FOR MASS DRUG ADMINISTRATION- MDA FOR THE FIVE KEY NTDS IN TANZANIA

Isaac K. Njau[1], Andreas Nshalla[2], Abdallah Ngenya[3], Alistidia Simon[3], Upendo J. Mwingira[1]

[1]Tanzania Neglected Tropical Diseases Control Program, Dar Es Salaam, United Republic of Tanzania, [2]IMA World Health, Dar Es Salaam, United Republic of Tanzania, [3]National Institute for Medical Research, Dar Es Salaam, United Republic of Tanzania

NTDs are among the greatest burden to the health and socio-economic well-being of majority poor in Tanzania. Majority of Tanzanians are at risk for co-infection of two or more of the five NTDs. Mass Drug Administration (MDA) for transmission control is a key intervention toward control and elimination of NTDs. The pre-MDA-training using cascade approach is designed to ensure effective mass drug administration, explore areas for improvement and upkeep required coverage for MDA. MDA approach at NTD Control Program is managed through monitoring and Evaluation, Supply Chain Management and MDA's Implementation and Supervision unit. Two coordinators from education and health departments foster the MDA implementation at regional and district level. Front line health workers (FLHW), teachers and community drug distributors (CDDs) are responsible for execution of drugs at community and school level. Our objective was to evaluate the impact of streamlined Pre MDA-cascaded training on raising the effectiveness and required therapeutic coverage for MDA campaigns in Tanzania. To attain high quality training to implementer; training manual for FLHWs and CDDs was reviewed in 2017. The teaching aid for the Regional and District Trainer of Trainee was updated. Standardized test to be administered before and after training for knowledge testing was reviewed. Term of reference for National trainers was refined and bound strict to every trainer. Application of the tools was affirmed at every level of training. Simulation and practical exercises was integrated as key and important sessions during training and supervision during training was strengthened. After institutionalization of revised training approaches, MDA coverage raised from an average 87% in 2016 to 93% in 2017 for all Key NTDs. Increased understanding of the NTDs among implementer and reduced community resistance to the drugs was observes. Mainstreaming pre-MDA training in a way that assures high quality at all levels of implementation remains a promising approach towards effective and increased MDA coverage as we are matching towards total control and elimination goals for NTDs by 2020.

548

SUCCESSFUL INTEGRATION OF A TRANSMISSION ASSESSMENT SURVEY FOR ONCHOCERCIASIS AND LYMPHATIC FILARIASIS IN FOUR DISTRICTS IN NIGERIA

Chukwu Okoronkwo[1], Kira Barbre[2], Emmanuel Davies[1], Yisa Saka[1], Ifeoma Anagbogu[1]

[1]Federal Ministry of Health, Abuja, Nigeria, [2]Neglected Tropical Diseases Support Center, The Task Force for Global Health, Decatur, GA, United States

Mass administration of medicine (MAM) with ivermectin (Mectizan) is the recommended strategy for elimination of onchocerciasis (OV) and, combined with albendazole, for lymphatic filariasis (LF). As areas begin reaching sufficient numbers of effective rounds of MAM, decisions on when to stop need to be made. The30-cluster, random-sample transmission assessment survey (TAS) is routinely used by LF programs to guide MAMstopping decisions. In 2016, the World Health Organization (WHO) published criteria for MAMstopping decisions for OV. This can also be used to identify areas of persistent transmission for further intervention. The present study useda modified TAS (iTAS) to informboth LF and OV stopping decisionsin 4 formerly-endemic local government areas (LGA) in Nigeria that had completed 16-17 years of MAM for OV and 5-6 years of MAM for LF. In each LGA, 3,000 children ages 5-9 were targeted for sampling via cluster random sampling of 30 schools. All were tested for LF antigenemia with the filariasis test strip (FTS) and for antibodies against OV and LF via the Ov16/Wb123 Biplex rapid diagnostic test (RDT). Dried blood spots were also taken. All 4 LGAs had FTS prevalence below the critical threshold for passing LF TAS (*i.e.,* stopping MAM).One LGA, Bade, passed the threshold for stopping OV treatment with 0% positive Ov16 results. The other 3 LGAs, Karim Lamido, Gashaka, and Bekwarra, did not pass with 0.03%, 1.7% and 3.6% Ov16 positivity respectively. In Gashaka and Bekwarra, positive results clustered in a few schools. In Gashaka, Ov16 prevalence ranged from 0-23%, with 11 schools having 0 positives. In Bekwarra, Ov16 prevalence ranged from 0-13% with 5 schools having 0 positives. Investigation ofthese 'hotspots' of ongoing OV transmission identified after many years of MAM is needed. This new iTAS appears to be successful in facilitating stopping decisions for both programs and identifying areas in need of further intervention.

549

SHADOW PUPPETS AND NEGLECTED DISEASES: EVALUATING A HEALTH PROMOTION PERFORMANCE

Johanna Kurscheid

Australian National University, Acton, Australia

'*Rama and the Worm'* is a shadow puppet production targeting neglected diseases in Central Java. It is an entertainment-based intervention study to promote health by reducing the impact of parasitic diseases such as soil-transmitted helminths (STH). The study uses a traditional Javanese shadow puppetry (*wayang kulit)* as a vehicle in village communities to disseminate health education and promote behaviour change to prevent diseases caused, primarily, by inadequate sanitation and poor hygiene. The health education messages contained in the play, although using traditional characters and themes, required the creation of a completely new narrative script, using characters and plot lines familiar to the *wayang kulit* repertoire, but placing them in new situations that relate specifically to health promotion objectives. The musical accompaniment is a musical-cultural fusion involving both the traditional musical accompaniment of Javanese gamelan and Western instruments, especially rock band instrumentation. The intervention was piloted in a village in Central Java, Indonesia using a pre/post design with both qualitative and quantitative analysis. A total of 96 male and female villagers, aged between 7 and 87 years provided both baseline and follow up data. Participant knowledge and behaviours related to gastrointestinal and helminth-related disease were assessed before and after the intervention through a questionnaire administered by interview. Results revealed statistically significant improvements in both knowledge and behaviour related to gastrointestinal and helminth disease. Findings of the study indicate the *wayang kulit* performance is an effective health education tool. The results provide proof of concept with scaling up the next step forward. The *wayang kulit* production provides a significant additional component for an integrated, comprehensive approach to reduction and elimination of STH infection.

THE ROLE OF SOCIAL SIGNALING IN COMMUNITY DEWORMING: EVIDENCE FROM A FIELD EXPERIMENT IN KENYA

Anne Karing[1], **Karim Naguib**[2]

[1]University of California Berkeley, Berkeley, CA, United States, [2]Evidence Action, Washington, DC, United States

A randomized control trial (RCT) was conducted to assess which social incentive intervention (voting ink, calendars, or bracelets) is the most effective at increasing adult community deworming treatment adoption. A community deworming exercise to treat soil-transmitted helminths was implemented in partnership with the Kenyan Ministry of Health in 3 counties in Western Kenya where an existing school-based deworming program operates. The health ministry, through its Community Health Extension Workers, offered free deworming treatment to adults at fixed-point locations, such as churches, and explicitly emphasized the public good aspect of deworming. Two types of social incentives were distributed to dewormed adults in the form of colorful bracelets and ink. The bracelets and ink made the decision to deworm or abstain from treatment observable and allowed adults to signal to others that they contributed to protecting their community from worms. Further, a calendar was introduced as a separate private incentive that was comparable in its consumption value to the bracelet but could not easily be observed by others. Finally, individuals in each study arm were randomly selected to receive text messages as a reminder to get treatment (this intervention included a household visit to recruit subjects). Findings show that offering bracelets incentivizes deworming treatment take-up (8.4 pp), increasing coverage within communities. Offering bracelets was found to be a low-cost intervention and was a more cost-effective incentive to increase treatment adoption when compared to ink and calendars. Text messages led to large increases (12.8-15.3 pp) in deworming take-up across all arms, supporting existing evidence on the power of personal nudges. The combination of bracelets and text message reminders led to treatment take-up as high as 60.9% (a 24.2 pp increase) in the adult community. These findings may help inform other community-based mass treatment and neglected tropical disease (NTD) programs aiming to reach higher treatment coverage.

551

TESTING A COMMUNITY BASED VECTOR CONTROL APPROACH FOR HUMAN AFRICAN TRYPANOSOMIASIS IN DRC

Catiane Vander Kelen

Institute of Tropical Medicine Antwerp, Antwerp, Belgium

DRC is the most affected country by Human African Trypanosomiasis (HAT). HAT is a parasitic disease caused by the infection with trypanosome through the bites of tsetse flies. WHO's objective is to eliminate HAT by 2020. Mathematic models demonstrate that to reach this objective it is necessary to combine active and passive surveillance, diagnosis and treatment strategies with a vector control (VC) strategy. Tiny targets (pieces of clothes impregnated with insecticide) are a new, cheap and effective tool to control tsetse flies. Currently vector control using tiny targets in the DRC is an expert-directed activity. Communities are little or not involved. However, in the context of vector control, community based approaches are often recommended because the action is implemented near to the daily activities of the affected people. Nevertheless, community based HAT vector control interventions are rare. The aim of this research is to evaluate if a community-led VC activity is feasible and suitable in a HAT elimination context in DRC. A community-led intervention is being implemented since 2017 in three villages in the Kwilu province. This intervention is evaluated through the Action-Research methodology and data is collected with different qualitative and quantitative methods. This research reveals that communities involved are capable of leading an effective VC activity. Further the communities implicated in the community-led VC show a better understanding and acceptance of the presence of the tiny-targets than parallel communities where expert-led tsetse control activities took place. During the study costing data is also collected which allows to present information regarding the costs per km² covered by community-led VC. However, it remains to evaluate if this approach is feasible at a bigger scale, cost effective and appropriate to reach the elimination objective for 2020.

552

A COMMUNITY STUDY OF THE IMPACT OF SEMIANNUAL ALBENDAZOLE ON LYMPHATIC FILARIASIS AND SOIL-TRANSMITTED HELMINTH INFECTIONS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Sebastien Pion[1], Cedric B. Chesnais[1], Naomi Pitchouna Awaca-Uvon[2], Jean-Paul Tambwe[2], Gary J. Weil[3], Michel Boussinesq[1]

[1]Institut de recherche pour le Développement, Montpellier, France, [2]Programme National de Lutte contre l'Onchocercose, Ministère de la Santé, Kinshasa, Democratic Republic of the Congo, [3]Washington University School of Medicine, St. Louis, MO, United States

Implementation of mass drug administration (MDA) with ivermectin plus albendazole (Alb) for lymphatic filariasis (LF) has been delayed in Central Africa, because ivermectin can induce serious adverse events in people with very high *Loa loa* microfilaremia. In 2012, the WHO recommended use of Alb MDA together with vector control to combat LF in areas with co-endemic loiasis. This strategy has been supported by the results of a 3-year community trial conducted in the Republic of Congo, where baseline circulating filarial antigenaemia (CFA, assessed using the immunochromatographic card test - ICT) and microfilaremia (Mf) rates were 17.3% and 5.3%, respectively. In June 2014, we started a parallel trial in an area with higher baseline infection rates (31.6% for antigenemia

and 11.8% for microfilaremia) in the Democratic Republic of the Congo. Therapeutic coverage for the population > 2 years of age was ~ 70% at all treatment rounds. Evaluation at year 1, 2 and 3 showed that the circulating filarial antigen (assessed using Filarial Test Strip - FTS) rate in the community decreased from 31.6% in 2014 to 28.7% in 2015, 20.6% in 2016 and 15.2% in 2017. Among 438 individuals who were examined both in 2014 and 2017, 149 were positive at baseline; 69 of those 149 (46.3%) cleared their antigenemia in 2017. Mf prevalence in the community decreased to 8.1% in 2015, 3.7% in 2016 and 1.9% in 2017. Mf density (geometric mean of positive counts) decreased from 171 mf/mL in 2014 to 104.4 mf/mL in 2015, 68.1 mf/mL in 2016 and was 197.8 mf/mL in 2017. A total of 63/72 (87.5%) microfilaremic individuals at baseline have cleared their microfilaremia in 2017. Soil-transmitted helminth infections were monitored using Kato-Katz method. Between 2014 and 2017, prevalence of *Ascaris lumbricoides* infection in the community decreased from 14% to 3.6%, prevalence of hookworm infection from 58.6% to 40.9%, and prevalence of *Trichuris trichiura* from 8% to 4.8%. Year 4 and final results from this study will be presented at the meeting. They should provide additional evidence regarding the use of semiannual MDA with Alb for elimination of LF in central Africa.

553

TARGETING THREE NEGLECTED TROPICAL DISEASES WITH ONE TRIPLE THERAPY MASS DRUG ADMINISTRATION IN FIJI IS SAFE

Myra Hardy[1], Josaia Samuela[2], Mike Kama[2], Mecisuela Tuicakau[2], Lucia Romani[3], Margot Whitfeld[3], John Kaldor[3], Andrew Steer[1]

[1]Murdoch Children's Research Institute, Melbourne, Australia, [2]Fiji Ministry of Health, Suva, Fiji, [3]University of New South Wales, Sydney, Australia

The first case of lymphatic filariasis (LF) in Fiji was reported in 1876 and the first mass drug administration program was implemented in 1961. Local efforts were enhanced by joining the Pacific Elimination of LF program of the World Health Organization with regular annual MDA using diethylcarbamazine and albendazole (DA) from 2002. Despite acceptable coverage of MDA, the Eastern Division of Fiji has been unable to break transmission. The addition of ivermectin to DA (IDA) is hypothesised to be more effective tool in eliminating LF. Fiji was one of 5 sites involved in cohort event monitoring to determine safety of IDA. In 2017, the villages of Rotuma and Gau islands, were randomised to receive IDA or DA in a 2:1 ratio. Over 97% of participants were actively followed up for adverse events (AE) daily for 2 days following treatment and passively followed thereafter to complete 7 days of monitoring. Half of the IDA villages received an additional dose of ivermectin after completion of the safety monitoring period in order to evaluate the efficacy of 1 versus 2 doses of ivermectin on community prevalence of scabies and soil transmitted helminths at 12 months. MDA was given to 3431 of the 3812 enrolled participants, 2272 received IDA and 1159 received DA. Of those treated, 502 (14.6%) were LF antigen positive and 139 (4%) were microfilariae positive. AEs of any severity were experienced by 591 participants (17%), with no difference between treatment groups. AEs were more likely if participants were LF antigen positive (27% vs 16%) or mf positive (43% vs 16%). Women were less likely to be mf positive (2% vs 6% in men) but more likely to report an AE (19% vs 16% respectively). 93% of AEs were mild, not affecting normal daily activities of work or school. Of people experiencing an AE after treatment, the top 5 symptoms were fatigue (32%), headache (10%), nausea (9%), dizziness (7%) and muscle weakness (7%). There were 3 serious advents - 2 occurred in the DA group. None were directly attributable to the MDA. The safety of IDA is comparable to standard DA for LF in Fiji. Adopting this LF elimination strategy is likely to have additional benefits on other NTDs of high burden in Fiji.

554

STATISTICAL MODELLING OF THE RELATIONSHIP BETWEEN MICROFILARIAE AND ANTIGENAEMIA PREVALENCE OF LYMPHATIC FILARIASIS INFECTIONS

Claudio Fronterre[1], Rachel Pullan[1], Jorge Cano[1], Emanuele Giorgi[2]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Lancaster University, Lancaster, United Kingdom

Lymphatic filariasis (LF) is a mosquito-borne neglected tropical disease targeted for global elimination by 2020. The majority of global cases are caused by three species of nematode worms: *Wuchereria bancrofti*, *Brugia malayi* and *Brugia timori*. Historically, surveys for LF have relied upon direct measures of infection (observation of microfilaria in night blood). In recent years, the mapping of LF has been greatly facilitated by the use of simple and rapid detection tests for *W. bancrofti* (antigen-based test) and *Brugia* (antibody-based test), based on the immuno-chromatographic test (ICT card test), which avoids the need to collect blood at night and the time-consuming preparation and examination of blood slides. Whilst highly practical, these diagnostics are less useful for describing ongoing transmission intensity, particularly after treatment. For example, while it is known that estimates of antigenaemia are generally higher than estimates of microfilaraemia, the extent and spatial heterogeneity of this relationship is not clear and changes after the implementation of control activities. Using both geostatistical and machine learning approaches we explore the relationship between microfilaraemia and antigenaemia prevalence across sub-Saharan Africa, and we show how to combine the two approaches to improve risk map predictions. The output of this research can lead to better informed implementantion strategies for the elimination of lymphatic filariasis.

555

SUSTAINABILITY ASSESSMENT OF NEGLECTED TOPICAL DISEASE PROGRAM IN ETHIOPIA

Birhan Mengistu

Federal Ministry of Health, Addis Abeba, Ethiopia

Since the launch of the federal Neglected Tropical Disease (NTD) Master Plan in 2013, significant achievements have been made in putting in place structures at the Federal Ministry of Health (FMOH) to coordinate NTD programing. With these structures in place, NTD control and elimination interventions have resulted in intensified country-wide mapping and, consequently, enhanced evidence-based policies, guidelines and program implementation. While these efforts have contributed to improved health outcomes, one of the main challenges that limits NTD programing from being fully sustainable is limited government ownership of the NTD programs. In partnership with CIFF and the Ethiopian FMOH, Dalberg conducted a sustainability assessment of NTD programing in Ethiopia in October 2017. The objective of this assessment is to provide FMOH and key partners with an understanding of areas where the government needs support to reach sustainability as well as provide recommendations on potential ways to achieve. Ethiopia has shown progress towards sustainability for most approaches. Policy and leadership is sustainable in most aspects, but there have been no detailed conversations about transition at national or regional levels. Budget is largely sustainable, however domestic funding and government ownership of budgets is limited. The government has taken steps to own delivery systems, going forward it needs to strengthen cross-sectoral collaboration. Organizational capacity is sustainable in most aspects, but it lacks sufficient HR capacity to meet programmatic needs. Although there is government demand for data-driven planning, there are parallel reporting systems used and limited data analysis. In order to ensure sustainability is important to develop transition plans which should outline the exact roles and responsibilities played by partners and government stakeholders, and should detail how these responsibilities can slowly transition over time.

WHO 2016 COVERAGE SURVEY GUIDELINES: A FIRST IMPLEMENTATION AND RESULTS IN TWO HEALTH DISTRICTS IN THE NORTHWEST CAMEROON

Serge Akongo, Makoge N N, Joseph E Oye, Henri C Moungui, Antoine Socpa

SIGHTSAVERS, Yaounde, Cameroon

The North West region of Cameroon is endemic to the main PCT NTDS. On the way to achieve elimination goals of onchocerciasis, an MDA campaign was implemented in the region in 2017 targeting at least 80% of the population. The objective was to verify the accuracy of the reported coverage. The study also helped in assessing peoples' perception and compliance on CDI. An ancillary objective of this exercise was to test the feasibility of the WHO 2016 guidelines for MDA coverage surveys and was the first time to be implemented in Cameroon. The survey was cluster-based and took place in two health districts, purposely selected. Data collection was paper-based and quantitative and qualitative interview techniques. Individuals of 5 years old and above were targeted. A total number of 3,454 individuals were surveyed. 57.5% of survey participants were female. The median age of the survey participants was 23 years old. Overall, 86.6% (95%CI: 85.5 – 87.7%) of interviewees received mectizan during the campaign. There were 89.6% in Fundong and 83.6% in Bali. Overall compliance was found at 84.9% (95%CI: 83.6 – 86.0%). The administrative coverage previously reported in Bali was higher than survey coverage, leading to conclusion of an over reporting. In Fundong, these results showed in contrary an under reporting. Reasons for non-compliance were programmatic issues (absenteeism, unawareness) and individual factors (underage, pregnant/breasfeeding, sick). The WHO tool showed to be adapted for a field implementation as tool for onchocerciasis elimination monitoring but implementers will gain in doing daily sample size monitoring through electronic data collection or daily calls to surveyors. Recommendation for program improvement include further investigation of non-compliance with the network analysis method and field supervision. Pictures in the poster used should be enlarged and texts should be made in simple words.

557

COMPOSITION OF THE MICROBIOME OF CHAGAS DISEASE VECTORS AND ITS INTERACTION WITH THE PARASITE *TRYPANOSOMA CRUZI* FOR THE DEVELOPMENT OF INNOVATIVE VECTOR CONTROL STRATEGIES

Audrey Arnal[1], Eric Dumonteil[2], Etienne Waleckx[1]

[1]Centro de Investigaciones Regionales Dr Hideyo Noguchi, UADY, Merida, Mexico, [2]Department of Tropical Medicine, School of Public Health and Tropical Medicine, Tulane University, New Orleans, LA, United States

Chagas disease is caused by the parasite *Trypanosoma cruzi*, which is transmitted to humans and other mammals mainly through the contaminated feces of hematophagous triatomine bugs. This is an anthropozoonosis that constitutes a major public health problem from the southern United States (US) to Argentina. *T. cruzi* infects at least 6 million people in endemic areas and is responsible for 10,000 deaths a year according to the WHO. In the absence of vaccines and effective therapies against the infection, accurate knowledge of the vectors´ ecology constitutes an essential need for the implementation of sustainable control strategies. Among the important vector ecological characteristics, the knowledge of the composition of the intestinal miocrobiome is particularly relevant. Indeed, the bacteria present in the intestine of the insect can positively or negatively affect the infection by *T. cruzi*. Unfortunately, this key aspect involved in the transmission of *T. cruzi* has been very little studied in triatomines and with techniques lacking sensitivity. Here, we use a metabarcoding approach to identify the diversity of intestinal bacteria of *Triatoma dimidiata*, the main vector in Yucatan, México. We analyse the variations of this diversity according to the food sources (blood hosts) of the vector and evaluate the impact of the microbiome on vector infection by *T. cruzi* comparing the microbiome between infected and uninfected insects. Based on these acquired knowledge, we will be able to propose vector control strategies based on modification of the microbiome composition.

558

THE TRYPANOCIDAL EFFECT OF BENZNIDAZOLE IS INCREASED BY PROBENECID, A BLOCKER OF CHANNEL BASED IN PANNEXIN AND INNEXIN

Juan Güiza[1], Iván Barría[1], Luis Rodriguez[1], Mayerline Narvaez[1], Constanza Cortéz[1], Siomara Vargas[1], Fredi Cifuentes[1], Francisco Solis[1], Valeska Molina[1], Pedro Zamorano[1], Jorge González[1], Juan Carlos Sáez[2], José Luis Vega[1]

[1]Universidad de Antofagasta, Antofagasta, Chile, [2]Pontificia Universidad Católica de Chile, Santiago, Chile

Trypanosoma cruzi is the etiological agent of Chagas Disease, a public health problem in Latin America. Previous studies showed that probenecid (a blocker of channel based on pannexin and innexin proteins) enhances the effect an antimalarial drug, interestingly until now presence of gap junction proteins has not been reported in any unicellular organisms. This study shows that probenecid produces a chemosensitization of *T. cruzi* to benznidazole, enhangins its antitripanocidal effect. This finding also suggest the presence of functional gap junction membrane channel related to innexin. The chemosensitization of probenecid to benznidazole was evaluated by flow cytometry in epimastigote of *T. cruzi* Clone H510 C8C3*hvir*. The proliferation and transformation was evaluated by counting in a hemocytometer, in presence and absence of probenecid. The search of putative sequences of gap junction protein was performed using TritrypBD database, and the membrane topology was analyzed with PROTTER software. Innexon functional assay was performed by dye uptake in epimastigotes, FITC-Dextran (70,000 Da) was used as control for cell membrane damage. Probenecid (400 µM) produce chemosensitization of epimastigotes to benznidazlole (1000 µM) increasing the parasites mortality of 14.7 to 30.5 %, and also reduced the transformation from trypomastigote to amastigote at 4 h (~35%) but did not affect the proliferation. *T. cruzi* presents a putative protein of 257 aa, with 4 TMD, intracellular C and N-terminals, and the highly conserved innexin motif YYQWV. Epimastigotes showed an innexon-like activity promoted by extracellular Ca^{2+}/Mg^{2+} free solution, permeable to YOPRO-1≤DAPI ≤EtBr ≤EvBl. Dye uptake was blocked by probenecid (400 µM), flufenamic acid (50 µM) or heptanol (2 mM). In conclusion, ihe chemosensitization of *T. cruzi* produced by probenecid, suggest the presence of membrane channel that belongs to the gap junction family. This channel cloud be a new molecular target for the development of novel drugs against *T. cruzi.*

559

ENDOGENOUS GENE TAGGING OF *PFR2* AND *PFR5* IN *TRYPANOSOMA CRUZI* USING CRISPR/CAS9

Naomi Bryant, Gabrielle Stryker

Central Washington University, Ellensburg, WA, United States

The flagellum of *Trypanosoma cruzi* contains the paraflagellar rod (PFR) an extra-axonemal scaffolding. The PFR consists of a lattice of cytoskeletal filaments that lies alongside the (9 + 2) microtubular axoneme, beginning at the flagellar pocket and extending to the flagellar tip. The PFR has only been observed within the phylums Euglenozoa and Dinoflagellata, although many eukaryotic organisms with long flagella have extra-axonemal structures that accommodate enzymes and regulatory proteins along with serving as scaffolding. The exact function and basic molecular composition of the PFR has yet to be determined although the major structural components, PFR1 and PFR2 and several minor proteins have been identified. The PFR is not only a complex structure that has been shown to be critical for motility, it also constitutes a unique set of proteins that are known to be immunogenic and provide protective immunity in

the *T. cruzi* system. PFR5, a hypothetical minor component of the PFR, contains a PFR internal domain and an SH3 binding domain. Currently it is unknown if the protein product of the *pfr5* gene localizes to the flagellum. We use the Cas9/pTREX-n vector to endogenously tag *pfr5* to investigate the subcellular localization of the protein. PFR2 serves as proof of principle for this system as previous studies have shown that this protein is a major component of the PFR. This gene tagging protocol uses a hemagglutinin (HA) tag system which incorporates a 3xHA tag onto the C-terminal end of the protein. Localization of the 3xHA tagged proteins are determined via immunofluorescence. Study of the organization of the PFR with its restricted evolutionary presence will help improve understanding of this unique structure.

560

DEEP SEQUENCING REVEALS MULTICLONALITY AND NEW DISCRETE TYPING UNITS OF *TRYPANOSOMA CRUZI* IN RODENTS FROM SOUTHERN USA

Henry Pronovost[1], Anna Peterson[2], Bruno Ghersi[2], Michael Blum[2], Eric Dumonteil[1], Claudia Herrera[1]

[1]Tulane University, New Orleans, LA, United States, [2]University of Tennessee, Knoxville, TN, United States

The parasite *Trypanosoma cruzi* is the causative agent of Chagas disease, a prominent anthropozoonosis in Central and South America that is an emerging concern in the southern United States (US). *T. cruzi* encompasses a diversity of genetic strains that have been grouped into seven discrete typing units (DTUs: TcI to TcVI and Tcbat). Epidemiological assessments of Chagas disease hinge on understanding the diversity and distributions of DTUs, many of which appear to be associated with distinct transmission cycles, geographical distributions, tissue tropism and clinical manifestations. Increasing evidence of multiclonal infection suggests, however, that transmission dynamics are more complex than currently acknowledged. In this study we explored the nature of *T. cruzi* infection in small rodents from New Orleans (LA, USA), an enzootic region of North America. We characterized the full complement of DTUs in rodent hosts through Next Generation metabarcoding, as conventional PCR and Sanger sequencing approaches only detect the dominant genotype in biological samples. We assayed DTU diversity in 5 rodents (3 sylvatic, 2 urban) selected from a cohort of 72 *T. cruzi* positive individuals, confirmed through a conventional PCR assay. The intergenic region of the mini exon gene was then amplified to distinguish TcI from other non TcI DTUs. Phylogenetic trees were inferred by Maximum Likelihood method to identify DTUs in the samples. We detected distinct and varying assemblages of DTUs in the rodent hosts. TcI was the dominant DTU in two sylvatic rodents that also carried TcII, TcV, and TcVI. The third sylvatic rodent was predominantly infected with TcII, TcV, and TcVI. The urban rodents also carried diverse DTU assemblages, but had proportionally more TcII and TcVI than their sylvatic counterparts. These results affirm that mammalian hosts can concurrently harbor a diverse complement of parasites, and indicate that there is greater diversity of DTUs present in North America than previously thought. Further investigation is warranted to understand the role of commensal rodents as a reservoir for *T. cruzi* in sylvatic and peridomestic environments.

561

EVIDENCE FOR ASSOCIATION OF THE INTEGRATED ENDOPLASMIC RETICULUM STRESS RESPONSE WITH *LEISHMANIA DONOVANI* -INDUCED CUTANEOUS LEISHMANIASIS IN SRI LANKA

Nuwani H. Manamperi[1], Steve Oghumu[2], Lakmali Pathiraja[3], Buthsiri Sumanasena[4], Wimaladharma Abeyewickreme[5], Abhay R. Satoskar[2], Nadira D. Karunaweera[6]

[1]University of Kelaniya, Ragama, Sri Lanka, [2]Ohio State University, Columbus, OH, United States, [3]Base Hospital, Padaviya, Sri Lanka, [4]Teaching Hospital, Anuradhapura, Sri Lanka, [5]General Sir John Kotelawala Defence University, Ratmalana, Sri Lanka, [6]University of Colombo, Colombo-08, Sri Lanka

The integrated endoplasmic reticulum stress response (IERSR) is a pathway that operates to regulate endoplasmic reticulum (ER) homeostasis in various conditions that increase the cellular stress, including infections. Three trans-membrane proteins, namely, IRE-1 that activates XBP-1, the pancreatic ER kinase (PERK) that phosphorylates the eukaryotic translation initiation factor 2 and transcription factor 6 (ATF6) are known to regulate the IERSR pathway. Emerging evidence suggest an important role for IERSR in the pathogenesis of *L. amazonensis* and *L. braziliensis* induced cutaneous leishmaniasis (CL). This study describes the association of IERSR with *L. donovani*-induced CL in Sri Lanka. Skin biopsies from 8 CL lesions and 8 healthy controls were included in the study and proteins were extracted and digested by trypsin. Two –dimensional liquid chromatography separation and subsequent tandem mass spectrometry was performed using a Thermo Orbitrap Fusion HPLC MS/MS system. Proteins were identified by searching against human data bases and the significance threshold for peptide identification was set at $p<0.05$. Patient and control groups were compared by ANOVA method. The p value obtained was adjusted for multiple correction using Benjamini-Hochberg procedure. All the proteins with an adjusted p value <0.01 were considered as significantly expressed between the groups compared. Significantly expressed proteins thus identified were entered into UniProt human database and converted to their corresponding gene names. Pathway analysis was done using the Reactome pathway portal, version 3.2. Out of the three pathways regulating IERSR, two namely ATF6 ($p<0.001$) and IRE-1 ($p<0.05$) were seen to be among the significant pathways. Induction of the IRE1/XBP1 arm of IERSR leads to less oxidative stress and is a mechanism by which these parasites survive within macrophages. Association of IERSR with *L.donovani*-induced CL is evident, which needs to be further validated.

562

STUDY OF A NEWLY DISCOVERED ONCOGENIC DOMAIN OF YINP FROM *LEISHMANIA* SP.

José Peña-Guerrero[1], Miriam Algarabel-Olona[1], Celia Fernández-Rubio1[1], Guillermo García-Porrero[1], Andrés Vacas-Oleas[1], Esther Larrea[2], Irina Tikhonova[3], Paul Nguewa[1]

[1]Institute of Tropical Health University of Navarra (ISTUN), Department of Microbiology and Parasitology, IdiSNA, navarra Institute for Health Research, Pamplona, Spain, [2]Institute of Tropical Health, University of Navarra (ISTUN), IdiSNA, Navarra Institute of Health Research, Pamplona, Spain, [3]School of Pharmacy, Queens University, Northern Ireland, Belfast, Ireland

Recently, our group has identified in *Leishmania major* promastigotes a gene, called *LmjYinP* We found that the highest expression of *LmjYinP* occurs during the infective stage of the parasites (metacyclics). Focusing on the relation between *LmjYinP* gene expression and *Leishmania* pathogenesis, we studied the infectivity of *LmjYinP* overexpressing parasites. Our results showed that *LmjYinP* over-expression enhanced parasites infectivity *in vitro*, and, increased metacyclogenesis process. To evaluate LmjYinP suitability as a drug-target, we analyzed *in silico* drugs that may bind to the protein. We built up a model of LmjYinP protein. Our docking results provided us information about the druggability of this protein, supporting that LmjYinP could be consider as a robust therapeutic target. In fact, our data showed that LmjYinP strongly interacts with drugs such as Paromomycin and Amphotericin B, used in clinic. Moreover, the physicochemical properties of the predicted binding sites allow us to propose new drugs potentially suitable against leishmaniasis. We also described that Lmj*YinP* is a highly conserved gene containing two main domains: YinP (N-terminus) and a newly discovered putative oncogenic domain named ONC. Therefore, we aimed to elucidate the function of ONC domain in *Leishmania* proteome as well as in the human host. This domain was overexpressed and downregulated in *L. major*. On the other hand, ONC from LmjYinP was also expressed in different mammalian cells to analyse the impact of the expression of this parasite domain in other

eukaryotic organisms. Additional experiments were also performed to better characterize the aforementioned domain (ONC) as well as Lmj*YinP,* a novel molecule involved in pathogenesis and drug resistance. All our data reinforce the hypothesis that LmjYinP and ONC domain may be robust druggable targets against leishmaniasis.

563

COMPARISON OF WHOLE-GENOME SEQUENCING, SANGER SEQUENCING, AND RESTRICTION FRAGMENT LENGTH POLYMORPHISM ANALYSIS FOR *LEISHMANIA VIANNIA* MIXED AND HYBRID INFECTION SPECIES IDENTIFICATION

Avinash N. Mukkala[1], Rachel Lau[2], Braulio M. Valencia[3], Alejandro Llanos-Cuentas[3], Andrea K. Boggild[1]

[1]University of Toronto, Toronto, ON, Canada, [2]Public Health Ontario, Toronto, ON, Canada, [3]Instituto de Medicina Tropical "Alexander von Humboldt", Lima, Peru

The prognosis and treatment of leishmaniasis is largely dependent on the infecting species. Varying degrees of disease severity are present, in addition to mixed and hybrid infections, which pose diagnostic challenges. The causative species identification of these types of infections relies on standard techniques such as restriction fragment length polymorphism (RFLP) analysis, and Sanger sequencing (SS). Whole-genome sequencing (WGS) is a robust and increasingly cost-efficient alternative that can improve *Leishmania* species identification. Here, we validated and compared WGS as a potential alternative to RFLP-SS standards in a cohort of 3 ATCC strains (*L. V. braziliensis*, *L. V. guyanensis* and *L. V. panamensis*) and 5 clinical *Leishmania Viannia* isolates of potential hybrids or mixed infections. DNA extraction, followed by *internal transcribed spacer1* (*ITS1)* and heat shock protein 70 (*HSP70*) PCR-RFLP was carried out and SS was performed for the *ITS2*, cysteine proteinase b, and *HSP*70 loci. After *de novo* assembly, sequences were mapped, and homology compared to both ATCC strains and reference genomes at NCBI. All samples went through a diagnostic pipeline to identify species present by all three techniques. Concordant validation was assessed within each isolate, over a 6-week period, to determine if final identification was consistent with the initial. All ATCC isolates were confirmed to be single-species of either *L. V. braziliensis*, *L. V. guyanensis*, or *L. V. panamensis* by WGS; whereas RFLP-SS was unable to definitively speciate two of three isolates. Clinical isolates were identified as a combination of single-species, mixed, and hybrid infections of a variety of *Viannia* species by WGS; while RFLP-SS was largely unable to definitively speciate four of five isolates. We have utilized WGS to differentiate mixed and hybrid infections by species. Ambiguous infection samples, previously speciated by RFLP-SS, were more reliably discerned into single-species, mixed, and hybrid categories by WGS. WGS is a potentially useful alternative to RFLP-SS for the diagnosis and species identification of complex tegumentary *Leishmania* infections.

564

THE GP63 GENE CLUSTER IS HIGHLY POLYMORPHIC IN NATURAL *LEISHMANIA (VIANNIA) BRAZILIENSIS* POPULATIONS, BUT FUNCTIONAL SITES ARE CONSERVED

Lilian S. Medina[1], Rafaela Ribeiro[1], Bruno A. Souza[1], Adriano Queiroz[2], Luiz Henrique Guimarães[3], Paulo Roberto L. Machado[1], Edgar M. Carvalho[1], Mary E. Wilson[4], **Albert Schriefer**[5]

[1]Hospital Universitário Prof. Edgard Santos, Salvador, Brazil, [2]Centro de Pesquisas Gonçalo Moniz, Salvador, Brazil, [3]Centro de Formação em Saúde, Salvador, Brazil, [4]Departments of Internal Medicine and Microbiology, University of Iowa and the Veterans Affairs Medical Center, Iowa City, IA, United States, [5]Hospital Universitário Prof. Edgard Santos, and Departamento de Ciências da Biointeração, Instituto de Ciências da Saúde, Universidade Federal da Bahia, Salvador, Brazil

GP63 or leishmanolysin is the major surface protease of *Leishmania* spp. involved in parasite virulence and host cell interaction. As such, GP63 is a potential target of eventual vaccines against these protozoa. In the current study we evaluate the polymorphism of gp63 in *Leishmania (Viannia) braziliensis* isolated from 41 American tegumentary leishmaniasis (ATL) cases from Corte de Pedra, Brazil. Parasites were obtained from lesions by needle aspiration and cultivation. Genomic DNA was extracted, and 405 bp fragments, including sequences encoding the putative macrophage interacting sites, were amplified from gp63 genes of all isolates. DNA amplicons were cloned into plasmid vectors and ten clones per *L. braziliensis* isolate were sequenced. Alignment of cloned sequences showed extensive polymorphism among gp63 genes within, and between parasite isolates. Overall, 45 different polymorphic alleles were detected. The predicted peptides showed overall conservation below 50%. In marked contrast, the conservation at segments with putative functional domains approached 90% (Fisher's exact test $p<0.0001$). Synthetic peptides based on these short, conserved sequences were capable of significantly inhibiting *in vitro* infection of monocyte derived macrophages by *L. braziliensis* in a dose dependent manner. These findings show that gp63 is very polymorphic even among parasites from a same endemic focus, but the functional domains interacting with the mammalian host environment are conserved.

565

EVALUATION OF REAL TIME PCR FOR DIAGNOSIS OF POST-KALA-AZAR DERMAL LEISHMANIASIS (PKDL) IN AN ENDEMIC *FOCI* OF BANGLADESH

Prakash Ghosh[1], Md Golam Hasnain[2], Faria Hossain[1], Md Anik Ashfaq Khan[1], Rajashree Chowdhury[1], Khaledul Faisal[1], Moshtaq Ahmed Mural[1], James Baker[1], Rupen Nath[1], Debasish Ghosh[1], Shomik Maruf[1], Rashidul Haque[1], Greg Matlashewski[3], Shinjiro Hamano[4], Malcolm Duthie[5], Dinesh Mondal[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]The University of Newcastle, New South Wales, Australia, [3]McGill University, Montreal, QC, Canada, [4]Nagasaki University, Nagasaki, Japan, [5]IDRI, Seattle, WA, United States

Post-kala-azar dermal leishmaniasis (PKDL) is a sequel of kala-azar or visceral leishmaniasis (VL) that is found in visceral leishmaniasis (VL) endemic countries including Bangladesh. Because of these enigmatic cases, the success of National Kala-azar elimination program (NKEP) is under threat. Unlike other endemic regions, the macular form of PKDL is the most common form in Bangladesh and diagnosis of these cases is more difficult than other forms. Until now, the diagnostic method for PKDL cases in endemic regions is limited to clinical examination and serology using the rK39 rapid test or microscopy. A suitable and accurate alternative method is necessary. In this study, we investigated the application of real time PCR as a potential method for diagnosis of PKDL in comparison with microscopy. For this study, 91 suspected macular PKDL cases from the Mymensingh district, Bangladesh were enrolled following diagnosis through clinical examination and the rk39 RDT. All cases were treated for PKDL and responded well after completion of the treatment. During enrollment, skin biopsy was collected from each patient and both microscopy and real time PCR were performed for detection and quantification of *leishmania donovani* body (LDB) and LD DNA respectively. Real time PCR detected 83 cases among all suspected PKDL patients with an encouraging sensitivity of 91.21% (83.41-96.13) whereas microscopy showed 50.55% (39.86-61.20) sensitivity only. These findings suggest that real time PCR is a promising tool for diagnosis of PKDL in endemic regions. In addition to diagnosis, the quantitative ability of this method could be exploited for after-treatment prognosis and cure assessment of PKDL cases.

566

NOVEL TETRACYCLIC IRIDOID COMPOUNDS ISOLATED FROM *MORINDA LUCIDA* BENTH INDUCES CELL CYCLE ARREST, PHENOTYPIC CHANGES AND APOPTOSIS IN *LEISHMANIA DONOVANI*

Faustus A. Azerigyik[1], Michael Amoa-Bosompem[1], Kofi B-A Owusu[1], Thelma Tettey[1], Georgina I. Djameh[1], Senyo K. Botchie[1], Ama N. Antwi[1], Frederick Ayertey[2], Kofi D. Kwofie[1], Irene Ayi[1], Alfred Appiah[2], Theresa M. Gwira[3], Nguyen H. Tung[4], Shiro Iwanaga[5], Yukihiro Shoyama[4], Nobuo Ohta[5], Mitsuko Ohashi[5]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]Centre for Plant Medicine Research, Accra, Ghana, [3]West African Centre for Cell Biology and Infectious Pathogens, University of Ghana, Accra, Ghana, [4]Nagasaki International University, Nagasaki, Japan, [5]Tokyo Medical and Dental University, Tokyo, Japan

Leishmaniasis threatens 350 million people with approximately 12 million people suffering from the disease worldwide. Antimonials remain the first line of treatment for many years. Despite increased progress in drug development, current drugs are challenged by high toxicity, and resistance issues, which necessitates continuous efforts to identify alternative chemotherapy. We previously identified novel tetracyclic iridoid compounds, molucidin, ML-2-3 and ML-F52 from the leaves of *Morinda lucida*, to have anti-trypanosomal activity. In this current study, we hypothesized that these compounds would have anti-*leishnania* properties since *Leishmania* also belongs to the class kinetoplastida and therefore may share some metabolic-pathways to trypanosomes which our compounds could interfere with. We therefore assessed the efficacy of the compounds and their mode of action on *Leishmania donovani* and *L. major*. A 50% inhibitory concentration (IC_{50}) was determined after 48 hours of treatment with or without compounds by Alamar blue assay. Molucidin and ML-F52 showed significant activities against *L. donovani* (molucidin = 2.94 μM, and ML-F52 = 0.91 μM), and against *L. major* (molucidin = 1.85 μM, and ML-F52 = 1.77 μM). No significant difference in IC_{50}s between species and compounds was observed. In further analysis by Nexin assay, ML-F52 induced significantly higher apoptotic effect (64.7 %) relative to molucidin (36.1 %) at twice IC_{50}. Though no significant change in the Kinetoplastid Membrane Protein was observed by immunostaining, Molucidin and ML-F52 induced morphological changes in promastigotes. Also in further analysis, treating of promastigotes at IC_{50}, molucidin induced significantly higher ''nectomonad-like" forms (50%), characterized as slow replicating forms, relative to ML-F52 (7%). ML-F52 induced higher 'cell-rounding' (93%) with either a shortened or complete loss of flagellum observed. Further analysis by Fluorescence-Activated Cell Sorting showed an enhanced cell growth arrest at the G2/M phase induced by Molucidin with significant peaks in sub-G1 populations.

CAPACITY BUILDING PLATFORM FOR CLINICAL AND OPERATIONAL RESEARCH ON HUMAN AFRICAN TRYPANOSOMIASIS

Floren Mbo Kuikumbi[1], Olaf Valverde[2]

[1]DNDi Geneva, Kinshasa, Democratic Republic of the Congo, [2]DNDi Geneva, Geneva, Switzerland

For the last 11 years, the HAT platform has been conducting research based on needs in the field and using an approach adapted to realities on the ground. The HAT platform is composed of representatives of national sleeping sickness control programs (NSSCP) and research institutions in its 9-member countries (DRC, Angola, Sudan, Guinea, Congo, Chad, Central African Republic, Uganda, and South Sudan), and foreign research groups such as DNDi, ITM, FIND, Swiss TPH, IRD, MSF, and University of Edinburgh, with the World Health Organization as an observer. The HAT platform is also collaborating with other African research platforms such as the East African Trypanosomiasis Network (EANETT). We will present a summary of the advances made within the framework of the HAT platform in the development of diagnostic and therapeutic tools, with the development and update of target product profile for HAT treatments, discovery of rapid diagnostic tests and development of oral treatments for HAT. Other achievements will be presented in this poster; including an important investment in different trainings, biannual scientific meetings and steering committees, newsletter publication, as well as current advances in clinical and operational trials conducted or in progress. This approach is adapted to the realities of the field and enables local partners, who are the end users of the results, to be important actors involved in clinical research. During these periods, most of NSSCP have adopted the results of this research to adapt their national policies, with or without the support of the HAT platform.

568

EVALUATION OF TWO NOVEL POINT OF CARE DIAGNOSTICS FOR CUTANEOUS LEISHMANIASIS

Henk Schallig[1], Ricardo Hu[2], Alida Kent[3]

[1]Academic Medical Centre, Amsterdam, Netherlands, [2]Dermatological Service of the Ministry of Health, Paramaribo, Suriname, [3]Anton de Kom Universiteit, Paramaribo, Suriname

The diagnosis of CL is mainly based on a variety of clinical signs, but requires laboratory confirmation as these symptoms are not very specific. The laboratory diagnosis of CL is mainly based on microscopic examination of Giemsa's stained skin scrapings or fine needle aspirates, but this approach is reported to have a low sensitivity. Recently, two point of care (POC) diagnostic tests have become available that could aid the diagnosis of CL: 1) a rapid diagnostic test (RDT), the CL Detect™ Rapid Test (InBios International Inc., USA), an immunochromatographic RDT for the detection of the peroxidoxin antigen of *Leishmania* species in CL skin lesions; 2) a molecular diagnostic test based on loop mediated isothermal amplification (LAMP) of a conserved region in the 18 S ribosomal RNA gene of *Leishmania* species and a specific sequence in the kinetoplast DNA of *L. donovani*, which is being marketed as Loopamp™ *Leishmania* Detection kit (Eiken, Japan). In the present study, the diagnostic performance of these two novel diagnostic tests was determined in comparison to microscopy in a specialized dermatology clinic and qPCR performed in a specialised molecular biology laboratory in Suriname, a country endemic for CL mainly caused by *L. guyanensis*. In total 93 suspected CL cases were enrolled in the study with a mean age of 33.6 years, predominantly male (92.5%), and with main location of the lesions on arm or leg. The infecting species was confirmed as *L. guyanensis* (97.5%) or *L. amazonensis* (2.5%). In total 79 (84.9%) of the suspected CL cases were found positive with microscopy. In contrast, only 31 (33.3%) were found positive with RDT testing. Molecular testing in Suriname found 75 (80.7%) cases positive with LAMP testing and 81 (87.1%) with qPCR. The RDT had a very low sensitivity compared to microscopy (36.7%) or qPCR (35.8%), respectively, due to a high number of false negative results. In contrast, the LAMP test had a moderate specificity (42.9%) and good sensitivity (84.8%) compared to microscopy, and a good specificity (91.7%) and sensitivity (91.4%) compared to qPCR. The RDT is not an alternative for the laboratory confirmation of CL by microscopy in Suriname.

569

CONGENITAL CHAGAS DISEASE: LONG TERM FOLLOW UP OF TREATED CHILDREN, PRELIMINARY REPORT

Jaime Altcheh, Samanta Moroni, Hector Freilij, Nicolas Gonzalez, Andres Bochoeyer, Alejandro Goldsman, Maria Grippo, Griselda Ballering, Guillermo Moscatelli

Parasitology and Cardiology Service, "Ricardo Gutiérrez" Children Hospital and Multidisciplinary Institute for Research in Pediatric Diseases, Buenos Aires, Argentina

The aim of pharmacological treatment for patients with Chagas is to prevent cardiac involvement. Electrocardiogram (ECG) is the first indicator

of cardiac involvement. A novel echocardiography (ECO) method for quantitative assessment of myocardial contractility deformation has been validated for detection of subclinical left ventricular dysfunction. Children treated for Chagas disease, with benznidazole or nifurtimox (for 60 days), with long term follow-up were enrolled. Clinical (ECG), parasitological (qPCR) and serological (IHA, EIA) data were collected at diagnosis, end of treatment and every 6 months thereafter. ECG was performed at diagnosis and every year after treatment. Also, Holter (24-hour ECG) and strain and speckle-tracking ECO were carried out at end of follow up for this study. As a control group, healthy children underwent the same cardiological evaluations. A total of 50 treated patients and 17 controls were enrolled. Treated patients: median age: 18.6 years (range 7-33). Median age at diagnosis was 2.35 years (range 0.04-20.3). Median follow-up: 12.5 years (range 6-19). Subjects were born in Argentina, and mainly congenitally infected. Persistent negative *T cruzi* qPCR and a decay of *T.cruzi* antibodies titers by IHA, EIA were observed. In 21/43 (48.8%) antibodies became negative. Cardiological evaluation by Holter and strain ECO were normal in 48/50 (96%) and in 41/41 (100%) patients, respectively. Only 2 treated patients showed sinus bradycardia and isolated premature ventricular beats (with normal strain ECO tests) and one beat 1st and 2nd AV blockade (with normal ECO) respectively. In control group (n: 17) median age was 12.91 years (range 6-23.8) One patient shown 2nd degree AV block with Wenckebach pattern and normal ECO and ergometer test. All infected patients showed parasitological and serological signs of treatment response. Only 2/50 patients in treated group and 1/17 in non-infective group showed signs of cardiac pathology, but we cannot rule out a chance finding at this stage. Further patients need to be included to evaluate cardiological involvement related to Chagas disease.

570

NEW APTAMER-BASED BIOSENSORS FOR THE DETECTION OF CHAGAS DISEASE

Katherin Peñaranda[1], Manuela Verástegui[2], Pohl Milón[1]

[1]Universidad Peruana de Ciencias Aplicadas, Lima, Peru, [2]Universidad Peruana Cayetano Heredia, Lima, Peru

Chagas is an infectious disease that generates severe morbidity and affects approximately eight million humans in the Americas. Although the clinical symptoms of Chagas disease are well characterized, direct detection of the parasite that causes it remains a challenge. In this work, bioinformatic and *in vitro* evolution techniques were used to identify new biomarkers and to develop aptamers as new biosensors, respectively. Using ribosome profiling databases, ten highly expressed proteins of *Trypanosoma cruzi* were identified as potential biomarkers and the protein encoded by the TcCLB.510323.60 gene was selected as a suitable candidate for aptamer development. This protein was the second most abundant in the metacyclic trypomastigote and was highly conserved among *T. cruzi* strains. Systematic evolution of ligands by exponential enrichment (SELEX) and Next-Generation Sequencing (NGS) allowed to identify a common guanine-rich motif for aptamers. These showed specific binding for a short segment of the protein biomarker (peptide TC1). An ELISA-like assay showed that the aptamers recognized the peptide in a controlled mixture and the complete protein in crude *T. cruzi* lysates. Comparisons between total protein and total membrane protein lysates suggest that the biomarker encoded by the TcCLB.510323.60 gene is membrane associated. The identified aptamers isolated in this work could be used to develop a direct detection assay for *T. cruzi* in biological samples.

571

DISCOVERY OF NOVEL SMALL SYNTHETIC MOLECULES WITH ANTI-PROTOZOAN ACTIVITIES

Danielle Turner[1], Susie Pham[2], Julie Starkey[2], Qiuying Cheng[2], Liliya Frolova[3], Douglas Perkins[2], Snezna Rogelj[1], Ivy Hurwitz[2]

[1]Biology Department, New Mexico Tech, Socorro, NM, United States, [2]Center for Global Health, Department of Internal Medicine, University of New Mexico Health Science Center, Albuquerque, NM, United States, [3]Chemistry Department, New Mexico Tech, Socorro, NM, United States

Chagas disease and Leishmaniasis are neglected tropical diseases caused by protozoans belonging to the family *Trypanosomatida*e. Nearly 20 million people are infected with *Trypanosoma cruzi*, the etiologic agent of Chagas disease. Leishmaniasis, a multi-spectrum disease, is caused by parasites of the genus *Leishmania*. Approximately 12 million people are infected, with an incidence rate ranging from 1 to 2 million new cases annually. No vaccines are currently available for either diseases. The suboptimal effectiveness and significant toxicities of existing systemic therapies for Chagas disease and Leishmaniasis are leading drivers for development of new and more efficacious therapeutic strategies. In previous work, we demonstrated that analogs based on the novel 2-aryl-2-(3-indolyl)-acetohydroxamates (AKS) scaffold displayed significant activities against cancer cells lines that are resistance to standard chemotherapy. While the mechanisms of action of these AKS analogs remain to be fully elucidated, they have been shown to exhibit their anti-proliferative activities through cytostatic non-apoptotic mechanisms. In this work, the anti-protozoan activities of a small library of AKS analogs was investigated. The ability of these analogs to inhibit proliferation of *Leishmania major* promastigotes was interrogated in primary screening. Two analogs, AKS7 and AKS26, effectively inhibited growth of *L. major* at 5 µM. In preliminary experiments, both analogs appear to also effectively clear *L. major* infected monocyte-derived macrophages (MDM) in a dose-dependent manner with minimal host cell cytotoxicity following singular treatment for 48-hrs. Similarly, *T. cruzi*-infected human retinal pigmented epithelium (ARPE) cells, treated with either a single dose of 2 µM or three doses of 1 µM AKS7 daily for 3 days, revealed a clearance of both the extracellular and the intracellular parasites and no detectable toxicity to ARPE host cells. These results provide a promising new lead for the development of therapeutic small molecules that may be effective for the treatment of Chagas disease and Leishmaniasis.

572

DIAGNOSTIC PERFORMANCE OF A RAPID DIAGNOSTIC TEST CL-DETECT FOR CUTANEOUS LEISHMANIASIS CAUSED BY *LEISHMANIA VIANNIA* SPECIES IN COLOMBIA

Alexandra Cossio[1], Sandra Jimena Jojoa[1], Maria del Mar Castro[1], Ruth Mabel Castillo[1], Max Grogl[2], Nancy Gore Saravia[1]

[1]Centro Internacional de Entrenamiento e Investigaciones Médicas (CIDEIM), Cali, Colombia, [2]U.S. Naval Medical Unit No.6, Lima, Peru

Parasitological confirmation of Cutaneous Leishmaniasis (CL) is mandatory to access treatment in Colombia. Direct smear and culture are the gold standards for diagnosis of CL. However, required technical expertise limits their availability in the remote settings where CL occurs. We assessed the diagnostic performance of the FDA approved rapid diagnostic test (CL-Detect) for CL caused by *L. Viannia* species in Colombia. As secondary aim, we evaluated a non-invasive sampling method for use with this rapid test. Patients ≥ 18 years of age, with cutaneous lesions (>15 days duration) suggestive of CL, were eligible. Mucosal leishmaniasis cases were excluded. Performance of CL-Detect rapid test (donated by *Inbios*) was blindly compared with direct smear and culture. Sensitivity of the test, using sampling procurement from lesions with the supplied dental broach (n=41), one pediatric swab *HydraFlock*® (n=11), one adult swab *Epicentre*® (n=10) and two pediatric swabs (n=29) were tested. Adverse events, Analogous Visual Scale for pain, and patient preferences were measured. Forty-one patients with suspected CL participated. Thirty-one were positive by gold standard (smear and/or culture). *Leishmania* species were identified in 71% of confirmed cases: 68% were *L. panamensis* (15/22), 27% *L. braziliensis* (6/22) and 5% *L. guyanensis* (1/22). Sensitivity of CL-Detect using dental broach was 38.7% (95%CI: 21.8-57.8), compared to gold standard. Sensitivity of CL-Detect using one (pediatric/adult) or two pediatric swabs ranged from 42.9 to 47.8 (95%CI: 26.8-69.4), respectively. The single pediatric swab was preferred (64%) by patients. Diagnostic performance of CL-Detect was similar among the

four tested sampling methods (dental broach versus pediatric and adult swabs). Sensitivity of CL-Detect increased with higher parasite burden in direct smears (p=0.003). CL-Detect had low sensitivity for diagnosing CL caused by *L. Viannia* species in Colombia, suggesting variation in sensitivity by region and species. The findings support the possibility of non-invasive sampling using CL-Detect to extend access to diagnosis to remote communities.

573

THE CHAGAS DISEASE STUDY LANDSCAPE: PRELIMINARY ANALYSIS OF A SYSTEMATIC REVIEW OF CLINICAL TRIALS AND OBSERVATIONAL STUDIES TO ASSESS THE FEASIBILITY OF ESTABLISHING AN INDIVIDUAL PARTICIPANT-LEVEL DATA (IPD) PLATFORM

Brittany J. Maguire[1], Eric Chatelain[2], Fabiana Barreira[3], Sergio Sosa Estani[3], Philippe J. Guérin[1]

[1]Infectious Diseases Data Observatory (IDDO), Centre for Tropical Medicine & Global Health, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom, [2]Drugs for Neglected Diseases initiative (DNDi), Geneva, Switzerland, [3]Drugs for Neglected Diseases initiative (DNDi) Latin America, Rio de Janeiro, Brazil

Significant limitations still exist in our understanding of Chagas disease including its pathologies, factors relating to progression, biomarkers to indicate parasite clearance or cure and optimal treatment regimens for all patient populations. Existing data collected in past trials could be standardised and pooled to address research priorities and knowledge gaps. We conducted a systematic literature review to understand the scope of Chagas clinical studies and assess the technical feasibility of establishing an individual participant-level data (IPD) platform. Following PRISMA guidance, a review of Chagas clinical drug trials and observational investigations conducted between 1998 and 2017 was performed across 4 databases and 2 clinical trial registries. All clinical studies enrolling patients with a confirmed Chagas diagnosis and at least one follow-up measurement was included. Descriptive and thematic analysis of study characteristics has been conducted and R statistical computing software for analysis where possible. A total of 10,319 articles were screened and 43 trypanocidal treatment trials have been identified. The 43 trials cover 12 different countries, 6 interventions, 67 study arms representing 25 different treatment regimens. A total of 9,803 Chagas patients were treated and followed-up, with 37 testing Benznidazole and 5 testing Nifurtimox, accounting for 74% of all patients. 38 out of 43 studies reported parasitaemia-related outcome measures assessed post-baseline. Serology and PCR were the primary methods for outcome measurement in 6,101 and 5,284 patients, respectively. Adverse events were reported in 33 studies representing 9,114 patients. Duration of follow-up ranged from 56 days to 20 years. The clinical need, potential utilisation and quantity of data identified from preliminary analysis of this systematic review suggests development of a Chagas IPD data platform for clinical research would enable optimisation of existing data and more in-depth analyses to strengthen evidence for treatment and diagnosis of Chagas disease and inform prospective data collection.

574

EVALUATION OF POINT-OF-CARE TESTS FOR CUTANEOUS LEISHMANIASIS DIAGNOSIS IN AFGHANISTAN

Martijn M. Vink[1], Sami M. Nahzat[2], Habiburrahman Rahimi[3], Cyril Buhler[4], Bashir A. Ahmadi[2], Mohammad Nader[3], Fazal R. Zazai[2], Abdul S. Yousufzai[5], Merlin van Loenen[6], Henk D. Schallig[6], Albert Picado[7], **Israel Cruz**[7]

[1]HealthNetTPO, Amsterdam, Netherlands, [2]National Malaria and Leishmaniasis Control Programme, Kabul, Afghanistan, [3]Health Protection and Research Organization, Kabul, Afghanistan, [4]ORDiagnostics SAS, Paris, France, [5]HealthNetTPO, Kabul, Afghanistan, [6]Academic Medical Centre, Department Medical Microbiology, Amsterdam, Netherlands, [7]FIND, Geneva, Switzerland

Afghanistan is one of the major *Foci* of cutaneous leishmaniasis (CL), being this an important public health problem in Kabul, where this is mainly caused by *Leishmania tropica*. Despite its low and variable sensitivity microscopy remains the reference test for CL diagnosis. Sensitive molecular diagnosis (i.e. PCR) cannot be applied routinely due to its technical complexity and logistics requirements. We aimed to evaluate two new point-of-care tests: Loopamp™ *Leishmania* Detection Kit (Eiken Chemical Co., Japan - LAMP) and CL Detect™ Rapid Test (InBios International Inc., USA - CL RDT), for the detection of *Leishmania* DNA and antigen, respectively. We conducted a prospective evaluation of these two new tests at the National Malaria & Leishmaniasis Control Program's (NMLCP) clinic in Kabul. Slit skin samples from lesions from 274 suspected CL cases were subjected to Giemsa's stain microscopy, while samples taken with a dental broach were tested with CL-RDT and LAMP. DNA samples and slides were further transferred to the Academic Medical Center (AMC), Amsterdam for PCR and LAMP analyses. The diagnostic performance of the tests was evaluated against a reference standard combining microscopy and PCR results. In Kabul the CL-RDT returned a sensitivity (Se) of 65.4% and specificity (Sp) of 100%, while this was 89.1% Se and 70.6% Sp for LAMP. LAMP accuracy improved when it was conducted at AMC (92.2% Se, 94.1% Sp). The high specificity CL-RDT enables its use at the peripheral level. The CL-RDT and LAMP could be applied sequentially in an algorithm to diagnose CL patients promptly and minimize the number of patients referred to specialized clinics.

575

NEOTROPICAL BATS THAT CO-HABIT WITH HUMANS FUNCTION AS DEAD-END HOSTS FOR DENGUE VIRUS

Amanda Vicente-Santos[1], Andres Moreira-Soto[1], Claudio Soto-Garita[1], Andrea Chaves[2], Luis G. Chaverri[3], Jan F Drexler[4], Juan A Morales[5], Alejandro Alfaro-Alarcón[5], Bernal Rodríguez-Herrera[2], **Eugenia Corrales-Aguilar**[1]

[1]Virology-CIET University of Costa Rica, San Pedro, Costa Rica, [2]Biology, University of Costa Rica, San Pedro, Costa Rica, [3]Exact and Natural Sciences School, National Distance Education University, San Pedro, Costa Rica, [4]Institute of Virology, University of Bonn Medical Centre, German Centre for Infection Research, Bonn-Cologne, Germany, [5]Department of Pathology, School of Veterinary Medicine, National University, Heredia, Costa Rica

Several studies have shown Dengue Virus (DENV) antibodies and /or nucleic acid present in neotropical wildlife including bats, suggesting that some bat species may be susceptible to DENV infection. Here we aim to elucidate the role of house-roosting bats in the DENV transmission cycle. Bats were sampled in households located in high and low dengue incidence regions during rainy and dry seasons in Costa Rica. We captured 318 bats specimens from 12 different species in 29 households. Necropsies were performed in 205 bats to analyze virus presence in heart, lung, spleen, liver, intestine, kidney, and brain tissue. Histopathology, serology and entomological studies were also performed. Histopathology studies from all organs showed no significant findings of disease or infection. Sera were analyzed by PRNT90 for a seroprevalence of 22% (53/241), and by PCR for 8.8% (28/318) positive bats for DENV RNA. From these 28 bats, 11 intestine samples were analyzed by RT-PCR. Two intestines were DENV RNA positive for the same dengue serotype detected in blood. Viral isolation from all positive organs or blood was unsuccessful. Additionally, viral load analysis in positive blood samples by qRT-PCR showed virus concentrations under the minimal dose required for mosquito infection. Simultaneously, 651 mosquitoes were collected using EVS-CO2 traps and analyzed for DENV and feeding preferences (bat cytochrome b). Only three mosquitoes were found DENV positive and none was positive for bat cytochrome b. Our results suggest an accidental presence of DENV in bats probably caused from oral ingestion of infected mosquitoes. Phylogenetic analyses suggest also a spillover event from humans to bats. We conclude

that bats in these urban environments do not sustain DENV amplification, they do not have a role as reservoirs, but function as epidemiological dead end hosts for this virus.

TRANSLATING PREDICTIONS OF EMERGING ZOONOTIC VIRUSES FOR POLICYMAKERS: PERSPECTIVES FROM CAMEROON

Seth D. Judson[1], Matthew LeBreton[2], Trevon Fuller[3], Risa M. Hoffman[1], Kevin Njabo[3], Timothy F. Brewer[1], Elsa Dibongue[4], Joseph Diffo[5], Jean-Marc Feussom Kameni[6], Severin Loul[6], Godwin W. Nchinda[7], Richard Njouom[8], Julius Nwobegahay[9], Jean Michel Takuo[5], Judith N. Torimiro[7], Abel Wade[10], Thomas B. Smith[3]

[1]David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, United States, [2]Mosaic, Yaounde, Cameroon, [3]University of California, Los Angeles, CA, United States, [4]Ministry of Public Health, Yaounde, Cameroon, [5]Metabiota Cameroon, Yaounde, Cameroon, [6]Ministry of Livestock, Fisheries and Animal Industries, Yaounde, Cameroon, [7]The Chantal Biya International Reference Centre for Research on the Prevention and Management of HIV/AIDS (CIRCB), Yaounde, Cameroon, [8]Center Pasteur, Yaounde, Cameroon, [9]Military Health Research Center, Yaounde, Cameroon, [10]National Veterinary Laboratory (LANAVET) Annex, Yaounde, Cameroon

From the Ebola virus disease epidemic of 2014 to the Lassa fever outbreak this year, zoonotic diseases continue to afflict humans and wildlife. Accurate predictions of where emerging zoonotic viruses occur could improve disease surveillance and response, especially in low and middle income countries. While published maps for emerging viruses such as Ebola virus exist, little is known about how these are perceived by national policymakers. Furthermore, these predictive maps use different models and are often continental in scale, so it is unknown how they compare with one another on a national level. Therefore, we aggregated predictions for 5 zoonotic viruses from the World Health Organization's list of high priority pathogens and analyzed them with national experts in Cameroon, a hotspot for potential zoonotic disease emergence in Central Africa. Together with a One Health team of physicians, veterinarians, scientists, and public health experts, we discussed ways of improving the predictions for national policymakers based on local data. We compiled published predictions for Crimean-Congo hemorrhagic fever virus, Rift Valley fever virus, Ebola virus, Marburg virus, and Lassa virus, using a qualitative visual referencing method. We identified 14 published predictions (an average of 3 per virus) and shared these aggregated predictions with national experts who represented 8 Cameroonian ministries and research institutions. We determined that current predictions are mainly based on environmental parameters and species distribution models. We also found that Crimean-Congo hemorrhagic fever virus and Rift Valley fever virus predictions contrasted with national expert opinion likely due to local livestock movements. Lastly, we received feedback on how to improve the presentation of predictive maps so that they may influence policy decisions. Overall, we discovered that including national experts could elicit additional data to improve predictions of emerging zoonotic viruses and help translate them for policymakers. This framework could be used in other tropical countries to improve zoonotic disease prevention.

577

SPATIAL DISTRIBUTION OF *YERSINIA PESTIS* FOUND IN A SENTINEL SPECIES ACROSS THE UNITED STATES WHILE ACCOUNTING FOR SAMPLING UNCERTAINTY

Ian D. Buller[1], A. Townsend Peterson[2], Sarah T. Bevins[3], Jeffrey C. Chandler[3], Kenneth L. Gage[4], Lance A. Waller[1]

[1]Emory University, Atlanta, GA, United States, [2]University of Kansas, Lawrence, KS, United States, [3]US Department of Agriculture, National Wildlife Disease Program, Wildlife Services, Fort Collins, CO, United States, [4]Centers for Disease Control and Prevention, National Center for Infectious Diseases, Division of Vector-Borne Infectious Diseases, Bacterial Zoonoses Branch, Fort Collins, CO, United States

Yersinia pestis is a gram-negative bacterium, primarily transmitted via flea bite, causing plague in numerous mammal species. While human cases are rare in the United States (US), plague can exhibit severe pathology, including death. Surveillance for plague antibodies in wildlife can shed light on disease occurrence and epizootics; however, sampling strategy influences the findings from wildlife surveillance. Therefore, the utility of using wildlife surveillance data to inform our understanding of plague ecology has been limited. Zoonotic diseases are influenced by climate variables because climate determines the ecological niche of and interactions between hosts, vector, and pathogen. *Canis latrans* (coyotes) are historically used as a sentinel species for plague. We applied a kernel density based ecological niche model using ~29,000 locations of coyotes tested for plague antibodies by US government agencies and PRISM Climate 30-Year Average Normals to determine the spatial distribution of *Y. pestis* in the US. A Monte Carlo based statistical comparison of spatial densities was used to detect significantly different habitat types where plague was and was not detected in coyotes. Areas predicted with higher likelihood of plague in coyotes include cooler, semi-arid areas across the Western US including mountain ranges and high-plateaued regions. The *Y. pestis* niche in coyotes was predicted in areas where coyotes were sampled historically and in areas where plague was not directly observed. Also, due to *C. latrans* behavior and limits of sampling resources, coyotes are collected and tested by US government agencies unevenly across the US. When compared to ~14,000 coyote observations from museum collections, coyotes tested for plague are undersampled in high precipitation areas such as the windward side of the Cascade Range and high alpine habitat, historically low plague prevalent areas. Future research will explore modeling-based approaches to incorporate these findings. These results allow us to strategize sampling and testing plans, particularly from historically undersampled areas, to better understand underlying risks.

578

POULTRY FARMING PRACTICES IN BANGLADESH: A POTENTIAL CONTRIBUTOR TO THE EMERGENCE AND TRANSMISSION OF ANTIMICROBIAL RESISTANCE IN THE COMMUNITY

Abdullah Al Masud[1], Mahbub-Ul Alam[1], Emily Rousham[2], Mohammad Aminul Islam[1], Muhammad Asaduzzaman[1], Mahbubur Rahman[1], Supta Sarker[1], Leanne Unicomb[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Loughborough University, Loughborough, United Kingdom

Intensive poultry farming in many developing economies has been associated with unregulated antibiotic use for disease prevention and growth promotion. This may contribute to the emergence of antimicrobial resistant bacteria in poultry with potential for transmission to humans through the food chain and environmental pathways; we explored potential risk behaviors. We conducted a cross-sectional qualitative study using in-depth interviews among purposefully selected farm workers from small-medium commercial poultry farms (n=10); peri-urban backyard poultry raisers (n=3), and urban live poultry market workers (n=5). Among the same groups we also conducted structured observations. In commercial broiler farms antibiotics were given to birds from day one to the end of production. Farm workers were observed and reported to dispose of poultry waste directly in agricultural fields or in water bodies. Farm workers used no biosecurity measures and frequently touched their facial areas and performed various tasks, subsequent to poultry handling without handwashing with soap. Domestic poultry raisers only used antimicrobials when the poultry is ill. They were similarly observed to minimally wash hands with soap after handling poultry, only washing before food preparation or eating. They used no safety precaution during poultry handling and disposed poultry waste into open ditches next to households. In urban live bird markets, poultry were usually

kept for a maximum of 2 days and sellers did not use antimicrobials. Slaughtering and poultry processing was done on site using a knife and bare hands. Hands were rinsed and dipped repeatedly into stored water containers. Poultry feces, feathers and blood were discarded in municipal waste disposal sites on the street adjacent to markets. Poultry offal was commonly sold as feed for farmed fish. To formulate effective intervention strategies, we need further assessment of the prevalence and risks of behaviors along these environmental pathways of antimicrobial resistance transmission.

579

SEROLOGIC EVIDENCE OF BAT ORTHOREOVIRUS IN SINGAPORE

Anna Uehara, Chee Wah Tan, Danielle E. Anderson, Lin-Fa Wang

Duke-NUS Medical School, Singapore, Singapore

Pteropine orthoreoviruses (PRVs) are a group of double-stranded RNA viruses associated with respiratory and gastrointestinal complications in humans. PRV was first isolated from Australian bats in 1968, but it was not until 2006 when the first human cases of PRV were reported in Malaysia. Since then, multiple countries in Southeast Asia have reported varying degrees of PRV seropositivity; however, no reports have come from Singapore. We sought to address whether members of the Singapore population have been exposed to PRVs through a retrospective study. We developed a Luciferase Immunoprecipitation System (LIPS) assay against PRVs and performed an initial screen on over 800 human samples. Individuals that were deemed positive for at least one PRV strain on LIPS were further tested through serum neutralization assay, leading to a total of seven individuals with neutralizing antibodies against one of the PRV strains, PRV3M. To determine whether other animal populations had prior exposure to PRVs, we next screened wild cynomolgus macaques in Singapore and identified several animals with neutralizing antibodies against not only PRV3M, but up to four other strains of PRV. PRV seropositivity in both macaques and humans suggest that the virus is able to cross over to different animal species, and emphasize the need for further surveillance studies to gain insights on the location and directionality of such events.

580

DIVERSITY AND PREVALENCE OF ARENAVIRUSES IN SMALL MAMMAL SPECIES IN SINGAPORE AND CAMBODIA

Sophie A. Borthwick, Ian Mendenhall, Gavin Smith

Duke-NUS Medical School, Singapore, Singapore

Southeast Asia is a hotspot for emerging infectious diseases, several of which are of a zoonotic origin and have the potential to cause disease in human populations. Mammarenaviruses have the potential for widespread zoonotic transmission from a large diversity of small mammal species that are commonly found in and around human settlements. The human disease burden caused by arenaviruses in Africa and America is well known, but relatively little is known about the zoonotic impact in Southeast Asia. We will screen small mammal lung samples from Singapore and Cambodia with a nested RT-PCR protocol targeting the RdRP gene. PCR will be performed to determine the presence of arenavirus in lung samples to understand the diversity and prevalence of arenaviruses in these two countries. We will also determine which species are reservoirs and which are most important in each country. Research is ongoing and we will report the findings.

581

BIOSECURITY PRACTICES IN BACKYARD POULTRY IN RURAL BANGLADESH: A MAJOR CONTRIBUTING FACTOR TO THE INCURSION OF NOVEL SUBTYPE OF AVIAN INFLUENZA AND ITS HUMAN SPILL OVER IN THE COMMUNITY

Mahfuza Talukder Flowra[1], Muhammad Asaduzzaman[2]

[1]Universitas Gadjah Mada (UGM), Indonesia, Yogyakarta, Indonesia, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Bangladesh is at risk of introduction of any emerged subtypes of avian influenza which are circulating in Asia. Being a small country with large human and poultry populations, it has been affected with frequent outbreaks of both high and low pathogenic avian influenza (HPAI and LPAI) since 2007. Very few studies have been carried out to reveal the farm biosecurity at backyard poultry that might have contributed to the spread of avian influenza, specially in rural areas. We aimed to characterize biosecurity practices of rural backyard poultry farms for rapid detection and effective risk management of incursion of HPAI and LPAI viruses. We conducted a cross-sectional study using pre-tested questionnaire among randomly selected backyard Poultry holdings (n=315) in two villages at Kalkini Upazila of Madaripur district. These villages, located within 3-5 km radius of a live bird market, have a relatively low proportion of commercial and high proportion of backyard poultry holdings. We found the water source for backyard poultry is largely based on pond or river (50%) which may facilitate the rapid spread of HPAI in that area. A significant number of farms (39%) used unhygienic ash and 49% farms use no litter materials, the most alarming finding. Few farms (8%) shared night shelter with ducks which is a proven risk factor for HPAI. The poultry was slaughtered within the home yard or adjacent to house at 57% households. The waste disposal system is also favourable for spreading disease. Poultry offal was just thrown away in 44% households. Free roaming of birds in the compound and sick birds remaining with healthy ones were observed in >80% and >60% farms respectively. In addition, daily cleaning of the coop was quite absent in all households. We found 98% farms having another backyard farm within 100 meter which may be a key factor in the spread of airborne infections. All these play an important role in spill over of avian pathogen to human. The findings from this study will support the development of risk-based One Health surveillance and contingency policies to minimize the spread of avian influenza between poultry units and also from poultry to people in Bangladesh.

582

NATIONWIDE SEROPREVALENCE AND GEOGRAPHIC DISTRIBUTION OF MURINE TYPHUS IN THAILAND

Siriphan Gonwong

Armed Forces Research Institute of Medical Sciences (AFRIMS), Bangkok, Thailand

Murine typhus is an acute febrile illness caused by Rickettsia typhi, a gram-negative, obligate, intracellular bacterium. Murine typhus is distributed worldwide, is endemic in tropical and sub-tropical coastal areas, and is transmitted by fleas carried by rats and mice. Nonspecific clinical signs (flu-like symptoms) and minimal diagnostic options contribute to murine typhus' status as a neglected disease. This retrospective study was conducted to identify the circulation and geographic distribution of murine typhus in Thailand. Serum from Royal Thai Army recruits (n = 7,760) collected during 2007-2008 were screened for antibodies against murine typhus by ELISA to determine the exposure distribution in Thailand. The nationwide murine typhus IgG seroprevalence was 6.8% (95% confidence interval = 6.3 - 6.4%) and the range by province was 1 - 18%, confirming murine typhus as an endemic disease throughout Thailand. Seroprevalence was slightly higher in rural areas than urban areas, at 7% and 6% respectively, supporting previous studies of increased murine

typhus in urban areas. This study generated a spatial distribution map of murine typhus seroprevalence across Thailand by province, demonstrating the extent of pathogen exposure as well as its dispersion in the natural ecology. The highest seroprevalence was in the South region, which is a peninsula between seas with suitable climate and resources to support murine typhus' lifecycle.Currently there is limited epidemiology data for murine typhus in Thailand. This nationwide distributed seroprevalence data raise concerns regarding implementing public health interventions such as improved reporting and surveillance, better access to diagnostic tools for enhanced disease awareness, and effective public health education and awareness to prevent this disease.

583

RETROSPECTIVE CASE HISTORY AND ANALYSIS OF KYASANUR FOREST DISEASE (KFD) IN INDIA

Sulagna Chakraborty, Marilyn O'Hara-Ruiz, Flavia Andrade

University of Illinois, Urbana Champaign, Champaign, IL, United States

Kyasanur Forest disease (KFD) was first discovered in Shimoga district in the Indian state of Karnataka. It is caused by a tick-borne pathogen that is deadly to monkeys (*Macaca radiata* and *Semnopithecus entellus*) and can cause hemorrhagic symptoms in humans. Case fatality is 3 - 10%. It is a highly infectious viral disease of the Flaviviridae group and belongs to the Russian Spring Summer Encephalitis complex of viruses. The disease has been expanding recently into new areas; however, there has been inadequacy in case reporting, lack of active surveillance measures and dearth of knowledge on the transmission patterns of this disease. Therefore, we conducted a thorough retrospective analysis to provide a comprehensive perspective of all KFD human cases from 1957 till 2017. Information was collected from peer reviewed journal articles, the ProMED database, historical newspapers, government and technical reports and other grey literature sources. Data was collated into a database that details the annual number and district of cases, and source of information. Upon completion, this meticulous process allowed us to map the cases and review spatio-temporal patterns. KFD has expanded to 12 districts in the states of Karnataka, Kerala, Goa and Maharashtra. The data indicate that there were major outbreaks in the years 1957 - 1958, 1983- 1984, 2002 - 2003 and 2016 - 2017. Factors associated with these outbreaks are major deforestation events, increased contact with infected or dead monkeys, survival of the virus within tick reservoirs, human population migration and climatic trends. The disease continues to expand into new territories and cause new cases and although human to human transmission has been ruled out so far, there is critical information lacking for this emerging infectious disease of concern. The results of this exploratory data will be used to perform further research on epidemiological patterns of Kyasanur Forest disease.

584

CHARACTERIZATION OF VIRUSES IN BATS COMMONLY HARVESTED BY HUMANS IN NAGALAND, NORTHEAST INDIA

Dolyce H.W Low[1], Pilot Dovih[2], Uma Ramakrishnan[2], Ian H. Mendenhall[3]

[1]National University of Singapore, Singapore, Singapore, [2]National Centre for Biological Sciences, Bangalore, India, [3]Duke-NUS Medical School, Singapore, Singapore

Nagaland is largely undeveloped, with numerous remote villages due to its geographical and political isolation from the rest of India. Similar to other sites, protein is often scarce and people maintain their traditional practices and rely heavily on bushmeat, hunting wildlife such as bats as a source of income and sustenance. We collected fresh swabs and tissues from bats (N=103, *Eonycteris spelaea* N=34; *Rosettus leschenaultii* N=69) harvested in 2017 and used family-specific primers and conventional PCR to screen them for viruses that have been associated with recent zoonotic epidemic/pandemic outbreaks (coronaviruses, filoviruses, paramyxoviruses), including astroviruses. We detected paramyxoviruses and astroviruses, but did not detect coronaviruses or filoviruses. Sanger sequencing of the PCR-positive products showed two distinct bat paramyxoviruses (high similarity to African megabat, *Eidolon helvum* paramyxovirus) detected in both bat species. This suggest the transmission of viruses between the species during co-roosting, and a lack of host specificity. Detection levels of the four virus families are low, and could be a result from a number of factors such as low viral load, under sampling (<1% of total bats harvested) or a lack of specificity with viral family screening primers. Further investigation and characterization of these viruses are required prior to making conclusive results. Thus, we will proceed with metagenomics analysis using next generation sequencing methods to obtain additional information about the astrovirus and paramyxoviruses detected, as well as to investigate the pathogen population and diversity between the two bat species that bat harvesters are potentially exposed to.

585

GREEN SYNTHESIS OF ISONIAZID-LOADED SILVER-STARCH NANOCOMPOSITE FOR THE TREATMENT OF TUBERCULOSIS

Martins Emeje, Christianah Isimi, Olubunmi Olayemi, Judith Okoh, Issac Ajeh, Kokonne Ekere

National Institute for Pharmaceutical Research and Development (NIPRD), Abuja, Nigeria

Tuberculosis (TB) has been declared a public health emergency by the World Health Organization (WHO). Estimates reveal that about 9 million cases occur globally, with Asia and Africa accounting for 85 %. Isoniazid (INH), an effective anti-tuberculosis drug used in many countries is poorly absorbed from the stomach; hence, low bioavailability remains its major challenge. Application of nanotechnology to solve this problem is gaining increasing interest in this regard. Starch isolated and purified from a cheap and renewable source, *Manihot esculenta* was modified to obtain acetylated form. Synthesis was confirmed using NMR, FTIR and Raman spectroscopies while DSC-TGA, SEM, XRD, viscosity profile, water absorption and solubility indices were used to characterize the new polymer. The INH nanoparticles (INH-NPs) were evaluated for mean particle size, polydispersity index, and zeta potential and further characterized by FTIR and SEM. *In vitro* release of INH-NPs as well as the effect of nano-encapsulation of INH on the antibacterial activity of INH against gram-positive and gram-negative bacteria was also evaluated on BACTEC-MGIT960. The results show spherical shapes of INH-NPs with monodispersed size distribution. The nanoparticles had mean particle size (245 nm), polydispersity index (0.320) and zeta potential (-18.16 mV) which were further confirmed by UV, FTIR and SEM. *In vitro* release of encapsulated nanoparticles showed significant rapid release profile in acidic pH of the stomach. INH-NPs exhibited minimum inhibitory concentration (MIC) value of 0.003 ug/mL, while INH-free drug had MIC value of 0.07 ug/mL. This study shows that, INH-NPs prepared from a cheap, non-toxic, renewable and generally compatible natural polymer could considerably improve the antibacterial efficacy of INH while still being economical.

586

IMPACT OF THE INTRODUCTION OF PCV7/13 ON ANTIMICROBIAL RESISTANCE IN INVASIVE PNEUMOCOCCAL DISEASE IN THE GAMBIA

Ebrima Mr Secka, Rsheed Mr Slaudeen, Momodou Mr Drammeh, Momodou Mr Drammeh

Medical Research Council, Banjul, Gambia

We describe antimicrobial resistance in invasive pneumococcal disease due to all serotypes and non-vaccine types (NVT) pre and post-pneumococcal conjugate vaccine (PCV) implementation in The Gambia in all age groupsWe identified, serotyped, and performed antimicrobial susceptibility testing using disc diffusion methods on pneumococcal isolates obtained from invasive samples collected from standardised population-based pneumococcal disease surveillance in the Basse Health

& Demographic Surveillance System. The study commenced May 2008. PCV7 was introduced in August 2009 and PCV13 in May 2011. Antibiotic susceptibility was interpreted using Clinical Laboratory Standard Institute guidelines. We plotted case counts of invasive pneumococcal disease in the pre-PCV, PCV- introduction, and post-PCV13 implementation period.396 pneumococcal isolates were screened against five antimicrobial agents. There was a moderate decline in antibiotic resistance in all age groups in invasive pneumococcal disease during vaccine implementation. In the 2-23 month age group, annual counts of oxacillin, chloramphenicol, and tetracycline resistant cases fell from 10-15 in 2009 and 2010 to 6-7 in 2014 and 2015. In the 24-59 month age group, there was a large fall in tetracycline resistant cases. In those >5 years, oxacillin, chloramphenicol, and tetracycline resistance fell to zero cases in 2013 and 2014. Resistance fell primarily due to reductions in vaccine-serotypes 1, 5,14 and 23F. The proportion of resistant NVT cases increased over time, particularly in the 2-23 month age group, with tetracycline resistance mainly in serotypes 10A, 12F, 11B, 7C and 25A and tetracycline resistance in serotype 12F in 2016. Isolates were generally sensitive to erythromycin but 95-98% were resistant to cotrimoxazole throughout the study. Although there is an overall reduction in cases of antimicrobial resistant IPD, resistance is emerging in NVT. We hypothesise that increased transmission of NVT after the introduction of PCV and exposure to antimicrobials facilitates the emergence of resistance in NVT. Ongoing surveillance is important.

587

DIMINISHED CIRCULATING PLASMA AND ELEVATED LYMPH NODE CULTURE SUPERNATANT LEVELS OF IL-10 FAMILY CYTOKINES IN TUBERCULOUS LYMPHADENITIS

Gokul Raj Kathamuthu[1], Kadar Moideen[1], Dhanaraj Baskaran[2], Subash Babu[1]

[1]NIH-ICER-NIRT, Chennai, India, [2]NIRT, Chennai, India

IL-10 family cytokines are associated with the host immune response to pulmonary tuberculosis (PTB), but their association with host response in tuberculous lymphadenitis (TBL) is not known. Hence, we examined the circulating levels of whole panel of IL-10 family cytokines in TBL (n=44) and compared them with PTB (n=44) and healthy control (HCs, n=44) individuals. We also assessed the pre and post-treatment cytokine levels in TBL individuals following the completion of anti-tuberculosis treatment (ATT). Next, we also compared the levels of IL-10 family cytokines in circulation versus lymph node (LN) culture supernatants in a subset of TBL individuals (n=22). Finally, we also measured the levels of IL-10 family cytokines in tuberculosis antigen (purified protein derivative, PPD) stimulated and unstimulated (UNS) LN culture supernatants. TBL individuals exhibit significantly decreased levels of IL-10, IL-19, IL-20, IL-24, IL-28B and IL-29 cytokines in the circulation when compared to PTB (except IL-10) and HCs (except IL-20 and IL-28B) and significantly increased levels of IL-22 cytokine when compared to PTB individuals. Following ATT, TBL individuals exhibit significantly elevated levels of IL-10, IL-19, IL-20, IL-24, IL-28B and IL-29 cytokines and significantly diminished levels of IL-26 cytokine. Similarly, TBL individuals also exhibited significantly increased levels of IL-10 (P<0.0001), IL-19 (P<0.0001), IL-20 (P<0.0001), IL-24 (P<0.0001), IL-28B (P<0.0001), IL-29 (P<0.0001) and decreased IL-22 (P<0.0001) cytokines in LN culture supernatants compared to plasma. This was associated with enhanced levels of IL-10 (P=0.0002), IL-19 (P=0.0259), IL-20 (P=0.0275), IL-24 (P=0.0246), IL-28B (P=0.0127) and IL-29 (P=0.0351) cytokines upon PPD stimulation of LN cultures. Therefore, we demonstrate that TBL is associated with significantly diminished plasma and elevated LN culture supernatant levels of most of the IL-10 family cytokines; which could perhaps involve in the immune modulation of TBL infection. This to our knowledge is the first comprehensive examination of IL-10 family cytokines in TBL.

588

EVALUATION OF THE EPIDEMIOLOGY, AETIOLOGY AND CLINICAL PRESENTATION OF ACUTE LOWER RESPIRATORY INFECTIONS AMONG CHILDREN UNDER FIVE YEARS OF AGE ADMITTED TO THE JIGME DORJI WANGCHUCK NATIONAL REFERRAL HOSPITAL IN THIMPHU, BHUTAN

Quique Bassat[1], Sophie Jullien[1], Ragunath Sharma[2], Kinley Tshering[3], Carmen Muñoz[4]

[1]ISGlobal, Barcelona, Spain, [2]JDWNRH, Thimphu, Bhutan, [3]Lungtephu, Thimphu, Bhutan, [4]Hospital Sant Joan de Deu, Barcelona, Spain

Pneumonia remains the major killer of children under five years globally. Most of these deaths could be prevented through the use of vaccines and the early identification and treatment of the disease. Local description of the disease is important to better characterize the major determinants of this clinical syndrome and to support the design and implementation of locally-tailored preventive and therapeutic strategies.We aim to evaluate the epidemiology, aetiology and clinic radiological presentation of WHO-defined pneumonia, and to assess the role of etiologic and prognostic biomarkers, among children under five years of age admitted to the Jigme Dorji Wangchuck National Referral Hospital (JDWNRH) in Bhutan, a lower middle income country locked in the Himalaya. With the exception of a specific influenza surveillance program ongoing in the country, scarce data are available regarding acute respiratory infections, and the Pneumococcal conjugate vaccine is not yet included in their immunization programme. This is a prospective study of children between two and 59 months of age who are admitted to the JDWNRH in Thimphu, Bhutan, with a primary diagnosis of WHO-defined clinical pneumonia, during 12 consecutive months. For each child whose parents consented to participate in the study, we collected demographic and clinical data through questionnaires and physical examination, as well as blood samples, nasal swab and nasopharyngeal washing for etiological study (culture and molecular study), and a chest X-ray. Prognostic and aetiological biomarkers were also assessed. We compared qualitative variables using a χ^2 test or Fisher's exact test, means of normally distributed variables using the Student's t-test or ANOVA and non-normally distributed variables using the Wilcoxon Rank sum or other non-parametric tests. Logistic and linear regression (univariate and multivariate) were used to identify predictors of study endpoints. It is the first time that a study of these characteristics has been conducted in the small kingdom of Bhutan. We will present the preliminary results of the approximately 180 children recruited in the study.

589

ISONIAZID AND RIFAMPICIN RESISTANCE AND PATIENT TREATMENT RESPONSE IN A TUBERCULOSIS AND HIV-1 CO-ENDEMIC POPULATION IN WESTERN KENYA

Clement Likhovole[1], Prof. Collins Ouma[1], Jeremiah Khayumbi[2], Wilfred Murithi[2], Albert Okumu[2], Susan Musau[3]

[1]Maseno University, Kisumu, Kenya, [2]Kenya Medical Resarch Institute, Kisumu, Kenya, [3]Maryland Global Initiatives Corporation, Nairobi, Kenya

In 2015, 10.4 million people worldwide had tuberculosis (TB) and 1.4 million deaths occurred, 400 000 of whom were HIV-positive, Sub-Saharan Africa accounted for 81% of these cases. In western Kenya, current data on the distribution of Rifampicin (RIF) and Isoniazid (INH) mutations is not available. In addition, the association of gene mutations with HIV infection and the treatment response of HIV infected and uninfected patients with TB are not known. The current study determined the proportion of drug resistant *Mycobacterium tuberculosis* in sputum isolates and investigated the association of RIF and INH gene mutations with HIV status and monitored the treatment response of TB and HIV co-infected patients. The present study was longitudinal and enrollment was done between 2012 and 2014 after the revision of the TB treatment regimen and patients with confirmed drug resistant TB were followed up for one year to establish the TB treatment response as confirmed by sputum smear microscopy. Patients

with suspected TB symptoms and Ziehl-Neelsen positive patients were targeted for enrollment. A total of 1381 new and 18 previously treated TB patients were enrolled. Sputum samples were cultured on *Mycobacteria* growth indicator tubes, drug susceptibility tests and line probe assay was performed to identify drug resistance and specific mutations on the *rpo* B, *kat* G and *inh* A genes. Discordant samples were sequenced. Conversion rate was calculated by finding the percentage of smear negative and positive patients at follow-up and initial visit, respectively. Regression analysis showed that RIF resistance was associated with HIV status (P = 0.025). Mann-Whitney tests revealed that the conversion time of HIV infected and uninfected patients with TB drug mutations was comparable (P = 0.180). The results of the study showed that INH mono-resistance was common. Detection of INH mono-resistance in TB endemic areas should be scaled-up as well as TB contact investigation studies to increase early detection of resistant strains.

590

INOCULUM DOSE DEPENDENCY OF INFLUENZA OUTCOME

Annaliese Wiens

University of Notre Dame, South Bend, IN, United States

Problems arise when studying influenza infections due to the ephemeral nature of the virus and sudden onset after exposure. Unlike long-term or chronic diseases such as tuberculosis or HIV, influenza patients only experience symptoms for a few days, so the virus must be detected within hours of initial exposure to record data accurately. Also, the amount of pathogen that the patient was exposed to cannot be known when the disease is acquired naturally. Influenza challenge studies have been performed since 1946 to test various prophylaxis and treatment methods as well as to study epidemiological trends. In these studies, volunteers are purposefully inoculated with a known amount and type of influenza virus in a controlled setting. The control groups of these studies, in which the patients are inoculated with the virus and given a placebo in place of prophylaxis or treatment, mimic natural infection but allow researchers to collect information than would be possible in a natural setting. This meta-analysis used data from the control groups of methodically reviewed literature in to determine patterns for how different conditions surrounding inoculations affect the severity of the disease. This information could suggest an efficient way to control the spread of influenza. Information was collected on demographic variables such as age and sample size; medical variables such as antibody titers and the inoculum dose, and outcome variables such as the number of volunteers with fever and the peak mean titer. A low-dose linear model was fitted to the data, and it was effective in showing the difference in infectivity between cold-adapted and wild-type viruses along with other preparations.

591

ACUTE RESPIRATORY INFECTIONS IN TRAVELERS RETURNING FROM AVIAN INFLUENZA AFFECTED AREAS

Kayur Mehta[1], Romy Olsha[2], Erik Kristjanson[2], Adriana Peci[2], Anne-Louise Winter[2], Jonathan B. Gubbay[2]

[1]The Hospital for Sick Children, Toronto, ON, Canada, [2]Public Health Ontario, Toronto, ON, Canada

In the highly inter-connected world today, global travel is common. People who travel to areas with endemic emerging infections are not only at risk of acquiring them, but can also import them to their own countries, potentially contributing to pandemics. In this study, we aimed to explore the array of respiratory pathogens in travelers arriving in Ontario, Canada from avian influenza affected areas. Persons Under Investigation (PUIs) for Avian Influenza were identified as per directives outlined by public health authorities in Canada. Nasopharyngeal samples and/or throat samples were collected and submitted to the Public Health Ontario Laboratory. Influenza viruses were detected by rRT-PCRs targeting the influenza A matrix gene and influenza B nonstructural 1 gene using CDC protocols; influenza A-positive specimens were subtyped. Between April 2013 and June 2017, 230 PUIs were identified. Mean age was 44 years (range <1-92 years); 52.3% were male and 70% arrived from China. For the 62 PUIs for whom data were available, 53 (85.5%) had respiratory samples collected within 14 days (median 4 days, IQR 2-8 days) from symptom onset, which varied from 30 days before return to 7 days after return (median 1 day after return). A total of 284 samples were tested; at least one respiratory pathogen was detected in 86 (37.3%) PUIs. Six PUIs had two different viruses detected. Influenza viruses were most commonly identified [influenza A, 36 (15.6%) PUIs; influenza B, 8 (3.5%) PUIs], followed by rhinovirus (13 PUIs), parainfluenza virus and human metapneumovirus (7 each). No respiratory pathogen was found for 144 (62.6%) PUIs; no PUI tested positive for Avian Influenza. Although the risk for importation of Avian Influenza is low, seasonal respiratory virus infections appear to be commonly acquired abroad or locally after returning to Canada. Further, given the high proportion of infection with influenza virus, vaccination is strongly advised for travelers to endemic areas.

592

PREVALENCE AND RISK FACTORS FOR DEPRESSION AMONG PATIENTS WITH DRUG-RESISTANT TUBERCULOSIS IN NEPAL

Sailesh K. Shrestha

National Tuberculosis Center, Bhaktapur, Nepal

The protracted course of illness, reduced efficacy of available treatment, associated stigma and financial implications put the patients with drug-resistant tuberculosis at increased risk of mental illness, particularly depression. The psychiatric side effects of the anti-tuberculosis drugs further aggravate the problem. Studies have reported the prevalence of depression to be as high as 69.5% among these patients. These mental health issues contribute to poor quality of life and influence adherence and cure rates. Addressing these conditions improves treatment outcomes. However, National Tuberculosis Programs insufficiently consider these issues. This study aims to determine the burden of depressive disorders among the patients with drug-resistant tuberculosis and assess the risk factors for the same. It is a cross-sectional study on 129 patients with drug-resistant tuberculosis treatment for at least two months selected from 11 random clusters of treatment centers across the country. Trained healthcare workers conducted face to face interview to collect data on treatment details and administer Patient Health Questionnaire (PHQ) 9 for screening depression. The PHQ9 has been validated in Nepal with a cut-off score of ≥ 10 shown to have a sensitivity of 94% and specificity of 80%. Descriptive statistics were used to summarize the treatment characteristics of the patients. Appropriate inferential statistics were used to test for the association of depression with the risk factors. A p value of less than 0.05 was considered significant. Of the 129 patients, 84.5% had multi-drug resistant tuberculosis and the rest 15.5% had even more extensive forms of drug-resistant tuberculosis. The median duration of illness was 12 months and 78.5% had past history of tuberculosis. Possible depressive disorder was found in 63.1% of the patients which had a statistically significant association with the duration of illness. The study has shown that screening for depression is feasible under program conditions and has revealed a high prevalence of depression among the patients with drug-resistant tuberculosis highlighting the need for actions.

593

INADVERTENT INTRAVESICAL BCG ADMINISTRATION IN NEWBORNS AT A TERTIARY CARE HOSPITAL, KARACHI

Sonia Qureshi, Rabia Hassan, Farah Naz Qamar

Aga Khan University Hospital, Karachi, Pakistan

Bacillus Calmette-Guérin (BCG) is given to newborns soon after birth in accordance with the immunization program by government of Pakistan. BCG vaccine overdose has been rarely reported. The aim of this study is to determine the frequency of adverse events after accidental administration of high dose intravesical BCG in neonates born at a tertiary

care hospital, Karachi. A crossectional study was conducted in which 25 newborns, who had received BCG overdose accidentally between 14-16th April 2016 in the well-baby nursery of Aga Khan University Hospital, Karachi were included. Participant's demographic; details of adverse reactions and treatment given were recorded from April 2016-Dec 2017 by reviewing medical records. Analysis was carried out by STATA. 24/25 (96%) newborns were followed. 1/25 was (4%) lost to follow up. 13/25 (52%) were males. 23/25(92%) were born on term gestation. 23/25(92%) received isoniazid and rifampicin for 3 months. Rifampicin was discontinued after 2 weeks in 1/23(4.3%) child due to vomiting. 16/25 (64%) developed skin lesions. 9/16 (56.2%) had skin papule, 1/9(11.1%) had ruptured skin papule. Skin erythema observed in 3/16 (18.7%) of children. 2/16(12.5%) each developed skin pustule and skin nodule.1/16(6.3%) had persistent weeping skin lesion and underwent skin biopsy at 3 months of age ,that showed inflammatory changes with eosinophilia. Coagulation was deranged in 2/25(8%) of babies at 1 month of age. Intracranial bleeding was observed in 1/25 (4%) of babies at 1 month of age and managed conservatively. Skin lesion was the most common adverse event observed. Close follow-up is the key for managing such accidental events.

594

PREVALENCE, ASSOCIATED FACTORS AND OUTCOMES OF VENTILATOR ASSOCIATED PNEUMONIA AMONG PATIENTS IN INTENSIVE CARE UNITS AT KILIMANJARO CHRISTIAN MEDICAL CENTER

Florida J. Muro[1], George Nyamboto[2]

[1]KCMC, Moshi, United Republic of Tanzania, [2]KCMUCo, Moshi, United Republic of Tanzania

Ventilator associated pneumonia (VAP) is a nosocomial pneumonia commonly in occurring in patient receiving mechanical ventilation 48-72hrs following endotracheal intubation. Although commonly reported, hospital acquired infection (HAI) in pediatrics than other age groups accounts for about 20% of all HAIs (Galal et al 2016). VAP is associated with an increase in hospital morbidity and mortality, duration of hospitalization (on average 7-9 days) and high health care costs. To determine the prevalence, associated factors and outcomes of ventilator associated pneumonia among the patients in intensive care units at Kilimanjaro Christian Medical Centre, Moshi -Tanzania. A retrospective, cross-sectional hospital based study design was used. A descriptive analysis was done using SPSS v.20 to summarize data using mean, for continuous variables and percentages for categorical variables. Multivariate logistic regression was used to express the magnitude and direction of association with odds ratio showing the strength of association and p-value of <0.05 was considered statistically significant. Of 138 files available, 58(42.0%) were of males and 80(58.0%) were of female patients with the average age of 51.81 years (SD±20). The point prevalence of VAP was 4.1%, in which the sex specific point prevalence was 3.5% and 4.5% for male and female respectively. Tracheostomy, re-intubation frequency, length of staying in Intensive care units (ICUs) were the clinical factors associated with VAP. *Acinobacter baumanii* was microorganism significantly associated with VAP. In this study the proportion of patient dying due to VAP was 38.7%. VAP remains a public health problem given the observed prevalence and proportion of deaths. It is associated with re-intubation frequency and prolonged mechanical ventilation thus effective intervention are necessary in combatting this problem and thus improve patient outcome.

595

COMPARISON AND DIAGNOSIS OF *ENTAMOEBA HYSTOLYTICA, E. DISPAR,* AND *E. MOSHKOVSKII* IN STOOL SAMPLE FROM RURAL COMMUNITY OF NEPAL

Sandeep Thapa[1], Ajaya Jang Kunwar[1], Nilam Thakur[1], Govardhan Joshi[1], Sony Shrestha[1], Rajesh Das[2]

[1]Kathmandu Center for Genomics and Research Laboratory, Gwarko, Nepal, [2]Kathmandu College of Science and Technology, Kathmandu, Nepal

Nepal is a developing country which has many health problems. Amebiasis is one of the infectious diseases that is highly seen in rural area of Nepal caused by *Entamoeba* species. Recent reports show that open defecation, contaminated water, unsanitary habits and lack of basic health knowledge cause higher mortality and morbidity in our country. *E. histolytica* is an anaerobic pathogenic parasitic. However, *E. dispar and E. moshkovskii* exists as non-pathogenic. Likewise, *E. histolytica*, *E. dispar* and *E. moshkovskii* are morphologically identical but genetically distinct species. A total of 270 faecal sample were collected from south eastern terai region of Nepal after the informed consent form. The samples were processed by direct wet smear. Eventually, microscopic examination as performed for the detection of *Entamoeba* species along with other intestinal parasites. Furthermore, enzyme immunoassay was executed to detect antigens of *E. histolytica*. Additionally, microscopically positive samples for *Entamoeba* species cysts were further characterized using a Nested- PCR targeting 16S-like ribosomal RNA gene. 8.52% of the total collected samples were microscopically positive for *Entamoeba* cysts either singly or in combination with other intestinal parasites. Among different organisms, *As. Lumbricoids* and *E. histolytica, G. lambia* and *H. nana* were identified in most of the patients accounting for 11.11%, 8.52%, 2.59% and 1.11% respectively. Among several symptoms, diarrhoea seems to be the common symptoms infecting all of the patients followed by fever (55.1 %), vomiting (46.2 %.) and nausea (14.4%). Consequently, 56 cases were PCR positive, 51 cases were ELISA positive whereas 47 were found to be positive by microscopy. In conclusion, This study reports a highly rapid, specific and sensitive molecular technique for detection and differentiation of *E. histolytica*, *E. dispar* and *E. moshkovskii*.

596

MOLECULAR CHARACTERIZATION OF *GIARDIA LAMBLIA* IN CHILDREN UNDER FIVE YEARS FROM THE MANHIÇA DISTRICT, SOUTHERN MOZAMBIQUE

Augusto Messa Junior[1], Marcelino Garrine[1], Delfino Vubil[1], Sozinho Acácio[1], Tacilta Nhampossa[1], Pedro Alonso[2], Inácio Mandomando[1]

[1]Centro de Investigação em Saúde de Manhiça - CISM, Manhiça, Mozambique, [2]ISGlobal, Hospital Clínic – Universitat de Barcelona, Barcelona, Spain

Giardia lamblia, the etiologic agent of giardiasis is responsible for over 2.5 million deaths per-year in children less than 5 years. Currently, 8 morphologically identical assemblages (A to H) are known, with assemblages A and B affecting humans and other mammalians. Data on molecular epidemiology of *Giardia* are scarce in Mozambique. Therefore, we aimed to retrospectively assess the assemblages of *G. lamblia* in stool samples from a case-control study (the Global Enteric Multicenter Study - GEMS1A) conducted in the Manhiça district between November 2011 and November 2012, that investigated the burden and microbiologic etiology of moderate-to-severe (MSD) and less-severe (LSD) diarrhea in children less than 5 years. DNA of 123 stool samples from cases and 259 from controls, positive for *G. lamblia* by immunoassay (TechLab, Inc., Blacksburg, VA, USA) were extracted using Qiagen kit (QIAamp DNA Stool Mini Kit) and typed for 2 assemblages (A and B) by conventional PCR targeting two genes (E1-HP and C1-P21). Overall 50% (191/382) of the samples amplified for at least one targeted gene, with assemblage B being the most frequently found, accounting for 89% of positives (170/191),

followed by A (8.4%; 16/191), and mixed assemblages (A+B) with only 2.6% (5/191). Among cases, 61% of typed samples (75/123) were positive compared to 44.8% (116/259) of controls, with assemblage B being predominantly in cases (59.4%, 73/123) compared to controls (39.4%, 102/259) (p<0.001); while assemblage A was slightly more frequent in controls (12.1%, 14/259) than in cases (2.7%, 2/123) (p=0.19), and mixed assemblages were the least common and found in similar proportions between cases and controls. Our data suggests that *G. lamblia* assemblage B is the most predominant circulating assemblage in children with diarrhea in the rural community of Manhiça, Southern Mozambique. Detailed molecular characterization including the analysis of a higher sample size is underway to better understand the local epidemiology of this parasite.

597

MOLECULAR DIAGNOSIS AND GENOTYPE ANALYSIS OF *CRYPTOSPORIDIUM* SP., *GIARDIA LAMBLIA* AND *ENTAMOEBA* SP. IN DIARRHEAL STOOL FROM CHILDREN AGED LESS THAN 12 YEARS IN GHANA

Georgina I. Djameh

Noguchi Memorial Institute for Medical Research, Accra, Ghana

Diarrhoeal diseases are common among children in developing countries including Ghana. These are caused by several etiological agents including viruses, bacteria and parasites. Parasites that are mostly implicated include *Cryptosporidium spp., Giardia lamblia and Entamoeba spp.* In Ghana, research into childhood diarrhoea mostly focus on children aged less than 5 years and viral isolation. This study aimed at detecting and genotyping *Cryptosporidium* sp., *G. lamblia* and *Entamoeba* sp. from diarrhoeal stool samples from children less than 12 years old. Genomic DNA was extracted from 339 diarrhoeal stool samples and subjected to PCR amplification. PCR-RFLP of the 18S rRNA gene was employed for the sub-typing of *Cryptosporidium* isolates. *Giardia lamblia*-positives were characterized by multilocus genotyping of SSU rDNA, gdh and tpi genes of the parasite. Detection and differential diagnosis of *Entamoeba* species was done by nested PCR. The overall prevalence of intestinal protozoan parasites among study participants was 48.9%. Overall prevalence of *Cryptosporidium* sp., *G. lamblia* and *Entamoeba* sp. were 23.9%, 12.7% and 20.4% respectively. Genotyping of *Cryptosporidium* sp. revealed 35/81 as *C. hominis*, 2/81 as *C. parvum*, *C. andersoni* (2/81), *C. meleagridis* (1/81) and *C. baileyi* (1/81). For *G. lamblia*, 12 out of 14 were identified as assemblage BIII whilst one each was identified as assemblages AII and BIV. *Entamoeba* isolates were 37/339 *E. histolytica* and 24/339 *E. moshkovskii* whilst 6 were *E. histolytica*/*E. moshkovskii* mixed infections. This is the first report of *C. andersoni*, *C. meleagridis*, *C. baileyi*, *E. moshkovskii*, *G. lamblia* assemblage AII, BIII and BIV in humans in Ghana. Our results suggest that cryptosporidiosis, giardiasis and amoebiasis represent a significant burden in Ghana and of public concern that need urgent attention.

598

THE "BRAIN- EATING" AMOEBA: A QUANTITATIVE ASSESSMENT OF SEASONAL VARIATIONS IN *NAEGLERIA FOWLERI* AND FECAL INDICATOR BACTERIA IN LAKE PONTCHARTRAIN OF LOUISIANA

Frederica G. Lamar[1], Jia Xue[1], Bowen Zhang[2], Siyu Lin[1], Jennifer G. Lamori[1], Samendra P. Sherchan[1]

[1]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States, [2]International Center for Climate and Global Change Research, Auburn, AL, United States

Naegleria fowleri is a free-living, pathogenic amoeba causing primary amoebic meningoencephalitis (PAM), a degenerative brain disorder with a 98% case fatality rate and median death within five days. PAM occurs when *N. fowleri* enters the nose and reaches the olfactory nerve, usually during swimming or sinus irrigation with neti pots. Given Louisiana's two fatal PAM cases in 2011, the goal of our study was to assess the presence of *N. fowleri* in brackish Lake Pontchartrain, which is used extensively by Southeast Louisiana residents for recreational purposes. Furthermore, we aimed to determine seasonal differences and its dependence on specific environmental conditions. We collected 160 surface water samples over a 10- month time period from 10 recreational sites in Lake Pontchartrain. Physical and water quality parameters were measured in situ. Using quantitative polymerase chain reaction (qPCR) methods, we quantified *N. fowleri*, *E. coli*, and *Enterococci*. *N. fowleri* target sequence was detected in 35.4% of the water samples ranging from 11.6 to 457.8 gene copies per 100 ml. *N. fowleri* had statistically significant positive correlations with water temperature (r = 0.62, p-value < 0.01) and *E. coli* concentration (r = 0.64, p-value < 0.01). *E. coli* and *Enterococci* were present in 90.6% and 95.8% of the samples, respectively. Multiple linear regression models confirmed seasonality of *N. fowleri*, *E. coli*, and *Enterococci*. Average concentrations of *N. fowleri* and *E. coli* were significantly higher during the summer than winter, and *Enterococci* concentrations were higher during the winter than summer. *N. fowleri* was widespread at the 10 recreational sites during our sampling period. Our study highlights the persistence of *N. fowleri* in a brackish water environment and its strong relationship with water temperature and *E.coli*. Future research examining subsurface water and whether sediment is a source of *N. fowleri* in the water column will lead to a better understanding of favorable conditions for *N. fowleri*, thus further describing its potential risk to human health.

599

GIARDIA/CRYPTOSPORIDIUM QUIK CHEK ASSAY FOR THE DETECTION OF *CRYPTOSPORIDIUM* DIARRHEA IN CHILDREN IN BANGLADESH

Mamun Kabir[1], Emtiaz Ahmed[1], Biplob Hossain[1], Masud Alam[1], Shahnawaz Ahmed[1], Mami Taniuchi[2], Carol A. Gilchrist[2], Eric R. Houpt[2], A.s.g. Faruque[1], William A. Petri[2], Rashidul Haque[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]University of Virginia, Charlottesville, VA, United States

Cryptosporidium is a major cause of childhood diarrhea. Current modes of cryptosporidiosis diagnosis involve procedures which are costly and require both a well-equipped laboratory and technical expertise. Therefore, a cost effective, user friendly and rapid method for point-of-care detection of *Cryptosporidium* species in fecal samples is desirable. A total of 832 diarrheal stool specimens collected from 200 children aged below two years were tested by *Giardia/Cryptosporidium* QUIK CHEK®, ELISA and qPCR to compare the performance of the individual techniques. We also tested the presence of other diarrheal pathogens in qPCR positive samples with a TaqMan Array Card (TAC) to assess whether *Cryptosporidium* was the sole causative agent for the diarrheal episodes. Of 832 samples, 4.4% were found positive for *Cryptosporidium* by QUIK CHEK®, 3.6% by ELISA and 8.8% by qPCR. Using "TAC attributed *Cryptosporidium* diarrhea" as the gold standard, the sensitivities of QUIK CHEK®, ELISA and qPCR were 92.3%, 71.8% and 100% respectively; while the specificities were 97.1%, 94.3% and 0% respectively. Analysis of the qPCR positive and QUIK CHEK® negative samples by TAC identified other enteropathogens as more likely than *Cryptosporidium* to be the causative agents of diarrhea. QUIK CHEK® was more sensitive and specific than ELISA and allowed for point of care use for the diagnosis of *Cryptosporidium* diarrhea. While qPCR detected *Cryptosporidium* in more samples than QUIK CHEK®, most of these were instances of qPCR detecting small quantitites of *Cryptosporidium* DNA in a diarrheal episode caused by another enteropathogens/ We concluded that QUIK CHEK® was comparable in sensitivity and superior in specificity to qPCR for the diagnosis of *Cryptosporidium* diarrhea.

600

IS *ENTAMOEBA DISPAR* PATHOGENIC?

Kimberly Mergen, Noel Espina, Susan Madison-Antenucci
New York State Department of Health, Albany, NY, United States

Entamoeba dispar is generally considered non-pathogenic while *E. histolytica* is known to cause human infections. Because the two species cannot be distinguished based on morphological characteristics, the Wadsworth Center Parasitology Laboratory within the New York State Department of Health, developed a real-time PCR assay to distinguish between the two species. Over 250 specimens were tested using stool samples received in 2017 and 2018. Interestingly, a majority of submitted specimens contained *E. dispar* and not *E. histolytica.* Only 5.3% of the cases submitted were positive for *E. histolytica* whereas a much greater proportion, 83.3%, were positive for *E. dispar.* Samples that were positive for *Entamoeba* based on microscopy but negative for both *E. dispar* and *E. histolytica* by molecular analysis account for 11.4% of specimens tested. Because the specimens were collected from individuals seeking medical attention for intestinal illness, our results suggest that the pathogenicity status of *E. dispar* should be revisited.

601

IMPACT OF *GIARDIA* ON INTESTINAL MICROBIOTA AND VITAMIN B12 BIOSYNTHESIS IN PRESCHOOL CHILDREN

Rojelio Mejia[1], Ashish Damania[2], Philip Cooper[3], Barton Slatko[4]
[1]Baylor College of Medicine, Houston, TX, United States, [2]Ashish Damania, Houston, TX, United States, [3]Universidad Internacional De Ecuador, Quito, Ecuador, [4]New England BioLabs, Inc, Ipswich, MA, United States

Depending on the species, parasites can disrupt intestinal bacterial flora affecting nutritional status. Using multi-parallel quantitative real-time PCR (qPCR) and whole genome sequencing analysis for bacterial microbiota and *Giardia lamblia* (assemblage A or B). Stool samples were collected longitudinally from 100 children sampled at 3 and again at 5 years old from Ecuador. Uninfected versus *Giardia* only groups were analyzed for microbiome and metagenomic differences and compared to growth delays. For *Giardia* only infected children, longitudinal sequencing data showed an increase in bacterial biodiversity compared to those uninfected that correlated with increasing *Giardia* burden (Shannon alpha diversity (*Giardia* only 2.7; uninfected 2.1, $p = 0.0317$; Spearman $r = -0.5491$, $p = 0.0244$)) within each age group but showed a significant increase in diversity from paired 3 to 5-year-old children ($p = 0.01838$). In *Giardia* only infections, microbiome taxonomy shifted to *Prevotella copri*, with the degree of shift related to the intensity of infection compared to uninfected (43.2 % versus 12%, $p = 0.012$). Metagenomic analysis of the bacterial microbiota showed the proportion of vitamin B12 producing bacteria (*Bifidobacteriaceae*) were diminished in the *Giardia* assemblage A group infected group compared to the non-infected group and also assemblage B group ($p = 0.038$). Specific genes in the cobalamin synthesis pathway (cobinamide kinase, ATP corrinoid adenosyltransferase) were proportionally decreased with the burden of *Giardia* infection ($p < 0.05$). Z-scores for both height and head circumference was decreased in the *Giardia* infected children at both time points ($p < 0.05$). The rate of decreased growth was larger in children infected with *Giardia* at both 3 and 5 years old ($p < 0.05$). Our data provide evidence for an effect of parasitic infections allowing permissive growth of anaerobic bacteria such as *Prevotella* and *Bifidobacteriaceae*, altering capacity of vitamin B12 biosynthesis and impacting growth in children.

602

VALIDATION OF A MULTIPLEX REAL-TIME PCR GASTROINTESTINAL PARASITE PANEL

Jason Kwan[1], Rachel Lau[2], Filip Ralevski[2], Andrea K. Boggild[3]
[1]McMaster University, Hamilton, ON, Canada, [2]Public Health Ontario, Toronto, ON, Canada, [3]University of Toronto, Toronto, ON, Canada

Microscopy is the conventional method for identification of gastrointestinal parasitic pathogens in fecal samples, however, it presents numerous challenges including high technical expertise and prolonged turnaround time. Molecular methods provide higher throughput and potentially higher sensitivity and specificity. We sought to validate a commercial multiplex parasitic real time PCR panel detecting 6 protozoal pathogens: *Blastocystis hominis (Bh)*, *Cryptosporidium*, *Cyclospora*, *Dientamoeba fragilis (Df)*, *Entamoeba histolytica (Eh)* and *Giardia lamblia (Gl)* in unpreserved fecal specimens submitted for diagnostic parasitology. We analyzed 192 specimens, including 84 banked, frozen known positive specimens containing all of the targeted pathogens (8 *Bh*, 13 *Crytosporidium*, 13 *Cyclospora*, 10 *Df*, 15 *Eh*, 13 *Gl* and 12 mixed protozoal infections) and 108 fresh specimens randomly selected from our prospective parasitology submissions, including 4 *Bh*, 3 *Df*, 2 mixed infections, and 99 microscopy negatives. DNA extraction and PCR were setup with the Hamilton Starlet automated platform and Seegene's extraction and PCR kits. Microscopy was the reference standard for all organisms with stool ELISA as an additional reference assay for *Eh*. Sensitivity, specificity, positive predictive and negative predictive values of the enteric multiplex were: 96%, 90%, 60%, and 99% for *Bh*; 100% for *Cryptosporidium*; 79%, 100%, 100%, and 98% for *Cyclospora*; 86%, 86%, 86%, and 98% for Df; 81%, 100%, 100%, and 98% for Eh; and, finally, 94%, 85%, 85% and 99% for *Gl*, respectively. The platform had high sensitivity for *Bh*, *Cryptosporidium* and *Gl*, but suboptimal sensitivity for detection of *Cyclospora, Df*, and *Eh*. Low positive predictive value for *Bh* may reflect challenges to accurate microscopic identification of this organism. Negative predictive value was excellent for all targets, supporting that the platform accurately determines true negatives. This particular enteric multiplex platform provides a useful diagnostic tool for *Bh*, *Cryptosporidium,* and *Gl*. Further optimization of the assay is required for *Cyclospora*, *Df,* and *Eh* prior to clinical use.

603

GENETIC DIVERSITY OF *TRICHOMONAS VAGINALIS* ISOLATES IN WESTERN AUSTRALIA, THE NORTHERN TERRITORY OF AUSTRALIA AND SOUTHERN GHANA

Daniel S. Squire, Alan J. Lymbery, Andrea Paparini, Frances Brigg, Rca Andrew Thompson
Murdoch University, Western Australia, Australia

Genetic diversity of *Trichomonas vaginalis* among regional populations has become more evident in studies over the last decade, with increasing cases of treatment failures and variable clinical presentations. We applied next generation-multilocus sequence typing (NG-MLST), comprising seven single-copy housekeeping genes to genetically characterize isolates of *T. vaginalis.* We examined one hundred and seventy-six archival and recently sampled *T. vaginalis* isolates from Western Australia, the Northern Territory and female patients visiting selected health care facilities in Southern Ghana, to assess the level of intra- and inter-population genetic diversity of *T. vaginalis* in these regions. Twenty-two zero-radius operational taxonomic units (ZOTUs) and 106 sequence types (ST) were distinguished among 176 isolates, suggesting diverse *T. vaginalis* populations within the three geographical regions. Each characterized locus comprised more than one allele and nucleotide diversity for the loci based on pairwise difference averaged 0.0175 differences/site. The number of different alleles for each locus ranged from 2 to 8. Eleven multiple infections with different genotypes were found among 6% of the samples, mostly those from Ghana. ZOTU diversity was greater among isolates from Ghana and one

novel *T. vaginalis* genotype was found in 1% of isolates from Ghana. We discuss how this genetic variation may affect clinical presentation and treatment of *T. vaginalis* infections.

604

PEDIATRIC CRYPTOSPORIDIOSIS IN SUB-SAHARAN AFRICA: GAPS IN ACTIONABLE GUIDANCE FOR CLINICAL MANAGEMENT AT THE BEDSIDE

Ingrid Chen[1], Ujjini Manjunatha[2], Roly Gosling[1], Thierry Diagana[2], Jonathan Spector[2], Paul Kelly[3]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Novartis Institute of Biomedical Research, Emeryville, CA, United States, [3]University of Zambia School of Medicine, Lusaka, Zambia

Cryptosporidium has emerged as a major contributor to pediatric diarrhea-associated harm in sub-Saharan Africa (SSA), accounting for an estimated 3 million cases and 125,000 deaths annually in children aged 0-24 months. Despite the high disease burden, it is unclear if frontline health workers in endemic settings are adequately equipped with knowledge and skills to detect and treat cryptosporidiosis at the bedside. We sought to understand what guidance is available for clinical management of this parasite in young, non-HIV infected children in SSA through analyses of four commonly used resources: published literature, World Health Organization (WHO) guidelines, national Standard Treatment Guidelines (STGs), and Essential Medicine Lists (EMLs). Inclusion criteria were materials that were developed or updated in the past 10 years. When relevant, we investigated for specific discussion of nitazoxanide, the only approved therapy for *Cryptosporidium* (acknowledging its clinical efficacy is variable, especially in malnourished children). Systematic review of Embase, Biosis, and Medline databases identified 528 unique articles that examined cryptosporidiosis in Africa, but only 20 discussed clinical diagnostics (15 articles) or therapeutic approaches (5 articles). WHO pediatric and malnutrition guidelines did not address *Cryptosporidium* as a cause of acute diarrhea in young children without HIV. We searched for STGs from 54 countries in SSA and reviewed guidelines from 15 countries that were retrievable online; none described specific guidance for cryptosporidiosis diagnosis or treatment. Finally, we reviewed EMLs from WHO and 24 SSA countries; only one (Zambia) listed nitazoxanide. Our study suggests that the epidemiologic discoveries revealing cryptosporidiosis to be an important diarrheal pathogen have yet to be translated to actionable guidance that could help practitioners advance population health. To improve survival, global stakeholders will need to empower health workers with effective tools to execute a paradigm shift in the way diarrheal illness is diagnosed and treated in young children in SSA.

605

GENETIC DIVERSITY OF *CRYPTOSPORIDIUM* IN A BANGLADESHI COMMUNITY

Carol A. Gilchrist[1], James A. Cotton[2], Cecelia Burkey[1], Tuhinur Arju[3], Allissia Gilmartin[1], Ye Lin[1], Emtiaz Ahmed[3], Kevin Steiner[1], Masud Alam[3], Shahnawaz Ahmed[3], Sultan Uz Zaman[3], Guy Robinson[4], Mamun Kabir[3], Mandy Sanders[2], Tahmeed Ahmed[3], Rachel M. Chalmers[4], Jennie Z. Ma[1], Rashidul Haque[3], A.s.g Faruque[3], Matthew Berriman[2], William A. Petri[1]

[1]University of Virginia, Charlottesville, VA, United States, [2]Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom, [3]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [4]Cryptosporidium Reference Unit, Public Health Wales Microbiology, Singleton Hospital, Swansea, United Kingdom

Cryptosporidiosis is one of the top 5 causes of diarrhea in children < 2 years in age from low-income countries. Between June 2014 to 2017 disadvantaged children were enrolled at birth at one of two study locations in Bangladesh (urban Mirpur: 231; rural Mirzapur: 254). During the study period *Cryptosporidium* infections were identified at the urban (240) and rural (138) sites. *C. hominis* was prevalent at the urban location whereas *C. meleagridis* was most common at the rural site. *C. hominis* and *C. meleagridis* are both transmitted by the fecal-oral route however the *C. hominis* parasite source is human whereas that of *C. meleagridis* is usually avian. Both these pathogens can be transmitted via contaminated water but infections increased only at the urban location during the monsoon season. We both gp60 genotyped and sequenced high burden parasites. In 32 samples >80% of the genome was covered with a depth of > 50X, sufficient depth to detect the SNPs present in an intra-host parasite population arising from a single infecting oocyst. 36,780 SNPs varied between the Bangladesh *C. hominis* isolates however only 1,582 occurred with a frequency > 20% (common SNPs). No linkage was observed between common SNPs if they were separated by more than 300 bp in the genome indicating that in Bangladesh parasites recombination was frequent. It was not therefore surprising that the genome clusters did not necessarily reflect the *gp60* genotype. Several hypervariable regions encoding membrane or secreted proteins were identified and the Tajima's D score was computed to confirm that variability was due to unusual selective pressure. As expected the hypervariable gp60 gene was picked out - other regions spanned the Cops-1, cgd8_690 and secreted SKSR family protein and two members of the insulinase family. Both non-synonymous changes in the encoded amino acids, internal deletions and the premature termination of some ORF occurred. Yet to be determined is if the regions of genomic diversity identified here are responsible in part for the high rate of reinfection, seasonality and varied clinical presentations of cryptosporidiosis in this population.

THE *THEILERIA PARVA* GENE CATALOG

Olukemi O. Ifeonu[1], Nicholas Palmateer[1], Kyle Tretina[1], Donald P. Knowles[2], Vish Nene[3], Claudia Daubenberger[4], Richard Bishop[2], Joana C. Silva[1]

[1]Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Department of Veterinary Microbiology and Pathology, Washington State University, Pullman, WA, United States, [3]Vaccine Biosciences, International Livestock Research Institute, Nairobi, Kenya, [4]Swiss Tropical and Public Health Institute, University of Basel, Basel, Switzerland

Theileria parva is a protozoan parasite that causes East Coast Fever (ECF) in cattle, killing over a million animals a year, and resulting in significant economic loss in the 12 countries in central, southern and eastern Africa where ECF is endemic. Currently, the only effective vaccine against *T. parva* is a live, multi-strain vaccine administered through an "infection and treatment method" (ITM) approach, which has several drawbacks, perhaps the most critical of which are standardization of vaccine production and the fact that cattle immunized through ITM become asymptomatic carriers. The importance of securing food resources in Africa has created an incentive to develop next generation of vaccines against ECF. To facilitate this goal, we generated a publicly available online resource named *Theileria parva* Gene Catalog (TpGC) that allows the user to prioritize *T. parva* proteins as vaccine candidates based on a variety of properties inferred from the amino acid composition of each protein. These properties are based on the recently updated *T. parva* genome annotation, and include physical attributes, antigenic potential and expression data. Also included are estimates, for each protein, of non-synonymous polymorphism in *T. parva* isolates from cattle and African cape buffalo, an asymptomatic reservoir of the parasite. Polymorphism estimates are based on whole genome sequence data we generated for 25 *T. parva* isolates from cattle and 28 others derived from buffalo and buffalo-associated *R. appendiculatus* ticks. Here, we evaluate the potential of polymorphism data for the identification of novel antigens. We hypothesize that firstly known antigens are frequently highly enriched for among proteins with the highest amount of non-synonymous polymorphism and, secondly, that the set of polymorphic proteins is highly enriched for genes encoding secreted and GPI-anchored proteins, presumably as a result of selection imposed by the host or tick vector.

DETECTION OF *URBANORUM SPP.* EMERGING MICROORGANISM BY AUTOFLUORESCENCE IN WET MOUNT COMPARED TO EXAMINATION WITH SALINE SOLUTION AND LUGOL IN HUMAN FECAL SAMPLES. NATIONAL INSTITUTE OF CHILD HEALTH, LIMA- PERU; APRIL TO OCTOBER 2017

Rito Zerpa[1], Jenny Alvarado[2], Rosario Esquivel[2], Nora Reyes[1]

[1]Instituto de Medicina Tropical, Lima, Peru, [2]Instituto Nacional de Salud del Niño, Lima, Peru

In the world literature and especially in Latin America, autofluorescence of *Urbanorum spp*., an emerging microorganism that causes diarrhoea in humans, has not yet been reported. Detection routinely is performed in wet assembly using saline solution and lugol with microscope light. Our objective was to use the autofluorescence of *Urbanorum spp.* in human fecal samples for laboratory diagnosis. 200 human fecal samples from the National Institute of Child Health were studied. They were received for routine parasitological diagnosis. Before discarding, wet mount and observation were performed using a fluorescence microscope with a blue excitation filter (length of wave = 450-490 nm) with 20X and 40X objectives to observe the autofluorescence of *Urbanorum spp.* At the same time, parasitological techniques with saline solution and lugol were used wet mount with 10X and 40X objectives of the light microscope. Autofluorescence of *Urbanorum spp.* - yellowish green color and size of 80-100um- was observed in 21/200 cases (10.5%), and 21/200 using saline solution and lugol, giving a 100% concordance; microorganism images are presented in microphotographs. Autofluorescence of *Urbanorum spp* facilitates laboratory diagnosis compared to saline solution and lugol techniques in wet mount. Autofluorescence, which is reported for the first time in this study, would be very useful to detect the presence of the emerging microorganism.

608

URBANORUM SPP. MICROORGANISM EMERGING IN HUMAN FECAL SAMPLES FROM THREE PERUVIAN HEALTH INSTITUTIONS, FROM OCTOBER 2017 TO MARCH 2018

Rito Zerpa[1], José María Guevara G[2], Flor de María Charca[3], Elsa Oré[3], Carmen Quispe[3], Javier Soto[4], Ana Huamán[1], Andreas Mühlbach[5], Luis Allcahuamán[6], Miguel Kuyoshi[7], Juan Castro[8]

[1]Instituto de Medicina Tropical, Lima, Peru, [2]Hospital Nacional Daniel A. Carrión, Callao, Peru, [3]Instituto Nacional de Salud del Niño, Lima, Peru, [4]Instituto Materno Infantil San Bartolomé, Lima, Peru, [5]Centro de Investigaciones Tecnologicas, Biomedicas y Medioambientales, Callao, Peru, [6]Universidad Peruana Cayetano Heredia, Lima, Peru, [7]Faculty of Medicine, San Marcos University, Lima, Peru, [8]Universidad Científica del Sur, Lima, Peru

Urbanorum spp. has been reported as an emerging microorganism in Colombia, Ecuador, Venezuela and Mexico and recently in Peru, with 4 reports from 2016 to 2017; described as a protozoon similar to amoebas, presenting rounded or oval shapes of 80-100um that emit "pseudopods", found in coproparasitic exams of patients, adults and children, with prevalences of 0-16%. Research on *Urbanorum spp.* in human fecal samples in three health institutions of Lima, Peru: National Institute of Child Health (INSN), Maternal and Child Institute of San Bartolomé (IMISB) and Daniel A. Carrión National Hospital (HNDAC) of Callao. Descriptive, transversal study. Before discarding, the fecal samples for routine parasitological diagnosis in the Microbiology Services of said institutions were collected by adding physiological saline solution v / v and transferred to the Institute of Tropical Medicine Daniel A. Carrión, Universidad San Marcos University (UNMSM), Lima, Peru, for the research of *Urbanorum spp.*, between October 2017 and March 2018. 2,800 samples were processed: 1,800 from the INSN, 500 from the IMISB and another 500 from the HNDAC, Callao; Samples were processed with saline solution and lugol. *Urbanorum spp.* was found in 556 of 2800 samples (20%); with 306 / 1,800 (17 %) at INSN, 105/500 (21%) at IMISB and 145/500 (29%) at HNDAC. *Urbanorum spp.* was found in a greater percentage (29%) in fecal samples of the HNDAC of Callao, followed with 21% in the IMISB and 17% in the INSN. Given the high percentage found, it is necessary to perform microbiological studies including electron microscopy, immunology, molecular biology, clinical epidemiology, pathogenesis, treatment and control of this emerging microorganism, find the reasons for the percentage difference between Lima and Callao.

INVESTIGATION OF NEURORETINAL INFILTRATION BY *TOXOPLASMA GONDII* IN A MOUSE MODEL OF OCULAR TOXOPLASMOSIS

Dong-Hee Kim, **Hyun Beom Song**

Department of Parasitology and Tropical Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea

The conversion of tachyzoites into bradyzoites is a way for *Toxoplasma gondii* to establish a chronic and asymptomatic infection and achieve lifelong persistence in the host. The bradyzoites form tissue cysts in the retina, but not much is known about the horizontal distribution of the cysts or their interactions with glial cells in the retina. A chronic ocular toxoplasmosis model was induced by per oral administration of *T. gondii* Me49 strain cysts to BALB/c mice. Two months after the infection, retinas were flat-mounted and immunostained to detect cysts, ganglion cells, Müller cells, astrocytes and microglial cells, followed by observation under fluorescence and confocal microscope. The horizontal distribution showed a rather clustered pattern but the clusters were not restricted to certain location of the retina. Axial distribution was confined to the inner retina, mostly in ganglion cell layer or the inner plexiform layer. Both ganglion cells, a type of retinal neurons, and Müller cells, predominant retinal glial cells, could harbor cysts. The cysts were spatially separated from astrocytes, the most abundant glial cells in the ganglion cell layer, while close spatial distribution of microglial cells were observed in two thirds of retinal cysts. In this study, we demonstrated the retinal cysts were not evenly distributed horizontally and were confined to the inner retina axially. Both neurons and one type of glial cells could harbor cysts and topographic analysis of other glial cells suggests role of microglial cells in chronic ocular toxoplasmosis.

SCHISTOSOMIASIS CONTROL IN EGGUA: COMBINING HEALTH EDUCATION, DRUG TREATMENT AND ALTERNATIVE WATER SOURCE

Chiaka Anumudu[1], Henrietta Awobode[1], Adewale Adebayo[1], Olugbenga Onile[2], Promise Ajide[1], John Osundiran[1], Precious Olayinka[1], Adebanke Ogunyinka[1], Raphael Isokpehi[3]

[1]University of Ibadan, Ibadan, Nigeria, [2]Elizade University, Ilara-Mokin, Nigeria, [3]Bethune Cookman University, Daytona Beach, FL, United States

This was a pilot intervention study for health communication in schistosomiasis control. A critical aspect of schistosomiasis disease control is the role of health communication for behavioural changes.In 2016, we used Focus Group Discussions, (FGD) to find out what the people living in Eggua Ward know about schistosomiasis after close to 10 years of research in Yewa North Local Government Area, and what sort of health initiatives they expect from the stakeholders in schistosomiasis control (the local and state governments, researchers, NGOs, etc). We then conducted a health education campaign using pamphlets, radio, town-crier announcements and seminars for the community. Trainings were also conducted for teachers, community health workers and officials of the State Schisto Control Programme. At the same time, anyone who was tested and positive for the disease was treated with praziquantel. A bore hole was provided for the community. The knowledge of the correct natural history of the disease was acquired by the people, and there was an increased awareness of how their behavior can impact the transmission

of the disease in their village. Prevalence was slightly lower a year later, but there were cases of reinfection. Open defeaction continued mostly unabated, since most people had no latrines. Indeed, we are aware that any behavioural change achieved may be temporary, and some even unfeasible, as long as there are limitations on infrastructural changes.

611

ADAPTIVE STRATEGIES FOR SCHISTOSOMIASIS CONTROL AND ELIMINATION IN HETEROGENEOUS ENVIRONMENTS: A MODEL-BASED ANALYSIS OF PUBLIC HEALTH GUIDELINES

David Gurarie[1], Charles H. King[1], Nathan C. Lo[2], Emily Li[1]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]Stanford University, Stanford, CA, United States

Schistosoma infection is endemic in many parts of the world, and WHO has made its control and elimination a high priority. Recently, a large-scale trial and multiple country control-surveillance programs have been conducted, including SCORE (Schistosomiasis Consortium for Operational Research and Evaluation, U. Georgia) and SCI (Schistosomiasis Control Initiative, Imperial College, London). The 5-year SCORE trial explored several control strategies with different target age groups and drug regimens. However, these studies have yielded mixed results in seemingly similar settings; whereas some communities achieved substantial gains, others deemed "hotspots" were highly resilient to the effects of mass drug treatment (MDA). We developed a simulation-based study with dynamic transmission models to investigate how complex environmental and life cycle aspects (e.g. host demographics, in-host biology, transmission environment, and host-vector interactions) can drive the differential response to MDA seen in SCORE and country programs, and compared new adaptive decision making strategies (updating strategy based on initial treatment response) to current WHO guidelines and targets. The models were fit to datasets from SCORE villages and related studies. Our model-based analysis revealed many key predictors of response to MDA, including those of intermediate snail host biology and infection dynamics. The new set of adaptive strategies achieved more rapid control of schistosomiasis with fewer treatment rounds compared to WHO guidelines. Finally, an adaptive strategy that included an integrated approach (MDA + snail control with molluscicide) was found to be optimal in control. This study found that across a broad range of host communities and environmental settings that adaptive decision making with integrated strategies (MDA + molluscicide) could achieve control of schistosomiasis in shorter time periods compared to current WHO guidelines and targets. Future policy decisions should consider adopting adaptive decision making to address "hot spot" settings.

612

SCHISTOSOMA MANSONI INFECTION IS DYNAMIC AND INCOMPLETELY TREATED WITH SINGLE-DOSE PRAZIQUANTEL IN ADULT WOMEN

Pallavi Mishra[1], Soledad Colombe[1], Ndalloh Paul[2], Jane Mlingi[2], Inobena Tosiri[2], Philibert Kashangaki[3], Honest Nagai[3], Claudia J. de Dood[4], Paul L. Corstjens[4], Pytsje Hoekstra[4], Joanna Gao[1], Julius Mngara[3], Govert J. van Dam[4], Jennifer A. Downs[1]

[1]Weill Cornell Medicine, New York, NY, United States, [2]Bugando Medical Centre, Mwanza, United Republic of Tanzania, [3]National Institute for Medical Research, Mwanza, United Republic of Tanzania, [4]Leiden University Medical Center, Leiden, Netherlands

Current WHO guidelines recommend annual mass praziquantel treatment in areas with high schistosome endemicity. Yet little is known about incidence and reinfection rates after treatment in women with daily exposure to schistosomes. We sought to quantify incident *Schistosoma mansoni* infections in this population and characterize their response to praziquantel treatment. We followed a cohort of rural women in northwest Tanzania starting in July 2017. Every 3 months, women provided urine, stool, and serum for schistosome testing and completed a survey. Microscopic examinations for ova were performed on filtered urine and Kato Katz slides, and serum Circulating Anodic Antigen (CAA) was quantified. We defined schistosome positivity as either positive microscopy or CAA >30 pg/mL. We enrolled women who were positive for *S. mansoni* ova and uninfected women. Those with schistosome infections were given praziquantel. We calculated cumulative incidence and incidence rates for schistosome infection. At initial screening, 150/349 (42.3%) women were schistosome positive. We enrolled 43 egg positive and 54 uninfected women. 31/43 (72%) and 43/54 (80%) respectively were followed up at 3 and/or 6 months. Of the *S. mansoni* infected group, 9 were CAA positive at 3 months and 7 were CAA positive at 6 months, including one who had been negative at 3 months. In total, 10/31 women with *S. mansoni* infection at baseline had infection at 3 or 6 months (32.3%). In addition, 3/43 women (7.0%) who were originally uninfected were newly CAA positive at 3 or 6 months. Only 2 women were egg positive at follow-up. Overall, the incidence rate was 3.5 per 100 person-months. No significant demographic differences were found between women who were successfully treated and those with recurrent or persistent infection. Our data suggests that annual praziquantel treatment is insufficient for nearly a third of women in endemic communities. Furthermore, microscopy lacks adequate sensitivity to evaluate efficacy of treatment in this population. The cohort is ongoing, and our work suggests that further investigation into treatment efficacy and reinfection rates in adults is warranted.

613

PROTEASE-BASED BIOREPORTERS FOR THE DETECTION OF *SCHISTOSOMA CERCARIAE*

Alexander J. Webb[1], Fiona Allan[2], Richard Kelwick[1], Kirsten Jensen[1], Michael Templeton[1], Paul Freemont[1]

[1]Imperial College London, London, United Kingdom, [2]Natural History Museum, London, United Kingdom

The parasitic infection Schistosomiasis affects over 200 million people worldwide. The causative agents are fluke worms of the *Schistosoma* genus, and infection only occurs when the cercarial larvae penetrate the hosts' skin barrier. To facilitate this, the cercariae secrete a serine protease called elastase, which degrades elastin in the skin barrier, enabling the parasite to burrow through the skin. Using a synthetic biology approach, we designed and characterised several modular whole-cell bioreporters that detect *Schistosoma* cercarial elastase activity. Our bioreporters incorporate a cercarial elastase detection system that is based on the specific recognition of its proteolytic activity, and upon detection to produce a bioreporter output that is easy to measure. Here, we report new data on our elastase bioreporter designs. We show how sensitive the bioreporters are in terms of number of cercariae required for detection. We also have additional data and exciting progress to report.

614

EPIDEMIOLOGY OF *FASCIOLA HEPATICA* INFECTION AMONG CHILDREN IN THE ANTA PROVINCE OF CUSCO, PERU

Camille M. Webb[1], Maria L. Morales[2], Martha Lopez[2], Miguel M. Cabada[1]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]Universidad Peruana Cayetano Heredia-University of Texas Medical Branch Collaborative Research Center, Cusco, Peru

Fasciola hepatica is the most widely distributed trematode infection, but half of human infections occur in countries of South America. Most *Fasciola* infections in the community remain undiagnosed. Children are disproportionately affected and develop anemia and under nutrition, which may cause devastating long-term consequences. We conducted a cross-sectional study on the epidemiology of fascioliasis among all children attending pre-school and school in 26 communities of the Anta province (elevation 3,350 meters) in the Cusco region of Peru. Interviews at school and at home collected information on demographics, socioeconomics, medical history, and nutrition. Blood from subjects was tested for

complete cell count, FAS2 ELISA antibodies, and transaminases. Three stool samples per subject were tested with Kato-Katz and Lumbreras rapid sedimentation for parasites. Overall, 2515 children were included, with mean age of 9.6 years and female/male ratio of 0.99. Few children had a history of treatment for anemia (6.4%, 154/2394), under nutrition (4.4%, 105/2,394), and parasites (14.2%, 338/2,388). The median HAZ was -1.45 (IQR: -2.07 – -0.81) and the mean BMI was 17.7 (±2.75). Ten percent (253/2,513) of the participants had one or more tests indicating *Fasciola hepatica* exposure with a range from 0% to 20.4% depending on community. Microscopy was positive in 6.1% (154/2,515) and Fas2 ELISA in 8.4% (211/2,513). The prevalence of chronic infection was 6.1% (154/2,515) and acute infection was 0.8% (19/2,512). *Fasciola* exposure was associated with older age (10.7 years (±3.4) vs. 9.5 years (±3.6), p < 0.01), higher altitude (3,486 meters vs. 3,453, p = 0.01)), and fewer years of education among parents (7.2 vs 7.8 in fathers p=0.02, 5.4 vs 6.3 in mothers, p<0.001). Those living in adobe houses and with higher probability of living in poverty were more likely to have *Fasciola* exposure. Fasciola exposure was not associated with anemia or stunting. The logistic regression analysis showed that age, district, and probability of living in poverty were associated with *Fasciola* exposure.

615

THE BURDEN OF *SCHISTOSOMA MANSONI* AND SAFETY OF PRAZIQUANTEL TREATMENT IN PRESCHOOL AGE CHILDREN FROM WESTERN KENYA

Fredrick O. Rawago, Philip Leakey, Musa Autta, Kennedy Andiego, Isaiah Omondi, Maurice Odiere, Pauline Mwinzi

Kenya Medical Research Institute, Kisumu, Kenya

Despite evidence of significant schistosome infection in preschool-aged children (PSAC), these young children remain excluded in many national mass drug administration (MDA) control programs partly due to paucity of data on the safety of praziquantel in treating these young children. This study therefore determined the burden of schistosomiasis, safety and side effects associated with praziquantel treatment in preschool children aged 1-5 years in western Kenya. The cross-sectional study was conducted between January-August 2017 among 877 children. Stool samples collected on three consecutive days were examined based on duplicate slides for eggs of *Schistosoma mansoni*. All children diagnosed with *S. mansoni* infection were treated with praziquantel (crushed, 40 mg/kg), and any observed or reported drug events documented within 3 days of drug administration. Overall, 181 (20.6%) were infected with *S. mansoni*. Of those surveyed, 115(63.5%), 51(28.2%) and 15(8.3) had low, moderate and heavy intensities of infection, respectively. Of the 181 treated children, 30(16.6%) experienced side effects which included loss of appetite 2 (6.7%), diarrhea 5 (16.7%), fatigue 3 (10%), fever 2 (6.7%), nausea 2 (6.7%), skin rash 4 (13.3), stomachache 8 (26.6%) and vomiting 4 (13.3%) which cleared within 3 days of drug administration. No serious adverse event was reported. Higher *S. mansoni* egg burdens were significantly associated with increased odds of adverse events; moderate infection intensity (OR=2.86 (95%C.I= (1.194, 6.865), P=0.018) and heavy infection intensity (OR=5.945 (95%C.I= (1.81, 19.48), P=0.003). There was no significant association between gender and adverse events. In conclusion, Side effects of praziquantel treatment in PSAC were mild, transient and non-life threatening. Our findings add to the body of evidence indicating the need for a policy change to include PSAC in routine mass deworming control programs.

616

IDENTIFYING INDIVIDUAL RISK BEHAVIORS AND COMMUNITY-LEVEL CONTRIBUTIONS TO REINFECTION WITH *SCHISTOSOMA MANSONI* IN SCHOOL-AGED CHILDREN IN RURAL UGANDA

Suzan C. Trienekens[1], Christina L. Faust[1], Lucy Pickering[2], Fred Beysige[3], Lazaro Mujumbusi[4], Edith Nalwadda[4], Candia Rowel[3], Poppy H. Lamberton[1]

[1]Institute of Biodiversity, Animal Health, and Comparative Medicine, University of Glasgow, Glasgow, United Kingdom, [2]Institute of Health and Wellbeing, College of Social Sciences, University of Glasgow, Glasgow, United Kingdom, [3]Vector Control Division, Ministry of Health, Kampala, Uganda, [4]Medical Research Council, Uganda Virus Research Institute, Entebbe, Uganda

Globally, over 200 million people are infected with *Schistosoma* parasitic helminths, and 400 million are at risk of infection, with school-aged children (SAC) disproportionately affected. The World Health Organization identified Uganda as one of the ten priority countries, highly endemic for schistosomiasis, with an estimated 4 million people infected. The national control programme focusses on mass drug administration (MDA) with praziquantel. However, MDA coverage is only ~37% of SAC and even lower in community members, and hotspots with high prevalence remain. SAC are also found to become rapidly reinfected after treatment and mean infection intensities and associated morbidity continue to be high. My interdisciplinary study uses ethnographic and population genetics in conjunction with standard epidemiological methods to better understand how, why and where certain children in Mayuge District, Uganda become rapidly reinfected with *S. mansoni* after treatment. Results from observational ethnographic appraisals of rapidly reinfected and non-infected children and focus group discussions with parents on water contact attitudes and practices will be presented. These methods help elucidate group and/or individual behaviours that affect children's risk of reinfection and how such risks might be reduced. Concurrently, intermediate snail hosts were collected from key water contact sites identified through the ethnographic appraisals. DNA extracted from *S. mansoni* cercariae shed from these snails will be compared to DNA from *S. mansoni* miracidia found in previously collected samples from SAC and community members to understand better who is driving these reinfections. Analyses of collected data and interpretation of results help provide recommendations for improvements to the national control programme with the aim to reduce *Schistosoma* reinfection in Uganda. I will present preliminary findings from Bugoto from Nov 2017 and March 2018.

617

THE ROLE OF HIGH RISK GROUPS IN MAINTAINING *SCHISTOSOMA MANSONI* TRANSMISSION DESPITE OVER A DECADE OF PRAZIQUANTEL TREATMENT

Christina L. Faust[1], Arinaitwe Moses[2], Andrina Nankasi[2], Fred Besigye[2], Atuhire Alon[2], Moses Adriko[2], Narcis Kabatereine[2], Edridah Tukahebwa[2], Poppy H. Lamberton[1]

[1]Institute of Biodiversity, Animal Health, and Comparative Medicine, University of Glasgow, Glasgow, United Kingdom, [2]Vector Control Division, Ministry of Health, Kampala, Uganda

Hotspots of schistosomiasis persist in Uganda despite over 14 years of mass drug administration (MDA). Although praziquantel is donated for free and recommended for community-wide treatment in high endemic areas, coverage remains low and global supplies are limited. A key question is how to optimize drug distribution to maximise success, reduce transmission and, in particular, reduce rapid reinfection of treated school-aged children (SAC). We describe a cross-sectional survey of a *Schistosoma mansoni* endemic community alongside a longitudinal survey of SAC to identify groups driving reinfection. We recruited 700 SAC (6 – 14 yrs) from

three schools by Lake Victoria, Mayuge District, Uganda, and collected samples 7 times over the 13 month study from March 2017. In Nov 2017, we recruited 103 pre-SAC (9 mths – 5 yrs) and 250 adults (≥15 yrs) from communities to compare infection rates and determine their contribution to transmission. At each timepoint we collected three days of stool for Kato-Katz to estimate infection intensity as eggs per gram (epg) and stored miracidia for genetic analyses with 18 microsatellites. Prevalence, ranging from 61.8% to 88.5% pre-treatment in SAC, and 39.8% in pre-SAC and 50% in adults, was partially explained by treatment history, age, household factors, and geographic location. Following national MDA, infection intensities were significantly higher in pre- SAC (μ = 118.0 epg) and young adults (15-29 yrs; μ = 162.34 epg) compared to SAC (μ = 72.6 epg). High infection intensities were driven by high exposure rates (water contact frequency and duration), ineligibility for MDA, and young adults systematically not offered treatment. We present differences in parasite genetic diversity between risk groups: pre-SAC, SAC, fisherfolk and other community members and results from statistical models exploring demographic, behavioural, and household indicators of parasite infection intensity and genetic diversity of community members. While SAC are often the focus of control programs, we provide genetic evidence that these target groups can be rapidly re-infected by an untreated reservoir of high-risk pre-SAC and young adults.

618

COMPARISON OF STOOL KATO-KATZ AND URINE POINT-OF-CARE ANTIGEN TEST TO DIAGNOSE SCHISTOSOMIASIS INFECTION IN A LOW PREVALENCE ENDEMIC AREA OF KENYA

Rebecca J. Chancey[1], Emmy K. Awino[2], Ryan E. Wiegand[1], Alex Mwaki[2], Alie Eleveld[2], W. Evan Secor[1], Maurice R. Odiere[2]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Safe Water and AIDS Project, Kisumu, Kenya

The Kato-Katz (KK) method to detect *Schistosoma mansoni* infection has limitations for program use. A commercial point-of-care (POC) urine test that detects *S. mansoni* circulating cathodic antigen (CCA) is an attractive potential replacement. In highly endemic areas, KK and POC-CCA estimate a similar prevalence. However, the limited data collected in lower prevalence settings suggest a much higher prevalence estimate when POC-CCA is used compared to KK. We aimed to collect additional data in areas with lower KK prevalence to better define the relationship between POC-CCA and KK measures. We sampled 30 schools at different distances from Lake Victoria for presence of *S. mansoni* using KK and POC-CCA. The number of children tested per school ranged from 69 to 107 with an average of 98 students per school. POC-CCA was measured as negative or positive with visual band intensity results labeled as negative = 0, trace = 0.5, 1+ = 1, 2+ =2 and 3+ = 3. KK prevalence and intensity were based on three stool samples with two slides per sample. Mean eggs per gram and POC-CCA visual band intensity were used as measures of intensity of infection. Nine schools with < 10% prevalence by KK had a median POC-CCA prevalence (95% CI) of 54.2 (36.8, 64.8) with a median visual band intensity of 0.4 (0.3, 0.5). For eight schools with KK prevalence of 10-19%, median POC-CCA prevalence (95% CI) was 60.8 (34.9, 67.6) and median intensity was 0.5 (0.2, 0.7). For six schools with KK prevalence of 20-29%, median POC-CCA prevalence (95% CI) was 59.0 (43.4, 74.7) and median intensity was 0.4 (0.3, 0.5). The remaining seven schools had KK prevalence > 30%; their median POC-CCA prevalence was 64.5 (41.4, 78.2) and median intensity was 0.5 (0.3, 0.7). Using Spearman's correlation coefficient, prevalence as measured by KK and POC-CCA ($r = 0.33$, $p = 0.08$) and intensity ($r = 0.13$, $p = 0.50$) were not correlated. We saw less variation in POC-CCA prevalence measures and visual band intensity scores by KK prevalence than we had anticipated. Additional investigation, including in the context of annual mass drug administration, will be necessary to determine whether POC-CCA can be used for monitoring control programs.

619

NOVEL SCHISTOSOMIASIS EDUCATION PROGRAM DEVELOPED FOR CHILDREN IN THE MAROLAMBO DISTRICT, MADAGASCAR

James M. Penney[1], Jemima Henstridge-Blows[2], Kate Hyde[2], Sheena Cruikshank[2], Cortland Linder[3], Hannah Russell[4], Russell Stothard[5], Stephen Spencer[6]

[1]NHS, Glasgow, United Kingdom, [2]The University of Manchester, Manchester, United Kingdom, [3]NHS, London, United Kingdom, [4]NHS, Reading, United Kingdom, [5]The Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [6]NHS, Bristol, United Kingdom

Improving health education and understanding of schistosomiasis is necessary to reduce transmission rates of this disease. A pilot education programme focussed on disease transmission and prevention in children in an area of Madagascar (Marolambo district) where 45% of children have daily contact with infested water and there is a Schistosoma mansoni infection prevalence of over 90%. This complements a series of prevalence and morbidity studies with treatment provision to this rural region in the East of Madagascar. A novel education programme was developed using the character of 'Scolly', a schistosome, to target understanding of schistosomiasis transmission, symptom awareness and prevention. Interactive teaching methods included a mix of stories, songs, games and theatre. This was delivered to children and adults from six villages. Knowledge, Attitude and Practices (KAP) questionnaires were used pre and post education in 298 children (5-14 years old) to assess understanding of the disease. Significant gaps in knowledge pre education were identified, with only 18% of children correctly identifying praziquantel as treatment. Post-education questionnaires showed consistent improvements in knowledge. Increases were seen in percentages of children able to identify water contact as a transmission mode (from 45% to 79%), showing knowledge of key symptoms (24% to 54%), understanding avoiding infested water as a preventative measure (11% to 37%) and awareness of praziquantel as treatment (18% to 80%). These early results show promising effects of a bespoke education programme on this high-risk population. Further studies with a longitudinal approach via annual research and education based expeditions will continue in 2018. This will assess efficacy and longevity of these novel education methods in improving disease understanding and attendance rates at treatment programmes, and in reducing disease transmission and morbidity.

THE PREVALENCE OF *SCHISTOSOMA MANSONI* INFECTION IN SNAILS IN SALVADOR, BAHIA, BRAZIL

Vanessa S. Zanardi[1], Lúcio M. Barbosa[2], Ronald E. Blanton[3], Fabiano Simões[4], Luciano K. Silva[1], Mitermayer G. Reis[1]

[1]Oswaldo Cruz Foundation, Bahia, Salvador, Brazil, [2]Bahiana School of Medicine and Public Health, Salvador, Brazil, [3]Case Western Reserve University, Cleveland, OH, United States, [4]Zoonotic Control Center, Department of Health, Salvador, Brazil

Human schistosomiasis is a neglected tropical disease transmitted by contact with fresh water contaminated with larvae of the trematode parasite of the genus *Schistosoma* In Brazil, schistosomiasis is still considered a serious public health problem primarily of rural areas, and affects around 7 million people. Bahia state has the second highest prevalence, but constitutes the largest endemic area. Salvador, the state capital, is Brazil's 4th largest city. The occurrence of schistosomiasis is dependent on the distribution of the intermediate snail host of the genus *Biomphalaria*. We evaluated the populations of *Biomphalaria sp* in urban water collections that were previously positive for *S. mansoni* to determine the prevalence of infection, to characterize the parasite populations, and to describe their distribution. We collected 828 *Biomphalaria glabrata*, which were distributed in 12 out of 17 water collections. Morphological identification of snail species was performed observing characteristics of the shell and mantle. Snails were evaluated for *S. mansoni* infection by

repeated light exposure for 30 days and then qPCR with an *S. mansoni*-specific primer. Five snails were positive by classical cercarial shedding, with infection rates of 1.9% and 5.5% in Horta de Saramandaia and Lagoa do IAT, respectively. Non-*Schistosoma* larvae were observed in 2.4% of the snails. They belonged to the genera *Xiphidiocercaria*, *Strigeidae*, *Spirorchiidae* and *Clinostomidae*. qPCR, however, detected *S. mansoni* in 3.4% to 60% of snails. These results demonstrate that *B. glabrata* species are widely distributed in the city of Salvador. The *S. mansoni* positivity rates found in the snails show that there are potential areas with active schistosomiasis transmission and additional surveys should be performed. qPCR technique can be used to complement the light exposition method. Estimates of snail *S. mansoni* prevalence only by light exposure may underestimate the problem.

621

QUANTITATIVE RISK ASSESSMENT OF NOROVIRUS AND ADENOVIRUS FOR THE USE OF RECLAIMED WATER TO IRRIGATE LETTUCE IN CATALONIA

Eloy Gonzales-Gustavson[1], Marta Rusiñol[2], Gertjan Medema[3], Miquel Calvo[2], Rosina Girones[2]

[1]San Marcos University, Jauja, Peru, [2]University of Barcelona, Barcelona, Spain, [3]KWR Watercycle Research Institute, Nieuwegein, Netherlands

Wastewater is an important resource in water-scarce regions of the world, and its use in agriculture requires the guarantee of acceptable risk levels in public health. The presence of fecal bacteria, indicators of contamination, does not correlate with the presence of viruses, which are the main potential health risks transmitted through water. Using viral pathogens as indicators could complement the use of fecal indicator bacteria in the evaluation of water quality. In this study, we characterized the concentration of human adenovirus (HAdV) and norovirus genogroup II (NoV GII), the most important human viruses found in wastewater, in two wastewater treatment plants (WWTPs) that use different tertiary treatments (natural wetland vs conventional UV, Cl and Actiflo treatments) for a year in Catalonia. The main objective of this study was to develop a quantitative microbial risk assessment to estimate the health risk associated with the ingestion of lettuce irrigated with tertiary effluents from these WWTPs. The results show that the disease burden of NoV GII and HAdV for the consumption of lettuce irrigated with tertiary effluent from either WWTP was higher than the WHO recommendation of 10^{-6} DALYs for both viruses. The WWTP with natural wetland showed a higher viral reduction on average (3.9 and 2.8 logs for NoV GII and HAdV, respectively) than conventional treatment (1.9 and 2.5 logs) but a higher variability than the conventional WWTP. Sensitivity analysis demonstrated that the input parameters used to estimate the viral reduction by treatment and viral concentrations accounted for much of the model output variability. The estimated reductions required to reach the WHO recommended levels in tertiary effluent depended mainly on the treatments developed in the WWTPs, and additional average reductions are necessary. The results suggest that the analyzed reclaimed water would require an extra disinfection treatment to achieve acceptable risk in the irrigation of vegetables with reclaimed water.

622

IDENTIFICATION OF EXPOSURES TO PATHOGENS CAUSING GASTROINTESTINAL DISEASE USING A ONE HEALTH APPROACH IN THE GALAPAGOS ISLANDS

Leigh E. Preston[1], Shelby Cummings[1], Gerald Parker[1], Enrique Terán[2]

[1]Texas A&M University, College Station, TX, United States, [2]Universidad San Francisco de Quito, Quito, Ecuador

The rich ecology of the Galapagos Islands draws many tourists and researchers to the locale, but approximately 25,000 Ecuadorians inhabit four of the islands in the archipelago. Hospital data obtained directly from doctors on San Cristobal, Santa Cruz, and Floreana Islands from 2014 indicate that the yearly prevalence of gastrointestinal infections is approximately 30% on each island, but records provided fail to identify specific pathogens causing disease. Previous research has revealed that fresh water sources in the Galapagos Islands are often contaminated by saltwater and human waste. Researchers have also isolated many pathogens in animals on the islands that can be transmitted to humans. We hope to provide more conclusive data on the pathogens causing diarrheal disease on these islands, and the probable sources of contamination. Data from hospital laboratory results of fecal sample evaluations and approximate location of residence of patients consulting the hospital physicians for the last year (May 2017 – May 2018) will be collected. This information will be entered in to ArcGIS in order to identify hotspots of gastrointestinal disease. Once the cases have been entered into the GIS software, water, soil, and animal fecal samples will be collected from areas with high prevalence of disease to attempt to identify sources of contamination. These samples will be analyzed with Next Generation Sequencing techniques to determine if the soil and water samples are contaminated, and with what organism they are contaminated. Animal fecal samples will be analyzed with standard fecal float techniques to determine if parasitic organisms colonize the animals, and with which organism animals are colonized. We are in the beginning stages of this research project, and expect our results to align with previous research, but we expect to provide a more defined model of the transmission cycle between animals, the environment, and the native population of humans on the Galapagos Islands. We expect to have preliminary results by the time of the annual meeting in late October.

623

IN VITRO EVALUATION OF ANTI-SNAKE VENOM PROPERTIES OF THE ETHANOLIC EXTRACTS FROM *ANNONA SENEGALENSIS* (PERS) AND *CINNAMOMUM ZEYLANICUM* (BLUME)

Sylvester Kaminta[1], **Daniel Boamah**[1], Oksana Debrah[1], Abraham Quarcoo[2], Mark Ofosuhene[3], Irene Ayi[3], Heroin Blagogee[1], Nana O. Boakye[3], Salomey Acheampong[1], Borge Leth Frempong[1], Dominic A. Edoh[1], Abraham K. Annan[3]

[1]Center for Plants Medicine Research, Mampong, Ghana, Mampong, Ghana, [2]Accra Technical University, Accra, Ghana, [3]Noguchi Memorial Institute for Medical Research. University of Ghana, Legon, Accra, Ghana

Snakebites cause serious health problems globally and mostly in poor rural communities in sub-Saharan Africa and South Asia resulting in about 20,000 deaths out of about 1,000,000 cases per year. Many more of its victims are left permanently disabled or disfigured. The clinical management of snake envenomation is mainly by the use of anti-venoms (anti-venin) which are in most cases specific for particular snakebites (monovalent) or in some cases for a number snake bites (polyvalent). It is well known that anti-venoms are not for treatment of local tissue damage which contributes to the high morbidity and mortality rates associated with snakebites. Anti-venom sera are also expensive and not readily available in remote farming communities where there is much demand. It is important that an alternative readily available and cheaper source of anti-snake venom agent be developed. In this work, the anti-snake venom properties of ethanolic leaves extracts of *Annona senegalensis* and *Cinnamomum zeylanicum* were evaluated. The anti-coagulation and anti-haemotoxic effects of the extracts were assessed against *E. ocellatus* and *B. gabonica* venom using *in vitro* assays. The results revealed that 50 mg/ml of *A. senegalensis* extract completely inhibited the coagulation activity of *E. ocellatus* venom on citrated human plasma whiles 25 mg/ml of *C. zeylanicum* extract was necessary. Indicating that *C. zeylanicum* extract had much stronger anti-coagulation activity than *A. senegalensis* with respect to *E. ocellatus* venom. On the anti-haemotoxic studies of the extracts, *A. senegalensis* exhibited stronger inhibition concentration (IC_{50}) 1.96 mg/ml against *B. gabonica* venom and 4.48 mg/ml against *E. ocellauts* venom. The *C. zeylanicum* extract had IC_{50} of 13.701 mg/ml against *B. gabonica* and 16.06 mg/ml against *E. ocellauts* venom. Thus, *A. senegalensis* and *C. zeylanicum* have anti-snake venom activities. This

study provides important data on anti-snake venom coagulation and haemolysis properties of ethanolic extracts from *A. senegalensis* and *Cinnamomum zeylanicum,* which is essential for drug discovery in anti-snake drugs development.

624

OUTBREAK INVESTIGATION OF FOOD POISONING AMONG PARTICIPANTS IN A WORKSHOP AT A HOTEL IN KOUDOUGOU, BURKINA FASO, NOVEMBER 2017

Hamadou P. Seogo[1], Cheick S. Compaoré[1], Brice W. Bicaba[1], Hyacinthe E. Sow[1], Denis Yelbeogo[2], Issaka Yameogo[1], Sonia Ouedraogo[1], Sidzabda C. Kompaoré[1], Yacouba Savadogo[1], Isaie Medah[2], Bernard Sawadogo[3]

[1]Directorate of Diseases Control of Burkina Faso, Ouagadougou, Burkina Faso, [2]Ministry of Health Burkina Faso, Ouagadougou, Burkina Faso, [3]West Africa Field Epidemiology Training Program, Ouagadougou, Burkina Faso

On November 7th, 2017, 4 participants of a workshop were admitted in Koudougou's Regional Hospital Center (CHR) for acute diarrhea and vomiting in one hour time. The Hospital staff informed Health authorities and an investigation was conducted to describe the outbreak, identify the source, risk factors and to prevent future outbreaks. We conducted a retrospective cohort study from November 7th to 24th, 2017. We reviewed medical records and interviewed participants and cooks. We defined a case as any person from the workshop in the Hotel with abdominal pain or vomiting and/or diarrhea (≥3 soft stools in 24 hours) between November 7- 8th , 2017. We conducted active search to identify other cases. We collected food and stools specimens for laboratory analysis. We observed food preparation and kitchen sanitation. We analyzed data using Epi Info 7.2. We calculated proportions, relative risks and 95 % confidence interval. Among the 65 attendees, we identified 18 cases (attack rate 27.69%), 67% (12/18) had nausea/vomiting, 61% (11/18) had abdominal pain and 50% (9/18) had acute diarrhea. Median age was 46 years old (range 40-63 years). Median incubation period was 1 hour 30 minutes (range 30 minutes-11 hours 20 minutes). Consumption of cucumbers (RR =1.6 [1.9-2.14]), lettuce leaves (RR = 1.45 [1.11-1.88]), tomato (RR=1.44 [1.06-1.86]) and onions (RR=1.34 [1.01-1.80]) were items significantly associated with the disease. Direct examination of untreated lettuce's leaves isolated lot of vegetative forms of *Balantidium coli* and larvae of *Strongyloides stercoralis*. Cultures of food samples and stools were negative for *Salmonella, Shigella, Vibrion* and *staphylococcus aureus* species. The laboratory was not able to measure toxins. In conclusion, this outbreak was associated with consumption of raw vegetables, possibly by poor hygiene or contaminated by enterotoxin. We recommend hotel to reinforce the kitchen hygiene measures, to sensitize and to train cooks and waiters on food safety.

625

FEASIBILITY AND ACCEPTABILITY OF AN INTERVENTION WITH HAND SANITIZER USE AND RESPIRATORY HYGIENE EDUCATION IN BANGLADESHI PRIMARY SCHOOLS

Debashish Biswas[1], Katherine Roguski[2], Makhdum Ahmed[3], Fahmida Chowdhury[1], Shahana Parveen[1], A. Danielle Iuliano[2]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]The Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]University of Texas MD Anderson Cancer Center, Houston, TX, United States

Transmission of respiratory pathogen among schoolchildren is common. Handwashing has been shown to decrease infections; however, it is often a challenge in Bangladeshi schools due to limited supply of soap and water. We evaluated the feasibility and acceptability of hand sanitizer in schools to promote hand hygiene. During Jun-Sep 2015, we implemented a hand sanitizer intervention with respiratory hygiene education at 12 schools in Dhaka (5,077 students). Both students and teachers of the study schools received hand sanitizer with hygiene education and were asked to use hand sanitizer at specific times each day while at school. We provided teachers with training about behavior change for students, and both teachers and students received training about hand sanitizer use and proper cough etiquette. We conducted interviews with 12 purposively selected teachers from six of the 12 schools to ask about experiences with the intervention. We also conducted six group discussions with students across all grades to understand their experiences with the intervention (48 students). At the end of the 10-week intervention period, most children had knowledge of the importance and benefits of hand and respiratory hygiene and recalled intervention messages. During the group discussion, children reported that if they did not wash their hands, germs could transmit to their friends. Students also reported that covering their mouth and nose while coughing and sneezing was very easy to practice and might protect classmates from germs. Teachers reported that it was easy to provide intervention messages since these were delivered in conjunction with regular hygiene classes. The majority of teachers thought the intervention was feasible but anticipated problems continuously procuring hand sanitizer for the primary schools. Two schools agreed in principle to buy hand sanitizer while the other ten requested hand sanitizer from the government. This school-based intervention was found to be acceptable and feasible for students in the short term; however, additional studies are needed to understand the sustainability, uptake and impact of such interventions.

626

DETECTION OF *SALMONELLA TYPHI* AND *S. PARATYPHI A* IN DRINKING WATER AT HYDERABAD, PAKISTAN: AN OUTBREAK AREA OF CEFTRIAXONE RESISTANT TYPHOID FEVER

Furqan Kabir, Fatima Aziz, Adil Kalam, Muhammad Buksh, Shahida Qureshi, Tahir Yousafzai, Sultan Karim, Farah Qamar

Aga Khan University, Hospital, Karachi, Pakistan

The availability of safe drinking water remains a challenge in developing countries, approximately one third of the population in developing countries combating serious morbidities and fatalities due to unsafe drinking water. Water sources in developing countries are often polluted with sewage run off and serve as a reservoir for diseases likes of typhoid and cholera. Typhoid fever continues to be a substantial threat in developing countries, with rates as high as 500-1000/100,000 in countries like Pakistan. An outbreak of ceftriaxone resistant typhoid due to *Salmonella.typhi* reported from Hyderabad, Pakistan last year. For the investigation of the source of the outbreak, water cultures had been performed. However, samples tested by routine water cultures showed high coliform counts but no *S. typhi* or *paratyphi* could be isolated. Later, PCR had performed on the same drinking water samples, n= *115* samples were tested from different drinking water sources in Hyderabad area. DNA extraction from water samples were performed, using Qiagen/ Mobio PowerWater® Sterivex™ DNA Isolation Kit. Briefly, water samples were spiked with 05 µl of PhHV, followed by sterivex filtration, lysis, bead beating, washing and elution. Multiplex real-time PCR for the detection of *S. typhi* and *S. paratyphi A* was performed, as described by Nga etal in 2010. Preliminary results showed an overall positivity of 11.3 % with 6.08%, 1.73% and 3.47 respectively for *S. typhi, S. paratyphi A* and co-infection of *S,typhi* and *S.paratyphi A.* our data suggests that drinking water sources in Hyderabad are the possible sources for transmission of *S. typhi* and *paratyphi.* Further, work on genotype of the organisms from the environment and human infection would close the circle on the role of the water delivery systems as a possible cause of this outbreak.

627

WHO IS SAFE; RICH OR POOR? A SANIPATH MICROBIAL ENVIRONMENTAL EXPOSURE PATHWAY ASSESSMENT IN DHAKA CITY

Nuhu Amin[1], Suraja Raj[2], Jamie Green[2], Mahbubur Rahman[1], Shahjahan Ali[1], Yuke Wang[2], Mohammad Aminul Islam[1], Shimul Das[1], Momenul Haque Mondol[1], Leanne Unicomb[1], Christine L. Moe[2]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Emory University, Atlanta, GA, United States

Rapid urbanization has led to a growing sanitation crisis in urban areas of Bangladesh. Limited data available on bacterial contamination in different environmental pathways in Dhaka slums but no data available from the non-slum settings. We conducted a cross-sectional study to explore the magnitude of fecal contamination in the environment of slum and non-slum areas in Dhaka city. We collected 10 different types of environmental samples [shared latrine walls and door, soil, produce, street food, drain, bathing water, municipal, and non-municipal drinking water (private wells or 20L jar water), surface water and flood] from 10 areas (4 poor, 4 non-poor and 2 floating (bus and train station)) in Dhaka city. From April-June 2017, ten samples of each category (N=[10*10*10])=1000) were collected from each area and analyzed with IDEXX-Colilert-24®and Quanti-Tray/2000 to determine most-probable-number (MPN) of *E. coli*. Among the 10 samples, drain (log_{10} mean=9.0[sd 0.91]), surface water (log_{10} mean=7.3 [sd 1.29]), flood (log_{10} mean=6.7 [sd 0.84]), soil (log_{10} mean=6.1 [sd 1.06]), municipal drinking water (log_{10} mean=2.6 [sd 1.19]), bathing water (log_{10} mean=2.65 [sd 1.09]), street food (log_{10} mean=2.7 [sd 1.12]), and produce (log_{10} mean=2.4 [sd 1.29]) had high *E. coli* contamination. We found similar level of *E. coli* contamination between poor and non-poor areas in latrine swabs, drain, municipal water, produce and street food samples. *E. coli* concentration between slum and non-slum varied for soil (0.70 log_{10} MPN/gram, P = 0.002), bathing water (0.63 log_{10} MPN/100 mL, P = 0.007), non-municipal water (0.61 log_{10} MPN/100 mL, P = 0.002), surface water (1.73 log_{10} MPN/100 mL, P < 0.001), and flood water (0.39 log_{10} MPN/100 mL, P = 0.038) samples. Almost all environmental samples in Dhaka city were highly contaminated with *E. coli*. Level of *E. coli* contamination was similar in both slum and non-slum neighbourhoods for samples which people directly exposed to. Future studies should assess health impacts of environmental contamination among the non-slum and slum communities in Dhaka city.

628

MEASURING IMPACT OF MENSTRUAL HYGIENE MANAGEMENT INTERVENTIONS ON SCHOOLS ATTENDANCE AND WOMEN'S EDUCATION IN BANGLADESH

Farhana Sultana[1], Sarah Sharmin[1], Shifat Khan[1], Md Nuruzzaman[1], Farhana Akand[1], Rezwana Hossain[1], Md Rafiquzzaman[1], Mahbub Sayeed[1], Md. Hafizur Rahman[1], Md. Mesbaul Azam[1], Md. Mahbubur Rahman[1], Leanne Unicomb[1], Peter J. Winch[2], Stephen P. Luby[3]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Johns Hopkins University, Baltimore, MD, United States, [3]Stanford University, Stanford, CA, United States

Girls from low-income countries, including Bangladesh, miss school days from lack of menstrual hygiene management (MHM) facilities. However, weak absenteeism measurement approaches limit the ability to detect impact of school MHM interventions and women's education. In this study, we piloted 4 absenteeism measurement systems: fingerprint device, barcode scanner, records from class captains, and mobile messaging in 2 urban and 2 rural schools from April-May 2017. From each enrolled student we took details for ID cards for the barcode and fingerprint scans. Researchers distributed attendance sheets to class captains, and a local software company sent mobile messaging and recorded absenteeism. Additionally, school girls recorded absenteeism causes on menstrual calendars. Researchers conducted 16 interviews with teachers and students, compared data with schools' absenteeism register book, and conducted biometric test efficiency to evaluate the 2 digital systems and compare with registers. Class captain and mobile messaging were feasible to implement. During interviews, class captains sometimes forgot to collect data, and students mentioned they sometimes forgot their ID cards for barcode scanning. The software company depended on schools' absenteeism register book to message staff for absenteeism data. Both fingerprint (US$ 400) and barcode (US$ 138) devices were expensive. Compared to school register and other 3 systems, the fingerprint device was accurate recognizing11% of 439 absences not recorded in the register, and students could not fake presence. However, 5% (12/244) of fingerprints could not be read due in part to dirty fingers, and school computer operators were initially reluctant to operate the system. Out of 171girl calendar users, 11% mentioned that they missed school due to menstruation. The fingerprint device provided most accurate absenteeism measure in terms of authentication which has the potential to measure the impact of MHM on school attendance and women's education. To prevent mismatch problems, we recommend using higher quality fingerprint scanners and train students to scan their own fingerprints.

629

SIMPLE SOLUTIONS TO LARGE PROBLEMS: CLEAN WATER AND HANDWASHING LOWER DISEASE BURDEN

Daphne Pariser

Humans for Education, Rochester, NY, United States

Mpopongi Primary and Destiny Shaper Primary schools are located in a rural area of Kenya and did not have access to clean water or handwashing. We partnered with these schools to provide clean water, handwashing stations, and menstrual pads. Both schools are in areas that are difficult to access and do not have proper sanitary facilities. Mpopongi Primary has over 570 students and Destiny has over 118 students under their care. Each school spends over 10% of their yearly budget on hospitalization visits for their students, which are normally for easily preventable water-borne diseases. A water filtration system was implemented along with water storage at both schools. The water filter used was the LifeStraw Community Filter, which can remove 99% of Bacteria, 99% of protozoa, 99% of viruses, and can filter 70,000-100,000 liters. The storage containers hold at least 10,000 L each and provide water in times of drought. Additionally, rudimentary handwashing stations, including anti-bacterial soap were implemented at each school, where one handwashing station will service about 50 students per day. Reusable female menstruation pads, which are built to last for 3 years, were given to the students. Educational classes on menstrual hygiene, handwashing, and clean water were taught to the students and staff. Data was collected daily to measure the impact of each program. Within 1 year >90% of the students were using the handwashing stations and water filters daily, there were no indicences of typhoid and dysentry and only 2 cases of malaria, and an increase in student attendance was observed. We also showed that schools were able to save 40% on hospitalization visits after the implementation of these programs. These data suggest that simple general hygienic methods and brief educational classes reduce the rates of disease among primary age students, while increasing their school attendance.

630

OCCURRENCE OF *CRYPTOSPORIDIUM* IN DOMESTIC WATER IN THE SOUTHERN CARIBBEAN

Akilah T. Stewart[1], Adesh Ramsubhag[1], Dave Duman Chadee[1], Adrian Cashman[2], Renee Ali[1]

[1]The University of the West Indies, St. Augustine, Trinidad and Tobago, [2]Centre for Resource Management and Environmental Studies, The University of the West Indies, Cavehill, Barbados

Parasitic protozoans are often considered less important than bacterial agents in causing water borne disease outbreaks. However, a lack of routine monitoring and sensitive detection methods may have contributed to the underreporting of water-borne morbidity and mortality from these agents. *Cryptosporidium* is the most important protozoan responsible for water borne diseases because minimal exposure can result in infection. As such this neglected tropical disease is important in domestic water quality in the Caribbean. There is limited data available on the occurrence of *Cryptosporidium* in water in the Caribbean region. This study investigated the prevalence of *Cryptosporidium* in domestic water in rural communities in the Southern Caribbean region. Two hundred and thirty-four domestic water samples were collected in the dry and wet season over a period of one year in the predominately rain-water harvesting communities in Carriacou island, off Grenada; Nariva, Trinidad and Speightstown, Barbados. Water samples were filtered and DNA extracted before polymerase chain reaction (PCR) based detection of *Cryptosporidium* was done based on amplification of the small subunit (SSU) of ribosomal RNA gene. The overall prevalence rate was 73% for the three islands, with more samples from the wet (75%) than dry (69%) season being positive for the parasite. The prevalence rate of *Cryptosporidium* in water samples was higher in Cariacou (wet season = 91%; dry season = 60%) and Nariva (wet season = 73%; dry season = 82%) as compared to Speightown (wet season = 25%; dry season = 40%). Generally, water from natural sources (stored rainwater, wells, springs, boreholes) had a higher prevalence rate (93%) than public water supplies (36%). Future work will focus on genotyping to determine the contributing species to further characterize Cryptosporidium in the region. The study shows potential risk of *Cryptosporidium* infections from domestic water in rural communities in the region. There is urgent need for implement appropriate water disinfection strategies for these communities.

631

SILICATE PNEUMOCONIOSIS IN DOMESTIC AND WILD ANIMALS FROM THE CARIBBEAN ISLAND OF ST. KITTS

Randall T. Walker, Oscar Illanes, Pompei Bolfa

Ross University School of Veterinary Medicine, Basseterre, Virgin Islands, British

Silicate pneumoconiosis is a well-known environmentally acquired lung disease in humans characterized by silicate crystal depositions within the pulmonary interstitium. A high incidence of silicate pneumoconiosis has been observed in domestic and wild species on the Caribbean island of St. Kitts. To estimate the prevalence, 258 lung samples, from selected species (chickens, mongoose, cattle, swine, small ruminants, felines, canines, equines, monkeys), were collected at the abattoir or from previous studies and examined by histopathology, scanning electron microscopy with energy dispersive x-ray analysis (SEM/EDXA), and x-ray diffraction (XRD). Microscopic findings, seen in 201/258 (77%) samples, included perivascular and interstitial accumulations of heterogeneous crystalloid particulate material, either free or intracytoplasmic within macrophages. The material was birefringent, acid-fast positive, and largely composed of SiO_4^{4-} based on SEM/EDXA. Forty-eight passive eight hour air samples were obtained from random geographical areas and animal collection sites throughout the island and analyzed by XRD for presence and density of silicates. Local topsoil samples and lung tissue were submitted for EDXA and XRD to determine the elemental composition and crystalline structure of particulate material. The lung lesions were graded based on severity (normal, grade I, grade II, grade III) based on affectation of larger airways. By assessing the prevalence of pneumoconiosis in the animal population and the composition/structure of the particulate material within samples (lung, air, topsoil), we intend to elucidate the silicate source of origin and to correlate environmental exposure with the presence and severity of silicate deposition within the lungs. Results from this investigation my warrant future studies on the prevalence of environmentally acquired pulmonary disease within the human population of St. Kitts.

632

LESSONS FROM A COMMUNITY-LEVEL WATER INTERVENTION STUDY IN KARNATAKA, INDIA

Sarah L. McGuinness[1], Joanne O'Toole[1], Kavita Patil[2], Fraddry D'Souza[2], Chetan A. Gaonkar[2], Asha Giriyan[2], Andrew B. Forbes[1], Thomas B. Boving[3], Karin Leder[1]

[1]Monash University, Melbourne, Australia, [2]The Energy and Resources Institute (TERI), Western Regional Centre, Goa, India, [3]University of Rhode Island, Kingston, RI, United States

Community-based studies assessing the health effects of interventions aimed at improving water quality and/or quantity in resource poor areas have provided mixed results. We performed a study in rural Karnataka, India, to evaluate the health impacts of an intervention delivering riverbank filtration technology (RBF)-treated water to community tanks. Our ultimate aim was to generalise conclusions of the utility of RBF for other rural villages situated in river basins in Southern India that are similarly affected by poor river water quality, monsoonal flooding and/or dry season water shortages. We employed a stepped wedge RCT design with villages as the cluster unit. Our primary outcome was self- or carer-reported diarrhoea, and we incorporated questions about symptoms unrelated to water consumption/exposure to check the validity of responses. During the study, inundation of RBF wells due to monsoonal rains and difficulties securing 24-hour electricity connections resulted in temporary RBF supply interruptions. Coincident with intervention delivery, the state government rolled out a rural water delivery scheme providing rural villages with reverse osmosis water stations, which resulted in the availability of an alternative improved water source for villagers. Reported rates of diarrhoeal illness were lower than expected, and qualitative data indicated a decline in willingness of villagers to answer questions about health as the study progressed. We failed to observe a measurable health benefit due to the RBF intervention. We expect that future studies may experience similar problems associated with unexpected introduction of new water treatment alternatives, infrastructure limitations, and waning community engagement. To counter these we recommend greater protection of the water supply and treatment system, contingency planning, close engagement with government authorities, careful measurement of intervention uptake and the incorporation of qualitative study components to understand the drivers of intervention uptake by villagers.

OCCUPATIONAL EXPOSURE OF HEALTH CARE WORKERS IN KINSHASA, DEMOCRATIC REPUBLIC OF THE CONGO

Kamy K. Musene[1], Nicole A. Hoff[2], D'Andre Spencer[2], Patrick Mukadi[3], Joseph Wasiswa[1], Adva Gadoth[2], Russell Williams[1], Camille Dzogang[1], Rachel Mutombe[3], Merly Tambo[3], Mathais Massoko[4], Beniot Kebela-Ilunga[4], Emile Okitolonda-Wemakoy[1], Jean-Jacques Muyembe-Tamfum[3], Anne Rimoin[2]

[1]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, [2]Fielding School of Public Health, University of California Los Angeles, Los Angeles, CA, United States, [3]Institut National de Recherche Biomédicale, Kinshasa, Democratic Republic of the Congo, [4]Direction de lutte contre la maladie, Ministère de la santé, Kinshasa, Democratic Republic of the Congo

Globally, health care workers (HCWs) are on the front line of illness management, treating sick patients who may carry and transmit any

number of infectious diseases. Their occupational health and safety is critical to disease control, especially during disease outbreak events. In November 2016, we conducted a survey on occupational risks in 3 distinct health zones of Kinshasa province, Democratic Republic of the Congo (DRC) as part of a larger serosurvey determining prevalence of Ebola antibodies in health care workers. Interviews and blood specimens were collected from all consenting individuals enrolled in Lingwala, Kinshasa and Maluku health zones. Questionnaires collected sociodemographic data, occupational and general exposure histories, and information on any previous known exposures to Ebola. In total, 263 HCWs (206 nurses, 15 physicians, and 42 room attendants) were included in this analysis. 54 HCWs reported needle-stick injuries (23.3% of nurses and 40% of physicians), 32 reported coming in contact with other sharps containing biological materials (13.6% of nurses and 26.7% of physicians), 126 reported contact with droplets of biological specimens (53.9% of nurses, 66.7% of physicians, and 11.9% of room attendants), and 38 reported contact with blood near an open wound (16.0% of nurses, and 33.3% of physicians). Respondents were also asked about their accessibility to personal protective equipment (PPE), including gloves, gowns and facemasks. Physicians reported the highest rate of regular PPE access (80%), followed by nurses (58.7%), and room attendants (50%). In aggregate, only 58.6% of participants reported regular access to PPE, with room attendants left the most vulnerable to unmet PPE needs. HCWs in Kinshasa appear to be highly exposed to patients' biological specimens, either through direct patient contact or via other occupational fomite exposures. This information may be used to make recommendations for improving HCW safety and increasing workplace access to PPE throughout DRC.

NEONATAL INFECTIONS IN LOW INCOME COUNTRIES: INCIDENCE, ETIOLOGY, RISK FACTORS AND OUTCOMES - EVIDENCE FROM A MULTICENTRIC COMMUNITY-BASED COHORT STUDY IN MADAGASCAR, SENEGAL AND CAMBODIA

Bich-Tram Huynh[1], Agathe de Lauzanne[2], Perlinot Herindrainy[3], Laurence Borand[2], Elsa Kermorvant-Duchemin[4], Muriel Vray[5], Abdoulaye Seck[5], Awa Ndir[5], Michael Padget[1], Arnaud Tarantola[2], Sok Touch[6], Patrice Piola[2], Alexandra Kerléguer[2], Frederique Randrianirina[3], Jean-Marc Collard[3], Didier Guillemot[1], Elisabeth Delarocque-Astagneau[1]

[1]Institut Pasteur, Paris, France, [2]Institut Pasteur, Phnom Penh, Cambodia, [3]Institut Pasteur, Antananarivo, Madagascar, [4]Hôpital Universitaire Necker-Enfants malades-Université Paris Descartes, Paris, France, [5]Institut Pasteur, Dakar, Senegal, [6]CDC Department at Ministry of Health, Phnom Penh, Cambodia

Almost 3 million neonatal deaths occurred yearly, mostly in low income countries, and around a quarter of which are due to infection. In these settings, data on the burden of neonatal infection is scarce and there is a particular lack of data regarding infections occurring in the community, which may differ from cases admitted to the hospital. Also, the role of the different factors involved in the transmission of bacteria remains unclear, particularly mother-to-child. Data are needed for these countries to prioritize interventions to decrease neonatal infections. We conducted a prospective cohort of 2500 newborns in Madagascar, Cambodia and Senegal between September 2012 and April 2018, both in rural and urban areas. Newborns were enrolled at birth at the community level and were actively followed-up. Data on clinical symptoms developed by the children and all results of biological and bacteriological samples taken were collected. The global incidence of community-acquired neonatal infections was 35.8 cases per 1,000 live births [95% CI, 25.4-50.8], with a great majority during the first week of life (75%). The most common bacteria isolated were gram-negative (70%). Almost two-thirds of the pathogens isolated were resistant to current WHO-recommended treatment for neonatal sepsis. Prevalence of extended-spectrum beta-lactamase producing Enterobacteriaceae and *agalactiae streptococcus* carriage among pregnant women were heterogeneous between the different countries and ranged from 19% to 78% and from 5% to14%, respectively. 48, 17 and 13 deaths occurred during the follow-up in Madagascar, Cambodia and Senegal, respectively. Preliminary analysis showed a high incidence of bacterial neonatal infections in the community and highlighted that current recommended treatment for neonatal sepsis is no longer adapted. Risk factors for neonatal infection, in particular the role of the mother to child transmission, and mortality outcomes will be presented. These results should help the implementation of interventions to improve the prevention, early diagnosis, and case management of neonatal infections to decrease neonatal mortality.

GUT BARRIER AND SYSTEMIC INFLAMMATION IN A MODEL OF MODERATE ACUTE MALNUTRITION

Grace Thaxton[1], Yaneth Osorio[1], Nadim Ajami[2], Peter Melby[1]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]Baylor College of Medicine, Houston, TX, United States

Moderate acute malnutrition (MAM) affects 35.1 million children worldwide. Children with MAM exhibit some signs of systemic inflammation, but responsible mechanisms are not known. We used a protein-energy and micronutrient deficient mouse model to investigate mechanisms of malnutrition-driven inflammation. We hypothesize that malnutrition-driven changes in intestinal microbiota and intestinal barrier dysfunction allows translocation of bacteria and bacterial products that lead to an exaggerated inflammatory response. After 4 weeks on either a well-nourished (WN) control or malnourished (MN) diet, MN mice exhibited increased translocation of bacteria to the spleen, liver, and mesenteric lymph nodes. MN mice also had decreased expression of tight junction proteins and cytokines related to barrier function in the ileum and colon. Peritoneal macrophages from MN mice exposed to lipopolysaccharide (LPS) or lipotechoic acid produced more TNF-α than cells from WN mice suggesting that the macrophages in MN mice were endotoxin and LTA primed. The cecal microbiota composition showed increased proportions of gram - Proteobacteria in MN mice, similar to what has been found in malnourished children. To determine if expansion of pathobiont groups coupled with increased gut leakiness was driving endotoxin priming, we gave MN mice oral colistin or vancomycin to selectively deplete intestinal gram - or gram + species. We found that vancomycin-treated, but not colistin-treated, mice exhibited significantly increased serum TNF-α and IL-6 upon intradermal challenge with LPS. This increased endotoxin priming is likely due to expansion of gram - groups upon depletion of gram + species. Similar trends of increased LPS-stimulated expression of neutrophil-related cytokines were observed in the skin of vancomycin-treated mice. Collectively, these data suggest that the altered intestinal microbiota, impaired intestinal barrier function and translocation of gram - bacteria or bacterial components drives dysregulated innate immune function and inflammation in malnutrition.

EVALUATING THE GUT MICROBIOME IN CHILDREN WITH STUNTING: FINDINGS FROM A SOUTH AFRICAN BIRTH COHORT

Shrish Budree[1], Majdi Osman[2], Polite Nduru[1], Mamadou Kaba[1], Caroline Zellmer[2], Shantelle Claasens[1], Heather Zar[1]

[1]University of Cape Town, Cape Town, South Africa, [2]OpenBiome, Somerville, MA, United States

Stunting remains a significant burden to child health globally. A large proportion of children in low and middle income countries develop stunting despite preventative nutritional and environmental interventions. Environmental Enteric Dysfunction (EED), a subclinical condition characterized by small intestinal villous blunting and increased permeability, is an important cause of stunting. Recent evidence suggests that the intestinal microbiome contributes to the development and

persistence of EED and stunting, however, there is a paucity of data on the microbiome in stunted African children. This study aims to describe the microbiome of African children with stunting compared to those with normal linear growth. Children enrolled into the Drakenstein Child Health Study (DCHS), a birth cohort, had stool collected at regular study visits during the first year of life. The DCHS was situated in a low income, peri-urban setting in South Africa. Anthropometry was measure during routine study visits by trained study staff according to standard procedures. Stool samples underwent standard 16S rRNA sequencing and of sequencing data was conducted using QIIME2 and the R statistical package, Phyloseq. Alpha (Shannon index) and beta diversity (Unifrac) were compared between the stunted and control groups and significant differences in microbial relative abundance between the 2 groups were assessed using DESEQ2 and MaAsLiN. We analyzed a subset of 90 children with complete clinical and microbial data. The mean age of participants was 8.7 months (SD =6.77) with 44% being female. The mean weight was 8.0kg (SD=2.49) and mean height 66.7cm (SD=9.30). A total of 34 children were stunted of which 17 (50%) had severe stunting (height-for-age z score < -3). The results of our microbiome analysis are currently pending. This is the first descriptive analysis of the intestinal microbiome in a cohort of African children in a peri-urban setting with stunting. Characterization of the microbial signatures in this condition may help inform the development of novel defined microbial therapeutics for the treatment of EED and stunting.

SPATIOTEMPORAL CLUSTERS OF YAWS ON LIHIR ISLAND, PAPUA NEW GUINEA ENCOMPASS MULTIPLE VILLAGES

Eric Q. Mooring[1], Oriol Mitjà[2], Megan B. Murray[3]

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Barcelona Institute for Global Health, Hospital Clinic-University of Barcelona, Barcelona, Spain, [3]Harvard Medical School, Boston, MA, United States

Yaws is a neglected tropical disease caused by the bacterium *Treponema pallidum* subspecies *pertenue*. It causes skin lesions, particularly in children. The World Health Organization has targeted yaws for eradication, and a better understanding of its spatial epidemiology is necessary to inform eradication strategies. We sought to understand the spatial and temporal clustering of yaws on Lihir Island (area 200 km^2, population about 16 000), Papua New Guinea. We analyzed 11 years (April 2005 through May 2016) of passive surveillance data on incident yaws (n = 1448) using SaTScan, a cluster detection algorithm commonly used in spatial epidemiology. After adjusting for age, sex, and spatial and temporal trends in health-seeking, we detected three statistically significant ($p < 1 \times 10^{-17}$, $p = 1.8 \times 10^{-14}$, $p = 1.6 \times 10^{-8}$) non-overlapping spatiotemporal clusters. These varied in duration from 28 to 47 months and each encompassed between four and six villages. In the geographically smallest cluster, the component villages were up to 5.1 km apart by road and in the geographically largest cluster, they were up to 10.7 km apart. In a second analysis, we assessed spatial clustering of prevalent serologically confirmed yaws cases (n = 532) that were detected in 7 biannual rounds of active case finding beginning in 2013. We identified 1 statistically significant ($\alpha = 0.05$) cluster in each round. The number of villages per cluster varied from 1 to 16 and most Lihir villages were part of a cluster at least once. We considered the possibility that schools that serve multiple villages might be loci of transmission. Using a permutation test, we found no evidence that incident cases of yaws among 8- to 14-year-olds clustered within primary school attendance areas (p = 0.6846). To our knowledge, our analysis is the first to analyze yaws spatial epidemiology at the scale of multiple neighboring villages. These clusters likely reflect transmission of yaws across village boundaries; villages may be epidemiologically linked to a degree such that mass drug administration may be more effectively implemented at a spatial scale larger than the individual village.

638

IDENTIFICATION AND CHARACTERIZATION OF A NOVEL ADHERING RECEPTOR FOR SPOTTED FEVER GROUP *RICKETTSIAE*

Bin Gong

University of Texas Medical Branch, Galveston, TX, United States

Spotted fever group (SFG) rickettsioses are tick-borne zoonotic diseases of global importance caused by obligatory intracellular bacteria of the genus *Rickettsia.* Although rickettsial infection is controlled by appropriate broad-spectrum antibiotic therapy, untreated or misdiagnosed SFG rickettsioses are frequently associated with severe morbidity and mortality. Endothelial cells (ECs) are the main mammalian host target cells of SFG rickettsiae. The most prominent pathophysiological effect is increased microvascular permeability, causing vasogenic cerebral edema and non-cardiogenic pulmonary edema with potentially fatal outcomes. The underlying mechanism(s) of rickettsial attachment to and anchoring on the endothelial cell luminal surface remains incompletely determined, including how the bacteria overcome shear stress from blood flow prior to host cell invasion. Here we examined the role of endothelial surface annexin A2 (ANXA2) during rickettsial adherence to human endothelial cells. We demonstrated that endothelial surface ANXA2 contributed to rickettsial attachment to endothelial cells as an adhering receptor. In vivo data from an anatomy-based *in vivo* quantitative bacterial adhesion analysis system revealed that global depletion of ANXA2 diminished rickettsial adherence to the blood vessel luminal surface. Investigation of *a protein-protein interaction* at a single-molecule level by *atomic force microscopy* (AFM) biomechanically characterized endothelial apical surface ANXA2 as a receptor for richettsial adhesin out membrane protein-B to bind. Coupled with site-directed mutagenesis investigation of protein-living cell interaction with AFM probed phosphorylation of the N-terminus of ANXA as a switch to control rickettsial adhering. Our study, targeting the pivotal initial step in successfully establishing bacterial infection, delineates both biomechanical and biochemical mechanisms underlying rickettsiae hijack endothelial surface ANXA2 for their adherence to non-phagocytic vascular endothelial cells.

HIGH-THROUGHPUT MULTI-PARALLEL NL-QPCR CHIP FOR THE DETECTION OF 17 ENTERIC PATHOGENS

Jessica A. Grembi, Koshlan Mayer-Blackwell, Stephen P. Luby, Alfred M. Spormann

Stanford University, Stanford, CA, United States

Molecular diagnostics deliver important insights on enteric pathogen load; however cost is still a barrier in assessing a broad suite of pathogens in large epidemiological studies (n > 1000). Recent developments in microfluidic technology offer the opportunity to increase throughput for quantitative analyses while decreasing the per-sample cost. Here, we introduce a nano-liter qPCR (nL-qPCR) chip configured for duplicate quantification of 17 enteric pathogens and total bacteria, archaea, and fungi in 96 samples, at a cost of approximately $10 per sample. Pathogen-specific targets include *Campylobacter jejuni/coli*, *Clostridium difficile* and *C. perfringens*, pathogenic *E. coli* (EAEC, EPEC, ETEC, STEC, EIEC/*Shigella* spp.), *Helicobacter pylori*, *Vibrio cholerae*, *Salmonella* spp., *Yersinia enterocolitica*, *Cryptosproidium* spp., *Entamoeba histolytica*, *Giardia* spp., *Ascaris lumbricoides, and Trichuris trichura*. The chip achieves a detection limit of 100 copies per 100nL reaction for most assays. Assay efficiencies, measured over a dynamic range from 10-10^6 copies, are between 90 and 112% with a mean standard error of 2.3. Reproducibility of standard curves across 10 chips run at two facilities over a minimum timespan of two years, yielded a standard deviation of C_T values (measured across all points of the standard curve) ranging from 0.41 to 1.45 (mean 0.68), with all pathogen-specific assays except *Cryptosporidium* spp. maintaining a mean standard deviation less than 1.0 C_T. We used the nL-qPCR chip to analyze 399 fecal samples. The mean coefficient of variation for the

calculated target copy number of four replicates analyzed over two separate chips was 0.26 [range 0.004 -1.33]. Specificity was verified by sequencing PCR amplicons. We compare results for the 399 fecal samples analyzed on both our nL-qPCR and an enteropathogen TaqMan array card (TAC) that has been widely used for large epidemiological studies.

640

IMPACT OF ENTEROPATHOGEN INFECTION ON LINEAR GROWTH USING QUANTITATIVE MOLECULAR DIAGNOSTICS: RESULTS FROM THE MAL-ED STUDY

Elizabeth T. Rogawski McQuade[1], James A. Platts-Mills[1], Jie Liu[1], Aldo A. Lima[2], Gagandeep Kang[3], Amidou Samie[4], Rashidul Haque[5], Estomih R. Mduma[6], Margaret N. Kosek[7], Jose Paulo Leite[8], Ladaporn Bodhidatta[9], Najeeha Iqbal[10], Nicola Page[11], Ireen Kiwelu[12], Zulfiqar Bhutta[10], Eric R. Houpt[1]

[1]University of Virginia, Charlottesville, VA, United States, [2]Federal University of Ceara, Fortaleza, Brazil, [3]Christian Medical College, Vellore, India, [4]University of Venda, Thohoyandou, South Africa, [5]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [6]Haydom Global Health Institute, Haydom, United Republic of Tanzania, [7]Johns Hopkins University, Baltimore, MD, United States, [8]Fundação Oswaldo Cruz (Fiocruz), Rio de Janeiro, Brazil, [9]Armed Forces Research Institute of Medical Sciences (AFRIMS), Bangkok, Thailand, [10]Aga Khan University, Karachi, Pakistan, [11]National Institute for Communicable Diseases, Johannesburg, South Africa, [12]Kilimanjaro Clinical Research Institute, Moshi, United Republic of Tanzania

Exposure to enteropathogens early in life not only causes diarrhea, but may also contribute to poor linear growth. In the multi-site longitudinal birth cohort, MAL-ED, we measured enteropathogen exposure in monthly non-diarrheal stools and during diarrhea with qPCR assays for 29 pathogens. We estimated the effects of etiology-specific diarrhea and subclinical enteropathogen infection on linear growth in 3 month intervals, at 2 years of age, and using a longitudinal model that accounted for temporality and time-varying confounding. We then used the parametric g-formula to estimate the impact of hypothetical interventions that would reduce enteropathogen infection. Among 1,469 children who completed follow-up to two years of age, 35,622 stool samples were tested and yielded valid results. Diarrhea episodes attributed to bacteria and protozoa, but not viruses, were associated with small decrements in length-for-age z-score (LAZ) after 3 months, but these associations were not maintained at 2 years of age. Conversely, subclinical infection with *Shigella* (LAZ difference: -0.15, 95% CI: -0.28, -0.02), enteroaggregative *E. coli* (-0.21, 95% CI: -0.37, -0.05), *Campylobacter* (-0.18, 95% CI: -0.34, -0.03), and *Giardia* (-0.18, 95% CI: -0.31, -0.06) were associated with significant decrements in LAZ at 2 years. A perfect quadrivalent vaccine against these four pathogens would be expected to raise the average LAZ at age 2 by 0.24 LAZ (95% CI: 0.08, 0.41). Conversely, individual-level provision of improved water and sanitation would not be expected to substantially reduce pathogen infection, such that no improvement in average LAZ would be expected after this intervention. Subclinical infection and quantity of select enteropathogens particularly *Shigella*, enteroaggregative *E. coli*, *Campylobacter,* and *Giardia*, had sustained negative associations with linear growth. The potential impact of a perfect vaccine was similar to effects of nutritional interventions, and though the impact of a realistic vaccine would be smaller, prevention of enteropathogen infection in early childhood may contribute to reductions in global stunting.

641

CLINICAL AND LABORATORY FEATURES ASSOCIATED WITH PROGRESSION TO SEVERE DENGUE AMONG POTENTIALLY HIGH-RISK DENGUE PATIENTS HOSPITALIZED IN SOUTHERN SRI LANKA

W M D Gaya B Wijayaratne[1], C. Lakmal Fonseka[1], Ajith de S Nagahawatte[1], Champica K Bodinayake[1], Nayani P Weerasinghe[1], M Ruvini P Kurukulasooriya[1], K V Thamali Anuradha[1], Niroshan J Dahanayake[1], Vasantha Devasiri[1], Harshani A Ubeysekara[2], A Dharshan De Silva[3], Bradly Nicholson[4], Truls Ostbye[5], Christopher W Woods[5], L Gayani Tillekeratne[5]

[1]University of Ruhuna, Galle, Sri Lanka, [2]Provincial Director of Health Office, Galle, Sri Lanka, [3]General Sir John Kothalawale Defense University, Rathmalana, Sri Lanka, [4]Durham Veterans Affairs Medical Center, Durham, NC, United States, [5]Duke University School of Medicine, Durham, NC, United States

Dengue is an important cause of acute febrile illness globally. The Sri Lankan government recommends hospital admission when the platelet count is <100x10^9/L. We determined predictors of severe dengue to identify patients for intensive vs ambulatory management. A prospective, cohort study was conducted from Jun-Oct 2017 at one tertiary and one secondary care hospital in southern Sri Lanka. Consecutive patients ≥1 year with fever were enrolled within 7 days of admission if they developed a platelet count <100x10^9/L and two clinical symptoms consistent with dengue with or without warning signs, as per the 2009 WHO criteria. Sociodemographic and clinical data were collected. Acute dengue was confirmed if NS1 rapid antigen test was positive (fever <6 days) or if dengue IgM test was positive (fever ≥6 days or NS1 test negative). Severe dengue was defined per the 2009 WHO criteria; features associated with severe dengue were determined using the Fisher exact and Kruskall-Wallis tests. Of 414 enrolled patients, most patients (323, 78.2%) had laboratory-confirmed dengue. Median age was 33 years (IQR 25- 46) and 200 (61.9%) of dengue patients were male. Overall, 59 patients (18.3%) developed severe dengue: 39 (12.1%) plasma leakage with respiratory distress, 12 (3.7%) severe organ failure, 10 (3.1%) shock, and 9 (2.8%) severe bleeding. Patients with severe vs non-severe dengue were more likely to be females (49.2% vs 35.6%, p=0.05). At admission, patients with severe dengue had a higher white cell count (4.3 x10^9 vs 3.9 x10^9 cells/L, p=0.05) and a lower platelet count (38.0 x 10^9/L vs 80.0 x 10^9/L, p=0.02) and were more likely to have a transaminitis (AST/ALT ≥120 U/L, 21.1% vs 12.6%, p=0.003). Patients with severe dengue were more likely to have ultrasound evidence of pleural effusions (14.0% vs 3.0%, p<0.001), fluid in the Morrison's pouch (17.5% s 8.7%, p=0.04), and pelvic fluid (8.8% vs 0.4%, p<0.001) at admission. Approximately one-fifth of hospitalized dengue patients developed severe dengue. Several laboratory and ultrasound findings at admission were associated with progression to severe disease and may be used for triaging patients with dengue.

642

EVALUATION OF THE CARESTART™ GLUCOSE-6-PHOSPHATE DEHYDROGENASE (G6PD) RAPID DIAGNOSTIC TEST AT COMMUNITY AND HEALTH CENTER LEVEL IN CAMBODIA

Bertha Wojnarski[1], Lon Chanthap[1], Darapiseth Sea[1], Threechada Boonchan[1], Sabaithip Sriwichai[1], Soklyda Chann[2], Sohei Hom[1], Worachet Kuntawunginn[1], Philip Smith[1], Michele Spring[1], Mitra Feldman[1], Sokna Ly[2], Nichapat Uthaimongkol[1], Panita Gosi[1], Mali Ittiverakul[1], Nillawan Buathong[1], Somethy Sok[3], Samon Nou[2], Pheaktra Oung[2], Nareth Kong[2], Vannak Pheap[2], Khengheang Thay[2], Vy Dao[2], Huy Rekol[4], Lek Dysoley[4], Mariusz Wojnarski[1], Mark Fakuda[1]

[1]US Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]US Armed Forces Research Institute of Medical Sciences, Phnom Penh, Cambodia, [3]Ministry of National Defense, Department of Health,

Phnom Penh, Cambodia, [4]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia

Primaquine (PQ) is the only FDA-approved drug for radical cure of *Plasmodium vivax* (*P.v*) malaria, but treatment can result in life-threatening hemolysis if given to a glucose-6-phosphate dehydrogenase deficient (G6PD*d*) patient. Therefore, the G6PD status of the patient with *P.v* must be known prior to prescribing PQ. To increase PQ access in Cambodia in the malaria endemic community, performance of CareStart™ G6PD rapid diagnostic tests (RDTs) needs to be evaluated in healthcare workers (HCWs) and village malaria workers (VMWs). Training materials on G6PD and PQ were developed for HCWs and VMWs, and each performed G6PD test on 8 -12 adult male volunteers, with pre- and post-training questionnaires completed by trainees and volunteers. The field performance of CareStart™ RDT for G6PD*d* screening was assessed against a quantitative G6PD test (Pointe Scientific, Inc., Canton MI). Descriptive and inferential statistics were used to analyze the data. 96 trainees and 960 G6PD volunteers were recruited in Anlong Veng, Cambodia from December 2017 to February 2018. Of the 960 volunteers, 156 (16%) were G6PD deficient based on a quantitative test activity threshold of 30%. The sensitivity, specificity, PPV and NPV of CareStart™ RDT was 96.77%, 95.54%, 80.21%, 99.37% for HCW/VMW trainees vs. 96.15%, 97.24%, 86.71%, and 99.26% for trained study staff in the field and 94.23%, 98.80%, 93.63% and 98.92% for experienced laboratory staff, with no statistical difference among the groups. The mean knowledge score pre-training was 33.86% (VMWs) and 56.4% (HCWs), with improvement to 89% and 90% post training ($p < 0.001$). The improvement in knowledge scores was independent of the years of experience, profession and education level. HCW/VMWs' perception of PQ risk based on RDT results was assessed pre and post counseling and will be presented. With minimal training, CareStart™ RDT is highly specific, feasible and a practical option for the identification of G6PD*d* male patients and its use may enable safer prescribing of PQ to decrease the burden of *P.v* relapse.

643

MULTIBEAD BASED ASSAY PROVIDES ONE-STEP SPECIES-SPECIFICITY FOR THE DIAGNOSIS OF FILARIAL INFECTIONS AND *STRONGYLOIDES STERCORALIS* IN TRAVELERS AND IMMIGRANTS

Joseph Kubofcik, Thomas B. Nutman

National Institutes of Health, Bethesda, MD, United States

Previously, antifilarial antibody testing in the evaluation of returned travelers and immigrants to North America has relied on IgG- and IgG4-specific responses to crude filarial extracts (BmA), tests that suffer from significant cross-reactivity with Strongyloides and cannot distinguish among the infecting filarial species. Nevertheless, between 1992 and 2016, testing of >11000 samples have been tested; close to 20% were able to be definitively diagnosed with a filarial infection (based on IgG4 anti-BmA reactivity) and ~50% had the diagnosis excluded (based on IgG anti-BmA seronegativity). Thus, to create an all-in-one assay for screening travelers and immigrants where infections with filariae or *Strongyloides stercoralis* (Ss) is being considered, we configured a multibead-based assay to measure simultaneously the IgG and IgG4 responses to BmA, and the species-specific recombinants Ll-SXP1, Ov-16, Wb-123, Ss-NIE and Ss-IR in a CLIA-certified fashion. By tuning the assays to >99% specificity for the species of interest (using ROC-based cutoffs) we have utilized this new assay to prospectively test samples from 712 unique patients. Of these 712 samples we have found that 166 (23%) were seropositive by IgG anti-BmA and 71(10%) were seropositive by IgG4 anti BmA. From these 237 (either IgG or IgG4 seropositive) we have been able to provide species-specific diagnosis for 137 samples (72 *Loa loa*, 3 *Wuchereria bancrofti*, 6 *Onchocerca volvulus*, and 56 *Strongyloides stercoralis*). Using this multiplex assay we have been able to deconvolute the anti-BMA reactivity and identify the species of infecting parasite responsible for the antibody positivity for better accuracy in the diagnosis of individual filarial and Ss infections and to help direct specific therapeutic options.

644

COMPARISON OF LUMINEX METHODS FOR ANALYSIS OF ANTIBODY RESPONSES AGAINST MARKERS OF VACCINE PROTECTION AND PARASITIC, WATER-BORNE AND NEGLECTED TROPICAL DISEASES

Gretchen Cooley[1], Sarah Gwyn[1], Jeffrey Priest[1], Heather Scobie[1], Eric Rogier[1], Nana Biritwum[2], Vitaliano Cama[1], Luis M. Camargo[3], Oscar Debrah[2], Guillherme Maerschner Ogawa[1], Delynn Moss[1], Harran Mkocha[4], Tallita Zamarchi[3], Ryan Wiegand[1], Diana Martin[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Ghana Health Services, Accra, Ghana, [3]Sao Paulo University, Sao Paulo, Brazil, [4]Kongwa Trachoma Project, Kongwa, United Republic of Tanzania

Serosurveillance is a useful tool for monitoring biomarkers in a population to estimate exposure to pathogens or vaccination protection. We use a multiplex bead assay (MBA) based on Luminex technology to simultaneously measure antibodies against antigens derived from malaria, neglected tropical diseases (NTDs), vaccine preventable diseases (VPDs), waterborne diseases, and arboviruses. These antigens can be combined into panels customized for conducting integrated serosurveillance in different epidemiological settings. Because international deployment of this technique may require use of different MBA instrumentation and beads, we compared assay performance of two commonly used Luminex instruments and bead types. 430 dried blood spot samples representing broad geographic areas were tested for antibody responses against 40 antigens from 28 different pathogens. Antigens were coupled to both magnetic and non-magnetic beads and read on Luminex 200 and MAPGIX instruments; assays were read immediately after completion and after overnight storage at 4°C. Linear regression was used to do pairwise comparisons of antibody responses for each antigen under different conditions. Percent seropositivity was calculated for each condition for the four VPDs (rubella, tetanus, measles and diphtheria) using international serum standards. The majority of antigens (37/40) had an $R^2 > 0.85$ across 5 pairwise comparisons. The comparisons with $R^2 < 0.85$ were based on comparisons that used different lots of beads on the two machines. Among tested samples, we measured seropositivity rates of 86-87% for tetanus, 91-94% for measles, 80-81% for rubella and 47-51% for diphtheria; 95% confidence intervals were overlapping for all estimates. Overall, there was excellent correlation between instruments and among samples tested at different times, indicating that with robust quality assurance and control, comparable data can be obtained from a variety of assay conditions run on different instrumentation. This gives programs flexibility in choosing platforms for integrated surveillance.

IS MELIOIDOSIS A SIGNIFICANT CAUSE OF ACUTE FEBRILE ILLNESS IN BANGLADESH?

Fazle R. Chowdhury[1], Lovely Barai[2], Tanjila Rahman[2], Mili R. Saha[2], Md. Robed Amin[3], Kaniz Fatema[4], Bikash C. Das[3], Md. Rokibul Hasan[2], K. M. Shahidul Islam[2], M. Abul Faiz[5], Nicholas P. Day[1], Direk Limmathurotsakul[6], David A. Dance[7], Susanna J. Dunachie[1]

[1]Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine,University of Oxford, Oxford, United Kingdom, [2]Department of Microbiology, BIRDEM General Hospital, Dhaka, Bangladesh, [3]Department of Medicine, Dhaka Medical College, Dhaka, Bangladesh, [4]Department of Critical Care Medicine, BIRDEM General Hospital, Dhaka, Bangladesh, [5]Dev Care Foundation, Dhaka, Bangladesh, [6]Mahidol Oxford Tropical Medicine Research Unit, Mahidol University, Bangkok, Thailand, [7]Lao-Oxford-Mahosot Hospital Welcome Trust Research Unit, Vientiane, Lao People's Democratic Republic

The etiology of febrile illness remains poorly characterized in many countries including Bangladesh. This carries the twin risks of incorrect treatment and inappropriate use of antibiotics fuelling antimicrobial

resistance (AMR). Melioidosis is a neglected tropical disease with a high case fatality rate caused by the Gram negative bacterium *Burkholderia pseudomallei.* It is rarely diagnosed in countries with limited facilities for accurate microbiology diagnosis, but may be a significant undiagnosed cause of infection and death in Bangladesh. We conducted a prospective clinical study of the etiology of fever in consecutive adult patients admitted to two hospitals in Dhaka: Dhaka Medical College Hospital and BIRDEM from June to October 2017. The capacity of the microbiological laboratory to identify *B. pseudomallei* and other bacteria from culture was strengthened by training prior to study commencement. Blood culture was performed for every patient, with further cultures, serology and imaging as clinically indicated. 210 patients were recruited: 57% male, 26% with diabetes and with a median (IQR) age of 35 (23-55) years. A definitive diagnosis was made for 74 (35%) cases. Overall, 28 (13%) had positive bacterial cultures including 18 (9%) with positive blood culture. Six patients (3%) had a positive culture for *B. pseudomallei,* with other positive cultures including *E. coli, Salmonella* Typhi*, Pseudomonas* species, *Klebsiella pneumoniae, Acinetobacter* species and *Staphylococcus aureus.* Antimicrobial resistance included extended-spectrum beta-lactamase production in Gram negatives and multi-drug resistance in 75% of *Salmonella* Typhi. Non-bacterial causes of fever included dengue (4%) and Chikungunya (2%). Overall mortality was 16% but 67% in melioidosis. We found melioidosis to be the commonest cause of bacteremia in Dhaka, Bangladesh with high rates of AMR in other Gram negative infections meaning that empirical cephalosporin treatment would likely have been ineffective. Strengthening the capacity of microbiology laboratories in Bangladesh is vital for accurate diagnosis of melioidosis and for surveillance of AMR.

NOVEL 3-DIMENSIONAL OPTICAL SCANNING IN THE ASSESSMENT OF PATIENTS WITH MYCETOMA

Eiman Siddig[1], Niels Liberton[2], Maureen van Eijnatten[2], Sjoerd te Slaa[3], Amir Faroog[1], Ahmed H. Fahal[1], Jan Wolff[3], Eduard E. Zijlstra[4]

[1]Mycetoma Research Center, Soba University Hospital, Khartoum, Sudan, [2]Department of Oral and Maxillofacial Surgery, 3D Innovation Lab, VU University Medical Center, Amsterdam, Netherlands, [3]Department of Oral and Maxillofacial Surgery, 3D Innovation Lab, VU University Medical Center, Amsterdam, Netherlands, [4]DNDi, Geneva, Switzerland

Magnetic resonance imaging (MRI), CT and ultrasound imaging modalities are currently used in the diagnosis of mycetoma lesions. The availability, cost or expertise needed for such modalities often preclude wide application under field conditions. Therefore, in practice, response to treatment is often assessed clinically by examining the affected area, which is subjective and may be inaccurate. Currently, 3-dimensional (3D) optical scanning technologies are used for an increasing range of medical applications. The resulting 3D surface models allow objective, quantitative 3D analysis of any body part over time with superior point accuracy up to 0.1 mm, and 3D resolution up to 0.5 mm. In this study we examined the usability of 3D optical scanning in patients with lower limb eumycetoma with a limited lesion size (2-10 cm) who were recruited in a randomized controlled phase 2 clinical trial in Khartoum, Sudan. Patients were monitored using MRI and optical 3D scans acquired at regular intervals. The resulting MRI and 3D scan images were reconstructed and the volume of the mycetoma lesion was measured. The skin surface volumes of the lesions acquired were compared during follow-up to monitor changes in volume and skin texture. The first evaluation obtained in ten patients studied the volume of the lesion varied between 3 and 30 ml. A reduction in size between months 1 and 2 could be detected in 3 of them. For the first time, we have shown that using optical 3D scanning, the volume of mycetoma lesions can be accurately quantified and monitored during treatment, allowing statistical assessment of treatment response. Optical 3D scanning was well accepted and the alignment and superimposition of 3D scans with the corresponding MRI scans was feasible in this setting. Novel, portable 3D scanning technologies offer an alternative to existing medical imaging technologies such as MRI and to clinical assessment when monitoring mycetoma lesions. This innovative and cutting-edge digital tool is suitable for use under field conditions and may be explored in other (tropical) skin lesions.

647

BRUCELLOSIS AMONG PATIENTS WITH PERSISTENT FEVER IN A RURAL HOSPITAL IN EASTERN SUDAN

Sayda El Safi[1], Enaam El Sanousi[2], Hussam Elshikh[1], Nagwa El Amin[1], Alfarazdag Mohammed[1], Manar Abdel-Rahman[3], Mohamed Mohamed[1], Salah Mohammed[2], Awad Malik[1], Abdallah Ahmed[1], Ahmed Farah[4], Barbara Barbé[5], Kristien Verdonck[5], Marleen Boelaert[5], Jan Jacobs[6], François Chappuis[7]

[1]Faculty of Medicine, University of Khartoum, Khartoum, Sudan, [2]Brucella Department, Veterinary Research Institute, Khartoum, Sudan, [3]Faculty of Mathematical Sciences, University of Khartoum, Sudan & College of Health Sciences, Qatar University, Qatar, Khartoum & Qatar, Sudan, [4]Suba University Hospital, Khartoum, Khartoum, Sudan, [5]Institute of Tropical Medicine, Antwerp, Belgium, [6]Institute of Tropical Medicine & Department of Microbiology and Immunology, KU Leuven, Antwerp & Leuven, Belgium, [7]Division of Tropical and Humanitarian Medicine, Geneva University Hospitals, Geneva, Switzerland

Brucellosis is a classic cause of prolonged fever but for most African countries, few data are available. We aimed to assess prevalence and clinical presentation of brucellosis among patients presenting with persistent fever in rural Sudan. This study was part of the Neglected Infectious Diseases Diagnosis (NIDIAG) project. Consecutive patients (more than 5 years old) with persistent 7 days or more) fever were recruited at Tabarak Allah Hospital, Gedaref State, eastern Sudan. Blood cultures and serum antibody testing (Rose Bengal test (RBT), Serum Agglutination Test (SAT) and cELISA) were performed in all patients to diagnose brucellosis, one of the study target diseases. Isolates were characterized by multiplex PCR (Bruce-ladder, using IS711 and bcsp31 primers). From February 2013 to June 2014, 667 patients were recruited; 28 of them (4.2%) had blood culture-confirmed (n=15; 2.2%) or probable (positive RBT, SAT or cELISA; n=13; 2.0%) brucellosis. All *Brucella* isolates were identified as *Brucella melitensis* biovar1. Patients with confirmed brucellosis had a median age (interquartile range (IQR)) of 23 (16-36) years and 9 were men; 5 were farmers, 2 herdsmen and 1 butcher. At time of presentation, median duration of fever was 14 days (IQR 8-26; range 7-56); median axillary temperature was 37.2°C (IQR 36.6°-38.2°C; range 35.9°-40.7C°). Other complaints were headache (12/15), joint pain (10/15), cough (10/15), abdominal pain (7/15) and sore throat (3/15). Of 41 working diagnoses at presentation (1-7/patient), the most frequent were visceral leishmaniasis (n=11), enteric fever (n=10) and brucellosis (n=6). In 2 patients, co-infections were diagnosed: enteric fever (blood culture-confirmed *Salmonella* Paratyphi) and visceral leishmaniasis (based on serology and response to treatment). In conclusion, brucellosis was a significant cause of persistent fever in rural Sudan. Local care-givers should have this diagnosis in mind and laboratories should install appropriate biosafety measures. Lack of accurate and field-friendly diagnostic tools remains an obstacle to proper diagnosis of clinically suspect patients in rural tropics.

648

PHASE 2 CLINICAL RESULTS - CHIKUNGUNYA VACCINE BASED ON MEASLES VECTOR (MV-CHIK) INDUCES HUMORAL AND CELLULAR RESPONSES IN THE PRESENCE OF PRE-EXISTING ANTI MEASLES IMMUNITY

Katrin Ramsauer[1], Emil Reisinger[2], Christa Firbas[3], Ursula Wiedermann-Schmidt[4], Eckehard Beubler[5], Judith Aberle[6], Matthias Müllner[1], Andrea Pfeiffer[1], Raimund Vielnascher[1], Erich Tauber[1]

Chikungunya is a rapidly spreading viral disease affecting significant parts of the Americas, India and South East Asia. Regional outbreaks are of increasing intensity, long lasting and difficult to control. In the majority of patients, the febrile acute disease turns into a chronic disease causing severe, debilitating arthritis. The chronic symptoms can last from months to years post-infection. So far, no vaccine or treatment has been licensed. MV-CHIK, a live recombinant measles vector-based vaccine induced a functional humoral immune response against CHIKV in healthy adult human subjects as tested in a Phase 1 clinial trial (EudraCT:2013-001084-23). Previously, interim safety and immunogenicity data from the ongoing Phase 2 study (NCT02861586) were presented. The vaccine presents with a safety profile in humans that is comparable to the approved control vaccine in the trial. The vaccine induced functional, neutralizing antibodies in 96% of the subjects after two vaccinations. Here, we present the final data collected during the Phase 2 clinical trial. We will show the immune profile, including cross-neutralizing antibodies and antibody persistency induced by the vaccine in a population of up to 300 subjects. In addition, we analyzed the cellular responses induced by the vectored vaccine in human subjects. Importantly, the vaccine induced a functional immune response even in the presence of pre-existing anti-measles immunity as demonstrated in a subset of subjects who received a measles prime immunization prior to the Chikungunya vaccine. The data show that the live recombinant MV-CHIK vaccine is a safe and tolerably vaccine that induces a robust immune response. The data clearly path the way for the preparation of a late stage clinical development program.

AUTOCIDAL GRAVID OVITRAPS LIMIT INTRA-COMMUNITY TRANSMISSION OF CHIKUNGUNYA VIRUS

Tyler M. Sharp[1], Olga Lorenzi[1], Brenda Torres-Velasquez[1], Veronica Acevedo[1], Janice Perez-Padilla[1], Aidsa Rivera[1], Gabriela Paz-Bailey[1], Brad J. Biggerstaff[2], Jorge Munoz-Jordan[1], Steve H. Waterman[1], Roberto Barrera[1]

[1]Centers for Disease Control and Prevention, San Juan, PR, United States, [2]Centers for Disease Control and Prevention, Fort Collins, CO, United States

Global public health responses to dengue, chikungunya (CHIKV), and Zika virus outbreaks are hampered by the inability to control *Aedes aegypti* mosquitos. Autocidal Gravid Ovitraps (AGO traps) have been shown to sustainably reduce the density of *Ae. aegypti* mosquito populations by >80%. To evaluate the effectiveness of AGO traps in limiting CHIKV transmission among humans, soon after the introduction of CHIKV to Puerto Rico in 2014 we conducted representative household surveys in two intervention communities (IC) where traps had been present for 3 years and two communities where no traps were present (NIC). Serum specimens were tested by anti-CHIKV IgM/IgG ELISA. We evaluated differences in CHIKV seroprevalence in IC and NIC using generalized linear models with a log-link adjusting for clustering and including an interaction between community type and human mobility. Of 1,218 and 1,284 IC and NIC residents, respectively, 175 (14%) and 152 (12%) participated. There were no differences between participants from IC and NIC by gender or age. IC participants less often reported daily or weekly mosquito bites (41% vs. 73%, $p < 0.001$) and daily use of repellent (6% vs. 24%, $p< 0.001$) or a bed net (1% vs. 9%, $p < 0.001$). Among IC participants, 47% spent more than half of weekly daylight hours in their community, while in NIC residents it was 73% ($p < 0.001$). After adjusting for differences in human mobility, seroprevalence of CHIKV antibodies in residents of IC and NIC was 26% and 44%, respectively (adjusted prevalence ratio [aPR] = 0.5, 95% confidence interval [CI]: 0.4-0.7). Seroprevalence in IC and NIC residents who spent less than half of daylight hours in their community was 34% and 59%, respectively (aPR = 0.6, CI: 0.4-0.9), whereas it was 17% and 38% in residents who spent more than half of daylight hours in their community (aPR = 0.4, CI: 0.3-0.7) (interaction $p = 0.48$). These findings demonstrate the effectiveness of AGO traps in protection of humans from CHIKV infection, which did not vary by time spent in their community. Evaluation of the effectiveness of AGO traps in a larger, urban setting is merited, potentially in combination with other prevention strategies.

TRANSMISSION OF CHIKUNGUNYA VIRUS USING TERRAFORMA ARTIFICIAL ECOSYSTEMS

Angela Bosco-Lauth, Airn Hartwig, Paul Gordy, Richard Bowen

Colorado State University, Fort Collins, CO, United States

Vector-borne and zoonotic diseases comprise the majority of emerging infectious diseases that impact human and animal health. These pathogens are part of a complex system of multifaceted and deeply integrated components that, when certain criteria are met, can lead to epidemics that are often poorly understood and difficult to contain. Our approach to elucidating some of the factors related to disease emergence is to integrate ecological pressures into controlled laboratory settings to tease out the drivers of an emergent event. The system we have designed, referred to as TerraForma, uses models in a BSL3 laboratory that mimic barnyards, wet markets, or terrariums where different animal species intermingle and abiotic factors can be altered to investigate causation of emergent events. Here we report using Chikungunya virus, a known human pathogen with an undetermined enzootic cycle, to answer the question of whether reptiles and amphibians can serve as reservoir hosts for viral maintenance. Previous studies have demonstrated that Chikungunya viremia develops in garter snakes, leopard frogs, and common toads following needle inoculation; in this experiment, we allowed these animals to comingle, and then introduced infected *Aedes albopictus* mosquitoes into the environment. Twenty-eight days following the mosquito introduction, one toad seroconverted; viremia was not detected. In a follow up experiment, naïve mosquitoes were released into the ecosystem with infected snakes, toads, and frogs. While all of the animals were viremic at the time of exposure, none of the mosquitoes that were harvested from the system developed disseminated Chikungunya infections following extrinsic incubation. While this model did not provide substantial evidence regarding the potential of these ectothermic vertebrate hosts to source an infection, it does provide the basis for any number of similar experiments to be performed utilizing a variety of hosts, including birds, rodents and bats, with varying vectors and pathogens.

IMPAIRED EXPRESSIVE LANGUAGE IN 24-MONTH-OLD INFANTS EXPOSED TO THE CHIKUNGUNYA VIRUS IN EARLY CHILDHOOD

Randall Waechter[1], Nikita Cudjoe[2], Trevor Noël[1], Amy Krystosik[3], Ashlee Watts[2], Bianca Punch[2], Hayley Crandell[2], Rashida Isaac[2], Toni Murray[2], Elbernezer Andrew[2], Veronica Mapp-Alexander[2], Shadona Baptiste[2], Priyanka Suresh[3], George Mitchell[4], Barbara Landon[1], Michelle Fernandes[5], Patrick Gerardin[6], Calum Macpherson[1], A. Desiree LaBeaud[3]

[1]St. George's University, St. George's, Grenada, [2]Windward Islands Research and Education Foundation, St. George's, Grenada, [3]Stanford University, Stanford, CA, United States, [4]Grenada Ministry of Health, St. George's, Grenada, [5]John Radcliffe Hospital, University of Oxford, Oxford, United Kingdom, [6]Centre Hospitalier Universitaire de la Réunion, Saint-Paul, Réunion

The chikungunya virus (CHIKV) was first reported in Grenada in July 2014, infecting about 65% of the population in six months. Approximately 1,750 women were pregnant, became pregnant, and/or gave birth during the outbreak. Little is known about the rate of CHIKV

transmission between mother and fetus during pregnancy or the impact of transmission on the developing fetus; however, a cohort study of 33 mother-to-child CHIKV infected 2-year old children in La Réunion showed significantly lower development quotient scores and greater rates of global neurodevelopmental delay compared to uninfected children. We used the Intergrowth-21st Neurodevelopment Assessment (Inter-NDA) to assess 2-year old infants born to mothers infected (n=332) and not infected (n=80) with CHIKV during the outbreak in Grenada and did not detect any differences in cognitive, fine motor, gross motor, receptive language, expressive language or overall neurodevelopment score between the groups. We also assessed neurodevelopment at 2 years of age in CHIKV infected infants (n=18) versus uninfected infants (n=413). CHIKV infected infants showed a trend for lower total composite score on the Inter-NDA than non-CHIKV infected infants [M=3.218 (95% CI: 2.904 - 3.533) v. M=3.488 (95% CI: 3.425 - 3.551), p=.086] but significantly lower scores on the overall language subscale [M=2.760 (95% CI: 2.385 - 3.135) v. M=3.090 (95% CI: 3.024 - 3.156), p<.05], which was driven by lower scores on the expressive language subscale [M=2.607 (95% CI: 2.246 - 2.969) v. M=2.931 (95% CI: 2.870 - 2.992), p<.05]. These results are driven partly by post-partum (mosquito-borne) infection as infants who were CHIKV IgG positive born to mothers who were IgG negative (n=7) had lower expressive language subscale scores than all the other infants (n=425) [M=2.191 (95% CI: 1.703 - 2.678)] v. [M=2.932 (95% CI: 2.871 - 2.992)], p<.01. These results confirm findings from La Réunion: while rates of maternal-fetal transmission are low, infant infection with CHIKV can have a significant impact on early neurodevelopment. Negative impact of post-partum infection on language function is a novel finding in this study.

652

A BRIEF HISTORY OF TIME AND ORIGIN OF CHIKUNGUNYA VIRUS SPREAD IN THAILAND AND PHILIPPINES

Irina Maljkovic Berry[1], Chonticha Klungthong[2], Wiriya Rutvisuttinunt[1], Piyawan Chinnawirotpisan[2], Damon W. Ellison[2], Butsaya Thaisomboonsuk[2], Prapapun Ong-ajchaowlerd[2], Maria Theresa Alera[2], Anon Srikiatkhachorn[3], Sarunyou Chusri[4], In-Kyu Yoon[5], Richard G. Jarman[1], Louis R. Macareo[2]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]University of Rhode Island, Providence, RI, United States, [4]Prince of Songkla University, Songkla, Thailand, [5]International Vaccine Institute, Seoul, Republic of Korea

Chikungunya virus (CHIKV) was first reported in Thailand in 1958, and cases of infections have been continuously described until the outbreak of 1995-96. This was followed by a period of low activity until 2008, when the disease emerged again. In order to investigate the spread of CHIKV in Thailand in greater detail, we sequenced and analyzed additional CHIKV samples from this country, collected between 1976 and 2012. Additional samples from the Philippines (2013-2014) were also available and analyzed to increase resolution of our results. Maximum likelihood trees showed that our new genomes fell within both Asian and ECSA lineages, which were subsequently analyzed separately by Bayesian tree inference. Thai genomes from 1976-1996 and the genomes from the Philippines were found within the Asian lineage. Our estimates indicate CHIKV entered Thailand in 1956 and moved into Indonesia around 1981. Indonesia seeded transmission to many other countries, including two separate introductions into the Philippines, in late 1984 and late 2006. This second introduction established a successful spread of the virus and the most recent Philippines genomes from 2013-14 still fall within this group of viruses. All the genomes from the Asian lineage, including Thailand and Philippines, had the E1-A98T mutation that imposes an epistatic constraint on the E1-A226V change, preventing the emergence of enhanced infection within *Aedes albopictus.* Thai samples collected 2008-2013 were found exclusively in the ECSA lineage, strongly suggesting complete replacement of the Asian lineage in Thailand. Our results indicate several introductions of the ECSA virus into Thailand, all seeded from Malaysia around 2007, with a single dominant cluster establishing successful spread until 2013. All Thai genomes from the ECSA lineage contained several mutations that enhance infection and fitness of CHIKV in both *Ae. albopictus* and *Ae. aegypti.* Although detection of the ECSA lineage in the Americas has been limited and sporadic, these adaptive mutations may increase the risk of virus spread to these regions and potential lineage replacement, as already observed in Thailand.

653

SOCIAL AND ENTOMOLOGICAL DRIVERS INTERCONNECT IN DRIVING SPATIAL PROPAGATION OF CHIKUNGUNYA VIRUS IN BANGLADESH

Quirine Astrid ten Bosch[1], Henrik Salje[1], Kishor K. Paul[2], Abu Mohd Naser[2], Mahmudur Rahman[3], James D. Heffelfinger[4], Shafiul Alam[2], H.m. Al-Amin[2], Ziaur Rahman[2], Sayma Afroj[2], Derek Cummings[5], Repon C. Paul[2], Stephen P. Luby[6], Emily S. Gurley[7], Simon Cauchemez[1]

[1]Institut Pasteur - Paris, Paris, France, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]Institute for Epidemiology, Disease Control and Research, Dhaka, Bangladesh, [4]US Centers for Disease Control and Prevention, Atlanta, GA, United States, [5]University of Florida, Gainsville, FL, United States, [6]Stanford University, Stanford, CA, United States, [7]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

An individual's risk of arboviral infection depends on behaviour and local environment. Understanding how these factors interconnect to drive transmission across spatial scales is pertinent for better preparedness and control efforts. Recent advances have been made at neighbourhood and country levels, but the drivers of pathogen dispersal between communities, the scale at which control programs often act, are poorly understood. We performed a household-based seroprevalence study in individuals of all ages in 40 randomly selected villages in Chapainawabganj, Bangladesh, following a chikungunya outbreak in the district. We collected information on demographics and travel behaviours, and trapped mosquitoes. Participants provided blood samples that we tested for evidence of chikungunya infection (IgG ELISA). We used final size distribution methods in a Bayesian framework to estimate local transmission parameters across villages and characterized proportion of transmission within the household and main determinants of spatial propagation. Among 1502 participants, 130 were seropositive (8.7%). We found significant spatial variability in seroprevalence across villages, ranging from 0% to 74% (median: 3%). The probability of vector-mediated transmission between household members was stable across the district yet varied by household size (2-person household:12%, 95% credible interval [95%CI]: 4-20%; 5-person household:5%, 95%CI 2-8%). Within-household transmission was responsible for 5% of infections. The abundance of *Aedes albopictus* (proportion of trap nights positive) explained 46% of total variance in community transmission as well as the observed spatial dependence between communities. Mosquito abundance was elevated in villages with high connectivity, as measured by the average time inhabitants spent in villages other than their own. This study shows that infection risk is driven by factors outside the household, including distance from affected villages, mosquito abundance, and connectivity. Surveys that identify *Aedes* habitat could help target interventions to the most at-risk communities.

654

IDENTIFICATION OF POSSIBLE MAYARO VIRUS VECTORS

Marco Brustolin, Sujit Pujhari, Cory Henderson, Jason L. Rasgon

The Pennsylvania State University, University Park, PA, United States

Mayaro virus (MAYV) is an *Alphavirus* (family Togaviridae) initially described in 1954 following isolation from the blood of five febrile workers in Mayaro County (Trinidad). Since then, minor MAYV outbreaks have been reported in several countries of South America and the Caribbean. More recently, international travel from endemic areas has increased the number of imported MAYV cases. MAYV thus poses a concern regarding

its invasion potential, similar to spread of Chikungunya and Zika viruses. With the exclusion of *Haemagogus* sp. and *Aedes aegypti*, little is known about the range of mosquito species that are competent to transmit MAYV. We tested vector competence of 2 different MAYV genotypes (D and L) for six different mosquito species across 3 genera (*Aedes aegypti*, *Anopheles gambiae*, *An. stephensi*, *An. quadrimaculatus*, *An. freeborni*, *Culex quinquefasciatus*) using the focus forming assay (FFA). Despite its status as the putative major vector of MAYV in South America, *Ae. aegypti* was almost completely refractory to infection by MAYV genotype L, and while genotype D was able to infect and disseminate, only one mosquito was able to transmit. *Cx. quinquefasciatus* was completely refractory to infection by genotype L, and very poorly infected by genotype D, with no mosquitoes transmitting. In contrast, all species of *Anopheles* were able to be infected with both MAYV genotypes. *An. stephensi, gambiae* and *quadrimaculatus* were able to transmit both genotypes, while *An. freeborni* was able to transmit the L genotype. This is the first study to indicate that *Anopheles* mosquitoes are competent vectors of MAYV. The 4 *Anopheles* species included in this study are highly divergent and native to widely separated geographic regions (Africa, Southeast Asia, and North America), suggesting that *Anopheles* mosquitoes may be important in the invasion and spread of MAYV across diverse regions of the world, including North America.

REACTIVE CASE DETECTION FOR THE ELIMINATION OF MALARIA IN CAMBODIAN FOREST GOERS: RESULTS FROM THE PACES TRIAL

Shunmay Yeung[1], Po Ly[2], Nicola James[1], Huy Rekol[2], Siv Sovannaroth[2], David Bath[1], Thavrin Bounkheng[3], Benoit Witkowski[4], Soy Ti[5]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Cambodia National Center for Malaria, Parasitology and Entomology, Phnom Penh, Cambodia, [3]Cambodia National Center for Malaria, Parasitology and Entomology School of Hygiene and Tropical Medicine, Phnom Penh, Cambodia, [4]Institut Pasteur Cambodia, Phnom Penh, Cambodia, [5]Centre for Health and Social Development, Phnom Penh, Cambodia

Cambodia is one the Greater Mekong Sub-region aiming for malaria elimination. Challenges include multi-drug resistant *Plasmodium falciparum* malaria which have necessitated a recent switch back to artesunate- mefloquine from dihydroartemisinin-piperaquine and a hard to reach high risk population of mobile forest-goers. In order to inform decision on how to operationalise key strategies for malaria elimination in this region we conducted mixed-methods operational research study in 130 villages on Cambodia-Thai border. At the core of the study was a cluster randomised control trial of reactive and proactive case detection using rapid diagnostic tests, PCR, LAMP and ultra-sensitive RDTs. Between May 2016 and Dec 2017 we received 344 notifications of symptomatic *P. falciparum* index cases we carried out 192 reactive case investigations and screened over 1000 contacts. Overall malaria positivity by PCR was 13%, predominantly *P. vivax*. Co-travellers who had visited the forest with the index case in the last month, and high-risk neighbours had the highest positivity rates for *P. falciparum*. Adherence to the 3-day course of treatment and general acceptance of the intervention was high. We will present final results from this study and discuss implications for scaling up and sustainability.

656

THE COST OF ACTIVE CASE DETECTION FOR MALARIA ELIMINATION: FINDINGS FROM THE PACES CLUSTER-RANDOMIZED TRIAL IN CAMBODIA

Blandine Binachon[1], David Bath[1], Po Ly[2], Siv Sovannaroth[2], Soy Ti[3], Shunmay Yeung[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Cambodia National Center for Malaria, Parasitology and Entomology, Phnom Penh, Cambodia, [3]Center for Health and Social Development, Phnom Penh, Cambodia

Cambodia aims to eliminate all malaria by 2025. Key strategies include reactive case detection and a focus on the forest going population. In 2016-2017, we conducted a cluster-randomisedtrial aiming at reducing malaria parasite reservoirs, with an active case detection approach targeting the forest goers. Case investigations were triggered upon notification of symptomatic falciparum malaria cases; high risk contact were screened using rapiddiagnostic tests and high sensitivity diagnostics. An economic evaluation was conducted alongside the trial. We assessed the financial and economic costs of implementing the intervention, using cost data from project accounts. We analysed separately the setup activities, investigation team, laboratory analyses, and other intervention costs. We adjusted costs to anticipate implementing in operational circumstances rather than under trial conditions. Research-related costs (project management, social sciences research, baseline and endline surveys) were excluded. For resources that were used for both research and intervention activities, we estimated the proportion allocated to one or the other from observations of the activities and interviews conducted with the study team. Over two malaria seasons, a total of 1,657 individuals were tested for malaria. After excluding research costs, we found that the financial cost to deliver the intervention was US$74 per person tested. The main cost drivers were the employment and other costs of the intervention team (63% of total costs), laboratory analyses (15%), and setup costs (13%). Our assumptions are tested by a series of sensitivity analyses. We also estimate the cost impact of delivering the intervention to the high risk population only.

657

RESULTS FROM THE CORE TRIAL IN SOUTHERN PROVINCE, ZAMBIA, COMPARING TWO REACTIVE RESPONSES IN A QUEST TO ACCELERATE ELIMINATION OF MALARIA

Daniel J. Bridges[1], John M. Miller[1], Victor Chalwe[2], Hawela Moonga[3], Busiku Hamainza[3], Richard W. Steketee[4], Brenda Mambwe[1], Conceptor Mulube[1], Chris Drakeley[5], Sandra Chishimba[1], Mulenga Mwenda-Chimfwembe[1], Kafula Silumbe[1], Jenala Nyangu[1], David A. Larsen[6]

[1]PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Lusaka, Zambia, [2]Zambia Ministry of Health, Provincial Medical Office, Mansa, Zambia, [3]National Malaria Elimination Centre, Zambia Ministry of Health, Lusaka, Zambia, [4]PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Seattle, WA, United States, [5]London School of Hygiene & Tropical Medicine, London, United Kingdom, [6]Syracuse University Department of Public Health, Food Studies and Nutrition, Syracuse, NY, United States

Zambia has seen impressive reductions in malaria transmission, such that the government has set ambitious targets of eliminating the disease by 2021. One key intervention in this success has been training community health workers to test and treat suspected cases, using rapid diagnostic tests and artemether-lumefantrine, as well as perform reactive focal test and treat (RFTAT) in the index case and neighbouring households. To accelerate toward zero, the use of a more aggressive approach; reactive focal drug administration (RFDA) using the longer lasting dihydroartemisinin-piperaquine, was evaluated against RFTAT in the Community-led Responses for Elimination (CoRE) randomized

controlled trial. Data from this two-year trial include: 1) a cross-sectional endline survey to measure seropositivity and *P. falciparum* prevalence in children under 15 years of age, to be performed in May 2018; 2) routine, aggregate health facility catchment area (HFCA) data, including community health worker health posts; and 3) longitudinal cohorts enrolled in reactive responses to measure clearance and re-infection rates for each arm. During the study, malaria incidence has dropped dramatically, with no significant difference in incidence between the two arms after the first year. However, in 2018, the control arm has reported 68 confirmed cases of malaria compared to only 27 in the intervention arm. PCR analysis of reactive responses strongly demonstrates the focal nature of transmission with >95% of all positives found in the index household. Further analyses of this study will follow final data collection. Optimizing the approach to malaria elimination through the use of community health worker responses to malaria cases is critical for rapidly achieving national strategic goals.

REACTIVE CASE DETECTION FOR MALARIA ELIMINATION IN ZANZIBAR - SYSTEM EFFECTIVENESS AND COST

Logan Stuck[1], Fakih Bakar[2], Abdul-Wahid Al-Mafazy[3], Abdullah Ali[3], Manuel Hetzel[4], Joshua Yukich[1]

[1]Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, [2]Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania, [3]Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania, [4]Swiss Tropical and Public Health Institute, Basel, Switzerland

Reactive case detection (RCD) for malaria is a surveillance strategy in which the detection of a malaria case by passive surveillance triggers a search for more cases in and around the household of the passively detected case. RCD is currently used in Zanzibar as part of their elimination strategy. This research aims to evaluate RCD as a surveillance strategy in Zanzibar and consists of a rolling cross-sectional survey and a cost analysis. In the survey, research staff attend RCD investigations to administer a household questionnaire and test all household members for malaria. In the costing component of the study the cost of the system as it currently operates is assessed and compared with hypothetical variants of the system. RDT prevalence was 2.5% amongst index household members and 0.4% amongst member of neighboring households. Logistic regression analyses on current data shows that the odds of being RDT-positive as a member of an index household are 6.3 times that of those in surrounding households (p<0.0001; 95% CI: 3.9-10.3). This heightened odds of infection reflects evidence in support of visiting the index household for the detection of new cases, and demonstrates much lower marginal return to expanding searches beyond the index household.

659

PRO-ACTIVE CASE DETECTION IN AN AREA OF ARTEMISININ RESISTANCE: IDENTIFYING ASYMPTOMATIC CARRIERS AND ACCELERATING ELIMINATION EFFORTS

Neil J. Saad[1], Caroline De Cramer[1], Sokha Thoang[1], Vuthea Van[1], Lieven Vernaeve[1], William Etienne[2], Rekol Huy[3], Chea Nguon[3], Nimol Khim[4], Benoit Witkowski[4], Jean-Marie Kindermans[5], Martin De Smet[5]

[1]Médecins Sans Frontières, Preah Vihear, Cambodia, [2]Médecins Sans Frontières, Phnom Penh, Cambodia, [3]Centre for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [4]Institut Pasteur du Cambodge, Phnom Penh, Cambodia, [5]Médecins Sans Frontières, Brussels, Belgium

Additional strategies are needed to accelerate malaria elimination, particularly in areas of artemisinin resistance. Therefore, Médecins Sans Frontières has implemented a novel pro-active case detection approach (ProACD) in Cambodia to detect asymptomatic malaria, complementary to a strengthened passive case detection (PCD). Here, we evaluate the feasibility and output of implementing this strategy and assess the profile of asymptomatic malaria cases, defined as absence of fever in the preceding two days. ProACD involves voluntary screening and treatment rounds in villages and targets at-risk individuals (forest and plantation workers). After a pilot with PCR-based screening, a new ProACD strategy started in Oct 2017 at 22 locations across 2 districts. ProACD is supported by a network of villagers and health promotion activities to sensitise the population. To increase cost-effectiveness, diagnosis is done using a hyper-sensitive rapid diagnostic test (Alere Malaria Ag Pf). *Plasmodium falciparum* (Pf) cases were confirmed with PCR and completed an interviewer-led questionnaire to characterise asymptomatic individuals. ProACD screenings were well accepted and overall 9827 individuals were screened. Of these, 6004 (61%) were unique visits, which gives an overall coverage of 36% (6004/16570). Overall, 62 Pf cases were detected (positivity rate: 0.6%), which were predominately male (52/62, 84%) and aged 15-45 yrs (43/62, 69%). Interviews were completed among 71% (44/62) of whom 20% (9/44) did not report an episode of sickness in the preceding two weeks. This was supported by a statistically significant lower estimated parasitaemia observed among the individuals not reporting any sickness in the preceding two weeks. In contrast, those labelled asymptomatic had a mean parasitaemia of 301 parasites/µL (SD: 599 parasites/µL). In the same period in the same villages we found 543 Pf PCD cases. We demonstrated the feasibility of introducing ProACD. We found that the majority of those labelled asymptomatic have parasitaemia well above submicroscopic levels and likely contribute to onward disease transmission.

EVALUATION OF A NEW HIGHLY-SENSITIVE RAPID DIAGNOSTIC TEST FOR REACTIVE CASE DETECTION IN RAKHINE STATE, MYANMAR

San K. Khine[1], Kyaw M. Tun[2], Kay T. Han[3], Zay Y. Han[3], Thant K. Oo[4], Aung Thi[5], Aye Nyein[5], Nay Y. Lin[5], Zaw M. Tun[5], Saw Lwin[6], Khin T. Win[2], Feliciano Monti[7], Jimee Hwang[8], Nelli Westercamp[8], Daniel J. Martinez[9], Zaw W. Thein[9], Thura Htay[9], Poe P. Aung[9], Christopher V. Plowe[9], **Myaing M. Nyunt**[9]

[1]Vector Borne Disease Control, Rakhine State, Myanmar Ministry of Health and Sports, Sittwe, Myanmar, [2]University Research Corporation, Yangon, Myanmar, [3]Department of Medical Research, Myanmar Ministry of Health and Sports, Yangon, Myanmar, [4]University Research Corporation, Washington, DC, United States, [5]National Malaria Control Program, Myanmar Ministry of Health and Sports, Nay Pyi Taw, Myanmar, [6]University Research Corporation, Washington, DC, United States, [7]President's Malaria Initiative, U.S. Agency for International Development, Yangon, Myanmar, [8]U.S. Centers for Disease Control & Prevention, Atlanta, GA, United States, [9]Duke Global Health Institute, Durham, NC, United States

Recent malaria surveys revealed unexpectedly high prevalence of asymptomatic malaria infections in Myanmar. Most of these "silent" infections have parasite densities below the limits of detection of conventional rapid diagnostic tests (cRDT) and are detectable only with ultrasensitive PCR (usPCR) methods that have lower limits of detection thousands-fold lower than those of cRDTs. Although usPCR has been used to target elimination interventions such as mass drug administration in Myanmar, the utility and scalability of usPCR is limited by its complexity, cost, and need for centralized testing. A new highly sensitive RDT (hsRDT) that targets *Plasmodium falciparum* HRP-2 offers an alternative point-of-contact test to detect asymptomatic falciparum malaria. A prospective community-based study was conducted in rural Sakhunmaw township of Rakhine State, western Myanmar, to assess the performance of hsRDT for reactive case detection, in comparison with cRDT, using usPCR as gold standard. Individuals with cRDT-confirmed *P. falciparum* malaria were enrolled as index cases. Reactive case detection was done by testing potential contacts from households surrounding the household of each index case. Ten households (average of 4 contacts per household) for each index case were tested, with a target sample size of 50 index cases and approximately 2,000 contacts. Preliminary analyses

after 36 index cases and 1,120 contacts had been enrolled showed that hsRDT identified 3.6-fold more *P. falciparum* infections than cRDT, and approximately 80% of usPCR-positive infections were detected by hsRDT, suggesting that this new point-of-contact test may be useful for targeting elimination interventions such as test-and-treat or mass treatment. Based on final results that will be available in July, 2018, test characteristics of the hsRDT and cRDT in relation to usPCR as a gold standard, including sensitivity, specificity, and positive and negative predictive value, as well as demographic and geospatial analyses of malaria risk, will be presented.

661

HOW RELEVANT IS ULTRA-SENSITIVE MALARIA DIAGNOSTICS FOR MALARIA ELIMINATION?

Natalie E. Hofmann[1], Maria Gruenberg[1], Elma Nate[2], Alice Ura[2], Daniela Rodriguez-Rodriguez[1], Ivo Mueller[3], Thomas A. Smith[1], Moses Laman[2], Leanne J. Robinson[4], Ingrid Felger[1]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]Papua New Guinea Institute for Medical Research, Madang, Papua New Guinea, [3]Institut Pasteur, Paris, France, [4]Burnet Institute, Melbourne, Australia

Sub-microscopic malaria infections are recognized as an important reservoir for mosquito infection. Their extent is underestimated even by standard molecular diagnostics and their relevance for malaria elimination is unclear. Sophisticated sampling of venous blood and ultra-sensitive molecular methods can maximize test sensitivity but are not feasible in routine surveillance. A recently developed ultra-sensitive *Plasmodium falciparum (Pf)* rapid diagnostic test (us-*Pf*RDT) promises high field applicability, but its usefulness in interventions aiming at elimination is disputed. To define the diagnostic sensitivity necessary to guide malaria interventions, venous blood was collected from 300 participants in a community survey in Papua New Guinea. Ultra-sensitive qPCR (us-qPCR) on concentrated high-volume blood samples (2ml) was used as reference to evaluate the sensitivity to detect *Pf* or *P. vivax (Pv)* infections as well as gametocyte carriers in 200µl finger-prick volumes, by the following diagnostics: standard qPCR (st-qPCR), us-qPCR, standard RDT (st-RDT) and us-*Pf*RDT. Relative to the positivity in high blood volumes, st-qPCR and us-qPCR on finger-prick volumes identified 51% and 61% of *Pf* infections and 54% and 61% of *Pv* infections. These constituted 76% and 82% of *Pf* gametocyte carriers and 86% and 91% of *Pv* gametocyte carriers. Sensitivity was much lower for both RDTs. us-*Pf*RDT detected 27% of *Pf* infections (i.e. half of *Pf* infections detectable by st-qPCR) and missed 59% of *Pf* gametocyte carriers, including high gametocyte densities. *Pf* and *Pv* infections undetectable by st-qPCR were evenly distributed in the population. Epidemiological patterns thus corresponded well between st-qPCR and the reference method. Alongside a decrease in *Pv* prevalence with age, the proportion of *Pv* infections undetectable by st-qPCR increased. In conclusion, finger-prick blood volumes suffice to identify virtually all potentially transmitting *Pf* and *Pv* carriers if analysed by molecular methods. Little can be gained from analysing larger blood volumes. Current RDTs cannot replace molecular diagnostics for identifying potential *Pf* transmitters.

MOLECULAR XENOMONITORING AND ANTIGEN SURVEYS REVEAL STRONG SIGNALS FOR PERSISTENT *WUCHERERIA BANCROFTI* INFECTION IN NORTHERN HAITI AFTER EIGHT ROUNDS OF MASS DRUG ADMINISTRATION

Joseph R. Fauver[1], Bernard A. Okech[2], Anita D. Sircar[3], Ramakrishna Rao[1], Madsen Beau de Rochars[2], Joshua Bogus[1], Abdel N. Direny[4], Jean R. Ernest[5], Carl R. Fayette[5], Katiuscia O'Brian[1], Daniel F. Sabin[5], Gary J. Weil[1], Jean Frantz Frantz Lemoine[6], Christine Dubray[3]

[1]Washington University in St. Louis, St. Louis, MO, United States, [2]University of Florida, Gainesville, FL, United States, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]RTI International, Research Triangle Park, NC, United States, [5]IMA World Health, Port-au-Prince, Haiti, [6]Ministère de la Santé et de la Population, Port-au-Prince, Haiti

Lymphatic Filariasis (LF) is a disabling vector-borne disease caused by thread-like filarial worms that affects some 100 million people in developing countries. The Global Program to Eliminate Lymphatic Filariasis is providing annual rounds of mass drug administration (MDA) with antifilarial drugs until specific human infection targets are met. In areas where *Culex* mosquitoes are the primary vector of *Wuchereria bancrofti*, detection of filarial DNA in mosquitoes (molecular xenomonitoring, MX) can identify residual infection in communities. Our group recently conducted a community treatment trial in 10 localities in Northern Haiti (population 12,384) that had persistent LF after 7 rounds of MDA. Localities were randomly assigned to receive treatment with either a 2-drug (diethylcarbamazine and albendazole [DA]) or a 3-drug (ivermectin, diethylcarbamazine, albendazole [IDA]) regimen. One year later, *Cx. quinquefasciatus* mosquitoes were collected using gravid traps placed near randomly selected residences in the 10 localities, and filarial antigen surveys were performed to estimate human infection rates in the same areas. 213 (40.1%) of 531 pools of mosquitoes that were collected from 180 trapping sites were positive for *W. bancrofti* DNA by real-time PCR. Filarial DNA rates in mosquitoes in areas treated with DA or IDA were estimated to be 2.4% (95%CI 1.9-2.9) and 2.7% (95%CI 2.2-3.2) respectively, well above the provisional target for LF elimination (upper 95%CI of the filarial DNA rate in mosquitoes < 1%). After MDA, filarial antigenemia rates in humans in the DA and IDA treatment areas were 10.0% (103/1032, 95%CI 6.3-13.6) and 8.5% (88/1032, 95%CI 0.6-16.5), respectively, well above the elimination target rate of < 2%. A spatial analysis showed similar distributions for positive mosquito trap sites and for houses with at least one infected inhabitant. This study has demonstrated the usefulness of MX to identify and indirectly assess human infection following MDA, and it provides a solid baseline for assessing the impact of future efforts to eliminate LF in this area.

PAST AND FUTURE SPREAD OF THE ARBOVIRUS VECTORS *AEDES AEGYPTI* AND *AE. ALBOPICTUS*

Moritz U. Kraemer[1], Robert C. Reiner Jr[2], Oliver J. Brady[3], Jane P. Messina[1], Marius Gilbert[4], Simon I. Hay[2], Nick Golding[5]

[1]University of Oxford, Oxford, United Kingdom, [2]University of Washington, Seattle, WA, United States, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom, [4]Universite Libre de Bruxelles, Brussels, Belgium, [5]University of Melbourne, Melbourne, Australia

Past and future spread of the arbovirus vectors *Aedes aegypti* and *Ae. albopictus* Dengue, yellow fever, chikungunya, and Zika are expanding their respective geographical ranges and causing severe outbreaks in many urban populations. Transmission of these viruses depends largely on the presence of the competent mosquito vectors *Aedes aegypti* and *Ae. albopictus*. The global spread of these two mosquitoes means they are now established on every human-inhabited continent and continuing to spread more widely overland. We show that quantitative estimates of human movement patterns explain the spread of both species in Europe and the United States of America (USA) following their introduction, thereby providing insights with which to predict future movements. We find that the spread of *Ae. aegypti* is characterised by long distance importations, whilst *Ae. albopictus* has expanded more along the fringes of its current distribution. We describe these processes and predict the future distributions of both species in response to accelerating urbanisation, connectivity and climate change. In the next 5-15 years the spread of both species is predicted to occur independently of any environmental changes, as both species continue to realise their newfound anthropogenic niches. *Aedes aegypti* is expected to occupy its niche in the next 5 years and will spread more slowly after 2020. Despite this, the human population living in areas suitable for the mosquitoes is projected to almost double, from ~2.4 billion to ~4 billion by 2050, mostly due to population growth in areas already at-risk. For *Ae. albopictus,* geographic

expansion driven by human introductions is expected to peak by 2050 and the population at risk is projected to increase from ~2.3 billion to ~3.9 billion. Global surveillance and control efforts that aim to mitigate the spread of chikungunya, dengue, yellow fever and Zika viruses must consider the so far unabated spread of these mosquitos. Our maps and predictions offer an opportunity to strategically target surveillance and control and thereby augment efforts to reduce arbovirus burden in human populations globally.

664

EXTENSION OF LIFESPAN IN *ANOPHELES COLUZZII* MOSQUITOES BY CLIMATIC MODULATION

Benjamin J. Krajacich, Lea Graber, Roy Faiman, Tovi Lehmann

National Institute of Allergy and Infectious Diseases, Rockville, MD, United States

The mechanisms by which *Anopheles* spp. mosquitoes persist through the dry season in Africa remain a critical knowledge gap to our understanding of these malaria vectors. To span this period in locations like the Sahelian zone of Mali, mosquitoes must migrate to areas of permanent water or survive in conditions including high temperatures, low humidity, and an absence of surface water (required for breeding). Adult mosquitoes surviving through this period must dramatically extend their typical lifespan (averaging 2-3 weeks) to 7 months. Previous work found *An. coluzzii* surviving over 200 days in the wild across rainy seasons in a presumed aestivation (hibernation) state, but this state has so far not been replicated in laboratory conditions. Thus, it is currently unknown how aestivation affects malaria vector competence, and other factors. To investigate how environmental conditions change mosquito lifespan (a key indicator of aestivation), we compared survivorship in climate controlled incubators that adjusted humidity (down to 40% RH), temperature (to 18°C), and light conditions (8 hours of light) to normal insectary conditions. These conditions were chosen to mimic the late rainy and dry seasons as well as relevant extremes these mosquitoes may experience during aestivation. We found that by priming mosquitoes in conditions simulating the late wet season in Mali, and keeping mosquitoes in reduced light and temperature, mean mosquito lifespan was increased from 18.34 ± 0.65 to 48.02 ± 2.87 days, median lifespan was increased from 19 (95% CI: 17-21) to 50 days (95% CI: 40-58), and the maximum longevity was increased from 34 to 102 days (p-adj < 0.001). While this increase falls short of the 200+ day survival seen in field mosquitoes, this extension is higher than has been previously reported through environmental or dietary modulation, and is hard to reconcile with states other than aestivation. Future work will expand on these findings, looking to extend the gains in life span while also investigating transcriptional changes in genes affecting aging, metabolism, and epigenetic regulation; hormone and nutrient levels; and vector competence.

665

FUNCTIONAL DISSECTION OF A NATURAL RESISTANCE PHENOTYPE AGAINST DENGUE-1 VIRUS INFECTION IN *AEDES AEGYPTI* MOSQUITOES

Sarah H. Merkling[1], Isabelle Moltini-Conclois[1], Odile Sismeiro[1], Hugo Varet[1], Rachel Legendre[1], Davy Jiolle[1], Christophe Paupy[2], Louis Lambrechts[1]

[1]Institut Pasteur, Paris, France, [2]Maladies Infectieuses et Vecteurs : Ecologie, Génétique, Evolution et Contrôle (MIGEVEC), Montpellier, France

Aedes mosquitoes are vectors of several medically significant arthropod-borne viruses (arboviruses), such as dengue viruses (DENV-1, -2, -3 and -4), threatening human health and causing viral epidemics. Natural mosquito populations display substantial variation in their susceptibility to arbovirus infection. Interrogating this natural variation is a powerful approach to understand how mosquitoes acquire and transmit arboviruses, and identify novel host restriction factors. This knowledge is essential to the development of innovative disease control strategies, such as the release of lab-engineered mosquitoes rendered unable to replicate arboviruses. We recently isolated an *Aedes aegypti* mosquito population from Bakoumba (Gabon) that exhibits a strong resistance phenotype to DENV-1 infection. After oral exposure to the same infectious dose, only 50% of Bakoumba mosquitoes become persistently infected with DENV-1, compared to 100% with DENV-3 and 75% with DENV-2. A time-course analysis of viral RNA levels in DENV-1-exposed mosquitoes revealed that resistance occurs during early infection of the midgut within 48 hours after the infectious blood meal. Resistance to DENV-1 is independent of the bacterial microbiota, as the phenotype remained unaffected upon antibiotic treatment of adult mosquitoes. We analyzed the transcriptomes of 'susceptible' (persistently infected) vs. 'resistant' (exposed but uninfected) individuals by RNA sequencing on single midguts, and identified a set of genes that were significantly differentially expressed only in the resistant midguts at 24 or 48 hours post exposure, thus potentially conferring resistance to virus infection. We next tested a shortlist of candidate genes in a functional screen *in vivo* based on RNAi-mediated gene silencing assays followed by oral infection challenge. This led to the identification of a set of 2 novel proviral and 2 novel antiviral genes that are currently undergoing functional characterization by CRISPR/Cas9-mediated transgenesis.

666

SUPERINFECTION EXCLUSION BETWEEN DENGUE AND ZIKA VIRUSES IN *AEDES* MOSQUITOES

Emily G. McDermott, H. Tara Olowolayemo, Lindsey S. Garver

Walter Reed Army Institute of Research, Silver Spring, MD, United States

Dengue (DENV) and Zika (ZIKV) viruses are emerging Flaviviruses transmitted by *Aedes* mosquitoes. After the 2015 ZIKV epidemic in Brazil, there was a great deal of interest in the ability of mosquitoes, particularly *Ae. aegypti*, to transmit multiple viruses. Subsequent work showed that *Ae. aegypti* is capable of becoming infected with and transmitting ZIKV and DENV after ingesting both viruses in a single blood meal. While human co-infections of DENV and ZIKV have been reported, mosquito co-infections resulting from a single blood meal are likely extremely rare. More commonly, mosquitoes would be exposed to multiple viruses via separate hosts. To assess whether *Ae. aegypti* and *Ae. albopictus* are able to co-transmit ZIKV and DENV, we exposed mosquitoes to both viruses sequentially. Mosquitoes were fed an infectious blood meal containing DENV, an uninfectious blood meal, or were intrathoracically-injected with DENV. On 7dpi, all mosquitoes were fed a second blood meal containing ZIKV. Saliva and bodies were collected on 16 and 23dpi. Individual mosquitoes were dissected, and the saliva, head/thorax, and abdomen were tested for DENV/ZIKV using multiplex qRT-PCR to assess transmission, dissemination, and infection. Mosquitoes that became infected with DENV prior to ZIKV exposure had significantly lower ZIKV dissemination rates than mosquitoes that were fed uninfected blood, or that did not develop DENV infections. Infection rates in the abdomen did not differ between groups, suggesting that DENV either prevented ZIKV escape from the midgut or establishment in secondary infection sites. Transmission rates were very low, regardless of treatment, even at 23dpi. A small number of individuals developed co-infections, but no co-transmission was observed. While it is possible for *Aedes* to co-transmit DENV and ZIKV if both viruses are ingested in a single blood meal, we have shown that co-infections resulting from sequential blood meals are rare. Further research is needed on the environmental, genetic, and behavioral drivers of vector competence that may affect susceptibility to co-infection in the field.

667

WOLBACHIA EFFECTS ON ARBOVIRUS INFECTION IN MOSQUITOES ARE VARIABLE AND DEPEND ON THE *WOLBACHIA* STRAIN, THE MOSQUITO SPECIES, AND THE PATHOGEN

Jason Rasgon[1], Brittany Dodson[1], Elizabeth Andrews[2], MIchael Turell[3], Laura Kramer[4]

[1]Pennsylvania State University, University Park, PA, United States, [2]CA Department of Public Health, Sacramento, CA, United States, [3]VectorID LLC, Frederick, MD, United States, [4]Wadsworth Center, Albany, NY, United States

The bacterial symbiont Wolbachia been shown to induce resistance to pathogen infection and transmission in vector arthropods, leading to trials examining Wolbachia for vector-borne disease control. However, some Wolbachia strains have been demonstrated to enhance rather than suppress pathogens in a variety of natural and artificially infected arthropod hosts. Here, we investigated the effects of multiple Wolbachia strains on flavivirus, alphavirus, and bunyavirus infection in Culex and Aedes mosquitoes. We show that depending on the mosquito host, the Wolbachia strain, and the pathogen, Wolbachia may suppress, enhance, or have no effect on virus infection and titer. These data indicate that the suppressive effects of Wolbachia infection on pathogens are not universal, but rather depend on the characteristics of the specific symbiont-vector-pathogen system in question. These results have important implications for the deployment of Wolbachia-infected mosquitoes into field populations for disease control.

668

COMPOSITION OF THE *AEDES AEGYPTI* MICROBIOME IS ALTERED BY *WOLBACHIA*, BUT IS NOT CRITICAL TO *WOLBACHIA* BLOCKING OF DENGUE VIRUS

Michelle D. Audsley[1], Andrei Seleznev[2], D. Albert Joubert[3], Yixin H. Ye[2], Megan Woolfit[3], Elizabeth A. McGraw[4]

[1]Biomedicine Discovery Institute, Monash University, Victoria, Australia, [2]School of Biological Sciences, Monash University, Victoria, Australia, [3]Institute of Vector-Borne Disease, Monash University, Victoria, Australia, [4]The Center for Infectious Disease Dynamics, The Pennsylvania State University, Pennsylvania, PA, United States

Dengue virus is primarily transmitted by the mosquito *Aedes aegypti*, and is the causative agent of dengue fever and the more severe dengue hemorrhagic fever/dengue shock syndrome. A method for dengue control being employed globally involves stable transinfection of *Ae. aegypti* with the common insect endosymbiont *Wolbachia*, which mediates an antiviral effect. However, the mechanism by which *Wolbachia* reduces the susceptibility of *Ae. aegypti* to dengue is not fully understood. In this study we considered the impact of *Wolbachia* infection on the intrinsic bacterial population (microbiome) of *Ae. aegypti*, and whether other bacteria that reside in the mosquito might affect the ability of *Wolbachia* to limit dengue virus infection. We used sequencing of the conserved 16S rRNA gene to compare the microbiome profiles of *Ae. aegypti* mosquitoes stably infected with *Wolbachia* to those without *Wolbachia*, collected from field release sites in Australia. We also used antibiotic treatment of laboratory-reared *Ae. aegypti* to shift their microbiome profiles and then assessed their susceptibility to dengue virus. We found that *Wolbachia* had significant interactions with numerous taxa in the field-collected *Ae. aegypti,* causing changes in their relative abundance. The microbiome of the laboratory-reared mosquitoes comprised a much lower number of bacterial species, and the effect of *Wolbachia* was less substantial. Importantly, despite alteration in the microbiome of *Wolbachia*-infected laboratory mosquitoes following antibiotic treatment, we found no change in dengue infection rates. Together these data indicate that *Wolbachia* has some effects on the *Ae. aegypti* microbiome, but it is unlikely that specific resident bacteria are required for the fundamental mechanism by which *Wolbachia* reduces susceptibility to dengue virus.

669

A REVERSE VACCINOLOGY APPROACH FOR IDENTIFYING STH VACCINE CANDIDATES

Makedonka Mitreva[1], Bruce Rosa[1], Dolores Hill[2], Valsin Fournet[2], Jozelyn Pablo[3], Andy Teng[3], Amit Oberai[3], Krista Trappl-Kimmons[3], Dante Zarlenga[2], Joseph Urban[4]

[1]Washington University School of Medicine, St. Louis, MO, United States, [2]U.S. Department of Agriculture, Agricultural Research Service, Beltsville Agricultural Research Center, Animal Parasitic Diseases Laboratory, Beltsville, MD, United States, [3]Antigen Discovery Inc, Irvine, CA, United States, [4]U.S. Department of Agriculture, Agricultural Research Service, Beltsville Human Nutrition Research Center Diet, Genomics, and Immunology Laboratory, Beltsville, MD, United States

Novel prophylactic and therapeutic strategies for STH control are needed because resistance has surfaced to all major anthelmintic drugs in parasites of veterinary importance and because this poses a risk to treating parasites of humans. Vaccines are one plausible solution to sustainable control; however, thus far, only parasite vaccines that attenuate rather than prevent infection have been developed. Omics driven, knowledge-based identification of anti-parasite intervention targets is now possible using the vast amounts of 'omics data available for many parasitic nematode species. To identify and prioritize parasite intervention targets, we employed a reverse vaccinology approach that uses bioinformatics to screen parasite omics data for putative immunoreactive antigens for experimental validation. We used a step-wise approach that: (i) identified putative vaccine targets conserved among gastrointestinal nematodes by constructing orthologous protein families from genomes that span the phylum Nematoda; (ii) prioritized OPFs based on taxonomic conservation, life-cycle expression profiles, proteomics data and secretion potential; and (iii) experimentally tested (ELISA) the top prioritized candidates using infection sera as a "proof-of-principle". As an orthogonal approach, we also independently and experimentally identified differentially expressed proteins through immunoblotting (parasite-susceptible vs resistant pig antibodies) for additional candidates. We intersected all putative vaccine targets from both approaches and experimentally evaluated the top candidates. Since 5 of the 6 prioritized candidates tested positive, we move to and will present our results from the more high-throughput screening using protein microarrays of over 200 proteins. This approach identified parasite proteins that activate immunity as potential vaccine targets, experimentally validated a subset of these as immunologically cross-reactive, and utilized high-throughput screening to demonstrate the use of omics data to facilitate sustainable control strategies for human and animal parasitic infections.

SELECTION AND CHARACTERIZATION OF A NOVEL WHIPWORM VACCINE CANDIDATE THAT INDUCES TYPE 2 PROTECTIVE IMMUNITY

Neima Briggs[1], Leroy Versteeg[2], Maria Elena Bottazzi[2], Bin Zhan[2], Jeroen Pollet[2], Ashish Damania[2], Brian Keegan[2], Junfei Wei[2], Carol Gomez[3], Kelly Hayes[4], Richard Grencis[4], Jagannadha Sastry[1], Peter Hotez[2]

[1]University of Texas - Houston / M.D. Anderson, Houston, TX, United States, [2]Baylor College of Medicine, Houston, TX, United States, [3]Clínica de Santa Ana, Santa Ana, Honduras, [4]University of Manchester, Manchester, United Kingdom

Trichuris trichiura, the common whipworm, is a leading cause of colitis in the developing world with an estimated 465 million people living with whipworms in their colon. The disease disproportionately affects children, resulting in malnutrition, growth stunting, and cognitive deficits.

Successful control of trichuriasis by mass drug administration has been limited due to the combination of poor drug efficacy, high rates of post-treatment reinfection, and failure to co-implement aggressive sanitation programs. Our long-term solution is to develop a vaccine against *T. trichiura*. There is no established laboratory animal model for this human pathogen, so we have adapted the closely related *Trichuris muris* parasite. Vaccination with *T. muris* excretions and secretions (*Tm*-ES) elicits protection in AKR mice. Using the protective anti-*Tm*-ES sera, we have identified 14 antigens by both immunoscreening the *T. muris* cDNA library and by two-dimensional electrophoretic separation of *Tm*-ES followed by western blotting. The most promising candidate, a recombinant *T. muris* whey acidic protein 49 (r*Tm*-WAP49), led to a significant reduction in larval worm burden. Endpoint ELISA titers revealed a high serum IgG1 to IgG2a ratio in protected groups, reflective of a type 2 humoral response. Similarly, a profound type 2 cellular response (interleukin-4 [IL-4], IL-5, IL-9, and IL-13) was measured in the spleens, mesenteric lymph nodes, and the vaccine-draining lymph nodes of protected mice by 23-plex Luminex analysis. Using immunofluorescent staining with anti-r*Tm*-WAP49 sera, we localized native WAP production to the stichosome of *T. muris.* In pursuit of a 'pan-anthelmintic' vaccine, we have fused a fragment of r*Tm*-WAP49 with the hookworm vaccine *Na*-GST-1, which together led to a similar type 2 protective immunity against whipworm. To determine whether our *T. muris* derived WAP proteins had conserved immunogenicity against *T. trichiura*, we measured the human serological and cellular reactivity to both WAP proteins using biological samples collected from adolescents and adults in Honduras naturally infected with whipworm.

671

EOSINOPHIL-DOMINATED PULMONARY TYPE-2 RESPONSE DRIVEN BY ALLERGIC SENSITIZATION INHIBITS LARVAL DEVELOPMENT AND CONTROLS HELMINTH PARASITE BURDEN IN THELUNGS

Pedro H. Gazzinelli-Guimaraes[1], Rafael Q. Prado[1], Alessandra Ricciardi[1], Sandra Bonne-Année[1], Joshua Sciurba[1], Ricardo Fujiwara[2], Thomas Nutman[1]

[1]NIAID, National Institutes of Health, Bethesda, MD, United States, [2]UFMG, Belo Horizonte, Brazil

Although chronic helminth infection has been associated with diminished allergic reactivity (hygiene hypothesis), the impact of pre-existing allergic sensitization on the outcome of helminth infection is less well-studied. Having previously demonstrated an augmented Th2-dominated parasite-specific $CD4^+$ response in the context of human helminth infection with coincident house dust mite (HDM) allergy, we sought to identify the mechanism driving this response and to understand how allergic sensitization may influence parasite burden at the site of inflammation. Using a murine model of HDM-induced allergic asthma and concomitant *Ascaris* spp. infection, our data show that HDM sensitization prior to infection with *Ascaris* induces a robust Type-2-associated inflammation in the lung characterized by an increase in both IL-5/IL-13 producing innate lymphoid cells (ILC2s; $17.9x10^3$ cells vs $2.4x10^3$ cells, $p<0.01$) and eosinophils (140-fold increase, $p<0.001$) when compared to non-allergic infected mice. This pulmonary Type-2 response led to an IL-4-rich environment (8.3 pg/mL vs 3.3 pg/mL, $p<0.01$) that drove the differentiation of lung macrophages towards the M2 phenotype expressing arginase-1 (17.6-fold increase, $p<0.01$), but not iNOS. When the *Ascaris* larvae migrate from the circulation to the lung tissue in their quest to reach the airways in these HDM-sensitized mice, the Type-2-associated inflammation led to a marked reduction (72%) in the number (20±9 larvae vs. 63±50 larvae; $p=0.044$) and in the development of lung-stage *Ascaris* larvae (size 24816 μM^2 vs 58170 μM^2, $p<0.001$) when compared with non-allergic infected mice. When eosinophil deficient (αdblGATA) mice were infected with *Ascaris* following HDM-induced asthma, the numbers of larvae were no longer reduced ($p=0.18$), nor was there any alteration in larval development when compared to αdblGATA non-allergic infected mice ($p=0.08$). Taken together, our data suggest that allergic sensitization coincident with helminth infection drives an eosinophil-rich pulmonary Type-2 response that limits helminth parasite numbers and also directly hinders their developmental program.

672

ASCARIS LARVAL MIGRATION CAUSES LONG-TERM CHANGES IN LUNG STRUCTURE AND FUNCTION

Jill Weatherhead, Evan Li, John Morgan Knight, Bin Zhan, Brian Keegan, Maria Elena Bottazzi, David Corry, Peter Hotez

Baylor College of Medicine, Houston, TX, United States

Ascaris (roundworm) is the most common helminth infection worldwide, infecting over 800 million people and accounting for significant morbidity, particularly in children. Following initial ingestion of *Ascaris* eggs larvae migrate through the host lungs releasing proteinases causing lung injury and hemorrhage. Due to high worm burdens and frequent re-infection, children are at particularly high risk of severe *Ascaris*-induced lung injury. We hypothesize that *Ascaris* larval migration through the lungs causes destruction of the lung extracellular matrix leading to changes in lung function similar to emphysema. BALB/c mice were infected with 2,500 embryonated *Ascaris suum* eggs. µCT imaging was completed to quantify lung volume. Lung compliance was measured using a standardized total pressure-volume (PV) curve based on residual volume and total lung capacity. H&E stained lung tissue was used to measure mean linear intercept (MLI), a standardized evaluation of emphysema-like changes in the lungs, to measure the mean free distance in air space. *Ascaris* infected mice had increased lung volumes measured by µCT at day 12 post-infection (p.i.) (434 vs 485, $p < 0.05$) and 1 month p.i. (458.3 vs 565.6, $p < 0.001$). Additionally, *Ascaris* infected mice had increased lung compliance at Day 12 (0.715 vs 0.846, $p = 0.03$), 1 month (0.9675 vs 1.152, $p <0.005$), and 2 months (0.9525 vs 1.3, $p = 0.01$) p.i. MLI was also increased at 2 months p.i. (33.26 vs 45.91, $p = 0.024$). *Ascaris* larval migration through the lungs causes significant damage to the lung extracellular matrix which impacts lung structure and function. Within the first 2 months p.i., mice develop increased lung volumes, compliance and MLI creating a pulmonary phenotype that resembles human emphysema.

673

THE STRUCTURE AND FUNCTION OF EXTRACELLULAR VESICLES SECRETED BY THE GASTROINTESTINAL NEMATODE PARASITE, *ASCARIS SUUM*

Wang Yuan[1], Hannah Loghry[1], Mostafa Zamanian[2], Michael Kimber[1]

[1]Department of Biomedical Sciences, College of Veterinary Medicine, Iowa State University, Ames, IA, United States, [2]Department of Pathobiological Sciences, University of Wisconsin Madison, Madison, WI, United States

The ability of helminth parasites to modulate or manipulate host biology to both establish and maintain infection is well described. This parasite-derived modulation is often directed towards the host immune response with the goal of suppressing, modifying, or evading the host response. Helminth excretory/secretory products have been the focus of much research effort to identify immunomodulatory molecules, however, specific parasite effectors, and the mechanisms by which they bring about host manipulation, are poorly understood. Extracellular vesicles (EVs) represent a class of newly-identified parasite-derived structures, containing putative protein and small RNA effector molecules. Emerging evidence from our lab, and others, suggest parasite EVs may be important factors operating at the host-parasite interface. We hypothesize that parasitic nematodes release EVs as a mechanism to deliver effector molecules to host tissues and modulate their biology. Here we isolated EVs secreted by adult *Ascaris suum*, a pig gastrointestinal nematode, to study their structure and function. We found that *Ascaris* EVs share the deflated ball morphology reported in the literature with a mean diameter of 168 nM, which is larger than reported in other species. Global proteomic profiling identified 519 proteins from the *Ascaris* EVs, including not only commonly reported

EV markers such as HSP70 and Annexin, but also immune modulation proteins such as macrophage migration inhibitor (MIF-1) and serine protease inhibitor (serpin). *Ascaris* EVs are rapidly internalized (within 24 hours) by primary murine bone marrow-derived macrophages (BMDM) and this uptake was blocked by Cytochalasin D, suggesting phagocytosis or macropinocytosis are possible uptake mechanisms. RNA-seq was used to reveal the small RNA contents of the EVs along with transcriptional changes elicited in BMDM after EV internalization. These data, and the role of *Ascaris* EVs in host immunomodulation, are discussed.

Human ascariasis is a neglected tropical disease caused primarily by the nematode *Ascaris lumbricoides*. At present, relatively little is known about the molecular makeup and local/global patterns of sequence variation of *Ascaris lumbricoides*. We sequenced germline DNA from a single female worm. Using a reference-based approach resulted in a high quality genome with no unplaced contigs. The *A. lumbricoides* sequences showed >99% sequence similarity with the recently completed *A. suum* genome. We used this new genome to map whole genomes of 77 individual adult Ascaris collected from individuals from 5 closely-separated villages in rural Kenya. Using SNPs from these adult parasites, we demonstrated that parasites clustered by village and that genetic distance between worms was associated with geographic distance between host residences, suggesting that worms in different villages were partially reproductively isolated from each other. Additionally, analysis of mitochondrial genomes, and particularly COX1, allowed for comparison with 88 additional publicly available COX1 sequences from *A. lumbricoides* and *A. suum*. A haplotype network based on a 300bp portion of COX1 from these (88+77) worms showed that the worms collected in Kenya were split between two highly similar worldwide clades; these 2 clades did not split clearly between pig- and human-derived samples. The limited mitochondrial genome diversity suggests a recent (<1000 years) Ascaris population expansion, which could have spread the worms around the world with people or livestock, explaining the similar set of haplotypes present in Kenya and other regions. In fact, there was no association between genetic distances and geographic distances based on the mitochondrial genomes of worms collected across different continents. These data suggest that, while there is some structuring of worm populations locally (which may provide information about transmission patterns), there was no evidence of a selection event or global divergence of haplotypes to differentiate populations from pigs or humans or one continent compared to another.

675

IMPROVED MOLECULAR DETECTION OF *ASCARIS LUMBRICOIDES* UTILIZING EMBRYONIC SEQUENCE FOR ASSAY DESIGN

Nils Pilotte[1], Alice V. Easton[2], Jessica R. Grant[1], Eric Dahlstrom[3], Thomas B. Nutman[2], Steven A. Williams[1]

[1]Smith College, Northampton, MA, United States, [2]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [3]National Institute of Allergy and Infectious Diseases, Hamilton, MT, United States

We have previously described a next generation sequencing (NGS)-based pipeline for the development of improved diagnostic real-time PCR assays based on the identification and targeting of highly repetitive, non-coding genomic DNA sequences. This pipeline has proven effective for improving the sensitivity and specificity of detection for various soil transmitted helminth (STH) species including *Necator americanus*, *Ancylostoma duodenale*, *Ancylostoma ceylanicum*, *Trichuris trichiura*, and *Strongyloides stercoralis*. However, previous attempts to utilize this pipeline for the development of an *Ascaris lumbricoides* assay have proven ineffective. As the aforementioned pipeline has relied upon the analysis of genomic DNA isolated from adult worms, *A. lumbricoides* has been refractory to successful analysis. Such failures have likely occurred due to the phenomenon of chromosome diminution, whereby large portions of the *A. lumbricoides* genome (especially repetitive sequences) are eliminated during embryonic development. As a result, would-be target sequences are not identified during analysis of DNA from adult somatic tissues. Recently, a reference level embryonic genome of *A. lumbricoides* has enabled the analysis of gDNA isolated from immature life stages. As the molecular identification of STHs relies upon the detection of DNA isolated from stool-derived eggs, embryonic targets make ideal assay candidates. Accordingly, utilizing the available embryonic gDNA sequences, we have employed our pipeline to identify a high copy number repeat, greatly improving the sensitivity of parasite detection and reducing Cq values in field-collected samples by as much as ten amplification cycles or more, which corresponds to an increase in sensitivity of approximately 1,000-fold. Given the importance of sensitive and specific detection of parasites for programmatic decision-making efforts, this assay eliminates a critical gap in the STH molecular toolbox.

676

ALGORITHMS BASED ON HOST BIOMARKERS TO IDENTIFY FEBRILE PATIENTS AT RISK OF LIFE-THREATENING INFECTIONS IN LOW RESOURCE SETTINGS

Melissa Richard-Greenblatt[1], Aleksandra Leligdowicz[1], Andrea L. Conroy[2], Noémie Boillat-Blanco[3], Michael Hawkes[4], Valérie D'Acremont[5], Kathleen Zhong[1], Kevin C. Kain[1]

[1]University Health Network/ University of Toronto, Toronto, ON, Canada, [2]University of Indiana, Indianapolis, IN, United States, [3]Lausanne University Hospital, Lausanne, Switzerland, [4]University of Alberta, Edmonton, AB, Canada, [5]Swiss Tropical and Public Health Institute, Basel, Switzerland

Fever is one of the most common reasons patients seek medical care; however, most infections are self-limited and in the absence of critical illness can be managed conservatively. The inability to identify individuals with acute febrile syndromes at risk of death is a barrier to effective triage and management of severe infections. As endothelial and immune activation contribute to the pathogenesis of life-threatening infections, we hypothesized that measuring biomarkers of these pathways could identify febrile individuals with impending life-threatening infections. Consequently, we assessed biomarkers of these pathways at clinical presentation in emergency departments in two separate cohorts: (i) febrile Ugandan children (n=2,084, 99 deaths), and (ii) febrile Tanzanian adults (n=507, 32 deaths). Lead single endothelial and immune activation biomarkers predicted mortality and were superior to CRP and PCT (P<0.0001). We show sTREM1 to be the top single biomarker for

predicting "all-cause" febrile mortality in Ugandan children (AUROC 0.88, 95% CI 0.84-0.92, negative predictive value [NPV] 99.0%) and Tanzanian adults (AUROC 0.87, 95% CI, NPV 97.9%). sTREM1 displayed non-inferior performance to established clinical disease severity scores (e.g. LODS: AUROC 0.90 95% CI 0.87-0.93, NPV 99.0%; qSOFA: 0.79, 95% CI 0.72-0.87, NPV 97.0%). Combinatorial models adding sTREM1 to either LODS or qSOFA significantly improved their predictive accuracy in both the pediatric (AUROC 0.93, 95% CI 0.90-0.96, NPV 99.5%) and adult (AUROC 0.91, 95% CI 0.88-0.94, NPV 99.7%) cohorts. These data indicate that measuring sTREM1 at clinical presentation, especially when combined with easy-to-measure clinical severity scores, can reliably identify febrile individuals at risk of death. Implementation of biomarker-based algorithms using point-of-care tests could improve the recognition, triage, and outcome of patients with life-threatening infections.

CUTANEOUS LARVA MIGRANS IN RETURNED CANADIAN TRAVELERS TO THE CARIBBEAN: SURVEILLANCE REPORT FROM CANTRAVNET, JANUARY 2009 — MARCH 2018

Andrea K. Boggild[1], Jennifer Geduld[2], Michael D. Libman[3], Cedric P. Yansouni[3], Anne E. McCarthy[4], Jan Hajek[5], Wayne Ghesquiere[5], Yazdan Mirzanejad[5], Katherine Plewes[5], Jean Vincelette[6], Susan Kuhn[7], Pierre J. Plourde[8], Christina Greenaway[3], Sumontra Chakrabarti[1], Kevin L. Schwartz[1], Kevin C. Kain[1]

[1]University of Toronto, Toronto, ON, Canada, [2]Public Health Agency of Canada, Ottawa, ON, Canada, [3]McGill University, Montreal, QC, Canada, [4]University of Ottawa, Ottawa, ON, Canada, [5]University of British Columbia, Vancouver, BC, Canada, [6]University of Montreal, Montreal, QC, Canada, [7]University of Calgary, Calgary, AB, Canada, [8]University of Manitoba, Winnipeg, MB, Canada

Cutaneous larva migrans (CLM) is one of the most common dermatoses with which travelers to the tropics return. We examined the demographic and travel correlates of Canadian travelers returning from the Caribbean with CLM over a 10-year period to illuminate the recent emergence of this disease in our traveling population. Data on all returned Canadian travelers presenting to a CanTravNet site between January 2009 and March 2018 who were diagnosed with CLM acquired in the Caribbean were analyzed. Of 22,169 travelers in the CanTravNet database over the enrolment period, 299 (1.3%) returned from the Caribbean with CLM. Median age of the returned travelers with CLM was 34 years (range 1 - 73 years), with males accounting for 41% of cases (n=123), and females 59% (n=176). Ninety-five percent (n=284) traveled for tourism. Jamaica was the most well represented source country, accounting for 188 cases (63%), followed by Barbados (n=27, 9%), Dominican Republic (n=25, 8%), Cuba (n=21, 7%), and Saint Lucia (n=11, 4%). In total, 17 different source countries in the Caribbean were represented. Over the first 10-weeks of 2018, 48 travelers with CLM from the Caribbean were evaluated at CanTravNet sites, which represents a 6-fold average increase in cases during those same first 10-weeks in each of the 5 prior years (average 8 cases during the first 10-weeks of each year prior to 2018). Cases in 2018 have been imported predominantly from Jamaica (n=27, 56%), Dominican Republic (n=13, 27%), and Barbados (n=2, 4%), with 1 case (2%) imported from each of Cayman Islands, Cuba, Guadeloupe, Martinique, Saint Lucia, and Saint Martin. Age, sex, and purpose of travel distributions were similar across years. We have documented a large increase in imported cases of CLM originating in the Caribbean in the year 2018, though have not noted any demographic or travel-related aberrations in our returned traveler population to explain this phenomenon.

678

ANTIBIOTIC MANAGEMENT OF MODERATE-TO-SEVERE DIARRHEA MAY REDUCE RISK OF LINEAR GROWTH FALTERING IN CHILDREN: A SECONDARY ANALYSIS OF GEMS CASES

Rebecca Brander[1], Judd Walson[1], Patricia Pavlinac[1], Grace John-Stewart[1], Abu Faruque[2], Anita Zaidi[3], Dipika Sur[4], Samba Sow[5], M Johangir Hossain[6], Pedro Alonso[7], Robert Breiman[8], Dilruba Nasrin[9], James Nataro[10], Myron Levine[9], Karen Kotloff[9]

[1]University of Washington, Seattle, WA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]Aga Khan University, Karachi, Pakistan, [4]National Institute of Cholera and Enteric Diseases, Kolkata, India, [5]Centre pour le Développement des Vaccines, Bamako, Mali, [6]Medical Research Council Unit, Fajara, Gambia, [7]Centro de Investigacao em Saude da Manhica, Maputo, Mozambique, [8]Centers for Disease Control and Prevention, Nairobi, Kenya, [9]University of Maryland, Baltimore, MD, United States, [10]University of Virginia, Charlottesville, VA, United States

Children with moderate-to-severe diarrhea (MSD) are at particularly high risk of linear growth failure and associated negative health outcomes. However, little is known about whether antibiotic treatment of MSD may protect against linear growth faltering. Using previously collected data from the Global Enterics Multicenter Study (GEMS) of children 0-59 months old with MSD in 7 low- and middle-income countries (LMICs), we conducted a retrospective cohort analysis to assess whether children with MSD who were treated with antibiotics had a lower risk of linear growth faltering in the 60-90 days following the episode. We used relative risk (RR) regression to evaluate loss of ≥1 length/height-for-age z-score [LAZ/HAZ] between enrollment and follow up, and linear regression to assess change in LAZ/HAZ, with propensity score adjustment for variables associated with antibiotic treatment. Of 7659 surviving MSD cases, mean LAZ/HAZ loss during follow up was 0.13, and 3% lost ≥1 LAZ/HAZ. Antibiotics were provided to 81% at presentation. Factors associated with antibiotic treatment included young age, nutritional status, hospitalization, GEMS site, and presence of fever, vomiting, or dysentery. After propensity score adjustment, children provided with antibiotics had a 41% lower risk of losing ≥1 LAZ/HAZ than those who received none (adjusted RR: 0.59; 95% confidence interval [CI]: 0.42, 0.82). Children provided antibiotics in the health center gained 0.06 LAZ/HAZ more than those who were not (95% CI: 0.03, 0.09). Among children ≤ 23 months, those who received antibiotics were less likely to lose ≥1 LAZ/HAZ (aRR: 0.67; 95% CI: 0.48, 0.94), and gained 0.03 LAZ/HAZ more than those who received no antibiotics (95% CI: -0.004, 0.07). Antibiotic treatment of MSD may preserve linear growth in young children in LMICs. Ongoing randomized trials will provide further evidence to evaluate the effectiveness of antibiotics in preventing linear growth faltering in this population. However, any potential benefit of antibiotic management of MSD must be weighed cautiously against negative consequences including antibiotic resistance and microbiome disruption.

679

CLINICAL FEATURES AND OUTCOME OF NEONATAL DENGUE AT THE CHILDREN'S HOSPITAL 1, HO CHI MINH, VIETNAM

Tuan M. Nguyen

Children's Hospital 1, Ho Chi Minh, Vietnam

Vertical transmission of dengue, a life-threatening disease transmitted by *Aedes* mosquitoes, has been reported in a few case reports. In this context, we tried to determine the clinical features and outcomes of neonatal dengue. We conducted a prospective study on 32 neonates with laboratory-confirmed dengue by positive for either NS1 antigen rapid test or IgM antibody with MAC-ELISA, who were hospitalized at the Children's Hospital 1, Ho Chi Minh, Vietnam from January 2010 to December 2016. Diagnosis of dengue was defined according to the World

Health Organization 2009 classification. The median time to onset of fever was on day 5 (IQR: 4, 8) after birth. The median time for diagnosis in neonates was at 7 (IQR: 6, 10) days of age while the median febrile phase was 3 (IQR: 2, 4) days. The median length of hospital stay was 6 (IQR: 4, 10) days. Petechiae, pharyngeal mucosal hemorrhage, and hepatomegaly were detected in 87.5% (28/32), 6.3% (2/32), and 75% (24/32) of cases respectively. The white blood cell counts in the febrile and critical phase were 7,800±800/mm^3 and 13,400±2,800/mm^3 respectively. The platelet counts in the febrile and critical phase were 97,111±37,826/mm^3 and 30,100±5,749/mm^3 respectively. Hematocrit levels during the febrile and critical phase were 49±1% and 47±1% respectively. Of the 12 patients undergoing abdominal ultrasonography, 2 (16.7%) cases showed gallbladder wall thickening. The C-reactive protein concentration at admission was 1.5±0.7 mg/L. All patients were classified as dengue with no warning signs and had a full recovery. The results of laboratory diagnosis were as follows: 56.3% (18/32) NS1(+) and IgM not performed; 15.6% (5/32) NS1(+) IgM (+); NS1(-) IgM (+), 15.6% (5/32) NS1 not performed and IgM (+). These findings emphasize that early diagnosis of neonatal dengue should be based on a history of maternal illness, NS1 rapid test, petechiae, hepatomegaly and low platelet counts, which tend to decrease significantly in the critical phase. Our study provides additional support for the vertical transmission of dengue, which emphasizes considerable insights into prevention and early detection.

680

SAFETY AND IMMUNOGENICITY OF AGS-V, A MOSQUITO SALIVA PEPTIDE VACCINE: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED PHASE 1 TRIAL

Jessica E. Manning[1], Fabiano Oliveira[1], Iliano V. Coutinho-Abreu[1], Samantha Herbert[1], Claudio Meneses[1], Shaden Kamhawi[1], Holly Ann Baus[1], Alison Han[1], Lindsay Czajkowski[1], Luz Angela Rosas[1], Adriana Cervantes-Medina[1], Rani Athota[1], Susan Reed[1], Ana Fernandez[2], Olga Pleguezuelos[2], Gregory Stoloff[2], Jesus G. Valenzuela[1], Matthew J. Memoli[1]

[1]National Institutes of Health, Bethesda, MD, United States, [2]SEEK Pep Tcell Limited, London, United Kingdom

Parasites and viruses carried within mosquito saliva appear to initiate or enhance severity of host infection by taking advantage of saliva-human host interactions. This leads to alteration of the cutaneous environment and modulation of the host's innate and adaptive immune responses, thereby providing a rationale for creating vaccines against mosquito salivary proteins rather than the pathogens contained within the saliva, or a combination of both. AGS-v is a vaccine composed of four salivary peptides isolated from *Anopheles gambiae* salivary glands, but that are common across a number of mosquitoes. In this first-in-human study, we enrolled and randomized 49 healthy adult participants to receive the AGS-v vaccine with and without adjuvant (Montanide ISA 51) versus placebo. Vaccinations occurred at Day 0 and Day 21 followed by an uninfected *Aedes aegypti* mosquito feeding at Day 42. Primary objectives are: 1) to assess safety via incidence of adverse events and 2) to evaluate humoral and cellular immunity by respectively measuring total AGS-v specific immunoglobulins and Th1-associated cytokine release after incubation of peripheral blood mononuclear cells with AGS-v antigens. Secondary objectives are post-mosquito feeding measures of AGS-v specific immunoglobulins and Th1-related cytokine release, mosquito survival and fecundity, as well as the effects of immunized individuals' peripheral blood mononuclear cells on Zika virus after stimulation with *Aedes aegypti* saliva. Results are pending until the data blind is lifted mid-2018, but will be available for presentation at the conference.

681

ACUTE KIDNEY INJURY IN SEVERE MALARIA: NEURODEVELOPMENTAL EFFECTS IN UGANDAN CHILDREN

Meredith R. Hickson[1], Andrea Conroy[2], Paul Bangirana[3], Robert O. Opoka[3], John S. Ssensuku[4], Chandy C. John[2]

[1]University of Michigan Medical School, Ann Arbor, MI, United States, [2]Indiana University, Indianapolis, IN, United States, [3]Makerere University College of Health Sciences, Kampala, Uganda, [4]University of Minnesota, Minneapolis, MN, United States

Acute kidney injury (AKI) is increasingly recognized as an important complication of severe malaria (SM) associated with adverse clinical outcomes. We recently reported that AKI is associated with impaired neurodevelopment in Ugandan children with SM. However, there are currently no data on specific cognitive and behavioral domains impacted by AKI in pediatric SM. We conducted a secondary analysis of a prospective study evaluating development in Ugandan children between 18 months and 12 years of age with cerebral malaria (n=226) or severe malarial anemia (n=209), and healthy community children (n=173). Assessments of cognition, attention, memory, socioemotional function, and executive function were performed at baseline and 6, 12, and 24 months later. Age-adjusted z-scores were computed for each domain using community children's raw scores. AKI was assessed using the Kidney Disease: Improving Global Outcomes (KDIGO) guidelines. AKI was defined as a 50% increase in creatinine from estimated baseline. The association between AKI and cognitive and behavioral outcomes across all time points was evaluated using linear mixed effect models adjusted for weight-for-age z-score, child's education, parental education, socioeconomic status, home environment, and severe malaria type (CM or SMA). Children <5 years with AKI on admission had lower scores on overall cognition (β=-0.28 (95% confidence interval, -0.55, -0.00), p=0.048) and attention (β=-0.29 (-0.51, -0.08), p<0.008). Children >5 years with AKI had lower memory scores (β=-0.43 (-0.81, -0.04), p=0.03); diminished executive functioning (β=0.75 (0.03, 1.5), p=0.04); and exhibited more externalizing symptoms (β=0.71 (0.26, 1.2), p<0.002) and more total behavioral problems (β=0.63 (0.18, 1.1), p<0.006). SM with AKI on admission affected multiple cognitive and behavioral domains in our population and may have the largest impact on children >5 years. Prevention, identification, and appropriate management of AKI in SM could help reduce the neurodevelopmental burden of malaria in endemic regions.

682

MAPPING DIPHTHERIA-PERTUSSIS-TETANUS VACCINE COVERAGE IN AFRICA, 2000-2016

Jonathan Mosser, Puja C. Rao, Aaron Osgood-Zimmerman, Nancy Fullman, Nicholas Graetz, Roy Burstein, Rachel L. Updike, Sarah E. Ray, Lucas Earl, Aniruddha Deshpande, Laura Dwyer-Lindgren, Stephen S. Lim, Robert C. Reiner, Simon I. Hay

Institute for Health Metrics and Evaluation, Seattle, WA, United States

Routine childhood vaccination is among the most cost-effective, successful public health interventions available. Amid substantial investments to expand vaccine delivery throughout Africa, most countries still lack robust measures of local routine vaccine coverage and changes in geographic inequalities over time. Here, we leverage data from 183 surveys conducted between 2000 and 2016, including 881,268 children in 49 African countries, to produce annual high spatial resolution (5x5 km^2) diphtheria-pertussis-tetanus (DPT) vaccine coverage estimates for children aged 12-23 months in 52 African countries from 2000-2016, using a Bayesian geostatistical model calibrated to results from the Global Burden of Diseases, Injuries, and Risk Factors Study 2017. Estimated DPT3 coverage increased in 78.7% (95% UI: 71.3 - 83.7%) of second-level administrative units in Africa from 2000-2016, yet substantial geographic inequalities in DPT coverage and dropout remained across and within African countries. In 2016, 10 of 52 countries had at least one local area (second-level administrative unit) with coverage less than half of the national average,

and only Morocco and Swaziland had achieved ≥ 80% DPT3 coverage in all second-level administrative units with high confidence (posterior probability ≥ 95%). Large areas of low DPT3 coverage (≤ 40%) were identified in the Sahel, Somalia and the Ogaden region of Ethiopia, and the Democratic Republic of the Congo (DRC). Low DPT1 coverage (≤ 50%) and high relative dropout rates (≥ 30%) together drove low DPT3 coverage across the Sahel, Somalia and the Ogaden, Central African Republic, Guinea, and Angola. Despite substantial progress in Africa, marked national and subnational inequalities in DPT coverage and dropout persist. These results can help identify areas of low coverage and vaccine delivery system vulnerabilities and ultimately support more precise targeting of resources to improve vaccine coverage and health outcomes for African children.

CLINICAL TRIAL EXPERIENCE WITH THE MERCK RVSVΔG-ZEBOV-GP EBOLA VACCINE: UPDATED SAFETY, IMMUNOGENICITY, AND EFFICACY

Jakub K. Simon[1], Scott A. Halperin[2], Rituparna Das[1], Matthew T. Onorato[1], Kenneth Liu[1], Jason Martin[1], Rebecca J. Grant-Klein[1], Rick Nichols[3], Frans A. Helmond[1], Beth-Ann Coller[1]

[1]Merck & Co., Inc., Kenilworth, NJ, United States, [2]Canadian Center for Vaccinology, Dalhousie University, IWK Health Centre, and Nova Scotia Health Authority, Halifax, NS, Canada, [3]NewLink Genetics, Inc.; BioProtection Systems, Ames, IA, United States

The 2013-2016 West African Ebola outbreak resulted in >28,600 cases and >11,300 deaths. In conjunction with private and public partners, Merck & Co., Inc., Kenilworth, NJ USA is developing a vaccine that demonstrated efficacy during this outbreak. The vaccine is a live recombinant vesicular stomatitis virus (VSV) containing the Zaire Ebola virus glycoprotein (GP) in place of the VSV GP (rVSVΔG-ZEBOV-GP). Vaccine safety, efficacy, and immunogenicity have been evaluated in 13 Phase 1-3 clinical trials. More than 17,000 subjects have received rVSVΔG-ZEBOV-GP vaccine (clinical dose: ≥$2x10^7$ plaque forming units/mL) in these clinical trials to date. Clinical trial data support a favorable safety profile. Common adverse events included injection-site reactions, fever, fatigue, myalgia, arthralgia, and headache, which were mostly mild to moderate in intensity and of short duration. Arthritis, which was also generally mild to moderate in intensity, has been reported at frequencies <5% in most trials. In a cluster-randomized ring vaccination trial in Guinea, subjects were randomized to immediate or delayed vaccination. As reported by Henao-Restrepo et al. in 2017 (*Lancet*; 389:505-518), while there were no confirmed cases of Ebola virus disease among those vaccinated in the immediate arm 10 days or more after randomization, 10 cases of confirmed disease (in 4 rings) were observed in eligible subjects in the delayed vaccination arm who consented on Day 0 (vaccine efficacy: 100%; 95% CI: 63.5-100%, *P*=0.0471). Immune responses, based on GP antibodies detected by GP-ELISA and neutralizing antibodies detected by plaque reduction neutralization test (PRNT), were detectable at 14 days in most vaccinated subjects, with nearly 100% seroconversion by 28 days. Durability of the anti-GP antibody responses was initially demonstrated through 6 months. Longer term durability of immunogenicity out to 24 months (by both GP-ELISA and PRNT) from a Phase 3 safety and lot consistency trial and updated safety data from across the program will be presented.

684

NEUROLOGICAL, COGNITIVE, AND PSYCHOLOGICAL FINDINGS AMONG SURVIVORS OF EBOLA VIRUS DISEASE FROM THE 1995 KIKWIT OUTBREAK IN DEMOCRATIC REPUBLIC OF CONGO: A CROSS-SECTIONAL STUDY

John D. Kelly[1], Nicole Hoff[2], D'Andre Spencer[2], Matt Bramble[3], David McIlwain[4], Kamy Musene[2], Ernesto Okitolonda[5], Travis Porco[1], George Rutherford[1], Maria Glymour[1], Patrick Mukadi[6], Anne Rimoin[2]

[1]University of California San Francisco, San Francisco, CA, United States, [2]University of California Los Angeles, Los Angeles, CA, United States, [3]Children's National Medical Center, Washington, DC, United States, [4]Stanford, Stanford, CA, United States, [5]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, [6]Institut National de Recherche Biomedicale, Kinshasa, Democratic Republic of the Congo

Without clear mechanisms of disease, except for uveitis, survivorship from Ebola virus disease (EVD) may have a long-term effect on health status. Among a cohort of EVD survivors and close contacts in Kikwit, Democratic Republic of Congo, we sought to describe the prevalence of adverse neurological, cognitive, and psychological findings and to determine the effect of EVD on these outcomes. From August to September 2017, we conducted a cross-sectional study in Kikwit, which is approximately nine hours by road from Kinshasa, the capital city of DRC. We recruited EVD survivors and close contacts. We conducted a physical examination and administered a questionnaire, including culturally adapted versions of Folstein mini-mental status exam (MMSE), Goldberg Anxiety and Depression Scale (GADS), and 7-item EVD-related stigma index. We described the prevalence of EVD sequelae among EVD survivors and among close contacts. Then we estimated the relationship between EVD survivorship (survivors vs. close contacts) and clinical outcomes. Potential confounders including age, sex, educational level, marital status and being a healthcare worker were used in linear regression models. Fourteen EVD survivors and 202 close contacts were enrolled. Among EVD survivors, 3 (21%) reported at least one abnormal neurological symptom and 2 (14%) had an abnormal neurological examination. The MMSE scores were 20.3 (Standard Deviation (SD), 17.1-23.4). Mean GADS scores were 8.3 (SD, 2.6-13.9). Nine survivors (64%) reported experiencing at least one item of EVD-related stigma since the outbreak, but none experienced EVD-related stigma in the six-months prior to the interview. EVD survivors had a statistically significant association with MMSE and GADS as compared to close contacts (MMSE: Adjusted Odds Ratio (AOR), -2.44; 95% Confidence Interval (CI), -4.47 to -0.41; GADS: AOR, 5.45; 95% CI, 2.92 to 7.97). In conclusion, this is the first study to suggest that EVD survivorship can have neurocognitive sequelae and be associated with depressive and anxious symptoms as long as 22 years after an Ebola outbreak.

685

DURABILITY OF IMMUNE RESPONSES INDUCED BY THREE LEADING CANDIDATE EBOLA VACCINE REGIMES; RVSV ZEBOV, CHAD3 EBO Z-MVA BN-FILO AND ADHU26.ZEBOV-MVA BN FILO

Katie J. Ewer[1], Catherine Smith[2], Esha Sarkar[2], Georgina Bowyer[1], Thomas Rampling[1], Catherine Mair[1], Duncan Bellamy[1], Suleman Sabir[3], Christopher Davies[3], Navin Venkatraman[1], Rebecca Conway-Jones[1], Danielle Campbell[2], Charlotte Boyer[2], Adrian V. Hill[1], Emma Thomson[3], Matthew D. Snape[2]

[1]The Jenner Institute, University of Oxford, Oxford, United Kingdom, [2]Oxford Vaccine Group, University of Oxford, Oxford, United Kingdom, [3]MRC-University of Glasgow Centre for Virus Research, Glasgow, United Kingdom

Of the vaccines developed in response to the 2014-16 Ebola outbreak in West Africa, three which encoded the Zaire Ebola glycoprotein, showed acceptable reactogenicity and promising immunogenicity in

early-stage clinical trials - a single-dose approach based on a replicating vesicular-stomatitis virus (rVSV ZEBOV) and two heterologous prime-boost combinations using replication-deficient adenoviruses (ChAd3 and AdHu26) to prime and the multivalent MVA BN-Filo to boost. The rVSV ZEBOV vaccine showed 100% vaccine efficacy in a phase III ring vaccination trial in the short-term following exposure to Ebola virus disease (EVD) cases. However, durability of protective efficacy has not been assessed. Although a number of publications reported clinical trials of these vaccines during the outbreak, immunogenicity was not reported using standardised or centralised assays and comparisons of relative immunogenicity could not be made. Clinical trials were undertaken in Oxford of both prime-boost regimes and volunteers have been followed up to determine durability of both humoral and cellular immunity. This revealed that 91% of 43 recipients of AdHu26/MVA vector vaccine recipients had positive glycoprotein specific IgG titres at 2.5 years post immunisation, as did 54% of 13 recipients of Chad3/MVA vectored vaccines. Furthermore, in October 2015, rVSV ZEBOV was administered to 26 contacts of a UK health-care worker who had become infected with EVD in Sierra Leone, recovered and then subsequently relapsed. Using samples from this cohort, we will be able to undertake for the first time comparative immunogenicity measurements using a standardised ELISA and validated ELISPOT assay to determine humoral and cellular immunity against the Zaire ebolavirus glycoprotein induced by these three vaccine regimes. Samples taken 2.5 years post-vaccination will be compared to determine whether differences in quality, quantity and persistence of immunity are observed. These data are important for long-term strategic planning for prophylactic protection of front-line healthcare workers in regions at risk of future outbreaks.

IMMUNOLOGICAL INSIGHTS BASED ON ANTIBODY BINDING EPITOPES ON THE EBOLA VIRUS GLYCOPROTEIN

Tabb Sullivan[1], Aubrey Bryan[1], Edgar Davidson[1], Andrew Flyak[2], Katie Howell[3], Javad Aman[4], James Crowe Jr[2], Benjamin J. Doranz[1]

[1]Integral Molecular, Inc., Philadelphia, PA, United States, [2]Vanderbilt University, Nashville, TN, United States, [3]Integrated BioTherapeutics, Inc., Rockville, MD, United States, [4]Integrated BioTherapeutics, Inc, Rockville, MD, United States

The recent disease outbreaks due to Ebola virus (EBOV) highlight the need to characterize the immune response to such viruses in order to help develop vaccines and therapies. We have mapped the epitopes for over 100 monoclonal antibodies (MAbs) that target the EBOV surface glycoprotein, GP, using extensive GP mutation libraries. A broad variety of MAbs have been mapped, as described in recent publications, including the ZMapp therapeutic MAb cocktail; MAbs from human survivors of EBOV and Bundibugyo ebolavirus infection; cross-neutralizing MAbs targeting the membrane proximal external region (MPER) of GP; a broadly cross-reactive MAb that binds to the GP head region and blocks the interaction of GP with its endosomal receptor Niemann-Pick C1; and MAbs whose synergistic combination transform a non-neutralizing MAb into a potent neutralizer. In partnership with the Viral Hemorrhagic Consortium at Scripps, we have also characterized how *in vitro* neutralization correlates with *in vivo* protection. The epitope maps obtained for different types of MAbs have expanded our understanding of how the immune system recognizes EBOV GP, and correlate MAb epitopes with their neutralizing capabilities to develop anti-EBOV therapeutics and vaccines. This includes identifying mutations that increase the exposure of neutralizing epitopes and that affect EBOV function, which can impact the design of future anti-ebolavirus vaccine strategies. These insights are now being used to design new immunogens that serve as improved vaccines.

POST-EXPOSURE PROTECTION AGAINST CONTEMPORARY NIGERIAN ISOLATES OF LASSA FEVER VIRUS IN CYNOMOLOGOUS MACAQUES WITH HUMAN MONOCLONAL ANTIBODIES

Robert W. Cross[1], Luis M. Branco[2], Chad E. Mire[1], Krystle N. Agans[1], Victorya Borisevich[1], Joan B. Geisbert[1], Daniel J. Deer[1], Karla A. Fenton[1], Robert F. Garry[3], Thomas W. Geisbert[1]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]Zalgen Laboratories, Germantown, MD, United States, [3]Tulane University School of Medicine, New Orleans, LA, United States

Lassa fever is serious viral zoonosis endemic throughout West Africa for which there are currently no regulatory approved medical countermeasures (MCMs) available. To date, most MCMs have been directed against the prototypical Josiah strain of Lassa virus (LASV) isolated from Sierra Leone in the late 1970s. A recent resurgence in cases and fatalities in Nigeria has reinforced the need for MCMs that can account for the genetic diversity of LASV across this region. Here we have characterized 3 contemporary lineage II viral isolates from Edo State, Nigeria in Cynomologous macaques. Two of the three isolates were uniformly lethal in this model and were characterized by hallmark features of Lassa fever including a fever, loss of appetite, weakness, followed by a fulminate vascular leak syndrome, hemorrhagic signs and neurological manifestations. One of these two isolates had shorter mean time to death than the LASV-Josiah. The remaining isolate caused no overt disease in this model despite clear viremia. After establishing the model largely recapitulated human Lassa fever, we assessed the protective efficacy of a monoclonal antibody (mAb) cocktail of 3 antibodies previously shown to protect against LASV-Josiah 8 days after challenge where complete protection was observed 35 days post challenge. In a follow up experiment, this treatment was then reduced to 2 mAbs and, again, complete protection was observed. This work is the first to describe pathogenesis of lineage II LASV and provides a platform for assessment of protective efficacy of a post exposure therapeutic in Cynomologous macaques against currently circulating isolates of LASV from Nigeria.

GENOMIC EPIDEMIOLOGY OF LASSA VIRUS IN NIGERIA DURING A SEASON OF UNUSUALLY HIGH INCIDENCE

Katherine J. Siddle[1], Philomena E. Eromon[2], Judith U. Oguzie[2], Samar Mehta[3], Ikponmwonsa Odia[4], Kayla G. Barnes[3], Sarah M. Winnicki[3], James Qu[3], Eghosa Uyigue[2], Paul Oluniyi[2], Onikepe A. Folarin[2], Robert F. Garry[5], Kristian G. Andersen[6], Daniel J. Park[3], Nathan L. Yozwiak[3], Bronwyn L. MacInnis[3], Peter Okokhere[7], Pardis C. Sabeti[1], Christian T. Happi[2]

[1]Harvard University, Cambridge, MA, United States, [2]Redeemer's University, Ede, Nigeria, [3]Broad Institute, Cambridge, MA, United States, [4]Irrua Specialist Teaching Hospital, Irrua, Nigeria, [5]Tulane University, New Orleans, LA, United States, [6]Scripps Research Institute, La Jolla, CA, United States, [7]Irrua Specialist Teaching Hospital, Irru, Nigeria

In early 2018 Nigeria experienced an unprecedented number of Lassa fever cases with widespread geographic distribution. Infection with Lassa virus, the etiological agent of Lassa fever, usually results from contact with infected Mastomys natalensis, though human-to-human transmission has been documented in hospital settings, and remains a priority for public health monitoring. Lassa virus is highly genetically diverse, especially in Nigeria where at least two distinct lineages circulate, posing challenges for the development of sensitive, comprehensive diagnostics. To investigate the epidemiology of Lassa virus in Nigeria and identify recent changes in the virus genome or its transmission route that may account for this increase, we performed genome sequencing on a large cohort of positive cases from 2018 and 2017. We combined this data with an extensive database of Lassa virus genomes spanning a decade of viral surveillance

in Nigeria. Our preliminary results suggest that the high case incidence in 2018 was not linked to a specific variant of the virus and that transmission continues to be sustained by multiple distinct cross-species transmission events. Additionally, we identified clear geographic population structure of the virus, demarcated by major rivers, suggesting the importance of established, local rodent populations in sustaining Lassa virus transmission in Nigeria. Ongoing sequencing of additional samples will further refine and inform these conclusions. Genomic sequencing is a powerful tool to understand the origins, transmission and evolution of Lassa virus and other important human pathogens. This knowledge can further assist in the development of diagnostics and vaccines as well as help to inform public health efforts for this high-priority pathogen.

DEVELOPMENT OF A TICK-TRANSMISSION MODEL FOR HEARTLAND VIRUS PATHOGENESIS

Erin S. Reynolds, Meghan E. Hermance, Saravanan Thangamani

University of Texas Medical Branch, Galveston, TX, United States

Heartland Virus (HRTV; Bunyaviridae: *Phlebovirus*) was initially isolated in 2009 from two patients in Missouri. Since that time there have been over 30 confirmed human cases, including three fatalities, across nine states. The Lone Star tick, *Amblyomma americanum*, has been determined as the arthropod vector. In order to understand disease transmission and pathogenesis it is necessary to develop an animal model which utilizes the natural route of transmission and manifests in a manner similar to documented human cases. In this work, we have attempted to develop a tick transmission model to mimic natural route of HRTV transmission. Our preliminary studies determined that A129 mice are the most appropriate animal model for HRTV pathogenesis. The diverse functional properties of tick saliva in modulating host immune responses to facilitate both feeding and pathogen transmission has been well documented. To initially evaluate the effects of tick saliva on HRTV infection, groups of 3 - 4 week old A129 mice were injected SQ via the foot pad with media, HRTV, or HRTV + tick salivary gland extract (SGE). Clinical observations were mild for both groups which received virus but there was a marked increase in the group which received virus + SGE. Viral load in the blood was detectable until 5 dpi in the virus only group and until study termination at 8 dpi for the virus + SGE group. At 1 and 5 dpi the viral load was similar in both groups but at 3 dpi it was ~1 log higher in the virus + SGE group. During necropsy splenomegaly was observed in both virus only and virus + SGE groups. At 3 dpi virus was detected via rt-qPCR for both groups in the spleen, liver, kidney, heart, lung, brain, stomach, intestine, and testes. The virus + SGE group had significantly higher viral loads in several tissues compared to the virus only group. This experiment clearly demonstrates the impact of tick saliva on HRTV disease severity and the need to further investigate how actual tick feeding will effect transmission and pathogenesis. Further experiments are ongoing to investigate the pathogenesis of HRTV infection acquired through natural route of transmission.

VESICULAR SYSTEM OF ARTEMISININ RESISTANCE ENHANCES BOTH PARASITE SURVIVAL AND HOST CYTOADHERENCE

Niraja Suresh[1], Isabelle Coppens[2], Souvik Bhattacharjee[3], Alassane Mbengue[1], Mehdi Ghorbal[1], Kasturi Haldar[1]

[1]University of Notre Dame, Notre Dame, IN, United States, [2]Johns Hopkins University, Baltimore, MD, United States, [3]Jawaharlal Nehru University, New Delhi, India

Artemisinin resistance threatens world-wide malaria control and elimination. Elevation of phosphatidylinositol-3-phosphate (PI3P) induces resistance in blood-stages of the human malaria parasite *Plasmodium falciparum*. The parasite unfolded protein response (UPR) has also been implicated, but how PI3P acts and its connection to the UPR are unknown. Our studies show that *P. falciparum* Kelch13 (K13), the marker of artemisinin resistance concentrates at PI3P-tubules/vesicles of the parasite's endoplasmic reticulum (ER), as detected by cryo-immunoelectron microscopy. K13 additionally co-localizes and co-purifies with the major virulence adhesin PfEMP1. The PfEMP1-K13 proteome is comprehensively enriched in multiple proteostatic systems of protein export, quality-control and folding in the ER and cytoplasm including the UPR. Synthetic elevation of PI3P that induces resistance in absence of K13 mutation also yields signatures of proteostasis, UPR and clinical resistance, concluding a key role for PI3P-vesicle amplification as a mechanism of artemisinin resistance. The major resistance mutation K13C580Y quantitatively increased PI3P-vesicles, exporting them throughout the parasite and the red cell. Alterations in PfEMP1 export to the red cell and cytoadherence of infected cells to a host endothelial receptor, are features of multiple K13 mutants. Together the data reveal an amplified PI3P-vesiclur system of artemisinin resistance enhances the parasite's capacity for mitigating artemisinins toxic proteopathy and promoting endothelial adherence, suggesting a strategy by which resistant organisms may persist in host tissues.

691

ARTEMISININ RESISTANCE GENE K13 IS LINKED TO DNA REPLICATION AND REPAIR

Justin Gibbons[1], Katie Button-Simons[2], Swamy R. Adapa[3], Suzanne Li[3], Maxwell Pietsch[4], Min Zhang[3], John H. Adams[3], Michael T. Ferdig[2], Rays H. Jiang[3]

[1]Morsani College of Medicine, University of South Florida, Tampa, FL, United States, [2]Eck Institute for Global Health, Department of Biological Sciences, University of Notre Dame, South Bend, IN, United States, [3]Department of Global Health, College of Public Health, University of South Florida, Tampa, FL, United States, [4]Department of Computer Science & Engineering, University of South Florida, Tampa, FL, United States

Plasmodium falciparum is evolving resistance to treatment with Artemisinin Combination Therapy (ACT) in South East Asia. The further spread of resistance will imperil malaria control efforts and put millions of lives at risk. Understanding the mechanism of resistance to the artemisinin component of ACT will aid in efforts to thwart the evolution to resistance. The gene with the strongest link to artemisinin resistance is K13, which has homology to the human gene Keap1 which regulates the transcription of stress response genes. However, the role K13 plays in *P. falciparum* remains unknown. Since multiple attempts to knockout K13 have failed, it is likely K13 is essential and regulatory mutants are one of the important ways to decipher its function. In this study, we performed RNA-seq on an isogenic K13 regulatory mutant that is more sensitive to arteminsins than the parent wild-type strain NF54. K13 is aberrantly down-regulated during the early ring stage and up-regulated during the early trophozoite stage of the mutant. This K13 dysregulation is associated with strong and consistent shifts in the expression of DNA replication and repair genes, but not other housekeeping pathways that undergo similar rates of transcriptional regulation at these life-cycle stages. The observed effect is specific to the K13 dysregulation and is not present in other *P. falciparum* mutants with the same transposon inserted in other loci. These results are consistent with other reports in the literature linking artemisinin resistance to changes in cell cycle regulation, indicating that specific alterations of DNA replication and repair pathways can significantly alter sensitivity to artemisinins.

692

A NOVEL IMMORTALIZED HEPATOCYTE-LIKE CELL LINE (IMHC) SUPPORTS *IN VITRO* LIVER STAGE DEVELOPMENT OF THE HUMAN MALARIAL PARASITE *PLASMODIUM VIVAX*

Rapatbhorn Patrapuvich[1], Yongyut Pewkliang[2], Siriwan Rungin[3], Kaewta Lerdpanyangam[3], Apisak Duangmanee[3], Phongthon Kanjanasirirat[2], Phichaya Suthivanich[2], Khanit Sa-ngiamsuntorn[4], Suparerk Borwornpinyo[2], Jetsumon Sattabongkot[3], Suradej Hongeng[5]

[1]Drug Research Unit for Malaria, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [2]Excellent Center for Drug Discovery (ECDD), Faculty of Science, Mahidol University, Bangkok, Thailand, [3]Mahidol Vivax Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [4]Department of Biochemistry, Faculty of Pharmacy, Mahidol University, Bangkok, Thailand, [5]Department of Pediatrics, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand

Eradication of malaria is difficult because of the ability of hypnozoite, the dormant liver-stage form of *Plasmodium vivax*, to cause relapse in patients. Research efforts to better understand the biology of *P. vivax* hypnozoite and design relapse prevention strategies have been hampered by the lack of a robust and reliable model for *in vitro* culture of liver-stage parasites. Although the HC-04 hepatoma cell line is used for culturing liver-stage forms of *Plasmodium*, these cells proliferate unrestrictedly and detach from the culture dish after several days, which limits their usefulness in a long-term hypnozoite assay. Here, a novel immortalized hepatocyte-like cell line (imHC) was evaluated for the capability to support *P. vivax* sporozoite infection. imHCs maintained major hepatic functions and expressed the essential factors CD81, SR-BI and EphA2, which are required for host entry and development of the parasite in the liver. imHCs could be maintained long-term in a monolayer without overgrowth and thus served as a good, supportive substrate for the invasion and growth of *P. vivax* liver stages, including hypnozoites. The observed high drug metabolism activity and potent responses in liver-stage parasites to primaquine highlight the potential use of this imHC model for antimalarial drug screening. Overall, imHCs constitute an alternative host for *in vitro Plasmodium* liver-stage studies, particularly those addressing the biology of *P. vivax* hypnozoite. Thus, imHCs potentially offer a novel, robust model for screening drugs against liver-stage parasites.

693

IT TAKES TWO TO TANGO: THE P52/P36 HEPATOCYTE INVASION COMPLEX

Silvia A. Arredondo[1], Kristian E. Swearingen[2], Thomas Martinson[1], Ryan Steel[1], Dorender Dankwa[1], Anke Harupa[1], Nelly Camargo[1], Vladimir Vigdorovich[1], Brian G. Oliver[1], Tomoko Ishino[3], Noah Sather[1], Sebastian Mikolajczak[1], Ashley M. Vaughan[1], Motomi Torii[3], Robert L. Moritz[2], Stefan H. Kappe[1]

[1]Center for Infectious Disease Research, Seattle, WA, United States, [2]Institute for Systems Biology, Seattle, WA, United States, [3]Ehime University, Ehime, Japan

Following an infected mosquito bite, a limited number of *Plasmodium* sporozoites will make their way to the liver to continue the cycle of infection in the mammalian host. Once in the liver, sporozoites traverse cells searching for a "suitable" hepatocyte, invading these cells through a process that results in the formation of a parasitophorous vacuole (PV), a protective compartment in which the parasite undergoes intracellular replication as a liver stage. Previous studies have established that two members of the *Plasmodium* s48/45 protein family, P36 and P52, are essential for productive invasion of host hepatocytes as their simultaneous deletion results in growth-arrested parasites lacking a PV. Recent studies point towards a pathway of entry possibly involving the interaction of P36 with hepatocyte receptors EphA2, CD81 and SR-B1. However, the relationship between P36 and P52 during invasion remains unknown. Here we show that parasites with a single P52 or P36 gene deletion lack a PV after hepatocyte invasion, thereby each pheno-copying the P52/P36 dual gene deletion parasite line and indicating that both proteins are important in the establishment of a PV and act in the same pathway. We then created a *Plasmodium yoelii* P36^{mCherry} tagged parasite line that allowed us to visualize the subcellular localization of P36 in the sporozoite secretory microneme organelles and found that it co-localizes with P52. Furthermore, through co-immunoprecipitation studies *in vivo*, we determined that P36 and P52 form a protein complex in sporozoites, implying a concerted function for both proteins within the PV formation pathway. In addition, we found that P36 is secreted from the sporozoite. Our results support a model in which glycophosphatidylinositol (GPI)-anchored P52 may serve as a scaffold to facilitate the interaction of secreted P36 with host receptors.

694

ROLE OF APICAL SUSHI PROTEIN IN SPOROZOITE INVASION OF SALIVARY GLANDS

Kazuhiro Matsuoka[1], Amporn Thongkukiatkul[2], Takafumi Tsuboi[3], Motomi Torii[1], **Tomoko Ishino**[1]

[1]Ehime University, Toon, Japan, [2]Burapha University, Chonburi, Thailand, [3]Ehime University, Matsuyama, Japan

The infective forms of apicomplexan parasites, including *Plasmodium*, have the conserved apical organelles named rhoptries and micronames. Several rhoptry proteins, released during the invasion process, have been revealed crucial for parasite invasion of target cells by forming tight junction between them. *Plasmodium* sporozoites, transmiting malaria disease from mosquito vector to mammalian hosts, firstly invade salivary glands in mosquitoes and then infect hepetocytes in mammals. Recently, we demonstrated that rhoptry neck protein 2 (RON2) has an important role in sporozoite invasion of salivary glands by using sporozoite-stage specific gene silencing system. This raised the possibility that other rhoptry proteins are also involved in sporozoite invasion mechanisms. Apical Sushi Protein (ASP) is known as a rhoptry protein in *Plasmodium* merozoites and *Toxoplasma* tachyzoites with Sushi and GPI-anchor domains. Here, we demonstrate that ASP is predominantly expressed in oocyst-derived sporozoites, that is more than in schizonts, and localized to rhoptries. Applying the conditional knockdown system by promoter swapping, we generated transgenic *Plasmodium berghei* expressing ASP only at schizont-stage. ASP-repressed sporozoites, formed normally in oocysts, failed to invade salivary glands, possibly due to the defect in their attachment and gliding abilities. In addition, RON2 amount in ASP-repressed oocyst sporozoites was reduced to one-tenth of that in control sporozoites, suggesting that ASP may contribute to the stability of RON2. Comprehensive functional analyses of rhoptry proteins in sporozoites might provide clues to elucidate the molecular mechanisms of sporozoite invasion of salivary glands.

695

THE IMPACT OF LONG-LASTING INSECTICIDAL (LLIN) NET EXPOSURE ON POST-EXPOSURE LONGEVITY OF PYRETHROID RESISTANT *ANOPHELES COLUZZII* MOSQUITOES IN BURKINA FASO

Natalie Lissenden[1], Gregory P. Murray[1], Kobié H. Toé[2], N'Fale Sagnon[2], Moussa Guelbeogo[2], Philip J. McCall[1], Hilary Ranson[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso

Insecticide resistance has the potential to erode recent gains in malaria control. Typically, resistance is determined by evaluating mosquito mortality at 24hrs post-exposure, while sub-lethal or delayed effects that might impact vectorial capacity (e.g. reduced fecundity, impaired feeding, longevity) are rarely documented. In Burkina Faso, we examined the impact of exposure to long-lasting insecticidal nets (LLINs) and untreated controls on the post-exposure longevity of wild pyrethroid-

resistant *Anopheles coluzzii* populations, in WHO cone-bioassays and experimental hut trials with a human-baited LLINs. Wild mosquitoes of unknown age entering huts ("wild") and adult mosquitoes of known age reared from larvae of the same population ("reared") were used in both tests. Reared mosquitoes of different ages (one vs seven-days-old) were also exposed to LLINs. Following exposure, daily mortality was recorded until all mosquitoes were dead. In cone and hut trials, accounting for blood-feeding, LLIN exposure had no effect on longevity of either reared (P=0.843) or wild (P=0.984) mosquitoes. Wild mosquitoes lived significantly longer than reared mosquitoes (P<0.000), and immediate mortality (24hrs) in experimental huts was higher in reared mosquitoes (36% compared to 9%). The method of exposure (i.e. cone vs hut) did not affect longevity (P=0.702). Comparison of one and seven-day-old reared mosquitoes in cone-bioassays, showed significantly higher immediate mortality (2% to 12% mortality) and reduced longevity in seven day-olds (P<0.000). In hut trials, blood-fed mosquitoes lived significantly longer post-exposure than unfed mosquitoes (P<0.000). In contrast to earlier laboratory studies reporting substantial delayed lethal effects in resistant colonies after LLIN exposure, these field experiments found no evidence of LLINs impacting longevity in this highly pyrethroid resistant population in Burkina Faso. The implications of these results for our understanding of the impact of resistance on vector control interventions are considered.

MAPPING SPATIO-TEMPORAL PATTERNS IN INSECTICIDE RESISTANCE PHENOTYPES IN MALARIA VECTORS ACROSS AFRICA

Penelope Hancock[1], Antoinette Wiebe[1], Katherine Gleave[2], Samir Bhatt[3], Ewan Cameron[1], Anna Trett[2], David Weetman[2], David Smith[4], Michael Coleman[2], Peter Gething[1], Catherine Moyes[1]

[1]University of Oxford, Oxford, United Kingdom, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Imperial College London, London, United Kingdom, [4]University of Washington, Seattle, WA, United States

The development of insecticide resistance in African malaria vectors threatens the continued efficacy of important vector control methods that rely on a limited set of insecticides. To understand the impact of insecticide resistance on malaria transmission, and develop effective resistance management strategies, we require comprehensive quantification of resistance in field populations to the suite of vector control insecticides. We apply Bayesian geostatistical and machine learning approaches to generate Africa-wide predictive maps of resistance phenotypes for commonly-used insecticides in mosquito species within the *Anopheles gambiae* complex. Our models incorporate data on resistance phenotypes as well as genetic resistance mechanisms in *An. gambiae* complex samples, together with high resolution data on potential environmental drivers of selection for resistance. Our resistance phenotype data set includes results of susceptibility bioassays conducted on 5595 samples across 1183 locations spanning 38 African countries and across insecticide types from four insecticide classes. We augment this with data on the frequency of mutations in the *Vgsc* gene, known to confer resistance to pyrethroid insecticides and DDT, from *An. gambiae* complex samples collected throughout Africa. Environmental covariates include data on the application of insecticide-based vector control interventions as well as potential predictors of mosquito exposure to insecticides used in agriculture. We were able to substantially improve predictive capacity by making use of consistent relationships between resistance phenotypes across different insecticide types, as well as relationships between phenotypic and genetic variation. We also identified environmental and intervention covariates that improve prediction, generating hypotheses about drivers of selection for insecticide resistance. Our maps provide an Africa-wide geostatistical quantification of trends in insecticide resistance, and incorporate measures of prediction uncertainty that highlight regions where field data collection is important.

697

JUST BREATHE: USING SIMPLE RESPIROMETRY TO CHARACTERIZE METABOLIC RESISTANCE TO INSECTICIDES IN MOSQUITO VECTORS

Gordana Rasic[1], Igor Filipovic[1], Lisa Rigby[2], Pablo Manrique-Saide[3], Gregor Devine[1]

[1]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [2]Australian Defence Force Malaria and Infectious Disease Institute, Enoggera, Australia, [3]Universidad Autónoma de Yucatán, Unidad Colaborativa de Bioensayos Entomológicos, Merida, Mexico

The rapid and widespread adaptation in mosquito populations to chemical insecticides is now compromising vector-borne disease control programs. Tools for monitoring and predicting the evolution of insecticide resistance in the field is paramount to devising successful mosquito control campaigns. However, there are major gaps in our understanding of the resistance mechanisms and their operational impact. Resistance to insecticides like pyrethroids has been associated with increased metabolism by multifunction oxidases and decreased neuronal target site sensitivity (also known as the knock down resistance, kdr). While kdr to pyrethroids seems to have a relatively simple genetic background (few major effect mutations in the insect para gene), metabolic resistance can be a result of alterations in a number of gene families. Identifying genetic architecture of metabolic resistance therefore requires screening of genetic variants across the genome, which is now attainable thanks to a lower cost of next generation sequencing (NGS) and annotated reference genome sequences available for major mosquito vectors. However, no genetic study can have meaningful results without a careful characterization of the phenotype, and we do not have well-established quantitative measures of metabolic resistance. Here we show that a simple method to measure changes in metabolic state of mosquitoes can be used to identify genetic preturbations affecting metabolic resistance. We used inexpensive respirometry technique to measure CO_2 production in *Aedes aegypti* mosquitoes from different strains with varying levels of resistance to deltamethrin. CO_2 output is a suitable indicator of substrate oxidation and energy expenditure that provides information about metabolic state. We tested the hypothesis that the basal metabolic rate is higher in more resistant mosquitoes, and that it is less altered after exposure to deltamethrin. Using NGS of pooled mosquitoes from different phenotypic groups, we show that differences in metabolic state correspond to differences across multifunction oxidase genes.

698

INSECTICIDE RESISTANCE IS NOT ASSOCIATED WITH *PLASMODIUM FALCIPARUM* INFECTION IN *ANOPHELES GAMBIAE* S.L. (DIPTERA: CULICIDAE) IN GUINEA

Emma Collins[1], Natasha Vaselli[1], Moussa Sylla[2], Abdoul Beavogui[2], James Orsborne[1], Seth Irish[3], Thomas Walker[1], **Louisa A. Messenger**[4]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Centre National de Formation et de Recherche en Santé Rurale de Maferinyah, Maferinyah, Guinea, [3]President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Centers for Disease Control and Prevention, Atlanta, GA, United States

The threat of insecticide resistance across sub-Saharan Africa is anticipated to have severe implications for the continued effectiveness of insecticide-based vector control interventions. In an area of high malaria transmission in Forecariah Prefecture, Guinea, we investigated the impact of insecticide resistance intensity on *Plasmodium falciparum* infection in *Anopheles gambiae* s.l. CDC bottle bioassays and synergists assays with PBO, were used to assess resistance intensity to carbamates and pyrethroids. A subset of specimens underwent ovarian dissection to determine parity and molecular assays were performed to detect insecticide resistance alleles (*Ace-1*, *kdr* and N1575Y) and *Plasmodium falciparum* infection

in abdomens or head/thoraxes. Pyrethroid resistance was intense as evidenced by mosquito populations that were not only resistant to ten times the insecticide concentration required to kill susceptible individuals, but were also capable of surviving these doses for up to two hours. By comparison, carbamate resistance was lower, with possible resistance restricted to two adjacent villages and significantly associated with the presence of *Ace-1* (p=0.001). Pyrethroid resistance was not associated with *P. falciparum* prevalence, with no significant differences in infection observed between susceptible or resistant vectors (p=0.345 and p=0.148, respectively). Pyrethroid-resistant mosquitoes had significantly lower parity rates, i.e. were younger, than susceptible individuals. However, the small proportion of intensely resistant vectors were more likely to be parous (p=0.042 and p=0.036, for survivors exposed to five and ten times the diagnostic dose of insecticides, respectively). Partial restoration of mosquito susceptibility to pyrethroids following pre-exposure to PBO and the non-association between *kdr*-N1575Y frequency and vector mortality rates indicate that oxidase-based mechanisms are important in driving local pyrethroid resistance. Our findings highlight the need for additional studies, directly examining the impact of insecticide resistance on mosquito fitness.

699

INSECTICIDE RESISTANCE MONITORING IN AFRICAN MALARIA MOSQUITOES USING HIGH-THROUGHPUT DIAGNOSTIC MARKERS

Arjen Van 't Hof, Eric R. Lucas, Amy Lynd, Dimitra Pipini, Emily Rippon, Martin Donnelly, David Weetman

Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Vector control programs strongly rely on effective insecticides. The African malaria mosquito *Anopheles gambiae* has developed a range of target site and metabolic resistance mechanisms which threatens the sustenance of recent achievements in the fight against malaria. Markers representing the genetic changes responsible for insecticide resistance can be used to monitor their presence in individuals, populations, and geographic areas. Detailed knowledge about the presence, abundance, and spread of insecticide resistance will be a major benefit to vector control strategy design. Recent technological developments greatly advanced both marker discovery and marker detection methods. Many new potential markers have been found in gene clusters associated with insecticide resistance such as cytochrome P450s and glutathione S-transferases. Single-locus genotyping methods such as Taqman assays are now routinely used to screen for established mutations including kdr east and west in VGSC and G119S in Ace1. Fluorescent Locked Nucleotide Acid (LNA) probes allow for more design flexibility at a greatly reduced cost compared to Taqman assays. Our group has designed several LNA assays including a three-dye method which can detect the presence of all three kdr alleles in a single reaction. LNA probes are also routinely used to validate candidate markers found in *Anopheles gambiae* genome projects. Full-scale screening of multiple markers in thousands of mosquitoes requires a high-throughput platform. We successfully genotyped 30 SNPs at once using the IPLEX Mass Array system, though this method is sensitive to background genetic variation and the technology is not widely accessible. Genotyping by sequencing using multiplexed amplicons on the illumina MiSeq allows scalability and flexibility of marker panels and numbers of mosquitoes screened per run. In collaboration with the Sanger Institute, we developed several panels of 25 multiplexed amplicons to allow mass screening of insecticide resistance markers. These panels can be tailored to suit their purpose and can be kept up to date by adding newly discovered insecticide resistance markers.

700

INCREASED SUSCEPTIBILITY OF *ANOPHELES GAMBIAE* TO *PLASMODIUM FALCIPARUM* IS NOT ASSOCIATED WITH MARKERS OF INSECTICIDE RESISTANCE IN TORORO, UGANDA

Melissa D. Conrad[1], Ambrose Aruni[2], Alison Isaacs[2], Emily Rippon[2], Alex Musiime[3], Maxwell Kilama[3], Moses Kamya[4], Grant Dorsey[1], Martin Donnelly[2], Philip J. Rosenthal[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Infectious Disease Research Collaboration, Kampala, Uganda, [4]Makerere University, Kampala, Uganda

Insecticide resistance threatens malaria vector control interventions and may impact on the efficiency of transmission of malaria to mosquitoes. West African lab studies showed that *ace-1* 119S and the *Vgsc*-1014F (*kdr-west*) mutations, which are responsible for organophosphate/carbamate resistance and pyrethroid resistance, respectively, increased susceptibility to *P. falciparum* (*Pf*) infection. Similarly, in wild-caught *A. gambiae* in Tanzania, pyrethroid resistant *Vgsc*-1014S (*kdr-east*) homozygotes had increased sporozoite rate compared to WT. We are studying whether similar associations are present in Tororo District, Uganda, where extensive resistance to DDT and pyrethroids, but not to carbamates or organophosphates, has been observed. 132 *Pf*-infected *A. gambiae s.s.* mosquitoes were collected from 100 randomly selected households from 2011 to 2015. Each infected (*Pf*+) mosquito was paired with 3 uninfected (*Pf*-) mosquitoes from the same collection. Taqman assays were used to genotype at *Vgsc*-L1014F/S and at polymorphisms in *Cyp4j5* and *Coeae1d* that were recently associated with pyrethroid resistance in Tororo. PCR was used to genotype the 2La inversion, which is associated with adaptation to aridity, indoor biting, and differential malaria infection. Most mosquitoes were homozygous for *Vgsc*-1014S (97.8% *Pf*- vs. 97.6% *Pf*+), with uncommon L/L homozygotes (1.3% *Pf*- vs. 1.6% *Pf*+), L/S heterozygotes (1.3% *Pf*- vs. 0% *Pf*+) and S/F heterozygotes (0.5% *Pf*- vs 0.8% *Pf*+). For *Cyp4j5*, the prevalence of homozygous resistant, (RR), heterozygous (SR), and homozygous susceptible (SS) genotypes were 19.2%, 38.7%, and 42.0% for *Pf*- mosquitoes and 14.6%, 40.7%, and 44.7% for *Pf*+ mosquitoes. *Coeae1d* prevalences were 28.1% RR, 49.0% SR, and 22.9% SS for *Pf*- mosquitoes and 35.3% RR, 46.7% SR, and 21.0% SS, for *Pf*+ mosquitoes. Prevalences of 2La inversion genotypes were 19.9% $2L+^a/2L+^a$, 28.1% $2L+^a/2La$, and 52.0% 2La/2La in *Pf*- mosquitoes, and 14.2% $2L+^a/2L+^a$, 28.6% $2L+^a/2La$, and 57.1% 2La/2La in *Pf*+ mosquitoes. To date we have found no significant associations between insecticide resistance polymorphisms and risk of mosquito *Pf* infection.

701

EFFECT OF PASSIVE METOFLUTHRIN EMANATORS ON LANDING AND MORTALITY OF PYRETHROID-RESISTANT *AEDES AEGYPTI*

Mike W. Dunbar[1], Gregor J. Devine[2], Pablo Manrique-Saide[3], José Manuel Vadillo-Sánchez[3], Evaristo Morales-Ríos[3], Wilbert Bibiano-Marín[3], Anuar Medina-Barreiro[3], Gonzalo M. Vazquez-Prokopec[1]

[1]Emory University, Atlanta, GA, United States, [2]QIMR Berghofer, Herston, Australia, [3]Universidad Autónoma de Yucatán, Merida, Mexico

Management of urban *Aedes aegypti* is currently challenged by the evolution of pyrethroid resistance. A tactic with potential for large-scale implementation is indoor deployment of passive emanators (small, 10% metofluthrin-impregnated nets) that are advantageous because they are rapidly installed, require no source of heat, and can act as confusants rather than repellents. We tested whether exposure to metofluthrin emanators installed in experimental houses located in Mérida, Mexico, affected landing and mortality among field-derived strains of *Ae. aegypti* that differed in pyrethroid susceptibility. Experimental houses (n = 8) were rented houses in Mérida where passive emanators could be deployed,

and were modified for experimentation with doubled screed entrances and standardized contents. Mosquitoes were released into paired houses (n = 25 mosquitoes/ house): one house with emanators and one control. Landing counts were performed before, 30 min, 24 hrs, and 72 hrs after emanator deployment. Mortality was measured both 24 and 72 hrs post-mosquito introduction. The experiment was repeated 17 times using different combinations of 5 *Ae. aegypti* strains; a lab insecticide-susceptible strain (New Orleans) (n = 4 paired house reps), 2 locally-derived susceptible strains (n = 11 and 19 reps), and 2 locally-derived pyrethroid-resistant strains (n = 11 and 4 reps). Landing counts did not differ among houses before the introduction of emanators ($F = 3.2$; $p = 0.09$), but were significantly reduced 30 minutes after emanator introduction among all strains in treated houses compared to control houses ($F = 59.8$; $p < 0.0001$). After 24 hrs, mortality was significantly greater in treated compared to control houses across all strains ($F = 21.9$; $p = 0.0002$), but landing counts recovered ($F = 3.42$; $p = 0.043$). After 72 hrs, the majority of susceptible *Ae. aegypti* had died within treated houses (99.5 ± 0.5%). Given the effects on *Ae. aegypti* mortality and landing, metofluthrin emanators could be an important addition to the vector control toolbox, however, additional research is still needed to explore how resistant populations will react to long-term exposure.

702

MOLECULAR DIAGNOSTICS OF POTENTIAL PATHOGENS IN THE WILDLIFE TRADE IN LAO PDR

Matthew T. Robinson[1], Pruksa Nawtaisong[1], Malavanh Vongsouvath[1], Khongsy Khammavong[2], Phonesavanh Milavong[3], Audrey Rachlin[1], Sabine Dittrich[1], Audrey Audrey Dubot-Pérès[4], Mathieu Pruvot[3], Paul N. Newton[1]

[1]LOMWRU, Vientiane, Lao People's Democratic Republic, [2]WCS Lao Programe, Vientiane, Lao People's Democratic Republic, [3]WCS Lao Programme, Vientiane, Lao People's Democratic Republic, [4]Unite des Virus Emergents (UVE: Aix-Marseille Univ – IRD 190 – Inserm 1207 – IHU Mediterranee Infection), Marseille, France

Wildlife trade is thought to be a major driver of emerging infectious diseases. As part of the Lao PDR-Cambodia One Health Surveillance and Laboratory Network Project (LACANET) we surveyed the presence of zoonotic pathogens in wildlife meat on sale at wet markets across Lao PDR. In total, 717 samples, including urogenital swabs, blood, urine and tissue samples, were collected from 359 animals (encompassing 32 species including squirrels, civet cats, rats and bats) across 11 markets and three Provincial Offices in Lao PDR. Using polymerase chain reaction (PCR) techniques, samples were screened for a variety of zoonotic bacterial and viral pathogens. We identified 69 animals (19.2%) positive for *Leptospira* spp. and 19 animals (5.3%) positive for *Rickettsia* spp., including three confirmed as *R. felis* and one *R. typhi*. Other potential human pathogens identified include *Orientia tsutsugamushi, Ehrlichia* spp. and *Anaplasma* spp. (*A. phagocytophilum, A. bovis*, and *A. marginale*). The most common wildlife meat being traded in markets are from the Sciuridae family (73.3%). Our observations indicate their potential as multiple disease reservoirs, with a total of six different pathogen species being identified, including the discovery of *R. felis*, an emerging rickettsial pathogen, and which is the first reported occurrence in squirrel species. Our results demonstrate that wildlife found for sale at wet markets are able to carry pathogens of public health importance such as *Leptospira* spp., *Rickettsia* spp., *O. tsutsugamushi*, *Ehrlichia* spp. and *Anaplasma* spp. The findings from this investigation highlight that wet markets in Lao PDR are potential sources of emerging infectious zoonotic diseases and thus appropriate measures and mitigation strategies must be taken into account to protect public health, including further ongoing work investigating the risk of transmission of zoonotic pathogens to vendors and buyers.

703

INDEX-CLUSTER STUDY OF INTERSPECIES DISEASE TRANSMISSION AT LOLA YA BONOBO SANCTUARY, DEMOCRATIC REPUBLIC OF CONGO

Bradly P. Nicholson[1], Raphaël Belais[2], Aleah Bowie[3], Chelsea McMullen[4], Patrick Mukadi[5], Nicole A. Hoff[6], Reena H. Doshi[6], Fanny Minesi[2], Claudine André[2], Brian Hare[3], Emile Okitolonda Wemakoy[7], Jean-Jacques Muyembe-Tamfum[5], Anne W. Rimoin[6], Christopher W. Woods[8]

[1]Institute for Medical Research, Durham Veterans Affairs Medical Center, Durham, NC, United States, [2]Lola ya Bonobo, Kinshasa, Democratic Republic of the Congo, [3]Duke University, Department of Evolutionary Anthropology, Durham, NC, United States, [4]Duke University, Global Health Institute, Durham, NC, United States, [5]Institut National de Recherche Biomedicale, Kinshasa, Democratic Republic of the Congo, [6]University of California Los Angeles, Department of Epidemiology, Jonathan and Karin Fielding School of Public Health, Los Angeles, CA, United States, [7]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, [8]Duke University Medical Center, Division of Infectious Diseases, Durham, NC, United States

Lola ya Bonobo (LyB) is a sanctuary for orphaned bonobos (Pan paniscus) outside Kinshasa, Democratic Republic of Congo. Orphaned infants transition to a juvenile group prior to one of three multi-hectare forested enclosures housing adult Bonobos. Animals often come into close contact (<1-2m) with keepers. In cooperation with LyB, we studied the potential for interspecies disease transmission during 2014. We collected baseline specimens from 73 Bonobos during an annual health check, and from LyB staff during enrollment. During the study, specimen collection was initiated by a symptomatic Bonobo (keeper observations) or human (self-reported), with other potentially ill animals or staff for up to five days. Illness would often begin in a living group and spread: Feb. 2014, 4 clusters; May 2014, 3 clusters; Aug. 2014, 2 clusters; single clusters in Sep. and Oct.; and 2 clusters in Nov. 2014. We collected closeout specimens (60 Bonobo and 28 Human) in Oct./Nov. 2015. Nasal/oral samples were analyzed with a Respiratory Pathogen Panel (RPP) which detects 18 viral and 3 bacterial pathogens. At baseline, 9/73 of Bonobos were positive (8 viral, 1 bacterial) and 7/42 of humans were positive via RPP (7 viral). The Feb. clusters were a multi-enclosure outbreak of Respiratory Syncytial Virus A (RSVA), with 29/30 of Bonobos positive. Bonobos in the three May clusters were 10/14 positive for RSVA and 4/14 positive with Rhino/Enterovirus. Of the 8 humans tested in May, only 1 was positive (Parainfluenza 2). The Aug. clusters were positive for Rhino/Enterovirus 10/10 Bonobos, 1/6 Humans. Only 1/6 Bonobos and 0/1 Humans were positive for Rhino/Entero in the Sep.–Oct. clusters. Rhino/Entero was present in the two Nov. clusters with 11/11 Bonobos and 1/5 humans positive. In closeout 5/60 Bonobos and 1/28 Humans positive for virus. This work represents an early analysis of observed contemporaneous respiratory infection of humans and non-human primates in a sanctuary environment. The Bonobos at LyB are at risk from exposure to human respiratory pathogens, however we are currently unable to determine the route of exposure.

704

EVIDENCE FOR ASYMPTOMATIC CIRCULATION OF ORTHOPOXVIRUS IN MFOU DISTRICT, CAMEROON

Sarah Anne Guagliardo[1], Ben Monroe[1], Christian Moundjoa[2], Ateba Athanase[3], Gordon Okpu[4], Omer Pasi[4], Jillybeth Burgado[1], Michael B. Townsend[1], Panayampalli Satheshkumar[1], Scott Epperson[5], Jeffrey Doty[1], Mary G. Reynolds[1], Elisabeth Dibongue[3], Andrea M. McCollum[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Ministry of Livestock, Fisheries, and Animal Industries, Yaounde, Cameroon, [3]National Zoonoses Program, Ministry of Health, Yaounde,

Cameroon, [4]Centers for Disease Control and Prevention, Yaounde, Cameroon, [5]University of Georgia, Athens, GA, United States

Monkeypox virus is a zoonotic orthopoxvirus that causes smallpox-like illness in humans. In Cameroon, human monkeypox cases were last confirmed in 1979 and outbreaks in captive chimpanzees occurred in 2014 and 2016. Although no humans had clinical signs or symptoms of monkeypox during recent chimpanzee outbreaks, several were exposed while caring for sick animals, raising questions about the threat of monkeypox to humans in this region. A survey was administered to staff employed at a primate sanctuary (the site of a recent chimpanzee outbreak) and residents from four nearby towns, documenting monkeypox symptoms and contact with wild animals including possible reservoir species, such as Gambian rats and rope squirrels, among others. We also collected one 5mL whole blood specimen from each participant, and performed an ELISA test to detect the presence of anti-orthopoxvirus IgG antibodies. In total, 43 of 125 (34.4%) participants were IgG positive. Among those under the age of smallpox vaccination (<37 years), four (6.3%) were IgG positive (one sanctuary employee and three community members). No one reported past clinical symptoms compatible with monkeypox in their lifetime. Eighty-six participants (68.8%) had recent contact with animals (since August 2016), but primate sanctuary workers were less likely to have frequent forest visits (Fisher's exact test $P<0.001$) and less likely to have contact with possible monkeypox reservoir species, Gambian rats, rope squirrels, sun squirrels, and dormice (Chi-square= 31.8, $P<0.0001$). Participants reported contact with porcupines (n=82), Gambian rats (n=71), sun squirrels (n=35), and rope squirrels (n=33). Among community members, men were significantly more likely than women to hunt or trap Gambian rats (Chi-square=5.9, $P<0.05$). Our results demonstrate evidence for asymptomatic orthopoxvirus infection in Mfou District, Cameroon. Contact with possible monkeypox reservoirs is also common among residents in this region. The present circulation of orthopoxviruses, monkeypox in particular, in an endemic area raises the need for continued surveillance for human and animal disease.

705

A MARKOV CHAIN MODEL TO EVALUATE THE HUMAN SAFETY OF ORAL ANIMAL VACCINES FOR WILDLIFE OR NON-ACCESSIBLE ANIMALS: A CASE STUDY OF AN ORAL RABIES VACCINE

Jennifer R. Head[1], Jesse D. Blanton[2], Julie Cleaton[2], Adrian Vos[3], Thomas Thomas Müller[4], Richard Chipman[5], Emily Pieracci[2], Ryan Wallace[2]

[1]Public Health Institute/Division of Global Health Protection, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Division of High-Consequence Pathogens and Pathology, National Center for Emerging and Zoonotic Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]IDT Biologika GmbH, Dessau-Tornau, Germany, [4]Institute of Molecular Virology and Cell Biology, Friedrich-Loeffler-Institut, Federal Research Institute for Animal Health, WHO Collaborating Centre for Rabies Surveillance and Research, Greifswald-Insel Riems, Germany, [5]Wildlife Services Rabies Management, Animal Plant and Health Inspection Service, United States Department of Agriculture, Concord, NH, United States

Baits containing oral vaccines aid immunization of animal populations less accessible to parenteral vaccination, but may contain live-attenuated viruses that pose risks of reversion to virulence or residual pathogenicity. Such is the case for first generation oral rabies vaccines, such as SAD-B19, used widely in Europe to manage fox rabies. International health organizations caution against using these vaccines in dogs, proposing instead highly attenuated strains, such as SPBN GASGAS, while requiring detailed risk assessment prior to their use in wildlife and dogs. We mapped pathways by which environmental distribution of oral vaccines may result in its mucosal, subcutaneous, or severe inoculation into people and applied a continuous-time Markov chain to estimate the expected and 95% confidence intervals of the number of severe adverse events (SAEs) under three scenarios. We validated the model by comparing a simulated SAD-B19 vaccination campaign in foxes to prior campaigns in which 250 million baits were dispersed and no SAEs detected. A low risk to humans was predicted with 0.25 deaths per 10 million baits distributed for fox rabies control. However, consistent with international concern, our model predicts that SAD-B19 could result in 7.0 human deaths per 10 million baits distributed if used for dogs. Conversely, our model predicts no human deaths per 10 million baits of SPBN GASGAS for dogs. Among all three scenarios, 98% of vaccine-induced SAEs were due to bites from rabid dogs that had experienced vaccine-induced rabies. Sensitivity analysis using Latin hypercube sampling show that parameters involved in the exposure route involving direct contact with vaccine in the environment most strongly influence outcomes of wildlife campaigns, while parameters involved in the dog bite exposure route most strongly influence dog campaign outcomes. No simulation of SPBN GASGAS resulted in SAEs in sensitivity analysis. This model highlights the safety of SPBN GASGAS and can be used as a standardized approach to inform risk assessments when planning vaccination campaigns of various vaccine types, distribution methods, and animal populations.

706

ELEVATED PREVALENCE AND NOVEL HOST INFECTION OF WEST NILE VIRUS AT THE NASHVILLE ZOO, TENNESSEE, USA

Thomas C. Moore[1], Kenna Graham[1], Heather Robertson[2], Margarita Woc Colburn[2], Rita McManamon[3], Jay Dihonov[2], Alessandra Rodriguez[1], John Dunn[1], Abelardo C. Moncayo[1]

[1]Tennessee Department of Health, Nashville, TN, United States, [2]Nashville Zoo at Grassmere, Nashville, TN, United States, [3]University of Georgia, Athens, GA, United States

On August 30, 2017, one of 5 bontebok in a mixed species exhibit at the Nashville Zoo at Grassmere exhibited acute hind-limb ataxia and altered demeanor. The 8-year-old male bontebok had no recent history of trauma, toxin ingestion, or travel. Initial examination revealed hyperesthesia, general ataxia, and moderate weakness, suggesting cerebellar/brain stem lesion. Complete blood count displayed lymphopenia and by day 4, ataxia worsened with frequent falling, short-strided gait, and dull mentation. Gross necropsy uncovered lung and liver congestion, mild abomasal ulcerations, and brain hemorrhage. Various tissues were sent to the University of Georgia College of Veterinary Medicine Infectious Disease Laboratory and showed necrotizing meningoencephalitis and spinal myelitis. Fresh brain tissue was submitted to the Tennessee Department of Health (TDH) Vector-Borne Disease (VBD) program for arbovirus testing. Molecular analysis identified West Nile Virus (WNV) as the etiology of illness. Environmental sampling at the zoo was conducted by mosquito capture during September 19 -October 13, 2017. There were a total of 3,998 mosquitoes tested, representing 5 species with the majority (72.06%) being *Culex pipiens*. Only *Cx. pipiens* had detection of WNV as well as St. Louis encephalitis virus (SLEV). The mean weekly maximum likelihood estimate for WNV prevalence among *Cx. pipiens* at the zoo was 9.56 (95% CI 4.13-21.59), or ≈1 WNV infected *Cx. pipiens* per 105 collected. Mosquito data showed a two-fold elevated prevalence of WNV compared to Tennessee. The TDH VBD program and the Nashville Zoo have obtained samples for seroprevalence of WNV from 11 unvaccinated animal species located at the zoo. To our knowledge, this is the first instance of WNV infection among bontebok on public record. Also, the park is centered in the Nashville suburbs and is a venue for large community events. The combined rare incidence of WNV infection in a novel host and the large presence of WNV and SLEV in the zoo mosquito population warrant mosquito control measures implemented in zoo habitats to reduce potential transmission to unvaccinated animal species and human visitors.

707

ZOONOTIC AND ENVIRONMENTAL DETERMINANTS OF TUNGIASIS IN A RURAL AREA ADJACENT TO A WILDLIFE RESERVE IN KWALE, KENYA

Peter S. Larson[1], Masanobu Ono[2], Morris Ndemwa[3], Juma Changoma[4], Noboru Minakawa[2], Kensuke Goto[5]

[1]University of Michigan, Ann Arbor, MI, United States, [2]Nagasaki University Institute of Tropical Medicine, Nagasaki, Japan, [3]Nagasaki University Institute of Tropical Medicine, Nairobi, Kenya, [4]Chemi Chemi, Kwale, Kenya, [5]Osaka Educational University National Mental Support Center for School Crisis, Osaka, Japan

Tungiasis is an inflammatory skin disease caused by the ectoparasite *Tunga pentrans*, which burrows into the skin. Tungiasis is associated with intense itching, pain, and secondary bacterial infections and, in severe cases, loss of limbs and death. Tungiasis is a zoonosis common throughout Sub-Saharan Africa, though little is known of the role of wildlife in human tungiasis transmission. Wildlife could become infested with T. penetrans, bring eggs to the vicinity of the household, whereby livestock become infected, thus increasing risk for disease in humans. Through a demographic surveillance system in Kwale, Kenya, located proximally to a large wildlife preserve, we tested associations between human tungiasis and presence of wildlife and other environmental factors. Using a complex survey sampling design, 319 households were selected from three regions. A survey instrument was administered which included questions on livestock assets, reported presence of various species of wildlife around the home, health seeking behaviors, basic demographics and socioeconomics. Humans and livestock were visually assessed for presence of tungiasis. Of the 319 households selected (12.8%) of them had at least one person who had tungiasis. Males were more likely to be infected than females (OR 5.07 (2.52, 10.8)). Increased distance (kms) to the wildlife reserve was found to be associated with decreased odds of infection (OR .90 (.81, .99)). Simple possession of domesticated animals was not found to be associated with tungiasis in humans. However, positive cases of animal tungiasis of all species were found to have positive though non-significant associations with human tungiasis. Out of all wildlife species only presence of stray dogs was found to be associated with an increased risk for human tungiasis (OR 2.37 (1.21, 4.65)). While our research confirmed earlier results that distance to the wildlife reserve was associated with tungiasis in humans, there was only weak evidence that animal tungiasis was associated with tungiasis in humans. More work needs to be done to assess tungiasis transmission between wildlife, livestock and humans.

SURVEILLANCE AT THE HUMAN-ANIMAL INTERFACE DURING ZIKA VIRUS TRANSMISSION - PERU

Maria Claudia Guezala[1], Tatiana P. Quevedo[2], Christian B. Albujar[1], J. Catherine Dupont T.[1], Helvio Astete[1], Nicholas Komar[3], Stephanie J. Salyer[4], Joel M. Montgomery[4], Christopher M. Mores[1]

[1]Naval Medical Research Unit 6, Lima, Peru, [2]Vysnova Partners Inc., Lima, Peru, [3]Arbovirus Diseases Branch, Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, Fort Collins, CO, United States, [4]EISL Branch, Division of Global Health Protection, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States

Zika virus has been diagnosed throughout the Americas, reporting over a million human cases (PAHO/WHO, 2018). As transmission wanes, questions remain as to whether a zoonotic cycle of virus maintenance will become established. Some reports found Zika virus in animals within an outbreak zone; however, more data is needed to understand which animal species may become infected during transmission among people. We studied if animals infected during an outbreak could be zoonotic reservoirs of Zika virus. We conducted animal and vector surveillance activities in areas with presence of human cases to determine such infections. Domestic dogs, cats and poultry were sampled, peri-domestic rodents (*Rattus spp*, *Mus musculus*) and bats were trapped and humanly euthanized to obtain biological samples. Other wildlife, such as wild rodents or birds were also trapped and sampled before releasing to their habitat. Non-human primates (NHPs) were sampled from local shelters or breeding facilities located in the vicinity of the areas with human cases. Finally, targeted collections of mosquitoes were performed in the same areas or households where animals were trapped/sampled. In all cases, samplings were performed within a 1 km radius of a reported human Zika case. Samples were obtained from 156 dogs, 18 cats, 153 chickens, 27 ducks, 3 wild rodents (*Proechymis* spp and *Oligoryzomys spp*), 36 *Mus musculus,* and 23 *Rattus sp.* from urban settings, 4 *Mus musculus* and 1 *Rattus rattus* from rural settings, 75 bats from 18 different species, 51 wild birds from 28 different species, and 141 NHPs from 9 different species. Mosquitoes from 62 different species were collected, including 1007 *Aedes spp* (308 males, 613 females, and 86 engorged females) among others. In total, 688 animals were sampled and 21,486 mosquitoes collected. Zika testing is underway, with whole blood and engorged mosquitoes to be tested using RT-PCR as an initial screening tool. Findings will be spatially correlated with the location of human cases, providing a more complete and ecological approach to the understanding of Zika virus transmission, and identifying possible candidates for zoonotic maintenance.

709

INTESTINAL PARASITOSIS IN RELATION TO CD4+T CELLS LEVELS AND ANEMIA AMONG HAART INITIATED AND HAART NAÏVE PEDIATRIC HIV PATIENTS IN MODEL ART CENTER, ADDIS ABABA, ETHIOPIA

Hylemariam Mihiretie Mengist

Debre Markos University, Debre Markos, Ethiopia

In the absence of highly active antiretroviral therapy (HAART), HIV/AIDS patients in developing countries, unfortunately, continue to suffer from the consequences of opportunistic and other intestinal parasites. The aim of the study was to determine the prevalence of intestinal parasites in relation to CD4+ T cells levels and anemia among HAART initiated and HAART naïve pediatric HIV patients in a Model ART center in Addis Ababa, Ethiopia. A cross-sectional study was conducted among pediatric HIV/AIDS patients attending a model ART center a between August 05, 2013 and November 25, 2013. A stool specimen was collected and processed using direct wet mount, formol-ether concentration and modified Ziehl-Neelsen staining techniques. CD4+ T cells and complete blood counts were performed using BD FACScalibur and Cell-Dyn 1800, respectively. The data were analyzed by SPSS version 16 software. The overall prevalence of IPs was 37.8% where 27.8% of HAART initiated and 45.5% of HAART naive pediatric HIV/AIDS patients were infected ($p < 0.05$). *Cryptosporidium* species, *E. histolytica/dispar*, *Hook worm* and *Taenia* species were IPs associated with CD4+ T cell counts <350 cells/μL in HAART naive patients. The overall prevalence of anemia was 10% in HAART and 31.7% in non-HAART groups. *Hookworm*, *S. stercoralis*, and *H. nana* were helminths significantly associated with anemia in non-HAART patients [AOR, 95% CI: 4.5(1.3, 15.2), P< 0.05]. The prevalence of IPs in non-HAART patients was significantly associated with eating unwashed/raw fruit [AOR, 95%CI: 6.3(1.2, 25.6), P<0.05], open field defecation [AOR, 95%CI: 9.3(1.6, 53.6), P<0.05] and diarrhea [AOR, 95%CI: 5.2(1.3, 21.3), P<0.05]. In conclusion. The overall prevalence of intestinal parasites significantly differed by HAART status and *Cryptosporidium* species were found only in HAART naïve patients with low CD4+ T cell counts. Anemia was also more prevalent and significantly associated with IPs in non-HAART patients. This study identified some environmental and associated risk factors for intestinal parasitic infections.

710

PERFORMANCE CHARACTERISTICS OF POINT OF CARE LYNX TEST IN EARLY INFANT DIAGNOSIS OF HIV

Nkumbula Moyo[1], Sylvia Maunga[1], Jane Mutanga[2], Simon Mutembo[3], Philip Thuma[1], William Moss[4], Catherine Sutcliffe[4]

[1]Macha Research Trust, Lusaka, Zambia, [2]Livingstone Central Hospital, Livingstone, Zambia, [3]Southern Province Medical Office, Choma, Zambia, [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Early infant diagnosis of HIV infection (EID) is challenging in rural areas because the currently used assays to detect HIV DNA require transportation of specimens to central laboratories. This leads to substantial delays in return of test results and linkage to care. The developed point of care (POC) diagnostics offer hope to minimize this challenge. This study was done to evaluate the performance characteristics of a POC test based on p24 antigen detection (LYNX) compared to HIV DNA testing for EID in Zambia. This was a prospective study conducted at 3 hospitals and 8 health centers in Southern Zambia from February, 2016 to February, 2018. Infants aged 0 hours to 18 months born to HIV-infected mothers were eligible. At urban sites, infants were enrolled at birth and discharged from the study when the HIV DNA results were issued to caregivers, while at rural sites infants were followed up until 6 weeks after cessation of breastfeeding. Each time an enrolled child had a DBS sample collected for HIV DNA testing at the central laboratory, a LYNX POC test was also conducted for comparison of results. 2181 LYNX POC tests were performed during the study; 1407 tests (65%) were included in the analysis. Of the 1407 test results, 909 (65%) were conducted at birth while 498 (35%) were conducted during routine clinical visits at 6 weeks of age or older. At routine visits, 16 (3.2%) participants were HIV DNA positive. The LYNX test had a sensitivity of 81.3% (CI: 54%, 96%) and specificity of 99.0% (CI: 98%, 99%). At birth, 12 (1.3%) participants were HIV DNA positive. The LYNX test had a sensitivity of 25.0% (95 % CI: 6%, 57%) and specificity of 99.6% (95 % CI: 98%, 99%). The LYNX test was easy to use and had many desirable characteristics for a POC test in a rural setting. However, the LYNX test had a lower sensitivity at 6 weeks of age or older compared to other available POC assays and a very low sensitivity at birth. LYNX POC test has potential to be of value as an EID screening test at routine clinic visits, particularly in rural areas. Its use could improve linkage to care for HIV-infected infants in settings where turnaround times for HIV DNA testing are long.

711

HIV+ PREGNANT WOMEN HAVE DIMINISHED TRANSPLACENTAL TRANSFER OF NATURALLY ACQUIRED ANTIMALARIAL ANTIBODIES COMPARED TO HIV- PREGNANT WOMEN IN KENYA

Jessica Ray[1], David Midem[2], Fredrick Opinya[2], Maxwel Omenda[2], Sidney Ogolla[2], Edwin Odhiambo[2], Peter Sumba[2], Katherine Dobbs[1], Amy Nowacki[3], Rosemary Rochford[4], **Arlene E. Dent**[1]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]Cleveland Clinic Foundation, Cleveland, OH, United States, [4]University of Colorado, Denver, CO, United States

The transfer of IgG from mother to fetus across the placenta is critical to protect infants during the first few months of life. Maternal infections during pregnancy such as HIV and/or malaria can negatively affect transplacental transfer of antibodies such as those to tetanus and measles. HIV exposed but uninfected (HEU) infants experience increased morbidity and mortality compared to HIV unexposed uninfected (HUU) infants. We hypothesized that *in utero* exposure to HIV affects transplacental transfer of antibodies. 50 HIV- mothers/HUU neonates and 49 HIV+ mothers/HEU neonates were included. All HIV+ women received HAART and were seen by health care workers monthly. We examined in maternal plasma at delivery and paired cord blood plasma 1) the magnitude of antibodies against 4 vaccine antigens (diphtheria, tetanus, hepatitis B, and measles) and 14 *P. falciparum* antigens, and 2) placental transfer of antibodies to neonates. Additional measurements included birth outcome measures and malaria infection prevalence during pregnancy. We found that birth outcomes between HUU and HEU groups were comparable. HIV- mothers had more frequent malaria infections during pregnancy than HIV+ mothers (70% vs 31% p=0.0001). HIV- mothers had higher tetanus antibodies at delivery compared to HIV+ mothers, but antibodies directed against other vaccines were not different between the groups. Vaccine Cord-to-Maternal Ratio (CMR), a measure of placental antibody transfer, were no different between the groups. Anti-malarial antibodies were generally higher in HIV- women than HIV+ women. Interestingly, CMRs were consistently lower in the HIV+/HEU pairs suggesting decreased transplacental antimalarial antibody transfer in HIV+/HEU pairs compared to HIV-/HUU pairs especially to MSP9 ($p = 0.0402$), CSP ($p = 0.0326$), and EBA181 ($p = 0.0166$) which remained statistically significant after adjustment for malaria in pregnancy. While CMRs of vaccine antibodies were not affected by HIV or malaria status, lower CMRs were observed in HIV+/HEU pairs antibodies to naturally acquired malaria infection revealing an important effect even in optimally treated HIV+ women.

712

HIV MULTI-CLASS RESISTANCE IN PATIENTS FAILING TO FIRST AND SECOND ART IN RESOURCES LIMITED SETTING, MALI

Almoustapha Issiaka Maiga[1], Oumar Dolo[1], Fatoumata Tata Traore[1], Josue Togo[1], Cathia Soulie[2], Zoumana Diarra[3], Arkietou Maiga[1], Mamadou Cisse[3], Mariam Sylla[4], Susan Orsega[5], Seydou Doumbia[1], Vincent Calvez[2], Anne-Genevieve Marcelin[2], Souleymane Diallo[1], Robert Murphy[6]

[1]UCRC/SEREFO, FMOS, USTTB, Bamako, Mali, [2]Virology Laboratory, Pitie-Salpetriere Hospital, Paris, France, [3]CESAC, ARCAD SIDA, Bamako, Mali, [4]Pediatric Department, CHU Gabriel Toure, Bamako, Mali, [5]National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD, United States, [6]Infectious Desease Department, Northwestern University, Chicago, IL, United States

Antiretroviral treatment has been widely implemented in resources constraint setting. Second-line ART has become more and more available but the biological monitoring is still limited. In order to achieve the goal of the three 90 of UNAIDS it will be interesting to know the resistance profile of the patients failing to ART. The objective of this study is to determine the prevalence of HIV multi-class resistance viruses and their impact the virological outcome. All patients with virological failure on first or second line ART in our routine genotyping system were included. The pol gene was sequenced by using viroseq or in house ANRS method. We identified 342 patients with genotypes availables, 21 (6%) patients had a wild-type viruses and 321 with multi-class resistant virus. Among this, 273 (79.9%) and 69 (20.1%) patients were respectively on first and second line ART. The median viral load (VL) was 69,740 copies/mm^3 and median CD4 276 cells/mm^3 at failure. The main first line regimen was TDF/3TC/EFV and second-line was AZT/3TC/LPVr. The prevalence of resistance mutations was: M41L (37%), A67G / N (42%), M184V (100%), T215F/Y (68%), K219E / Q (37%) and Q151M (16%) for the nucleoside. For non-nucleoside: K103N (32%), K101E/H/P (11%), Y181C/I/V (37%) and H221Y (21%). For PI: L76V (42%), V82A/F/T/S (21%) and I84V (37%). Patients were resistant to NRTIs in 83%, NNRTIs 94% and PIs 42%. Among the second-line ART failure 19% were resistant to darunavir. After 6 and 12 months of ART 63% and 76% of patients had suppressed HIV RNA less 40 copies/ml. In conclusion, the resistance genotypic testing is crucial to achieve the goal of the three 90 for patient failing to ART in resources limited setting.

713

COMPARISON BETWEEN HUMAN IMMUNODEFICIENCY VIRUS (HIV) POSITIVE AND NEGATIVE PATIENTS ADMITTED WITH RESPIRATORY ILLNESSES IN SIAYA COUNTY REFERRAL HOSPITAL (SCRH), WESTERN KENYA, 2014-2016

Diba Dulacha[1], Bryan Nyawanda[2]

[1]Kenya Field Epidemiology and Laboratory Training Program, Nairobi, Kenya, [2]Kenya Medical Research Institute, Nairobi, Kenya

Data on etiology of respiratory illnesses (RI) among HIV patients in resource-limited settings are scarce. A population-based surveillance for RI (cough or difficulty breathing) hospitalizations in ≥13 years was set up in Western Kenya. Patients were matched with community controls by HIV status, age and time. Clinical data were obtained, naso/oropharyngeal swabs collected and tested using Taqman Array Cards (TAC) for 15 viruses, 14 bacteria and 1 fungi. Odds ratios (OR) were used to compare characteristics and pathogen-specific distribution by HIV status, and between cases vs controls. A total of 1,572 RI cases were admitted, 728 (46%) were HIV positive of which 474 (65%) were female. Median ages (interquartile range) were: RI cases (35.8, 26.6-55.8) and HIV positive (34.8, 28.8-45.5). HIV positive cases had worse outcome: oxygen supplementation (11.3% vs 7.4%, p=0.036), referral to intensive care unit (7.0% vs 4.0%, p=0.009) and death (21.1% vs 8.8%, p<0.001). A total of 1,004 RI cases (45% HIV positive) were tested using TAC. Comparing cases and controls, more *K. pneumoniae* (11% vs 5%)*, M. tuberculosis* (4% vs 0.3%) and *Rhinovirus* (21% vs 10%) were detected in cases than controls for HIV-positive stratum, while *S. aureus* (17% vs 30%), *S. pneumoniae* (25% vs 48%), *Adenovirus* (0.7% vs 6%), *H. influenza* (18% vs 40%) and *S. pyogenes* (0.7% vs 12%) were the most common pathogens in controls in HIV-negative stratum. It may be challenging to determine specific pathogens causing severe RI among HIV patients. There were not many differences in detection of respiratory pathogens between cases and controls which could reflect asymptomatic carriage among health populations. Identification of more than one potential pathogens in patients also indicate co-infections which warrants further investigation.

714

GLOBAL HEALTH ENGAGEMENT VIA THE AFRICAN COHORT STUDY: QUANTIFYING THE PREVALENCE AND INCIDENCE OF HIV-ASSOCIATED CO-INFECTIONS IN SUB-SAHARAN AFRICA

Christina S. Polyak[1], Trevor A. Crowell[1], Allahna L. Esber[1], Domonique M. Reed[1], Ajay P. Parikh[1], Francis Kiweewa[2], Jonah Maswai[3], John Owuoth[4], Lucas Maganga[5], Emmanuel Bahemana[5], Yakubu Adamu[6], Leigh Anne Eller[1], Patrick W. Hickey[7], Merlin L. Robb[1], Nelson L. Michael[7], Julie A. Ake[7]

[1]US Military HIV Research Program, Walter Reed Army Institute of Research; Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD, United States, [2]Makerere University-Walter Reed Project, Kampala, Uganda, [3]Henry M. Jackson Foundation Medical Research International, Kericho, Kenya, [4]Henry M. Jackson Foundation Medical Research International, Kisumu, Kenya, [5]Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania, [6]US Military HIV Research Program, Walter Reed Army Institute of Research, Abuja, Nigeria, [7]US Military HIV Research Program, Walter Reed Army Institute of Research, Bethesda, MD, United States

The Department of Defense Global Health Engagement strategy helps partner nations combat global health threats like HIV, which is responsible for over 1.5 million annual deaths worldwide. We leveraged facilities supported by the President's Emergency Plan for AIDS Relief (PEPFAR) to develop an open-ended prospective cohort that characterizes medical care and clinical outcomes, such as prevalence and incidence of HIV-associated co-infections, in four African countries. The African Cohort Study prospectively enrolls adults at 11 PEPFAR-supported facilities in Uganda, Kenya, Tanzania, and Nigeria. Adults were evaluated at enrollment and every 6 months for tuberculosis (GeneXpert; only HIV-infected), hepatitis B virus (hepatitis B surface antigen; HBV), and syphilis (rapid plasma reagin with a confirmatory treponemal test). Hepatitis C virus was evaluated at enrollment only (anti-HCV antibody assay; HCV). Prevalence and incidence of these infections were compared between participants with and without HIV using Chi-Square and Fisher's exact tests. From January 2013-September 2017, we enrolled 3220 adults (58% female) with a mean age of 38.9 (SD 10.5) years. Of these, 2678 (83%) were HIV-infected, 1793 (67%) were ART-experienced and 1620 (60%) were virally suppressed <1000 copies/mL. At enrollment, tuberculosis was observed among 80 HIV-infected participants (29.9%); HBV among 119 (4.4%) HIV-infected and 22 (4.1%) HIV-uninfected participants (p=0.81); HCV among 43 (1.6%) HIV-infected and 14 (2.6%) HIV-uninfected participants (p=0.09); and syphilis among 291 (10.9%) HIV-infected and 25 (4.6%) HIV-uninfected participants (p=0.63). The incidence of TB was 12.7/1000 person-years (PY). Throughout follow-up, HBV incidence did not differ between participants with and without HIV (6.3/1000PY and 6.1/1000PY; p=0.72), nor did the incidence of syphilis (16.6/1000PY and 13.9/1000PY; p=0.32). This large African cohort demonstrates a high burden of HIV-associated co-infections. Co-infections should be a focus for further capacity building with partner nations.

715

TRACKING HIV/AIDS FINANCING AND THE RESPONSE TO DECLINES IN DEVELOPMENT ASSISTANCE FOR HIV/AIDS

Mark Moses[1], Annie Haakenstad[2], Miranda Tao[1], Abby Chapin[1], Joseph Dieleman[1]

[1]IHME, Seattle, WA, United States, [2]Harvard T.H. Chan School of Public Health, Boston, MA, United States

Since 2005, the international community rallied to mobilized a total of 123 billion dollars to fight HIV/AIDS. These investments helped reduce HIV/AIDS incidence and mortality; however, ongoing progress may be at risk as development assistance for HIV/AIDS (DAH-HIV/AIDS) steadily declined by 6.6% since 2012 and calls to reduce future aid spending continue to echo. With this analysis, we track HIV/AIDS spending across financing sources and functions in 188 countries from 2000 to 2015 and estimate governments' responses to reduced DAH-HIV/AIDS. We collected and extracted 5,385 data points from public available reports and databases. We used spatiotemporal Gaussian process regression to estimate a complete times series of HIV/AIDS spending by financing source (government, prepaid private, and out-of-pocket) and function (care and treatment, prevention, and other). We used system generalized method of moments estimation to predict the effects of reductions in DAH spending. In 2015, global HIV/AIDS spending amounted to $48.1 ($45.7-52.1) billion. Of this total, governments financed 62.2% (56.6-66.7%), but in high prevalence countries, DAH financed 76.6% (73.6-79.4%). In low-income countries, for every dollars of DAH-HIV received, governments spent $0.11. We estimated that a 10% reduction in DAH-HIV/AIDS, is associated with a .03% decline in government spending. This effect is stronger for spending on HIV/AIDS care and treatment: a 10% decrease in DAH-HIV/AIDS for care and treatment was associated with a 0.6% increase in domestic HIV/AIDS care and treatment spending. Both domestically and internationally, vast sums of financial resources were mobilized to fight HIV/AIDS since 2000. While governments financed the majority of this fight, 19.3 million people with HIV/AIDS live in countries where DAH-HIV/AIDS finances over 50% HIV/AIDS spending. The lives of these 19.3 million people may at risk as potential reductions in DAH-HIV/AIDS are not likely to be filled domestically. This conclusion jeopardizes the progress made against HIV/AIDS and the hope of an AIDS free generation.

716

BEYOND IGG4 ANTIBODIES TO OV-16: *ONCHOCERCA VOLVULUS*-SPECIFIC BIOMARKERS THAT PUSH SENSITIVITIES FOR INFECTIONS ABOVE 95%

Sasisekhar Bennuru[1], Chinweoke Osigwe[1], Georgiette Oduro-Boateng[1], David Abraham[2], Sara Lustigman[3], Thomas Nutman[1]

[1]National Institutes of Health, Bethesda, MD, United States, [2]Thomas Jefferson University, Philadelphia, PA, United States, [3]New York Blood Center, New York, NY, United States

As efforts shift from control to elimination of *Onchocerca volvulus (Ov)*, additional tools to identify those contributing to ongoing *Ov* transmission in low transmission settings will be needed to get beyond the ~80% sensitivity of the IgG4 Ov16 assays (ELISAs, RDTs). By isotype-specific screening of protein arrays developed from ~400 *O. volvulus* proteins, we identified several biomarkers. Two of these biomarkers OVOC10469 and OVOC3261 tested against panel of *Ov*-, *W. bancrofti*-, *L. loa*-infected and healthy controls (~300 samples), in conjunction with Ov16 enhanced the sensitivity for detecting infections from 80% (with Ov16 alone) to ~95% in a luciferase immunoprecipitation system (LIPS) assay with >99% specificity. To understand the kinetics of the response to these 2 "new" antigens, sero-reactivity to OVOC10469 and OVOC3261 were analyzed in archived longitudinally collected sera of 7 chimps experimentally infected with *O. volvulus* and compared to the kinetics of Ov16 antibody. Anti-Ov16 IgG was detectable as early as 100 days of post-infection, while the IgG4 responses coincided with the onset of patency (350-500 days). In contrast to Ov16, the IgG responses to OVOC10469 and OVOC3261 were patency dependent, with IgG4 responses appearing even later. Preliminary analyses with sera from *Ov*-infected patients followed for more than 5-10 years following treatment showed a dramatic drop in anti-OVOC10469 and anti-OVOC3261 IgG levels ($p<0.001$). These data suggest that seroreactivity to these 2 antigens are indicative of the presence of microfilariae (in a surveillance setting). When the prevalence of seroreactivity is sufficient high, this not only suggest likely transmission but may help to develop more informed and refined models. Both OVOC10469 and OVOC3261 have been expressed recombinantly are currently being tested in conjunction with Ov16 for a potential point of care test.

717

DEVELOPMENT OF *IN NEW VITRO* CULTURE SYSTEMS FOR THE MAINTENANCE OF MICROFILARIAE AND INFECTIVE LARVAE OF *LOA LOA* FOR DRUG SCREENING

Abdel Jelil Njouendou[1], Fanny Fri Fombad[1], Narcisse Victor Gandjui[1], Maeghan O'Neill[2], Denis Zofou[1], Chuck Nutting[3], Chuck Nutting[3], Patrick Chunna Ndongmo[1], Peter Ayuk Enyong[1], Mark J. Taylor[4], Timothy G. Geary[2], Joseph D. Turner[4], Charles D. Mackenzie[5], Samuel Wanji[1]

[1]University of Buea, Buea, Cameroon, [2]Institute of Parasitology, McGill University, Ste-Anne-de-Bellevue, QC, Canada, [3]Department of Biological Sciences, Western Michigan University, Kalamazoo, MI, United States, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [5]Department of Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI, United States

Co-infection with loiasis remains a potential problem to control programs targeting filarial infections. Suitable *in vitro* culture systems for *Loa* parasite maintenance are needed to foster drug research. This study investigated systems for drug screening against microfilariae (mf) and infective larvae (L3) of *L. loa*, then documented the microfilaricidal effects of 13 anti-parasitic drugs. *In vitro* culture conditions were evaluated by varying three basic media: RPMI-1640, DMEM and IMDM; four sera/proteins: newborn calf serum (NCS), foetal bovine serum (FBS), bovine serum albumin (BSA) and AlbuMax® II (ALB); then co-culture with LLC-MK2 cell line. Motility (T_{90} = mean duration at which 90% of parasites are fully active) and moulting rates of L3 were determined. The effect of antimalarial, anthelmintics, trypanocidal and anticancer agents on *L. loa* mf was evaluated.The media DMEM and IMDM were the most suitable sustaining the maintenance of both parasite stages. Sera and LLC-MK2 significantly improved the survival of parasites (T_{90} of 16.4–19.5 days for *L. loa* mf). The most effective culture systems promoting moulting and maintenance of L3 were DMEM + serum + LLC-MK2. From the GLM analysis, factors that promoted *L. loa* mf viability included feeder cells ($\beta = 0.490$), both IMDM ($\beta = 0.256$) and DMEM ($\beta = 0.198$) media and the protein supplements NCS ($\beta = 0.052$) and FBS ($\beta = 0.022$); while for *L. loa* L3, the protein BSA ($\beta = 0.029$) was included. Inhibition of *Loa loa* motility was seen with mefloquine and amodiaquine (CR_{50} values of 3.87 and 4.05 µg/ml, respectively). Imatinib and SCYX-7158 also induced a concentration-dependent reduction in mf motility. A range of requirements for the *in vitro* maintenance of *Loa loa* stages, suitable for developing an effective platform for drug screening was identified. The considerable action of mefloquine and amodiaquine on *Loa* mf *in vitro* highlights the possibility of repurposing anti-infectious agents for loiasis drug development, while the heterogeneity in the activity of anti-parasitic agents on *Loa loa* mf supports the need for further investigation using *in vivo* models.

718

WHOLE BLOOD TRANSCRIPTOME ANALYSIS IDENTIFIES A 7-GENE CLASSIFIER FOR *ONCHOCERCA VOLVULUS* INFECTION

Ole Lagatie[1], David D'Haese[1], Linda Batsa Debrah[2], Alex Debrah[3], Lieven J. Stuyver[1]

[1]Janssen Diagnostics, Janssen R&D, Beerse, Belgium, [2]Kumasi Centre for Collaborative Research into Tropical medicine, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [3]Faculty of Allied Health Sciences, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

Identifying the molecular mechanisms controlling the host's response to infection with *Onchocerca volvulus* are important to understand how the human host controls such parasitic infection. Little is known of the cellular immune response upon infection with *O. volvulus*. We performed a transcriptomic study using PAXgene preserved whole blood from 30 nodule positive individuals and 21 non-endemic controls. It was found that of the 45,042 transcripts that were mapped to the human genome, 544 were found to be upregulated and 447 to be down-regulated in nodule positive individuals (adjusted p-value <0.05). Within this set of differentially expressed genes a strong enrichment was found for genes related to translation and ribosomes (corrected p-value <0.05). Mammalian phenotype analysis demonstrated an association with abnormal immune system. Elastic net regression was used to identify the top list of 22 genes that can contribute significantly in the generation of a classifier. For these 22 genes, as well as for 8 reference target genes, validated RT-qPCR assays were developed and used to re-analyze the discovery sample set. These data were used to perform elastic net regularized logistic regression and a panel of 7 genes was found to be the best performing classifier. The resulting algorithm returns a value between 0 and 1, reflecting the predicted probability of being infected. ROC analysis resulted in an area under curve of 0.860 (95% CI: 0.747-0.974). A validation panel of 69 nodule positive individuals and 9 non-endemic controls was used to set a cutoff for positivity and to determine the performance of this classifier. Based on this validation set only, a sensitivity of 60.9% and a specificity of 100% was obtained. When combining the discovery test set and validation set, a sensitivity of 67.7% and a specificity of 93.1% was obtained. Large-scale validation approaches will be necessary to define the intended use for this classifier. Besides the use as marker for infection in MDA efficacy surveys and epidemiological transmission studies, it might also hold potential as pharmacodynamic marker in macrofilaricide clinical trials.

719

DIFFERENTIAL MODULATION OF HUMAN INNATE LYMPHOID CELL FUNCTION BY IL-10 AND TGF-B

Sandra Bonne-Annee, Thomas Nutman

National Institutes of Health, Bethesda, MD, United States

Human filarial infections are associated with an expansion of innate lymphoid cell (ILC) subsets that mirror in many ways the CD4+ helper cell (Th) subsets: ILC1s (IFN-γ), ILC2s (IL-5 and IL-13) and ILC3s (IL-17A or IL-22). Chronic filarial infections are also associated with an immune-modulatory environment mediated largely by IL-10 (and to a lesser extent TGF-β), cytokines that alter antigen-specific effector T cell responses. Using multiparameter flow cytometry human ILC subsets can easily be detected in the circulation accounting for only 0.35% (range 0.04-4.51%) of CD45+ leukocytes under homeostatic conditions. Despite the low frequency of ILCs in circulation, *ex vivo* experiments have demonstrated that these ILCs release extremely large per cell quantities of cytokines following activation and, if left unchecked, these ILC-derived cytokines can have deleterious effects on the host. To explore the mechanisms underlying the inhibition of ILC cytokine production, we observed IL-10R and TGF-βRI gene expression in all ILC subsets found in circulation. We examined the expression of IL-10R on ILC subsets and found that ~14-25% of each subset expressed IL-10R and did so at the same per cell intensity (GeoMFI=663) as did human monocytes, known to express IL-10R. To explore the mechanisms that regulate ILC activation, ILC subsets were isolated from the peripheral blood of healthy donors by flow cytometry-based sorting and activated in the presence or absence of IL-10 or TGF-β. ILC2s stimulated in the presence of IL-10 had a marked reduction in IL-5 ($p<0.01$) and IL-13 ($p<0.05$) production when compared to ILC2s activated in the absence of IL-10. A similar cytokine regulation was not observed for ILC1s stimulated in the presence of IL-10. Conversely, TGF-β had an inhibitory effect on ILC1 production of IFN-γ following stimulation but not on ILC2 production of IL-5 and IL-13 following stimulation. Studies are currently underway to explore the downstream effects of IL-10 and TGF-β on ILCs and to identify additional mechanisms that regulate ILC cytokine production.

IMMUNIZATION WITH RECOMBINANT DIM-1 PROTEIN OF *BRUGIA MALAYI* INDUCE T AND B CELL IMMUNOGENICITY AND PROTECT MICE AGAINST *B. MALAYI* INFECTION

Vikas Kushwaha

Panjab Univesity, Chandigarh, India

Lymphatic filariasis, a chronic disease affecting over 120 million people worldwide, endemic in 73 countries. Several attempts (MDA, vector control measures and vaccine development) have been made to control filariasis but there is no licensed vaccine for human use, up to date. The study aims to know the effect of short term (3 dose) or long term (till 3 or 6 weeks) recombinant DIM-1protein of *Brugia malayi* (rDIM-1bm) immunization on modulation of T cell and B cell immunogenicity and its protective efficacy against *B. malayi*. *B. malayi* DIM-1 was successfully cloned, expressed and recombinant DIM-1bm protein (~40 kDa) purified. *Mastomys coucha* were immunized in 3 immunization schedules, 3-dose (3 injections: 0 day, 14 days and 21 days), 3 weeks (Injections at 3 or 4 days interval till 3 weeks) and 6 weeks (Injections at 3 or 4 days interval till 6 weeks) with subsequent inoculation of 100 L_3 after immunization. Of the 3 different immunization schedules, 3-dose immunization was the most effective in protecting *M. coucha* against establishment of L_3 induced infection as inferred by a low recovery of mf in circulation (63%) and parasite burden (52%). The enhanced activity of macrophages, cellular proliferation and NO responses, and elevated levels of specific IgG, IgG1, IgG2a, IgG2b, IgE and IgA, and intense upregulation of both Th1 (IFN- γ, TNF-α and IL-2) and Th2 (IL-4, IL-5, IL-6, IL-10 and IL-13) responses produced by 3-dose rDIM-1bm immunization schedule correlated with parasitological findings. Three or six weeks immunization schedule provided poor protection against L_3 initiated infection and produced mixed immunological responses. These findings suggest that 3-dose schedule protects the host from infection via Th1/Th2 type responses and may be important protein for exploring its vaccine potential. This information would help in evolving effective control and prevention strategies for human lymphatic Filariasis.

721

EVALUATION OF EIGHT NOVEL PEPTIDES FOR THE SEROLOGICAL DETECTION OF INFECTIONS WITH *ONCHOCERCA VOLVULUS*

Guilherme Maerschner Ogawa[1], Ole Lagatie[2], Lieven J. Stuyver[2], Paul T. Cantey[1], Vitaliano A. Cama[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Janssen Diagnostics, Beerse, Belgium

Current serologic assessments for human exposure to *Onchocerca volvulus* are performed by detection of IgG4 antibodies against the OV-16 antigen. However, additional confirmatory or complementary serological assays are needed to verify exposure/infection status in humans. Eight novel peptides, selected from a proteome scan of linear epitopes of *O. volvulus*, were evaluated for IgG reactivity by ELISA using a panel of 50 sera from persons with responses to OV-16, 26 of whom were also microfilariae positive by skin snip. Samples from 50 OV-16 nonreactive individuals, including people with other filarial infections, were used as controls. Performance characteristics of the peptides (sensitivity, specificity, optimal threshold and area under the curve (AUC)) were determined by receiver operator characteristic (ROC) analyses. Correlation analyses were used to determine the association between the reactivity to OV-16 and the peptides as measured by optical density (OD). Three of the 8 peptides, OvMP-23, OvNMP-17 and OvNMP-18, had ROC AUC values >90%, with 90-92% sensitivity and 80-82% specificity. There was 85-86% agreement when comparing calls from these three peptides to OV-16. In a subset analysis using only the 26 positive samples from people with microfiladermia and excluding 5 OV-16 negative individuals from potentially co-endemic settings, four of the peptides had ROC AUC values >90%. The sensitivity and specificity for these peptides were 88% and 86% for OvMP-1, 88% and 89% for OvMP-23, 85% and 93% for OvNMP-16 and 73% and 100% for OvNMP-18. Analysis of the correlation between OD values for OV-16 and each of the peptides showed no correlation, suggesting that the peptides represent antigens that are independent of OV-16. These preliminary analyses suggest that peptides OvMP-23 and OvNMP-18 may be candidates to complement OV-16 serology. Additional evaluations with expanded serum panels are needed to better define appropriate thresholds and determine if the use of these peptides in tandem with OV-16 will improve serologic detection of onchocerciasis.

722

A NEW SYSTEM FOR THE PRODUCTION OF INFECTIVE LARVAE OF *LOA LOA* USING INTRATHORACIC INJECTION OF MICROFILARIAE TO *CHRYSOPS SILACEA*

Wanji Samuel[1], Bertrand Ndzeshang Lontum Lontum[1], Winston Ndongmo Chounna[1], Fanny Fri Fombad[1], Abdel Jelil Njouendou[1], Anizette Chi Kien[1], Manuel Ritter[2], Peter Ayuk Enyong[1], Mark Taylor[3], Joseph Turner[3], Achim Hoerauf[2]

[1]University of Buea, Buea, Cameroon, [2]Institute of Medical Microbiology, Immunology and Parasitology, University Hospital of Bonn, Bonn, Germany, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Research and drug development for Loiasis is hindered due to the lack of suitable methods of obtaining parasite material. The present work aimed to develop a method for production of *Loa loa* infective larvae (L3) by intrathoracic injection of its vector, *Chrysops silaceae* with microfilariae. Purified *L. loa* mf from baboon blood were injected into the thorax of wild caught *Chrysops* (group 1 = 50mf/fly, group 2 = 100mf/fly). The L3 were

recovered from flies 16 days post injection and quantified per fly section (head, thorax and abdomen). Part of L3 were maintained *in vitro* in DMEM + 10% FBS and feeder layer for 30 days, while recording survival, motility, and moulting. *In vivo* conditions were met by inoculating the other L3 into RAG2IL-2Rγ-deficient C57BL/6 mice and dissecting these 60 days PI. Fly survival differed per group; 55.2% for group 1 and 34.7% for group 2, $p < 0.001$. The L3 yield/fly was higher in group 2 (75.2 %) than in group 1 (50.5%). Parasite survival was > 90% and L3 molting rate was >head (61.3%)>thorax (60.2%)>abodomen (56.4%) ($p = 0.610$). Mice dissection revealed a mean worm recovery rate of 10.7%. Mice infected with L3 from fly heads obtained the highest worm recovery (17.2%), followed by those from thorax (9.8%) and abdomen (8.1 %). Worms recovered measured in average 24.3 mm and 11.4 mm in length and 0.35mm and 0.27 mm in width for females and males respectively. Conclusively, L3 obtained using this new system remained viable (both *in vitro* and *in vivo*). In addition, L3 were able to mature into young adult worms in Rag2IL-2Rγ C57BL/6 mice. This approach presents a novel platform for in-depth research in Loiasis and offers opportunities to unravel mysteries about the biology of this filarial nematode.

IDENTIFYING A ROLE FOR SETPOINT ANTIBODY TITERS IN DENGUE INFECTION AND DISEASE RISK

Henrik Salje[1], Derek Cummings[2], Isabel Rodriguez-Barraquer[3], Leah Katzelnick[4], Chonticha Klungthong[5], Butsaya Thaisomboonsuk[5], Ananda Nisalak[5], Alden Weg[5], Damon Elison[5], Louis Macareo[5], Justin Lessler[6], In-Kyu Yoon[7], Richard Jarman[8], Stephen Thomas[9], Alan Rothman[10], Timothy Endy[11], Simon Cauchemez[1]

[1]Institut Pasteur, Paris, France, [2]University of Florida, Gainsville, FL, United States, [3]University of California San Francisco, San Francisco, CA, United States, [4]University of Florida, Gainesville, FL, United States, [5]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [6]Johns Hopkins University, Baltimore, MD, United States, [7]IVI, Seoul, Korea, Democratic People's Republic of, [8]Walter Reed Army Institute of Research, Silver Sprng, MD, United States, [9]SUNY, Buffalo, NY, United States, [10]University of Rhode Island, Providence, RI, United States, [11]SUNY, Syracuse, NY, United States

Across infectious diseases, complex host immunity-pathogen interactions shape disease risk. Immunity derived from prior infections or vaccination may positively or negatively affect our ability to fend off infection or disease from related pathogens; however, immune correlates are rarely known. For dengue, this uncertainty is driven by frequent subclinical and therefore unobserved infection coupled with a limited understanding of how serological markers behave over time. We use detailed cohort data from Thailand (3,453 individuals with blood draws every 91 days, 140,612 hemagglutination inhibition antibody titer measurements in all) to develop a framework that simultaneously characterizes antibody dynamics and identifies subclinical infections via Bayesian augmentation. We identify 1,149 infections (95% CI: 1,135-1,163) that were not detected by active surveillance and estimate that 65% of infections are subclinical. Each increase in $\log_2$-titers is associated with a 0.71 times relative risk of infection (95% CI: 0.67-0.76). Further, individuals with pre-existing adjusted $\log_2$-titers of ≤1:40 develop dengue hemorrhagic fever 7.4 (95% CI: 2.5-8.2) times as often than naïve individuals compared to 0.0 times as often for individuals with titers >1:40 (95% CI: 0.0-1.5). PRNT titers ≤1:100 were similarly associated with severe disease. Post infection, individuals develop a stable setpoint antibody load after 1y that places them within or outside a risk window. At this time, we observe a 2.1 times increased risk of infection for those with setpoint antibody loads of ≤1:40 compared to those with greater antibody loads and an 8.9 times increased risk developing hemorrhagic fever. The apparent stability of setpoint antibody loads points to an ability to assess an individual's long-term risk. The current licensed vaccine moves previously naïve individuals into this risk window but also has the potential to move previously infected individuals out of it.

WANING OF ANTI-DENGUE VIRUS ANTIBODIES FOLLOWING PRIMARY AND SECONDARY DENGUE VIRUS INFECTION AND IMPLICATIONS FOR SEROTYPE TRANSMISSION DYNAMICS

Leah Katzelnick[1], Juan Carlos Mercado[2], Damaris Collado[3], Lionel Gresh[3], Douglas Elizondo[3], Sonia Arguello[3], Andrea Nuñez[2], Sergio Ojeda[3], Nery Sanchez[3], Brenda Lopez[3], Raquel Burger-Calderon[1], Aubree Gordon[4], Guillermina Kuan[5], Angel Balmaseda[2], Eva Harris[1]

[1]Division of Infectious Diseases & Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, [2]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministry of Health, Managua, Nicaragua, [3]Sustainable Sciences Institute, Managua, Nicaragua, [4]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States, [5]Centro de Salud Sócrates Flores Vivas, Ministry of Health, Managua, Nicaragua

The mosquito-borne dengue flaviviruses (DENV1-4) are major causes of disease globally. Cohort studies have found that ≥2 years after primary (1°) DENV infection, children are at elevated risk of dengue, which is thought to be due to waning of cross-protective antibodies. In contrast, secondary (2°) DENV infection is thought to induce long-lived, cross-protective antibodies. We measured rates of antibody waning after 1° and 2° DENV infection in the Nicaraguan Pediatric Dengue Cohort Study (PDCS, n=6684) in healthy annual serum samples (n=41,302) over a period of 12 years (2004-2015). Antibody (Ab) titers were measured with the Inhibition ELISA, an assay predictive of both protection from dengue and risk of severe dengue. We used linear mixed-effects models with random effects for individual intercepts (peak) and slopes (waning). The Ab titer half-life after any infection was 4.00 years [95%CI: 3.81-4.20]. However, after 1° infection, initial Ab titer varied by individual but did not wane over time, suggesting individual-level Ab titer "set points". In contrast, Ab titers were higher post-2° infection but waned for many years. Raw post-2° infection Ab titers suggest waning for multiple years with eventual stabilization to a new individual "set-point". We explored the implication of these observations for DENV transmission. A spatiotemporal analysis of RT-PCR-serotyped dengue cases in the PDCS showed that dengue cases were significantly more likely to be of the same serotype if they occur <2 years and <1km of each other but of a different serotype when separated by ≥2 years. We hypothesize that population-level immunity with spatial heterogeneity drives transitions in serotype dominance and are using statistical and mathematical transmission models to explain how spatial and temporal patterns of homotypic vs heterotypic serotypes could account for the interval of protection from symptomatic infection given stable Ab titers after a 1° infection. These findings suggest an alternate model of DENV immunity with important implications for measuring vaccine efficacy in clinical trials and for building mathematical models of DENV transmission.

FLAVIVIRUS INDUCED T CELL CROSS-REACTIVITY

Alba Grifoni[1], Patrick H. ORourke[1], Aruna D. de Silva[2], Priscilla R. Costa[3], Anna Durbin[4], Sean A. Diehl[5], Cristhiam Cerpas[6], Angel Balmaseda[6], Esper G. Kallas[3], Eva Harris[7], Alessandro Sette[1], **Daniela Weiskopf**[1]

[1]La Jolla Institute for Allergy and Immunology, La Jolla, CA, United States, [2]Kotelawala Defense University, Ratmalana, Sri Lanka, [3]University of São Paulo, Brazil, Sao Paulo, Brazil, [4]Johns Hopkins University, Baltimore, MD, United States, [5]University of Vermont, Burlington, VT, United States, [6]National Virology Laboratory, Managua, Nicaragua, [7]University of California Berkeley, Berkeley, CA, United States

Dengue Virus (DENV) is a flavivirus closely related to Zika virus (ZIKV), Japanese encephalitis virus (JEV), West Nile virus (WNV), and Yellow fever virus (YF), all of which are transmitted primarily by mosquitoes. The issue of potential cross-reactivity and how pre-existing T cell immunity to one flavivirus modulates T cell responses to another is of great relevance for

both diagnostic tests and vaccines as these viruses often co-circulate in the same geographical regions. To address this question we have established peptide pools derived from the polyproteins of DENV 1-4, ZIKV, JEV, WNV and YF viruses by generating consensus sequences and predicting MHC binding affinities to HLA alleles most commonly expressed in endemic areas. Subsequently, these pools were tested in blood donors naturally exposed to DENV, ZIKV and WNV or experimentally vaccinated against DENV, JEV and YF for their potential to elicit antigen specific CD4 and CD8 T cell responses as measured by intracellular cytokine staining. Interestingly, T cell cross reactivity could be observed between all flaviviruses tested, albeit to various degrees. Cross-reactivity was more pronounced for MHC II restricted CD4 responses than MHC I CD8 T cell responses for all viruses tested. We are currently characterizing these cross-reactive responses in more detail in terms of T cell memory phenotype and specific activation markers. Knowledge of immunity between related flaviviruses is crucial to understand potential implications for vaccination and diagnostics in highly endemic settings.

726

ENDOCYTOSIS OF DENGUE VIRUS NS1 BY HUMAN ENDOTHELIAL CELLS IS REQUIRED FOR NS1-MEDIATED BARRIER DYSFUNCTION AND IS ABOLISHED BY A SINGLE N-GLYCOSYLATION SITE MUTATION

Chunling Wang, Henry Puerta-Guardo, Dustin R. Glasner, Edwina Beryl Tran, Carmel Malvar, Mark Patana, Eva Harris

Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States

Dengue virus (DENV) is the most prevalent arbovirus worldwide, and infection with any of the four serotypes leads to a range of outcomes, from inapparent disease to dengue fever to dengue hemorrhagic fever and dengue shock syndrome. Recently, we described a novel role for DENV nonstructural protein 1 (NS1) in triggering hyperpermeability of human endothelial cells and systemic vascular leak *in vivo* via disruption of the endothelial glycocalyx layer (EGL). However, the molecular determinants of NS1-induced endothelial hyperpermeability have not yet been identified. Here, using *in vitro* model systems, we report that a glycosylation site (Asn-207) is required for DENV NS1 internalization by endothelial cells and activation of endothelial cell-intrinsic pathways characterized by degradation of EGL components. This mutation (N207Q) completely prevents (i) NS1-induced hyperpermeability, as measured by trans-endothelial electrical resistance, TEER, and (ii) EGL disruption in human pulmonary microvascular endothelial cells (HPMEC), as determined by activation and/or increased expression of cathepsin-L, heparanase, and sialidases leading to shedding of heparan sulfate and sialic acid at the cell surface. As a potential mechanism to explain this phenomenon, we found that DENV2 NS1 N207Q mutant is less efficiently internalized by HPMEC than the wild-type protein at 37°C as determined by Western blot and colocalization by confocal microscopy using Rab5 as an early endosome marker. However, similar binding levels were found for both proteins at 4°C, suggesting that the N207Q mutation does not affect NS1 interaction with the cell surface but abrogates its internalization by HPMEC. These results describe a new molecular determinant of NS1 required for induction of endothelial hyperpermeability and EGL degradation in HPMEC that relies on its endocytosis. These findings may be crucial for developing antiviral therapies and NS1-based vaccine approaches.

727

DENGUE VIRUS NS1 PROTEIN ACTIVATES ENDOTHELIAL CELLS

Arturo Barbachano-Guerrero, Christine King, Timothy Endy

SUNY Upstate Medical University, Syracuse, NY, United States

Dengue virus (DENV) causes an estimated 390 million infections around the world annually. Severe forms of disease (dengue hemorrhagic fever and shock syndrome) are marked by vascular leakage and increased concentration of vasoactive mediators, such as histamine, VEGF and leukotrienes. Endothelial cells (ECs) are directly responsible for vascular homeostasis and are highly responsive to circulating mediators but are not commonly infected by DENV. DENV encodes 10 proteins; one highly conserved protein (NS1) is secreted from infected cells, correlates with severity and is implicated in increased vascular permeability. We hypothesized that NS1 directly interacts with ECs to promote activation. To address our question, we used a complimentary array of *in vitro* assays with primary ECs aimed to evaluate activation and cellular reorganization. To evaluate the mechanism of action of NS1 we analyzed the ability of NS1 to directly interact with ECs. Confocal immunofluorescence microscopy demonstrated that NS1 binds to the surface of ECs, is internalized rapidly, and accumulates in the cytoplasm over time. RNA-seq and pathway analysis showed a significant upregulation of genes associated with an angiogenic phenotype, including those involved with migration, cellular reorganization and proinflammatory responses. Furthermore, functional significance assessed using *in vitro* migraion and tube formation assays, demonstrated NS1 promoted an increase in the rate of migration and tube formation in ECs, in a dose-dependent manner. Taken together, our results indicate that NS1 directly induces functional and structural changes in ECs that are compatible with an aberrant angiogenic phenotype.

728

GENETIC VARIATION BETWEEN DENGUE VIRUS TYPE 4 STRAINS IMPACTS HUMAN ANTIBODY BINDING AND NEUTRALIZATION AFTER INFECTION AND VACCINATION

Ralph S. Baric[1], Emily N. Gallichotte[1], Thomas J. Baric[1], Usha Nivarthi[1], Rachel Graham[1], Douglas Widman[1], Boyd Yount[1], Anna Durbin[2], Steve Whitehead[3], Aravinda de Silva[1]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

One third of the world's population lives in areas with active transmission of dengue viruses (DENVs), the etiological agents of dengue fever and dengue hemorrhagic fever/shock syndrome. There are four antigenically distinct DENV serotypes (DENV1-4). A primary infection with one serotype generates a durable neutralizing and protective antibody response to the serotype of infection only. Within the DENV4 serotype, there are at least five distinct genotypes. The impact of DENV4 genotypic diversity on antigenic variation has not been rigorously examined, nor is it clear whether infection with one DENV4 genotype results in protection against all other DENV4 genotypes, which is crucial for vaccine design. To measure the impact of genetic diversity within DENV4 on the binding and neutralization of human antibodies, we generated an isogenic panel of recombinant viruses containing envelope protein sequences from the different genotypes of DENV4. We characterized the properties of these viruses, including their sensitivity to neutralization by human monoclonal antibodies and polyclonal immune sera. We found that a small number of amino acids within the envelope glycoprotein have disproportionate impacts on virus maturation, growth and ability to infect cells. Additionally, we observed large differences in the ability of DENV4 serotype-specific antibodies and immune sera to neutralize the panel of viruses, suggesting that DENV4 immunity might not be protective against all circulating DENV4 viruses. Individuals vaccinated with a live attenuated DENV4 vaccine displayed greater than 10 fold differences in the ability to neutralize different DENV4 genotypes. Our results have implications for understanding the impact of DENV intra-serotype genotypic variation on natural infection and vaccine performance and suggest that genotypic variation could lead to re-infection by the same serotype or vaccine failure.

729

MODEL-BASED ASSESSMENT OF PUBLIC HEALTH IMPACT AND COST-EFFECTIVENESS OF ROUTINE VACCINATION WITH DENGVAXIA® FOLLOWING SCREENING FOR PRIOR DENGUE VIRUS EXPOSURE

Guido España[1], Yutong Yao[1], Kathryn Anderson[2], Meagan Fitzpatrick[3], David L. Smith[4], Amy C. Morrison[5], Thomas W. Scott[5], Alex Perkins[1]

[1]University of Notre Dame, Notre Dame, IN, United States, [2]University of Minnesota, Minneapolis, MN, United States, [3]University of Maryland, College Park, MD, United States, [4]University of Washington, Seattle, WA, United States, [5]University of California Davis, Davis, CA, United States

A safe and effective vaccine for dengue could have a major public health impact for billions of people at risk of this mosquito-borne viral disease. Currently, Dengvaxia® from Sanofi Pasteur is the only licensed dengue vaccine, but there are concerns about its safety and effectiveness. In response to new phase-III trial results reported by Sanofi Pasteur in late 2017, the World Health Organization revised its position on Dengvaxia® to recommend that this vaccine only be administered to people known to have prior exposure to dengue virus (DENV), given that the vaccine appears safe and effective only for individuals in that category. Previously, we and seven other modeling groups made projections of the public health impact and cost effectiveness of routine vaccination with Dengvaxia®, but those projections are now obsolete given that they were based on the assumption that children would be vaccinated regardless of whether they have prior exposure to DENV. Using an agent-based model, we made projections of the percentage of symptomatic and hospitalized cases averted after 30 years of routine vaccination at age 9 with prior exposure to DENV confirmed by a diagnostic test with a range of values of sensitivity and specificity. In general, our results suggest that vaccinating individuals who test positive with a highly specific diagnostic (>0.8) can reduce symptomatic disease and hospitalizations at the population level, and that it can do so under a broader range of transmission settings than is possible under vaccination without diagnostic testing. Our results also suggest that the cost effectiveness of vaccination following diagnostic testing depends heavily on who is paying, with cost effectiveness appearing higher from the individual perspective than from that of a healthcare provider. Based on economic cost estimates for Brazil, a highly specific diagnostic would need to cost less than $100 to be cost-effective from the individual perspective and less than $30 from the healthcare provider perspective.

730

REGULATORY RESPONSES TO *SCHISOSOMA MANSONI* ARE INITIATED IN THE HUMAN SKIN: SKIN PENETRATING CERCARIAE INDUCE REGULATORY DERMAL APCS

Béatrice M. Winkel[1], Mirjam R. Dalenberg[1], Carola Feijt[1], Clarize M. de Korne[1], Janneke Kos-van Oosterhoud[1], Marijke C. Langenberg[1], Leonard R. Pelgrom[1], Munisha S. Ganesh[1], Hermelijn H. Smits[1], Fijs W. van Leeuwen[1], Maria Yazdanbakhsh[1], Esther C. de Jong[2], Bart Everts[1], Cornelis H. Hokke[1], Meta Roestenberg[1]

[1]Leiden University Medical Center, Leiden, Netherlands, [2]Academic Medical Center, Amsterdam, Netherlands

Following initial invasion of *Schistosoma mansoni* (*Sm*) cercariae, schistosomula reside in the skin for days during which they interact with the dermal immune system. The prolonged interaction of radiation-attenuated cercariae with innate antigen presenting cells (APCs) in the skin is presumed to orchestrate the ensuing protective immunity. To dissect the protective immune responses induced by radiation-attenuated cercariae, we studied the interaction between non-attenuated and radiation-attenuated (RA) *Sm* cercariae and dermal APCs in human skin explants. We exposed human skin explants to either cercariae or RA cercariae and visualized cercarial penetration into human skin using novel imaging technologies. Subsequently, we analysed crawl-out immune cells for their phenotype. Dermal dendritic cell (DDC) subset distribution as well as activation markers in the three-day craw-out compartment was unaltered upon cercarial penetration. However, DDCs showed an increased expression of immune-modulators programmed death ligand (PDL) 1 and 2 and enhanced production of regulatory cytokine interleukin (IL)-10, pro-inflammatory cytokine IL-6 and macrophage inflammatory protein (MIP)-1α/β, primarily after exposure to non-attenuated cercariae. These cytokine responses were absent or decreased after exposure to RA parasites. Coculturing of *ex vivo* primed DDCs with naïve CD4 T cells revealed suppressed T cell secretion of IFNγ and increased IL-10 production, confirming the regulatory potential of these APCs. Using human-monocyte derived dendritic cells (MoDCs) in a transwell model, we showed upregulation of PDL-1 and 2 is mediated by direct contact of MoDCs with cercariae. In conclusion, we are first to investigate human dermal immune responses to *Sm* cercariae in full thickness skin explants and reveal a mixed innate, regulatory response to non-attenuated *Sm* cercariae. Radiation-attenuation of cercariae partially reverses this response. An understanding of the immune suppressive capacity of *Sm* at the site of the human dermis may give clues towards the development of an effective schistosome vaccine.

731

FIBROBLAST-SPECIFIC INTEGRIN ALPHA V DIFFERENTIALLY REGULATES TYPE 2 AND TYPE 17 DRIVEN INFLAMMATION AND FIBROSIS IN *SCHISTOSOMA MANSONI* INFECTION

Joshua C. Sciurba[1], Kevin M. Hart[1], Richard L. Gieseck III[1], Nikhil Jiwrajka[1], Sandy White[1], Neil C. Henderson[2], Thomas A. Wynn[1]

[1]National Institutes of Health, Bethesda, MD, United States, [2]The University of Edinburgh, Edinburgh, United Kingdom

Fibroproliferative diseases will affect a significant proportion of the world's population. Despite this the core mechanisms that drive organ fibrosis of diverse etiologies remain ill-defined. Recent studies suggest integrin-alpha V (Itgav) serves as a master driver of fibrosis in multiple organs. However, these studies have overlooked a significant population of fibrotic patients, which have a parasitic disease insult and fibrosis driven by type 2 (IL-4/IL-13) rather than type 1 (TGF-β/IFNγ/IL-17) immune responses. To investigate if Itgav is critical for the development of type 2 fibrosis, we analyzed fibroblast-specific Itgav knockout mice (Itgav-KO) during the course of natural *Schistosoma mansoni* infection as well as in models of lung fibrosis and of severe asthma. Surprisingly, while we confirmed a role for Itgav in models of TGF-β driven fibrosis, Itgav was not critical for the development of fibrosis during *Schistosoma mansoni* infection and other type 2 driven disease models as shown by no change in hydroxyproline quantification and collagen gene expression in Itgav-KO animals. Nevertheless, type 17 (IL-17) responses were impaired by Itgav deficiency, independent of its effect on fibrosis (IL-17$^+$CD4$^+$ t-cell frequency: 0.811% vs 0.460% $p < 0.05$). As IL-17 has been found to serve as an important activator of TGF-β-driven fibrosis, the preferential suppression in the IL-17 inflammatory pathway likely explains the critical role of Itgav in TGF-β-dependent but not IL-13-dependent fibrosis seen in a helminth infection. Finally, during a mixed IL-17/IL-13 inflammatory model of severe asthma, Itgav deficiency led to a substantial immune skewing away from type 17 and towards type 2 inflammation in Itgav-KO animals (IL-17$^+$CD4$^+$ t-cell frequency: 6.108% vs 4.218%, $p < 0.05$; IL-13$^+$CD4$^+$ t-cell frequency: 0.769% vs 2.534 %, $p < 0.0001$). Together, these findings have important therapeutic implications, as they suggest targeting both the Itgav/TGF-β and type 2 pathways may be needed to more effectively resolve fibrosis and prevent rebound of opposing pro-fibrotic mechanisms.

During filarial infection eosinophils mediate protection against adult worms and microfilariae (MF), whereas they are only essential against infective L3 larvae following re-infection or vaccination. Similar to neutrophils, eosinophils are able to produce extracellular DNA traps (ETosis), a form of cell death where intracellular DNA is explosively released. The aim of this study was to analyze the impact of eosinophil ETosis in response to MF of the rodent filarial nematode *Litomosoides sigmodontis*. Bone-marrow-derived eosinophils released DNA in response to MF as was shown by scanning electron and confocal microscopy as well as by DNA quantification using a fluorescence assay. Subsequent PCR analysis revealed that the released DNA was of nuclear and mitochondrial content. This eosinophil ETosis reduced MF motility *in vitro* in a DNA- and contact-dependent manner, whereas addition of serum of naïve and infected animals inhibited the ETosis-dependent MF trapping. Stimulation of eosinophils with the small molecule analog 5 (SMA5) of the filarial immunomodulatory excretory-secretory product ES-62 enhanced DNA release and MF trapping by eosinophils. Comparison of the efficacy of bone-marrow-derived eosinophils and eosinophils from the thoracic cavity and gut of *L. sigmodontis*-infected animals further revealed that eosinophils from infected animals are more potent in inhibiting MF motility, which was independent on the local immunomodulation by the adult worms. These results demonstrate that eosinophils impair MF motility in an ETosis-dependent mechanism by releasing nuclear and mitochondrial DNA. Ongoing experiments address the *in vitro* impact of eosinophil ETosis on adult worms and L3 larvae and indicate that eosinophils only trap L3 larvae when specific antibodies are present, as it occurs during filarial re-infection or vaccination. In addition, current *in vivo* experiments are investigating eosinophil ETosis in response to MF and L3 larvae during primary infection and re-infection.

733

IL-10 AND ITS RELATED SUPERFAMILY MEMBERS IL-19 AND IL-24 PROVIDE PARALLEL/REDUNDANT IMMUNE-MODULATION IN *LOA LOA* INFECTION

Alessandra Ricciardi, Thomas B. Nutman

Helminth Immunology Section, Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

IL-10 has been implicated as the major cytokine responsible for the modulation of parasite-specific T cell responses in active filarial infections; however, IL-10 belongs to a superfamily of cytokines, and the role of other superfamily members in filarial infection is less well studied. We have previously shown that the induction of the IL-10 superfamily members IL-24 and IL-19 are increased in active (antigen positive) *W. bancrofti* infections and can regulate both Th1/Th17 and Th2 responses. To address the role of IL-10 and its superfamily members (IL-24, IL19, IL-22, IL-28a) in the related filarial infection *Loa loa* and to understand the role played by microfilaria (mf) in their induction, peripheral blood mononuclear cells from 31 patients with loiasis were stimulated with or without filarial antigen, 2 non-parasite antigens (streptolysin O, or tetanus toxoid), or mitogen (PHA), and production of 17 cytokines was assessed using a multiplex Luminex platform for Th1/Th2/Th9/Th17/IL-10 (and IL-10 superfamily)-associated cytokines. All of the patients produced significant levels of IL-10 ($p=0.0414$), IL-13 ($p<0.0001$), IL-5 ($p<0.0001$), IL-4 ($p=0.0094$), IL-9 ($p=0.0016$), IL-2 ($p<0.0001$), and IL-27 ($p=0.0204$) in response to filarial antigen indicating a common infection-driven response. When comparing mf positive (mf+) and mf negative (mf-) patients, there were no significant differences in spontaneous cytokine production nor in parasite driven IL-10, IL-13, IL-5, IL-4, IL-9, Il-2, IL-22, IL-28a, or IL-27 production. In marked contrast, mf+ individuals had significantly increased filarial antigen-driven IL-24 (9.2-fold increase vs. 1.2-fold, $p=0.026$), and IL-19 (2.3-fold increase vs. 1.3-fold increase, $p=0.0497$) compared to mf- subjects. There were no differences in the IL-24 and IL-19 responses to non-parasite antigens and to mitogen between mf+ and mf- patients. These data provide an important link between IL-10 and its related family members IL-19 and IL-24 in the modulation of the immune response in human filarial infections that appears to be driven by microfilaria.

734

ABSENCE OF S100A9 INCREASES INFLAMMATORY IMMUNE RESPONSES AGAINST *LITOMOSOIDES SIGMODONTIS* L3 LARVAE AND IMPAIRS LARVAL MIGRATION

Stefan J. Frohberger[1], Frederic Fercoq[2], Surendar Jayagopi[1], Anna-Lena Neumann[1], Wiebke Stamminger[1], Achim Hoerauf[1], Coralie Martin[2], Marc P. Hübner[1]

[1]Institute for Medical Microbiology, Immunology and Parasitology, University Hospital Bonn, Bonn, Germany, [2]Unité Molécules de Communication et Adaptation des Microorganismes (MCAM, UMR 7245), Sorbonne Universités, Muséum national d'Histoire naturelle, CNRS, Paris, France

In the *Litomosoides sigmodontis* (*L.s.*) mouse model of filariasis, infective L3 larvae migrate from the site of infection within the skin via the lymphatics and the pulmonary capillaries to the thoracic cavity, where the filariae reside. We previously demonstrated that neutrophils mediate protective immune responses within the skin against invading L3 larvae and contribute to L3-induced lung pathology. S100A9 is a damage-associated protein, which is highly expressed by neutrophils and increasingly found in the lung during the acute phase of *L.s.* infection. In the present study we investigated the impact of S100A9 on *L.s.* infection in S100A9$^{-/-}$ C57BL/6 mice. Following natural infection with *L.s.,* S100A9$^{-/-}$ mice had a significantly reduced worm burden at 12 days post infection that was still observed following subcutaneous infection, which circumvents the first barrier, the skin. The reduced worm burden in S100A9$^{-/-}$ mice correlated with increased frequencies of neutrophils, macrophages and eosinophils as well as increased levels of CXCL1, CXCL2, CXCL5 and neutrophil elastase in the bronchoalveolar and thoracic cavity lavage indicating a pronounced inflammatory response. Furthermore, neutrophils of S100A9$^{-/-}$ mice showed an increased *in vitro* and *ex vivo* activation compared to neutrophils of wild type animals. Pulmonary neutrophils were essential for the protective effect seen in S100A9$^{-/-}$ mice, as depletion of neutrophils by intranasal administration of anti-Ly6G antibodies significantly increased the worm recovery in S100A9$^{-/-}$ mice. Similarly, upon intravenous injection of L3 larvae, S100A9$^{-/-}$ mice had an increased worm burden, suggesting that the simultaneous entrance of the L3 larvae from the pulmonary capillaries into the thoracic cavity reduces inflammatory responses L3 larvae encounter overcoming the protective effects otherwise observed in S100A9$^{-/-}$ mice. These results suggest that S100A9 inhibits L3-induced inflammatory responses in the bronchoalveolar lavage and thoracic cavity, reducing chemokine production and granulocyte recruitment as well as neutrophil activation, facilitating larval migration.

735

EVALUATING INTESTINAL PROTEINS OF ADULT FILARIAL WORMS AS POTENTIAL VACCINE AND DRUG TARGETS

Alexander F. Flynn[1], Rebekah T. Taylor[2], Sasisekhar Bennuru[3], C. Paul Morris[4], Thomas B. Nutman[3], Edward Mitre[1]

[1]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [2]Frostburg State University, Frostburg, MD, United States, [3]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [4]Department of Pathology, Johns Hopkins Hospital, Baltimore, MD, United States

The goal of this study is to identify drug and vaccine targets for filarial diseases such as lymphatic filariasis and onchocerciasis. We conducted proteomic analyses of the *Brugia malayi* adult worm intestinal tract and identified transmembrane intestinal proteins with high homology to other filarial worms, low homology to humans, and a large predicted luminal surface. We hypothesize that such "hidden" antigens would not naturally induce IgE-specific responses in endemic populations but would still be accessible to antibodies ingested by the filarial worms. Using fluorescent microscopy, we observed ingestion of cy3-labeled polyclonal mouse IgG antibodies by filarial adult worms into their intestinal tract. Potential vaccine and drug targets were identified from 9 pre-selected intestinal antigens by observing which proteins were essential for worm survival. After siRNA knockdown of these proteins, adult worms were monitored *in vitro* for motility, microfilaria (mf) release, and metabolism by MTT reduction over 6 days. Knockdowns were confirmed by quantitative PCR and, for proteins showing a robust phenotype, Western blot. Of the 9 candidate proteins, we found two that are essential for worm survival, a UDP-glucoronosyl transferase (UGT) and an IgI-set domain containing protein (IgI-DCP). Knockdown of each protein individually caused a 75% reduction in motility by day 1 and over 70% decrease in mf release by day 6. Additionally, use of FDA-approved commercially available UGT inhibitors *in vitro* resulted in adult worm death. We then performed luciferase immunoprecipitation system assays on serum samples from filarial patients (n=30) and did not detect IgE antibodies against these antigens. These studies have identified two intestinal tract proteins essential for adult filarial worm survival that could be targeted by antibodies but do not naturally induce IgE in infected individuals. Furthermore, demonstration of adult worm killing *in vitro* by currently available medications suggests that UGT is potentially a novel drug target.

736

A HUMAN 3D CELL-BASED PLATFORM FOR DRUG DISCOVERY TARGETING *PLASMODIUM* HEPATIC INFECTION

Sofia Rebelo[1], Francisca Arez[1], Diana Fontinha[2], Daniel Simão[1], Marta Machado[2], Tatiana Martins[1], Manuel Carrondo[1], Thomas Spangenberg[3], **Catarina Brito**[1], Beatrice Greco[3], Miguel Prudêncio[2], Paula Alves[1]

[1]iBET - Instituto de Biologia Experimental e Tecnológica and Instituto de Tecnologia Química e Biológia António Xavier, Universidade Nova de Lisboa, Oeiras, Portugal, [2]iMM - Instituto de Medicina Molecular João Lobo Antunes, Lisboa, Portugal, [3]Merck Global Health Institute, Darmstadt, Germany

The liver stage of *Plasmodium* infection is the first step of the parasite's life cycle in the mammalian host and obligatorily precedes the pathological blood stage of infection. Moreover, the liver constitutes the reservoir of dormant forms of *P. vivax* or *P. ovale*, termed hypnozoites, which are responsible for disease relapse in humans. Therefore, hepatic stages of *Plasmodium* infection is an important target to prevent disease, stop malaria transmission, as well as to achieve radical cure. Currently, few of the available therapeutics target the hepatic stage of infection and several have been associated with development of resistance. Furthermore, primaquine, the only marketed drug with activity against hypnozoites once metabolically activated, cannot be widely distributed due to haemolytic effects on 6GPD-deficient individuals, a common trait in malaria endemic areas. These hurdles highlight the demand for *in vitro* models that closely recapitulate the *Plasmodium* hepatic infection and human drug metabolism. Here, we present a 3D human cell-based platform suitable for the discovery of novel drugs targeting *Plasmodium* hepatic infection. The platform relies on human hepatic spheroids generated in bioreactors that sustain crucial hepatic features, such as the cell polarity and long-term metabolic performance. We established and optimized the *Plasmodium* infection procedure in 3D cultures, and extensively characterized the dynamics of infection in this system. The data demonstrates that *P. berghei* infects and develops in the hepatic spheroids, completely maturating into blood-infecting merozoites that effectively infected blood cells *in vivo*. The 3D hepatic infection platform was validated by assessing the activity of antiplasmodial drugs such as atovaquone. Moreover, the long-term 3D hepatic cultures represent a promising tool to target hypnozoite-forming *Plasmodium* parasites. Besides their usefulness for drug discovery, such models could further be applied to unveil aspects of the fundamental biology underlying *Plasmodium* invasion and development in hepatic cells.

737

PROTEASOME INHIBITOR-BASED COMBINATION THERAPY POTENTLY INHIBITS ARTEMISININ-RESISTANT *PLASMODIUM FALCIPARUM*

Barbara H. Stokes[1], Euna Yoo[2], James M. Muriungi[1], Sabine Ottilie[3], Madeline R. Luth[3], Elizabeth A. Winzeler[3], Matthew S. Bogyo[2], David A. Fidock[1], **Caroline L. Ng**[4]

Malaria remains a significant global health problem. In 2016, there were 216 million cases and ~0.5 million malaria-related deaths. The WHO recommends artemisinin-based combination therapy (ACT) as first line treatment for uncomplicated falciparum malaria. Alarmingly, artemisinin resistance (ART-R) has arisen in Southeast Asia (SEA) and South America and threatens to spread to Africa. Mutations in the propeller domain of Kelch 13 (K13) correlate with ART-R in field isolates, and have been confirmed to confer resistance by *in vitro* gene editing. Compounding the situation, resistance to the ACT partner drug piperaquine is now arising in SEA. Novel drugs that are uncompromised by existing drug resistance are urgently needed. The parasite proteasome is vital for parasite proliferation, and the *P. falciparum*-specific proteasome inhibitors WLL and WLW were recently generated. We sought to determine suitable compounds to be used in combination with WLL/WLW and to characterize WLL/WLW resistance traits. Using K13-isogenic Cambodian parasites that are ART-S or ART-R, we performed isobolograms using WLL/WLW in combination with antimalarials that have distinct targets. We found that regardless of K13 status, WLL and WLW are synergistic with DHA, OZ439, and the deubiquitinase inhibitor b-AP15, and antagonistic with protein translation inhibitors and the 4-aminoquinolines chloroquine and piperaquine. Low-level *in vitro* resistance to WLL and WLW is mediated by mutations in proteasomal subunits. *In silico* modeling revealed that mutations in the β_2 and β_5 subunits are close to inhibitor binding sites. Importantly, WLL-resistant lines retain sensitivity to WLW, and vice versa. This was demonstrated by dose-response curves and a fluorogenic activity-based probe to the proteasome catalytic subunits. Altogether, the data show that WLL and WLW are promising drug candidates and that several antimalarials synergize with parasite-selective proteasome inhibitors. Importantly, these drug combinations potently inhibit ART-R *P. falciparum*.

738

ANTIMALARIAL PYRROLIDINAMIDES FAST-ACTING COMPOUNDS WITH A NOVEL MODE OF ACTION

Laura M. Sanz, Maria G. Gomez, Maria Jose Lafuente, Isabel Castellote, John Haselden, Francisco Javier Gamo

GlaxoSmithKline, Tres Cantos (Madrid), Spain

Malaria continues to be a major global disease still causing impermissible number of deaths. The effectiveness of current antimalarial therapy is under continuous threat through the spread of resistance. Last reports suggest that even the latest class of antimalarials, artemisinins, are also being affected by resistance. Consequently, there is an urgent need to identify novel therapies that overcome resistance issues and offer significant advantages over the current standard of care. Within the TCAM set of phenotypic hits identified at GSK, a pyrrolidinamide chemical series was selected because its chemical novelty offering exciting properties as antimalarial. Pyrrolidinamides exhibit potent *in vitro* activity against asexual stages of both sensitive and multi-drug resistant (MDR) *Plasmodium falciparum* strains including fresh clinical isolates. This chemical series has demonstrated potent oral efficacy in the *P. falciparum* humanised mouse model. Noteworthy, series displays a rate of killing comparable or even superior to that from endoperoxides. Furthermore, pyrrolidinamides display a new mode of action (MoA) based on functional assays and a lack of cross-resistance against a panel of strains with mutations producing resistance to known antimalarial drugs. Parasites exposed to pyrrolidinamides select for resistant mutations that target the acyl CoA synthetase (ACS) pathway. This putative new MoA that shows an outstanding fast rate of killing offers differentiation against all other antimalarials. In this work we will show a detailed parasitological profile of this novel antimalarial series and the promising properties that could be of paramount importance for new combination treatments.

739

A RANDOMIZED CONTROLLED TRIAL COMPARING PARASITE CLEARANCE PROFILES AFTER SINGLE DOSE ARTESUNATE AMONG SUBJECTS EXPERIMENTALLY INFECTED WITH ARTEMISININ-RESISTANT OR ARTEMISININ-SENSITIVE *PLASMODIUM FALCIPARUM* PARASITES

Rebecca E. Watts[1], **Maria Rebelo**[1], Anand Odedra[1], Jörg J. Möhrle[2], Stephan Chalon[2], Louise Marquart[1], James S. McCarthy[1]

[1]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [2]Medicines for Malaria Venture, Geneva, Switzerland

Since its first recognition in 2008, artemisinin resistance has spread across the Greater Mekong Subregion and poses an important threat to malaria control. Novel treatment strategies effective against artemisinin-resistant infections are urgently needed. We recently established an induced blood stage malaria (IBSM) model in which subjects are inoculated with a *P. falciparum* artemisinin-resistant *kelch13* parasites (K13 isolate) carrying the R539T mutation. This model was established to allow investigation and prioritization of novel drugs effective against artemisinin-resistant parasites. The aim of this study was to validate this model by comparing the parasite clearance profiles of K13 to an artemisinin-sensitive isolate (3D7). Healthy subjects were randomized and intravenously inoculated with ~2,800 parasite-infected erythrocytes, either K13 (Day 0, n=10) or 3D7 (Day 1, n=6). Parasitemia was measured by quantitative PCR targeting the *P. falciparum* 18S rRNA gene. On Day 9, all subjects received a single oral dose of artesunate (~2 mg/kg). Recrudescent parasitemia was treated with 960 mg piperaquine. To ensure cure, subjects were treated with atovaquone/proguanil and primaquine before the end of the study. K13 parasites took significantly longer to clear after artesunate treatment: the parasite clearance half-life of K13 was 6.51h (95% CI 6.23-6.82) compared to 2.85h for 3D7 (95% CI 2.68-3.03; $p<0.001$). Adverse events (179) reported were mostly mild (77%; 138/179) and attributed to malaria (74%; 133/179). Two adverse events (1.1%) were attributed to drug treatment (artesunate, n=1; atovaquone/proguanil, n=1). No serious adverse events were reported. Rapid early recrudescence occurred in all K13 subjects (within 48 hrs of treatment), while several days of static low level parasitemia, suggestive of dormancy was observed among 3D7 subjects before recrudescence occurred. These results concur with observations in field studies. This new K13 IBSM model can be used to determine the activity of antimalarial treatments against artemisinin-resistant parasites.

740

SJ733, AN ORAL, INHIBITOR OF PFATP4 COMBINED WITH A PHARMACOKINETIC ENHANCER (CYP3A INHIBITOR): A NOVEL APPROACH IN ANTIMALARIAL DRUG DEVELOPMENT

Aditya H. Gaur[1], John C. Panetta[1], Tracy B. Stewart[1], Ronald Dallas[1], Kristen C. Branum[1], Li Tang[1], Burgess B. Freeman III[1], Shelley Ost[2], Nehali D. Patel[1], Ryan N. Heine[1], Elizabeth John[3], Stephan Chalon[4], Julie L. Richardson[1], Robbin Christensen[1], Andrew Slade[4], Patricia M. Flynn[1], Fabian Gusovsky[5], R. Kip Guy[6]

[1]St. Jude Children's Research Hospital, Memphis, TN, United States, [2]University of Tennessee, Memphis, TN, United States, [3]EJOHN Consulting, Richland, WA, United States, [4]Medicines for Malaria Venture, Geneva, Switzerland, [5]Eisai Inc., Andover, MA, United States, [6]University of Kentucky College of Pharmacy, Lexington, KY, United States

SJ773 is a novel, orally available inhibitor of *P. falciparum* ATP4 (PfATP4; a critical sodium-proton antiporter in the parasite), and the second in class to enter clinical development. In Phase 1 studies to date, SJ733 demonstrated favourable safety profiles and rapid antiparasitic effect but insufficient duration of antimalarial effect with a single dose. Therefore, the novel approach of inhibiting CYP3A, the dominant enzyme metabolizing SJ733, to increase drug exposure was considered. Specifically, three additional fasting dose cohorts combining SJ733 (75, 300 or 600 mg single dose) with a single dose of the known CYP3A4 inhibitor (pharmacokinetic enhancer or booster) cobicistat (150 mg dose, currently FDA-approved to boost certain antiretrovirals medications), were evaluated in an ongoing Phase 1a First-In-Human Safety and Pharmacokinetic (PK) adult healthy volunteers study (ClinicalTrials.gov: NCT02661373). All 18 male subjects in the cobicistat boosted dose cohorts tolerated SJ733 co-dosed with cobicistat well with no serious adverse events, dose limiting toxicities, Grade 3 or 4 adverse events (AE), or clinically significant ECG/safety laboratory tests findings. All reported AEs were Grade 1, clinically not significant and considered unlikely or unrelated to SJ733. Compared to the equivalently dosed unboosted cohorts, the SJ733 cobicistat-boosted cohorts showed an overall median increase in area under the concentration curve (AUC), maximum concentration (Cmax), and duration above a drug-exposure threshold of 3.7X, 2.5X, 2X respectively and a median, decrease in SJ733 clearance and major N-oxide metabolite SJ506 to parent drug ratio of 3.8X and 4.6X, respectively. In summary, this novel pharmacoboost approach demonstrates a significant increase in drug exposure and duration of a promising new antimalarial SJ733 with no drug toxicity signals noted. This supports further drug development of SJ733 and serves as the first example of a pharmacoboost approach for an antimalarial.

741

KAF156 AND LUM-SDF COMBINATION PHASE 2 STUDY PHARMACOKINETIC RUN-IN COHORT RESULTS

Bakary Fofana[1], Martin Grobusch[2], Jay Prakash Jain[3], Djimde Abdoulaye[4], Sophie Biguenet[5], **Cornelis Winnips**[6]

[1]Malaria Research and Training Center (MRTC), Bamako, Mali, [2]Academic Medical Center, Amsterdam, Netherlands, [3]Novartis Institute for Biomedical Research, Emeryville, CA, United States, [4]USTTB, Bamako, Mali,

[5]Medicines for Malaria Venture, Geneva, Switzerland, [6]Novartis Pharma AG, Basel, Switzerland

The safety and efficacy of different doses of the combination of KAF156 and Lumefantrine-Solid Dispersion Formulation (LUM-SDF) in patients with acute malaria are currently explored in the Phase 2 clinical study NCT03167242. The protocol for this study includes a PK run-in to exclude a potential pharmacokinetic interaction between the two drugs and the risk of overexposure. In this first part of the study, the pharmacokinetics and safety of the KAF156/LUM-SDF combination was evaluated to understand the impact of LUM-SDF on KAF156 (victim drug) exposure. In the scenario of an increase in KAF156 exposure beyond the acceptable limit, doses in Part A of study NCT03167242 would be adjusted as pre-specified in the protocol. Six male and six female Malian adult/adolescent patients (≥12 years old and ≥35.0 kg) infected with *P. falciparum* were enrolled in Bougoula-Hameau in the PK run-in and given a single dose of 200 mg KAF156 and 960 mg LUM-SDF. The drug-exposure results of these patients confirmed that there is no increase in KAF156 exposure beyond protocol-defined limits when given in combination with LUM-SDF in humans. The combination was well tolerated, and all 12 patients were clear of the initial malaria infection by Day 3 and remained parasite-free at Day 28. Consequently, dosing in study NCT03167242 is proceeding as planned, without any adaptation of the dose of KAF156.

742

PHARMACOGENETICS OF THE IVERMAL TRIAL: HUMAN METABOLIC GENES AND MOSQUITO MORTALITY RESPONSE TO HIGH-DOSE IVERMECTIN CO-ADMINISTERED WITH DIHYDROARTEMISININ-PIPERAQUINE

Menno R. Smit[1], Helmi E. Pett[2], Katriina E. Tarkiainen[2], Eric O. Ochomo[3], Ghaith Aljayyoussi[1], David Waterhouse[1], Aaron M. Samuels[4], Meghna R. Desai[4], Steve A. Ward[1], Simon K. Kariuki[3], Feiko O. ter Kuile[1], Teun Bousema[5], Mikko O. Niemi[2]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]University of Helsinki, Helsinki, Finland, [3]Kenya Medical Research Institute, Kisumu, Kenya, [4]U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [5]Radboud University Medical Center, Nijmegen, Netherlands

High-dose ivermectin, co-administered for 3-days with dihydroartemisinin-piperaquine (DP), killed mosquitoes feeding on individuals for at least 28-days post-treatment in a recent trial. Further pharmacokinetic-pharmacodynamic (PK-PD) analysis showed that this prolonged effect-duration could be explained by ivermectin alone, without invoking an unidentified mosquitocidal metabolite or drug-drug-interaction. Ivermectin and piperaquine are both primarily metabolized by *CYP3A4*. The current pharmacogenetic analysis aimed to assess to which degree the inter-individual variability observed for both ivermectin and piperaquine pharmacokinetics, pharmacodynamics, and related adverse events, can be attributed to human metabolism genetics by *CYP3A4* and other enzymes. In the main trial, 3-days ivermectin 0, 300, or 600 mcg/kg/day plus DP was randomly assigned to 141 adults with uncomplicated malaria in Kenya. All participants were genotyped for a total 67 single nucleotide variations (SNV; including five *CYP3A4/5* and three *ABCB1* SNVs) using Taqman allelic discrimination assays. During 28-days follow-up, 1,393 venous and 335 paired capillary plasma samples, 850 mosquito-cluster mortality rates, and 524 QTcF-intervals were collected. Using population modeling, PK and PD parameters were obtained for all dosed participants: ivermectin (n=95) and piperaquine (n=141). The incidence of related adverse events were: 5/45 (11%), 2/48 (4%), and 0/46 (0%) with 600, 300, and 0 mcg/kg/day. Genotypes were correlated with PK-PD parameters and related adverse events. Ivermectin clearance normalized by bodyweight (mean±SD; L/h) differed by *CYP3A4* genotype: *1/*1 (0.0109±0.0035), *1/*1B (0.0091±0.0029), *1B/*1B (0.0125±0.0026) (One-way ANOVA: $F(2,91)=4.14$, $p=0.019$). Similar analysis for piperaquine showed no difference ($F(2,137)=0.10$, $p=0.90$). *CYP3A4* genotype was not associated with adverse events. *CYP3A4* genotype was associated with ivermectin clearance, when co-administered with DP, however there was no association between *CYP3A4* genotype and piperaquine clearance.

743

SEVERE MALARIAL ANEMIA AND IN-HOSPITAL MORTALITY IN ZAMBIAN CHILDREN WITH AND WITHOUT BLOOD TRANSFUSION

Matthew Ippolito[1], Manuela Hauser[2], Emmanuel Mpundu[3], Jean-Bertin Kabuya[4], Jay F. Sikalima[4], Luc K. Kamavu[3], Catherine Tente[3], Modest Mulenga[4], William J. Moss[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD, United States, [2]University Children's Hospital, Zurich, Switzerland, [3]Saint Paul's General Hospital, Nchelenge, Zambia, [4]Tropical Diseases Research Centre, Ndola, Zambia

Severe malaria is the leading parasitic cause of death, and severe malarial anemia, defined as a hemoglobin (Hb) concentration ≤ 5 g/dl, is the most common clinical presentation. In resource-limited settings where blood stockouts present a challenge to clinical care, distinguishing patients who are most likely to benefit from transfusion can help inform allocation when inventories are scarce. We present preliminary results of a cross-sectional study of hospitalized children (n=329) with severe malarial anemia in a high transmission area of northern Zambia to investigate associations among Hb concentration, blood transfusion, and mortality. Data are from January 2017 to January 2018, with collection ongoing. The median age was 22 mos. (IQR: 12-31 mos.) and 49% were girls. The case fatality ratio was 14%. According to hospital protocol, blood transfusion was indicated for all children. However, due to blood product stockouts, 38 children (12%) did not undergo transfusion. To investigate the interaction between Hb concentration and the survival benefit of blood transfusion, we stratified children by level of anemia (severe: >3 to 5 g/dl, profound: ≤ 3 g/dl). In a preliminary effect-measure modification analysis, children in both strata had similarly increased odds of death if no transfusion was given relative to receiving at least one transfusion (summary OR: 2.84, 95% CI: 1.21-6.68, P=0.016). Previous reports suggest that sub-stratification by degree of anemia might identify patients who are most likely to benefit from transfusion. In contrast, our preliminary analysis shows that children with profound (Hb ≤ 3 g/dl) and severe (Hb >3 to 5 g/dl) malarial anemia gained a similar survival benefit from blood transfusion. Our early results indicate that during periods of looming blood product stockouts, children with malarial anemia should be equally prioritized for blood transfusion regardless of the profundity of anemia.

744

PROFILING MALARIA HIGH-RISK GROUPS IN ACEH PROVINCE, INDONESIA: A CASE-CONTROL STUDY

Jennifer L. Smith[1], Chris Cotter[1], Martha G. Silaen[2], Iska Zarlinda[2], Jerry O. Jacobson[1], Iqbal RF Elyazar[3], Farah N. Coutrier[2], Adam Bennett[1]

[1]Malaria Elimination Initiative, Global Health Group, University of California San Francisco, San Francisco, CA, United States, [2]Eijkman-Institute for Molecular Biology, Jakarta, Indonesia, [3]Eijkman-Oxford Clinical Research Unit, Jakarta, Indonesia

Malaria transmission in Aceh Province, Indonesia, has been linked to forest activities in young adult males, whose occupations and behaviors increase their exposure to outdoor-biting and forest mosquito vectors. A case-control study was carried out between April 2017 and September 2018 in Aceh Besar and Aceh Jaya districts to evaluate spatial clustering of cases and quantify specific risk factors. All malaria cases identified at health facilities in four subdistricts and confirmed by microscopy, rapid diagnostic test or loop mediated isothermal amplification (LAMP) were included in the study. Two control groups were recruited, one from health facilities and one from neighborhoods of cases. The first control group included febrile patients aged 15 years or older testing negative for

malaria by rapid diagnostic test or microscopy at selected health facilities and recruited in proportion to the expected gender distribution of cases. Community controls were selected from microscopy-negative participants surveyed during malaria screening in neighborhoods of index cases and individually matched to incident cases by neighborhood, age category and gender. All participants were interviewed about potential environmental, socio-demographic, intervention, behavioral and forest-related exposures. As of April 2018, 41 incident malaria cases, 358 health facility controls and 152 neighborhood controls had been recruited into the study. Cases represented all three *Plasmodium* species (*P. falciparum*, *P. vivax* and *P. knowlesi*), were predominantly male (95%), and the majority (78%) aged between 30 and 60 years. Preliminary results suggest that malaria cases were more likely to have a second residence in the forest/forest-fringe and have worked in forest/forest-fringe areas in the past 30 days. Trip duration was positively associated with the odds of malaria, as was reported presence of long-tailed macaques around the primary household. Final results describing spatial patterns of malaria risk and the use of latent class analyses to identify species-specific risk profiles will be presented.

745

WHY SOME CHILDREN WITH UNCOMPLICATED MALARIA PROGRESSED TO SEVERE MALARIA IN UGANDA

Arthur Mpimbaza[1], Grace Ndeezi[2], Anne Katahoire[1], Charles Karamagi[3], Philip J. Rosenthal[4]

[1]Child Health and Development Centre, Makerere University-College of Health Sciences, Kampala, Uganda, [2]Department of Pediatrics and Child Health, Makerere University-College of Health Sciences, Kampala, Uganda, [3]Clinical Epidemiology Unit, Department of Medicine, Makerere University-College of Health Sciences, Kampala, Uganda, [4]Department of Medicine, University of California, San Francisco, CA, United States

We studied associations between social and host biological factors and risk of severe malaria in Ugandan children. We enrolled 325 severe malaria cases and 325 uncomplicated malaria controls matched by age and residence in Jinja District. Patient details and an itinerary of events in response to illness were captured. Caregivers of children with severe malaria were interviewed to explore behavioral factors contributing to delayed care seeking. Conditional logistic regression was used to determine risk factors for severe malaria and delayed care seeking. Independent risk factors for severe malaria included: 1) delayed care seeking (> 24 hours after fever onset; OR 5.88; 95% CI 2.75, 12.5); 2) seeking care at a drug shop as the initial response to illness (OR 3.37; 95% CI 1.66, 6.83); and 3) distance from place of residence to the nearest health center (OR 1.52; 95% CI 1.21, 1.91). Seeking care at a drug shop (OR 3.85, 95% CI 1.19, 12.3) and increasing distance to the nearest health center (OR 1.93, 95%CI 1.21, 3.08) were independent risk factors for delayed care seeking. Drug shops were the most common type of provider (31.6%) initially sought by caregivers of children with severe malaria. However, compared to public health facilities, drug shops offered sub-optimal services, with children less likely to have been examined (46.1% vs. 80.0%; p< 0.001) or referred to another facility (14.6% vs. 68.9%; p<0.001), based on reports from caregivers. Caregivers reported drug shops as convenient, but unable to manage severe illness, contributing to delay. Of host biological factors studied, Hemoglobin S heterozygotes (HbAS; OR 0.48; 95%CI 0.24, 0.96, p=0.038) and alpha thalassemia heterozygotes (_α/αα; OR 0.54; 95% CI 0.36, 0.82, p=0.004) and homozygotes (OR 0.47; 95% CI 0.30, 0.74, p=0.001) were protected against severe malaria. A significant (p=0.05) epistatic effect was noted between _α/αα and HbAS, such that protection was diminished when both mutations were present. Determinants of severe malaria were complex. Key among these was delay in care seeking. Seeking care at drug shops appears to contribute to delay and severe malaria.

746

EVALUATION OF MALARIA RECURRENCE IN BRAZIL

André Daher

Oswaldo Cruz Foundation, Rio de Janeiro, Brazil

In vivax endemic areas, malaria control must tackle relapses. Although a surveillance system records every single malaria case in Brazil, it does not provide accurate information on recurrences. The aim of this study is to improve the use of the information from the Health Surveillance System, in order to shed light on the actual recurrence epidemiological profile and the effectiveness of the current treatment using chloroquine in combination with a short course of primaquine (7-9 days: total dose 3-4.2 mg/kg) in Brazil. In this observational retrospective open cohort, the data matching was done using bloom filters to deduplicate records of the National System of Malaria Surveillance from 1st July 2014 till 31st May 2015. The impact of baseline characteristics in the frequency of recurrences was tested using Generalized Estimation Equation (GEE). The effectiveness of the current treatment and the synergic effect of primaquine and chloroquine in the blood stage and its causal prophylactic effect were also tested using GEE. Prentice, Willians and Peterson model was used to evaluate the influence of population characteristics in time to recurrence. Among 153,203 malaria cases reported during this year, 24,528 recurrences were identified using the bloom filter matching strategy and the Dice threshold defined for this dataset. The models demonstrated a significant effect of the baseline characteristic and treatment in the relative risk of recurrence. The study demonstrates the feasibility of improving the use of Health Surveillance Systems data. An accurate picture of recurrence may provide evidence to refine the guidelines in Brazil. This study also shed light on the effectiveness of primaquine short course and the synergic effect of its concomitant use with chloroquine. Finally, these results may be used to guide future public health interventions to amplify their effect by targeting high-risk populations.

747

IMPACT OF IMPROVED MALARIA CONTROL ON THE FORCE OF INFECTION OF *PLASMODIUM FALCIPARUM* AND *P. VIVAX* IN YOUNG PAPUA NEW GUINEAN CHILDREN

Maria A. Ome-Kaius[1], Eline Kattenberg[2], Matthew Siba[3], Shadrach Jally[3], Zahra Razook[1], Daisy Mantila[3], Desmond Sui[3], Jason Ginny[3], Stephan Karl[1], Thomas Obadia[4], Moses Laman[3], Daniel Tisch[5], Ingrid Felger[6], James Kazura[5], Ivo Mueller[1], Leanne Robinson[7]

[1]Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [2]Institute of Tropical Medicine in Antwerp, Antwerp, Belgium, [3]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [4]Institut Pasteur, Paris, Paris, France, [5]Case Western Reserve University, Cleveland, OH, United States, [6]Swiss Tropical and Public Health Institute, Basel, Switzerland, [7]Burnet Institute of Medical Research, Melbourne, Australia

With declining malaria transmission, reliable quantification of ongoing transmission is vital and becomes increasingly difficult using classical entomological measures. Molecular force of blood-stage infection ($_{mol}$FOB), a measure of exposure to new blood-stage infections, has been demonstrated to be a suitable proxy for measuring transmission but is yet to be applied to directly assess the impact of intensified control measures on *Plasmodium falciparum* and *P. vivax* transmission. Using three consecutive longitudinal child cohorts, we investigated the impact of improved control measures on the changing patterns of $_{mol}$FOB, incidence of clinical illness and the cumulative prevalence of infections and to gain insight into how these metrics perform for the two-main species, *P. falciparum* and *P. vivax*. The cohorts included children 1-5 years of age and were conducted before (2006), during (2009) and after scale up of control interventions. Incidence analyses was conducted using the number of clinical episodes and molecularly determined new blood-stage infections in each interval between active case detection (ACD) time-points when

the child was considered at risk. Prevalence analyses was conducted using longitudinal binary outcomes measuring the presence of infection which were measured at each ACD time-point and diagnosed by microscopy and PCR. After scale-up, an immediate reduction in *P. falciparum* $_{mol}$FOB and incidence of clinical episodes, as well as *P. vivax* clinical episodes was observed. There was a delayed impact on *P. vivax* $_{mol}$FOB. After 5 years of intensified control, there was a marked reduction in the incidence of new infections by 73% for *P. falciparum* and 87% for *P. vivax*, and the incidence of clinical episodes by 90% and 88%, respectively. We demonstrate the utility of $_{mol}$FOB in measuring the impact of control interventions on transmission for the first time observing marked differences for *P. falciparum* and *P. vivax.*

748

MALARIA IN THE FIRST TRIMESTER OF PREGNANCY IS ASSOCIATED WITH NON-MALARIA FEVER DURING THE FIRST THREE MONTHS OF LIFE IN A BENINESE INFANT POPULATION

Gino C. Agbota[1], Manfred Accrombessi[1], Sem Ezinmegnon[2], Urbain Ahouayito[3], Basile Agossou[3], Achille Massougbodji[3], Laurence Ganee[4], Javier Yougueros Marcos[4], Alexandre Pachot[4], Pierre Tissieres[5], Nadine Fievet[6], Michel Cot[6], Valérie Briand[6]

[1]Centre d'Etude et de Recherche sur le Paludisme Associé à la Grossesse et à l'Enfant (CERPAGE); UMR216 / Institut de Recherche pour le Développement (IRD), Cotonou, Benin, [2]Centre d'Etude et de Recherche sur le Paludisme Associé à la Grossesse et à l'Enfant (CERPAGE); bioMérieux / UMR9198, Cotonou, Benin, [3]Centre d'Etude et de Recherche sur le Paludisme Associé à la Grossesse et à l'Enfant (CERPAGE), Cotonou, Benin, [4]Medical Diagnostic Discovery Departement (MD3), bioMérieux, Grenoble, France, [5]UMR 9198, Institut de biologie Intégrative de la cellule - Université Paris Saclay, Paris, France, [6]UMR216 / Institut de Recherche pour le Développement (IRD), Paris, France

Malaria in pregnancy (MiP) is responsible for maternal anemia, stillbirth, preterm birth and fetal growth restriction. While MiP has also been associated with a higher risk of malaria during infancy, few studies have evaluated its association with non-malaria fever. This study aims to assess the effect of MiP on the risk of non-malaria fever in infants from birth until 3 months of life, especially malaria in the 1st trimester of pregnancy, which is a period of high risk of malaria and of fetal and placental development. From 2014 to 2017, in southern Benin, women were followed from the pre-conception period until delivery (RECIPAL cohort) with monthly detection of malaria using thick blood smear (TBS). Then, a sub-sample of their newborns were followed up from birth until 3 months of age (SEPSIS cohort). Malaria in the 1st trimester of pregnancy was defined as the occurrence of at least one peripheral malaria infection before 15 weeks gestation (ultrasound data). In the child, a non-malaria fever episode was defined as the association of a temperature ≥37.5°C with a negative TBS (performed fortnightly, and anytime during follow-up in case of symptoms). A Poisson regression model was used to assess the effect of MiP in the 1st trimester on the number of child's non-malaria fever episodes. A total of 160 mother-child pairs were included in the analysis. The cumulative incidence of malaria in the 1st trimester of pregnancy was 15.1%. During the first 3 months of life, 20.6% of the children had at least one episode of non-malaria fever. They mainly consisted of moderate respiratory and gastrointestinal infections. After adjustment for potential maternal and infant confounding factors, malaria in the 1st trimester was statistically associated with a higher risk of non-malaria fever (adjusted incidence rate ratio=2.9; 95%CI: 1.5–5.5; p<0.01). Other factors associated with a higher risk of non-malaria fever were prematurity, maternal anemia and a low educational level. These results reinforce the need for the prevention of MiP, especially in early pregnancy, in order to reduce its consequences during infancy.

749

MAJOR RESURGENCE OF MALARIA FOLLOWS PREVIOUSLY UNPRECEDENTED DECLINE IN PAPUA NEW GUINEA

Manuel W. Hetzel[1], Olga P. Saweri[2], Joseph J. Kuadima[2], Iso Smith[2], Lina Lorry[2], Anthony Tandrapah[2], Sharon Jamea-Maiasa[2], Leanne J. Robinson[2], Peter M. Siba[2], Justin Pulford[3]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]Papua New Guinea Institute of Medical Research, Goroka & Madang, Papua New Guinea, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Malaria cases declined worldwide following increased investment in malaria control after the year 2000, but more recent data suggests that this decline has stalled. Papua New Guinea (PNG), long considered to harbor the highest malaria transmission outside of sub-Saharan Africa, made major progress in malaria control following the introduction of long-lasting insecticidal nets (LLIN) and the roll-out of artemisinin-based combination therapy (ACT). Malaria prevalence in the lowlands dropped from 11% in 2008-09 to <1% in 2013-14 and incidence of confirmed cases decreased. A country-wide Malaria Indicator Survey was conducted in 2016-17 to assess intervention coverage and prevalence of malaria in all age groups in comparison with data from previous national surveys (08-09, 10-11, 13-14). The survey was carried out in 102 villages including 2,743 households. A total of 11,358 blood samples were examined for malaria infection by light microscopy. Below 1600 m altitude, 7.1% of the population was infected with malaria parasites, up from 0.9% in 2013-14. Sub-national heterogeneity in prevalence was high. In the Highlands, malaria infections were rare and only found in adults (0.9%), suggesting importation of infections rather than local transmission. Infections with *Plasmodium falciparum* were more common than *P. vivax*. Compared to 2013-14, LLIN ownership (80%) and use (51%) remained largely unchanged and in the malarious lowlands one million people still lack access to an LLIN in their household. Treatment from a health facility was sought for 41% of recent fevers and a diagnostic test was performed in 23% of cases. The first-line ACT was used by 85% of test-positive persons. Malaria control efforts in PNG have suffered a major setback in the last three years. Vector control coverage has plateaued, access to prompt diagnosis and appropriate treatment remains poor and investment in malaria control has decreased. The longer-term goal of malaria elimination from PNG by 2030 is under threat unless malaria control is re-intensified without delay, inclusive of the provision of sufficient funding for interventions and supporting operational research.

THE EFFECT OF PHYSIOLOGICAL STATE ON POWASSAN VIRUS INFECTION OF SALIVARY GLAND CULTURES FROM FEMALE *IXODES SCAPULARIS* (BLACK-LEGGED TICK): A POTENTIAL ROLE FOR A PUTATIVE TICK TRANSCRIPT

Jeffrey M. Grabowski[1], Elizabeth R. Fischer[2], Daniel Long[3], Dana P. Scott[3], Marshall E. Bloom[1]

[1]Biology of Vector-Borne Viruses Section/Laboratory of Virology/Rocky Mountain Laboratories/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Hamilton, MT, United States, [2]Microscopy Unit/Research and Technologies Branch/Rocky Mountain Laboratories/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Hamilton, MT, United States, [3]Rocky Mountain Veterinary Branch/Rocky Mountain Laboratories/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Hamilton, MT, United States

The tick, *Ixodes scapularis*, transmits a number of pathogens, including *Borrelia burgdorferi* and tick-borne flaviviruses (TBFVs). TBFV infections cause thousands of human encephalitis cases worldwide each year. In the US, confirmed human infections with Powassan virus (POWV) have a fatality rate of 10-30% and are increasing. The attenuated Langat virus (LGTV) is often used as a convenient experimental TBFV model.

The tick salivary glands (SGs) serve as the primary organ barrier to TBFV transmission. Recent optimization of TBFV growth in *ex vivo* tick organ cultures allows a deeper understanding of virus biology in viable organs. Information on host proteins and cellular processes involved in TBFV infection of ticks is limited. Transcript knockdown of a putative tick gene, H576, decreased LGTV infection of *I. scapularis* ISE6 embryonic cells, suggesting a potential role for this hypothetical gene. The goals of this study were to advance these findings by using SG cultures with the pathogenic POWV and to compare the following in SG cultures from blood-fed and unfed ticks: (1) viability, (2) infectious TBFV replication, and (3) effect of transcript knockdown of H576 on POWV infection. SGs from blood-fed ticks were viable for three days less than SGs from unfed ticks. Infectious TBFV replication was higher in SGs from blood-fed than SGs from unfed ticks. This suggested that the tick's physiological state can alter TBFV replication. Transcript knockdown of H576 decreased infectious replication in POWV-infected SG cultures from both blood-fed and unfed ticks. Future research may include similar studies in tick midgut cultures and in TBFV-infected ticks to determine effect on TBFV infection and transmission. This research helps to identify novel host proteins as potential targets for countermeasure development against TBFV infection and transmission. In addition, this system may prove useful as a translational tool for identifying potential tick transcripts/proteins that can be used as targets for TBFV therapeutics. This research was supported by the Intramural Research Program of the NIH, NIAID.

THE ROLE OF DEER TICK SALIVARY MICRORNAS IN REGULATING POWASSAN VIRUS INFECTION

Meghan E. Hermance, Charles E. Hart, Erin S. Reynolds, Steven G. Widen, Thomas G. Wood, Saravanan Thangamani

The University of Texas Medical Branch, Galveston, TX, United States

Powassan virus (POWV) is a North American tick-borne flavivirus that is the causative agent of a severe neuroinvasive illness. POWV is transmitted to humans by infected ticks, and transmission of POWV can occur within three hours of *Ixodes scapularis* attachment. Successful tick feeding is facilitated by an assortment of bioactive salivary factors which are secreted into the feeding pool that the tick creates on the vertebrate host. It was previously shown that *I. scapularis* saliva facilitates POWV infection and influences the disease outcome for mice inoculated with a low dose of POWV; however, the specific tick salivary components responsible for enhancing POWV transmission have yet to be identified. The objective of this research is to identify and characterize exogenous *I. scapularis* salivary microRNAs (miRNAs) and their potential role in POWV infection. Distinct salivary gland miRNA expression profiles are related to tick blood feeding, and this research will be the first to evaluate specific tick salivary miRNAs for their role in regulating the host immune response and establishment of a pathogen. We hypothesize that the exogenous miRNAs in POWV-infected *I. scapularis* salivary glands regulate the host immune response to create an immunologically privileged microenvironment that facilitates the establishment of POWV infection. For the present study, we fed POWV-infected and uninfected *I. scapularis* females on naïve mice for 1, 3, and 6 hours (1 tick per mouse, n=6), and dissected the tick salivary glands at each time point. miRNAs were extracted from each tick salivary gland and submitted for next generation sequencing (NGS). After aligning the NGS reads from the 6 hour fed *I. scapularis* salivary glands to the *I. scapularis* miRNA database, 40 distinct known miRNAs were identified in both uninfected and POWV-infected tick salivary glands. NGS analysis is currently underway to identify known and novel exogenous salivary miRNAs that are differentially expressed upon POWV infection. Select *I. scapularis* salivary miRNAs will be examined for their potential to enhance POWV replication and the host immunologic response *in vitro*.

752

RISK FACTOR COMPARISON OF HUMAN-TICK ENCOUNTERS BETWEEN LYME DISEASE ENDEMIC AREAS OF THE NORTHEAST AND MIDWEST UNITED STATES

Gebbiena M. Bron[1], Maria P. Fernandez[2], Pallavi A. Kache[2], Scott R. Larson[1], Lyric C. Bartholomay[1], Jean I. Tsao[3], Maria I. Diuk-Wasser[2], Susan M. Paskewitz[1]

[1]University of Wisconsin - Madison, Madison, WI, United States, [2]Columbia University, New York City, NY, United States, [3]Michigan State Universtiy, East Lansing, MI, United States

Disease dynamics and prevention strategies are often extrapolated beyond the area, state or country studied in an effort to find a one size fits all control method. However, the dynamics of zoonotic vector-borne diseases are determined by a complex set of parameters including human behavior that may vary within socio-ecological contexts. In the case of Lyme disease, anthropogenic factors affect the enzootic transmission cycle of *Borrelia burgdorferi* and the populations of its vector, *Ixodes scapularis*, including changes in land use and habitat, which in turn affect the likelihood of tick-human contact and human infection. Here we compare the behavioral risk factors associated with human-tick encounters between highly endemic areas for tick-borne diseases in the Northeast and Midwest of the United States, with different landscape configurations, and compare the relative importance of peridomestic versus recreational risk between both regions. We also hypothesize that human behavior will vary between the two areas, especially in regards to self-protection and interactions with animal hosts; for example, practicing rodent control and implementing deer deterrents versus attracting small mammal reservoirs and baiting deer. Using a novel smartphone application, The Tick App, as a survey tool, we collected fine temporal and spatial data regarding daily outdoor activities, tick encounters and protection methods. During spring and summer of 2018, The Tick App was made available to the public, and implemented in two communities in each region, where participants were actively recruited to use the application in combination with an acarological assessment of their backyards. Within each region, the selected sites vary in levels of Lyme and babesiosis endemicity from emerging to endemic, demographics, and land cover/land use, from urban (Staten Island, NY) to rural. The comparison of environmental and human risk factors for encountering ticks, and by extension tick-borne diseases, between two highly endemic regions will help inform regionally tailored prevention tool development and public health messaging.

753

ECOLOGICAL FACTORS DRIVING THE EMERGENCE OF BABESIOSIS IN THE UNITED STATES: THE ROLE OF CONFECTION AND ALTERNATIVE TRANSMISSION PATHWAYS

Maria A. Diuk-Wasser[1], Danielle Tufts[1], Ana Bento[2]

[1]Columbia University, New York, NY, United States, [2]University of Georgia, Athens, GA, United States

Babesiosis continues to increase in incidence as well as expand geographically on the heels of the Lyme disease epidemic. The incidence of babesiosis is significantly lower than that of Lyme disease (~1,700 cases/year compared to ~30,000 Lyme disease cases/year). However, increased infection of the shared blacklegged tick vector with *Babesia microti* in some regions suggests future increases in human disease or the presence of significant underdiagnosis and underreporting. We hypothesize two non-exclusive mechanism could enhance *B. microti* transmission in the natural cycle: a positive effect of *B. burgdorferi* coinfection on *B. microti* in mice - as we previously demonstrated in a laboratory setting - or a 'cryptic' transmission pathway. To evaluate these alternatives, we conducted a 3-year (2004-16) longitudinal study at six sites in Connecticut and Block Island, RI. Between May and August each year, small mammals were trapped biweekly; 1,245 unique individuals were trapped. We a suite of used mixed effects models to inform spatio-temporal and

demographic covariate choice and multi-state markov models to infer interactions and transmission. We detected a potential facilitative effect between pathogens, mediated by demographic structure. In addition, the higher prevalence of *B. microti* suggested alternative, non-vector mediated transmission pathways, consistent with our previous detection of transplacental transmission of *B. microti*. Our results indicate both mechanisms are partially implicated in the increased tick infection with *B. microti* and consequent increased risk of babesiosis. At the regional level, these mechanisms may facilitate the invasion and persistence of *B. microti* in previously unoccupied locations or areas with reduced tick populations.

COME RAIN OR COME SHINE. DIFFERENTIAL SPATIOTEMPORAL DYNAMICS OF SCRUB TYPHUS AND MURINE TYPHUS IN THE LAO PDR

Tamalee Roberts[1], Sayaphet Rattanavong[1], Ivo Elliot[1], Koukeo Phommasone[1], Mayfong Mayxay[1], Vilada Chansamouth[1], Anousin Homsana[1], Matthew Robinson[1], Stuart Blacksell[2], Daniel Parker[3], Paul N. Newton[1]

[1]Lao-Oxford-Mahosot hospital- Wellcome-Research unit, Vientiane, Lao People's Democratic Republic, [2]Mahidol- Oxford- Research Unit, Bangkok, Thailand, [3]University of California Irvine, Irvine, CA, United States

Scrub typhus and murine typhus are endemic to South and South East Asia and are a major causes of treatable febrile illness. In this study we analysed the annual patterns of incidence of scrub typhus and murine typhus in Lao PDR (Laos) and the spatiotemporal dynamics from reported patients. Serology and PCR data from consenting febrile patients admitted to Mahosot Hospital between 2004 and 2016 with suspected typhus were analysed with demographic, clinical, weather and geographical data. These data were then tested against equivalent data from three Lao provincial hospitals. Over the 12 year period, 820 scrub typhus and 559 murine typhus patients were identified. The median days of fever was 7 days (range 0-60 days) and the median age was 30 years (range 1.8- 80 years). The proportion of scrub typhus patients with an eschar identified was 19%. The majority of patients came from Vientiane Capital Province (71%) followed by Vientiane Province (16%). There was a peak in number of patients with murine typhus in 2009 and 2010 while there was a dramatic increase in scrub typhus cases in 2011 from 56 cases in 2010 to 174 in 2011. Scrub typhus patient presentations peaked in the wet season months of July and August while murine typhus was most frequent in the hot, dry months of March to May. The full differential spatiotemporal results for both murine typhus and scrub typhus will be presented in relation to weather and habitat and tested against data from Lao provincial hospitals. This is the first study to look at the dynamics of geography and temporal conditions for the prevalence of scrub and murine typhus in Lao PDR. With increasing concern of the global spread of scrub typhus and of the focal importance of murine typhus, knowledge of temporal and spatial patterns will inform targeted public health interventions for environments and seasons of high burden.

755

DIAGNOSIS OF SPOTTED FEVER GROUP RICKETTSIOSES IN UNITED STATES TRAVELERS RETURNING FROM AFRICA, 2007—2016

Cara Cherry, Amy Denison, Cecilia Kato, Katrina Thornton, Christopher Paddock

Centers for Disease Control, Atlanta, GA, United States

Spotted fever group rickettsioses (SFGR), such as African tick bite fever (ATBF), are among the most commonly diagnosed diseases for ill travelers returning from southern Africa. We summarized demographic, clinical, and diagnostic features of imported SFGR cases in U.S. travelers returning from Africa that had laboratory specimens submitted to the Centers for Disease Control and Prevention. Diagnosis of SFGR was performed by indirect immunofluorescence antibody assay, immunohistochemical staining, PCR, or culture. Cases defined as probable SFGR, confirmed SFGR, or confirmed ATBF. Clinical and epidemiological categorical variables were described as counts and proportions; continuous variables were described using geometric mean titers (GMT), median, and range. 127 patients satisfied laboratory criteria for confirmed or probable SFGR. Fever was the most common symptom (n = 88; 69%), followed by ≥ 1 eschars (n = 70; 55%). Paired serums were submitted for 36 patients (28%); 12 patients (33%) had non-reactive initial serum sample, but converted to a titer ≥ 64 with the convalescent sample. 27 patients (21%) had infection with *R. africae* based on PCR analysis of eschar swab (n = 8) or biopsy (n = 23). 15 patients had eschar biopsy or swab samples and serum sample(s) submitted together; 9 (60%) had PCR-positive eschar results and non-reactive acute serology. Healthcare providers should consider SFGR when evaluating patients for a febrile illness with eschar and compatible foreign travel history. PCR testing of eschar biopsies or swabs provides a confirmed diagnosis in early stages of disease; eschar swabs or biopsies are an underutilized diagnostic technique.

756

TRANSCRIPTIONAL RESPONSE OF THE RAT FLEA, *XENOPSYLLA CHEOPIS*, TO BLOOD FEEDING AND INFECTION WITH *YERSINIA PESTIS*

David M. Bland[1], Kimmo Virtaneva[2], Daniel P. Bruno[2], Kishore Kanakabandi[2], Craig A. Martens[2], Jose M. Ribeiro[3], B. Joseph Hinnebusch[1]

[1]Laboratory of Bacteriology, Rocky Mountain Laboratories, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Hamilton, MT, United States, [2]Genomics Unit, Research Technologies Branch, Rocky Mountain Laboratories, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Hamilton, MT, United States, [3]Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States

Yersinia pestis, the causative agent of plague, is a highly lethal pathogen transmitted by the bite of infected fleas. *Xenopsylla cheopis*, the rat flea, is a vector of several zoonotic bacterial pathogens that in addition to *Y. pestis,* includes *Bartonella* spp. and *Rickettsia typhi*. Once ingested by a flea, these pathogens must overcome host immunity, establish a replicative niche in the gut, and alter gene expression to promote survival and transmission. However, the rat flea genome has not been sequenced and the nature and kinetics of the gut immune response to bacterial infection remains poorly characterized. To address this, groups of *X. cheopis* fleas were fed sterile Brown Norway rat blood, or rat blood containing $5x10^8$ CFU/ml *Y. pestis* KIM6+ using an artificial membrane feeding device. The midgut and proventriculus was dissected from 10 fleas from each group 4h after feeding, and from a third group of fleas that had not fed for 5 days. RNA was extracted from pooled digestive tracts and the transcriptional profiles were determined by next-generation RNA sequencing and *de novo* transcriptome assembly. Analysis of differentially expressed transcripts indicates that expression of antimicrobial peptides (attacin and coleoptericin), chitin-binding proteins (peritrophins), and a serine protease (chymotrypsin) is upregulated in digestive tract epithelial cells in response to infection with *Y. pestis*. Interestingly, fleas are not thought to produce a peritrophic matrix (PM); thus, the upregulation of peritrophin genes that are frequently integral to PM formation was unexpected. Upcoming studies will use histochemistry and confocal microscopy to image the *X. cheopis* midgut and determine whether a PM is produced. Cumulatively, the data indicate that the immune deficiency pathway (IMD) regulates early flea immune responses to infection. RT-qPCR studies are underway to determine expression kinetics of peritrophin and IMD-regulated transcripts during the first 24h of infection. Mechanistic understanding of flea gut immunity and physiology may lead to unique strategies to block transmission of flea-borne pathogens.

757

WORMS AND WELLBEING: 15 YEAR ECONOMIC IMPACTS FROM KENYA

Sarah Baird[1], Joan Hicks[2], Michael Kremer[3], Edward Miguel[4]

[1]George Washington University, Washington, DC, United States, [2]University of Oklahoma, Norman, OK, United States, [3]Harvard University, Cambridge, MA, United States, [4]University of California Berkeley, Berkeley, CA, United States

Estimating the impact of child health investments on adult living standards faces several major methodological challenges, including the paucity of experimental interventions for which it is feasible to locate participants many years later, as well as difficulties in accurately measuring economic outcomes. This study exploits a randomized school health intervention that provided deworming treatment to Kenyan children. We estimate impacts on their living standards and wellbeing 15 years later, at which point the effective respondent tracking rate was 85%. In our main finding, we show that deworming beneficiaries experience a large and persistent 15% gain in total adult earnings. Treatment group individuals also have significantly higher total consumption expenditures, are more likely to live in urban areas, and are more likely to state that they are "very happy" in surveys. Given deworming's extremely low cost, a conservative estimate of deworming's annualized social internal rate of return is 42.5%.

758

RISK FACTORS FOR INFECTION WITH SOIL TRANSMITTED HELMINTHS INTIMOR-LESTE: A LONGITUDINAL ANALYSIS DURING A COMMUNITY INTEGRATED WASH ANDDEWORMING INTERVENTION

Susana Vaz Nery[1], Naomi E. Clarke[1], James S. McCarthy[2], Rebecca Traub[3], Alice Richardson[1], Darren J. Gray[1], Suzy J. Campbell[1], Andrew J. Vallely[4], Gail M. Williams[5], Ross M. Andrews[6], Archie C. Clements[1]

[1]Australian National University, Canberra, Australia, [2]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [3]The University of Melbourne, Melbourne, Australia, [4]University of New South Wales, Sydney, Australia, [5]The University of Queensland, Brisbane, Australia, [6]Charles Darwin University, Darwin, Australia

Ascaris spp., hookworm (*Necator americanus, Ancylostoma duodenale* and *A. ceylanicum*) and *Trichuris trichiura* are the most common soil transmitted helminths (STHs). Given their faecal-oral route of transmission and direct penetration of the skin by hookworm, STHs are common in poor communities. Factors previously shown to be associated with infection are poor sanitation, lack of water, deficient hygiene and low socio-economic index. In the WASH for WORMS cluster randomised controlled trial, 23 communities (clusters) received a deworming intervention consisting of albendazole administered to all eligible residents every 6 months for two years. Additionally, 11 intervention clusters received a WASH programme that included improving water access, increasing improved household sanitation, and promoting hand-washing with soap. We have previously published a cross-sectional analysis reporting on WASH risk factors associated with STH infection at trial baseline. Here we report the results of a WASH risk factor analysis including all four time-points of the RCT after intervention implementation, spanning a two-year period. Surprisingly, for *Ascaris* spp., no associations were found between STH infection and individual sanitation or hygiene variables nor household sanitation variables. Disposal of household garbage by digging or burying resulted in higher odds of infection. For school-aged children, using a toilet at school was associated with higher odds of infection. For *N. americanus*, practising open defecation at the previous time point was a risk factor, while wearing shoes indoors was protective and there were no significant associations with household or school sanitation variables. For both *Ascaris* spp. and *N. americanus*, using an unprotected spring or dugwell or surface water was associated with higher odds of infection, while using a water source more than 15 minutes away resulted in lower odds. This study adds to the body of evidence exploring the links between WASH related conditions and behaviours and the risk of STH infection.

ULTRASENSITIVE DETECTION OF *TOXOCARA CANIS* EXCRETORY-SECRETORY ANTIGENS BY A NANOBODY ELECTROCHEMICAL MAGNETOSENSOR ASSAY

Francisco Morales-Yánez[1], Trashin Stanislav[2], Hermy Marie[3], Sariego Idalia[4], De Wael Karolien[2], Polman Katja[3], Muyldermans Serge[5]

[1]Vrije Universiteit Brussel, Brussel, Belgium, [2]University of Antwerp, Antwerp, Belgium, [3]Institute of Tropical Medicine Antwerp, Antwerp, Belgium, [4]Institute of Tropical Medicine Pedro Kourí, Havana, Cuba, [5]Vrije Universiteit Brussel, Brussels, Belgium

Human Toxocariasis (HT) is a zoonotic disease caused by the migration of the larval stage of the roundworm *Toxocara canis* in the human host. Despite of being the most cosmopolitan helminthiasis worldwide, its diagnosis is elusive. Currently, the detection of specific immunoglobulins IgG against the *Toxocara* Excretory-Secretory Antigens (TES), combined with clinical and epidemiological criteria is the only strategy to diagnose HT. Cross-reactivity with other parasites and the inability to distinguish between past and active infections are the main limitations of this approach. Here, we present a sensitive and specific novel strategy to detect and quantify TES, aiming to identify active cases of HT. High specificity is achieved by making use of nanobodies (Nbs), recombinant single variable domain antibodies obtained from camelids, that due to their small molecular size (15kDa) can recognize hidden epitopes not accessible to conventional antibodies. High sensitivity is attained by the design of an electrochemical magnetosensor with an amperometric read-out with all components of the assay mixed in one single step. Through this strategy, 10-fold higher sensitivity than a conventional sandwich ELISA was achieved. The assay reached a limit of detection of 2 and15 pg/ml in PBST20 0.05% or serum, spiked with TES, respectively. These limits of detection are sufficient to detect clinically relevant toxocaral infections. Furthermore, our nanobodies showed no cross-reactivity with antigens from *Ascaris lumbricoides* or *Ascaris suum*. This is to our knowledge, the most sensitive method to detect and quantify TES so far, and has great potential to significantly improve diagnosis of HT. Moreover, the characteristics of our electrochemical assay are promising for the development of point of care diagnostic systems using nanobodies as a versatile and innovative alternative to antibodies. The next step will be the validation of the assay in clinical and epidemiological contexts.

760

LONGITUDINAL CHANGES IN RISK AND INTENSITY OF INFECTION WITH SOIL-TRANSMITTED HELMINTHS AFTER COMMUNITY-WIDE MASS DRUG ADMINISTRATION IN RURAL MYANMAR

Julia C. Dunn[1], Alison A. Bettis[1], Nay Yee Wyine[2], Aye Moe Moe Lwin[3], Aung Tun[4], Nay Soe Maung[3], Roy M. Anderson[1]

[1]Imperial College London, London, United Kingdom, [2]Myanmar NTD Research Collaboration, Yangon, Myanmar, [3]University of Public Health, Yangon, Myanmar, [4]Ministry of Health and Sports, Naypyitaw, Myanmar

Mass drug administration (MDA) targeted at school-aged children is the method recommended by the WHO for soil-transmitted helminth (STH) control in endemic countries. However, MDA alone does not prevent reinfection between treatments. In endemic countries that have been providing MDA for many years, such as Myanmar, the levels of reinfection will determine how effective MDA is in suppressing infection in the long-term. Longitudinal data from three STH epidemiology surveys, conducted between June 2015 and June 2016 in the delta region of Myanmar, were

analysed to determine the risks of STH infection in the whole community, including two MDA rounds. Risk ratios (RRs) were calculated to compare risks of infection with each STH between different time points. Mean change in eggs per gram of faeces (EPG) were calculated for each age group. Overall STH prevalence fell by 8.99% from the first to the last survey. However, EPG only significantly decreased for hookworm. RRs for any STH infection were 0.68 for survey 1 to 2 (four months reinfection) and 1.0 for survey 2 to 3 (six months reinfection). Age and sex stratified RRs for the four-month reinfection period were generally below one, whereas RRs for the six-month reinfection period were above one, indicating that more people were infected after six months reinfection post-MDA. Mean EPG generally decreased between the surveys in all age groups. However, *Ascaris lumbricoides* and *Trichuris trichiura* EPG increased between surveys 2 and 3 in the 5-14 age group. This analysis demonstrates that there is a significant increase in risk of STH reinfection after six months compared to four months. Whilst STH prevalence decreased over the course of the study, EPG did not significantly decrease for *A. lumbricoides* and *T. trichiura*. This potential increase in infection risk is important and requires further investigation, especially as MDA programmes are known to experience delays in treatment due to competing priorities, lack of staff/resources, delay in drug delivery, etc. MDA in Myanmar may need to be either expanded or the frequency increased to prevent reinfection and achieve sustainable reductions in STH infection.

GLOBAL STATE OF INEQUITY IN DEWORMING COVERAGE IN LOW-INCOME AND MIDDLE-INCOME COUNTRIES: A SPATIOTEMPORAL STUDY OF HOUSEHOLD HEALTH SURVEYS

Nathan C. Lo[1], Sam Heft-Neal[2], Jean T. Coulibaly[3], Eran Bendavid[1], David G. Addiss[4]

[1]Stanford University School of Medicine, Stanford, CA, United States, [2]Stanford University, Stanford, CA, United States, [3]Swiss Tropical and Public Health Institute, University of Basel, Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Université Félix Houphouët-Boigny, Abidjan, Côte D'Ivoire, [4]Task Force for Global Healthedicine, Decatur, GA, United States

Over the past 15 years, deworming programs for soil-transmitted helminths have scaled up across many low and middle-income countries. Deworming has become a major focus of global public health programs and is designed to be "pro-poor." This study quantifies inequities in receipt of deworming across and within countries over time to guide future policy and investment. We used nationally representative, geospatial survey data from pre-school age children (age 1-4 years) contained in the Demographic and Health Surveys from 2003-2016. Deworming was measured using the mother's report of whether her child received drugs for intestinal parasites in the previous 6 months. We used the mother's location to map geospatial variation in deworming coverage. We computed predictors of receipt of deworming, and assessed inequity by disaggregating deworming by wealth quintile and gender, computing a country-level wealth concentration index (measure of inequity), and examining trends across space and time. We included 372,050 pre-school children from 45 endemic countries. Of these, 46.5% were reported by their mothers to have received deworming during the previous 6 months. Deworming coverage varied by country, from 8.1% in Zimbabwe (2010) to 91.1% in Rwanda (2014), and varied substantially within countries and over time. Dewormed children were more likely to be older, wealthier, and have mothers that were older and more educated; rural residence was only weakly predictive of deworming. Globally, deworming increased monotonically with family wealth, ranging from 42.8% in the lowest quintile to 51.9% in the highest. We found a positive wealth concentration index (deworming concentrated in the wealthy) in 41 of 45 countries. Deworming equity improved over time in the majority of countries and deworming was equitable by gender. Although deworming pre-school age children is considered "pro-poor", these data suggest that, in most countries, deworming coverage is lowest among the poorest children. These inequities appear to be improving over time and we found no evidence of gender-related inequity. This study can be used to monitor deworming equity over time.

MIGRATION AND LOCAL MOVEMENT CAN IMPEDE ELIMINATION EFFORTS OF SOIL-TRANSMITTED HELMINTHS (STH) BY MASS DRUG ADMINISTRATION (MDA)

Carolin Vegvari[1], Klodeta Kura[1], James Truscott[1], Alison Ower[1], Rachel Pullan[2], Katherine Halliday[2], Roy Anderson[1]

[1]Imperial College London, London, United Kingdom, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom

Soil-transmitted helminth (STH) infections affect predominantly socio-economically disadvantaged populations in sub-Saharan Africa, East Asia and the Americas. One of the WHO 2020 goals is the elimination of STH as a public health problem, defined as reducing the prevalence of medium-to-heavy STH infection among school-aged children (SAC) to less than 1%. WHO guidelines recommend 75% coverage among pre-SAC and SAC to achieve this goal. Previous epidemiological studies, in part based on mathematical models, have evaluated optimal intervention strategies of mass drug administration (MDA) to clusters of villages. These studies assumed that villages are closed independent units with no movement of people in or out of communities. Here we examine how local and regional migration, for example, of seasonal migrant labourers, and local movement among villages within the same regional cluster affect the outcome of MDA programmes. We derive migration rates from the Tumikia trial dataset that includes records of the movements of individuals and GPS mapping of households in the region. We show that even if on average 80% of the entire resident population within a village cluster are treated, an inward migration rate of defined sizes of infected individuals per treatment cycle can prevent STH elimination in this cluster. We detail calculations of these migration rates that prohibit elimination of transmission for low, medium and high transmission settings. We also show that local movements, for example, children's daily trips to school, can reduce the effectiveness of MDA programmes if schools are located outside of treated clusters or represent transmission hotspots with high amounts of contaminated infectious material in the environment within treated clusters. In general, if STH prevalences in villages within a regional treatment cluster are very heterogeneous, frequent movements among villages within a cluster may postpone the time when elimination is reached during MDA programmes. We discuss what measures can mitigate these migration inputs that can sustaining transmission.

Recherche en Hémato-Immunologie (SRHI), Hôpital Saint-Louis, IUH, Paris, France

HLA-G plays a key role on immune tolerance. Pathogens can induce soluble HLA-G (sHLA-G) production to down-regulate the host immune response, creating a tolerogenic environment favorablefor their dissemination. To our knowledge, no study has yet been conducted to assess the relationship between sHLA-G and geohelminth infections. The study was conducted in Allada, Southeastern Benin, from 2011-2014. The study population encompassed 400 pregnant women, included before the end of the 28th weekof gestation and followed-up until delivery. At two antenatal care visits and at delivery, stool and blood samples were collected. Helminths were diagnosed by means of the Kato-Katz concentration technique. We used quantile regression to analyze the association between helminth infections and sHLA-G levels during pregnancy. sHLA-G levels gradually increased during pregnancy and reachedmaximal levels at delivery. Prevalence of helminth infections was low, with a majority of hookworm infections. We found significantly more hookworm-infected women above the 80th quantile (Q80) of the distribution of the mean sHLA-G level ($p<0.03$, multivariate quantile regression). Considering only women above the Q80 percentile, the mean sHLA-G level was significantly higher in hookworm-infected compared to uninfected women ($p=0.04$). In our study, we found that high levels of sHLA-G were associated with hookworm infection in pregnant women. This result is consistent with the potential involvement of sHLA-G in immune tolerance induced by helminths during pregnancy.

Over the past several decades dengue has become hyper-endemic in all tropical and sub-tropical regions of the world. Current estimates report nearly 100 million symptomatic and 300 million asymptomatic dengue infections annually. We have evaluated the live attenuated tetravalent (LATV) candidate dengue vaccines TV003 and TV005 in hundreds of dengue-naïve and dengue-exposed individuals in the United States, Thailand, and Bangladesh. A single dose of either vaccine was 100% efficacious against challenge with DENV-2 administered 6 months after vaccination in a controlled human infection model (CHIM). TV003 is currently in Phase 3 clinical trial enrolling 17,000 participants in Brazil. In the current clinical trial, we sought to evaluate the early efficacy of TV003 against DENV-2 and DENV-3 using our dengue CHIM. We enrolled 60 subjects in a randomized, double-blind, placebo-controlled trial. At study day 0, 40 subjects received TV003 and 20 subjects received placebo. At study day 28, 30 subjects received 10^3 PFU of DENV-2 and 30 subjects received 10^3 PFU DENV-3. Subjects were evaluated approximately every other day in the clinic through Day 16 post-vaccination and then on Study days 21 and 28 (Day of challenge). The returned to the clinic approximately every other day through day 16 post-challenge and 21, 28, 56, 90, and 180 days post-challenged. Blood was drawn for clinical laboratory assays and for the recovery of vaccine or challenge virus through Study day 21 post-vaccination and post-challenge. Blood was drawn for immunology and several time-points post-vaccination and post-challenge. The primary efficacy endpoint was protection against viremia induced by either DENV-2 or DENV-3. Secondary endpoints included protection against rash and neutropenia. Clinical, virologic, and serologic data post-vaccination and post-challenge and the efficacy against DENV-2 and DENV-3 will be reported. Results from this study will be informative to better understanding the early development of a protective immune response to the usefulness of this candidate vaccine for travelers.

UTILIZING THE DENV HUMAN CHALLENGE MODEL TO DEFINE THE MOLECULAR DETERMINANTS OF THE MEMORY B CELL RESPONSE FOLLOWING HETEROLOGOUS DENV INFECTIONS

Ciara Gimblet-Ochieng[1], Huy A. Tu[2], Jesica A. Swanstrom[3], Sean A. Diehl[2], Stephen S. Whitehead[4], Anna P. Durbin[5], Ralph S. Baric[3], Aravinda M. de Silva[1]

[1]Department of Microbiology and Immunology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [2]Department of Medicine-Infectious Diseases and Vaccine Testing Center, University of Vermont, Burlington, VT, United States, [3]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [4]Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [5]Johns Hopkins Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States

Dengue virus (DENV) is a mosquito-borne flavivivirus responsible for the syndromes dengue fever (DF), dengue hemorrhagic fever (DHF), and dengue shock syndrome (DSS). Vaccine efforts have been complicated by varying protection against all 4 serotypes of the virus and poor performance in DENV naïve individuals. Individuals who have experienced naturally occurring secondary infections develop DENV serotype cross-reactive strongly neutralizing antibodies (Abs), but it remains unclear how these responses are formed, what targets they recognize, and how they are maintained over time. In this study we utilize a human challenge model, in which subjects were infected with an attenuated DENV1 (n = 6) strain or placebo (n = 2), followed by an attenuated DENV2 strain 9 months later. Plasma and PBMC samples were collected at various time-points before and after the second infection. To examine how the DENV serotype cross-reactive (CR) and type-specific (TS) neutralizing Ab responses evolve following sequential DENV infections, we used antibody depletion assays, and neutralization assays with recombinant chimeric DENVs. Following the primary DENV1 infection, the majority of the neutralizing Ab response (79.7%) was directed TS epitopes on DENV1. In 4/6 subjects, the DENV1 TS neutralizing Ab response mapped to an antigenic site on domain I of the envelope protein defined by human MAb 1F4. Following the secondary DENV2 infection, individuals developed high levels of neutralizing Abs to all 4 serotypes. The majority of the DENV1 (76.8%), DENV2 (86%), DENV3 (98.7%) and DENV4 (97.8%) neutralizing antibodies recognized epitopes that were conserved (cross-reactive) between serotypes. Studies to map the conserved epitopes recognized by serum neutralizing Abs and memory B cells are ongoing. Our results provide valuable information about how the memory B cell response develops following heterologous DENV infections to provide cross-reactive and protective immunity.

A RANDOMIZED, CONTROLLED AGE DE-ESCALATION TRIAL DEMONSTRATES THAT THE TETRAVALENT DENGUE VACCINE TV005 IS SAFE AND IMMUNOGENIC IN DENGUE-ENDEMIC BANGLADESH

Mary Claire R. Walsh[1], Rashidul Haque[2], Marya P. Carmolli[1], Dorothy M. Dickson[1], Mohammad Shaiful Alam[2], Masud Alam[2], Sajia Afreen[2], Daniel M. Bak[1], Sean A. Diehl[1], Kristen K. Pierce[1], Mohammad Golam Kibria[2], Anna P. Durbin[3], Stephen S. Whitehead[4], Beth K. Kirkpatrick[1]

[1]Larner College of Medicine, University of Vermont, Burlington, VT, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh,

Dhaka, Bangladesh, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [4]Laboratory of Infectious Diseases, National Instititue of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Over half the world's population is at risk of dengue virus infection. Each of the four dengue serotypes can cause the full spectrum of disease ranging from asymptomatic infection to life-threatening illness characterized by plasma leakage and vascular collapse. Dengue was first reported in Dhaka, Bangladesh in the 1960s and our data from a recent seroprevalence study in Dhaka demonstrates that 68% of adults have evidence of exposure to one or more serotypes. The NIH live attenuated tetravalent TV005 vaccine has been examined extensively in US-based studies, but evaluation in both naïve and previously exposed endemic populations is critical. As such, we sought to evaluate the safety and immunogenicity of TV005 in Dhaka. We performed a placebo-controlled, double-blind, age de-escalation study in Dhaka and enrolled 192 participants with 48 participants in each of four age cohorts (36 TV005, 12 placebos). Following dosing, participants were re-evaluated on days 7, 14, 28, 56, 180, 360, 720 and 1080. Adverse events were recorded through day 28. Viremia (days 7 and 14) and immunogenicity (days 0, 28, 56, and 180) were evaluated. All cohorts have completed one year of follow-up; surveillance for dengue infection remains ongoing through the 3-year study follow-up. TV005 was well-tolerated; no differences were observed in fever, headache, or safety labs (WBC, ANC, platelets, ALT, or PT/PTT) between treatment arms. An asymptomatic rash occurred more frequently in TV005 recipients ($p = 0.04$). Using culture-based methods, six (4.2%) vaccine recipients were viremic by day 14, with a mean peak titer of 0.5 $\log_{10}$ PFU/mL. In the youngest two age cohorts, 95% (5-10 years of age) and 97% (1-5 years) had a trivalent or better response. A tetravalent response was seen in 64% and 72% of these same cohorts, respectively. Serologic data on the older cohorts is forthcoming. In this endemic region, data demonstrate that TV005 is well-tolerated and elicits a balanced serologic response in children. For the NIH tetravalent dengue vaccine, these data contribute to the understanding of safety and immunogenicity in naïve or partially-immune subjects in endemic regions.

767

SAFETY AND IMMUNOGENICITY OF DIFFERENT FORMULATIONS OF A TETRAVALENT DENGUE PURIFIED INACTIVATED VACCINE (DPIV) IN HEALTHY ADULTS FROM PUERTO RICO THROUGH THREE YEARS OF FOLLOW-UP

Michael Koren[1], Clemente Diaz[2], Leyi Lin[1], Luis J. Martinez[1], Kenneth H. Eckels[1], Maribel Campos[2], Richard G. Jarman[1], Rafael De La Barrera[1], Edith Lepine[3], Irma Febo[2], Bruce L. Innis[3], David W. Vaughn[3], Todd M. Wilson[3], Alexander C. Schmidt[3], Robert Paris[3], Stephen J. Thomas[1]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]University of Puerto Rico School of Medicine, San Juan, Puerto Rico, [3]GSK, Rockville, MD, United States

We report here the final results after a 3-year follow-up of a Phase 1, observer-blind study (NCT01702857) aimed to assess the safety and immunogenicity of 2 doses of an investigational tetravalent DPIV in Puerto Rico. One-hundred healthy adults (predominantly dengue virus [DENV]-primed) were randomized 1:1:1:1:1 to receive saline placebo or 1 of 4 DPIV formulations (1µg per DENV type adjuvanted with aluminum hydroxide [Alum], $AS01_E$ or $AS03_B$, or 4µg per DENV type adjuvanted with Alum) at day (D) 0 and D28. Serious adverse events (SAEs), potential immune-mediated diseases (pIMDs), medically-attended AEs (MAEs), and clinical DENV cases were recorded up to study end (year [Y] 3 post-vaccination). Functional antibody responses were determined by microneutralization assay at various time points. Two participants in the 4µg+Alum group reported 4 SAEs, and 2 in the placebo group reported 5 SAEs up to month (M) 14; all were considered unrelated to vaccination. No SAEs were reported during Y2 and Y3 follow-up. Two cases of auto-immune thyroiditis (placebo: 1; 1µg+$AS01_E$: 1) and worsening of pre-existing rheumatoid arthritis (1µg+$AS03_B$) were reported up to M14, and 1 case of rheumatoid arthritis (1µg+$AS03_B$) and reactive arthritis (1µg+Alum) up to Y3; no pIMDs were considered vaccination-related. Forty-eight participants reported MAEs up to M14, without notable differences across groups, and 2 in the Y2 and Y3 follow-up. Fourteen cases of suspected dengue disease, all negative by RT-qPCR, were reported by 9 participants. The Y3 per-protocol immunogenicity cohort included 79 participants (76 seropositive for ≥1 DENV type). Geometric mean titers (GMTs) against DENV types 1-4 at Y2 and Y3 post-vaccination waned slightly from M13 levels, but remained mostly higher than pre-vaccination, with highest GMTs for 1µg+$AS03_B$ (1220, 921, 819, 941 at Y2; 1329, 1169, 1220, 719 at Y3 for DENV types 1-4, respectively). Increased GMTs were observed at Y3 post-vaccination for placebo, consistent with seasonal exposure to dengue or other flavivirus infections. All DPIV formulations were well tolerated and no safety signals were identified during the 3-year follow-up.

768

CELL-MEDIATED IMMUNITY GENERATED BY TAKEDA'S LIVE-ATTENUATED DENGUE VACCINE (TDV)

Jeffrey R. Currier[1], Heather Friberg[1], Vianney Tricou[2], Michael Egan[3], Kaitlin Victor[1], Kristin Hatch[1], Jenny Low[4], Helen Oh[5], Richard Jarman[1], Derek Wallace[6], Hansi Dean[3]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]Takeda Vaccines, Pte. Ltd., Singapore, Singapore, [3]Takeda Vaccines, Inc., Cambridge, MA, United States, [4]Tan Tock Seng Hospital, Singapore, Singapore, [5]Changi General Hospital, Singapore, Singapore, [6]Takeda Pharmaceuticals International AG, Zurich, Switzerland

A Phase II study (DEN-205) was performed to test the impact of dosing and sero-status on the performance of Takeda's tetravalent dengue vaccine candidate (TDV) in a dengue endemic location. Here we report that potent cell-mediated immunity (CMI) was generated after a single dose of the vaccine, independent of vaccine formulation and baseline sero-status. For testing, PBMC collected pre-vaccination (day 1) and at months 1, 6 and 12 post-vaccination were assessed for vaccine-induced responses using an IFNγ ELISpot assay. Peptide pools matching all vaccine components - the complete DENV-2 proteome (C, prM/E, NS1, NS2, NS3, NS4, and NS5) and prM/E from DENV-1, -3 and -4 – were used as antigens for testing. In addition, peptide pools matching the NS1, NS3 and NS5 proteins from DENV-1, -3 and -4 were used to assess serotype-cross-reactivity of vaccine induced responses. Potent IFNγ ELISpot responses were detected at month 1 and demonstrated durability out to 12 months post-vaccination. Response rates of >90% were detected in the TDV vaccine formulation recipients at 6 and 12 months post-vaccination and were comparable between sero-negative and sero-positive subjects. Response rates generated by the high-dose formulation (HD-TDV) did not exceed those of the TDV formulation and were in fact lower at all comparable time-points. Median response magnitudes among the positive responders exceeded 1000 SFC/10^6 PBMC for the TDV formulation, were maintained at these high levels at the 12 month post-vaccination time-point, and were not significantly different when baseline sero-status was considered. Response magnitudes for HD-TDV did not exceed those for TDV and were often lower. Importantly, response magnitudes for DENV-1, -3 and -4 derived peptide pools were high, but response rates were ~50% lower than for the DENV-2 responses; however, these response rates were well maintained out to 12 months post-vaccination. NS3 and NS5 were majority targets of the response regardless of vaccine formulation or baseline sero-status. Overall, the vaccine was highly immunogenic and induced potent and durable CMI independent of formulation and baseline sero-status.

769

EFFICACY PROFILE OF THE CYD-TDV DENGUE VACCINE: BAYESIAN SURVIVAL ANALYSIS OF INDIVIDUAL PHASE III TRIAL DATA

Daniel J. Laydon[1], Ilaria Dorigatti[1], Robert Small[2], Nick Jackson[3], Laurent Coudeville[4], Neil M. Ferguson[1]

[1]Imperial College, London, United Kingdom, [2]Sanofi Pasteur, Orlando, FL, United States, [3]Sanofi Pasteur, Marcy-l'Étoile, France, [4]Sanofi Pasteur, Lyon, France

Dengue infection confers lifelong type-specific immunity, but enhances risk of severe disease upon secondary infection. Phase II and III trials of Sanofi Pasteur's CYD-TDV dengue vaccine showed an overall protective effect, varying by serotype and prior exposure. To characterize CYD-TDV efficacy, we employ a survival model with time varying hazards including subjects' age, country and baseline serostatus. We consider vaccination to give temporal cross-immunity and alter risk of disease associated with prior exposure, by acting as a silent, disease-free infection. The model is fitted to three years of individual level phase III trial data for >30,000 children aged 2-16 years. Using data augmentation to predict participants' serostatus, we estimate vaccine efficacy by prior exposure and serotype. The effects of age upon vaccine efficacy, duration of protection, and infection are examined. Our model reproduces observed age-specific Kaplan-Meier survival curves and attack rates well. We find an overall beneficial effect of vaccine, and support for our hypothesized mechanism of vaccine action. Cross immunity is significantly positive and long lived in seropositive vaccinees, but non-significant in seronegative vaccinees. Both the magnitude and duration of cross immunity are higher in seropositives and increase with age, independently of baseline serostatus. Cross immunity further varies by serotype. Among seropositive recipients, cross immunity is significantly positive for each serotype and is highest in serotypes 3 and 4. For seronegative recipients, cross immunity is significantly greater than zero for serotype 4 only. A sensitivity analysis of a model without explicit age effects gives an inferior but reasonable fit, though it fails to reproduce attack rates observed in the first year of passive surveillance. Our model refines existing efficacy estimates and demonstrates that the 'silent infection' hypothesis of vaccine action largely explains the complex and heterogeneous vaccine efficacy profile. Funding: DJL, NMF - Bill & Melinda Gates Foundation. ID - Imperial College JRF scheme. RS, NJ & LC employed by Sanofi Pasteur.

COMPREHENSIVE ANALYSIS OF THE IMMUNE RESPONSE ELICITED BY TAKEDA'S TETRAVALENT DENGUE VACCINE CANDIDATE

Hansi J. Dean[1], Michael A. Egan[1], Derek Wallace[2]

[1]Takeda Vaccines, Cambridge, NY, United States, [2]Takeda Pharmaceuticals International AG, Zurich, Switzerland

Dengue viruses cause a global disease burden of approximately 100 million apparent infections annually. Takeda Vaccines is developing a live attenuated tetravalent dengue vaccine candidate (TDV) based on a recombinant attenuated dengue serotype 2 virus (TDV-2). For dengue virus serotypes 1, 3, and 4, the pre-membrane (prM) and envelope (E) genes replace the corresponding DENV-2 genes in the attenuated backbone to form chimeric viruses (TDV-1, TDV-3, and TDV-4). The safety and efficacy of TDV is currently being evaluated in a double-blinded phase III controlled study being conducted in eight dengue-endemic countries in Latin America and Asia. Dengue vaccine development has been hampered by an incomplete understanding of the host immune response following vaccination and the lack of clear immune correlates of protection. To address these issues, we have taken a systematic approach towards detailed characterization of humoral, cellular and innate immune responses elicited by TDV. Data will be presented on characteristics of neutralizing antibody responses, magnitude, functionality and specificity of T cell responses, innate immune responses and characterization of anti-NS1 antibody responses following vaccination. Currently, pre- and post-vaccination clinical samples from early and late timepoints from children and adults participating in phase 2 randomised double-blind trials conducted in dengue-endemic countries are being used to fully characterize the immune response to TDV. We will present our progress on the comprehensive analysis of the immune response elicited by TDV, and opportunities to compare immune responses elicited by tetravalent vaccination with immune responses following natural infection. Development of a panel of immunological assays may be applied to case-controlled analysis of breakthrough dengue infections in the on-going efficacy trial to identify immune correlates or surrogates of protection against dengue.

771

IMPACT OF MASS DRUG ADMINISTRATION FOR LYMPHATIC FILARIASIS ON *STRONGYLOIDES STERCORALIS* AND HOOKWORM INFECTION IN PAPUA NEW GUINEA

Jannet A. Tobon Ramos[1], Tobias Maure[2], Lenore Carias[3], Livingstone W. Tavul[4], Moses Laman[4], Leanne J. Robinson[5], William Pomat[2], Christopher L. King[3]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea, [3]Case Western Reserve University and Veterans Affairs Medical Center, Cleveland, OH, United States, [4]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [5]Brunt Institute, Melbourne, Australia

Strongyloides stercoralis and hookworm are intestinal nematodes that often co-infect individuals with lymphatic filariasis. Currently, annual mass drug administration with diethylcarbamazine (DEC) + albendazole (ALB) is used for elimination of lymphatic filariasis, but new evidence has shown that adding ivermectin (IVM) to DEC + ALB markedly enhanced anti-filarial efficacy and potentially accelerate reducing the prevalence and intensity of *Strongyloides* and hookworm infections. Stool and dried blood spot samples were collected as part of an open label, randomized clinical trial conducted in 2017/18 to assess the community safety and effectiveness of 2-drug (DEC/ALB) versus 3-drug therapy (IVM/DEC/ALB) for lymphatic filariasis in the Bogia District of Papua New Guinea. Samples were collected prior to administration of therapy (n=267), 4 weeks after therapy (n=141) and the collection of 1 year follow up samples is currently ongoing. In 2017, 58 % of participants were male with a mean age 28 ± 16 years. To assess the prevalence and intensity of *Strongyloides* and hookworm, we performed Kato katz, duplex quantitative PCR in stool, and ELISA using NIE recombinant antigen for *S. stercoralis* in dried blood spots elute. On kato katz, 78% of samples were positive for hookworm eggs with a geomean of 227 (0-4,012) ova/gm and PCR positivity of 95% at baseline. *Strongyloides* was present in 3% of samples by PCR and 10.5 % positive by NIE ELISA at baseline. No other intestinal parasites were observed. Prevalence of *Strongyloides* and hookworm were similar between the two treatment arms at baseline. Four weeks following therapy mean egg reduction rate for hookworm was 97% in both arms. The samples size at 4 weeks was too small to see a meaningful difference in *Strongyloides*. Changes in the prevalence and antibody levels by NIE ELISA one year following treatment are being evaluated. Hookworm and *Strongyloides spp* are endemic in Papua New Guinea, with almost 100% infection rate for hookworm in our study population. The impact of DEC/ALB versus IVM/DEC/ALB on *Strongyloides* and hookworm in communities at one year following treatment will be discussed.

772

INTEGRATED BURDEN ESTIMATION SURVEY OF SKIN-PRESENTING CASE MANAGEMENT NTDS (BURULI ULCER, LEPROSY, LYMPHATIC FILARIASIS AND YAWS) IN MARYLAND, LIBERIA

Joseph W. Timothy[1], Emerson Rogers[2], Michael Marks[1], Katherine Halliday[1], Tarnue Mulbah[2], Anna Wickenden[3], Rachel Pullan[1], Karsor Kollie[2]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Ministry of Health, Monrovia, Liberia, [3]AIM Initiative, Accra, Ghana

Successful control of case management neglected tropical diseases (CM-NTDs) requires provision of significant resources and skilled healthcare staff among affected communities. Understanding the true burden of these diseases represents the first step towards developing a rational control strategy and achieving 2020 elimination targets. As CM-NTDs are focally distributed and population prevalence can be less than 1 per 10,000, this presents distinct economic and logistical challenges to measure disease burden and no validated strategies for an integrated approach currently exist. By exploiting the shared clinical characteristics of Buruli ulcer, leprosy, lymphatic filariasis-associated morbidity and yaws, we have developed a novel integrated two-stage cluster randomised survey to concomitantly estimate the burden of all four conditions within existing health infrastructure. This group of CM-NTDs are conducive to an integrated approach as all four share primary clinical presentation via the skin. Our method capitalises on these characteristics through door-to-door screening surveys conducted by community health workers trained to identify prevalent cases using visual aids that display common CM-NTD skin lesions. An expert team trained in the diagnosis of CM-NTDs visiting the home of every suspected case subsequently confirm or refute diagnosis and all stages undergo stringent quality control assessment. This protocol and the novel suite of tools developed for implementation have been tested across three pilot studies in Nimba County, Liberia and we present the results of all survey stages - screening, verification and quality control - from all pilot investigations and a population-level proof-of-principle survey conducted in Maryland County, Liberia (population 167,340).

773

ESTIMATING NEGLECTED TROPICAL DISEASES AND ENVIRONMENTAL RISK FACTORS WITH SPATIO-TEMPORAL GAUSSIAN PROCESS REGRESSION

Hayley Tymeson, Robert Reiner

Institute for Health Metrics and Evaluation, Seattle, WA, United States

The Institute for Health Metrics and Evaluation (IHME) create estimates of disease burden at the national and subnational level worldwide through its Global Burden of Disease study. IHME seeks to utilize all existing, high quality data, to create time-series estimates of health-related risk factors and diseases from 1980-2017. The abundance of data strengthens the validity of our estimates, yet creates its own challenges in data synthesis. In order to synthesize large quantities of spatially, temporally, and age-correlated data, IHME developed Spatio-Temporal Gaussian Process Regression (ST-GPR) for risk factor and disease modeling. ST-GPR is currently used to model many of the risk factors, vaccine-preventable diseases, and neglected tropical diseases for the Global Burden of Disease study. ST-GPR involves three stages: first, a linear mixed effects model incorporates covariate information to create a full time-series for the risk or disease being estimated. We then calculate a weights matrix across space, time, and age, to capture residual variability missed by the linear stage, and add the weighted residuals back in to the model to create a non-parametric second stage (spacetime) estimate. Lastly, we run a Gaussian process regression on the data and our mean function, the stage 2 estimate. We have recently made significant improvements to this modeling strategy. We created new methods of quantifying variance on our stage 2 estimate, allowing for more accurate uncertainty in model estimates. We are exploring techniques to create consistent prevalence estimates, modeled in logit space, within nested location hierarchies. Finally, we incorporated space-time interactions in our weights matrix to capture more subtleties in spatial and temporal trends.

774

INTEGRATED MAPPING ASSESSMENT FOR TREATMENT DECISION-MAKING IN AREAS SUSPECTED TO BE CO-ENDEMIC FOR ONCHOCERCIASIS, LYMPHATIC FILARIASIS AND LOIASIS: A CASE STUDY OF TWO LGAS IN RIVERS STATE, NIGERIA

Chukwu Okoronkwo[1], Kira A. Barbre[2], Emmanuel Davies[1], Yisa Saka[1], Ifeoma Anagbogu[1]

[1]Federal Ministry of Health, Abuja, Nigeria, [2]The Task Force for Global Health, Decatur, GA, United States

Many areas co-endemic for onchocerciasis (OV) and loiasis have been excluded from mass administration of medicine with ivermectin because treatment with ivermectin can cause serious adverse events among individuals with high-intensity *Loa loa* infection. In the context of OV elimination, all areas with ongoing transmission require treatment; consequently, rigorous mapping of untreated areas suspected to be endemic for loiasis is needed to determine whether ivermectin treatment is both necessary and safe. The present study used probability proportionate to estimated size to select 30 communities in each of two local government areas (LGAs), Andoni and Bonny, in Rivers State, Nigeria. Both LGAs are ivermectin-naive and have communities with >40% RAPLOA prevalence. In each selected community, 100 individuals ages 16 and older were randomly selected and tested between 10 AM and 4 PM for Loa intensity with CellScope Loa, lymphatic filariasis (LF) antigenemia with the filariasis test strip (FTS), and antibodies against OV and LF via the Ov16/Wb123 Biplex rapid diagnostic test (RDT). Dried blood spots were also taken for confirmatory testing. No evidence of OV transmission was found in either Andoni or Bonny, with prevalence of 0.04% and 0.0% by Ov16 RDT respectively. Results from Ov16 ELISA analysis are pending. In both Andoni and Bonny, evidence of pockets of LF transmission was found, with antigenemia prevalence of 1.8% (95% CI: 1.1-2.7%, range: 0.0%-9.6%) and 1.2% (95% CI: 0.01-2.3%, range: 0.0%-12.8%) respectively. No individuals with Loa intensity of greater than 20,000 mf/ml were identified in either LGA. Biannual administration of albendazole is recommended for LF treatment in areas co-endemic for Loiasis Mapping surveys that include Ov16 as well as CellScope testing have the potential to resolve uncertainty about both the need for and safety of ivermectin treatment, potentially reducing the map of areas for which ivermectin treatment is necessary but cannot be given.

775

COMPARISON BETWEEN PAPER-BASED AND M-HEALTH TOOLS FOR COLLATING AND REPORTING CLINICAL CASES OF LYMPHATIC FILARIASIS AND PODOCONIOSIS IN ETHIOPIA

Sarah Martindale[1], **Hayley E. Mableson**[1], Biruk Kebede[2], Fikre H/Kiros[2], Abraham Tamiru[2], Belete Mengistu[3], Anna Krueger[1], Charles Mackenzie[1], Louise A. Kelly-Hope[1]

[1]Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]National Podoconiosis Action Network, Addis Ababa, Ethiopia, [3]Federal Ministry of Health, Addis Ababa, Ethiopia

Lymphatic filariasis (LF) and podoconiosis are disabling diseases, endemic in Ethiopia. The main clinical manifestations include lymphoedema (LF and podoconiosis) and hydrocele (LF only). To ensure access to morbidity management and disability prevention (MMDP) services, data on patient numbers in each implementation unit is required. House-to-house census is considered the gold standard for estimating patient numbers, and data are usually collated and reported using paper-based methods. However, often there are delays in data reaching the regional and central level,

which leads to subsequent delays in rolling out and prioritising MMDP services. The increase in mobile phone mHealth tools offer an alternative, potentially more rapid and cost-effective, approach. As part of a LF and podoconiosis burden assessment conducted in Hawella Tula and Bensa districts in Ethiopia, this study compared the standard paper-based methods with the new *MeasureSMS-Morbidity* tool for clinical cases data collation and reporting. Health extension workers (HEWs) were trained on both methods. Comparisons were made on patient information; age, gender, location (*i.e. kebele)*, condition, severity of condition and acute attacks. Data were analysed for trends, including the differences in ranking the villages in each district based on the highest to lowest number of cases. In addition, financial and human resource requirements were compared. In total, 59 HEWs (19 from Hawella Tula; 40 from Bensa) collated and reported a similar number of cases by paper-based (n=2377) and SMS (n=2372) methods. Significant correlations were found between the two methods for all cases and lymphoedema cases in both districts, and for hydrocele cases in Bensa district only. The total cost of paper-based reporting was 13.7% more expensive than SMS reporting due to costs associated with data collection and entry. The rank correlation showed the same villages would be prioritised for delivery of MMDP services, with time and cost-savings observed using SMS reporting, suggesting it is an effective and efficient alternative tool to help facilitate care to those who need it most.

776

MEASURING PROGRESS OF CONTROL AND ELIMINATION PREVENTIVE CHEMOTHERAPY NEGLECTED TROPICAL DISEASES IN ETHIOPIA

Mesfin S. Kassa

Federal Ministry of Health, Addis Ababa, Ethiopia

Ethiopia has one of the highest burden of Neglected Tropical Diseases (NTDs) in Africa. The national NTD program targets schistosomiasis, trachoma, lymphatic filariasis(LF), onchocerciasis, and soil transmitted helminthiasis(STH) through community and school-based mass drug administration (MDA) of preventive chemotherapy. The national program conducted a desk review of program progress and assessment reports to evaluate the achievements of the national program toward the global and national strategic goals for NTD control and elimination for the period 2013 to 2018. By 2013, the geographical coverage for disease specific preventive chemotherapy was 47% for LF, 81% for onchocerciasis, 79% for schistosomiasis, 92% for STH, and 58% for trachoma. Through increased donor support and government commitment, the national NTD program reached 100% geographic coverage for all PCT diseases. In 2017 and the national program coverage was 88% for LF, 77% for STH, 76.5% for schistosomiasis and 86% for trachoma. The national program started carrying out LF transmission assessment surveys (TAS) and trachoma impact surveys. By 2017, 5 districts had reached the criteria for stopping MDA for LF and 66 districts for trachoma. This progress means that 1.1 million people are no longer at risk of LF and 5.6 million people for trachoma. Based on both epidemiological and entomological survey 7 onchocerciasis endemic districts have achieved the criteria to stop MDA. STH and schistosomiasis are considered endemic throughout Ethiopia, however data from sentinel site and spot check sites shows that prevalence in many districts is declining year by year. In conclusion the national program has made remarkable progress toward the 2020 global target for control and elimination of NTDs. However, further efforts are needed to address disease specific inadequate MDA coverage in the hard to reach districts, and address water, sanitation and hygiene interventions to control disease and interrupt transmission.

777

AN INTEGRATED APPROACH FOR THE CONTROL OF INTESTINAL PARASITES, SOUTH-CENTRAL CÔTE D'IVOIRE

Gaoussou Coulibaly[1], Mamadou Ouattara[1], Kouassi Dongo[1], Eveline Hurlimann[2], Jürg Utzinger[2], Kouakou Eliézer N'Goran[1], Giovanna Raso[2]

[1]University Félix Houphouët-Boigny, Abidjan, Côte D'Ivoire, [2]Swiss Tropical and Public Health Institute, Basel, Switzerland

Hundreds of millions of people are infected with helminths and intestinal protozoa, particularly children in low- and middle-income countries. Preventive chemotherapy is the main strategy to control helminthiases. However, rapid re-infection occurs in settings where there is a lack of clean water, sanitation and hygiene. From August to September 2014, a cross-sectional epidemiological survey was conducted in 56 communities of three departments Djékanou, Toumodi and Taabo in south-central Côte d'Ivoire. Each study participant was invited to provide a stool and urine sample. Stool samples were examined for intestinal helminth and protozoa infections using the Kato-Katz and formalin-ether concentration methods, respectively, and *Schistosoma haematobium* eggs detected in urine by a filtration technique. Socio-demographic characteristics and knowledge, attitude, practices and beliefs with regard to hygiene, sanitation and intestinal parasitic diseases were collected using a questionnaire administered to household heads. Multivariable logistic regression models were used to analyse the association between parasitic infections and potential risk factors. A total of 4305 participants had complete parasitological and questionnaire data. The prevalence of hookworm was 35.3%, 34.2% and 10.9% in the departments of Djékanou, Toumodi and Taabo, respectively. Other helminth species (*Schistosoma mansoni*, *S. haematobium*, *Ascaris lumbricoides* and *Trichuris trichiura*) were found with prevalences below 10%. Intestinal protozoa, e.g. *Entamoeba histolytica/dispar* and *Giardia lamblia* were similarly prevalent in the three departments. Hookworm infection was associated with open defecation, sex and age. *E. coli* infection was negatively associated with the use of tap water in households (OR = 0.66; $p = 0.032$). Garbage deposit near the household was positively associated with *G. lamblia* infection (OR = 1.30; $p = 0.015$). Our results will serve as baseline to monitor the effect of a package of interventions, including preventive chemotherapy, sanitation and health education on re-infection with helminths and intestinal protozoa.

778

EFFECTS OF WATER, SANITATION, HANDWASHING, AND NUTRITIONAL INTERVENTIONS ON ENVIRONMENTAL ENTERIC DYSFUNCTION IN YOUNG CHILDREN: A CLUSTER-RANDOMIZED CONTROLLED TRIAL IN RURAL KENYA

Audrie Lin[1], Beryl S. Achando[2], Gouthami Rao[2], Holly N. Dentz[3], Benjamin F. Arnold[1], Amy J. Pickering[4], Christine P. Stewart[3], Andrew N. Mertens[1], Mohammad Alauddin[5], Cecilia Nekesa[2], John P. Buleti[2], Priscah Cheruiyot[2], Theodora Meerkerk[2], Charles D. Arnold[3], Md. Ziaur Rahman[6], Marlene Wolfe[4], Maryanne Mureithi[2], Kendra Byrd[3], Marion C. Kiprotich[2], Geoffrey M. Nyambane[2], Sammy M. Njenga[7], Sarah T. Alauddin[5], Sandra G. Minchala[5], Rabije Cekovic[5], Anne M. Williams[8], Ryan Mahoney[2], Alan E. Hubbard[1], Kathryn G. Dewey[3], Stephen P. Luby[9], John M. Colford Jr.[1], Clair Null[10]

[1]University of California Berkeley, Berkeley, CA, United States, [2]Innovations for Poverty Action, Kakamega, Kenya, [3]University of California Davis, Davis, CA, United States, [4]Tufts University, Medford, MA, United States, [5]Wagner College, Staten Island, NY, United States, [6]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [7]Kenya Medical Research Institute, Nairobi, Kenya, [8]Emory University, Atlanta,

GA, United States, [9]Stanford University, Stanford, CA, United States, [10]Mathematica Policy Research, Washington DC, United States

Nutrition-specific interventions have typically achieved modest reductions in childhood stunting. Recurrent enteric infections leading to chronic gut inflammation and structural changes may contribute to early life growth faltering. Within a cluster-randomized trial in rural Kenya that enrolled pregnant women and followed their children (ClinicalTrials.gov, NCT01704105), we evaluated whether improvements to drinking water quality (W), sanitation (S), handwashing (H), and nutrition (N) would prevent or reduce gut inflammation and permeability. This substudy included children in four arms of the trial: combined WSH; N, which consisted of lipid-based nutrient supplementation from 6-24 months and age-appropriate feeding counseling; N+WSH; control. We measured biomarkers of gut inflammation (myeloperoxidase and neopterin) and permeability (alpha-1-antitrypsin, lactulose, and mannitol) at ages 6, 17, and 22 months. Analysis was intention-to-treat. We evaluated 1485 children. At age 6 months, compared to controls, urinary lactulose was higher in the nutrition (+0.45 log mmol/L, CI 0.23, 0.67) and N+WSH (+0.27 log mmol/L, CI 0.05, 0.49) arms. Similarly, urinary mannitol was higher in the nutrition (+0.46 log mmol/L, CI 0.23, 0.69) and N+WSH arms (+0.25 log mmol/L, CI 0.02, 0.47). At age 17 months, compared to controls, lactulose and mannitol remained elevated in the N+WSH arm only (+0.32 log mmol/L, CI 0.02, 0.62 and +0.25 log mmol/L, CI 0.01, 0.49 respectively). At 22 months, there were no differences between the arms. At all three time points, none of the interventions impacted the urinary lactulose to mannitol ratio (L:M). Although child linear growth was improved in the N and N+WSH arms, elevated lactulose and mannitol in these arms suggest that the nutrition intervention increased gut permeability. These unexpected results highlight the importance of understanding the pathophysiology of gut inflammation and permeability and the mechanism underlying the intervention effects. Fecal myeloperoxidase, neopterin, and alpha-1-antitrypsin results are forthcoming.

779

THE IMPACT OF HOUSEHOLD CLUSTERING ON ENTERIC PATHOGEN INFECTION IN RURAL LAOTIAN COMMUNITIES

Anna N. Chard[1], Howard H. Chang[1], Karen Levy[1], Kelly K. Baker[2], Matthew C. Freeman[1]

[1]Emory University, Atlanta, GA, United States, [2]University of Iowa, Iowa City, IA, United States

Recent large-scale studies that focused on household-, rather than community-level WASH improvements found limited impact on health. WASH conditions may influence both intra- and inter-household transmission of pathogens, but there is limited evidence on the relative importance of these different transmission pathways across pathogens. We conducted a variance decomposition analysis to quantify the extent to which an individual's log odds of enteric infections were explained by WASH access (household sanitation, improved water, and soap) versus household clustering. We surveyed 25 randomly selected households in 50 randomly selected villages in Saravane Province, Laos. Stool samples were collected from a primary school-aged child, their sibling <5 years old, and their parent, and analyzed for 25 enteropathogens using the TaqMan Array Card, a qPCR-based diagnostic assay. All 3 samples were returned from 297 households, for a total of 891 samples. TAC analysis will be complete in June 2018; to date, 291 (33%) samples have been analyzed. Initial results indicate that giardia (77%), hookworm (71%), EPEC (51%), and rotavirus (42%) were the most prevalent pathogens. WASH covariates explained 13% of the total variance in log odds of giardia infection; of the variability not explained by WASH covariates, 18% was due to household clustering. WASH covariates explained 9% of the total variance in log odds of hookworm infection; 47% of the remaining variability came from household clustering. WASH covariates explained 29% of the total variance in log odds of EPEC infection, while >99% of the remaining variability was the effect of household clustering. Lastly, WASH covariates explained 3% of the total variance in log odds of rotavirus infection, whereas 33% of the remaining variability was due to household clustering. The relative influence of WASH covariates (3-29% of variability) and household clustering (18-99% of variability) on log odds of enteric infection differed by pathogen. A more nuanced understanding of pathogen transmission within and between households and variations by pathogen could help better target WASH improvements.

780

THE EFFICACY OF CONSUMER HANDWASHING AGENTS FOR REMOVAL OF DIARRHEAL AND RESPIRATORY PATHOGENS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF LABORATORY BASED STUDIES

Marlene K. Wolfe, Daniele Lantagne

Tufts University, Medford, MA, United States

Respiratory and diarrheal diseases are leading causes of morbidity worldwide, and handwashing is commonly recommended to prevent disease transmission. Despite increasing availability of various consumer handwashing products, to our knowledge the existing evidence on product efficacy has not been summarized. The objective of this study was to evaluate the efficacy of consumer handwashing products against diarrheal and respiratory pathogens. A systematic review was performed by developing inclusion criteria, searching and selecting papers, assessing quality, and extracting and summarizing the results of included studies on handwashing efficacy. Studies were included if they reported an experiment on human hands showing the percent or log reduction value (LRV) of bacterial or viral diarrheal/respiratory pathogens after washing with a consumer product. A Mantel-Haenszel random effects meta-analysis was used to generate a summary LRV describing the reduction in contamination on hands. Overall, 31 papers met inclusion criteria, describing efficacy for hand rubs, soaps, and water only against two bacteria and eight viruses. For bacteria, hand rubs resulted in a 3.4 LRV (95% CI 3.2-3.7), soap a 2.2 LRV (2.0-2.4), and water only a 1.8 LRV (1.5-2.2). For viruses, hand rubs resulted in a 1.0 LRV (0.8-1.1), soap a 1.3 LRV (0.8-1.7), and water only a 1.0 LRV (0.7-1.4). Results for bacteria were consistent across studies; virus results had higher heterogeneity. Findings were robust to removal of lower quality studies. Both hand rubs and soaps meet United States regulatory requirements of ≥ 2-log reduction; no product met this standard for viruses, although information on viral pathogens was limited compared to bacteria. Thus, for bacterial pathogens both soaps and antiseptic rubs are likely to be effective for handwashing, and the most readily available option should be used to maintain good hygiene. However, as many emerging infectious diseases are viral respiratory pathogens, we recommend further research on the efficacy of products against viruses to develop appropriate recommendations for handwashing for existing and emerging diseases.

781

PREDICTED SHORT AND LONG-TERM IMPACT OF DEWORMING AND WASH ON TRANSMISSION OF SOIL-TRANSMITTED HELMINTHS

Luc E. Coffeng[1], Susana Vaz Nery[2], Darren J. Gray[3], Roel Bakker[1], Sake J. de Vlas[1], Archi C. Clements[3]

[1]Department of Public Health, Erasmus MC, University Medical Center, Rotterdam, Netherlands, [2]Kirby Institute, University of New South Wales, Sydney, Australia, [3]Research School of Population Health, College of Medicine, Biology and Environment, The Australian National University, Canberra, Australia

Regular preventive chemotherapy (PCT) targeting high-risk populations is a highly effective way to control STH in the short term, but sustainable long-term STH control is expected to require improved access to water, sanitation, and hygiene (WASH). However, experimental studies conducted so far have not always been able to demonstrate that WASH prevents STH (re-)infections. The aim of the current study was to investigate the

impact of WASH on STH infections during and after a PCT programme using a mathematical model. We use the individual-based transmission model WORMSIM to predict the short and long-term impact of WASH on roundworm, whipworm, and hookworm transmission in contexts with and without PCT. In the model, we distinguish two WASH modalities: sanitation, which reduces individuals' contributions to environmental contamination; and hygiene, which reduces individuals' exposure to the environmental reservoir. We simulate the impact of varying levels of population-level uptake and individual-level effectiveness (reduction in contribution and/or exposure) of the two WASH modalities, as well as their combined impact. We predict that WASH has little observable short-term impact on STH infections levels in the context of PCT programmes, but is pivotal to sustain control or eliminate infection levels after scaling down or stopping PCT. The impact of hygiene interventions is determined more by the effectiveness of the intervention at the individual level than population-level uptake, whereas the impact of sanitation interventions depends more directly on the product of uptake and the effectiveness. In conclusion, there is a clear added benefit of WASH to sustain the gains made by PCT in the long term, although its impact can be difficult to measure in the context of deworming programmes. Because the impact of WASH is expected to vary with chosen modality, level of uptake, and quality of execution, trials should disentangle exposure and contribution-related interventions, provide detailed reports on access to and use of each modality, and should focus on the long-term impact on transmission and risk of recrudescence after stopping PCT.

782

ANTIBIOTIC RESISTANCE IN *ESCHERICHIA COLI* AND *KLEBSIELLA* SPP. ISOLATES FROM HOUSEHOLD WATER, FOOD PREPARATION SURFACES, AND SOIL IN COMPOUNDS IN MAPUTO, MOZAMBIQUE: POTENTIAL SOURCES OF ENVIRONMENTAL TRANSMISSION OUTSIDE THE CLINIC

David Berendes[1], Liliana Dengo-Baloi[2], David Holcomb[3], Jackie Knee[4], Rassul Nala[2], Joe Brown[4]

[1]Division of Foodborne, Waterborne, and Environmental Diseases, Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Mozambican Ministry of Health, Maputo, Mozambique, [3]Environmental Sciences and Engineering Department, Gillings School of Public Health, University of North Carolina, Chapel Hill, NC, United States, [4]School of Civil and Environmental Engineering, Georgia Institute of Technology, Atlanta, GA, United States

Environmental conditions may be important drivers of antibiotic resistant (AR) infections, especially in low-income, pathogen-rich environments. We examined potential environmental reservoirs of AR bacteria in households in a controlled before-and-after study of a sanitation intervention in Maputo, Mozambique. Samples of household source and stored water, food preparation surfaces, household soil, and soil at the latrine doorstep were collected in 30 intervention and 30 control compounds 1 year after the intervention. Samples were cultured in mTEC broth and confirmed as *E. coli* or *Klebsiella* spp., followed by disk diffusion to assess antibiotic susceptibility. From each sample, 1-2 isolates were tested for the 12 National Antibiotic Resistance Monitoring System for Enteric Bacteria antibiotics of interest for *E. coli*. To-date, 227/505 (45%) isolates have been cultured, with 35 (15%) confirmed as *E. coli* and 63 as *Klebsiella* spp. (28%, though only 36 tested to-date for AR). Approximately 55% have been culturable, with remaining non-culturable isolates likely due to long storage time at -80°. After completing AR testing in May, we will compare isolate AR results by environmental conditions (i.e. WASH infrastructure) assessed at concurrent household surveys. To-date, 19/35 *E. coli* isolates were resistant to ampicillin, including isolates within all sample types. Resistance to cefoxitin, nalidixic acid, streptomycin, tetracycline, and sulfamethoxazole-trimethoprim (SXT) was also observed. Most *Klebsiella* spp. isolates (34/36) were also resistant to ampicillin, with resistance to amoxicillin-clavulanic acid, azithromycin, cefoxitin, gentamicin, streptomycin, tetracycline, and SXT detected as well. Although only about half of household environmental isolates have been tested, we have already observed high levels of resistance to ampicillin - a first-line drug for pediatric enteric infections - among other AR across all types of environmental samples. These data provide early evidence of the potential importance of contaminated environments as sources of exposure to AR bacteria in dense, low-income household settings.

783

DEFINING DIARRHEA: A POPULATION-BASED VALIDATION STUDY OF CAREGIVER-REPORTED STOOL CONSISTENCY IN THE AMHARA REGION OF ETHIOPIA

Kristen Aiemjoy[1], Solomon Aragie[2], Sintayehu Gebresillasie[2], Dionna Fry[1], Adane Dagnew[2], Dagnachew Hailu[2], Meslew Chanyalew[3], Zerihun Tadesse[2], Aisha Stewart[4], Kelly Callahan[4], Mathew Freeman[5], John Neuhaus[1], Benjamin F. Arnold[6], Jeremy D. Keenan[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]The Carter Center, Addis Ababa, Ethiopia, [3]Amhara Regional Health Bureau, Bahir Dar, Ethiopia, [4]The Carter Center, Atlanta, GA, United States, [5]Emory University, Atlanta, GA, United States, [6]University of California Berkeley, Berkeley, CA, United States

Diarrhea is a leading cause of death among children aged less than five years globally. Most studies of pediatric diarrhea rely on caregiver-reported stool consistency and frequency to define the disease. Research on the validity of caregiver-reported diarrhea is sparse. We collected stool samples from 2,398 children participating in two clinical trials in the Amhara region of Ethiopia. The consistency of each stool sample was graded by the child's caregiver and two trained laboratory technicians according to an illustrated stool consistency scale. We assessed the reliability of graded stool consistency among the technicians, and then compared the caregiver's grade with the technician's grade. We also tested if the illustrated stool consistency scale could improve the validity of caregiver's report. The weighted kappa measuring the agreement between the two laboratory technicians reached 0.90 after 500 stool samples were graded. The sensitivity of caregiver-reported loose or watery stool was 15.5% (95% confidence interval [CI]: 9.7, 24.2) and the specificity was 98.4% (95% CI 97.1, 99.1). With the illustrated scale, the sensitivity was 68.5% (95% CI: 58.5, 77.1) and the specificity was 86.1% (95% CI: 79.3, 90.9). The results indicate that caregiver-reported stool consistency using the terms "loose or watery" does not accurately describe stool consistency as graded by trained laboratory technicians. Given the predominance of using caregiver-reported stool consistency to define diarrheal disease, the low sensitivity identified in this study suggests that the burden of diarrheal disease may be underestimated and intervention effects could be biased. The illustrated scale is a potential low-lost tool to improve the validity of caregiver-reported stool consistency.

HOUSEHOLD AIR POLLUTION EXPOSURE AND MITOCHONDRIAL DNA COPY NUMBER IN CORD BLOOD: IDENTIFYING SENSITIVE WINDOWS AND SEX-SPECIFIC EFFECTS

Seyram Kaali[1], Darby Jack[2], Rupert Delimini[3], Steven Chillrud[4], Jones Opoku-Mensah[1], Katrin Burkart[2], Oscar Agyei[1], Ashlinn Quinn[5], Abena K. Yawson[1], Blair Wylie[6], Ellen A. Boamah-Kaali[1], Patrick Kinney[2], Kenneth Asayah[1], Andrea Baccarelli[7], Kwaku Poku Asante[1], Alison G. Lee[8]

[1]Kintampo Health Research Centre, Kintampo, Ghana, [2]Columbia University, Mailman School of Public Health, Department of Environmental Health Sciences, New York City, NY, United States, [3]University of Health and Allied Sciences, Ho, Ghana, [4]Lamont Doherty Earth Observatory, Columbia University, New York City, NY, United States, [5]Household Air Pollution Investigation Network, Division of International Epidemiology and Population Studies, Fogarty International Centre, National Institutes of Health, US Department of Human and Health Services, Rockville,

MD, United States, [6]Center for Maternal Fetal Medicine, Department of Obstetrics and Gynecology, Beth Israel Deaconess Medical Center, Boston, MA, United States, [7]Columbia University, Mailman School of Public Health, Department of Environmental Health Sciences, New York City, NY, United States, [8]Division of Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai, New York City, NY, United States

Household air pollution (HAP) exposure during sensitive windows of development, beginning *in utero*, may program future disease risk through oxidative stress (OS) pathways. Mitochondria may respond to OS by increasing DNA copy number (mtDNAcn), however when compensatory mechanisms are overwhelmed mtDNAcn may be decreased. Prior studies suggest that females may be more adaptive to *in utero* OS. The Ghana Randomized Air Pollution and Health Study (GRAPHS) recruited nonsmoking pregnant women and randomized them to one of two cookstove interventions or control. Four, 72- hour carbon monoxide (CO) personal air pollution exposure measurements were performed over pregnancy and interpolated to estimate weekly prenatal CO exposure. Venous umbilical cord blood was collected, cord blood mononuclear cells isolated, and DNA extracted in 164 samples. Multiplex quantitative real-time polymerase chain reaction (qPCR) was used to determine mtDNAcn. Distributed lag models (DLMs) estimated the time-varying association between mtDNAcn and CO exposures. Models were adjusted for maternal age, body mass index (BMI), marital status, socioeconomic status, child sex, gestational age at delivery. Sex-stratified analyses were performed. Median prenatal CO exposure was 0.91ppm (0.51-1.48). Overall, DLMs identified a significant association between a 1ppm increase in prenatal CO exposure and increased mtDNAcn in cord blood from 5-10 weeks gestation. Sex-stratified analyses identified a significant association between a 1ppm increase in prenatal CO exposure and decreased mtDNAcn in boys from 5-10 weeks gestation but increased mtDNAcn in girls from 0-10 weeks gestation. These findings suggest that *in utero* HAP exposure, as measured by CO exposure, alters mitochondrial function and that sex may modify the effect. An increase in mtDNAcn, as seen in girls, may reflect a compensatory mechanism for cell survival. Conversely, mtDNA damage secondary to OS may limit mitochondrial replication thus decreasing mtDNAcn, as seen in boys. These data support prior work demonstrating sex-specific responses to *in utero* OS, with females being more resilient.

"MAD DOGS AND ENGLISHMEN: THE "SEASONING" OF THE MILITARY, MISSIONARIES, AND MAGISTRATES IN 19TH CENTURY COLONIAL OUTPOSTS

David Adams[1], Valerie Adams[2], Jessmarie Gonzalez[3], Colette Ryset[3], Femi Taiwo[4]

[1]Point University, Savannah, GA, United States, [2]Georgia Southern University, Statesboro, GA, United States, [3]South University, Savannah, GA, United States, [4]Texas A & M University, College Station, TX, United States

The first wave of European colonialism into Africa and the Far East occurred between about 1450 and 1600. By the 19th century, Britain (and other countries) had established a significant foothold in territories throughout Africa and the Indian subcontinent. Once military forces had stabilized these regions, ranks of missionaries and civil servants soon followed. What they found, however, were conditions that were extremely different from those that they had left behind in the United Kingdom. In short, they were completely unprepared for what they found. This presentation examines the process of "seasoning" (known more commonly today as acclimatization) on British arrivals to the tropical reaches of Africa and the Indian subcontinent. Drawing on diaries and medical literature of the 19th century, the authors will show how imperfectly these ex-patriots appreciated what awaited them in the far corners of the Empire. Advice on becoming "seasoned" to the tropical climate--offered by many commentators who had never been abroad—often proved as useless as it was potentially dangerous.

786

DATA QUALITY IN THE ERA OF "LIVE DATA": CHAMPS DATA QUALITY MONITORING SYSTEM

Joanna Boyles[1], Navit Salzberg[2], Tim Morris[1], CHAMPS Network Consortium[3]

[1]The Task Force for Global Health, Decatur, GA, United States, [2]The Emory Global Health Institute, Atlanta, GA, United States, [3]Child Health and Mortality Prevention Surveillance Network, Atlanta, GA, United States

The Child Health and Mortality Prevention Surveillance (CHAMPS) Network seeks to identify definitive causes of stillbirth and under-5 deaths in countries with high child mortality. The network is comprised of 7 sites in Africa and South Asia that are using post-mortem and pathology techniques with the goal of determining cause of death via a panel of experts. Through a consistent set of data specifications defined by the CHAMPS Program Office (PO), sites primarily capture data via a survey web application (REDCap) and transmit weekly to the PO, where the cumulative data are stored in SQL servers. The requirement to make data rapidly publically available according to the open access policies of the study sponsor, the need for validated data at the point of expert panel review, combined with challenges of managing transactional data from ongoing data collection and transmissions, require unique strategies to data quality evaluation and resolution at the PO and site levels. The PO developed a data quality monitoring and feedback system that works on multiple fronts: site-level capacity strengthening through REDCap rules implementation and dynamic resolutions at the point of data entry, data validation of the raw csv files at the point of data upload and processing into the SQL warehouse, and development of matching SQL based data quality algorithms with metadata to manage the SQL and REDCap data quality rules. The PO has defined 61 REDCap data quality rules applying to demographic, laboratory, and clinical data which can be implemented at a site-level, with an additional 6 rules applying across REDCap projects that are implemented at a PO level. When an incongruous set of data is identified, a new data quality rule is developed through the gathering of requirements (both logic and resolution language). Rules are developed and released in batches, typically every 2 weeks, and documentation supports versions of the data quality rules through the agile lifecycle. This multi-faceted approach has established a robust data quality monitoring system, capable of rapid error identification and resolution to support sharing valid data across the network.

787

HEALTH, NUTRITION AND FOOD SECURITY AMONG ADOLESCENT REFUGEES

Sarah Baird[1], Zulfiqar Bhutta[2], Joan Hicks[3], Nicola Jones[4], Shaneka Thurman[1]

[1]George Washington University, Washington, DC, United States, [2]The Aga Khan University, Karachi, Pakistan, [3]University of Oklahoma, Norman, OK, United States, [4]Overseas Development Institute, London, United Kingdom

The rights of all people to the highest standards of physical and mental health, as well as freedom from hunger and malnutrition, underlie a human rights based approach to health policy. This applies equally to refugees who have been forced to flee their homelands. However, maintaining basic health standards for refugee populations remains a challenge. While existing research tends to focus on maternal and child health, relatively little is known about the health of adolescents in refugee settings. Using quantitative data collected by the authors in 2018 from over 5,000 adolescents in two diverse refugee settings—Syrian refugees in Jordan and Rohingya refugees in Bangladesh—we describe the multitude of health and nutrition challenges faced by adolescent refugees. We explore physical and mental health, as well as dietary diversity and food security. We look at variation by gender, age, and location of the refugee population (camp vs. non-camp). In addition, we look at the role of programs (emergency relief and social protection) and health infrastructure in improving health outcomes for this population. As increasing numbers

of refugees cross international boundaries, understanding the health problems they face is critical in ensuring appropriate health care, in particular for adolescents who are on the verge of entering their prime fertility and labor productivity years.

788

A QUALITATIVE STUDY TO UNDERSTAND POPULATION'S PERCEPTION ON PLAGUE AFTER THE 2017 EPIDEMIC, ANTANANARIVO, MADAGASCAR

Sitraka Rakotosamimanana[1], Chiarella Mattern[1], Elliot Rakotomanana[1], Emma Raboanary[1], Elodie Chevallier[1], Joselyne Ramamonjisoa[2], François Taglioni[3], Minoarisoa Rajerison[1], Fanjasoa Rakotomanana[1], Laurence Baril[1]

[1]Institut Pasteur de Madagascar, Antananarivo, Madagascar, [2]Antananarivo University, Antananarivo, Madagascar, [3]La Réunion University, Saint Denis, France

Yersinia pestis continues to threaten the Malagasy population with around 300 reported cases/year during September - April. In 2017, Madagascar experienced a large urban epidemic of Pneumonic Plague (PP). We are conducting a study to explore the knowledge, attitudes, perceptions and practices (KAPP) regarding plague of the population living in Antananarivo, the capital city. Here, we present the results of initial interviews among a sample of residents living near treatment centers. We used the epidemic database from the Institut Pasteur de Madagascar (IPM) to identify three Fokontany (smallest administrative unit) close to two plague treatment centers and conducted individual and group interviews among recovered plague patients, health care professionals and residents living nearby the treatment center. Interviews were conducted by a multidisciplinary team composed of health geographers and anthropologists using semi-structured questionnaires and the photovoice methodology. Photovoice is a qualitative process by which individuals can represent their reality using photographic technique. We also collected information on antibiotic usage and health care utilization. Five photovoice and group interviews were conducted among 21 participants. Participants where aged between 18 to 40 years old. Men's and women's groups have been separated. A camera was provided to each participant. Each participant was asked to take three photos and afterwards to describe the reasons why they took such photos. The discussion from these collective interviews highlighted gaps and confusion regarding plague, including the mode of propagation (air and/or water), in all the investigated fokontany. The proximity of individual's location to the plague treatment center may influence their knowledge and perceptions regarding plague. Understanding the spatial and social features related to plague could improve next plague outbreak/epidemic preparedness. This work will support health community communication during sensitization campaigns and reduce the knowledge gaps for the general population.

789

IS GOVERNMENT VECTOR CONTROL PERCEIVED AS EFFECTIVE? A BINATIONAL COMPARISON BETWEEN TWO US AND TWO MEXICAN CITIES WITH DISPARATE LEVELS OF TRANSMISSION

James K. Romine[1], Pablo Reyes-Castro[2], Lucia Castro-Luque[3], Kathleen R. Walker[4], Mary H. Hayden[5], Kacey C. Ernst[1]

[1]University of Arizona, College of Public Health, Tucson, AZ, United States, [2]Center for Studies on Health and Society, El Colegio de Sonora, Hermosillo, Sonora, Mexico, [3]Center for Studies on Health and Society, El Colegio de Sonora, Hermosillo, Mexico, [4]University of Arizona, Tucson, AZ, United States, [5]National Center for Atmospheric Research, Boulder, CO, United States

As has been evidenced during multiple vector-borne outbreaks across the world, perceptions about the government can greatly influence vector-control success. In turn, the success of vector-control programs will influence the perceived effectiveness of those programs. These perceptions may influence community uptake of recommended vector control strategies. Preliminary evidence from Hermosillo, SN suggested that community awareness of government insecticidal spraying may cause a "false sense of security" and reduce household mosquito avoidance behavior. In this work, we investigated perceptions toward the effectiveness of government-led vector control strategies, knowledge of the activities conducted and the association between perceived effectiveness and uptake of generally recommended public health strategies. Cross-sectional knowledge, attitudes, and practice (KAP) surveys were conducted in Hermosillo, Sonora; Nogales, Sonora; and Tucson, Arizona; and Key West, Florida. Responses pertaining to demographics, knowledge of mosquito-borne diseases, attitudes towards government vector-control, and household mosquito avoidance practices were assessed. Multivariable regression models were used to characterize participants who perceived government activities to be effective. In terms of a Likert scale (1-5), more people in Hermosillo (mean = 3.15, sd = 1.01) and Tucson (mean = 2.91, sd = 1.11) reported that government programs are "somewhat effective", those in Nogales reported that government programs are "hardly effective" (mean = 1.83, sd = 1.19), while Key West considered government activities to be "very effective" (mean = 3.72, sd = 1.04). Separate regression models for each city indicate associations between government effectiveness and the amount of exposure to mosquito-borne disease prevention information, as well as history of Dengue infection. More studies should take into account perceptions towards government activities when conducting surveys to understand the dynamics of uptake of household level vector control activities.

790

CLINICAL CAPACITY BUILDING TO ADDRESS DIABETES PREVENTION AND CONTROL IN A COMMUNITY HEALTH CENTER IN JALISCO, MEXICO

Ella Harris[1], Martin Sandoval[2], Sharon Rose[1], Emily Hall[1], Luis Hernandez Larios[2], Kimberly Baltzell[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Tiopa Tlanextli, Autlan, Mexico

Diabetes is the most costly illness for the Mexican healthcare system, and the government has declared the epidemic a national emergency. In response, the state of Jalisco created the Overweight, Obesity, and Diabetes Prevention and Control Strategy. The strategy highlights working in interdisciplinary teams in primary care settings to deliver a comprehensive approach to diabetes prevention, screening, care and control at the population level. Community clinics outside of the public health care system are designated to play an important role, although most lack the operational system to plan and implement targeted public health programming. This abstract describes a capacity-building initiative led by University of California San Francisco (UCSF) advanced practice nurses and public health practitioners to build clinical systems that contribute to a comprehensive diabetes prevention and control program at Tiopa Community Clinic in Autlán, Jalisco, Mexico. The "Tiopa Sustainability Collaboration" embeds UCSF advanced practice nurses with Mexican national registered nurses to form a clinical operations management team at Tiopa. Initial assessments of facility staffing, operations, and services identified necessary system changes to 1) improve delivery of quality diabetes care, and 2) align facility services with the state's strategy for diabetes prevention and control. Specifically, the program engages interprofessional clinical staff in continuing education, population health program development, and quality improvement initiatives. To date, activities carried out by the nurse led clinical operations management team include: (1) data collection and analysis of a community health assessment; (2) initiation of quality improvement committee projects; (3) systemization of clinical documentation procedures to improve case identification; and (4) interdisciplinary case conferences for end-stage renal disease patients. The ultimate goal of this project is to

provide a comprehensive, cost-effective, community-level diabetes care model aligned with government strategies for diabetes screening and treatment.

791

A MULTI-YEAR PROJECT IMPLEMENTING KANGAROO MOTHER CARE IN RURAL TANZANIA

Linda A. Winkler[1], Shana Noon[1], Theophila Babwanga[2]

[1]Wilkes University, Kingston, PA, United States, [2]Nyakahanga Hospital, Karagwe, United Republic of Tanzania

WHO has recommended Kangaroo Mother Care (KMC) as routine care for all infants. As a result, implementation plans are underway in many less developed countries around the world. This paper discusses a multi-year project begun in 2014 to implement KMC with low birth weight (LBW) and high risk newborns at a rural district hospital in Tanzania. The research involves the use of de-identified retrospective medical records (analysis of 116 KMC mother-baby dyads, all LBW with 45% at or under 1500 gr.) and case studies supplemented by clinical observations. Data collected include infant weight, infant body temperature, breast milk (BM) production, survival period, and cause of death if death occurred. Results from 2014 indicate that even with KMC, many LBW neonates die due to insufficient BM and introduction of cow's milk substitutes. As a result, the research team and program introduced manual breast pumps and a training-feeding protocol for mothers to enhance breast milk extraction and the use of Kangaroo (KMC) for LBW and high risk newborns. Existing hospital feeding protocols have been used to guide feeding and mothers self-monitor and record their breast milk production. With the new protocol, neonatal temperature stability, breast milk output, feeding success, weight gain, and survival have increased in our case study group. An analysis of KMC log records indicates 74% survival rate in this LBW group. Only one baby weighing less than 1000 gr. weight has survived (25%), but this baby was part of our KMC intensive education case study group in 2016. Prematurity and respiratory distress, hypothermia, and infection are frequent causes of death with hypothermia accounting for 29% of the deaths. Efforts for education in 2018 will accentuate this factor in addressing deaths. Our study indicates that KMC is very effective in enhancing survival, but that protocol enhancements may be necessary with LBW babies and that intensive support and education of new mothers are also crucial to success.

792

CHALLENGES FOR IVERMECTIN UPTAKE TO PREVENT NODDING SYNDROME IN ONCHOCERCIASIS HYPER-ENDEMIC AREAS OF CAMEROON, TANZANIA AND UGANDA

Julia Irani[1], Maya Ronse[1], Alfred Njamnshi[2], Peter Ntaimah Tatah[3], Ezekiel Mangi[4], Innocent Semali[4], Joseph Rujumba[5], Richard Idro[5], Amos Mwaka[5], Kristien Verdonck[1], Robert Colebunders[6], Sarah O'Neill[1], Koen Grietens Peeters[1]

[1]Institute of Tropical Medicine, Antwerp, Belgium, [2]University of Yaoundé I, Yaoundé, Cameroon, [3]University of Buea, Buea, Cameroon, [4]Muhimbili University of Health and Allied Sciences, Dar es Salaam, United Republic of Tanzania, [5]Makerere University, Kampala, Uganda, [6]University of Antwerp, Antwerp, Belgium

Evidence suggests an association between onchocerciasis and epilepsy, including Nodding Syndrome. Community-directed treatment with Ivermectin (CDTI) to control onchocerciasis has been on-going in Cameroon since 1998, in Tanzania since 1997 and in Uganda since 2009. Our aim was to assess social factors limiting ivermectin (IVM) uptake in areas hyper-endemic to onchocerciasis and with high prevalence of epilepsy. Ethnographic research was carried out between 2015 and 2017 in Cameroon, Tanzania and Uganda. Data from participant observation, informal conversations, in-depth interviews and focus group discussions were triangulated and compared and contrasted across the three countries. Sampling was theoretical and retroductive data analysis was conducted using NVivo 10. Common barriers to IVM uptake included lack of motivation for community directed implementors (CDI). CDIs needed more time and support in reaching remote or people absent during distribution period. Supportive supervision for CDI was limited and inadequate. Some eligible individuals were excluded due to alcohol consumption, having seizures, being migrants or living in remote parts of the village. Fear of side effects that limit ability to work, prohibition of alcohol consumption, distrust in the drug and distribution system and a lack of perceived benefits to individuals feeling healthy, were the main barriers to adherence. Respondents mentioned that radio programs were effective in improving community attitudes towards IVM and suggested that non-financial contributions from the community members themselves, like free labour on farms of CDIs, may help incentivize CDIs. Continued community sensitisation, monitoring of IVM distribution, improved training of CDIs, creation of audit cycles to efficiently address suspected adverse effects and rumours, alternative options of IVM administration for missed / unforeseen people is necessary in onchocerciasis hyper-endemic areas of Cameroon, Tanzania and Uganda. These findings are in line with earlier claims in literature that reported coverage of ivermectin may be overestimated currently and could be improved.

793

WHAT IS THE SOCIO-ECONOMIC IMPACT OF LEG LYMPHOEDEMA ON PATIENT CAREGIVERS IN A PODOCONIOSIS AND LYMPHATIC FILARIASIS CO-ENDEMIC DISTRICT OF ETHIOPIA?

Sarah Martindale[1], Thais Caprioli[1], Asrat Mengiste[2], Dereje Assefa[2], Fikre H/Kiros[2], Mossie Tamiru[3], Nebiyu Negussu[3], Mark Taylor[1], Hannah Betts[1], Louise A. Kelly-Hope[1]

[1]Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]National Podoconiosis Action Network, Addis Ababa, Ethiopia, [3]Federal Ministry of Health, Addis Ababa, Ethiopia

Lymphatic filariasis (LF) and podoconiosis are neglected tropical diseases (NTDs) endemic in Ethiopia. Both diseases cause painful and disabling lymphoedema of the lower limbs, and people affected require a range of morbidity management and disability prevention measures. Lymphoedema patients are often subject to a complex range of physical, social and economic hardships. These hardships are likely to extend beyond the patient, to the people who care for them. However, little is known about the caregivers; who they are - how they assist - what impact it has on their own lives. Further, it is not known if the different stages of lymphoedema (i.e. mild, moderate, severe) have a corresponding impact on caregivers. The aim of this study was to determine the socio-economic impact of leg lymphoedema on patient caregivers in the Simada District, Amhara Region of Ethiopia where over 1000 cases of leg lymphoedema have been reported. The objectives were to 1) identify lymphoedema patients with different stages of severity and to examine the potential impact on their caregivers and family unit; 2) determine the characteristics and role of primary caregivers; and 3) quantify the quality of life and economic impact on the primary caregivers. In total, 90 lymphoedema patients, grouped by the stage of their lymphoedema (30 mild, 30 moderate, 30 severe) were identified. Their primary caregiver was interviewed using a semi-structured questionnaire including a range of information e.g. type of assistance provided, frequency and duration of tasks, and number of days off work or school, and comparisons made between the different patient caregiver groups. The study is ongoing and the findings will be presented to provide a better understanding of the role of LF and podoconiosis caregivers, which has previously been unrecognised, and is crucial in making progress towards Sustainable Development Goal 5, in recognising and valuing unpaid care and domestic work.

794

IMPROVING HEALTHCARE DECISION MAKING IN RURAL BANGLADESH THROUGH A PHYSICIAN CALL CENTER

Afruna Rahman[1], Sanwarul Bari[1], Qazi Sadeq-ur Rahman[1], Hossain M s Sazzad[1], Shams El Arifeen[1], Emily S. Gurley[2]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Johns Hopkins University, Baltimore, MD, United States

Despite progress in many health indicators, maternal and child mortality in Bangladesh remain unacceptably high. Delays in recognizing danger signs and seeking care contribute to these deaths. Mobile phones are widely available in Bangladesh and over 87% of households own a cell phone. As part of a study to understand etiology of child mortality, we aimed to enhance patient access to physician consultation and ability to make informed healthcare seeking decisions using a physician call center. From September 2017 to February 2018, a private company provided toll-free access to a physician by phone 24/7 for a population of 203,000, living in 52,295 households of rural Bangladesh. Physicians screened calls for danger signs that required quick referral and advised referral to six designated facilities. Since September 2017, 1568 calls were received and 560 (36%) were regarding illnesses among children under-5; diarrhoea and cough were the most common complaints. A total of 172 children were referred to the facilities and among them 103 were referred with danger signs. The key reasons for overall referral were diarrhoea (23%), feeding difficulty (19%) and respiratory illness (16%). Among 172 referred cases, we were able to follow up with 99 children and only 21% of those sought care. For pregnancy and post-partum complications, 129 calls were made and 24 (19%) were referred. Major causes for referral were vaginal bleeding (21%) and premature rupture of membrane (17%). In the first 6 months this call center functioned, about 1 in every 50 households called to avail services. A total of 303 callers (57% under-5, 8% pregnant/post-partum, 35% from others category) received referral to aid in healthcare seeking, suggesting that this system has the potential to have a positive impact on maternal and child health. Yet, the low proportion of people who sought care following advice to do so warrants further inquiry. Future work to learn if the most vulnerable groups within this population can access the call center would be beneficial to describe its potential as an intervention and could be favorable for broader public health improvement interventions.

795

MENTAL DISORDERS AND PATHWAYS TO CARE IN RURAL UGANDA

Nandini DP Sarkar[1], Joan Muela Ribera[2], Bart Criel[1], Koen Peeters Grietens[1]

[1]Institute of Tropical Medicine, Antwerp, Belgium, [2]Universitat Rovira i Virgili, Tarragona, Spain

Integrating mental health into public health systems has become a global priority, with mental health and well-being now part of the Sustainable Development Goals. In the aim to provide good quality care for mental disorders, understanding patients' pathways to biomedical care as well as alternate therapy choices is key. As part of a larger mixed-methods study in eastern rural Uganda, the present qualitative study inquired into the health seeking itineraries of patients who attended the outpatient mental health clinic of Iganga district hospital. Out of 28 in-depth interviews with patient caregivers, four case-studies were selected for further analysis to assess differences in pathways to care at the intra-household level, where several family members suffered from similar mental disorders. Data analysis was based on emergent and thematic content analyses using NVivo 11. Health seeking itineraries were largely pluralistic, combining and alternating between traditional healing practices and biomedical care, regardless of the specific mental disorder. Intra-household differences in care seeking pathways - e.g. where one patient received traditional help or no care at all, while the other received biomedical care - depended on the caregiver's perceived explanatory illness model for each patient. If interpreted as a form of bewitchment, traditional medicine and healing was the first form of care sought, while the mental health clinic was seen as a recourse to "free" care. Patients who showed visible improvements once stabilized on psychotropic medication provided motivation towards continued biomedical care. However, stock-outs of the free psychotropic medication at the clinic led to dissatisfaction with services due to out-of-pocket expenses, and eventually a return to alternative therapy choices. Various combinations of cultural, structural and socioeconomic factors affect caregivers' choices of pathways to care for mental health patients. These cumulative processes, which ultimately impact patient treatment outcomes, need to be first addressed if we are to promote more inclusive and effective public mental health systems.

796

EFFECTIVENESS OF USING COMMUNITY HEALTH WORKERS TO CONDUCT HEALTH EDUCATION ON ECHINOCOCCOSIS PREVENTION AMONG TIBETAN VILLAGERS IN WESTERN SICHUAN PROVINCE, CHINA, 2015-2016

Chong Yang[1], Richun Li[2], Changning Li[1], Jeanette Rainey[2], Yamei Zhang[3], Junxiang Song[4], Anpin Yang[4], Jianli Kan[5], Dehua Yang[3], Junxuan Li[1], Yingying Zhang[1], Yan Dang[1], Ronald Moolenaar[2], Ruiqian Xie[1]

[1]Chinese Center for Health Education, Beijing, China, [2]Division of Global Health Protection, Centers for Disease Control and Prevention, USA, Beijing, China, [3]Affiliated Hospital & Clinical Medical College of Chengdu University, Chengdu, China, [4]Kangding County Center for Disease Control and Prevention, Ganzi, China, [5]Chinese Center for Disease Control and Prevention, Beijing, China

Echinococcosis is a potentially severe zoonotic parasitic infection and highly endemic in some communities in western Sichuan province, China where dogs and wild animals serve as intermediate hosts. Human infections occur in both children and adults and range from asymptomatic to disabling or fatal. There are not enough local health department staff and resources in this region to focus on echinococcosis awareness and prevention. In this project, we explored the effectiveness of using locally trained community health workers (CHWs), equipped with digital audio players, to conduct a 12-month (September 2015 to August 2016) echinococcosis prevention health education intervention in a Tibetan village located in Ganzi Tibetan autonomous prefecture in Sichuan Province. CHWs provided information on disease transmission and prevention approaches during household visits and at community gatherings. We evaluated this approach using pre- and post-intervention surveys and focus group interviews; villagers were recruited through convenience sampling. Following the intervention, 98.4% of 64 post-survey villagers indicated awareness of both the importance of not feeding offal to their dogs and of not drinking river water directly, compared with 56.1% and 61.4% of 57 pre-survey villagers, respectively. During focus group interviews, the majority of 22 participating villagers indicated that the CHW health education interventions improved their health behavior practice, including drinking only boiled water and avoiding consumption of raw meat. Ten of 12 CHWs indicated that the audio player was an effective tool for communicating echinococcosis messages. Although the intervention appeared to have increased villagers' knowledge about echinococcosis transmission and prevention and their health practice, follow-up assessments are needed to confirm this finding. We recommend using CHWs to conduct similar echinococcosis interventions in other high-risk communities along with additional evaluations aimed estimating impact on behavioral change.

797

AWARENESS ABOUT APPROPRIATE ANTIBIOTIC USE IN A RURAL DISTRICT IN SUB-SAHARAN AFRICA: WHERE IS THE STARTING POINT FOR PREVENTION OF ANTIBIOTIC RESISTANCE?

Olga Cambaco[1], John Kinsman[2], Betuel Sigauque[1], Heiman Wertheim[3], Nga Do Thi Thuy Nga[4], Johannes Langba[4], Esperanca Sevene[1], Khatia Munguambe[1]

[1]Manhica Health Research Centre, Vila da Manhica, Mozambique, [2]Umea University, Umea, Sweden, [3]Oxford University, Oxford, United Kingdom, [4]INDEPTH Network, Accra, Ghana

Misuse of antibiotics and antibiotic resistance (ABR) are global concerns particularly affecting low-and middle income countries. In Mozambique, the community awareness of antibiotics and ABR has not yet been explored. This study aimed to describe community understanding of antibiotics and ABR, as a means of providing an empirical basis for message development and positioning. The study was conducted in Manhiça, a rural district of Southern Mozambique, from 2016 to 2018, and followed a qualitative research design. 16 in-depth interviews and 4 focus group discussions were conducted among community members. The data was analyzed following a grounded theory approach. Half of the participants recognized the term antibiotic, even though their definition was rarely aligned with the biomedical. Participants associated antibiotics to colors, shapes and diseases. The majority of participants did not recognize the term ABR and only two had an understanding of it. Limited knowledge about the biomedical terms and definition of antibiotics and ABR was the main finding of this study. However, community members were willing to build constructs around these terms. Such constructs were built from own experience, exposure to antibiotics, contact with different formal and informal sources and social interactions. Our findings support the need for educational interventions based on the current local knowledge, perceptions and experience to increase antibiotic awareness.

AN OPEN SOURCE PLATFORM FOR THE DEVELOPMENT OF CLINICAL TRIAL PROTOCOLS FOR POVERTY-RELATED DISEASES

Magdalini Moutaftsi[1], Ole Olesen[1], Trudie Lang[2]

[1]EDCTP (European & Developing Countries Clinical Trials Partnership), The Hague, Netherlands, [2]University of Oxford, Oxford, United Kingdom

The most important preparation for successful clinical trials is the conception, development and refinement of a clinical trial protocol that is of high quality and integrity. Protocols are typically being conceived, reviewed and finalised within relatively small groups of researchers. With the support of The Global Health Network (TGHN), The European & Developing Countries Clinical Trials Partnership (EDCTP) aims to develop an open source platform for designing and refining protocols for clinical trials that will be performed in resource-limited settings on medicinal products such as drugs, vaccines, microbicides and medical diagnostics for poverty-related infectious diseases (PRDs). The goal of the platform is to provide guidance for researchers from low- and middle-income countries, who want to develop clinical trial protocols using input from limited, closed groups or the entire scientific community ("open source") for the optimisation of the final protocol. First, we will conduct a landscape analysis of existing resources and a gap analysis of resources, tools and repositories for clinical protocol building. Second, we will create a repository of resources and tools about data repositories and guidelines related to clinical protocol development and develop appropriate training material applicable to trials in resource-limited settings for PRDs. Third, we will develop an online, interactive toolkit to assist researchers in protocol planning and development and allows any interested party to make comments and suggest improvements to the protocol. This will include a dynamic web space to host the web tools and will combine a community of practice made up of researchers in low- and middle-income countries, with resource areas, eLearning courses, examples of well-written protocols etc. This toolkit will be linked with the EDCTP data sharing resource platform (accessible via 'EDCTP Knowledge Hub' currently developed by TGHN) to support researchers to think about data sharing from the outset of clinical trial planning.

DEVELOPING AN EARLY WARNING SYSTEM TO SCREEN FOR GONORRHEA INFECTION IN GHANA USING COST SENSITIVE CLASSIFICATION AND REGRESSION TREE

Behene Eric[1], Baidoo Isaac[2], Mettle 0. Felix[2], Attram Naiki[3], Dela Helena[1], Addo Kwasi Kennedy[1], Nyarko Owusu Edward[4], Kyei N. Nicholas[4], Carroll John Nii Ayite[4], Kwakye Cynthia[5], Duplessis Anthony Christopher[6], Nhkonti Adams[7], Letizia Andrew Gordon[3]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]University of Ghana, Accra, Ghana, [3]Naval Medical Research Unit 3 - Ghana Detachment, Accra, Ghana, [4]Ghana Armed Forces (GAF), Accra, Ghana, [5]Ghana Health Service, Accra, Ghana, [6]Naval Medical Research Center, Maryland, MD, United States, [7]NMPDC, Maryland, MD, United States

Statistical regression models, such as logistic regression, have been widely employed to analyse gonorrhea occurrence. However, this model has its own assumptions between dependent and independent variables which when violated, can lead to erroneous estimation of gonorrhea occurrence likelihood. To overcome this challenge, a non-parametric model such as Classification and Regression tree (CART) can be used. CART has been employed in business administration, industry, engineering and Medical diagnosis. It is a powerful tool for dealing with prediction and classification. However, most researchers who have used this method in medical diagnosis do not integrate misclassification cost in their model development process. Instead, they focus to improve prediction accuracy assuming equal misclassification cost i.e that the cost of false positives is equal to the cost of false negatives.. This work seeks to develop an early warning system using Cost Sensitive Classification and Regression Tree (CS-CART) which would reduce the false negative (Type II error) prediction when classifying gonorrhea infection status. Gonorrhea surveillance data from five Health facilities in Ghana and spanning the years 2012 to 2016 included 906 patients; 254 positive and 652 negative gonorrhea cases diagnosed by Nucleic Acid Amplification Test (NAAT) were analyzed. The dataset was partitioned into two; training (637 patients) and testing (269 patients) data.A CART model assuming equal and unequal misclassification cost was developed to classify gonorrhea infection status. The results indicate that false negative rate of the CART and CS-CART was 57% and 0% respectively for the training data while for the testing data, the false negative rate for CART and CS-CART was 82% and 26%, respectively. CS-CART can be used as an early warning system in which most individuals who are not at risk of gonorrhoea would likely be identified and those who are at risk of gonorrhoea would be confirmed using laboratory techniques. This could help save treatment cost and lessen the potential burden of antimicrobial resistance in Ghana.

BURNOUT AND WHO'S WHO IN PEDIATRIC GLOBAL HEALTH: A LOOK AT NATIONAL TRENDS

Stephanie M. Lauden[1], Paria M. Wilson[2], **Maureen M. Faust**[1], John D. Mahan[1], Maneesh Batra[3], Charles J. Schubert[4]

[1]The Ohio State University, Columbus, OH, United States, [2]The University of Pittsburgh, Pittsburgh, PA, United States, [3]Seattle Children's Hospital, Seattle, WA, United States, [4]Cincinnati Children's Hospital, Cincinnati, OH, United States

Burnout affects up to 50% of residents, yet little is known about the relationship between participation in global health (GH) and burnout. Secondary analysis of a national cross-sectional electronic survey,

developed by the Pediatric Resident Burnout and Resilience Study Consortium (PRBRSC). Pediatric and IM/peds residents from 34 member institutions were eligible to participate. Chi-squared analyses compared burnout, empathy, spirituality, resilience, and mindfulness in GH and non-GH residents. GH involvement was measured in terms of track participation and also recent/current GH elective. Measurement tools included Davis Empathy Scales including Empathy concern (IRLEC) and Perspective taking (IRLPT), Hatch Spirituality scale, Smith's Brief Resilience Scale, Maslach Burnout Inventory, and Cognitive and Affective Mindfulness Scale. P-values ≤ 0.05 were considered significant. In 2016-2017, 3830 surveys were completed, with 486 (12%) residents reporting GH involvement (GH track or recent/current elective). Residents involved in GH were less likely to be married or have children, and more likely to be IM/Peds residents, when compared to those not involved in GH ($p \leq 0.05$). Residents in GH tracks had higher IRLEC and Hatch scores ($p \leq 0.05$). However, track participants who had completed a recent GH elective (current or last rotation) scored no differently than their GH peers. In conclusion, although GH involvement can enhance personal and professional development and is associated with higher resident empathy and spirituality, the data suggest that it may not offer protection against burnout. Future work should focus on preparing residents for GH with effective pre-departure training, adjusting workloads, and encouraging use of mental health resources to diminish burnout in GH participants.

THE EBOLA DATA PLATFORM: A NOVEL COLLABORATION FOR TRAINING AND RESEARCH IN EMERGING INFECTIONS

Mahamoud S. Cherif, Elaine Craig, Samantha Strudwick, Alice Hawryszkiewycz, Laura Merson

Infectious Diseases Data Observatory, Oxford University, Oxford, United Kingdom

Despite the potential public health gains of enabling access to patient-level data on emerging infections, the launch of a centralised, international platform to deliver on this remit has not been achieved to date. Barriers include concerns over retention of national data ownership, patient privacy, appropriate consent, loss of academic recognition, criticism or exploitation of the data generators, perceived data misuse and the challenges of sharing benefits with communities where data is generated. Opinions on how to address these barriers vary among the many stakeholders implicated in outbreaks and response, yet the success of a central platform relies on surmounting all of them. In the aftermath of the West African Ebola outbreak, significant collaborative efforts by the affected governments, funders, public health authorities, NGOs and academic institutions have resulted in the establishment of a governance framework to collate and enable access to emerging infections data, beginning with the data from the outbreak. Resources have been invested in developing software, hardware, standards as well as technical expertise in Ebola-affected countries to ensure robust data management and to deliver a secure and consolidated database. The inclusion of scientific and statistical training in the remit of the platform promotes use of the data by the health and research communities in West Africa. The Ebola Data Platform aims to enable ethical, equitable and rapid access to data and information on Ebola and, in the future, other emerging pathogens in resource-limited settings. The platform ultimately seeks to improve patient outcomes, public health preparedness and outbreak response by establishing a new paradigm in data access that can change the global response to public health emergencies.
